**Conclusion:** In a network meta-analysis of randomised controlled trials of pharmacological therapies for IBS-D and IBS-M, we found all drugs to be superior to placebo, but the 5HT<sub>2</sub>-receptor antagonists alosetron and ramosetron appeared to be the most effective. Unfortunately, these drugs are unavailable in the UK and Europe. Ondansetron, which is available although unlicensed, ranked well across all analyses, but was only superior to placebo for its effect on stool consistency, based on the inclusion of a single small trial. Overall, improving access to 5HT<sub>3</sub> receptor antagonists may be helpful for the management of IBS-D and IBS-M, and the result of further trials of ondansetron will be informative.

### P1220 COST-EFFECTIVENESS OF THE USE OF HLA-DQA1-HLA-DRB1 POLYMORPHISM TO IDENTIFY PEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE AT RISK FOR AZATHIOPRINE-INDUCED ACUTE PANCREATITIS

**Introduction:** Thiopurines may be effective for maintaining remission in pediatric inflammatory bowel disease (IBD), but due to their low safety profile, the most recent evidence-based guidelines recommend they should be reserved as second-line therapy after 5-ASA has failed (1). One idiosyncratic adverse effect of thiopurines is acute pancreatitis and affects 2-7% of patients treated with azathioprine (AZA) (2,4). Its development

is unpredictable and usually leads to drug withdrawal. An association within the HLA-DQA1\*02:01-HLA-DRB1\*07:01 haplotype has been previously identified (3). The risk of pancreatitis during AZA-therapy was highly predictable and genotype-dependent: 0.5% for wild-type (A/A), 4.3% for heterozygous (A/C), and 14.6% for homozygous patients (C/C). Some authors even propose a new AZA treatment algorithm that could help to select those patients with higher risk of pancreatitis (4).

**Aims & Methods:** The aim of our study was to conduct a cost-effectiveness analysis of the use of HLA-DQA1-HLA-DRB1 polymorphism to identify pediatric patients with inflammatory bowel disease at risk for azathioprine-induced acute pancreatitis (A-IAP).

We performed a theoretical analysis of costs and benefits resulting from routinely studying the HLA-DQA1\*02:01-HLA-DRB1\*07:01 haplotype in those pediatric patients with IBD that are candidates for the use of azathioprine as maintenance therapy, in order to avoid using this treatment in those at risk of A-IAP. We calculated the number needed to screen (NNS), defined as the number of patients that need to be screened to prevent one adverse event, based on the available data. This was computed as the inverse of the Absolute Risk Reduction (ARR), defined as the difference in percentage outcomes between the related and un-related haplotype.

The costs of the HLA typing were based on the INNO-LiPA® test (FUJIRE-BIO, Spain).

The costs of acute pancreatitis cases were based on the diagnosis-related group (DRG) weights applied by the Spanish Ministry of Health. These relative weights represent the expected cost of a particular kind of patient compared to the average cost of all the acute hospitalized patients.

**Results:** The cost of the screening for the HLA-DQA1\*02:01-HLA-DRB1\*07:01 haplotype was approximately 90€ per patient. Considering the previously reported incidence of A-IAP of 0.5% in the A/A, 4.3% in the A/C and 14.6% in the C/C genotype; NNS was 5.4. NNS was rounded up to 6 patients, so the expected cost for avoiding one case of A-IAP was 540€.

The A-IAP diagnose in the DRG 32<sup>nd</sup> version (DRG 282.3) has a mean weight of 1.15. The total cost of a case of A-IAP was about 20.109 € per patient. This leads to saving up to 19.569€ for every 6 patients screened before starting the AZA treatment.

**Conclusion:** Based on our results, routinely performing HLA-DQA1-HLA-DRB1 genotyping prior to initiation of AZA could be cost-effective in order to avoid A-IAP. Furthermore, the caregivers' absenteeism costs derived from a child hospitalization were not included in this analysis and would reinforce our conclusions. However, the costs derived from the therapeutic alternative that would be considered for those who could not receive AZA should be considered. But, most importantly, and beyond the economic rationale, preventing this potentially severe adverse effect could improve the clinical outcomes of our patients and allow an individualized management. This patient-tailored approach should be the goal of clinicians, not only to optimize the use of Public Health Funds, but also to maximize our patients' quality of life.

**Introduction:** The usefulness of granulocyte and monocyte adsorptive apheresis (GMA) in paediatric patients with inflammatory bowel disease (IBD) has not been evaluated in detail. We investigated the safety and effectiveness of GMA in paediatric patients with IBD who participated in the "Post-marketing surveillance study on the safety and response of GMA treatment in patients with Crohn's disease or ulcerative colitis with at least one special situation who received Adacolumn (PARTICULAR)".

**Aims & Methods:** The aim of this study is to investigate the safety and effectiveness of GMA in paediatric patients with IBD who participated in the PARTICULAR study. This retrospective, multicentre cohort study included patients with ulcerative colitis (UC) or Crohn's disease (CD) who had at least one special situation feature and who had received GMA therapy in medical institutions of Japan between November 2013 and March 2017. Patients with at least one special situation, including elderly patients, patients with anaemia and patients on multiple immunosuppressants were enrolled. Patients >18 years were excluded from this study. GMA was performed using Adacolumn (JIMRO, Takasaki, Japan). Each patients received up to a maximum of 11 sessions. All adverse events (AEs) were recorded during the observation time interval. In addition, feasibility problems (FPs) during the operation of the GMA column were recorded. Any AE for which the causality of GMA could not be ruled out was classified as adverse device effect (ADE). The safety of GMA was assessed in all patients. The effectiveness of GMA was assessed in patients with UC with a partial Mayo (pMayo) score of  $\geq 3$ . Remission was defined as a pMayo score of  $\leq 2$ , while response was defined as a decrease in the pMayo score by  $\geq 2$  points and by  $\geq 30\%$  decrease relative to that at baseline plus all 3 sub-scores  $\leq 1$ . Patients receiving concomitant treatment with infliximab, adalimumab or calcineurin inhibitors were excluded from the effectiveness assessment.

**Results:** A total of 53 paediatric patients (40 UC, 13 CD; 30.2% female) from 27 institutions, with a median age of 16.0 years [range 6-12 (9 patients), 13-15 (14 patients) and 16-18 (30 patients)]; median body weight 49.6 Kg and median duration of disease 0.7 years. The incidence of AEs, ADEs and FPs were 18.9%, 5.7% and 20.8%, respectively. The ADEs included abdominal discomfort in 2 patients (3.8%) and one patient each with fever, nausea/vomiting and headache (1.9% each). The FPs included blood access failure in 10 patients (18.9%), venous pressure elevation in 4 patients (7.5%), clot formation in the apheresis lines in 2 patients (3.8%) and venous access difficulty in 1 patient (1.9%). GMA therapy was discontinued in 17 patients (32.1%) ahead of their planned treatment schedule. Among these patients, the GMA therapy was discontinued for the following reasons: (1) decision by the physician (n = 12), (2) withdrawal due to AE (n = 4) and (3) withdrawal by own will (n = 1). No patients discontinued GMA therapy due to ADE and FP. The effectiveness of GMA was assessed in 29 patients with UC. The remission and response rate of the paediatric patients with UC were 55.2% and 65.5%, respectively.

**Conclusion:** There were AEs and FPs in approximately 20% of paediatric patients with IBD who were treated with GMA. However, none of these discontinued GMA treatment owing to ADE or FP. Remission and response were achieved by GMA in 55% and 66% of paediatric patients with UC, respectively. These data suggest that GMA is a well-tolerated treatment alternative for paediatric patients with IBD.

## P1222 EXCLUSIVE ENTERAL NUTRITION FOR INDUCTION OF REMISSION IN PAEDIATRIC CROHN'S DISEASE: COMPARISON BETWEEN A DISEASE-SPECIFIC FORMULA AND STANDARD POLYMERIC FORMULAS

Martínez Ibeas M.A., Rodríguez Manchón S., Babelo Ruano I., Viada Bris J.F., Velasco Rodríguez-Belvis M., Cañedo Villarroya E., Pedrón Giner C., Muñoz Codoceo R.A.  
Hospital Infantil Universitario Niño Jesús, Paediatric Gastroenterology and Nutrition Department, Madrid, Spain

**Contact E-Mail Address:** martavrb@gmail.com

**Introduction:** Exclusive enteral nutrition (EEN) is effective and currently recommended as the first line of treatment to induce remission in children and adolescents with acute active Crohn's disease (CD). Standard enteral nutrition (polymeric, normocaloric with moderate fat content) can be used for primary and supportive nutritional therapy in active CD.

**Aims & Methods:** The main aim was to demonstrate the non-inferiority of an age-appropriate normocaloric polymeric formula (Fo) versus an inflammatory bowel disease (IBD) specific normocaloric polymeric formula (F1) to induce remission in paediatric patients newly diagnosed of CD. Secondary objectives were to evaluate the nutritional status and analyze the percentage of withdrawal before 8 weeks, their causes and the need of other treatments. This observational, descriptive and retrospective study included patients under 18 diagnosed with CD from September 2008 to December 2018 in the paediatric IBD Unit of a tertiary care hospital in whom EEN was indicated to induce remission at diagnosis. Patients were divided into two groups (EEN with Fo or EEN with F1), comparing clinical, analytical and anthropometric data at diagnosis, and after 2 and 8 weeks of EEN. Clinical remission was defined as a Paediatric Crohn Disease Activity Index (PCDAI)  $\leq 10$ .

**Results:** We included 29 patients, 9 (31%) women and 20 (69%) men with a mean age of 9.9 years (2.1-17.5) at diagnosis. Eleven patients (37.9%) received Fo and 18 (62.1%) F1. The mean duration of EEN was 56.3 days (18-78). One patient (3.5%) refused the treatment and required tube feeding and 6 (20.7%) dropped out from EEN before 8 weeks (33.3% Fo and 66.7% F1). Among 6 withdrawals, 5 (83.3%) developed a fistulizing perianal disease (40% Fo and 60% F1) and required biological therapy, and 1 (16.7%) did not respond to EEN with F1, requiring corticosteroids. The PCDAI mean value was 36.4 (20-52.5) at diagnosis in the group with Fo and 31.47 (12.5-57.5) with F1. After 2 weeks, 62.5% of patients with Fo and 56.3% with F1 reached clinical remission. After 8 weeks, 90.9% of patients with Fo and 77.8% with F1 maintained clinical remission. There were no statistically significant differences between the 2 groups at both endpoints. The C-reactive protein (CRP) mean value at diagnosis, and after 2 and 8 weeks was 7.7 mg/dl (0.2-27.3), 1.7 y 1.1 mg/dl respectively in the Fo group, and 5.6 mg/dl (0.2-12.8), 1.2 y 0.9 mg/dl in the F1 group, without statistically significant differences (p=0.7; 0.93; 0.34 respectively). After 8 weeks, median CRP decreased significantly in Fo group (p=0.01) and F1 group (p<0.0005). The mean erythrocyte sedimentation rate (ESR) at diagnosis, at 2 and 8 weeks was 39.1 mm (11-69), 26 and 17 mm respectively in the Fo group, and 42.4 mm (11-78), 23.2 and 14.6 mm in the F1 group, without statistically significant differences (p=0.65; 0.64; 0.43). Median ESR decreased significantly at week 2 with F1 (p=0.001) but not with Fo (p=0.17). However, there was a significative reduction in both of them at week 8 (p<0.05). Weight and body mass index (BMI) improved with Fo and F1, but only the F1 group reached statistical significance (p=0.007 for weight and p=0.003 for BMI), and not the Fo group (p=0.24 and 0.37).

**Conclusion:** The use of Fo was not inferior to F1, without any statistically significant differences in the percentage of patients in clinical remission after 2 and 8 weeks with EEN, nor in the decrease of CRP and ESR after 8 weeks. Faster ESR reduction was found in patients treated with F1 and only these ones presented a statistically significant improvement in their nutritional status.

## P1223 LONGTERM CLINICAL OUTCOME AFTER THIOPURINE DISCONTINUATION IN ELDERLY IBD PATIENTS

**Contact E-Mail Address:** celinejorissen@hotmail.com

**Introduction:** Thiopurines - although still used frequently in treatment of inflammatory bowel diseases (IBD) - carry a significant malignancy risk, particularly with prolonged use and in patients over the age of 60. Mainly the risk of lymphoma, but also non-melanoma skin cancer and nodular regenerative hyperplasia of the liver are well reported. These concerns question the continuation of thiopurines in IBD patients above 60. Stopping therapy however may trigger relapses and therefore needs to be balanced against the safety risk. We assessed the longterm outcome of elderly IBD patients after discontinuation of thiopurines (TP) while in clinical remission with emphasis on relapse rates and the management thereof in these patients.

**Aims & Methods:** The electronic medical records from all IBD patients above the age of 60 followed at our referral center who ever received treatment with TP were reviewed. Patients who stopped TP after 60 years of age while in clinical (symptom control) and endoscopic remission (mucosal healing) were the target population. Longterm outcomes of interest included duration of thiopurine-free clinical remission, time to clinical relapse and therapies given in case of relapse. The risk for malignancies was also recorded.

**Results:** From the 674 identified patients who ever received TP therapy, 532 patients stopped therapy < 60 years of age (regardless of reason for withdrawal). A total of 142 patients >60 years of age on TP were identified. Of those, 91 patients (55 Crohn's disease (CD) and 36 ulcerative colitis (UC)), stopped TP at >60 years while in clinical and/or endoscopic remission and 51 stopped while not in remission. After a median follow up of 31.4 months after TP discontinuation, 63 (69.2%) patients remained in clinical and endoscopic remission and 28 (30.8%) relapsed. Remission rates and median time to relapse were similar between CD patients (40/55 or 72%; median 22 months) and UC patients (23/36 or 64%; median 20 months). However, the median duration of TP therapy in the patients with relapse was significantly shorter than in the patients who remained in remission (median duration of TP 45 months versus 102.5 months respectively;  $p=0.005$ ). Of the patients who relapsed, 17 were initiated on a biological (61%) and 7 patients received a short course of steroids (25%). However, surgery was eventually needed in 36% of patients (10/28), including total colectomy with ileostomy in 2 UC patients. In the total group of 142 IBD patients on TP at >60 years, 26 malignancies (18%) developed: non-melanoma skin cancers (8), colon adenocarcinoma (5), hematologic malignancies (3), lung (2), breast (2), brain (1), endometrium (1), prostate (1), glottis (1), bladder (1) and melanoma (1). For 7 patients, the development of a malignancy was the direct reason for stopping TP.

**Conclusion:** In this single center retrospective cohort of elderly IBD patients in remission and on TP, discontinuation of TP resulted in sustained clinical remission in 69% of patients after a median of 20 months. Patients who flared after discontinuation of TP were mostly rescued with biological therapies although more than one third of patients necessitated surgery. A significant proportion of patients developed malignancies under TP but also after TP discontinuation, indicating that these patients necessitate a continued close follow up. Decision making in this vulnerable subgroup of patients remains difficult with a careful balance between adverse events when continuing TP and risk for major surgery when stopping TP.

**Contact E-Mail Address:** hoffmaka@mac.com

**Introduction:** *Klebsiella* (K.) *oxytoca* is a gastrointestinal pathobiont that has the potential to produce the cytotoxin tilivalline, which causes antibiotic-associated haemorrhagic colitis. *K. oxytoca* colonizes healthy adults in up to 9%, however, there is no data on the natural occurrence and its potential to produce tilivalline in healthy children.

**Aims & Methods:** We investigated *K. oxytoca* colonization and its ability for toxin production in healthy infants. We collected stool samples of healthy infants at 3 different time points (week 0, 4 and 8). *K. oxytoca* colonization was determined using conventional stool culture and PCR analysis. Toxicity of isolated *K. oxytoca* strains was analysed by cell culture MTT toxin assay and *K. oxytoca* toxin PCR.

**Results:** Of 61 infants (25 male, 36 female, age 1 - 28 weeks) 30 (49%) tested positive for *K. oxytoca* in conventional stool culture and 44 (72%) tested positive in *K. oxytoca* PCR. Colonization increased with time: 21% / 62% (culture / PCR) at week 0, 26% / 67% at week 4, 31% / 69% at week 8. One patient tested negative for PCR but positive for conventional stool culture. 48% of *K. oxytoca* positive infants were exclusively breastfed at the time of study inclusion, compared to 82% of *K. oxytoca* negative patients ( $p=0.02$ , Fisher's exact). There were no statistical differences between positive and negative infants in regard to age, weight or sex, C-section, use of probiotics, previous antibiotic therapy or previous diseases. The cell culture MTT toxin assay confirmed toxicity of culture positive *K. oxytoca* isolates in 49%. *K. oxytoca* toxin PCR was positive in 75% of PCR isolates. Conformity of cell culture toxin assay and toxin PCR was noted in only 71% of the analyses, whereas the negative predictive value of the toxin PCR was 100%.

**Conclusion:** In contrast to adults, more than 70% of healthy infants were colonized with *K. oxytoca*, the majority of which possessed the ability to produce the cytotoxin tilivalline. Exclusive breastfeeding might decrease the probability of *K. oxytoca* colonization. PCR shows a higher detection rate of *K. oxytoca* compared to conventional stool culture but lacks information about the clinical significance (e.g. relative abundance) of *K. oxytoca* colonization. *K. oxytoca* toxin PCR alone can not be used to confirm actual toxin production, but with a negative predictive value of 100% can be used to rule out the potential of toxin production of the isolated strain. Pediatricians have to be aware of the high prevalence of toxin producing *K. oxytoca* in infants, especially when confronted with haemorrhagic colitis during antibiotic therapy in this age group.

**Introduction:** Irritable Bowel Syndrome (IBS) symptoms in school children and adolescents are relatively common, often causing considerable embarrassment, social withdrawal, disruption to education and psychological distress. Pharmacological options in this group are limited due to safety concerns concerning antidepressants, making behavioural therapies such as gut-focused hypnotherapy an attractive treatment option.

**Aims & Methods:** Here, we evaluated outcomes from gut-focused hypnotherapy in patients with IBS  $\leq 18$  years of age. Consecutive young patients ( $\leq 18$  years of age) with severe IBS symptoms referred to our tertiary neuro-gastroenterology unit received 12 sessions of gut-focused hypnotherapy at weekly intervals using the Manchester Protocol. All patients completed the Tellgen Absorption Scale before treatment and all completed the following measures before and after hypnotherapy; IBS symptom severity score (IBS-SSS), Hospital Anxiety and Depression scale (HADS), Non Colonic Symptom score and quality-of-life (QoL) score. Interference with education and the impact of hypnotherapy was also recorded. The primary outcome measure was response to hypnotherapy defined by a 50 point reduction in IBS-SSS. Data, expressed as mean  $\pm$  standard error, were compared statistically before and after treatment using paired t-tests.

**Results:** 26 young patients fulfilling Rome III diagnostic criteria for IBS (median age 16 (range 8-18) years,  $n=17$  (65%) female, mean duration of IBS  $5.3 \pm 0.9$  years, IBS-D  $n=11$ , IBS-C  $n=6$  and IBS-mixed  $n=9$ ), completed the hypnotherapy programme. Mean baseline IBS-SSS was  $321.5 \pm 16.0$ . After hypnotherapy,  $n=23/26$  (88%) responded, with an overall mean reduction in IBS-SSS of  $-160.9 \pm 15.4$  ( $P < 0.0001$ ), and  $n=19/26$  (73%) achieved the FDA recommended outcome of  $\geq 30\%$  reduction in abdominal pain scores. Hypnotherapy also improved; mean non-colonic symptom score by  $102.1 \pm 15.0$  ( $P < 0.0001$ ), mean HADS-anxiety by  $-3.0 \pm 0.8$  ( $P = 0.0007$ ), mean HADS-depression by  $-2.1 \pm 0.6$  ( $P = 0.002$ ), and improved mean QoL score by  $+89.7 \pm 13.1$  ( $P < 0.0001$ ).

**Conclusion:** These data, which form one of the largest reported series of gut-focused hypnotherapy in children and adolescents with severe IBS, suggest that this treatment is even more effective in this group of patients than in adults. Hypnotherapy in severe childhood IBS patients may therefore have a role in preventing further suffering in adult life, reducing healthcare utilisation and related costs with wider socio-economic benefits. Furthermore, it allows many of them to return to full time education. These results, taken with previous clinical trial data, raise the possibility that early intervention with hypnotherapy for childhood IBS might reduce the subsequent burden of this problem in adults.

**Contact E-Mail Address:** nicolas.poirier@ose-immuno.com

**Introduction:** It remains unknown what causes inflammatory bowel disease (IBD), including signaling networks perpetuating chronic gastrointestinal inflammation in Crohn's disease (CD) and ulcerative colitis (UC), in humans.

**Aims & Methods:** According to an analysis of up to 500 patients with IBD and 100 controls, we report that key transcripts of the IL-7 receptor (IL-7R) pathway are accumulated in inflamed colon tissues of severe CD and UC patients not responding to either immunosuppressive/corticosteroid, anti-TNF, or anti- $\alpha 4\beta 7$  therapies.

**Results:** High expression of both IL7R and IL-7R signaling signature in the colon before treatment is strongly associated with nonresponsiveness to anti-TNF therapy. While in mice IL-7 is known to play a role in systemic inflammation, we found that in humans IL-7 also controlled  $\alpha 4\beta 7$  integrin expression and imprinted gut-homing specificity on T cells. IL-7R blockade reduced human T cell homing to the gut and colonic inflammation in vivo in humanized mouse models, and altered effector T cells in colon explants from UC patients grown ex vivo. Our findings show that failure of current treatments for CD and UC is strongly associated with an overexpressed IL-7R signaling pathway. In addition, we observed a significant increase of IL-7 concentration in the serum of UC and CD patients compared to various autoimmune diseases such as multiple sclerosis or autoimmune hepatitis.

**Conclusion:** Thoses results point to IL-7R as a relevant therapeutic target and potential biomarker to fill an unmet need in clinical IBD detection and treatment.

**Disclosure:** BV and NP are shareholders of OSE Immunotherapeutics, a company owning IL-7 receptor antagonists.

### P1227 AN IMMUNOSUPPRESSIVE PD-L1 POSITIVE TUMOUR MICROENVIRONMENT MARKS OESOPHAGEAL ADENOCARCINOMAS REFRACTORY TO NEO-ADJUVANT CHEMORADIO THERAPY

**Introduction:** Oesophageal adenocarcinoma is an aggressive cancer with a poor overall prognosis. For patients with a locally advanced resectable tumour and no distant metastases neo-adjuvant chemoradiotherapy (nCRT) followed by oesophageal resection is associated with better survival than surgery alone. However, a large proportion of patients still develop disease recurrence. The mechanism of poor response to nCRT is not yet understood. An effective antitumour immune response is critical for a successful tumour elimination. Therefore, an immunosuppressive tumour microenvironment may play an important role in failure of standard therapies.

**Aims & Methods:** The aim of this study was to characterize tumour microenvironment and immune infiltrate in oesophageal adenocarcinoma patients in relation to pathological treatment response to nCRT.

**Methods:** Surgical resection specimens were used from 65 patients with oesophageal adenocarcinoma treated with nCRT: 40 responders (Mandard tumour regression grade 2) and 25 non-responders (Mandard tumour regression grade 4 or 5). Tumour sections were stained with pSTAT1, CD3, CD8, FOXP3 and PD-L1 antibodies. Immunostained slides were scanned at high resolution and digital image analysis was performed using Halo software (version 2, Indica Labs, Corrales). Group differences were analysed using the chi-square test or the Mann-Whitney U test.

	Total	Responders	Non-responders	p-value
Patients	65	64	25	
Median age in years (range)	63 (44-82)	64 (44-82)	63 (46-78)	
Gender				0.811 <sup>^</sup>
Male	51 (79%)	31 (78%)	20 (80%)	
Female	14 (21%)	9 (22%)	5 (20%)	
pT stage				0.012 <sup>^</sup>
pT1	13 (20%)	11 (27%)	2 (8%)	
pT2	10 (15%)	9 (23%)	1 (4%)	
pT3	40 (62%)	20 (50%)	20 (80%)	
pT4	2 (3%)	0 (0%)	2 (8%)	
pN stage				0.203 <sup>^</sup>
pN0	38 (58%)	27 (68%)	11 (44%)	
pN+	27 (42%)	13 (32%)	14 (56%)	
PD-L1 expression*				0.006 <sup>^</sup>
Positive	18 (28%)	6 (15%)	12 (48%)	
Negative	42 (65%)	30 (75%)	12 (48%)	
Unknown	5 (7%)	4 (10%)	1 (4%)	
Mean CD3 density/mm2	1693	1295	2332	0.002 <sup>o</sup>
Mean CD8 density/mm2	654	486	924	0.014 <sup>o</sup>
Mean FOXP3 density/mm2	218	215	224	0.182 <sup>o</sup>

pT stage = pathological T stage; pN stage = pathological N stage (TNM 7th edition)

\*Oesophageal tumours were designated as PD-L1 positive if at least 10% of stroma cells demonstrated membranous staining

<sup>^</sup>chi-square test; <sup>o</sup>Mann-Whitney U test

[Table 1]

**Results:** Both responders and non-responders displayed active interferon gamma signaling in the tumour cells as judged by positive pSTAT1 staining, suggesting that tumour antigen presentation on MHC class I and tumour-specific stimulation of the immune system were common in both groups.

Surprisingly, a significantly higher amount of CD3+ ( $p=0.002$ ) and CD8+ ( $p=0.014$ ) tumour infiltrating lymphocytes was seen in non-responders as compared to responders. Thus, differences cannot solely be explained by induction of T-cell infiltration in responders compared to non-responders. Also, the amount of FOXP3+ regulatory T-cells was similar in both groups. Significantly more non-responders were found to have PDL-1 expression in the tumour stroma than responders (48% versus 15%,  $p=0.006$ ).

**Conclusion:** In tissue samples of oesophageal adenocarcinoma patients treated with neo-adjuvant chemoradiotherapy, the presence of an immunosuppressive tumour microenvironment was associated with absence of treatment response, suggesting that cancer immunotherapy may be a valuable alternative treatment option for this group of patients.

**Disclosure:** Nothing to disclose

## P1228 AUTOANTIBODIES TOWARDS ATP4A AND ATP4B SUBUNITS OF GASTRIC PROTON PUMP H<sup>+</sup>,K<sup>+</sup>-ATPASE ARE RELIABLE SEROLOGICAL PRE-ENDOSCOPIC MARKERS OF CORPUS ATROPHIC GASTRITIS

**Introduction:** Corpus atrophic gastritis (CAG) is a risk factor for gastric cancer and carcinoids. Histology is the gold standard for diagnosis, non-invasive serological tests include gastrin, pepsinogens and parietal cells autoantibodies (PCA)(1,2). Autoantibodies targeting the H<sup>+</sup>/K<sup>+</sup>-ATPase are considered diagnostic markers of autoimmune atrophic gastritis, whose diagnostic utility remains to be defined(3). A high diagnostic performance of a luminescent immunoprecipitation system (LIPS) assay detecting autoantibodies to H<sup>+</sup>/K<sup>+</sup>-ATPase alpha (ATP4A) or beta (ATP4B) subunits in patients with known diagnosis of CAG has been shown(4).

**Aims & Methods:** To validate the diagnostic performance of ATP4A and ATP4B LIPS assays as pre-endoscopic diagnostic tools for detecting CAG in patients at clinical suspicion for this condition as compared to histology of gastric biopsies as reference test.

Prospective study on 211 consecutive patients (age 65, range 18-90 years, female 61.6%) with clinical suspicion of CAG collected between May 2017-April 2018. Inclusion criteria were: anemia (iron or cobalamin deficiency), autoimmune diseases, family history for CAG, history of long-standing non-investigated dyspepsia, chronic proton pump inhibitors. Exclusion criteria were: age < 18 years, previous diagnosis of CAG. Included patients underwent gastroscopy with standard biopsies for histopathology (updated Sydney). A serum sample for each patient was preserved at -20°C for the LIPS ATP4A and ATP4B assays, pepsinogen I, and EIA parietal cell antibodies (PCA). Serological results were compared with histology to assess the diagnostic performance of LIPS assays. For ATP4A and ATP4B LIPS assays, recombinant antigens fused to a luciferase reporter were incubated with test sera and immune complexes recovered using protein A-sepharose; after addition of the luciferase substrate light output was measured in a luminometer and converted to arbitrary units using results from a positive serum as reference (5). Pepsinogen I and EIA PCA were assessed by commercial kits.

**Results:** Histopathology of gastric biopsies proved presence of CAG in 115(54.5%) and absence in 96(45.5%) patients. ATP4A LIPS yielded a 76.5% sensitivity and a 86.4% specificity, ATP4B LIPS a 77.4% sensitivity and a 87.5% specificity. EIA PCA showed a 65.1% sensitivity and a 91.7% specificity, and Pepsinogen I a 71.3% sensitivity and a 92.7% specificity. The areas under the ROC curve of ATP4A (0.822) and ATP4B (0.836) were similar to that of EIA PCA (0.820,  $p>0.05$ ), while that of pepsinogen I was higher (0.907,  $p<0.01$ ). Considering both LIPS assays or EIA PCA and pepsinogen I together, sensitivity increased to 83.5% or 83.3% at cost of specificity, 82.3% or 88.3%, respectively.

Regarding ATP4A LIPS, in false negative patients (23.5%) severe corpus atrophy ( $p<0.001$ ), intestinal metaplasia ( $p=0.001$ ), and age < 65 years were less frequent ( $p=0.043$ ) than in true positives. Regarding ATP4B LIPS,

in false negative patients (22.6%) severe corpus atrophy ( $p<0.001$ ), and intestinal metaplasia ( $p=0.05$ ) were less frequent than in true positives, but age was similar.

**Conclusion:** The LIPS assays detecting autoantibodies against ATP4A and ATP4B subunits showed a good pre-endoscopic diagnostic performance in patients with clinical suspicion of CAG, with higher specificity but lower sensitivity than traditional EIA PCA. Sensitivity of LIPS assays and EIA PCA was increased by combining pepsinogen I. These autoantibodies seem promising serological biomarkers of CAG suggesting a close relationship between their expression and advanced oxyntic mucosa damage.

## P1229 NLRP3 INFLAMMASOME-DERIVED INTERLEUKIN-1 $\beta$ ATTENUATES STRESS-INDUCED GASTRIC INJURY VIA THE COX-2/PGE<sub>2</sub> AXIS

Higashimori A., Watanabe T., Nadatani Y., Nakata A., Otani K., Taira K., Hosomi S., Tanaka F., Nagami Y., Tanigawa T., Fujiwara Y.

**Contact E-Mail Address:** higamo@med.osaka-cu.ac.jp

**Introduction:** Activation of inflammasomes, a multiprotein complex consisting of one of NOD-like receptors (NLRs), ASC, and pro-caspase-1, resulted in cleavage of pro-caspase-1, leading to processing of pro-IL-1 $\beta$  into its mature form. Water immersion restraint stress (WIRS) can induce inflammatory responses and severe mucosal injury in the stomach. We recently reported that inflammasomes were activated to protect the damage during the development of WIRS-induced gastric injury (*Gastroenterology* 2018: S-207, 2018).

**Aims & Methods:**

**Aims:** We investigated the mechanisms by which the inflammasome protected WIRS-induced gastric damage. We also determined which inflammasome was involved in the protection of the injury.

**Methods:** After fasting for 24 h, male wild-type, caspase-1-knockout (KO) and NLRP3 KO mice were placed in a restraint cage and immersed in the water bath. Mice were sacrificed after WIRS, and mucosal lesions were subjected to measurements of ulcer size and assay of mRNA levels by real-time RT-PCR. Protein levels of mature IL-1 $\beta$  and cleaved caspase-1 in stomach were measured by Western blotting. Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) production by gastric tissue was assessed by enzyme immunoassay. Some animals were given rabeprazole, a proton pump inhibitor, before administration of the stress to examine the involvement of gastric acid in the inflammasome activation.

**Results:** Macroscopic gastric injury developed 3 h after WIRS, while significant increases in mRNA expression of IL-1 $\beta$  and protein levels of mature caspase-1 and IL-1 $\beta$  were observed on 30 min. NLRP3 mRNA expression increased by WIRS, whereas that of other NLRs did not change during experimental period. NLRP3 KO as well as caspase-1 KO mice exhibited high sensitivity to the stress induced injury with reduced expression of mature IL-1 $\beta$  protein. Administration of recombinant IL-1 $\beta$  (rIL-1 $\beta$ ) abolished such aggravation of the injury in these KO mice without affecting gastric mucosal pH. In wild-type mice, the levels of cyclooxygenase (COX)-2 mRNA and PGE<sub>2</sub> production by gastric tissue significantly increased on 30 min after WIRS. Supplementation of rIL-1 $\beta$  further increased COX-2 expression and PGE<sub>2</sub> production and inhibited the injury. Immunoneutralization of IL-1 $\beta$

exerted opposite effects on the injury and COX-2/PGE<sub>2</sub> axis. Rabeprazole attenuated the stress-induced injury with the increase of gastric mucosal pH, but failed to prevent inflammasome activation.

**Conclusion:** These results suggest that NLRP3 inflammasome-mediated IL-1 $\beta$  plays a protective role in stress-induced gastric injury via activation of the COX-2/PGE<sub>2</sub> axis. Gastric acid may not be involved in the activation of the NLRP3 inflammasome in stress-induced gastric injury.

## P1230 REAL WORLD DATA ON EMOTIONAL STRESS, DISABILITY AND SOCIAL CARE FOR CED PATIENTS

Kubesch A.<sup>1</sup>, Hausmann J.<sup>1</sup>, Boulahrou P.<sup>2</sup>, Filmann N.<sup>3</sup>, Blumenstein L.<sup>1</sup>

<sup>1</sup>University-Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt am Main, Germany, <sup>2</sup>Frankfurt University of Applied Sciences, Department 4 Social Work and Health, Frankfurt am Main, Germany, <sup>3</sup>University-Hospital Frankfurt, Institute of Biostatistics and Mathematical Models, Frankfurt am Main, Germany

**Contact E-Mail Address:** irina.blumenstein@kgu.de

**Introduction:** Inflammatory bowel disease (IBD) often manifests itself at a young age before or in the middle of working life. There has been insufficient research into the emotional stress levels of IBD patients, how often they suffer from a recognised

**Aims & Methods:** The aim of this study was to assess the level of emotional stress and the degree of recognised disability in IBD patients. The aim was also to evaluate whether there was any contact with the social system. Furthermore, it was examined whether predictive parameters regarding recognised disability can be identified in IBD patients. Between 15 November and 21 December 2018, patients with IBD and non-IBD volunteers were invited to participate in an online survey developed specifically for this study (accessible via [www.soscsurvey.de](http://www.soscsurvey.de)).

**Results:** 505 patients with IBD (441 women, 87.3%) and 166 non-IBD patients (control group; 109 women, 65.7%) participated in the online survey. Patients with IBD reported significantly increased levels of everyday and work-related stress within the last six months and five years ( $p=0.0001$ ), respectively. IBD patients were more likely to have a recognised disability ( $p=0.0001$ ). A low academic status was the strongest indicator ( $p=0.006$ ). Interestingly, only 153 IBD patients (30.3%) reported that they had been in contact with social workers or other forms of social support due to their illness. A recognised disability was the strongest indicator for this ( $p=0.0001$ ).

**Conclusion:** Our study provides real-world data on emotional stress and the disability in a large German IBD cohort. It could be shown that patients with IBD suffer more often from emotional stress and more often have a recognised disability than non-IBD patients. There were differences between Crohn's disease and Ulcerative colitis. In addition, it was found that only about 1/3 of the patients had come into contact with the social system and the corresponding support and that this patient group is therefore apparently undersupplied in this area.

**Disclosure:** Nothing to disclose

**Introduction:** Based on our observations, as physicians in a referral hospital, we have been noticing the association between history of enteric fever and somatic disorders associated with low mood. At 2 hospitals: Al-Husseini university hospital, Cairo; National Liver Institute hospital, Menoufia; we are receiving patients from all over Egypt, including rural areas where enteric fever is endemic.

**Aims & Methods:**

**Aim:** Here we report this series for 60 Egyptian patients referred to us for evaluation of different somatic disorders.

**Methods:** After extensive evaluations, the patients' symptoms were proved to be functional, their typhoid carrier states were documented, they were evaluated for depression using Hamilton-D questionnaire and the severity of depression was recorded. All patients were treated by ceftriaxone, 2 gm, IV, daily for 15 days. Clinical evaluation and Hamilton score were reassessed at the end of treatment and 6 weeks thereafter. The patients did not receive any anti-depressant nor anti-anxiety treatment during their course. Typhoid carrier was defined by documenting the history of typhoid fever that was diagnosed by culturing the salmonella species not by serology, plus at least one occasion of salmonella isolates from stool culture while a febrile, plus absence of fever in the past 3 weeks. The Widal test wasn't accepted as a criterion for enrollment.

**Results:** Typhoid carrier status was diagnosed in 60 patients, 32 males (53%) and 28 females (47%), the median age was 47 and the age range was 19-63 years. All patients were Egyptians and were referred to us from rural/villages area. 40 patients (66%) weren't complaining of any chronic diseases while 12 (20%) had diabetes mellitus, 16 (26%) had hypertension and 4 (6%) were suffering from bronchial asthma. As regarding smoking, 24 patients were smoker (40%) while 60 % weren't smoking before. Patients showed clinically significant improvement in term of the presenting somatic complaints as well as their Hamilton-D score immediately post-treatment and consolidate for 6 weeks post-treatment completion. The changes in the presenting somatic complaints were highly statistically significant  $P$  value < 0.01. It shows that fatigue and myalgia were present in 60 (100%) patient, anorexia in 48 (80%), chronic abdominal pain in 44 (73%), change in bowel habits in 52 (86%), vomiting in 24 (40%), myalgia in 28 (46%), atypical chest pain in 16 (26%), palpitations in 36 (60%), dyspnea in 32 (53%), urinary frequency in 24 (40%), erectile dysfunction in 18 out of 32 males (50%), while menstrual disturbance was present in 12 out of 28 females (42%). At the 6<sup>th</sup> week point the figures and percentages were 4 (6%), 12 (20%), 16 (26%), 28 (46%), 24 (40%), 0 (0%), 0 (0%), 4 (6%), 8 (13%), 4 (6%), 12 (20%), 4 (6%) and un-applicable, respectively.

**Conclusion:** Typhoid carrier, in our study, was associated with psychosomatic depression that improved on antibiotic therapy.

**Disclosure:** Nothing to disclose

## P1232 WITHDRAWN

## P1233 PERCUTANEOUS TREATMENT OF COMPLICATED HYDATID LIVER CYSTS: ABOUT 49

Chabib F.-Z., Benelbarhdadi I., Ajana F.-Z.  
Ibn Sina University Hospital, Medical Unit C, Rabat, Morocco

**Contact E-Mail Address:** dr.chabib.fatimazahra@gmail.com

**Introduction:** The of the liver hydatid cyst (LHC) is a parasitic disease due to the development of the larval form of the taenia of the dog echinococcus granulosus. This pathology remains frequent and constitutes a public health problem. Infectious, biliary and thoracic complications are present in 40% of cases. Topographic diagnosis has become easy thanks to advances in medical imaging. Percutaneous treatment was validated by the WHO in 1997 for uncomplicated cysts, and its place in the treatment of complicated forms remains controversial.

**Aims & Methods:** The aim of this work is to evaluate, the place of percutaneous treatment in complicated liver hydatid cysts (LHC) essentially those are infected or with biliary fistula.

this is a retrospective and descriptive study included all patients with complicated(HLC), confirmation of biliary fistula (BF) was done by bilious aspect of the aspirated liquid, or on the determination of bilirubin level with a rate higher than 5 mg / l, the diagnosis of infected (HCL) was made on the purulent aspect of the liquid and the bacteriological exam . All our patients had percutaneous treatment either by suction aspiration drainage or by PAIR (puncture, aspiration, injection, reaspiration), and received albendazole. The evaluation of the efficacy was made on ultrasound criteria. **Results:** Forty-nine patients followed for (HLC) complicated with biliary fistula and / or infection had received percutaneous treatment in our department, their average age was 33 years [5- 75], with no predominance of sex: 25 F and 24 H, 47% had history of (HLC) surgery, and most of them had a recurrence, and only two (4%) patients had previous PAIR . For the (HLC) treated , the average size was 9.4 cm [3.3-20]; 60% of (HLC) were type I, 38% type II and only 2% type III according to the GHARBI classification. Twenty-five patients presented with biliary fistula (51%), five had an infected (HLC) (10%), both complications were present in nineteen patients (38.7%) and the success rate in our series was of 73% :100% in infected cysts, 76% in case of biliary fistula, 68% in case of combination of the two complications.

**Conclusion:** Percutaneous treatment is an effective and safe method to treat complicated (HLC). Further studies are needed to confirm these results. But the best treatment of liver hydatid cyst remains the prevention.

**Disclosure:** Nothing to disclose

## P1234 RELATIONSHIP BETWEEN PATIENT BACKGROUND AND THE CAUSATIVE BACTERIA OF CHOLANGITIS AND DRUG SENSITIVITY

Itoh T.<sup>1</sup>, Tanaka M.<sup>2</sup>, Naritomi T.<sup>3</sup>, Fukuya Y.<sup>3</sup>, Nagahara H.<sup>3</sup>

Japan, <sup>3</sup>Social Welfare Organization Saiseikai Imperial Gift Foundation inc Saiseikai Kurihashi Hospital, Gastroenterology, Kuki, Japan

**Contact E-Mail Address:** ito.taito@twmu.ac.jp

**Introduction:** Cholangitis increases the internal pressure of the biliary duct, resulting in bacteria in the bile flowing out from the hepatic vein into the systemic circulation, which is said to cause bacteremia. This study aimed to identify the effective initial pharmacotherapy that is suitable for individual patients by investigating the relationship between patient background and the causative bacteria of cholangitis and drug sensitivity.

**Aims & Methods:** The study conducted a statistical analysis on the relationship between the primary disease of cholangitis, details of biliary drainage treatment, causative bacteria, and drug sensitivity of the bacteria in 107 patients with cholangitis who were admitted to the hospital between April 2014 and October 2018, where the causative bacteria could be identified using endoscopic retrograde cholangiopancreatography in blood and bile cultures.

**Results:** The 107 patients were comprised of 46 men and 51 women, with a mean age of 77 years. A total of 308 strains of causative bacteria were identified from blood cultures, and 333 strains were identified from bile cultures. The primary disease was cancer such as pancreatic cancer in 80 patients and non-cancerous conditions such as choledocholithiasis in 27 patients. The biliary drainage treatment in the patients with cancer consisted of self-expandable metal (n = 49) and plastic stents (n = 31),

with significantly more self-expandable metal stents used in the cancer patients (p < 0.001). The culture results indicated that the patients with cancer tended to have a significantly higher number of strains resistant to third-generation cephalosporin antibiotics such as cefotaxime and fourth-generation cephalosporin antibiotics such as cefepime. In particular, while ESBL-producing *Escherichia coli* was not isolated from the patients without cancer, it was detected 22 times in the patients with cancer. A significantly higher number of resistant strains were found in the plastic stent group in the subgroup analysis of the patients with cancer.

**Conclusion:** This study found a significantly higher number of resistant strains in the patients with cancer and cholangitis, which was particularly high in the patients where drainage was performed with a plastic stent. Possible causes include the following: patients with cancer have repeated occlusion of the bile duct as the cancer progresses, the plastic stent is more prone to occlusion than the self-expandable metal stent, and the patients have a greater exposure to antibiotics due to their immunocompromised state. Broad-spectrum antibiotics, excluding cephalosporin antibiotics, are preferable as initial treatment for cholangitis caused by cancer.

**Disclosure:** Nothing to disclose

## P1235 VARIATION IN PNEUMONIA RATES BY ENDOSCOPIC PROCEDURE AND SEDATION PERFORMED IN OUTPATIENT SETTINGS

Hutfless S.<sup>1</sup>, Chu D.<sup>2</sup>, Liu S.<sup>3</sup>, Kalloo A.<sup>3</sup>

<sup>1</sup>Johns Hopkins University, Department of Medicine, Baltimore, United States,

<sup>2</sup>Johns Hopkins University, Baltimore, United States, <sup>3</sup>Johns Hopkins Medical Institution, Baltimore, United States

**Contact E-Mail Address:** shutfle1@jhmi.edu

**Introduction:** Aspiration pneumonia following endoscopic procedures is associated with anesthesia assistance. We aimed to examine the type of sedation and rates of hospitalization for pneumonia following endoscopic procedures performed in the outpatient hospital setting.

**Aims & Methods:** The January 2015-December 2018 United States Medicare fee-for-service claims of individuals 65 and older were queried. This age groups represents about 30% of the United States population. Bronchoscopy, colonoscopy (diagnostic and screening), cystoscopy, EGD and ERCP were included. Monitored anesthesia care (MAC) and moderate sedation were identified by Healthcare Common Procedure Coding System (HCPCS) and associated modifiers. Simultaneous anesthesia care for 2-3 and 4 or more procedures was examined. Aspiration pneumonia within 7 days was identified by a hospitalization with ICD codes 5070, 5078, J690 or J698 and infectious pneumonia was identified by codes 480-486 and J12-J18. Only pneumonia recorded as present on admission was considered an event to increase specificity that the patient was admitted with this condition. Logistic regressions for pneumonia included the sedation variables, type of procedure, age, sex, race, year, comorbidities, screening vs diagnostic procedure, and procedure discontinuation.

**Results:** There were 9,023,288 eligible procedures (4,096,589 colonoscopy [26% screening], 3,853,942 EGD, 178,350 ERCP, 633,864 cystoscopy, and 351,527 bronchoscopy). MAC was documented for 58% of procedures (56% colonoscopy, 62% EGD, 81% ERCP, 69% cystoscopy and 43% bronchoscopy). Aspiration pneumonia was recorded in only 19 patients; older age and male sex were associated with an increased risk of aspiration pneumonia. There were only 40 admissions for infectious pneumonia; no factor was associated with infectious pneumonia.

**Conclusion:** In the outpatient hospital setting in the United States, pneumonia after endoscopy procedures that the hospital considered as present on admission was rare.

**Disclosure:** Nothing to disclose

**Introduction:** The incidence of yellow fever in Brazil has been low during the last decades, but since December 2016, an epidemic yellow fever has resurged in this country. In the severe form (15%-60%), gastrointestinal hemorrhage can be present, with a high mortality rate (20-50%). This is one of the first studies reporting the causes of gastrointestinal bleeding in patients with severe yellow fever. We aimed to describe the main endoscopic findings in patients with severe yellow fever in whom an emergency upper gastrointestinal endoscopy (UGE) was performed.

**Aims & Methods:** This is a retrospective case series study that included a total of 26 patients referred to a tertiary care center in Brazil for suspected severe form yellow fever diagnosis (between December 2017 and April 2018), undergoing UGE for acute upper gastrointestinal bleeding. The principal reasons of hospitalization of these patients in our hospital were acute liver failure (88%).

**Results:** The mean age was 36 years (range 16 yo - 63 yo), and 84,61% were men.

The table 1 summarizes main endoscopic findings and treatments

In the esophagus, four cases of Mallory-Weiss syndrome (three with active bleeding treated endoscopically with adrenaline injection in two cases and band ligation in one case); two cases of active variceal bleeding treated with band ligation and one case of esophageal perforation (Boerhaave's syndrome) that evolved into a bilateral esophago-mediastinal fistula treated with endoscopic placement of two plastic pigtail stents and bilateral pleural drainage.

In the stomach, eight cases presented with severe hemorrhagic gastritis (four with diffuse oozing bleeding that did not allow adequate endoscopic hemostasis and four without active bleeding); one case with focal oozing hemorrhage of the gastric mucosa, which resolved after a second UGE with hemoclip placement; four cases with gastric ulcers (two with active bleeding treated with hemoclip); one case with a vascular Dieulafoy lesion treated with hemoclip.

In the duodenum, one case presented with hemorrhagic duodenitis with diffuse oozing bleeding that did not allow adequate endoscopic hemostasis; one case with an active duodenal ulcer treated with hemoclip; one case with bulbar telangiectasias without bleeding. In two cases the specific cause of bleeding was not determined, due to the presence of large amounts of non-aspirable blood clots in the stomach and duodenum.

**Conclusion:** This is one of the first series describing the endoscopic findings and experience in this subset of patients. Liver acute failure due to yellow fever is an uncommon condition for endoscopists worldwide. 88% of the patients included in this study were hospitalized due to acute liver failure.

Severe vomiting episodes before gastrointestinal bleeding explained Mallory-Weiss and Boerhaave's syndrome cases. Most cases presented diffuse hemorrhagic gastritis probably due to the severe coagulopathy that limited endoscopic therapeutic options. UEG in severe yellow fever patients is challenging and required endoscopic treatment in 32 % in this case series study.

**Disclosure:** Nothing to disclose

## P1237 EPIDEMIOLOGY AND TIME TRENDS OF UPPER GASTROINTESTINAL BLEEDING - A POPULATION BASED COHORT STUDY OVER MORE THAN 30 YEARS

Vora P.<sup>1,2</sup>, Pietilä A.<sup>3</sup>, Brobert G.<sup>4</sup>, Salomaa V.<sup>3</sup>

**Contact E-Mail Address:** pareen.vora@bayer.com

**Introduction:** Gastrointestinal bleedings (GIBs) are acute events which are potentially severe but not always life threatening and often can be safely treated. There have been numerous studies reporting on the rates of GIBs associated with use of drugs but very few studies have examined the rates of upper GIBs (uGIBs) in the general population and trends over time

**Aims & Methods:** The aim of this study was to evaluate the incidence rates of uGIBs and the trends over time in the general population of Finland. Data from participants of prospectively conducted population-based FINRISK health examination surveys was utilized for this study. FINRISK enrolled persons aged 25-74 years, recruited by random sampling from the population register, stratified by 10-year age group, sex and study area. The total number of participants in each survey was approximately 6000-8000. The participation rate in 1972 survey was >90% with a gradually declining trend to 57% in men and 67% in women in 2012. The follow-up took place using record linkage to the country-wide electronic health registers which included hospital discharge register and causes of death register. With the help of these national registers, the coverage of the follow-up was 100% for persons living in Finland. The follow-up period was from the enrollment up to the onset of an uGIB leading to hospitalization, death due to any cause, or end of the follow-up period which was December 31<sup>st</sup>, 2016. Participants with a history of GIBs before the baseline were excluded from the analyses. Incidence rates, recurrence rates (events recorded were >30 days apart), cause-specific mortality rates and 28-day case-fatality rates for uGIBs were calculated with 95% confidence intervals (CIs). The time-trends in event rates were calculated using a log-linear poisson regression model adjusting for baseline age, gender, region, and the year of enrollment. Age standardization was conducted using weights from the European standard population

**Results:** A total of 71,068 participants were included in the study and they experienced 1643 incident uGIBs. The median age of participants experiencing uGIBs was 48.6 years, among the ones without GIBs it was 45.4 years. The age standardized incidence rates for uGIBs in males and females were 1.59 and 0.95 per 1000 py, respectively. Among men, the incidence rates declined approximately by half by the end of the study period compared to late 1980's (ref. period), and among women a consistent decline was seen, so that at the end of the study period the rates were less than 20% of those in the late 1980's. Among incident uGIBs, the recurrence rates of uGIBs in males and females were 20.3 and 13.3 per 1000 py, respectively. There was a substantial random variation but the general trend in proportion of recurrent uGIBs was increasing. Cause-specific mortality rates from uGIBs in males and females were 0.14 and 0.07 per 1000 py, respectively. Compared to the late 1980's, mortality due to uGIBs decreased sharply in the early 1990s by 40-60% and remained stable since the late 1990s, approximately at 20% of the level in the late 1980's. The 28 day case-fatality rates in males and females were 8.2% and 6.6%, respectively. The case-fatality rate for overall uGIBs for males and females calculated for 5-year periods since 1987 showed a declining trend up to the period 2002-06. However, no further decline was seen in the last decade.

**Conclusion:** Overall, the age-standardized incidence rates of uGIBs are higher in males than in females. The rates of uGIBs and deaths due to uGIBs have significantly decreased since the late 1980's over the years.

**Introduction:** Gastrointestinal (GI) bleeding is a common cause for hospitalization, resulting in significant mortality and morbidity. Innovative topical hemostatic modalities have been developed for endoscopic use. Our aim is to demonstrate the efficacy, feasibility and safety of Purastat to control GI bleedings. Puramatrix is a synthetic, bioresorbable material used to produce Purastat, created to control venous/arteriolar bleedings. It's easy, quick and transparent allowing to continue the procedure/to use other haemostatic therapies.

**Aims & Methods:** We report a case series of 33 patients (23 males, 10 women, median age 74 years) recovered to two endoscopy units (Garbagnate Milanese and Monza) for acute GI bleeding after failure of other hemostatic strategies (injection/clipping/thermal coagulation). 14/25 patients presented a lower GI haemorrhage from an oozing site after mucoscopy for non polypoid colon adenomas in different sites of the colon (8 pts from the right colon) 5 patients showed melena for duodenal bleeding from bulbar kissing ulcers, 4 patients with melena and anemia after duodenal mucoscopy for a laterally spreading tumor of the second part of the duodenum, 4 patients had ematemesis after Vater papilla's sphincterotomy, 1 patient showed progressive anemia for bleeding inside a pseudocyst after endoscopy ultrasound guided drainage, 1 patient presented with a massive rectal bleeding after a prostatic biopsy, 3 patients from neoplastic gastric ulcer localized in the body and in the fundus and 1 patient with a massive bleeding after gastric random sampling due to obscure underlying arteriovenous in-wall malformation.

**Results:** In all these patients, we tried to achieve a successful hemostasis first of all using an adrenaline injection and subsequently with clipping and/or argon plasma coagulator application without success. Finally we used a strate of Purastat applying 3 ml of gel, with a successful, stable hemostasis and a complete patients recovery in few days after the procedure, no pain and haemodynamical stability. No need to surgery or radiological haemostatic procedures

**Conclusion:** Purastat is a new, safe and feasible hemostatic device capable to control different types of GI haemorrhages even if the arteriolar massive ones.

**Disclosure:** Nothing to disclose

## P1239 ARE THERE ANY EPIDEMIOLOGIC OR MANAGEMENT DIFFERENCES BETWEEN UPPER GASTROINTESTINAL BLEEDING NOT ASSOCIATED AND ASSOCIATED TO PORTAL HYPERTENSION? COMPARATIVE ANALYSIS IN A SOUTHERN SPANISH AREA

Díaz Jiménez J.A.<sup>1,2</sup>, Leal Téllez J.<sup>2</sup>, Calle Gómez A.R.<sup>2</sup>

**Contact E-Mail Address:** adiazjime@gmail.com

**Introduction:** The aim is to evaluate comparatively different epidemiologic and management aspects of Upper Gastrointestinal Bleeding not associated (UGBNPH) and associated (UGBPH) to Portal Hypertension, in Puerta del Mar Hospital, Cádiz, Andalucía, Spain.

**Aims & Methods:** Retrospective research including every patient admitted to Gastroenterology Department of Puerta del Mar Hospital (Cádiz), between January 2016 and December 2016, because of Upper Gastrointestinal Bleeding (UGB).

We analysed different variables: relation to Portal Hypertension, age, cardiovascular risk factors such Arterial Hypertension (AHT), Diabetes Mellitus (DM) and Dyslipidemia (DLP); concomitant treatment with Proton Pump Inhibitors (PPIs), Antiplatelets, Antithrombotics, Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and Antidepressants; clinical and en-

doscopic findings; red blood cells and iron requirement. We also analysed short and medium term survival rates and recurrence rate in one-year period.

**Results:** We included 105 patients admitted because of Upper Gastrointestinal Bleeding (71,4% not associated to Portal Hypertension; 28,6% associated to Portal Hypertension), with an average age older in the first group (UGBNPH 69,7 years old; UGBPH 59,8 years old).

We did not find significant differences by etiology when analyzing DM (29,5%). However, it was more usual the AHT (53,3% vs 36,7%) and DLP (34,7% vs 16,7%) in not associated to Portal Hypertension group.

We did not find significant differences when analyzing use of PPIs (37,1%) and Antidepressants (17,1%). Nevertheless, it did exist a higher frequency of Antiplatelets (29,3% vs 6,7%), Antithrombotics (29,3% vs 3,3%) and NSAIDs (20% vs 0%) in patients with UGBPH.

Clinical debut as Melena (66,7%) and Hematemesis (61,9%) was similar, with no differences depending on etiology of bleeding.

Regarding Endoscopic findings, we found more frequently Gastric Ulcer in UGBPH (37,3%) and Esophageal Variceal bleeding among UGBPH (70%).

We did not find significant differences by etiology regarding amount of patients that required red blood cells transfusion during admission (62,9%), the number of packed blood cells used (4 as average) and iron treatment beginning (21,9%).

Short and medium-term survival rates were slightly higher in not associated to Portal Hypertension group: short-term (94,7% vs 90%) and medium-term (one year after admission) (84% vs 80%). Finally, recurrence rate in one-year period was fairly higher in associated to Portal Hypertension group (40,7% vs 14,1%), especially in women and Portal Hypertension Gastropathy bleeding.

**Conclusion:** Upper Gastrointestinal Bleeding not associated to Portal Hypertension is more frequent than the associated one in our environment. Cardiovascular risk factors such as Arterial Hypertension, Dyslipidemia or concomitant treatments as Antiplatelets, Antithrombotics and NSAIDs are more often related to UGBPH. The amount of patients with red blood cells transfusion requirement was similar by different etiologies. Survival rates are slightly higher in UGBPH, while bleeding recurrence is quite more frequent in UGBPH.

## P1240 NOVEL HEMOSTATIC POWDER STOPS BLEEDING IN A LIVE PORCINE MODEL OF UPPER GI BLEEDING

Donnellan F.<sup>1</sup>, Ali-Mohamad N.<sup>2</sup>, Baylis J.R.<sup>2</sup>, Cau M.<sup>2</sup>, McFadden A.<sup>1</sup>, Kastrup C.J.<sup>2</sup>

<sup>1</sup>Vancouver General Hospital, Vancouver, Canada, <sup>2</sup>University of British Columbia, Vancouver, Canada

**Contact E-Mail Address:** fdonnellan77@hotmail.com

**Introduction:** Hemostatic powders are an attractive option in upper GI bleeding. However, currently available powders are not effective in Forrest Ia bleeds and are associated with unacceptably high rebleeding rates. These limitations are related to their mechanism of action which is based on provision of a mechanical bandage on, rather than delivery of any therapeutic agents to, the site of injury.

CounterFlow is a novel hemostatic powder which based on self-propelling technology can deliver thrombin against blood flow and into the site of injury.

**Aims & Methods:** To determine efficacy of CounterFlow hemostatic powder in stopping bleeding in a live porcine model of acute severe upper GI bleeding.

Bleeding model includes anesthetized pig, surgical laparotomy and 1cm gastrotomy, placement of gastroepiploic vascular bundle into gastric lumen, incision of artery with ERCP needle knife to create an actively spurting bleed, and delivery of powder by upper endoscopy and a 7Fr catheter using a CO2 powered hand held delivery system.

**Results:** A total of 8 bleeds were created in 4 different pigs. Successful hemostasis was achieved in 100% of bleeds. Average time to achieve hemostasis was 4.31 mins (range 1 -11 mins). Average mass of powder required to achieve hemostasis was 2.4g (range 1.1 - 6.7g).

**Conclusion:** A novel self-propelling hemostatic powder has shown early promise in stopping bleeding in a live porcine model of acute severe upper GI bleeding.

**References:** Self-propelled particles that transport cargo through flowing blood and halt hemorrhage. Baylis JR et al. Sci Adv. 2015 Oct 2;1(9):e1500379

**Disclosure:** Drs. Kastrup and Baylis have filed patent applications regarding CounterFlow, and are co-founders of a start-up company, CoMotion Drug Delivery Systems, Inc. ("CoMotion"), whose focus is commercializing CounterFlow. Dr. Donnellan is also a shareholder in CoMotion.

## P1241 EFFICACY OF HEMOSTATIC POWDERS IN THE TREATMENT OF GASTROINTESTINAL BLEEDING RELATED TO NEOPLASTIC OR NON-NEOPLASTIC LESIONS

**Contact E-Mail Address:** car.cardamone@gmail.com

**Introduction:** EndoClot System (Endoclot Plus Inc., Santa Clara, CA, USA) and Hemospray (Cook Medical, Winston-Salem, NC, USA) are two sprayable powders for induction of immediate bleeding stop recently introduced in gastrointestinal endoscopy.

**Aims & Methods:** Aim of the study was to evaluate the efficacy and safety of the two kinds of hemostatic powder (HP) in the management of gastrointestinal bleeding (GIB). From September 2017 to March 2019, all patients with endoscopically confirmed GIB were considered eligible for the study. Inclusion criteria were active bleeding at the time of the endoscopy and the failure (complete or partial ineffectiveness) or inapplicability of standard procedures of hemostasis (local adrenaline infiltration, argon plasma coagulation or electrohemostasis, mechanical with clips). Once identified the source of GIB, Endoclot System or Hemospray was sprayed over the lesion and the short-term efficacy was evaluated observing the bleeding lesion for several minutes. The choice of which kind of HP to be used was arbitrary or related to the availability of the product in the endoscopy room. The efficacy of HP was evaluated according to the hemostasis which was defined as follows: immediate =no bleeding after application up to end of the procedure; stable=no bleeding recurrence in the 72 hours after the procedure; definitive =no more episodes of bleeding till the discharge. We also evaluated any adverse event possibly related to the use of HPs.

**Results:** A total of 29 patients (19 males; median age: 72 years, range: 32-89) were included. All patients had symptoms of upper GIB but two with rectal bleeding (one following an endoscopic submucosal dissection and one due to colorectal cancer). Of 29 patients, 20 were at first episode of GIB while 9 had already been submitted to an endoscopic hemostatic procedure for GIB. All patients were found to have an active GIB due to: chemotherapy-related mucosal damage or graft versus host disease (two patients, both with extensive mucosal denudation in the esophagus); ulcer in the stomach (3 patients), in the duodenum (4 patients), and in the gastric anastomosis (4 patients); inoperable malignancy infiltrating the wall of the stomach (8 patients), duodenum (4 patients), or colon (one patient); post-endoscopy procedures (sphincterotomy in two patients and endoscopic submucosal dissection in the rectum in one patient). The use of HP achieved immediate hemostasis in 28 out of 29 patients (97%), stable hemostasis in 23 patients (79%) and definitive hemostasis in 22 patients (76%). No adverse events occurred.

**Conclusion:** The HPs are effective for stopping GIB related to different kinds of neoplastic and not neoplastic lesions, not responding or not amenable to be treated with standard hemostatic techniques.

**Disclosure:** Nothing to disclose

## P1242 OUTCOME OF UPPER GI HAEMORRHAGE IN PATIENTS WITH ACUTE OR CHRONIC RENAL FAILURE AND INFLUENCE OF RENAL FAILURE ON RISK STRATIFICATION SCORING

Murray I.A.<sup>1</sup>, Haddock R.<sup>2</sup>, Fuchtbauer D.<sup>3</sup>, Menzies A.<sup>4</sup>, Michell N.<sup>4</sup>, Laursen S.B.<sup>3</sup>, Stanley A.J.<sup>5</sup>

**Contact E-Mail Address:** rosiehaddock1@doctors.org.uk

**Introduction:** Renal failure is associated with poorer outcome following upper gastrointestinal haemorrhage (UGIH) and is a parameter in some pre-endoscopy risk stratification scores which are used to identify low-risk patients who may be safely managed as outpatients. We studied the outcome of patients admitted with UGIH in relation to their renal function and risk stratification scores.

**Aims & Methods:** Prospectively collected data from a 1-year international multi-centre study of consecutive patients presenting with UGIH. Demographics, endoscopic findings, treatment and outcomes were recorded. eGFR was determined retrospectively from admission creatinine. If eGFR was < 60ml/minute, it was recorded whether this was acute kidney injury (AKI) or chronic kidney disease (CKD) by review of electronic patient notes. Glasgow Blatchford (GBS), admission Rockall (aRS), AIMS65 and PNED scores were determined. Need for endoscopic therapy, transfusion, surgery, rebleeding within 7days and 30-day mortality rates were recorded.

**Results:** The main findings are shown in table 1 and are median or percentage except where indicated.

	Normal renal function	AKI	CKD	p value
<b>Number</b>	1208	165	250	
<b>Age</b>	52	75	82	<0.0001
<b>Female</b>	39.7%	42%	50%	<0.05
<b>Endoscopy findings</b>				
<b>Normal</b>	12.0%	11.5%	12.4%	
<b>Benign ulcer</b>	17.9%	24.2%	19.2%	
<b>Varices</b>	5.2%	6.7%	4.4%	
<b>Cancer</b>	2.2%	0%	2.4%	
<b>Not scoped</b>	27.6%	24.2%	18.4%	NS
<b>Endoscopic therapy</b>	18.6%	25.9%	27.6%	<0.001
<b>Surgery</b>	0.6%	0%	1.2%	NS
<b>Rebleed &lt;7days</b>	4.6%	8.4%	6.8%	0.06
<b>30-day mortality:</b>				
<b>Bleed related</b>	1.2%	7.2%	4%	
<b>Non bleed related</b>	3.1%	10.8%	13.2%	<0.0001
<b>Transfusion</b>	27.7%	41.6%	49.6%	<0.0001
<b>Transfusion (average units)</b>	3.7	4.7	4.4	<0.05
<b>Need for treatment or Died</b>	37.5%	57.8%	63.2%	<0.0001
<b>Length of stay (average in days)</b>	3.96	8.11	6.58	<0.0001

[Table 1. Results summary]

In determining low risk patients who did not require endoscopic therapy, transfusion, surgery, radiological embolisation and did not die within 30d, GBS < 1 gave highest sensitivity for those patients with normal renal function, AKI or CKD (94.8-100%). Specificity was 51.6-64.8%, although GBS < 1 only identified "low risk" patients in 1.9% and 2.0% of AKI and CKD patients compared to 30% of those with normal renal function.

In comparison, AIMS65=0 had sensitivity 70.4-80%, specificity 54.1-94.3% identifying more patients as low risk (44.2%, 22.7%, 6.4% respectively). Admission Rockall = 0 identified a similar percentage to GBS as low risk with poorer sensitivity (75-100%). PNED < 1 identified the highest number of low risk patients (52.8%, 18.9% and 12.4%) but had low sensitivity (53.6-80.5%).

**Conclusion:** Patients admitted with UGIH and renal impairment are older and more likely to be female, than those with normal renal function. Transfusion requirements, need for endoscopic therapy, rebleed rate and mortality (bleed and non-bleed related) and are all increased in this group. GBS identifies low risk patients with AKI or CKD with high sensitivity, although few low risk patients are in this group. No other commonly used pre-endoscopy risk score is accurate in identifying low-risk patients with renal impairment.

<sup>1</sup>Hospital General Universitario, Unidad de Gastroenterología, Alicante, Spain, <sup>2</sup>Hospital General Universitario, Unidad de Gastroenterología, Alicante, Spain, <sup>3</sup>Hospital General de Elche, Elche, Spain, <sup>4</sup>Hospital General de Alicante, Alicante, Spain

**Contact E-Mail Address:** omp.89@hotmail.com

**Introduction:** The evolution of admitted patients due to gastrointestinal bleeding (GB) and previously treated with new oral anticoagulants (NOAC) has not completely characterized and compared to admitted patients with GB and previous treatment with other antiplatelet (AP) or anticoagulant (AC) therapy.

**Aims & Methods:** Our aim was to compare re-bleeding and mortality rates between both groups. A prospective multicenter cohort study was design and patients with AP-AC treatment for cardiovascular disease and acute GB were consecutively included between January 2017 and march 2018 in Alicante, Spain. Demographic, physical, endoscopic, blood parameters, previous treatment and evolution outcomes were recorded. Descriptive and analytic analysis were performed, comparing outcomes between patients with NOACs vs patients with other AP-AC therapy. Chi-square and t-Student test were used in univariate analysis for comparative analysis, while mean +/- standard deviation (SD) or frequencies and percentages showed descriptive results.  $P < 0.05$  was considered significant.

**Results:** 170 patients were included with a mean length of admission of 11.0 days (SD 9.8). 59% of patients were men and the mean age was 76.3. 50 (29.4%) had suffered a previous GB. NOACs were part of therapy in 61 (35.9%) patients, whereas the rest were being treated with other AP-AC therapy. During their stay at the hospital, a total of 24 patients rebled, 5 patients had ischemic complications and 6 patients died. Comparisons show that NOAC group had lower systolic pressure (118 vs 127;  $p=0.05$ ) and a trend to higher cardiac frequency (87 vs 80 bpm;  $p=0.06$ ). A lower but non-significant cypher of hemoglobin was also detected (8.9 vs 9.8 g;  $p=0.39$ ).

No differences were seen in the number of transfusions and Blatchford score. The length of admission was also similar between them (mean 11.3 vs 11.0 days,  $p=0.87$ ). Rebleeding ( $p=0.23$ ), ischemic complications ( $p=0.46$ ) and mortality ( $p=0.47$ ) rates did not differ between both groups. Comparing different NOACs, no significant differences were seen in the same rates either.

**Conclusion:** In our prospective cohort study, no differences were detected during the admission of patients with acute bleeding concerning related complications and mortality in patients with NOACs vs patients with other AP-AC therapy.

**Contact E-Mail Address:** tawfik.khoury.83@gmail.com

**Introduction:** Upper gastrointestinal bleeding is a complication often encountered in inpatients hospitalized for another reason. Often these patients are unstable and the decision to perform upper endoscopy in these patients is not easy.

**Aims & Methods:** To characterize variables that may predict endoscopic intervention in inpatients admitted for non-gastrointestinal bleeding (GIB) causes who later developed inpatient upper GIB. A retrospective analysis of patients who underwent inpatient gastroscopy from 5.2014 to 12.2017 at two academic medical centers were performed. Clinical and laboratory data were collected.

**Results:** One-hundred and seven patients were included. Nineteen patients (17.8%) underwent endoscopic intervention (group A) and 88 patients underwent endoscopy without intervention (group B). Average age in groups A and B was  $66.7 \pm 18.4$  and  $71.1 \pm 14.6$  years ( $P=0.13$ ), respectively. Predictors of endoscopic intervention were cirrhosis (31.5% vs. 3.4%,  $P < 0.0001$ ), lower blood pressure ( $109.8/60.8$  mmHg vs.  $126.8/68.3$  mmHg,  $P < 0.03$ ) and higher heart rate before gastroscopy ( $97.7$  vs.  $87.7$ ,  $P=0.03$ ), mechanical ventilation during admission (41.7% vs. 18.7%,  $P=0.04$ ), number of blood units administered (4.3 vs. 2.6 units,  $P=0.001$ ), lower hemoglobin level at time of gastroscopy (8.3 mg/dl vs. 9.3 mg/dl,  $P=0.04$ ), increase in urea level delta (7.1 vs. 2.55,  $P=0.05$ ) and higher Glasgow Blatchford (13.9 vs. 11.2,  $P=0.0004$ ), AIMS-65 (2.3 vs. 1.5,  $P=0.001$ ) and Rockall (6.4 vs. 4.3,  $P < 0.0001$ ) scores, respectively.

Recent antiplatelets, anticoagulation use and infectious etiology didn't predict endoscopic intervention ( $P > 0.1$  and  $P=0.6$ , respectively). Proton pump inhibitors at admission and prior to endoscopy didn't decrease the need of endoscopic intervention ( $P=0.3$ ). Mortality rate was similar between groups A and B (36.8% vs. 39.7%,  $P=0.4$ ).

**Conclusion:** Several clinical and laboratory parameters were found to predict endoscopic intervention in inpatients with DE NOVO upper GIB. Further prospective studies are needed to validate our findings

**Disclosure:** Nothing to disclose

### **P1245** OVER-THE-SCOPE CLIP AS A RESCUE THERAPY FOR FIBROTIC BLEEDING ESOPHAGEAL VARICES: A SINGLE-CENTER EXPERIENCE

Oleas R., Alcivar-Vasquez J., Alvarado-Escobar H., Puga-Tejada M., Robles-Medrand C.

Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Gastroenterology and Endoscopy Division, Guayaquil, Ecuador

**Contact E-Mail Address:** robertoleas@gmail.com

**Introduction:** Repetitive endoscopic band ligations (EBL) are associated with fibrosis of the esophageal wall. Fibrosis of the esophageal wall impaired the band ligation of esophageal varices during endoscopy. Sclerotherapy is the standard rescue therapy for the management of fibrotic esophageal varices; however, feasibility and safety are a concern for sclerotherapy.

**Aims & Methods:** **Aim:** We aimed to evaluate the safety and efficacy of Over-The-Scope clip in the management of actively bleeding fibrotic esophageal varices.

**Methods:** This was a historic cohort study. Data from patients with upper gastrointestinal bleeding from a single tertiary center were retrospectively recorded and prospectively analyzed. Patients in whom endoscopic band ligation failed to adhere to fibrotic esophageal varices were treated with the deployment of over-the-scope clips.

**Results:** Ninety-six patients with actively bleeding esophageal varices were included from September 2016 to January 2019. Five patients had fibrosis within the esophageal wall and active bleeding esophageal varices. Thus, the over-the-scope clip was deployed over the bleeding fibrotic varix as rescue therapy. The median age was 65 years old (range: 52 - 83); three

patients were female. The cirrhosis etiology was alcohol in one patient, and NASH in four patients. Two patients had two previous EBLs, two patients had three previous EBLs before the index bleed and one patient a single previous EBL. Four patients have a Child-Pugh B and one patient a Child-Pugh C. During follow-up esophagogastroduodenoscopy, two patients were submitted to further EBL for variceal eradication after the index over-the-scope clip therapy. Neither re-bleeding nor mortality during the index bleeding was documented. Table 1 summarizes patients data per each case.

Patient No.	Age (years)	Etiology	Child score	Previous EBL	Further EBL	Mortality
1	69	Alcohol	B	2	2	No
2	60	NASH	B	3	0	No
3	65	NASH	B	3	0	No
4	52	NASH	C	1	2	No
5	83	NASH	B	2	0	No

[Table 1. Characteristics of patients with fibrotic esophageal varices treated with Over-The-Scope Clip (OTSC).]

**Conclusion:** The over-the-scope clip is a safe and effective alternative in the management of fibrotic esophageal varices. The over-the-scope clip might be considered as an alternative to sclerotherapy in the management of fibrotic esophageal varices. Randomized controlled trials are required to validate these data.

**Introduction:** Peptic ulcers are the commonest cause of upper Gastrointestinal (GI) bleeding (UGIB), accounting for 44% of all UGIBs. The mortality from GI bleeding remains high at 7%. Hemospray (Cook Medical, North Carolina, USA) is a novel haemostatic powder aimed to treat GI bleeding. The aim of this study is to look at outcomes in patients with GI bleeds secondary to peptic ulcers treated with hemospray in 14 centres, and examine outcomes based on baseline ulcer morphology based on the Forrest classification.

**Aims & Methods:** Data was prospectively collected on hemospray use in UGIBs in the UK, France, Germany and the USA (Jan'16-March'19). Hemospray was used during emergency endoscopy for UGIBs secondary to peptic ulcers (oesophageal, gastric or duodenal) at the discretion of the endoscopist as a monotherapy, dual-therapy with standard haemostatic techniques or rescue therapy once standard methods have failed. Haemostasis was defined as cessation of bleeding within 5 minutes of hemospray application. Rebleeding was defined as a sustained drop in Hb (>2g/l), haematemesis or melaena with haemodynamic instability following index endoscopy.

**Results:** 202 patients with UGIBs secondary to peptic ulcers were recruited (136M, 66 F, 125/202 (62%) duodenal, 47/202 (23%) gastric, 30/202 (15%) oesophageal). Immediate haemostasis was achieved in 178/202 (88%) patients. The median Blatchford score was 12 at baseline (IQR, 10-14), median rockall score was 7 (IQR, 6-8).

Immediate haemostasis was achieved in 34/39 (87%) patients with Forrest 1a ulcers, 99/117 (85%) with Forrest 1b, 25/25 (100%) with Forrest 2a, 20/21 (95%) with Forrest 2b. There was 7/29 (24%) rebleeds with Forrest 1a ulcers, 13/84 (15%) with Forrest 1b. In the 24/196 (12%) patients who did not achieve haemostasis 18/24 (75%) were Forrest 1b ulcers.

In the total PUD cohort treated with hemospray, 26/154 (17%) had a re-bleed, the median rockall score in this group was 7 (IQR, 6-8). The number of rebleeds in oesophageal ulcers was 2/23 (9%), 6/38 (16%) in gastric ulcers, 18/93 (19%) in duodenal ulcers.

	Forrest 1a (n=39)	Forrest 1b (n=117)	Forrest 2a (n=25)	Forrest 2b (n=21)
Haemostasis	34/39 (87%)	99/117 (85%)	25/25 (100%)	20/21 (95%)
Median Blatchford score	13 IQR: 11-14	12 IQR: 10-15	12 IQR: 11-14	13 IQR: 11-14
Median Rockall score	7 IQR: 6-8	7 IQR: 6-8	7 IQR: 6-8	7 IQR: 6-8
Rockall score 7 predicted re-bleeding rate: 25-40%				
Re-bleeding	7/29 (24%)	13/84 (15%)	2/23 (9%)	4/18 (22%)
Rockall score 7 predicted mortality: 20-30%				
7-day mortality	7/34 (21%)	11/99 (11%)	1/23 (4%)	3/19 (16%)
30-day mortality	9/34 (26%)	21/99 (21%)	3/23 (13%)	5/19 (26%)

[Outcomes in different Forrest classification groups]

**Conclusion:** Hemospray is effective in achieving immediate haemostasis in UGIBs secondary to peptic ulcers. The baseline Blatchford score and rockall scores in our cohort are high with patients recruited from tertiary centres with a complex mix of potentially high-risk cases compared to community centres. The rebleeding and mortality rates are in keeping/below the predicted rate based on the scores.

The best outcome with hemospray was seen in patients with Forrest 2a ulcers, with 100% haemostasis, lowest number of re-bleeds and lowest overall 30-day mortality. The majority that did not achieve haemostasis were Forrest 1b ulcers. Highest rebleeding rate was in duodenal ulcers. The hemospray registry will continue the expand with the recruitment of US sites.

## P1247 COMPARISON OF ENDOSCOPIC HEMOSTASIS AND TRANSARTERIAL EMBOLIZATION (TAE) OF HEMORRHAGIC GASTRIC ULCER AT OUR HOSPITAL

Sugiyama Y., Fukami Y., Ishii R., Hara H., Machida T., Yonemoto Y., Ikemiyagi H., Yoshino K., Sakita S.

**Introduction:** Endoscopic hemostasis is the first choice of treatment for hemorrhagic gastric ulcers; however, if endoscopic hemostasis fails, switch to transarterial embolization (TAE) and surgery should always be considered. It may be possible to provide prompt treatment by examining predictive factors of switch from endoscopic hemostasis to TAE. This time we retrospectively compared endoscopic hemostasis with TAE for the treatment of hemorrhagic gastric ulcer at our hospital.

**Aims & Methods:** This study was aimed to assess predictive factors for requirement of switch from endoscopic hemostasis to TAE. Patients with benign hemorrhagic gastric ulcer requiring endoscopic hemostasis (clip method, coagulation method, and injection of hypertonic saline epinephrine(HSE)) who visited the hospital between December 2009 and December 2018 (n= 393) were enrolled. They were classified into two groups; one group underwent only endoscopic hemostasis, while the other received endoscopic treatment and TAE. Age, medical history, medication, Glasgow-Blatchford score (GBS), number of endoscopic hemostasis, total blood transfusion volume, and blood test of hemoglobin (Hb), serum albumin (Alb), blood urea nitrogen (BUN) and PT-INR were retrospectively reviewed and statistically considered.

**Results:** Of the 393 patients with hemorrhagic gastric ulcer underwent endoscopic hemostasis, hemostasis was achieved with endoscopy alone in 382 cases (97.2%) and 11 cases (2.8%) were switched to the TAE. The overall mean age was 68.7 years, and there was no significant difference between the 2 groups in terms of the medical and oral history (antithrombotic drugs, gastric acid inhibitors, and NSAIDs). Eight patients (72.7%) of TAE were able to achieve complete hemostasis; however, 2 did not achieve hemostasis with TAE, and surgery was performed. One patient was unable to identify point of bleeding; however, natural hemostasis was achieved. In one case, a splenic abscess was formed after the TAE, and splenectomy was performed, suggesting a complication due to TAE. There was no intestinal necrosis or perforation after TAE. The mean GBS at the first examination was  $10.0 \pm 3.3$  in endoscopic hemostasis group and  $12.2 \pm 3.5$  in TAE group, which was significantly higher in TAE group ( $p=0.0382$ ); further, number of endoscopic hemostasis was  $1.1 \pm 0.3$  and  $2.5 \pm 1.1$  ( $p=0.0008$ ), and total blood transfusion volume was  $3.8 \pm 3.8$  units and  $20.8 \pm 11.3$  units ( $p=0.0007$ ) respectively, which were also statistically higher in TAE group. Hb and Alb at the first visit were significantly lower in TAE group (Hb;  $p=0.0241$ , Alb;  $p=0.0230$ ).

**Conclusion:** As predictive factors of cases switching from endoscopic hemostasis to TAE, it is suggested that GBS at the first examination, number of endoscopic hemostasis, total blood transfusion volume, blood parameters of Hb and Alb at the first examination could be useful indices.

**Disclosure:** Nothing to disclose

## P1248 ASSESMENT OUTCOMES OF NEW THRESHOLDS OF THE GLASGOW BLATCHFORD SCORE IN MANAGING PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING. THE EXPERIENCE OF A TERTIARY CENTER

Jiménez-Rosales R.<sup>1</sup>, Vadillo-Calles F.<sup>1</sup>, Ortega-Suazo E.J.<sup>1</sup>, Martínez-Cara J.<sup>1</sup>, Redondo-Cerezo E.<sup>2</sup>

<sup>1</sup>Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain, <sup>2</sup>Hospital Virgen de las Nieves, Digestive Diseases, Granada, Spain

**Contact E-Mail Address:** ritajimenezrosales@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) remains a significant cause of hospital admission. In order to stratify patients according to the risk of complications and to predict the need of clinical intervention, several risk scores (RS) have been proposed and their in the early patients assesment is repeatedly recommended by international guidelines to distinguish high-risks patients, who may need clinical intervention and hospitalization, from low risk patients with a lower chance of developing complications (1). Many RS have been developed, being pre-endoscopy scores more appropriate because it seems more important to predict risk as soon as possible after the UGIB onset to help direct management, especially when the endoscopist is on-call (2). The most well established pre-endoscopic score is the Glasgow-Blatchford score (GBS). Patients with a GBS=0 have less than 1% likelihood of requiring endoscopic intervention and may safely be discharged before undergoing endoscopy; however, 90% of patients have a GBS>0 and would require inpatient management. A more recent study used a cutoff of  $\leq 1$  and show a 99.2% sensitivity when identifying low-risk patients, which identification would decrease the number of admitted patients admitted by half (3).

**Aims & Methods:** The aim of our study is to assess outcomes in patients with UGIB and GBS  $\leq 1$ .

This was a prospective study on consecutive UGIB patients (variceal and non variceal) treated in "Virgen de las Nieves" University Hospital from 2013 to 2018. All patients underwent upper endoscopy. Information regarding clinical and biochemical data and procedures was collected. Documented clinical outcomes were in-hospital and delayed (6-months) mortality, rebleeding and delayed 6-months hemorrhagic and cardiovascular events. Descriptive and inferential statistical analysis was carried out.

**Results:** 632 UGIB patients were included, 613 GBS>1 and 19 GBS $\leq 1$ . GBS $\leq 1$  patients differed from GBS>1 in comorbidities (26.3%vs.75.4%;  $p<0.001$ ), antithrombotic use (10.5%vs.38.2%;  $p=0.014$ ), smoking habit (0%vs.20.8%;  $p=0.026$ ), alcohol intake (5.26vs.18.99;  $p=0.001$ ), melena at presentation (31.6%vs.70.1%;  $p<0.001$ ), loss of consciousness (0%vs.12.2%;  $p=0.027$ ), pulse (80.26vs.90.32;  $p=0.003$ ), urea (31.68vs.86.11;  $p<0.001$ ), creatinine (0.79vs.1.21;  $p<0.001$ ), hemoglobin (13.8vs.9.4;  $p<0.001$ ), INR (1.01vs.1.56;  $p<0.001$ ), endoscopic treatment (10.5%vs.43.9%;  $p=0.004$ ), rebleeding (0%vs.17.8%;  $p=0.043$ ), red cell units transfusions (0vs.2.78;  $p<0.001$ ), days of admission (1.37vs.8.89;  $p<0.001$ ), in-hospital mortality (0%vs.10.1%;

$p=0.047$ ), delayed mortality (0%vs.11.1%;  $p=0.036$ ), delayed hemorrhagic events (0%vs.19.2%;  $p=0.035$ ), delayed cardiovascular events (0%vs.9.5%;  $p=0.045$ ). No differences were found in terms of sex, age, hematemesis, blood pressure, albumin, platelets and need for surgery or interventional radiology (0%vs.4.1%;  $p=0.360$ ).

**Conclusion:** This study showed patients with GBS $\leq 1$  are less complex and have great outcomes. This finding is similar to what has been previously described (3).

Being a referral center, our hospital takes care of a high number of patients with a special dedication to GI bleeding. This fact, as well as a 24/365 on-duty gastroenterologist determines a low threshold to perform urgent GI endoscopy.

In light of these findings we support what has been published previously, that is the safe outpatient management of patients with a GBS $\leq 1$ . Delaying endoscopy in these cases would not have changed the results, with healthcare savings.

In conclusion, as international guidelines recommend, we should use a risk score to guide our performance.

## P1249 THE IMPACT OF ON-CALL VS. ON-DUTY ENDOSCOPIST IN MORTALITY AND CLINICAL OUTCOMES FOR PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING: A PROSPECTIVE STUDY IN A TERTIARY CENTER

Jiménez-Rosales R.<sup>1</sup>, Vadillo-Calles F.<sup>1</sup>, Ortega-Suazo E.J.<sup>1</sup>, Martínez-Cara J.<sup>1</sup>, Redondo-Cerezo E.<sup>2</sup>

**Contact E-Mail Address:** ritajimenezrosales@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) is a true emergency, associated with significant morbidity, mortality and healthcare costs. Several factors have been found to influence UGIB outcomes including the experience of the endoscopist, off-hours hospital admission, hospital volume and time to endoscopy (1). A recent meta-analysis shows that patients with UGIB who were admitted during off-hours had a significantly higher mortality and were less likely to receive endoscopy within 24 hours of admission. Indeed, there seems to be a strong correlation between timely endoscopic management and staff coverage in the hospital, particularly the availability of on-call endoscopists during off-hours (2).

**Aims & Methods:** The aim of our study was to compare whether there are differences in UGIB outcomes between two periods in our hospital, one with on-call endoscopist (OCE) and another with on-duty endoscopist (ODE). This was a prospective study on consecutive UGIB patients (variceal and non variceal) treated in "Virgen de las Nieves" University Hospital from 2013 to 2018 (OCE until July 2016, ODE afterwards, always a resident on-duty). Every patient underwent upper endoscopy in the first 24h. Information regarding clinical and biochemical data and procedures was collected. Documented clinical outcomes were in-hospital and delayed (6-months) mortality, rebleeding and delayed (6-months) hemorrhagic and cardiovascular events. Descriptive and inferential statistical analysis was carried out. **Results:** 638 patients with a diagnosis of UGIB were included, 505 OCE and 133 ODE. No differences were found between OCE and ODE in terms of in-hospital complications (15.8%vs.16.5%;  $p=0.845$ ), number of red blood cell units transfusions (2.84vs.2.28;  $p=0.441$ ), days of hospital stay (8.98vs.8.61;  $p=0.463$ ), rebleeding (16.9%vs.18.9%;  $p=0.575$ ), need for surgery or interventional radiology (4.4%vs.3%;  $p=0.484$ ), acute mortality (9.7%vs.9.5%;  $p=0.960$ ), delayed mortality (11.6vs.7.3%;  $p=0.177$ ), delayed hemorrhagic events (18.5%vs.17.4%;  $p=0.855$ ) or delayed cardiovascular events (9.1%vs.8.7%;  $p=0.922$ ). Patients managed by ODE presented higher rate of mayor bleeding stigmata (64.2%vs.48.8%;  $p=0.005$ ) and need for endoscopic treatment (50.4%vs.41.2%;  $p=0.045$ ).

**Conclusion:** Our hospital is a tertiary and referral center, with an 24/365 on-duty endoscopist. In this study, we observed no differences in the main UGIB outcomes between patients management by OCE vs. ODE, compen-

sated probably by optimal timing and performance of endoscopy within 24 hours by an experienced endoscopist in the first period. This finding is in accordance with previous result from Xian Feng Xia et al. showing that in hospitals providing endoscopy outside normal hours, off-hours admission was not associated with an increased risk of mortality(2).

However, we found a higher rate of bleeding stigmata and need for endoscopy in ODE. This finding may be explained by the shortened lapse between admission and endoscopy. Longer delays might allow the physiological healing process to downstage endoscopic lesions, reducing endoscopic therapy requirements.

In conclusion, endoscopic attention during off-hours is important for the quality of care for patients with UGIB to warrant endoscopic performance within 24 hours(3) with no relevant differences between an on-call vs. on-duty endoscopist schedule.

## P1250 OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING SECONDARY TO NEOPLASM

Vadillo-Calles F<sup>1</sup>, Jiménez-Rosales R<sup>1</sup>, Ortega-Suazo E.J.<sup>1</sup>, Martínez-Cara J.<sup>1</sup>, Redondo-Cerezo E.<sup>2</sup>

<sup>1</sup>Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain, <sup>2</sup>Hospital Universitario Virgen de Las Nieves, Digestive Diseases, Granada, Spain

**Contact E-Mail Address:** ritajimenezrosales@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments and represents a true emergency, associated with significant morbidity, mortality and healthcare costs.

Bleeding from upper GI neoplasms (UGIN) has been reported to be responsible for 1-5% of all acute UGIB (1). Although surgical treatment has been shown to control the bleeding episode and improve survival, most patients present with advanced-stage unresectable cancer (2).

Endoscopy therapy has proven to be effective in these cases and hemostasis has been achieved in 67-100% of patients (3).

However, treatment outcomes for UGIB caused by neoplasms have been scarcely reported.

**Aims & Methods:** The aim of our study was to compare the outcomes of patients with UGIB secondary to neoplasms with those with UGIB secondary to other causes.

This was a prospective study on consecutive patients with UGIB (variceal and non variceal) treated in "Virgen de las Nieves" University Hospital from 2013 to 2017.

All patients underwent upper endoscopy, and information regarding clinical and biochemical data, procedures, and outcomes for 6 months after admission were collected. The clinical outcomes documented were in-hospital mortality and rebleeding. Descriptive analysis, bivariate analysis and multivariate logistic regression models were carried out.

**Results:** 638 patients with a diagnosis of UGIB were included, in 28 secondary to neoplasms. We included gastric neoplasm (12 patients), gastric polyps (8 patients), gastrointestinal stromal tumors (GIST)(4 patients), gastric lymphoma (3 patients) and a duodenal tumor invasion (1 patient). These patients differed from the rest in age, previous neoplasms history, heart failure, haemoglobin and platelets levels at admission, anticoagulant drugs intake and mortality within 6 months (table 1). They did not differ in comorbidities, interventions, complications, acute and rebleeding.

There were 5 patients (17,9%) who died in hospital, only one associated with the hemorrhage. Within the first 6 months, 6 patients died (21%), all of them due to disseminated cancer, not to GI bleeding.

Age (OR 1,04; 95% CI 1,01-1,07. p,01) and previous neoplasm history (OR 20,78; 95% CI 1,63-265,44. p,02) were independent risk factors for delayed-6months mortality.

**Conclusion:** In this study, we observed that UGIB due to neoplasms has a similar clinical course in the acute episode than bleeding secondary to other causes with regards to in-hospital mortality, complications, need for interventions or rebleeding. We observed some differences in the long term outcomes such as mortality within 6 months after discharge. As expected, a previous neoplasm history is a clear predictor of mortality for these patients.

	Neoplasm	Others	p
Age	73,4	64,3	0,001
Previous neoplasm history	28,6%	12,3%	0,012
Heart failure	21,42%	9,67%	0,04
Haemoglobin	8,38	9,56	0,022
Platelets	269821	207542	0,006
Anticoagulant	32,1%	16,1%	0,026
Comorbidities (ASA>2)	64,3%	68,05%	0,67
Hospital stay (days)	12,29	8,92	0,12
Blood unit transfusion	3,29	2,69	0,38
Blood pressure	110,7	112,7	0,66
Endoscopic treatment	25%	39,7%	0,12
Rebleeding	3,7%	7,7%	0,71

**Introduction:** Upper gastrointestinal bleeding (UGIB) remains a common cause of presentation and admission to hospital in the UK, with the incidence in Scotland one of the highest in the world. Over the past 15 years there have been several developments to improve management of patients with UGIB. Our aim was to investigate the number of patients presenting to Scottish hospitals with UGIB between 2000-2015 and assess the difference in demographics, aetiology of bleeding and clinical outcomes, including those for weekends and weekday presentations.

**Aims & Methods:** Data were collected from SMR01 hospital admissions records and GRO death certificates for the period 1<sup>st</sup> January 2000 to 31<sup>st</sup> December 2015 and analysed in the national safe haven. All outputs were disclosure-checked for confidentiality purposes. Admission and death rates were computed for each year with trends over the study period estimated using Poisson regression. Standard errors were adjusted to account for any serial dependence.

**Results:** A total of 129,404 patients presented to Scottish hospitals with UGIB between January 2000 and December 2015. Mean age at admission increased over this period from 59.2 years to 61.4 years (P=0.049). There was no difference in the annual number of patients over the 15-year pe-

riod. The incidence of UGIB was highest in the more deprived quintiles, although there was a reduction in incidence in the three most deprived quintiles over the study period (SIMD1;  $P < 0.001$ ; SIMD2;  $P = 0.002$ ; SIMD3;  $P = 0.001$ ). There was a significant decrease in 30-day case-fatality from 10.1% in 2000 to 7.9% in 2015 ( $p < 0.001$ ), which was significant across all the deprivation quintiles ( $P < 0.001$ ). This reduction was seen for both variceal and non-variceal bleeding (IRR 0.967;  $P < 0.001$  and IRR 0.980;  $P < 0.001$  respectively) with deaths as a proportion of admissions declining fastest in the variceal compared to the non-variceal group (24.4% to 14.5%, and 9.8% to 7.8% respectively). The mean length of stay also fell from 3.9 days to 2.1 days, an average decline of 0.14 days per year (95% CI .15612 - .11723;  $P < 0.001$ ). There was no difference in 30-day case-fatality between patients presenting at weekdays or weekends.

**Conclusion:** The number of patients presenting with UGIB to Scottish hospitals annually has remained similar over the 15-year study period. However case-fatality and length of hospital stay has fallen, despite a rise in the mean age of patients.

**Disclosure:** Nothing to disclose

## P1252 PEPTIC ULCER BLEEDING - TIME TREND ANALYSIS OF INCIDENCE AND OUTCOME BETWEEN 2007 AND 2017

**Introduction:** The aim of this study was to demonstrate differences in epidemiological, clinical, endoscopic characteristics and outcome of peptic ulcer bleeding (PUB) between 2007 and 2017.

**Aims & Methods:** From January 2007 to December 2007 a total of 137 patients referred to our emergency department due to PUB, and from January 2017 to December 2017 a total of 128 patients referred to our emergency department due to PUB. They were screened and enrolled in this study.

**Results:** There was no statistically significant difference in PUB incidence between 2007 and 2017 (38.8/100000 vs 36.3/100000). In 2017 74% patients with PUB was older than 65 years ( $p < 0.001$ ). Men were the majority in both groups of patients (over 60%) and most of the patients were bleeding from stomach ulcers (more than 55%). In the year 2017 more patients were bleeding from high risk peptic ulcers (Forrest 1a, 1b, 2a i 2b) (63.3 vs 48.9%,  $p < 0.001$ ). In 2017 most patients had moderately severe to severe comorbidities (50.3 vs 34.3%,  $p < 0.001$ ). Initial hemostasis was performed more in 2017 than 2007 (61.7 vs 40.9%,  $p < 0.001$ ). There was no difference in the recurrence of bleeding (8.6 vs 6.7%), in required for surgical intervention (4.7 vs. 6.6%), 30-day mortality (7 vs. 4.4%) and need for red blood cell transfusion (55.5 vs 50.4%) between year 2017 and 2007. In 2017 significantly more patients received fresh frozen plasma transfusion (12% vs 4.4%,  $p < 0.05$ ) and patients were longer hospitalized (7 vs. 6 days,  $p < 0.01$ ). In the year 2017 and 2007 the majority of patients with PUB were taking agents that attenuate cytoprotective function of stomach and duodenal mucosa (51.1 vs 52.4%). In 2017 higher number of patients was taking anticoagulant and antiplatelet therapy compared to 2007 (32.8 vs 13.3%,  $p < 0.01$ ).

**Conclusion:** PUB predominantly occurs in older age groups with significant comorbidities, and it is associated with taking agents that attenuate cytoprotective function of stomach and duodenal mucosa, especially with antiplatelet and anticoagulant therapy.

**Introduction:** previously we reported that Rikkunshito (RKT), Japanese herbal medicine improved urocortin1-induced appetite loss through an increase in ghrelin secretion in rats [Am J Physiol Endocrinol Metab 2011; 301: E72-82, Psychoneuroendocrinology, 2014;50:300-10]. Recently RKT was also elucidated to improve symptoms of functional dyspepsia (FD) [Neurogastroenterol Motil 2018; 30]. In the present study, we undertook to elucidate a mechanism for orexigenic effects of RKT in the central nervous system using in-vivo experiment with rats. To study effects of RKT on the function of brain, we evaluated expression of c-Fos as an indicator of activation of neurons in the nuclei of appetite control system and reward system in the brain. Then the activation of dopamine neuron was also evaluated using immunohistochemical staining of tyrosine hydroxylase (TH) which is the rate-limiting enzyme in the synthesis of dopamine and norepinephrine.

**Aims & Methods:** Study on appetite: As anorexic models, rats with cholecystokinin-8 (CCK) administration and restraint stress (RS) were used, because these factors were known to induce anorexia and were supposed to be involved in the pathophysiology of FD. Effects of CCK or/and restraint stress on food intake were examined with or without RKT. To elucidate the involvement of brain in the actions of RKT, RKT was given to rats 2 hrs before treatments with CCK and RS. The brains were fixed with transcardial perfusion with paraformaldehyde and glutaraldehyde, and the brains were removed and continuously fixed and cut into serial transverse sections. The sections were incubated with anti-c-Fos polyclonal antibody solution followed by incubation with anti-TH antibody and the immunohistochemical staining was performed. Numbers of c-Fos-immunoreactive (ir) neurons or TH-immunoreactive (ir) neurons were counted under bright field microscope.

**Results:** 1. RKT significantly ( $p < 0.05$ ) restored food intake inhibited by the combination of CCK and RS. RKT increased c-Fos-ir neurons not only in the nuclei on hypothalamus but also in ventral tegmental area (VTA) [RKT(-): RKT (+) 298±34 : 631.3±30,  $p < 0.01$ ] and nucleus accumbens (Nac) [RKT(-): RKT (+) 111.0±19 : 232±35,  $p < 0.05$ ] in CCK and RS-treated rats. Number of neurons double-stained with anti-c-Fos antibody and anti-TH antibody was markedly increased by RKT in VTA [RKT(-): RKT (+) 13±1.7 : 74±17,  $p < 0.05$ ]. GHSR1A (ghrelin receptor) antagonist, D-Lys<sup>3</sup>-GHRP-6 suppressed RKT-induced increase in food intake and c-Fos expression in the neurons of VTA in CCK and RS-treated rats.

**Conclusion:** The result suggests that RKT restores appetite through the ghrelin-dependent activation of the neurons in reward system such as VTA and Nac. The results may explain the mechanism for the effects of RKT to improve appetite in patients with anorexia due to FD and other causes.

## P1254 EX VIVO IMAGING OF NEURONAL ACTIVATION BY USING GCAMP6S IS SUITABLE FOR PHARMACOLOGICAL STUDIES OF ION CHANNELS MEDIATING ACTION POTENTIAL CONDUCTION IN THE AXONS OF VISCERAL NOCICEPTORS

Lipták P.<sup>1</sup>, Patil M.J.<sup>2</sup>, Pavelková N.<sup>3</sup>, Kollárik M.<sup>3</sup>

<sup>1</sup>Jessenius Faculty of Medicine, Clinic of Gastroenterological Internal Medicine, Martin, Slovakia, <sup>2</sup>Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, <sup>3</sup>Morsani College of Medicine, University of South Florida, Department of Molecular Pharmacology & Physiology, Tampa, United States

**Contact E-Mail Address:** liptak@jfm.uniba.sk

**Introduction:** The information about noxious and inflammatory stimuli in the visceral organs is transmitted to the central nervous system by the action potentials conducted in the axons of visceral pain-mediating afferent nerves (nociceptors). Although it is well established that the voltage-gated sodium channels (NaV1) are essential for the action potential conduction, it is unknown which of 9 known NaV1 subunits (NaV1.1 thorough NaV1.9) mediate the action potential conduction in the axons of visceral nociceptors. Selective inhibition of the NaV1s mediating action potential conduction in nociceptors could aid the treatment of visceral pain. Unfortunately, the electrophysiological single fiber recording is extremely time consuming for this type of studies.

**Aims & Methods:** To evaluate the hypothesis that ex vivo imaging of neuronal activation by the calcium indicator GCaMP6s expressed in sensory neurons is suitable for pharmacological studies of NaV1 channels mediating the action potential conduction in the axons of visceral nociceptive (capsaicin-sensitive) neurons.

**Methods:** The vagus nerve with the sensory jugular/nodose ganglion (JNG) was isolated from the Pirt-Cre;R26-GCaMP6s mice in which virtually all JNG neurons express GCaMP6s. The distal end of the vagus nerve was electrically stimulated by the concentric electrode and the resulting activation of JNG neurons was detected by imaging GCaMP6s with multiphotone microscopy (excitation wavelength 920nm, 6-10 optical sections separated by 20µm, frame rate 0.17Hz). NaV1 inhibitors were selectively superfused (37°C) over the desheathed segment of the vagus nerve between the stimulation electrode and JNG. The putative nociceptive subset of vagal neurons was identified by the GCaMP6s response to capsaicin (1µM) applied to JNG.

**Results:** Vagal electrical stimulation with increasing frequency 0.5-10Hz (pulse 1ms, 100V) for 20s evoked increasing intensity of the GCaMP6s signal in JNG neurons. When normalized to the signal at 5Hz, the signal evoked by 0.5, 1, 3, 5 and 10Hz was 6±1%, 16±1%, 67±2%, 100±0% and 134±5%, respectively (N=160 capsaicin-sensitive neurons). Therefore, the stimulation with 5Hz was used. The NaV1 inhibitor tetrodotoxin (TTX, 0.1µM) applied to the vagus nerve completely abolished activation evoked by 5Hz electrical stimulation of the vagus nerve in 88% of capsaicin-sensitive neurons (N=93). This is consistent with the previous findings that TTX-sensitive NaV1s are required for action potential conduction in the vast majority of axons in the vagus nerve. The selective NaV1.7 inhibitor PF-05089771 (3µM) applied to the vagus nerve completely abolished activation evoked by 5Hz electrical stimulation of the vagus nerve in 57% of capsaicin-sensitive neurons (N=282).

**Conclusion:** Our data show that the activation of vagal neurons evoked by electrical stimulation of the vagus nerve and detected by calcium reporter GCaMP6s expressed in vagal neurons can be abolished in the predictable all-or-none fashion by NaV1 inhibitors applied to the vagus nerve. We conclude that ex vivo imaging of neuronal activation by the GCaMP6s expressed in sensory neurons is suitable for the pharmacological studies of the NaV1 channels mediating the action potential conduction in the axons of visceral nociceptive neurons.

**Contact E-Mail Address:** arinbox@list.ru

**Introduction:** Glutamate (Glu) is the major excitatory neurotransmitters of a brain, but an excess of Glu, results in hyperactivation and subsequent death of neurons. The tripeptide Pro-Gly-Pro (PGP) is a fragment of various regulatory oligopeptides. PGP effectively protects the gastric mucosa from stress-induced ulcers and damage caused by prolonged administration of monosodium glutamate (food supplement).

**Aims & Methods:** We studied the effects of PGP (10 µM), its N-acetylated and N-phosphorylated derivative (AcPGP and P-PGP) on the intracellular  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ), mitochondrial potential ( $\Delta\Psi_m$ ) and cell survival of primary neuroglial cultures subjected to glutamate excitotoxicity. Primary cultures were prepared from the cortex 1-2-day old Wistar rats. Single cell  $[Ca^{2+}]_i$  and  $\Delta\Psi_m$  fluorescence microscopy measurements were performed employing Fura-FF and Rh123, respectively. The survival of neuroglial cultures was studied using vital fluorescent dyes Syto-13 and EthD-1. Peptides were synthesized at the IMG RAS. The experiments with animals were carried out in accordance with the declaration on the human behavior towards animals and in accordance with the Order of the Ministry of Healthcare and Social Development of Russia "On Approval of Laboratory Practices".

**Results:** PGP and AcPGP by itself were not neurotoxic. In contrast to them P-PGP revealed a weak neurotoxicity reducing cell survival by ~20%. Glu reduced the ratio of live/dead cells by ~45%. Addition of PGP ~30min prior to Glu application increased the proportion of live cells by ~27%. It has been shown earlier that the acetylation of PGP makes it more resistant to prolyl peptidases preventing its hydrolysis. However PGP but not AcPGP delayed the development of the Glu-induced delayed calcium deregulation (DCD) and synchronous with DCD profound drop of  $\Delta\Psi_m$ .

**Conclusion:** Uncovered earlier gastroprotective effect of the peptide PGP against monosodium Glu-induced ulcer could be, at least partially, related to neuroprotection of gut innervation. We have shown that PGP (10 µM) diminish the excitotoxic effect of Glu 33 µM and promote recovery of  $[Ca^{2+}]_i$  and mitochondrial potential after Glu removal from the cell culture. Acetylation or phosphorylation of the N-terminus of PGP prevented its neuroprotective effect. In our early studies it has been shown that dipeptide GP has a pronounced gastroprotective effect on the stressor model of ulcer formation. Probably the gastro-neuroprotective effect of PGP is partially mediated by its dipeptide moiety GP.

**Disclosure:** Nothing to disclose

## P1256 EVALUATION OF GASTROINTESTINAL MOTILITY IN PATIENTS WITH MIONEUROGASTROINTESTINAL ENCEPHALOPATHY (MNGIE)

Alcala L.<sup>1</sup>, Accarino A.<sup>1</sup>, Marti R.<sup>2</sup>, Barba Orozco E.<sup>3</sup>, Malagelada J.-R.<sup>1</sup>, Azpiroz F.<sup>4</sup>, Malagelada C.<sup>5</sup>

<sup>1</sup>Vall d'Hebron University Hospital, Department of Gastroenterology and Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain, <sup>2</sup>Vall d'Hebron Research Institute, Barcelona, Spain, <sup>3</sup>Hospital Valle Hebron Gastrointestinal Motility, Digestive System Research Unit, Barcelona, Spain, <sup>4</sup>University Hospital General Vall d'Hebron, Gastroenterology Department, Barcelona, Spain, <sup>5</sup>Hospital Vall d'Hebron, Digestive Diseases, Barcelona, Spain

**Contact E-Mail Address:** lgalcala1986@gmail.com

**Introduction:** Myoneurogastrointestinal encephalopathy (MNGIE) is a rare mitochondrial disease caused by mutations in the thymidine-phosphorylase enzyme gene. Clinically it is characterized by severe gastrointestinal dysmotility associated with cachexia and a demyelinating sensory-motor

polyneuropathy. Given the low incidence (1-9 per million), most patients are mistakenly diagnosed of other digestive diseases. Despite the fact that gastrointestinal symptoms are progressive and invariably lead to death, there are so far no studies evaluating gastrointestinal function in these patients.

**Aims & Methods:** We retrospectively studied patients with biochemically and genetically confirmed MNGIE who had been referred for evaluation of gastrointestinal function to our Motility Unit between August 2008 and January 2019.

**Results:** In this period, 8 patients ultimately diagnosed of MNGIE (age range 16-41 years, 5 men and 3 women) were evaluated. At the time of referral, 5 of the 8 patients were misdiagnosed as Crohn's disease (n = 2), celiac disease (n = 1) and superior mesenteric artery syndrome (n = 2). All patients were severely underweight (BMI range 9 - 15.4 kg/m<sup>2</sup>) and complained of chronic digestive symptoms including abdominal pain, vomiting and diarrhea; six of them required total parenteral nutrition. All patients except one, showed radiological signs suggestive of intestinal pseudo-obstruction: air-fluid levels by plain abdominal x-ray and intestinal dilatation by CT scan in the absence of mechanical obstruction. Specific motility tests were performed depending on clinical symptoms and the patient's tolerance. Gastric emptying evaluation by scintigraphy was performed in 5 patients and detected gastroparesis in 4. Esophageal manometry was performed in 5 patients, all of which exhibited ineffective motility and a hypotensive lower esophageal sphincter. Small bowel manometry was performed in 4 patients and all showed a rare giant non-propagating contraction pattern. In 3 of them this manometric pattern helped to establish the diagnosis of MNGIE within the clinical context. Six of the 8 patients died (1 to 60 months after diagnosis, median 2 mo) due to gastrointestinal complications of the disease.

**Conclusion:** In patients with MNGIE severe digestive symptoms due to gastrointestinal dysmotility often lead to misdiagnosis. We have detected a specific intestinal dysmotility pattern which may help to identify patients with MNGIE.

**Disclosure:** Nothing to disclose

## P1257 OBESITY DOES NOT IMPACT OUTCOMES OR RATES OF GASTROESOPHAGEAL REFLUX AFTER PERORAL ENDOSCOPIC MYOTOMY IN ACHALASIA

**Contact E-Mail Address:** chadalp@ccf.org

**Introduction:** Outcomes of laparoscopic Heller's myotomy (LHM) in obese patients with achalasia are sub-optimal along with increased risk of gastroesophageal reflux disease (GERD). The impact of obesity on treatment success and GERD after POEM are not well known. Hence our study aims were to compare the clinical outcomes and rates of GERD after POEM in non-obese versus obese patients with achalasia.

**Aims & Methods:** Chart review of all achalasia patients who underwent POEM at our institution between April 2014 and June 2018 was performed. Patients with timed barium oesophagram (TBE) and high-resolution oesophageal manometry (HREM) prior to POEM along with post-POEM TBE, HREM and oesophageal pH study were included. Patients were categorized into two groups, non-obese (body mass index, BMI < 30 kg/m<sup>2</sup>) and obese (BMI ≥ 30 kg/m<sup>2</sup>). Patient demographics, TBE, HREM, pH study findings and Eckardt scores were compared between the two groups.

**Results:** A total of 89 patients (46 non-obese; 43 obese) met the study criteria. There were no significant differences in age, gender, achalasia subtype, operative time, length of stay (LOS) and complication rates between the two groups. Treatment success (Eckardt score < 3) was similar in both groups (97.7% non-obese vs 92.7% obese, p=0.35). Abnormal DeMeester scores on pH study (>14.72) were similar in non-obese and obese patients (58.7% versus 46.5%, p=0.25). Symptomatic GERD was also similar in both groups (17.8% in non-obese vs. 20% in obese, p=0.79).

**Conclusion:** POEM is an equally safe and effective treatment option for both non-obese and obese patients with achalasia in the short term. Interestingly, POEM does not lead to higher rates of GERD in obese compared to non-obese patients.

**Disclosure:** Nothing to disclose

Factor	Non-obese (n=46) (mean BMI: 25.1 ± 2.4 kg/m <sup>2</sup> )	Obese (n=43) (mean BMI: 36.2 ± 5 kg/m <sup>2</sup> )	p-value
Age at POEM (years)	58.1±16.4	56.6±13.9	0.64
Operative time (minutes)	102.5[84.0,120.0]	98.0[79.0,118.0]	0.51
Rate of complications	2.2%	4.7%	0.61
Pre-POEM Eckardt score	7.0[5.0,8.0]	6.0[5.0,8.0]	0.46
Post-POEM Eckardt score	0.00[0.00,1.00]	1.00[0.00,2.0]	0.16
POEM success rate	97.7%	92.7%	0.35
POEM failure rate	2.3%	7.3%	0.35
Rate of symptomatic GERD	17.8%	20%	0.79
Abnormal DeMeester score on 24-hr oesophageal pH study	58.7%	46.5%	0.25

Nicolle, Dept. of Digestive Physiology, Rouen Cedex, France

**Contact E-Mail Address:** abdellah.hedjoudje@gmail.com

**Introduction:** Gastric electrical stimulation has been shown to relieve vomiting and nausea in medically refractory patients. Efficacy of gastric electrical stimulation has been reported mostly in short term studies, however no studies have evaluated its efficacy beyond 10 years after implantation.

**Aims & Methods:** Patients implanted at our center for medically refractory severe and chronic nausea and/or vomiting were evaluated at baseline and over 10 years after implantation using symptomatic scale and quality of life score (GIQLI score). Improvement was defined as a reduction of more than 50% of the vomiting frequency.

**Results:** 50 patients were implanted from January 1998 to December 2009. The mean follow-up was 10.5 (+/- 3.7) years. Among the 50 patients, 7 were explanted due to a lack of efficacy, 2 patients died and 4 were lost to follow-up. Out of the 37 patients evaluated, 27 (73%) showed a reduction of the frequency of vomiting episode by at least 50%. In intention to treat analysis, 27/50 (54%) of patients reported an improvement. Beyond 10 years, an score improvement of early satiety (3.05 vs 1.76, < 0.001), bloating (2.51 vs 1.70, p = 0.012), nausea (2.46 vs 1.35, p=0.001), and vomiting (3.35 vs 1.49 p < 0.001) was observed. Quality of life was improved over 10 years (GIQLI score: 69.7 vs. 86.4, p = 0.005) as well as body mass index (BMI: 23.4 vs. 26.2 p = 0.048).

**Conclusion:** Gastric electrical stimulation is safe and effective in the long term in patients with medically refractory nausea and vomiting, with an efficacy of 54% at 10 years on an intention to treat analysis.

## P1259 PER-ORAL ENDOSCOPIC MYOTOMY (POEM) IS A SAFE AND EFFECTIVE TREATMENT OPTION FOR MORBIDLY OBESE PATIENTS WITH ACHALASIA

Parikh M.P.<sup>1</sup>, Chadalavada P.<sup>1</sup>, Gupta N.M.<sup>1</sup>, Thota P.N.<sup>1</sup>, Lopez R.<sup>2</sup>, Gabbard S.<sup>3</sup>, Murthy S.<sup>3</sup>, Raja S.<sup>3</sup>, Sanaka M.R.<sup>1</sup>

<sup>1</sup>Cleveland Clinic Foundation, Gastroenterology and Hepatology, Cleveland, United States, <sup>2</sup>Cleveland Clinic Foundation, Bio-Statistics, Cleveland, United States, <sup>3</sup>Cleveland Clinic Foundation, Thoracic and Cardiovascular Surgery, Cleveland, United States

**Contact E-Mail Address:** chadalp@ccf.org

**Introduction:** With global epidemic of obesity, it is not uncommon to encounter morbidly obese patients with achalasia. The management of morbidly obese or class III obesity patients (BMI

≥40 kg/m<sup>2</sup>) with achalasia is complex and the existing literature is sparse. We conducted a study to assess the outcomes of per-oral endoscopic myotomy (POEM) in morbidly obese patients with achalasia.

**Aims & Methods:** Medical records of all the achalasia patients who underwent POEM between April 2014 and June 2018 at our institution were reviewed. Morbidly obese patients (BMI ≥40) who underwent timed barium oesophagram (TBE) and high-resolution oesophageal manometry (HREM) prior to POEM along with 2-month post-POEM oesophageal pH study, TBE and HREM were included. Demographics, type of achalasia, prior interventions, TBE, HREM, Eckardt scores and pH study findings were analyzed. Eckhardt score of ≤3 was considered as successful palliation of symptoms. Wilcoxon signed rank tests were used to assess changes in HREM and TBE findings (pre-POEM vs. 2 month post-POEM) and a p-value < 0.05 was considered statistically significant.

**Results:** A total of 13 patients met the study criteria. Average age at POEM was 56.1±1 years, with majority of the patients being females (69%; n=9) and Caucasians (58.3%; n=7). Mean duration of achalasia symptoms was 6 years [1.0, 8.0] and type-II achalasia was most prevalent. 23% (n=3) and 30% (n=4) patients had undergone prior treatment with botulinum toxin and pneumatic dilation respectively. Median operative time was 80 minutes [63.0,100.0] and average total myotomy length was 8.8±0.80 cm. There were no complications except for post-operative pneumonia in 1 patient. POEM was successful in 92% (12/13) of the patients. Significant improvement was noted in post-procedure Eckhardt's scores, basal mean pressure and integrated relaxation pressure on two month follow up. In addition, there was significant improvement in the width of barium column at 1 minute and height at 5 minutes. A trend of improvement was noted in height of barium column at 1 minute and width at 5 minutes, but it did not reach statistical significance. In the post-POEM pH study, DeMeester scores were abnormal in 70% (7/10) of patients, however only 10% (1/10) of patients complained of gastro-oesophageal reflux (GOR) symptoms.

**Conclusion:** POEM is a safe and effective treatment option for morbidly obese patients with achalasia. POEM leads to significant improvement in Eckardt scores, HREM and TBE parameters at short-term follow up. Although symptomatic reflux was low, a significantly higher rate of abnormal oesophageal acid exposure was noted on objective testing.

**Disclosure:** Nothing to disclose

Factor	Class III obese patients (n=13)
Age at POEM (years)	56.1±13.5
Operative time (minutes)	80.0 [63.0,100.0]
Complications	7.6% (n=1) post-operative pneumonia
Pre-POEM Eckardt score	6.0[6.0,8.0]
Post-POEM Eckardt score	0.00[0.00,1.5]
POEM success rate	91.7%
POEM failure rate	8.3%
Rate of symptomatic GERD	10% (n=1)
Abnormal DeMeester score on 24-hr oesophageal pH study	70% (n=7)

**Introduction:** Long term results of G-POEM for refractory gastroparesis are lacking. Here we report the results of the largest multicenter study with long term follow up about G-POEM for refractory gastroparesis.

**Aims & Methods:** Retrospective, multicentric study of all G-POEM cases, performed in seven French expert centers, for refractory gastroparesis, within at least one year of follow up

**Primary Endpoint:** One year clinical success defined by improvement of GCSI by at least one point.

**Secondary Endpoints:** complications rate, identification of predictors of clinical success, clinical success at two years.

Our inclusion criteria were, at least one year follow up, and available GCSI score prior GPOEM and 12 months after.

Exclusion criteria were missing GCSI score, technical failure, normal gastric emptying scintigraphy and loss of follow up.

**Results:**

Description of the population: 133 patients were analysed in 7 French expert centers and 10 different operators. Among them we included 92 patients for the efficacy analysis, 61% were women, the median age was 55 years old. About aetiologies : 35% diabetes, 26% post-surgery, and 33% idiopathic. The median evolution duration of the symptoms was 40 months. Twenty seven percents had already a prior interventional treatment. The median 4h% remaining in stomach before G-POEM, was 45%. The mean GCSI average before G-POEM was 3,6.

Technical success was achieved in 99,2%.

**Primary Endpoint:** Clinical success was achieved in 65,2% at one year, with a mean GCSI amelioration of 41%. The GCSI score decrease significantly one year after the GPOEM (p=0,0001)

**Secondary Endpoints:** In univariate analysis, we identified predictive factors of success, which are a high Satiety subscore in GCSI score (2,12 [1,31-3,44], p=0,002), an elevated pre-operative GCSI score (1,85 [1,07-3,20], p=0,027) and an advanced age (1,03 [1,00-1,06], p=0,04). We also identified predictive factors of failure, which are a BMI >20kg/m<sup>2</sup> (0,62 [0,39-1,00], p=0,048) and an elevated gastric retention rate on pre-operative gastric emptying scintigraphy (0,98 [0,961,00], p=0,048).

We noticed any immediate complication, and only 6% of later complications.

At two years clinical success was maintained at 73,2% (n=41).

**Conclusion:** This large and multicentric study confirms the efficiency and safety of G-POEM in the treatment of refractory gastroparesis. The clinical success after one year is achieved for 65% of the patients. We identified interesting predictive factors of success. G-POEM should be the first treatment in case of refractory gastroparesis.

**Contact E-Mail Address:** yichkha1@jhmi.edu

**Introduction:** Gastroparesis is a complex and a disabling gastrointestinal motility disorder characterized by delayed gastric emptying without physical stomach obstruction and its management is challenging due to the limited relief that traditional treatment options provide. Gastric peroral endoscopic myotomy (GPOEM) has emerged as a promising novel endoscopic technique for the management of refractory gastroparesis. Despite the promising outcomes, the main challenge remains in identifying the subset of patients with pylorospasm that will potentially benefit the most from the procedure. Endoluminal Functional Lumen Imaging Probe (EndoFLIP) is a novel device that evaluates sphincter physiologic parameters including distensibility; however, the role of EndoFLIP in G-POEM is still unknown.

**Aims & Methods:** Aim is to determine the association of EndoFLIP measurements with symptoms improvement following GPOEM in patients with refractory gastroparesis. In this prospective multicenter study, EndoFLIP evaluation was performed on patients who underwent G-POEM procedure for management of gastroparesis. EndoFLIP measurements, including pre- and post-G-POEM pylorus diameter (D) (mm), cross-sectional area (CSA) (mm<sup>2</sup>), pressure (P) (mmHg), compliance (C) (mm<sup>2</sup>/mmHg), and distensibility index (DI) (mm<sup>2</sup>/mmHg), were recorded at 40 ml bag volume. Delta (d) of each measurement was defined as the change of value from prior to after G-POEM. Clinical success was defined by at least one score decrease in the total Gastroparesis Cardinal Symptom Index (GCSI) scoring system with more than a 25% decrease in at least 2 of its sub-scales.

**Results:** A total of 36 patients (23 [63.9%] female, median age 55yr [IQR: 43.3-62.0]) at 4 tertiary centers (3 US, 1 Europe) underwent G-POEM with EndoFLIP evaluation and were followed for 6 months. Clinical success was achieved in 19 (52.8%) patients at 6 months. Comparing mean EndoFLIP measurements between patients with and without clinical success, pre G-POEM P was significantly lower (14.22 ± 4.54 vs 19.04 ± 7.81, p=0.35), while post G-POEM D (14.59 ± 2.54 vs 10.91 ± 4.62, p=0.007) and post G-POEM CSA (171.97 ± 56.88 vs 108.92 ± 82.53, p=0.016) were significantly higher in patients who achieved clinical success (Table. 1).

	Pre-GPOEM measurements		P-Value	Post-GPOEM measurements		P-Value
	Patients without symptom improvement	Patients with symptoms improvement		Patients without symptom improvement	Patients with symptoms improvement	
Diameter	12.08 (SD 3.81)	11.99 (SD 3.17)	0.938	10.91 (SD 4.62)	14.59 (SD 2.54)	0.007
CSA	125.22 (SD 77.38)	120.33 (SD 51.27)	0.831	108.92 (SD 82.53)	171.97 (SD 56.88)	0.016
Pressure	19.04 (SD 7.81)	14.22 (SD 4.54)	0.035	17.44 (SD 7.56)	17.44 (SD 5.22)	0.942
DI	6.57 (SD 3.63)	9.94 (SD 6.14)	0.086	7.58 (SD 8.24)	7.58 (SD 8.24)	0.362
Comp-liance	131.48 (SD 72.37)	198.09 (SD 121.45)	0.087	151.65 (SD 164.45)	151.65 (SD 164.45)	0.265

[Comparison of EndoFLIP measurements in patients with vs without symptoms improvement]

Logistic regression model identified pre G-POEM C (OR = 1.023, 95% CI 1.001-1.045), dD (OR = 2.156, 95% CI 1.106-4.204), and dP (OR = 1.311, 95% CI 1.001-1.716) to be independent predictors of clinical success at 6 months after G-POEM. Receiver operating characteristic (ROC) analysis revealed that dD, with an area under the curve (AUC) of 0.785 (95% CI 0.625-0.946), had the highest accuracy for prediction of clinical success, providing specificity of 77% and sensitivity of 63% at a cut-off point of 2.3 mm. On the other hand, dP with AUC of 0.737 (95% CI 0.564-0.909), and pre G-POEM C with AUC of 0.664 (95% CI 0.470-0.858) had lower predicting accuracies. **Conclusion:** Increase of at least 2.3 mm in pylorus diameter post-GPOEM procedure is useful for predicting clinical success in patients with gastroparesis. EndoFLIP may have a potential role in identifying G-POEM candidates among patients with refractory gastroparesis, thus allowing better. **Disclosure:** Dr. Mouen Khashab is a consultant for Medtronic, Dr. Vivek Kumbhari is a consultant for Medtronic.

## P1262 COMPARISON OF PER-ORAL ENDOSCOPIC MYOTOMY (POEM) OUTCOMES BETWEEN PATIENTS WITH RECURRENT SYMPTOMS AFTER PRIOR PNEUMATIC DILATATION (PD) AND PRIOR LAPAROSCOPIC HELLER'S MYOTOMY (LHM)

Parikh M.P.<sup>1</sup>, Chadalavada P.<sup>1</sup>, Gupta N.M.<sup>1</sup>, Thota P.N.<sup>1</sup>, Lopez R.<sup>2</sup>, Wadhwa N.<sup>1</sup>, Ray M.<sup>1</sup>, Gabbard S.<sup>1</sup>, Murthy S.<sup>3</sup>, Raja S.<sup>3</sup>, Sanaka M.R.<sup>1</sup>  
<sup>1</sup>Cleveland Clinic Foundation, Gastroenterology and Hepatology, Cleveland, United States, <sup>2</sup>Cleveland Clinic Foundation, Bio-Statistics, Cleveland, United States, <sup>3</sup>Cleveland Clinic Foundation, Thoracic and Cardiovascular Surgery, Cleveland, United States

**Contact E-Mail Address:** chadalp@ccf.org

**Introduction:** Pneumatic dilation (PD) and laparoscopic Heller's myotomy (LHM) are established treatment options for achalasia. However, recurrence of symptoms requiring re-interventions is not uncommon during long-term follow-up. Per-oral endoscopic myotomy (POEM) is emerging as an effective treatment modality for palliation of symptoms in such patients. In this study, we compared the outcomes of POEM between patients with recurrent symptoms after prior PD and LHM.

**Aims & Methods:** Medical records of all the achalasia patients who underwent POEM between April 2014 and June 2018 were reviewed. Patients who underwent timed barium oesophagram (TBE) and high-resolution oesophageal manometry (HROM) prior to POEM along with 2-month post-POEM oesophageal pH study, TBE and HROM were included. Patients were categorized into two groups as: failed PD (no exposure to LHM) and failed LHM (no exposure to PD). Patients in either groups might have had prior Botox injections. Patient details, TBE, HROM, pH study findings and Eckardt scores were compared between the two groups.

Analysis of covariance was performed to assess the association between prior treatment groups and 2-month outcomes while adjusting for possible confounders and a p-value < 0.05 was considered statistically significant.

**Results:** A total of 49 patients (failed PD=28; failed LHM=21) met the study criteria. There were no significant differences in demographics, myotomy length or complication rates between the two groups. However, patients with failed PD were more likely to be obese, with higher ASA classification and required shorter operative time. There was a significant improvement in Eckardt scores, HROM and TBE parameters at 5 minutes in both groups. POEM success rate was similar at 96.3% and 90% in failed PD and failed LHM groups respectively (p=0.57).

Patients in failed LHM group did not have a significant change in 1-minute TBE measures. On univariate analysis, patients in failed PD group had significantly higher pre-POEM LES basal pressure and lower width of barium column at 1 and 5 minutes. In addition, patients in failed PD group had significantly lower post-POEM barium height and width at 1 and 5 minutes. On adjusted analysis, change in height of barium column at 1-minute was significantly higher in patients in failed PD group. There were no differences in the pH study findings such as DeMeester scores and/or total acid exposure times between the two groups.

**Conclusion:** POEM is safe and equally effective treatment modality for successful palliation of symptoms in patients with recurrent symptoms after both PD and LHM. Operative time is shorter and there was greater improvement in TBE parameters in prior PD group. Post POEM GERD rates were similar in both groups. Long-term efficacy studies of POEM are needed in these patients.

**Disclosure:** Nothing to disclose

Factor	Failed pneumatic dilatation (PD); (n=28)	Failed laparoscopic Heller myotomy; (n=21)	p-value
Operative time (minutes)	80.5 [70.0,101.0]	110.0 [87.0,130.0]	<b>0.008</b>

**Contact E-Mail Address:** marcodelacoletta@gmail.com

**Introduction:** According to Chicago Classification vers. 3.0, Esophago-Gastric Junction Outflow Obstruction (EGJ-OO), is a major oesophageal motor disorder characterized by an elevated IRP (i.e. higher than 15 mmHg\*s\*cm with Medtronic device) and preserved peristalsis. Pathogenesis and treatment of this high-resolution manometry (HRM) diagnosis is unknown, although the majority of the experts agree on using endoscopic dilation or botox injection, particularly in patients reporting dysphagia and weight loss. To date, limited data are available to support the hypothesis that HRM may be of clinical value in identifying patients who will respond to endoscopic therapy.

**Aims & Methods:** We aimed to investigate whether HRM features could be useful to predict the therapeutic outcome in EGJ-OO patients undergoing endoscopic therapy. Patients with symptoms of esophageal dysfunction (e.g. dysphagia, chest pain, and regurgitation) underwent upper endoscopy to rule out organic disease, and thereafter HRM. Symptom severity was assessed by a Likert type scale with four items, from 0 (absent symptom) to 3 (severe symptom), for each symptom. A manometric diagnosis of EGJ-OO was made according to CC ver. 3.0. and in case of drugs-unresponsive (i.e. calcium channel blockers or phosphodiesterase 5 inhibitors) symptoms after six months, an endoscopic treatment (pneumatic dilation or botox injection) was proposed to the patients. We opted for using botulinum toxin injection in elderly subjects (> 75 years) or in case of relevant comorbidities. Clinical response was defined by a symptom score of 0 or 1 for the main symptom (i.e. the leading one requiring outpatient visit and further investigations). Only patients with a follow-up of at least 6 months were considered.

**Results:** Thirteen [8M, mean age 64 (50-83)] patients with EGJ-OO underwent endoscopic treatment (11 pneumatic dilation and 2 botulinum toxin injection). In the group treated by pneumatic dilation, 9/11 (82%) had a good response and 2 failed the treatment. Among the two patients who underwent botox injection, 2/2 (100%) had a good response. The difference in efficacy of the two treatments was found to be not statistically significant by Fisher's test (p=ns) analysis. By using uni- and multivariate regression analysis, a monometric parameter predictive of response to treatment was not observed (p=ns).

**Conclusion:** Traditional HRM parameters are not useful to predict the response of EGJ-OO patients to endoscopic treatment. Further metrics should be developed in order to understand which patients may benefit of endoscopic treatment in case of EGJ-OO diagnosis

**Disclosure:** Nothing to disclose

### P1264 MULTIPLE RAPID SWALLOW DISCRIMINATES FUNCTIONAL FROM ANATOMICAL ESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION

Della Coletta M.<sup>1</sup>, Ghisa M.<sup>2</sup>, Alessandro G.<sup>3</sup>, Frazzoni M.<sup>4</sup>, Frazzoni L.<sup>5</sup>, Tolone S.<sup>6</sup>, De Bortoli N.<sup>7</sup>, Zingone F.<sup>8</sup>, Savarino V.<sup>9</sup>, Savarino E.V.<sup>8</sup>

**Contact E-Mail Address:** marcodelacoletta@gmail.com

**Introduction:** According to Chicago Classification vers. 3.0, Esophago-Gastric Junction Outflow Obstruction (EGJ-OO), is a major oesophageal motor disorder characterized by an elevated IRP (i.e. higher than 15 mmHg\*s\*cm with Medtronic device) and preserved peristalsis. In case of EGJ-OO, an evaluation by using Computer tomography (CT) or ultrasound endoscopy (EUS) has been suggested in order to rule out presence of organic disease. Indeed, at least 50% of EGJ-OO is associated with anatomical abnormalities, including hiatal hernia, peptic stricture, previous foregut surgery or EGJ cancer.

**Aims & Methods:** We aimed to evaluate whether additional high-resolution manometry (HRM) tests such as multiple rapid swallow (MRS) and rapid drinking challenge (RDC) can discriminate between functional and anatomical EGJ-OO in order to further select which patients should undergo radiology or EUS. Consecutive patients referred to Digestive Pathophysiology Unit of the Gastroenterology Unit of Padua University and complaining of oesophageal symptoms were enrolled. Each patient underwent to upper endoscopy and esophagogram with barium and thereafter an oesophageal HRM was performed. In case of IRP>15 mmHg\*s\*cm without a pattern of achalasia, a diagnosis of EGJ-OO was established. Anatomical EGJ-OO was defined by the presence of: hiatal hernia, abnormalities induced by previous foregut surgery, peptic strictures, mucosal or submucosal lesions, and eosinophilic esophagitis. Only in absence of any of these diagnoses, a functional EGJ-OO was defined. Patients assuming opioid drugs chronically were excluded from the analysis.

**Results:** Forty-nine patients with EGJ-OO were enrolled [24 Male, mean age 49 (10-83)]. Fourteen (29%) presented an anatomical abnormality, whereas thirty-five (71%) were has a functional EGJ-OO. Multiple Rapid Swallow test was available in thirty-seven patients and was abnormal in 8/9 of anatomical EGJ-OO and in 13/28 of functional EGJ-OO. Using Fisher's test, the difference in percentage of abnormal MRS test in the two groups was statistically significant (p< 0.05). Mean DEA and peak-DCI were higher in the functional EGJ-OO as compared to the anatomical EGJ-OO (68±28 vs 108±49 and 2409±1702 vs 4763±3701, respectively). In contrast, the mean DCI was higher in functional EGJ-OO compared to anatomical EGJ-OO (1379±1050 vs 2752±2535), but this difference was not statistically significant (p=0.07). RDC was not different between the two groups (p=ns).

**Conclusion:** Abnormal MRS test in patients with EGJ-OO could be a useful tool to segregate anatomical from functional EGJ-OO patients. Among the functional EGJ-OO patients, a major contractile force seems to be present, suggesting that this could be correlated with inadequate adaptation of the esophageal body motility to the appearance of a recent flow obstruction.

**Contact E-Mail Address:** amanwl@yahoo.com

**Introduction:** Per-oral endoscopic myotomy (POEM), a highly-effective treatment for Achalasia cardia has also been associated with increased risk for post-procedure gastroesophageal reflux (GER). One of the risk factors for post-POEM GER seems to be the dissection of both circular and longitudinal muscle fibers (full-thickness myotomy-FTM). Irrespective of whether it is intentional or accidental, selective and full-thickness dissection may coexist, making it difficult to determine whether e.g. a partial FTM has a functional consequence.

**Aims & Methods:** To investigate whether the disturbance of post-swallow transient proximal, "elevation" of the esophagogastric junction (EGJ), mediated by contraction of the longitudinal muscle fibers, could serve as a reliable objective indicator of a POEM with FTM. Forty-four patients with achalasia -mean age (standard deviation): 53 (15), male:female ratio 1.1:1- that underwent posterior POEM at Showa University Koto Toyosu Hospital were included. POEM reports, videos, pre- and post-POEM High Resolution Manometry (HRM-Star Medical Inc, Tokyo, Japan) images were examined and compared to determine the presence/absence of esophageal shortening/EGJ vertical elevation as well as absent, segmental or full-length FTM.

The Chicago Classification 3.0 was utilized to distinguish achalasia subtypes: type I (N=14), type II (N=23), type III (N=3) and early onset achalasia (N=4). HRM assessment was performed in a blinded fashion for presence/absence of FTM.

**Results:** Selective myotomy/absent FTM was documented in 27 patients (61%), segmental in 11 (25%) and full-length FTM in 6 (14%). Pre-POEM HRM was consistent with absent/minimal EGJ elevation in 13 cases (30%), all diagnosed as type I achalasia. Post-POEM HRM revealed 7 additional cases (20 in total, 45%, P=0.19), with absent/minimal EGJ elevation that received either full-length (N=5) or long-segment (N=2) FTM. The sensitivity and specificity of absent EGJ elevation for the detection of FTM post-POEM, was 87.5% and 64%, respectively. A limitation of the present study is that comparison could not be performed in the case of type I achalasia, as HRM-documented EGJ elevation was predominantly absent both pre- and post-POEM.

**Conclusion:** Utilizing HRM and the "elimination" of EGJ elevation as a marker, the occurrence of significant FTM during POEM can be reliably documented in patients with all achalasia subtypes except type I.

**Disclosure:** A. Manolakis received grant from the Hellenic Society of Gastroenterology H. Inoue is an advisor for Top Corp and Olympus Corp

## P1266 DUODENAL HYPERPERMEABILITY AND SYSTEMIC MARKERS OF LOW-GRADE INFLAMMATION ARE LINKED WITH GASTRIC EMPTYING AND SYMPTOMS IN FUNCTIONAL DYSPEPSIA PATIENTS WITH POSTPRANDIAL DISTRESS

**Introduction:** We previously demonstrated increased duodenal mucosal permeability and low-grade inflammation with eosinophils in functional dyspepsia (FD) patients (1). However, the role of duodenal alterations in relation to gastric emptying and symptoms in functional dyspepsia (FD) patients is still unclear.

**Aims & Methods:** FD patients with symptoms of postprandial distress (PDS) according to Rome IV criteria were recruited. Gastric emptying for liquids and solids was determined using the calculated half emptying time of the <sup>13</sup>C-glycin (significantly delayed > 75 min) and <sup>14</sup>C-octanoic acid (significantly delayed > 110 min) breath tests, respectively. Duodenal biopsies were collected to measure the transepithelial electrical resistance (TEER) and paracellular passage of a fluorescein-labeled dextran (4kDa) in Ussing chambers. After the endoscopy, a naso-duodenal tube was positioned in the second part of the duodenum with aspiration of fluids before and after a liquid meal (Fortimel, 300kCal) with measurement of pH. Plasma samples were collected to measure high-sensitivity C-reactive protein (hs-CRP) and patients filled out the Patient Assessment of Gastrointestinal Disorders Symptom Severity Index (PAGI-SYM). Descriptive and correlation analyses were performed to determine markers of gastric emptying and FD symptoms.

**Results:** In total, 17 FD patients (15 females, median (IQR) age 28 (22-34) years) with 15 (88%) belonging to the pure PDS group and 2 (12%) the overlap group with epigastric pain syndrome (EPS). The median gastric half emptying time was 68 (41-76) min for liquids and 66 (57-80) min for solids. Significantly delayed gastric emptying was present in 4 patients (24%) for liquids and only in 1 patient (6%) for solids. Median TEER was 22.1 (19.2-27)  $\Omega \cdot \text{cm}^2$  and paracellular passage 25.2 (20-30.3) pmol. Fasting and fed pH were similar (7 (5.2-7.3) vs. 6.5 (6.2-6.8), p=0.72) and median hs-CRP was 2 (0.6-5.5) mg/L. Fasting duodenal pH correlated positively with gastric emptying for liquids (r= 0.59, p=0.02). Gastric emptying for solids was positively correlated with both duodenal paracellular passage (r=0.62, p=0.03) and plasma hs-CRP (r=0.57, p=0.03). In addition, gastric emptying for solids was negatively correlated with the intensity of bloating (r=-0.53, p=0.04).

**Conclusion:** Although delayed gastric emptying for solids is uncommon, duodenal alterations with increased permeability and low-grade systemic inflammation are linked with gastric emptying in FD patients with PDS-symptoms. These data provide further substance for the potential central role of the duodenum in symptom generation and gastric motor abnormalities.

## P1267 EVALUATION OF A PROTOCOL FOR MEASUREMENT OF DISTENSIBILITY OF THE LOWER ESOPHAGEAL SPHINCTER IN THE CLINICAL FOLLOW UP OF PATIENTS WITH ACHALASIA

Medhus A.W.<sup>1</sup>, Evensen H.<sup>1,2</sup>, Kristensen V.<sup>1</sup>, Larssen L.<sup>1</sup>, Hauge T.<sup>1,2</sup>, Sandstad O.<sup>1</sup>

<sup>2</sup>University of Oslo, Institute of Clinical Medicine, Oslo, Norway

**Contact E-Mail Address:** uxmesl@us-hf.no

**Introduction:** The Endoflip™ (Crospon Ltd, Ireland) impedance planimetry system is now commonly applied to assess the distensibility of the lower esophageal sphincter (LES), which is of particular relevance in the diagnosis, treatment and follow up of patients with achalasia. A suggested procedure protocol is available (1), and a graded filling approach of the balloon up to maximum fill volume of 50 ml is recommended. The 40 ml volume is most reliable to determine the distensibility of LES (1). Limited data are available on the use and feasibility of assessment of LES distensibility in clinical follow up of patients with achalasia.

**Aims & Methods:** The aim of the present study was to evaluate the feasibility and the recommended protocol for LES distensibility measurements by applying the Endoflip™ system in the clinical follow up of patients with achalasia one year after per oral endoscopic myotomy (POEM).

At our department, achalasia patients are routinely having a clinical follow up one year after POEM. After acquiring the Endoflip™ system, distensibility measurement of LES with the probe EF-325 was included in this follow up and performed directly after an upper endoscopy with the patient in the supine position. The recommended protocol with graded filling of the balloon at 30, 40 and 50 ml fill volume was applied. After reaching the maximum fill volume of 50 ml, a repeated measurement at 40 ml was performed. To compare the two measurements at 40 ml fill volume, Wilcoxon signed rank test was applied. Summary values are given as median (range).

**Results:** During the first four months with distensibility measurements, the Endoflip™ system was applied without complications in eleven consecutive POEM controls (four females) with a median age of 54 years (26-73).

The two distensibility measurements at 40 ml performed prior to and after 50 ml fill volume differed significantly (Table).

**Conclusion:** Performing LES distensibility measurement is feasible in clinical follow up of patients treated for achalasia by POEM. However, LES distensibility at the recommended 40 ml balloon fill volume is significantly higher when measured after maximum fill volume. The protocol for measurements should thus be standardized with respect to whether results have been acquired prior to or after maximum balloon fill volumes to ensure reliability and validity of the results.

Balloon fill volume	30 ml	40 ml	50 ml	40 ml	p-value*
Luminal diameter (mm)	8.7 (6.1-13.0)	13.1 (10.3-19.9)	16.9 (13.8-23.8)	15.3 (12.1-20.1)	0.05
Intra balloon pressure (mm Hg)	34.4 (15.9-78.0)	31.8 (24.5-92.0)	42.4 (19.9-109.0)	30.3 (22.5-88.0)	0.11
Distensibility (mm <sup>2</sup> /mm Hg)	2.7 (0.8-7.3)	3.8 (1.5-7.9)	6.2 (2.1-12.2)	5.6 (2.1-8.9)	<0.01

[Endoflip™ measurements with different balloon fill volumes (\*comparison of the two measurements with 40 ml fill volume)]

**Introduction:** By-pass surgery is currently one of the most effective treatments available for obesity and type II diabetes. Some limited data reports increased gastric belching after sleeve gastrectomy. However, there is no data about bariatric by-pass surgery and belching.

**Aims & Methods:** We aimed to evaluate belching after bariatric by-pass surgery. Seventeen morbid obese patients and 12 healthy volunteers were enrolled in the study. Twelve patients had Roux-en-Y gastric bypass (RYGB) and the other 5 pts had gastric mini-bypass surgery, median 24 months (18-54 months) ago. All patients were questioned about the presence of symptoms for belching, gastroesophageal reflux disease, and dyspepsia. 24-hour pH-impedance were performed in all patients and healthy volunteers. Each of the patients underwent gastroscopy before 24-hour pH-impedance.

**Results:** Female dominance was observed in patients group [%76.5 (n=13) vs %41.7 (n=5)]. However, ages and gender were not statistically different in both groups ( $P > 0.05$ ). The mean DeMeester score was significantly higher in patients ( $9.11 \pm 19.40$  vs  $6.04 \pm 5.60$ ,  $P = 0.048$ ). However, pathologic acid reflux (DeMeester score  $>14$ ) rate were similar in both groups (11.8% vs %8.3). Symptom association probability positivity was detected in 11.8% of patients in the impedance study. The rate of alkaline reflux rate was higher in patients (6% vs 0%). The belching rate was 50% in patients according to questionnaire. Esophagitis was detected in 25% of patients in gastroscopy. The number of gas reflux ( $123.24 \pm 80$  vs  $37.2 \pm 21.5$ ,  $P = 0.001$ ) and Supragastric/Gastric belches was significantly higher in patients ( $182 \pm 64/228 \pm 66.69$  vs  $25.08 \pm 15.20/12.17 \pm 17.65$ ,  $P = 0.001$ ). Although number of supragastric belching is higher in controls. Gastric belching was higher than supragastric belching in patients.

**Conclusion:** Belching is increasing after the bariatric by-pass surgery in the long term period. Gastric belching frequency is higher than supragastric belching in these patients.

**Introduction:** Endoscopic features of autoimmune gastritis (AIG) include severe atrophy of the gastric body and lesser atrophy of the gastric antrum. Strict criteria for diagnosing AIG are important because this condition can cause anemia, gastric neoplasms, and autoimmune polyendocrine syndrome. However, diagnostic criteria for AIG have not yet been determined.

**Aims & Methods:** We investigated AIG at our center from 2007 to 2018. This retrospective cohort study evaluated patients' gender, medical history, history of *Helicobacter pylori* eradication, laboratory data [serum gastrin, parietal cell antibody (PCA), intrinsic factor antibody (IFA), anti-*H. pylori* antibody, and pepsinogen (PG) I and II levels], and histological diagnosis of AIG. We defined complete AIG as severe atrophy of a gastric body, as evidenced on endoscopy, predominantly of the gastric body rather than the gastric antrum, hyper serum gastrin ( $>200$ pg/ml), positive PCA or IFA, and histological diagnosis of AIG. We defined suspected AIG as patients who did not meet the criteria for complete AIG.

**Results:** Twenty-eight of the 87951 patients who underwent endoscopy were enrolled in this study. There were 16 cases of complete AIG and 12 cases of suspected AIG. The mean patient age was 69.1 (range, 41-87) years for complete AIG and 71.5 (range, 52-86) years for suspected AIG. Males constituted only 4 (25.0%) of all complete AIG cases. Furthermore, 4 (25%) of all complete AIG cases had history of cancer (stomach, breast, and colon). All patients exhibited severe endoscopic atrophy, predominantly of the gastric body. Mean serum gastrin levels were 2939 (range, 225-9590) in patients with complete AIG and 1026 (range, 180-2270) in patients with suspected AIG. Two (12.5%) cases were negative for PCA and positive for IFA in the complete AIG group. In the suspected AIG group, six cases were negative for both PCA and IFA; however, they still exhibited severe atrophy of the gastric body on endoscopy and elevated gastrin levels (range, 490-5410). Two cases in the complete AIG group were *H. pylori*-antibody positive (2/16); in contrast, there were five positive cases in the suspected AIG group (5/12). PG I level (range, 3.8-19.9) was low among all patients in the complete AIG group and in 4 patients with suspected AIG. In one patient with suspected AIG, we could not calculate PCA because of the anti-mitochondrial antibody and IFA negativity; however, this patient exhibited severe atrophy of the gastric body on endoscopy and was histologically diagnosed with AIG. Two cases had histories of *H. pylori* eradication and exhibited more severe atrophy of the gastric body on endoscopy after (rather than before) *H. pylori* eradication.

**Conclusion:** Diagnostic criteria for AIG are warranted, and further study is needed. *H. pylori* eradication therapy may contribute to easy detection of AIG with *H. pylori* infection, because this therapy reduces the influence of *H. pylori* in patients with autoimmune gastritis with *H. pylori* infection.

**Contact E-Mail Address:** florence.carbone@uzleuven.be

**Introduction:** Gastroparesis (GP) is defined as "a combination of symptoms and documented delay in gastric emptying (GE) in the absence of mechanical obstruction". The main causes of GP are Idiopathic gastroparesis (IGP) and Diabetes gastroparesis (DGP). To date, no validated patient reported outcomes (PRO) for evaluation of treatment efficacy in these conditions

are available. According to FDA guideline, PRO instrument item generation and selection should be derived from patient focus groups (FGs) and cognitive interviews (CIs).

**Aims & Methods:** Our aim was to perform FGs and cognitive interviews for the development of a new questionnaire for the assessment of symptom pattern and severity in both IGP and DGP. Patients with IGP, a negative endoscopy and a strongly delayed GE rate ( $T_{1/2} > 109$ min, GE breath test) were invited to participate. During the FGs, symptom spectrum of gastroparesis was discussed to determine type of symptoms, triggering by meals or factors, duration, bothersomeness, predictability and impact. A verbal descriptor for each symptom was proposed to the patients after discussion of the symptom. Threshold for selection of symptoms was 50%. From the list of emerged relevant symptoms, Subsequently, FGs for DGP patients were organized using the same framework.

**Results:** 14 IGP (11 Females,  $43.6 \pm 3.3$  years,  $T_{1/2}: 155.2 \pm 16.2$ ) patients participated. All (100%) confirmed experiencing symptoms that were triggered or aggravated by ingestion of a meal. Main symptoms corresponded to postprandial fullness (PPF:100%), epigastric pain (EP:100%), early satiation (ES:100%), nausea (N:100%), retching (RT:71%) and vomiting (V:57%). Other relevant symptoms were bloating (B:86%), abdominal distention (AD:71%), heartburn (H:79%) and regurgitation (RG:64%). In **diabetic gastroparesis** ( $n=10$ , 7 Females,  $45.5 \pm 3.7$  years,  $T_{1/2}: 156.9 \pm 17.0$  min) symptoms were also meal related (100%) and comprised PPF (100%), EP (100%), ES (70%) N (100%), V (70%), RT (70%), RG (50%), B (90%), AD (70%), belching (70%) and H (80%). Following this, pilot instruments were developed and customized through CIs for qualitative and cognitive debriefing to establish content validity.

**Conclusion:** This study confirm that symptoms corresponding to postprandial fullness, epigastric pain, early satiation, nausea, vomiting, retching regurgitation, bloating and heartburn are the key items for developing a PRO for both idiopathic and diabetic gastroparesis.

**Disclosure:** Nothing to disclose

## P1271 DOES MEASUREMENT OF SYMPTOMS DURING A GASTRIC EMPTYING TEST IMPROVE CORRELATION BETWEEN SYMPTOMS AND EMPTYING RATE?

Carbone F.<sup>1</sup>, De Buysscher R.<sup>2</sup>, Van den Houte K.<sup>3</sup>, Tack J.<sup>4</sup>

<sup>1</sup>University of Leuven, Gastroenterology, Leuven, Belgium, <sup>2</sup>University of Leuven, Leuven, Belgium, <sup>3</sup>KU Leuven, TARGID, Leuven, Belgium, <sup>4</sup>University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

**Contact E-Mail Address:** florence.carbone@uzleuven.be

**Introduction:** Functional dyspepsia (FD) and idiopathic gastroparesis (IGP) are characterised by upper gastrointestinal symptoms and a negative endoscopy, and severely delayed emptying in case of gastroparesis. It is argued whether distinguishing these entities is necessary as previous studies showed a poor correlation between delayed gastric emptying (GE) and symptom severity.

**Aims & Methods:** We aim to evaluate the relationship between symptom severity and GE when simultaneously assessed. During a GE test (breath test with <sup>13</sup>C-octanoic acid labelled 250 Kcal meal), severity (0-4) of 6 symptoms (postprandial fullness (PPF), epigastric pain (EP) and burning (EB), bloating (BL), nausea (N) and belching (B)) was assessed before and every 15 min for 4hs postprandially. The sum of individual symptom scores generates the meal-related symptoms score; the sum of all symptoms generates overall global meal-related symptom severity. Data were compared in patients with normal and delayed GE (cut-off  $T_{1/2} > 109$  min) using non-parametric statistical tests, Mann-Whitney test, 2-Way-Anova with Bonferroni posthoc-test correction and spearman correlation.

**Results:** Of 504 FD patients (70% females (F),  $43.6 \pm 0.7$  years,  $23.3 \pm 0.2$  kg/m<sup>2</sup>), 382 patients (67% F,  $43.8 \pm 0.8$  years,  $23.3 \pm 0.2$  kg/m<sup>2</sup>) had normal and 122 patients (77% F,  $42.7 \pm 1.5$  years,  $23.2 \pm 0.6$  kg/m<sup>2</sup>) had delayed GE. Global symptom severity tended to be higher in patients with delayed GE ( $81.9 \pm 3.4$  vs.  $99.5 \pm 7.1$ ,  $p=0.06$ ). Only nausea was significantly increased in patients with delayed GE ( $10.7 \pm 0.8$  vs.  $15.9 \pm 1.6$ ,  $p=0.01$ ). However, no correlations were observed between GE rate and any of the symptoms (global symptom score:  $r=0.06$ ,  $p=0.2$ ; nausea:  $r=0.08$ ,  $p=0.09$ ). In all analysis, 2-Way-Anova showed significant interactions for increasing symptoms over time, but no significant differences were observed between normal and delayed GE. Only nausea showed partially significant increase in delayed GE 90 min after the meal ( $p < 0.01$ ) compared to normal GE.

**Conclusion:** IGP patients tend to display higher dyspeptic symptoms severity, but only meal-related nausea scores were significantly higher. The severity of symptoms, even when assessed during the meal, was not associated to the GE rate. These findings have important implications for the value of routinely applying GE testing in clinical practice.

**Contact E-Mail Address:** g.tziatzios@yahoo.gr

**Introduction:** Functional dyspepsia (FD) is a multifactorial disorder as its development may be based on several different pathophysiological mechanisms. Small intestinal bacterial overgrowth (SIBO) is characterized by either increased numbers or presence of colonic type bacteria in the upper gastrointestinal tract. FD could be related to SIBO since impaired motility of the gastrointestinal tract is one of the main etiologic factors involved in both diseases pathogenesis.

**Aims & Methods:** Consecutive outpatients fulfilling Rome IV criteria for FD underwent upper gastrointestinal endoscopy. Severity of FD symptoms was graded by the patient assessment of upper gastrointestinal symptom severity index (PAGI-SYM) questionnaire. 2cc of duodenal juice (3<sup>rd</sup> - 4<sup>th</sup> part) was aspirated in special sterile traps. SIBO was defined as  $\geq 10^3$  CFU/ml of duodenal aspirate and/or presence of colonic type bacteria. Patients with Irritable Bowel Syndrome (IBS) and healthy controls (HC) - undergoing gastroscopy due to gastroesophageal reflux disease (GERD) - comprised positive and negative controls, respectively. Concentrations (pg/ml) of tumor necrosis factor-alpha (TNF $\alpha$ ), interleukin (IL)-1 $\beta$  and IL-6 were measured in the duodenal fluid. We aimed to compare the SIBO prevalence between FD patients, IBS patients and healthy controls.

**Results:** We enrolled 347 subjects (FD 227/90 IBS/30 HC) aged  $53.7 \pm 14.6$  years. Among FD patients, 144 (63.4%) had Postprandial Distress syndrome (PDS), 64 (28.2%) Epigastric pain Syndrome (EPS) and 19 (8.4%) mixed type. SIBO was diagnosed in 44/227 FD patients, with Gram (-) bacteria being the predominant species (24/44, 54.5%). SIBO prevalence among FD subtypes was: PDS 30/114 (26.3%); EPS 8/64 (12.5%); mixed 6/19 (31.6%). Overall, SIBO prevalence was significantly higher in FD compared to HC [44/227(19.3%) vs. 1/30(3.3%),  $p=0.037$ ] and it was similar to IBS [44/227(19.3%) vs. 15/90(16.7%),  $p=0.63$ ]. SIBO prevalence was lower in the EPS group as compared to the PDS and mixed symptoms groups (12.5% vs. 27.1%,  $p=0.11$ ). SIBO presence correlated neither with total nor with any subscale score of the PAGI-SYM questionnaire. Mean concentration of IL-1 $\beta$  was similar between FD and HC subjects ( $5.13 \pm 17.9$  vs.  $6.3 \pm 14.3$ ,  $p=0.65$ ) but it was significantly lower than that of IBS individuals ( $402 \pm 89.6$  vs.  $5.13 \pm 17.9$ ,  $p < 0.001$  and  $401.9 \pm 89.6$  vs.  $6.3 \pm 14.3$ ,  $p < 0.001$  respectively). TNF $\alpha$  and IL-6 concentrations did not differ between the three groups.

**Conclusion:** In a cohort of Greek FD patients, SIBO prevalence is similar to that of IBS subjects and higher compared to that of healthy controls.

## P1273 GASTRIC EMPTYING SCANS: POOR ADHERENCE TO NATIONAL GUIDELINES

Lacy B., Wise J., Vazquez-Roque M.

Mayo Clinic, Gastroenterology, Jacksonville, United States

**Contact E-Mail Address:** lacy.brian@mayo.edu

**Introduction:** Gastric-emptying scintigraphy (GES) is considered the gold standard for measuring gastric emptying. Performing the test correctly is critical as it ensures an accurate diagnosis which directly influences patient care from both a diagnostic and therapeutic perspective. While published protocol guidelines for GES exist, national compliance with

these guidelines has not been thoroughly studied. This study aimed to determine whether facilities that perform GES adhere to well-established national guidelines published 10 years ago.

**Aims & Methods:** To assess compliance with GES protocol guidelines, we developed a questionnaire that evaluated a total of 51 measures addressing the relevant procedure subcategories of the published Procedure Guideline for Adult Solid-Meal Gastric Emptying Study 3.0. Questions focused on patient preparation (16), pertinent medical history (15), precautions/contraindications (2), radiopharmaceuticals (5), image acquisition (4), processing (2), interpretation criteria (5) and reporting (2). Demographic data was also collected. The anonymous questionnaire was distributed electronically. Responses were entered into an excel table and analyzed using standard statistical methods.

**Results:** 109 medical institutions (MI) responded; of these, 45 (41.3%) were academic/teaching medical centers. The mean number of annual GES procedures was 165.9 (range, 12 to 450 GES/year). The validated egg meal is utilized in 58.4% of the MI and 60.0% of MI conduct a 4 hour GES. 89.2% ask if the patient has an egg allergy prior to GES, although 92.8% do not stop the test if the patient reports an egg allergy. Blood glucose levels of diabetic patients are tested in 17.5% of the MI prior to GES. Discontinuation of opioids is required in 65.0% of MI prior to GES and 50% of these MI require at least two days of discontinuation of opioids. 36.4% of MI record dose and frequency of pain medications. 29.5% of MI ask if the patient uses tobacco products. 69.5% of MI report GES results at 1, 2, and 4 hours. Metoclopramide or erythromycin is administered during the test in 2.3% of the MI. Academic/teaching medical centers had the lowest compliance rate on twelve (23.5%) of the 51 adherence measures.

**Conclusion:** Our results suggest that adherence to national guidelines for performing GES is low, even at academic medical centers. This suggests that a barrier exists between established clinical guidelines and institutional implementation that has a direct impact on patient care.

**Disclosure:** Nothing to disclose

**Introduction:** In the recent EOS-1 trial, a 6-week therapy with a novel budesonide orodispersible tablet (BOT), with a unique mode of delivery and esophageal targeting, given twice daily (1mg BID) led to a significant improvement in the validated disease specific overall Adult Eosinophilic Esophagitis Quality of Life (EoE-QoL-A) questionnaire and all of its sub-scores (1).

**Aims & Methods:** This maintenance study also assessed the Health related Quality of life (HRQoL) and its change from baseline over 48 weeks of treatment. In total, 204 patients being in clinico-histological remission were randomized (1:1:1) to a 48-weeks treatment with BOT 1 mg BID, BOT 0.5 mg BID or placebo.

The overall EoE-QoL-A 30 items score was assessed with a weighted average score between 0 to 4 at baseline and end of treatment (EOT) - higher scores denoted better HRQoL.

**Results:** For the overall EoE-QoL-A 30 items score a statistically significant increase (i.e., improvement in QoL) from Baseline to EOT was observed in both budesonide groups. In contrast, the overall EoE-QoL-A 30 items score showed a statistically significant decrease (i.e., deterioration in QoL) from Baseline to EOT in the Placebo group. The differences in the absolute changes from baseline between the budesonide groups and placebo were also clinically relevant and statistically significant (see Table).

	BOT 1mg BID (n=68)	BOT 0.5mg BID (n=68)	Placebo BID (n=68)
Baseline, Mean (SD)	3.2 (0.59) n=64	3.2 (0.56) n=64	3.0 (0.70) n=64
EOT, Mean (SD)	3.5 (0.48) n=67	3.3 (0.46) n=66	2.8 (0.75) n=65
Absolute change from DB Baseline to EOT, Mean [95% CI]	0.3 [0.14; 0.39] n=63	0.2 [0.12; 0.34] n=62	-0.2 [0.39; 0.08] n=61
Difference between absolute changes from Baseline to EOT (BUL vs. Placebo)* [95% CI]*	0.50 [0.30; 0.70] p<0.0001 (2-sided)	0.46 [0.27; 0.66] p<0.0001 (2-sided)	

\*For intergroup differences (BOT 0.5mg BID or BOT 1mg BID vs Placebo) between absolute changes from Baseline to EOT a two-sided t-test was used for exploratory testing.

[Disease specific overall Adult Eosinophilic Esophagitis Quality of Life (EoE-QoL-A) 30 item questionnaire]

**Conclusion:** Both, BOT 1mg BID and BOT 0.5mg BID were able to maintain and even further improve patient's HRQoL compared to placebo over 48 weeks.

**Contact E-Mail Address:** matteoghisa@yahoo.it

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic disease characterized by significant impairing of quality of life (QoL). Current methods for measure QoL are almost tricky and not easy to use routinely. Starting from the validated EoE-QoL-A questionnaire (EQA), we elaborated the EoE Visual Score (EVS), an easy and quick, self-administered questionnaire for daily clinical practice.

**Aims & Methods:** The aim of this pilot study was to evaluate EVS and its correlation with clinical response to therapy, histological disease activity and EQA.

Thirty patients (7 Female, mean age 33-yo, range 18-75-yo) with a definite diagnosis of EoE, referred to our Unit, were included. The diagnosis was done according to the latest international criteria. Patients were enrolled at outpatient level, at first admission or follow-up, between January 2018 to February 2019. The EVS is a 10-scale, 11-item pictogram, depicting the different areas involved in the assessment of QoL in EoE patients (eating/diet impact, social impact, emotional impact, disease anxiety, choking anxiety). Patients, were clinically and histologically evaluated, before (baseline) and after medical therapy (proton pump inhibitors or topical

steroid for 8 weeks). At both time points, all patients completed the EQA and EVS. Histologic activity was described as dichotomous parameter: 0 for less than 15 eos/hpf and 1 for more than 15 eos/hpf. Pearson correlation coefficient and paired t test were used for the analysis.

**Results:** At baseline, patients were all histologically active, with a mean value of EQA and EVS of  $45.07 \pm SD 32.69$  and  $26.37 \pm SD 20.43$ , respectively. After 8 weeks of medical treatment, mean value of EQA and EVS were  $37.63 \pm SD 28.37$  and  $21.43 \pm SD 20.92$ , respectively. A strong significant correlation between EQA and EVS at both time points ( $r=0.784$   $p < 0.001$  and  $r=0.816$   $p < 0.001$ , respectively) was observed. EVS had a significant mean value difference before and after treatment ( $p=0.032$ ). After 8 weeks of medical treatment, 21 patients (70%) achieved histological response, but no difference in EVS mean values was found between histological responders and non-responders ( $p=0.222$ ). Moreover, no significant difference for EVS mean values was observed before and after treatment in both histological non-responder ( $p=0.064$ ) and responders ( $p=0.105$ ).

**Conclusion:** The EVS is an effective and quick tool for daily clinical practice, able to depict patients QoL and to facilitate the assessment of therapeutic response. It well correlates with the already validated EQA. Nevertheless, further larger studies are required to evaluate the usefulness of EVS in clinical practice.

**Contact E-Mail Address:** matteoghisa@yahoo.it

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic disorder, characterized by symptoms of esophageal dysfunction and, histologically, by eosinophilic-infiltration. Endoscopic and histological examination is required both at diagnosis and follow-up, since a reliable non-invasive marker has not been identified yet. Eosinophil cationic protein (ECP) is released during eosinophils degranulation and it can be assessed in human faeces.

**Aims & Methods:** The aim of the study is to evaluate the potential use of ECP in EoE patients' faeces (F-ECP) as a potential marker of disease activity.

29 consecutive EoE-patients assessed at our Unit between January 2018 to January 2019 for endoscopic follow-up, were included. Faecal and histological specimen were collected on the same day. Histological activity was staged considering the number of eosinophils for high-power field (Eos/HPF). A control-group of 71 patients (mean age 52-yo, range 35-64, 38 Male), in whom EoE had been ruled out according to International criteria, was included. F-ECP was evaluated with a fluorescence-enzyme-immunoassay (PHADIA, Thermo Fisher Scientific). Spearman's rank correlation was applied for statistical analysis and F-ECP predictive positive and negative values (PPV, NPV) were calculated.

**Results:** EoE-study-population consisted of 29 patients affected by EoE (mean age 32-yo, range 18-62 yo, 24 M), showing F-ECP values ranging from 0 to 172 ug/L (mean value 17,3 ug/L), compared to values ranging from 0 to 32 ug/L (mean value 8,1 ug/L) in the control-group. A statistically significant relationship between F-ECP and Eos/HPF was observed ( $p$  2-tailed = 0.02438). PPV and NPV of F-ECP were evaluated using two cut-off values, F-ECP < 2 ug/L (as negative) and F-ECP < 8,1 ug/L (as mean value in the control group). Among the study group, 21 patients (72%) showed histo-

logical remission, but only 8 (38%) had F-ECP negative values. Setting a cut-off value of 8,1 ug/L, F-ECP NPV and PPV for histological remission were 86% and 40%, respectively, while they were 100% and 38% with cut-off value of 2 ug/L.

**Conclusion:** Our preliminary data show a good correlation of F-ECP values with histology activity and a clear difference in terms of levels between EoE patients and controls. However, the wide variability of ECP levels evaluated in our series requires further cases and more histologically-active patients, in order to assess its usefulness in clinical practice.

**Introduction:** Some patients with eosinophilic esophagitis (EoE) do not have typical endoscopic findings. Therefore, multiple esophagus biopsies are recommended regardless of endoscopic findings in patients with dysphagia. This study aimed to investigate the prevalence and clinical features of endoscopy negative EoE.

**Aims & Methods:** We conducted two retrospective studies. In the first study, forty-seven patients with dysphagia were included. All patients underwent endoscopy and esophageal high resolution manometry (HRM) test. Multiple esophageal biopsies were taken from the middle and lower esophagus. The prevalence of EoE and the presence or absence of endoscopic findings were examined. In the second study, thirty-five patients diagnosed with EoE in the same period were included. Patients were divided into those with typical endoscopic findings and those without, differences of clinical features were examined.

**Results:**

Study 1: Of the 47 patients, 12 patients (26 %) were diagnosed with achalasia, 3 (6 %) with ineffective esophageal motility, 5 (11%) with esophago-gastric junction (EGJ) outflow obstruction, 4 (9%) with Jackhammer esophagus, 5 (11%) with absent contractility, and 2 (4%) with distal esophageal spasm (DES). The remaining 16 patients' (34%) results were normal. As a result of biopsies, 6 patients (13%) were diagnosed with EoE (HRM results: normal in 4, DES in 1, and EGJ outflow obstruction in 1).

Study 2: Of 35 patients with EoE, 21 (60%) had white plaques, 22 (63%) had longitudinal furrows, and 11 (31%) had esophageal rings. Eight patients (23%) did not have typical endoscopic findings. We examined differences between patients with endoscopic findings and those without. Symptom severity (Frequency Scale for Symptoms of GERD: FSSG score) was 10.18 for endoscopic findings and 18.43 for negative cases, and there was a significant difference ( $p = 0.021 < 0.05$ ) between the two groups. There were no significant differences without FSSG score (gender, age, height, weight, BMI, presence or absence of allergic disease, esophagus eosinophil count, proton pump inhibitor and steroid history, blood eosinophil count, and IgE levels).

**Conclusion:** Thirteen percent of the patients with dysphagia were diagnosed with EoE, and 23 % of EoE patients do not have typical endoscopic findings. Patients with negative endoscopic findings had more severe symptoms than those with positive findings.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** okimotoeiko@outlook.com

**Introduction:** Eosinophilic esophagitis (EoE) is a clinicopathological disease diagnosed by symptoms related to esophageal dysfunction accompanied by esophageal eosinophilia, and its prevalence has been rapidly increasing in Western and Asian countries. Subjective symptoms associated with EoE such as dysphagia are not specific, thus endoscopic identification of suggestive EoE findings is quite important for facilitating endoscopic biopsy sampling, leading to histopathological identification of esophageal eosinophilia. However, poor inter-observer agreement regarding diagnosis among endoscopists has become an issue, especially with inexperienced practitioners. On the other hand, image recognition performed with artificial intelligence (AI) with deep learning through convolutional neural network (CNN) has dramatically improved and is increasingly applied for diagnostic imaging in a variety of medical fields, though its effectiveness for endoscopic diagnosis of EoE has not been evaluated.

**Aims & Methods:** We evaluated the diagnostic utility of AI for EoE with endoscopic imaging. A total of 1484 training images of 165 patients histologically proven to be in an active phase of EoE ( $\geq 15$  eosinophils per high power field), including 1182 obtained with white light imaging (WLI) and 302 with narrow band imaging (NBI), as well as 2318 normal esophagus images, including 1292 obtained with WLI and 1026 with NBI, were examined retrospectively. All images were obtained from the records of Shimane University Hospital and related facilities, and used to develop deep learning through CNN to diagnose EoE. Additionally, we prepared a second set of 1156 test images from 40 patients with EoE and 96 subjects with a normal esophagus, including 336 with EoE and 820 with a normal esophagus, and used those to evaluate the diagnostic accuracy of the CNN for each image and case. When more than half of the images were diagnosed as EoE or normal, that was used as the final diagnosis for each case.

**Results:** The CNN required 31 seconds to analyze 1156 test images from 136 cases, and correctly diagnosed EoE in 79.8% using comprehensive diagnosis of WLI and NBI per image analysis, with an overall sensitivity of 78.6% and specificity of 80.2%. Diagnosis using only WLI tended to have a higher level of sensitivity than that with both WLI and NBI (92.8% vs. 78.6%), while accuracy and specificity were not significantly different between them. For each case, the CNN correctly diagnosed 36 of 40 EoE cases using comprehensive diagnosis of WLI and NBI, with overall sensitivity and specificity of 90.0% and 90.6%, respectively. Likewise, diagnosis with only WLI tended to have a higher sensitivity than that with both WLI and NBI (94.9% vs. 90.0%).

**Conclusion:** We developed a new CNN system for detecting EoE using endoscopic images, which provided accurate diagnosis based on WLI within a very short time period. Our findings indicate the usefulness of CNN when diagnosing EoE, especially for aiding inexperienced endoscopists.

**Contact E-Mail Address:** phamkdc@gmail.com

**Introduction:** Eosinophilic esophagitis (EoE) is an immune-mediated condition associated with chronic allergy. Endoscopic findings in EoE may include linear furrowing of the mucosa, white plaques or exudates, concentric rings, friable and diffuse luminal narrowing or strictures, but can often be normal. Biopsies are taken randomly and are often negative. The

aim of the study was to evaluate whether chromoendoscopy with Iodine/Potassium iodine solution (IPIS) is useful for identification of EoE during endoscopy, target and reduce the numbers of needed biopsies.

**Aims & Methods:** We included 10 patients with known EoE and 10 patients with dyspepsia. All underwent gastroscopy with IPIS staining 0.5-1% of the whole esophagus. Selective biopsies were taken from the areas without uptake and areas with uptake of IPIS stain for histopathological comparison and diagnosis.

**Results:** Normal squamous esophageal epithelium took up IPIS and colored it dark brown, while pathologic epithelium become light yellowish due to reduced iodine uptake. In all 10 patients with EoE we observed diminished uptake of IPIS in whole length of the esophagus. 4 patients with EoE had leopard skin pattern after installation IPIS. In these patients, all biopsies from areas with low uptake, showed histologically confirmed EoE (mean 88 eosinophils per high power field (HPF)), whereas areas with more normal uptake showed significantly lower number of eosinophils (mean 18 eosinophils/HPF). In the group with dyspepsia, the uptake of IPIS was found to be normal, with even dark brown colorization of the esophageal mucosa.

**Conclusion:** IPIS seems to be useful for identification of patients with EoE during endoscopy. Areas with uptake deficit in otherwise normal looking squamous epithelium should be biopsied. The technique allows targeted biopsies for improved identification of EoE and reduce sampling errors. Further studies in an unselected patient population must be performed to further explore this finding.

## P1280 EOSINOPHILIC OESOPHAGITIS: THE RISING INCIDENCE AND BURDEN OF DISEASE IN A LARGE NHS TRUST

Tierney M., Fricker J., Gordon J.N.

Hampshire Hospitals NHS Foundation Trust, Department of Gastroenterology, Winchester, United Kingdom

**Contact E-Mail Address:** maeve.tierney@nhs.net

**Introduction:** Eosinophilic oesophagitis (EoE) is an immune-mediated inflammatory condition of the oesophagus that, despite an increasing awareness and incidence of the disease in the last few years, remains poorly characterised and poorly understood. The diagnosis is relatively easily made on biopsy by the presence of an eosinophilic infiltrate ( $>15$  eos/HPF) in patients presenting with symptoms of oesophageal dysfunction and/or suggestive endoscopic features.

Despite this in many cases opportunities for diagnosis are missed and the diagnosis delayed which a potential impact on disease severity and progression. The spectrum of disease is wide and is putting an increasing burden and economic cost on specialist services managing the disease.

**Aims & Methods:** The aim of our study was to quantify the scale of the problem, the spectrum of disease, and the disease burden in a large NHS Trust covering a population of 600,000. We performed a retrospective search was performed of the histopathology database using the term 'eosinophilic oesophagitis' to identify positive oesophageal biopsies, cross-referencing with the endoscopic database. Demographic data was collected including indication for endoscopy, endoscopist, relevant endoscopic findings, and treatment. Patients for whom full endoscopy records were unavailable were excluded as were those with reflux related eosinophilia.

**Results:** 136 cases of definite EoE were identified over a four year period with a year-on-year increase in cases. 96 (70.6%) cases were male with a mean age at diagnosis 44.6 years. The vast majority of cases were identified by either nurse endoscopists (45%) or medical gastroenterologists (41%) with the nurse endoscopists with the highest proportion of biopsies taken in patients presenting with dysphagia (63.7%), food bolus obstruction (16.4%), known eosinophilic oesophagitis (6.6%), stricture/dilatation (5.5%) and reflux (5.5%).

The endoscopic appearance was recorded as normal in 51% of cases. In the remaining patients the most common findings were concentric rings (24%), fibrotic stricture (12%), narrowed impassable lumen (9%) and reflux oesophagitis (4%).

These findings support a spectrum of disease. Approximately 50% of patients responded to acid suppression with the rest treated with oral topical steroid and dietary manipulation. A small number of patients (11%) had strictures that required endoscopic dilatation.

**Conclusion:** The incidence of EoE in our population was high considering it is a relatively rare condition. There was male predominance in keeping with the known literature. Dysphagia was the most frequent indication for endoscopy and there were a few known cases of eosinophilic oesophagitis undergoing reassessment after treatment. Nurse endoscopists appeared particularly effective at appropriately biopsying and diagnosing the disorder which may represents a greater awareness of the condition and a greater adherence to current guidelines regarding biopsy. However in a significant minority of cases opportunities for diagnosis were missed and the diagnosis delayed. In 51% of cases the oesophagus looked normal which has important implication regarding biopsy. The severity of disease appears to vary widely from asymptomatic non-progressive disease to severe fibrosis and stricturing. This study has provided an insight into an increasingly important condition and provides a basis to improve case finding and prompt earlier diagnosis.

**Introduction:** Gastroesophageal reflux disease (GERD) is one of the most common upper gastrointestinal disease with prevalence reaching 25.9% in Europe. Current therapy of GERD aims primarily at decreasing the acid secretion in the stomach and the most effective drugs are proton pump inhibitors which are the first-line treatment. Noteworthy, the Barrett's esophagus (BE) and thus esophageal adenocarcinoma (EA) may develop on a basis of GERD. The marker of such transformation is still sought after to lower the cost of potential surveillance of patients. Free fatty acid receptors (FFARs) are G protein-coupled receptors playing a role in immune responses and tumorigenesis, the two processes involved in the GERD-BE-EA transformation. The role of FFARs in GERD has not been yet investigated.

**Aims & Methods:** The primary aim was to compare the expression of FFARs 1-4 in esophageal mucosa between the patients with GERD and healthy controls (HC). FFAR expression was quantified using quantitative RT-PCR in esophageal samples obtained from patients with GERD and healthy controls. Moreover, patients were asked to fill GERD-Health Related Quality of Life (GERD-HRQL) questionnaire. Student's t-test was chosen when comparing two means; one-way ANOVA followed by the Newman-Keuls post-hoc test was used for analyses of multiple treatment means. Pearson correlation was used to assess the correlation between the FFARs expression and GERD-HRQL results.

**Results:** A total of 35 patients with GERD (27 with non-erosive reflux disease (NERD) and 8 erosive reflux disease (ERD)) and 8 HC were recruited to the study. Overall, the relative expression of FFARs 1-4 were non-significantly higher in esophageal biopsies taken from patients with GERD than in HC. FFAR1 appeared to be the most profoundly expressed FFAR in esophageal mucosa of either GERD patients or HC and presented a non-significantly higher relative expression compared to three other FFARs (2938.00±726.90 for FFAR1 vs 1802.00±454.30 for FFAR2 vs 2136.00±703.00 for FFAR3 vs 64.17±9.07 for FFAR4 for GERD patients and 1846.00±707.00 for FFAR1 vs 1145.00±447.00 for FFAR2 vs 640.00±219.00 for FFAR3 vs 34.59±6.18 for FFAR4 for HC). Expression of FFAR4 was the lowest of all FFARs in all biopsies. When classifying patients with regard to endoscopic findings, all FFARs exhibited higher expression in NERD vs. ERD patients and HC. The expression of FFAR2 was non-significantly lower in patients with ERD vs HC. All other FFARs demonstrated similar expression when comparing ERD to HC. Lastly, we performed Pearson correlation test to analyze possible association between the relative expression of FFARs to GERD-HRQL score. All correlations were negative and only FFAR3 expression significantly, negatively correlated with GERD-HRQL score ( $r=-0.4305$ ,  $p=0.025$ ).

**Conclusion:** We observed an increase in relative expression of FFARs in esophageal biopsies from GERD patients compared to HC, especially in

case of NERD. This trend was most profoundly visible for FFAR1 and least for FFAR4. Noteworthy, FFARs expression negatively correlated with patients' quality of life, meaning that the higher expression of these receptors may be associated with lower intensity of symptoms perceived by patients with GERD. Taken together, our results show that FFARs indeed may play a role in GERD pathophysiology.

**Disclosure:** Nothing to disclose

## P1282 TRANSEPITHELIAL TISSUE PERMEABILITY IN ESOPHAGEAL EPITHELIUM DECREASES IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE FOLLOWING ANTI-REFLUX SURGERY

Ergun P.<sup>1</sup>, Kipcak S.<sup>2</sup>, Bor S.<sup>3</sup>, Ege Reflux Study Group

University, Gastroenterology / Medical Biology, Izmir, Turkey, <sup>3</sup>Ege University,

Ege Reflux Study Group, School of Medicine, Gastroenterology, Izmir, Turkey

**Contact E-Mail Address:** pelinergun@yahoo.com

**Introduction:** Gastroesophageal reflux disease (GERD) is a chronic disorder and typical symptoms recur six months after the discontinuation of medical therapy in 75-80% of patients. Anti-reflux surgery is a successful alternative in some cases and success rate is high. It is also a good model to evaluate the recovery of the epithelium with decreasing the contact time of noxious gastric refluxate including acid, pepsin, bile acids and pancreatic juice.

**Aims & Methods:** We aimed to evaluate the electrophysiological recovery in esophageal epithelium of the cases before and after laparoscopic anti-reflux surgery and compare with healthy controls. Esophageal biopsies from 15 patients with GERD and predominantly typical symptoms included (10 men;  $43.7 \pm 12.6$  years). All patients were evaluated with GERD and quality of life questionnaires, high resolution esophageal manometry, 24 h impedance-pH monitoring, upper gastrointestinal endoscopy with distal esophageal biopsies. 3-4 months after laparoscopic anti-reflux surgery upper gastrointestinal endoscopy repeated in asymptomatic patients and esophageal biopsies were taken. 23 healthy controls (7 men;  $41.9 \pm 10.8$  years) were also included. The transepithelial resistance (TEER) and tissue permeability via fluorescein diffusion within 2 hours were recorded.

**Results:** TEER of esophageal epithelium was significantly higher after the surgery ( $p=0.0002$ ) and healthy controls (HC) ( $p=0.0009$ ). There was no difference between pre-operative patients and HC in TEER. Mucosal permeability measured with fluorescein diffusion of post-operative measurements was significantly decreased than pre-op patients ( $p=0.038$ ). There was no significant difference neither pre-operative nor post-operative measurements than HC (Table).

**Conclusion:** The TEER and permeability results implicate that laparoscopic anti-reflux surgery showed an efficient recovery within esophageal epithelium in patients with GERD. One possible explanation of the higher tissue resistance following the surgery than HC might be explained with the continue "silent" reflux in HC.

**Disclosure:** Nothing to disclose

	TEER (Ohms)	Flourescein permeability (pmols)
Healthy controls	$166.8 \pm 46.2$	$36.9 \pm 13.5$
Pre-op patients	$151.0 \pm 51.6$	$48.6 \pm 27.8$
Post-op patients	$214.8 \pm 61.0^*$	$29.5 \pm 17.3^{**}$

**Introduction:** Stretta is an option for patients with gastroesophageal reflux disease (GERD), offering an alternative to invasive surgery, endoscopic therapies or continue PPI therapy.

**Aims & Methods:** We aim to investigate the electrophysiological differences and diffusion characteristics as a reflection of tissue integrity within esophageal mucosa before and after stretta. Patients with predominantly typical symptoms and true nonerosive reflux disease or LA-esophagitis A were included. GERD and quality of life questionnaires, high resolution esophageal manometry, 24 h impedance-pH monitoring, upper gastro-intestinal endoscopy with distal esophageal biopsies were performed in nine patients before stretta (4 men, 44.5±10.4 years). 3-4 biopsies were put into the chambers to measure the transepithelial resistance (TEER), potential difference (PD) and tissue permeability via fluorescein diffusion within 2 hours as well as evaluation of dilated intercellular spaces with light microscopy. The Stretta procedure performed under sedation with regular protocol without any complication. Three weeks of PPI therapy was given to all patients following the procedure than stopped. All patients were symptom free or have less than 50% of typical symptoms at the end of the 8 weeks of follow up. Approximately two months after stretta, upper GI endoscopy repeated, esophageal biopsies were taken. All results were compared with 23 healthy controls (7 men; 41.9 ± 10.8 years). 24 h impedance-pH monitoring was performed in eleven out of 23 HC.

**Results:** TEER of pre-stretta group was significantly lower than healthy controls (HC) (p=0.037). But no significance was found between pre-stretta and post stretta group (p=0.17) even though there was a great margin (124.6 ± 55.7 vs 157.2 ± 61.3). No difference was shown in post stretta group compared to HC (166.8 ± 46.2) (p=0.59). Mucosal permeability in pre-stretta group was significantly lower than post-stretta group (p=0.006) and HC (p=0.015) while there was no significance between post stretta and HC (Table).

	TEER (Ohms)	Flourescein permeability (pmols)
Pre-stretta	124.6 ± 55.7*	67.2 ± 31.5*
Post-stretta	157.2 ± 61.3	28.5 ± 18.2**
Healthy controls	166.8 ± 46.2	36.9 ± 13.5

(\*; p<0.05 pre-stretta vs HC, \*\*; p<0.05 pre-stretta vs post-stretta)

[Transepithelial resistance and flourescein permeability results of the groups]

**Conclusion:** Electrophysiological results indicate that epithelial permeability and possibly mucosal damage has recovered after stretta treatment within esophageal epithelium. Those changes might be explained with less reflux load at the distal esophagus. A direct effect of the procedure inside the tissue is a low possibility since application effects only a small area.

**Disclosure:** Nothing to disclose

## P1284 PAR2, P2X2 AND P2Y2 MRNA EXPRESSION IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE AND THEIR RELATIONSHIP TO REFLUX SYMPTOMS: A PILOT STUDY

**Introduction:** Current treatment of gastroesophageal reflux disease (GERD) aims primarily at decreasing the acid secretion, however there is still a group of patients not responding to conventional therapy. According to recent model of GERD pathogenesis, reflux esophagitis is an immune cell-mediated damage, rather than a caustic chemical injury. Acid exposure

can increase expression of several receptors on esophageal epithelial cells. The proteinase-activated receptor-2 (PAR2) is a member of the G protein-coupled receptor family and has been involved in inflammation, visceral hyperalgesia, and in transepithelial resistance. Purinergic receptors are a family of membrane-bound receptors using ATP as transmitter. P2X and P2Y receptors play important roles in signaling visceral pain and esophageal hypersensitivity. Thus these receptors represent a potential target for future pharmacological treatment of GERD.

**Aims & Methods:** The aim was to assess the expression of PAR2, P2X2 and P2Y2 mRNA in esophageal mucosa in different groups of GERD patients as well as to compare with reflux symptoms and HRQL.

PAR2, P2X2 and P2Y2 mRNA expression was quantified using quantitative RT-PCR in esophageal samples obtained from patients with GERD and healthy controls. Moreover, patients completed the GERD-Health Related Quality of Life (GERD-HRQL) questionnaire. Student's t-test was chosen when comparing two means; one-way ANOVA followed by the Newman-Keuls post-hoc test was used for analyses of multiple treatment means. Using Pearson correlation test we analyzed relationship between the relative expression of receptors and GERD-HRQL score.

**Results:** A total of 53 patients with GERD (37 with non-erosive reflux disease (NERD) and 16 erosive reflux disease (ERD)) and 9 healthy controls were recruited to the study. Overall, the relative expression of PAR2, P2X2 and P2Y2 were non-significantly higher in esophageal biopsies taken from patients with GERD than in controls (77.60±28.50 vs 284.60±67.72; 26.81±10.27 vs 274.40±77.46; 3476.0±508.2 vs 7215.0±1338.0, accordingly).

When classifying patients to non-erosive and erosive reflux disease PAR2 receptor expression was non-significantly higher in ERD compared to NERD and controls (326.10±112.30 vs 266.90±84.76 vs 77.60±28.50).

P2X2 exhibited the highest expression in NERD compared to ERD and controls (302.20±82.94 vs 40.18±17.78 vs 26.81±10.27), similarly to P2Y2 which expression was higher in NERD than in ERD and controls (7321.00±1651.00 vs 5306.0±1738.00 vs 3476.00±508.0).

GERD-HRQL scores revealed significant positive correlation to PAR2 expression (r=0.03883), as well as to P2Y2 expression (NS), however were negatively correlated with P2X2 expression (r=-0.2991).

**Conclusion:** Higher PAR2 expression was found in erosive reflux disease and may be associated with higher intensity of symptoms perceived by patients with GERD. Relative expression of P2X2 and P2Y2 were increased particularly in NERD, where they could mediate sensitization of esophagus. Our results show that PAR2, P2X2 and P2Y2 may play a role in GERD inflammation and could be in future a therapeutic targets for reflux symptoms.

**Disclosure:** Nothing to disclose

## P1285 THE EFFECT OF DIFFERENT PH REFLUXATE ON THE TYPE OF IMMUNE RESPONSE IN GERD PATIENTS

**Introduction:** Assessment of 24-hour pH-monitoring can provide confirmatory evidence of gastroesophageal reflux disease (GERD). The primary outcome of 24-hour pH-monitoring is the distal oesophageal acid exposure time (AET) < 6%. Currently, discusses the possible impact of immune response (Th1 or Th2) in the development of the inflammatory response in the esophagus.

**Aims & Methods:** The aim of the study was to investigate interleukin (IL)-8 and IL-10 expression after exposure to different human refluxates (pH< 5, pH 5-7, pH>7) to peritoneal macrophages of C57/BL6 mice (n=68) with the following macrophage culturing in standard conditions (10% FBS, RPMI1640) for 36 hours. According to data of endoscopy and 24-hour pH-monitoring (normative value of AET< 6%\*) we divided 68 patients with GERD to 28 (14 men, 45.74±2.23 yr) non-erosive reflux disease (NERD), 22 (15 men, 45.0±3.24 yr) erosive reflux disease ERD and 18 (13 men, 47.22±2.95 yr) Barrett's esophagus (BE). We performed 24-hour pH-monitoring on the Omega - Ambulatory Impedance-pH Recorder (Medi-

cal Measurements Systems (MMS), Netherlands). Macrophage culturing (RPMI1640 medium, 10% FBS) in standard conditions (37°C, 5% CO<sub>2</sub>) for 36 hours flow cytometry (Beckman Coulter, FC500). Assessment of secretory activity of peritoneal macrophages (proinflammatory cytokine IL-8 and anti-inflammatory cytokine IL-10). The statistical analysis was done using SPSS Statistics 17.0.

**Results:** In NERD patients median pH of refluxates was 6.18 [4.2; 7.4], in ERD - 6.71 [5.7; 8.1], in BE - 6.24 [4.6; 7.3]. Median value of the level of IL-8 after exposure refluxates with pH < 5 was 69.0 [42.1; 125.3] pg/mL, with pH 5-7 was 60.3 [15.4; 120.0] pg/mL, with pH > 7 - 37.6 [8.7; 73.4] pg/mL. Median value of the level of IL-10 after exposure refluxates with pH < 5 was 4.1 [1.5; 10.2] pg/mL, with pH 5-7 was 7.8 [1.3; 33.8] pg/mL, with pH > 7 - 16.8 [5.7; 61.3] pg/mL. Exposure to acid refluxates causes an increased production of Th1 proinflammatory cytokine IL-8 ( $r = -0.352$ ,  $p = 0.026$ ), but exposure to non acid refluxates causes an increased production of Th2 anti-inflammatory cytokine IL-10 ( $r = 0.697$ ,  $p = 0.001$ ). The results of 24-hour pH-monitoring demonstrated that in NERD patients median AET was 4.7 [0.3; 18.0] %, in ERD - 9.3 [0.2; 57.8] %, in BE - 14.5 [1.3; 49.9] %.

**Conclusion:** Exposure to acid refluxates causes an increased of Th1 immune response with increased production of Th1 cytokine (IL-8). Exposure to non acid refluxates causes an increased of Th2 immune response with increased production of Th2 cytokine (IL-10). Th1 and Th2 cytokines production demonstrates statistically significant different with acid and non acid refluxates. We observed that AET was higher in ERD and BE patients than in NERD patients. It suggests that high level AET may lead to Th1 immune response.

## P1286 ESOPHAGEAL INFUSION OF MENTHOL DOES NOT AFFECT ESOPHAGEAL MOTILITY BUT EVOKES HEARTBURN IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE (GERD)

**Introduction:** A common food additive menthol is thought to trigger the symptoms of GERD by influencing esophageal peristalsis and the lower esophageal sphincter (LES) function. However, recent studies reported the expression of TRPM8 receptor for menthol and cold in esophageal sensory C-fiber nerves.

**Aims & Methods:** We evaluated the effect of esophageal infusion of menthol on esophageal motility and the sensations evoked from the esophagus. High resolution manometry (HRM) catheter with attached thin tube for menthol infusion (opening 5 cm above LES) was placed transnasally. HRM protocol which included baseline recording and 10 water (5ml) swallows was performed in supine position before and after esophageal infusion of menthol (3mM, 20 min, 8ml/min). The sensations evoked by menthol infusion were evaluated for quality and for intensity of painful component by visual analogue scale (VAS, range 1-10). In additional subjects menthol infusion was performed without HRM and only the sensations were evaluated.

**Results:** Menthol did not appreciably affect HRM measurements characterizing LES function and esophageal peristalsis in healthy subjects (N=12) or GERD patients (N=10). For example, in healthy subjects esophageal infusion of menthol did not change the magnitude of the inspiratory augmentation of LES (10.6±1.8 mmHg before vs. 9.1±1.6 mmHg after menthol,  $P=0.3$ ), distal contractile integral (DCI, 742±137 vs. 840±124,  $P=0.5$ ) nor the percentage of ineffective swallows (40±10% vs. 23±8%,  $P=0.13$ ). Similarly, in GERD patients menthol did not change the inspiratory augmentation of LES (9.5±1.2 mmHg vs. 9.1±1.2 mmHg,  $P=0.6$ ), DCI (287±86 vs. 314±102,  $P=0.7$ ) nor ineffective swallows (75±10% vs. 71±13%,  $P=0.6$ ).

In contrast, menthol had a striking effect on esophageal sensations in patients with GERD. While the esophageal infusion of menthol evoked only a cold sensation in 11 of 12 healthy subjects, it evoked heartburn in 10 of 10 patients with GERD ( $P < 0.01$ ).

In healthy subjects the cold sensation was perceived only as a minor discomfort (VAS score 1.9±0.3) but in patients with GERD the menthol-induced heartburn was perceived as painful (VAS score 5.6±0.5,  $P < 0.01$ ).

The intensity of menthol-induced heartburn was comparable to the intensity of heartburn evoked by a brief infusion of acid (pH=1.0, 10min) in a separate group of patients (VAS score 7.1±0.7, N=12).

**Conclusion:** We conclude that esophageal infusion of menthol does not affect esophageal motility. However, the sensations evoked by menthol change dramatically from a relatively non-painful cold sensation in healthy subjects to painful heartburn in patients with GERD. Our results suggest that menthol triggers the symptoms of GERD directly by influencing esophageal nerves rather than indirectly by affecting esophageal motility. Supported by VEGA 1/0304/19.

## P1287 EFFICACY AND SAFETY OF TRANSORAL INCISIONLESS FUNDOPPLICATION (TIF) IN REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Gopalakrishnan Ravikumar N.P.<sup>1</sup>, Sannapaneni S.<sup>2</sup>, Thota P.<sup>3</sup>, Sanaka M.<sup>4</sup>

<sup>1</sup>University at Buffalo, Internal Medicine, Buffalo, United States, <sup>2</sup>Texas Health Presbyterian Hospital, Dallas, United States, <sup>3</sup>Cleveland Clinic Foundation Digestive Disease Institute, Cleveland, United States, <sup>4</sup>Cleveland Clinic Foundation Digestive Disease Institute, Gastroenterology, Cleveland, United States

**Contact E-Mail Address:** ravikumar.naveen1@gmail.com

**Introduction:** Refractory gastroesophageal reflux disease (GERD) is common and can affect up to 40% of patients who are on proton pump inhibitor therapy. Surgical fundoplication (Nissen fundoplication) has proven to be an effective treatment option for these patients but it remains an invasive procedure in this era of minimally invasive surgery. Several endoluminal approaches to GERD management have been developed as a potential bridge between medical management and surgical fundoplication. Transoral incisionless fundoplication (TIF) is a novel endoscopic technique which has shown some promise in early studies; however, its safety profile and efficacy remain uncertain.

**Aims & Methods:** We aimed to assess the efficacy and safety of TIF in refractory GERD through a systematic review and meta-analysis. We performed a thorough literature search using PubMed, EMBASE, Cochrane library, Medline, Google Scholar and Science citation index between January 2010 to January 2018. Search terms included MeSH and non-MeSH terms relating to gastroesophageal reflux disease, refractory gastroesophageal reflux disease, endoscopic techniques in gastroesophageal reflux disease and transoral incisionless fundoplication. Additional case-reports, case series, and abstracts were retrieved by searching from references of relevant studies. Primary outcomes measured were cumulative technical success rate and adverse events. Secondary outcomes measured were the improvement in Gastroesophageal Reflux Symptom Score (GERSS), DeMeester score and Reflux symptom index (RSI).

**Results:** Based on our search criteria, 41 studies were identified and 6 were excluded after careful review. 35 studies which included 1586 patients (49.4% males) were analyzed. The overall technical success rate of TIF was 98.4% (95% confidence interval [CI] 96 to 99,  $p < 0.001$ ) and had an adverse event rate of 3.2% (95% CI 1 to 4,  $p < 0.001$ ). Post TIF, there was a significant improvement in GERSS score (mean difference 17.29, 95% CI 17.26 to 18.28,  $p < 0.001$ ), RSI (mean difference 14.37, 95% CI 13.39 to 15.19,  $p < 0.001$ ) and DeMeester score (mean difference 9.78, 95% CI 8.12 to 11.89,  $p < 0.001$ ).

**Conclusion:** TIF is a technically feasible and effective endoscopic therapeutic option for refractory GERD with good clinical responses. However, more controlled trials are required in future to compare the efficacy and safety between TIF and Nissen fundoplication.

**Disclosure:** Nothing to disclose

## P1288 COMPARISON OF THE EFFICIENCY OF TWO DIFFERENT PPI FORMULA IN TREATMENT OF ATYPICAL GERD PATIENTS, A RANDOMIZED STUDY

Ting P.H., Luo J.C.

Taipei Veterans General Hospital, Department of Internal Medicine, Taipei, Taiwan

**Contact E-Mail Address:** seohyun1130@gmail.com

**Introduction:** Patients with atypical gastro-esophageal reflux disease (GERD), including cough, globus, and hoarseness usually require more aggressive or double dose proton pump inhibitor (PPI) therapy than patients with typical GERD. The prospective, open-label, randomized study aims to compare the efficacy of lansoprazole, a fast orally-disintegrating PPI and dexlansoprazole, a dual delayed release PPI in patients with atypical GERD symptoms.

**Aims & Methods:** Patients with atypical GERD symptoms and a total Reflux Symptom Index (RSI) score  $\geq 11$  were eligible for enrollment. From Jan. 2017 to Dec. 2018, 232 subjects were randomly assigned (1:1 ratio) to receive oral lansoprazole 30 mg, once daily before breakfast or oral dexlansoprazole 60 mg, once daily before breakfast for 8 weeks. The primary endpoint is to compare the response rate after 8-week PPI therapy between the two groups.

**Results:** There were 101 (43.5%) with cough, 144 (62.1%) with globus, and 41 (17.7%) with hoarseness among these 232 study subjects. After 8-week PPI therapy, dexlansoprazole treated group had a significantly higher symptoms response rate than lansoprazole treated group in cough (76.5 % vs. 38.0 %) and globus (69.7 % vs. 30.8 %) ( $p$  all  $< 0.05$  by intention to treat). Multivariate logistic regression analysis showed that use of dexlansoprazole, presence of dyslipidemia and typical GERD symptoms (acid reflux and heart burn) and absence of globus symptom were predictors for symptom response for cough; use of dexlansoprazole, no cough symptom, and presence of erosive esophagitis were predictors for symptom response for globus ( $p$  all  $< 0.05$ ). No predictor for therapy response to hoarseness was noted.

**Conclusion:** There is a higher response rate for cough and globus symptoms in atypical GERD patients after a 8-week PPI therapy with dexlansoprazole rather than lansoprazole.

**Disclosure:** Nothing to disclose

## P1289 EFFICACY OF DA-5204 (STILLEN 2X®) FOR PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PILOT STUDY

Shim H.L., Cho J.H., Shin C.M., Yoon H., Park Y.S., Kim N., Lee D.H.

Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea (Republic of)

**Contact E-Mail Address:** sharpsim1222@naver.com

**Introduction:** Proton pump inhibitor (PPI) alone is not satisfactory for the treatment of gastroesophageal reflux disease (GERD). Therefore, we investigated the efficacy of DA-5204 (Stillen 2X®, 90mg of Artemisia asiatica 95% ethanol extract per tablet) and PPI combination therapy on GERD in comparison to PPI alone.

**Aims & Methods:** This randomized, double-blind, placebo-controlled study randomly assigned 70 patients with endoscopically proven esophageal mucosal injury (Los Angeles classification A or B) into 2 groups: pantoprazole 40mg once daily with DA-5204 twice daily (DA-5204 group) or pantoprazole 40mg once daily with placebo twice daily (placebo group) for 4 weeks. The primary endpoints were endoscopically effective (normal mucosa or minimal change) or complete healing (normal mucosa) rates, and secondary endpoint was sufficient relief ( $\geq 50\%$  reduction) of reflux symptoms using Gastroesophageal Reflux Disease Questionnaire (GerdQ) questionnaire.

**Results:** Final analyses included 29 patients with the DA-5204 group and 30 patients with the placebo group. At weeks 4, there was a significant difference of the endoscopically effective healing rate between the two groups (DA-5204 group vs. placebo group; 93.1% vs. 56.7%;  $p = 0.001$ ) as well as the complete healing rate (DA-5204 group vs. placebo group; 82.8% vs. 33.3%;  $p < 0.000$ ). The rates of sufficient relief for reflux symptoms according to GerdQ tended to be higher in the DA-5204 group than in the placebo group, with no significant difference.

**Conclusion:** Our findings suggest that combined therapy with PPI and DA-5204 is more effective in treating GERD than PPI alone.

**Disclosure:** Nothing to disclose

## P1290 ON-DEMAND VERSUS CONTINUOUS PROTON PUMP INHIBITOR THERAPY AS FIRST-LINE TREATMENT FOR GASTROESOPHAGEAL REFLUX DISEASE: A SINGLE-CENTER PROSPECTIVE STUDY

Yoon J.Y., Kim D.H.

University of Ulsan College of Medicine, Asan Medical Center, Gastroenterology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** fatei@hanmail.net

**Introduction:** The recommended schedule of proton pump inhibitor as first-line treatment for gastroesophageal reflux disease (GERD) is 4-8 weeks of continuous medication; however, patients often do not take all prescribed medication and spontaneously resort to on-demand schedule. We compared the efficacy of esomeprazole as first-line treatment according to the pattern of medication adherence (on-demand vs. continuous).

**Aims & Methods:** Patients who diagnosed with GERD by GERD questionnaire (Gerd-Q) between December 2017 and May 2018 were enrolled. The patients were prescribed with daily esomeprazole 20 mg for 4 weeks. After regularly taking the medicine for at least 1 week, the patients were allowed to choose between continuous and on-demand therapy during the remaining 3 weeks depending on the degree of the subjective measure of symptoms. The number of remaining pills in the on-demand group was calculated, and Gerd-Q scores of the two groups were compared at baseline and after the 4-week study period.

**Results:** Out of a total of 94 patients, 62 enrolled in the on-demand group and 32 in the continuous group. In the on-demand group, the median number of remaining pills was 7.50 (range, 1-21). In the on-demand group and the continuous group, the mean Gerd-Q scores were 9.42 and 9.47 at baseline ( $p=0.850$ ) and 7.21 and 6.91 at 4 weeks ( $p=0.149$ ), respectively. Total and individual item scores of the Gerd-Q were significantly decreased in both groups at the end of the study period ( $p < 0.001$ ). There were no significant differences between the two groups in terms of mean changes in the Gerd-Q score (on-demand vs. continuous groups: -2.21 vs. -2.56,  $p=0.537$ ).

**Conclusion:** On-demand therapy with esomeprazole 20 mg showed comparable efficacy to continuous therapy in terms of subjective symptom management in patients with GERD.

**Disclosure:** Nothing to disclose

## P1291 ADMINISTRATION OF A BITTER TASTANT HAS NO INFLUENCE ON THE NUMBER OF TRANSIENT LOWER OESOPHAGEAL SPHINCTER RELAXATIONS IN HEALTH

Geysen H.<sup>1</sup>, Geeraerts A.<sup>1</sup>, Vanuytsel T.<sup>2</sup>, Tack J.<sup>3</sup>, Pauwels A.<sup>4</sup>

<sup>1</sup>KU Leuven, TARGID, Leuven, Belgium, <sup>2</sup>KU Leuven, Department of Gastroenterology, Leuven, Belgium, <sup>3</sup>University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium, <sup>4</sup>Katholieke Universiteit Leuven, TARGID, Leuven, Belgium

**Contact E-Mail Address:** hannelore.geysen@kuleuven.be

**Introduction:** Dietary measures such as avoiding high fat meals, sweets, coffee, alcoholic and carbonated beverages are often advised to patients with gastro-oesophageal reflux disease (GORD) due to their 'reflux inducing' characteristics. However, the evidence for these advices is weak due to conflicting findings and the small number of patients included in the currently available clinical studies. Our group previously showed that administration of a bitter compound can alter the intragastric pressure (IGP) after a meal (1). Additionally, we demonstrated the existence of a negative correlation between IGP and the number of transient lower oesophageal sphincter relaxations (TLOSRS) (2). However, the effect of a bitter compound on TLOSRS and subsequent reflux episodes has never been investigated and it is unclear whether bitter food items should be avoided in GORD. We hypothesise that bitter administration in healthy volunteers (HV) will lead to an increase in the number of TLOSRS.

**Aims & Methods:** After an overnight fast, 19 female HV (36 y [21-63]) underwent a high-resolution impedance manometry (HRiM) measurement. After placement of the HRiM probe (Unisensor, Attikon, Switzerland), 10  $\mu\text{mol/kg}$  (0.1 mL/kg) of a 100 mM denatonium benzoate solution or an identical volume of placebo (water) was administered directly into the stomach. The number of TLOSRS and reflux episodes were quantified 30 minutes before and two hours after consumption of a high caloric meal (mashed potatoes, apple sauce and meatloaf; 1000 kcal), using the dedi-

cated software (Solar GI, Laborie, Canada). The HV were asked to complete a questionnaire concerning the presence and intensity of different upper gastro-intestinal (GI) symptoms every 15 minutes. The study was organised in a double-blind, randomized, cross-over design with at least one week washout between both administrations. Results were analysed using a paired t-test or Wilcoxon signed rank test when appropriate.

**Results:** There was no significant difference in the number of TLOSRS nor the number of reflux episodes between the bitter and placebo condition (Table 1).

	Bitter	Placebo	p-value
TLOSRS	17 ± 5.5	15 ± 4.4	0.14
Reflux episodes	10 ± 6.0	10 ± 4.7	0.73

[Table 1: The number of TLOSRS and reflux episodes in the two different conditions (mean ± SD).]

Additionally, no differences were observed in the nature (gas or liquid) and extent of reflux events between the different conditions. LOS pressures dropped significantly in the first postprandial hour to start recovering slowly back to baseline values during the second postprandial hour ( $p < 0.0001$ ), without any difference between both conditions. No difference in GI symptom occurrence was noted.

**Conclusion:** Administration of the bitter tastant denatonium benzoate, had no influence on the number of TLOSRS nor on the number of reflux episodes compared to placebo. Therefore, we speculate that the consumption of bitter food will not have an influence on the number of reflux episodes nor on the occurrence of GORD-related symptoms in GORD patients.

**Contact E-Mail Address:** ronnie.fass@gmail.com

**Introduction:** Proton pump inhibitors (PPIs) are the standard therapy for gastroesophageal reflux disease (GERD). However, it is estimated that approximately 30% of patients with GERD have persistent symptoms despite taking label-dose PPIs. GERD and persistent GERD are characterized by reflux of stomach contents into the esophagus resulting in heartburn (HB) and regurgitation (RG), esophageal injury, and complications. IW-3718 is a novel gastric-retentive bile acid sequestant in clinical development for persistent GERD. The positive impact of IW-3718 was previously reported for HB and RG, based on derived endpoints. The aim of this study was to determine the impact of IW-3718, added to label-dose PPIs, on individual GERD symptoms measured by the modified Reflux Symptom Questionnaire-electronic Diary (mRESQ-eD), a patient-reported, evidence-based clinical outcomes assessment.

**Aims & Methods:** This double-blind, placebo-controlled study included a screening, a 2-week pretreatment, and an 8-week treatment period. Enrolled patients were taking label-dose PPIs; had GERD, evidenced by erosive esophagitis (EE) on esophagogastroduodenoscopy (EGD) and/or abnormal acid exposure while taking PPIs ( $\text{pH} < 4$  for  $\geq 4.2\%$  of a 24-hour interval; "Bravo-positive"); and had HB or RG symptoms  $\geq 4$  days per week for 8 weeks despite ongoing use of label-dose PPIs. Patients were strati-

fied by baseline (BL) EE status and randomized (1:1:1:1) to placebo (PBO) or IW-3718 (500, 1000, or 1500 mg) twice daily (BID) in addition to once-daily (QD) PPI. During the pretreatment and treatment periods patients self-reported the severity (6-point scale [0=did not have, 5=severe]) or frequency (5-point scale [0=never, 4=very often]) of 10 symptoms associated with GERD on the mRESQ-eD daily. The symptoms assessed for "severity" were HB, burning feeling behind breastbone or center of upper stomach, pain behind breastbone or center of upper stomach, difficulty swallowing, hoarseness, and cough. The symptoms assessed for "frequency" were RG (liquid or food) moving upward toward throat or mouth, acid or bitter taste, coughing, and burping. For each of the 10 symptoms, change from BL to Week 8 in the weekly average was analyzed using an analysis of covariance model with treatment group and EE status as factors and BL score as a covariate. No adjustment was made for multiplicity.

**Results:** The modified intent-to-treat population included 280 patients (68-71/arm). At BL, 52% had EE and 73% were Bravo-positive. Demographics were similar across groups. Changes from BL to Week 8 for each of the 10 mRESQ-eD symptom items are presented in Table 1. Greater improvements were seen for all symptom items in the 1500-mg IW-3718 group compared with PBO ( $P \leq 0.05$ ), except burping frequency ( $P = 0.17$ ).

**Conclusion:** In addition to improving HB and RG, IW-3718 (1500 mg BID) improved other GERD-related symptoms in patients with persistent GERD who continued receiving PPIs QD.

Endpoint Statistic: Mean change from Baseline	PBO (PPI alone) BID n=69	IW-3718 500 mg BID n=71	IW-3718 1000 mg BID n=71	IW-3718 1500 mg BID n=68	P value IW-3718 1500 mg vs PBO
Heartburn severity	-1.4	-1.5	-1.7	-1.8	0.03
Burning feeling behind breastbone or center of upper stomach severity	-1.3	-1.4	-1.6	-1.8	0.01
Pain behind breastbone or center of upper stomach severity	-1.3	-1.3	-1.5	-1.7	0.03
Difficulty swallowing severity	-0.9	-0.8	-1.0	-1.2	0.03
Hoarseness severity	-0.6	-0.7	-1.0	-1.1	<0.01
Cough severity	-0.6	-0.7	-1.0	-1.2	<0.01
Regurgitation (liquid or food) moving upward toward throat or mouth frequency	-0.8	-1.0	-1.0	-1.2	<0.01
Acid or Bitter Taste Frequency	-0.9	-0.9	-1.1	-1.2	0.05
Coughing frequency	-0.6	-0.6	-0.7	-1.0	<0.01
Burping frequency	-0.8	-1.0	-0.9	-1.0	0.17

## P1293 DIAGNOSING DYSPLASIA IN BARRETT'S OESOPHAGUS - THE SEATTLE PROTOCOL REMAINS THE DOMINANT STRATEGY IN NON EXPERT CENTRES

Keyte G.<sup>1</sup>, Iqbal M.<sup>1</sup>, Viswanath Y.<sup>1</sup>, Khan A.<sup>2</sup>, Wells C.<sup>2</sup>, Vasani J.<sup>2</sup>, Beintaris I.<sup>2</sup>, Dhar A.<sup>1</sup>

<sup>1</sup>Darlington Memorial & Bishop Auckland Hospitals, Gastroenterology, Co. Durham, United Kingdom, <sup>2</sup>University Hospital of North Tees, Gastroenterology, Stockton-on-Tees, United Kingdom

**Contact E-Mail Address:** muhammad.iqbal16@nhs.net

**Introduction:** Detection of dysplasia at Barrett's surveillance depends on a number of factors including: the endoscopist's skill, use of advanced imaging (NBI, Acetic acid), adherence to Seattle protocol, and high-risk patient factors like male sex, smoking, length of Barrett's segment and

family history of oesophageal adenocarcinoma. Whether the high rates of visible dysplasia diagnosis reported from expert tertiary centres needs further study.

**Aims & Methods:** The aim of this pre-EQULP study was to analyse routes to dysplasia diagnosis in a dedicated Barrett's surveillance programme, specifically looking at the grade of the endoscopist, use of image enhancement (IE), diagnosis by Seattle biopsy protocol vs. random biopsy, and the nature of dysplasia (Low grade, LGD vs. high grade, HGD). An electronic database search of over 600 Barrett's surveillance histology was carried out for the period 2015-2018 in two NHS Trusts, extracting all reported dysplasia. The endoscopy database was then interrogated for the following: patient demographics, grade of endoscopist (medical consultant gastroenterologist, non-medical endoscopist and surgical consultant), sedated vs. unsedated procedure, visible dysplasia, HD-white light vs. IE, length of Barrett's segment and Prague classification, Paris classification of any visible lesions, targeted vs. Seattle Protocol biopsies, and grade of dysplasia. All endoscopies were done with high-resolution scopes; where a visible lesion was identified, a targeted biopsy was taken.

**Results:** 148 patients with dysplasia were analysed, M:F ratio 4.5:1, mean age 68yrs. Barrett's length ranged from 1-14cm, with 50% endoscopists reporting the Prague classification. Surveillance was done by: consultant gastroenterologists (70pts), nurse endoscopists (55pts), consultant surgeons (15pts) and registrars (8pts). At Site A only 3.2% of endoscopists explicitly mentioned a Seattle biopsy protocol in their report. Across both sites histology showed that protocol had been followed in 56.7% of endoscopies, with 54.2% gastroenterologists, 52.6% nurse endoscopists and 73.7% surgeons taking multi-level biopsies (Seattle equivalent protocol). The distribution of dysplasia LGD:HGD:carcinoma in the Seattle group was 1:1.48:1.32 vs. random biopsy of 2.54:2.47:1. In Site A, there was a statistically significant difference between the two groups, showing that more carcinomas were picked up in the Seattle group, chi-square statistic 12.65, DF=3 p=0.0018.

**Conclusion:** In this real-world NHS study, we found that after 4 years of the BSG guidelines, visible dysplasia is extremely difficult to detect. The Seattle biopsy protocol was followed in only 56.7% of endoscopies and is the dominant route, indicating a need for quality improvement & training amongst medical and non-medical endoscopists, including IE surveillance and chromoendoscopy.

**Disclosure:** Nothing to disclose

## P1294 RELATIONSHIP BETWEEN BARRETT'S ESOPHAGUS AND COLONIC DISEASES: REFERENCE TO ENDOSCOPIC SURVEILLANCE

**Contact E-Mail Address:** pppryoutarou@yahoo.co.jp

**Introduction:** Given that the risk factor of Barrett's carcinogenesis is predictable, an appropriate management and surveillance of Barrett's esophagus (BE) may be provided. There are many reports regarding positive relationship between BE and colorectal neoplasm (CNs) in Western countries, this has been suggested BE and esophageal adenocarcinoma (EAC) are related with some colonic disease. However, it is still conflicting and little is known in Asian countries whose EAC has been also increasing. The purpose of this retrospective study was to investigate the relationship between BE or EAC, and colonic diseases including CNs, colon diverticulosis and inflammatory bowel diseases (IBD).

**Aims & Methods:** We retrospectively reviewed the medical records of 5606 patients (male gender: 56.9%, and median age: 68.2, range 16-98 years old) received both of colonoscopy and esophagogastroduodenoscopy between January 2016 and December 2017 in 3 core hospitals, and investigated their endoscopic findings and clinical covariables were age, gender, BMI, smoking, alcohol intake drug use (aspirin/NSAIDs, anti-coagulants, proton pump inhibitors, statins, anti-diabetics). BE was defined when Barrett's mucosa with more than 1.0cm of M-extent according to the Prague C and M criteria.

**Results:** BE with more than 1cm in length were found in 728 out of 5606 (12.9%) patients. The Predictors for BE were male gender (63.4%, P< 0.001), age (mean 69.3 +/- 11.8 years old, P< 0.001), PPI administration (35.2% vs. 29.0%, P< 0.001), anti-diabetics administration (12.3% vs. 9.8%, P=0.041), reflux esophagitis (15.6% vs. 7.9%, P< 0.001), hiatal hernia (59.0% vs. 34.5%, P< 0.001), presence of CNs (74.0% vs. 54.0%, P< 0.001), colon diverticulosis (34.0% vs. 29.3%, P=0.011) and IBD (0.6% vs. 1.8%, P=0.020). Related CNs were adenoma and adenocarcinoma, but not hyperplastic polyp, especially located in the proximal colon. Multivariate analysis showed that colon neoplasms (t = 8.54, P< 0.001), reflux esophagitis (t = 5.27, P< 0.001), and hiatal hernia (t = 11.73, P< 0.001) were positively correlated with presence of BE.

**Conclusion:** Presence of CNs was strongly associated with patients with BE. Colon diverticulosis and IBD may be a positive and negative predictor for BE. Information provided from colonoscopy appear useful to establish the strategy for the surveillance of BE.

**Introduction:** The ABC is an Asia-Pacific workgroup on BO, affiliated to the National Cancer Institute in the United States. At present, guidelines from major societies worldwide provide differing definitions and viewpoints, making the standardization of the diagnosis of BO challenging. As a result of studies using different methodologies, endoscopic practices and histopathological criteria used in the diagnosis of BO, there is substantial variability in the published prevalence of BO in Asia.

**Aims & Methods:** We aim to better understand current practices and perceptions of Asian endoscopists regarding BO. We designed an online survey of 11 key questions to understand the preferred diagnosis and management practices of Asian Endoscopists on BO.

**Results:** Of 985 invited respondents, 593 completed the survey (response rate of 60.2%) with 60.5% from Japan vs. 39.5% outside Japan. 90.6% were physicians, and 77.4% of respondents spend at least 20% of time performing endoscopy. Results are shown in Table 1. The preferred landmark of the oesophagogastric junction in Japan was the distal margin of palisade vessels in 59.3% of Japanese but outside Japan, the squamocolumnar junction was preferred in 59.8% (P< 0.001). Any length of columnar-lined epithelium was the preferred definition of BE in 63.5% of Japanese vs. 71% outside Japan that preferred a minimum length of 1cm (P< 0.001). 46% respondents from Japan did not use the Prague C&M criteria, whereas outside Japan, 82.5% of respondents did so to varying extents (P< 0.001). The Seattle protocol for biopsies was not a routine among 73% of Japanese respondents, whereas outside Japan there was increased adherence although only 12% routinely do so (P< 0.001). Regarding histology, in Japan, a third (32.9%) felt that no histological confirmation was required but another third (35.4%) required only columnar tissue, but outside Japan, 38% preferred only columnar tissue while 36.3% required specialized intestinal metaplasia to diagnose BO (P< 0.001). Two-yearly surveillance endoscopy for long segment BO without dysplasia was performed in 81.3% within Japan vs. 59.4% outside Japan (P< 0.001). For treatment of BO without dysplasia with Proton Pump Inhibitors (PPI) only for esophagitis or when symptomatic, it was preferred by 80.8% in Japan vs. 69.7% outside Japan

Q1. What is your preferred endoscopic landmark of the esophagogastric junction?	Squamo-columnar junction (Z-line): 27.9% (Japan) vs 59.8% (Outside Japan)	Proximal margin of gastric folds: 11.7% (Japan) vs 26.9% (Outside Japan)	Distal margin of palisade vessels: 59.3% (Japan) vs 10.7% (Outside Japan)	Diaphragmatic pinch: 1.1% (Japan) vs 2.6% (Outside Japan)			p<0.001
Q2. What is your preferred endoscopic definition of Barrett's esophagus?	Length of columnar lined epithelium ≥ 2 cm: 23.4% (Japan) vs 38.9% (Outside Japan)	Length of columnar lined epithelium ≥ 1 cm: 13.1% (Japan) vs 32.1% (Outside Japan)	Any length of columnar lined epithelium in the esophagus : 63.5% (Japan) vs 29.1% (Outside Japan)				p<0.001
Q3. How often do you use the Prague C & M criteria in your assessment of Barrett's esophagus?	All the time: 12% (Japan) vs 22.2% (Outside Japan)	>70% of the time: 5.3% (Japan) vs 15% (Outside Japan)	30-70% of the time: 8.6% (Japan) vs 13.7% (Outside Japan)	<30% of the time: 28.1% (Japan) vs 31.6% (Outside Japan)	Never: 46% (Japan) vs 17.5% (Outside Japan)		p<0.001
Q4. What is your preferred histologic definition of Barrett's esophagus?	Any columnar tissue: 35.4% (Japan) vs 38% (Outside Japan)	Specialized Intestinal Metaplasia: 17% (Japan) vs 36.3% (Outside Japan)	Gastric Metaplasia: 14.8% (Japan) vs 20.1% (Outside Japan)	No histological confirmation required: 32.9% (Japan) vs 5.6% (Outside Japan)			p<0.001
Q5. In your practice, how regular do you survey your long-segment Barrett's esophagus without dysplasia?	Every 2 years: 81.3% (Japan) vs 59.4% (Outside Japan)	Every 3 years: 5% (Japan) vs 18.8% (Outside Japan)	Every 5 years: 1.4% (Japan) vs 4.7% (Outside Japan)	None at all: 12.3% (Japan) vs 17.1% (Outside Japan)			p<0.001
Q6. How often do you follow the Seattle protocol (i.e. four-quadrant biopsies every 2 cm) in your biopsies of Barrett's esophagus during surveillance endoscopy?	All the time: 2.5% (Japan) vs 12% (Outside Japan)	>70% of the time: 3.6% (Japan) vs 8.5% (Outside Japan)	30-70% of the time: 3.6% (Japan) vs 16.2% (Outside Japan)	<30% of the time: 17.3% (Japan) vs 44.4% (Outside Japan)	Never: 73% (Japan) vs 18.8% (Outside Japan)		p<0.001
Q7. What is your preferred treatment of Barrett's esophagus without dysplasia?	Lifelong Proton Pump Inhibitor (PPI) : 17% (Japan) vs 22.6% (Outside Japan)	PPI only when patient has symptoms of gastroesophageal reflux or evidence of esophagitis : 80.8% (Japan) vs 69.7% (Outside Japan)	Radiofrequency Ablation: 0.8% (Japan) vs 4.3% (Outside Japan)	Anti-reflux procedure (e.g. fundoplication): 1.4% (Japan) vs 3.4% (Outside Japan)			p=0.002
Q8. For Barrett's esophagus patients whose biopsies showed indefinite for dysplasia, your preferred approach is:	Confirm with second pathologist and repeat endoscopy after a course of PPI: 33.1% (Japan) vs 58.5% (Outside Japan)	Surveillance 6 monthly: 36.5% (Japan) vs 20.5% (Outside Japan)	Surveillance yearly: 29.8% (Japan) vs 19.7% (Outside Japan)	Surveillance 3-5 yearly: 0.6% (Japan) vs 1.3% (Outside Japan)			p<0.001
Q9. For Barrett's esophagus patients without a lesion but whose biopsies showed low grade dysplasia, your preferred approach is:	Surveillance 6 monthly: 61.3% (Japan) vs 48.3% (Outside Japan)	Surveillance yearly: 22.3% (Japan) vs 20.9% (Outside Japan)	Surveillance 3-5 yearly: 1.1% (Japan) vs 3% (Outside Japan)	Ablative therapy, e.g., radiofrequency, cryotherapy, argon plasma coagulation : 1.1% (Japan) vs 17.9% (Outside Japan)	Endoscopic mucosal resection: 2.2% (Japan) vs 6.8% (Outside Japan)	Endoscopic submucosal dissection: 12% (Japan) vs 3% (Outside Japan)	p<0.001
Q10. For Barrett's esophagus patients without a lesion but whose biopsies showed high grade dysplasia, your preferred treatment is:	Endoscopic mucosal resection: 14.2% (Japan) vs 22.6% (Outside Japan)	Endoscopic submucosal dissection: 82.5% (Japan) vs 54.7% (Outside Japan)	Ablative therapy, e.g., radiofrequency, cryotherapy, argon plasma coagulation: 2.2% (Japan) vs 17.9% (Outside Japan)	Surgery, e.g., esophagectomy: 1.1% (Japan) vs 4.7% (Outside Japan)			p<0.001

[P1295 Table 1]

( $P=0.002$ ). For biopsies indefinite for dysplasia, a third (33.1%) of Japanese would confirm with a second pathologist and another third (36.5%) would rescope 6 monthly but outside Japan, 58.5% of respondents would perform the former ( $P<0.001$ ). For low grade dysplasia without a lesion, 6 monthly surveillance was preferred in 61.3% within Japan vs 48.3% outside Japan ( $P<0.001$ ). For high grade dysplasia without lesion, endoscopic submucosal dissection was the preferred option for 82.5% of Japanese vs. 54.7% outside Japan ( $P<0.001$ ).

**Conclusion:** In conclusion, diagnosis and management approach of BO appear to vary widely within Asia, with stark contrast between Japanese and non-Japanese endoscopists. Lack of standardization, education and research are possible causes for the observed differences.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** weikeithan@gmail.com

**Introduction:** Radiofrequency ablation (RFA) has been validated as a safe and effective treatment modality for dysplastic Barrett's esophagus (BE). The standard protocol of RFA includes an intermediary cleaning phase between two ablation session. A simplified protocol which omits this cleaning phase is less labour intensive and has shown to be as efficacious in studies based on single ablation procedures.

**Aims & Methods:** The aim of this study was to compare the efficacy and safety of the standard and simplified RFA protocols used for the whole treatment pathway and including both circumferential and focal devices. We performed a retrospective analysis of prospectively collected data on patients who received RFA between 2007-2017 at two institutions within the UK. Outcomes assessed were: 1) complete remission of dysplasia (CR-D) and intestinal metaplasia (CR-IM) at 18 months, and 2) rate of esophageal stricture. Patients that received a combination of both treatment protocols were excluded.

**Results:** 145 patients were included in the analysis of which 73 patients received the standard protocol and 72 patients received the simplified protocol. CR-D was achieved in 94.5% and 95.8% of patients receiving either the standard or simplified protocol, respectively (p=0.71). CR-IM was achieved in 84.9% and 77.8% of patients in the standard and simplified protocol groups, respectively (p=0.27). Complications were observed in 11.4% of patients, including 13 cases oesophageal strictures, and 1 case of mild esophageal tear during sizing of RFA balloon. Esophageal strictures were significantly more common among patients who received the simplified protocol (12.5%) compared to the standard protocol (1.4%, p=0.008). The median number of esophageal dilatation required was 1 (range 1-7).

Variable	Standard protocol	Simplified protocol	All patients	P value
Number of patients	73	72	145	-
Age, mean (SD)	66.3 (9.0)	67.0 (9.7)	66.6 (9.3)	0.66
Gender (% males)	86.3	86.2	86.2	0.97
BE length, M value (median, IQR)	5.0 (5.0)	4.0 (4.0)	4.0 (4.0)	0.35
Prior-EMR, n (%)	47 (64.4)	42 (58.3)	89 (61.4)	0.45
Extent of prior-EMR (median, IQR)	2 (2)	3 (3)	3 (2)	0.12
Number of RFA (median, IQR)	3 (1)	2 (1)	2 (1)	0.17
Dysplasia Grade, n (%) - LGD - HGD - IMC	- 7 (9.6) 27 (37.0) 39 (53.4)	- 13 (18.1) 33 (45.8) 26 (36.1)	- 20 (13.8) 60 (41.4) 65 (44.8)	0.082
CR-D, % (95% CI)	94.5 (89.2-99.9)	95.8 (91.1-100)	95.2 (91.6-98.7)	0.71
CR-IM, % (95% CI)	84.9 (76.5-93.3)	77.8 (67.9-87.6)	81.4 (75.0-87.8)	0.27
Rescue EMR, % (95% CI)	9.6 (2.7-16.5)	6.9 (0.9-13.0)	8.3 (3.7-12.8)	0.56
Strictures, % (95% CI)	1.4 (0-4.1)	12.5 (4.7-20.3)	6.9 (2.7-11.1)	0.008

[Table 1. Patient baseline characteristics and comparative outcomes stratified by different RFA protocols]

**Conclusion:** The simplified RFA protocol is equally effective compared to the standard protocol in terms of eradication of dysplasia and IM. When deciding treatment options for patients, the advantages of the simplified protocol which includes shorter procedural time and reduced discomfort for patients will need to be balanced against the significantly higher risk of strictures.

**Disclosure:** Nothing to disclose

## P1297 NARROW BAND IMAGING ENDOSCOPY WITH TARGETED BIOPSIES VERSUS STANDARD ENDOSCOPY WITH RANDOM BIOPSIES IN PATIENTS WITH BARRETT'S OESOPHAGUS: A META-ANALYSIS

**Introduction:** Barrett's oesophagus (BO) is the only identifiable premalignant condition for oesophageal adenocarcinoma (OAC) which represents the eighth most common cancer and the sixth cause of cancer-related deaths worldwide. Surveillance in BO aims to detect and subsequently eradicate dysplasia and early OAC. The present guidelines<sup>2</sup> recommend surveillance endoscopy in BO to be performed with random biopsies (Seattle protocol) every 2-3 years.

However, this method has high sample errors, laborious and correctly implemented only by half of endoscopists. Image enhancing technologies such as narrow band imaging (NBI) could provide an alternative to random biopsies. NBI has the ability to enhance the features of oesophageal mucosa and submucosa potentially allowing the endoscopist to take only targeted biopsy from areas that show an abnormal mucosal pattern that could be harporing dysplasia. Although NBI-targeted biopsy has been shown to perform equally or better in several studies, random biopsies remains up-to-date the standard of care.

**Aims & Methods:** This metanalysis intends to critically evaluate all available literature in this field and determine based on a comparative meta-analysis if NBI targeted biopsies equally performs or outperforms random biopsies method for surveillance of BO.

This metanalysis was conducted according to the Preferred Reporting Items of Systematic reviews and Meta-Analyses (PRISMA) recommendations. It has been registered in advance in PROSPERO under ID: CRD42017073281.

A comprehensive search for studies utilising NBI for BO was conducted by two researchers in the Cochrane Register, MEDLINE/Pubmed, EMBASE and grey literature. Human studies that compared NBI targeted biopsies with random biopsies for BO were retrieved. Methodological quality of included studies was assessed by the Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2). Data from included studies were extracted, entered and analysed using the RevMan version 5 software. Analysis was performed with random effects method and the results reported per-patient rather than per-lesion.

**Results:** 14 studies were initially selected for the systematic review but only 6 studies with total 493 patients have fulfilled our inclusion criteria for metanalysis. The overall sensitivity (Sn), specificity (Sp), negative predictive value (NPV), and positive predictive value (PPV) for NBI-targeted biopsy detecting all dysplasia is 76%(95% CI 0.61-0.91), 99%(95% CI 0.99-1.00), 97%(95% CI 0.96-0.99), and 84% (95% CI 0.69-0.99), respectively. For high-grade dysplasia, the results respectively are 83%(95% CI 0.73-0.93), 99%(95% CI 0.99-1.00), 97%(95% CI 0.93-1.00), and 92%(95% CI 0.84-1.00). For detection of intestinal metaplasia, the same parameters respectively are: 0.83 (95% CI 0.63-1.00) 0.89 (95% CI 0.81-0.97).

**Conclusion:** NBI-guided targeted endoscopic biopsy has high diagnostic accuracy and can replace the current standard of care of random method in expert tertiary centres. For wider adoption of this NBI method more studies with better methodology are needed in the future.

**Introduction:** Hybrid APC is a novel technique that has been recently developed for the ablation of Barrett's Esophagus. It is based on the combination of APC and submucosal saline injection to overcome some of the disadvantages of standard APC ablation. The current literature on this method is however limited.

**Aims & Methods:** The aims of this US pilot study were to evaluate the efficacy, tolerance and safety of Hybrid-APC for the treatment of BE.

Patients with biopsy proven BE were eligible with both treatment-naïve and patients previously treated included. Procedures were performed by two expert endoscopists using a standardized technique. Efficacy of ablation was measured on by demonstrating either a reduction of visible BE or biopsies proving complete resolution of intestinal metaplasia (CRIM). To evaluate tolerance and safety, patients were called on post-procedure days 1 and 7.

**Results:** 22 patients with BE (4.5% Intramucosal CA, 31.8% High Grade Dysplasia, 18.1% LGD, 36.3% non-dysplastic, 9.1% indefinite for dysplasia) underwent 40 treatments with Hybrid APC. Average age was 67.5 years, 86% male. Mean initial Prague score was C0.73, M1.99. 50% of patients had undergone prior RFA, 22.7% prior EMR, 13.6% prior cryotherapy, and 36.3% were treatment naïve. The average index treatment time was 23.9 minutes. With regards to efficacy, 17 out of 22 (77%) patients achieved CRIM. All patients had endoscopic improvement of BE disease with an average length of BE at follow-up of C0.21, M0.63. Average pain scores (0-10 scale) on follow up were 2.65 and 0.62 at day 1 and 7 respectively. There were two treatment-related strictures (9%) which required a single balloon dilation. There were no other early or late complications.

**Conclusion:** Based on this US pilot study, Hybrid APC appears to be promising in the treatment of Barrett's Esophagus. The ablation protocol used in this study demonstrated efficacy, tolerability and a safety profile similar to radiofrequency ablation. Given the significant price difference of Hybrid APC with other modalities for Barrett's ablation, this modality may be more cost effective.

**Disclosure:** None

## **P1299 REDUCED STRICTURE RATES WITH A NOVEL HALO 360 RADIOFREQUENCY REGIME FOR BARRETT'S DYSPLASIA**

Saffouri E.<sup>1</sup>, Haddock R.<sup>1</sup>, Berriman T.J.<sup>1</sup>, Pugmire J.<sup>2</sup>, Fullarton G.<sup>1</sup>, Morris A.J.<sup>1</sup>

**Introduction:** In the UK, radiofrequency ablation (RFA) is established as treatment of choice for flat oesophageal neoplasia or after removal of focal lesions by endoscopic mucosal resection (EMR) to eradicate Barrett's mucosa<sup>1</sup>. A specific complication of RFA is oesophageal stricture develop-

ment. The UK national RFA registry has quoted a 11-17% rate of strictures requiring dilatation, with higher rates in patients treated with 12J rather than 10J paired ablations using the HALO 360 Express RFA catheter ( $p < 0.01$ ). Two 10J ablations, separated by a cleaning step requiring removal of the catheter, is now standard of care. The cleaning step is time-consuming and can be poorly tolerated.

**Aims & Methods:** In December 2017 we adapted our practice to include irrigation with 30cc normal saline between 10J ablations as a cooling phase during the HALO RFA procedure and removed the cleaning phase between ablations. We have audited patient and disease demographics and outcomes data, especially oesophageal stricture rate, for all patients who had first HALO 360 express for 12 months before and after technique modification (1/12/16-1/12/18) in our hospital. Statistical analysis of variables was calculated using Fisher's exact test, Wilcoxon ranksum, and logistic regression analysis.

**Results:** In the capture period, 36 patients had standard treatment and 48 patients underwent the modified technique. In the latter group, a significantly longer mean Barrett's segment was observed (6.1cm vs 8.2cm;  $p = 0.01$ ). We observed a stricture rate of 22.2% (8/36) in the standard treatment group, and 4.2% (2/48) in the modified group ( $p = 0.014$ ).

Stricture rate was significantly higher ( $p = 0.026$ ) with increasing Prague circumferential and maximum Barrett's length ( $p = 0.023$ ). There was no statistical difference in stricture rate when prior EMR or degree of dysplasia was considered.

The modified treatment was the only variable independently associated with stricture formation. A logistic regression model showed 85% reduced odds of stricture using the modified treatment ( $p = 0.036$ ) after adjusting for age, procedure type, grade of dysplasia, prior EMR, and Prague measurements.

**Conclusion:** These findings suggest a benefit of our novel adaptation of HALO 360 RFA treatment in Barrett's neoplasia with the novel treat-cool-treat technique resulting in significantly lower rate of stricture development.

**Introduction:** Esophagogastric junction adenocarcinoma includes Barrett's esophageal adenocarcinoma and gastric cardia adenocarcinoma. Curative criteria for endoscopic submucosal dissection in esophagogastric junction adenocarcinoma patients are controversial. Therefore, we elucidated the clinicopathological differences between Barrett's esophageal adenocarcinoma and gastric cardia adenocarcinoma and estimated risk factors of lymph node metastasis.

**Aims & Methods:** Patients who underwent surgical resection or endoscopic submucosal dissection for superficial esophagogastric junction adenocarcinoma of Siewert type II were included.

**Results:** Sixty-nine patients (44.2%) had Barrett's esophageal adenocarcinoma, and 87 (55.8%) had gastric cardia adenocarcinoma. Barrett's esophageal adenocarcinoma patients were significantly younger (62 vs 70 years,  $p < 0.01$ ) and had a high frequency of poorly differentiated adenocarcinoma components (30% vs 15%,  $p = 0.02$ ) and lymphatic invasion (28% vs 12%,  $p = 0.01$ ). There was lymphovascular invasion in the deep muscularis mucosa in 31.6% of patients with Barrett's esophageal adenocarcinoma. Ten cases of lymph node metastasis were identified. Lymph node metastasis was not identified in patients with standard submucosal invasion  $< 500 \mu\text{m}$  without risk factors [tumor size  $> 30 \text{ mm}$ , lymphovascular invasion, poorly differentiated components]. Frequency of tumor size  $> 30 \text{ mm}$  (60% vs 17.1%  $p < 0.01$ ), undifferentiated adenocarcinoma (40% vs 2.7%  $p < 0.01$ ), poorly differentiated component (80% vs 17.8%  $p < 0.01$ ), and lymphovascular invasion (90% vs 20.5%  $p < 0.01$ ) was significantly higher in Barrett's esophageal adenocarcinoma patients.

**Conclusion:** Standard submucosal invasion < 500 µm without lymphovascular invasion, poorly differentiated components, and tumor size >30 mm were considered candidates for curative endoscopic resection for esophagogastric junction adenocarcinoma. Furthermore, histopathological surveillance for lymphovascular invasion is important for deep muscularis mucosa invasion of Barrett's esophageal adenocarcinoma.

**Introduction:** The majority of patients with esophageal adenocarcinoma (EAC) present with advanced disease, resulting in poor survival rates. Screening for EAC and its precursor Barrett's esophagus could possibly reverse the increasing incidence of EAC. In order to realize screening, it is important to understand the factors that influence population preferences for different EAC screening strategies and using them to achieve high attendance rates for a screening program for EAC.

**Aims & Methods:** We aimed to determine individuals' preferences for EAC screening and to assess to what extent procedural characteristics of EAC screening tests predict willingness for screening participation. A discrete choice experiment questionnaire was sent by postal mail to 1000 individuals aged 50 to 75 years who were randomly selected from the municipal registry. Each subject answered 12 discrete choice questions of two hypothetical screening tests that comprised five attributes: EAC-related mortality risk reduction, procedure-related pain and discomfort, screening location, test specificity, and costs. A multinomial logit model was used to estimate patient preferences for each attribute level and to calculate relative importance scores of each attribute and expected rates of uptake. Regression analyses was performed to determine if socio-demographic characteristics predicted how respondents made decisions.

**Results:** In total, 375 patients (37.5%) completed the questionnaire. Test specificity had the highest impact on respondents' preferences, accounting for 27.2%, followed by pain and discomfort (26.8%), and mortality reduction (24.6%). Women were twice as much likely than men to value pain and discomfort as the most important attribute category (OR 2.08; 95%CI 1.28 - 3.33; P=0.003). In contrast, men were more likely to report mortality reduction as the primary determinant (OR 1.83; 95%CI 1.08-3.11). Individuals who worry about their own risk of developing cancer consider pain and discomfort to be important (OR 2.17; 95%CI 1.25-3.75) and worry less about test specificity (OR 0.45; 95%CI 0.25-0.82). Respondents preferred a test causing no or moderate pain and they were willing to give up 29 avoided EAC-related deaths per 10,000 screened individuals if the test causes only moderate instead of heavy pain.

The average expected uptake of EAC screening was 62.8% (95%CI 61.1-64.5). However, with the most preferred screening test, the probability of screening participation increased to 88.9% (95%CI 87.1%-90.4%). Heavy pain and discomfort had the largest impact on screening uptake (-22.8%; 95%CI -26.8 - -18.7). Male gender ( $\beta$  2.81; P< 0.001), cancer worries ( $\beta$  1.96; P=0.01), upper endoscopy ( $\beta$  1.46; P=0.05) or population-based screening ( $\beta$  2.47; P=0.05) experience, and upper gastrointestinal symptoms ( $\beta$  1.50; P=0.05) were significantly associated with screening participation.

Attributes	Impact of attribute levels on probability of screening participation (%) (* indicates p<0.05)			
Mortality reduction (per 1000 screened individuals)	2 per 1000 Reference	3 per 1000 +5.8%*	4 per 1000 +14.0%*	5 per 1000 +17.8%*
Pain and discomfort	No pain Reference	Mild pain -1.5%	Moderate pain -2.0%	Heavy pain -22.8%*
Out-of-pocket costs (€)	Costs: €0 Reference	Costs: €25 -6.2%*	Costs: €50 -10.3%*	Costs: €75 -16.7%*
Specificity (%)	Specificity: 50% Reference	Specificity: 70% -3.2%	Specificity: 90% +12.7%*	Specificity: 100% +17.1%*

[Effects of changing the screening program characteristics on the probability of participation in esophageal cancer screening.]

**Conclusion:** This study suggests a substantial interest in EAC screening in the general population. Based on our results, an optimal screening test should have high specificity, cause no or mild to moderate pain or discomfort and result in a decrease in EAC-related mortality. Understanding individuals' preferences for EAC screening tests helps to further design the optimal screening modality by selecting the attributes that maximize attendance and further reduce morbidity and mortality from EAC.

**Disclosure:** Nothing to disclose

### P1302 BARRETT'S ESOPHAGUS SCREENING: ACCURACY OF EXHALED BREATH ANALYSIS USING AN ELECTRONIC NOSE DEVICE

Peters Y.<sup>1</sup>, Schrauwen R.W.M.<sup>2</sup>, Tan A.C.<sup>3</sup>, Bogers S.K.<sup>2</sup>, De Jong B.<sup>1</sup>, Siersema P.D.<sup>1</sup>

**Contact E-Mail Address:** y.peters@radboudumc.nl

**Introduction:** The majority of patients with esophageal adenocarcinoma (EAC) present with advanced disease, resulting in poor survival rates. Timely detection of EAC and its precursor Barrett's esophagus (BE) could decrease both cancer mortality and incidence. Currently, an accurate, minimally-invasive screening method for BE for widespread use is not available.

**Aims & Methods:** We aimed to assess the accuracy with which an electronic nose for breath analysis could discriminate patients with BE from controls without BE.

In this multicenter, cross-sectional, proof-of-principle study, patients undergoing a clinically indicated upper endoscopy between August 2017 and March 2019 were invited to provide a 5-minute breath sample using an electronic nose immediately prior a scheduled endoscopy. Patients were subdivided in three subgroups: BE (defined as  $\geq 1$  cm of columnar mucosa with histopathologic confirmation of intestinal metaplasia without dysplasia), gastroesophageal reflux disease (GERD) (defined as GerdQ-score  $\geq 8$  or the endoscopic presence of reflux esophagitis), and controls without BE or GERD.

The Aeonose™ is an olfactory system that analyses volatile organic compounds (VOC). Three metal-oxide sensors interact with VOCs in the breath sample to create a digital breath print specific to the VOCs. Data is analyzed by an artificial neural network to identify data classifiers to extract breath-print differences between patients with BE, GERD and controls, respectively. Optimal models were cross-validated using a leave-10%-out approach. Main outcomes were sensitivity and specificity for detecting BE compared with upper endoscopy as the reference standard.

**Results:** Breath samples were obtained from 212 individuals. Recruitment rates were 95%. Mean age of participants was 59.6 years and 56% were male. Seventy-three patients had a diagnosis of BE with a median (IQR) length of the BE segment of 4 (3-7) cm, 68 patients were diagnosed with GERD (32.4% reflux esophagitis), and 71 control patients did not have any esophageal abnormalities except for hiatal hernia. Diagnostic accuracy was high for discrimination of BE from both GERD and controls (area under the curve [AUC] 0.80, sensitivity 85% [95%CI: 74% - 92%], specificity 66% [95%CI: 58% - 74%]). Similarly, breath prints of BE patients could be differentiated from GERD patients (AUC 0.78, sensitivity 82% [95%CI: 71% - 90%], specificity 68% [95%CI: 55% - 78%]).

In a sub-analysis of patients using proton pump inhibitors for at least 1 month prior to study enrolment (n = 157; 68 BE, 46 GERD and 43 controls), a similar diagnostic accuracy for discriminating BE from both GERD and controls was observed: BE versus both GERD and controls AUC 0.81, sensitivity 71% and specificity 80%; BE versus GERD AUC 0.86, sensitivity 93% and specificity 70%; BE versus controls AUC 0.87, sensitivity 74% and specificity 88%.

**Conclusion:** This portable electronic nose is able to detect the presence or absence of BE in patients with and without GERD with good diagnostic accuracy. Given the high tolerability, high acceptability and low costs, breath testing may be a promising approach to be used for non-invasive screening for BE in a primary care setting.

**Disclosure:** The eNose company supplied the electronic noses used in this study for free.

### P1303 STUDIES TO DETERMINE RISK FACTORS FOR BARRETT'S NEOPLASIA IN WOMEN SHOULD FOCUS ON A FAMILY HISTORY OF ESOPHAGEAL CARCINOMA, ONGOING GERD SYMPTOMS AND OBESITY

Iwaya Y.<sup>1,2</sup>, Shimamura Y.<sup>2,3</sup>, Mosko J.<sup>2</sup>, Teshima C.<sup>2</sup>, Kandel G.<sup>2</sup>, Kortan P.<sup>2</sup>, May G.<sup>2</sup>, Marcon N.<sup>2</sup>

**Contact E-Mail Address:** yiwaya@shinshu-u.ac.jp

**Introduction:** Current guidelines do not recommend endoscopic screening for Barrett's esophagus (BE) in females, except in patients who have multiple risk factors for BE and esophageal adenocarcinoma (EAC). However, it is unclear which factors most predict BE neoplasia risk in females. Therefore, identifying how females with EAC and high-grade dysplasia (HGD) differ from males may be useful to develop screening recommendations for women.

**Aims & Methods:** We conducted a retrospective analysis of a prospectively maintained database comprising consecutive patients with early stage EAC (T1a and T1b) and HGD at a single, tertiary-referral center from March 2001 to July 2017. Information regarding baseline clinical characteristics, drug and risk factor exposures, clinicopathological staging of EAC/HGD and follow-up status including treatment outcome such as complete remission of dysplasia (CR-D) and complete remission of intestinal metaplasia (CR-IM) were determined. Univariate and multivariate analyses were performed to identify factors that differed significantly between female and male patients with EAC/HGD.

**Results:** We identified 511 patients with T1 EAC and HGD (383 and 128, respectively); 88 (17%) patients were female. Compared to male patients, female patients were more likely to have ongoing GERD symptoms and a family history of esophageal carcinoma (51% vs. 39%,  $p=0.045$ ; 8.3% vs. 2.8%,  $p=0.033$ , respectively) and less likely to have ever been smokers or drinkers of alcohol (65% vs. 76%,  $p=0.030$ ; 58% vs. 81%,  $p<0.001$ , respectively) on univariate analysis. On multivariate analysis, ongoing GERD symptoms, family history of esophageal carcinoma and obesity ( $BMI>30$ ) were significant independent factors. Although the maximum length of BE in females was significantly shorter than in males (4.1 cm vs. 5.0 cm,  $p=0.024$ ), there were no significant differences in terms of pathological findings such as tumor depth of invasion, differentiation, lymphovascular invasion or deep margin positivity. Furthermore, there were no significant differences between the groups regarding outcomes of endoscopic therapies with CR-D, CR-IM and recurrence of dysplasia and intestinal metaplasia with a mean follow-up period of  $44.3 \pm 30.2$  months.

**Conclusion:** Female patients with T1 EAC or HGD were more likely to have a family history of esophageal carcinoma, ongoing GERD symptoms and obesity compared to male patients despite similar clinical outcomes with endoscopic therapies. While guidelines recommend BE screening in male patients, female patients should be considered for screening endoscopy if they possess these risk factors.

**Disclosure:** Nothing to disclose

### P1304 THE IMPACT OF IMAGE ENHANCED ENDOSCOPY SCREENING FOR SYNCHRONOUS ESOPHAGEAL NEOPLASM ON SURVIVALS OF HEAD AND NECK CANCER PATIENTS

**Introduction:** The incidence of esophageal second primary tumor (SPT) in head and neck cancer (HNC) patients is not low. The impact of routine image-enhanced endoscopy (IEE) screening for SPT of esophagus on the prognosis of HNC patients is not elucidated.

**Aims & Methods:** Patients with registered malignancies of head and neck region and esophagus were recruited from a hospital-based cancer registry between July 2000 and December 2016. Magnifying endoscopy with narrow-band imaging and chromoendoscopy with Lugol's solution was performed for IEE screening. The biopsied specimen reported with revised Vienna classification category 1 and 2 was defined as group I and category 3 to 5 as group II. The outcome assessment was connected to national death registry database and Kaplan-Meier estimate and Cox regression model were used for survival analysis.

**Results:** Finally, 1,577 HNC and 501 esophageal cancer patients were enrolled for analysis. The 5-year overall survival (OS) rate of stage I/II HNC, stage III/IV HNC and esophageal cancer patients were 58%, 29%, and 8%, respectively ( $p<0.01$ ). The 5-year OS rate of HNC patients with negative IEE results were higher than HNC patients without IEE screening, followed by IEE screening group I and II, and esophageal cancer patients (44% vs. 39% vs. 35% vs. 11% vs. 8%,  $p$  for trend  $<0.01$ ).

Among advanced HNC patients, those who received IEE screening of esophagus had a trend of better prognosis than those without (5-year OS rate of 31% vs. 28%,  $p=0.17$ ).

In multivariate analysis of OS, age [hazard ratio (HR) 1.01,  $p<0.01$ ] and cancer of oropharynx (HR 1.43,  $p=0.01$ ) were associated with poor survival. Compared with stage I/II HNC who received IEE screening of esophagus, stage III/IV patients with IEE (HR 2.33,  $p<0.01$ ) and without IEE (HR 2.77,  $p<0.01$ ) screening had worse survival.

**Conclusion:** The application of IEE screening for esophageal SPTs is helpful in risk stratification and prognosis prediction for HNC patients. Routine IEE screening is recommended in newly-diagnosed HNC patients.

**Disclosure:** Nothing to disclose

### P1305 SIGMOID TYPE AND AGING AS POTENTIAL RISK FACTORS FOR DEVELOPING ESOPHAGEAL SQUAMOUS CELL CARCINOMA IN ACHALASIA PATIENTS: A RETROSPECTIVE STUDY

Abad M.R.A., Iwaya Y., Nishikawa Y., Fujiyoshi Y., Quarta Colosso B.M., Ueno A., Shimamura Y., Tanabe M., Sumi K., Tomida H., Ikeda H., Onimaru M., Inoue H.

Showa University Koto Toyosu Hospital, Digestive Diseases Center, Tokyo, Japan

**Contact E-Mail Address:** yiwaya@shinshu-u.ac.jp

**Introduction:** Incidence of esophageal cancer has been reported to be increasing recently. Achalasia has been considered as one of the risk factors for developing esophageal squamous cell carcinoma (ESCC). Although patients with achalasia were reported to have a higher risk of developing ESCC compared to the general population, details and characteristics of achalasia patients who develop ESCC are still not clearly defined.

**Aims & Methods:** This study aims to evaluate the characteristics of patients with achalasia associated with developing ESCC. A retrospective analysis study between January 2010 and November 2018 has been conducted at Showa University Koto Toyosu Hospital, Tokyo, Japan. Database of patients who underwent Per-oral Endoscopic Myotomy (POEM) has been reviewed. Patients who were diagnosed with esophageal achalasia based on the Modified Chicago Classification were included in the study.

**Results:** A total of 19 patients (1.5%) were identified to have ESCC from 1256 achalasia patients. Eleven (57.9%) were males and 8 (42.1%) were females. Median age was 64 (IQR= 55.5-75). Based on the Modified Chicago Classification, the type of achalasia seen were as follows: Type I/II/III= 9/7/3. In terms of histopathological findings, 17 patients (89.47%) exhibited mucosal ESCC, and 2 patients (10.53%) showed SCC extending to the submucosal layer. The occurrence of ESCC in achalasia patients was noted to be more likely in the older population (median: 68 vs 46,  $p=<0.001$ ) compared to achalasia patients without ESCC.

Furthermore, a higher prevalence of sigmoid type (56% vs 12%,  $p=<0.001$ ) was observed in achalasia patients with ESCC in comparison with those non-ESCC achalasia patients. There were no significant differences between the two groups in terms of gender, types of Chicago classification, and Eckardt Score. All patients underwent successful endoscopic resection without any complications.

**Conclusion:** Achalasia has been deemed to be a risk factor for developing ESCC which involves various mechanisms. Patients with achalasia who belong in the older population and presenting with a sigmoid type were recognized to be at a higher risk for developing ESCC and should be monitored more closely during follow-up.

**Contact E-Mail Address:** kuma7srg1@gmail.com

**Introduction:** Endocytoscopy (ECS) is a novel endoscopic technique that allows detailed diagnostic examination of the gastrointestinal tract at the cellular level. ECS was first developed and applied for clinical use in 2003 in our own study.

**Aims & Methods:** In the present study, we used the ECS to observe various esophageal lesions, and evaluated the diagnostic accuracy in distinguishing neoplastic from non-neoplastic lesions using both endoscopist's and pathologist's opinion. Further, we applied deep-learning artificial intelligence (AI) to analyse ECS images of the esophagus to determine whether AI can support endoscopists for the replacement of biopsy-based histology. We examined the morphology of surface cells using vital staining with toluidine blue and compared the histological features of 272 cases, including 129 cases of esophageal squamous cell carcinoma (ESCC) and 143 non-neoplastic esophageal lesions (65 cases of radiation esophagitis, 54 case of gastro esophageal reflux disease (GERD), and 13 cases of other esophagitis, 3 cases of benign tumor and 8 cases of normal squamous epithelium). One endoscopist classified the lesions using the type classification (Type 1; surface epithelial cells have a low N/C ratio and cell density but without evident nuclear abnormality. Type 2; surface epithelial cells have a high nuclear density but no evident nuclear abnormality and clear borders between cells. Type 3; surface epithelial cells have evidently increased nuclear density and nuclear abnormality, such as irregular nuclear size and shape.). Further, we consulted one pathologist for judgement in each case as "neoplastic", "borderline", or "non-neoplastic" from the ECS cell images.

Using 4,715 ECS images (1141 malignant and 3574 non-malignant images) from 240 cases, a deep learning AI was trained. To evaluate the diagnostic accuracy of the AI, test set of 1520 ECS images, collected from 55 patients (27 ESCCs and 28 benign esophageal lesions) were examined.

**Results:** On the basis of *in vivo* ECS observation, the endoscopist classified 82 cases as type1, 57cases as type2, and 133 cases as type3. The sensitivity, specificity and overall accuracy of ECS for malignant lesions by the endoscopist were 96.1%, 93.0% and 94.5%, respectively, if Type 3 was considered to be malignant. The pathologist classified 130 cases as non-neoplastic, 17 cases as borderline, and 125 cases as neoplastic. With regard to the pathologist's interpretation of the ECS images, the sensitivity, specificity and overall accuracy of ECS for malignant lesions were 96.1%, 94.4% and 95.2%, respectively if borderline category is considered to be correctly diagnosed. On the basis of ECS images, neither the endoscopist nor the pathologist was able to clearly distinguish regenerative squamous epithelium and pseudo-malignant erosion in gastroesophageal reflux disease and esophagitis after radiotherapy from esophageal cancer. In such cases, biopsy histology would be necessary in addition to ECS diagnosis. The AI correctly diagnosed 25 of the 27 ESCC cases, with an overall sensitivity of 92.6%. 25 of the 28 non-cancerous lesions were diagnosed as non-malignant, with a specificity of 89.3% and an overall accuracy of 90.9%. Although this result was inferior but close to the result obtained by the endoscopist.

**Conclusion:** ECS diagnosis for the esophagus realize the concept of optical biopsy, and enables us to omit biopsy histology. AI may support endoscopists in diagnosing ESCC based on ECS images in the future.

**Contact E-Mail Address:** yukohara0526@yahoo.co.jp

**Introduction:** Endoscopic laryngopharyngeal surgery (ELPS) for superficial pharyngeal squamous cell carcinoma (SPSCC) has been reported as a minimally invasive treatment. However, the usefulness of ELPS for SPSCC was not investigated well because a small number of patients was involved in previous studies and an indication of ELPS for SPSCC invading up to subepithelial layer was still controversial. This study aimed to reveal the effectiveness of ELPS for pharyngeal squamous cell carcinoma (SCC) invading up to epithelial and subepithelial layer with short- and mid-term outcomes.

**Aims & Methods:** The patients who underwent ELPS for SPSCC between April 2015 and March 2019 were included. We retrospectively analyzed a clinical course, adverse events, en bloc/R0 resection rate, recurrence, and prognosis. Tumor thickness was evaluated from the tumor surface to the base of the malignant tissue in the thickest tumor section based on general rules for clinical studies on Head and Neck Cancer 2018. After ELPS, surveillance was performed with physical examination and laryngoscope observation every three months, computed tomography at intervals of every 6 months and endoscopic observation under narrow band imaging (NBI) every year.

**Results:** Forty-three patients with 56 SPSCCs were included this study. Table shows outcomes of ELPS for SPSCC. The median hospitalization was 11 days (range, 7-38). Dysphagia was found in 5 cases and 3 of them required hospitalization for more than 30 days. In those 5 cases all lesions were located in the hypopharynx and the resected lesion size was 35 mm or more. There were statistically significant differences in removed lesion size between patients with dysphagia (n=5) and without dysphagia (n=46) (median; 40mm vs. 25mm, p< 0.001). No patients received additional treatment even though lymphovascular invasion was found. During the follow-up (median=24 months; range, 1-43) no local recurrence was observed but pharyngeal lymph node metastasis was found in a case who had SCC located in the hypopharynx invaded up to subepithelial layer (tumor diameter: 17mm, tumor thickness: 3500µm, ly[+], v[+]) after 16 months from ELPS. This patient received chemoradiotherapy and survived for 24 months without recurrence. Metachronous H&N and oesophageal SCC were found in three cases (7%) and six cases (14%), respectively during follow-up period. All lesions were found under endoscopic observation with NBI and those were completely removed by additional ELPS. Two patients died of oesophageal cancer recurrence.

Patient (n=43)	
Male	41 (95%)
Age; median (range)	70 (59-85)
Synchronous or metachronous squamous cell carcinoma; head and neck / oesophagus	15 (35%) / 36 (84%)
Lesions (n=56)	
Location; oropharynx / hypopharynx	5 / 51
Tumor diameter; median (range), mm	17 (3-40)
En bloc resection rate / R0 resection rate	98% / 71%
Invasion depth (epithelial / subepithelial)	16 / 40
Adverse event; post-operative bleeding / perforation / dysphagia	0 / 0 / 5

[Outcomes of ELPS for SPSCC]

**Conclusion:** ELPS was effective for SPSCC including tumors invaded into the subepithelium. Resection of larger lesion was a risk factor for dysphagia, which affected the prolonged hospital stay. After ELPS, surveillance with NBI endoscopy should be performed considering the high cumulative incidence of metachronous pharyngeal and oesophageal carcinoma.

## P1308 TREATMENT STRATEGY FOR CERVICAL ESOPHAGEAL CANCER

Mori N.<sup>1</sup>, Tanaka T.<sup>2</sup>, Matono S.<sup>3</sup>, Saisho K.<sup>1</sup>, Akagi Y.<sup>1</sup>

<sup>1</sup>Kurume University School of Medicine, Surgery, Kurume, Japan, <sup>2</sup>Kurume University, Dept. of Surgery, Kurume, Japan, <sup>3</sup>Kurume University, School of Medicine, Kurume, Japan

**Contact E-Mail Address:** mori1118@med.kurume-u.ac.jp

**Introduction:** Treatment for cervical esophageal cancer (CEC) is mainly surgery and definitive chemo-radiotherapy (dCRT). However, treatment strategy for CEC recently has been changed in consideration of quality of life after treatment. We have been performing neoadjuvant chemotherapy for CEC using FP (5FU/CDDP) from 2003 and using DCF (Docetaxel/CDDP/5FU) from 2009, and have decided to perform whether operation or dCRT by response of NAC.

**Aims & Methods:** 59 esophageal cancer patients who underwent operation or dCRT between 2003 and 2017 were analyzed as to treatment outcome, retrospectively.

**Results:** There were 43 men and 16 women, with a median age 64years. The average of duration of follow-up periods were 1367±1587 days. Tumors were located at CePh in 17 patients, Ce in 26, and CeUt in 16. Clinical T stage was 1b in 2 patients, 2 in 4, 3 in 21, and 4a in 32. Clinical N stage was 0 in 20 patients, 1 in 16, 2 in 18, and 4 in 4. Clinical Stage was I in 1 patient, II in 13, III in 20, and IVa in 25. 30 patients underwent FP, and 29 underwent DCF as NAC. After NAC, no patients were obtained complete response (CR), 19 exhibited a partial response (PR), 31 had a stable disease (SD), and 1 presented with progressive disease (PD). 40 patients underwent surgery, and 19 received dCRT. Of 40 patients, 35 underwent pharyngo-laryngo-esophagectomy (PLE), and 5 cervical esophagectomy. 36 patients obtained a pathologically complete response (pCR) by surgery. Of 19 patients who received dCRT, 12 patients obtained a clinical CR. Post-operative complications were developed in 10 patients and detail as follows: 4 had recurrent nerve palsy, 3 necrosis or ulcer of trachea, 2 necrosis of free jejunum, 1 osteomyelitis, and 5 others. 24 patients were received adjuvant therapy. Of 24, 11 received radiotherapy, 9 chemoradiotherapy, and 4 chemotherapy. 21 patients had recurrences after surgery. Of 21, 17 had distant metastasis, 11 lymph node metastasis, and 3 local recurrence. Of 12 patients who had obtained CR by dCRT, 8 had no recurrence. The 4 remained patients and 2 patients who obtained non-CR by dCRT underwent salvage surgery (PLE). The overall survival rates at 5 years (OS) were 47%, and those of patients who underwent surgery and dCRT were 39% and 74 %, respectively (p=0.07).

**Conclusion:** It suggests that dCRT could become alternative therapy of surgery for cervical esophageal cancer. Surgery for non-responder for NAC and salvage surgery for patients with recurrence after clinical CR by dCRT would play an important role. It is necessary for improvement of treatment outcome to find a new treatment for recurrence after surgery, because of high incidences of recurrence.

**Introduction:** To investigate the effect of prior chemotherapy on self-expanding metal stent (SEMS)-related complications in patients with locally advanced primary esophageal cancer.

**Aims & Methods:** Data from patients with locally advanced primary esophageal cancer who received SEMS placement with or without prior chemotherapy were retrospectively reviewed. Patients were grouped according to prior palliative therapy: group A had received SEMS only, and group B had received palliative chemotherapy prior to SEMS placement. Patient age, stricture length, location, and dysphagia score prior to SEMS placement were evaluated. Outcomes after SEMS placement, including technical and clinical success rates, the occurrence of complications and survival, were compared.

**Results:** The study included 105 patients (group A, n = 41; group B, n = 64). There were no significant differences between the two groups prior to SEMS placement. SEMS placement was technically successful in all patients, with no procedure-related complications reported. Clinical success was achieved in 95.1% of patients in group A and 96.8% of patients in group B. The duration of stent patency was significantly shorter in group B (162 days; 95% CI, 126.6-198.4 versus group A (339 days; 95% CI, 258.8-419.3), p = 0.001. No significant differences were seen between the two groups regarding dysphagia score improvement (p = 0.66), complications (p = 0.094), or survival (p = 0.592).

**Conclusion:** Prior chemotherapy did not increase the risk of complications following SEMS placement in patients with locally advanced esophageal cancer.

**Contact E-Mail Address:** kazuki\_forest\_0422@yahoo.co.jp

**Introduction:** Predicting the invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is crucial for determining the precise indication for endoscopic submucosal dissection (ESD), because the rate of lymph node metastasis increases in proportion to the invasion depth of SESCO. Recently, the Japan Esophageal Society (JES) developed a simplified classification for SESCO based on the degree of microvascular irregularity observed on magnifying endoscopy (ME). The JES classification defines severely irregular microvessels as type B vessels, which corresponds to cancerous lesions. The type B vessels are subclassified into type B1, B2, and B3 vessels that are correlated to histological invasion depth of T1a-EP or T1a-LPM, T1a-MM or T1b-SM1, and T1b-SM2, respectively. According to previous studies, the diagnostic accuracy of type B2 vessel is about 60%-70%, which is considered to be relatively low and unsatisfactory.

**Aims & Methods:** Predicting the invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is crucial for determining the precise indication for endoscopic submucosal dissection (ESD), because the rate of lymph node metastasis increases in proportion to the invasion depth of SESCO. Recently, the Japan Esophageal Society (JES) developed a simplified classification for SESCO based on the degree of microvascular irregularity observed on magnifying endoscopy (ME). Type B vessels are subclassified into type B1, B2, and B3 vessels that are correlated to histological invasion depth of T1a-EP or T1a-LPM, T1a-MM or T1b-SM1, and T1b-SM2, respectively. According to previous studies, the diagnostic accuracy of type B2 vessel is about 60%-70%, which is considered to be relatively low and unsatisfactory.

**Results:** Of the 50 target areas, the number of the areas showing type B1, B2, and B3 vessels were 39, 9, and 2, respectively. The number of SESCO with tumor depths T1a-EP or T1a-LPM, T1a-MM or T1b-SM1, and T1b-SM2 were 44, 4, and 2, respectively. The sensitivity/specificity/positive predictive value (PPV)/negative predictive value (NPV) of the B1, B2, and B3 vessels were 86.4%/83.3%/97.4%/45.5%; 75%/87%/33.3%/97.6%; and 100%/100%/100%/100%, respectively. The accuracy of the B1, B2, and B3 vessels were 86%, 86%, and 100%, respectively. The PPV of B2 vessels was relatively low.

We noted 3 and 6 cases in the B2-narrow and B2-broad groups, respectively. The sensitivity/specificity/PPV/NPV of the B2-narrow and B2-broad groups were 0%/16.7%/0%/50% and 100%/50%/50%/100%, respectively. The accuracy of the B2-narrow and B2-broad groups were 33.3% and 66.7%, respectively. We noted 4 and 5 cases in the B2-only and B2-mixed groups, respectively. The sensitivity/specificity/PPV/NPV of the B2-only and B2-mixed groups were 100%/83.3%/75%/100% and 0%/16.7%/0%/25%, respectively. The accuracy of the B2-only and B2-mixed groups were 88.9% and 11.1%, respectively.

**Conclusion:** The accuracy of type B2 vessel was 86% whereas its PPV was as low as 33.3%. Contrastingly, the accuracy of the B2-only group, a proposed subcategorization of type B2 vessels, was 86%. The B2-only group was considered to be a useful predictor of T1a-MM or T1b-SM1.

**Contact E-Mail Address:** jsroseira31@gmail.com

**Introduction:** Primary esophageal cancer (EC) frequently presents as an advanced disease with airway involvement. Placement of combined esophageal (eS) and airway stents (aS) have been reported in small series to be effective palliation strategies.

**Aims & Methods:** Our aim is to present the largest cohort of EC patients who underwent double stent palliation, and to evaluate the safety and efficacy of this approach. Methods - Longitudinal cohort study of patients with primary EC undergoing 2-stage esophageal and airway stent placement at an oncology referral institute (Jan2000-Jan2019). Assessments: baseline demographics and clinical variables; baseline and week 2 dysphagia, dyspnea and performance status [PS] scores; baseline and week 8 BMI; overall survival. Statistics: Paired t-Test; Kaplan-Meier method.

**Results:** Seventy patients (89% men, mean age 60.20 ± 8.41) underwent double stenting. eS was placed for esophageal stenosis and dysphagia (n=41; placement of a second eS due to recurrence in 9 cases) or ERF (n=29); aS was required for ERF sealing (n=29+7 new ERF after eS) and to ensure airway patency due to malignant stenosis (n=29; placement of a second aS due to recurrence in 13 cases) or compression (n=5).

There were 13, endoscopically managed, major complications after eS (hemorrhage [n=1] migration [n=5], new fistulas [n=7]). As for aS, 4 major complications were recorded (hemorrhage [n=1] and 3 deaths due to respiratory infection and ultimately respiratory failure 3 to 7 days after the procedure).

Overall, patients showed significant improvement in dysphagia and dyspnea symptoms (3,21vs.1,31 e 15,56vs.10,87;  $p=0,00$ ). Along with symptom outcomes, there was a PS improvement for 89,2% (n=58) of the patients. BMI at week 8 was comparable to baseline records.

Mean survival was 137.83 ± 24.14 days (95% CI: 90.51-185.15). Survival was longer for lower performance status (PS1, 249.95 days; PS2, 83.74 days; PS3, 22.43 days; PS4, 30.00 days)

**Conclusion:** This is the largest comprehensive assessment of double stent palliation in advanced incurable EC. For both esophageal or airway stenosis and fistula, placement of combined eS and aS was a feasible, effective, fast-acting and safe modality for symptom palliation and BMI maintenance. Patient autonomy followed symptom improvement.

Since it is impossible to provide treatment for cure in most of these cases, this endoscopic strategy, performed in differentiated units with the required technical capacity, may guarantee treatment for the relief of palliative EC.

**Disclosure:** Nothing to disclose

## P1312 IS BIPOLAR KNIFE SAFE THAN MONOPOLAR KNIFE IN ENDOSCOPIC SUBMUCOSAL DISSECTION FOR ESOPHAGEAL NEOPLASIA

Nagami Y.<sup>1</sup>, Ominami M.<sup>1</sup>, Fukunaga S.<sup>1</sup>, Hirano S.<sup>1</sup>, Tanigawa T.<sup>1</sup>, Watanabe T.<sup>1</sup>, Fujiwara Y.<sup>2</sup>

<sup>1</sup>Osaka City University Graduate School of Medicine, Department of Gastroenterology, Osaka, Japan, <sup>2</sup>Osaka City University, Dept. of Gastroenterology, Osaka, Japan

**Contact E-Mail Address:** yasuaki1975@hotmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) is a standard treatment for early stage esophageal neoplasia. It was reported that the bipolar knife required significantly less energy and resulted in less tissue damage, and can decrease the incidence of perforation in animal model. On the other hand, all cases had submucosal fibrosis and it was not decreased esophageal stricture under esophageal ESD using bipolar knife compared with monopolar knife in porcine model. However, little is known the efficacy and safety of bipolar knife for esophageal ESD in clinical.

**Aims & Methods:** In the absence of prior reports, we evaluated the efficacy and safety of bipolar knife for esophageal ESD.

This was a retrospective observational study in a single institution. Between May 2012 and July 2018, 543 consecutive patients with 918 esophageal lesions were treated with ESD. Cases using multiple device and cases for esophageal SMT were excluded. The largest lesion was the target in patients with multiple lesions. Bipolar knife were used in anterior half and monopolar knife were used in posterior half. The primary outcomes were resectability and adverse events of esophageal neoplasia such as perforation, delayed bleeding, stricture, subcutaneous emphysema, pneumothorax, and mediastinal emphysema. We compared these outcomes of cases using bipolar needle knife with monopolar needle knife. Perforation was defined as a visible hole in the esophageal wall, exposing the mediastinal space. Generalized estimating equation were used for statistical analysis, and inverse probability of treatment weighting (IPTW) with propensity scores was used to reduce selection bias between the groups.

**Results:** A total of 531 cases with 633 lesions were evaluated. Monopolar and bipolar group were 368 case with 440 lesions and 163 cases with 193 lesions.

No significant difference was observed between the groups, such as age, gender, comorbidities, antithrombotic use, history of previous chemoradiotherapy, CO2 use, location, macroscopic appearance, lesion size, lesion circumference, clinical invasion depth, hemostatic forceps use, prophylactic steroid use and traction method use. En bloc and complete (Ro) resection rates in the monopolar and bipolar group were high and similar, (99.5% vs 100.0%, and 97.0% vs 96.9%). Perforations and postoperative bleeding also occurred similar rate (2.7% vs. 2.1%,  $p=0.79$ , and 1.4% vs 1.0%,  $p=1.00$ ). The incidence of subcutaneous emphysema and pneumothorax also similar, (1.1% vs 0.5%,  $p=0.67$ , 0.0% vs 0.5%,  $p=0.13$ ). However, mediastinal emphysema were observed more frequently in the bipolar group than monopolar group (19.2% vs 11.4% vs,  $p=0.01$ ). All cases could be treated with endoscopic and conservative management. The incidence of stricture was similar between the groups (8.6% vs 5.2%,  $p=0.15$ ). IPTW methods showed similar results and mediastinal emphysema occurred more frequently in bipolar group (OR=6.32, 95% CI: 1.79-22.38,  $p=0.004$ ). Limitations of this study were retrospective single center analysis and all cases were not evaluated mediastinal emphysema by computed tomography after ESD.

**Conclusion:** ESD for esophageal neoplasia using bipolar needle knife was safe and effective as well as that using monopolar knife. Mediastinal emphysema might increase than monopolar knife.

**Disclosure:** Nothing to disclose

## P1313 ENDOSCOPIC THERAPY IS AS EFFECTIVE AS SURGICAL RESECTION FOR EARLY OESOPHAGEAL CANCER: A TERTIARY REFERRAL EXPERIENCE OF 251 CONSECUTIVE CASES

**Introduction:** Endoscopic eradication therapy (EET) is considered first line for the management of early oesophageal adenocarcinoma, but the transition from surgical management with primary oesophagectomy, the historical treatment of choice for high grade dysplasia and early cancer, has been challenging. Recent National audit data from the UK (NOGCA) demonstrated access to EET was variable according to geographic region, and only 65% were offered EET as first line. This study therefore aimed to compare the short and long term outcomes of consecutive patients with early oesophageal cancer treated during a transition period from oesophagectomy to EET in a single tertiary referral centre.

**Aims & Methods:** A single centre contemporaneously maintained database of consecutive patients treated for High grade dysplasia (HGD) and early oesophageal adenocarcinoma at a tertiary referral centre between 2000-2018. All patients were discussed at MDT and histology confirmed by central pathology review by 2 expert GI pathologists. EET was adopted as first choice treatment in 2012. All patients underwent EMR using Duette MBM kit by 2 experienced operators (JD,SZ). Follow up was either with RFA or APC according to standard protocols. Oesophagectomy was not preceded by neoadjuvant chemotherapy although some patients underwent resection following an initial attempt at EMR. Primary outcomes were overall and disease specific survival. Secondary outcomes included hospital stay, complications and cancer recurrence.

**Results:** 251 patients were identified; 113 patients underwent oesophagectomy and 138 patients were treated with EMR +/- further EET (59% + RFA/APC, 25% + RFA, 9% + APC, 7% stepwise EMR). The mean age for oesophagectomy was 64.6 years vs. EET 71.6 years ( $p < .0001$ ). The mean follow up time for oesophagectomy patients was 5.6 years vs 2.4 years after EET. The proportion of T1b cancers was higher in the oesophagectomy group (HGD 25% vs 39%, T1a 17% vs 34%, T1b 43% vs 16%,  $p < 0.001$ ). Poor differentiation (23% vs 5%,  $p < 0.001$ ) and lymphovascular invasion (19% vs 4%,  $p < 0.001$ ) were also significantly higher in the surgical group. Inpatient hospital stay was significantly higher in the oesophagectomy group (median 14 days vs 1.5 days EMR;  $p < .0001$ ). In-hospital and 30 day mortality was 0% in both groups. The surgical group was associated with more significant complications (Clavien dindo  $\geq 3$ ) 26% vs. EMR 1%,  $p < .0001$ . Cancer recurrence occurred in 18% of patients after oesophagectomy (local 4%, systemic 9%, mixed 5%) vs. 5% following EET (all local). The time to recurrence in both groups was not statistically significant. There was no difference in overall survival between both groups (HR 0.83 95%CI 0.45-1.54). Stage matched survival in the HGD, T1a and T1b sub-groups did not significantly differ between the groups.

**Conclusion:** In this large consecutive series of early oesophageal adenocarcinoma patients treated during a transition period from oesophagectomy to EET, there was no difference in overall disease free survival between both modalities. Post procedure mortality was zero in both groups. Importantly EMR/EET was safe, with no patients requiring surgery or ICU admission. Oesophagectomy was associated with prolonged recovery and significant post-operative morbidity - complications were more common and severe. These data add weight to the argument that EET should be available for all patients with early OAC as the gold standard of care. After EMR, patients with adverse prognostic features may still benefit from oesophagectomy.

**Disclosure:** Nothing to disclose

## P1314 APPLICATION OF CONVOLUTIONAL NEURAL NETWORKS TO EVALUATING THE INVASION DEPTH OF EARLY GASTRIC CANCER BASED ON ENDOSCOPIC IMAGES

**Introduction:** Endoscopic diagnostic accuracy of the invasion depth of early gastric cancer is reported to range from 71% to 95% [1]. Recently, artificial intelligence (AI) has been applied to endoscopic examination and is expected to improve endoscopic diagnosis [2, 3].

**Aims & Methods:** The aim of this study was to evaluate the feasibility of convolutional neural networks (CNN), a type of AI, for evaluating the invasion depth of early gastric cancer based on endoscopic images. From patients who underwent treatment for early gastric cancers in our hospital between January 2012 and December 2016, we selected 100 patients with mucosal cancers that were treated with endoscopic resection (ER) (M group), 50 patients with cancers invading the submucosa that were initially treated with ER (SM-ER group), and 50 patients with cancers invading the submucosa that were treated surgically (SM-OPE group). A total of 3508 non-magnifying endoscopic images of early gastric cancers, including white-light imaging, linked color imaging, blue laser imaging-bright, and chromoendoscopic images with indigo-carmin, were included in this study. The following images were excluded: narrow-band imaging, blue laser imaging, magnifying endoscopic images, poor images because of bleeding or edema caused by scope contact, and poor images because of halation or tarnishing of the lens. Three-fold cross-validation was conducted, and the results are presented as the mean value of three tests. The patients of each group were divided into three subgroups each. A deep CNN was pre-trained and fine-tuned on a dataset of endoscopic images from two-thirds of patients in the M and SM-OPE groups, and a dataset of endoscopic images from the other one-third of patients in all three groups was evaluated by the CNN. Invasion depth was evaluated for each image and patient. Majority decision was applied to the patient evaluation and a lesion was diagnosed as a mucosal cancer when the number of images diagnosed as mucosal cancers and as cancers invading the submucosa was the same.

**Results:** Regarding the image evaluation, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for diagnosing mucosal cancer were 82.7%, 63.0%, 69.1%, and 78.4%, respectively. Regarding the patient evaluation, the sensitivity, specificity, PPV, and NPV for diagnosing mucosal cancer were 82.0%, 71.0%, 73.9%, and 79.8%, respectively. The diagnostic accuracy for early gastric cancer, including both mucosal cancer and cancer invading the submucosa was 72.8% and 76.5% for the image and patient evaluations, respectively.

**Conclusion:** The application of CNN to evaluating the invasion depth of early gastric cancer based on endoscopic images is feasible, although some devices are required to improve diagnostic accuracy.

**Contact E-Mail Address:** kiguchiyoshiyuki@gmail.com

**Introduction:** Underwater EMR (UEMR) has been reported as an alternative to EMR for superficial non-ampullary duodenal epithelial tumor (SNADET). However, the detailed outcomes are still unclear.

**Aims & Methods:** This study aimed to compare the clinical outcomes of UEMR and EMR for SNADETs smaller than 20 mm. This was a prospective observational study with a comparison to historical controls. From November 2017 to December 2018, 104 consecutive cases with SNADETs smaller than 20 mm were prospectively included (UMIN000025442). A total of 240 cases of attempted EMR were chosen as historical controls. We compared the adverse event rates, rates of conversion to ESD, en bloc resection rate and R0 resection rate. Next, multivariate analysis was constructed to identify predictors for conversion to ESD, piecemeal resection, and RX or R1 (RX/R1) resection.

**Results:** Concerning adverse events, there were no significant differences between the two groups (delayed bleeding: 2% for UEMR and 1% for EMR; perforation: 0% in both groups). The conversion rate to ESD in the UEMR group was significantly lower than that of the EMR group (13% vs 30%,  $p < 0.01$ ). Conversely, the en bloc resection rate and R0 resection rate of the UEMR group were significantly lower than those of the EMR group (en bloc resection: 87% vs 96%,  $p < 0.01$ , R0 resection: 67% vs 80%,  $p = 0.05$ ). In multivariate analyses, attempted EMR, lesion size and depressed type were independent predictors of conversion to ESD. Attempted UEMR was an independent predictor of piecemeal resection and RX/R1 resection.

**Conclusion:** The present study revealed that UEMR was equivalent to EMR in terms of safety. UEMR reduced the number of cases requiring conversion to ESD. However, it increased the risk of piecemeal and RX/R1 resection.

**Introduction:** Early gastric cancer (EGC) occurring after successful *Helicobacter pylori* eradication is difficult to diagnose, due to non-neoplastic epithelia covering the periphery of the surface of cancerous areas. This might lead to unclear demarcation of the cancer when observed using narrow band imaging with magnifying endoscopy (NBI-ME).

**Aims & Methods:** This retrospective control study aimed to clarify the histopathological characteristics of EGC that has cancerous areas covered with non-neoplastic epithelia. There were 383 cases of EGC that underwent endoscopic submucosal dissection (ESD) between November 2011 and January 2019 at Okayama Medical Center. Sixty two lesions from 55 patients who had received *H. pylori* eradication before ESD were included. The specimens resected by ESD were cut by a width of 2 mm. For each lesion, every section was evaluated histopathologically, and the percentage of sections that had non-neoplastic epithelia covering the carcinoma was calculated. Based on the percentages calculated, the lesions were classified into two groups: covered group (27 lesions, 143 sections) (50% or more) and non-covered group (35 lesions, 139 sections) (less than 50%). Baseline characteristics, endoscopic features, and histological findings were evaluated. For endoscopic features, the following were evaluated: irregular microvascular/micro-surface pattern, light blue crest, green epithelium, intraepithelial microinvasion, over flow, and demarcation line.

The lengths of non-neoplastic epithelia covering the carcinoma, percentage of sections in which non-neoplastic tubules exist among cancer tubules, and background mucosa (fundic or pyloric glands/intestinal metaplasia) were evaluated in the histopathological evaluation.

**Results:** No significant differences were observed for the baseline characteristics. For the endoscopic features, only the demarcation line demonstrated a significant difference; the lesions classified as covered group had a higher proportion of unclear demarcation lines ( $p = 0.0006$ ). For the histopathological evaluation, the average length of non-neoplastic epithelia covering the carcinoma was 1.11 mm in the covered group, which was significantly longer than 0.57 mm in the non-covered group ( $p = 0.001$ ). The proportion of sections in which non-neoplastic tubules exist among cancer tubules was 77.8% in the covered group; this was significantly higher than the 48.6% observed in the non-covered group ( $p = 0.001$ ). The proportion of background mucosa which were fundic or pyloric glands was 62.7% in the covered group; this was significantly higher than the 49% observed in the non-covered group ( $p = 0.02$ ).

**Conclusion:** EGC occurring in the area where background mucosa is a fundic or pyloric gland tends to be covered with non-neoplastic epithelia peripherally. More careful observation is required in the fundic or pyloric gland area than in the intestinal metaplasia area.

**Introduction:** The value of investigating isolated hypoferritinaemia is unclear. The BSG guidelines on iron deficiency anaemia (IDA) suggest consideration of endoscopic investigation in those aged >50 after discussing the risk and potential benefit.

**Aims & Methods:** We prospectively evaluated consecutive patients seen by a consultant gastroenterologist who had been referred from primary care with isolated hypoferritinaemia. All patients were offered investigation as per IDA guidelines following clinic consultation. Data was collected from the initial consultant consultation letter and from Infoflex (endoscopy) and Sunquest ICE system (blood results, radiology and histology). Lesions judged to be sources of significant blood loss were as defined by Rockey et al<sup>1</sup> (carcinomas, adenomatous polyps >15mm, vascular ectasia  $\geq 5$  or >8mm, duodenal / gastric / colonic ulcers >1cm, oesophagitis [LA grade D], erosive gastritis and active colitis).

**Results:** Eighty-two patients (median age 67.5 {42-93}; 58 females) were seen over a 5-year period (2014-2019). Thirty patients (36%) were asymptomatic (no symptoms or lethargy only). Fifty-eight patients (71%) had bidirectional endoscopies, 15 (18%) a combination of endoscopic and radiological imaging, and 6 (7%) having imaging alone. Two patients were excluded (1 died before investigations and 1 investigated as part of BCSP). Colonic carcinoma was discovered in 1 patient (1.3%). No gastric carcinomas were found (although a gastric carcinoma was discovered 12 months following a normal examination in a patient with a partial gastrectomy for previous gastric carcinoma). Other significant findings were: colonic polyps in 2 (2.5%); coeliac disease (serology negative, Marsh 3a) in 1 (1.3%); complex renal cyst resulting in nephrectomy in 1 (1.3%); hyperplastic/regenerative gastric polyps in 2 (2.5%); and an oozing gastric polyp in 1 (1.3%). There were no significant gastric or duodenal ulcers or angiodysplasias. Investigations were normal or non-significant in 74 (93%) patients: normal 25 (31%), gastritis 24 (30%), gastric polyps 10 (13%), colonic adenomas 8 (10%), oesophagitis LA grade A-B 4 (5%), haemorrhoids 4 (5%), duodenitis 2 (2.5%), Barrett's 1 (1.3%), duodenal adenoma 1 (1.3%), gastric ulcer 1 (1.3%), oesophageal erosions 1 (1.3%). Lung carcinoma was discovered in 1 patient who had a CT for associated weight loss; and a hepatocellular carcinoma in 1 patient, identified on renal tract ultrasound.

**Conclusion:** Gastrointestinal malignancy is rarely found in investigation of isolated hypoferritinaemia.

**Introduction:** The Baveno VI and the expanded Baveno VI criteria were proposed to help identify patients who could safely avoid screening esophagogastroduodenoscopy (EGD) for clinically significant varices among patients with compensated advanced chronic liver disease (cACLD). Although several studies have meanwhile validated those criteria, all fail to acknowledge the possible role of the avoided EGD for the same time screening of gastric neoplasia in cACLD population. Liver diseases are associated with an increased risk of extra-hepatic malignancies. Previous epidemiological studies have suggested that patients with cirrhosis have an increased risk for gastric cancer.

**Aims & Methods:** We aimed to evaluate the prevalence of gastric neoplasia in patients with cACLD who underwent screening EGD in a country with intermediate gastric cancer risk and high *Helicobacter pylori* prevalence. This retrospective cohort study enrolled all asymptomatic cACLD patients who underwent EGD for varices screening from January 2008 to June 2018. Cases were matched with asymptomatic healthy individuals who underwent EGD for gastric cancer screening at the same time as colonoscopy performed for colorectal cancer screening. Patients with prior history of organ transplantation and/or GI bleeding were excluded.

**Results:** We included 1974 subjects (610 patients, 1364 controls) 46.3% male, with a median age of 58 (50-66) years. Besides a male predominance in cases (69.0% vs. 45.6%,  $p < 0.001$ ), no other demographic characteristic differed between cases and controls. The leading aetiology of cACLD was alcoholic liver disease (53.3%), followed by chronic hepatitis C (16.2%). Of the 610 patients with cirrhosis, 13 (2.1%) had gastric neoplasia [gastric cancer,  $n=10$ ; high-grade dysplasia (HGD),  $n=2$ ; low-grade dysplasia (LGD),  $n=1$ ]. Most of the lesions (61.5%) were located in the gastric body, with a median size of 18 mm (15-24). Eight patients underwent surgical resection (RO resection rate of 100%). Complications were observed in three of these patients (anastomotic leak  $n=2$ ; nosocomial pneumonia  $n=1$ ), with associated decompensated liver disease, leading to death in two of them. Three patients underwent endoscopic resection [ $n=2$  endoscopic submucosal dissection (ESD),  $n=1$  endoscopic mucosal resection (EMR)], with an en bloc resection rate, RO resection rate and curative resection rate of 100%, without complications. Two patients were referred for palliative care due to decompensated liver disease. Compared to controls, cirrhotic patients had a higher prevalence of gastric neoplasia (2.1% vs. 1%,  $p=0.044$ ; gastric cancer 1.6% vs. 0.8%,  $p=0.08$ ). The prevalence of *Helicobacter pylori* infection was lower in patients compared to controls (36.2% vs. 47.2%,  $p=0.004$ ). In the 13 cACLD patients in whom were detected neoplastic gastric lesions, 8 were diagnosed on the initial screening endoscopy. Four of these patients would have an avoidable EGD according to the Baveno VI criteria.

**Conclusion:** The prevalence of gastric neoplasia is significantly increased in cACLD patients compared to healthy screening population. Despite growing evidence supporting the role of non-invasive methods to rule out varices, EGD should still be considered in these patients, at least in those from countries with intermediate gastric cancer risk. Detection at an early stage may allow adequate treatment with less invasive techniques such as ESD, avoiding the considerable morbidity and mortality associated with surgical intervention in these patients.

**Introduction:** Gastric cancer (GC) is the second leading causes of malignancy-related death in Vietnam, with increasing incidence of non-cardia early gastric cancer (EGC). Data on accurate diagnosis of EGC and treatment of this disease by endoscopic submucosal dissection (ESD) in Vietnam is still very limited.

**Aims & Methods:** To describe the characteristics of non-cardia EGC and evaluate the effectiveness and the safety of ESD in the context of Central Vietnam.

We prospectively enrolled patients with EGC detected by magnified chromoendoscopy from December, 2013 to December, 2018 at Hue University Hospital, Vietnam. Selected cases of non-cardia EGC received standardized ESD technique and have been following up carefully as in protocol.

**Results:** Among 606 cases of GC, 46 cases were non-cardia EGC and underwent ESD. The depth of invasion was T1a in 33 (71.7%), T1b1 in 10 (21.7%), and T1b2 in 3 (6.6%) cases. Mild- moderate chronic atrophic gastritis background, most being C2, and the gastritis-like with little malignant appearance EGC was the predominant type (63%). Severe chronic atrophic gastritis was found in only 2.2% of cases. ESD was performed of which 97.8 % received en-bloc resection; the mean procedure time was 76 ± 22 minutes (24-155), and mean sample size was 28 ± 7 mm (16.5-60). Complications consisted of two patients with severe bleeding and one case with minor perforation, all was successfully managed endoscopically. The longest follow-up time was 5 years with no recurrence. However, there were 2 cases who developed new high-grade dysplasia lesions and both of them underwent ESD second time successfully.

**Conclusion:** In Central Vietnam, a significant proportion with non-cardia EGC have a background mucosa of mild chronic atrophic gastritis and the gastritis-like with little malignant appearance. ESD treatment has demonstrate early promising results in that it appears effective and relatively safe.

## P1320 EFFECT OF POTASSIUM-COMPETITIVE ACID BLOCKER TO HEALING OF ARTIFICIAL ULCER AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION: PROSPECTIVE RANDOMIZED TRIAL

Ban H.<sup>1</sup>, Otsuka T.<sup>2</sup>, Sugimoto M.<sup>2</sup>, Andoh A.<sup>3</sup>

<sup>1</sup>Kusatsu General Hospital, Gastroenterology, Kusatsu, Japan, <sup>2</sup>Shiga University of Medical Science Hospital, Division of Digestive Endoscopy, Otsu, Japan, <sup>3</sup>Shiga University of Medical Science, Gastroenterology, Otsu, Japan

**Contact E-Mail Address:** hban@kusatsu-gh.or.jp

**Introduction:** Recently, endoscopic submucosal dissection (ESD) is commonly carried out to treat early-stage gastric cancer. Patient age, lesion size, location, and histology of tumor are related to the incident rate of complications and the healing speed of artificial ulcers after ESD. Vono-prazan (VPZ) is a novel potassium-competitive acid blocker (P-CAB), which exerts faster, more potent, sustained gastric acid inhibition than proton pump inhibitors (PPIs). However, it remains unclear whether the P-CAB effectively plays for the healing of artificial ulcer after ESD.

**Aims & Methods:** We compared healing process of artificial ulcer after ESD between treatment of P-CAB and PPI, as a prospective study at a single center. In addition, we evaluated influence of Helicobacter pylori (H. pylori) infection status in healing speed of artificial ulcer. One hundred nineteen six patients with gastric cancers or gastric adenomas treated by ESD at Shiga University of Medical Science from September 2015 to August 2018. By the minimization method using location of tumor (upper, middle or lower of the stomach) and tumor size (less than 20 mm or more), we randomly divided kinds of acid inhibitory drugs (VPZ 20mg for 8 weeks or lansoprazole (LPZ) 30mg for 8 weeks). Artificial ulcer size was endoscopically measured at the 1<sup>st</sup>, 2<sup>nd</sup>, 4<sup>th</sup> and 8<sup>th</sup> weeks after ESD. In addition, based on H. pylori status, we finally classified into 4 groups: V+ subgroup: H. pylori-positive and VPZ, V- subgroup: H. pylori-negative and VPZ, L+ subgroup: H. pylori-positive and LPZ, and L- subgroup: H. pylori-negative and LPZ.

**Results:** There were no significant differences in patient characteristics, location, depth and size of tumor among 2 groups. Reduction rates of artificial ulcer of VPZ were 37.8±32.8% at the 1<sup>st</sup> week, 73.8±19.4% at the 2<sup>nd</sup> week, 94.0±6.2% at the 4<sup>th</sup> week, and 99.8±0.1% at the 8<sup>th</sup> week, respectively. Reduction rates of LPZ were 30.2±34.0% at the 1<sup>st</sup> week, 69.4±24.7% at the 2<sup>nd</sup> week, 93.4±8.1% at the 4<sup>th</sup> week, and 99.9±0.1% at the 8<sup>th</sup> week, respectively. There was no significant difference between the 2 groups. In H. pylori-negative status, reduction rates were similar for V- and L- subgroup. In H. pylori-positive status, reduction rates of V+ subgroup was relatively higher than L+ subgroup at 2<sup>nd</sup> week (75.3±16.2%, 67.5±15.8%, P=0.06).

**Conclusion:** P-CAB has advantage to healing of artificial ulcer after ESD due to faster, more potent, sustained gastric acid inhibition than PPIs, especially in early phase within 2 weeks after ESD. These observations suggested that VPZ has high potential to prevent adverse events including bleeding, irrespective with H. pylori-infection status.

## P1321 GASTRIC CANCER PATIENTS WHO UNDERWENT GASTRECTOMY ARE HIGH RISK FOR COLORECTAL NEOPLASIA: A CASE CONTROL STUDY

Lee J.S., Gweon T.G.

Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Korea (Republic of)

**Contact E-Mail Address:** leejaesin@daum.net

**Introduction:** Several studies suggested that colorectal neoplasia could be prevalent in gastric cancer patients. However, most of studies included gastric cancer patients before gastrectomy. The aim of this study was to investigate whether colorectal neoplasia was more prevalent in gastric cancer patients after gastrectomy than normal population.

**Aims & Methods:** We reviewed medical records of consecutive gastric cancer patients who underwent screening colonoscopy in 2017. Colonoscopy was done after at least 1 year of gastrectomy. Healthy individuals who received colonoscopy during the same period were matched to gastric cancer group by age and sex, at a 2:1 manner. We compared the frequency of colorectal neoplasia, advanced neoplasia, and cancer among gastric cancer patients with that of the control group.

**Results:** A total of 354 (118, gastric cancer; 236, control group) were included in this study. The rate of colorectal neoplasia and advanced neoplasia were higher in the gastric cancer patients than the control group (colorec-

tal neoplasia, 49.2% vs 33.5%,  $p < 0.01$ ; advanced neoplasia, 21.2% vs 11.0%,  $p < 0.01$ ). The rate of colorectal cancer didn't differ between the two groups (3.4% vs 0.8%,  $p = 0.10$ ). Age  $\geq 50$ , male gender, and gastrectomy for gastric cancer were significant risk factors for colorectal neoplasia in multivariate analysis.

	Gastric cancer group (total 118)	Control group (total 236)	P-value
Colorectal neoplasm	58 (49.2%)	79 (33.5%)	< 0.01
Advanced colorectal neoplasm	25 (21.2%)	26 (11.0%)	< 0.01
Colorectal cancer	4 (3.4%)	2 (0.8%)	0.10

[Rate of colorectal neoplasm in gastric cancer patients who underwent gastrectomy]

**Conclusion:** Colorectal neoplasia and advanced neoplasia were significantly more prevalent in patients with gastric cancer who underwent gastrectomy than the control group. Gastric cancer was independent risk factor for colorectal adenoma. We recommend regular colonoscopy in gastric cancer patients after gastrectomy.

**Disclosure:** Nothing to disclose

## P1323 FLAT ELEVATED LESIONS WHICH HAVE BEEN DIAGNOSED WITH ADENOMA JUST BY CONVENTIONAL ENDOSCOPY CAN BE DISCRIMINATED BETWEEN EARLY GASTRIC CANCER AND ADENOMA BY MAGNIFIED ENDOSCOPY WITH NBI

Iwasaki T., Uchita K., Kojima K., Iwamura S.

Kochi Red Cross Hospital, Dept. of Gastroenterology, Kochi, Japan

**Contact E-Mail Address:** space-rendez-vous@sings.jp

**Introduction:** A white and flat elevated lesion is a typical endoscopic finding of gastric adenoma with an intestinal phenotype. However, histopathological studies have recently revealed that some of these lesions which have a gastric phenotype just in part are consequently diagnosed as gastric cancers, because disease progression are faster than adenoma. Thus it is crucial to distinguish between these two phenotypes.

**Aims & Methods:** Magnified endoscopic findings were compared between lesions with a gastric phenotype (gastric cancers) and those with an intestinal phenotype (adenomas), all of which were detected as white and flat elevated lesions by conventional endoscopy. A total of 211 gastric neoplasias were treated by endoscopic submucosal dissection (ESD) at Kochi Red Cross Hospital between October 2010 and November 2018. In these lesions, 51 lesions which showed white and flat elevated were included in this study. All lesions were examined by ME-NBI before ESD and resected en bloc. The central region of the lesions was immunostained by MUC5AC, MUC6, MUC2, and CD10. These lesions were divided into 2 groups, Group A and Group B, according to the result of immunostaining. Group A was the lesions which had gastric phenotype, positive for MUC5AC and / or MUC6, diagnosed of gastric cancers. Group B was the lesions which had only intestinal phenotype, positive for only MUC2 and/or CD10, diagnosed of typical gastric adenoma. Mucin expression in  $\geq 10\%$  and  $< 10\%$  of cells was defined as positive and negative, respectively, in accordance with previous reports

1). The magnified endoscopic findings were retrospectively examined and compared between the groups: microstructure of the surface, microvascular pattern, deposition of white opaque substances (WOS), and the presence of a crypt opening (CO). Microstructure pattern was classified as having an intralobular loop (ILL) pattern, which was defined as having a papillary or granular structure containing looped vessels; a fine network pattern (FNP), which was defined as having a regular crypt opening with regular polygonal microvessels; and a mixed pattern  
2). Microvascular pattern was classified according to the VS classification system reported by Yao et al.

**Results:** There were 21 lesions in Group A and 30 lesions in Group B. The ILL pattern was dominant in Group A (81.0%, 17/21), and the FNP was dominant in Group B (60.0%, 18/30). Only one case had vessels exhibiting an epithelial circular (VEC) pattern. The microvascular pattern was irregular in 47.6% (10/21) of cases in Group A and in only 3.3% (1/30) of cases in Group B. The proportion of lesions with WOS deposition was slightly higher in Group B (50.0%, 15/30) than in Group A (42.9%, 9/21), and the proportion of lesions with the presence of a CO was higher in Group B (86.7%, 26/30) than in Group A (19.0%, 4/21).

**Conclusion:** Among white and flat elevated lesions that are diagnosed with adenomas by standard endoscopic observation, those with a gastric phenotype, which are diagnosed with cancers, have characteristic magnified endoscopic findings, including an ILL pattern and an irregular microvascular pattern. These findings will be important for distinguishing between adenomas and adenocarcinomas.

**Introduction:** A reddish semipedunculated polyp with a morphological raspberry-like appearance in *Helicobacter pylori* (*Hp*)-negative patients has been recognized to be hyperplastic polyp (HP) conventionally. However, part of this polyp is reported as gastric adenocarcinoma of foveolar-type (GAFV) which has recently proposed as a new rare variant of gastric adenocarcinoma and has garnered much attention as one of *Hp*-negative gastric cancer [1]. In this way, this type of polyp which is newly categorized as a raspberry shaped gastric lesion (RSGL) includes various lesions. However, clinicopathological and endoscopic features and differential diagnosis of RSGLs in *Hp*-negative patients have not been elucidated.

**Aims & Methods:** This study aimed to clarify the clinicopathological and endoscopic features of RSGLs in *Hp*-negative patients. We collected RSGLs from endoscopic database in our hospital between April 2014 and February 2019 including 556 EGCs which underwent endoscopic resection. We classified RSGLs histopathologically, and analyzed their clinicopathological and endoscopic features.

**Results:** A total of 17 RSGLs (10 males, 7 females) in *Hp*-negative patients were collected (Table), and classified into 6 histological types as follows;

	GAFV	GAFG	GAFGM	HP	FGP like lesion with atypical foveolar hyperplasia	Hyperplasia of foveolar epithelium and parietal cell
Number of cases	7	2	2	4	1	1
Age	52.5	65.5	41.5	69	70	65
Gender (male/ female)	5/2	0/2	1/1	2/2	1/0	1/0
Location (U/M/L)	4/3/0	2/0/0	2/0/0	3/0/1	1/0/0	0/1/0
Location (Greater curvature/ Lesser curvature)	7/0	2/0	2/0	1/3	1/0	0/1
Tumor size(mm)	5(3-8)	8.5(5-12)	4.5(4-5)	5.5(3-9)	12	6
Macroscopic type (elevated / depressed)	7/0	2/0	2/0	4/0	1/0	1/0
Depth of invasion (M/SM)	7/0	0/2	1/1			

[Clinicopathological findings of raspberry shaped gastric lesion in *Helicobacter pylori*-negative patients]

1. GAFV (7cases), 2. gastric adenocarcinoma of fundic gland type (GAFG, 2cases), 3. gastric adenocarcinoma of fundic gland mucosal type (GAFGM, 2cases), 4. HP (4cases), 5. fundic gland polyp (FGP) like lesion with atypical foveolar hyperplasia (1cases), 6. Hyperplasia of foveolar epithelium and parietal cell (1cases). "FGP like lesion with atypical foveolar hyperplasia" and "hyperplasia of foveolar epithelium and parietal cell" showed parietal cell protrusions histopathologically, which considered to be associ-

ated with long-term use of proton pump inhibitors. Clinicopathologically, RSGLs were frequently found in the greater curvature of upper gastric body except for HP. All RSGLs showed strongly reddish protruded lesions macroscopically. In white-light endoscopic images, GAFV were observed as entirely reddish lesions, however, other lesions partially accompanied with whitish areas. Magnifying endoscopy with narrow-band imaging was performed in 9 cases (GAFV/ GAFG/ GAFGM/ HP/ FGP like lesion with atypical foveolar hyperplasia / hyperplasia of foveolar epithelium and parietal cell=3/2/2/1/1). Only 2 case of GAFGM was diagnosed as cancer with MES-DA-G [2], however, GAFV and GAFG were diagnosed as non-cancer. There were no endoscopic findings that were useful to distinguish each lesion.

**Conclusion:** RSGLs in *Hp*-negative patients could be classified into various types histopathologically and should be suspected as gastric cancer. Though RSGLs are characterized by the location, RSGLs may be difficult to diagnose endoscopically. Therefore, RSGLs should be diagnosed histopathologically, and further examination will be needed for precise endoscopic diagnosis of RSGLs.

## P1325 SARCOPENIA IS A RISK FACTOR FOR ASPIRATION PNEUMONIA ASSOCIATED WITH ESOPHAGEAL AND GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) IN ELDERLY PATIENTS

Arao M.<sup>1</sup>, Araki H.<sup>2</sup>, Ibuka T.<sup>3</sup>, Shimizu M.<sup>1</sup>

<sup>1</sup>Gifu University Hospital, Dept. of Internal Medicine, Gifu, Japan, <sup>2</sup>Gifu University Hospital, Dept. of Gastroenterology, Gifu, Japan, <sup>3</sup>Gifu University School of Medicine, Dept. of Gastroenterology, Gifu, Japan

**Contact E-Mail Address:** aryao\_poor\_boy@yahoo.co.jp

**Introduction:** Endoscopic submucosal dissection (ESD) is a safe and effective treatment for gastric and esophageal neoplasms even in elderly patients. However, this approach involves adverse events, including perforation, bleeding, and aspiration pneumonia. Although aging is an independent risk factor to develop aspiration pneumonia, other risk factors for aspiration pneumonia among elderly patients are unclear. Here, we aimed to investigate risk factors for aspiration pneumonia among elderly patients.

**Aims & Methods:** This was a retrospective observational study conducted at a single center, which included 170 patients ≥80 years of age who had undergone esophageal or gastric ESD. We compared patients with sarcopenia (sarcopenia group) with patients without sarcopenia (non-sarcopenia group). The presence of sarcopenia and aspiration pneumonia were confirmed by computed tomography.

**Results:** The overall incidence of sarcopenia was 42.9%. In the sarcopenia group, the incidence of aspiration pneumonia was 21.9% whereas it was 9.3% in the non-sarcopenia group (p=0.0212). Body mass index was significantly lower in the sarcopenia group than in the non-sarcopenia group (20.6±2.9 vs 23.6±3.1, p<0.001). Procedure time did not significantly differ between the two groups (72±54 minutes vs 62±44 minutes, p=0.201) nor did the proportion of abnormal respiratory function tests was not significantly different between two groups (62.1% vs 63.5%, p=0.87). On multivariate analysis, sarcopenia was an independent risk factor for the development of aspiration pneumonia (odds ratio=2.61, 95% confidence interval 1.07 to 6.37, p=0.0347).

**Conclusion:** Sarcopenia was a risk factor for aspiration pneumonia after esophageal or gastric ESD.

**Introduction:** Neuroendocrine Neoplasia (NENs) are rare and heterogeneous diseases, in terms of both pathological and clinical features. Their prognosis is affected by including primary tumor site, staging, and grading. Due to the complexity of NENs management, a multidisciplinary approach is widely advised for an effective care of patients with this uncommon kind of cancer. Multidisciplinary care is strongly encouraged by both Neuroendocrine Tumor Society (ENETS and NANETS). Since data on multidisciplinary management of patients with NENs in specialized centers with dedicated MDT are scanty.

**Aims & Methods:** Aimed to analyze modality of presentation and clinical outcome in patients with NENs managed in a center of excellence with dedicated MDT. Prospective observational study including all consecutive newly patients visited at the Sant'Andrea Hospital site of the Rome ENETS - Center of Excellence between January 2014 and June 2018. All the major clinical and pathological data were collected in an electronic anonymized database. All patients were discussed in a NEN multidisciplinary team which included clinicians involved in patients' management

**Results:** A total of 318 patients were evaluated. Of these, 122 patients were excluded because referred to the center for a second opinion; since these patients no data on their follow-up were available. Thus, the final analysis was performed on 196 patients, including with a median age of 59 yr (IQR 50.5 - 70.5 yr). Of these, 164 patients had GEP NENs (83.7%), and 19 patients had lung primary NEN (9.7%). At time of initial visit at the center, Ki67 value was available in 178 patients (90.8%), median value being 3% (IQR 2 - 9). Overall, 159 patients (81.1%) already had NEN diagnosis at time of referral; in these patients, median interval between initial NEN diagnosis and time of referral to the center was 4 months (IQR 2 - 12 months). The remaining 37 patients (19.9%) were newly diagnosed at the center. A total of 64 patients (32.7%) got in touch with the center by using the center's website form, whereas 132 patients (67.3%) booked the first visit by public health regional system tools. Overall, 74 patients (37.8%) were referred to the center by other hospitals. Median waiting time to obtain the first visit in the NEN-dedicated ambulatory was 7 days (IQR 7 - 10 days). After first visit, all patients were discussed at the MDT meeting. Additional cross-sectional radiological examinations or nuclear medicine diagnostic procedures were requested in 164 patients (83.7%). After these procedures, a change in disease staging was performed in 50/164 patients (30.5%). After MDT meeting discussion, pathological revision of available histological slides was advised in 53 patients (27%), whereas new biopsic sampling was advised in 30 patients (15.3%). Overall, a change in clinical management was observed in 98 patients (50%) after MDT discussion. Of these, 67 patients (68.4%) received medical treatment (somatostatin analogs 37 pts 37.8%; everolimus 15 pts, 15.3%; systemic chemotherapy 6 pts, 6.1%; peptide receptor radionuclide therapy 4 pts 4%), 9 patients (9.2%) underwent surgery, and 19 pts (19.4%) were followed up without medical or surgical intervention. The remaining 3 patients were treated by endoscopic resection (n=2) or liver radiofrequency (n=1).

**Conclusion:** This study reports the features of NEN pts admitted to an Italian center of Excellence, which mostly had non-functioning tumors, advanced disease and low Ki67. In those pts referred by other hospital, the median interval between initial diagnosis and taking care by the center was 4 months.

## P1327 ENDOSCOPIC ULTRASOUND-GUIDED ANGIOTHERAPY OF GASTRIC VARICES WITH COMBINED COILS AND GLUE INJECTION: AN EUROPEAN STUDY

Privat L.<sup>1</sup>, Donatelli G.<sup>2</sup>, Demmak H.<sup>1</sup>, Keita A.<sup>1</sup>

<sup>1</sup>Hopital de Vichy, Endoscopy, Vichy, France, <sup>2</sup>Hôpital Privé des Peupliers, Ramsay Générale de Santé, Unité D' Endoscopie Interventionnelle, Paris, France

**Contact E-Mail Address:** jocelyn.privat@ch-vichy.fr

**Introduction:** Gastric varices (GV) represent 20% of patients with portal hypertension.

Endoscopic cyanoacrylate injection is recommended in bleeding gastric varices.

Nevertheless, it is associated with more than 25% of re-bleeding and serious adverse events, mainly glue embolization. Endoscopic ultrasound (EUS)-guided and combined coil and glue injection provide a new alternative treatment for bleeding varices.

**Aims & Methods:** This is a retrospective analysis of EUS-guided coil and glue injection for gastric varices bleeding from 10/2013 to 03/2019. We used linear therapeutic ultrasound endoscopes without fluoroscopic control. The procedures were performed on general anesthesia and antibiotic prophylaxis. We injected cyanoacrylate combined with Lipiodol after the application of one or many coils (5 x 50 mm). A control EUS was done at 4 weeks.

The primary outcomes were varices obliteration and the need of reintervention.

**Results:** 33 patients were treated by EUS-guided coil and glue injection, 26 (78%) for recent bleeding varices and 7 (22%) for primary prophylaxis. There was 60% of males and the mean age is 61 years (28-84). Technical success was achieved in all patients (100%). The mean number of coil was 1.2 (1-3 coils) and the mean volume of glue injected was 1.5 mL (0.5-3 mL). Complete obliteration was confirmed for the 33 patients (100%), 30 after one session (91%), 2 after 2 sessions and one after 4 sessions. Post-procedure pain occurred in 3 patients (9%) during 1 to 7 days. No symptomatic embolization was observed with a mean follow-up of 436 days (21-1818).

**Conclusion:** EUS-guided combined coil and glue injection for gastric and ectopic varices appears to be a feasible and highly effective technique with less re-bleeding and complication than the classic endoscopic glue-only injection.

**References:** EUS-guided treatment of gastric fundal varices with combined injection of coils and cyanoacrylate glue. Bhat YM, Weilert F, Fredrick Rt, Kane SD, Shah JN, Hamerski CM, Binmoeller KF. *Gastronintest Endosc.* 2016 Jun;83(6):1164-72.

## P1328 SHARED ANGIOGENIC DRIVERS OF INTESTINAL VASCULAR DISORDERS

Douglas A.R.<sup>1</sup>, Smith S.<sup>1</sup>, Ryan B.<sup>2</sup>, Breslin N.<sup>3</sup>, Murphy G.<sup>3</sup>, Ismail M.S.<sup>3</sup>, Holleran G.<sup>2</sup>, O'Connor A.<sup>4</sup>, McNamara D.<sup>1,5</sup>

<sup>1</sup>Trinity College Dublin, Clinical Medicine, Dublin, Ireland, <sup>2</sup>Adelaide and Meath Hospital, Gastroenterology, Dublin, Ireland, <sup>3</sup>Tallaght University Hospital, Gastroenterology, Dublin, Ireland, <sup>4</sup>Tallaght Hospital/Trinity College Dublin, Gastroenterology, Dublin, Ireland, <sup>5</sup>Tallaght Hospital, Gastroenterology, Dublin, Ireland

**Contact E-Mail Address:** douglaar@tcd.ie

**Introduction:** Neovascularisation is common to a variety of GI disorders with differing etiologies and presentations. Shared angiogenic factors modulated by disease specific elements could be a common denominator and represent novel diagnostic and therapeutic targets. As yet, assessment of angiogenic factors across common GI vascular disorders has not been reported.

**Aims & Methods:** To assess serum levels of angiogenic factors in intestinal vascular disorders.

Following ethical approval and informed consent, serum from patients with small bowel angiodysplasia (SBA), portal hypertensive gastropathy (PHG), gastric antral vascular ectasia (GAVE) and non-bleeding, non-anemic controls were collected. Using ELISA, concentrations (ng/ml) of Angiopoietin 1 (Ang-1), Angiopoietin 2 (Ang-2) and Vascular Endothelial Growth Factor (VEGF) were measured. Results were expressed as a mean

and compared between groups using a T-test, p-value of < 0.05 was considered significant. The relative expression of Ang-1 and Ang-2 was calculated between groups.

**Results:** To date 44 samples were tested: 10 SBA, 11PHG, 8 GAVE and 15 Controls. Mean age 60 (range 20-86) years and 20 (45%) were males. Controls were significantly younger (49 vs 66yrs)  $p = 0.0005$ . There was no difference in VEGF levels between the groups, 443 ng/ml, 316 ng/ml, 435 ng/ml V's 421 ng/ml ( $p=0.59$ ). SBA, PHG and GAVE Ang-1 levels were similar and were significantly lower than controls: 35696 ng/ml, 23111 ng/ml, 30753 ng/ml, V's 53115 ng/ml, ( $p=0.0002$ , 95%CI 241 to 701). Ang-2 levels were higher in PHG and GAVE cases: 4298 ng/ml, 4232 ng/ml, V's 1899 ng/ml in controls ( $p=0.01$ , 95%CI 77.8 to 668) but were similar for SBA 2803 ng/ml ( $p=0.4$ ).

As a result, the ratio of Ang-1/Ang-2 was found to be significantly lower in PHG 10 ( $p=0.002$ , 95%CI 8.65 to 35.50) and GAVE 10 ( $p=0.004$ , 95%CI 7.82 to 35.28) groups compared to Controls 32 respectively. While SBA Ang-1/2 ratios were similar to controls 32.

The ratio of Ang-1/Ang-2 did not differ within the control group by age, < 65 years Ang1/2 ratio 33 V's >65 years Ang-1/2 ratio 22 ( $p=0.4$ ). The mean age within disease groups was similar SBA 69 (range 53-86); PHG 60 (range 38-81); GAVE 68 (range 58-85). Age is therefore unlikely to explain the discrepancy in Ang-2 levels and resultant Ang-1/Ang-2 ratios between the SBA and the other disease groups.

**Conclusion:** Our novel study of intestinal vascular disorders suggests a common alteration in Ang-1 levels, a vascular factor associated with vessel stabilization and maturation, across a variety of GI vascular disorders. Differences in Ang-2 profiles and resultant Ang-1/Ang-2 ratios among vascular disorders suggest disease-specific modulation and reflects the known variability in Ang-2 roles. VEGF appears not to play a significant role in the vascular conditions investigated.

**Disclosure:** Nothing to disclose

## P1329 ACUTE NECROTIZING OESOPHAGITIS: A VIEW INTO THE DARK

S G.<sup>1</sup>, Pavão Borges V.<sup>2</sup>, Saraiva R.C.<sup>3</sup>, Gamelas V.<sup>2</sup>, Mendez Santos S.<sup>4</sup>, Rocha M.<sup>5</sup>, Bettencourt M.J.<sup>2</sup>

**Contact E-Mail Address:** ritaosaraiva@gmail.com

**Introduction:** Acute necrotizing esophagitis (ANE), also known as "black oesophagus", is a rare condition characterized by circumferential necrosis of varying lengths in the oesophagus.

The aim of this study was to determine the incidence of ANE, its clinical presentation and endoscopic appearance, risk factors and associated conditions, related complications, management, short and long-term outcomes.

**Aims & Methods:** The aim of this study was to determine the incidence of ANE, its clinical presentation and endoscopic appearance, risk factors and associated conditions, related complications, management, short and long-term outcomes.

Retrospective analysis of all upper endoscopies performed over an eight-year period (2011-2018) in a tertiary care hospital. We considered acute necrotizing esophagitis the endoscopic appearance of diffuse or spotty dark pigmentation oesophageal mucosa with abrupt transition to normal-appearing mucosa at gastroesophageal junction in a patient without any other cause to explain it and with no previous history of relevant oesophageal disease.

**Results:** Over an eight-year period, there were performed 37 403 upper endoscopies and 7103 were done in an urgent setting. Acute necrotizing esophagitis was observed in 13 patients and all underwent urgent upper endoscopy. Therefore, overall prevalence was 0.03% and in urgent setting it was 0.18%. The median age was 67 years-old ( $\pm 12$ ) and 77% (10/13) were male. The main clinical manifestation of AEN was upper gastrointestinal bleeding, which occurred in 77% (10/13) of the patients. At the time of clinical manifestation 85% (11/13) of the patients had severe comorbid conditions and it was possible to identify previous hemodynamic instability in 62% (8/13).

In all cases the endoscopy was done within 12 hours of clinical manifestation. Endoscopically besides the black-appearing oesophageal mucosa, 71% (10/14) had other abnormal endoscopic findings, the most common finding was peptic ulcer disease. All patients underwent CT that ruled out AEN complications, except for one patient that had mediastinitis, which was successfully treated conservatively.

Regarding the treatment, cases were managed with supportive therapy and endovenous proton pump inhibitor. Most of the patient were also on broad-spectrum antibiotics (77%).

23% (5/13) of the patients died during the hospital stay and 40% (2/5) of them died in the first 24h after clinical manifestation of AEN. None of the deaths were related with AEN or its complications. All causes of death were related to underlying clinical condition, the most common cause of death was sepsis. All the discharged patients had no complications related with AEN and were alive in the 2 years follow-up. In all the endoscopically re-evaluated patients the condition had completely resolved.

**Conclusion:** AEN is an important cause of upper gastrointestinal bleeding in critically ill patients with severe co-morbidities. AEN is an important marker of severe disease and increased overall mortality. Even though AEN it is not a serious clinical condition per se, its association with high mortality will largely depend on the underlying critical illness.

**Disclosure:** Nothing to disclose

<sup>1</sup>University of Latvia, Faculty of Medicine, Riga, Latvia, <sup>2</sup>University of Latvia, Institute of Clinical and Preventive Medicine, Riga, Latvia, <sup>3</sup>International Agency for Research on Cancer, Lyon, France

**Contact E-Mail Address:** d.razuka.ebela@gmail.com

**Introduction:** Prevalence of *H. pylori* (HP) infection is higher in developing countries comparing with developed ones and is linked to lower socioeconomic status. Studies covering the association between HP and individual level characteristics other than socioeconomic factors are lacking in Europe [1]. To our knowledge, no such studies have been published for Northern and Eastern European populations, where several countries have a high prevalence of HP infection.

**Aims & Methods:** The aim of the current study was to identify individual characteristics associated with HP infection in a high income country with high HP prevalence (79%) and gastric cancer incidence (27/100,000) [2,3]. 1855 participants aged 40-64 years from the "*Helicobacter pylori* eradication and pepsinogen testing for prevention of gastric cancer mortality (GISTAR) study" in Latvia were included in the analysis [2]. All participants were tested for *H. pylori* IgG antibodies (Eiken Chemical, Japan). Data on sociodemographic characteristics (gender, age, income, education, employment status), diet (consumption of  $\geq 400$ g of fruit/vegetables,  $\geq 200$ g dairy, portions of red and white meat daily, frequency of consumption of meat products, pickled, smoked, salted, and spicy products, coffee, tea (days per week), very hot food/drinks weekly, adding salt to already salted food), exercise, smoking (current, former), alcohol consumption, binge-drinking, and medical history (self-reported history of disease, surgery, drug use) were obtained by survey and compared for participants positive (HP+) and negative for HP (HP-). A multiple logistic regression model was built adjusting for potential confounders (income, age and gender [1]). Individual characteristics with  $p < 0.10$  in univariate analysis investigating their association with HP+ were included in the final model as follows: level of education, smoking, binge-drinking, consumption of  $\geq 200$ g dairy,  $\geq 400$ g of vegetables/fruit daily, very hot food/drinks, pickled products, adding salt to food, self-reported history of HP eradication, peptic ulcer, thyroid and cardiovascular disease.

**Results:** 1044 (56.3%) participants were HP+. In fully adjusted multiple logistic regression HP+ was positively significantly associated with consumption of dairy (OR 1.36; 95% CI 1.10, 1.67), very hot food/drinks weekly (OR 1.33; CI 1.04, 1.69), and addition of extra salt to already salted food (OR 1.29; CI 1.04, 1.60), current smoking (OR 1.43, CI 1.07, 1.91) and binge-

drinking (OR 1.34, CI 1.02, 1.75). In addition, HP+ was inversely associated with consumption of fruit/vegetables (OR 0.77; CI 0.61, 0.97), self-reported history of HP eradication (OR 0.56; CI 0.38, 0.82), peptic ulcer (OR 0.56; CI 0.38, 0.80), and cardiovascular disease (OR 0.78; CI 0.61, 0.98).

**Conclusion:** We found HP+ to be associated with lifestyle factors, rather than socioeconomic indicators. Lifestyle intervention and possibly *H. pylori* eradication may be especially beneficial in this subset of the population because those HP+ were also more likely to have other and multiple risk factors for the development of gastric cancer (smoking, increased salt, but decreased fruit/vegetable intake, history of peptic ulcer disease).

**Introduction:** *H. pylori* (HP) is the most common bacterial infection in the world. The increase in bacterial resistance to the antibiotics most used against this microorganism significantly conditions the treatment of this infection. Recently, the new recommendations of the International and National Consensus have proposed different therapeutic strategies to improve the eradication.

**Aims & Methods:** To evaluate the preferences and current therapeutic decisions of the Spanish Gastroenterology Specialists in the management of HP infection. An online survey was designed to register 21 variables regarding demographics, type of practice, continuous education received and preferences on management. Responses were anonymously codified. Responses were weighted by age, years of experience, training received in HP treatment and type of center (public, private) where work.

**Results:** A total of 369 gastroenterologist participated in the study giving response to the survey. The study was performed between March and May 2018. 54% were women and the average age was 39 years ( $\pm 10.2$ ). 92% of responses came from public practices and 44% from private sector, meaning that many participants worked in both. 17.6% worked in populations of more than 500,000 inhabitants, 62.1% in populations from 100,001 to 500,000 inhabitants and 20.3% in populations of less than 100,000 inhabitants. 53% have received continuous education program on HP infection in the last 12 months. 16% have participated in some research program about infection. 75% of the surveyed doctors said that the management of the infection is a decision of each doctor, there was no protocol in their workplace for the management of the infection. The most common first-line therapy of choice was non-bismuth quadruple concomitant therapy [57%, with clarithromycin, metronidazole, amoxicillin and a proton pump inhibitor (PPI)] followed by bismuth quadruple single capsule therapy (36%, with a PPI, tetracycline, metronidazole and bismuth), triple therapy (5%, with a PPI, clarithromycin and amoxicillin) and other (2%). Triple therapy was more used in private practice and by gastroenterologists with more than 20 years of professional experience. The factors that most influenced the decision of the choice of first-line treatment were therapeutic efficacy (53%), over prescription limitations in their sanitary environment (29%), economic burden (5%), safety (4%), lower risk of side effects (4%), patient characteristics (2.4%), possible interactions with other medications (1.6%) and treatment characteristics that may favor adherence to treatment (1.6%).

**Conclusion:** This survey shows how Spanish gastroenterologists have adapted rapidly to current HP consensus recommendations, using quadruple therapeutic strategies in first line to ensure greater efficacy of treatment against increased bacterial resistance. It draws attention to how the management of HP infection is a decision of each doctor, without following an established protocol in their workplace.

## P1333 MODIFIED 7-DAY VERSUS STANDARD 10-DAY CONCOMITANT THERAPY FOR HELICOBACTER PYLORI ERADICATION: A RANDOMIZED CONTROLLED TRIAL

Rojsanga W., Chanpiwat K., Bunchorntavakul C., Rajavithi Hospital, Gastroenterology, Bangkok, Thailand

**Contact E-Mail Address:** dr.chalermrat@gmail.com

**Introduction:** Eradication rates for *H. pylori* with a standard triple therapy have declined globally. A 10-day standard concomitant therapy (SCT) is associated with slightly higher eradication rates, but with more side effects, when compared to that of the triple therapy. More aggressive acid suppression may allow shortening treatment duration without compromising eradication rates.

**Aims & Methods:** This study aimed to compare the *H. pylori* eradication rates between a 7-day modified concomitant therapy (MCT) and a 10-day SCT.

This open-label, randomized study was conducted at Rajvithi Hospital, Bangkok, Thailand during November 2016-2017. Patients with active *H. pylori* infection were included (n=240) and randomized (1:1) into either 7-day MCT (omeprazole 40 mg BID, amoxicillin 1000 mg BID, clarithromycin 500 mg BID and metronidazole 400 mg TID for 7 days) or 10-day SCT (omeprazole 20 mg BID, amoxicillin 1000 mg BID, clarithromycin 500 mg BID, and metronidazole 400 mg TID for 10 days). *H. pylori* eradication was evaluated by <sup>14</sup>C-urea breath test at 4-6 weeks after the completion of treatment. Eradication rates were analyzed by per-protocol (PP) and intention-to-treat (ITT) analysis. Side effects and patient compliance were recorded. **Results:** A total of 120 patients were randomized into each treatment group. There was no significant difference in baseline patient characteristics between groups. In ITT analysis, *H. pylori* eradication rates were 88.3% (106/120) and 88.3% (106/120) in the 7-day MCT and 10-day SCT groups, respectively ( $p>0.99$ ). In PP analysis, *H. pylori* eradication rates were 94.6% (106/112) and 95.5% (106/111) in the 7-day MCT and 10-day SCT groups, respectively ( $p=0.77$ ). Bitter taste was the most common treatment-related side effect in both groups (72.3% in the 7-day MCT vs. 66.7% in the 10-day SCT,  $p=0.36$ ). Headache (9.8% vs 18.9%,  $p=0.05$ ) and diarrhea (17% vs 27.9%,  $p=0.05$ ) were less commonly reported in the 7-day MCT than in the 10-day SCT group, respectively.

**Conclusion:** The 7-day MCT was safe and able to achieve similar eradication rate, as compared with a 10-day SCT. Due to its better tolerability, 7-day MCT may be a practical alternative first-line treatment option for *H. pylori* eradication.

## P1334 COMPARATIVE STUDY OF SEQUENTIAL VERSUS CONCOMITANT NON-BISMUTH QUADRUPLE THERAPY AS FIRST-LINE ERADICATION FOR HELICOBACTER PYLORI

Pereira F., Azevedo R., Linhares M., Ramos D., Pinto J., Caldeira A., Tristan J., Pereira E., Sousa R., Banhudo A., Hospital Amato Lusitano, Gastroenterology, Castelo Branco, Portugal

**Contact E-Mail Address:** pereiraf14@gmail.com

**Introduction:** Helicobacter pylori (Hp) is a major cause of peptic ulcer disease and gastric malignancies. Hp eradication rate has reduced, in part because of increased antibiotic therapy resistance. Recent international guidelines have shown preference towards Concomitant non-bismuth quadruple therapy as first-line empirical option, instead of sequential treatment, when choosing a non-bismuth regimen.

**Aims & Methods:** We aim to compare the efficacy of the sequential and concomitant non-bismuth quadruple therapy as first line empirical antibiotic regimens in terms of Hp eradication rate. We conducted a retrospective study between January/2015 and March/2019 including patients with Hp infection. Patients were treated as first-line eradication therapy with the Sequential quadruple treatment (comprising 5 days of proton-pump inhibitor and amoxicillin, followed by 5 days of proton-pump inhibitor, clarithromycin and metronidazole) or the Concomitant non-bismuth quadruple therapy (comprising 14 days of proton-pump inhibitor, amoxicillin, metronidazole and clarithromycin). Eradication of Hp was confirmed after treatment. Eradication rate was calculated for each treatment regimen.

**Results:** 101 patients were included (52,5% female, mean age of 55,4±13,4 years). Main indications for Hp testing were dyspepsia (33%), peptic ulcer disease (31%) and erosive gastritis/bulbitis (27%). The tests more frequently used for diagnosis of Hp infection were histology (56%) and rapid urease test (35%). 55 (54,5%) and 46 (45,5%) patients were treated with Sequential and Concomitant therapies, respectively. Hp eradication was mainly confirmed by stool antigen test (53%), histology (20%) and urea breath test (18%). Global eradication rate was 88%. Hp eradication rate achieved 89% with Sequential therapy and 87% with Concomitant treatment, with no statistical difference ( $p>0,05$ ).

**Conclusion:** Global eradication rate with non-bismuth quadruple regimens was good (88%), with no statistical difference between Sequential and Concomitant treatments. Therefore, we suggest that both the protocols may be used in current clinical practice as first line empirical eradication treatment.

**Contact E-Mail Address:** b9002007@hotmail.com

**Introduction:** The prevalence of antibiotic resistance varies greatly among countries and increases gradually in recent years. Declined first-line *Helicobacter pylori* (*H. pylori*) eradication rate becomes a significant healthcare burden and challenge for prescribing adequate second-line eradication therapy. Secondary antibiotic resistance to clarithromycin, metronidazole, and levofloxacin were more than 15% after first-line treatment failure. Optimal second-line eradication regimen to achieve best eradication rate remain elusive.

Therefore, we conducted a network meta-analysis to compare the relative efficacy of second-line *H. pylori* eradication among 15 regimens since 2000 to find the favorable regimens in treatment-experienced patients.

**Aims & Methods:** We reviewed three major bibliographic databases, including PubMed, Embase, and Cochrane Central Register of Controlled Trials, and enrolled relevant randomized trials and cohort studies that evaluated second-line *H. pylori* eradication rate between January 2000 and September 2018. We performed network meta-analysis by WinBUGS and STATA software and assessed the quality of enrolled articles with RoB 2.0 tool for randomized trials and ROBINS-I tool for non-randomized studies of interventions.

The odds ratio (OR) was calculated for the comparative treatment effects between second-line therapies when compared to 7-days clarithromycin-based triple therapy as well as in subgroup analysis.

**Results:** In our study 66 trials with 10582 treatment-experienced participants were recruited in the network meta-analysis. Among all regimens, add-on therapy of probiotics after and/or during second-line antibiotic therapy (OR 4.39, 95% CrI 1.46-12.80), quinolone-based sequential therapy for 10-14 days (OR 3.38, 95% CrI 1.29-8.65), quinolone-based quadruple therapy for 10-14 days (OR 3.32, 95% CrI 1.28-8.47), add-on therapy of probiotics before and/or during second-line antibiotic therapy (OR 3.12, 95% CrI 1.01-9.32), and add-on therapy of probiotics during second-line antibiotic therapy (OR 3.03, 95% CrI 1.09 - 8.22) had greater efficacy with statistical significance. Besides regimens with longer duration tend to show higher efficacy of eradication compared with regimens with shorter duration.

**Conclusion:** In our meta-analysis we found add-on therapy of probiotic before/during/after second-line antibiotic therapy, quinolone-based sequential therapy for 10-14 days, and quinolone-based quadruple therapy for 10-14 days are superior to the rest of regimens in treatment-experienced patients. In addition, extending the duration of regimens achieved higher efficacy of eradication rate than those with shorter duration.

**Disclosure:** Nothing to disclose

**Introduction:** International guidelines suggest bismuth quadruple (BQ) or non bismuth quadruple (i.e. concomitant) (CT) therapy as first line regimens to eradicate *H. pylori* infection. Choice should be based on knowledge of prevalence of antimicrobial resistance in a particular area, previous antimicrobial exposure, drug allergy. In areas of high clarithromycin (CLA) or dual (i.e. CLA + metronidazole) resistance BQ should be preferred because of its higher efficacy compared to CT. We hypothesized that previous exposure to CLA might be more likely associated to infection with a CLA resistant strain.

**Aims & Methods:** In this real life study, therefore, we evaluated the efficacy of BQ vs CLA-containing CT (10 or 14 days) in *H. pylori* infected subjects naïve to treatment. Patients who had previously been exposed to CLA were given BQ whereas those who had not were given CT. In Italy BQ is only possible through the 3-in-1 pill formulation for 10 days. Two hundred and 1 patients (pts) (125F and 76M, mean age 47.3yrs) were treated with BQ (esomeprazole (ESO) 40 mg bid, 3-in-1 pill formulation 3 tablets qid), 203 patients received CT (ESO 40 mg bid + CLA 500mg bid + amoxicillin 1gbid + tinidazole 500mg bid) of these 100 pts for 10 days (CT10d) (54F and 46M, mean age 46.4 yrs) and 103 (55F and 48M, mean age 48.3 yrs) pts for 14 days (CT14d). All pts received probiotics during therapy. Diagnosis of *H. pylori* infection was through <sup>13</sup>UBT or histology in those pts who underwent esophagogastroduodenoscopy. Assessment of eradication was through <sup>13</sup>CUBT at least 1 month after the end of therapy. Incidence of treatment-related adverse events (TRAEs) was evaluated by a questionnaire at the end of therapy. Compliance was considered to be good if at least 80% of medications had been taken. Intention-to-treat (ITT) and Per Protocol (PP) analysis was performed, 95% confidence intervals (CI) were calculated and significance of differences was assessed by Chi square test.

**Results:** Ten pts in BQ group, 6 pts in CT10d group and 3 pts in CT14d discontinued therapy because of side effects; 2) ITT and PP eradication rates in BQ were 184/201 (91.5%, 95%CI 86.8-95) and 183/191 (95.8%; 95%CI 91.9-98.2), respectively; 3) ITT and PP eradication rates in CT10d were 80/100 (80%; 95%CI 70.8-87.3) and 80/94 (85.1%; 95%CI 76.3-91.6), respectively; ITT and PP eradication rates in CT14d were 99/103 (96.1%; 95%CI 90.3-98.9) and 97/100 (97%; 95%CI 91.5-99.4), respectively; 4) BQ vs CT10d:  $p<0.004$  and  $p<0.001$  (ITT and PP, respectively); BQ vs CT14d:  $p:ns$  (ITT and PP); CT14d vs CT10d:  $p<0.001$  and  $p=0.003$  (ITT and PP, respectively); 5) Prevalence of TRAEs was 26.9%, 26%, and 22.3% in BQ, CT10d and CT14d, respectively ( $p:ns$ ); 6) Treatment discontinuation due to TRAEs was 5.5%, 6%, and 2.9% in BQ, CT10d and CT14d, respectively ( $p:ns$ ).

**Conclusion:**

- 1) In an area of high prevalence of CLA and dual resistance BQ and CT14d are highly and equally effective in the treatment of *H. pylori* infection in pts naïve to treatment and significantly superior to CT10d;
- 2) No significant differences as to compliance or incidence of TRAEs between treatment was detected;

3) Prescribing therapy based on knowledge of previous exposure to CLA may represent a winning strategy.

**Introduction:** *Helicobacter pylori* is a gram-negative bacterium responsible for many gastric conditions. Due to increasing antimicrobial resistance, eradication rates employing currently available treatment options, have significantly declined. Local antimicrobial surveillance is needed to guide therapies and improve outcomes.

**Aims & Methods:** To evaluate the prevalence of *H. pylori* primary, secondary and multidrug resistance and the impact on treatment outcome. Following ethical approval and informed consent, antral and corpus biopsies were prospectively obtained from patients undergoing routine endoscopy who required *H. pylori* testing at Tallaght University Hospital during 2018-2019. Culture samples were processed if subjects were CLO positive. Antimicrobial susceptibility to seven antibiotics: Metronidazole, Clarithromycin, Amoxicillin, Levofloxacin, Rifampicin, Tetracycline, Moxifloxacin was tested as standard by Etest strips. The minimum inhibitory concentration (MIC) was evaluated and susceptibilities were assigned according to the EUCAST clinical breakpoints. Patients were treated with standard eradication regimens and success was determined by C<sup>13</sup>UBT with a Delta value of < 4.0. **Results:** 66 patients were recruited, mean age 51 (31-81) years, 19 (56%) females. Culture was successful in 33 (50%). 61% (20/32) with no prior treatment (PR= primary resistance) and 39% (13/33) (SR= secondary resistance) having failed prior treatment. PR and SR groups were demographically similar.

Few individuals were sensitive to all antibiotics; 4/20 (20%) PR vs 1/13 (8%) SR.

Primary resistance rates were high; Metronidazole 12/20 (60%), Clarithromycin 9/20 (45%), Amoxicillin 7/20 (35%), Levofloxacin 6/20 (30%), Rifampicin 9/20 (45%), Tetracycline 5/20 (25%), Moxifloxacin 2/20 (10%). Unexpectedly, secondary resistance rates were similar; Metronidazole 11/13 (85%)  $p=0.1$ , Clarithromycin 9/13 (69%)  $p=0.2$ , Amoxicillin 6/13 (46%)  $p=0.4$ , Levofloxacin and Tetracycline 4/13 (31%)  $p=0.6$  and  $p=0.5$ , Rifampicin 2/13 (15%)  $p=0.08$ , Moxifloxacin 3/13 (23%)  $p=0.3$ .

Dual resistance to Metronidazole and Clarithromycin was common 52% (17/33) and similar in PR and SR groups (9/20 45% and 8/13 62%)  $p=0.3$ . The multidrug (>3 antibiotics) resistance rate was 48% (16/33) and was also similar in PR and SR groups, 45% and 54% respectively.

Overall our eradication rate was disappointing 39% (13/33) and did not differ between PR and SR groups; 45% (9/20) and 31% (4/13) ( $p=0.48$ ). Successfully eradicated patients had similar resistance rates to Clarithromycin, Metronidazole and Amoxicillin (46%, 54%, 31%) compared to non-eradicated patients (60%, 80%, 45%).

**Conclusion:** Primary, secondary, dual and multidrug *H. pylori* resistance is very high in our cohort and has increased significantly from previous published Irish data. Unsurprisingly, our high resistance rates were reflected in poor overall, first line and second line eradication rates. The very high levels of primary resistance account for the lack of difference in the eradicated vs non-eradicated groups. Based on this data novel approaches to eradication in Ireland are warranted.

### **P1338** COMPARISON OF EFFICACY OF BISMUTH-CONTAINING QUINTET THERAPY AND MOXIFLOXACIN-BASED SEQUENTIAL THERAPY AS FIRST-LINE ERADICATION REGIMEN FOR *HELICOBACTER PYLORI* INFECTION

**Kim G.**, Lee D.H., Shim H.I., Cho J.H., Yoon H., Shin C.M., Park Y.S., Kim N.  
Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea (Republic of)

**Contact E-Mail Address:** kimgun13@naver.com

**Introduction:** Recently, the eradication rate of *Helicobacter pylori* (*H. pylori*) infection has been decreasing. We investigated the efficacy of bismuth-containing quintet therapy compared with moxifloxacin-based sequential therapy as a first-line eradication treatment.

**Aims & Methods:** We enrolled 164 patients with *H. pylori* infection from October 2015 to October 2016, and randomly assigned into 2 groups: bismuth-containing quintet therapy (BCQT group; rabeprazole 20mg bid, amoxicillin 1g bid, metronidazole 500mg bid, moxifloxacin 400mg qd, and tripotassium dicitrate bismuth 600mg bid for 7 days) or moxifloxacin-based sequential therapy (MBST group; rabeprazole 20mg bid and amoxicillin 1g bid for 7 days, followed by rabeprazole 20mg bid, metronidazole 500mg bid, and moxifloxacin 400mg qd for 7 days). Successful eradication was defined as negative for <sup>13</sup>C-urea breath test after 4 weeks of treatment.

**Results:** The eradication rates by intention-to-treat analysis were 76/82 (92.7%, 95% confidence interval [CI] 89.8-95.6%) in the BCQT group and 70/82 (85.4%, 95% CI 81.5-89.3%) in the MBST group ( $p = 0.066$ ). The eradication rates by per-protocol analysis were 76/79 (96.2%, 95% CI 94.0-98.4%) in the BCQT group and 70/80 (87.5%, 95% CI 83.8-91.2%) in the MBST group ( $p = 0.043$ ). Compliance was good (100%) in both groups. The adverse event rates were lower in the BCQT group (9/79, 11.3%) than in the MBST group (12/80, 15.0%) ( $p = 0.048$ ).

**Conclusion:** The bismuth-containing quintet therapy was more effective and safe compared to the moxifloxacin-based sequential therapy as a first-line eradication treatment of *H. pylori* infection.

**Introduction:** Concomitant therapy and bismuth quadruple therapy are both recommended as 1<sup>st</sup> line treatment regimens for the empiric treatment of *Helicobacter pylori*, especially after the increased resistance to clarithromycin. Our goal is to compare both of the treatment regimens among a representative sample of the Lebanese population to eventually conclude whether or not one of these therapies has a higher efficacy as a 1<sup>st</sup> line treatment regimen. This study also aims to compare the efficacy of these regimens when given as 2<sup>nd</sup> line therapy after crossover.

**Aims & Methods:** It is a randomized, prospective and crossover study, started from March 2016 to December 2018. Participants were randomly chosen and diagnosed with active *Helicobacter pylori* through histology. None of them had a prior eradication therapy or had a recent exposure to antibiotics. Patient were randomized into two equal groups: patients in the first group received 10 days of concomitant therapy (Esomeprazole 40mg twice a day, Amoxicillin 1g twice a day, Clarithromycin 500mg twice a day and Metronidazole 500mg twice a day), while patients in the second group received 10 days of bismuth quadruple therapy (Esomeprazole 40mg twice daily, and a capsule containing all three components: Bismuth, Tetracycline and Metronidazole) 3 capsules were taken four times a day. Eradication was evaluated by the <sup>14</sup>C urea breath test done 6 weeks after the end of antibiotic use. Esomeprazole was also stopped for at least two weeks prior to testing. A negative breath test indicated a successful eradication. All patients with a positive breath test were switched to the other treatment regimen for 10 days and then re-evaluated for eradication according to the same protocol.

**Results:** The eradication rate was 91.43% in the concomitant group and 94.25% in the Bismuth group (NS). 14 out the 15 patients who failed eradication after concomitant treatment as first line, achieved eradication after crossover. All 10 patients who failed Bismuth based first line treatment and received concomitant second line regimen, had a negative breath test at the end of the study.

**Conclusion:** Bismuth quadruple therapy and concomitant therapy are equally effective as 1<sup>st</sup> line treatment regimens for *Helicobacter pylori* eradication in a naïve Lebanese population. They are also highly and equally effective when used as 2<sup>nd</sup> line after crossover.

**Introduction:** After a failed eradication attempt, *H. pylori* treatment's efficacy is compromised due to the selection of resistant strains.

**Aims & Methods:** To evaluate the efficacy by intention-to-treat (ITT) and per-protocol (PP) of second-line treatments in Europe.

A systematic prospective registry of the clinical practice of European gastroenterologists regarding *H. pylori* infection and treatment (27 countries

and 300 recruiting investigators). An e-CRF was created on AEG-REDCap to systematically register all adult patients infected with *H. pylori*. **Variables included:** Patient's demographics, previous eradication attempts, prescribed eradication treatment, adverse events (AEs), and outcomes (cure rates, compliance, follow up, etc.). **Data extraction:** All cases with treatment failure after just one eradication attempt. **Analysis:** Cases with an empiric treatment were evaluated separately from those with a tailored therapy.

**Results:** Overall, 4,388 second-line patients were included. Culture was performed in 9% of the total of cases. Resistance rates (when available) were: 63% to clarithromycin, 52% to metronidazole, and 40% to both. In total 4,019 were treated empirically: mean age was of 50 years, 64% were women and 5% had penicillin allergy. 58% of indications were dyspepsia and 17% gastroduodenal ulcer. <sup>13</sup>C-UBT was used in 49% of the cases to diagnose the infection. Mean efficacy was 77% (by ITT) and 83.5% (by PP). 7 and 10-days regimens did not reach optimal efficacy except for single-capsule bismuth quadruple therapy (>90% PP). 14-days regimens with double doses esomeprazole reported better results (>90% PP) when quinolones were used in triple regimens and bismuth quadruple therapies. After non-bismuth quadruple failure, efficacy was reported higher when the triple therapy with moxifloxacin or the bismuth quadruple therapy with levofloxacin were used. Over 97% of patients were compliant. AEs were reported in 29% of the cases and tolerance was similar among therapies. Most frequent second-line use and efficacy per antibiotic combination is shown in the table.

Treatment	N	% Use	N (ITT)	ITT (%)	(95% CI)	N (PP)	PP (%)	(95% CI)
Triple-A+L	1,449	36.1	1,349	77	(75-79)	1,271	81	(79-83)
Pylera	510	12.7	466	87	(84-90)	442	91	(88-94)
Quadruple-A+L+B	459	11.4	446	88	(85-91)	421	90	(87-93)
Triple-C+A	414	10.3	358	51	(46-56)	221	79	(74-84)
Quadruple-M+Tc+B	179	4.5	167	81	(75-87)	158	84	(78-90)
Quadruple-C+A+M	145	3.6	133	83.5	(77-90)	131	84	(78-90)
Triple-A+Mx	140	3.5	138	88	(83-93)	134	91	(86-96)
Triple-A+M	85	2.1	79	56	(45-67)	73	59	(48-70)
Total	3,966	98.7	3,689	77	(76-78)	3,346	83	(82-8)

ITT - intention to treat, PP - per-protocol, 95%CI - 95% confidence interval, PPI - proton pump inhibitor, C - clarithromycin, M - metronidazole, T - tinidazole, A - amoxicillin, L - levofloxacin, B - bismuth salts, Tc - tetracycline, Mx - moxifloxacin, N - Total of patients receiving an empiric treatment

[Most frequent second-line use and efficacy per antibiotic combination]

**Conclusion:** Second-line triple therapies generally provide low eradication rates except when prescribing moxifloxacin for 14 days. Bismuth-containing quadruple therapies seem to provide higher efficacy, especially the combination of bismuth with a PPI, levofloxacin and amoxicillin or single capsule bismuth quadruple therapy.

**Introduction:** *Helicobacter pylori* (HP) infection is significantly more frequently diagnosed in patients with diabetes. Patients with type 2 diabetes infected with HP showed higher values of estimated Homa insulin resistance factor (HOMA-IR) than those without coexisting infection. Insulin

resistance in patients with type 1 diabetes (DMT1) is associated with thickening of the intima media complex thickness complex (IMT), accumulation of *advanced glycation end products (AGEs)* in the skin and progression of chronic complications.

**Aims & Methods:** The aim of this study is to assess the relationship between the incidence of *H. pylori* infection and the accumulation of *AGEs* in the skin in patients with type 1 diabetes.

The study included 103 patients with DMT1 meeting the criteria for inclusion. Inclusion criteria were: age > 18 years, caucasian, duration of DMT1 > 5 years. Exclusion criteria: treatment with proton pump inhibitors, H2 blockers and bismuth preparations, steroids, non-steroidal anti-inflammatory drugs and antibiotics within one month prior to the start of the study, pregnancy, and other chronic gastrointestinal diseases. A fast, qualitative, one-step test was performed to detect the HP antigen in faecal samples (Helicobacter Antigen Test by Hedrex). The content of AGEs in the skin was estimated using an AGE Reader device (DiagnOptics). The AF score was calculated automatically (the amount of light emitted by the skin to the amount of light emitted by the device).

Anthropometric parameters (height, body weight, BMI, waist and hip circumference, WHR index) were analysed. Basic laboratory parameters: glycated haemoglobin value (HbA1c), lipid profile, inflammatory marker (C-reactive protein) ALT, AST, creatinine and eGFR (MDRD) were also evaluated.

**Results:** HP positive (n=72) and HP negative (n=31) groups did not differ in age, sex, duration of diabetes, metabolic control and inflammatory response markers. The studied groups differed in the amount of AGEs in the skin. This relationship between *H. Pylori* infection and increased AGEs content in the skin was confirmed in a multifactor regression model taking into account age, sex, DM duration, HbA1c, BMI, LDL cholesterol and the presence of hypertension and tobacco use.

**Conclusion:** Increased accumulation of *AGEs* in the skin in patients with DMT1 with coexisting *H. pylori* infection, may be an indication to pay special attention to eradication treatment in this group of patients.

**Contact E-Mail Address:** moonsin12345@naver.com

**Introduction:** *Helicobacter pylori* (HP) infection is well known to contribute to the development of gastric cancer (GC). Eradication after endoscopic treatment of early GC is recommended to prevent metachronous cancer in the remnant stomach. In addition, HP eradication therapy after surgical treatment of GC can improve the survival rate of GC patients. In this study, we aimed to investigate the rate of HP diagnosis and eradication treatment after GC surgery in a tertiary institute in Korea.

**Aims & Methods:** Patients who received surgical treatment after diagnosis of GC at Seoul National University Bundang Hospital from 2003 to 2017 were retrospectively analyzed using Electronic Medical Recording and Clinical Data Warehouse (CDW). HP examinations (histology CLO test, and urea breath test) before and after surgery, prescription for eradication, and follow-up examination results are reviewed in detail.

**Results:** Total 3,734 patients were diagnosed with GC and received surgical treatment. 2,272 patients (60.8%) were tested (1,372 patients preoperatively; 905 patients after surgery) (Fig.). 1,283 patients (56.5%) were positive for HP infection. Among HP+ GC patients 354 patients (27.6%) received eradication treatment and 89 patients were followed-up loss. 237 of 265 patients (89.4%) were finally successfully eradicated, but 28 patients were failed to eradicate. Among 929 HP+ GC patients who did not receive HP treatment 345 showed spontaneous negative conversion during follow-up tests. 71 patients showed fluctuation of test results without eradication (dynamic changes for HP), and 989 patients were persistently negative for HP (Fig.).

**Conclusion:** Both diagnostic test and eradication treatment rates in patients received GC surgery were significantly low, about one-third patients were not tested even once, and only about 20% of HP-positive patients were successfully eradicated. Considering the high prevalence of GC in Korea and potential benefits of eradication therapy in GC patients, these low rates are disappointing. More attentions and interests of clinicians for GC patients with surgery are needed in terms of HP eradication.

**Introduction:** Early gastric cancer patients have a good prognosis after radical resection. However, there is risk of metachronous gastric neoplasm (MGN) if the patients have a gastric remnant after the surgery. The aim of this study was to clarify the risk factors for MGN after partial gastrectomy for gastric cancer.

**Aims & Methods:** Data of 680 patients who received surgical treatment after diagnosis of gastric cancer (GC) at Seoul National University Bundang Hospital from 2003 to 2017 were retrospectively analyzed using Electronic Medical Recording and Clinical Data Warehouse (CDW). A univariate Cox proportional hazards model was used to identify possible covariates as significant risk factors for MGN. Then, the variables with  $p < 0.2$  were subjected to multivariate Cox proportional hazards model to identify independent contribution. In addition, the variables which were considered to be possible risk factors for MGN based on the previous studies were also analyzed in multivariate model.

**Results:** Total 680 patients were diagnosed with GC and received surgical treatment, and 524 patients who received subtotal, proximal, or distal gastrectomy for curative purposes were enrolled. Baseline characteristics of the patients were shown in Table 1. Among these patients, 11 patients (1.6%) were diagnosed as having MGN in the gastric remnant. Clinicopathologic characteristics of MGNs were summarized in Table 2. 6 of 11 (55%) were treated by endoscopic resection, and 4 of 11 (36%) were received surgery. Statistical analysis showed that male sex was the only independent risk factor (Table).

Variable	Patients with MGN (%) (n=11)	Patients without MGN (%) (n=513)	P value
Sex: Female	0 (0%)	198 (39%)	<b>*0.01</b>
Male	11 (100%)	315 (61%)	
Family history of GC: No	6 (55%)	107 (21%)	0.06
Yes	5 (45%)	406 (79%)	
Smoking status: No	2 (18%)	205 (40%)	0.21
Yes	9 (82%)	308 (60%)	
Alcohol drinking: No	3 (27%)	168 (33%)	1.00
Yes	8 (73%)	345 (67%)	
Gastric Atrophy: Absent or mild	11 (100%)	458 (89%)	0.62
Moderate or severe	0 (0%)	55 (11%)	
Intestinal Metaplasia: Absent or mild	7 (64%)	412 (80%)	0.24
Moderate or severe	4 (36%)	101 (20%)	
HP status: Never	6 (55%)	170 (33%)	0.25
Past	3 (27%)	138 (27%)	
Current	2 (18%)	205 (40%)	
Type of initial GC: EGC	8 (73%)	322 (63%)	0.75
AGC	3 (27%)	191 (37%)	

MGN, metachronous gastric neoplasm; *H. pylori*, *Helicobacter pylori*; IM, intestinal metaplasia.

\*Results were considered statistically significant when p-values were less than 0.05

[Table 1. Clinicopathological characteristics of patients with and without MGN.]

There is a possibility that family history of GC might be also a risk factor for MGN, but the probability value was not statistically meaningful ( $p=0.06$ ) mainly because the recurrence number was low.

**Conclusion:** Our data suggested that more intensive surveillance including follow-up endoscopy is needed for the remnant stomach in patients with these risk factors to detect MGN at its early stage. Further analysis is undergoing.

**Disclosure:** Nothing to disclose

**Introduction:** *Helicobacter pylori* (*Hp*) infection is widely known as a main cause of gastric cancer. In the past, most gastric cancer cases were infected with *Hp*. Therefore, *Hp*-negative gastric cancer (HPNGC) cases were uncommon, most of which were undifferentiated adenocarcinoma (UDA=diffuse-type adenocarcinoma in Lauren classification). Nowadays, the rate of *Hp* infection is decreasing with passing generations in Japan. HPNGCs, which were considered rare, are now being reported more often including specific histological types of cancers like gastric adenocarcinoma of fundic gland type (GAFG) and UDA [1,2]. However, the histological classification, and the endoscopic and clinicopathological features of HPNGC have not been fully described.

**Aims & Methods:** HPNGCs were extracted from 849 lesions of early gastric cancers resected endoscopically from April 2009 to January 2019. The samples were classified histologically, and their endoscopic and clinicopathological features were analyzed retrospectively.

**Results:** We found 51 cases (55 lesions) of HPNGC (6.5%) which were classified into: GAFG, gastric adenocarcinoma of fundic gland mucosal type (GAFGM), gastric-phenotype differentiated adenocarcinoma (G-DA), gastrointestinal-phenotype differentiated adenocarcinoma (GI-DA), and UDA=25/4/6/11/9 lesions, respectively (differentiated adenocarcinoma = intestinal-type adenocarcinoma in Lauren classification). GAFG was found in 13 males and 12 females with a mean age of 66.6 years (location: U/M/L=21/3/1, tumor size: 7.4mm, color: white(W)/red(R)=22/12, macroscopic type: elevated/flat or depressed=17/8; invasion depth: mucosa(M)/submucosa(SM)=7/18). GAFGM was found in 3 males and 1 female with a mean age of 51.7 years (location: U/M/L=4/0/0, tumor size: 8.7mm, color: W/R=1/3, macroscopic type: elevated/flat or depressed=4/0, invasion depth: M/SM=1/3). G-DA was found in 4 males and 2 females with a mean age of 57.8 years (location: U/M/L=3/3/0, tumor size: 6.9mm, color and macroscopic type: 5 reddish protruded lesions like a raspberry and 1 whitish flat-elevated lesion). A total of 4 out of 5 raspberry-shaped lesions were disappeared by biopsy and their invasion depth could not be measured. The invasion depth was M in the other 2 cases. GI-DA was found in 6 males and 5 females with a mean age of 56.8 years (location: U/M/L=3/1/7, tumor size: 9.2mm, color: W/R=2/9, macroscopic type: elevated/flat or depressed=6/5, invasion depth: M/SM=11/0). UDA was found in 6 males and 3 females with a mean age of 54.9 years (location: U/M/L=0/6/3, tumor size: 7.9mm, color: W/R=8/1, macroscopic type: elevated/flat or depressed=0/9, invasion depth: M/SM=9/0). All of UDA were signet-ring cell carcinoma. No vascular invasion and relapse-free survival was confirmed in patients with cancer of all histological types. Magnifying endoscopy with narrow-band imaging (M-NBI) was performed in 51 out of the 55 lesions at maximum magnification. Of these, 33 lesions were diagnosed as non-cancer by M-NBI (33/51; 64.7%).

**Conclusion:** This study clarified the characteristics of HPNGCs, such as location, color, and macroscopic findings differed by their histological type as follows: (1) GAFG, GAFGM, and G-DA tended to occur in U/M as red or white elevated lesions; (2) UDA tended to occur in M/L as white flat or depressed lesions; and (3) GI-DA tended to occur in U/M/L as red elevated or depressed lesions. There were many lesions difficult to diagnose as cancer by M-NBI. We conclude that understanding the endoscopic and clinicopathological features of each histological type may provide more precise endoscopic diagnosis of HPNGC.

**Contact E-Mail Address:** nohkkang@hanmail.net

**Introduction:** Recently we have shown reversibility of atrophic gastritis and intestinal metaplasia after *Helicobacter pylori* eradication up to 10-year follow-up study. Only a few studies have evaluated pepsinogen (PG) change after eradication of *H. pylori* but there was no study regarding this issue in patients with gastric cancer (GC) and dysplasia.

**Aims & Methods:** The aim of this study is to evaluate the effect of *H. pylori* eradication on PG in GC and dysplasia patients in comparison to control group with a long-term follow-up. From March 2003 to February 2019, we prospectively enrolled 368 subjects with GC and dysplasia and 610 subjects with non-GC and non-dysplasia as control group. All of GC and dysplasia patients were treated by endoscopic mucosal resection or submucosal dissection. *H. pylori* tests (Giemsa stain, CLotest and culture) were performed to evaluate HP status. Serum PG levels were measured using a Latex-enhanced Turbidimetric Immunoassay (Shima Laboratories, Tokyo, Japan) before and after eradication, compared by using linear mixed model and student's t-test. The follow-up points were classified as 1-11 months, 12-23 months, 24-35 months and more than 36 months.

**Results:** Among 368 GC/dysplasia patients, 102 (27.7%) were *H. pylori*-negative, 179 (48.6%) were *H. pylori*-eradicated, and 87 (23.7%) were *H. pylori* non-eradicated/eradication failure. Among 610 control group patients, 373 (61.1%) were *H. pylori*-negative, 168 (27.6%) were *H. pylori*-eradicated, and 69 (11.3%) were *H. pylori* non-eradicated/eradication failure. In GC/dysplasia there were not significantly different in PG values in *H. pylori*-negative and *H. pylori* non-eradicated/eradication failure group at all follow-up points compared to those at baseline (Table).

	Before	1-11 months	p-values	12-23 months	p-values	24-35 months	p-values	≥36 months	p-values
Control	168	98		65		22		19	
PG I	75.6 (3.18)	64.0 (3.73)	0.006	55.2 (4.59)	<0.001	44.4 (7.70)	0.001	49.2 (8.67)	0.037
PG II	23.5 (1.07)	11.7 (1.34)	<0.001	10.4 (1.67)	<0.001	8.93 (2.86)	<0.001	10.8 (3.12)	0.001
PG I/II ratio	3.94 (0.16)	5.99 (0.20)	<0.001	5.38 (0.25)	<0.001	5.09 (0.42)	0.106	4.65 (0.47)	1.000
GC/ Dysplasia	179	76		89		51		57	
PG I	55.7 (2.65)	41.0 (3.68)	<0.001	40.3 (3.56)	0.002	36.8 (4.55)	0.003	40.8 (4.53)	0.043
PG II	20.7 (0.70)	10.6 (1.05)	<0.001	9.12 (0.98)	<0.001	8.75 (1.29)	<0.001	10.4 (1.23)	<0.001
PG I/II ratio	2.80 (0.12)	4.04 (0.16)	<0.001	4.38 (0.15)	<0.001	4.59 (0.19)	<0.001	4.19 (0.20)	<0.001

[Table. Comparison of gastric cancer and dysplasia with control in pepsinogen levels before and after eradication of *H. pylori*]

In contrast *H. pylori*-eradicated group of GC/dysplasia mean serum PG I (55.7 vs. 41.0,  $p<0.001$ ) became significantly lower and mean PG I/II ratio (2.80 vs. 4.04,  $p<0.001$ ) became higher at 1-11 months after eradication compared to those at baseline (Table). This improvement of PG values after eradication maintained during all follow-up points with no significant

differences between *H. pylori*-eradicated and *H. pylori*-negative group. However, mean serum PG II did not show any change in both of control or GC/dysplasia group. Control group showed similar tendency to the GC/dysplasia (Table).

Between the control and GC/dysplasia groups significant difference in mean serum PG I and mean PG I/II ratio were observed at 1-11 months (PG I: 41.0 vs. 64.0,  $p < 0.001$ , PG I/II ratio: 4.04 vs. 5.99,  $p < 0.001$ ) and 12-23 months (PG I: 40.3 vs. 55.2,  $p = 0.01$ , PG I/II ratio: 4.38 vs. 5.38,  $p = 0.001$ ) after eradication. These differences disappeared from  $\geq 24$  months of follow-up

**Conclusion:** Considering the PG I and PG I/II ratio of GC/dysplasia group become similar to those of control group at the long-term follow-up after eradication, *H. pylori* eradication plays an important role in the prevention of metachronous cancer/dysplasia development.

### P1346 THE PREVALENCE OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN PATIENTS WITH HYPERLIPIDEMIA

Kvit K.<sup>1</sup>, Kharchenko N.<sup>2</sup>, Chornenko O.<sup>3</sup>, Dorofeeva U.<sup>3</sup>

<sup>1</sup>Danylo Halytsky Lviv National Medical University, Therapy №1 and Medical Diagnostics, Lviv, Ukraine, <sup>2</sup>Shupyk National Medical Academia of Postgraduate Teaching, Gastroenterology, Dietology and Endoscopy, Kyiv, Ukraine, <sup>3</sup>Medicover Ukraine, Lviv, Ukraine

**Contact E-Mail Address:** akskris@ukr.net

**Introduction:** Microorganisms which colonize the intestine are capable to impact on cholesterol metabolism by affecting the key stages of its synthesis. Excessive microbial growth of anaerobes in the jejunum, which is typical for syndrome of bacterial overgrowth (SIBO), leads to its damage, with the development of system inflammation, that causes early deconjugation of bile acids with the formation of their toxic salts and impaired enterohepatic circulation. In this case, induction of hypercholesterolemia is possible, especially in individuals with hereditary predisposition.

**Aims & Methods:** The aim of this study was to determine the prevalence SIBO in a series of patients with hyperlipidemia and in controls. 30 patients with hyperlipidemia (14 men and 16 women) average age 33,69 $\pm$ 1.73 years with average BMI 24,4 $\pm$ 1.54 were examined in "Medicover Ukraine" (Lviv, Ukraine). The diagnostic criteria were: BMI not more than 25, waist circumference < 94 cm for male, < 80 cm for female, no significant alcohol consumption. 20 control subjects (8 men and 12 women), an average 29,9 $\pm$ 0.68 years, BMI 24,2 $\pm$ 1.21 were matched with main group patients. All controls had normal lipid range. Both groups of patients underwent biochemical evaluation - lipid profile, C-reactive protein, ALT, AST, GGTP, bilirubin, apoB. Ultrasound examination was proved to all patients of both groups. with aim to exclude the patients with fatty liver disease as one of the reasons of increased lipids level. All subjects were examined by a lactulose breath test.

**Results:** The prevalence of SIBO in hyperlipidemia group was 78.9%. Small intestinal transit time amounted 100 minutes. Meanwhile, the SIBO occurrence in controls was 40% with average time of small intestine transit 140 minutes. The measurement of SIBO by lactulose test showed the equal result of the basal dose of hydrogen in both groups. In contrast, the maximal dose was particularly higher in patients with hyperlipidemia in comparison with control group (94,7 $\pm$ 13,69 vs. 36,13 $\pm$ 5,4). There was remarkable positive connection between LDL, TG, VLDL and the dose of exhaled hydrogen on 120 minute ( $r=0.6$ ,  $r=0.62$ ,  $r=0.7$  respectively) and strong negative correlation between HDL and 120 minutes dose ( $r=-0.74$ ) in main group. Surprisingly, CRP did not interrelate with bacterial overgrowth in both groups. In contrast, there was strong correlation relationship between AST and AST/ALT ratio and SIBO existence.

**Conclusion:** The prevalence of SIBO in patients with hyperlipidemia is predominantly higher than in patients without lipid metabolism disturbance. The hydrogen level is significantly higher in patients with hyperlipidemia in comparison with controls. There is an axis between high LDL, VLDL and TG level and hydrogen rate in patients with hyperlipidemia.

**Introduction:** Although aspirin (ASA) is widely used all over the world to prevent cardiovascular diseases, ASA is well known to cause peptic ulcer. Proton pump inhibitor (PPI) is also used to prevent ASA induced peptic ulcer. However, with the recent development of enteroscopy, it has been reported that not only ASA causes small intestinal injury, but also PPI deteriorates the injury in human. Establishing the animal model of ASA induced small intestinal injury has been difficult since administration of ASA cannot stably induce mucosal injuries in mice. The animal model should be established to reveal the mechanisms underlying the deterioration due to PPI in order to establish possible treatment.

**Aims & Methods:** Our aims are to establish the mouse model of ASA induced small intestinal injury, to investigate the effect of PPI on gut microbiota, and to find the possible treatment using probiotics.

Male C57BL/6Jcl mice were fed with 60% fructose diet for 9 weeks, and administered 200mg/kg of ASA 3 hours before sacrifice. To investigate the effect of PPI on ASA induced small intestinal injury, 20mg/kg of omeprazole was administered intraperitoneally once a day. *Bifidobacterium bifidum* G9-1 was administered orally ( $1 \times 10^9$  CFU / head) from 1 week before sacrifice until the end. The degree of small intestinal injury was assessed using histological score. *Akkermansia muciniphila* was administered ( $1 \times 10^9$  CFU / head) orally for 9 weeks instead of PPI.

**Results:** By feeding high fructose diet, ASA induced small intestinal injury was successfully created. On the other hand, no damage was found in the mice fed with basal diet. These intestinal damages were exacerbated with PPI, whose histological score was higher than that of ASA without PPI group. As PPI has been reported to cause gut dysbiosis, we investigated gut microbiota in small intestine. *Bifidobacterium* was decreased by PPI administration, and was decreased when mice were fed with high fructose diet compared to the mice fed with basal diet. The relative abundance of *Akkermansia* in jejunum dramatically increased from 0.08% to 2.5% after the administration of ASA and PPI ( $p < 0.05$ ), but was significantly suppressed from 2.5% to 0.3% after the administration of *Bifidobacterium bifidum* G9-1 with ASA and PPI ( $p < 0.05$ ).

Furthermore, when administered ASA and PPI, the thinning of mucus layer in jejunum was significantly induced. It was also observed in the mice that received an oral administration of *Akkermansia muciniphila* instead of the administration of PPI. On the other hand, when administered *Bifidobacterium bifidum* G9-1, thinning of mucus layer was ameliorated. While the number of goblet cells in jejunum were significantly lower in ASA + PPI group than that of vehicle group ( $p < 0.05$ ), reduction of goblet cells was significantly improved with the administration of *Bifidobacterium bifidum* G9-1 ( $p < 0.05$ ).

	vehicle	ASA	ASA+PPI	ASA+PPI+Gg-1	Akkermansia
Injury	-	+	++	-	
Thinning of mucin layer	-		+	-	+

[Small intestinal injury and thinning of mucin layer]

**Conclusion:** These results suggest that gut dysbiosis caused by PPI such as increase of *Akkermansia* and reduction of *Bifidobacterium*, leads to the thinning of mucus layer through the reduction of goblet cells in small intestine. That may cause dysfunction of intestinal barrier, which results in the susceptibility to ASA induced small intestinal injury.

**Introduction:** Genome wide association studies identified a plethora of risk genes for the development of Crohn's disease (CD) one of which is glutathione peroxidase 4 (GPX4) (1). Its main function is to maintain cellular homeostasis by reducing lipid peroxides (LPO) in cellular membranes (2) and to prevent cell death. The prime substrate for LPO are polyunsaturated fatty acids (PUFA) in cellular membranes. The increasing consumption of specific PUFAs, such as AA and DHA, due to an increasing consumption of a western style diet was paralleled by a rising incidence of IBD during the last decades. However, the impact of increased PUFA uptake on the development of CD remains elusive.

**Aims & Methods:** The aim of the study was to analyse the influence of dietary lipids in a genetically susceptible host. We crossed *Gpx4<sup>flox/flox</sup>* (3) mice with *Villin-Cre<sup>+/+</sup>* mice to obtain *Gpx4<sup>flox/wt</sup>;Villin-Cre<sup>+/+</sup>* (*Gpx4<sup>+/IEC</sup>*) mice, that specifically delete one allele of *Gpx4* in the intestinal epithelium. WT and *Gpx4<sup>+/IEC</sup>* littermates were fed a western style diet (WD) or a PUFA enriched western style diet (PUFA WD) for 3 months. Inflammation was assessed on H&E tissue sections. Staining for neutrophils was done with MPO and GR1. Microbiota was analysed in fecal samples by 16s amplicon sequencing.

**Results:** *Gpx4<sup>+/IEC</sup>* mice on a PUFA enriched western style diet developed small intestinal inflammation while WT littermates were unaffected. The inflammation mainly occurred in the jejunum while other parts of the small intestine and as well as the colon were not affected. Inflammation was characterised by infiltrating neutrophils and mononuclear cells as well as the formation of granuloma like lesions. Additionally, increased levels of the IL-8 homologue CXCL-1 were found in epithelial cell scrapings of *Gpx4<sup>+/IEC</sup>* mice. The fecal microbiota analysis revealed a decreased  $\alpha$ -diversity in PUFA WD fed mice as well as a distinct  $\beta$  diversity when compared to WD fed mice. However, we found no differences between WT and *Gpx4<sup>+/IEC</sup>* mice.

**Conclusion:** Here we show that PUFAs in a western style diet evoke small intestinal inflammation in GPX4 deficient hosts, independent from microbiota alterations. We identified these PUFAs as a non toxic dietary component that evokes CD like inflammation in the small intestine.

**Introduction:** Genetic variation of Glutathione peroxidase 4 (GPX4) is associated with the development of Crohn's disease (CD) (1). GPX4 is an anti-oxidative acting enzyme particularly reducing lipid peroxides (LPO) within biomembranes, and particularly polyunsaturated fatty acids (PUFAs) which are prone to oxidation due to their carbon-carbon double bond backbone (2).

PUFAs are essential fatty acids and enriched in a common western style diet rich in red meat, eggs and oils. Dietary enrichment of arachidonic acid, an  $\omega$ -6 PUFA, paralleled a rising incidence of inflammatory bowel disease (3). How dietary PUFAs affect the development of CD remains currently unknown.

**Aims & Methods:** In MODE-K cells, a small intestinal epithelial cell line (IECs), *Gpx4* siRNA silencing was established. Silenced cells were stimulated with palmitic acid, a saturated fatty acid, oleic acid and palmitoleic acid, two monounsaturated fatty acids as well as a range of  $\omega$ -3 and  $\omega$ -6 PUFAs (stearidonic acid, eicosapentaenoic acid, docosapentaenoic acid, arachidonic acid, docosahexaenoic acid), respectively. LPO was measured with BODIPY 581/591 C11 by flow cytometry and cytokine production was assessed and confirmed by a multiplex ELISA in the supernatant.

**Results:** *Gpx4* silencing led to increased levels of LPO, which was further aggravated by the stimulation with  $\omega$ -6 PUFA arachidonic acid and a range of  $\omega$ -3 PUFAs. Stimulation with the same PUFAs led to an increased release of IL-6, CXCL-1 as well as other pro-inflammatory cytokines and chemottractants only in *Gpx4*-deficient IECs. The addition of  $\alpha$ -tocopherol, a lipophilic reactive-oxygen species scavenger, prevented the formation of LPO and the release of cytokines. Interestingly saturated and monounsaturated fatty acids neither induced cytokine production nor aggravated LPO in *Gpx4*-silenced IECs.

**Conclusion:** Our data provides evidence that specific non-toxic dietary lipids, which are enriched in a western-style diet, induce cytokine production in GPX4-deficient IECs which is accompanied by increased levels of LPO which could be reversed by LPO scavenging.

**Introduction:** Potential probiotic strains protect the intestinal barrier in animal models, but human data are lacking. We aimed to study the effect of *Lactobacillus rhamnosus* CNCM I-3690 on intestinal hyperpermeability, occurring during public speech (1), and the relation with stress-related symptoms and fecal microbiota diversity.

**Aims & Methods:** Healthy students were randomized to the *L. rhamnosus* fermented milk or placebo (acidified milk) consumed daily (2 x 125g) for 4 weeks prior to public speech (exam) and 2 more weeks until NSAID-administration (indomethacine 125mg; positive control). Small intestinal permeability was quantified by a 2h lactulose-mannitol ratio (LMR), fractional excretion of mannitol (FEM) and lactulose (FEL) at baseline and after the exam. Salivary cortisol was measured with ELISA and the State-Trait Anxiety Inventory (STAI) and Perceived Stress Scale (PSS) were completed at both visits. Stool samples were collected for 16S sequencing in a subset of subjects (n= 76) at both visits. Primary outcome was the change during stress vs. baseline of LMR between treatment groups. Mixed models with contrasts between groups were applied with correction for multiple testing for secondary endpoints only. Within-group changes were compared to nominal alpha 5%.

**Results:** In total, 92 students (55 female, mean age 23±1.9 years) were included (46 per group). No differences between groups were found for change in LMR (delta=-0.003, 95%CI [-0.01;0.005], p=0.51), FEL or FEM. Within-group analyses showed similar LMR and FEL but an increase of FEM during exam vs. baseline for placebo but not *L. rhamnosus* (Table 1). LMR and FEL increased in both groups after NSAIDs (all p< 0.001) with a trend for an increase in FEM in the placebo (p=0.07) but not *L. rhamnosus* group (p=0.39). Salivary cortisol increased during exam vs. baseline in the placebo and *L. rhamnosus* group with no difference between groups. The increase in STAI before the exam vs. baseline was significant in the placebo and *L. rhamnosus* groups with a lower increase in *L. rhamnosus* vs. placebo (delta=-4.73, 95%CI [-8.84;-0.62], p=0.02). The increase in PSS before the exam vs. baseline was significant in the placebo and not *L. rhamnosus* group with a trend for a lower increase in *L. rhamnosus* vs. placebo (delta=-2, 95%CI [-4.24;0.32], p=0.09). Preliminary analyses of the fecal microbiota suggested an increase of the alpha-diversity in the *L. rhamnosus* group vs. placebo group after the exam. No serious adverse events occurred.

**Conclusion:** Despite the primary endpoint was not reached, *L. rhamnosus* CNCM I-3690 seems to prevent stress-induced hyperpermeability to mannitol, a pathway that differs from NSAID-induced hyperpermeability to lactulose. Subjective but not objective stress-markers were reduced suggesting gut-brain mediated effects via the microbiota, for which preliminary analyses suggested an increase of the alpha-diversity upon consumption of the *L. rhamnosus* vs placebo.

Variable	Placebo (n= 46)			L. rhamnosus (n= 46)		
	baseline	exam	p-value	baseline	exam	p-value
LMR	0.03±0.01	0.03±0.01	0.78	0.03±0.02	0.03±0.01	0.54
FEL (%)	0.10±0.05	0.12±0.07	0.28	0.12±0.05	0.12±0.05	0.76
FEM (%)	9.3±2.5	10.6±3.7	0.02	9.5±3.9	10±4	0.23
Cortisol (ng/ml)	5.8±5.4	13.9±7.1	<0.0001	4.9±3	12.6±6.2	<0.0001
STAI	28.7±6.4	45.2±1.4	<0.0001	29.8±5.7	41.8±1.7	<0.0001
PSS	7.8±4.9	10.3±5.1	0.002	7.9±4.7	8.4±5.4	0.58

**Introduction:** Irritable bowel syndrome (IBS) is a chronic gastrointestinal disorder characterized by recurrent abdominal pain associated with altered bowel motility and high frequency of mental comorbidities such as psychological stress, anxiety and depression. IBS remains a chronic debilitating disorder with undefined pathophysiological mechanisms for which specific biomarkers are lacking. Enhanced humoral immunity has been identified in the intestinal mucosa; however, the role of plasma cells has not been addressed.

**Aims & Methods:** Our aim is to characterize the antibody-mediated response and its association with IBS pathophysiology. Mucosal jejunal biopsies and stool samples were obtained from diarrhoea-IBS (IBS-D; n = 18) patients meeting Rome III criteria and age-matched healthy volunteers (H; n = 18) as the control group. Bowel movements, stool consistency and abdominal pain were monitored (10 days prior to biopsy). Psychological stress and depression were assessed by validated questionnaires. The number and the activation of mucosal plasma cells were determined by transmission electron microscopy. Luminal immunoglobulins (Ig) were determined in faecal content by ELISA.

**Results:** Mucosal plasma cells were found in the subepithelial area and located in proximity to nerve endings. This distance was significantly lower in samples from IBS-D compared to H (IBS-D: 1.26 (0.21-4.25); H: 2.13 (0.26-7.06) micrometers; P< 0.05). Plasma cells showed morphological signs of activation such as enlarged cytoplasm and expanded endoplasmic reticulum cisterna, features mainly observed in IBS-D. Moreover, while individual plasma cells were observed scattered in control group, clusters of long-lived plasma cells featured the jejunal mucosa of IBS-D. The number of plasma cells was higher in IBS-D respect to H (IBS-D: 1,407±257; H: 336 ± 83.9 plasma cells/mm<sup>2</sup>, P< 0.05) as previously reported (Gut, 2015) and significantly correlated with proximity to nerve endings (r<sup>2</sup>=0.63, P< 0.01). The quantification of Ig in faeces revealed no differences in sIgA, IgM and IgE concentration between groups, while IBS-D showed significantly higher concentration of total IgG (IBS-D: 11.38 (1.5-45.82); H: 3.68 (0.61-35.34) ng/mg protein; P< 0.05), IgG2 (IBS-D: 0.71± 0.53; H: 0.40 ± 0.29 ng/mg protein; P< 0.05) and IgG3 respect to H, the later not reaching statistical significance (IBS-D: 1.05 (0.28-3.65); H: 0.91 (0.19-1.83) ng/mg protein; P=0.08). Both, H and IBS-D groups had equivalent concentration of IgG1 and IgG4. Notably, luminal IgG positively correlated with abdominal pain (r<sup>2</sup>=0.50; P< 0.05) and distance of plasma cells to nerves negatively correlated with psychological stress (r<sup>2</sup>=0.55; P< 0.05) and depression (r<sup>2</sup>=0.46; P< 0.05).

**Conclusion:** Mucosal humoral immunity and its interaction with nerves are identified as potential factors associated with brain-gut axis dysfunction in IBS-D. Studies aimed at determining the underlying mechanisms warrant further investigation.

**Introduction:** Patients undergoing open abdominal surgery often suffer from a transient episode of intestinal dysmotility referred to as postoperative ileus (POI). Intestinal manipulation (IM) during the surgery evokes tissue damage and consequently an inflammatory response leading to impaired gastrointestinal (GI) motility. Recently our lab revealed a critical role for monocyte-derived macrophages (MΦs) in supporting neuromuscular function and restoring intestinal homeostasis after surgical trauma. Blocking monocytes recruitment to the muscularis externa (ME) after IM increased neutrophil-mediated immunopathology and prolong the clinical outcome of POI.

**Aims & Methods:** Despite significant advances in our understanding of MΦ regulation and function during intestinal inflammation, the factors and the effector molecules responsible for the pro-resolving MΦ-effect remain not well defined. To answer these questions, we have employed state of the art single cell RNA sequencing (sc-RNA seq) of different subset of intestinal MΦs at the steady state and during the acute and resolution phase of POI.

Wild-type female mice (WT; C57BL/6J<sup>OlaHsd</sup>) and Csf1rCreERT2/+ Arg1fl/fl were subjected to IM to induce POI. The severity of POI was evaluated by assessing GI transit, and ME inflammation via flow cytometric analysis of recruited immune cells. Immune cells infiltrating the muscularis externa of naïve mice and of mice 1 day and 3 days after IM were analysed by sc-RNA seq. Sc-RNA seq was performed on the Chromium Single Cell Gene Expression Solution (10x Genomics). Seurat R package was used for graph-based clustering and visualizations. 'SingleR' package was used for immune cell type annotations. Trajectory analysis was performed with Monocle2. Gene set enrichment analysis (GSEA) was done on the average expression of the cell clusters using java GSEA Desktop Application.

**Results:** Sc-RNAseq of immune cells from the naïve, inflamed and resolving muscularis revealed a complex immune cell landscape during different phases of POI. Resident immune cell populations including muscularis MΦs were seen in naïve ME as expected. At day 1 post IM, myeloid cell infiltration was apparent including mainly monocytes and neutrophils. At day 3 post IM, most of the infiltrated myeloid cells seemed to be cleared as the inflammation resolves. The heterogeneity between the myeloid cell types seen on Day1/Day3 go beyond the current understanding by using conventional cell surface marker-based flow cytometry. Trajectory analysis revealed possible differentiation trajectory of classical monocytes to give rise to mature MΦs via multiple intermediate phenotypes. GSEA analysis showed that PPAR-γ targets are differentially upregulated between the cells at the beginning and end of the trajectory hinting at a possible role for PPAR-γ in driving the differentiation of monocytes towards mature MΦs. During this differentiation, the monocyte derived Ly6C low and MHCII low MΦs express the major pro- resolving MΦ factor Arginase 1. Mice lacking Arginase 1 in myeloid cells failed to recover gastrointestinal transit after IM. Hence, the Arg1 expressing myeloid cells could be directly responsible for supporting the recovery of gastrointestinal motility after damage.

**Conclusion:** Our study reveals a critical role for monocyte-derived MΦs in restoring intestinal homeostasis after surgical trauma. The specific functions of each of these myeloid sub populations has to be further analysed to deepen our understanding of the intestinal inflammatory cascade and the process of resolution of inflammation which could be key in developing novel therapy.

**Introduction:** Video capsule enteroscopy (VCE) is considered the reference standard for the assessment of small bowel disorders since it has the highest diagnostic yield for the detection of luminal and mucosal alterations. There are no studies comparing VCE with small bowel ultrasonography (B-US). The aim of this study is to compare the diagnostic yield of VCE and B-US in the diagnosis of small bowel disorders.

**Aims & Methods:** The aim of this study is to compare the diagnostic yield of VCE and B-US in the diagnosis of small bowel disorders.

We retrospectively enrolled 159 patients undergoing VCE and B-US for the following indications: obscure gastrointestinal bleedings, suspect or follow-up of known complicated celiac disease, chronic diarrhea or malabsorption syndromes. The interval between the two exams had to be inferior to one year. We evaluated the diagnostic yields of the two techniques. The accuracy of small bowel ultrasonography was determined using VCE as the reference standard.

**Results:** The diagnostic yields calculated in the whole sample were 55% for VCE and 33% for B-US ( $p < 0.05$ ). The subgroups analysis showed that VCE ability to detect pathological signs is higher; there was a statistical significant difference between the diagnostic performances of the two techniques in patients with OGIB (62% vs 14%,  $p < 0.05$ ) and suspect or known complicated celiac diseases (55% vs 35%,  $p < 0.05$ ), while the difference was not statistical significative among patients with chronic diarrhea and malabsorption syndromes (51% vs 46%,  $p = 0.8$ ).

**Conclusion:** Compared to B-US, VCE is more accurate to detect lesions in patients with OGIB and suspect or known complicated celiac disease. B-US could have a role in the screening of celiac disease complications, since it was able to detect patients with severe complications (RCD II, EATL, adenocarcinoma).

In patients with chronic diarrhea and malabsorption syndromes, B-US was able to detect signs suggestive for enteropathies, especially in patients with Chron's disease.

### P1354 COULD NEUTROPHIL-TO-LYMPHOCYTE RATIO PREDICT ULCERATIVE COLITIS FLARE DURING PREGNANCY?

El-Sadek H.

Faculty of Medicine, Zagazig University, Gastroenterology & Hepatology Unit, Internal Medicine Department, Zagazig, Egypt

**Contact E-Mail Address:** hanyelsadek75@yahoo.com

**Introduction:** Women with ulcerative colitis (UC) in remission, frequently suffer from flaring of disease activity during pregnancy. Predicting such problem early in pregnancy, would arouse not to decrease the dose or number of medications used to maintain remission, and hence UC relapse could be avoided. Serum neutrophil-to-lymphocyte ratio (NLR) is a promising simple marker of systemic inflammation.

**Aims & Methods:** The aim of this study was to assess the value of neutrophil to lymphocyte ratio (NLR) in predicting UC flare during pregnancy. In this study, clinical and laboratory data of 27 female patients with UC who got pregnant while in remission were retrospectively analyzed. Baseline serum measurements (early at first trimester) of NLR and other inflammatory markers were recorded. Disease activity during pregnancy was assessed using Truelove and Witts criteria.

**Results:** Flare up of UC throughout pregnancy was noticed in ten patients (10/27, 37.0%), and was significantly associated with increased mean baseline values of platelets count, ESR, CRP and NLR ( $P = 0.035$ ,  $P = 0.014$ ,

$P=0.006$  and  $P<0.001$ , respectively). Using logistic regression analysis, baseline NLR was the only independent predictor of UC flare ( $P=0.002$ ). Spearman's correlation analysis showed significant positive correlation between NLR and each of CRP ( $r=0.418$ ,  $P=0.030$ ) and ESR ( $r=0.522$ ,  $P=0.005$ ). The sensitivity and specificity of NLR (90.0% and 88.2%, respectively), at a cut-off level  $\geq 2.85$ , for prediction of UC flare (area under the curve [AUC]=0.915,  $P<0.001$ ), are much higher than that of CRP and ESR. **Conclusion:** The NLR is an effective, simple and readily available biomarker for prediction of UC flare during pregnancy. **Disclosure:** Nothing to disclose

### P1355 GUT MICROBIOTA AND SMALL BACTERIAL OVERGROWTH IN PATIENTS WITH HYPERLIPIDEMIA

Kvit K.<sup>1,2</sup>, Kharchenko N.<sup>3</sup>, Dorofeeva U.<sup>2</sup>, Chornenka O.<sup>2</sup>, Draganchuk O.<sup>2</sup>  
<sup>1</sup>Danylo Halytsky Lviv National Medical University, Therapy №1 and Medical Diagnostics, Lviv, Ukraine, <sup>2</sup>Medicover Ukraine, Lviv, Ukraine, <sup>3</sup>Shupyk National Medical Academia of Postgraduate Teaching, Kyiv, Ukraine

**Contact E-Mail Address:** akskris@ukr.net

**Introduction:** Current data suggests that the intestinal microbiota is involved in the cardiovascular disease occurrence with the host-microbe interaction regulating metabolic pathways. Microorganisms which colonize the intestine are capable to impact on cholesterol metabolism by affecting the key stages of its synthesis. Excessive microbial growth of anaerobes in the jejunum, which is typical for syndrome of bacterial overgrowth (SIBO), leads to its damage, with the development of system inflammation, that causes early deconjugation of bile acids with the formation of their toxic salts and impaired enterohepatic circulation. In this case, induction of hypercholesterolemia is possible, especially in individuals with hereditary predisposition.

**Aims & Methods:** The aim to evaluate the SIBO prevalence in patients with hyperlipidemia. One more idea was to examine the prevalence of SIBO in such patients. 96 patients with hyperlipidemia (average age  $43.03 \pm 2.67$  and BMI  $26.15 \pm 0.67$ ) were examined in "Medicover Ukraine". 47 control subjects, an average age  $48.25 \pm 2.47$  and average BMI  $24.2 \pm 1.21$  were matched with main group by metabolic characteristics. All control subjects had normal lipid range and no history of coronary disease. The average waist circumference in main group was  $98.6 \pm 1.09$  cm (in men),  $86.3 \pm 0.65$  cm (in women), in controls -  $91.2 \pm 2.1$  cm in men,  $82.7 \pm 1.8$  in women. Both groups of patients underwent biochemical evaluation of serum that included blood cell count, lipid profile, C-reactive protein, ALT, AST, GGTP, bilirubin, apo B, apo A. Determination of microbial composition at the level of major microbial phyla was carried out by identification of total bacterial DNA, and DNA of Bacteroidetes, Firmicutes and Actinobacteria was performed with quantitative real-time PCR (qRT-PCR), using gene-targeted primers. All subjects were examined by a lactulose breath test what is one of the most diagnostically valuable methods for determining excessive bacterial growth.

**Results:** The prevalence of SIBO in hyperlipidemia group was 78.9%. Meanwhile, the SIBO occurrence in controls was 40%. The composition of microbiota was not significantly different between main group and control - Bacteroidetes, Firmicutes, Actinobacteria, Firmicutes/Bacteroidetes ratio was equal in both groups ( $p>0.05$ ). Strong negative correlation between Bacteroidetes and Firmicutes ( $r=-0.74$ ), and Bacteroidetes and Firmicutes/Bacteroidetes index ( $r=-0.69$ ) was marked in patients of main group. Moreover, there was strong positive correlation among Firmicutes and CRP ( $r=0.6$ ) and apo B ( $r=0.8$ ). Meanwhile, Actinobacteria in patients with hyperlipidemia had the negative correlation within total, direct, indirect bilirubin ( $r=-0.52$ ,  $r=-0.75$ ,  $r=-0.52$  respectively), CRP ( $r=-0.86$ ) and apo B ( $r=-0.52$ ). BMI strongly correlated with different phyla of bacteria - there was negative correlational relationship between BMI and Bacteroidetes and Actinobacteria ( $r=-0.98$ ), and positive association between BMI and Firmicutes ( $r=0.98$ ).

**Conclusion:** The prevalence of SIBO in patients with hyperlipidemia is predominantly higher than in patients without lipid metabolism disturbance. The decreasing of Bacteroidetes leads to Firmicutes increasing on the background of hyperlipidemia. The growth of Firmicutes level influences on the CRP and apo B level increasing in patients with hyperlipidemia. The increasing of Actinobacteria leads to the bilirubin, CRP and apo B level decreasing in patients with hyperlipidemia. BMI in patients with hyperlipidemia interrelates with gut bacteria.

**Disclosure:** Nothing to disclose

### P1356 CONDITIONED MEDIUM DERIVED FROM BONE MARROW MESENCHYMAL STEM CELLS WITH INFLAMMATORY ACTIVATION REGULATES INFLAMMATORY RESPONSE TO ACUTE RADIATION-INDUCED INTESTINAL INJURY

Zhou W.<sup>1</sup>, Chen H.<sup>1,2</sup>, Zheng Y.<sup>1</sup>, Sha W.<sup>1,3</sup>, Luo Y.<sup>1</sup>

<sup>1</sup>Guangdong Provincial people's Hospital and Guangdong Academy of Medical Sciences, Gastroenterology, Guangzhou, China, <sup>2</sup>Guangdong general hospital, Guangdong general hospital, GuangZhou, China, <sup>3</sup>Guangdong General Hospital Dept. of Gastroenterology, Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** 464695938@qq.com

**Introduction:** Bone marrow mesenchymal stem cells (MSCs) have powerful anti-inflammatory and imm) could improve the structural and functional repair of the small intestine afterunomodulatory properties. Our previous experiments have demonstrated that conditioned medium from bone marrow MSCs with inflammatory activation (MSC-CM<sup>IEC-6(IR)</sup>) acute radiation-induced intestinal injury, but its effects on the inflammatory response to acute radiation-induced intestinal injury have not been defined.

**Aims & Methods:** To investigate the effects of MSC-CM on the inflammatory response to acute radiation-induced intestinal injury. Eighty Sprague-Dawley rats (provided by the experimental center of the North Campus of Sun Yat-Sen University in China) were randomly divided into four groups ( $n=20$ /group): control group, irradiation (IR) group, irradiation+MSC-CM<sup>IEC-6(NOR)</sup> group (IR+MSC-CM<sup>IEC-6(NOR)</sup> group) and irradiation+MSC-CM<sup>IEC-6(IR)</sup> group (IR+MSC-CM<sup>IEC-6(IR)</sup> group), followed by continuous administration via the tail vein and abdominal cavity. Intestinal tissue and serum samples were collected 1, 3, 5, 7 days after radiation for hematoxylin-eosin staining and analysis of the concentrations of inflammatory factors via ELISA. Mesenteric lymph nodes were collected 3 days after radiation for analysis of the percentage of CD4+Foxp3+Treg cells via flow cytometry.

**Results:** Compared with the IR group and IR+MSC-CM<sup>IEC-6(NOR)</sup> group, the intestinal structure (small intestine epithelial villi and crypt) was significantly improved and the pro-inflammatory factors such as interleukin-1 $\beta$ , interleukin-6 and tumor necrosis factor- $\alpha$  in the small intestine were significantly decreased in the IR+MSC-CM<sup>IEC-6(IR)</sup> group, whereas the level of anti-inflammatory factor interleukin-10 was significantly increased. Similarly, the levels of pro-inflammatory factors such as Activin A, interleukin-1 $\beta$ , interleukin-6 and tumor necrosis factor- $\alpha$  in the serum samples were significantly decreased and the level of anti-inflammatory factor IL-10 was significantly increased. The changes in the levels of inflammatory factors were most significant at 3 days after irradiation. The number of CD4+Foxp3+ Treg cells in mesenteric lymph nodes in the IR+MSC-CM<sup>IEC-6(IR)</sup> group was significantly higher than that in control group and IR+MSC-CM<sup>IEC-6(NOR)</sup> group.

**Conclusion:** These results suggest that MSC-CM<sup>IEC-6(IR)</sup> can regulate the balance of pro-inflammatory factors and anti-inflammatory factors, and increase the number of CD4+Foxp3+ Treg cells in mesenteric lymph nodes, thus inhibiting the inflammatory response at systemic and mucosal levels in acute radiation-induced intestinal injury and promoting the repair of small intestinal mucosal injury.

**Contact E-Mail Address:** m.rostami@gmail.com

**Introduction:** A strict gluten-free diet (GFD) is currently the only recommended treatment for celiac disease (CD). Despite apparent compliance with the diet, 30-50% of treated patients have gastrointestinal (GI) symptoms. We explore the effect of a three-month course probiotic supplement on persistent symptoms in patients with CD following a long-term GFD.

**Aims & Methods:** We conducted a prospective, randomized, double-blind, placebo-controlled trial. Adult patients were enrolled if they were on a GFD for at least two years and were symptomatic at screening according to the GI symptom rate score (GIRS). 31 patients were randomized to receive probiotic (n=16) or placebo (n=15) for 12 weeks. Patients who answered "considerably relieved" or "completely relieved" over the 12 weeks of intervention were defined as responders.

**Results:** Thirty one patients including 16 in probiotic group (with mean age= 31±15, 50% female) and 15 in placebo group (with mean age= 39.5±20, 53.3% female) were enrolled. At the baseline analysis, there were no significant differences in the total score and subscales comparing probiotics vs. placebo. After 12 weeks trial, there was statistically significant relief in symptoms for diarrhea (46.7% vs. 12.5%, p=0.04) and fatigue (40% vs. 6.2, p= 0.03); But there were no significant differences for abdominal cramp (93.3% Vs. 93.75%, p=0.38), bloating (86.7% Vs. 87.5%, p=0.25), fatty diarrhea (93.3% Vs. 87.5%, p=0.13), gas feeling (93.3% Vs. 81.25%, p=0.38), weight loss (80% Vs. 81.25%, p=0.38), heartburn (93.3% Vs. 81.25%, p=0.82), muscle pain (73.3% Vs. 81.25%, p=0.96), nausea/vomiting (33.3% vs. 31.2%, p=0.90), and bloody diarrhea (6.7% vs. 6.2%, p=0.97), anemia (46.7% Vs. 37.5 %, p=0.72), depression mood (13.3% Vs 50.0%, p=0.09) and stress (53.3% Vs 81.2%, p=0.12) between two groups.

**Conclusion:** This experimental study suggests that probiotic supplement may improve specific CD symptoms in a subgroup of treated patients with higher symptomatic burden despite adherence to the diet. Further studies are require to confirm these findings.

**Disclosure:** no conflict of interest

### P1358 MARSH SCORE AT THE DIAGNOSIS OF COELIAC DISEASE PREDICTS THE PRESENCE OF OSTEOPENIA AND OSTEOPOROSIS

Silva L., Peixoto A., Santos A.L., Dias E., Costa-Moreira P., Rodrigues-Pinto E., Macedo G.  
Centro Hospitalar de São João, Department of Gastroenterology, Porto, Portugal

**Contact E-Mail Address:** jom\_73@hotmail.com

**Introduction:** Patients with coeliac disease (CD) frequently have mineral bone density (MBD) alterations. Implications of this alterations and the best way to monitor them are yet to be defined. Our objective was to evaluate the prevalence of MBD alterations at the diagnosis of CD and the associated risk factors.

**Aims & Methods:** A retrospective study of 96 patients (median age 25 years old; 79,6% women) with MBD evaluation at the diagnosis of CD was performed. Patients were divided into three groups: normal MBD (t score > -1.0), osteopenia (t score -1.0 to -2.5) and osteoporosis (t score < -2.5). Different clinical, serologic and histopathologic data were analyzed. Logis-

tic regression of the variable with statistical significance was performed. In patients with MBD alterations and subsequent follow-up, associations with MBD normalization were also searched.

**Results:** Osteopenia was present in 53,1% of the patients and osteoporosis in 7,3%. Osteopenia group presented more frequently Marsh score >2 when compared with normal MBD group. The osteoporosis group was older (p=0,011) and had more frequently Marsh score > 2 in histopathologic analysis (p=0.019) and vitamin D deficiency (p=0.039), when compared with normal MBD group. In logistic regression, Marsh score >2 (OR 1.4, p=0.005) was statistically significant in the osteopenia group. Age >45 years old (OR 3,19; p=0,036), male gender (OR 3,51; p=0,027) and Marsh >2 (OR 2,17; p=0,001) were statistically significant in the osteoporosis group. MBD normalization occurred in 25% in subsequent follow-up. Anti-transglutaminase antibody normalization was associated with MBD normalization (OR 2,5; p=0.012).

**Conclusion:** MBD is frequently decreased at the time of CD diagnosis. Osteoporosis had an association with older age, male gender and marsh score >2. Osteopenia presented an association with Marsh >2. In face of this evidence, MBD should be performed at the diagnosis of CD, especially if the patient presents a Marsh score >2. Normalization of anti-transglutaminase antibody is associated with MBD normalization.

**Disclosure:** Nothing to disclose

### P1359 SCREENING FOR COELIAC DISEASE IN ELDERLY PATIENTS PRESENTING WITH IRON DEFICIENCY ANAEMIA

Ayebo-Sallah B., Adam I., Yusuf A.  
East Sussex Healthcare NHS Trust, Gastroenterology, Eastbourne, United Kingdom

**Contact E-Mail Address:** ben.ayebo-sallah@nhs.net

**Introduction:** Iron deficiency anaemia (IDA) is a common indication for referral to gastroenterology. Gastrointestinal blood loss from colonic or gastric cancers as well as malabsorption in coeliac disease are the main causes of IDA in developed countries. Screening for coeliac disease in all patients with IDA is recommend by national guidelines<sup>1</sup>.

**Aims & Methods:** The aim of our study was to assess whether screening for coeliac disease is routinely performed for elderly patients with IDA. We retrospectively reviewed the electronic health records of all patients ≥65 years with IDA who underwent colonoscopy at our hospital between 01 October 2018 and to 31 March 2019. We collected data on demographics, cancer findings and tests for coeliac disease, either serology or histology of duodenal biopsies.

**Results:** A total of 291 patients with an average age of 74.7 years (range 65 to 93) were included in our study. There were 19 (6.5%) cases of cancer in this cohort. 225 patients (77.3%) had a duodenal biopsy or coeliac serology as part of investigation for IDA. Of those screened, five patients (2.2%) were tested positive for coeliac disease. There were no cases of cancer and coeliac disease in the same patient in this cohort.

**Conclusion:** Coeliac disease remains an important cause of IDA, even in the elderly patients. However, we found that over twenty percent of elderly patients who presented with IDA at our hospital were not screened for coeliac disease, which might potentially lead to unnecessary further investigations for their IDA.

**Contact E-Mail Address:** marjorie.walker@newcastle.edu.au

**Introduction:** Patients with psoriasis are at approximately 3-fold increased risk of coeliac disease (CD) (1). Psoriasis has also been linked with non-coeliac gluten or wheat sensitivity (2). Anti-gliadin antibodies (AGA) have been shown to correlate with psoriasis severity and those with psoriasis and AGA antibodies experience improved symptoms on a gluten free diet (3). Our aim was to determine the link between coeliac disease, self-reported non-coeliac wheat sensitivity and psoriasis in a population study.

**Aims & Methods:** A total of 3542 people randomly selected from the Australian population returned a survey (the Digestive Health and Wellbeing Survey, response rate = 43%) which contained questions on GI symptoms, such as heartburn, epigastric burning, pain, swelling and bloating in the last 3 months and included a self-reported physician diagnosis of coeliac disease and/or psoriasis. Wheat sensitivity was defined as those with GI symptoms on wheat ingestion without a formal diagnosis of CD. There was minimal response bias. Associations between categorical variables were evaluated using Pearson chi-squared test. A total of 3542 people randomly selected from the Australian population returned a survey (the Digestive Health and Wellbeing Survey, response rate = 43%) which contained questions on GI symptoms, such as heartburn, epigastric burning, pain, swelling and bloating in the last 3 months and included a self-reported physician diagnosis of coeliac disease and/or psoriasis. Wheat sensitivity was defined as those with GI symptoms on wheat ingestion without a formal diagnosis of CD. There was minimal response bias. Associations between categorical variables were evaluated using Pearson chi-squared test.

**Results:** The prevalence of psoriasis by self-report was 4.5%. Of those with psoriasis 22.5% reported coeliac disease compared to only 4.2% who did not have CD (unaffected cohort) (OR 6.5, 95% CI 2.95-13.4). There was a significant association between psoriasis, CD and frequent bloating ( $p=0.027$ ). In those with CD and psoriasis, 36% reported bloating on more than one day per week compared to only 13% in those with CD only. There was no significant association with other GI symptoms. There was no significant association between non-coeliac wheat sensitivity and psoriasis with 16.0% of patients with wheat sensitivity reporting psoriasis compared to 13.4% reporting no psoriasis ( $p=0.349$ ). There was a significant association between having CD, psoriasis and other autoimmune disorders. These included rheumatoid arthritis ( $p=0.004$ ), asthma ( $p=0.0001$ ) and scleroderma ( $p=0.0001$ ). The prevalence of self-reported wheat sensitivity in this cohort was 14.9% (95% CI 13.7-16.2) and CD, 1.2% (95%CI 0.8-1.6) (4).

**Conclusion:** In this cohort, coeliac disease, but not self-reported non-coeliac wheat sensitivity, is strongly associated with psoriasis. Those with coeliac disease who report bloating are more likely to report psoriasis. Those with other autoimmune diseases and psoriasis are more likely to have coeliac disease. It may be worthwhile screening such patients by serology and asking whether ingesting wheat worsens their symptoms to improve diagnosis of coeliac disease in this population.

## P1361 DUODENAL BIOPSIES ARE UNNECESSARY FOR THE EXCLUSION OF COELIAC DISEASE IN PATIENTS WITH A NEGATIVE TRANSGLUTAMINASE (TTG)

Stonelake S.<sup>1</sup>, Wilkinson J.<sup>2</sup>, Gulmez S.<sup>2</sup>, Leung E.<sup>1</sup>

<sup>1</sup>Hereford County Hospital, Hereford, United Kingdom, <sup>2</sup>Hereford County Hospital, General Surgery, Hereford, United Kingdom

**Contact E-Mail Address:** jessica.wilkinson6@nhs.net

**Introduction:** The British society of Gastroenterology guidelines (BSG) recommend that if coeliac serology (tissue transglutaminase (tTG) antibody 27 or endomysial antibody) is negative, small-bowel biopsies need not be performed unless there are other features which make a diagnosis of coeliac disease more likely.

**Aims & Methods:** Patients undergoing oesophagogastrroduodenal (OGD) endoscopy between November 2018 and March 2019 for iron deficiency anaemia were identified. Demographics and investigations for anaemia and coeliac disease (Hb, MCV, ferritin, tTG antibodies, endomysial antibody, IgA levels) were collected. Electronic clinic letters were opened to identify patients who had diarrhoea, making a diagnosis of coeliac disease more likely. The OGD report, number of duodenal biopsies and histopathology results were collected. Sensitivity and specificity of tTG levels for coeliac disease were calculated.

**Results:** There were 120 patients identified. Mean age was 68 years, male to female ratio of 30:90. Mean haemoglobin, MCV and ferritin was 105 g/l, 81 fl/red cell, and 27 ng/ml respectively. Ninety (75%) patients had tTG levels tested. Endomysial antibody and IgA levels were measured in 7 (6%) and 71 (59%) patients respectively. The tTG levels and endomysial antibodies were positive in 3 patients. There were no patients with IgA deficiency. All 120 patients had duodenal biopsies regardless of the tTG or endomysial antibody result. Eighty-seven (97%) of the patients undergoing tTG levels had a negative result. Of these, 12 patients had diarrhoea necessitating biopsy. No patients with a negative tTG was found to have coeliac disease from duodenal biopsy histology. Of the 3 positive tTG and endomysial antibody tests for coeliac disease (3%), two were confirmed with duodenal biopsy as coeliac disease and one patient had suboptimal biopsy which showed likely coeliac disease. There was a mean of 3 duodenal biopsies per patient (range 1-7). In this series tTGA was 100% sensitive and specific for coeliac disease. Seventy-five patients (63%) had an inappropriate biopsy according to the BSG guidelines.

**Conclusion:** Small bowel biopsy is not necessary to confirm a negative tTGA result in patients with iron deficiency anaemia. There was no increased yield of coeliac disease detection in the context of diarrhoea. These results support the BSG guidance stating biopsies should be reserved to confirm a positive tTG result or where tTG levels have not been performed.

**Introduction:** Gluten free diet (GFD) decreases the quality of life of patients with celiac disease (CD) who frequently ask to occasionally ingest gluten containing food.

**Aims & Methods:** We evaluated CD patients reporting voluntary and occasional transgressions to the GFD. CD patients undergoing annual follow-up were enrolled and divided in two groups:

- patients reporting an occasional and voluntary gluten ingestions (GFD-transgression) and;
- patients following a strict GFD (GFD-adherent).

Patients underwent clinical examination, blood tests, duodenal biopsy. In the GFD-transgression group a capsule enteroscopy, a validated food-frequency questionnaire (FFQ) assessing the frequency and quantity of gluten intake and mortality were assessed.

**Results:** 197 patients were included into the study (age  $45 \pm 16$  years, age at diagnosis 30 range 6-49 years, 38 females). In patients not adhering to the GFD (n=48), mean gluten intake was  $185.2 \pm 336.9$  g/year, duration of GFD transgression was  $8.6 \pm 6.9$  years. Most of the patients reported an ingestion of gluten per week or per months. Among uncompliant patients, 23(47%) did not present any histological alteration; Marsh score profile was not different among the two groups. 75% of patients did not report any gastrointestinal symptoms after gluten ingestion. 23% of patients in the GFD-transgression group presented positive tTG-IgA vs none in the GFD-adherent group (n=149). No association was found between gluten intake, clinical symptoms and biomarkers. Mortality was not different between groups and general population.

**Conclusion:** Our results showed that a group of CD patients with a long-term gluten intake does not show significant clinical symptoms or histological abnormalities, suggesting that a degree of tolerance towards gluten consumption can be reached. Although a strict GFD remains the only treatment available for CD patients, its tolerance should be accurately monitored over time.

**Contact E-Mail Address:** thomaskroner@gmail.com

**Introduction:** Patients with Celiac disease (CD) are at increased risk of infections, as evidenced by increased prevalence of tuberculosis, influenza, and sepsis. Alterations in immunity and microbiota can contribute to this predisposition. Although the prevalence of *Clostridioides difficile* (C.Diff) continues to increase in the US, there is little data on the association and outcomes in patients with CD.

**Aims & Methods:** Therefore, the aim of this study was to assess inpatient prevalence, outcomes and resource utilization of patients with CD and C.Diff infection in the US in the past decade.

This was an observational retrospective cohort study using the NIS 2007 to 2016, the largest publically available inpatient database in the US. All patients with CD were included using ICD9-10CM codes. The cohort was stratified according to the coexistence of C.Diff infection. No patients were excluded. The primary outcome was determining the association of CD with C.Diff infection. Secondary outcomes were determining the C.Diff inpatient prevalence trend in the CD patients, as well as mortality, morbidity, length of hospital stay (LOS), total hospital charges and costs, which were adjusted for inflation using the Consumer Price Index. Multivariate regression was used to adjust for age, gender, income in patient zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

**Results:** A total of 337,201 patients with CD were identified, of which 5,500 had associated C.Diff. Mean age was 55 years and 71% were female. The inpatient prevalence of C.Diff in patients with CD increased from 0.9/100,000 admissions in 2007 to 1.65/100,000 admissions in 2016. After adjusting for confounders, patients with CD displayed increased adjusted odds (aOR:1.56,  $p < 0.01$ ) of having coexisting C.Diff compared to patients without CD. In addition, patients with CD had lower odds of mortality, ICU, shock, multiorgan failure, but increased odds of requiring TPN. Patients with CD also had lower adjusted mean hospital costs, charges, and LOS than the general admitted population with C.Diff. All outcomes are displayed in tables 1 and 2.

**Conclusion:** Patients with Celiac Disease had higher odds of C.Diff compared to non-CD patients, which could be attributed to CD-related gut mucosal integrity, immunological or microbiome alterations. The inpatient prevalence of C.Diff in patients with CD increased from 2007 to 2016. This may be a reflection of the general increase of C.Diff cases in the inpatient population coupled with improved CD diagnostic modalities. Overall, patients with CD and C.Diff infection did show decreased morbidity/mortality and resource utilization, suggesting that the clinical course is less severe.

Further studies should continue to assess the gut immunological and microbiome changes in CD to further clarify potential factors associated with increased C.Diff infections.

**Contact E-Mail Address:** lucelli@yahoo.com

**Introduction:** Gluten free diet is the only recognized treatment for patients with celiac disease. Follow up for these patients is not standardized and the adherence to gluten free diet is not always easy to monitor.

**Aims & Methods:** We aimed to develop a novel questionnaire to monitor adherence to gluten free diet in celiac disease.

The 'Milano' questionnaire is composed of 9 items: 6 questions are based on a visual analogue scale (VAS, obtaining continuous variables) and 3 of them are yes/no questions. Questions have been expressly formulated in order to investigate factors strictly connected with adherence to gluten free diet (GFD). In particular: voluntary gluten assumption, accidental gluten assumption (i.e. possibility of contaminations) and attention paid on the control of nutritional labels of GF products.

Two questions evaluate the presence and severity of symptoms experienced in case of accidental or voluntary gluten assumption. The questionnaire was compared to tTGA titres and duodenal histology.

**Results:** The Milano questionnaire was administered to 285 patients (209 females and 76 males). We observed a significant correlation between the score obtained and serological status of the patients. In particular lower scores obtained were associated with higher probability of positivity to tTGA, suggesting a score of 30 as a cut off value. In particular, among the questionnaire items, 3 of them resulted significantly different between the groups based on tTGA positivity: question number 1 about general attention to GFD, question number 2 concerning the frequency of voluntary assumption of gluten and question number 7 about the eventual check of nutritional labels of products. We also observed a positive correlation between a score minor than 30 and the grade of villous atrophy at biopsy obtained during GFD.

**Conclusion:** This study shows that a new dietary questionnaire, the Milano questionnaire, is an useful tool to evaluate compliance to the GFD of celiac patients during clinical follow up.

<sup>4</sup>Centro Hospitalar e Universitário São João, Gastroenterology, Porto, Portugal

**Contact E-Mail Address:** pedromoreira.med@gmail.com

**Introduction:** Celiac hepatitis characterized by gluten-responsive mild elevation of transaminases is the more common liver manifestation of celiac disease (CD). It has been assumed that celiac hepatitis is related with the disruption of the "gut-liver axis". In the same way, a nutritional deficiency in CD is an indirect marker of intestinal absorptive function damage, as well as a possible precipitant of the systemic inflammatory cascade.

**Aims & Methods:** We aimed to study the relationship between nutritional deficiencies and the presence of abnormal liver function tests at the time of CD diagnosis.

A retrospective analysis of a CD cohort followed in a specialized outpatient clinic was performed. For each case, clinical and laboratory data at the time of diagnosis was collected. Within laboratory values, ferritin, folic acid, calcium, magnesium, phosphorus and vitamins A, B12, D and E were recorded. The correlation between continuous variables was established by Spearman's correlation; statistical differences between medians was assessed with the Mann-Whitney U test.

**Results:** We included 161 cases (mean age  $35.5 \pm 13.9$  years old, 78.3% female) with an average follow-up of  $10.6 \pm 9.7$  years. At diagnosis, 14.9% (n=24) of the patients had abnormal liver tests compatible with celiac hepatitis [median ALT 54 (IQR 41-62) IU/L; median AST 43 (IQR 39-53) IU/L; median GGT 15 (IQR 10-26) IU / L; median FA 99 (72-127) IU/L; median total bilirubin 0.55 (IQR 0.42-1.73) mg/dL].

At the time of CD diagnosis, the value of ALT showed a significant correlation with the value of anti-transglutaminase immunoglobulin A (TTG-IgA) ( $k=0.23$ ;  $p=0.02$ ).

Using regression analysis, the presence of abnormal liver tests was associated with iron-deficiency anemia (OR 3.12; CI95% 1.31-8.24,  $p=0.04$ ).

The median value of ALT was significantly higher in the presence of folic acid deficiency (median 34 (IQR 20-39) vs.18 (IQR 14-29),  $p=0.02$ ) and vitamin D deficiency [median 21 (IQR 16-37) vs.16 (IQR 14-25),  $p=0.02$ ].

**Conclusion:** We found a statistically significant relationship between the presence of celiac hepatitis and iron deficiency anemia. Also, the serum value of ALT was significantly increased in folic acid and vitamin D deficiency. Gut dysfunction leading to an increased intestinal permeability and consequent liver tissue exposure to endotoxins may explain the previously mentioned relationship.

## P1367 PROGNOSTIC FACTORS ON BODY WEIGHT LOSS BY AN INTRAGASTRIC BALLOON THERAPY

Ohta H.

Sapporo Orthopedics and Cardiovascular Hospital, Gastroenterology, Sapporo, Japan

**Contact E-Mail Address:** hideohta@true.ocn.ne.jp

**Introduction:** Intra-gastric balloon therapy (IGBT) is a non-invasive modality of the bariatric therapy and can reduce 10 to 14 % of total body weight (TBW) before the therapy [1]. FDA recommends that doctors should indwell the balloon during only 6 months in stomach and then excrete it after therapy. If we can estimate the effect of bariatric balloon therapy before the therapy, it is clinically very useful.

**Aims & Methods:** Our aim is to clarify the key factors which can maximize the body weight loss by IGBT. We analyzed the correlation between TBWL (TBW loss) and BMI, visceral and subcutaneous fat amount, leptin, insu-

lin in sera, liver dysfunction, metabolic complications and its drugs, gut microbiomes before therapy in our clinical trial [UMIN 0008675] which enrolled 25 patients with obesity. On analyzing, we took some biases (sex, age) into account. In multivariable logistic regression analysis, TBWL (1:  $\geq 10\%$ , 0:  $< 10\%$ ) was assigned for independent variables and aforementioned factors were assigned for dependent variables.

### Results:

1) Visceral fat amount was closely correlated with TBWL (correlation coefficient: 0.76). On the other hand, subcutaneous obesity group and high BMI  $> 40$  group could not reduce TBW over 5%.

2) Obese patients complicated with diabetes realized nearly 14~18% TBWL after 6 months therapy if their primary diabetes were regulated very well.

3) The patients with hyperleptinemia could reduce only 4.3% of TBW before therapy.

4) Patients with NAFLD could reduce 13.2% of TBW and improve the liver function adequately by IGBT.

5) HR was higher in visceral fat, complication and drug, anti-obesity microbiota.

**Conclusion:** Visceral fat amount and metabolic complication have possibility of becoming better prognostic factors in bariatric balloon therapy.

**Contact E-Mail Address:** michel\_ble@hotmail.com

**Introduction:** Obesity and hepatic steatosis are major diseases with high morbidity. Treatment for patients (px) with hepatic steatosis (HS) with or without liver fibrosis is weight loss. Intra-gastric balloon is the endoscopic gold standard on short time weight loss. Endoscopic plication can offer better middle long-term results than balloon for its durability. Liver stiffness (LS) and hepatic steatosis (HS) can be estimated with transient elastography (TE) and controlled attenuation parameter (CAP).

**Aims & Methods:** Multi-center, prospective pilot study intended to evaluate the safety and efficacy of the Gastric Endoscopic Sleeve Plication procedure (mid & distal body plications) (GESP) and its effect on hepatic fibrosis and steatosis.

Study was approved by ethic committee at both institutions. Px signed a written consent. Px with grade I-II obesity were included for the procedure. Use of the Incisionless Operating Platform (IOP)<sup>TM</sup> (USGI Medical, San Clemente, CA, USA) with a defined new pattern of disposition of the transmural plications with the g-cath<sup>TM</sup> EZ suture anchors in the greater curvature shortening and tubulizing the stomach to potentially delay gastric emptying and reduce gastric volume/accommodation for an enhanced physiological effect.

LS and CAP was measured with Fibroscan<sup>®</sup> device provided with M or XL probe (Echosens, France) by experienced personnel. Quality criteria for LS by TE were: 10 measurements obtained with a success rate  $\geq 60\%$  and a IQR  $\leq 30\%$  of the median. Blood test was evaluated at baseline (BL) and 6 months post-GESP.

**Results:** 39 px were included in these multicenter-trial. 17 pxs (44%) from Centro Medico Teknon (CMT) were analyzed. 17 GESP in 17 pxs were successfully performed in CMT (59% females) without serious adverse events. LS+CAP was successful in all px (82% with XL probe).

Preliminary data on LS+CAP was obtained in 16 px (94%) at 2 months and in 7 px (42%) at 6 months. Body weight loss at 2 (n=14) and 6 months (n=8) was  $14 \pm 4\%$  ( $13.1 \pm 4.2$  kg) and  $19 \pm 11\%$  ( $15.8 \pm 7.2$  kg).

At BL, 11 px had absent/mild fibrosis (Fo-F1), 4 px had significant fibrosis (F2), 1 px had severe fibrosis (F3) and 1 px cirrhosis (F4), with a mean LS of  $4.1 \pm 0.9$ ,  $8.2 \pm 0.4$ , 9 and  $12.3$  kPa, respectively; HS S0, S1, S2, S3 was present in 4, 2, 3 and 8 px, with a mean CAP of  $205 \pm 19$ ,  $248 \pm 5$ ,  $285 \pm 8$  and  $342 \pm 21$ , respectively.

At 2 months, 3 px (19%) with BL F2 (mean LS  $8 \pm 0.4$  kPa) had a statistically significant improvement of LS (mean LS  $6.6 \pm 0.2$ ,  $p=0.007$ ). In regard to HS, 50% ( $n=8$ ) of px had a reduction of HS in 2 stages and 19% ( $n=3$ ) in 1 stage; 4 S0 at BL and 1 (6%) S3 at BL had no variation. A total of 5 px (31%) with BL HS (3 S2 and 2 S1) achieved S0. The only px with BL cirrhosis had a mild improvement of LS ( $12.3$  vs  $11.3$  kPa) with an associated reduction in 2 stages of HS (S3 to S1); unfortunately, we still not have data on 6 months evaluation of this patient.

At 6 months, all 7 px had BL F0-F1 and showed a significant reduction in HS ( $303 \pm 47$  vs  $221 \pm 24$ ,  $p=0.001$ ) along with lower ALT levels ( $34 \pm 20$  vs  $17 \pm 4$  IU/L,  $p=0.46$ ) and elevation of HDL cholesterol ( $53 \pm 15$  vs  $60 \pm 19$ ,  $p=0.036$ ). LS, hemoglobin, platelets, creatine, total and LDL cholesterol, triglycerides, AST and total bilirubin were no significant different.

**Conclusion:** Preliminary results with reduction of weight loss with GESP procedure are promising for treatment of hepatic fibrosis and steatosis in patients with grade I-II obesity. Long term follow-up its necessary to assess its value for treatment of HS and LS.

**Contact E-Mail Address:** brunosander@hotmail.com

**Introduction:** With the current picture of obesity pandemic, the Endoscopic Sleeve Gastroplasty technique (ESG) has become an important tool as an option for treatment<sup>1</sup>. The therapeutic success rates described in literature vary from 50% to 100%, with little or no complication during or after the procedure, without cases of mortality, as well. This study was developed to analyze the results obtained by the respective technique in different treatment centers for obesity.

**Aims & Methods:** Three treatment centers for obesity from the main capitals of Brazil participated in this study. All patients were instructed on the ethical aspects of the research, and were followed for eighteen months after the procedure by a multidisciplinary team. Since July 2017, a total of 126 patients (109 submitted to full-thickness U-shaped sutures = SU; 17 submitted to full-thickness U-shaped sutures + Reinforcement = SUR) were randomly assigned to the study. Among the seventeen patients in the SUR group, only eight reached six months of follow-up.

**Results:** The sample profile consists of young adults with a mean age of  $41.3 \pm 10.5$  years, being most of them women (63.5%). Initially, the patients presented mean weight:  $97.4 \pm 20.6$  kg and mean BMI:  $34.3 \pm 4.9$  kg / m. There was a significant\* mean decrease of weight (6 months:  $10.3 \pm 5.1$  kg, 12 months:  $17.5 \pm 8.6$  kg, 18 months:  $23.1 \pm 8.2$  kg) and BMI (6 months:  $3.6 \pm 1.6$  kg / m, 12 months:  $6.5 \pm 2.6$  kg / m; 18 months:  $7.9 \pm 2.4$  kg / m). The results observed for the TBWL % (Total Body Weight Loss percentage) parameters were: 6 months =  $10.3 \pm 3.9$ ; 12 months =  $16.6 \pm 6.2$ ; 18 months =  $21.3 \pm 5.1$ . And the mean EWL % (Excessive Weight Loss percentage) was  $41.8 \pm 21.2$ ,  $64.1 \pm 29.3$  and  $73.3 \pm 27.6$  at 6 months, 12 months and 18 months respectively.

Patients submitted to SUR presented superior results in EWL % (when compared to patients submitted to SU in 6 months of follow-up: SU =  $38.1 \pm 19.6$ , SS =  $43.9 \pm 15.9$ . A mean of  $62.5 \pm 6.1$  and  $89.2 \pm 4.9$  bites per suture was observed, with a mean of  $4.6 \pm 0.5$  and  $7.2 \pm 0.5$  threads respectively for SU and SUR suture. There was no case of complication during or after the procedure.

\* Parametric t test;  $p < 0.05$

**Conclusion:** The results described in this sample confirm the data pointed out in the literature<sup>1, 2</sup>, ESG is a safe procedure and with high rates of therapeutic success. The results also showed that SUR procedures clinically imply double the rates of long-term therapeutic success. In this sample, 100% of patients submitted to SUR at 06 months had lost almost 45% of excess weight and no weight regain was observed in this group. We believe that these findings may be due to the mechanical response of SUR, as it promotes an even greater reduction of the lumen of the gastric tube, inducing with more intensity and for a longer time the delay of the gastric emptying and increasing the satiety.

It is important to emphasize that the high success rates described in this study are a direct consequence of a precise and adjusted interaction of the multidisciplinary support team. The data presented in this study are part of a larger ongoing study.

**Contact E-Mail Address:** brunosander@hotmail.com

**Introduction:** Weight regain has been a constant concern, as reports in literature indicate that rates can reach up to 50%, especially in patients who have undergone bariatric surgery. However, it is not yet clear how weight regain occurs because it is a variable that undergoes various intrinsic and extrinsic interferences of the individual. The technique to reduce the anastomotic size has been successfully developed around the world. Thus, this paper aims to describe the initial results of a long-term clinical study in Brazil.

**Aims & Methods:** Three treatment centers for obesity from the main Brazilian capitals participated in this study. All patients were instructed on the ethical aspects of the research, and were followed for eighteen months after the procedure by a multidisciplinary team. Thirty-one patients (twenty-one submitted to full-thickness Z-shaped sutures and ten submitted to full-thickness Z-shaped sutures + Reinforcement) participated in this study, since July 2017, and were followed up for eighteen months.

**Results:** Thirty-one patients with a mean age of  $42.9 \pm 8.7$  years participated in this study, most of them women (84.4%). Pre-intervention data: Weight:  $103.7 \pm 17.9$  kg and BMI:  $36.2 \pm 6.1$  kg / m. A mean of  $28.9 \pm 9.3$  bites per suture and  $2.1 \pm 0.7$  threads were used in the procedure. There was a significant\* mean reduction of  $11.9 \pm 5.3$  kg,  $15.2 \pm 6.1$  kg and  $19.3 \pm 8.9$  kg at 6 months, 12 months and 18 months respectively. A mean reduction of  $4.1 \pm 1.5$ ,  $5.5 \pm 2.1$  and  $6.7 \pm 2.5$  points in the BMI parameter was observed for follow-up times of 6 months, 12 months and 18 months, respectively. There was progressively an increase of TBWL % (Total Body Weight Loss percentage) =  $11.3 \pm 3.6$ ,  $14.6 \pm 3.8$  and  $17.7 \pm 4.5$  for 6, 12 and 18 months respectively. The Excessive Weight Loss was significant at 6 months (EWL % =  $40.4 \pm 13.5$ ), at 12 months ( $50.3 \pm 17.7$ ) and 18 months at follow-up ( $56.3 \pm 8.6$ ). No complications were observed during or after the procedure.

**Conclusion:** The data so far have shown very significant results in relation to the main outcome (EWL %), as this study presented an approximate loss of 50% of the excess weight in the first 12 months. There was a slight increase in this parameter in later follow-up. There should be pointed out that between one year and a year and a half, the weight loss was kept going on. In this initial cut of the study, no complications were observed during or after the procedure. These results are due in large part to the multidisciplinary work employed throughout the follow-up of these patients.

## P1371 ENDOSCOPIC GASTRIC MUCOSAL RESECTION FOR WEIGHT LOSS AND SUPPRESSING SYSTEMIC GHRELIN LEVELS IN VIVO MODEL

Liu B.-R.<sup>1</sup>, Liu D.<sup>1</sup>, Zhao L.<sup>2</sup>, Kong L.<sup>1</sup>, Li D.<sup>1</sup>, Yang H.<sup>1</sup>, Ahmed M.R.<sup>1</sup>

<sup>1</sup>The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China, <sup>2</sup>The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

**Contact E-Mail Address:** bingrongliu@qq.com

**Introduction:** Obesity is a chronic metabolic disorder that is challenging to control. Ghrelin may be involved in the occurrence of obesity and associated with weight-loss resistance<sup>1</sup>. Endoscopic gastric mucosal resection (EGMR) is performed by the combination of endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR).

**Aims & Methods:** The aim of this study was to analyze the impact of EGMR on body weight and ghrelin levels to explore its potential as a novel weight-loss technology. EGMR procedure was carried out to resect the mucosal layer of the fundus and body of the stomach in five healthy pigs, while another five were untreated as controls. Weight was monitored continuously for 12 weeks and fasting plasma ghrelin levels were analyzed by enzyme-linked immunosorbent assay (ELISA) within 1 and 2 months after the EGMR procedure.

**Results:** Compared with the control group, pigs in the experimental group exhibited reduced gastric volume and weight-loss with time after the EGMR procedure. The average weight in the experimental group was 51.6±17.27 kg at 12 weeks after the EGMR procedure and 64.00 kg±11.86 kg in the control group ( $P = 0.0001$ ). There were significant differences in ghrelin levels. Compared with baseline, ghrelin levels decreased to 250.72±15.57 pg/ml at 1 month after the EGMR procedure, and continued to decrease to 169.15±17.93 pg/ml at 2 months after the EGMR procedure. In contrast, there were no obvious changes in the ghrelin levels between the experimental and control groups ( $F = 90.11$ ,  $P = 0.0007$ ).

**Conclusion:** EGMR procedure can effectively reduce stomach volume permanently and suppress ghrelin, indicating the potential of this approach as a novel weight-loss technology.

## P1372 LARGEST MUCOSAL RESECTION IN THE WORLD FOR WEIGHT LOSS

Liu B.-R., Ahmed M.R., Fang M.

The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China

**Contact E-Mail Address:** bingrongliu@qq.com

**Introduction:** Obesity is one of the most ubiquitous chronic diseases<sup>1</sup>. Inspired by the complication of esophageal stenosis after endoscopic submucosal dissection (ESD)<sup>2</sup>, we hypothesized that resection of a sufficiently large area of the gastric mucosa should result in contracture and a reduction in gastric volume and provide a new strategy for medical treatment of obesity.

**Aims & Methods:** The aim of this study was to evaluate large gastric mucosal resection using combination methods of ESD and endoscopic mucosal resection (EMR) procedures for weight loss. A cap-based single-channel endoscope was used to resect 80% of the circumference of the anterior, posterior, greater curvature mucosal layer of the stomach. Small portions of mucosa (mucosal islands) were left to promote wound healing and regeneration of the gastric mucosa after the procedure. Finally, coagulation forceps were used to coagulate the bleeding or potential bleeding sites in the submucosal and muscular layer to prevent recurrent bleeding.

**Results:** From December 2015 to March 2019 a total of eight patients ( $n=8$ ) underwent gastric mucosal resection procedure for weight loss and two patients ( $n=2$ ) were associated with type 2 diabetics. The mean initial body weight was 108.56 kg (range, 75-135kg). One week after the procedure, gastroscopy showed a large area of ulceration on the greater curvature of the stomach covered by yellow plaque. One month after the procedure, the area of the ulcer was noticeably smaller, the mucosal islands were wider, and the plaque was white and clean. The mean BMI was decreased to 32.24 kg/m<sup>2</sup> from 37.13 kg/m<sup>2</sup>. Eighteen months after the procedure, gastroscopy confirmed ulcer healing completely with a normal appear-

ing mucosa. CT scan confirmed that the gastric volume was reduced. The mean follow-up time was 12.66 months (range, 3-30 months). All patients experience early satiety after eating and lost most of the excess weight. Following the procedure, the mean BMI reduction was 29.73 kg/m<sup>2</sup>, 28.05 kg/m<sup>2</sup>, 27.59 kg/m<sup>2</sup>, 27.15 kg/m<sup>2</sup>, and 27.19 kg/m<sup>2</sup> at three months ( $n=8$ ), six months ( $n=8$ ), twelve months ( $n=6$ ), twenty-four months ( $n=2$ ), and thirty months ( $n=2$ ), respectively. One patient ( $n=1$ ) had recurrent vomiting and could not take food one month after the procedure, and received stent implantation in our hospital. There were no others major adverse effect intra-procedure or during 30 months follow-up period. The blood glucose level was decreased to normal and no therapy was needed.

**Conclusion:** This new procedure appears to be an effective, safe, and less invasive restrictive-type bariatric procedure with low technical complexity and complications.

**Introduction:** Maternal obesity is associated with adverse pregnancy outcomes with both maternal and neonatal complications. Probiotic supplementation during pregnancy may have positive effects on maternal blood glucose, gestational weight gain (GWG), and the risk of gestational diabetes mellitus (GDM).

**Aims & Methods:** The primary aim of this study was to determine the feasibility of probiotic intervention in obese pregnant women from the early second trimester until delivery. The secondary aim was to investigate the effect of daily probiotic supplementation on GWG, maternal glucose homeostasis, infant birthweight, and maternal gut microbiota.

We carried out a randomized double-blinded placebo-controlled study in 50 obese pregnant women with pre-pregnancy body mass indices between 30 and 35 kg/m<sup>2</sup>. Participants were randomly allocated to two treatment groups, Vivomixx ( $n=25$ ) or placebo ( $n=25$ ) at 14-20 weeks of gestation (baseline) and followed with two pre-delivery visits at gestational week 27-30 and 36-37 and with one post-delivery visit 2-3 days after birth. All visits included blood and fecal sampling. An oral glucose tolerance test was performed at baseline and gestational week 27-30.

**Results:** Forty-nine participants completed the study, Vivomixx ( $n=25$ ), placebo ( $n=24$ ). Thirty-eight participants took more than 80% of the capsules, Vivomixx ( $n=21$ ), placebo ( $n=17$ ). There was no significant difference in HbA1c levels and the occurrence of GDM between groups. There was, however, a trend towards lower GWG and lower infant birthweight in the probiotic group. Fecal microbiota analyses showed an overall increase in  $\alpha$ -diversity over time only in the Vivomixx group ( $p=0.016$ ).

**Conclusion:** Administration of probiotics is feasible, and a multi-strain probiotic were able to increase  $\alpha$ -diversity during pregnancy in obese women. A larger study population is needed to uncover whether the trends found regarding probiotic effects on GWG and lower infant birthweight become significant.

**Disclosure:** Both the probiotic and placebo capsules as well as half a year's salary to the study have been donated to Copenhagen University Hospital Hvidovre by Next Gen Pharma India Pvt. Ltd., H. No. 331, 1st Floor, Sector 15A, Noida 201301, National Capital Region, India. The funding source

Clinical Medicine and Surgery, Naples, Italy, <sup>4</sup>Federico II University, Naples, Italy

**Contact E-Mail Address:** iolanda.cioffi@unina.it

**Introduction:** The assessment of body composition (BC) can offer a practical approach to identify malnutrition, frequently observed in patients with Crohn's disease (CD). Bioelectrical phase angle (PhA) provides crucial information on cell mass quality and hydration status.

**Aims & Methods:** The aim of this study was to assess BC, PhA and muscle strength in CD patients as indicators of both nutritional and functional status.

Consecutive adult CD patients aged between 18-65 years were recruited for this cross-sectional study. Disease activity was clinically defined by Crohn's Disease Activity Index (CDAI) in active (>150) and quiescent (< 150) phase. All participants underwent anthropometry, BC and handgrip-strength (HGS) measures; additionally, biomarkers involved in the nutritional status were assessed. Data from CD patients were also compared with a group of healthy subjects age-, sex- and BMI- matched.

**Results:** A total of 140 CD patients with a mean age of 38.8 ±13.9 years and an average body weight of 64.9±12 kg were recruited and compared to controls. Findings showed that all nutritional parameters, especially PhA (CD: 6.35±0.94° vs. Controls:6.81±0.79°; p=0.000), were lower in CD patients, especially in the active group, compared to controls. Active-CD patients had also a lower body weight and fat mass compared both to the quiescent and control groups. PhA was also negatively correlated with age (r=-0.362; p=0.000) and CDAI (r=-0.315; p=0.000), whereas was positively associated with FFM (r=0.443; p=0.000) and HGS (r=0.539; p=0.000). Similarly, serum protein markers are lower for active-CD patients compared to the quiescent group (p< 0.05); while, CRP meaningfully increased.

**Conclusion:** Overall, nutritional indicators tend to be lower in CD patients compared to controls. Specifically, PhA-values impaired with increasing of disease activity, being a sensitive marker of nutritional status. Therefore, the assessment of BC should be recommended in clinical practice for screening and monitoring nutritional status of CD patients.

**Contact E-Mail Address:** helwig@internisten-ol.de

**Introduction:** Patients with chronic inflammatory bowel disease (IBD) might have a greater likelihood of also being fructose malabsorbers as

compared to healthy controls. The aim of this study was to determine the prevalence and symptom severity of fructose malabsorption in patients with active and inactive IBD compared to healthy controls.

**Aims & Methods:** The present study was a multi-center non-interventional diagnostic pilot trial approved by the Ethics Committee of the Christian-Albrechts-University Kiel, Germany. Fifty-seven patients with active IBD, 93 patients with IBD in remission, and 101 healthy controls admitted to twelve different out-patient clinics for Internal Medicine in Germany were included prospectively. Fructose malabsorption was diagnosed by hydrogen breath testing after the ingestion of 50g fructose diluted in 300ml water and defined as an increase in H<sub>2</sub> levels by at least 20 parts per million compared to baseline. Patients diagnosed with bacterial over-population as diagnosed by the glucose breath test and non-H<sub>2</sub> producers as diagnosed by the lactulose breath test that were tested negatively on fructose as well as lactose were excluded from the analyses. Gastrointestinal symptoms during the breath tests were evaluated using four-point items to determine subjective severity of bloating, abdominal pain and diarrhea.

**Results:** 251 participants were included in the study (table 1). 205 patients (45 with active IBD, mean age 39.20 ± 13.48 years, 55.6% female; 80 with IBD in remission, mean age 43.03 ± 11.79 years, 58.8% female; 81 healthy controls, mean age 28.92 ± 8.81 years, 61.7 % female) remained after diagnosing for bacterial over-population and non-H<sub>2</sub> producers. The number of patients diagnosed with fructose malabsorption - 35/44 (79.6%) in patients with active IBD, 59/80 (73.8%) in patients with inactive IBD, and 66/81 (81.5%) in healthy controls - did not differ between the three groups ( $\chi^2(2, N=205) = 1.48, p = .48$ ). Abdominal pain was more frequent in patients with active IBD than in patients with IBD in remission ( $z = -2.936, p = .010$ ) and diarrhea was more frequent in patients with active IBD than in healthy controls ( $z = 2.489, p = .038$ ).

**Conclusion:** Within the present study, fructose malabsorption is not more common in patients with IBD than in healthy subjects. However, the stronger symptoms of the patients with IBD may have pathological and therapeutic relevance.

### P1376 LACTOSE SENSITIVITY AND LACTOSE MALABSORPTION. THE TWO FACES OF LACTOSE INTOLERANCE IN PATIENTS WITH FUNCTIONAL BOWEL DISORDERS

Bouchoucha M.<sup>1</sup>, Romptaux P.<sup>1</sup>, Steuer N.<sup>2</sup>, Raynaud J.-J.<sup>1</sup>, Sabate J.M.<sup>1</sup>, Benamouzig R.<sup>3</sup>

<sup>1</sup>Hopital Avicenne, Gastroenterology, Bobigny, France, <sup>2</sup>Hopital Avicenne Service de Gastroenterologie, Gastroenterology, Bobigny, France, <sup>3</sup>Hopital Avicenne, Service de Gastroenterologie, Bobigny, France

**Contact E-Mail Address:** michel.bouchoucha@avc.aphp.fr

**Introduction:** In France, 30 to 50% of adults have incomplete digestion of lactose. The importance of the symptoms is a function of the residual lactase activity and the amount of lactose ingested. These symptoms are more frequent in postprandial period, 30 minutes to 2 hours after ingestion of food containing lactose. They are not specific, evoking bowel disorders (gas, bloating, abdominal cramps, diarrhea, nausea, vomiting) or general disorders. They are frequently confused with irritable bowel syndrome, that may delay the prescription of an adapted regime.

**Aims & Methods:** The purpose of this study is to evaluate the frequency of lactose malabsorption and the frequency of lactose sensitivity in patients with functional bowel disorders, with symptoms revealed or increased after lactose ingestion.

We included 142 consecutive patients (104 women, 73%) with functional bowel disorders. In all patients, the search for a small intestine bacterial overgrowth by glucose breath test was negative. These patients have completed a Rome III questionnaire and performed the lactose absorption test that measures the blood glucose before and 15, 30, 45 and 60 minutes after ingestion of 50 g of lactose. A malabsorption was diagnosed when the peak blood glucose level was below 0.20 g/l and a lactose sensitivity was registered if digestive signs appeared during the test.

**Results:** Lactose sensitivity without malabsorption was present in 58 patients (group I, 41%), a malabsorption without lactose sensitivity was found in 14 patients (group II, 10%) and 23 patients (group III, 16%) exhibited at the same time lactose malabsorption and lactose sensitivity. 47 patients (Group IV, 33%) showed neither malabsorption nor sensitivity to lactose. Compared with group IV patients, patients in group I were younger (38.8

$\pm 1.5$  vs  $44.4 \pm 2.7$  years,  $P = 0.039$ ) and complained of greater incidence of chest pain (29% vs. 26%,  $P = 0.042$ ). Other demographic parameters, frequency of other symptoms (esophageal, gastroduodenal, intestinal and anorectal according to Rome III) were similar in the four groups of patients.

**Conclusion:** The joint study of lactose absorption and lactose sensitivity is useful to eliminate the pathogenesis of this sugar in patients with disorders intestinal function and justify the establishment of a lactose-free diet. In symptomatic patients after ingestion of lactose, we suggest distinguish patients suffering from malabsorption of lactose by decreased Intestinal lactase activity from patients with lactose sensitivity characterized by the appearance of symptoms without decrease of lactose absorption.

### **P1377** PATTERNS OF FIBER INTAKE AMONG BRAZILIAN ADULTS: A NATIONWIDE WEB-BASED SURVEY

Passos M.C.F.<sup>1</sup>, Guedes L.S.<sup>2</sup>, Takemoto M.L.S.<sup>3</sup>

<sup>1</sup>Federal University of Minas Gerais, Alfa Institute of Gastroenterology, Belo Horizonte, Brazil, <sup>2</sup>Takeda Pharmaceuticals, São Paulo, Brazil, <sup>3</sup>ANOVA Consultoria em Saúde, São Paulo, Brazil

**Contact E-Mail Address:** mcpassos@medicina.ufmg.br

**Introduction:** Adequate fiber intake has been directly linked to physiological gut balance and is recognized as essential for human health. The World Health Organization (WHO) recommends for adults a daily fiber consumption of  $\geq 25$  g, but previous studies observed a fiber intake in Brazil lower than recommended.

**Aims & Methods:** We aimed to describe fiber intake among adults in Brazil, through a nationwide web-based survey. Data was collected in September 2018 using an online platform with closed-ended questions. A representative sample of Brazilian internet users stratified by sex, age, socioeconomic status and geographic region was adopted. Sample size was calculated using a 2% error margin and 95% confidence interval ( $n=2,000$ ). Data was descriptively analyzed using measures of frequency, central tendency and dispersion.

**Results:** Sample included 2,000 individuals who were well-balanced in terms of sex (51% female), with mean age of 36 years (most represented age group was 35-54 years, 40%) and from all country geographic regions (49% from Southeast). Most subjects (64%) were classified as having low socioeconomic status/income, consistent with Brazilian general population. 70% of them consider their usual diet as healthy and 78% reported consuming fibers regularly. Fibers from natural sources are consumed at least once a day by 69% of the sample, while daily fiber supplements were reported by 30%. Absence of regular fiber intake was reported by 22% of respondents and the most common reason was "lack of knowledge about fiber sources" (39%), followed by "daily inclusion of fibers would be expensive" (30%) and "lack of time" (22%). Fibers sources with higher frequency of daily intake in the sample were: beans and pulses (67%), whole grains (57%), and vegetables (56%). Nuts were the least frequent group with only 13% of daily intake (18% never consume). 74% of the sample informed that they knew about the role of fibers in improving intestinal function, but only 30% knew the difference among soluble and insoluble fibers. When informed about the food sources of each type of fiber (soluble and insoluble) and asked about the regular intake of each type, only 2% answered that they do not consume any of them regularly (as opposed to 22% before receiving information about specific fiber sources). 87% of the individuals who reported taking regular fiber supplements classified their intestinal function as normal. Men reported having better intestinal function than women.

**Conclusion:** Our findings indicate that fiber intake in Brazil is probably insufficient with a high proportion of individuals reporting irregular or absent ingestion of fiber sources in their daily lives. Lack of knowledge about fiber sources and fiber types seems to play a role in this inadequate intake, highlighting the need for nutritional education to achieve healthy dietary patterns in the country.

### **P1378** IRREGULAR DIETARY HABITS WITH A HIGH INTAKE OF CEREALS AND SWEETS ARE ASSOCIATED WITH MORE SEVERE GASTROINTESTINAL SYMPTOMS IN IBS PATIENTS

Nilholm C.<sup>1</sup>, Larsson E.<sup>1</sup>, Roth B.<sup>1</sup>, J Gustafsson R.<sup>2</sup>, Ohlsson B.<sup>3</sup>

<sup>1</sup>Skane University Hospital, Department of Clinical Sciences, Malmö, Malmö, Sweden, <sup>2</sup>Skåne University Hospital Malmö, Department of Gastroenterology, Malmö, Sweden, <sup>3</sup>Skanes Universitetssjukhus, Department of Clinical Sciences, Malmö, Malmö, Sweden

**Contact E-Mail Address:** clara.nilholm@med.lu.se

**Introduction:** Dietary advice constitutes one of the first choices of treatment for irritable bowel syndrome (IBS). However, almost 50% of the IBS population do not improve their symptoms following accepted recommendations such as the NICE guidelines or a low FODMAP diet. The sucrase-isomaltase (SI) genes are responsible for the enzymatic breakdown of starch and sucrose in the small intestine. Recently, we have recognized that an increased prevalence of functional SI gene variants can be seen in patients with IBS, resulting in enzymatic defects and possible difficulty digesting starches and sucrose [1].

**Aims & Methods:** The primary aim was to examine participants' dietary habits at baseline, and to correlate the dietary habits with gastrointestinal (GI) symptoms and blood levels of minerals and vitamins. Secondly, we wanted to examine the effect of a starch- and sucrose-reduced diet (SSRD) on GI symptoms. IBS patients, without any organic GI disease, and total IBS-SSS score  $>175$ , were randomized to either the dietary intervention group ( $n=80$ ); following a SSRD for 2 weeks or to the control group ( $n=25$ ) who continued with their ordinary eating habits. The main dietary advice was to decrease the intake of cereals, sweets/soft drinks, and to avoid vegetables and fruits with high content of starch (2). All subjects had blood samples drawn and completed questionnaires regarding GI symptoms (visual analog scale for irritable bowel syndrome (VAS-IBS), irritable bowel syndrome symptom severity scale (IBS-SSS) and Rome IV), and two 4-day food diaries, at baseline and after 2 weeks. The food intake was categorized into regular (3-6 meals/day) or irregular food habits, the intake frequency of fast food and soda was counted, and an on-going current diet was registered. Food items were categorized into meat, fish, vegetables, fruits, dairy products, cereals, and sweets/soft drinks.

**Results:** Patients with regular dietary habits exhibit less pronounced GI symptoms, measured as total IBS-SSS score, than patients with irregular habits ( $p=0.029$ ). Intake frequency of sugar-rich soda correlated with total IBS-SSS score, vomiting and nausea and intestinal symptoms' influence on daily life. Women with an on-going diet had lower levels of ferritin than women without diet ( $p<0.029$ , adjusted for age). A majority of the patients had serum levels of 25-OH vitamin D below reference values. IBS patients randomized to the intervention group showed significant improvement of several symptoms after the 2-week dietary intervention, in contrast to controls, with 31.1% of subjects in the intervention group being responders ( $>50\%$  decrease in total IBS-SSS score). The change in GI symptoms between 2 weeks and baseline, delta values, differed between the intervention and control group regarding total IBS-SSS score ( $p<0.001$ , abdominal pain ( $p=0.001$ ), diarrhea ( $p=0.002$ ), bloating and flatulence ( $p=0.005$ ), psychological well-being ( $p=0.048$ ), intestinal symptoms' influence on daily life ( $p<0.001$ ). The decreased intake of cereals and sweets/soft drinks correlated with decreased scores of total IBS-SSS, abdominal pain, diarrhea and bloating and flatulence. The dietary advice was easy to adhere to.

**Conclusion:** Dietary habits affect the experience of GI symptoms and blood levels of minerals and vitamins in patients with IBS. A starch- and sucrose-reduced diet with reduced intake of cereals and sweets/soft drinks has marked effect on reducing GI symptoms in this cohort. The pathologic mechanisms behind this improvement need to be further researched in future studies.

**Introduction:** The last decade has seen a steady increase in the number of persons with pancreatic pathology, which is becoming an important social and economic problem. Both acute and chronic pathology of the pancreas can lead to the development of endocrine and exocrine pancreatic insufficiency, disrupting the processes of digestion, absorption.

**Aims & Methods:** Compare nutrient intake for patients with pancreatic cancer (PC), acute pancreatitis (AP) and chronic pancreatitis (CP).

166 patients were examined in the clinical study. Of these, 43 patients with pancreatic cancer (62.8 ± 4.7 years) and 123 patients with acute pancreatitis (AP) and chronic pancreatitis (CP), the average age of patients with pancreatitis is 50.4 ± 2, 2 years. Of these, 42 patients with acute pancreatitis and 81 patients with chronic pancreatitis. All patients underwent an ultrasound examination of the pancreas, liver and biliary tract, patients with PC were performed computed tomography of the pancreas. A survey of patients with AP was conducted in the first 5-10 days from the day of hospitalization, patients with CP - during the exacerbation. The actual nutrition was assessed using a questionnaire, including 142 product names indicating the portions of this product and the frequency of consumption over the past 3 months. Indicators of consumption of basic nutrients were calculated in grams and as a fraction of the daily caloric value they provide. The nutrient set was compared with the "Norms of physiological needs for energy and nutrients" (V. Tutelyan, 2009).

**Results:** The total caloric content of the daily diet of patients with various pathologies of the pancreas did not differ. The energy of the diet was: in patients with PC - 2593.7 ± 309.1 kcal / day, in patients with CP - 2553 ± 586.7 and in patients with AP - 2438 ± 224.2 kcal / day.

The diet of patients with pancreatic pathology was unbalanced by the fat and carbohydrate components. The high proportion of total fat intake (PC - 48.5% of kcal / day, CP - 46.2%, AP - 47.8%) and insufficient consumption of carbohydrates (35.3% of kcal / day, 39.1% and 38.0%, respectively). In individuals with pancreatic cancer, the diet included 135.2 ± 18.1 g / day of total fat and 235.3 ± 27.2 g / day of total carbohydrates.

The proportion of protein in the diet of patients with PC was 102.3 ± 12.2 g / day, which is higher than the recommended physiological intake rate - 16.2% of kcal / day, as well as in patients with CP and AP - 14.7% and 14, 2%. The content of vitamins B1, B2, PP in the diet of patients with various pathologies of the pancreas is within the recommended standards, but there is a significant excess of the norms of consumption of vitamins A and C in the diet of patients with prostate cancer (1787.8 ± 558.4 mkg ret. Equiv. and 335.5 ± 84.1 mg, respectively, p < 0.05), and in patients with AP, the content of beta-carotene in the diet is reduced (3.6 ± 0.9 mg / day).

**Conclusion:** The levels of nutrient intake in individuals with different pathologies of the pancreas were significantly different, the daily diet was unbalanced. The consumption of proteins, fats, vitamins A and C exceeds the recommended consumption rates. The share of total carbohydrate intake reduced in patients with cancer of the pancreas and in patients with acute and chronic pancreatitis. Probably, this can be regarded as an indirect sign of low adherence of patients with pancreatic diseases to compliance with medical recommendations, including dietary recommendations.

**Contact E-Mail Address:** sugimura.mikako.fp@mail.hosp.go.jp

**Introduction:** The number of women entering medical school increased remarkably over the past several decades and nearly a third of the graduates are female in Japan. However, the percentage of female gastroenterology fellows has remained stable at approximately 10%. Therefore, the Japanese society of Gastroenterology (JSGE) organized the Supporting Women in Gastroenterology group at each 10 regional bureau nationwide in 2016 and started to discuss this issue.

**Purpose:** The purpose of this study was to clarify the current situation and how to get more females in the field of gastroenterology area in Japan.

**Aims & Methods:** We conducted a survey by questionnaire for female member of JSGE Tohoku branch from October to December in 2016. That includes ; age distribution, marital status, specialized field, working hours, working condition during pregnancy and child care or elderly care, evaluation of current working environment, and desired support measures for continuous service.

**Results:** Of 233 female doctors in gastroenterology, 120 (53.8%) returned the questionnaire. The results are as follows ; age distribution (-29 years old ; 8.3%, 30-39; 41.7%, 40-49; 29.2%, 50-59; 15.0 %, 60-; 5.8 %), marital status (married; 68.3%, unmarried; 31.7%), specialized field (gastroenterology; 78.3%, surgeon ; 4.2%, others; 17.5%), working hours (8-10 hours per day ; 30.8%, 10-12 ; 17.5%, more than 12; 19.2%), approximately 90% of them came back to work soon after short maternity leave and 91% of those who were entitled to didn't take elderly-care leave. Many working mothers feel that they aren't fully understood by their colleagues. On the contrary, some unmarried female doctors complained of heavier workload due to other person's maternity leave and/or exemption from their duties. Most of the respondents thought that the understandings and supports from their boss and colleagues, working flexibly and/or sharing their work are essential for continuing their work.

**Conclusion:** Current working environment of women in gastroenterology field in Japan are tough. To get more female to this area and enable them to work with less burden, improvement of long working hours and change in awareness of their boss and colleagues are very important.

**Introduction:** Functional gastrointestinal diseases describe a spectrum of gastrointestinal dysfunctions, mainly functional dyspepsia (FD) and irritable bowel syndrome (IBS). Symptoms include abdominal pain, nausea, fullness and stool irregularities, leading to a severely impaired quality of life (1).

**Aims & Methods:** Given the high medical need in these indications especially in children (2), there is a requirement for effective and well-tolerated treatment options in this age group.

A PubMed-Medline search for clinical studies and reviews regarding FD and IBS in children in compliance with the PRISMA statement was conducted and complemented by hand searching and cross-referencing.

**Results:** The search gained 79 hits for FD in children, thereof 13 on pharmacological treatment options, 2 of which were herbals. For IBS, it gained 321 hits, including 23 on pharmacological treatments, thereof 5 herbals. These were Psyllium, Peppermint oil and STW 5 as well as Turmeric, Cannabis, Aloe vera and Ginger, with clinical studies in children mentioned only for Psyllium, STW 5 and Peppermint oil (1-5). For FD, Hippophae rhamnoides and STW 5 were identified, both with clinical evidence (1, 6). Only STW 5 was mentioned for both diseases.

A closer look into the evidence for this preparation showed a number of studies supporting the therapeutic usefulness in children of all ages, retrospectively (7, 8) as well as prospectively (9-14). These included 44,488 children, showing an excellent safety profile with only few mild side effects in this age group, and a convincing rating of the therapeutic usefulness.

**Conclusion:** Functional GI diseases are an important indication especially in children, where herbal preparations provide effective treatment options with a low risk profile and therefore play a prominent role in their management. Grades of evidence are different and most convincing for STW 5 likewise in FD and IBS, while Psyllium and Peppermint oil as well as Hippophae rhamnoides show evidence only for IBS or FD, respectively.

**Introduction:** According to the Rome IV criteria the diagnosis of rumination in children is based on typical symptoms during clinical evaluation. High

resolution manometry/impedance (HRM/Z) can be used to confirm the clinical suspicion of rumination but is rather poorly tolerated in children and only records one postprandial period.

**Aims & Methods:** The aim of our study was to identify a specific diagnostic pattern of rumination during ambulatory Impedance-pHmetry (MII-pH). We retrospectively assessed MII-pH tracings from children with clinical diagnosis of rumination syndrome confirmed by HRM/Z (minimal 2 typical rumination episodes in postprandial evaluation). We then compared the MII-pH parameters of these patients with those from children with GERD and "non-GERD" children (investigated for possible GERD but with normal MII-pH). We established cut-off levels for significant MII-pH parameters and developed a rumination-specific scoring system. We then validated the scoring system on another group of patients who underwent both HRM/Z and MII-pH (traces scored blindly).

**Results:** We identified 12 children with confirmed diagnosis of rumination based on HRM/Z findings (median age: 13.9 years, 6M:6F). Another 18 children were identified with GERD (median age: 8.1 years, 8M:10F) and 12 children with non-GERD (median age: 12.4 years, 6M:6F). Children with rumination had significantly higher number of total reflux events (RE)/24 hrs, total number of proximal RE/24 hrs ( $p < 0.0001$ ) and postprandial non-acid RE/hr ( $p = 0.0072$ ) compared to GERD and non-GERD groups. The SAP for regurgitation/reflux/vomiting was significantly higher in the rumination group ( $p = 0.0009$ ). The scoring system includes: 1) Total proximal RE/24hrs  $> 57.5$ , 2) Postprandial non-acid RE/hr  $> 2$ , 3) SAP for regurgitation/reflux/vomiting  $> 97.5$ . Each parameter scores 1 and rumination is diagnosed if the score is  $< 2$ . We validated the scoring system in a group of 18 children who underwent both a HRM/Z and MII-pH (8 diagnosed with rumination - 3M:5F, median age: 13 years - and 10 with a negative HRM/Z - 4M:6F, median age: 8.5 years). The sensitivity and specificity of the score is 75% and 80% respectively.

**Conclusion:** Children with rumination have many more symptomatic reflux episodes (SI/SAP positive) with high proximal extent, particularly during postprandial periods compared to GERD and controls. Our scoring system allows for early identification of children with rumination syndrome.

## P1383 ADULT ABDOMINAL PAIN CAN BE PREDICTED FROM EARLY CHILDHOOD SYMPTOMS AND PSYCHOSOCIAL FACTORS

**Contact E-Mail Address:** mike.jones@mq.edu.au

**Introduction:** Early childhood factors have been implicated in the development of chronic functional gastrointestinal (GI) symptoms in adulthood, including the irritable bowel syndrome. A number of specific factors have been suggested, including early GI symptoms<sup>1</sup>, early life events<sup>2</sup> exposure to immune-activating events<sup>3</sup> and the child's psychosocial environment<sup>4</sup>. However most of these studies are based on recall of childhood events after the individual has reached adulthood and hence may be subject to recall bias. In a prospective birth cohort our group recently demonstrated that mode of delivery and early psychosocial factors influenced the development of abdominal pain to 12 years of age<sup>5</sup> but were unable to confirm other factors such as early immune-activation by exposure to environmental factors such as pets in the household.

**Aims & Methods:** We now report on additional data collected on the birth cohort at average age 20 years, aiming to identify early childhood factors that are associated with the prevalence of abdominal pain. 5478 individuals (response rate 32%) were able to be contacted and agreed to participate in a follow-up. Factors recorded during early childhood and previously identified as associated with adult FGIDs were evaluated using logistic regression.

**Results:** 55% of the sample was female. Overall the prevalence of GI pain was 20% (95% confidence interval 19-21%). Increased abdominal pain in adulthood could be predicted from GI pain reported by parents as early as two years of age although the predictive ability improved when measured later in childhood (Table 1). In addition, poor appetite reported by parents at age five was also associated with increased prevalence of GI pain in adulthood (Table 1). The occurrence of serious life events in the child's year of birth and parental concerns for the child as early as two years of

age were all associated with increased prevalence of GI pain in adulthood, in addition to female gender (Table 1). In contrast, neither number of pets in the household at age 1 (OR=1.04, p=0.4) nor age 5 (OR=0.98, p=0.7) were associated with adult abdominal pain. We also considered early (< 5 years) allergy to milk, eczema and asthma, social support, marital status of parents, mental health conditions, temperament, antibiotic use, mode of delivery at birth and duration of breast feeding but none of these were associated with adult abdominal pain.

Factor	GI pain +	GI pain -	Odds ratio	95% CI	p-value
Female gender (%)	71	51	2.42	2.10, 2.80	<.001
GI pain at 2 years (%)	8	5	1.74	1.24, 1.44	.001
GI pain at 5 years (%)	12	9	1.42	1.05, 1.93	.02
GI pain at 8 years (%)	17	9	2.15	1.53, 3.02	<.001
GI pain at 12 years (%)	21	10	2.36	1.74, 3.20	<.001
Life events (%)	6	4	1.49	1.04, 2.15	.03
Parent worries at 2 years (mean/SD)	2.57 (1.21)	2.45 (1.14)	1.10	1.02, 1.18	.02
Parent worries at 8 years (mean/SD)	2.39 (1.00)	2.22 (0.98)	1.18	1.05, 1.32	.006

[Table 1. Early childhood factors univariately associated with adult abdominal pain prevalence]

Female gender (OR=2.39, 95% confidence interval 2.07, 2.76, p<.001) and GI pain at eight years (OR=1.35, 95% confidence interval 1.09, 1.67, p=.006) were statistically independent predictors of adult GI pain.

**Conclusion:** GI pain experienced in adulthood appears to result from a process that starts early in a child's development and is influenced by its psychosocial environment. Greater attention to signs evident as early as infancy may have long-lasting benefits to patients. In contrast to previous findings, the child's physical environment appears to be less relevant, in including the presence of immune-stimulating factors.

## P1384 CLINICAL AND PROGNOSTIC VALUE OF THE FECAL ZONULIN IN EXTREMELY PREMATURE BABIES

Khasanova S.<sup>1</sup>, Kamilova A.<sup>2</sup>

<sup>1</sup>Republican Perinatal Center, Neonatology, Tashkent, Uzbekistan,

<sup>2</sup>Republican Specialized Scientific and Practical Medical Center of Pediatrics, Gastroenterology and Nutriciology, Tashkent, Uzbekistan

**Contact E-Mail Address:** okamilova@mail.ru

**Introduction:** The state of integrity of the intestinal barrier is significant in the development of conditions associated with digestive disorders of varying severity, especially in premature babies. Increased zonulin in the tissues of the intestine leads to the expansion of intercellular contacts and an increase in intestinal permeability. [1-6]

**Aims & Methods:** The aim of the study is to evaluate the clinical and prognostic significance of fecal zonulin in extremely premature babies up to 32 weeks.

**Material and methods:** We examined 108 premature babies with gestational age at birth from 22 to 32 weeks and 27 full-term newborns who constituted the control group. Studies of fecal zonulin were carried out in

dynamics on the 3rd, 7th and 14th days of life. The content of zonulin in feces was determined using Immunodiagnostik (Germany) reagents (ELISA) by enzyme-linked immunosorbent assay.

**Results:** We found an increase in the level of fecal zonulin (FZ) in 17 times on the third day of life, 8 times on the 7th day of life and almost 5 times on the 14th day of life compared to the control group, whose values were -28.5 ± 3 on the 3rd day, 6 ng / ml, on day 7 - 61.1 ± 5.1 ng / ml and 14 days of life - 89.8 ± 5.8 ng / ml. To identify parallels between the values of the FZ and other clinical and laboratory parameters, we divided all children into clusters with certain limits of fluctuations of the values of the FZ. Cluster A consisted of patients with fecal zonulin values up to 500 ng / ml (n = 52), cluster B - children with values from 500 to 1000 ng / ml (n = 40) and cluster C - 16 children with fecal zonulin values (more than 1000 ng / ml). In cluster B, on the 7th day of life, along with higher rates of fecal zonulin, the marker of the inflammatory process - C-reactive protein (respectively, cluster A-9.6 ± 1.0 and B-18.0 ± 2.7, t-2.94, p < 0.001). The hemoglobin values determined on the first day of life in newborns in cluster B had significantly lower values than in cluster A. (175.1 ± 2.7 g / l and 152.5 ± 4.2 g / l, t-2.31, p < 0.001).

On day 14 of life in cluster A, the mother's prothrombin index was significantly lower than in cluster B (cluster A-82.0 ± 1.4%, cluster B-96.0 ± 1.9%; t-5.89, p < 0.001).

To study the relationship between the values of fecal zonulin and the prognosis of necrotizing enterocolitis, we divided all patients into 2 groups. The first group consisted of 10 children who developed necrotizing enterocolitis by 10.2 ± 4.5 days of life and 81 children entered the 2nd group without necrotizing enterocolitis.

In the group of children with NEC on the 7th day of life, we observed an almost twofold, significantly significant increase in zonulin values compared with the compared group without NEC (343.5 ± 76.7 and 618.4 ± 89.9 with p < 0.05).

**Conclusion:** The dynamics of fecal zonulin in premature babies revealed a multiple increase in its values within 14 days of life compared with healthy full-term babies. The level of faecal zonulin on day 7 of life is a predictor of the development of NEC in very premature babies.

## P1385 THE USEFULNESS OF PROBIOTIC ADMINISTRATION IN OBESE CHILDREN WITH NONALCOHOLIC FATTY LIVER DISEASE

Belei O., Olariu L., Marcovici T., Marginean O.

University of Medicine and Pharmacy Victor Babes, First Pediatric Clinic, Timisoara, Romania

**Contact E-Mail Address:** beleioana@gmail.com

**Introduction:** The increasing rate of pediatric obesity imposed nonalcoholic fatty liver disease (NAFLD) as the most frequent cause of chronic liver conditions in children. It includes simple liver steatosis and may progress to non-alcoholic steato-hepatitis and cirrhosis. Recent studies suggested that intestinal dysbiosis and gut-derived endotoxins may be important in this progression, therefore probiotics may have a positive role in improving liver parameters.

**Aims & Methods:** The aim of this paper was to evaluate the usefulness of probiotics administration to obese children with NAFLD to optimize metabolic parameters and to reduce intestinal dysbiosis. Methods: 102 obese children aged 10-18 years were enrolled in this double-blind,

placebo-controlled study. NAFLD was assessed in all children using abdominal imaging and laboratory findings. All children underwent clinical and anthropometric evaluation, liver and renal function tests, glycemia, insulinemia and lipid metabolism assessment. Glucose hydrogen breath test was performed for small intestinal bacterial overgrowth (SIBO) assessment at baseline and after 12 weeks of probiotic intervention. NAFLD subjects were equally randomized to receive either probiotic *Lactobacillus reuteri* (10<sup>8</sup> CFU/day) or placebo for 12 weeks add on hypo-caloric diet and increased physical activity.

**Results:** 36/102 (35%) of obese children presented NAFLD. Children who received probiotic supplementation had a significant higher reduction of body mass index after 12 weeks compared to placebo group ( $P < 0.01$ ). There was a significantly higher reduction of intestinal dysbiosis, amino-transferases level and serum triglycerides levels after the intervention period in the probiotic group compared to placebo ( $P < 0.05$ ).

**Conclusion:** In this study, decreasing in body mass index was higher in the group receiving probiotics compared to placebo. *Lactobacillus reuteri* added to proper diet had a beneficial effect on lipid profile and transaminases level and significantly decreased the intestinal dysbiosis in obese children with NAFLD.

**Contact E-Mail Address:** doctscases90@gmail.com

**Introduction:** The prevalence of obesity is increasing worldwide among children and adolescents. Although obesity in children has a relatively low risk of metabolic complications, those with more severe types of obesity may be at higher risk in adults. In many countries with moderate increase of the obesity epidemic, the association between severe obesity and metabolic complications has been rarely reported in pediatric populations.

**Aims & Methods:** The purpose of this study is to assess the prevalence of severe and extremely severe obesity and each metabolic complication using a nationally representative data in Korea and to identify proper monitoring tools for assessing the current obesity epidemic.

A total of 790,653 student (380,580 female) aged 5-19 years were recruited from the Korean student health examination, 2011-2018. Obesity was defined by age- and sex-specific BMI reference according to the WHO Growth reference data (2007). Obesity was defined by using the skinner's new classification: Class I obesity (BMI  $\geq 100\%$  of 95th percentile), Class II (severe obesity, BMI  $\geq 120\%$  of 95th percentile), and Class III (extremely severe obesity, BMI  $\geq 140\%$  of 95th percentile). Metabolic complications included hypertension, hyperglycemia, hypercholesterolemia, and elevated aminotransferase. All analyses were performed using SAS software (Version 9.4).

**Results:** Comparing 2011 and 2018, the overall prevalence of Class II (severe) obesity have increased by 63% (from 3.0% to 4.9%) ( $p < 0.0001$ ) and Class III (extremely severe) obesity increased by 100% (from 0.4% to 0.8%) ( $p < 0.0001$ ), whereas Class I (conventional) obesity increased by 28.7% (from 15.7% to 20.2%) ( $p < 0.0001$ ). In logistic regression analysis, the adjusted odds ratios (ORs) for Class III obesity were calculated according to each metabolic complications; hypertension was 10.3 times higher than non-obese group ( $p < 0.001$ ), hyperglycemia was 2.6 times higher ( $p < 0.001$ ), hypercholesterolemia was 2.1 times higher ( $p < 0.001$ ), and elevated aminotransferase was 12.7 times higher ( $p < 0.001$ ). The mean numbers of metabolic complications in each obesity group was 1.14 in Class III obesity, 0.76 in Class II, 0.5 in Class I, and 0.29 in non-obese group. (Table 1)

Obesity group	The number of metabolic complications (%)					mean (95% CI)	mean difference <sup>1</sup> (95% CI)	p-value
	0	1	2	3	4			
Non-obese	75.7	20.3	3.7	0.3	0.1	0.29 (0.27, 0.31)		
Class I Obesity	60.1	30.8	8	1	0.02	0.5 (0.49, 0.51)	0.21 (0.19, 0.24)	<.0001
Class II Obesity	43.7	39.5	14.3	2.3	0.16	0.76 (0.73, 0.78)	0.47 (0.44, 0.5)	<.0001
Class III Obesity	22.8	47.9	22.8	5.6	0.9	1.14 (1.08, 1.2)	0.85 (0.79, 0.92)	<.0001

[Table 1. The mean numbers of metabolic complications in each obesity group, 2011-2018]

**Conclusion:** We found that the prevalence of Class II and III obesity (severe and extremely severe) is highly increasing and the risk of metabolic complication is sharply increasing according to severity of obesity in childhood. Close monitoring of metabolic complications is important to track severe obesity. Further longitudinal studies are needed to verify childhood obesity at the highest metabolic risk.

**Contact E-Mail Address:** crisan.dc@gmail.com

**Introduction:** There is an established correlation between the PNPLA3 rs738409 C>G single nucleotide polymorphism (SNP) and hepatic steatosis and fibrosis in HCV infected patients. However not all data is convergent regarding the exact impact of this SNP on the pattern of disease progression in different clinical settings.

In this study, **we aimed** to further bridge the knowledge gap on this topic by investigating the role of the G allele in promoting steatosis, fibrosis and disease progression in relation to other metabolic and anthropometric host factors.

**Aims & Methods:** Two hundred and fifty consecutive patients, previously diagnosed with chronic hepatitis C (CHC) underwent liver biopsy. Histology was assessed using the Metavir scoring system. Transient elastography was used for follow-up. Ninety-eight patients were genotyped for PNPLA3 rs738409 and followed up for fibrosis progression.

**Results:** PNPLA3 rs738409[G] allele was significantly correlated with severe steatosis ( $p = 0.04$ ), severe fibrosis at the time of enrollment ( $p = 0.0005$ ) and fibrosis progression with an OR of 10.31 (95% CI 1.06-99.59,  $p=0.04$ ), after a mean follow-up time of 62.85 (95%CI: 52.21-76.15) months. Severe steatosis at the time of enrollment had an OR of 11.02 (95% CI 1.48-82.09,  $p=0.01$ ) for the association with fibrosis progression. The HOMA-IR index was also positively correlated with severe fibrosis ( $p=0.03$ ) and fibrosis progression on univariate analysis ( $p=0.02$ ).

**Conclusion:** PNPLA3 rs738409[G] allele is a reliable predictor for steatosis and fibrosis in CHC. The presence of G allele, along with severe steatosis and insulin resistance are significant predictors for fibrosis progression.

**Introduction:** Transient hepatic elastography is widely used in staging and monitoring of fibrosis in patients with non-alcoholic steatohepatitis (NASH). According to the European Association for the Study of Liver (EASL) recommendations, the evaluation of transient elastography should be complemented with non-invasive markers to improve its accuracy.

**Aims & Methods:** We aimed to evaluate the correlation between the variation of the transient elastography (TE) and noninvasive fibrosis markers in a historical cohort of biopsy-proven NASH patients.

For this, we performed an observational and retrospective study in a random sample of NASH patients in whom diagnosis was established by liver histology. For each case, TE and NAFLD activity score, fibrosis-4 index for liver fibrosis (FIB-4), AST to platelet ratio (APRI) and AST/ALT ratio data were documented at the time of the diagnosis and at the date of the last clinical contact. The difference between the final and initial values was calculated for each variable ( $\Delta$ , "delta"). The statistical relationship between the  $\Delta$ TE and variation in noninvasive fibrosis markers was established in a linear regression model.

**Results:** We evaluated 62 cases (mean age at diagnosis  $49.9 \pm 12.9$  years, 56.5% of the male gender) with an average follow-up time of  $3.54 \pm 1.54$  years. Liver disease was diagnosed in the cirrhotic stage in 16.1%.

During follow-up, we observed the presence of an acute cardiovascular event in 5 patients; one case developed hepatocellular carcinoma. The therapeutic goals of weight reduction and regular physical activity were reached in 30.6% and 27.4% of the patients, respectively.

The mean  $\Delta$ Transient Elastography value was  $-0.38 \pm 7.6$  kPa. Bivariate correlation test showed a statistically significant correlation between the  $\Delta$ Transient Elastography and  $\Delta$ NAFLD activity score ( $k = 0.48$ ,  $p < 0.01$ ),  $\Delta$ FIB-4 ( $k = 0.65$ ,  $p < 0.01$ ) and  $\Delta$ AST/ALT ratio ( $k=0.37$ ,  $p=0.2$ ). After adjustment of the  $\Delta$  values for the follow up time in a linear regression multivariate model, this significant relationship was maintained (NAFLD activity score:  $\beta 3.01$ ,  $p < 0.01$ ; FIB-4:  $\beta 3.36$ ,  $p < 0.01$ ; AST/ALT ratio:  $\beta=8.38$ ,  $p = 0.2$ ).

**Conclusion:** In this sample of NASH patients, the variation of the NAFLD activity score, FIB-4 and AST/ALT ratios was correlated with the variation of EHT values. Among the formulas, the variation in FIB-4 values presented a better correlation with the transient elastography values.

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** Advanced liver fibrosis was proved to correlate positively with mean platelet (PLT) volume (MPV) to PLT ratio (MPR) and neutrophil to LYM ratio (NLR) and negatively with PLT to LYM ratio (PLR). However, the number of available analyses in this field of hepatology is still limited.

**Aims & Methods:** The aim of our investigation was to evaluate the diagnostic accuracy of MPR, NLR and PLR in the assessment of liver fibrosis in alcoholic liver cirrhosis (ALC) and non-alcoholic fatty liver disease (NAFLD) patients and to compare it with serological: indirect and direct markers of liver fibrosis. Another goal was to assess relationships between above-mentioned hematological indices and clinical progression of ALC. Three hundred and two participants were recruited to the study: 142 patients with ALC, 92 with NAFLD and 68 healthy volunteers in control group. Hematological indices (MPR, NLR and RLR) were measured in each person. Indirect markers of liver fibrosis were also obtained: AAR [aspartate aminotransferase (AST) to alanine aminotransferase (ALT) ratio], APRI (AST to PLT Ratio Index), FIB-4 (Fibrosis-4) and GPR ( $\gamma$ -glutamyl-transferase to PLT ratio). Among direct indices of liver fibrosis, procollagen I carboxyterminal propeptide (PICP), procollagen III aminoterminal propeptide (PIIINP), platelet-derived growth factor AB (PDGF-AB), transforming growth factor- $\alpha$  (TGF- $\alpha$ ) and laminin were assessed. The assessment of clinical progression of liver failure in ALC patients was done with MELD score. NAFLD fibrosis score and BARD score were calculated in NAFLD patients. Achieved results were compared to controls and between ALC and NAFLD groups. Then a correlation between evaluated indices was done. Diagnostic value of each assessed haematological parameter together with proposed cut-off in research group were measured with AUC (area under the curve).

**Results:** MPR and NLR values in ALC patients were significantly higher in comparison to controls ( $p < 0.0001$ ); PLR level was significantly lower ( $p < 0.0001$ ). MPR and PLR correlated positively with indirect markers of liver cirrhosis (APRI, FIB-4;  $p < 0.001$ ). Positive (but weaker) relationships were found between NLR and both: AAR and GPR ( $p < 0.05$ ). MPR correlated negatively with PDGF-AB ( $p < 0.0001$ ); positive relationship was observed between PLR and PDGF-AB ( $p < 0.01$ ).

Additionally, NLR correlated negatively with PIIINP ( $p < 0.05$ ). MELD score correlated positively with NLR ( $p < 0.0001$ ) and negatively - with PLR ( $p < 0.001$ ). NLR level in NAFLD patients was significantly higher in comparison to controls ( $p < 0.0001$ ). MPR and PLR values did not differ significantly. MPR correlated positively with indirect markers of liver fibrosis - APRI ( $p < 0.0001$ ), FIB-4 ( $p < 0.0001$ ) and GPR ( $p < 0.01$ ).

A strong positive relationship between MPR and NAFLD fibrosis scale was noted, too ( $p < 0.0001$ ). MPR and NLR values were significantly higher in ALC patients compared to NAFLD group ( $p < 0.0001$ ); PLR level was significantly lower ( $p < 0.0001$ ). AUC values and proposed cut-offs for MPR, NLR and PLR in ALC patients were: 0.929 ( $> 0.048$ ), 0.821 ( $> 2.227$ ) and 0.675 ( $< 70.445$ ), respectively. AUC values and proposed cut-offs for MPR, NLR and PLR in NAFLD patients were: 0.547 ( $> 0.038$ ), 0.725 ( $> 2.034$  %) and 0.528 ( $> 97.101$  %), respectively.

**Conclusion:** PLR and NLR turned out to be the most powerful markers of liver fibrosis in ALC patients. Moreover, they also correlated with clinical progression of the disease. Diagnostic accuracy of MPR, NLR and PLR was found to be weaker in examined NAFLD patients.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) comprises a spectrum of stages from simple steatosis to non-alcoholic steatohepatitis (NASH). Recent evidence supports a functional role for microRNAs (miR-NA/miRs) in regulating NAFLD progression. In particular, pro-apoptotic miR-34a expression has been reported to sequentially increase during disease progression in both experimental and human NAFLD.

**Aims & Methods:** We now aimed to elucidate whether modulation of miR-34a in NAFLD constitutes a key, primary event and which disease hallmarks correlate with its expression, hinting at its multiple roles in disease pathogenesis.

C57BL6 mice were fed five different NAFLD-inducing diets, namely a methionine and choline-deficient diet for 2 and 8 weeks; a high-fat choline-deficient diet for 14 weeks; a high fat, 2% cholesterol diet with high fructose for 25 weeks; a high-fat/calorie diet with high fructose/glucose in drinking water for 16 weeks; and a choline-deficient amino acid-defined diet for 32 weeks. Liver biopsies were obtained from a cohort of 166 NAFLD patients, histologically and metabolically characterized (NAS 0 to 4; n=89; NAS > 4: n=77). Human liver total RNA was used for analysis of miR-34a by Taqman Advanced Real-Time RT-PCR.

**Results:** Mice fed with any of the five diets developed different degrees of NASH, paralleling liver triglyceride deposition, steatosis, inflammation and weigh gain. Mild-to-severe fibrosis was observed in all animals, except for mice fed the high fat, 2% cholesterol diet, where fibrosis was ab-

sent. Nonetheless, miR-34a expression levels were significantly increased in the livers of all these mice (at least  $p < 0.05$ ), comparing with control diets-fed animals.

NAFLD patients exhibited different degrees of steatosis and NASH, with or without the presence of fibrosis and concomitant diseases, including diabetes, arterial hypertension and cholelithiasis. Liver miR-34a expression was found to progressively and significantly increase with the raise of steatosis, lobular inflammation and NAS score (at least  $p < 0.05$ ). Furthermore, miR-34a expression levels were also significantly higher in patients with bridging fibrosis and cirrhosis (at least  $p < 0.05$ ), as well as in those with concomitant diabetes, arterial hypertension and cholelithiasis (at least  $p < 0.05$ ). Finally, liver miR-34a expression levels positively correlated with histological analysis (steatosis, lobular inflammation, fibrosis and NAS score), serum hepatic enzymes (AST and ALT), hepatic triglyceride content and age (at least  $p < 0.05$ ).

**Conclusion:** In conclusion, liver miR-34a appears to be a key player in NAFLD pathogenesis and progression, correlating with several well-characterized disease hallmarks. A better understating of the overlapping roles of miR-34a in NAFLD development may help in establishing novel and appealing therapeutic targeting options (Gilead Sciences International - Research Scholars Program in Liver Diseases; PTDC/MED-PAT/31882/2017 and SFRH/BD/104160/2014, FCT, Portugal).

### P1391 ESTABLISHMENT OF A NOVEL DIETARY-INDUCED MOUSE MODEL SHOWING STEATOHEPATITIS WITH SEVERE FIBROSIS

Ichimura M., Ogawa H., Matsumoto M., Tsuneyama K.  
Tokushima University, Pathology and Laboratory Medicine, Tokushima, Japan

**Contact E-Mail Address:** ichimura.mayuko@tokushima-u.ac.jp

**Introduction:** Experimental induction of liver fibrosis is still difficult in rodents. Carbon tetrachloride-induced fibrosis is secondary to hepatocellular necrosis that is similar to human viral hepatitis, while nonalcoholic steatohepatitis (NASH) is characterized by perivenular-pericellular fibrosis with elongation of delicate fiber rather than remarkable necrosis.

**Aims & Methods:** We previously made a model of NASH-related cirrhosis mimicking human fibrotic pattern of NASH using a rat fed with a high-fat and cholesterol (HFC) diet; thus, the aim of this study was to establish a mouse model of liver fibrosis. Six-week-old male Tsumura-Suzuki obese diabetes (TSOD) mice, a model of spontaneous metabolic syndrome and NASH, and Tsumura-Suzuki non obese (TSNO) mice that are control of TSOD mice were fed with a HFC diet and normal diet for 12 months. Blood and liver were collected at 20, 32, 44 and 56 weeks of age.

**Results:** TSOD mice fed the HFC diet showed obesity, diabetes and steatohepatitis with slight fibrosis. On the other hand, TSNO mice of normal control did not show obesity and diabetes but exhibited severe fibrosis in addition to steatohepatitis. The pattern of fibrosis in TSNO mice resembled human NASH, namely, delicate perivenular and perisinusoidal fibrosis. We initially hypothesized that hepatic fibrotic change of TSOD mice could be enhanced by intake of the HFC diet due to their background of spontaneous metabolic syndrome, however, TSNO mice showed much more severe fibrosis. It is speculated that fibrosis-prone traits may be enriched in the process of selective breeding of non-obese and non-diabetic mice. The fibrotic lesions in TSNO mice lasted until 56 weeks of age, but there was only one case of onset of liver tumor. It is known that carcinogenesis attenuates background liver pathology including fibrosis and tumor onset provides endpoint in experiments assessing fibrosis. Receptor interacting protein 3 which promotes cell death by necroptosis was positive in the liver of TSNO mice fed with the HFC diet, suggesting that necroptosis pathway might upregulate and resulting in low occurrence of liver tumor in this model. Because our model persists in fibrosis over a long period without carcinogenesis, it can be considered to be a useful model not only for preventive but also for therapeutic experiments.

**Conclusion:** The HFC diet-loaded TSNO mice developed NASH with marked fibrosis with quite similar pattern of human fibrotic NASH. Our model induced by not genetically modification but simple diet that imitated human dietary habits has many advantages that can simply analyse the mechanism of development of liver fibrosis.

**Introduction:** microRNAs (miRNAs) are modulated in non-alcoholic fatty liver disease (NAFLD) and are being studied as putative diagnostic and prognostic biomarkers. Further, as post-transcriptional modulators of gene expression, miRNAs appear to contribute to NAFLD pathogenesis by regulating distinct cellular pathways, impacting on lipid and glucose metabolism, energy homeostasis, cell death, cell proliferation and differentiation, among others.

**Aims & Methods:** Here, we aimed to identify and validate novel metabolism-associated miRNAs modulated during experimental NAFLD. C57BL/6N male mice were fed distinct NAFLD-inducing diets, namely a methionine and choline deficient diet (MCD; n=30) for 2 and 8 weeks; a high fat, 2% cholesterol diet with high fructose - fast-food diet (FF; n=12) - for 25 weeks; and a choline-deficient amino acid-defined diet (CDAA; n=28) for 32 and 66 weeks. Liver samples were collected and processed for histological and miRNA analyses. Liver RNA from 8 week MCD-fed mice was analysed using TaqMan™ array microRNA cards, containing sequences for ~740 of the most relevant human or rodent miRNAs. qPCR array data was analysed using the HTqPCR package in Bioconductor. We found significant differences in the expression of 52 miRNAs, with 25 miRNAs increasing and 27 miRNAs decreasing in the liver of MCD diet-fed mice, comparing with chow-fed animals. Differentially expressed miRNAs were subjected to an *in silico* analysis to exclude previously reported associations with NAFLD or related metabolic liver diseases. Based on this, a panel of different upregulated (miRNA-127, miRNA-136, miRNA-411) and downregulated (miRNA-107, miRNA-455) miRNAs was selected for downstream validation analyses.

**Results:** miR-136 was found to be up-regulated in MCD-fed animals alone. In turn, both miRNA-127 and miR-411 were found consistently up-regulated in both MCD and CDAA diets, but unaffected in the FF diet, suggesting a possible association with liver damage rather than overall metabolism. Interestingly, miRNA-107 and, in particular, miRNA-455, were consistently downregulated in all diets, comparing with control diet-fed animals, suggesting that they may constitute major regulators of disease pathogenesis.

**Conclusion:** In conclusion, we have identified novel miRNAs modulated during experimental NAFLD, associating with distinct pathogenic signalling pathways. A better characterization of the role of these miRNAs in disease could translate into prospective therapeutic strategies as well as putative biomarkers in NAFLD.

### P1393 IL-2, IL-15 AND STEM CELL FACTOR ENHANCE CYTOTOXICITY OF CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK CELLS AGAINST HUMAN HEPATOCELLULAR CARCINOMA CELL LINES

Luo Y.<sup>1</sup>, Chen H.<sup>1,2</sup>, Zhou W.<sup>1,3</sup>, Sha W.<sup>1,4</sup>

<sup>1</sup>Guangdong Provincial People's Hospital, Gastroenterology, Guangzhou, China, <sup>2</sup>Guangdong general hospital, Guangdong general hospital, Guangzhou, China, <sup>3</sup>South China University of Technology, Guang Zhou, China, <sup>4</sup>Guangdong General Hospital Dept. of Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** 464695938@qq.com

**Introduction:** Liver cancer is a kind of malignant tumor, which seriously affects people's health.

**Aims & Methods:** To investigate the effects of IL-2, IL-15 and stem cell factor (SCF) on the efficiency of expansion, expression of NKG2D and the cytotoxicity of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells against human hepatocellular carcinoma cell lines. The CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells purified by the sorting method of MACS (magnetic microbeads activated cells sorting) were expanded in the presence of IL-2 or IL-15 or IL-2/IL-15/SCF with or without anti-NKG2D monoclonal antibody. The efficiency of expansion, the expression of NKG2D

and the cytotoxicity of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells against HepG2, SMMC-7721 were determined using trypan blue staining, flow cytometry and CCK-8 assay, respectively.

**Results:** The efficiency of expansion, the expression of NKG2D and the cytotoxicity of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells treated with IL-2/IL-15/SCF were significantly increased than those in other groups. Most interestingly, the cytotoxic effects of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells on HepG2 cells were significantly reduced by the pretreatment with anti-NKG2D monoclonal antibody. However, the treatment with the same antibody had little influence on the cytotoxicity of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells against SMMC-7721 cells.

**Conclusion:** IL-2/IL-15/SCF enhances the efficiency of expansion, the expression of NKG2D and the cytotoxicity of CD3<sup>+</sup>CD56<sup>+</sup>CD16<sup>+</sup> NK cells against human hepatocellular carcinoma cell lines. NKG2D plays an important role in mediating the cytotoxicity of NK cells on specific types of tumor cells.

### P1394 GYNECOLOGICAL HISTORY AND PREGNANCY OUTCOMES IN WILSON'S DISEASE PATIENTS UNDER THERAPY - A BICENTRIC CONTROLLED STUDY

Roseira L.<sup>1</sup>, Lopes R.<sup>2</sup>, Silva M.J.<sup>3</sup>, Vieira A.M.<sup>4</sup>, Sampaio M.<sup>1</sup>, Calinas F.<sup>3</sup>

<sup>1</sup>Algarve University Hospital Center, Gastroenterology Department, Portimão, Portugal, <sup>2</sup>University of the Algarve, Biomedical Sciences and Medicine, Faro, Portugal, <sup>3</sup>Capuchos Hospital, Center of Lisbon Hospital Center, Gastroenterology Department, Lisboa, Portugal, <sup>4</sup>Algarve University Hospital Center, Centro Hospitalar do Barlavento Algarvio, Portimão, Portugal

**Contact E-Mail Address:** jsroseira31@gmail.com

**Introduction:** Untreated Wilson Disease (WD) is associated with menses irregularities and obstetric complications. Research in this area is scarce and most studies narrowly focus on pregnancy outcomes comparisons between WD patients with and without treatment.

**Aims & Methods:** **Aims:** Identify menses irregularities in WD; evaluate the impact of under treatment WD in pregnancy, compared with two control groups (with and without liver disease).

Data collection was carried in two hospital centers in order to identify the maximum number of women diagnosed with WD. For the control groups, women with Hepatitis C (controls with liver disease) and women with other gastrointestinal conditions (controls without liver disease), were consecutively identified from the hepatology and gastroenterology clinics. Sociodemographic characterization and gynecological history were collected. Statistics: chi-square test, multinomial logistic regression.

**Results:** We identified 18 women ongoing treatment for WD (11 pregnancies) and 20 women for each control group. Stage of liver disease between controls and the study group was adjusted (p = 0.65).

The incidence of menses irregularities was higher in the WD group (late menarche, 15 vs. 2 vs. 2 [p < 0.01], irregular cycles, 18 vs. 4 vs. 4 [p < 0.01], amenorrhea, 12 vs. 2 vs. 1 [p < 0.01]).

The logistic regression model identified the WD group as a predictor of miscarriage and low birth weight (odds ratio: 9.0 [1.4-57.1], p = 0.02). Concerning "fetal malformations", the WD group had the highest rate of events (3/11) but the difference was not significant (p = 0.51). The type of therapy (D-Penicillamine or zinc acetate), and the clinical presentation of the disease (hepatic or/and neurological) was not associated with the identified obstetric complications in WD.

**Conclusion:** There was a higher incidence of menses irregularities in the WD group. Also, this work adds to the literature as it suggests that WD under therapy still maintains a higher risk of spontaneous abortion and low birth weight, compared to control groups with and without liver disease. Despite the theoretical teratogenic potential of the drugs, the risk of fetal malformations under chelation therapy (D-Penicillamine 300mg) or zinc acetate (150mg) was not significant, which reinforces the need to maintain therapy throughout pregnancy.

**Disclosure:** Nothing to disclose

## P1395 WHY GASTROENTEROLOGISTS MUST LOOK FOR TYPE 2 DIABETIC PATIENTS?

Sporea I.<sup>1</sup>, Mare R.G.<sup>2</sup>, Sirli R.L.D.<sup>3</sup>, Popescu A.<sup>3</sup>, Silviu N.<sup>4</sup>, Sima A.<sup>5</sup>, Timar R.<sup>5</sup>

**Contact E-Mail Address:** ruxi2323@yahoo.com

**Introduction:** Non-alcoholic fatty liver disease and type 2 diabetes commonly coexists. The risk of developing NAFLD in these patients is high due to high prevalence of obesity.

**Aims & Methods:** The aim of the study was to assess the severity of liver fibrosis and steatosis in a cohort of pure type 2 diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP).

The study included 704 type 2 diabetic patients, who were prospectively randomized evaluated in the same session by means of TE and CAP (FibroScan EchoSens) to assess both liver fibrosis and steatosis. Reliable liver stiffness measurements (LSM) were defined as the median value of 10 LSM with an IQR/median < 30%. A cut-off value of 10.1 kPa[1] was used to define severe fibrosis (F≥3). For differentiation between stages of steatosis we used the following cut-off values proposed by the manufacturer: S1 (mild) 230-275, S2(moderate) 275-300 db/m, S3(severe) > 300 db/m.

**Results:** Out of 704 diabetics screened we excluded those with associated viral hepatitis, those with an AUDIT-C score ≥8 and those with unreliable LSM. 14 patients had associated viral B or C hepatitis (1.9%), 17 patients an AUDIT-C score ≥8 (2.4%) and 15 patients (2.1%) had other hepatopathies (autoimmune, toxic, cholestatic). After excluding those with unreliable LSM, the final analysis included 546 diabetic patients without other hepatopathies (53.8% women, mean age 60 ±9.5; BMI=31.6± 6.1 kg/m<sup>2</sup>). 59.9% of them had BMI ≥ 30kg/m<sup>2</sup>. Mild, moderate and severe steatosis by means of CAP was found in 17 %, 14.5 % and 58.8% cases respectively. The median CAP value of patients with mild, moderate and severe steatosis was 260 db/m, 287 db/m and 356 db/m. Severe fibrosis was detected by means of TE in 19% (104/546) of subjects and the median value was 12.5 kPa.

**Conclusion:** In our group, approximately 77.6% were diabetic patients with reliable LSM. Presence of steatosis was found in 90.3% of patients by means of CAP and 19% of them had severe fibrosis suggesting the need for further assessment.

**Introduction:** There is emerging evidence for the positive effects of coffee consumption in patients with liver disease. Our aim was to determine the effects of coffee intake on a liver enzymes, inflammation parameters, non-invasive elastographic markers of liver steatosis and fibrosis, as well as to degree of NAFLD detect by liver biopsy.

**Aims & Methods:** In this cross-sectional study we have analyzed 575 patients with NAFLD. There was 273 (47.5%) man and the mean age was 59±13 years. NAFLD was detected by controlled attenuation parameter (CAP) and liver stiffness measurements (LSM) assessed by transient elastography (TE). In part of the patients (113) the liver biopsy was done as well. Coffee drinking was recorded using semi-quantitate questionnaire and categorized as yes vs. no and as 0, 1, 2, ≥3.

**Results:** The great majority were coffee drinkers (77.6%). Patients were divided into four subgroups of patients depending on the number of cups of coffee per day (0, 1, 2, ≥3). Firstly we have analyzed the influence of coffee drinking on the elastographic parameters of liver steatosis and fibrosis (CAP and LSM). Interestingly, patients that were drinking more cups of coffee had higher CAP, while the same group of patients had lower LSM values in comparison to nondrinkers or those who were drink only one cup of coffee per day, although that was not statistically significant. Next we have investigated the influence of coffee drinking on biopsy findings. There was no significant difference in the degree of NASH, although patients who were not coffee drinkers had lower degree. On the other hand those who drank more coffee had the lowest degree of fibrosis, although this difference is not statistically significant. Furthermore, drinking coffee had no influence on liver enzyme levels. Finally, drinking coffee had beneficial influence on ferritin and CRP values as inflammation parameters.

**Conclusion:** According to our results drinking coffee have beneficial effect on degree of fibrosis detected by TE (LSM) and liver biopsy, as well as on inflammation parameters.

**Disclosure:** Nothing to disclose

## P1397 GENDER BIAS IN POLYCYSTIC LIVER DISEASE: ESTRADIOL STIMULATES PROLIFERATION AND INFLUENCES ESTROGEN RECEPTOR EXPRESSION IN PRKCSH KNOCKOUT CHOLANGIOCYTES

Bernts L.H.P., van Bakel K., Sahin A., te Morsche R.H.M., Drenth J.P.H. Radboud University Medical Center, Gastroenterology and Hepatology, Nijmegen, Netherlands

**Contact E-Mail Address:** lucas.bernts@radboudumc.nl

**Introduction:** Polycystic liver disease (PLD) is a rare genetic disease and PRKCSH has been identified as one of the causative genes. In large cohort studies, over 80% of patients are female. In addition, the severity of PLD correlates with the use of exogenous estrogens [1]. We aimed to find experimental evidence for the effect of estradiol on proliferation of cholangiocytes *ex vivo*. Furthermore, we studied the expression of estrogen receptor (ER)-α, ER-β and the G protein-coupled estrogen receptor (GPER) in cholangiocyte cell lines, organoids and hepatic cyst tissue.

**Aims & Methods:** We used H69 wild type (WT) and H69 PRKCSH knock out (KO) cholangiocyte cell lines, patient-derived organoids (n=10) and hepatic cyst tissue (n=9). H69 cell lines were incubated in a dilution series of estradiol. A possible additive effect of progesterone was also assessed in a dilution series. With the use of WST-1 assays, the effect of the hormones on the relative proliferation between treated and non-treated WT and KO cholangiocytes was determined. PCNA expression was used to identify proliferative effects in organoids. For RNA isolation we cultured WT and

KO cholangiocytes, and organoids in medium with either the optimal hormone concentration for proliferation, or vehicle. RNA was isolated using Trizol to determine the expression of estrogen receptors (ER- $\alpha$ , ER- $\beta$  and GPER) and PCNA by quantitative polymerase chain reaction (qPCR). The relative expression fold change ( $2^{-\Delta\Delta Ct}$ ) between WT and KO cholangiocytes, and treated and non-treated cholangiocytes and organoids was measured. Finally, we studied the expression of estrogen receptors in hepatic cyst tissue obtained from surgical fenestration and patient-derived organoids. The organoids were derived from cyst fluid obtained during aspiration or tissue during fenestration of hepatic cysts.

**Results:** We found that mainly estradiol, but also progesterone to a minor extent, stimulates proliferation in PRKCSH KO and WT cholangiocytes. The optimal estradiol concentration was 10 nM. Without estradiol, GPER expression was higher in KO cholangiocytes compared to WT ( $2^{-\Delta\Delta Ct} = 6.19$ ). When treated with estradiol, the relative expression decreased, but was still higher in KO compared to WT ( $2^{-\Delta\Delta Ct} = 2.47$ ). This is explained by an increase in GPER expression in WT ( $2^{-\Delta\Delta Ct} = 1.58$ ) and reduction of GPER expression in KO ( $2^{-\Delta\Delta Ct} = 0.63$ ) after estradiol treatment. ER- $\alpha$  and ER- $\beta$  were not detectable with qPCR in the cell lines, nor did we detect any estrogen receptor expression in organoids. After addition of estradiol to organoids, PCNA expression was 6 times higher, which is indicative of a proliferative effect. In 7/9 (78%) cyst tissue samples, expression of any estrogen receptors was found. In 6/9 (66%) samples ER- $\alpha$  was expressed, in 3/9 (33%) ER- $\beta$  and in 7/9 (78%) GPER. We detected both GPER and ER- $\alpha$  in 5/9 (56%) samples.

**Conclusion:** In this study we provide evidence for the proliferative effect of estradiol on cystic cholangiocytes, which may be regulated by multiple estrogen receptors in cystic epithelia. With the results of this study, we confirm that gender bias in polycystic liver disease is to some extent explained by estradiol exposure.

**Introduction:** According to current data connection between nonalcoholic fatty liver disease

(NAFLD) and gastroesophageal reflux disease (GERD) is controversial. Our aim was to analyze relationship between GERD and NAFLD.

**Aims & Methods:** In this cross-section study we have analyzed 436 patients mean age 63.3 $\pm$ 13.5 in whom upper gastrointestinal endoscopy (GE) was done. There were 215 (49.3%) male patients. On upper GE endoscopy we were interested to analyze presence of hiatal hernia, cardiac insufficiency and the presence and degree of GERD. NAFLD was diagnosed by liver enzymes and transient elastography [controlled attenuation parameter (CAP) for detection of liver steatosis and liver stiffness measurements (LSM) for liver fibrosis detection]. In part of the patients the liver biopsy was done.

**Results:** Firstly we have analyzed difference between patients with mild steatosis (first group had CAP < 268 db/m) and advanced steatosis (second group had CAP  $\geq$  268 db/m). As we expected patients with advanced steatosis had higher values of anthropometric parameters of obesity, the XL probe was dominantly used and they had higher incidence of dyslipidemia. There was no significant difference due to GERD frequency and degree as well as frequency of hiatal hernia between two group of patients, but patients with advanced steatosis had higher incidence of cardiac insufficiency (p=0.04). Next, we were interested to analyze is there a difference in upper GI endoscopy findings between NAFLD patients with normal and elevated LSM values. There was no difference in anthropometric parameters of obesity between NAFLD patients with normal LSM values and those with elevated LSM values, while second group of patients had higher

incidence of other components of the metabolic syndrome. Interestingly we didn't find any significant difference in upper GI endoscopy between two groups of patients. Finally we have analyzed what are the difference in liver enzymes, elastographic and liver biopsy findings between patients with GERD and those without GERD. We didn't find any significant difference in liver enzymes, elastographic parameters of steatosis (CAP) and fibrosis (LSM) and liver biopsy findings among two group of patients.

**Conclusion:** According to our results and in contrary to recent data, we didn't find the connection between frequency and degree of GERD and degree of NAFLD diagnosed by liver enzymes, elastographic parameters of steatosis (CAP) and fibrosis (LSM) and liver biopsy findings, except patients with advanced steatosis defined by CAP values had higher incidence of cardiac insufficiency.

**Introduction:** Non-alcoholic fatty liver disease is becoming the most common cause of chronic liver disease.

**Aims & Methods:** The aim of this study was to identify factors associated with significant liver disease in a cohort of type 2 diabetes patients and to develop a simple score for clinicians to identify more easily patients at risk. Patients were recruited prospectively in the study. Every first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day. Evaluation of liver fibrosis (stiffness) was made using Transient Elastography (FibroScan), performed in fasting conditions, with M and XL probes. Each patient was evaluated biologically for the presence of viral hepatitis (B and C) and an AUDIT-C score was performed to exclude alcohol abuse. Also subjects characteristics, epidemiological data and biochemical tests were recorded. Variables tested for the association with advanced liver fibrosis were: age, body mass index (BMI), abdominal circumference, hypertension, years after diagnosis of diabetes, glycemia, glycosylate hemoglobin, AST, ALT. Logistic regression was used for multivariate model to assess the association between advanced liver fibrosis and other variables. The cut-off value for significant fibrosis was >8.4 kPa [1].

**Results:** The total number of diabetics evaluated was 641. After the exclusion of others conditions, 468 patients with NAFLD were included, mean age 60.2 $\pm$ 9.2, 55% women and 45% men. Advanced fibrosis was found in 29.4% (138/468) patients. To assess the advanced fibrosis predicting score, all clinical variables associated with significant fibrosis, with p < 0.05 in the univariate analysis were considered in a multivariate regression model (BMI, glycemia, glycosylate hemoglobin, AST, ALT, abdominal circumference) and gave us the following predicting score: 1 point for AST > 30 U/L, ALT > 35 U/L, BMI > 30, abdominal circumference and 2 points for HbA1c > 7.5%, glycemia > 200mg/dl. The score ranged from 0 to 8 with maximum predictability at 8. The best cut-off value for predicting significant fibrosis was  $\geq$  4, with a sensitivity of 83.3%.

**Conclusion:** A simple score consisting of body mass index (BMI), abdominal circumference, glycemia, glycosylate hemoglobin, AST, ALT can identify NAFLD patients with significant fibrosis.

**Introduction:** The diagnosis of non-alcoholic fatty liver disease (NAFLD), non-alcoholic steatohepatitis (NASH) and fibrosis relies on liver biopsy. Non-invasive assessments are urgently needed. Thus, our aim was to evaluate cell apoptotic marker cytokeratin-18 M30 and total cell death markers cytokeratin-18 M65 for the assessment of NAFLD.

**Aims & Methods:** A cohort of 136 patients mean age 58.3±11.3 with biopsy-proven NAFLD were enrolled. There was 69 (50.7%) male patients. NAFLD was by transient elastography [controlled attenuation parameter (CAP) for detection of liver steatosis and liver stiffness measurements (LSM) for liver fibrosis detection]. NASH diagnosis was based on Brunt's criteria and the NAFLD activity score (NAS) and the presence of fibrosis were determined. The diagnosis of NASH was based on NAS≥5. Biomarkers were determined by enzyme-linked immunosorbent assay.

**Results:** Of 136 analyzed patients, 67 patients had NAS≥5 defined as NASH (according to the NAS score). Interestingly, there was no significant correlation between the M30 and M65 levels and CAP measurements. On the other hand, there was significant positively correlation of M65 and LSM measurements ( $r=0.228$ ;  $p=0.007$ ), while the correlation between M30 and LSM didn't reach the significant level ( $r=0.156$ ;  $p=0.06$ ). There was significant positive correlation between NAS score and M30 ( $r=0.193$ ;  $p=0.02$ ) and M65 ( $r=0.300$ ;  $p=0.0004$ ). M30 levels were significantly higher in NASH group of patients in the comparison to the non-NASH patients according to the NAS score ( $351.2\pm655.6$  vs.  $90.1\pm62$ ;  $p=0.001$ ) (figure 1a). Also, M65 levels were significantly higher in NASH group of patients in the comparison to the non-NASH patients according to the NAS score ( $585.1\pm886.5$  vs.  $207.2\pm33.2$ ;  $p=0.0006$ ). M30 levels was a moderate predictor of NASH on biopsy with an area under the curve (AUC) of 0.722 (95% CI 0.639 to 0.795). A M30 cut-off of >74 had a sensitivity of 52.2%, specificity of 90% in NASH diagnosis. Similar, M65 level was a moderate predictor of NASH on biopsy with an area under the curve (AUC) of 0.781 (95% CI 0.595 to 0.759). A M65 cut-off of >274 had a sensitivity of 38.8%, specificity of 97.1% in NASH diagnosis. Interestingly, M30 levels were significantly higher and in patients with significant fibrosis (grade 2-4) in comparison to the patients without fibrosis and to those with mild fibrosis (grade 1) ( $303.6\pm658.4$  vs.  $143.3\pm197.4$ ;  $p=0.05$ ). Also, M65 levels were significantly higher in patients with significant fibrosis (grade 2-4) in comparison to the patients without fibrosis and to those with mild fibrosis (grade 1) ( $494.9\pm802.7$  vs.  $295.6\pm317.4$ ;  $p=0.05$ ).

**Conclusion:** Serum biomarkers M30 and M65 had a moderate accuracy in detecting NASH. Combination of non-invasive marker could improve the sensitivity.

**Contact E-Mail Address:** ivana.mikolasevic@gmail.com

**Introduction:** Nonalcoholic fatty liver disease is the most common form of chronic liver disease that affects around 25% of population. No licensed medical treatment exists. We investigated efficacy and safety of a 48-week treatment with vitamin D in patients with transient elastography (TE) defined NAFLD.

**Aims & Methods:** TE defined NAFLD patients with decreases 25-OH vitamin D level at baseline received vitamin D (1000 IU/per day) or placebo orally over a 48-week period. The primary endpoint of this study was the changes of elastographic parameter of liver steatosis (controlled attenuation parameter - CAP) and fibrosis (liver stiffness measurements - LSM) from the baseline to the end of treatment. The secondary aim was the changes of liver enzymes (AST, ALT, GGT) from the baseline to the end of treatment.

**Results:** Patients were randomly assigned to intervention (N=175) or placebo group (N=90). Average age of population was 62.4 years with 42% of male participants. There was no significant differences in intervention or placebo group in baseline age, gender, BMI, waist, hip and thigh circumference, but also there was no significant difference in baseline serum vitamin D levels in intervention and placebo group ( $55.7\pm30.3$  vs  $50.7\pm27.9$ ,  $P=0.22$ ). There was significant decrease in CAP (dB/m) values in intervention group through follow up of 12 months ( $317.5\pm39.6$  vs  $277.01\pm53.35$ ,  $P<0.0001$ ) comparing to placebo group where there was significant increase in CAP values ( $309.2\pm41.7$  vs  $323.8\pm41.5$ ,  $P=0.019$ ). We have not noticed significant changes in LSM (kPa) values in placebo or intervention group, however it is important to notice that there was a trend towards lower values of LSM in intervention group in the follow-up period ( $6.23\pm3.73$  vs  $5.65\pm3.26$ ,  $P=0.12$ ) comparing to the placebo group ( $6.13\pm3.85$  vs  $6.17\pm2.7$ ,  $P=0.931$ ).

**Conclusion:** Treatment with 1000 IU of vitamin D over 48 weeks was well tolerated and led to a significant improvement of CAP values.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** ivana.mikolasevic@gmail.com

**Introduction:** The aim of this prospective study was to monitor the progression of elastographic parameters of liver steatosis [controlled attenuation parameter (CAP)] and fibrosis [liver stiffness measurement (LSM)] in patients with elastography proven NAFLD using Fibroscan 502 Touch. Furthermore, using elastographic parameters in patients with one or more MetS components and NAFLD, we were estimating the effects of clinical

and laboratory parameters on progression of elastographic parameters of steatosis and fibrosis (CAP and LSM). Finally, according to different BMI categories.

**Aims & Methods:** For the time period between May 2014 and October 2014 there were 606 consecutives ambulatory NAFLD patients enrolled in this prospective study. During each visit, that is every three months, Transient elastography (TE) examinations were performed in each patient. First of all, we were interested in analyzing the time to CAP (i.e. elastographic parameter of steatosis) and LSM (i.e. elastographic parameter of fibrosis) progression by at least 20% in total population and in identifying independent predictors of CAP and LSM progression in total population. Secondly, we were interested in analyzing the time to CAP and LSM progression by 20% in different BMI categories.

**Results:** This cohort consisted of 507 patients, 53.3% males. Median age was 62 (63-68) years and median BMI was 29.6 kg/m<sup>2</sup>, with relatively high proportion of overweight (41%, n=208) and obese (45.8%, n=232) patients and only 13.2% (n=67) having BMI < 25. There was a high proportion of patients with hypertension (71%), T2DM (39.1%), hyperlipidemia (68.6%), CKD (24.9%) and MetS (44.6%). Median values of CAP were 305 (269-337) and liver stiffness 5.3 (4.3-6.9). The cohort was followed for a mean period of 15.46 months (±11.3, range 0.4-41.4 months), corresponding to 663.58 person years.

During follow-up in 84 patients (16.5%) progression of liver steatosis for 20% occurred. On the other hand, in more patients, 201 (39.6%), occurred progression of liver fibrosis for 20%. After that we analyzed patients divided into three groups based on BMI status; < 25 (lean), 25-29.9 (overweight), and ≥30 kg/m<sup>2</sup> (obese). When stratified for BMI category, significant difference was found in occurrence of fibrosis progression, with obese patients having the highest proportion. There was no difference in occurrence of steatosis progression, or time to steatosis or time to fibrosis progression.

Obese patients have 1.66 (1.23-2.25) higher risk of developing fibrosis progression compared to overweight patients which were taken as the reference category. Kaplan-Meier survival curves stratified per BMI category were different (P=0.023) with obese patients having the highest risk of liver fibrosis progression. This was not the case for progression of liver steatosis. In multivariate Cox-regression analysis significant predictor of fibrosis progression was HOMA-IR.

**Conclusion:** By this study we have shown that for the progression of elastographic parameters of steatosis and fibrosis (i.e. CAP and LSM) are important the same factors (i.e. MetS and its individual components) that were reported to be associated with NAFLD progression detected by other methods. Thus, indicating that by this method we could monitor NAFLD progression in everyday clinical practice by patient-friendly method. However further studies are needed.

**Disclosure:** Nothing to disclose

### P1403 THE PSYCHOLOGICAL ASPECTS AND HEALTH-RELATED QUALITY OF LIFE IN OBESE PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE WITH MILD FIBROSIS

**Contact E-Mail Address:** olenabaka@yahoo.com

**Introduction:** The non-alcoholic fatty liver disease (NAFLD) is considered to be the most common liver disease in the world in recent years. It is closely linked to metabolic disorders and, in the first place, with obesity. This greatly impairs the quality of life of the patients, and may also be accompanied depressive disorders.

**Aims & Methods:** The aim of the study was to assess depressive disorders and health related quality of life of obese patients with NAFLD in the initial stages of liver fibrosis (non-cirrhotic NAFLD). 45 patients (20 men and 25 women, aged 23- 78 years, mean BMI 30.47 kg/m<sup>2</sup>) were divided into 4 groups: 10 obese without fibrosis (age 48.6±18.4, BMI 32.2±2.4 kg/m<sup>2</sup>), obese with 1 stage of fibrosis (age 55.8±13.6, BMI 32.7±4.7 kg/m<sup>2</sup>), 11 obese with 2-3 stage of fibrosis (age 63.3±7, BMI 34.8±3.7 kg/m<sup>2</sup>), and 11 lean

without fibrosis (control group) (age 49.6±17.7, BMI 22.2±2.1 kg/m<sup>2</sup>). Liver stiffness was measured by shear wave elastography, HRQL was measured using the Ukrainian version of the SF-36 Health Survey.

We assessed the depression with the help of The Beck Depression Inventory (BDI).

**Results:** Main domains of the HRQL score were significantly lower in obese patients with NAFLD in comparison to the lean patients: comparing of three groups of obese patients with different stages of fibrosis with lean patients we found statistically significant difference in Physical health: control- F0 (t=2.6 p=0.017), in control -F1 (t=3.6 p=0.002) and in control -F2-3 groups (t=3.53 p=0.002). Data of Mental health in the comparing group control- F0 (t=2.7 p=0.013), control- F1 (t=2.5 p=0.019). In comparing group with advanced fibrosis no statistically significant difference in Mental health control F2-3 (t=1.27 p=0.216).

The depression level is higher in the group of obese patients comparing to the lean and its stage is the highest in the F2-F3 group.

**Conclusion:** In obese people HRQL is lower than in lean and it decreases with the stage of fibrosis. We suppose that our data show deterioration of the critical assessment of their condition in patients with advanced fibrosis.

**Disclosure:** Nothing to disclose

### P1404 THE EFFECT OF SILYMARIN AND VITAMIN E IN THE TREATMENT OF NON-ALCOHOLIC FATTY LIVER DISEASE: A RANDOMIZED, DOUBLE-BLIND CLINICAL TRIAL

Akhondi-Meybodi M.<sup>1</sup>, Baghbanian M.<sup>2</sup>

<sup>1</sup>Shahid Sadoghi, Dept. of Gastroenterology, Yazd, Iran (Islamic Republic of),

<sup>2</sup>Shahid Sadoghi University of Medical Sciences and Health Services, Yazd, Iran (Islamic Republic of)

**Contact E-Mail Address:** akhondei@yahoo.com

**Introduction:** Lifestyle modification is the only currently recommended treatment for nonalcoholic fatty liver disease (NAFLD). Preliminary studies of vitamin E and silybin showed beneficial effects on liver function. We report on a double-blind clinical trial the effect of Silymarin and vitamin E in patients with NAFLD.

**Aims & Methods:** Randomized, double-blind, clinical trial conducted at 2 university clinical research centers in 80 patients (aged years) with NAFLD conducted between September 2014 and March 2015. All patients were randomized to receive vitamins E (400 IU) and Silymarin 280mg daily for 4 months. Additionally, all patients were given standard weight-loss counseling and encouraged to follow a low fat diet (< 30 fat g/day). Patients were obtained at baseline and on after 4 months for measurement of ALT and ultrasonography. Given the two planned primary comparisons, P values of less than 0.05 were considered to indicate statistical significance.

**Results:** There was no significant difference in terms of sex and BMI between the groups. At the end of the 12-week treatment period there was a significant decrease in the serum ALT levels in both treatment groups. The mean change in ALT level from baseline to 4 months was 31.6 U/L with Silymarin group vs. -15.1 U/L with vitamin E (P = .07). Therefore, effects in the Silymarin were larger than vitamin E (p < 0.0001). The mean ALT levels changed to normal 55.0% (22 of 40 cases) in the Silymarin group and 45.0% (18 of 40 patients) vitamin E group (P=0.04). Based ultrasonography findings after 4 months in the vitamin E group 4 patients and in the Silymarin group 2 cases were normalized. Adverse events (AEs) were generally transient and included diarrhea, dysgeusia, and pruritus; no serious AEs were recorded.

**Conclusion:** In Silymarin and vitamin E treatment appears to be significantly effective in biochemical improvement in decreasing the ALT and ultrasonographic measurement, respectively

**Disclosure:** Nothing to disclose

## P1405 SYMPATHETIC OVERACTIVITY AND EARLY SODIUM RETENTION IN EXPERIMENTAL LIVER CIRRHOSIS: A ROLE FOR RENALASE

Sansoe' G.<sup>1</sup>, Aragno M.<sup>2</sup>, Leone N.<sup>1</sup>, Berrutti M.<sup>1</sup>, Ayoubi M.<sup>1</sup>, Castellino F.<sup>1</sup>  
<sup>1</sup>Humanitas Gradenigo Hospital, Division of Gastroenterology, Torino, Italy,  
<sup>2</sup>University of Torino, Department of Clinical and Biological Sciences, Torino, Italy

Contact E-Mail Address: giovannisan@iol.it

**Introduction:** Sympathetic overactivity promotes sodium retention and functional renal failure in liver cirrhosis. Renalase, 38 kDa amine oxidase with just 13% aminoacid identity with monoamine oxidase A, is secreted into the blood by the kidney and is the only identified form of amine oxidase that clears plasma of circulating catecholamines.

**Aims & Methods:** To study plasma and tissue content and function of renalase in experimental preascitic and ascitic cirrhosis. In normal rats (group G1), rats with CCl<sub>4</sub>-dependent liver cirrhosis without ascites (G2) and with ascites (G3) we evaluated: renalase levels and activity in plasma, liver and kidney; renalase gene transcription and immunohistochemical localization in liver and kidney; liver histology and matrix deposition, hormonal status and kidney function.

**Results:** In plasma, mature (38 kDa) contents and activity, well detected in normal rats, were virtually absent in rats with compensated or ascitic cirrhosis (all P < 0.01 vs. G1). In G2 and G3 rats, but not in G1, we found large amount of enzymatically active high-molecular-weight (78 kDa) renalase and very little 38 kDa protein in hepatocytes of regenerative nodules of the cirrhotic liver and in kidney tubules. RT-PCR confirmed higher levels of renalase gene transcription in both liver and kidney of G2-3 (P < 0.03 vs. G1). Rats with preascitic liver damage showed increased plasma catecholamines, normal renin-angiotensin system activation and sodium retention, while ascitic rats had both secondary aldosteronism and increased adrenergic activation.

**Conclusion:** High-molecular-weight forms of functional renalase accumulates in diseased liver and kidney, but tissue processing and release into blood of mature (38 kDa) renalase is almost absent, contributing to increased levels of plasma catecholamines and sodium retention in both preascitic and decompensated cirrhosis.

<sup>2</sup>University of Torino, Department of Clinical and Biological Sciences, Torino, Italy

Contact E-Mail Address: giovannisan@iol.it

**Introduction:** Catecholamines promote proximal tubular fluid retention and decrease Na<sup>+</sup> and water delivery to the diluting segment of the Henle's loop, thereby reducing renal excretion of solute-free water. In advanced cirrhosis, non-osmotic hypersecretion of vasopressin (ADH) has a role in causing dilutional hyponatremia, but the advantage of ADH V<sub>2</sub> receptor antagonists is controversial in the treatment of ascites.

**Aims & Methods:** By means of the use of sympatholytic agents (α<sub>2</sub> adrenergic receptor agonists), we assessed the hypothesis that adrenergic hyperfunction might contribute to water retention in experimental ascitic cirrhosis. Hormonal status, renal function and tubular free-water reabsorption (TFWR) were evaluated in four groups of rats with ascitic cirrhosis: rats with cirrhosis due to 13 weeks of CCl<sub>4</sub> (group G1); cirrhotic rats receiving, from 11<sup>th</sup> to 13<sup>th</sup> CCl<sub>4</sub> week, daily diuretics alone (0.5 mg/kg furosemide plus 2 mg/kg K<sup>+</sup> canrenoate) (G2), or diuretics plus guanfacine oral prodrug (α<sub>2</sub> adrenergic receptor agonist and sympatholytic agent) 2 mg/kg (G3). Group G4 received diuretics plus SSP-004240F1 (V<sub>2</sub> receptor antagonist) 1 mg/kg.

**Results:** Compared to G2, guanfacine plus diuretics (G3) reduced serum norepinephrine from 423 ± 22 to 211 ± 41 ng/L and plasma renin activity from 35 ± 8 to 9 ± 2 ng/mL/h (all P < 0.03). Compared to G1 and G2, TFWR was significantly reduced, and to the same extent, with low-dose guanfacine plus diuretics (G3) and with V<sub>2</sub> antagonist plus diuretics (G4) (all P < 0.03). TFWR correlated with plasma aldosterone (r=0.51, P < 0.01) and urinary potassium excretion (r=0.90, P < 0.001).

**Conclusion:** In ascitic cirrhosis, reduced volaemia, secondary aldosteronism and adrenergic hyperfunction, especially when exacerbated by potassium-depleting diuretics (furosemide), contribute to tubular retention of water and dilutional hyponatremia. Low-dose sympatholytic agents are as effective as V<sub>2</sub> antagonists to achieve aquaretic effects in this setting.

## P1407 REBALANCED HEMOSTASIS IN LIVER CIRRHOSIS

Hospital Amato Lusitano, Gastroenterology, Castelo Branco, Portugal

Contact E-Mail Address: pereiraf14@gmail.com

**Introduction:** Traditional concepts of liver cirrhosis believed that it presented a pro-haemorrhagic tendency, thought to be the result of laboratory abnormalities such as thrombocytopenia and prolongation of the international normalised ratio (INR). However, recent evidence indicates that the hemostasis in liver cirrhosis is more complex than previously thought. Production of both procoagulant and anticoagulant factors is affected, leading to a delicate hemostatic rebalance, where a higher risk for both bleeding and thrombosis coexists.

**Aims & Methods:** We aimed to investigate the coagulation abnormalities in patients with acute decompensated cirrhosis. We conducted a prospective observational study including patients admitted with acute decompensated cirrhosis. Measurement of serum level of platelets, von Willebrand factor antigen (vWF), prothrombin time (PT), INR, coagulation factors II, V, VII, VIII and procoagulant protein C (PC) and antithrombin (AT). Statistical analysis with SPSS v25.

**Results:** 55 patients included (91% male; mean age of 61±10 years; 93% alcoholic etiology; mean MELD 17±5.6 points; Child-Pugh C 62%). Mean serum level values: platelets 115000±64000; PT 20.9±6.9; INR 1.42±0.27; FII 43.3±15.2 (reference value 50-150); FV 49±22.3 (62-139); FVII 33.5±31.2 (50-129); FVIII 231±186 (50-150); vWF 491±236 (42-176.3), PC 29.1±17.5 (70-140), AT 45.1±25 (83-128).

Patients with platelet levels below 100 000/uL had higher values of vWF (562 vs 405; p<0.05). There was a moderate inverse correlation between INR and PC (p<0.05; R=-0.462) and AT (p<0.05; R=-0.434); and there was a strong positive correlation between INR and vWF (p<0.001; R=0.544). There was also a strong positive correlation between AT and factors V (p<0.01; R=0.759) and VII (p<0.01; R=0.657).

**Conclusion:** This study corroborates the concept that the patient with liver cirrhosis presents a complex and fragile hemostatic profile, with prohemostatic and antihemostatic factors that tend to rebalance. Thrombocytopenia and prolongation of the INR are compensated by an increase in vWF values; a reduction of procoagulant factors (V and VII) is counterbalanced by a decrease in PC and AT.

**Introduction:** The eradication of HCV infection by direct-acting antiviral agents (DAAs) has been linked to an amelioration of liver synthesis and a regression of fibrosis. Although changes in number and type of circulating microvesicles (MVs) have been reported in cirrhosis, conclusive data on the effect of DAAs treatment on MVs profile in HCV cirrhotic patients remain scarce.

**Aims & Methods:** To prospectively characterize changes in plasmatic levels of endothelial, platelet and hepatocyte MVs, and MVs expressing versican core protein (VCAN+) in patients with HCV-related cirrhosis at baseline, end of therapy (EOT), at 12, 24 and 48 weeks (W) after EOT by new generation flow-cytometry, and to correlate these changes with clinical outcome.

**Results:** Fifty-eight patients were enrolled (86% Child's A). MVs were increased at EOT versus baseline, though only platelet MVs revealed a statistically significant difference ( $p < 0.01$ ). MVs levels did not change significantly after EOT notwithstanding a steady downward trend towards baseline levels. In contrast, VCAN+MVs dropped significantly at EOT ( $p < 0.001$ ) and remained low throughout the follow-up. Hepatocyte MVs significantly correlated with liver stiffness ( $r = 0.40$ ,  $p = 0.0021$ ). Eight composite outcomes occurred during the 1-year follow-up: 3 portal vein thromboses, 2 hepatocellular carcinomas and 3 liver decompensation. Child's B, the presence of F2 oesophageal varices (OR for interaction 19.2 [95%CI 1.45-253.7],  $p = 0.023$ ) and platelet MVs (OR 1.026 [95%CI 1.00-1.05,  $p = 0.023$ ) correlated significantly with clinical outcomes.

**Conclusion:** VCAN+MVs appear to mirror the profibrotic status of the cirrhotic disease; hepatocyte MVs correlate with liver stiffness and platelet MVs might be associated with a worse clinical outcome.

**Introduction:** Ultrasound based elastography methods and biological markers can be used as non-invasive tools for predicting the presence of esophageal varices,

**Aims & Methods:** The aim of the study was to formulate and assess the usefulness of a new non-invasive score to predict the presence of esophageal varices (EV) in cirrhotic patients.

A prospective study was performed in 77 subjects with compensated liver cirrhosis (diagnosed based on clinical, biological and elastographic criteria -Liver transient elastography>12.5kPa[1]), who underwent upper endoscopy, abdominal ultrasound, spleen and liver stiffness measurements (SSM and LSM, respectively) with a 2D-SWE technique from General Electric (Logiq E9) and biologic tests in the same session. Reliable SSM and LSM were defined as the median value of 10 measurements acquired in a homogenous area with IQR/M < 0.30.

**Results:** We obtained reliable SSM in 98.7% (76/77) subjects and reliable LSM in 97.4% (75/77). 75 subjects were included in the final analysis, 64% (48/75) with EV. The mean SS, LS, spleen size (cm) were significantly higher in patients with EV (16.77±2.92 kPa vs. 13.2±2.66 kPa,  $p < 0.0001$ ; 14.12±2.09 kPa vs. 11.5±1.56 kPa,  $p < 0.0001$ ; 14.49±2.09 cm vs. 13.05±1.86 cm,  $p = 0.004$ , respectively). Thrombocytes were significantly fewer in patients with EV (90,125±34,425 vs. 135,738 ± 58,905,  $p = 0.0001$ ).

In univariate analysis, SSM, LSM, spleen size and thrombocytes were associated with the presence of EV, all  $p < 0.0001$ . In multivariate analysis, the model including SSM, LSM, spleen size and thrombocytes had the following p-values:  $p = 0.01$ ,  $p = 0.01$ ,  $p = 0.03$  and  $p = 0.01$ . Using these factors as predictors, by multiple regression analysis, we obtained the following score: Presence of EV =  $0.04 * \text{SSM} + 0.06 * \text{LSM} + 0.04 * \text{spleen size} - 1 * 10^{-6} * \text{thrombocytes} - 1.17$ . The score had a cut-off value >0.48 (AUROC=0.9, Se=95.8%, Sp=96.3%, PPV=97.9%, NPV=92.9%) for predicting the presence of EV.

**Conclusion:** Using the model including SSM, LSM, spleen size and thrombocytes we can rule in the presence of EV with a positive predictive value of 97%.

**Introduction:** Ultrasound based elastography methods can be used as non-invasive tools for predicting the presence of esophageal varices.

**Aims & Methods:** The aim of the study was to establish the usefulness of spleen stiffness (SS) values measured by means of two elastographic techniques: point shear wave elastography (pSWE) and 2D-shear wave elastography (2D-SWE) as non-invasive markers for predicting the presence of esophageal varices (EV) and to compare their performances.

A prospective study was performed, including 86 subjects with compensated liver cirrhosis who underwent both upper endoscopy and SS measurements (SSM) by means of two elastographic techniques: pSWE - using virtual touch quantification (VTQ) technology (Acuson S2000-Siemens Medical Solutions); and 2D-SWE (LOGIQ E9-General Electric), in the same admission. Reliable SSM were defined for both techniques as the median value of 10 measurements acquired in a homogenous area with (IQR/M) < 0.30. Compensated liver cirrhosis was diagnosed based on clinical, biological and elastographic criteria (Liver transient elastography>12.5 kPa) [1].

**Results:** We obtained reliable SSM in 98.8% (85/86) by means of 2D-SWE. GE and in 96.5% (83/86) subjects by means of pSWE-VTQ. 83 subjects were included in the final analysis, 63.8% (53/83) of them with EV. The best SS cut-off value by 2D-SWE.GE for predicting the presence of EV in our study group was 13.4 kPa (AUROC-0.89; sensitivity-85%; specificity- 93.3%; PPV-95.7%; NPV-77.8%), while for pSWE-VTQ it was 2.8 m/s (AUROC-0.65; sensitivity-60%; specificity-70%; PPV-78%; NPV-50%). Based on AUROC comparison, 2D-SWE.GE performed significantly better than pSWE-VTQ to predict the presence of EV ( $p = 0.001$ ).

**Conclusion:** Although there are no significant differences between the feasibility of the two methods ( $p = 0.62$ ), it seems that 2D-SWE.GE has a better performance in predicting the presence of EV as compared with pSWE-VTQ ( $p = 0.001$ ).

**Introduction:** Liver stiffness (LS) and spleen stiffness (SS) are two most widely accessible non-invasive parameters for predicting esophageal varices (EV), but the reported accuracy of the two predictors have been inconsistent across studies.

**Aims & Methods:** The aim of the study was to establish the usefulness of spleen stiffness (SS) and liver stiffness (LS) values measured by 2D-shear wave elastography (2D-SWE.GE) as non-invasive markers for predicting the presence of esophageal varices (EV) and to compare their performances. A prospective study was performed, including 90 subjects with compensated liver cirrhosis who underwent both upper endoscopy and spleen and liver stiffness measurements (SSM, LSM) by means of 2D-SWE (LOGIQ E9-General Electric), in the same admission. Reliable SSM were defined as the median value of 10 measurements acquired in a homogenous area with (IQR/M) <0.30. Compensated liver cirrhosis was diagnosed based on clinical, biological and elastographic criteria (Liver transient elastography >12.5 kPa) [1].

**Results:** We obtained reliable SSM in 96.7% (87/90) and reliable LSM in 97.7% (88/90) by means of 2D-SWE.GE. 85 subjects were included in the final analysis, 63.5% (54/85) of them with EV. The best SS cut-off value by 2D-SWE.GE for predicting the presence of EV in our study group was 13.7 kPa (AUROC-0.88; sensitivity-78%; specificity- 90.3%; PPV-93%; NPV-66.8%), while the best LS cut-off value was 11.1 kPa (AUROC-0.78; sensitivity-98.1%; specificity-52%; PPV-77.9%; NPV-94.1%). Based on AUROC comparison, SS performed significantly better than LS to predict the presence of EV (p=0.0253).

**Conclusion:** SS seems to be a better tool than LS for predicting the presence of EV in cirrhotic patients.

**Introduction:** The advent of direct-acting antivirals (DAAs) is a major breakthrough in hepatology representing the therapeutic standard of care in patients with chronic hepatitis C virus infection over the past few years. Despite high rates of sustained virological response (SVR), DAAs therapy doesn't eliminate the risk of thrombotic events.

**Aims & Methods:** In our study we aimed to assess the occurrence of thrombotic events and clinical presentation in patients treated with DAAs and sustained virological response.

We retrospectively analyzed a cohort of patients with HCV-related liver cirrhosis treated with PrOD ± ribavirin and LED/SOF ± ribavirin for 12/24 weeks, in a tertiary gastroenterology center from Romania, between January 1st 2016 and July 1st 2018. All patients with presumption of thrombosis were evaluated by vascular Doppler, abdominal ultrasound and confirmed by CT scan.

**Results:** The study included 473 HCV-infected cirrhotic patients treated with PrOD or LED/SOF, with documented SVR, mean age 69.7 ± 5.5 years, predominantly female (59%). Of the total number, 284 (60.04%) received PrOD and 189 (39.95%) patients were treated with LED/SOF. Thrombotic complications were reported in 23 (4.86%) patients: 3 (13.04%) with deep vein thrombosis, 14 (60.86%) with portal vein thrombosis (PVT), 6 (26.08%) with malignant PVT.

All patients had associated cardiovascular (15-65.21%) and metabolic comorbidities (8-34.78%). The main clinical manifestations at diagnosis were: swelling, edema, erythema and lower limb pain in 3 patients, upper digestive haemorrhage in 8 patients, ascitic decompensation in 4 patients, abdominal pain in 5 patients and 3 patients were asymptomatic.

Biologically there was no significant change in prothrombin serum levels (baseline values in patients treated with PrOD was 11.67 ± 0.91 versus 11.70 ± 0.83 at SVR, p=0.993, respectively 11.5 ± 0.84 sec at baseline versus 11.4 ± 0.68 at SVR, p=0.715 in patients treated with LED/SOF ± RBV) and platelet count (126 000 (101 500-162 000) vs. 131 000 (101 000-165 000), p=0.818 in patients treated with PrOD, respectively 94 857.14 ± 32 vs. 92 428.57 ± 35, p=0.853, in patients treated with LED/SOF ± RBV).

**Conclusion:** We conclude that thrombotic events in patients with HCV-related liver cirrhosis treated with DAAs are not influenced by the variations of coagulation parameters, rather correspond to the hypercoagulability status and the natural evolution of the cirrhotic patient.

**Disclosure:** Nothing to disclose

## P1413 SPONTANEOUS BACTERIAL PERITONITIS: WILL THE DIAGNOSTIC FOLLOW-UP PARACENTESIS BE ESSENTIAL IN APPROACHING THESE PATIENTS?

**Introduction:** Recent studies suggest that follow-up paracentesis, in cases of spontaneous bacterial peritonitis (SBP) should only be performed if there is a clinical and/or analytic worsening.

**Aims & Methods:** Our aims were to evaluate which patients with SBP benefit from the diagnostic follow-up paracentesis, according to clinical and analytical predictive factors of an inadequate response at the third day of treatment.

Retrospective study conducted in a tertiary center, included the patients with SBP between January 2011 and June 2018. Clinical/analytical data was obtained at baseline and at the third day of antibiotic therapy. An adequate response to therapy, at the third day, was defined by a decrease of ≥25% in neutrophil count of the ascitic fluid.

**Results:** We included 103 cases of SBP with a mean age of 61±11 years. 30.1% of cases the patients were under antibiotic prophylaxis for SBP. At the third day, 30.1% had an inadequate response to antibiotic therapy.

At admission, the presence of diabetes mellitus (p=0.034), a higher serum neutrophils count (p=0.043), a lesser level of serum total proteins (p=0.040) and a positive culture in ascitic fluid (p<0.001) were related to inadequate response. At day 3, a higher level of serum urea (p=0.018), creatinine (p=0.030), CRP (p=0.001), a higher count of serum leucocytes (p=0.001) and neutrophils (p=0.001), the presence of fever (p=0.047) and abdominal pain (p<0.001) were associated to absence of response, too.

In the multivariate analysis, diabetes mellitus (OR=5.33; 95% CI:1.24-22.96), positive ascitic fluid culture at admission (OR=15.66; 95% CI:2.41-101.94), abdominal pain at day 3 (OR=3.94; 95% CI:0.94-16.45; p<0.06) and CRP at day 3 (OR=1.02; 95% CI:1.00-1.03) were independently and significantly associated to inadequate response at the third day of empiric therapy.

The predictive model presented good accuracy [AUROC of 0.85 (p<0.001) (Fig. 1)] - a cutoff of 0.055 had a sensitivity, specificity, positive predictive value, and negative predictive value for absence of response to antibiotic of 100%, 35%, 42%, and 100%, respectively.

With this model cutoff, 24% of repeated paracentesis could be precluded in our population sample.

**Conclusion:** These results evidence that, in approach of SBP, the performance of follow-up paracentesis, three days after the beginning of empiric therapy, should be individualized, according the conjugation of clinical and analytic variables. With our model a considerable number of unnecessary procedures may be avoided.

**Introduction:** Poor muscle function and sarcopenia has previously been shown to be a negative prognostic factor in advanced liver disease (Hanai et al, Nutrition 2015). However, the impact of muscle function on prognosis in compensated chronic liver disease (CLD) is unknown.

**Aims & Methods:** We aimed to assess the potential prognostic value of muscle performance in a cohort of patients with a variety of common CLDs. Our primary aims were to assess mortality and transplant-free survival.

We followed a consecutively recruited cohort of patients with compensated CLD (Child- Pugh < B/C) that were enrolled in a study on muscle function and CLD in our institution between 2010 and 2014. In all, 270 CLD outpatients accepted inclusion (52±15 years at baseline, 59±15 at follow up, mean±SD; 151 females). Twenty-nine patients with a history of hepatic decompensation (e.g., ascites) or Fibrosis 4 score (FIB-4) ≥3.25 indicating cirrhosis were excluded. Diagnoses in the remaining 241 subjects were primary biliary cholangitis (PBC; n=41), primary sclerosing cholangitis (PSC; n=42), autoimmune hepatitis (AIH; n=48), and viral hepatitis (HBV, n=51; HCV, n=59). All subjects performed four validated tests of muscle function: "Timed Up and Go" test (TUG, dichotomized into >10 seconds), walking speed (self-chosen and maximal walking speed, 30 m distance; m/s), handgrip strength with a dynamometer (maximum and average strength over 10 sec; N), and standing heel-rise test (number of heel-rises). In addition, using a seven-grade scale questionnaire for physical activity level, from 0 = no to 6 = regular strenuous physical activity several times/week, we dichotomized the study population into those with levels 0-4 and 5-6. By comparisons with data of an age and gender matched reference population we estimated muscle performance as percentage of normal and dichotomized patients into groups with normal or impaired muscle performance for each muscle test. Follow up data for mortality and liver transplantation was obtained through hospital records and Swedish population registries.

**Results:** In our population, at baseline muscle function was impaired in several tests: standing heel-rise test (n=16 normal test, 7%), maximum (n=54, 22% normal test) and average grip strength (n=56, 23% normal test), self-chosen (n=169, 70% normal test) and maximum walking speed (128, 53% normal test), TUG>10 seconds (n=42, 17%). Physical activity level 5-6 (n=35, 15%).

During a follow up of a mean of 6.75±1.4 years, 14 patients died (6%) and 10 (4%) patients underwent liver transplantation. TUG over 10 seconds was associated with a lower survival (Kaplan-Meier, log rank test p=0.041), however not with transplant free survival (p=0.248). The other physical functioning tests including physical activity level, self-chosen and maximum walking speed, maximum and average handgrip strength were not significantly associated with mortality or transplant free survival (Kaplan-Meier, log rank test p>0.05 for all).

**Conclusion:** Timed up and go test was a predictor of mortality in our population of compensated chronic liver disease. The prognostic value of this test in patients with fully compensated liver disease should be evaluated in further trials.

**Disclosure:** Nothing to disclose

### **P1415** ANTICOAGULANT TREATMENT FOR CIRRHOTIC NON-MALIGNANT PORTAL VEIN THROMBOSIS -EFFICACY AND SAFETY

**Introduction:** Portal vein thrombosis (PVT) is recognized as one of the complications of liver cirrhosis. Anticoagulation treatment could be indicated in patients with PVT, but the efficacy remains unclear.

**Aims & Methods:** We aim to investigate the characteristics of PVT and the efficacy of anticoagulation treatment in cirrhotic patients diagnosed with PVT. A total of 116 cirrhotic patients who were diagnosed with PVT between January 2018 and December 2018 were retrospectively analyzed in this study. Complete response (CR) for anticoagulation treatment was defined as repermeabilization of PVT assessed by dynamic imaging.

**Results:** The baseline characteristics of all patients were as follows : age, 61.26±11.33 years old; platelet counts, 90 × 106 /L; ALT, 30 U/L; albumin, 3.2 g/dL; PT, 64%; D-dimer, 4.6 ng/mL; AT-3 56% and the etiology of the liver cirrhosis (viral B hepatitis/ viral C hepatitis/alcoholic/ NASH/other), 17.2%/33.6%/22.4%/22.4%/4.3%.

Among patients with liver disease, 51 patients (44.0%) had history of liver cancer and the mean MELD score was 15.21±7.11. Almost half of PVT were located in the main trunk of portal vein (61/116.) Twenty seven patients (23.3%) received an anticoagulant treatment.

Most of the patients received low weight molecular heparine (59.3%), followed by acenocoumarol (25.9%) and only 14.8% of the patients received direct oral anticoagulant treatment. During the study period half of the patients 58 (50.0%) remained stationary, 40 patients had improvement of the PVT (34.5%) and in 18 patients PVT worsened. The anticoagulant treatment did not influenced PVT evolution. In 24 patients that received an anticoagulant treatment PVT improved or remained stable.

However, 14 patients (12.1%) died during the study, none of them from bleeding complications. The anticoagulant treatment was not associated with an increased mortality rate (OR 0.899, CI 0.228-3.440, p=0.862).

**Conclusion:** Anticoagulation treatment for PVT was safe, although did not influenced PVT evolution. Careful management should be necessary after anticoagulation treatment.

**Introduction:** The non selective beta-blockant (NSBB) treatment in cirrhotic patients has several limitations regarding side effects, as arterial hypotension or bradycardia. Caution should be taken in cirrhotic patients with refractory ascites, hyponatremia or arterial hypotension, as NSBB could precipitated the development of the acute kidney injury.

**Aims & Methods:** The aim of this study was to evaluate the risk of variceal bleeding after the NSBB treatment is stopped in patients with refractory ascites. All consecutive patients with liver cirrhosis and refractory ascites admitted to the Institute of Gastroenterology and Hepatology from January 2017 to December 2017 were included in this study. The diagnosis of refractory ascites was established according to the current guidelines.

**Results:** During the study period a total of 57 patients were diagnosed with refractory ascites. In more than half of them, 29 patients (50.8%), the NSBB treatment was stopped, the main cause of stopping the treatment being systolic blood pressure less than 90 mmHg. The majority of the patients were receiving propranolol (86.2%), and only 4 patients (3.8%) received carvedilol. Out of the 29 patients that stopped the treatment, 21 (72.4%) were Child-Pugh class C, and 5 patients (17.2%) developed variceal bleeding. The risk of variceal bleeding was not increased in cirrhotic patients with refractory ascites that stopped the NSBB treatment (OR 1.207, CI 0.361-4.039, p=0.796).

**Conclusion:** Stopping the NSBB treatment in patients with refractory ascites is not associated with an increased risk of variceal bleeding, despite the severity of liver disease.

**Introduction:** Baveno criteria safely identify patients who can avoid variceal screening endoscopy: A diagnostic test accuracy meta-analysis.

**Aims & Methods:** This meta-analysis aimed to quantify the safety and efficacy of these criteria. A systematic search was conducted in nine databases for diagnostic accuracy studies. Eligible papers discussed chronic liver diseases (CLD) and tested Baveno criteria against endoscopic variceal screening. Our main focus was the predictive power of Baveno criteria for varices needing treatment. We calculated pooled spared endoscopy rate,

sensitivity, specificity, and negative and positive predictive values with 95% confidence intervals (CIs). Heterogeneity was tested by I<sup>2</sup>-statistics and explored by subgroup analysis (cACLD) and meta-regression.

**Results:** The search yielded 27 eligible papers including 6739 CLD cases. Pooled spared endoscopy rate was 26.4% (CI: 21.6-31.5%; I<sup>2</sup>=95.1%). Pooled negative predictive value proved to be 99.3% (CI: 98.4-99.8%; I<sup>2</sup>=21.5%). In the subgroup of cACLD, heterogeneity disappeared while negative predictive value was maintained.

Pooled sensitivity was 97.9% (CI: 95.1-99.7%; I<sup>2</sup>=49.4%), with an I<sup>2</sup>=9.8% in the subgroup of cACLD. Pooled positive predictive value was 8.1% (CI: 13.3-23.5%; I<sup>2</sup>=93.0%). Pooled specificity was 31.0% (CI: 23.5-39.0%; I<sup>2</sup>=96.5%). Meta-regression proved that body mass index (p=0.042), the percentage of non-alcoholic fatty liver disease (p=0.038), and platelet count (p=0.027) correlated positively with specificity.

**Conclusion:** The application of Baveno criteria significantly reduces the number of unnecessary variceal screening endoscopies while being safe: patients with liver stiffness < 20 kPa and platelet count >150x10<sup>9</sup> cells/L carry a very low risk of having varices needing treatment.

**Introduction:** To date few evidences are available on the risk of hepatic decompensation (HD) related to portal hypertension (PH) after therapy with new direct-acting antivirals (DAAs) in patients with HCV-related advanced chronic liver disease (ACLD). Furthermore, the predictive role of non-invasive markers of PH, such as liver (LSM) and spleen (SSM) stiffness measurement after DAA therapy is still debated and should be clarified. We previously reported that SSM≥54 kPa was able to predict HD in untreated HCV patients, better than LSM.

**Aims & Methods:** The aim of this study is to assess the role LSM and SSM in HD prediction after sustained virologic response (SVR).

A cohort study in 146 ACLD patients treated with DAAs and with available LSM and SSM both before and 6 months after end-of treatment (EOT) was performed in our centre. Patients were prospectively followed up from EOT and PH related events were registered. Time-dependent models for HD prediction after SVR were applied to account for changes in LSM and SSM after DAA therapy.

**Results:** During a follow-up of 33,5 months a total of 20 (13.7%) patients developed at least one episode of HD (among these, 3 presented a second HD event). The first decompensating event was ascites in the majority (17/20, 85%) of patients.

Three patients developed a second episode of HD. Besides HD development, 18 (12.3%) patients developed hepatocellular carcinoma after DAA therapy; 3 (2.1%) developed portal vein thrombosis, 4 (2.7%) underwent high-bleeding risk varices prophylaxes, 3 (2.1%) underwent liver transplantation and 7 (4.8%) patients died.

At the multivariate analysis, previous HD (HR, 8.065; 95%CI 2.806 - 23.180) and SSM≥54 kPa (HR, 4.678; 95%CI 1.307-16.744) were independently associated with a higher risk of HD development after DAAs treatment. Kaplan-Meier curves were estimated and drawn by the SSM cut-off of 54 kPa; in term of survival, the difference between the two curves was statistically significant (p= 0.0007). The time-dependent model including SSM values at baseline and at 6 months after EOT predicted post-SVR HD development better than the models including LSM and its changes after therapy.

**Conclusion:** SSM is confirmed to be an accurate surrogate of portal hypertension also after SVR achieved with DAA therapy. Moreover, SSM is able to stratify for the risk of HD development after DAA therapy more accurately than LSM.

**Introduction:** Portal vein thrombosis (PVT) is being increasingly recognized in patients with advanced cirrhosis and in those undergoing liver transplantation. Therapy with low molecular weight heparin and vitamin K antagonists has been shown to achieve complete and partial recanalization. Although anticoagulation therapy related bleeding is the most feared complication, studies are showing no increase in the risk of bleeding related to coagulation

**Aims & Methods:** Clinical, demographic, and biochemical data were retrospectively analyzed from a cohort of 150 consecutive patients with cirrhosis and portal vein thrombosis who presented from 2010 until 2018 in Fundeni Clinical Institute. The patients were followed until death, liver transplantation or last contact. Survival models were built based on univariate and multivariate Cox regression analysis

**Results:** There were 51% men (77 patients), median age at inclusion 54 years, the main etiology of LC was viral (69%), 70 patients having VHB or VHB+VHD infection and 34 patients with VHC infection. Portal vein thrombosis was complete in 47 (31%) patients and localised at portal trunk in 72% (109 patients), confluent of the PV 55% (83 patients) and superior mesenteric vein 35%. (56 patients). LT was performed in 22 (14.66%) patients. Therapy with anticoagulants was administered in 80 (53%) patients. Median overall survival from diagnosis of LC was 57.3 months and median survival since diagnosis of PV thrombosis was 16 months. Predictive factors for death identified by univariate Cox regression analysis were: age of the patient, initial lab MELD score at diagnosis of PV thrombosis and after 6 months of follow-up, absence of administration of anticoagulants, progression of PV thrombosis during follow-up, refractory ascites and bleeding complications after PV development. Independent predictors of death identified by multivariate analysis were: increased age of the patient (HR=1.09, p=0.02), increased MELD score at 6 months after diagnosis of PV thrombosis (HR=1.27, p=0.01), occurrence of hemorrhagic complications after PV diagnosis (HR=4.47, p=0.004). There was no statistical association between administration of anticoagulants/type and occurrence of hemorrhagic complications.

**Conclusion:** Anticoagulant therapy should be administered to all patients with portal vein thrombosis. Lower survival rates should be expected in patients with LC and PV thrombosis that are older at diagnosis and have an accelerated impairment of liver function and portal hypertension after PV development

**Disclosure:** Nothing to disclose

## P1420 WITHDRAWN

## P1421 NOVEL RISK SCORE FOR PREDICTION OF HEPATOCELLULAR CARCINOMA AFTER DIRECT ACTING ANTIVIRAL DRUGS

**Akl M.**<sup>1</sup>, Kohla M.<sup>2</sup>, Elsabaawy M.<sup>3</sup>, Allam M.<sup>1</sup>, Helal A.<sup>4</sup>

**Contact E-Mail Address:** akrlady@yahoo.com

**Introduction:** Direct acting antivirals (DAAs) are a novel and completely oral hepatitis C therapy. DAAs are used in most patients being treated for hepatitis C, including those with decompensated cirrhosis. Cirrhotic patients should be closely monitored after treatment. HCC is thought to develop over time as the liver is exposed to inflammation and develops fibrosis.

**Aims & Methods:**

1. To detect risk factors for HCC in cirrhotic patients after DAAs.
2. To evaluate new score for HCC prediction after DAAs in chronic Hepatitis C.

We retrospectively evaluated 1240 patients treated with DAAs but 124 patients who had fibroscan in virology unit, National Liver Institute, Menoufia University after informed written consent. Pre-treatment laboratory data were collected after multivariate analysis to data we found risk factors for HCC with DAAs (High fibroscan, Diabetes mellitus, low paltates and older age) this data show in novel score to detect HCC (Age >60 equal points 2 or younger 1, Fibroscan > 18.5 kPa equal 2 or other equal 1, presence of DM equal 2 or other equal 1 and paltates < 100 lu/ml equal 2) and calculated from (4-8 points).

**Results:** All patients who developed HCC was group (I) (35 patients; 0.028%) and who did not develop HCC group (II), Risk score was calculated from 124 patients who had fibroscan at base line assesment with AUC (0.90) and significant in table (1); after Demographic, clinical and laboratory data were compared between group developed HCC and not developed HCC, Multivariate models showed that Age (Age >60 years) (OR 8.9), CI (2-40.8), presence of DM (OR 8.9) CI(3.1 - 26.1), Fibroscan (OR 37) CI (5.6-257), Platlates (OR 3.2)CI(0.99 - 1.1).

Test Result Variable	Area	Std. Error	Asymptotic Significance	Asymptotic 95% Confidence Interval
Novel score	0.906	0.027	0.000	Lower Bound (0.853); Upper Bound(0.959).

[Novel score Area Under the Curve :]

**Conclusion:**

1. Novel risk score for HCC after DAAs with cut off level (6) with sensitivity (80%) and specificity (85%) can predict HCC with DAAs.
2. Higher LSM by fibroscan, older age, DM and lower paltates are risk factors for HCC after HCV eradication by DAAs.

**Disclosure:** Nothing to disclose

## P1422 NON-INVASIVE PREDICTION OF HIGH-RISK VARICES IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS BY TWO-DIMENSIONAL SHEAR WAVE ELASTOGRAPHY

**Yan Y.**<sup>1</sup>, Xing X.<sup>1</sup>, Yang J.<sup>1</sup>, Yang L.<sup>2</sup>

**Introduction:** Variceal bleeding is one of the most fatal complication in patients with liver cirrhosis. A screening esophagogastroduodenoscopy (EGD) is recommended in all patients with cirrhosis to detect those patients at risk of variceal bleeding.

However, with the progressive introduction of non-invasive methods for the diagnosis of cirrhosis, an increasing number of patients are diagnosed at an earlier, fully compensated stage of the disease, resulting in a large number of unnecessary screening endoscopies [1]. Thus, there is an urgent need for noninvasive screening methods for varices in patients with chronic liver disease.

Two-dimensional shear wave elastography (2D-SWE) is a promising new type of shear wave-based ultrasound technique for measuring liver stiffness. The shear waves are generated directly within the tissue, allowing measuring stiffness also in patients with ascites. The liver stiffness values can be obtained on the basis of anatomic information to control major measurement bias [2]. This method has equal or superior diagnostic accuracy for the staging of liver fibrosis and portal hypertension in patients with chronic liver disease [3, 4].

Primary biliary cholangitis (PBC) is one of cholestatic autoimmune liver diseases, rare etiology of chronic liver disease. However, there was also no coincident cut-off value for predicting high varices, and only several studies about SWE evaluating the varices in compensated liver cirrhosis, and all of studies with all etiology of cirrhosis and small sample sizes [5, 6]. The aim of this study was to investigate the diagnostic performance of 2D-SWE for predicting high-risk varices in patients with PBC related chronic liver disease.

**Aims & Methods:** To investigate the diagnostic performance of 2D-SWE for predicting high-risk varices in patients with PBC related chronic liver disease. Clinical data from 182 patients with PBC related chronic liver disease who underwent 2D-SWE and endoscopy were collected consecutively. Liver stiffness (LS) was measured by 2D-SWE. The time interval between 2D-SWE and endoscopy examination no more than 3 months. Comparisons of the accuracy of prediction between groups were made by areas under the receiver operating characteristic curves (AUROCs).

**Results:** The optimal cutoff value for predicting high-risk varices was 13.65 kPa, AUROC of LS was 0.886(95% CI: 0.837-0.935), sensitivity was 0.759 and specificity was 0.898. The optimal cutoff value for predicting high-risk varices in PBC patients without ascites was 10.2 kPa, AUROC of LS was 0.887 (95% CI: 0.816-0.959), sensitivity and specificity were 0.957 and 0.721, respectively.

**Conclusion:** LS of 2D-SWE is reliable predictor for predicting presence of high-risk varices in patients with PBC related chronic liver disease. In addition, SWE is a reliable noninvasive tool for predicting esophageal varices with ascites.

**Introduction:** In liver cirrhosis, especially in advanced stages, portal vein thrombosis(PVT) is one of the most common complications and its prevalence increases with disease severity. PVT is mainly due to hypercoagulable state and altered dynamic of blood flow in the portal vein. Studies reported a prevalence of 10-28% in cirrhotic patients, excluding those with HCC. Association between liver cirrhosis and malignancies, especially HCC, may increase PVT prevalence up to 44%.

**Aims & Methods:** In our study we aimed to evaluate the prevalence of portal vein thrombosis in a cohort of patients with liver cirrhosis based on Child Pugh score (CPS). We retrospectively analyzed a cohort of pa-

tients with livercirrhosis in a tertiary gastroenterology referral center from North-Eastern Romania, between January 1st 2017 and December 31st 2018. All patients with presumption of thrombosis wereevaluated by abdominal ultrasound and confirmed by CT scan. Were excluded from patientswith thrombophilia.

**Results:** The study included 2734 cirrhotic patients with mean age 56,7 ± 5,3 years, predominantly female (1558 - 57%). Of the total number, 143 (5.23%) patients presented PVT, of which 21 (14.68%) patients with acute PVT and 122 (85.31%) patients with chronic PVT. The main clinical presentation at diagnosis were variably: upper digestive haemorrhage in 26 (18.18%) patients, ascitic decompensation in 80 (55.94%) patients, abdominal pain in 25(17.48%) patients and 12 (8.39%) patients were asymptomatic. The commonest causes of cirrhosis and PVT were alcoholic liver disease (30, 20.97%), viral hepatitis B±D (13, 9.09%)viral hepatitis C (74, 51.74%), malignant PVT (19, 13.28%) and other causes (7, 4.89%). Of the patients included in study, 12 (8.39%) Child-Pugh class A, 81 (56.64%) class B and 50(34.96%) class C cirrhotic patients. PVT prevalence is 2.1% in compensated liver cirrhosis and up to 23% in decompensated liver cirrhosis. Association between liver cirrhosis and malignancies, especially HCC, increased PVT prevalence to 42%.

**Conclusion:** Child-Pugh score was higher in patients with PVT, which confirms that the prevalence of PVT increases with the severity of cirrhosis liver. Thus, PVT prevalence is low in compensated liver cirrhosis and is increased in decompensated liver cirrhosis. In addition, in patients with liver cirrhosis and HCC, the PVT prevalence was higher, data confirmed by the literature.

**Contact E-Mail Address:** uriahglaza@gmail.com

**Introduction:** Digestive hemorrhages (DH) represent high morbidity and mortality clinical emergency<sup>1</sup>. They can manifest in the form of hematemesis, melena, enterorrhagia and hematochezia<sup>2</sup>. The main cause of DH non related to digestive tract affections is the hypertension of the portal system. This clinical syndrome is frequent in the liver cirrhosis and the growth of esophageal varices (EV) is one of its main complications, with predominance in 60% and 80% of the cases<sup>3</sup>. Hemorrhage by rupture of EV constitutes a bad prognosis in cirrhosis, with mortality between 17% and 57%<sup>4</sup>. For proper management, endoscopic treatment is indicated, through sclerotherapy and elastic ligation of the esophageal varices<sup>3</sup>.

**Aims & Methods:** To investigate the clinical and demographic profile of the cirrhosis patient hospitalized with DH in a university hospital in the period from September 2017 to January 2019. This is a retrospective study, made through records' data collection, of 772 patients attended in the Digestive Hemorrhage Department of the Hospital Universitário Evangélico Mackenzie in this period. In September 2017, this hospital became a unique reference for acute cases of GIB sent by the Public Health System in Curitiba (about 3.5 million people). A descriptive and statistical analysis of prevalence by age, sex, transfusion, decease, symptomatology of admission, smoking, alcoholism, medicine, comorbidities, clinical-surgical conduct, endoscopic diagnosis and endoscopic treatment was made.

**Results:** From the 772 patients with gastrointestinal bleeding, 139 presented with cirrhosis diagnosed. The main etiology was alcoholism (76.2% patients), followed by hepatitis C and hepatitis B. The most prevalent gender was male (107 patients, 77%). The mean age was 55 years old. The age range compromised was between 41-50 years old (29.5%). 43 patients (30.9%) were deceased throughout the internment, 30 men and 13 women. The mortality rate was higher between women, 40.6% against 28% of the men. Red blood cells transfusion was necessary in 81 of the patients (58.2%). The most common entry symptom was hematemesis, with 123 cases (88.4%) and the most common association was hematemesis and melena with 64 cases (46%). The medium level of hemoglobin at admission was 8,9 g/dL (3.2-17.6). Among patients, 76.2% were alcohol-

ism and 28.7% patients were tobacco users. The most frequent comorbidity was systemic arterial hypertension (26.6%) and medication most associated with digestive bleeding was the usage of anti-inflammatory, 9 cases (6.4%). At the endoscopic exam, the most frequent finding was esophageal varices, 71/139 (51%) of which 24 (33.8%) needed endoscopic treatment by elastic ligature. Besides EV, 35 patients (25.17%) presented hypertensive gastropathy and 8 manifested gastric varices (5.75%). Ten patients had liver transplants and 3 (33.3%) died.

**Conclusion:** The profile of the patients with hepatic disease and cirrhosis admitted for digestive hemorrhages is represented by a male patient, above 55 years, alcoholics and with high mortality risk. The main symptom observed is hematemesis and presenting esophageal varices.

**Introduction:** Bacterial infections (BI), which are frequent and late complications of cirrhosis, increase the frequency of hospitalizations, morbidity and mortality.

**Aims & Methods:** Our objective was to determine the prevalence of BI and to identify predictive factors for readmission within 30 days for all causes in cirrhotic patients treated for first BI.

We performed a retrospective analysis of data from consecutive cirrhotic patients hospitalized for an IB, recruited from January 2010 to December 2017.

**Results:** A total of 252 cirrhotic patients were included. Eighty-one (32.1%) of them were hospitalized for an IB with average age of 61.6 years [37-87] and sex-ratio of 0.39. The etiology of cirrhosis was dominated by viral origin in 47% of cases. The infection was Community-Acquired in 70.3% and nosocomial in 29.6%. These consisted mainly of urinary tract infection (49.4%), respiratory infection (14.1%) and ascitic fluid infection (15.1%) with two cases of ascitic fluid tuberculation. *Escherichia coli* (E. coli) was the most common germ (52%). E.coli ESBL (extended spectrum beta-lactamases) was the predominant germ in nosocomial infections (35.7%). The median hospital stay was 31 days [6-90]. sixteen patients (19.7%) died during hospitalization. During follow-up, 11 patients (13.5%) were readmitted within 30 days of discharge. Predictive factors of early readmission in univariate analysis were: anemia (p=0.02), hepatocellular carcinoma (HCC) (p=0.01), a history of diabetes (p< 0.05), undernutrition (p< 0.05). In multivariate analysis, only anemia and HCC were independent predictors of early readmission.

**Conclusion:** In our study, BI were dominated by E.coli urinary tract infections. These infections may represent a relatively higher risk of early readmission with anemia and HCC as predictive factors.

**Disclosure:** Nothing to disclose

## P1426 ASSESSMENT OF THE PROGNOSTIC IMPACT OF KIDNEY FAILURE ESTIMATED BY THE ROYAL FREE HOSPITAL CIRRHOSIS GLOMERULAR FILTRATION RATE (RFHCGFR) IN CASE OF VIRAL CIRRHOSIS C

Trad N.<sup>1</sup>, Issaoui D.<sup>2</sup>, Kchir H.<sup>3</sup>, Sabrine S.<sup>4</sup>, Said Y.<sup>5</sup>, Ben Hassine H.<sup>3</sup>, Chaabouni H.<sup>3</sup>, Maamouri N.<sup>3</sup>

**Contact E-Mail Address:** yosrasaid10@yahoo.fr

**Introduction:** The occurrence of renal failure during viral cirrhosis is frequently associated with a poor prognosis. Since most glomerular filtration rate (GFR) formulas in these patients are often inaccurate due to the inclusion of serum creatinine, a new more specific formula (RFHCGFR) has been proposed.

**Aims & Methods:** Our objective was to evaluate the prognostic impact of kidney failure estimated by RFHCGFR during viral cirrhosis C.

We performed a retrospective analysis of data from consecutive patients followed in our department for viral cirrhosis C recruited from January 2010 to December 2017. GFR was estimated by MDRD and RFHCGFR. Survival associated with GFR was estimated by Kaplan Meier method using the Log-rank.

**Results:** A total of 112 patients were included with an average age of 62.9 years [43-83] and sex-ratio of 0.3. Patients were classified by the Child-Pugh (CP) score into CP A in 42.8%, CP B in 41.9% and CP C in 15.1% of cases. The median GFR was 96.3 ml/min evaluated by MDRD and 72.3 ml/min/1.73<sup>2</sup> by RFHCGFR. GFR estimated by RFHCGFR was significantly correlated to GFR estimated by MDRD (p < 0.0001). Using RFHCGFR, the survival at two years was 73.3% in patients with GFR>30 ml/min/1.73<sup>2</sup> and 5.2% in patients with GFR< 30 ml/min/1.73<sup>2</sup> (p=0.02). For the MDRD, there was no difference in survival between patients with GFR>30 ml/min and those with GFR< 30 ml/min (p=0.09). A significant correlation was noted between kidney failure estimated by RFHCGFR and ascitic decompensation (p=0.005), bacterial infections (p=0.05) and early readmission within 30 days (p=0.03).

**Conclusion:** In our study, renal failure estimated by RFHCGFR was a prognostic factor correlated with survival, ascitic decompensation, bacterial infections and early readmission.

**Disclosure:** Nothing to disclose

## P1427 CIRRHOSIS ASSOCIATED WITH WORSE OUTCOMES IN PATIENTS UNDERGOING BARIATRIC SURGERY

Kroner P.T.<sup>1</sup>, Wijarnprecha K.<sup>2</sup>, Hoogenboom S.<sup>2</sup>, Taner B.<sup>3</sup>, Croome K.<sup>2</sup>, Harnois D.<sup>2</sup>, Pungpapong S.<sup>4</sup>

<sup>1</sup>Mayo Clinic, Gastroenterology, Jacksonville, United States, <sup>2</sup>Mayo Clinic, Jacksonville, United States, <sup>3</sup>Mayo Clinic, Transplant Surgery, Jacksonville, United States, <sup>4</sup>Department of Transplantation, Mayo Clinic, Jacksonville, United States

**Contact E-Mail Address:** thomaskroner@gmail.com

**Introduction:** Obesity is directly linked to non-alcoholic steatohepatitis (NASH). Bariatric surgery (BS) has emerged as a successful treatment option for obesity, and used as a way to decrease the BMI and positively influence a patient's NASH. Cirrhosis, a complication of NASH, confers an increased risk for a broad range of surgical interventions. Smaller studies have shown that BS is safe in compensated (Child A) cirrhosis. However, large studies examining bariatric surgical outcomes in patients with cirrhosis with and without PVT lack.

**Aims & Methods:** The aim of this study is to determine the inpatient outcomes of non-transplant patients with liver cirrhosis undergoing BS. Case-control study using the 2012-2016 NIS, the largest public inpatient database in the US. All patients with ICD9-10CM procedural codes for BS were included. Patients with history of liver transplant (LT) and those who underwent LT during that admission were excluded. The cohort was stratified into two groups: 1) cirrhosis without PVT and 2) cirrhosis with PVT. These groups were compared to non-cirrhotic patients undergoing BS. The primary outcome was determining the odds of inpatient mortality in the two cohorts. Secondary outcomes included determining inpatient morbidity, resource utilization, hospital length of stay (LOS), and inflation-

adjusted total hospital costs and charges. Multivariate regression analyses were used to adjust for age, gender, Charlson Comorbidity Index, income in patient zip code, hospital region, location, size and teaching status.

**Results:** 965,595 patients underwent BS in the study period, of which 6,470 had cirrhosis without PVT and 160 had cirrhosis with coexisting PVT. The mean age for patients with cirrhosis and no PVT was 58.8 years, while the mean age for patients with cirrhosis and PVT was 59.0 years (53% and 31% were female, respectively). For the primary outcome, patients with cirrhosis and no PVT had increased inpatient mortality odds of 4.03 ( $p < 0.01$ ), while patients with cirrhosis and PVT had inpatient mortality odds of 13.86 when compared to patients undergoing BS without cirrhosis. For the secondary outcomes, patients with cirrhosis with and without PVT displayed increased odds of shock, ICU stay, AKI, and multiorgan failure. In addition, both cohorts displayed significantly higher additional hospital costs. However only patients with cirrhosis and PVT displayed higher total hospitalization charges and LOS compared to patients without cirrhosis who underwent BS (Table 1).

Variable	Cirrhosis without PVT	Cirrhosis with PVT
Mortality	4.03 (3.24,5.03) <0.01	13.86 (5.44,35.32) <0.01
Shock	2.56 (2.10,3.12) <0.01	9.02 (3.64,22.32) <0.01
ICU	2.25 (1.91,2.65) <0.01	7.81 (3.56,17.16) <0.01
AKI	1.71 (1.46,2.02) <0.01	6.74 (3.07,14.83) <0.01
Multi-organ failure	1.93 (1.67,2.23) <0.01	5.81 (2.66,12.71) <0.01
Additional Adjusted Costs	\$2,549 (368,4729) 0.02	\$43,334 (24637,62035) <0.01
Additional Adjusted Charges	\$8,826 (-742,18394) 0.07	\$182,059 (67762,296357) <0.01
Additional Adjusted LOS (days)	0.1 (-0.5,0.7) 0.76	13.3 (7.7,19.0) <0.01

[Adjusted odds ratio and additional adjusted means in patients with cirrhosis and no PVT and cirrhosis with PVT undergoing BS.]

**Conclusion:** Patients with cirrhosis with and without PVT had higher associated inpatient mortality and morbidity odds during the admission for bariatric surgery compared to patients without cirrhosis. Patients with cirrhosis and PVT had higher mortality and morbidity odds than patients with cirrhosis alone. This reflects the risk that cirrhosis in itself confers to patients undergoing bariatric surgery. Thus, this should continue to be an important consideration in patients with cirrhosis evaluated for bariatric surgery. Prospective studies are required to better understand the impact of cirrhosis, both compensated and decompensated, on bariatric surgical outcomes.

**Contact E-Mail Address:** jonathansoldera@gmail.com

**Introduction:** Hepatorenal syndrome (HRS) is one of the deadliest complications of cirrhosis and carries a high mortality. It is treated with an association of terlipressin plus albumin. This treatment is very costly, and it is paramount to choose wisely those patients who benefit from it. Our hospital had an evidence-based protocol for treatment of HRS instituted as standard-of-care in 2013.

**Aims & Methods:**

**Purpose:** Analyze variables associated to survival in patients diagnosed with HRS.

**Study design:** Historical cohort.

**Methods:** A search for every patient who received terlipressin in our hospital from 2010 to 2016 was performed, ranging from three years prior and after the institution of the protocol. Every chart was reviewed in order to determine the diagnosis of cirrhosis and HRS. The data in these charts was reviewed and multiple variables were collected. A cox-regression multivariate analysis was performed to determine mortality.

**Results:** It was included 46 patients who were diagnosed with HRS, 20 pre-protocol and 26 post-protocol. Mean age was 58 years-old and 80% were male. Most common cause of cirrhosis was alcohol abuse (76%). Respectively, mortality for 30-day, 90-day and 365-day was 75%, 89% and 89% for the pre-protocol period and 61%, 69% and 80% for the post-protocol period. In multivariate analysis, AST > 40, pre-protocol period and Child-Pugh score were associated with higher 30-day and 90-day overall mortality. Also, the total mean dose of terlipressin and albumin used per patient reduced with the institution of the protocol, reducing from 27 to 22 mg of terlipressin and from 236 to 144 g of albumin per patient. This was not associated with higher mortality.

**Conclusion:** The use of an evidence-based protocol in the treatment of HRS translated in a higher survival. Also, it was associated with lower drug use.

**Disclosure:** Nothing to disclose

## P1429 FACTORS ASSOCIATED WITH AN INCREASE OF LIVER STIFFNESS VALUES IN PATIENTS WITH HCV HEPATITIS WITH SUSTAINED VIROLOGIC RESPONSE

**Contact E-Mail Address:** sirli.roxana@umft.ro

**Introduction:** Several studies demonstrated a significant decrease in liver stiffness (LS) values in most, but not all patients following sustained virologic response (SVR).

**Aims & Methods:** The purpose of this study was to highlight the factors associated with an increase in LS following SVR.

The study included 254 patients with genotype HCV hepatitis who had a SVR following DAA treatment. All were assessed by transient elastography (TE) at the start of treatment and 12 weeks after the end of treatment, when SVR was assessed. In each patient, 10 valid LS measurements were obtained either with M or XL probes. Reliable LSM were defined as median value of 10 measurements with Interquartile range/median (IQR/M)  $\leq 30\%$ . Demographic, biologic (including FibroMax), ultrasonographic data were collected and analyzed.

**Results:** Of the 259 patients evaluated, 47 (22.4%) patients had elevated LS values at SVR12 as compared to start point, but in only 27 all data was available, so the final analysis included 27 patients. In univariate analysis only obesity and elevated transaminases at SVR12 were associated with LS increase at SVR12 ( $p=0.0007$  and  $p=0.0008$ , respectively). In multivariate analysis, the presence of steatosis on ultrasound, obesity and elevated transaminases were independently associated to LS increase at SVR12.

**Conclusion:** Obesity, cytotoxicity and steatosis were associated with LS increase after SVR in patients with HCV hepatitis treated with DAA.

## P1430 IMPACT OF GENETIC POLYMORPHISMS OF INTERLEUKIN 28B AND ICAM-1 ON RESPONSE TO DIRECT ANTIVIRAL TREATMENT AMONG CHRONIC HEPATITIS C EGYPTIAN PATIENTS

Elsheredy A.<sup>1</sup>, Almaeen A.<sup>2</sup>, Ghazy A.<sup>2,3</sup>, Helaly G.<sup>1</sup>, Amer I.<sup>4</sup>, Ghazy H.<sup>5</sup>, Hydara I.<sup>6</sup>

**Contact E-Mail Address:** tamerhydara@yahoo.com

**Introduction:** Complete eradication of HCV virus is one of the most important goals for antiviral treatment research. New direct antiviral agent (DAA) therapy has revolutionized for HCV; with higher efficacy and safety than peg IFN- $\alpha$ /RBV. However, easy access to DAAs, availability of reliable HCV prognostic tests, and affordable costs still remain important goals that must be reached to globally eliminate hepatitis C. Genotyping of interleukin-28B (IL28B) and intra-cellular adhesion molecule-1 (ICAM-1) single nucleotide polymorphisms (SNPs) may be helpful to predict response to treatment of HCV infected patients; especially when double or triple therapy can be used. Thus they could have a role in predicting early virological response to DAA.

### Aims & Methods:

**The aim of the current study** was to investigate the impact of IL-28B rs860, rs917 and ICAM-1 rs1437 single nucleotide polymorphisms on response to treatment with sofosbuvir + Daclatsvir  $\pm$  Ribavirin, among chronic hepatitis C Egyptian patients.

**Subjects and Methods:** Genomic DNA was extracted from a total of 120 subjects; including 40 healthy volunteers, 80 chronic HCV patients who were subdivided into responder and non-responder to direct antiviral drugs. IL-28B and ICAM-1 SNP was assessed by 5' nuclease assay with a TaqMan MGB (minor groove binder) probe using StepOne™ Real-Time PCR System (Applied Biosystems, Life Technologies). Liver functions' tests, Anti-HCV antibodies, quantification of HCV-RNA and HCV Sequence analysis were done for all subjects under the study.

**Results:** AST and ALT values showed statistically significant increase among non-responder HCV patients compared to the other studied groups ( $P=0.001^*$ ) while serum albumin and ALK levels did not show any statistically significant differences ( $P=0.173$  and  $0.076$ , respectively). All HCV patients were positive for anti-HCV antibodies. All samples of HCV patients were successfully genotyped and sub-genotyped; 72 patients (90%) have HCV genotype 4a, while the remaining 8 cases (10%) have genotype 4l. The frequencies of IL 28B rs860 T and ICAM-1 rs 437 C alleles were higher among HCV patients, either responders or non-responders, when compared to the control group but statistically insignificant ( $P=0.280$ ,  $0.305$ , respectively). On the other hand, IL 28B rs917 G allele is more frequent among healthy controls; suggesting their protective role against HCV infection ( $P=0.045^*$ ). Regarding relation between IL-28B and ICAM-1 polymorphism and response to treatment with DAA, HCV patients with IL-28B rs917 GG alleles showed an early viral responder compared to those carrying TT alleles; these differences were found to be statistically significant ( $P=0.050^*$ ). Also, ICAM-1 rs437 CT alleles were more frequent among responders and control groups but statistically insignificant. On the other hand, for IL 28B rs860 HCV patients with either CT or TT alleles did not show any statistically significant differences among all the studied groups. **Conclusion:** IL-28B rs917 represents protective genotypes as HCV infected patients have a statistically significant lower prevalence of IL-28B rs917 GG genotype when compared to uninfected individuals. Considering response to DAA treatment, the higher frequency of ICAM-1 rs437 CT genotypes observed among responder HCV patients elucidate that ICAM-1 rs437 genotyping could be a useful independent tool for predicting outcome of treatment with DAA.

## P1431 MINIMAL RISK OF HBV REACTIVATION IN RESOLVED HBV-INFECTED PATIENTS DURING IMMUNOSUPPRESSIVE THERAPY

Tokmak S.<sup>1</sup>, Gümürdülü Y.<sup>2</sup>

<sup>1</sup>Çukurova University, Gastroenterology, Adana, Turkey, <sup>2</sup>Çukurova University, School of Medicine, Gastroenterology, Adana, Turkey

**Contact E-Mail Address:** stokmak@cu.edu.tr

**Introduction:** Hepatitis B virus reactivation (HBVr) during immunosuppressive drug therapy (ISDT) is a growing concern; however, prospective long-term follow-up studies are rare.

**Aims & Methods:** In this cross-sectional, prospective study, we analyzed two groups of patients showing hepatitis surface antibody (anti-HBs) positivity/HBV surface antigen (HBsAg) negativity among 225 patients receiving immunosuppressive therapy and 157 patients receiving antineoplastic therapy in our tertiary care center between January 2016 and January 2018. We also analyzed the associated factors and determined the necessity of prophylactic antiviral treatment. Baseline hepatitis serology, PCR measurements, liver alanine transaminase (ALT) levels and the international normalized ratio (INR) were recorded. Routine monthly follow-up of patients consisted of a complete physical examination and analyses of liver enzymes, the INR and HBV serology. According to the national healthcare policy, HBV-DNA levels were measured by PCR every three months. Patients who were HBsAg (+), HBV-DNA (+), anti-HCV (+), anti-HDV (+) or anti-HBc (-) were excluded. Because HBVr typically occurs during the first six months of ISDT, patients who discontinued treatment because of HBV-unrelated reasons and/or died before the six-month follow-up threshold were excluded and patients with a history of treatment with interferon (IFN) or antiviral drugs were excluded. HBVr criteria defined as: loss of HBV immune control in HBsAg (-) / anti-HBc (+) patients (i) receiving ISDT for a concomitant medical condition; (ii) a rise in HBV-DNA compared to baseline; and (iii) reverse seroconversion (seroreversion) from HBsAg-negative to HBsAg-positive for HBsAg (-) anti-HBc (+). To examine the association between anti-HBs titers and HBVr, anti-HBs (+) patients were divided into three subgroups: (i) anti-HBs > 1000 mIU/mL (Group A), (ii) anti-HBs between 100 and 1,000 mIU/mL (Group B) and anti-HBs between 0 and 100 mIU/mL (Group C).

**Results:** Among the 579 patients recruited to this study, 144 were excluded according to the above-mentioned criteria (74 patients did not meet the criteria, and 70 patients were either lost to follow-up, discontinued the treatment or died before the 6-month threshold); thus, 435 patients were included. The mean follow-up time was 25.8 months. We did not detect any cases of HBVr, even among 86 patients receiving rituximab (49 of which are anti-HBc positive only) and 132 patients receiving tumor necrosis factor inhibitors (84 of which are anti-HBs positive only). Furthermore, we did not find an association between anti-HBs changes and HBVr, although a role for anti-HBs in reactivation has previously been suggested. A subgroup analysis showed that during the study period, the antibody levels did not change in Group A, changed non-significantly in Group B ( $p=0.25$ ) and significantly declined in Group C ( $p=0.002$ ). However, despite the marked decline in antibody levels in Group C, we did not observe any cases of HBVr. Changes in the mean ALT and INR levels were not significant ( $p=0.36$  and  $p=0.54$ , respectively).

**Conclusion:** The risk of reactivation of HBV infection by immunosuppressive and antineoplastic therapy is lower than that suspected in published anecdotal reports.

**Disclosure:** Nothing to disclose

**Introduction:** Patients with advanced hepatic fibrosis due to chronic hepatitis C (HCV) receive successful treatment for hepatitis with direct-acting antivirals (DAA); however, many of them are still at risk of decompensation, mainly at the expense of portal hypertension. There are data that reflect a lower risk of decompensation in those who achieve sustained viral response (SVR), although they are scarce and in the short term.

**Aims & Methods:** We want to make a comparison using an innocuous and widely available indirect method such as abdominal ultrasound of the most accessible parameters of portal hypertension before and after treatment with DAA in patients who achieve SVR.

Retrospective study of patients with HCV hepatitis and F4 fibrosis treated in our center between 2015 and 2017. Data was collected in 2019. The diameter of the portal vein (PVD), the superior mesenteric and splenic veins diameter (SMVD, SVD), the bipolar diameter of the spleen (BPSD), and the presence of ascites is compared before (in the previous 12 months) and after the end of treatment at the first, second and third year. The variables PVD, SMVD, SVD, BPSD and ascites are collected as qualitative variables (normal vs. pathological); in the case of pathological PVD and BPSD ( $\geq 13$ mm and  $\geq 120$ mm respectively), they are expressed as quantitative variables in millimeters.

**Results:** There is a decrease in the incidence of splenomegaly after treatment so that those with enlarged BPSD at the start of treatment normalized it by 21.2% in the first year ( $p = 0.023$ ), 28.2% in the second ( $p = 0.001$ ), and 30.8% in the third ( $p = 0.000$ ), so that the prevalence of splenomegaly changes from 46.45% to 40.43% after one year, 37.42% after the second, and 43.63% after the third. Among those with pathological BPSD, a statistically significant decrease of 4.22 (1.50-7.21, 95% CI) mm was observed at the first year ( $p = 0.006$ ), 5.57 (2.80-8.55, 95% CI) at the second year ( $p = 0.001$ ), and 6.61 (2.60-10.63, 95% CI) mm at the third year ( $p = 0.002$ ). With regard to the presence of ascites, among the 10 patients who presented it at the beginning of treatment, only 2 presented it after one year (with 2 new patients who did not present it before), although this difference did not reach statistical significance ( $p = 0.109$ ). By the second year, only 1 patient of the initially decompensated remained this way, and none of the patients in the third year (with a total of 3 decompensated patients who were not decompensated at the beginning of the treatment in both the second and the third year), these differences are not significant ( $p = 0.227$ , and  $0.727$  respectively).

With respect to PVD, there are no differences before or after treatment, nor are there any differences with SMVD or SVD. Among those with a pathological PVD, its quantitative measurement does not show improvement in the first, second or third year.

**Conclusion:** An improvement in BPSD (splenomegaly) is observed. This could translate an improvement in the hepatic venous pressure gradient (HVPG) with a lower risk of decompensation in these patients, as an indirect parameter of portal hypertension and predictor of the existence of esophageal varices in cirrhosis. We observed for the first time that this change is maintained in the long term (3 years), which could translate changes in the hepatic architecture with regression of fibrosis.

Likewise, the data seem to suggest a lower incidence of ascites, without being statistically significant. However, other sonographic parameters such as PVD, SMVD, or SVD show no improvement.

**Introduction:** Aim was to follow patients profile and effectiveness of chronic hepatitis C (CHC) treatment with glecaprevir/pibrentasvir (GP) a pangenotypic regimen in real world settings.

**Aims & Methods:** Patients treated with GP were selected from 10 161 included in the EpiTer2 database of treated for CHC between 2015 and 2018. Analysis was carried out in 381 patients which started therapy with GP in 2018, that was compared to data from general population of treated in corresponding period ( $n=3938$ ).

**Results:** Gender distribution (51% females) and age ( $49 \pm 14$  years) of patients treated with GP were similar to general population. Majority of patients on GP were infected with genotype 1b (51%) or 3 (39%) and these proportions were different than in general population (78% and 13% respectively). Majority of GP patients (69%) were treatment naïve, but it was lower than in general population (85%). Proportions of cirrhotics (14%), decompensation history (0.5%) and Child-Pugh >A (1.2%) in patients treated with GP were similar to general population (15%, 0.8%, 1.1% respectively). Majority of patients received 8 weeks regimen (65%), followed by 12 weeks (28%). Since there were three treatment failures, sustained virologic response rates available in 111 patients for intent to treat and in 110 per protocol analysis, were 96% and 97% respectively, that was similar to general population data. Much more subpopulation analysis, including cirrhotics, genotype 3 infected and failures to previous therapies will be available in mid 2019 for possible presentation at the meeting.

**Conclusion:** Glecaprevir/pibrentasvir compared to other regimens, was administered more frequently to patients infected with genotype 3 and treatment experienced. Effectiveness of this novel regimen in this real world study reached up to 97%.

## P1434 HCVKID-STUDY: COMPARISON FOR PREVALENCE OF EARLY RENAL FINDINGS AMONG HEPATITIS-C POSITIVE AND NEGATIVE POPULATIONS USING URINE AND PLASMA BIOMARKERS

Kaartinen K.<sup>1</sup>, Vuoti S.<sup>2</sup>, Honkanen E.<sup>1</sup>, Färkkilä M.A.<sup>3,4</sup>

**Introduction:** Hepatitis C (HCV) infection is known to cause extrahepatic kidney manifestations, which are typically discovered at a late stage. HCV-related nephropathy may show different histopathologic patterns, as both glomerular and tubulointerstitial damage have been described in the literature. Early identification of patients with kidney derangements would be beneficial to enable treatment and to avoid progression to chronic kidney disease.

**Aims & Methods:** The primary objective of the prospective, observational HCVKID-study is to evaluate the prevalence of renal manifestations among HCV+ patients in Finland and to compare those findings to HCV-negative

controls complemented by long-term analyses to identify changes from baseline. This is a cross-sectional analysis to compare baseline characteristics between HCV+ patients and healthy controls. 208 HCV-PCR-positive male and female patients ( $\geq 18$  years old) were eligible for the study. The HCV-negative control group ( $n = 492$ ) was enrolled by an occupational healthcare provider. Exclusion criteria were HIV or Hepatitis B or other underlying diseases that may influence kidney function.

**Results:** The prevalence of any renal finding (abnormal proteinuria, occurrence of hematuria or serum creatinine over upper normal limit) was significantly more frequent in the HCV+ population compared to healthy controls (41/208 vs. 45/492),  $p = 0.0002$ . Occurrence of abnormal proteinuria as evaluated by various methods was the most common urinary finding among HCV+ patients. Protein dipstick test was positive in 4/201, tubular proteinuria marker A1Miglo in 22/208 and albuminuria marker AlbCrea in 8/208. Elevated serum cystatin-C was also prevalent among HCV+ patients (72/208), however s-creatinine was abnormal only in 7/208. Glomerular filtration rate (eGFR<sub>epi</sub>) was significantly lower in the HCV+ population with renal findings, albeit within normal limits. Estimated time from HCV transmission, infection genotype or stage of liver fibrosis were not significantly different between HCV+ with renal finding vs. HCV+ without renal finding. Baseline blood values and liver parameters were similar among both HCV+ populations. SVR12 data on 97 patients revealed early improvements in liver enzymes and APRI scores, but not in proteinuria markers, serum creatinine or cystatin-C.

**Conclusion:** HCV seems to influence both renal tubular and glomerular cells as judged by different proteinuria profiles. Tubular cell damage may be the earliest sign of renal dysfunction caused by HCV and could potentially be used to identify patients with a higher risk to develop more severe renal manifestations.

## P1435 DAPS SCORE: PREDICTIVE MODEL FOR SIGNIFICANT FIBROSIS IN IDAHS

Sundaram S., Darak H., Bhatia S.

Seth GS Medical College & King Edward Memorial Hospital, Department of Gastroenterology, Mumbai, India

**Contact E-Mail Address:** drsridharsundaram@gmail.com

**Introduction:** Up to 20% of Incidentally Detected Asymptomatic Hepatitis B patients (IDAHS) have significant fibrosis at presentation. Management of IDAHS, especially those with normal Alanine Transaminase (ALT) has been a topic of debate. We aimed to study predictors of significant fibrosis in IDAHS and to develop a composite clinical score for prediction of significant fibrosis.

**Aims & Methods:** A retrospective review of IDAHS referred to the Liver clinic at King Edward Memorial Hospital from May 2018 to December 2018 was done. Demographic details of the patients were noted. Patients underwent investigations including complete blood count, liver function tests, HBeAg assay, HBV DNA PCR and ultrasound of abdomen. Liver stiffness measurements were taken using the Fibroscan 430 Mini machine (Echosens Ltd., Paris, France) using the M or XL probe attachments after an overnight fast. 10 readings were taken with success rate of  $>80\%$  and interquartile range of  $<30\%$  as standard. Fibroscan values of  $>8$  kPa were classified as significant fibrosis ( $>F2$ ) as per the APASL criteria and those with values  $>11$  kPa were considered as cirrhosis.

**Results:** 299 patients were included, of which 63% were male with mean age of 42.6 years. 20% patients were obese as per BMI criteria. 226 (75.9%) were HBeAg non-reactive. 5 patients had concomitant HCV and 4 had HIV infection. Significant fibrosis was seen in 82 (27.4%) patients. 36 patients (12%) were cirrhotic on VCTE. 39 (19.6%) patients with normal SGPT had evidence of significant fibrosis. Higher Age, Higher mean SGPT, lower platelets and presence of Diabetes was associated with significant fibrosis ( $p < 0.05$ ) on Univariate Analysis. HBV DNA levels, HBeAg and presence of obesity were not associated with significant fibrosis. Multivariate analysis revealed higher SGPT, lower platelets, higher age and Diabetes

were associated with fibrosis. Hence prediction model using Platelets ( $>240000/\text{cu.mm} = 0$ ,  $<240000/\text{cu.mm} = 1$  point), Age ( $<45$  yrs  $= 0$ ,  $>45$  yrs  $= 1$  point), presence of Diabetes (No  $= 0$ , Yes  $= 1$  point) & SGPT ( $<45$  U/L  $= 0$ ,  $>45$  U/L  $= 1$  point) was developed. Patients were sub-stratified based on cumulative score as low risk (0-2 points) and high risk (3-4 points). Those with high risk had OR of 14.9 (95% CI- 4.89-45.84) over those with low risk for fibrosis. On internal validation, DAPS score had accuracy of 77.3% with specificity of 98.2%.

Parameter	Points= 0	Points= 1
Associated Diabetes Mellitus	No	Yes
Age	$<45$ years	$>45$ years
Platelets	$>240,000/\text{cu.mm}$	$<240,000/\text{cu.mm}$
SGPT	$<45$ U/L	$>45$ U/L
Total score- 0-2 Low risk 3-4 High risk		

[DAPS Score for fibrosis prediction in IDAHS]

**Conclusion:** High proportion of IDAHS have significant fibrosis (27%) at presentation. 20% patients with normal SGPT have fibrosis on VCTE. In low resource settings where non-invasive assessment of fibrosis is not feasible, DAPS score can be used for prediction of significant fibrosis in IDAHS with high specificity.

## P1436 USEFULNESS OF SHEAR WAVE ELASTOGRAPHY BEFORE AND AFTER DIRECT-ACTING ANTIVIRAL TREATMENT FOR HEPATITIS C VIRUS

Kasai A., Mawatari S., Taniyama O., Ijuin S., Sakae H., Tabu K., Oda K., Kumagai K., Ido A.

Kagoshima University Graduate School of Medical and Dental Sciences, Digestive and Lifestyle Diseases, Kagoshima, Japan

**Contact E-Mail Address:** a-kasai@m3.kufm.kagoshima-u.ac.jp

**Introduction:** Direct-acting antivirals (DAA) for hepatitis C virus have helped achieve a high sustained virologic response (SVR). While the ideal method of determining the risk of hepatocellular carcinoma (HCC) development is unclear, some studies have shown an association of liver stiffness and Mac-2 binding protein glycosylation isomer (M2BPGi) with liver carcinogenesis. We evaluated the liver stiffness using shear wave elastography (SWE) before and after DAA treatment and examined its usefulness for predicting HCC development.

**Aims & Methods:** We enrolled 84 patients with hepatitis C virus infection who underwent SWE before and after DAA treatment at our hospital and examined the relationship between the SWE value and fibrosis markers, such as M2BPGi and hyaluronic acid. The SWE value was measured using a Logiq E9 (44 cases; General Electric Company) or an Aplio 500 (40 cases; TOSHIBA). The SWE value was measured with the same device throughout a given patient's course.

**Results:** The average age was 67 years old (range 43-87), 38 patients were men, and 20 had cirrhosis (23.5%). Nine patients (11%) had a history of HCC. DAA treatment comprised Daclatasvir and Asunaprevir in 27 cases, Sofosbuvir and Ledipasvir in 38 cases, Ombitasvir and Paritaprevir in 1 case, Sofosbuvir and Ribavirin in 15 cases, and Elbasvir and Grazoprevir in 3 cases. The SVR rate with treatment was 92.9%. The pre-treatment SWE values measured with the Aplio 500 were positively correlated with the FIB-4 index (Correlation coefficient,  $r = 0.8$ ,  $p < 0.001$ ), hyaluronic acid level ( $r = 0.515$ ,  $p = 0.014$ ), M2BPGi level ( $r = 0.671$ ,  $p = 0.024$ ), and alpha-fetoprotein (AFP) level ( $r = 0.421$ ,  $p = 0.007$ ). There was a negative correlation with the platelet count ( $r = -0.652$ ,  $p < 0.001$ ) and albumin level ( $r = -0.374$ ,  $p = 0.019$ ). Similarly, the pre-treatment SWE values measured with the LogiqE9 were positively correlated with the FIB-4 index ( $r = 0.353$ ,  $p = 0.019$ ), hyaluronic acid level ( $r = 0.345$ ,  $p = 0.042$ ), and M2BPGi level ( $r = 0.474$ ,  $p = 0.013$ ). The average SWE value with the Aplio500 was 1.94 m/s in cases with an FIB-4 index  $< 3.25$  (equivalent to F0-2) and 2.43 m/s in those with a value  $\geq 3.25$  (equivalent to F3 or higher); those respective values with the Logiq E9 were 1.39 m/s and 1.49 m/s. The SWE value decreased in 67.9% of cases after DAA treatment, and the average value before treatment, at the end of treatment (EOT), 6 months after the EOT, 12 months after the EOT and 24 months after the EOT were 2.18, 2.18, 2.01, 1.98, and

1.86 m/s with the Aplio 500, respectively, and 1.45, 1.36, 1.29, 1.28, and 1.19 m/s, with the LogiqE9, respectively. We divided patients with SVR who had no history of HCC into two groups based on whether or not the SWE value decreased after the EOT. We compared the baseline values of alanine aminotransferase, platelet, AFP, and FIB-4 index between these two groups but noted no marked differences. However, in the patients whose SWE value decreased, the M2BPGi level was significantly lower at 6 and 12 months after the EOT than at EOT ( $p < 0.001$ ,  $0.002$ , respectively), with no such changes noted in the patients whose SWE value did not decrease ( $p = 0.467$ ,  $0.921$  respectively).

**Conclusion:** A decrease in the SWE value after DAA therapy likely reflects improvement in the liver inflammation. However, there were some patients in whom the SWE levels did not decrease after the EOT. In those patients, the M2BPGi also did not decrease, suggesting that these patients may be at risk of liver carcinogenesis.

**Contact E-Mail Address:** aymanahmedsakr@gmail.com

**Introduction:** Direct-acting antiviral drugs (DAAs) have revolutionized the treatment for patients with chronic hepatitis C virus (HCV) infection, with excellent rates of sustained virologic response (SVR). Patients with HCV-related Child -B liver cirrhosis are poorly evaluated in the clinical trials of DAAs.

**Aims & Methods:** In this cohort multicenter cross-sectional study, we focused on the effectiveness and safety of DAAs for the treatment of Child B- cirrhotic Egyptian patients with chronic HCV infection genotype (GT-4) in a routine clinical practice. Child -Pugh score was calculated for all patients, those with score 7 to 9 was selected (Child-B). All patients' data including demographic, clinical and laboratory measures were recorded. Child B patients (hard to treat) with a total number ( $n=326$ ); 269 naïve and 57 experienced were compared to Child A patients (easy to treat) ( $n=275$ ), all of them were naïve.

**Results:** In Child A patients, 260 had sofosbuvir (SOF) and daclatasvir (DAC) for 12 weeks, 13 had SOF plus simeprevir (SIM) for 12 weeks and 2 had Ritonavir-Paritaprevir-Ombitasvir-Ribavirin for 12 weeks. While, in Child B patients; 86 had SOF-DAC for 24 weeks, 233 patients had SOF-DAC-RVB for 12 weeks. (98.9%) of Child A patients had completed their course and 1.1% stopped treatment due to pregnancy. However, in Child B only (91.1%) had completed their course ( $P < 0.001$ ); 29 stopped treatment due to complications (hematemesis 2.8%, jaundice 1.8%, ascites 0.6% or anemia aggravation 2.8%, hepatic encephalopathy 0.6%) with statistically significant difference between both groups ( $P = 0.001$ ). SVR-12 achieved in 98.5% & 86.7% in Child A & B, respectively with statistically significant difference ( $P < 0.001$ ). In both groups, HB, PLT, ALT, AST, s.albumin and bilirubin improved post- than pre-treatment levels ( $p < 0.001$ ). Regarding the risk factors for non-SVR-12; increasing age, male gender, experienced patients, with SOF-DAC for 12 weeks, moderate to severe ascites and Child score 9 were highly statistically significant difference ( $p$ -value=0.000). At SVR-12 in Child B group, 3/297 (1%) patients developed hepatic focal lesions (HFLs), 5 (1.7%) developed new jaundice, 20% has developed new-onset or a deterioration of pre-existing ascites and 1.2% developed upper gastrointestinal bleeding.

**Conclusion:** Real-world results of generic DAAs combinations in Egyptian patients with chronic HCV-Child B were very safe and effective with SVR-12 (98.5% & 86.7%) with very rare reported complications (0.01%, 0.9%) in Child A & B, respectively.

**Introduction:** Hepatitis Delta Virus (HDV) is a defective virus that can only cause hepatitis on hosts already infected with Hepatitis B virus (HBV).

Compared with other viral hepatitis; chronic delta hepatitis (CDH) has a higher incidence of end stage liver disease and hepatocellular carcinoma. Treatment goal of HDV infection is either eradication of both HBV and HDV or long-term suppression of disease activity.

Today the only approved treatment opportunity of CDH is alpha interferon (IFN $\alpha$ ). Previous clinical trials claim a high dose long term IFN $\alpha$  treatment has a higher chance of virological, biochemical and histological response with a ameliorated natural course of disease.

**Aims & Methods:** This study aims to assess long term histological, virological and biochemical outcomes of our patients treated with IFN $\alpha$ . Data of 48 CDH patients who had been treated with IFN $\alpha$  for at least 1 year and who were non cirrhotic at the beginning of follow up were assessed retrospectively. Demographic characteristics, biochemical, serological and histological parameters of patients were reviewed. Cirrhosis diagnosis was supported with objective findings of portal hypertension. Pre and post treatment liver biopsy Ishak fibrosis staging scale scores were compared. Patients were grouped according to fibrosis score change as increasing, decreasing and steady groups. Histological course, virological and biochemical responses were comparatively analyzed.

**Results:** 48 patients were followed for mean 7 years. Post treatment follow up was mean 5 years. 24 of 48 patients were observed to be cirrhotic during follow up. Virological response rate of patients treated with classical IFN $\alpha$  was %37 while patients treated with pegylated IFN $\alpha$  had % 41 virological response rate. Sustained virological response (SVR) rate among patients was %37 at the end of follow up. There was statistical correlation in between histological response rates and virological and biochemical responses. Biochemical response is accepted as normalized serum ALT value. Pre - post treatment liver biopsy fibrosis scores of 24 patients who were non cirrhotic at the end of follow up; were compared, the result was statistically non - significant ( $p=0.979$ ). Patients with decreasing or steady fibrosis scores are accepted as histological responders. 6 patients (%13) were in decreasing fibrosis score group, 10 patients (%21) were in steady fibrosis score group while 8 patients (%16) were in increasing fibrosis score group of total 24 patients with both pre and post treatment liver biopsies.

**Conclusion:** This study revealed long term natural course of patients treated with IFN $\alpha$  at least for 1 year. IFN $\alpha$  therapy hasn't changed the natural course, however 2 of 3 patients have clinically and histologically progressed.

**Disclosure:** Nothing to disclose

### P1439 ADHERENCE TO TREATMENT AND THERAPEUTIC SUCCESS IN PEOPLE WHO INJECT DRUGS WITH HEPATITIS C VIRUS INFECTION IN A TERTIARY CARE HEPATOLOGY CENTER

Bota S., Razpotnik M., Hucke F., Flatscher K., Peck-Radosavljevic M. Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt, Austria

**Contact E-Mail Address:** bota\_simona1982@yahoo.com

**Introduction:** Hepatitis C therapy with directly-acting antiviral agents (DAA) (especially pangenotypic) is associated with a sustained virological response (SVR) >95% in a real world setting with almost no adverse events. The World Health Association published a strategy to eliminate hepatitis C by 2030. People who inject drugs (PWIDs) are often less-compliant to treatment and have a high risk of reinfection. Hepatitis C elimination will be difficult in this group of patients.

**Aims & Methods:** The aim of this study was to investigate the adherence to treatment, SVR rate and reinfection rate in PWIDs with hepatitis C. Our retrospective study included PWIDs with hepatitis C which were evaluated in our Hepatology outpatients clinic between 2014-2018.

The following information was extracted: presence of positive viral load, HCV genotype, treatment regimen, SVR achievement, reinfection with hepatitis C virus, HIV coinfection, recent (in the last 6 months) i.v. drugs use, on-going opioid agonist therapy, fibrosis stage according to Transient Elastography -TE (Fibroscan). The following TE cutoff values were used (Tsochatzis et al - JHepatol 2011; 54: 650-659):  $F \geq 2$ : 7 kPa  $F \geq 3$ : 9.5 kPa and  $F \geq 4$ : 12 kPa  
**Results:** We included 202 PWID with hepatitis C in our analysis with a mean age of  $34.1 \pm 9.6$  years (70.7% male). Intravenously drugs use in the last 6 months was reported in 20.8% of patients and 51.9% of the whole cohort were under opioid substitution therapy. HIV coinfection was diagnosed in 1.9% of patients.

Positive HCV viral load was present in 179/202 patients (88.6%).  
 HCV genotype distribution was: 1 (subtyping not possible)-1.8%, 1a-30.2%, 1b-8.4%, 2-1.5%, 3-49.8%, 4-2.8%, 6-2.2%, unknown (viral load very low)-2.8%.

TE was available in 145/179 (71.7%) of patients and the following fibrosis grades were observed: F0-1-68.9%, F2-16.6%, F3-4.1%, F4-10.4%.

40/179 (22.3%) of patients with a positive viral load were not treated (2.8% very low viral load with suspicion of acute hepatitis C in healing, 0.5% because of pregnancy and 19% because the patients did not show up to start therapy).

The first treatment-regimen used were: DAA-69.1%, DAA+Ribavirin-23.1%, PegInterferon+Ribavirin-4.3%, DAA+PegInterferon+Ribavirin-3.5%.

SVR12 was documented after first therapy in 76/139 (54.6%) of patients. 6/76 (7.9%) patients presented in follow-up with reinfection with hepatitis C virus.

Currently, the treatment status of our treated patients is: SVR12 - 80/139 (57.5%), viral load negative by end of treatment (EOT), but patients did not show up to SVR12 visit - 40/139 (28.8%), viral load negative at EOT and SVR12 visit will follow-10/139 (7.2%), ongoing therapy-5/139 (3.7%), therapy discontinued-3/139 (2.1%)(2/3 patients were on DAA therapy and did not show up after first prescription was given) and relapse - 1/139 (0.7%)(after therapy with PegInterferon+Ribavirin).

Relapse after DAA+/- Ribavirin therapy was observed by 4 patients (genotype 1a-2 patients and genotype 3-2 patients). 2/4 patient achieved SVR after therapy with another DAA regimen. The other two patients are currently under therapy.

**Conclusion:** To achieve hepatitis C elimination, better strategies regarding PWIDs are needed. In our cohort, around 20% of the patients with positive viral load are not treated and they can infect other people, especially by sharing needles.

**Disclosure:** Nothing to disclose

#### P1441 DO HLA-DP/DQ POLYMORPHISMS AND/OR SERUM IP-10 AFFECT RESPONSE TO DIRECT ANTIVIRAL DRUGS THERAPY AMONG HEPATITIS C EGYPTIAN PATIENTS?

Hydara T.<sup>1</sup>, Ghazy A.<sup>2</sup>

**Contact E-Mail Address:** tamerhydara@yahoo.com

**Introduction:** Recent genome-wide studies have demonstrated that antigen-presentation genes, particularly HLA class II gene may play an important role in pathogenesis and response to antiviral therapy among chronic hepatitis C patients. During viral infection, IP-10 is secreted by hepatocytes and correlates with hepatic inflammation due to induction of cellular immunity. It could predict sustained non-response to antiviral therapy.

**Aims & Methods:** Thus in the current study aimed to investigate the impact of HLA-DP/DQ single nucleotide polymorphisms and serum IP-10 levels on response to treatment with sofosbuvir + Daclatasvir ± Ribavirin, among chronic hepatitis C Egyptian patients.

**Subjects & methods:** This study was conducted on 80 HCV infected patients (40 responder and 40 non-responder) and 40 healthy volunteers. History taking, thorough clinical examination, CBC, liver functions tests, AFP, anti-HCV antibodies and viral load were done for all subjects under the study. Genomic DNA was extracted from a total of 120 subjects, including 40 healthy volunteers, 40 HCV responder patients, and 40 HCV non responder chronic HCV patients. HLA-DP-rs3077 and HLA-DQ-rs3920 SNP was assessed using 5' nuclease assay with a TaqMan MGB (minor groove binder) probe in a StepOne™ Real-Time PCR System. Serum Levels of IP-10 were measured in all serum samples, using commercial human IP-10 Instant ELISA kit.

**Results:** Allelic discrimination of HLA-DP-rs3077 and HLA-DQ-rs3920 SNP revealed a statistical significant correlation between HLA-DP-rs3077 AA genotype and response to treatment ( $P = 0.001^*$ ). Also, there was a statistical significant correlation between HLA-DQ-rs3920 AG variant and HCV infection as it was markedly expressed in both responders and non-responders groups when compared to the controls ( $P = 0.004^*$ ); regardless the outcome after treatment.

Moreover, there was statistically significant increase in IP-10 levels among the non-responder group when compared with other groups ( $P = 0.001^*$ ) and IP-10 showed 95% sensitivity and 15% specificity with area under curve (AUC) of 0.889 (95% Confidence Interval=0.776-1.001,  $P = 0.0001^*$ ); indicating a good negative test that is good for catching actual cases of HCV but it also comes with some false positives. So, it could be considered the excellent for screening test.

**Conclusion:** Our work provides more detail about HLA-DP/DQ gene polymorphism and serum IP-10 among chronic hepatitis C patients as new independent tools for anticipating HCV infection susceptibility (particularly HLA-DQ-rs3920 AG genotype and IP-10) and response to direct antiviral drugs (especially HLA-DP-rs3077 AA).

**Contact E-Mail Address:** mohamed.abbasy@yahoo.com

**Introduction:** Hepatitis C virus (HCV) recurrence after liver transplantation (LT) is universal and associated with an accelerated disease course. Second generation direct acting antivirals dramatically improved viral clearance. Their use in the post-transplant still needs to be studied.

**Aims & Methods:** we aimed in our study to evaluate safety and efficacy of sofosbuvir based regimens in treatment of HCV recurrence after liver transplantation.

Sixty patients with HCV recurrence after LT were included. They received sofosbuvir (SOF) in combination with: ribavirin (SOF/RBV) for 24 weeks ( $n = 20$ ), simeprevir (SOF/SIM) for 12 weeks ( $n = 21$ ), and daclatasvir with or without ribavirin (SOF/DCV±RBV) for 12/24 weeks according to the stage of liver fibrosis and eligibility for ribavirin ( $n = 19$ ). All patients who received (SOF/SIM) were on Tacrolimus or rapamune based immunosuppression

**Results:** Mean age of the studied patients was  $52.5 \pm 7.9$  years (range 28-68), mostly males (99.7%). All patients achieved end-of-treatment response. Sustained virological response at 12 weeks after cessation of treatment (SVR12) was 100% with the SIM/SOF and SOF/DCV±RBV regimens and 85% ( $n = 17$ ) with SOF/RBV. The commonest adverse event was fatigue, which occurred in 15 (75%), 18 (85.7%) and 0%, followed by hemoglobin drop  $< 9$  g/dl in 3 (15%), 1 (4.8%) and 2 (10.5%), and hyperbilirubinemia in 2 (10%), 2 (9.5%) and 0% in the SOF/RBV, SIM/SOF and SOF/DCV±RBV groups respectively.

**Conclusion:** Sofosbuvir based combinations are safe and effective in the treatment of recurrent HCV after LT, especially when combined with another directly acting antiviral.

**Disclosure:** Nothing to disclose

## P1443 NUCLEOS(T)IDE ANALOGUES WITHDRAWAL IN AGHBE-NEGATIVE CHRONIC HEPATITIS B: EXPERIENCE OF 2 YEARS OF FOLLOW-UP

S G.<sup>1</sup>, Rocha M.<sup>2</sup>, Gamelas V.<sup>3</sup>, Silva M.J.<sup>3</sup>, Calinas F.<sup>3</sup>

<sup>1</sup>Centro Hospitalar e Universitário Lisboa Central, Gastroenterology, Camarate, Portugal, <sup>2</sup>Centro Hospitalar Universitário de Lisboa Central EPE, Gastroenterology, Loures, Portugal, <sup>3</sup>Centro Hospitalar Universitário de Lisboa Central EPE, Gastroenterology, Lisboa, Portugal

**Contact E-Mail Address:** veronicagamelas@gmail.com

**Introduction:** The nucleos(t)ide analogues (NUCs) are the mainstay treatment for chronic hepatitis B (CHB). It was recently recommended to stop NUCs in selected patients with HBeAg-positive CHB and without cirrhosis. However, it is not yet defined what is the best moment to discontinue NUCs neither is clear what are the predictors of remission.

**Aims & Methods:** We aimed to analyse the outcomes after NUC withdrawal in a selected group of HBeAg-positive CHB patients.

Evaluation of all patients that discontinued NUCs and had at least 2 years of follow-up in a hepatology unit of a tertiary care hospital. To stop NUCs the patients had to have at least 3 years of virus load undetectability, no past history of clinical or laboratorial exacerbation of hepatitis and a transient elastography < 6kPa. Relapse was defined as alanine aminotransferase (ALT) elevation over 2 times the upper limit of normal and HBV DNA levels over 20000 UI/mL.

**Results:** 21 patients were evaluated, 17 men, average age of 59 (±12) years old, treated with NUCs for an average time of 103 (±29) months, with an average time of undetectability of HBV-DNA levels of 85 (±25) months and an average value of ALT before the beginning of NUCs treatment of 187UI/L (range: 52-674UI/L). The average value of qAgHBs at the time of NUCs discontinuation was 2203 UI/mL (range: 2.9-12804UI/mL).

Relapse was observed in 10 (52%) patients, in all cases it occur in the first 6 months after discontinuation of NUCs. These patients had an average value of ALT at the hepatitis flare of 349 UI/L (range: 85-873UI/L) and none had liver failure. All these patients were restarted on NUCs and it was observed AgHBs seroconversion in 20% (2/10) at 20 and at 26 months after NUCs discontinuation.

In the 11 patients without recurrence, in an average follow-up of 28 months, there was one case of seroconversion of AgHBs.

In multivariate analysis, none of the variables analysed (duration of treatment, duration of undetectable viral load, ALT before starting NUCs, qAgHBs before NUCs discontinuation) pointed out any significant predictor for need to restart NUCs or to seroconversion.

**Conclusion:** The NUCs withdrawal in a selected group of patients with HBeAg-negative CHB was safe, permitted to stop long-term NUCs therapy in most patients and resulted in the seroconversion of the AgHBs in a considerable percentage of patients.

**Disclosure:** Nothing to disclose

**Introduction:** Portal hypertension (PHT) is the main complication and cause of death during cirrhosis. The signs of PHT (collateral circulation) in imaging are sufficient, according to BAVENO VI recommendations, to affirm the presence of a clinically significant PHT (defined by a hepatic venous pressure gradient > 10 mmHg).

**Aims & Methods:** Our objective was to evaluate the performance of imaging, especially abdominal ultrasound (AU), in the prediction of esophageal varices (OV).

We performed a retrospective study including, between January 2010 and December 2016, all patients with chronic liver disease, followed in our department and who had within 3 months, upper gastrointestinal endoscopy (UGIE) and AU.

**Results:** We included 198 patients (69 men and 129 women) with an average age of 60.5 years. The main etiologies of chronic liver disease were viral infection C (44.9%) and viral infection B (19.7%). OV were found in 116 patients. Ultrasound signs of PHT were found in 92 patients. A significant correlation was noted between the presence of signs of PHT at AU and the presence of OV at UGIE ( $p < 0.001$ ). The sensitivity, specificity, positive predictive value, and negative predictive value of AU in OV prediction were 73.8%, 66%, 79.7%, and 58.2%, respectively, with an area under the curve ROC of 0.65 (0.56-0.74).

**Conclusion:** The good sensitivity of AU, which is a non-invasive examination, in the prediction of OV didn't exempt the UGIE, but could provide a better selection of patients requiring this invasive exploration.

**Contact E-Mail Address:** ayari.myriam@hotmail.fr

**Introduction:** Ursodesoxycholic acid (UDCA) remains the mainstay of management of primary biliary cholangitis (PBC). However the course of this disease can be variable. Numerous criteria for predicting outcome of treatment have been studied based on biochemical response to UDCA, though it does not take the stage of the disease into account. More recently the globe score have been validated to identify patients at risk of poor prognosis by estimating transplant-free survival.

**Aims & Methods:** We aimed to assess the prognostic ability of the GLOBE score alongside with Paris-2 criteria. We performed a retrospective analysis of data from 53 consecutive patients with PBC from 2009 to 2018. We enrolled all patients from our department with PBC and receiving UDCA therapy 13-15mg/kg/day. The diagnosis of PBC was done according to EASL criteria. The response to treatment was evaluated according to Paris-2 criteria at 1 year of treatment. The GLOBE score was calculated in all patients. The parameters of this score are: age at diagnosis and levels of bilirubin, alkaline phosphatase, albumin, platelet count at 1 year of treatment with UDCA.

**Results:** A total of 53 consecutive patients were included: 45 women and 8 men (sex ratio F/M=5.6). The mean age at diagnosis was 55 years (range 19-78 years). The median follow-up was 6 years. Cirrhosis was present at the diagnosis in 39% of cases (n=21). The mortality rate was 15% (n = 8). Factors associated with poor response to UDCA therapy were: stage of cirrhosis at diagnosis of PBC ( $p = 0.04$ ), associated autoimmune disease ( $p = 0.024$ ) and elevated pre-therapy level of total bilirubin ( $p = 0.01$ ). The average Globe score was 2.05 (extremes -0.91-5.55). This score was significantly correlated with response to treatment ( $p < 0.001$ ) and mortality ( $p = 0.04$ ). Patients fulfilling Paris II criteria had a significantly lower score globe than those who did not (mean 0.35 vs 2.28;  $p = 0.028$ ).

**Conclusion:** Our study found a significant association between the globe score and the response to the UDCA therapy. The use of this score will allow early identification of patients at risk of poor response in order to optimize treatment, prevent progression to end stage liver disease and improve the prognosis.

## P1446 SERUM AND BILIARY PROTEOMICS AS SURROGATE MARKERS FOR DISEASE PROGRESSION AND RISK FOR BILIARY NEOPLASIA IN PRIMARY SCLEROSING CHOLANGITIS

Färkkilä M.A.<sup>1</sup>, Saraswat M.<sup>2</sup>, Tohmola T.<sup>2</sup>, Joenväärä S.<sup>2</sup>, Tenca A.<sup>3</sup>, Arola J.<sup>4</sup>, Renkonen R.<sup>5</sup>

**Contact E-Mail Address:** martti.farkkila@hus.fi

**Introduction:** Primary sclerosing cholangitis [PSC] is a chronic inflammatory disease leading to strictures of intra- and extrahepatic bile ducts, cholestasis and eventually to biliary cirrhosis (1). The chronic inflammation and increased proliferation of biliary epithelial cells are associated with development of biliary dysplasia and cholangiocarcinoma [CCA] (2-3), with the lifetime risk around 10% (4-5). Several serum surrogate markers (6) have been developed to predict the risk for liver cirrhosis, transplantation free survival or death, such as decrease of P-ALP (7), IL-8 (8), and ELF® (9). However, all of these variables are very late endpoints and not suitable for monitoring bile duct inflammation, progression of bile duct disease or development of risk of biliary dysplasia - before development of CCA.

**Aims & Methods:** The aim of the study is to evaluate the proteomic profiles in serum and bile in PSC patients with

- 1) non-advanced,
- 2) advanced bile duct disease or
- 3) biliary neoplasia to find better markers for disease progression and risk for biliary neoplasia.

In total, 79 patients with confirmed PSC referred for ERC for diagnosis and surveillance of the disease were included (48 females) and another 12 patients with CCA. During ERC bile sample was aspirated using balloon catheter and then stored in -80°C. Brush cytology (BC) was collected both from extra- and intrahepatic bile ducts for Papanicolaou staining for grading dysplasia. Cholangiographic findings are scored according to modified Amsterdam score (Helsinki score). Serum samples are collected at the time of ERC.

Label-free quantitative proteomics from serum and bile from the same individuals was performed UDMSE mode in Synapt G2-Si with nUPLC-TRI-ZAIC C18 tile as previously described (10).

**Results:** Quantitative serum and bile proteomics from 43 patients with PSC with a small ERC score < 4 were compared to PSC 36 patients with ERC score of >4 as a marked of disease progression. The bile proteome was significantly different in PSC compared to CCA patients. 93 bile proteins showed were significantly (Mann-Whitney) differentially expressed and the changes were up to 15-fold. These proteins were enriched on the e.g. inflammatory pathways. Concomitantly the serum proteomics showed only mild alterations, with only 14 significantly altered proteins with a maximum 2-fold increase.

Quantitative serum and bile proteomics from 79 patients with PSC, but not dysplasia or CCA were compared to 12 serum from patients with CCA. The bile proteome was significantly different in PSC compared to CCA patients. 156 bile proteins showed were significantly (Mann-Whitney) differentially expressed and the changes were up to 53-fold. Concomitantly the serum proteomics did not show essentially any significantly altered protein expressions between PSC and CCA patients. The upregulated proteins were enriched on e.g. inflammatory and gluconeogenesis/glycolysis.

**Conclusion:** Analyses of bile proteomics showed significant alterations during the disease progression of PSC. Similarly the bile proteomics was profoundly altered during the progression from an inflammatory disease (PSC) to a malignant process (CCA). While the bile proteome was found to be modified significantly during these disease states the serum proteomics did not display these alterations at the same level.

**Contact E-Mail Address:** belhadjmabrouk.emna@gmail.com

**Introduction:** Primary biliary cholangitis (PBC) is an auto-immune disease characterized by destructing the biliary ducts. It affects women in their fifties. The actual treatment is the ursodesoxycholic acid (UDCA). Association with auto-immunes diseases (AID) has been already established.

**Aims & Methods:** The aim of this study is to describe the different auto-immune diseases found in a population of PBC and to study their impact on the treatment response.

**Methods:** Retrospective study from January 2000 to August 2018. All patients hospitalized in the gastroenterology department for PBC were included. PBC diagnosis was based on the EASL criteria. The response to treatment was evaluated by the Paris II criteria at one year of treatment.

**Results:** We included 53 patients. The sex ratio M/F was 0,18. The mean age of our patients at the time of the positive diagnosis of PBC was 55 years old. Family history of auto-immune hepatitis was found in 11,3% of the cases. AID were found in the first consult in 60,4% of the patients. The different AID were type 1 diabetes (n=1), celiac disease (n=6), hypothyroidisms (n=10), systemic lupus erythematosus (n=2), vitiligo (n=1), Sjogren syndrome (n=13), hemolytic anemia (n=8) and auto-immune hepatitis (n=6). 13 patients had at least two of these associated AID. The influence of the AID on the response to the treatment by UDCA was studied. Diabetes type1, hypothyroidism, and celiac disease influenced significantly the response to treatment (respectively p= 0,024, p=0,001, p=0,024). Generally, the response to UDCA was better in the group with no AID with a difference statistically significant (p< 0,005).

**Conclusion:** Auto-immune diseases, when associated with PBC influence the response to UDCA. They need to be researched and treated since the positive diagnosis of PBC to ameliorate the response to the treatment and therefore the survival of the patients.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** jukka.koskela@helsinki.fi

**Introduction:** Primary sclerosing cholangitis (PSC) is a rare and progressive inflammatory disease of the bile ducts with no effective therapy currently available. While the prevalence of PSC has been reported only at 15.3-32/100,000, PSC is the most common cause of liver transplantations in Nordic countries. Additionally, PSC patients are at high risk of cholangiocarcinoma (up to 1000-fold) compared to population control and substantial risk of colorectal cancer. PSC is commonly associated with inflammatory bowel disease (IBD) as ~70% of PSC-patients present with PSC-IBD. When co-occurring with IBD, PSC is most often (80% of cases) associated

with ulcerative colitis (UC). So far it is unclear whether PSC-IBD is an independent entity or whether it only manifests as an IBD subtype, however up to 8% of patients with IBD have diagnostic findings in MRI. A recent (and largest) genome wide association study using imputed array data of 4,796 PSC cases estimated the genetic correlation of IBD and PSC to 29%, while confirming most previously reported variants and identifying 4 new loci, as up to 19 loci have now been associated with PSC.

**Aims & Methods:** This study aims to assess the (possibly rare and hence not captured by array genotyping and imputation) coding mutations relevant to PSC risk. In this present study, we perform the largest exome-wide association study on PSC to date, to further extend our understanding of genetic determinants of biliary and intestinal inflammation in patients with PSC. We are currently analyzing the largest so far whole exome sequencing (WES) study on PSC, aiming at meta-analyzing > 1100 patients of Finnish (n~720) and European (n~400) ancestry. The Finnish PSC patients represent ~15% of total estimated Finnish PSC population.

In addition to DNA, deep phenotyping and health status information, sequential endoscopic retrograde cholangiographic examinations (ERC), biliary cytology, bile samples have been collected from the Finnish patients.

**Results:** Our preliminary analysis focused on a Finnish subset and suggests that out of the 19 loci described so far, we identify nominally significant ( $p < 0.05$ ) associations in 8 genes and in 12 loci within a 500kb window of the previously implicated gene ( $p < 0.01$ ). Additionally, we confirm a strong MHC component and replicate 14/312 Finnish signals ( $p < 0.0001$ ) in a non-Finnish-European population ( $p < 0.05$ ).

**Conclusion:** The summary statistics-level results of a full meta-analysis will be made available online for UEG Week.

**Disclosure:** Nothing to disclose

**Introduction:** The use of obeticholic acid (OCA) is approved as second line therapy for patients with primary biliary cholangitis (PBC) with insufficient response or intolerance to ursodeoxycholic acid (UCDA).

**Aims & Methods:** To assess the efficacy and safety of obeticholic acid as second line therapy in patients with PBC (as monotherapy or add-on to UCDA) in a real-world cohort in Austria.

Our study included 33 PBC patients (87.8% women) with a mean age of  $60.7 \pm 10.8$  years from 10 Austrian centers (Klagenfurt, Villach, Salzburg, Linz, Vienna - 2 center, Eisenstadt, Ried, Graz and Innsbruck), who received therapy with OCA because of intolerance or insufficient response to the maximal dose of UCDA (12.2% monotherapy with OCA, 87.8% combination therapy OCA + UCDA).

We evaluated the response of alkaline phosphatase (AP), alanine transaminase (ALT), gamma-glutamyltransferase (GGT) and bilirubin during therapy with OCA. Furthermore, adverse events were assessed.

Fibrosis stage at the start of therapy with OCA was assessed by Transient Elastography -TE (Fibroscan, Echosens, France). The following TE cutoff values were used (Corpechot et al - Hepatology 2012; 56: 198-208): F  $\geq 1$ : 7.1 kPa, F  $\geq 2$ : 8.8 kPa, F  $\geq 3$ : 10.7 kPa and F4: 16.9 kPa

**Results:** The median follow up of therapy with OCA was 13 months (between 0.5 and 27 months).

TE was available in 26/33 (78.7%) when OCA was started. The fibrosis stages observed were: F0-19.2%, F1-19.2%, F2-7.8%, F3-26.9% and F4-26.9%. A significant reduction of AP, GGT and ALT was observed with obeticholic acid treatment (Table).

	Baseline values (n=33)	Values after 1 month of therapy (n=32)	Values after 3 months of therapy (n=28)	Values after 6 months of therapy (n=27)	Values after 12 months of therapy (n=18)	p value
AP (U/l) Median (IQR)	237 (204-300)	189 (168-280)	166 (144-244)	156 (116-213)	136 (100-171)	$p < 0.05$ between Baseline and 3, 6, 12 months of therapy
GGT (U/l) Median (IQR)	180 (109-432)	98 (53-219)	76 (51-159)	73 (42-152)	41 (20-82)	$p < 0.05$ between Baseline and 3, 6, 12 months of therapy
ALT (U/l) Median (IQR)	51 (33-73)	33 (27-48)	35 (23-52)	34 (25-54)	27 (20-32)	$p < 0.05$ between Baseline and 1, 3, 6, 12 month of therapy
Bilirubin (mg/dl) Median (IQR)	0.7 (0.55-1.11)	0.67 (0.5-1)	0.6 (0.47-0.85)	0.6 (0.47-0.95)	0.47 (0.42-0.74)	$p < 0.05$ between Baseline and 12 month of therapy

[Table]

Adverse events were observed in 18/33 (54.5%) of patients. Adverse events recorded were: pruritus 12/33 (36.3%), fatigue 4/33 (12.1%), joint pain 4/33 (12.1%), abdominal pain 2/33 (6.1%), peripheral edema 1/33 (3.1%), nausea 1/33 (3.1%), exanthem 1/33 (3.1%), and generalized musculoskeletal pain 1/33 (3.1%) of patients. The treatment was stopped in 7/33 (21.2%) patients: in one case because of increase of AP and bilirubin after 7 months of therapy, in one case because non response+pruritus after 7 months of therapy and in 5 cases because of adverse events (pruritus - 2 cases, severe joint pain and peripheral edema - 1 case, exanthem-1 case and generalized musculoskeletal pain-1 case). One patient was lost to follow-up.

**Conclusion:** The second-line therapy with obeticholic acid is effective and safe in patients with PBC also in a real-world setting.

**Disclosure:** Nothing to disclose

## P1451 RECURRENCE OF PRIMARY BILIARY CHOLANGITIS AFTER LIVER TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

Drastich P.<sup>1</sup>, Bajaj L.<sup>1</sup>, Chmelova K.<sup>1</sup>, Brezina J.<sup>1</sup>, Macinga P.<sup>1</sup>, Sticova E.<sup>2</sup>, Trunecka P.<sup>1</sup>, Taimr P.<sup>1</sup>, Spicak J.<sup>1</sup>  
<sup>1</sup>IKEM, Hepatogastroenterology, Prague, Czech Republic, <sup>2</sup>IKEM, Pathology, Prague, Czech Republic

**Contact E-Mail Address:** lukasbajaj1@gmail.com

**Introduction:** Primary biliary cholangitis (PBC) is a chronic autoimmune liver disorder that may progress to cirrhosis and eventually to liver failure and death. For those who develop end - stage liver disease, orthotopic liver transplantation (OLT) should be considered. Moreover, recurrent form of PBC (rPBC) appears in significant proportion of patients after OLT. Recurrent PBC is usually characterized by mild clinical course. In minor group of patients however, rPBC may eventually lead to graft loss and liver re - transplantation (re - OLT).

**Aims & Methods:** The aim of this study was to evaluate outcome of OLT for PBC in our center and to identify recipient risk factors for rPBC. A total number of 82 orthotopic liver transplantations for PBC were performed at Institute for Clinical and Experimental Medicine, Prague between January 1995 and January 2017. The diagnosis of rPBC was based on protocolary and/or on - demand liver graft biopsies. We retrospectively analyzed all relevant medical records from our computed database. Input statistical data were analyzed using JMP software. Survival ratio was determined from Kaplan - Meier curves. Pearson's chi-squared test and Fisher's exact test were used to assess the potential risk factors for rPBC. A  $p$ -value  $\leq 0.05$  was considered as statistically significant.

**Results:** Out of 82 transplanted patients with median 158 (23 - 261) months of follow-up, 73 (89 %) were female and 9 (11 %) were male with median age of 56.9 (36 - 71) at the time of OLT. 3/82 (3.7 %) had hepatocellular carcinoma (HCC) in the liver explant. Except 3 (3.7 %) who received split, all patients were transplanted with whole graft. 9/82 (11 %) had overlap-

ping features of autoimmune hepatitis. 1-, 3-, 5-years patient survival was 92.7 %, while 10-years survival was 84.6 %. Graft survival was 91.7 % at 1, 3 and 5 years and 83.7 % at 10 years. 3 (3.7 %) patients received retransplant: 1 (1.2 %) for primary graft dysfunction and 2 (2.4 %) for rPBC. For analysis of rPBC risk factors, we excluded the patients monitored outside our center and those who died sooner than 3 years after OLT. Out of 74 analyzed patients, 45 (54.9 %) developed rPBC after median time of 46 (11 - 239) months. 22 (29.7 %) received cyclosporin and 52 (70.3 %) received tacrolimus as their primary immunosuppressive agent.

None of the potential risk factors (age, sex, type of immunosuppression, features of AIH prior OLT, AMA and ANA positivity prior OLT) were significantly associated with rPBC ( $p > 0.1$ ). However, the rate of rPBC had statistical tendency to be higher in patients who had HCC in their explants ( $p = 0.056$ ).

**Conclusion:** Recurrent PBC is frequent but usually not serious clinical condition. In our cohort, rPBC rate was relatively high, presumably due to long median follow - up after OLT.

**Disclosure:** Nothing to disclose

**Introduction:** In 10% of the autoimmune hepatitis (AIH) patients features of primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC) are present, called overlap or variant syndromes. The aim of this study was to characterize AIH-PBC and AIH-PSC patients and compare outcome to AIH patients.

**Aims & Methods:** In a retrospective cohort study all patients with AIH-PBC and AIH-PSC were included in 3 hospitals. AIH-PBC patients had to fulfil the strict Paris criteria. AIH-PSC patients needed a definite diagnosis of AIH according to the simplified criteria and signs of PSC on ERCP, MRCP or onion ring fibrosis on liver biopsy. Characteristics and outcome were compared to AIH in a case-control design matched on age and cirrhosis.

**Results:** Twelve AIH-PBC, 25 AIH-PSC and 74 AIH patients were included. AIH-PSC patients were more often males compared to AIH patients (56% vs 28%;  $p = 0.007$ ) and had large duct PSC in 92%. AIH-PBC patients had higher AF and GGT ( $p < 0.001$  and  $p = 0.006$ ) and presence of AMA antibodies in 75%. AIH-PSC and AIH-PBC had lower ALAT than AIH at diagnosis ( $p = 0.014$ ) but IgG levels and SMA antibodies did not differ ( $p = 0.79$ ;  $p = 0.58$ ).

Treatment with prednisone, azathioprine and ursodeoxycholic acid (UDCA) was started in all AIH-PBC and AIH-PSC patients, except UDCA in 2 patients. Complete AIH remission was obtained in 8 (67%), 16 (64%) and 61 (82%) of the AIH-PBC, AIH-PSC and AIH patients ( $p = 0.12$ ).

The median GLOBE score in AIH-PBC patients was -0.41 (range: -1.6 - 2.9) resulting in an expected median 10 year survival of 89% (range: 4-97%). The median Amsterdam Oxford score was 2.45 (range: 0.9-3.8) in AIH-PSC patients resulting in an expected median 10 year survival of 59% (range: 14-88%).

At the end of median follow-up of 107 months (range: 1-353) 4 (33%) AIH-PBC, 8 (32%) AIH-PSC and 8 (11%) AIH patients had progressed to liver transplantation or liver related death ( $p = 0.023$ ). Four (16%) AIH-PSC developed a cholangiocarcinoma.

**Conclusion:** In 12 AIH-PBC patients and 25 AIH-PSC patients using strict criteria no difference was found regarding IgG, SMA antibodies and response to therapy compared to AIH patients. Survival was worse in AIH-PSC and AIH-PBC patients than AIH patients. Survival of AIH-PBC patients was worse than expected according to the GLOBE score and survival of AIH-PSC patients was better than expected according to the Amsterdam Oxford score although AIH-PSC patients are at risk for developing cholangiocarcinoma.

**Disclosure:** Support by unrestricted grants from Zambon Pharma and Chiesi Pharma were received

## P1454 THE PROGNOSTIC FACTORS FOR PRIMARY SCLEROSING CHOLANGITIS, INCLUDING OXIDATIVE STRESS MARKERS

Oyama A.<sup>1</sup>, Takaki A.<sup>2</sup>, Adachi T.<sup>1</sup>, Wada N.<sup>1</sup>, Sakata M.<sup>1</sup>, Yasunaka T.<sup>1</sup>, Onishi H.<sup>1</sup>, Shiraha H.<sup>1</sup>, Okada H.<sup>1</sup>

**Introduction:** Primary sclerosing cholangitis (PSC) is a rare chronic liver disease, with 0.95 cases reported per 100,000 people in Japan. Because of its rarity in Japan, the clinical characteristics are still not clear. Recent investigations have shown that general conditions, such as oxidative stress, affect the course of chronic diseases. We investigated the clinical course and oxidative stress-related condition of PSC to determine the prognostic factors of PSC.

**Aims & Methods:** We analyzed 41 PSC patients who attended our department from June 2008 to June 2018. The clinical characteristics, including concomitant inflammatory bowel disease (IBD) or bile duct carcinoma and liver transplantation experience, were investigated in order to define the prognostic factors. The oxidative stress status was evaluated by two types of markers and the ratio: serum d-ROM (oxidative stress marker, as reflecting serum active-oxygen metabolism), OXY (antioxidant marker, as reflecting anti-oxidation power) and Oxidative Index (Standardized d-ROM / SD - Standardized OXY / SD).

**Results:** The median age was 35 years (14-74 years), and male sex was predominant (27:14). The average observation period was 1226 days, and 9 patients died. The Mayo risk score was able to significantly discriminate the poor overall survival ( $p < 0.001$ ). Significant poor prognostic factors were higher age, higher Mayo risk score, higher FIB-4 index, lower Child-Pugh grade, higher hemoglobin, higher Albumin, lower Bilirubin according to the log rank test. A lower anti-oxidant marker OXY was also included as a poor prognosis-related factor, while d-ROM was not. In a multivariate analysis, while properly excluding confounding factors, FIB-4 index and Mayo risk score were the markers proven to be significant ( $p < 0.01$ ). A receiver operating characteristic (ROC) analysis revealed the usefulness of Mayo PSC risk score and FIB-4. High AUC ( $> 0.8$ ) indicate FIB-4 index and Mayo risk score were indicated very useful markers for predicting the PSC prognosis.

**Conclusion:** The FIB-4 index and Mayo risk were shown to be a prognostic factor for PSC in our study. Maintaining antioxidant stress will lead to a good prognosis and suggests the efficacy of antioxidant treatment.

**Introduction:** The rheumatic manifestations of gastrointestinal pathology, in particular of hepatobiliary diseases, in addition to being a diagnostic challenge, complicate the natural course of the primary disease and worse the prognosis due to the multiorganic affection they often have. The aim of this study is to characterize the prevalence of confirmed rheumatic disease associated with hepatobiliary diseases in a tertiary reference center.

**Aims & Methods:** All patients with simultaneous diagnosis of hepatobiliary pathology and rheumatologic pathology were retrospectively evaluated between 2007 and 2017. All patients with the following confirmed rheumatologic diagnoses (ICD9) were studied: Rheumatoid arthritis; Undifferentiated polyarthritis; Ankylosing spondylitis; Spondylarthritis; Psoriatic Arthritis; Polymyalgia Rheumatica; Diffuse Connective Tissue Diseases; SLE - Systemic lupus erythematosus; Systemic Sclerosis; Sjögren's Syndrome; Vasculitis; Behçet's disease; Drop; Pseudogout; Osteoarthritis; with a diagnosis of concomitant confirmed hepatobiliary disease.

**Results:** From a sample of 2169 consecutive patients, simultaneously in consultation with Gastroenterology and Rheumatology, we were able to identify 51 patients with the above mentioned requirements, and 3 patients were excluded after subsequent exclusion of rheumatologic disease. The majority of the patients were females (58.3%). The mean age at diagnosis was 53.2 years (range 29-91 years).

Hepatitis C was diagnosed in 26 patients (54%), autoimmune hepatitis in 6 patients (12.5%), primary biliary cholangitis in 3 patients (6.25%), primary sclerosing cholangitis in 2 patients (4.2%), non-alcoholic steatohepatitis (4.2%), cryptogenic cirrhosis (4.2%), Wilson's disease (4.2%), and other diagnoses (10.4%) in 5 patients (hepatitis B, alcoholic liver cirrhosis, toxic hepatitis, alpha 1 antitrypsin deficiency and hemochromatosis).

Rheumatoid arthritis was diagnosed in 13 patients (27.1%), spondylarthritis in 13 patients (27.1%), ankylosing spondylitis in 5 patients (10.4%), undifferentiated polyarthritis in 4 patients (8.3%), SLE in 4 patients (8.3%), psoriatic arthritis in 2 patients (4.2%) and other diagnoses (2.1%) in 7 patients (systemic sclerosis, Sjögren's syndrome, vasculitis, Behçet's disease, gout, osteoarthritis and connective tissue diseases).

Particularly, regarding the rheumatologic manifestations of Hepatitis C, we identified rheumatoid arthritis in 6 patients (23%), spondylarthritis in 6 patients (23%), undifferentiated polyarthritis in 4 patients (15.4%), and ankylosing spondylitis in 4 patients (15.4%). SLE in 4 patients (15.4%), psoriatic arthritis in 2 patients (4.2%)

It should be noted that 27.1% of this group of patients were currently under biological therapy.

**Conclusion:** Given that 2.2% of patients, followed in both specialties, present simultaneous digestive and rheumatologic pathology, it is fundamental to characterize the impact and therapeutic repercussions that come from the clinical overlap between pathologies.

**Introduction:** Total glucosides of paeony (TGP), an active mixture extracted from paeony root, has anti-inflammatory, immune regulatory effects and is widely used for the treatment of autoimmune diseases such as rheumatoid arthritis. However, the role of TGP in autoimmune hepatitis (AIH) is still unknown. Here, we investigate the effect of TGP in concanavalin A (Con A) induced experimental autoimmune hepatitis (EAH) and the molecular mechanisms *in vitro*.

**Aims & Methods:** C57BL/6 female mice were injected intravenously with Con A (20 mg/kg) to generate a model of EAH. TGP (936mg/kg) was administered by gavage once daily for 3 days before Con A challenge. The levels of serum liver enzymes, variations of immune cells recruited in liver including dendritic cells (DCs), T cells, macrophages and myeloid-derived suppressor cells (MDSCs), liver pathologic examines were determined 12 h after Con A injection. *In vitro*, the LO2 cell lines were used to examine the susceptibility of hepatocyte to Con A and explore the underlying mechanisms.

We treated the hepatocyte with Con A (10µg/mL) and TGP (100mg/L). Mitochondrial membrane potential ( $\Delta\Psi_m$ ), reactive oxygen species (ROS) level, apoptosis related proteins including Bax, Bcl2 and cleaved-Caspase3 were detected.

Moreover, immature DCs were generated from mice bone marrow dendritic cells (BMDCs) and then cultured with GM-CSF, IL-4 and  $\beta$ -ME. We then treated the immature BMDCs with Con A (10µg/mL) and TGP (100mg/L) for 24 hours. The expression of major histocompatibility complex II (MHCII), CD11C and CD80 was determined by flow cytometry (FCM).

**Results:** In Con A- induced EAH mice, pretreatment with TGP reduced the levels of serum liver enzymes including alanine transaminase (ALT), aspartate transaminase (AST). Moreover, decreased histopathological damage was detected in the TGP-pretreated condition. Importantly, the FCM data showed that pretreatment with TGP reduced the infiltration of mature DCs and activated CD4<sup>+</sup> T cells in liver.

*In vitro*, MTT assay showed that TGP (100mg/L) had protective effect on LO2 cell lines as compared with cells treated with Con A alone. Pretreatment with TGP ameliorated  $\Delta\Psi_m$  decline, ROS level imbalance and apoptosis increase of hepatocytes stimulated by Con A. In addition, The expression of Bcl2 was increased during this process, accompanied with decreased level of Bax and cleaved-Caspase3. Therefore, TGP might decrease hepatocytes apoptosis through a mitochondrial apoptotic pathway. In the meantime, the maturation of BMDCs was inhibited by TGP as evidenced by lower levels of MHCII and CD80 as compared with Con A treated cells.

**Conclusion:** TGP could ameliorate Con A-induced EAH by regulating apoptosis of hepatocytes and maturation of DCs. It might be a potential compound in treating AIH.

**Contact E-Mail Address:** manel.moalla@hotmail.com

**Introduction:** The non-invasive markers of fibrosis are currently validated in viral hepatopathies but less validated in other dysimmune liver diseases. Very few studies have focused on the place of non-invasive markers of fibrosis in the overlap syndrome. The aim of our study is to determine the correlation between non-invasive markers of fibrosis and histological fibrosis scores in overlap syndrome.

**Aims & Methods:** A retrospective study that collects all patients with an overlap syndrome: primary biliary cholangitis - autoimmune hepatitis or primary sclerosing cholangitis - autoimmune hepatitis. The APRI and FIB-4 scores were calculated at the time of diagnosis and one year after treatment. A liver biopsy specifying the degree of fibrosis according to Metavir was performed at the time of diagnosis. Liver elastography was done after one year of treatment. Fibrosis was considered significant from F2 for hepatic elastography and Metavir score and a cut-off > 1.5 and > 3.25 for APRI and FIB-4, respectively. The Spearman correlation test and the ROC curve were used to analyze the data.

**Results:** Our study involved 56 patients divided into 52 women and 4 men of average age 51.1 years (30-73 years). Autoimmune hepatitis was associated with primary biliary cholangitis in 89.3% of cases and primary sclerosing cholangitis in 10.7% of cases. Spearman's correlation analysis did not show a correlation between serum markers measured at the time of diagnosis and the degree of histological fibrosis ( $r = 0.5$ ,  $p = 0.001$ ). Among the 52 patients who would have significant fibrosis according to the APRI score, 20 patients had no significant histological fibrosis (F0, F1). Among the 48 patients who would have significant fibrosis according to the FIB-4 score, 30 actually had significant fibrosis ( $\geq F2$ ). After one year of treatment, 54 patients underwent hepatic elastography, which showed significant fibrosis in 70.3% of cases (38 patients). Correlation analysis did not show any correlation between serum markers of fibrosis and hepatic elastography. Among the 38 patients with significant fibrosis according to the measurement of hepatic elastography, 16 patients and 12 others were presumed to have no significant fibrosis according to the APRI and FIB-4 scores, respectively.

**Conclusion:** In our study, we did not find any correlation between the different non-invasive markers of fibrosis and the results of the liver biopsy, which remains to this day the gold standard for assessing liver fibrosis in dysimmunitary disorders like overlap syndrome.

**Disclosure:** Nothing to disclose

**P1458 PREDICTION OF THE PROGNOSIS OF ADVANCED HEPATOCELLULAR CARCINOMA PATIENTS BY HTERT PROMOTER MUTATION IN CIRCULATING TUMOR DNA**

Hirai M., Kinugasa H., Nouse K., Terasawa H., Yamamoto S., Oyama A., Adachi T., Wada N., Sakata M., Yasunaka T., Onishi H., Shiraha H., Takaki A., Okada H.  
Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Gastroenterology and Hepatology, Okayama, Japan

**Contact E-Mail Address:** mami\_k@live.jp

**Introduction:** Human telomerase reverse transcriptase (hTERT) promoter mutation is found in about 50% of hepatocellular carcinoma (HCC), which is the most frequent somatic genetic alteration in HCC. Several clinical studies have revealed that the presence of the hTERT promoter mutation was closely correlated with poor prognosis in solid tumors such as lung and breast cancers. However, the association between the mutation and clinicopathologic features in patients with HCC has not been elucidated well. Recently, cell-free circulating tumor DNA (ctDNA) in plasma/serum has been applied as a noninvasive marker for cancer diagnosis.

**Aims & Methods:** This study was designed to estimate the clinical utility of ctDNA for detecting hTERT promoter mutation in patients with advanced HCC and to reveal the correlation between hTERT promoter mutation and prognosis. Eighty-six patients with advanced HCC who were treated with sorafenib or lenvatinib at Okayama University Hospital between September 2013 and September 2018 were enrolled in this study. The plasma or serum samples were obtained from their blood prior to the drug administration. ctDNAs extracted from 1ml of plasma or serum samples with QIAamp Circulating Nucleic Acid Kit (QIAGEN, Hilden, Germany) were used to detect hTERT promoter mutations by digital droplet PCR (ddPCR; Bio-Rad, Hercules, CA, USA), and correlations between the presence of the mutation and clinical outcome of the patients were analyzed.

**Results:** The median follow-up period was 11 months (interquartile range, 6.8-17.7months). The median age of the patients was 73 years and 72% were male. Clinical stages of 4, 11, 31 and 40 patients were II, III, IVa and IVb, respectively. HBs antigen and HCV antibody were detected in 16 (18.6%) and 37 (43.0%) patients, respectively. As for HCC treatments, 71 and 15 patients received sorafenib and lenvatinib, respectively. In the 86 patients examined, 45 patients (52.3%) were positive for hTERT promoter mutation in ctDNA. Presence of the hTERT promoter mutation was correlated with low serum albumin ( $P=0.048$ ), high aspartate aminotransferase ( $P=0.016$ ), high alanine aminotransferase ( $P=0.022$ ), low prothrombin activity ( $P=0.044$ ), large intrahepatic tumor size ( $P=0.032$ ), and high PIVKA-II ( $P=0.032$ ). Overall survival (OS) of the patients with the mutation was significantly shorter than those without it ( $p=0.001$ ). Median survival time of each group was 11.2 months and 22.2 months, respectively. In univariate analysis with Cox's proportional hazards model, the presence of hTERT promoter mutation [Hazard ratio (HR), 2.13; 95% Confidence interval (CI), 1.20-3.88;  $P=0.009$ ], low albumin ( $<3.6$  g/dL) (HR, 1.81; 95%CI, 1.03-3.21,  $P=0.040$ ), high aspartate aminotransferase ( $\geq 25$  IU/L) (HR, 1.83; 95%CI, 1.45-3.28;  $P=0.034$ ), Child-Pugh class B (HR, 2.54; 95%CI, 1.22-4.92;  $P=0.015$ ), vascular invasion (HR, 2.34; 95% CI, 1.29-4.12;  $P=0.006$ ) were significant factors for poor OS. Multivariate analysis revealed that hTERT promoter mutation (HR, 2.01; 95% CI, 1.09-3.83;  $P=0.025$ ) and vascular invasion (HR, 2.57; 95% CI, 1.31-4.97;  $P=0.006$ ) were significant factors for poor OS.

**Conclusion:** hTERT promoter mutation in ctDNA was associated with short survival and could be a valuable biomarker for predicting prognosis of the patients with advanced HCC treated with molecular target drugs.

**Introduction:** Metformin has been well known to have antineoplastic activity in hepatocellular carcinoma (HCC) cells. Studies on AMP-activated protein kinase (AMPK)-related studies and cell cycle inhibition have been reported as HCC inhibitory mechanisms of metformin. Insulin growth factor 1 receptor (IGF-1R) is a receptor involved in cell proliferation, inhibition of apoptosis, angiogenesis and tumorigenesis and tumor-associated inflammation, and targeted therapies for these have been developed and used clinically.

**Aims & Methods:** This study was performed to determine whether metformin inhibits survival of HCC cells through IGF-1R pathway. HCC cell line HepG2 cells were cultured. In order to investigate the effect of metformin on HepG2 cells according to glucose level, cells were cultured in 5mM glucose and 25mM glucose medium. 3-(4, 5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assays were performed to determine the effect of metformin on the cell proliferation. Apoptosis was measured by a cell death detection enzyme-linked immunosorbent assay and a caspase-3 activity assay. Expression levels of various proteins, with or without specific small interfering ribonucleic acid-induced gene disruption, were measured by Western blot analysis.

**Results:** Metformin induces apoptosis of HepG2 cells and reduces cell viability. However, the efficacy of metformin-induced apoptosis was reduced in the hyperglycemic environment (25mM glucose). Metformin reduced IGF-1R activity in HCC cells and decreased IRS-1, PI3K, and Akt activities in IGF-1R pathway, leading to increased TSC-2 activity and decreased mTOR activity. When AMPK siRNA was also used to block AMPK function, metformin caused HepG2 cell apoptosis.

In addition, in the normal environment, metformin increased AMPK Thr 172 activity and decreased AMPK Ser 485 activation. However, AMPK Ser 485 activity was increased in hyperglycemic environment as well as AMPK Thr 172.

**Conclusion:** The inhibitory effect of metformin on HCC cells induces a decrease in IGF-1R activity by metformin and thus promotes apoptosis. In the hyperglycemic environment, the efficacy of metformin on HCC inhibitory effect is decreased, which suggests that the action of mTOR is elevated by AMPK Ser485 phosphorylation. Therefore, the use of metformin is helpful in the treatment of liver cancer, especially in hyperglycemia.

**P1460 FIFTEEN YEARS OF HEPATOCELLULAR CARCINOMA, A PARADIGM SHIFT FROM INFECTIOUS TO NON-INFECTIOUS ETIOLOGY**

Pangilinan J.A.R.<sup>1</sup>, Alcantara-Payawal D.<sup>2</sup>

<sup>1</sup>Cardinal Santos Medical Center, Internal Medicine, Quezon City, Philippines,

<sup>2</sup>Cardinal Santos Medical Center, Gastroenterology, San Juan City, Philippines

**Contact E-Mail Address:** dianapayawal@yahoo.com

**Introduction:** Hepatocellular carcinoma (HCC) is a malignant tumor that is the fifth most common type of cancer and the third leading cause of cancer-related death globally. A study in 2009 concluded that in the Philippines, the most common risk factors leading to the disease were chronic hepatitis B infection and alcoholic liver disease. With an ever-evolving paradigm and change in the trends of diseases, it is imperative to update current knowledge with a more recent collection of data providing essential information on the pre-cursors of Hepatocellular carcinoma.

**Aims & Methods:** This is a single-center retrospective, descriptive study of all adult patients with hepatocellular carcinoma at Cardinal Santos Medical Center (CSMC) in a fifteen-year span (2003-2018).

Clinical data, including essential demographics such as age, sex, etiology of HCC were obtained and analysis was done using chi-square and t-test, respectively.

**Results:** Comparison of data showed a statistically significant change in the infectious and non-infectious causes of HCC. Time 1 showed predominance of HCC with infectious etiology, representing 67% of all cases, with most cases from Hepatitis B. Time 2 showed a 22% decrease in this etiology, which could be inferred to be an effect of vaccination readily producing this endpoint. But with a predominantly older age group (mean age 64), a large segment of the population in time 2, specifically 45% had an infectious etiology.

An interesting note is the prominent increase in the number of HCC cases arising from non-infectious causes, with a modest 21% of cases in time 1, to a little over two times of that in time 2. With 73 cases in time 1 and 137 in time 2 representing a statistically significant two-fold increase in these cases, the breakdown shows a shift from a prominent non infectious cause from alcoholic disease towards NAFLD. 72% of non infectious cases in time 2 arose from NAFLD, with ALD, showing significant decrease percentage-wise with the number of cases seemingly overshadowed by the large increase in cases on NAFLD.

	N = 674	Time 1 (2003-2010) N=378	Time 2 (2010-2018) N=296	P - Value
Age		63±12.5	66±12.5	1.00
M/F		250/128	255/41	>0.99
HBV		247	104	<0.002*
HCV		7	10	<0.2241
NAFLD		15	99	<0.0000001*
ALD		58	33	<0.035*
Unknown		0	45	NA
DIH		5	0	NA
AIH		0	0	NA

[Table: Results of data from two time periods]

**Conclusion:** Hepatitis B is still the most common etiology of Hepatocellular Carcinoma. There has been a significant increase in the development of HCC from non-infectious etiologies. Of the non-infectious etiologies, NAFLD seems to be an emerging threat in the development of Liver Cancer.

**Disclosure:** Nothing to disclose

## P1462 C<sub>60</sub> FULLERENE: ANTIFIBROTIC, ANTITUMOR AND ANTIMETASTATIC NANOTHERAPEUTIC FOR HEPATOCELLULAR CARCINOMA TREATMENT

Kuznietsova H.<sup>1</sup>, Dziubenko N.<sup>1</sup>, Herheliuk T.<sup>1,2</sup>, Hurmach V.<sup>1</sup>, Lynchak O.<sup>3</sup>, Prylutsky Y.<sup>1</sup>, Ritter U.<sup>4</sup>

**Contact E-Mail Address:** biophys@gmail.com

**Introduction:** The excessive production of reactive oxygen species is the main cause of liver cancer initiation and progression, therefore the use of antioxidants could be a promising treatment. Biocompatible pristine C<sub>60</sub> fullerene is the powerful antioxidant demonstrating low toxicity and ability to be accumulated in liver, so have a prospect as liver disease therapeutic.

**Aims & Methods:** C<sub>60</sub> fullerene impact on liver fibrosis, tumor growth and metastasis were aimed to be discovered using rat hepatocellular carcinoma (HCC) model. HCC was initiated by N-diethylnitrosamine (DEN, 200 mg/kg) injection. Two weeks later tumor promotion was achieved by subcutaneous CCl<sub>4</sub> (0.1 ml/100g) injections twice/week continuously. Pristine C<sub>60</sub> fullerene aqueous colloid solution (C<sub>60</sub>FAS; 0.15 mg/ml, size of aggregates 1.2-100 nm [1]), was administered daily (0.25 mg/kg) starting in 2 weeks from DEN injection. Its impact on liver fibrosis and cirrhosis was assessed at 10<sup>th</sup> and 15<sup>th</sup> week, impact on tumor development and metastasis - at 22<sup>nd</sup> week. Liver injury was evaluated according to [2], by histological (HE staining) and biochemical (plasma blood markers) methods. C<sub>60</sub>FAS impact on EGFR and pan-cytokeratin expression was assessed in HepG2 cells (IHC). C<sub>60</sub> fullerene ability to interact with EGFR, FGFR, PDGFR and VEGFR was assessed by molecular docking and molecular dynamics.

**Results:** C<sub>60</sub>FAS attenuated liver steatohepatitis and fibrosis and improved liver state in HCC-rats at 10-week stage (as evidenced by histological and biochemical assay). In HCC-rats at 15-week stage C<sub>60</sub>FAS also diminished liver injury (as evidenced by liver damage score, depression of elevated serum markers and histological assay) and avoided dysplastic cells appearance in pancreas. In HCC-rats at 22-week stage C<sub>60</sub>FAS prevented tumor development (no tumors in liver compared to well-developed tumors in non-treated rats), attenuated liver injury (liver enzymes decreased, bilirubin was levelled, morphology was improved) and prevented metastasis (no atypical cells in pancreas compared to neoplastic cells aggregates and even well-developed tumors in non-treated animals). Reference 5-fluorouracil demonstrated less efficacy: small single tumors were observed, liver enzymes remained elevated, bilirubin retained higher than that in control.

	10 weeks		15 weeks		22 weeks	
	HCC	HCC +C60FAS	HCC	HCC +C60FAS	HCC +C60FAS	HCC +5-fluorouracil
Liver damage score	8.2*	7.25*	9.2*	7.8*	11.33*	9.25*
ALT		307	193	215		
AST		268	185	152	74	54
Conjugated bilirubin			133		171	56
Non-conjugated bilirubin			74		118	49
ALP			345	273		
LDH			2750	1002	150	67
GGT			115	49	380	307
α-amylase					-91	-56

[Parameters of liver state, specified in per cent compared to control; only statistically significant values (p<0.05) are presented, \*absolute values]

C<sub>60</sub>FAS applying in 10-100 μmol/ml concentration inhibited EGFR and pan-cytokeratin expression in HepG2 cells in a dose-dependent manner (by 39-70%). C<sub>60</sub> fullerene ability to form complexes with ATP-binding sites of EGFR and FGFR but not VEGFR and PDGFR was also demonstrated, which let us to suggest the possibility of such impact in *in vivo* system.

**Conclusion:** C<sub>60</sub>FAS can inhibit fibrogenesis, malignant degeneration and metastasis in liver and maintain its functional activity. C<sub>60</sub> fullerene ability to inhibit EGFR and pan-cytokeratin expression and to block EGFR and FGFR could contribute to its biological activity.

## P1463 3-MERCAPTOPYRUVATE SULFURTRANSFERASE REPRESSES TUMOR PROGRESSION AND PREDICTS PROGNOSIS IN HEPATOCELLULAR CARCINOMA

Li M., Jin Q., Zhang J., Cen L., Yu C., Li Y.

The First Affiliated Hospital, College of Medicine, Zhejiang University, Gastroenterology, Hangzhou, China

**Contact E-Mail Address:** lemon2323@126.com

**Introduction:** The prognosis for hepatocellular carcinoma (HCC) remains dismal in terms of overall survival (OS), and its molecular pathogenesis has not been completely defined. 3-mercaptopyruvate sulfurtransferase (MPST) is one of enzymes to regulate endogenous hydrogen sulfide (H<sub>2</sub>S) biosynthesis. The expression and functional role of MPST in HCC has never been investigated. We aimed to clarify the role of MPST in HCC.

**Aims & Methods:** MPST protein expression in HCC specimens was mainly analyzed by immunohistochemistry (IHC) using a tissue microarray (TMA) containing HCC tumor tissue and matched adjacent tissues from 90 patients. Another 12 paired clinical HCC samples were used for MPST protein determination. The effect of MPST on HCC progression was studied *in vitro* and *in vivo*. A diethylnitrosamine (DEN)-induced liver cancer model was used to evaluate the role of MPST in hepatocarcinogenesis.

**Results:** TMA in 90 cases revealed that MPST was significantly downregulated in 80 HCC clinical specimens compared to their paired non-tumor tissues by IHC staining, with negative expression in one case. Clinically, a low MPST expression was associated with a worse OS ( $p < 0.05$ ) and larger tumor size ( $p < 0.05$ ). Downregulation of MPST protein was further detected in all 12 HCC patients compared with their nontumor counterparts. Downregulation of MPST was also investigated in 5 HCC cell lines compared with normal human hepatocyte by using both qPCR and Western blot analysis. Functional studies showed that overexpression of MPST in HCC cells inhibited cell proliferation, clonogenicity and induced apoptosis.

Furthermore, MPST overexpression significantly suppressed the growth of tumor xenografts in nude mice, whereas silencing MPST by intratumor delivery of siRNA markedly promoted tumor growth. Moreover, DEN-induced murine HCC was aggravated by MPST gene knockout. Mechanistically, MPST overexpression induced G1-phase arrest via inhibition of pRb/E2F1 signaling pathway. Consistently, MPST expression correlated negatively with pRb in HCC specimens and was associated with HCC outcomes.

**Conclusion:** MPST may function as a tumor suppressor gene that plays an essential role in HCC proliferation and liver tumorigenesis. It is a candidate predictor of clinical outcome in patients with HCC, with possible use as a biomarker and intervention point for new therapeutic strategies.

## P1464 VALUE OF SERUM ENDOCAN IN PREDICTION OF POST-ABLATION RECURRENCE OF HEPATITIS C RELATED HEPATOCELLULAR CARCINOMA

El-Sadek H.<sup>1</sup>, Fawzy E.<sup>1</sup>, Saber S.<sup>2</sup>, Hassaneen A.<sup>3</sup>

<sup>1</sup>Faculty of Medicine, Zagazig University, Gastroenterology & Hepatology Unit, Internal Medicine Department, Zagazig, Egypt, <sup>2</sup>Faculty of Medicine, Zagazig University, Radiology Department, Zagazig, Egypt, <sup>3</sup>Faculty of Medicine, Zagazig University, Clinical Pathology Department, Zagazig, Egypt

**Contact E-Mail Address:** hanyelsadek75@yahoo.com

**Introduction:** Hepatitis C virus (HCV)-related hepatocellular carcinoma (HCC) remains a major global health problem. The recurrence of HCC after curative ablation is common, and mandates frequent costly post-ablation investigations especially triphasic computerized tomography (TCT). Serum endocan (a soluble proteoglycan) has been used as a biomarker to predict prognosis in various inflammatory and neoplastic diseases.

**Aims & Methods:** The aim of this study was to assess the performance of serum endocan level in prediction of HCC recurrence after curative radiofrequency ablation (RFA), in a subset of patients with HCV-related HCC.

In this prospective study, 56 HCV-related HCC patients treated with curative RFA were enrolled, and tumor recurrence was evidenced by typical radiologic criteria using repetitive TCT (quarter yearly), over a mean follow up period of 23.79±7.56 months. Routine clinical and laboratory assessment, estimation of liver disease severity as class A/B according to Child-Turcotte-Pugh (CTP) scoring, and tumor staging (0/A) using Barcelona Clinic of Liver Cancer (BCLC) system, were performed.

In addition, all studied patients underwent baseline (one month after curative RFA) measurement of suggested serum biomarkers of tumor recurrence including endocan, des-gamma-carboxy prothrombin (DCP) and alpha fetoprotein (AFP).

**Results:** There were significant associations between HCC recurrence (24/56 patients, 42.86%) and several parameters; tumor size  $\geq 3$  cm ( $p = 0.025$ ), multiple tumor foci ( $p = 0.028$ ), BCLC stage A ( $p = 0.042$ ), CTP class B ( $p = 0.005$ ), low serum albumin ( $p = 0.007$ ), high serum bilirubin ( $p = 0.011$ ), as well as increased mean values of endocan ( $p < 0.001$ ), DCP ( $p = 0.004$ ) and AFP ( $p = 0.039$ ).

Using logistic regression analysis, only serum endocan and DCP were independent predictors of HCC recurrence ( $p < 0.001$  and  $p = 0.003$ , respectively). Serum endocan (at a cut-off level  $\geq 2.09$  ng/mL) had the highest sensitivity (95.8%) and specificity (87.5%) for prediction of HCC recurrence ( $p < 0.001$ ), followed by DCP  $\geq 208.5$  mAU/mL (sensitivity 79.2%, specificity 71.9%,  $p = 0.003$ ), and lastly by AFP  $\geq 75.0$  ng/mL (sensitivity 75.0%, specificity 71.9%,  $p = 0.001$ ). Endocan level  $\geq 2.09$  ng/mL carries a significantly high risk of HCC recurrence (Odds Ratio: 161.0, Confidence Interval: 16.8-1542.3,  $p < 0.001$ ).

Using Kaplan-Meier survival analysis, the mean recurrence-free survival time was significantly shorter in patients with endocan level  $\geq 2.09$  ng/mL than in those with a level  $< 2.09$  ng/mL (16.78 vs. 35.24 months, log-rank

test,  $p < 0.001$ ), and the mean overall survival time was significantly shorter in patients with endocan level  $\geq 2.09$  ng/mL than in those with a level  $< 2.09$  ng/mL (24.95 vs. 32.58 months, log-rank test,  $p < 0.001$ ).

**Conclusion:** Serum endocan is a useful biomarker that can significantly predict HCC recurrence and survival after radiofrequency ablation.

**Disclosure:** Nothing to disclose

## P1465 SERUM SEROTONIN AS A POTENTIAL DIAGNOSTIC MARKER FOR HEPATOCELLULAR CARCINOMA

Attalla M.A.A.<sup>1</sup>, Mamdouh F.<sup>2</sup>, Abdelaleem S.<sup>1</sup>, Abdelaal A.<sup>2</sup>, E. Salem A.<sup>3</sup>, Rabiee A.<sup>3</sup>, Elsisy O.<sup>2</sup>

<sup>1</sup>Cairo University Hospital (Kasr Al Ainy), Endemic Medicine and Hepatology, Cairo, Egypt, <sup>2</sup>Cairo University Hospital (Kasr Al Ainy), Clinical and Chemical Pathology, Cairo, Egypt, <sup>3</sup>Cairo University Hospital (Kasr Al Ainy), Internal Medicine Department, Cairo, Egypt

**Contact E-Mail Address:** mahmoudabdelalim@yahoo.com

**Introduction:** Hepatocellular carcinoma (HCC) is a major health problem in Egypt and its incidence is increasing<sup>1</sup>. Alpha fetoprotein (AFP), the most widely used biomarker for HCC diagnosis, is not sensitive for early HCC detection<sup>2</sup>. So, there was a need for other diagnostic seromarkers to replace, or be used in combination with, AFP

**Aims & Methods:** We aimed to assess the potential role of serum serotonin level in HCC diagnosis. This study was conducted on 75 Hepatitis C virus (HCV)-positive patients. Twenty five healthy age- and sex-matched subjects were included as a control group. Diagnosis of HCC was done according to the American Association for the Study of Liver Disease (AASLD) guidelines. Staging of patients into early- and late-stage HCC was done according to Barcelona Clinic Liver Cancer (BCLC) criteria.

Subjects were divided into 4 groups:

Group I (late-stage HCC) included 21 patients with late-stage HCC on top of liver cirrhosis.

Group II (Early-stage HCC) included 28 patients with early-stage HCC on top of liver cirrhosis.

Group III (cirrhotic) included 26 patients with liver cirrhosis with no evidence of HCC.

Group IV was the Control group.

Serum serotonin level was determined in all recruited subjects using High Performance Liquid Chromatography (HPLC)-fluorescent detection method.

**Results:** AFP had a statistically significant elevation in group I (late-stage HCC) with a median of 1300 ng/L (195 - 2544 ng/L) compared to groups II and III (early-stage HCC and cirrhosis) ( $P \leq 0.01$ ). Regarding serum serotonin level, it had a statistically significant elevation in group II (Early-stage HCC) with a median of 275 (204.7-400) compared to groups I, III, and IV (Late-stage HCC, Cirrhosis and control) with median of 33 ng/μL (30-50 ng/μL), 50 ng/μL (30-60 ng/μL) and 102 (85-150 ng/μL), respectively ( $P = 0.001$ ). Receiver operating characteristic (ROC) curve showed that serum serotonin had a sensitivity of 100%, specificity 92.3%, Positive Predictive Value (PPV) 93.3%, Negative Predictive Value (NPV) 96% and accuracy of 96.3%, in discriminating early-stage HCC from cirrhosis. The best values were obtained when using serotonin at cut-off value of 108 ng/μL. There was no correlation between serotonin and AFP.

**Conclusion:** serum serotonin level is a rapid, sensitive, noninvasive diagnostic biomarker for the detection of early-stage HCC. It may improve the sensitivity of AFP for the detection of early-stage HCC if used in combination.

**Contact E-Mail Address:** doctorhodaelgamal@gmail.com

**Introduction:** Vascular endothelial growth factor (VEGF) increases in hepatocellular carcinoma (HCC) patients. Many studies had evaluated levels of VEGF in conventional transarterial chemoembolization (cTACE) but assessment of VEGF levels in TACE using drug eluting beads (DEB-TACE) versus cTACE has not been sufficiently studied.

**Aims & Methods:** Aim of the study was to estimate VEGF levels and their relation to response and recurrence in both DEB-TACE and cTACE in patients with unresectable HCC.

**Subjects & methods:** This parallel concurrent interventional study included 114 unresectable HCC patients: 58 patients underwent cTACE and 56 patients underwent DEB-TACE. All included patients were classified as Barcelona clinic liver cancer (BCLC) stage B. Three samples of venous blood were obtained from all HCC patients one day before, day 1 and day 30 after TACE for estimation of VEGF levels. According to response after TACE, patients in each group were classified into progressive disease (PD), partial response (PR), and complete response (CR) which was followed for complete one year. The results were statistically analyzed.

**Results:** VEGF levels at day 1 and day 30 were higher than their basal levels in both cTACE and DEB-TACE groups, while no significant difference was found in VEGF levels between the two groups. Patients with PD after TACE in both groups showed significantly higher VEGF than those with PR and CR.

VEGF levels (basal, day 1 and day 30) at cut off values 97.3, 149.8 and 104.1 pg/ml respectively could discriminate treatment success from disease progression with area under receiver-operating characteristic curves (AUCs) 0.806, 0.775, and 0.771 respectively; sensitivity 88.9%, 88.9% and 77.8% respectively and specificity 62.5%, 64.6 and 66.7% respectively (table 1), but had no relation to HCC recurrence in complete response group after 12 months.

	Basal VEGF	VEGF at day 1	VEGF at day 30
AUC	0.806	0.775	0.771
Diagnostic point	VEGF >97.3 pg/ml have poor prognosis	VEGF >149.8 pg/ml have poor prognosis	VEGF >104.1 pg/ml have poor prognosis
sensitivity	88.9%	88.9%	77.8%
specificity	62.5%	64.6%	66.7%
PPV	96.8%	96.9%	91.4%
NPV	30.8%	32%	27.3%

[Diagnostic performance of different VEGF levels]

**Conclusion:** VEGF may predict response to therapy in both DEB-TACE and cTACE but it has no relation to HCC recurrence.

**Disclosure:** Nothing to disclose

## P1467 DEVELOPMENT OF A SCORING SYSTEM THAT OUTMATCH OTHER SPECIFIC SCORES IN TRANSARTERIAL CHEMOEMBOLIZATION FOR HEPATOCELLULAR CARCINOMA

**Contact E-Mail Address:** jom\_73@hotmail.com

**Introduction:** Barcelona clinic liver cancer (BCLC) is the most accepted staging system in hepatocellular carcinoma (HCC) in Europe. BCLC recommends treatment with transarterial chemoembolization (TACE) in patients with intermediate-stage HCC (BCLC B). Despite this, TACE is also used in patients with more advanced disease.

**Aims & Methods:** The aim of this study was to develop a prognostic model of TACE treated patients, that relates to complete response at 1 month after TACE according to the mRECIST criteria, and compare it with other TACE specific staging systems. A cohort of 206 patients treated with TACE was analyzed. Using univariable analysis, different prognostic factors were identified and included in the construction of a prognostic model. Subsequently, we simplified the model by categorizing the albumin and C-reactive protein variables. The model was constructed using backward cox regression. We evaluated the capability of our model to predict complete response at 1 month after TACE according to the mRECIST criteria. Finally, the model was compared with BCLC and established TACE specific staging systems (STATE-score and HAP-score) using ROC curve for prediction of mortality at 1 year.

**Results:** Our cohort had a median age of 68.75±0.8 year, 77.2% were male; etiology of liver disease was hepatitis C virus in 32%, alcoholic liver disease in 40% and hepatitis B virus in 10%, other causes in 18%. BCLC-A was present in 37.4% of the patients, BCLC-B in 50% and BCLC-C in 12.7%. The median survival time was 18.64 months. Patients with mRECIST complete response at 1 month survived longer than other patients (37.44 vs 23.42 months, p=0.034). In Kaplan-Meier analyses presence of portal thrombosis (p=0.009), up-to 7 criteria (p=0.009), C-reactive protein (p< 0.001) and albumin (p=0.002) were identified as independent prognostic factors and used to construct our model with backward cox regression. By dividing in terciles, we identified three different groups of patients, with median survival times of 37.86, 22.87 and 9.61 month respectively (p< 0.0001). BCLC did not differentiated survival in the Kaplan-Meier analyses (p=0.345). HAP-score (p=0.027) and STATE-score (p< 0.001) differentiated survival. Using this model, we identify differences in the 3 groups for proportion of mRECIST complete response with TACE at 1 month (group A: 19.3%, group B: 18%, group C 2.6%; p=0.018). Unlike HAP-score (p=0.41), BCLC (p=0.135) and STATE-score (p=0.845) did not related with mRECIST complete response at 1 month. When compared with BCLC (AUC 0.468), HAP-score (AUC 0.549) and STATE-score (AUC 0.601), our model presented a stronger capacity to predict mortality at 1 year (AUC 0.696).

**Conclusion:** Patients outside the BCLC-B stage might benefit from TACE, since survival in patients with BCLC-C was not different from intermediate-stage in our population. Different staging systems for better patient selection are necessary. We identified prognostic factors for patients treated with TACE. Our model is apparently better at predicting mortality at 1-year when compared with BCLC, HAP-score and STATE-score. This model is also able to identify patients with poor response to TACE according to mRECIST criteria. External validation is necessary to confirm these results.

**Disclosure:** Nothing to disclose

## P1468 LIVER TRANSPLANTATION FOR HEPATOCELLULAR CARCINOMA IN PATIENTS OVER 65 YEARS OF AGE IN IRELAND: IS THIS THE BEST USE OF OUR GRAFTS?

Murphy A.<sup>1</sup>, Bourke M.<sup>1</sup>, O'Brien A.<sup>2</sup>, Appel J.<sup>3</sup>, Houlihan D.D.<sup>1</sup>

<sup>1</sup>St. Vincent's University Hospital, Department of Hepatology, Dublin, Ireland,

<sup>2</sup>St. Vincent's University Hospital, Dublin, Ireland, <sup>3</sup>University College Dublin (UCD), Dublin, Ireland

**Contact E-Mail Address:** aislingmurphy\_ie@hotmail.com

**Introduction:** Liver Transplantation (LT) is an established therapy for patients with hepatocellular carcinoma (HCC) with good long term survival. There are however, an increasing number of effective loco-regional therapies (LRT) available with much lower morbidity and mortality risk. It is not well established whether older HCC patients ( $\geq 65$  years) have worse outcomes after LT and might be better served with LRT. This might free up grafts for patients with decompensated liver disease and reduce waiting list mortality.

**Aims & Methods:** 1. Compare the survival of older ( $\geq 65$  years) and younger ( $< 65$  years) patients that received LT for HCC.

2. Compare the survival of older patients following listing for LT to patients treated only with LRT and resection.

Data was collected retrospectively from both, the prospectively maintained national liver transplantation database from January 1993 to December 2017 and our HCC database from January 2014 to December 2018, in St Vincent's University Hospital. Ethical approval for this study was obtained from the local ethics committee. LRT included transarterial chemoembolization, thermal ablation and selective internal radiation therapy. Survival was compared by using Kaplan Meier curve and log-rank tests.

**Results:** In total, 156 ( $n=128 < 65$  years) patients received LT for HCC in our hospital during the study period. The main aetiology of liver disease were alcohol 26.9% ( $n=42$ ), viral 39.7% ( $n=62$ ), haemochromatosis 12.1% ( $n=19$ ) and non-alcoholic fatty liver 6.4% ( $n=10$ ). The majority of patients were male (83.9%) and the median age at the time of LT was 59 (IQR 53-63). Most patients were within Milan criteria ( $n=111$ , 86.4%) and this proportion was similar in the older and younger age groups (82.1% and 87.4% respectively;  $p=0.45$ ). Older patients had a worse 4-year survival than younger patients (62% vs 78%,  $p=0.07$ ). We therefore sought to compare the survival of elderly patients considered for LT from the time of listing, to those treated with LRT or resection only ( $n=79$ ). There was no survival difference between the groups during the follow period ( $P>0.05$ ). The survival for both groups was 62% at four years.

### Conclusion:

Our data suggest that patients over 65 years have higher peri-operative and early mortality following LT compared to younger patients. LRT or resection has proven to be an effective alternative treatment at least in the short to medium term and offers equivalent survival compared to LT in this group. We therefore question the appropriateness of organ allocation to elderly patients with HCC.

## P1469 VALIDATION OF ALPHA FETO PROTEIN MODEL AS A PREDICTOR OF RESPONSE, RECURRENCE AND SURVIVAL IN EGYPTIAN PATIENTS WITH HEPATOCELLULAR CARCINOMA UNDERWENT TRANS ARTERIAL CHEMOEMBOLIZATION

Shaker M.K., Abdella H.M., Eltabbakh M., Abu Hashima M.A.  
Ain Shams University, Tropical Medicine, Hepatology and Gastroenterology Department, Cairo, Egypt

**Contact E-Mail Address:** midoatif.2014@gmail.com

**Introduction:** In Egypt, liver cancer forms 23.81% of the total malignancies.<sup>1</sup> Recently, the French study group for liver transplantation reported on a new predictive model for hepatocellular carcinoma (HCC) recurrence post liver transplant, namely the alpha feto protein (AFP) model which considered superior to Milan criteria in predicting recurrence in a training set of HCC patients, and was subsequently validated in a cohort of French patients followed prospectively under the control of the French organization for organ sharing.<sup>2</sup>

### Aims & Methods:

**Aim:** To validate the use of AFP model as a predictor of response, recurrence and survival in Egyptian patients with hepatocellular carcinoma undergoing trans arterial chemoembolization (TACE).

**Methods:** This cohort study was conducted at Tropical Medicine department at Ain Shams University Hospitals. We included all newly diagnosed patients with HCC who were fit for TACE according to Barcelona Clinic Of Liver Cancer (BCLC) 2012 starting from January 2012 till January 2016. The AFP model was calculated for each patient enrolled in the study before TACE according to the following (Simplified, user-friendly version of the AFP model):

Largest diameter of hepatic focal lesion ( $\leq 3$  cm, 3-6 cm,  $> 6$  cm took points 0, 1, 4 respectively).

Number of nodules (1-3,  $\geq 4$  took points 0, 2 respectively).

Alpha feto protein level (AFP level (IU/ml)  $\leq 100$ , 100-1000,  $> 1000$  took points 0, 2, 3 respectively).

Then the patients were classified before intervention into low risk group for TACE (total points  $< 2$ ) and high-risk group for TACE (total points of 2 or more). The patients were followed up by AFP level, and triphasic spiral CT performed 1 month after TACE to evaluate the response then at 4 months and 7 months post TACE to evaluate the local and distant recurrence.

**Results:** One hundred and thirty two patients who underwent TACE were included in the study with mean age  $57.28 \pm 7.46$  years and HCV Ab positive predominance (89.4%). According to alpha feto protein model, the patients were classified into low risk group for TACE (43.2% of patients) with median alpha feto protein model equal zero and high risk group for TACE (56.8% of patients) with median alpha feto protein model equal 3. Complete response was achieved in higher percentage of patients in low risk group (91.2%) than high risk group (73.3%) but without reaching statistical significance ( $P=0.057$ ). The one and three years recurrence free survival were 50% and 24.1% in low risk group Versus 29.1% and 16.2% in high risk group respectively. Also, the one and three years overall survival rate were 97% and 37.3% in low risk group Versus 98.1% and 11.6% in high risk group respectively but all without reaching statistical significance. On classifying our patients with alpha feto protein level  $< 100$  IU/ml (79 patients) into low risk patients (57 patients) and high risk patients (22 patients) according to alpha feto protein model, we found that complete response was achieved in significantly higher percentage of patients in low risk group (91.2%) than high risk group (69.6%) ( $P < 0.05$ ). Also, recurrence occurred in a less percentage of patients in low risk group (71.2%) than high risk group (81.2%) but without reaching statistically significant difference between the 2 groups ( $P > 0.05$ ). Median overall survival was significantly higher in low risk group (18 months) than high risk group (16 months) ( $P < 0.01$ ).

**Conclusion:** AFP model could be used as a predictor of response, recurrence and survival in HCC patients undergoing TACE especially in patients with alpha feto protein level less than 100 IU/ml.

**Introduction:** Cholangiocarcinomas (CCAs) are a heterogeneous group of tumors that arise from the biliary tract epithelia, and account for nearly 3% of all gastrointestinal tumors. Although CCA is on the rise in most countries, the epidemiology of these cancers has been poorly understood.

**Aims & Methods:** We therefore aim to assess the prevalence, demographics and risk factors of patients with new diagnosis of CCA presenting in the Emergency Room (ER) of an Academic Italian Hospital. We retrospectively analyzed all ER cases between January 2010 and December 2017 at Humanitas Research Hospital in Milano Italy.

**Results:** From January 2010 to December 2017 403295 patients entered the ER, in 203 (0.05%) of them the diagnosis was CCA. CCA cases increased from 38 in the 2010-2011 period (38/102103: 0.03%) to 66 in the 2016-2017

period (66/101337: 0.07%) ( $p=0.007$ ). The most frequent reasons for hospitalization in patients with CCA were jaundice ( $n=106$ , 52%), abdominal pain ( $n=30$ , 15%) and abnormal liver function tests ( $n=13$ , 6%). During the study period 1224 patients (0.3%) entered the ER for jaundice, CCA accounted for 9% of those cases. Out of the 203 patients with CCA, 109 were male (53.7%), the mean age was 68 years (24-88).

No patient had PSC, only 6 (2.9%) had cirrhosis, while 32 had diabetes (15.7%). The anatomical location of the identified CCA was intrahepatic in 21.6% of the cases, perihilar in 29%, distal in 26.6%, and gallbladder in 21%. Tumor staging was 1 in 27 (13.3%), 2 in 57 (28.1%), 3 in 29 (14.3%) and 4 in 90 patients (44.3%). Treatment of CCA could be analyzed in 135 patients, 51 patients (38%) received best supportive care, 43 received Chemotherapy (32%), while 41 underwent surgery (30%). The rates of surgery increased during the enrolment period however without reaching significant differences (19.7% in 2010-2011 vs 32.5% in 2016-2017,  $p=0.3$ ).

**Conclusion:** CCA is a rare presentation in the ER, however with increasing incidence. CCA was found in 9% of all cases presenting with jaundice. Importantly, none of the identified CCA patients had PSC. Further, the low rate of patients with coexisting liver disease (2.9%), the high prevalence of advanced cancer stage (47%) as well as the low rate of surgical treatment (30%) reported by our study highlights the need for research in the field.

**Introduction:** The advent of direct-acting antiviral agents (DAAs) against hepatitis C virus (HCV) with high-sustained virological response rates, represents a major breakthrough in hepatology. The impact of DAAs on hepatocellular carcinoma risk after obtaining sustained virological response (SVR) in patients with chronic HCV infection and advanced liver fibrosis remains to be clarified.

**Aims & Methods:** The aim of our study was to assess the incidence of de novo hepatocellular carcinoma in a cohort of patients with SVR after antiviral therapy. We prospectively analyzed a cohort of patients with HCV related liver cirrhosis treated with paritaprevir/ritonavir, ombitasvir and dasabuvir (PrOD)  $\pm$  ribavirin for 12 weeks. Patients were followed between 01 December 2015 and 01 March 2019, in a tertiary referral center from North-Eastern Romania. All patients were evaluated pretreatment according to our National Protocol.

**Results:** We enrolled in our study 480 patients (mean age 59.1 $\pm$ 8.3 years), predominantly female (54.8%), with no prior history of hepatocellular carcinoma. During the study period we recorded a number of 27 (5.6%) de novo hepatocellular carcinoma cases, predominantly males (68%), mean age 61 $\pm$ 5.9 years. The mean period between SVR and hepatocellular carcinoma diagnosis was 28 $\pm$ 4 weeks. The sonographic findings revealed the predominance of unicentric lesions in 21 (70%) patients and the predominant localization of the lesions were in the VIII liver segment (23%). During follow-up, the main alpha-fetoprotein levels were significantly higher at the time of hepatocellular carcinoma diagnosis compared to baseline (68.01 $\pm$ 5.72 vs 11.22 $\pm$ 2.21,  $p<0.0001$ ).

**Conclusion:** In conclusion, obtaining viral clearance does not seem to decrease the risk of hepatocellular carcinoma in patients with HCV-related liver cirrhosis after obtaining SVR with DAAs, the percentage of 5.6% being in the range described for the annual incidence of HCC in untreated HCV cirrhosis (between 3% and 7%). The impact of the DAA therapy impact on hepatocarcinogenesis remains pivotal.

**Introduction:** Immunotherapy in hepatocellular carcinoma (HCC) is a recent and very promising approach, namely the inhibition of the PD/programmed death-ligand 1 (PD-L1) axis. After tumor ablation or surgical treatment the 5 years recurrence rate is beyond 50%. Until now, no serum biomarker has proved to accurately discriminate patients who will develop recurrence from those who will not.

**Aims & Methods:** In this prospective on-going clinical study we aim to investigate the prognostic value of a soluble form of PD-L1 in HCC patients. During 2016 to 2019 a total number of 267 patients with HCC have been evaluated for possible inclusion in the study. In total 123 patients with Child-Pugh class A, BCLC class 0 or A treated by either ablation (microwave or radiofrequency) or surgery were analyzed. Pre-treatment serum sPD-L1 levels were measured with an enzyme-linked immunosorbent assay (ELISA). Additionally, in 40 out of 123 patients sPD-L1 was also measured 4-6 weeks after ablation or surgery.

**Results:** Median sPD-L1 concentrations in patients with HCC was 95 (range 47.6-305.4) pg/mL. Using the cut-off value of 95 pg/mL patients were stratified into low (< 95 pg/mL) and high sPD-L1 ( $\geq$  95 pg/mL). 108 out of 123 had a minimal follow-up of at least 6 months. After a median follow-up of 18 months the recurrence rate was 10.63% in patients with low sPD-L1 compared to 68.85% in patients with high sPD-L1 ( $p<0.001$ ). Disease-free survival was 14.2 months compared to 6.3 months in low vs. high sPD-L1 patients ( $p=0.001$ ). In 23 out of 40 patients sPD-L1 increased 4-6 weeks after treatment while in 17 out of 40 patients it remained stable or decreased.

**Conclusion:** We conclude that a high sPD-L1 level is a possible prognostic indicator for a poor outcome in HCC patients after curative treatment. Patients with high sPD-L1 might benefit from combination therapies (e.g. tumor ablation and PD-1/PD-L1 inhibitors). Nevertheless, the predictive value of sPD-L1 levels for a successful anti-PD1/PD-L1 therapy should be investigated in the future.

**Introduction:** Sorafenib is associated with various adverse events (AEs) potentially leading to permanent drug discontinuation. Common sense suggests that cumulative experience over a long timeframe might improve the

management of drug-related AEs, with a potential benefit to the patients. However, the actual existence and the full extent of this phenomenon have never been investigated.

**Aims & Methods:** We analyzed a large retrospective-prospective database gathering the clinical data of 201 patients from our Centre, who were consecutively prescribed with sorafenib between 2008 and 2017. We divided these patients in two groups according to the start date of sorafenib (2008-2012 vs 2013-2017), comparing clinical, laboratory and tumor characteristics. In particular, we verified: treatment duration, medium daily dose, reason of sorafenib discontinuation and overall survival (OS).

**Results:** One-hundred-three and 98 patients started sorafenib in 2008-2012 and 2013-2017, respectively. These groups did not differ in age, sex, performance status, liver function, and tumor staging. Due to more frequent dose reductions, the median average daily dose of sorafenib was lower in the 2013-2017 group (413 vs 518 mg/day,  $p < 0.001$ ). In parallel, the median treatment duration increased in the same group (145 vs 112 day,  $p = 0.027$ ), with no remarkable difference in the cumulative drug dose between the two groups (61.6 vs 58.1 g,  $p = 0.440$ ). The rate of patients permanently stopping sorafenib for intolerance dropped from 23.3% in 2008-2012 to 7.1% in 2013-2017 ( $p = 0.002$ ). The median OS was similar in the two groups (11.1 vs 11.6 months), but the rate of long-survivors (OS > 3 year) was higher in the 2013-2017 group (23.4 vs 9.7%,  $p = 0.001$ ).

To reduce the influence of deaths due to early progression, we performed a subgroup analysis of patients who achieved disease control as their best radiologic response. In this case, the OS in the 54 patients treated in 2013-2017 was significantly higher compared to that of the 51 patients treated in 2008-2012 (24.4 vs 20.6 months, HR 0.63, 95%CI 0.42-0.96,  $p = 0.031$ ).

**Conclusion:** Increased experience in the management of sorafenib-related AEs may lead to increased treatment duration and better outcomes in sorafenib-responsive patients. This factor may be of paramount relevance in the era of sequential treatments based on tyrosine-kinase inhibitors, as these molecules share a common toxicity-profile.

**Introduction:** Indeterminate biliary strictures still represent a major challenge in endoscopic diagnostics today [1], [2]. ERCP, EUS-FNA and cholangioscopic guided biopsy show unsatisfactory sensitivity and may not exclude malignancy [3], [4]. The cryobiopsy technique (CB) is a new method for tissue extraction which is already used for endobronchial biopsies in clinical routine. Several studies have demonstrated that CB is superior to conventional biopsy techniques such as forceps biopsies (FB) [5], [6].

**Aims & Methods:** The aim of this ex-vivo clinical study was to investigate feasibility and tissue quality of CB in comparison to FB forceps for the retrieval of native and pathologically altered bile duct tissue.

We Included 14 patients with suspected tumor obstruction of the common bile duct who underwent a pancreaticoduodenectomy. Postoperatively, the bile duct was exposed by lengthwise incision. Tissue samples were then taken either from visibly altered areas or, if not visible, from native bile ducts. A new prototype of a cryoprobe with a diameter of 1.1 mm (Erbe Elektromedizin GmbH, Tübingen, Germany) that was connected to a gas supply device (ERBECRYO2) as well as a standard forceps for the gastrointestinal tract (Boston Scientific Radial Jaw 4 Marlborough, Massachusetts, USA) were used for comparison. CB activation time differed from 1 to 6 seconds. A minimum of 3 biopsy attempts per patient were performed with each method. All biopsy specimens were assessed by two pathologists who were blinded to the biopsy method. Data was collected and analyzed for general feasibility, specimen area, and histological as-

sessability (evaluated by using a 7-point Likert scale ranging from 0-6). Samples were defined as representative, if the samples were big enough, had no or negligible crush artefacts and a score  $\geq 2$ .

**Results:** In total 76 biopsy attempts were made from 14 patients. Biopsy retrieved a macroscopically sufficient tissue sample in 22/30 (73.33%) attempts using standard forceps and 25/46 (54.3%) using CB ( $p = 0.014$ ). The success rate of CB was 10/11 (90.90%) when carcinoma tissue was sampled compared to FB 6/9 (66.60%;  $p = 0.285$ ). The agreement between the two pathologist regarding representativity was good, with Cohen's Kappa of 0.69.

Significantly larger samples were obtained by CB ( $5.60 \pm 5.0 \text{ mm}^2$ ) compared to FB ( $3.23 \pm 5.00 \text{ mm}^2$ ;  $p = 0.005$ ). Superior histologic assessability scores were achieved by CB ( $4.58 \pm 2.51$ ) compared to FB ( $3.1 \pm 1.6$ ;  $p = 0.002$ ). More representative samples were obtained by CB (92%) compared to FB (58%;  $p = 0.011$ ).

**Conclusion:** CB in the bile duct is feasible and the quality of the obtained tissue is high. FB was more successful in retrieving tissue sample from the native bile duct than CB. There was no statistically significant difference in pathologically altered areas. If CB was successful, larger tissue amounts and more representative samples can be retrieved than with a standard biopsy forceps. With these promising results, an in-vivo study is justified.

**Contact E-Mail Address:** yasakamo@iuhw.ac.jp

**Introduction:** Gemcitabine (GEM) and cisplatin (CDDP) combination therapy (GC) is the primary standard chemotherapy for advanced biliary tract cancer (BTC) worldwide; however, its pharmacotherapeutic activity remains unclear. This study aimed to assess the effects of GC in several BTC cell lines.

**Aims & Methods:** We evaluated the dose-response activity of GEM and CDDP in 17 BTC cell lines; the cell lines were stratified into three groups based on their sensitivity as effective ( $IC_{50}$  of  $< 1 \mu\text{M}$  and calculable  $\leq IC_{70}$ ), resistant ( $IC_{50}$  could not be determined), and medium (sensitivity  $\leq IC_{70}$ ) using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTS) assay. Eleven cell lines were selected for analysis of GC activity using the MTS assay. Synergistic, antagonistic, and additive effects of GEM and CDDP were determined by the Bliss additivity model (BM) and combination index (CI) at a GEM:CDDP molar ratio of 7:1 based on human renal clearance.

The effect with a CI score of  $> 1.25$  was categorized as antagonistic, that with 0.7-1.25 as additive, that with 0.3-0.7 as synergistic, and that with  $\leq 0.3$  as strongly synergistic. Pharmacotherapeutic effects were evaluated by comparison of the  $IC_{50}$  value of GEM alone and that of GEM plus CDDP at a 7:1 molar ratio.

**Results:** GEM was effective against four of the BTC cell lines; four cell lines were resistant and three had medium sensitivity. The results of BM revealed GC had synergistic effects against all cell lines. The CI values against GC at a molar ratio of 7:1 revealed that antagonistic, additive, synergism, and strong synergism were 0, 3, 4, 4, respectively. The cell lines, on which GC had strong synergistic effect, were all GEM-resistant, and  $IC_{50}$  by GC was  $>1 \mu M$ . In GEM-sensitive cell lines, the  $IC_{50}$  at the 7:1 combination ratio was  $<1 \mu M$ . The difference in the  $IC_{50}$  values for GEM and GC administration was small. If the  $IC_{50}$  value is low, the drug therapy is effective. A strong synergistic effect by GC therapy (molar ratio 7:1) was observed against the GEM-resistant cell lines; however, the corresponding  $sIC_{50}$  value was high, indicating a discrepancy between the CI and  $IC_{50}$  values.

**Conclusion:** BM and CI show that GC combination treatment has a high synergistic effect. However, the pharmacotherapeutic activity of GC combination treatment did not considerably differ in GEM-sensitive cells. Strong synergy was noted in GEM-resistant cells, but the pharmacotherapeutic effects were not adequate. To treat advanced BTC more effectively, predictive efficacy markers for GEM to select patients who should be treated with GC and a third therapeutic agent in the GC combination are needed.

## P1478 BLOOD NEUTROPHIL-LYMPHOCYTE RATIO AND PLATELET-TO-LYMPHOCYTE RATIO CAN BE EARLY PREDICTORS FOR THE SEVERITY OF ACUTE PANCREATITIS

Liu C.

Jinglin Hospital, Nanjing University, Gastroenterology and Hepatology, Nanjing, China

**Contact E-Mail Address:** liuchang\_gi@163.com

**Introduction:** Given the evidence that Neutrophil-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) can early predict the severity and outcome of many inflammation-association diseases and neoplasm. In this study, we aimed to investigate the value of NLR and PLR in early prediction of the severity of acute pancreatitis.

**Aims & Methods:** Clinical data of 629 acute pancreatitis patients were collected and then NLR and PLR were calculated on the first admission and correlated with subsequent severity. Severe acute pancreatitis (SAP) is defined by persistent organ failure more than 48 hours, while mild severe acute pancreatitis (MSAP) and mild acute pancreatitis (MAP) were defined into Non-SAP.

**Results:** Among 629 acute pancreatitis patients, 396 were classified into Non-SAP and 233 into SAP. NLR was 6.79 (0.73-46.00) in Non-SAP group and 16.33 (2.91-96.70) in SAP group, respectively. PLR and NLR were the most significant variables after all the data was analyzed. Receiver operating characteristics (ROC) curves of NLR and PLR were performed to determine the optimal cut-off value to predict SAP. NLR (AUC 0.789; 95% CI: 0.755 to 0.820) combine with PLR (AUC 0.770; 95% CI: 0.729-0.807) can get more accurate value (AUC 0.799; 95% CI: 0.760-0.835) for predicting SAP. Then the receiver operating characteristic areas between each predictive model was compared, there was no significant difference between each group, and NLR combined with PLR (N-PLR) did not have a significant better performance than PLR independently. It demonstrated that PLR and NLR were two independent predictors for the severity of acute pancreatitis.

**Conclusion:** PLR and NLR can be simple and effective indicators for predicting SAP in early stage.

**Disclosure:** Nothing to disclose

**Introduction:** Despite the lack of specific treatment of acute pancreatitis (AP), there are relatively few clinical trials that investigate this disease. Our aim was to analyze a large, high-quality, multicenter, international cohort to provide necessary information for study feasibility calculation, study design, sample size calculation and primary outcome selection for clinical trials in AP.

**Aims & Methods:** First, we searched the medical literature for studies which used C-reactive protein level (CRP) or white blood cell count (WBC), to describe their current role in trials on AP. Second, we analyzed the data of 1435 patients in our multinational registry of AP. Data on CRP and WBC: on admission, within 24 hours from the onset of pain and their highest values during hospitalization were analyzed to investigate their correlation with severity and mortality of AP. Descriptive statistical tools as Kruskal-Wallis, Mann-Whitney U, Levene's F tests, Receiver Operating Characteristic (ROC) curve analysis and AUC (Area Under the Curve) with 95% confidence interval (CI) were performed.

**Results:** Our literature review showed that CRP is used as an inclusion criterion or as a primary outcome or both (17, 10 and 2 studies respectively) in the earlier and current clinical trials on AP. Its use is extremely variable and not well described. In our cohort, CRP levels on admission predicted mortality and severe cases of AP poorly (AUC: 0.669 (CI: 0.569-0.770); 0.681 (CI: 0.601-0.761) respectively). CRP levels measured within 24 hours from the onset of abdominal pain equally failed to predict mortality or severity (AUC: 0.741 (CI: 0.627-0.854; AUC: 0.690 (CI: 0.586-0.793) respectively). The highest CRP and WBC during the entire hospitalization had equally poor predictive accuracy for mortality and severity of AP. However, if CRP within 24 hours from the onset of pain is an inclusion criterion, then it can markedly elevate the combined even rate of mortality and severe cases of AP (13% for CRP  $>25 \text{ mg/l}$  and 28% for CRP  $>200 \text{ mg/l}$ ). WBC did not show the same characteristics as CRP.

**Conclusion:** We found that increasing the CRP as an inclusion criterion from the onset of abdominal pain can elevate the event rates of mortality, and severity. This novel finding may decrease the number of patients required for clinical trials in the future. Based on our results, CRP should not be used as a primary outcome in clinical trials and WBC should not be used as an inclusion criterion or outcome in clinical trials on AP.

**Introduction:** Walled-off pancreatic necrosis (WOPN) is a complication of acute pancreatitis that affects approximately 20% of patients and still carries high risk of morbidity and mortality. Endoscopic drainage by either Lumen Apposing Metal Stents (LAMS), Self Expanding Metal Stents (SEMS) or Double Pigtail Stents (DPS) can help to drain the liquid component of WOPN.

However solid debris may remain in the cavity and can act as a source of ongoing infection and sepsis-related multi-organ failure. Therefore endoscopic debridement is usually recommended but a limitation of the approach is the lack of dedicated devices; this results in the need for multiple, repetitive and time-consuming procedures to achieve complete resolution. A new 3.1 mm flexible mechanized microdebrider catheter can now be deployed through a 3.2 mm endoscopic working channel to resect and remove solid debris under direct endoscopic visualization, and may overcome the limitation.

**Aims & Methods:** The aim of the ongoing prospective international multicenter study is to explore feasibility and safety of necrosectomy with the flexible endoscopic microdebrider in patients with WOPNs. All patients underwent prior CT scan which had to show WOPN of  $\geq 6$  cm and  $\leq 22$  cm in size with  $\geq 30\%$  solid component. Endoscopic drainage (by either LAMS, SEMS or DPS) was carried out at least three days before endoscopic microdebrider-assisted necrosectomy was performed through the gastrostoma under direct visualization.

Adverse events (AE), procedure times, number of procedures until resolution, percentage decrease of solid necrosis per session, decrease of WOPN size on follow-up CT scans (21 days after final session) and time to discharge were documented.

**Results:** 19 patients with WOPN were screened in the study between November 2018 and March 2019. 12 patients underwent microdebrider-assisted necrosectomy. No microdebrider-associated adverse events, including bleeding were reported. However, one patient died during the study period not attributed to microdebrider use. A mean of 1.8 interventions (range 1-4) were required with an average microdebrider procedure time of 77 minutes and total procedure time of 180 minutes. There was a mean 63.0% reduction of solid necrosis after the first session. The mean decrease of cavity size was 86.8% in the 5 patients so far reported with completed pre- and post-CT scans. Time from microdebrider-assisted necrosectomy to discharge averaged 6 days (range 0-12 days).

**Conclusion:** Microdebrider-assisted necrosectomy for WOPN seems to be a feasible and safe procedure that can provide very effective endoscopic clearance of solid debris without device-associated adverse events. Compared to endoscopic necrosectomy using conventional, non-dedicated instruments endoscopic microdebrider-assisted necrosectomy appears to be superior with regard to the number of procedures required for resolution and to overall procedure time.

**Introduction:** Acute (necrotizing) pancreatitis may result in disrupted or disconnected pancreatic duct syndrome, which is associated with a further complicated clinical course. Diagnosis of disconnected pancreatic duct syndrome is not standardized in clinical practice or international guidelines. We therefore performed a systematic review of the current literature on imaging modalities for diagnosing disruption or disconnection of the pancreatic duct in patients with acute pancreatitis.

**Aims & Methods:** A systematic search was performed in MEDLINE, Embase and Cochrane library databases up to October 2018 to identify all studies evaluating diagnostic modalities for the diagnoses of a disrupted or disconnected pancreatic duct in acute pancreatitis. All data regarding diagnostic accuracy were extracted.

**Results:** We included twelve studies, evaluating 286 relevant patients, reporting on five different diagnostic modalities. The overall diagnostic accuracy of amylase-measurement in drain fluids for detecting a disrupted pancreatic duct was 65%, with a sensitivity of 100% and a specificity of 50%. One study evaluated endoscopic retrograde cholangiopancreatography (ERCP), as compared with surgically confirmed disruption, showing a sensitivity of 100%, with no reported specificity. In a selected study population, endoscopic ultrasound (EUS) also demonstrated a 100% sensitivity in detecting a disrupted pancreatic duct. The sensitivity of (secretin)-magnetic resonance cholangiopancreatography (MRCP), as compared with several other diagnostic modalities, ranged from 83.3%-100%, with a specificity of 100%. For secretin-MRCP, sensitivity was 83.3% and specificity was 100%. The sensitivity for computed tomography was 68%.

**Conclusion:** This systematic review suggests that EUS, ERCP and (secretin)-MRCP are all accurate in diagnosing a disruption or disconnection of the pancreatic duct in patients with acute pancreatitis. Given the poor overall visualization of the pancreatic duct on EUS and the invasive nature of ERCP, however, (secretin)-MRCP would be recommended as first diagnostic modality. Further prospective studies are needed to define the optimal timing and diagnostic value of (secretin)-MRCP in different subgroups of patients with acute (necrotizing) pancreatitis.

**Disclosure:** Nothing to disclose

## P1482 LONG TERM RECOVERY OF PANCREATIC FUNCTION AFTER ENDOSCOPIC TRANSGASTRIC DRAINAGE AND NECROSECTOMY FOR ACUTE PANCREATITIS WITH WALLED-OFF NECROSIS

**Introduction:** Acute pancreatitis (AP) can lead to both endocrine and exocrine pancreatic insufficiency. Necrotizing pancreatitis is a severe disease that can lead to changes in body composition and earlier findings show that necrotizing pancreatitis is associated with a high risk of exocrine insufficiency.

**Aims & Methods:** The aim of this study was to investigate the long-term changes in pancreatic function and body composition in patients with AP and walled-off pancreatic necrosis (WON) following endoscopic transgastric drainage and necrosectomy (ETDN).

We prospectively included patients with WON who underwent ETDN. Patients were evaluated during admission and at 1, 3, 6 and 12 months after discharge with faecal elastase (f-elastase), Haemoglobin A1c (HbA1c), C-peptide, and body composition with dual-energy x-ray absorptiometry (DXA). At 12 months Lundh's test was performed to directly assess exocrine function. Before treatment was initiated, all patients underwent a computed tomography (CT) scan, and CT severity index (CTSI) as well as modified CTSI was calculated.

**Results:** Eighteen patients were included (67% men; median age 63 years; 44% gallstones; 39% alcohol; 17% other). At 12 months follow-up 57% of the patients had exocrine insufficiency based on Lundh's test and 67% based on f-elastase. Two patients (11%) developed signs of endocrine insufficiency, based on both HbA1c and C-peptide, two patients with only HbA1c being affected.

From discharge to up to 3 months after discharge, we found a loss in mean total body mass from 78.2 ± 18.4 kilogram (kg) to 73.9 ± 18.1 kg (p=0.03), in mean total fat mass from 25.9 ± 11.0 kg to 23.5 ± 9.9 kg (p=0.14) and in mean muscle mass from 49.6 ± 10.1 kg to 47.7 ± 10.3 kg (p=0.15). Between 3- and 12-months follow-up, the mean total body mass increased to 78.6 ± 13.7 kg (p=0.001), mean muscle mass to 49.6 ± 9.6 kg (p=0.03) and mean fat mass to 26.4 ± 7.0 kg (p=0.06). We found no correlation between the changes in body composition and endocrine or exocrine function.

**Conclusion:** More than half of the patients in present study developed exocrine insufficiency one year after treatment for WON with ETDN. Our results support earlier findings, that patients with WON are at risk of developing especially exocrine insufficiency and that a minor group develop endocrine insufficiency. Although exocrine insufficiency is evident, its influence on changes in weight and body composition is questionable as our patients regained their weight on 12 months follow-up. Furthermore, our results question whether enzyme supplement should be supplemented per se in cases of low f-elastase values, or if the clinical decision should include other parameters such as changes in weight and in muscle and fat mass.

## P1483 ENDOSCOPIC ULTRASOUND (EUS) FOR EVALUATION OF PATIENTS WITH ACUTE PANCREATITIS WITHOUT OBVIOUS BILIARY ETIOLOGY

Bota S., Razpotnik M., Essler G., Urak C., Weber-Eibel J., Peck-Radosavljevic M.

Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt, Austria

**Contact E-Mail Address:** bota\_simona1982@yahoo.com

**Introduction:** Endoscopic ultrasound (EUS) has emerged as an important tool in diagnostic evaluation of patients with acute pancreatitis (biliary or unknown etiology). The current guidelines recommend performance of endoscopic retrograde cholangiopancreatography (ERCP) by patients with acute biliary pancreatitis only in the presence of cholangitis, dilated biliary ducts or confirmed choledocholithiasis.

**Aims & Methods:** The aim of this study was to utility of EUS by patients with biliary or unknown etiology of acute pancreatitis.

Our retrospective study included EUS investigations performed between 06/2017-03/2019 in our newly established GI-Department, which features a centralized endoscopy-service in a University affiliated tertiary care teaching hospital.

EUS was performed in patients with biliary pancreatitis without cholangitis or dilated biliary ducts in order diagnose/exclude choledocholithiasis. Patients with acute pancreatitis of unknown etiology were investigated with EUS in order to identify a possible etiology (especially biliary).

**Results:** 60 patients were included in this analysis (33 with biliary pancreatitis and 27 with unknown etiology of acute pancreatitis).

Choledocholithiasis was diagnosed in 12/33 (36.3%) patients with acute biliary pancreatitis. All these patients received ERCP and biliary duct stones were removed. In one patient with acute pancreatitis and gallstones, but without choledocholithiasis, EUS also diagnosed a tumor in the pancreatic head (this was not seen in CT scan). A biopsy was performed and showed an adenocarcinoma.

In 1/20 (5%) biliary pancreatitis cases with negative EUS, the patient developed jaundice on follow-up and ERCP with extraction of bile duct stones was performed.

EUS identified an etiology in 16/27 (59.2%) of cases with initially unknown etiology of acute pancreatitis: biliary-11/27 (40.7%), autoimmune pancreatitis - 2/27 (7.4%), pancreatic tumor (undiagnosed in CT scan)- 1/27 (3.7%), pancreatolithiasis -1/17 (3.7%) and chronic pancreatitis - 1/27 (3.7%).

Magnetic resonance imaging (MRI) was available in 8/11 (72.7%) patients with pancreatitis of unknown etiology and negative EUS. Pancreas divisum was diagnosed in 1/8 cases. In all other cases MRI was also negative.

Negative MRI was present in 3/16 (18.7%) pancreatitis cases with biliary etiology in EUS. No MRI was available in the other cases.

**Conclusion:** EUS is a very sensitive method for diagnosing choledocholithiasis in patients with biliary pancreatitis and provide an etiology in two thirds of cases with initially unknown etiology of acute pancreatitis.

**Disclosure:** Nothing to disclose

## P1484 TO COMPARE THE CLINICAL OUTCOME OF PATIENTS OF ACUTE PANCREATITIS (AP) HAVING INTRA-ABDOMINAL HYPERTENSION (IAH) WITH THAT OF PATIENT WITH NORMAL INTRA-ABDOMINAL PRESSURE (IAP)

Singh A.<sup>1</sup>, Samanta J.<sup>1</sup>, Rana A.<sup>1</sup>, Bellam B.L.<sup>1</sup>, Gupta P.<sup>1</sup>, Gupta V.<sup>2</sup>, Yadav T.D.<sup>2</sup>, Sinha S.K.<sup>1</sup>, Kochhar R.<sup>1</sup>

<sup>1</sup>Post Graduate Institute of Medical Education and Research, Gastroenterology, Chandigarh, India, <sup>2</sup>Post Graduate Institute of Medical Education and Research, Surgical Gastroenterology, Chandigarh, India

**Contact E-Mail Address:** anupam.pgi@gmail.com

**Introduction:** Acute pancreatitis patients, mainly severe acute pancreatitis, tends to have elevated intra-abdominal pressure which may progress to intra-abdominal hypertension (IAH) and abdominal compartment syndrome (ACS). ACS is shown to correlate with poor outcome and increased mortality in AP. However, outcome of AP with IAH is rarely studied.

**Aims & Methods:** Study was aimed to compare the clinical outcome of patients of AP with IAH with those with normal IAP. Retrospectively data was analysed of 105 patients of AP from Jan 2016 to May 2018. Parameters

measured included the demographic profile, clinical severity scores, CT severity score (CTSI), persistent organ failure (OF), hospital and ICU stay, need and outcome of percutaneous catheter drainage (PCD), surgery requirement and mortality. Patients were divided into two groups based on presence or absence of IAH and were analysed.

**Results:** Among 105 patients of AP, IAH was present in 48 (45.7%) patients. Both the groups were comparable for clinical characteristics. Patients with IAH had more often severe disease, BISAP  $\geq 2$ , higher APACHE II scores and CTSI. IAH group had more often OF (87.5% vs. 70.2%,  $p$  value=0.033), prolonged ICU stay (12.5 vs. 6.75 days,  $p$  value=0.007) and higher mortality (52.1% vs. 15.8%,  $p$  value < 0.001). In the IAH group, reduction of IAP by less than 35% at 48 hours post-PCD compared to baseline correlated with higher mortality (81.2% vs. 37.5%,  $p$  value = 0.004) while in patients with normal IAP no correlation with decrease in IAP and mortality was noted. Need for PCD, surgery and hospital stay were similar in two groups. On multivariate analysis, presence of IAH and CVS failure at presentation were independent predictors of mortality ( $p$  value < 0.001 and 0.004, respectively). APACHE  $\geq 10$  and CTSI  $\geq 8$  at presentation was found to predict the development of IAH ( $p$  value 0.014 and 0.019, respectively) on multivariate analysis.

**Conclusion:** IAH is an independent predictor of mortality in AP. Patients with APACHE  $\geq 10$  and CTSI  $\geq 8$  at presentation are likely to develop IAH and require IAP monitoring.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** foldimarcsi4@gmail.com

**Introduction:** Pain is the most common symptom in acute pancreatitis (AP), and is part of the diagnostic criteria. However, its clinical characteristics in AP have not been detailed in the literature. Our aim was to objectify the diagnostic and prognostic role of acute abdominal pain in AP.

**Aims & Methods:** Our aim was to objectify the diagnostic and prognostic role of acute abdominal pain in AP. The Hungarian Pancreatic Study Group (HPSG) has prospectively collected multicenter clinical data of 1432 adult patients between 2012 and 2017. The specific pain questionnaire contained data in four categories: intensity of pain (Visual Analog Scale; 1-10, mild [mild]: 1-3, moderate [modP]: 4-6, severe [sevP]: 7-10), duration of pain prior to admission (hours), localization of pain (9 regions of the abdomen), and type of pain (sharp, dull, or cramping). These data were compared to parameters on admission and with the outcome of AP. Statistical analyses were performed accordingly.

**Results:** Pain contributed to the 'on admission' diagnosis in 99.6% (n=1426) of cases. It was mostly severe (mildP: 5%, n=38; modP: 25%, n=178; sevP: 70%, n=511), cramping (61%, n=705), and epigastric (48%, n=687). Severe pain was associated with a more severe disease course ( $p$  < 0.05); however, it failed to predict mortality ( $p$ =0.826). Sharp pain was associated with AP severity ( $p$  < 0.001), mortality (OR=2.263, 95% CI: 1.199-4.059), and systemic complications (OR=2.263, 95% CI: 1.550-3.970). Localization of pain was not associated with the main outcomes. Thrombocyte ( $r$ =0.074,  $p$  < 0.05), CRP ( $r$ =0.322,  $p$  < 0.001) alkaline phosphatase ( $r$ =0.171,  $p$  < 0.001),  $\gamma$ -GT ( $r$ =0.071,  $p$  < 0.05), and total bilirubin ( $r$ =0.147,  $p$  <

0.001) were positively correlated with duration of pain prior to admission, whereas amylase ( $r$ =0.212,  $p$  < 0.001), lipase ( $r$ =0.257,  $p$  < 0.001), hemoglobin ( $r$ =0.090,  $p$  < 0.05) and triglyceride ( $r$ =0.892,  $p$  < 0.05) showed negative correlation with the duration of pain. Pain within the first 24 hours was accompanied by elevated amylase levels in 78% of cases on admission. If pain lasted more than 72 hours, amylase was only increased in 62% of cases on admission. Furthermore, longstanding (>3 days) pain was associated with milder ( $p$  < 0.001) and rather dull pain ( $p$  < 0.05), localized in the right abdomen ( $p$  < 0.005).

**Conclusion:** Pain was associated with the main outcomes and different, prognostically or diagnostically important laboratory parameters. Pain later in the disease course becomes atypical, and amylase or lipase reach the diagnostic level less frequently. Our work comprehensively objectified the diagnostic and prognostic role of pain in AP.

**Disclosure:** Nothing to disclose

## P1486 DUAL CENTER EXPERIENCE OF EARLY PANCREATIC NECROSIS LOCATION AND ACUTE PANCREATITIS SEVERITY

**Introduction:** Acute pancreatitis is a severe and frequently a life-threatening disease, which can lead to pancreatic necrosis, acute lung injury, SIRS and MODS. In this study, we hypothesized that the early radiologically determined location of pancreatic necrosis can serve as a determinant of acute pancreatitis severity, thus lead to more systematic complications.

**Aims & Methods:** Acute pancreatitis (n=100) patients in two institutions were studied. Contrast CT scan was performed either on admission or between Days 3-10 during the hospital stay. In addition, CT index, percentage of non-enhancement pancreas, Balthazar score, CTSI score and modified CTSI score were evaluated. A particular emphasis was to the location of non-enhancement pancreas and pattern of pancreatic necrosis. Other findings, such as pleural complications, ascites, pericardial effusion, vascular complications, peripancreatic collections, wall and shape of necrosis and extra-pancreatic organ involvement were evaluated. All CT scans were evaluated by two different radiologists in both institutions.

**Results:** The subjects were selected based on confirmation of acute pancreatitis diagnosis. We report the preliminary results of the first ten (10%) patients from our cohort. Balthazar score: E-7/10, D-3/10 and CTSI score of 10-10%, 6-40%, 8-10%, 4-10%, 3-20% subsequently. While modified CTSI score of 10-30%, 8-40%, 6-30%, 8-20%, 4-10% accordingly. The presence of pancreatic necrosis was determined by four types of spread patterns based on location. Our data demonstrate location of collections as: bilateral- 4 (40%), central-7 (70%), right-sided-2 (20%), scattered necrosis-3 (30%), left sided-2 (20%), right sided-1 (10%), extension below iliac crest-2 (20%), thus 2 (20%) patients had hyperdense adrenals as sign of shock. In addition, non-enhanced pancreas >50%- 1/10, < 30%- 4/10, while subtotal necrosis >90%-2/10 patients.

**Conclusion:** Further studies are now underway to analyze the remaining cohort to determine whether early identification of location of pancreatic necrosis can determine severity of acute pancreatitis disease course, thus prevent systemic complications.

**References:** Types of spread patterns of EXPN (based on the dominant pattern observed, modified from Madry et al 1994 and Ishikawa et al 2006); right EXPN, central EXPN, left EXPN, and bilateral EXPN.

**Introduction:** Acute pancreatitis is a common disease worldwide, with the majority of patients having a rapidly favorable outcome. Nevertheless, 20% will develop moderate to severe disease with a high risk of infection of necrosis and organ failure; in these cases mortality can reach 15%. Infected necrosis requires management with antibiotics and invasive interventions. However, differentiating sterile from infected necrosis can be challenging. Diffusion-weighted magnetic resonance imaging (DW-MRI) has shown promising results regarding the presence of infection or not in pancreatic pseudocysts. These results have not been generalized to pancreatic necrosis or walled-off necrosis (WON). On the other hand, there is limited data regarding microbiology and antibiotic use in these patients.

**Aims & Methods:** The aim of the study is to assess the diagnostic potential of DW-MRI to detect infected necrosis, as well as determining the microbiology and antibiotic use in patients with necrotizing pancreatitis. This is a retrospective study on patients with necrotizing acute pancreatitis admitted from 2010-2018, having undergone invasive interventions and MRI before intervention. Patients with chronic pancreatitis were excluded. Microbiology results based on fluid collected during drainage and sequential antibiotic use were recorded. Gold standard for an infected collection was considered when the culture of fluid collected during the initial drainage was positive. MRIs were reviewed and infection of the necrosis or WON was considered in case of a restricted diffusion signal.

**Results:** Sixty-seven patients were identified. The majority (67.2%) were men, and the main etiology was alcoholic in 30/67 (44.6%). Intensive care unit admission was required for 37/67 (53.8%) who presented with organ failure for a median duration of 12 (1-121) days. Median hospital stay was 70 (15-345) days. All patients had, at least, one endoscopic drainage (overall 2(1-8)). Endoscopic necrosectomy was required in 24/67 (36%) and combined percutaneous drainage in 18 (26.9%). DW-MRI was performed in 56 patients; sensitivity of DW-MR to detect infection was 67% and specificity 58%. CT revealed air bubbles in 8 patients; sensitivity and specificity of this sign was respectively 19% and 100%. Cultures collected during the first drainage were positive in 57/67 patients (85%). Microbiology results from the first drainage revealed more frequently gram-negative rods: *E. Coli* (n=15), *Klebsiella Pneumoniae* (n=6) and *Pseudomonas aeruginosa* (n=3) with already 9 multidrug resistant bacteria, whereas fungi were found in 17 patients (*Candida albicans* n=13). All patients were treated with antibiotics with a median duration of 43 (1-137) days, with 3 (0-12) adaptations according to clinical evolution or further bacteriological findings. Amoxicillin-clavulanic acid was the most used first choice antibiotic (n=22), followed by piperacillin-tazobactam (n=14). 35 patients (52%) were treated with antifungal therapy, mostly Fluconazole. Mortality during the initial hospitalization occurred in 12/67 (17.9%) patients.

**Conclusion:** DW-MRI could be a useful additional tool to distinguish between sterile and infected necrosis. Antibiotics are overused in patients with necrotizing acute pancreatitis with suspected infection, resulting in an increase of multidrug resistant bacteria and fungal infections.

**Disclosure:** Nothing to disclose

## P1488 PATIENT CHARACTERISTICS AND PREDICTORS OF DISCHARGE AGAINST MEDICAL ADVICE IN ACUTE PANCREATITIS POPULATION

Enofeik L.<sup>1</sup>, Yam J.<sup>2</sup>, Obano S.<sup>3</sup>, Khan N.<sup>4</sup>

<sup>1</sup>Michigan State University, Internal Medicine, Lansing, United States,

<sup>2</sup>Michigan State University, Gastroenterology, East Lansing, United States,

<sup>4</sup>Michigan State University, East Lansing, United States

**Contact E-Mail Address:** enofeik@yahoo.com

**Introduction:** Discharge Against Medical Advice (DAMA) which is the patient's discontinuation or refusal of medical care is a health problem in the United States (U.S) contributing to worse morbidity, mortality and frequent re-hospitalizations. Despite the significant burden DAMA imposes on healthcare cost and utilization, there is a lack of understanding of the characteristics of patients who DAMA and factors associated with DAMA especially among hospitalized gastrointestinal patients. Acute pancreatitis (AP) on the other hand, is the most frequent gastrointestinal reason for hospitalization in the U.S. We therefore aim to examine the characteristics of patient who DAMA and determine factors associated with DAMA among patients admitted with AP.

**Aims & Methods:** A retrospective study utilizing the 2014 National Inpatient Sample (NIS) database was performed. All adult patients admitted with a primary or secondary diagnosis of AP were included in this study. Patients who died during index hospitalization or transferred to another facility were excluded. Patient and hospital level characteristics were obtained. Discharge diagnosis and DAMA outcome data were collected. Patient and population characteristics of patients who DAMA were examined using descriptive analysis. Multivariable logistic regression was used to determine factors associated with DAMA in this population. We adjusted for patient and hospital-level characteristics, possible etiologies, type of procedure, and complications.

**Results:** A total of 51,607 discharge records met our inclusion criteria. N=1,893 (3.5 %) of all discharges were against medical advice. 69% of patients were in the 35-65 years age bracket and 60% were Whites. A total of 58% had some type of government insurance (Medicare or Medicaid) and patients with  $\geq 3$  co-morbidities had the highest proportion of DAMA (43%).

After adjusting for covariates, patients who use tobacco (OR 1.54, 95% CI 1.31 - 1.80), cannabis (OR 1.26, 95% CI 1.01 - 1.59), and other illicit drugs (OR 1.50, 95% CI 1.27 - 1.77) were more likely to DAMA compared to non-smokers, non-cannabis and non-illicit drug users. Patients on government insurance (OR 2.28, 95% CI 1.98 - 2.62), and self-pay (OR 2.34, 95% CI 1.99 - 2.78) were more likely to DAMA compared to patients with private health insurance. Interestingly, patients with a diagnosis of gallstone (OR 2.76, 95% CI 1.89 - 4.03) and alcoholic AP (OR 2.31 95% CI 2.01 - 2.66) were found to be more likely to DAMA compared to AP from other etiologies. Other factors associated with DAMA in this population include males (OR 1.36, 95% CI 1.51 - 1.23), younger patients and patients with less than 3 comorbidities (OR 1.51, 95% CI 1.79-1.28).

**Conclusion:** In the acute pancreatitis population, factors associated with DAMA include younger male patients, the use of tobacco and illicit drugs, patients on government insurance, patients with gallstone, alcohol-induced pancreatitis and patients with fewer number of comorbidities. Understanding the characteristics of patients discharged against medical advice and the factors that may influence the decision to DAMA may help identify specific populations for pre- and in-hospital intervention to help reduce the incidence of DAMA and its associated morbidity and mortality, as well as reduce the overall cost related to re-hospitalizations in this patient population.

## P1489 SPECIFIC CRYSTALLOID SOLUTIONS VERSUS NORMAL SALINE FOR ACUTE PANCREATITIS - META-ANALYSIS WITH TRIAL SEQUENTIAL ANALYSIS

Poropat G.<sup>1</sup>, Radovan A.<sup>2</sup>, Vranic L.<sup>2</sup>, Stimac D.<sup>3</sup>

<sup>1</sup>Clinical Hospital Center Rijeka, Gastroenterology, Rijeka, Croatia, <sup>2</sup>Clinical Hospital Center Rijeka, University of Rijeka, Department of Gastroenterology, Rijeka, Croatia, <sup>3</sup>Clinical Hospital Center Rijeka, University of Rijeka, Rijeka, Croatia

**Contact E-Mail Address:** gporopat8@gmail.com

**Introduction:** Intravenous fluid resuscitation is a cornerstone of treatment for pts with acute pancreatitis (AP) directed to prevent hypovolaemia and organ hypoperfusion. Specific crystalloid solutions with additional potential anti-inflammatory and buffer agents such as lactate or acetate, and lower chloride levels have been researched in different critically-ill pts compared to the use of normale saline, showing potential superiority.

**Aims & Methods:** We aimed to evaluate the effects of these specific crystalloids in AP pts and assess the level of available evidence. We performed electronic searches of Medline, Web of Science, Scopus, and The Cochrane Library for randomized controlled trials assessing the use of specific crystalloid solutions for treatment of AP. Mortality and organ failure (OF) were assessed as primary outcomes. Secondary outcomes included SIRS, pancreatic necrosis (PN), infected pancreatic necrosis (IPN), local complications (LC), and length of hospital stay. TSA was performed for the primary outcomes, and secondary outcomes showing a significant result in meta-analysis, with alpha of 5%, and power of 80%. Results for dichotomous outcomes were expressed as risk ratios (RRs) with 95% confidence intervals (CIs), and continuous results were expressed as mean differences (MDs) with 95% CIs.

**Results:** Three RCTs with a total of 127 patients were included in the analysis. All trials compared the use of RL (n=) compared to NS (n=). The mortality and OF rates were similar in both groups with RRs 0.36 (95% CI 0.04 to 3.30; I<sup>2</sup>=0%) and 0.39 (95% CI 0.09 to 1.76; I<sup>2</sup>=0%), respectively. Development of PN was reduced with RL (RR 0.28; 95% CI 0.09 to 0.91; I<sup>2</sup>=0%). SIRS rates at 24h were lower among pts receiving RL (RR 0.38; 95% CI 0.15 to 0.98; I<sup>2</sup>=36%) and the length of hospital stay was shorter (MD -0.80; 95% CI -1.23 to -0.37; I<sup>2</sup>=78%). TSA was not performed for mortality due to too little information available. To detect a RR reduction (RRR) for OF of 30% and a rate of 20% among controls, a total of 1231 pts are required. A 30% RRR with 30% PN rate among controls would require a 1151 pts, while a 30% RRR with 40% SIRS rate among controls would require 2227 pts. A required information size of 218 pts was calculated based on a minimal relevant effect of reducing hospital stay for 1 day (SD=1.52). To detect All TSA analyses were performed for the total of 127 randomized pts.

**Conclusion:** Evidence favoring use of Ringer's lactate over normal saline for treatment of AP is very low. We couldn't identify RCTs evaluating other specific and balanced crystalloid solutions. Further research is needed.

## P1490 EXPERIENCE OF HOT-AXIOS STENT INSERTION IN A TEACHING HOSPITAL IN WEST LONDON

Cavazza A., Brett J., Vlavianos P.

Hammersmith Hospital, Dept. of Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** a.cavazza1@gmail.com

**Introduction:** Pseudocysts are a known complication of acute or chronic pancreatitis which can require intervention if symptomatic. The drainage can be achieved endoscopically, surgically or by Interventional Radiology. The endoscopic approach has been shown to be associated with less complications than the other routes.

**Aims & Methods:** We have analysed data from January 2016 to February 2019 of patients that underwent Hot Axios stent insertion. The data were stored in the electronic endoscopic and patient's record. We collected data on gender, age at stent insertion, patient's background, symptoms that led to endoscopy, hospital stay length and outcome.

**Results:** Total of patients that had Hot Axios inserted were 41.

Mean age at diagnosis was 53 years. 17 (41%) were females and 24 (59%) were males. 44% patients presented with abdominal pain and vomiting and 22% had associated weight loss. 17% (n 7) had chronic pancreatitis and 5% (n 2) had underlying cancer. Length of hospital stay median of 7

days (0-135). 20 patients had no complications (49%), 4 (10%) reported pain, 9 (22%) sepsis, 2 (5%) bleeding. Sepsis was controlled with repeat necrosectomies and antibiotics.

All patients had resolution of symptoms necessitating cystgastrostomy.

In our cohort there were 2 deaths (5%) which were not related to the stent insertion.

**Conclusion:** We described our experience over 3 years in a London teaching hospital which receives referrals from all over the region. Sepsis appears to be a relatively common complication of Hot Axios pancreatic pseudocyst drainage necessitating further endoscopic procedures. Accurate selection of patient may help to improve clinical outcome and decrease the complication rate.

## P1491 PERFORMANCE OF FAECAL ELASTASE 1 TEST AGAINST THE "GOLD STANDARD" 3 DAY FAECAL FAT COLLECTION TEST FOR THE DIAGNOSIS OF PANCREATIC EXOCRINE INSUFFICIENCY (PEI) IN PATIENTS WITH CHRONIC PANCREATITIS: IT IS TIME TO CHANGE TO CUT-OFF VALUE!

Nguyen N.Q.<sup>1</sup>, Safaieian R.<sup>1</sup>, Zobel J.<sup>1</sup>, Lebreton L.<sup>2</sup>, Smith G.<sup>3</sup>, Jais P.<sup>2</sup>, Schué M.<sup>2</sup>, Spoor T.<sup>4</sup>

<sup>1</sup>Royal Adelaide Hospital, Department of Gastroenterology and Hepatology, Adelaide, Australia, <sup>2</sup>AzurRx, Langlade, France, <sup>3</sup>Syneos Health, London, United Kingdom, <sup>4</sup>AzurRx, New York, United States

**Contact E-Mail Address:** romina.safaieian@sa.gov.au

**Introduction:** Correct diagnosis of pancreatic exocrine insufficiency (PEI) is very important as pancreatic enzyme replacement therapy improves patient's outcomes. Faecal elastase 1 test is increasingly use as the test of choice for establishing the diagnosis, with the cut-off value varies between >200 and >100mcg/g. With such cut-off values, although the prevalence of PEI in relative benign conditions such as irritable syndromes, diabetes mellitus and age has been reported up to 15%, a majority of these patients did not have pancreatic abnormality on further evaluation. These findings question the validity of the FE1 test and its cut-off values. Validating data of FE1 test against the gold-standard 3-day faecal fat test are lacking.

**Aims & Methods:** To assess the performed of FE1 test against the gold standard 3-day faecal fat test for diagnosing PEI in patients with chronic pancreatitis.

This was a multicenter study (NCT03481803) that evaluated the presence of PEI in patients with a known history as well as imaging changes of chronic pancreatitis. All patients underwent a screening test for PEI using the FE1 test, which was defined as FE1 < 100mcg/g. Only patients who had FE1 value of less than 100mcg/g underwent further testing with an in-patient 3-day faecal fat test with standardized high fat meal. Both FE1 and 3-day faecal fat tests were evaluated in a centralized laboratory (Sonic, Australia). The 3-day faecal fat test was further validated by another tertiary laboratory in France. Coefficient of Fat Absorption (CFA) is calculated and value of less than 50% indicates the presence of PEI. Descriptive statistics as well ROC analyses were performed.

**Results:** Of a total 56 patients with clinical and imaging diagnosis of chronic pancreatitis, only 24 (43%) patients had FE1< 100mcg/g. Based on the 3-day faecal fat test, only 5 (21%) patient had PEI, with 11 patients had CFA≥80% and 8 patients had 80%>CFA≥50%. Even if PEI is defined as CFA of less than 75%, PEI is presence in only 9 (37.5%) patients. This would give a false positive PEI diagnostic rate by FE1 test of 79% and 64.5%, respectively. Whilst all patients with CFA< 50% had FE1 of less than 20mcg/g, 10/19 (53%) patients with CFA>50% had FE1< 50mcg/g. Using the ROC analyses, the cut-off value of 37.5mcg/g given the best sensitivity (65%) and specificity (100%).

**Conclusion:** In patients with clinically proven chronic pancreatitis, only 21% of patients with FE1 < 100mcg/g have PEI. Even if the PE1 cut-off value for PEI is lowered to 50mcg/g, the false positive rate is still 53%. Our study suggests that the cut-off value of FE1 to define PEI should be lowered, and a value of less than 37.5mcg/g gives the best diagnostic performance and negate the risk of false positivity.

**Disclosure:** Nothing to disclose

## P1492 PANCREAS VOLUME AND FECAL ELASTASE-1 AS PROGNOSTIC MARKER FOR PANCREATIC EXOCRINE INSUFFICIENCY FOLLOWING PANCREATIC RESECTION

Cho Y.W.<sup>1</sup>, Jung M.K.<sup>1</sup>, Heo J.<sup>2</sup>

<sup>1</sup>Department of Internal Medicine, Kyungpook National University School of Medicine, Gastroenterology, Daegu, Korea (Republic of), <sup>2</sup>Kyungpook National University Hospital/Kyungpook National University, Department of Internal Medicine, Daegu, Korea (Republic of)

**Contact E-Mail Address:** minky1973@hanmail.net

**Introduction:** Pancreatic resection can lead to pancreatic exocrine insufficiency (PEI). Fecal elastase-1 (FE-1) test is an effective marker for assessment of PEI in patients who underwent pancreatic resection. We measured pancreas volume, FE-1 level, and BMI of 36 patients who underwent pancreatic resection. The aims of this study were (1) to assess the relevance between reduced pancreas volume and decreased FE-1 level, (2) to assess the effectiveness of FE-1 level as predictive marker on underweight caused by PEI in patients with pancreatic resection.

**Aims & Methods:** 36 Patients who underwent pancreatic resection at Kyungpook national university hospital between April 2015 and December 2018 were enrolled. Pancreas volume, FE-1 level and BMI were measured in all 36 patients after pancreatic resection. Patients were divided into three groups according to FE-1 level: "normal" ( $\geq 200 \mu\text{g/g}$ ), "intermediate decrease" ( $15-199 \mu\text{g/g}$ ), "severe decrease" ( $< 15 \mu\text{g/g}$ ). The association of pancreas volume, FE-1 level, and BMI was analyzed respectively.

**Results:** Mean FE-1 level was  $100.3 \mu\text{g/g}$ . 7 patients (19%) had normal pancreatic exocrine function and 29 patients (81%) had PEI in patients who underwent pancreatic resection. In PEI patients, 19 patients had "intermediate decrease" FE-1 level and 10 patients had "severe decrease" FE-1 level. 8 patients had underweight on BMI ( $\text{BMI} < 18.5$ ). Reduction of pancreas volume was not significantly associated with decrease of FE-1 level and body weight loss as indicated by BMI ( $P = .14$ ,  $P = .33$ , respectively). And also, FE-1 level was not significantly associated with BMI ( $P = .80$ ). However, decreased FE-1 level has weak correlation with decrease of BMI ( $P = .16$ ). Especially, "severe decrease" of FE-1 level has the greater correlation with decrease of BMI ( $P = .15$ ).

**Conclusion:** Decrease of FE-1 level is a simple and useful predictive marker for PEI in patients who underwent pancreatic resection.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** drdunajskastreda@gmail.com

**Introduction:** Early diagnosis of chronic pancreatitis (CP) would be important in order to stop the disease progression in time. Unfortunately, neither definitions nor biomarkers of early CP are available. It has been reported that recurrent acute pancreatitis (RAP) can lead to CP, therefore, the number of previous attacks or RAP-associated parameters may be suitable for characterizing early CP. The main aim of this study is to identify biomarkers which are significantly different in acute pancreatitis (AP), RAP, and CP. Another aim is to understand the modifying effect of the number of acute episodes which could be considered as early CP.

**Aims & Methods:** The Hungarian Pancreatic Study group has built up a prospective register of subjects with AP. In the last six years, precise clinical data were collected from 1435 patients. In this study, data on the number of episodes from 1315 patients with high data accuracy were analyzed.

**Results:** In our cohort, 983 (74.75%), 270 (20.53%), 62 (4.72%) patients had a single episode of AP, RAP, and CP, respectively. In the RAP group, 173 patients (64.07%) had 2 episodes, 43 (15.93%) had 3 episodes, 24 (8.89%) had 4 episodes, and 30 (11.11%) had 5 or more episodes. Thirteen biomarkers were significantly different in the first attack of AP and CP. The significant difference between AP and CP disappeared after the second episode of AP concerning 8 biomarkers (gender, age, biliary etiology, alcohol consumption, pseudocyst development, gammaGT, amylase, and red blood cell count), as did after the third episode concerning 3 biomarkers (biliary etiology, body mass index, ASAT) as did after the fourth and fifth episodes concerning 2 biomarkers (ALAT and smoking). As an average, the significant differences between AP and CP disappeared from 2.63 attacks. The average number of acute episodes of patients with preexisting morphological alterations of the pancreas (CP group) was 4.77.

**Conclusion:** A definition of early CP may be 3 or more previous attacks of AP without chronic morphological alterations in the pancreas.

**Disclosure:** Nothing to disclose

## P1494 PHENOTYPIC AND GENOTYPIC PROFILES IN CHRONIC PANCREATITIS ASSOCIATED WITH CYSTIC FIBROSIS GENE CARRIER STATUS

Ahmed A.Y.M.<sup>1,2</sup>, McLaughlin J.<sup>2</sup>, Levison S.<sup>1,2</sup>, Makin A.<sup>3</sup>

<sup>1</sup>Manchester Foundation Trust, Gastroenterology, Manchester, United Kingdom, <sup>2</sup>Manchester University, Manchester, United Kingdom, <sup>3</sup>Manchester Foundation Trust, Manchester, United Kingdom

**Contact E-Mail Address:** abubaker.ahmed@postgrad.manchester.ac.uk

**Introduction:** Pancreatic function has been used in the literature to assess the severity of Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) gene mutations. The mutations are classified from I to VI; Class I produce no protein, in class II the protein fails to reach the apical membrane, and class III produce protein that fails to respond to cAMP. Classes I to III are called severe mutations and associated with pancreatic insufficiency. Class IV (reduced conductance) and class V (reduced protein synthesis or partially defective) are mild mutations and associated with pancreatic sufficiency.

**Aims & Methods:** To examine the relationship between cystic fibrosis mutations classifications and pancreatic function in a cohort of patients with chronic pancreatitis and CFTR gene mutations. We conducted a retrospective analysis of all the genetic and the pancreatic function data for all the patients in Manchester Royal Infirmary Pancreatology Unit with Chronic pancreatitis and CFTR gene carrier status between 1999 to 2018.

**Results:** Analysis of pancreatic function was carried out in 42 chronic pancreatitis patients with CFTR mutations. 36 were heterozygous and 6 compound heterozygous. In the heterozygous cohort 30 genes were identified as severe mutations (22 F508, 2 G551, 1 I148T/7T, 2 D1152H, 1 TG115T5, 1 1679G, 1 R553X). The overall prevalence of PI is 50%. There was no statistical difference in this prevalence on further subdividing the genes to class I, II, and III. The majority presented as pancreatic sufficient (99%) and later on developed PI. The remaining 6 in the heterozygous group carried mild mutations (Arg117) class IV. PI prevalence was 66%, 33% were pancreatic insufficient at presentation. The prevalence of PI in the 6 compound heterozygous group was 66% (4), 3 were combination of severe and mild mutations F508/Arg117 the other 3 combination of severe and severe mutation (D1151/F508del and F508/G511). Both groups had the same prevalence of PI.

**Conclusion:** Pancreatic function does not correlate with the class or the severity type of the mutation in both the heterozygous and the compound heterozygous in CFTR patients. In this cohort of patients Presenting with pancreatitis most are pancreatic sufficient which implies additional factors might play a role in the development of pancreatic insufficiency.

**Disclosure:** Nothing to disclose

## P1495 ETIOLOGY AND MORPHOLOGY IMPACT CLINICAL COURSE OF CHRONIC PANCREATITIS

Perkhofer L.<sup>1</sup>, Hann A.<sup>1</sup>, Seufferlein T.<sup>2</sup>, Wagner M.<sup>1</sup>, Kleger A.<sup>2</sup>, Müller M.<sup>3</sup>

<sup>1</sup>Ulm University, Internal Medicine I, Ulm, Germany, <sup>2</sup>Universitätsklinikum Ulm, Klinik für Innere Medizin I, Ulm, Germany, <sup>3</sup>Ulm University Hospital, Gastroenterology, Ulm, Germany

**Contact E-Mail Address:** martin.mueller42@gmx.de

**Introduction:** Symptoms caused by chronic pancreatitis (CP) are common but often elusive hampering therapeutic decisions. Though correlations of morphologic findings in imaging and clinical appearance remain vague. We aimed in investigating whether a distinct combination of clinical parameters can better define the extent of pancreatic insufficiency and disease burden.

**Aims & Methods:** The aim of the study was to assess the impact of etiology and endosonographic morphology on the clinical course of chronic pancreatitis. Data from 350 CP patients were evaluated retrospectively from a single center data base following predefined criteria:

- (i) Confirmed CP,
- (ii) endoscopic ultrasound (EUS) plus
- (iii) fecal elastase-1 testing,
- (iv) age >18 years,
- (v) Cambridge Score >1 on EUS evaluation.

**Results:** In total 182 patients (137 male, 45 female) fulfilled criteria. Median age was 52 years (range 19-88 years). Etiology distributed as follows: idiopathic 50%, alcohol 42.3%, autoimmune 7.7%. 56.6% of patients suffered from chronic pain that was significantly associated with male sex and younger age. Stool elastase-1 activity discriminated exocrine pancreatic function in Cambridge IV significantly better than in lower stages. Similarly, the endocrine function was significantly more reduced in Cambridge IV CP.

**Conclusion:** A high disease burden is linked to extensive morphological alterations in EUS while pain is more frequent in younger and male patients. The etiology of CP is a predictor for the extent of exocrine impairment.

**Disclosure:** Nothing to disclose

## P1496 IGG4-RELATED DISEASE RESPONDER INDEX BUT NOT SERUM IGG4 CORRELATES WITH DISEASE ACTIVITY AND THE RISK OF 1 YEAR RELAPSE IN TYPE 1 AUTOIMMUNE PANCREATITIS

**Introduction:** Type 1 autoimmune pancreatitis (AIP) is one of the possible manifestation of IgG4 related disease (IgG4-RD). A score system to evaluate the IgG4-RD activity (IgG4-RD responder index - IgG4-RD RI) has been recently published. IgG4-RD RI can be used as an outcome measure both for clinical assessment and for the evaluation of drug response in clinical trials.

**Aims & Methods:** Aim of the study was to establish the reliability of IgG4-RD RI before and after steroid treatment compared to clinical remission and 1 year relapse.

We retrospectively studied all patients observed in our center with a diagnosis of type 1 AIP based on International Consensus Diagnostic Criteria (ICDC) from January 2012 to December 2016. IgG4-RD RI was calculated at baseline (before steroid treatment - time 0), 1 month after the beginning of the treatment (time 1) and at the end of steroid therapy (time 2). We excluded patients who did not undergo MRI and serum IgG4 dosage at any time.

**Results:** 33 patients (27 males, 6 females, mean age 60.2±17.2 years) were included. IgG4-RD.

RI was 8.9±4 at baseline, 2.5±3.4 at time 1 (p<0.0001 vs. time 0), and 4.5±3.9 at time 2 (p=0.029 vs. time 1). IgG4-RD RI was higher at time 0 in 14 patients who relapsed within 1 year (10.9) vs. 19 who did not (7.4) (p=0.009). This difference was not observed at time 1 (3.1 vs. 2.1; p=ns), but it was again documented at time 2 (7.1 vs. 2.5; p=0.002). Serum IgG4 levels were similar at any time in patients who relapsed and in those who did not.

**Conclusion:** IgG4-RD RI is a useful tool for the management of patients suffering from IgG4-RD, especially for the early detection of disease relapse within 1 year. Its levels seem to correlate with disease activity, whereas serum IgG4 levels are not associated neither with disease activity nor with the risk of disease relapse. Prospective studies with larger cohorts of patients are needed to confirm our data.

**Introduction:** The timing and frequency of Branch Duct Pancreatic Intraductal Mucinous Neoplasms (BD-IPMN) malignant progression is unknown. Knowledge of predictive features of advanced histology is fundamental in BD-IPMN management (as an indication for resection surgery). In addition to the American Gastroenterological Association (AGA) guidelines, it was recently published the Fukuoka (2017) and the European Study Group on Cystic Tumors of the Pancreas (ESGCTP, 2018) recommendations. **Aims & Methods:** We aimed to compare the diagnostic yield between AGA, Fukuoka and European recommendations in the prediction of advanced histology features in patients with BD-IPMN.

For this, we performed a retrospective analysis of the surgical referral criteria according to the previous mentioned guidelines in the cases of BD-IPMN submitted to surgical resection in a tertiary center between 2010-2018. Advanced Histology was defined by the presence of either high grade dysplasia or adenocarcinoma in the surgical specimen.

**Results:** We reviewed 54 cases (mean age 63.9 ± 14.6 years, 67% were female). Two-thirds of the lesions were diagnosed incidentally, with a mean diameter of 32.3 ± 15.8 mm. After surgical resection, 17 lesions (31.5%) met criteria for advanced histology.

The Fukuoka and AGA guidelines presented a similar probability ratio for the presence of advanced histology features (Fukuoka: OR 26.81, p < 0.01; AGA: OR 29.87, p < 0.01).

The presence of a relative or an absolute criteria of the European guidelines presented the highest sensitivity for the diagnosis of advanced histology between the three guidelines (Fukuoka 76.5%, AGA 82.4%, ESGCTP 100%), with the lowest positive predictive value (PPV) (Fukuoka 76.5%, AGA 74.7%, ESGCTP 50%).

When considering only the presence of an absolute criteria for surgical resection, European guidelines had greater specificity, PPV and odds ratio (sensitivity 52.9%, specificity 97.3%, PPV 90%, OR 40.5, p < 0.01). However, it also had the higher number of "false negatives" results (Fukuoka n = 4, AGA n = 3, ESGCTP n = 8).

All cases with European absolute criteria also presented with AGA and Fukuoka criteria for surgical resection.

**Conclusion:** The new European criteria presented the highest specificity for the presence of advanced histology features in the surgical specimen. The combination of the European guidelines criteria with Fukuoka or AGA criteria allowed the optimization in sensitivity/PPV of the European guidelines absolute criteria.

**Introduction:** Intraductal papillary mucinous neoplasms (IPMNs) of the pancreas are being increasingly detected on an incidental basis given the widespread use and availability of cross-sectional imaging. Given the increased risk of metachronous development of pancreatic cancer, the recommendations for follow-up pancreatic imaging are becoming clearer. However, the association between IPMNs and colorectal polyps and adenocarcinoma is not as clear, resulting in an uncertain recommendation for endoscopic examination.

**Aims & Methods:** This retrospective study aims to establish the prevalence of endoscopic findings such as polyps and colorectal adenocarcinomas on colonoscopy in IPMN patients. The indications for colonoscopy included screening in asymptomatic individuals and investigation of non-specific abdominal pain. This study also aims to determine whether IPMN characteristics differ according to colonoscopy findings. All IPMNs incidentally identified on cross-sectional imaging between 2007 and 2017 in a single-centre in Malta were included. For those patients who underwent a colonoscopy, endoscopic and histology findings were noted. The respective IPMN classification (branch-duct: BD or main-duct: MD), size and location were recorded.

**Results:** A total of 355 patients with an IPMN were enrolled, 72 of which underwent a colonoscopy. Adenomatous polyps found in 50% (n=36) of colonoscopies, the majority of which had low-grade dysplasia: 11% had either moderate or high-grade dysplasia. Benign hyperplastic polyps were present in 14% (n=10), while colorectal adenocarcinoma was present in 15% (n=11). Colonoscopy was normal in 21% (n=15).

	Colonoscopy Finding			
	Adenomatous Polyps	Hyperplastic Polyps	Colorectal Adenocarcinoma	Normal Colonoscopy
Frequency of finding on colonoscopy (%)	50 (n=16)	14 (n=10)	15 (n=11)	21 (n=15)
Average age (min-max)	70; (58-85)	66; (55-80)	69; (49-84)	67; (54-86)
Male:Female ratio	1.4:1	1.5:1	1.2:1	1:2
IPMN classification	86% BD-IPMNs; 8% MD-IPMNs; 6% Mixed-IPMNs	100% BD-IPMNs	100% BD-IPMNs	100% BD-IPMNs
Average IPMN size (mm); (min-max)	16; (5-46)	12; (5-21)	18; (7-50)	12; (5-23)
IPMN location - head & neck of pancreas (%)	50 (n=18)	60 (n=6)	64 (n=7)	73 (n=11)
IPMN location - body of pancreas (%)	31 (n=11)	0 (n=0)	27 (n=3)	0 (n=0)
IPMN location - tail of pancreas	19 (n=7)	40 (n=4)	9 (n=1)	27 (n=4)

### [IPMN Characteristics According to Colonoscopy Finding]

All IPMN patients with a colonoscopy revealing colorectal adenocarcinoma underwent follow-up imaging (staging and monitoring response to treatment). No change in IPMN size was noted over an average follow-up period of 22 months. 46% (n=5) of adenocarcinomas were located in the caecum and ascending colon, 9% (n=1) in the transverse colon, 18% (n=2) in the descending and sigmoid colon, whilst 27% (n=3) were present in the rectum.

**Conclusion:** The diagnostic yield of a colonoscopy for an adenomatous polyp or adenocarcinoma in a patient with IPMN is around 65% in our cohort of patients. The IPMNs in these patients tend to be of a larger size when compared to those with a normal colonoscopy or benign hyperplastic polyp. Female IPMN patients are twice as likely to have a normal colonoscopy when compared to males. The location of the IPMN itself does not vary significantly between the different groups. These findings are derived from

a retrospective study and hence are subject to bias, however, given the fact that both colorectal adenocarcinomas and IPMNs are epithelial neoplasms within the gastrointestinal tract, a possible association between the two entities remains to be investigated further with prospective studies. At present, recommendations for colonoscopy remain based on conventional practice in gastroenterology.

**Contact E-Mail Address:** sandrarfaias@hotmail.com

**Introduction:** Pancreatic cystic lesions (PCLs) are frequent findings frequently require repeated imaging surveillance. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA and cytology in pancreatic cystic fluid (PCF) is an accurate diagnostic method. Current guidelines recommend EUS-FNA in PCLs with at least one of these worrisome features (size ≥ 3 cm, mural nodule < 5 mm, main duct dilation 5-10 mm). The value of pancreatic cystic fluid (PCF) analysis in small PCLs is not clear.

**Aims & Methods:** To evaluate if patients with PCLs < 3 cm, submitted to EUS-FNA for cystic fluid analysis with CEA, amylase and cytology, had adequate cyst classification and an alteration in clinical decision.

**Methods:** Retrospective analysis of a EUS database including 167 patients with PCLs < 3 cm evaluated by EUS from 2007-16, of which 115 had additional FNA performed for PCF analysis. Clinical, imaging, PCF features (cytology, CEA level, amylase), and clinical decision were prospectively registered. We defined two groups of lesions, Group A (without mural nodule/mass) and Group B (with mural nodule/mass).

**Results:** In 115 patients, 65% were females, with a mean age of 63 ± 12 years old (33-86), and a mean follow-up time of 37±30 months (6-134). Cyst location in: head/body/tail/multiple: 45/42/23/5. Mean cyst size=19±6 mm, with percentage of cysts by size (mm): < 10/10-20/>20 in 8.7%/48.7%/42.6. Mass/mural nodule present in 27% (31/115) of PCLs. PCF analysis, with CEA level < 5/5-192/>192 in 18.2%/42.4%/39.4%, amylase < 250 in 40%, and with cytology acellular/benign or inflammatory/LGD/malignant or atypical or NET, in 65%/17%/3%/15% of PCLs. Strategy before EUS-FNA: Imaging surveillance/surgery/other: 71%/18%/11%. Strategy after EUS-FNA: Stop imaging surveillance/imaging surveillance/surgery/other: 6%/66%/17%/11%. A total of 19 patients, were referred for surgery, including 10 in Group A and 9 in Group B. Surgical pathology diagnosis (Group A + Group B): PDAC (0+1), IPMN-ADC (1+1) + NETs (2+0), IPMN (3+3), MCN (1+1), SCA (2+2), lymphangioma (1+0), pseudocyst (0+1), what corresponds to 3 vs 2 malignant, 4 vs 4 pre-malignant cysts, and 3 vs 2 benign cysts in Groups A and B, respectively. CEA was < 5 ng/mL in 20% and 14% of patients in Groups A and B, respectively. Comparing the group of patients referred for surgery with other patients, there was a statistically significant difference with a positive cytology and presence of a mural nodule or mass in the surgery group, but no significant differences in age, cyst size, and presence of septations or CEA level between groups. In Group A, older age and malignant/suspicious cytology but not size, CEA or amylase level in PCLs were related with a malignant final diagnosis and in Group B only a positive cytology correlated with a malignant final diagnosis. In Groups A and B, 29% and 22% of PCLs referred for surgery were malignant, corresponding to 3/84 (3.6%) in group A and 2/31 (6.5%) in Group B.

**Conclusion:** EUS-FNA in small PCLs (< 3 cm) allows cytological confirmation of malignancy prior to surgery, even in pancreatic cysts without worrisome features (mural nodule or mass) and it should not be delayed in small cysts because 26% of surgical specimens were malignant lesions. On the other hand, low CEA (< 5 ng/mL) occurred in about 1 in every 5 patients, with a possible opportunity to stop surveillance, particularly in PCLs without mural nodules, but in clinical practice surveillance stopped for 6% of patients only.

**Disclosure:** Nothing to disclose

## P1500 PANCREATIC CYSTS: DOES EUS-FNA ADDS VALUE OVER EUS MORPHOLOGY AND MRI? EXPERIENCE OF A TERTIARY-CARE ACADEMIC MEDICAL CENTER

Oria L., Pizzala J., Rivera Flores J., Villaverde A., Pasqua A., Abecia V., Marcolongo M.  
*Hospital Italiano de Buenos Aires, Gastroenterology, Buenos Aires, Argentina*

**Contact E-Mail Address:** ines.oria@hospitalitaliano.org.ar

**Introduction:** Endoscopic ultrasound (EUS) and magnetic resonance imaging (MRI) are valuable tools in the assessment of cystic pancreatic lesions (CPLs). However, achieving a preoperative diagnosis of CPLs still remains a challenge. EUS-guided fine needle aspiration (FNA) provides a method to obtain cyst fluid for analysis to gain additional information.

**Aims & Methods:** The aim of our study was to compare the concordance between the diagnosis of the cyst by FNA, with that obtained by two diagnostic imaging methods (EUS morphology and MRI). In addition, evaluate if EUS-FNA offered any benefit in cases of inconclusive MRI.

We performed a retrospective analysis of a prospectively collected database at a tertiary-care academic medical center between January 2015 and December 2018. All patients who were referred for EUS were reviewed, and patients with diagnosis of pancreatic cysts were included. Imaging, pancreatic cyst fluid (PCF) and follow-up were analyzed. Cysts were classified as mucinous or non-mucinous based on any of the following parameters: 1) PCF was grossly mucinous on examination (string sign positive) 2) positive cytology 3) CEA level was >192 ng/mL.

**Results:** A total of 2238 EUS were performed during the study period and 319 of them had a final diagnosis of pancreatic cysts (70% women, mean age 64.46 +/- 13.35 SD). The most frequent indication was surveillance of already known lesions (56%) and inconclusive findings in previous images (32%). The most frequent cystic lesions were IPMN 2 and serous cystic neoplasms (50% and 17% by EUS and 53% and 17% by MRI). FNA was performed on 139 cysts (37%), according to the presence of suspicious signs of malignancy, or at the request of the attending physician. From 139 FNAs, 62 were diagnosed as mucinous by PCF. The agreement between the diagnosis of the cyst by FNA, with that obtained by EUS morphology was 89.2% (Kappa 0.78,  $P < 0.001$ ). The concordance between the diagnosis of the cyst by FNA and that obtained by MRI was 72.66 (Kappa 0.41,  $P < 0.001$ ). In the correlation with the images, of the 62 patients with mucinous cysts, 55 had a diagnosis of mucinous by EUS morphology (88% CI 95% 78.1-95.3), while only 27 had mucinous diagnosis by CRMN (43.5% CI 95% 31-56.7).

From the 319 patients with pancreatic cysts 60 (18.8%) had inconclusive results on MRI and EUS morphology was able to make a diagnosis in 31 of them. When we analysed the 139 punctured cysts, MRI was indeterminate in 40 patients and FNA diagnosed 36 of the 40 patients (90%): 13 mucinous, 18 serous, 4 cystic neuroendocrine tumors (NET) 1 pseudocyst.

**Conclusion:** In our study, EUS with or without FNA was superior to MRI specially in cases of inconclusive MRI.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** robbie.valente@gmail.com

**Introduction:** Intraductal papillary mucinous neoplasms (IPMNs) are increasingly considered "the polyps of the pancreas", possibly harboring several degrees of cellular atypia up to invasive cancer. If high-grade dysplasia/cancer is suspected, the patient should be considered for surgical resection. No diagnostic tool can preoperatively predict the degree of dysplasia and, on the contrary of other cancer types, no chemoprevention is available to slow progression and cancer related death. Aspirin (ASA), ACE Inhibitors/Sartans (ACEI/ARB) and Statins (STAT) are widely used in the setting of primary and secondary cardiovascular prevention. Such drugs seem to play a role in modulating incidence and prognosis of different type of tumors such as colon cancer. Such drugs have been suggested to possibly influence also pancreas cancer incidence and prognosis by inhibiting respectively COX 1-2, VEGFR and MAPK cascades. No study has previously evaluated their effect on operated IPMNs.

**Aims & Methods:** to evaluate the effect of ASA, ACEI/ARB and STAT on cancer related death in a cohort of operated IPMNs patients.

**Results:** single-center retrospective cohort study on prospectively collected patients operated for pancreatic IPMN. Known risk factors for PDAC and exposure to the target drugs were retrospectively collected. Chi-square, t-test, univariate and multivariate logistic and cox hazard regression analysis were applied when needed.

Results, among 274 operated IPMNs patients, 210 were included in the final analysis, 47.61% males. ASA, ACEI/ARB and STAT were used respectively in 29.18%, 51.90% and 36.84% of cases. At univariable cox hazard regression analysis ASA users displayed a borderline significantly higher risk of cancer related death HR 2.11 (0.90-4.94, 95% CI,  $p=0.08$ ) while STAT and exclusive ACEI/ARB users did not (respectively HR= 0.77, 95% CI 0.32-1.89,  $p=0.58$  and HR= 1.18, 95% CI 0.49-2.82,  $p=0.69$ ). At multivariable cox hazard regression analysis adjusted for sex, age, clinical factors associated with both pancreas cancer and cardiovascular risk (such as smoking, diabetes, first degree family history, overweight/obesity and elevated Ca19.9) ASA users were confirmed to be associated with increased risk of cancer related death (HR=2.70, 95% CI 1.10-6.59,  $p=0.02$ ).

**Conclusion:** The use of ASA but not STAT and ACEI/ARB is associated to cancer related death after surgical resection for pancreatic IPMNs. Further studies are needed to investigate if this association is the result of an underlying pathophysiologic mechanism or the result to a common and yet unknown risk factors exposure.

**Disclosure:** Nothing to disclose

## P1503 VON HIPPEL-LINDAU (VHL) SYNDROME - PRESENTATION AND PANCREATIC FINDINGS OF OUR CASE SERIES

Duman D.G., Keklikkiran Ç., Kani H.T., Demirtaş C.&  
*Marmara University School of Medicine, Gastroenterology, Istanbul, Turkey*

**Contact E-Mail Address:** drdenizduman@yahoo.com

**Introduction:** Von Hippel-Lindau (VHL) disease is a rare autosomal dominantly inherited familial syndrome with an incidence of 2-3 cases per 100,000 population. This disease is associated with a high morbidity and mortality involving different organs and have varying phenotypes from family to family. Central nervous system, retina, kidneys and pancreas are the main organs affected by the disease. Pancreatic lesions may range from benign cystic lesions to malignant solid neoplasms. The discovery of any of the syndrome components should raise suspicion of this disease and other organ involvements should be investigated.

We present seven cases of Von Hippel Lindau syndrome evaluated in our pancreas clinic.

**Aims & Methods:** We present seven cases of VHL disease who were admitted to our pancreas clinic between 2008 and 2018. Three of the seven patients referred to us by neurosurgery department following the cranial hemangioblastoma diagnosis. Three patients already had a family history of VHL disease in their first or second degree relatives. One patient was referred to us due to the pancreatic cystic lesions incidentally diagnosed with transabdominal ultrasound and endoscopic ultrasound (EUS) showed multiple cysts in pancreas varying in size.

**Results:** In our case series, all the patients were female and they were evaluated using a linear array EUS prob. Most common pancreatic manifestation was multiple cysts with clear fluid content without any solid component or debris or calcification in 6/7 patients. Cysts were scattered almost all parts of the organ. Their highest diameters range from 21 to 51 mm. One patient had side branch intraductal papillary mucinous neoplasm (IPMN) with solid components. None of the cases had any pancreas related mortality throughout our follow up period that range from 6 months to 10 years. Their age on application to our pancreas clinic range from 28 to 61 years. One patient had a history of recurrent acute pancreatitis while the rest of them were asymptomatic regarding pancreatic disease. 3/7 patients had accompanying renal cysts.

**Conclusion:** The hemangioblastomas of the CNS are the most frequent lesions in VHL disease seen in 60 - 84% of the cases while it was diagnosed in 42% of patients in our series. The average age of diagnosis is 29 years, mostly presented as single tumor (58%). Multiple tumors are always associated with the VHL syndrome. Pancreatic cysts are the most common form of presentation in the VHL syndrome. Pancreatitis and pancreatic insufficiency are rare complications. In our series only 1 patient was symptomatic with recurrent pancreatitis history. The identification of the VHL is important as the syndrome cause high risk of complications that can be avoided with a proper diagnosis and early treatment. Early recognition of unaffected family members of patients via genetic testing has contributed to the improved prognosis of these patients. Nevertheless, our results showed that cysts constitute main pancreatic finding and they live uneventful with regard to their pancreatic lesion. One side branch IPMN case in our study represent an unusual pancreatic manifestation of VHL disease. Therefore, it is wise to avoid unnecessary cyst sampling or drainage attempts in VHL disease patients as those interventions may pose risk of infection, hemorrhage etc. to the patient unless the suspicion of malignancy is positive.

## **P1504** IMPACT OF POST-OPERATIVE INFECTIOUS COMPLICATION ON HEMATOGENOUS LIVER METASTASIS AFTER CURATIVE RESECTION FOR GASTRO-INTESTINAL CANCERS: ESPECIALLY IN TERMS OF PRE-METASTATIC NICHE FORMATION THROUGH IMMUNE-THROMBOSIS IN THE LIVER

Ohta T.

Kanazawa University Hospital, Department of Gastroenterological Surgery, Kanazawa, Japan

**Contact E-Mail Address:** ohtat@staff.kanazawa-u.ac.jp

**Introduction:** Post-operative infectious complications including anastomotic leakage are well known to increase hematogenous liver metastasis and long-term mortality after curative resection for gastro-intestinal cancers. Many strong innate immune cells including Kupffer, NK, NKT, and  $\gamma\delta$ T cells can exist in the liver and eliminate circulating tumor cells (CTC). However, liver metastasis often occurs in such a situation and not much is known about the mechanism of immune escape of cancer cells.

**Aims & Methods:** We investigated the crucial mechanism of immune escape of cancer cells in the liver. First, in vitro experiment, we co-cultured human pancreatic cancer cell line, BxPC-3 (CD44v and epithelial phenotype) or BxPC3 treated with 10 nM TGF- $\beta$  (CD44s and mesenchymal phenotype) with activated platelets from both human and mouse, in order to clarify the molecular mechanisms of interactive cell to cell adhesion manner between cancer cells and activated platelets, because it is well known that activated platelets can express p-selectin on the cell surface and can adhere to CD44s, a ligand of p-selectin.

Next, in vivo experiment using immuno-competent mice (n=10), we examined whether LPS (1 mg/kg)-mediated intraperitoneal infection could induce neutrophil extracellular trap (NETs) in the liver sinusoid and form the immuno-thrombosis cooperatively with activated platelets. In addition,

24hrs after intraperitoneal injection of LPS (1 mg/kg) in immune-competent mice (n=20), BxPC3 xenografts (n=10) or BxPC3 treated with 10 nM TGF- $\beta$  (n=10) were transplanted intrasplenically.

Then, each mouse was sacrificed at each time point of 10 min and 90 min after transplantation of xenografts and subjected to the pathological examinations.

**Results:** In vitro experiment, numerous activated platelets from both human and mouse could be adherent to BxPC3 treated with TGF- $\beta$ , but not much adherent to parental cell line BxPC-3. In vivo experiment using immune-competent mice, the heterogeneous NETs formation in the liver sinusoid was found in LPS group (n=5), although the liver was not the organ of surgical site infection. Numerous activated platelets were also present around NETs. However, in saline group (n=5), NETs were not found in the liver. In addition, in mouse model of transplanting parental cell line BxPC-3 xenografts intrasplenically (n=10), these xenografts were entirely eliminated by the innate immune surveillance at the time point of 90 min after transplantation, although xenograft cancer cells were present in the liver at the time point of 10 min after transplantation. In contrast, some clusters of BxPC-3 treated with 10 nM TGF- $\beta$  were surprisingly found to be vigorous in the liver at the time point of 90 min after transplantation and these xenografts were surrounded by numerous activated platelets even in immune-competent mice (n=5).

**Conclusion:** We demonstrated that intraperitoneal injection of LPS could induce NETs in the liver sinusoid and form the immuno-thrombosis cooperatively with activated platelets, resulting in the formation of pre-metastatic niche in the liver through a lot of alarmin which were well known to be released from NETs and activated platelets, and have a function to recruit myeloid derived suppressor cells (MDSC) from the bone marrow. In addition to such a pre-metastatic niche formation as the "soil", the induction of epithelial mesenchymal transition (EMT) of cancer cells was considered to be necessary as the "seed" in order to preferably adhere to the activated platelets and escape the innate immune surveillance of the liver as a first step of hematogenous liver metastasis.

**Introduction:** RINT-1 (RAD50-interacting protein 1) is a multifunctional protein playing a role in cell cycle regulation, genomic stability, telomere maintenance, ER-Golgi trafficking and autophagy. Beside facilitating cellular homeostasis, rare missense mutation found in RINT-1 and overexpression of RINT-1 were associated to increase the risk of development of different kind of tumors including breast cancer, colorectal cancer, and Lynch-syndrome type cancers.

**Aims & Methods:** To characterize more in details the mechanisms of RINT-1 regulation and to ultimately identify RINT1-dependent pathways that could be targeted in PDAC, an extensive interaction study through yeast-two hybrid assay and mass spectrometry was preliminary performed.

**Results:** We discovered hundreds of new RINT1-interaction partners including E3 ligases interacting with RINT-1 allowing a better understanding of RINT-1 biological function. In addition, we identify several post-translational modifications including ubiquitination and sumoylation and demonstrated that ubiquitination is a key regulator of RINT-1 stability and biological function.

Hereby, we show that RINT-1-depletion in PDAC cell lines leads to severe growth defects in vitro and in vivo associated with massive Golgi fragmentation and G2 cell cycle arrest followed by ER-stress and autophagy. Complete collapse of cellular homeostasis finally results in activation of apoptosis. In addition, subcutaneous xenografts showed strong infiltration of B220+ immune cells in RINT-1-deficient tumors.

**Conclusion:** These data suggest that RINT-1 homeostasis is essential for PDAC survival and represents therefore a putative therapeutic target. Altogether, these data reveal the key role of RINT-1 in PDAC homeostasis.

**Introduction:** Cell bioengineering approaches not only hold great promise to replace and regenerate dysfunctional tissue for improved life quality of the diseased patient but may also provide more sophisticated disease models. Engineering approaches to build human pancreatic tissue resembling acinar, ductal and endocrine tissue have been hampered by the complexity of the pancreas. Human pluripotent stem cells (PSCs) may provide the appropriate bioengineering platform for developmental and biomedical studies due to their capability to differentiate into every cell type in the human body.

However, PSCs typically yield heterogeneous population, while certain disease models require homogenous populations. Our initial protocol was powered to generate virtually pure cultures of human pancreatic progenitor cells followed by spontaneous differentiation in a 3D-culture environment to allow acinar ductal commitment (Hohwieler, GUT, 2017). Here, we have implemented signals controlling embryonic lineage fate bifurcations to efficiently yield the desired cell types through exclusion of alternate fates.

**Aims & Methods:** Here, we have implemented signals controlling embryonic lineage fate bifurcations to efficiently yield the desired cell types through exclusion of alternate fates: Specifically, we applied signaling molecules and growth factors inducing ductal cells, while inhibiting the respective counter lineage with inhibitors. Afterwards, we genome edited human PSCs to specifically design the core machinery of the pancreatic cancer genome. Orthotopic transplantation was additionally incorporated into the experimental work flow.

**Results:** This approach yields virtually pure pancreatic duct-like cells generated from human PSCs resembling key features of adult human pancreatic ducts: A robust test battery including functional Carbanhydrase and CFTR activity and homogenous ductal marker expression underpinned ductal identity. Transcriptional profiles of engineered ducts match the one of human mature ducts. In line orthotopic transplantation reveals human untransformed ducts in the murine host. Pluripotent stem cells armed with oncogenic KRAS were similarly differentiated to the ductal lineage followed by oncogene activation *in vitro* and *in vivo*. Here, mutant KRAS alters ductal organoid polarity as early sign of dysplastic growth *in vitro*, followed by the generation of moderately differentiated human PDAC *in vivo*.

**Conclusion:** Summarized, this novel and unique differentiation platform generates human untransformed ducts allowing modelling of plasticity, dysplasia and cancer formation in a human and genetically defined background in the pancreas. Thereby, we also show that human ducts are indeed permissive to generate human PDAC. Tailored genome editing strategies mimicking the mutational make-up of human PDAC will open novel opportunities to provide a unique and valuable human PDAC model.

**Disclosure:** Nothing to disclose

## P1507 THE ROLE OF MMP9 AND HIF1 EXPRESSION IN TUMOR-INFILTRATING LYMPHOCYTES (TIL) IN PANCREATIC DUCTAL ADENOCARCINOMA (PDAC)

**Contact E-Mail Address:** mario.capasso@studenti.unipr.it

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) has high invasiveness, tendency to locally infiltrate and to show nodal and distant metastasis.

MMPs' overexpression is frequently associated with high invasiveness related to ECM degradation. Also HIF1 overexpression, caused by hypoxia adaptation, is involved in malignant behavior.

**Aims & Methods:** Aim of this study is to explore the relationship between MMP9 and/or HIF1 expression and grading, nodal metastasis, perineural and angiolymphatic invasiveness.

Based on records from Parma's Department of Pathology, a database was created collecting a series of 73 surgical samples of PDAC, from 2007 to 2017. On these samples an histological evaluation was performed considering grading, nodal metastasis and perineural and angiolymphatic invasiveness. In addition, to investigate MMP9 and HIF1α histological expression, an immunohistochemical evaluation was carried out. The positivity was evaluated as Tumor-Infiltrating Lymphocytes (TIL) considering three grades observing the number of cells/high power field (TIL1< 30/HPF 40x; TIL2=30-60/HPF 40x; TIL3>60/HPF 40x).

**Results:** In the assessment of MMP9, TIL1 was 38 (52.1%), TIL2 19 (26%) and TIL3 16 (21.9%).

Sorting by tumor grading, 13 out of 16 (81.25%) TIL3 were G3 and all G1 samples were TIL1 (p=0.03). Perineural infiltration was shown in 55.2% of TIL1, 73.6% of TIL2 and 81.25% of TIL3; angiolymphatic invasiveness was shown in 26.3% of TIL1, 57.8% of TIL2 and 62.5% of TIL3 (p=0.014). Nodal metastasis were detected in 36.8% of TIL1, 57.9% of TIL2 and 68.7% of TIL3 (p=0.06).

In the achievement of HIF1α, TIL1 was 29 (39.7%), TIL2 21 (28.7%) and TIL3 23 (31.5%).

Sorting by tumor grading, there were no statistical significance because all the gradings were equally distributed. Perineural infiltration was shown in 27.5% of TIL1, 52.3% of TIL2 and 52.1% of TIL3; angiolymphatic invasiveness was shown in 48.2% of TIL1, 71.4% of TIL2 and 82.6% of TIL3 (p=0.01). Nodal metastasis was in 31% of TIL1, 52.3% of TIL2 and 69.5% of TIL3 (p=0.03).

Moreover, the more MMP9 and HIF1 positivity increase, the more malignant pattern such as perineural and angiolymphatic infiltration and nodal metastasis can be detected.

**Conclusion:** The results show that TIL evaluated both with MMP9 and HIF1 could exert a relevant role in neoplastic invasiveness phenotype, in particular considering perineural and angiolymphatic infiltration and tendency to nodal metastasis. Finally, MMP9 and HIF1 both expressed could characterize a more malignant phenotype.

**Disclosure:** Nothing to disclose

## P1508 ANGIOGENESIS ASSESSMENT OF PANCREATIC ADENOCARCINOMA BY CONFOCAL LASER ENDOMICROSCOPY

**Introduction:** Pancreatic cancer (PC) represents one of the major therapeutic challenges because most of the patients are diagnosed in an advanced stage, when available therapies barely influence the overall survival rate. In PC the vascularization is characterized by a high microvascular density and poor perfused vessels with heterogenous distribution. Confocal laser endomicroscopy (CLE), with various miniprobe available is accessible tool for different lesions providing a live diagnosis.

**Aims & Methods:** Angiogenesis assessment in pancreatic adenocarcinoma (PDAC) by fluorescently labelled antibodies with confocal laser endomicroscopy on fresh harvested samples immediately after surgery.

**Materials and method:** Ten consecutive patients diagnosed with PDAC following fine needle aspiration - endoscopic ultrasound underwent curative therapy with tumor resection. Fresh specimens from both normal and tumor tissue were washed in saline solution and incubated for one hour in the dark at 37 °C, with Alexa-Fluor 488 anti-CD105/Endoglin antibody (mouse anti-human IgG2a, Exbio Prague, Czech Republic). And CLE imaging was performed to assess the microvascularization in an ex vivo setting by direct contact with the specimen. We all tested mesothelin as a potential marker to differentiate between normal and tumor pancreatic tissue.

All aquired images were assessed with a dedicated processing software to obtain a Z projection of confocal serial stacks. Next we measured the vascular density and vessel diameters within  $50 \mu\text{m} \times 475 \mu\text{m}$  rectangular regions previously chosen. We also compared the results with classic immunohistochemistry technique.

**Results:** CD105 expression on CLE was present within PDAC samples with a microvascular density of  $13.56 \pm 6.88$  compared to normal pancreatic tissue  $1.1 \pm 0.857$  ( $p < 0.001$ ). Mesothelin was clearly proved to be present in every PDAC samples suggesting a potential direct target for future oncologic therapies.

**Conclusion:** This pilot study proves that CLE targeted CD105 for tumoral vascular network might represents a potential tool for future studies regarding PDAC neoangiogenesis and future therapies.

**Disclosure:** Nothing to disclose

## P1509 THE OBESTATIN/G-PROTEIN COUPLED RECEPTOR 39 (GPR39) SYSTEM IS INVOLVED IN THE PROLIFERATION OF PANCREATIC CANCER CELL LINES

**Introduction:** Obestatin is a 23-aminoacid peptide derived from preproghrelin, was first isolated from stomach in 2005 and binds to the GPR39 receptor. Our group has described obestatin/GPR39 expression in human healthy pancreas, as well as in pancreatic adenocarcinomas. These studies support the hypothesis that this endogenous system plays a regulatory role in the physiology of the exocrine pancreas and in the mechanism of the pancreatic regeneration. In addition, this system seems to be involved in the pathogenesis and/or pancreatic cancer prognosis.

**Aims & Methods:** The objective of this study is to evaluate the involvement of this system in the proliferation of cell lines of human pancreatic cancer with different degrees of differentiation: PANC-1, which comes from an undifferentiated carcinoma of ductal origin; RWP-1, a well/moderately differentiated ductal adenocarcinoma; and BxPC3, derived from a primary adenocarcinoma, which in nude mice produces well/moderately differentiated adenocarcinomas to poorly differentiated.

In vitro study of the obestatin/GPR39 system expression by using immunocytochemical techniques in tumor the cell lines PANC-1, RWP-1 and BxPC3. In addition, cell proliferation assays were performed after obestatin treatment (100 and 200 nM) by BrdU and manual counting. 10% FBS was used as positive control.

**Results:** The obestatin/GPR39 system was expressed intensely in the three pancreatic cancer cells. No immunoreactivity was observed in negative controls incubated without primary antibody. Obestatin administration (100 and 200nM) provoked a mitogenic effect in the RWP-1 cell line ( $46.31 \pm 3.45\%$  over control;  $p < 0.05$ ) although less pronounced than in the PANC-1 cell line at 48 h ( $64.12 \pm 2.64\%$  over control;  $p < 0.05$ ). In the case of BxPC3, no stimulation of proliferation was observed ( $-1.05 \pm 3.32\%$  over control).

**Conclusion:** This study offers two main findings: 1) the obestatin/GPR39 system was intensely expressed in the human pancreatic tumor cell lines; 2) exogenous obestatin increased the proliferation of these cell lines. The differences observed in the obestatin mitogenic effect may be due to the expression differences of key molecules in the signaling pathway of the obestatin/GPR39 system, such as the EGF receptor. The obtained results showed that the obestatin/GPR39 system was involved in the proliferative processes of pancreatic cancer.

**Introduction:** The role of immune cells on the pancreatic cancer microenvironment has increasingly gained attention over the past decade, however, whether the invasion of nerves by cancer cells is regulated by the presence of tumor-infiltrating leucocytes is still unexplored.

**Aims & Methods:** In this study we aim to uncover novel immune-mediated pathways in the pathogenesis of neural invasion in pancreatic cancer.

We performed a comprehensive histopathological analysis of the intratumoral and perineural immunological infiltration in a cohort of 40 PDAC-patients through immunohistochemical and double immunofluorescence stainings and automated quantification algorithms.

Furthermore, using in vitro migration assays we evaluated the influence of natural killer (NK) cells and myeloid derived suppressor cells (MDSCs) on the chemoattractive gradient towards nerves and analyzed it via digital time-lapse microscopy.

**Results:** Among the analysed immune cell types, the intratumoral density of MDSCs ( $p = 0.00029$ ), NK cells ( $p < 0.0001$ ) and CD8+ T ( $p = 0.0003$ ) cells showed the highest correlation with neural invasion. In the perineural niche, the presence of neural invasion was associated with the infiltration by MDSCs ( $0.00005562 \pm 0.00007588$  vs  $0.00002839 \pm 0.00003435$ ,  $p = 0.0009$ ) and NK cells ( $0.0001881 \pm 0.00003231$  vs  $0.00007007 \pm 0.00001280$ ,  $p = 0.0005$ ). Mechanistically, the migratory behaviour of pancreatic cancer cells towards neurons was significantly enhanced by the interaction with MDSCs ( $-0.004685 \pm 0.001074$  vs  $-0.1188 \pm 0.01002$ ,  $p < 0.0001$ ) and NK cells ( $0.09274 \pm 0.01496$  vs  $-0.1537 \pm 0.009966$ ,  $p < 0.0001$ ).

**Conclusion:** MDSCs and NK cells raise as the key regulators in the perineural niche promoting neural invasion, constituting therefore attractive targets for immunotherapy aiming to decrease tumor-associated pain and cancer spread.

**Disclosure:** Nothing to disclose

## P1511 SYNERGISTIC TARGETING OF DNA REPAIR PATHWAYS TO DECIPHER PARP-INHIBITOR RESISTANCE IN ATM-DEFICIENT PANCREATIC CANCER

Perkhofer L., Gout J., Seufferlein T., Frappart P., Kleger A. Universitätsklinikum Ulm, Innere Medizin I, Ulm, Germany

**Contact E-Mail Address:** lukas.perkhofer@gmail.com

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) is today's 4th leading cause of cancer-associated death in the Western World with an increasing tendency. Thereby it relies on a core of driver mutations and dozens of passenger mutations refining a strong intratumoral heterogeneity. Ataxia-Telangiectasia Mutated (ATM) is the most frequently mutated DNA-damage repair gene and missense mutations can be found in both sporadic and familial pancreatic cancer. We previously showed that ATM levels inversely correlate with patient's prognosis and the deletion of ATM in a mouse model of pancreatic cancer (AKC) accelerates tumorigenesis, metastasis and leads to genomically instable tumours. The latter characteristic opens vulnerability for a synthetic lethal attack using Parp inhibitors.

**Aims & Methods:** However, we faced early resistance and tumour control required additional chemotherapy. In the current study, we systematically performed combinational screening for synergistic routes based on actionable perturbations in the DNA damage response to present an ATM null tailored targeted therapy at low dosage.

**Results:** Synergistic tumour impact was found upon simultaneous inhibition of Parp-, Atr-, and DNA-Pkc-signaling (termed PAD) leading to synthetic lethality in AKC cell lines *in vivo* and *in vitro*. Mechanistically, PAD lead to cytokinesis failure, replication fork stalling, Parp trapping, reversal of Atr-induced track lengthening finally leading to p53-mediated apoptosis. Chemical and genetic targeting of ATM together with PAD in human

PDAC lines and organoid cultures substantiated these data. Additionally, we elaborated consequences of Parp1 inhibitor resistance within the AKC background. Arising cell clones were aneuploid, highly genomically unstable and underwent epithelial-mesenchymal transition to boost an intrinsically program present in Atm-deficient PDAC. These features were associated with the acquisition of a multi-drug resistant phenotype caused by up-regulation of drug-transporters and de-toxification enzymes. Finally, exome-sequencing identified Drg1 loss as an additional crucial mediator in resistant cells.

**Conclusion:** Thus, we provide coherent understanding of the molecular mechanism occurring upon Atm deletion in PDAC to precisely interfere with tumor characteristic for therapeutic success in mice and men.

**Disclosure:** Nothing to disclose

**Introduction:** Based on recent studies, current guidelines recommend against routine preoperative biliary drainage (PBD) in patients with pancreatic head cancer if bilirubin levels are < 250 µmol/l. However, patients with higher bilirubin levels still undergo PBD, despite the lack of clinical studies including these patients. To evaluate the rationale for a different PBD approach in high bilirubin patients, tumor characteristics, PBD technical success- and complication rates, and postoperative complication rates were compared in patients with a bilirubin level ≥250 and < 250.

**Aims & Methods:** In this retrospective cohort study, patients diagnosed with resectable pancreatic head cancer and cholestasis (bilirubin >40) from 2008 until 2018 were identified in three centers of the Regional Academic Cancer Center Utrecht. Analyses were performed in patients with a bilirubin level ≥250 versus < 250 at diagnosis (1) and prior to PBD and surgery (2) to reflect the moment of clinical decision making (1) and the actual effect of the bilirubin level on procedural outcomes (2). Multivariable logistic regression analyses were performed to identify independent predictors of PBD complications and severe postoperative complications (Clavien-Dindo ≥3), including bilirubin level as a continuous variable.

**Results:** A total of 244 patients were included, 191 with bilirubin < 250 at diagnosis and 53 with bilirubin ≥250. PBD was performed in 64% (123/191) and 91% (48/53), respectively. Tumor characteristics did not differ between patients with bilirubin ≥250 versus < 250 at diagnosis. In patients undergoing PBD, no differences in technical success (83% vs. 81%, p=0.80) and complication rates (33% vs. 29%, p=0.60) were found between patients with bilirubin ≥250 versus < 250 at diagnosis. The use of metal stents was equal between the two groups (40% vs. 36%, p=0.66).

Ultimately, 212/244 (87%) patients underwent surgery, of which 168 patients had a bilirubin level at diagnosis < 250 and 44 ≥250. PBD was performed in 143/212 (67%) of these patients. The rate of severe postoperative complications did not differ between patients with bilirubin ≥250 versus < 250 at diagnosis (40% vs. 30%, p=0.26). In addition, when analyzing bilirubin levels ≥250 versus < 250 directly prior to PBD and surgery, no differences in PBD technical success and complications and severe postoperative complications were found. Bilirubin level at diagnosis was no independent predictor for PBD complications (OR 1.00 per 1 µmol/l, 95% CI 1.00-1.00),

nor for severe postoperative complications (OR 1.00 per 1 µmol/l, 95% CI 1.00-1.01). Also, no significant association between severe postoperative complications and PBD was found (OR 0.77, 95% CI 0.40-1.51).

**Conclusion:** Tumor characteristics, PBD technical success and complications, and postoperative complications did not differ between patients with pancreatic head cancer and a bilirubin level ≥250 and < 250. Although cautious interpretation of these data is mandatory given the retrospective nature, our study does not support a different approach regarding PBD in patients with severe jaundice and suggests omitting routine PBD in these patients either.

Moreover, the perioperative benefit of PBD in these patients should be convincing in order to compensate for the serious drainage related morbidity. Whether a subgroup of patients with pancreatic head cancer and cholestasis might benefit from PBD (e.g. in the setting of prehabilitation) needs to be further evaluated.

**Disclosure:** Nothing to disclose

## P1514 METABOLOMIC PROFILING OF PANCREATIC CANCER

**Contact E-Mail Address:** habartol@vscht.cz

**Introduction:** With biomarkers lacking specificity and local symptoms appearing late, pancreatic cancer is a silent killer. Although much effort has been invested into modern imaging methods and new treatment approaches in the last decades, the prognosis remains unfavorable, with the 5-year survival rate of only 5-7%. Therefore, intense research has been focusing on the identification of early symptoms and PC-specific markers. Several approaches have been tested, ranging from the inspection of pancreatic stellate cells to the analysis of microRNAs. As the cancerous pathology induces alterations of many essential biochemical pathways, the affected cells and tissues exhibit altered metabolism. This phenomenon may be easily inspected by metabolomics, an analytical platform with the ability to detect metabolites. Metabolites are produced by all bodily cells, thus, their analysis is usually performed using the tissue with suspected pathology or biofluids.

**Aims & Methods:** To ensure minimal invasiveness and, thereby, a minimal burden for the patient, we used blood plasma for our metabolomics study. The blood plasma is not only easy to obtain, but it also comprises the majority of metabolites produced by the whole body. In our study, the blood plasma of PC patients (stage III-IV) and healthy controls was subjected to two sets of experiments.

First, clinically recognized markers of oxidative stress related to cancerous diseases were detected and quantified. Subsequently, we performed a multi-marker screening, i.e. the identification of other metabolites that might be considered clinically significant for PC.

After initial pre-treatment (extraction, homogenization, centrifugation), the plasma samples were analyzed using high-performance liquid chromatography coupled with electrospray-ionization tandem mass spectrometry in a gradient elution program.

The clinically recognized markers were quantified after measuring their standards; the molecules resulting from the multi-marker screening were identified via Human Metabolome Database.

**Results:** We detected multiple markers pointing to oxidative stress caused by reactive oxygen species forming during cancer growth, such as ortho-tyrosine or 8-isoprostane, the levels of which were significantly elevated in the plasma of PC patients compared to healthy controls. Damage to the genetic information in DNA/RNA was indicated by higher levels of 8-hydroxy-2'-deoxyguanosine and 8-hydroxyguanosine, respectively. In the PC patients, the multimarker screening revealed enormously decreased levels of lysophosphatidylcholine, which means poor control of cell proliferation and a major disruption of lipid metabolism. Severe disturbances of lipid metabolism during PC were also illustrated by the increase in chenodeoxycholic acid and carnitine derivatives. The presence of docosahexaenoic acid and its metabolites revealed the activation of the immune system.

**Conclusion:** Apart from markers of oxidative stress, which have been previously clinically recognized for several cancerous diseases, we identified molecules that have not been connected to PC so far. Thus, we believe that metabolomic profiling may serve as a reliable platform for the identification of a panel of potential biomarkers, which would facilitate the diagnosis of pancreatic cancer.

The study was supported by the Ministry of Health of the Czech Republic (project Nr. 16-31028A).

## **P1515** PANCREATIC CANCER-DERIVED ORGANOIDS RECAPITULATE CORE FEATURES OF THE PRIMARY CANCER TO PREDICT DRUG RESPONSE

Frappart P., Walter K., Hermann P., Seufferlein T., Kleger A.  
*Universitätsklinik Ulm, Internal Medicine 1, Ulm, Germany*

**Contact E-Mail Address:** alexander.kleger@uni-ulm.de

**Introduction:** Organotypic cultures derived from pancreatic ductal adenocarcinoma (PDAC) termed pancreatic cancer organoids (PDO) recapitulate the primary cancer and can be derived from primary or metastatic biopsies. Although isolation and culture of patient derived pancreatic organoids have been established several years ago, advantages and constraints for individualized medicine have not been comprehensively investigated yet.

**Aims & Methods:** We conducted a feasibility study, systematically comparing head-to-head xenografted primary tissue and xenograft-derived organoids by rigorous immunohistochemical and molecular characterization. Subsequently, a drug testing platform has been set-up and validated *in vivo*.

**Results:** Firstly, PDAC organoids faithfully recapitulate morphology and marker protein expression patterns of the original tumors.

Secondly, quantitative proteomes from the patient-derived xenografts as well as from corresponding organoid cultures showed high concordance. Thirdly, genomic alterations as assessed by array-based comparative genomic hybridization revealed similar results in both groups.

Fourthly, we established a small-scale, pharmacotyping platform adjusted to operate in parallel considering potential obstacles such as culture conditions, timing, drug dosing and interpretation of the results.

*In vitro* predictions were successfully validated in an *in vivo* xenograft trial. Finally, the organoid phenotyping outcome was compared with the predictive value of gene mutations obtained by panel sequencing.

**Conclusion:** In conclusion, small-scale drug screening in organoids appears a feasible, robust and easy-to-handle method to allow response predictions in parallel to daily clinical routine. PDO based phenotyping faithfully reflects genotypes. Therefore, our fast and cost-efficient assay is a reasonable approach in a predictive clinical setting.

**Introduction:** The treatment options and survival of locally advanced pancreatic cancer (LAPC) have improved in recent years. However, it is unknown whether elderly patients (*i.e.*  $\geq 75$  years) have benefited from these improvements. With the ongoing aging of the patient population and an increasing incidence of pancreatic cancer, this patient group deserves more attention. This study aims to assess the influence of age on treatment and overall survival in patients with LAPC.

**Aims & Methods:** Consecutive patients diagnosed with LAPC were prospectively registered in 14 Dutch centers (April 2015 to December 2017). Patients were divided in three groups according to age ( $< 65$ , 65-74 and  $\geq 75$  years). We evaluated the influence of age on type of treatment and overall survival by using logistic regression and Cox regression analyses.

**Results:** Overall, 425 patients with LAPC were included; 163 patients (38.4%) aged  $< 65$  years, 184 patients (43.3%) aged 65-74 and 78 patients (18.4%) aged  $\geq 75$  years. Both patients aged  $< 65$  years and 65-74 years were in good condition (WHO ps 0-1 in 88.3% and 73.2% respectively) and were mostly treated with chemotherapy (87% and 81.3%). Elderly patients were in good clinical condition as well (WHO ps 0-1 in 73.2%), 49.9% was treated with chemotherapy and 43.6% received best supportive care. Median overall survival in elderly patients receiving treatment was longer as compared to those receiving best supportive care (9.0 vs 3.0 months). Multivariate logistic regression analysis demonstrated that each additional year in age is associated with a decreasing probability to receive chemotherapy (hazard ratio [HR] 0.948, 95% confidence interval [CI] 0.903-0.994,  $p = 0.028$ ). In multivariate analysis an increase in age was not associated with a decrease in overall survival (HR 1.001, 95% CI 0.987-1.015,  $p = 0.892$ ). A better WHO performance score and receiving treatment were predictors for an increased overall survival.

**Conclusion:** Elderly patients with LAPC are less often treated with chemotherapy. However, chemotherapy was associated with improved survival in elderly patients and age was not independently associated with lower survival. Therefore, treatment with chemotherapy should probably be considered more often in fit elderly patients with LAPC.

**Disclosure:** Nothing to disclose

## **P1517** PROGNOSTIC FACTORS OF UNRESECTABLE PANCREATIC CANCER BEFORE CHEMOTHERAPY

**Contact E-Mail Address:** ysk.s1231@gmail.com

**Introduction:** The prognosis of patients with unresectable pancreatic cancer is difficult to predict during the initiation of systemic chemotherapy treatment. In most cases, determining the appropriate chemotherapy drugs and dosages for each patient is challenging. Recent studies have reported that the modified Glasgow prognostic score (mGPS) and neu-

trophil-to-lymphocyte ratio (NLR), as the indices of the inflammatory response of the body and nutritional condition, are associated with cancer prognosis. However, only few studies have demonstrated the use of these indices in predicting the prognosis of patients with unresectable pancreatic cancer.

This report is a retrospective study on the prognostic factors of unresectable pancreatic cancer prior to chemotherapy.

**Aims & Methods:** In this study, 56 patients with unresectable pancreatic cancer (stages III and IV as per the General Rules for the Study of Pancreatic Cancer, 7th Edition, edited by Japan Pancreas Society) who were treated with chemotherapy from August 2010 to September 2017 were included. In accordance with the mGPS definition, we categorised the patients as follows: both high CRP ( $>1.0$  mg/dL) and low albumin ( $<3.5$  mg/dL) levels, 2 points; only high CRP level, 1 point and only low albumin level or neither of those, 0 points. We retrospectively discussed sex, age at diagnosis, performance status (PS), CRP, CA 19-9, NLR, platelet-to-lymphocyte ratio (PLR), CRP-to-albumin ratio (CAR), mGPS and overall survival. Furthermore, we predetermined the cut-off value of NLR/PLR/CAR to be 5.0/190/0.09, divided mGPS into 2 groups (0 and 1-2 points).

**Results:** The subjects included 34 men and 22 women, with a mean age of 69.1 years, at stage III/IV (13/43), PS (27/28/1/0/0) (PS = 0/1/2/3/4). Using univariate analysis for each item (sex, age at diagnosis, CRP, CA 19-9, NLR, PLR, CAR and mGPS), PLR ( $p = 0.06$ ), CAR ( $p = 0.03$ ) and mGPS (1, 2) ( $p = 0.0027$ ) were significantly different. Nonetheless, based on the results of the multivariate analysis, mGPS (1, 2) is the only independent significant factor among the 3.

**Conclusion:** These findings indicate that mGPS, prior to chemotherapy, can be a predicting factor for the prognosis of patients with unresectable pancreatic cancer.

**Disclosure:** Nothing to disclose

## P1518 ELEVATED CA 19-9 PREDICTS THE PRESENCE OF METASTATIC AORTOCAVAL LYMPH NODES AND IMPAIRED SURVIVAL IN RESECTED PATIENTS WITH BORDERLINE AND LOCALLY ADVANCED PANCREATIC CANCER

**Contact E-Mail Address:** elena.rangelova@ki.se

**Introduction:** Surgery has been shown to improve the survival of patients with borderline and locally advanced pancreatic cancer (BR-LAPC). There are technical, but no clear biologic criteria how to select which patients would benefit from resection.

**Aims & Methods:** To evaluate the impact of elevated Ca 19-9, mGPS, and positive aortocaval lymph nodes (ACLN) on survival of resected patients with BR-LAPC. Retrospective analysis from a prospectively collected database was done on all patients resected for BR-LAPC at Karolinska University Hospital between 2008-2018. AOCL were routinely sampled for staging, but did not preclude resection.

**Results:** Overall 270 patients with BR-LAPC were resected with perioperative mortality of 2.6% ( $n=7$ ). Mean age was 67 years, male:female ratio 1.1:1. Positive AOCL were found in 38 patients (14.1%) and had the strongest association with impaired survival: median, 1-3-5-year survival of 11 months, 40%, 7%, 0% and 18 months, 70%, 29%, 19%, respectively. Modified GPS 0, 1 or 2 was neither associated with the presence of positive ACLN nor survival ( $p=ns$ ). Elevated Ca 19-9  $>200$ , compared to  $\leq 200$ , showed clear association with the presence of positive ACLN (positive:negative ACLN = 26:58 versus 11:86, respectively,  $p < 0.05$ ) and impaired survival: median, 1-3-5-year survival of 15 months, 56%, 10%, 7% versus 22 months, 69%, 35%, 21% ( $p=0.0005$ ). Adjuvant, but not neoadjuvant, chemotherapy had significant positive impact on survival: 24 months, 75%, 34%, 23% versus 14 months, 55%, 21%, 12%, respectively ( $p=0.0004$ ).

**Conclusion:** Patients with BR-LAPC and elevated Ca 19-9 might need routine sampling of ACLN before decision for resection to better select who would benefit from surgery

**Disclosure:** Nothing to disclose

## P1519 EARLY ONSET PANCREATIC CANCER (EOPC): POST-OPERATIVE OUTCOME AND POSSIBLE RISK FACTORS IN A LARGE CASE-CONTROL STUDY

**Contact E-Mail Address:** vespasiano.francesca@gmail.com

**Introduction:** Pancreas cancer (PDAC) is expected to become the 2nd most common cause of cancer related death within 2030. Its occurrence is higher in the late life, with a peak of incidence in the seventh decade. Nevertheless, 10% of patients is affected at an age  $< 50$  years. Such population identifies the so called "early onset pancreatic cancers" (EOPC). Although it is known that EOPC are generally diagnosed in a more advance stage of disease and often in a metastatic status already at diagnosis, it is virtually unknown whether this poorer prognosis is the epiphenomenon of a different underlying pathophysiological mechanisms, or the result of a merely delayed diagnosis. So far few, small and heterogeneous series have investigated the prognosis in EOPC compared to non-early onset pancreatic cancer (NOPC). None of them through a strict matching for sex and stage of disease (pTNM). Additionally, most of the previous studies relied on non-surgical series describing the clinical outcomes of patients who have not undergone treatments with curative intent.

**Aims & Methods:** To investigate post-operative survival and possible risk factors worse outcome in EOPC and NOPC patients.

A case-control study on consecutive patients operated for PDAC between 2008 and 2017 at HPB Disease Unit, Karolinska Hospital, Stockholm. Data about demographics, known risk factors for PDAC, exposures, pathological information, treatment and survival were recorded. Cases: PDAC patients aged  $\leq 50$  years (EOPC). Controls: 1:5 sex and stage (pTNM) matched patients consecutively recruited in the same period, aged  $> 50$  years (NOPC). Chi square was used to analyze categorical variables, t test for continuous ones. Survival was assessed through Kaplan Meier method and statistically significant results were evaluated through univariable and multivariable Cox hazard regression analysis.

**Results:** 24 EOPC and 120 stage controls were recruited. 1.3,5 years overall survival was similar in cases and controls (respectively 70.8% vs 72.5%; 30.1% vs 28.9% and 24.1% vs 12.5%;  $p=0.63$ ). The use of adjuvant chemotherapy was confirmed to improve the outcome in both cases and controls (respectively HR=0.30; 95%CI 0.10-0.91,  $p=0.03$  vs HR 0.61; 95% CI 0.36-1.00,  $p=0.05$ ). No statistically significant difference was found regarding the prevalence of genetic syndromes, exposures and known risk factors for PDAC. At univariable cox hazard regression analysis, diabetes (HR=1.60; 95%CI 0.95-2.69,  $p=0.07$ ) and underweight (HR=5.59; 95%CI 2.01-15.51,  $p=0.0009$ ) were significantly associated to an increased risk of cancer related death in controls. Such increased risk was not confirmed in cases. At multivariable cox regression analysis underweight was confirmed to be significantly associated to an increased risk of mortality in controls (HR 4.31; 95%CI 1.51-12.30,  $p=0.006$ ).

**Conclusion:** Overall survival is similar in operated EOPC and NOPC patients. Adjuvant chemotherapy was confirmed as a factor positively influencing prognosis in both cases and controls. Metabolic and nutritional status play a role in influencing prognosis in NOPC but not in EOPC.

**Disclosure:** Nothing to disclose

## P1520 SAROPENIA AS A PROGNOSTIC FACTOR OF SURGICAL OUTCOMES FOLLOWING PANCREATODUODENECTOMY IN PATIENTS WITH PANCREATIC ADENOCARCINOMA

**Introduction:** To assess the impact of sarcopenia on the occurrence of postoperative complications and mortality after pancreatic resection in patients with pancreatic adenocarcinoma.

**Aims & Methods:** This study included 137 patients with pancreatic adenocarcinoma, who underwent pancreaticoduodenectomy in our institution in the period 2017-2018. Preoperative computed tomography (CT) was performed for all patients. Sarcopenia was quantified using two approaches: the Total Psoas Index (TPI) and the Hounsfield Unit Average Calculation (HUAC). They were measured at the level of the third lumbar vertebral body (L3).

**Results:** Sarcopenia was diagnosed in 49 (39.8%) patients using TPI. Postoperative complications occurred in 24 (48.9%) patients, in patients without sarcopenia postoperative complications occurred in 23 (31.0%) patients, ( $\chi^2 = 4.1$ ,  $p=0.04$ ). Mortality was 3 (6.1%) and 1 (1.3%) respectively, ( $\chi^2 = 0.09$ ,  $p=0.7$ ).

In 53 (38.7%) patients sarcopenia was diagnosed using HUAC. Postoperative complications occurred in 25 (47.2%) patients in the group with sarcopenia and in 19 (22.6%) patients in the group without sarcopenia ( $\chi^2 = 8.9$ ,  $p=0.003$ ). Mortality was 3 (5.6%) and 1 (1.2%) respectively ( $\chi^2 = 2.2$ ,  $p=0.1$ ).

In patients with sarcopenia determining by HUAC pancreatic fistula Grade B or C occurred in - 14 patients, delayed gastric emptying - in 3, haemorrhage - in 6, infections complications occurred in 2 patients.

In patients without sarcopenia pancreatic fistula Grade B or C occurred in - 5 patients, delayed gastric emptying - in 2, haemorrhage - in 4, infections complications occurred in 5 patients and lymphorrhea occurred in 3 patients. We did not find any significant difference in the increase of delayed gastric emptying ( $\chi^2 = 0.02$ ,  $p=0.8$ ), haemorrhage ( $\chi^2 = 0.05$ ,  $p=0.8$ ), infections complications ( $\chi^2 = 0.09$ ,  $p=2.7$ ), but the level of pancreatic fistula Grade B or C was significantly higher in patients with sarcopenia ( $\chi^2 = 0.04$ ,  $p=3.8$ ).

In patients with sarcopenia determining by TPI pancreatic fistula Grade B or C occurred in - 12 patients, delayed gastric emptying - in 2, haemorrhage - in 6, infections complications occurred in 4 patients.

In patients without sarcopenia pancreatic fistula Grade B or C occurred in - 5 patients, delayed gastric emptying - in 4, haemorrhage - in 5, infections complications occurred in 9 patients. We did not find any significant difference in the increase in the number of infections complications ( $\chi^2 = 2.9$ ,  $p=0.08$ ), delayed gastric emptying ( $\chi^2 = 0.74$ ,  $p=0.3$ ) and haemorrhage ( $\chi^2 = 0.07$ ,  $p=0.8$ ), but the level of pancreatic fistula Grade B or C was also significantly higher in patients with sarcopenia ( $\chi^2 = 4.06$ ,  $p=0.04$ ).

**Conclusion:** HUAC and TPI could be easily calculated preoperatively in patients with pancreatic cancer. Present results suggest that sarcopenia, determined by HUAC and TPI is a reliable indicator of the surgical outcome and significantly affects the level of postoperative complications and pancreatic fistula. Determination of sarcopenia can be used to improve the selection of patients with pancreatic cancer prior to resection and to predict of pancreatic fistula.

**Disclosure:** Nothing to disclose

## P1521 PANCREATIC RESECTION LEADS TO LOSS OF ADIPOSE TISSUE BUT DOES NOT INFLUENCE MUSCLE WASTING IN PANCREATIC CANCER PATIENTS

**Contact E-Mail Address:** teagjini@hotmail.com

**Introduction:** Patients with pancreatic cancer are commonly affected by a pronounced perioperative sarcopenia and cachexia, which are associated with poorer overall survival. The aim of this study is to test the impact of pancreatic resection on body composition parameters in pancreatic cancer patients.

**Aims & Methods:** Body composition parameters were measured using computed tomography (CT) images at L3 vertebral level prior to surgery (timepoint 1, T1) as well as 6 (T2) and 12 months (T3) after pancreatic resection were assessed using Slice-O-Matic® software version 4.3. Following body compositions parameters were estimated: subcutaneous adipose tissue area index (SATI), visceral tissue area index (VATI), intramuscular tissue area index (IMATI), total adipose tissue area index (TATI), as well as skeletal muscle mass index (SMAI).

Sarcopenia was defined by consensus thresholds before surgery with the cut-off points for SMI (skeletal muscle tissue area index) < 52.4 cm<sup>2</sup>/m<sup>2</sup> for male and < 38.5 cm<sup>2</sup>/m<sup>2</sup> for female patients. 248 patients with pancreatic cancer from cachexia database treated in the Department of Surgery, Klinikum Rechts der Isar, 2006-2019, were screened for this retrospective study.

From 219 resected patients with the presence of preoperative CT, only 63 patients had CTs at T1, T2, and T3. 42 (67%) of these patients were sarcopenic before surgery; 36 (57%) were sarcopenic 6 months after surgery, and 41 (65%) were sarcopenic 12 months after surgery.

**Results:** Median value of TATI decreased from 95 cm<sup>2</sup>/m<sup>2</sup> at T1 to 52 cm<sup>2</sup>/m<sup>2</sup> at T2 ( $p < 0.001$ ) and slightly increased to 62 cm<sup>2</sup>/m<sup>2</sup> at T3 ( $p < 0.001$  T1 vs. T2;  $p = 0.724$  T2 vs. T3). Median value of VATI decreased from 35 cm<sup>2</sup>/m<sup>2</sup> at T1 to 20 cm<sup>2</sup>/m<sup>2</sup> at T2 ( $p < 0.001$ ) and slightly increased to 21 cm<sup>2</sup>/m<sup>2</sup> at T3 ( $p < 0.001$  T1 vs. T2;  $p = 0.913$  T2 vs. T3). Median value of SATI decreased from 53 cm<sup>2</sup>/m<sup>2</sup> at T1 to 32 cm<sup>2</sup>/m<sup>2</sup> at T2 ( $p < 0.001$ ) and slightly increased to 36 cm<sup>2</sup>/m<sup>2</sup> at T3 ( $p < 0.001$  T1 vs. T2;  $p = 0.576$  T2 vs. T3). IMATI and SMAI did not change significantly after pancreatic resection.

**Conclusion:** Resected pancreatic cancer patients are affected by a significant adipose tissue loss 6 months after surgery, which doesn't improve until 12 months after surgery. Surprisingly, though the most of pancreatic cancer patients suffer from sarcopenia before surgery, no additional muscle wasting occurs after pancreatic resection.

**Disclosure:** Nothing to disclose

[P1523 Table 1: Comparison of decompensated cirrhotic children with relative adrenal insufficiency with and without future complications at baseline and day]

#### Aims & Methods: We aimed to study

- 1) prevalence of RAI in decompensated cirrhotic children using low dose short synacthen test,
- 2) assess the surrogatory markers of RAI [interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )] and serum high density lipoprotein (HDL), precursor of serum cortisol and
- 3) assess outcome over 180 days follow-up.

This is a prospective longitudinal observational study enrolled hemodynamically stable cirrhotic patients with ascites after excluding patients on corticosteroids, adrenal insufficiency, terminally ill, concurrent infections and shock. They were sampled for serum basal cortisol (BC), peak cortisol (PC; after 30 minutes of 1 mcg intravenous synacthen), serum TNF- $\alpha$ , IL-6 and HDL levels at D1 and D21. Delta cortisol was defined as difference between BC and PC. RAI was diagnosed as PC < 500nmol/L. Cohort was analysed in terms of severity of liver disease, previous event (hepatic encephalopathy, gastrointestinal bleeding, systemic infection and spontaneous bacterial peritonitis) in past 180 days, complications (new onset organ failures, infection and hospital readmissions) at follow-up and death.

**Results:** Prevalence of RAI on D1 was 54% in decompensated cirrhosis (n=63). Significant differences of D1-RAI patients (n=34) vs normal adrenal functions (NAF, n=29) were age (135±43 vs 119±53 mo, p=0.18), platelet count (109±63 vs 170±95  $\times 10^3/\mu\text{L}$ , p=0.003), BC (275±92 vs 517±135 nmol/L, p< 0.001), PC (356±93 vs 673±165 nmol/L, p< 0.001) and delta cortisol (90±84 vs 174±170 nmol/L, p=0.04), complications in follow up (53% vs 24%, p=0.023). D1-RAI, significant varices, hypersplenism, serum albumin, INR, PELD (pediatric end-stage liver disease) score, serum HDL were the statistically significant determinants of follow-up complications on regression analysis in decompensated cirrhotics. Independent factors on multivariate analysis for follow-up complications and mortality were PELD score and hypersplenism. RAI progressed to 61% by D21. Patients with RAI (n=34) with or without complications at follow-up were compared (table 1). In this subgroup, INR, PELD score and serum HDL were risk factors for complications and death. In RAI patients, PELD >7 predicted follow-up complications (AUC: 86%, p< 0.001, sensitivity 100%, specificity 50%) and PELD >11 predicted death (AUC: 86%, p=0.003, sensitivity 100%, specificity 50%).

**Conclusion:** Half of the decompensated cirrhotic children have RAI. RAI determines the follow-up complications. RAI patients with complications have higher PELD scores, lower HDL levels and higher mortality.

**Disclosure:** Nothing to disclose

#### P1524 SCREENING AND FOLLOW-UP OF BILIARY DYSPLASIA IN PRIMARY SCLEROSING CHOLANGITIS PATIENTS WITH DISEASE ONSET IN CHILDHOOD/ADOLESCENCE

**Introduction:** The natural history of biliary dysplasia (BD) in children and young adolescents with primary sclerosing cholangitis (PSC) is lacking.

**Aims & Methods:** Aim of this study was to report the role of endoscopic retrograde cholangiography (ERC) with systematic brush cytology (BC) for screening and follow-up of BD in this setting of patients.

**Study design:** Retrospective cohort study.

**Population, timing, area:** All patients with PSC diagnosed in childhood/adolescence between 1993-2017 at Helsinki University Hospital (HUH) were identified.

**Disease diagnosis:** PSC was diagnosed based on:

1. Elevation of liver enzymes,
2. Liver biopsy,
3. ERC. Notably, ERC with BC is performed in all the patients referred for a suspicious of PSC regardless the severity of the disease in HUH:

1. To confirm/exclude the diagnosis and
2. To assess the individual risk of progression based on BC; patients with a repeatedly confirmed BD are referred for liver transplantation (LT). ERC images were scored using a modified version of Amsterdam PSC score; a global score combining intra- (0-8) and extra- (0-8) hepatic score was obtained (0-4: mild, 5-8: moderate, 9-16: severe changes). Cytology samples were graded as benign (i.e., normal or inflammatory/regenerative atypia), suspicious (for BD or malignancy) or malignant (i.e., CC).

**Data:** Clinical data and lab tests were reviewed.

**End-points:** A composite of LT + cirrhosis at last follow-up were evaluated. Follow-up: All patients were censored by the end of March 2019.

**Results:** Baseline characteristics: 68 patients (42 males, median age at diagnosis 16, range: 5-21 years) were included; 22 patients (32%) had an overlap with autoimmune hepatitis (AIH) and 57 patients (84%) had concomitant inflammatory bowel disease (IBD).

**Follow-up duration:** The median follow-up time was 8 (range: 2-25) years. At the last follow-up the median age was 23 (range: 10-43) years.

**Screening ERC:** At first ERC the global score was: 0-4 in 46 (68%), 5-8 in 8 (12%) and 9-16 in 14 (20%) patients. Gamma-glutamyltranspeptidase (GGT) and Ca 19.9 were higher in patients with more advanced changes (p= 0.05 and 0.01), respectively. Suspicious of malignancy (low-grade dysplasia, LGD) was detected in four patients (6%) (one was cirrhotic, 2 had also aneuploidy): 2 received LT (LGD was confirmed in one and cirrhosis without LGD in one) and 2 LGD were not confirmed on following BC.

**Follow-up ERC:** A median of 2 (range: 0-11) ERCs with brush cytology were performed. Suspicion of malignancy (LGD) was raised in 5 (3% of the ERC:s): one was transplanted (LGD was not confirmed, but severe cholangitis) and 4 were not confirmed on following BC but one was listed for LT because of cirrhosis. One patient underwent right hepatectomy for a liver mass, consistent with biliary LGD.

End of follow-up: Eight patients (12%) had received LT: 4 for decompensated cirrhosis (one with biliary LGD), one for a markedly increased S-Ca19-9 (cirrhosis on histology) and 2 for suspicion of malignancy. Five patients (7%) were cirrhotic. No cases of CC were detected.

Survival (Logrank test for trend): Probability for the end-point LT + cirrhosis at last follow-up was higher in patients with more advanced bile duct disease at their first ERC ( $p=0.04$ ).

Multiple linear regression: Elevated GGT ( $p=0.02$ ), ALP ( $0.01$ ) and bilirubin ( $0.05$ ) at first ERC were independent factors for the end point LT + cirrhosis at last follow-up.

**Conclusion:** In patients with a PSC-onset at childhood/adolescence biliary dysplasia may develop within a median time of 3 years necessitating thorough follow-up.

**Disclosure:** Nothing to disclose

## P1525 ROLE OF GENETIC EVALUATION IN CHILDREN WITH IDIOPATHIC ACUTE RECURRENT PANCREATITIS

Nabi Z., Chavan R., Shava U., Reddy D.N.

Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India

**Contact E-Mail Address:** drradhikachavan@gmail.com

**Introduction:** Acute recurrent pancreatitis (ARP) is poorly understood in children. Several genetic risk factors have been identified in adults with ARP. However, literature regarding genetics of ARP is sparse in pediatric age group.

**Aims & Methods:** All children (< 18 years) with ARP from Jan 2016 to May 2018 were prospectively enrolled in the study. Children with a known cause of ARP like obstructive, toxic/metabolic and autoimmune were excluded from the final analysis. Children with idiopathic ARP (IARP) underwent genetic testing for mutations/polymorphisms in genes known to predispose to ARP {SPINK1, PRSS1, CTSC (Chymotrypsin C), CTSB (Cathepsin B), CLDN-2 (Claudin-2) and CFTR}.

**Results:** A total of 239 children (116 boys,  $10.3 \pm 3.7$  years) were enrolled during the study period. Of these, 204 (85.35%) children were identified as IARP. The mean age of symptom onset and the average number of acute episodes were  $8.3 \pm 3.7$  years and  $3.3 \pm 1.8$ , respectively. In 4.6% (11/239) family history of pancreatitis was noted. Pancreas divisum was found in 18.7% (27/144) children. Genetic evaluation was performed in 144 (70.6%) children with IARP. Mutations/polymorphisms in at least 1 gene was identified in 89.5% (129/144) children including SPINK1 in 41.9%, PRSS1 (rs 10273639) in 58.2%, CTSC in 25.6%, CLDN -2 in 72.9% and CFTR in 2.3%. There was no significant difference in the incidence of genetic mutations/polymorphisms in IARP with or without pancreas divisum (95.7 vs 88.4%;  $p=0.467$ ).

**Conclusion:** Genetic mutations are the most common cause of IARP in children. The incidence of genetic mutations is similar in children with or without pancreas divisum. The role of pancreas divisum in causing ARP in the absence of a genetic mutation should be evaluated in future studies.

**Disclosure:** Nothing to disclose

**Introduction:** The documented incidence of acute pediatric pancreatitis (APP) is low, but it shows a rising pattern from Eastern to Western Europe and the USA. An American study established close correlation between serum pancreas enzyme measurement (sPEM) and the incidence of APP.

**Aims & Methods:** The aim of the PINEAPPLE-R study is to retrospectively investigate the diagnostic practice for APP and to estimate the incidence of pancreatitis among children suffering from abdominal pain worldwide. PINEAPPLE (Pain IN EARly phase of Pediatric PancreatitIs) is a registered (ISRCTN35618458), observational, multinational clinical trial (<http://www.ncbi.nlm.nih.gov/pubmed/26641250>). The PINEAPPLE-R sub-trial is a retrospective review of pediatric ER medical records, collecting symptoms, results of abdominal imaging and pancreatic enzyme measurements. We have already overviewed 46190 pediatric patient records and obtained the requested data from 4 countries' 15 hospitals for the PINEAPPLE-R trial.

**Results:** Retrospectively 10.4% (4782/46190) of the children appeared at ER units had abdominal pain. In case of abdominal pain sPEM was performed in 13.8% (662/4782), 23.1% (1104/4782) of the patients had abdominal imaging and the incidence of pancreatitis was 0.2% (11/4782). The number of sPEM decreased from the USA to Eastern Europe (21.6% to 5.6%) and clearly correlated with the incidence of APP (0.5% to 0%,  $R^2=0.958$ ). The most accurate diagnostic workup has been performed in Israel, where the sPEM was measured in 62.9% (165/262) and the abdominal imaging 41.6% (109/262) of patients with abdominal pain, resulted in 3 (1.14%) diagnosed APP.

**Conclusion:** The PINEAPPLE-R shows that the incidence of APP is 0.2% based on the current diagnostic practice. Better awareness of APP results 1.14% incidence of APP as a reason of abdominal pain. These data strongly suggest that the majority (86%) of APP is not diagnosed.

**Introduction:** Endoscopic resection for superficial non-ampullary duodenal neoplasms (SNADEN) is gradually spreading, and recurrence after endoscopic resection sometimes occurs. However, conventional endoscopic mucosal resection (EMR) for recurrent lesion with submucosal saline injection is difficult because of submucosal fibrosis. Furthermore, endoscopic submucosal dissection (ESD) for duodenal neoplasm accompanies a high risk of perforation, and highly advanced skills are demanded to perform ESD especially on recurrent lesions. Underwater EMR (UEMR) was developed and described by Binmoeller *et al* in 2012. We previously reported the usefulness of UEMR for primary SNADENs.

**Aims & Methods:** We retrospectively analyzed patients diagnosed with recurrent duodenal neoplasm and treated with UEMR at Osaka International Cancer Institute from 2015 to March 2019. For UEMR procedure, a waterjet endoscope with distal attachment was used. We evacuated air from the affected segment of lumen and infused water until the lumen was complete full, then we performed hot snare polypectomy without submucosal injection.

**Results:** During the study period, 7 patients (6 men, 1 woman; age, 59-78 years) were treated with UEMR for recurrent SNADENs. All lesions were flat elevated, and located at the descending duodenum. The period from previous treatment to the treatment of recurrence were  $1.4 \pm 1.1$  years. Tumor size was 2 to 11 mm. *En bloc* resection was performed in 5 cases and piecemeal resection in 2 cases without complications during the procedure. The procedure time was  $18 \pm 17$  min. 2 patients presented melena and were performed endoscopic examination 3 and 4 days after UEMR, respectively, and 1 required hemostasis by clipping. Pathological diagnosis was intramucosal adenocarcinoma in 4 cases, and tubular adenoma in 3.

**Conclusion:** UEMR for recurrent duodenal lesion is feasible and effective, which is difficult to be treated with conventional EMR, or ESD.

**Contact E-Mail Address:** apopapp300@yahoo.com

**Introduction:** Germline mutation in the *E-cadherin* gene (*CDH1*) is found in approximately 30% of individuals fulfilling the clinical criteria for hereditary diffuse gastric cancer (HDGC) and is an indication for prophylactic gastrectomy. However, endoscopic surveillance is recommended for those individuals that refuse gastrectomy and prefer to delay it for medical or psychosocial reasons, in order to identify foci of intramucosal signet ring cell carcinoma (SRCC) and inform the best timing of surgery. The recommended endoscopic protocol involves 30 random mapping biopsies in 6 gastric anatomical regions (Cambridge protocol), which is tedious and time-consuming. In order to save time, two specimens could be taken during a single passage of the biopsy forceps ("double-bite" technique). Previous studies on the efficacy of this technique, in both the upper and lower gastrointestinal tract, have generated conflicting results.

**Aims & Methods:** The aim of this study was to determine the adequacy and utility of the "double-bite" technique for mapping biopsies in patients undergoing surveillance for HDGC. The primary outcome was identification of SRCC foci in the two arms. The secondary outcomes included time to perform biopsy protocol, biopsy size, patients comfort and dose of sedation. Patients were randomized to the single or double-bite arm. Procedures were performed by 3 trained endoscopists with high-resolution white-light and narrow band imaging with targeted biopsies on visible lesions followed by Cambridge protocol biopsies. Randomization was revealed to the endoscopist just before the mapping biopsies. The time taken for the procedure was recorded between the first and last mapping biopsy. A comfort score was assigned by an endoscopy nurse after the procedure, according to the modified Gloucester scale. Biopsy specimens were assessed for size and presence of SRCC foci by two upper GI pathologists, who had significant experience in identification of SRCC and were blinded to study arm.

This study was powered for the secondary endpoint related to the procedural time and we estimated that 13 cases at least in each arm were required to show a difference with a power of 0.95 at a significance level of 0.01.

**Results:** Twenty-five patients were included in the single-bite and 23 in the double-bite arm. There was no difference in patient demographics, including age and gender. In the mapping biopsies, 2 SRCC foci were detected in the single-bite arm and 5 in the double-bite arm ( $p=0.24$ ). The Cambridge biopsy protocol in the double-bite arm was significantly faster compared to the single-bite arm ( $11 \pm 2.7$  min vs  $13 \pm 2.4$ ;  $p=0.004$ ). The mean size of the biopsies in the double-bite arm was significantly smaller than in the single-bite arm ( $2.5$  vs  $3$  mm,  $p=0.001$ ). There was no difference in sedation dose and comfort score.

**Conclusion:** The double-bite technique is significantly faster than the single-bite method for performing the Cambridge biopsy protocol in patients undergoing surveillance for HDGC. Despite the smaller size, the double-bite technique does not reduce the yield of SRCC.

## P1529 TT-J KNIFE INCREASES SPEED OF PER-ORAL ENDOSCOPIC MYOTOMY: A COMPARISON OF UK AND JAPANESE PRACTICE

Patel M.<sup>1</sup>, Shimamura Y.<sup>2</sup>, Gulati S.<sup>1</sup>, Gunasingam N.<sup>1</sup>, Haji A.<sup>3</sup>, Hayee B.<sup>4</sup>, Inoue H.<sup>5</sup>

<sup>1</sup>King's Institute of Therapeutic Endoscopy, Gastroenterology, London, United Kingdom, <sup>2</sup>Showa University Koto Toyosu Hospital, Digestive Disease Center, Tokyo, Japan, <sup>3</sup>Kings College Hospital, Colorectal Surgery, London, United Kingdom, <sup>4</sup>Kings College Hospital, Gastroenterology, London, United Kingdom, <sup>5</sup>Showa University Northern Yokohama Hospital, Digestive Disease Center, Yokohama, Japan

**Contact E-Mail Address:** mehulpatel1@doctors.org.uk

**Introduction:** Per-oral endoscopic myotomy (POEM) is an effective treatment for achalasia but requires a high level of technical expertise with a steep learning curve limiting its accessibility to select centres. The TTJ knife unlike the conventional TT knife offers an integrated water jet during tunnelling and submucosal dissection.

**Aims & Methods:** This study aims to determine if the TTJ knife increases the speed of myotomy and could be a beneficial tool for less experienced endoscopists. Procedure data was retrospectively analysed for 107 cases performed at a UK centre (2013-2019) and 1549 cases performed at a more experienced Japanese centre (2008-2019). Case matching was executed between sites for: prior therapies, sigmoid shape oesophagus, knife (TT/TTJ) and total myotomy length ( $\pm 5$  cm). Independent samples t-test was undertaken to compare outcome measures (myotomy speed (cm/minute) and procedure time (minutes)) for TTJ and TT knives.

**Results:** Mean speed of myotomy for all cases was significantly faster for the TTJ knife ( $0.16$  vs  $0.21$ ,  $p < 0.001$ ) and mean procedure time was significantly shorter ( $68.35$  vs  $88.81$ ,  $p < 0.001$ ). Differences in mean myotomy speed by knife (TTJ vs TT) were greater in the UK cohort ( $0.21$  vs  $0.14$ ,  $p < 0.001$ ) than the Japanese cohort ( $0.21$  vs  $0.17$ ,  $p < 0.05$ ) but still significantly faster in both cohorts. Mean procedure time with TTJ was significantly shorter in the UK cohort ( $57.0$  vs  $88.7$ ,  $p < 0.001$ ), while there was no significant difference in the Japanese cohort ( $79.7$  vs  $89.0$ ,  $p=0.17$ ). The speed of myotomy using the TT knife was significantly faster in the Japanese cohort compared to the UK cohort ( $0.17$  vs  $0.19$ ,  $p < 0.05$ ), there was no significant difference by centre for the TTJ knife ( $0.21$  vs  $0.20$ ,  $p=0.72$ ).

**Conclusion:** The TTJ knife increases the speed of myotomy and reduces procedure time for all levels of operator. The magnitude of this effect appears to be smaller for a high-volume centre, but still significantly different. Furthermore, myotomy speed with TTJ was the same in both groups suggesting a real advantage for a jet-type knife in this scenario.

**Disclosure:** Nothing to disclose

## P1530 OUTCOMES FROM THE UK ENDOSCOPIC SUBMUCOSAL DISSECTION (UK ESD) NATIONAL REGISTRY: MOVING TOWARDS AN ALTERNATIVE APPROACH FOR UNDERTAKING ESD IN A WESTERN SETTING

**Contact E-Mail Address:** shar811@googlemail.com

**Introduction:** The practice of endoscopic submucosal dissection (ESD) as a viable technique for resection of early gastrointestinal neoplasia has been growing in the West. However, its uptake has been slow due to a long learning curve, higher complication rate and lack of a reimbursement tariff in many centres.

**Aims & Methods:** The aim of this study was to analyse the ESD practice in the UK through the development of the country's first national ESD registry. The registry was established in 2016 with 4 major tertiary referral centres performing ESD Data was prospectively collected and captured on a national electronic database for subsequent analysis. Baseline demographics, procedure and lesion details as well as en bloc, R0 resection and complication rates were recorded. Both conventional ESD and hybrid (knife assisted resection or KAR, where a snare is used) techniques were used.

**Results:** A total of 249 ESD procedures were included. The average age of the patients was 70 years with a male:female ratio of 2:1. The ESD completion rate was 98.4% (245/249). 13.8% of the lesions were scarred from previous endoscopic resection attempts. Of the completed procedures, 70 were undertaken in the oesophagus, 55 rectal, 54 colonic, 64 gastric and 3 in the duodenum. The average lesion size was 3.2cm. The average procedure time was 58, 62, 87 and 127 minutes for oesophageal, duodenal, colorectal and gastric lesions respectively.

The majority of the lesions (177/249, 71.1%) were removed using a standard ESD technique compared to 72/249 (28.9%) using a KAR technique where piecemeal resection was more likely. The table below stratifies the procedure outcomes according to standard ESD versus KAR techniques.

	Standard ESD				Knife assisted resection (KAR)			
	En bloc resection rate	R0 resection rate	Bleeding	Perforation	En bloc resection rate	R0 resection rate	Bleeding	Perforation
<b>Oesophageal (n=70)</b>	60/61 (98.4%)	52/61 (85.2%)	1/61 (1.6%)	0	9/9 (100%)	8/9 (88.9%)	0	0
<b>Gastric (n=64)</b>	56/57 (98.2%)	51/57 (89.5%)	1/57 (1.8%)	3/57 (5.3%)	6/7 (85.7%)	6/7 (85.7%)	0	0
<b>Duodenal (n=3)</b>	N/A	N/A	N/A	N/A	2/3 (66.7%)	2/3 (66.7%)	0	1/3 (33.3%)
<b>Colorectal (n=108)</b>	54/55 (98.2%)	48/55 (87.3%)	2/55 (3.6%)	2/55 (3.6%)	18/53 (33.9%)	18/53 (33.9%)	1/53 (1.9%)	2/53 (3.8%)

[Analysis of ESD by location and resection method]

The overall stricture rate for oesophageal ESD was 8.6% (6/70, with 2 occurring using KAR and 4 using standard ESD). Notably, the complication (bleeding/perforation) rate for oesophageal lesions was lower than that of colorectal despite fewer cases being performed. The en bloc resection rate using KAR for colorectal lesions was low due to piecemeal removal.

**Conclusion:** This data provides insight into the practice of ESD in the UK through a national registry. Overall en bloc resection rates are high when conventional ESD is undertaken and complication rates low when a KAR approach is used.

Most of the procedures were carried out in the colorectum and oesophagus reflecting the local pathology burden. Bleeding and perforation rates were low and procedure time shortest in oesophageal ESD despite a similar number of rectal, gastric and oesophageal cases being undertaken.

This may provide a basis for training in oesophageal ESD in parallel with rectal and gastric cases rather than the traditional model of Eastern training that advocates step wise progression starting with gastric ESD. Tailoring this model of practice may increase the uptake of ESD as a safe procedure in the West with appropriate training.

**Disclosure:** Nothing to disclose

## P1531 OCCURENCE OF BLACK ESOPHAGUS IN A SINGLE TERTIARY CENTER: A RETROSPECTIVE ANALYSIS OF 11 YEARS

Andrea, Medical and Surgical sciences, Rome, Italy

**Contact E-Mail Address:** davidegiuseppeorlando@hotmail.it

**Introduction:** Acute esophageal necrosis so called black esophagus (AEN), is a rare clinical condition characterized by the endoscopic finding of diffuse, often circumferential, black mucosal pigmentation of esophagus, which typically stops at gastro-esophageal junction. Duodenal involvement has been described in this condition. Epidemiological data of AEN are scanty, in fact until now only small case series and case reports are available.

**Aims & Methods:** To assess the occurrence of AEN in a consecutive endoscopic cohort over an 11 years period.

**Results:** 15 patients out of 2.515 emergency esophagogastroduodenoscopy [EGDS] (0.59%) were found with AEN. Only 1 out of 23.455 patients were diagnosed during elective EGDS (0.004%). Median age was 75 yrs (range 47-89), 63% were men. Upper gastrointestinal bleeding was the clinical presentation and indication for endoscopy in 13 patients (81.25%). In the other three cases, anemia, persistent vomiting and dysphagia were the indications for EGDS. Only three patients presented hypotension at the time of endoscopy. AEN involved the entire length of esophagus in 7 patients (43%); distal third in 5 patients (32%) and inferior two thirds in 4 patients (25%). Concomitant duodenal abnormalities were reported in 12 patients (75%): 8 patients presented frank duodenal ulcers and 2 patients presented duodenal erosions, whereas the other 2 patients a necrotic aspect of duodenum was found.

Further endoscopic findings included 7 cases of hiatal hernia, one case of Mallory-Weiss lesion, one case of oozing bleeding from the distal esophagus, in one case, a gastric volvulus was diagnosed. No gastric endoscopic abnormalities were described with the exception of one patient presenting necrotic aspect of pylorus.

Laboratory findings showed anemia in 11 patients (68%), neutrophilic leucocytosis in 13 patients (81%) elevated creatinine level reported in 12 patients (75%), hyperglycemia observed in 13 patients (81%).

All patients reported one or more pre existing comorbidities: 7 patients (43%) were diabetic, 5 patients (31%) had history of chronic renal failure, 3 patients (18%) had cardiovascular disease, 2 patients (12.5%) had active malignancy.

Acute events were reported in almost all patients: 7 cases (43%) pneumonia, 6 cases (37%) acute renal failure, 2 cases (12.5%) Clostridium Difficile colitis, 1 case acute myocardial infarction and one patient developed AEN few days after orthopaedic surgery. Two patients developed AEN as first presentation of Zollinger Ellison Syndrome.

**Conclusion:** AEN is a rare cause of upper gastrointestinal bleeding representing the most common clinical manifestation of this disorder. Concomitant duodenal alterations are associated in two third of cases. Exception-

ally, AEN is observed in elective endoscopy. Combination of acute events and pre-existing comorbidities characterize the clinical setting in which AEN may arise.

**Disclosure:** Nothing to disclose

## P1532 WITHDRAWN

### P1533 POLYSOMNOGRAPHIC ASSESSMENT OF RESPIRATORY DISTURBANCE DURING DEEP PROPOFOL SEDATION FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC TUMORS

Uesato M., Urahama R., Aikawa M., Maruyama T., Matsubara H.  
*Chiba University Graduate School of Medicine, Frontier Surgery, Chiba, Japan*

**Contact E-Mail Address:** uesato@faculty.chiba-u.jp

**Introduction:** Although drug-induced sedation can improve outcomes in advanced gastrointestinal endoscopic procedures, sedation-related critical cardiorespiratory complications are of significant concern, and recent guidelines recommend pulse oximetry monitoring during sedation.

**Aims & Methods:** To investigate that polysomnographic monitoring can accurately evaluate respiratory disturbance incidence during sedation for gastrointestinal endoscopy compare to pulse oximetry alone. This prospective observational study included 10 elderly patients with early gastric cancer undergoing endoscopic submucosal dissection (ESD) under propofol sedation. Apart from routine cardiorespiratory monitoring, polysomnography measurements were acquired. The primary hypothesis was tested by comparing the apnea hypopnea index (AHI), defined as the number of apnea and hypopnea instances per hour during sedation, with and without hypoxemia; hypoxemia was defined as the reduction in oxygen saturation by  $\geq 3\%$  from baseline.

**Results:** Polysomnography (PSG) detected 207 respiratory disturbances in the 10 patients. PSG yielded a significantly greater AHI ( $10.44 \pm 5.68 \text{ hour}^{-1}$ ) compared with pulse oximetry ( $1.54 \pm 1.81 \text{ hour}^{-1}$ ,  $p < 0.001$ ), thus supporting our hypothesis. Obstructive AHI ( $9.26 \pm 5.44 \text{ hour}^{-1}$ ) was significantly greater than central AHI ( $1.19 \pm 0.90 \text{ hour}^{-1}$ ,  $p < 0.001$ ). Compared with pulse oximetry, PSG detected the 25 instances of respiratory disturbances with hypoxemia 107.4 seconds earlier on average.

**Conclusion:** Compared with pulse oximetry, PSG can better detect respiratory irregularities and thus provide superior AHI values, leading to avoidance of fatal respiratory complications during ESD under propofol-induced sedation.

**Introduction:** Gastric cancer is one of the most common oncological diseases, which is diagnosed only at the last stage<sup>1</sup>. Photodiagnosis (PDD) is a promising method in the diagnosis of stomach cancer<sup>2</sup>. However, this method has drawbacks: similar spectra for inflammation and cancer<sup>3</sup>. The search for effective diagnostic parameters of PDT can give an impulse for progress in the early diagnosis of gastric cancer and reduce the mortality from this disease. Here we analyzed parameters of PDD that might be effective for early prognosis of gastric cancer in rats.

**Aims & Methods:** The results were carried out with adult rats using our model of gastric adenocarcinoma<sup>4,5</sup> induced by combination of two factors:

- 1) stress (overpopulation) and
- 2) nitrites: toluidine (2g/kg) in food and nitrites (2g/l) in water.

Rats underwent chronic social stress for 9 months. The upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay was performed to analyze the changes in the gastric tissues. Biochemical analysis were used for additional confirmation of oncological changes: the levels of sialic acids, TBA-active products, lactic acid were measured by standard methods given in test kits.

Delta-ALA (20 mg/kg) was applied intravenously 2 hours before the spectroscopic observation. Excitation source at 405 nm (AFS-405, Polironik Ltd., Moscow, Russia) coupled with fiber-optical probe with 25 mW output power on the end of the fiber tip was used for induction of 5-ALA-PpIX fluorescence in the lesions under interest. Fluorescence emission of endogenous autofluorescence (420-630 nm) and exogenous 5-ALA-PpIX fluorescence (630-710 nm) was detected using microspectrometer coupled to the fiber probe (USB4000, Ocean Optics Inc., Dunedin, USA).

**Results:** Our results demonstrated that in 9 months of observation all rats, that underwent chemical and social stress showed development of peptic ulcers. In 38% of rats with peptic ulcers were associated with intestinal metaplasia of goblet cells, which is morphological pre-cancer symptom. Other 62% of rats had gastric adenocarcinoma. Tumor lesions were accompanied by the migration of cancer cells through the lymphatic vessels to the liver and the lungs. The number of metastatic nodes varied from 1 to 5.

Development of gastric adenocarcinoma was confirmed by biochemical analysis of blood serum. Levels of sialic acids, TBA-active products, lactic acid increased significantly in all animals with gastric cancer.

The spectral measurements were made on normal mucosa and suspicious sites. Normal mucosa has significant autofluorescence. The tumor area has reduced autofluorescence signal and well pronounced signal at 635 nm and 704 nm, typical for 5-ALA-PpIX. Inflammatory areas showed intermediate levels of the fluorescence at 635-704 nm. However, the spectral intensity at 635 nm was two times lower than the signal obtained from cancerous sites, which allows to differentiate the areas based on the spectroscopic detection of exogenous fluorophores.

**Conclusion:** Collectively, our results clearly show that combination of two factors as chronic social stress and nitrites in food provoke gastric adenocarcinoma formation in rats. The intensity of autofluorescence signal is a marker of gastric mucosa injuries. The analysis of two specific maxima of laser at 635 nm and 704 nm in PDD demonstrate more effectiveness of spectral intensity at 635 nm for early differentiation of areas based on the spectroscopic detection of exogenous fluorophores.

### P1535 PHOTOGRAPHIC DOCUMENTATION OF UPPER GASTROINTESTINAL LANDMARKS AT GASTROSCOPY: HOW GOOD IS IT?

Patel R.N., Christie S., Canda R., El-Masry A., Besherdas K.  
*Royal Free London NHS Trust, Gastroenterology, London, United Kingdom*

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** The British Society of Gastroenterology (BSG) and Association of Upper Gastrointestinal Surgeons (AUGIS) recently published a position statement in view of the variability of performance of a high-quality gastroscopy and an unacceptably high rate of failure to diagnose cancer at endoscopy. This set out the minimum expected standards in diagnostic upper gastrointestinal endoscopy. One recommendation is that photo-documentation should be made of relevant anatomical landmarks and any detected lesions. This practice encourages mucosal cleansing, mucosal inspection and ensures a complete examination. The European Society of Gastrointestinal Endoscopy (ESGE) guidelines describe a systematic approach to photo-documentation with a recommendation of eight anatomical landmarks to improve diagnostic endoscopy quality of endoscopy.

**Aims & Methods:** The aim of this study was to retrospectively assess the photo-documentation at gastroscopy in clinical practice and compare this to the recommended sites as per the ESGE guidelines. This was a single centre, retrospective analysis of 250 consecutive gastroscopies in a district general hospital endoscopy unit in London over a two week period from 2nd April 2019. The gastroscopy reports were scrutinized for photographic evidence of the anatomical landmarks. The images capture on the Unisoft GI Reporting Tool were analysed and compared to the recommended ESGE guidelines. The patient comfort scores of the procedures (0 = no discomfort, 1 = one or two episodes, 2 = more than 2 episodes, 3 = significant discomfort) were examined in relation to number of photographs obtained.

**Results:** Of the 250 gastroscopies performed, the eight anatomical landmarks were photographed during only 33 procedures (13%). In these 33 procedures the patient comfort scores were >1 (more than two episodes of discomfort) in 3 patients (9%) compared with 60 (28%) in the 217 patients with suboptimal photo-documentation ( $p = 0.02$ ). In the 33 procedures where all the landmarks were photographed; 22 patients (66%) had sedation, 11 (33%) patients had xylocaine throat spray.

Anatomical site	Site photographed, n (%)
Upper Oesophagus	77 (31%)
Gastro-Oesophageal	178 (71%)
Fundus in retroflexion	126 (50%)
Body of stomach	130 (52%)
Incisura in retroflexion	70 (28%)
Gastric Antrum	148 (59%)
Duodenal bulb	98 (39%)
Duodenum second part	178 (71%)

[Table 1. Frequency of anatomical sites photographed during gastroscopy.]

**Conclusion:** In this study, photographic evidence of anatomical landmarks as per ESGE guidelines is only documented in 13%. Better comfort scores and procedures under conscious sedation increase compliance with optimal photo-documentation. Photographic documentation improves the diagnostic quality of endoscopy and acts as a medico-legal record of an adequate/complete procedure. There is much room for improvement in the photographic documentation of anatomical landmarks during gastroscopy.

## P1536 ODYNOPHAGIA - IS IT A SYMPTOM WORTHY OF URGENT GASTROSCOPY?

Patel R.N., Canda R., Haghollahi S., Besherdas K.  
Royal Free London NHS Trust, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** Odynophagia is defined as a painful sensation in the oesophageal region that occurs in relation to swallowing. Endoscopy is the gold standard investigation for the diagnosis of mucosal lesions in the oesophagus. Unlike dysphagia, which has historically been an alarm symptom of oesophageal cancer, odynophagia does not form part of the suspected upper gastrointestinal (GI) cancer referral in the UK.

**Aims & Methods:** We aimed to compare the standard 'red flag' indications for gastroscopy to odynophagia in terms of cancer detection. A retrospective analysis of all patients who underwent upper GI endoscopy for standard upper GI 'two-week-wait' (2WW) criteria compared with odynophagia as a primary symptom over a 14-year period (2005-2019) within an NHS Trust in North London. Data was obtained from the Unisoft Endoscopy reporting software. The findings at endoscopy for all indications were scrutinised.

**Results:** During the study period, a malignant oesophageal tumour was identified in 21 patients (4%) endoscoped for odynophagia (total 530 patients scoped for odynophagia). This compared to Anaemia (17936 endoscoped and 94 tumours identified (0.5%)); Dysphagia (10954 endoscoped and 562 tumours identified (5%)); Nausea and vomiting (N&V) (6380 endoscoped and 64 tumour identified (1%)); Weight loss (6157 endoscoped and 119 tumours identified (2%)).

Of the 530 patients who were endoscoped for odynophagia during the

study period, 240 (45%) had oesophageal mucosal lesions: Reflux oesophagitis 193 (36%); Barrett's oesophagus (26 (5%)); Malignant tumour 21 (4%). 32 (6%) had an oesophageal stricture.

Indication for gastroscopy	Number of endoscopies	Malignant tumour identified (%)
Odynophagia	530	4
Dysphagia	10954	5
Anaemia	17936	0.5
Nausea/Vomiting	6380	1
Weight loss	6157	2

[Table 1. Indication for gastroscopy and percentage of cancers detected]

**Conclusion:** From this study, almost half of patients endoscoped for odynophagia have a positive endoscopic mucosal abnormality. 4% of patients endoscoped for odynophagia had oesophageal cancer compared with 5% of dysphagia patients. Anaemia (0.5%), weight loss (2%) and N&V (1%) all have inferior cancer pick up rates. We recommend that odynophagia be re-classified as an 'alarm symptom' and those presenting with this significant symptom undergo an urgent upper GI endoscopy to define the exact mucosal abnormality and exclude oesophageal cancer.

**Introduction:** The endoscopic submucosal dissection (ESD) is the treatment of choice for most gastric superficial neoplastic lesions owing to its potential for a curative en bloc resection and low risk of recurrence. At a minimum, ESD allows a complete histopathological evaluation of the lesion. In recent years, good clinical outcomes from several studies have expanded the indication criteria for gastric ESD.

**Aims & Methods:** The aim of this study is to report the short- and long-term outcomes of a cohort of patients from a single Italian center who underwent gastric ESD. A retrospective analysis of a prospectively maintained registry of all gastric ESDs performed at Humanitas Research Hospital during a 10-year period (January 2010 - January 2019) was performed. Expanded indication criteria for gastric ESD were used. Demographic, clinical, endoscopic, histological and follow-up data were extracted and analyzed.

**Results:** During the study period, 158 consecutive gastric lesions were treated by ESD. On final pathology, 91 lesions were adenocarcinoma (57.4%) with a subclassification of pT1a: 56 (61.5%), pT1b: 31 (34.%) and pT2: 4 (4.4%). Thirty-eight lesions were diagnosed as high grade dysplasia (24.%), 23 were low grade dysplasia only (14.5%) and 6 were non-adenomatous (3.8%). An en-bloc resection was achieved in 136 patients (86%). R0 resection was reported in 116 patients (73.4%), while 30 yielded a R1 resection (19%) and the remaining 12 procedures (7.6%) were classified as Rx. Twenty-two patients (14%) experienced a complication (11 early, 10 delayed, 1 both early and delayed). The most common complication was bleeding (17 patients, 10.7%) while 5 perforations (3%) were reported. All these complications were successfully treated endoscopically except 3 patients who required surgery because recurrent bleeding after failure of endoscopic treatment and radiologic embolization in 1 case and due to early (1 case) or delayed perforation (1 case). No deaths occurred related to the ESD procedure. Overall, 23 patients (14.5%) underwent surgery because of non-curative resections. Thirteen patients (8.2) were lost at follow-up. Mean follow-up was 37.2 months (range 12-3). During follow-up, 6 local recurrences of adenoma with LGD at the previous ESD site were diagnosed while 2 patients developed a cancer in a site different from ESD and were referred to surgery.

**Conclusion:** In a large western series of ESD for early gastric neoplasia ESD was associated with a significant proportion of curative resection and quite low rate of complications as well as disease recurrence. Overall, surgery was required in 17.7% mostly because of non-curative ESD resection.

## P1538 USEFULNESS OF TRANSNASAL HYBRID ENDOSCOPIC SUBMUCOSAL DISSECTION

Minato Y., Ohata K., Matsuhashi N.

NTT Medical Center Tokyo, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** yoheiminato55925@gmail.com

**Introduction:** Endoscopic Submucosal Dissection (ESD) is technically difficult and time-consuming procedure which is usually performed under sedation. Therefore, ESD has definite risks especially for elderly patients. And due to the physiological constriction, the conventional scope is sometimes not reached to the target lesions. In these situations, transanal hybrid ESD(T-ESD) maybe alternative therapeutic option for superficial gastrointestinal neoplasms.

**Aims & Methods:** We evaluated the clinical outcome of T-ESD. After informed consent, T-ESD was performed without sedation for elderly patients whose age were over 80 years old or the patient having the trouble of physiological constriction. For this study, the target size was defined 10mm or less intramucosal gastric cancer. And the ulcerative lesions were excluded. Clinical characteristics and outcomes were evaluated retrospectively. 13 gastric lesions were resected by T-ESD between April 2016 and March 2019. All of the T-ESD steps were performed using EG-580NW2 endoscope (Fujifilm, Tokyo, Japan), with a diameter of the distal end of 5.8mm and inner diameter of the instrument channel of 2.4mm and a newly developed multifunctional snare 'SOUTEN' (Kaneka Medics, Tokyo, Japan) which is design to achieve Hybrid ESD which is available through the transnasal endoscope. The knobshaped tip attached to the loop top helps to stabilize the needle-knife, making it less likely to slip during circumferential incision and enables partial submucosal dissection. For hemostasis, RAICHO(Kaneka Medics, Tokyo, Japan) was used which ensure the suction ability of the scope even with the transnasal endoscope.

**Results:** The mean age was 80.5±6.5 years old, the male to female ratio was 8:5. The lesions locations were U/M/L:1/5/7. Mean tumor size and resected specimen size were 10.4±3.2mm and 21.1±6.0mm. And mean procedure time was 15.3±3.1min. En-bloc R0 resection rate were 100% respectively. In all patients, face scale was 1 and oxygen saturation could keep more than 95% during procedure, therefore oxygen administration was not needed. Incidence of perforation and postoperative hemorrhage were 0% and 7.7%(1/13).

**Conclusion:** We confirmed favorable clinical outcomes of T-ESD. On the other hand, We need pay attention to the fact that the weaker suction ability and lack of the water jet may make hemostasis more difficult to achieve. Though we believe this is a useful therapeutic option, additional studies would be needed to determine if this modality is also useful for beginners.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** yichkha1@jhmi.edu

**Introduction:** Peroral Endoscopic Myotomy (POEM) is considered a primary treatment for patients with achalasia and a safe alternative to pneumatic dilation (PD) and laparoscopic Heller myotomy (LHM). Although highly effective, clinical failure may occur. It is currently unknown how patients who fail POEM are best managed. Options include conservative management, botulinum toxin injection (BTX), redo POEM, PD, and LHM.

**Aims & Methods:**

- (1) To describe a cohort of patients who failed POEM;
- (2) Compare clinical success [Eckardt ≤ 3] and safety [severity of adverse events (AEs) per ASGE Lexicon] of the above described treatment modalities in patients with failed POEM.

This is an international, multicenter, retrospective study at 19 tertiary centers between 1/2012 and 8/2018. All patients who underwent POEM for the treatment of achalasia, esophagogastric junction outflow obstruction (EGJO), hypercontractile esophagus (jackhammer), and diffuse esophageal spasm (DES), who failed POEM were included. Patients with an Eckardt score >3 after POEM or during follow-up were considered clinical failures.

**Results:** A total of 3251 patients underwent POEM and 110 (3.38%) experienced clinical failure (46.46% F, mean age 51yr). Main type of motility disorder was achalasia (82.72 %) and most commonly was type 2 (46.36%). The mean integrated relaxation pressure (IRP) after failed POEM was 15.28±11.97 mmHg. The mean Eckardt score prior to retreatment was 5.64±2.24. A total of 38 (34.5%) patients underwent redo POEM, 28 (25.5%) had PD, 4 (3.6%) had standard balloon dilation, not pneumatic, 8 (7.3%) LHM, 2 (1.8%) BTX, and 30 (27.3%) were treated conservatively (Table 1). Regarding retreatment, in the redo POEM group, the mean length of esophageal and gastric myotomy were 6.77±3.25 and 2.8±1.4 cm, respectively, and mean procedure time was 116.43 ± 65.07 min. In the retreatment with LHM group, the mean length of esophageal and gastric myotomy were 4.4±2.7 and 2.4±0.54 cm, respectively, and the mean procedure time was 135 ±17.32 min. In the PD group, mean dilation diameter and procedure time were 32.31±3.53 mm [1 dilation (n=18), 2 dilation (n=10) sessions] and 20.91±21.2 min. Overall, clinical success was achieved in 40/80 (50%) patients who underwent retreatment during a mean follow-up of 265.76 days. Two (5.2%) patients had AEs during redo POEM [1 muco-

sotomy (mild) and 1 esophageal leak (moderate)]. Mean Eckardt score post retreatment was  $2.83 \pm 2.38$  [ $2.19 \pm 2.2$  in Redo POEM,  $3.28 \pm 2.4$  in PD,  $4.2 \pm 2.8$  in LHM]. Clinical success was similar between redo POEM, PD and LHM ( $p=0.096$ ). PD had the shortest mean procedure time ( $p<0.001$ ), and length of hospitalization ( $1.1$  vs  $1.92$  vs  $2.5$  d;  $p=0.006$ ) (Table 1).

**Conclusion:** This international study comprehensively assessed a cohort of patients who failed POEM. Redo POEM, LHM, and PD are equally effective and safe retreatment options for these patients.

**Disclosure:** This abstract has been submitted and accepted for oral presentation at the Digestive Disease Week (DDW) 2019.

## P1540 PROSPECTIVE RANDOMIZED STUDY ON THE USE OF A COMPUTER-BASED ENDOSCOPIC SIMULATOR FOR TRAINING IN ESOPHAGOGASTRODUODENOSCOPY

Ait Errami A.<sup>1</sup>, Jiddi S.<sup>2</sup>, Oubaha S.<sup>3</sup>, Zouhour S.<sup>3</sup>, Krati K.<sup>3</sup>

**Contact E-Mail Address:** adil.ae@hotmail.fr

**Introduction:** Computer-based endoscopic simulators have been developed in recent years, and their usefulness has been reported. There are a few reports that have evaluated the effectiveness and drawbacks of a computer-based simulator.

**Aims & Methods:** The present study aimed to assess the effectiveness of a computer-based simulator for basic training in EGD.

The GI-Mentor II simulator was used. The subjects were 16 hospital medical residents. After receiving an explanation regarding the fundamentals of endoscopy, 8 trainees were each randomized into a simulator group and a non-simulator group.

The simulator group received 4h of training with the GI-Mentor II plus bedside training, while the non-simulator group received bedside training. Subsequently, each subject performed endoscopy twice for assessment. Performance was evaluated according to a five-grade scale for a total of 11 items.

**Results:** The score was significantly higher in the skills required for insertion into the esophagus, passing from the esophagogastric junction (EGJ) to the antrum, passing through the pylorus, and examination of the duodenal bulb and the fornix.

**Conclusion:** The performance of endoscopy was improved by 4 h of simulator training. The simulator was more effective with regard to the items related to manipulation skills. Computer-based simulator training in EGD is useful for beginners.

**Disclosure:** Nothing to disclose

## P1541 IMPLICATIONS OF RANDOM UPPER GI ENDOSCOPIC BIOPSIES ON COST; A RETROSPECTIVE CLINICAL AUDIT

Ahmed S.<sup>1</sup>, Amin M.N.<sup>1</sup>, Saleem M.U.<sup>1</sup>, Richards C.<sup>2</sup>, Robinson R.<sup>1</sup>

<sup>1</sup>University Hospitals Leicester, Gastroenterology, Leicester, United Kingdom,

<sup>2</sup>University Hospitals Leicester, Histopathology Department, Leicester, United Kingdom

**Contact E-Mail Address:** saeed5198@gmail.com

**Introduction:** Oesophago-gastro-duodenoscopy is the major tool for investigation of Upper GI tract symptoms. In view of recent upcoming cancer investigation pathways and campaigns the number of biopsies required is likely to increase<sup>1</sup>. Cancer detection rates remained unchanged by random non-diagnostic biopsies<sup>2</sup>.

Non targeted biopsies to investigate Helicobacter Pylori are not cost effective as cheaper non invasive modalities are readily available. Literature review showed that biopsies for weight loss without serological evidence of coeliac disease, is diagnostic in less than 1%<sup>3</sup>.

**Aims & Methods:** This retrospective clinical audit was performed on all diagnostic gastroscopies at the University Hospitals of Leicester within the month of January in 2018. In the initial audit cycle, practice was compared to British Society of Gastroenterology guidelines, recently published recommendations from the Newcastle group as well as our local biopsy protocol<sup>4,5</sup>. All planned therapeutic procedures as well as incomplete or failed procedures were excluded. The local guidelines were updated following

initial audit results and disseminated across the trust. Practice was then re-audited against the updated guidelines. Finally the findings were analysed to evaluate any cost implications.

**Results:** First cycle: A total of 731 gastroscopies were performed during January 2018. Diagnostic biopsies were obtained in 261 out of 570 eligible cases. According to study criteria total of 102 (13.95%) out of 731 patients were biopsied inappropriately. The assumed cost of a single biopsy set was around 145£. The monthly cost of unnecessary biopsies was 14,790£ (estimated to be 177,480£ annually).

Second cycle: A total of 802 gastroscopies were performed during January 2019. Diagnostic biopsies were obtained in 253 out of 666 eligible patients. According to the study criteria 66 (8.2%) out of 802 biopsies were obtained inappropriately. Keeping the assumed cost for the single biopsy set remained unchanged. The monthly cost was therefore 9,570£ (estimated to be 114,840 annually).

**Conclusion:** We have detected a sizeable number of inappropriate biopsies resulting from local and national guidelines not being followed. This has a significant cost implication. By updating local protocols and emphasising the importance of avoiding unnecessary non targeted biopsies we have demonstrated potentially significant cost savings.

## P1542 CORRELATION OF ENDOSCOPIC AND HISTOLOGICAL FEATURES IN ADULTS WITH SUSPECTED CELIAC DISEASE

Salma B.<sup>1</sup>, Sabbah M.<sup>2</sup>, Kchaou Ouakaa A.<sup>1</sup>, Trad D.<sup>2</sup>, Elloumi H.<sup>2</sup>, Gargouri D.<sup>2</sup>

<sup>1</sup>Habib Thameur Hospital, Gastroenterology, Tunis, Tunisia, <sup>2</sup>Habib Thameur Hospital, Tunis, Tunisia

**Contact E-Mail Address:** baghdadi.selma@gmail.com

**Introduction:** Clinical presentation of celiac disease is extremely variable and the diagnosis relies on serologic tests, mucosal intestinal biopsy and clinic and serologic response to a gluten-free diet. The aim of our study is to correlate the endoscopic and histological aspects of adult patients with suspicion of celiac disease and to evaluate the correlation with histological findings.

**Aims & Methods:** A retrospective study was conducted between January 2015 and december 2018. Endoscopic aspects of 61 adult patients were evaluated and correlated with the histological features according to the Marsh classification system.

**Results:** Sixty one patients were included, mean age was 42.9 years [16-83] and sex ratio was 0.8. No statistically significant correlation was showed between the age and gender and pathology features and endoscopy manifestations ( $p>0.05$ ).

The most prevalent clinical data in patients with histological diagnosis of CD were iron-deficiency anemia (29.5%), chronic diarrhea (9.8%), and malabsorption syndrome (8.2%).

The endoscopic study of the duodenum showed: normal mucosa in 5 cases (8.2%); scalloping folds in 3 (4.9%), and total villous atrophy in 52 (85.2%). Among these patients, histological examination showed CD in 38 (23%), intraepithelial lymphocytosis in 40 (65.5%) and was normal in 9 (5.4%) We did not observe a significant correlation between endoscopy results and pathology features ( $p=0.235$ ).

**Conclusion:** Our data confirmed Endoscopic markers have disappointing sensitivity. Endoscopic markers of villous atrophy are not useful for screening for celiac disease and duodenal histological assessment remains mandatory

**Disclosure:** Nothing to disclose

## P1543 GASTRIC PER ORAL ENDOSCOPIC PYLOROMYOTOMY (G POEM) FOR REFRACTORY GASTROPARSIS: A SINGLE CENTRE EXPERIENCE

Gunasingam N.<sup>1</sup>, Patel M.<sup>1</sup>, Gulati S.<sup>1</sup>, Haji A.<sup>2</sup>, Hayee B.<sup>3</sup>

<sup>1</sup>King's Institute of Therapeutic Endoscopy, Gastroenterology, London, United Kingdom, <sup>2</sup>King's College Hospital, Colorectal Surgery, London, United Kingdom, <sup>3</sup>King's College Hospital, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** nishmi@gmail.com

**Introduction:** Gastroparesis (GP) is a disorder evidenced by delayed gastric emptying in the absence of mechanical obstruction, commonly idiopathic or secondary to diabetes mellitus. G-POEM has been used to treat refractory gastroparesis and we present our initial experience with this novel endoscopic technique.

**Aims & Methods:** All patients undergoing G-POEM for refractory GP from May 2018 onwards were included, with data extracted from the hospital electronic patient record. Procedures were performed by one endoscopists at our centre with experience in submucosal endoscopy. Efficacy at 3 months was assessed by reduction of symptom score (Gastroparesis Cardinal Symptom Index; GCSI), with secondary considerations including technical success, procedural complications, hospital length of stay and hospitalisations after treatment.

**Results:** 10 patients (10F; mean age 40.3±15.4 y) were included (5 diabetic, 5 idiopathic). Mean duration of disease was 9.5±5.6 y, with 4 months median duration of follow-up post-procedure. 6 patients had previous treatment with botulinum toxin, and one gastric electrical stimulator. Technical success was achieved in all cases while, at 3 months, 8 had improvement total GCSI (mean scores 3.978 vs 2.076 (p = 0.008)) and each GCSI subtype score: nausea and vomiting (3.63 vs 1.70, p = 0.012); fullness (4.30 vs 2.30, p = 0.012); bloating (4 vs 2.22, p = 0.28). Mean hospital stay was 9±13 d, with 5 patients staying less than 4 days and two with prolonged admission. One significant adverse event was recorded: abdominal collection around the myotomy site requiring a prolonged hospital admission of 18 days for intravenous antibiotics in one patient.

Only one patient required hospitalisation for gastroparesis symptoms after their G-POEM procedure (this was the same patient who did not achieve clinical success with reduction in their GCSI scores).

**Conclusion:** G-POEM is a promising therapeutic treatment for patients with refractory GP, with significant improvement in symptoms and, in our cohort a dramatic reduction in the need for hospitalisation in short-term follow up. A European sham-controlled study is under way and longer-term data are required to confidently determine its role in the management of such a challenging condition.

**Disclosure:** Nothing to disclose

## P1544 LONG-TERM OUTCOMES AFTER PER-ORAL ENDOSCOPIC MYOTOMY FOR TREATMENT OF ESOPHAGEAL ACHALASIA

Pellegatta G.<sup>1</sup>, Maselli R.<sup>1</sup>, Galtieri P.A.<sup>1</sup>, Belletrutti P.<sup>1</sup>, Carlini E.<sup>1</sup>, Omodei P.D.<sup>2</sup>, Preatoni P.<sup>1</sup>, Castoro C.<sup>3</sup>, Spadaccini M.<sup>1</sup>, Fugazza A.<sup>1</sup>, Palma R.<sup>1</sup>, Orlando V.<sup>1</sup>, Repici A.<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital, Gastroenterology Unit, Rozzano, Italy, <sup>2</sup>Istituto Clinico Humanitas, Gastroenterology Unit, Rozzano, Italy, <sup>3</sup>Humanities Research Hospital, Rozzano, Italy

**Contact E-Mail Address:** gaia.pellegatta@gmail.com

**Introduction:** Per-oral endoscopic myotomy (POEM) is a relatively novel endoscopic therapy for esophageal achalasia. The outcome and safety of peroral endoscopic myotomy (POEM) in patients with achalasia has been mostly reported with relatively short/mid-term follow-up data. As a matter of fact, studies reporting long-term clinical outcomes and the incidence of gastroesophageal reflux (GER) after POEM are still limited.

**Aims & Methods:** The aim of this study was to assess the long-term outcomes and the incidence of GER in a cohort of consecutive patients treated with POEM for achalasia between June 2012 and December 2015. A retrospective analysis of a prospectively maintained procedure database was conducted and included clinical assessment in combination with findings at interval upper GI endoscopies, manometry and pH monitoring. Scheduled follow-up included clinical assessment by Eckardt symptoms, high resolution manometry, upper-gastrointestinal endoscopy and pH monitoring at 3-6, 12-24, 36 and 60 months after POEM. A post-POEM Eckardt

score ≤3 was considered a clinical success. Regarding pH monitoring, a percentage of time with esophageal exposure to acid (pH < 4) > 4.2% was considered positive for GER.

**Results:** A total of 60 achalasia patients (type I 9.8%, type II 82.3% and type III 7.9%) with follow-up longer than 36 months were included. The median age of the patients was 54 years (range 17-86); no patients with ASA class IV were treated with POEM. Nineteen patients had received prior interventional treatment (32.7%) and five patients had a sigmoid esophagus (8.3%).

Adverse events occurred in 7 patients (11.6%); according to the AGA Lexicon classification, 5 were mild, 2 were moderate. Median length of hospital stay was 2.1 days (range 1-9).

The mean pre-POEM Eckardt score was 6.5 (±2.3) and it significantly decreased 3-6 months after POEM (0.75±1.5, p<0.0001), remaining stable 12-24, 36 and 60 months after POEM (0.74±1.1, 1.11±1.7 and 0.88±1.5, respectively; p<0.0001). The mean integrated relaxation pressure (IRP) before POEM was 26.12±11.2 mmHg and significantly decreased at 3-6 months after POEM (9.42±3.54 mmHg, p<0.0001), remaining stable 12-24, 36 and 60 months after POEM (9.81±3.9, 9.6±5 and 10.6±4.5, respectively; p<0.0001). During follow-up, clinical success was maintained in 95% at 3-6 months, 93.3% at 12-24 months, 91.6% at 36 months and 90% at 60 months after POEM.

Clinical reflux symptoms occurred in 25%, 28.3%, 23.3% and 17.7% of patients, respectively, after 3-6, 12-24, 36 and 60 months after POEM. Upper-GI endoscopy revealed erosive esophagitis in 30%, 28.3%, 31.6% and 35.0% of patients, respectively, at 3-6, 12-24, 36 and 60 months after POEM. Cases of Grade C and D erosive esophagitis were present only 3-6 months after the procedure. There were no confirmed reflux-related post-POEM strictures or diagnoses of Barrett esophagus. Twenty-four hour pH monitoring studies revealed pathological esophageal acid exposure time in 26.3%, 24.2%, 27.6% and 20.0% of patients, respectively, 3-6, 12-24, 36 and 60 months after POEM.

**Conclusion:** POEM is a highly safe and effective treatment for esophageal achalasia with favourable clinical outcomes up to 60 months post-procedure. GER occurs 20-30% of patients post-POEM. Moreover, our results emphasize the importance of long-term follow-up in all patients after POEM.

## P1545 THE "OVER-THE-SCOPE-GRASPER" - A NEW INSTRUMENT FOR FLEXIBLE ENDOSCOPY

Epp S.<sup>1</sup>, Hann A.<sup>1</sup>, Meining A.<sup>2</sup>

<sup>1</sup>Ulm University, Department of Internal Medicine I, Ulm, Germany,

<sup>2</sup>University of Würzburg, Gastroenterology, Würzburg, Germany

**Contact E-Mail Address:** sonja.epp@outlook.com

**Introduction:** Removal of blood clots, necrotic tissue and occasionally foreign bodies is a significant problem in flexible endoscopy. There are no special gripping instruments for the removal of viscous materials and suction alone is often limited.

**Aims & Methods:** A special gripping instrument (Over-The-Scope-Grasper: OTSG) was designed to overcome those problems. It can be attached to the tip of a conventional gastroscope, similar to a conventional cap. Two excavator-like jaws are attached to the tip of the cap, which can be opened and closed by a pull mechanism running on the outside of the endoscope. Thus, the working channel of the endoscope remains available for suction/irrigation or insertion of additional instruments. The total diameter of the system is 13 mm.

**Results:** In one patient, the OTSG was used for necrosectomy after the formation of a gastrocystostomy. In another patient, the OTSG was used to remove a large coagulum after ESD in the middle esophagus after removal with a Dormia basket ended frustratingly. The insertion of the endoscope was possible without any problems when the OTSG was closed. By opening and closing the jaws with simultaneous suction, it was possible to remove necrotic material or large parts of the coagulum respectively.

**Conclusion:** The OTSG was successfully used for the removal of necrotic tissue and blood clots. Further evaluation based on a larger case series is still pending.

**Disclosure:** Nothing to disclose.

## P1546 THE ROLE OF MULTIDISCIPLINARY EVALUATION IN ENDOSCOPIC SLEEVE GASTROPLASTY

Gemelli IRCCS, Internal Medicine and Gastroenterology Unit, Rome, Italy

**Contact E-Mail Address:** vinbove@alice.it

**Introduction:** Endoscopic sleeve gastroplasty (ESG) is a relatively novel endoscopic procedure that reduces the gastric lumen with proven less complications and almost same 6 months weight loss compared to laparoscopic sleeve gastroplasty (LSG). To our knowledge there are no trials investigating the role of multidisciplinary evaluation (ME) before and after ESG.

The aims of the present study were to evaluate the role of ME prior and after ESG in terms of weight loss outcomes, quality of life improvements and adverse events.

**Aims & Methods:** From May 2016 to April 2019 all patients that underwent ESG were retrospectively evaluated from a prospective database. Included patients had 2° and 3° degree of obesity or 1° with comorbidities. All patients underwent upper GI endoscopy to exclude pathologies. Until September 2017 before ESG only psychiatric evaluation was requested, while after this date we adopted the guidelines of the Italian Society for Obesity Surgery and all patients were evaluated on a multidisciplinary fashion prior ESG.

The ME team was composed by: gastroenterologist, surgeon, psychiatrist, endocrinologist and dietitian. Patients were divided in two groups: group 1 were patients with ESG done before ME while group 2 were patients with ESG done after ME.

We compared this two groups in terms of weight loss outcomes, quality of life improvements and adverse events. Quality of life was measured with the Bariatric Analysis and Reporting Outcome System (BAROS). ESG was done with the Apollo Overstitch suturing system (Apollo Endosurgery) and a double channel gastroscope Olympus 2TGIF-160 (Olympus Japan) in general anesthesia and with insufflation of CO<sub>2</sub>.

All patients had ambulatory visit t 1, 3, 6 and 12 months after ESG and weight loss outcomes were measured in terms of Excess Weight Loss (%EWL), the Total Body Weight Loss (%TBWL) and BAROS scale were assessed. Statistical analysis was done with chi-square test and < 0.05 value was considered significant.

The study was approved by the local Ethical Committee (N° 19211/18).

**Results:** A totally of 89 ESG were performed. Mean procedure time was 51 minutes (range 28-92). Mean number of stitches were 4.7/patient (range 3-8). No procedure related complications were observed. Female were 56 patients; mean age was 45.4 (range 23-73). Mean BMI at inclusion was 41.6 (range 31.6-62.4).

Twelve months follow-up was done in 34 patients, 6 months in 26, 3 months in 10, while in 19 patients follow up was 1-month. Mean %EWL and %TBWL at 12 months was 37.6 and 15.6 respectively, at 6 months was 37.1 and 16.7, at 3 months was 30.6 and 13.8, while for 1 month was 16.9 and 7.8 respectively. Mean Baros score was 4.6 at 12 and 6 months, 3.9 at 3 months, while for 1 month was 2.7.

Comparing the two groups (11 patients in group 1 and 78 patients in group 2) there was significant (P< 0.05) difference in terms of %EWL and %TBWL (Table 1) for all periods of follow-up, with better results in group 2. There was also a significant improvement in the BAROS scale in the patients in group 2 (Table 1).

**Conclusion:** ME before and after ESG has a fundamental role in terms of better procedure outcomes for both weight loss and quality of life in obese patients.

**Disclosure:** Nothing to disclose

	WL (Kg)		%EWL		%TBWL		BAROS		p
	pre-ME	post-ME	pre-ME	post-ME	pre-ME	post-ME	pre-ME	post-ME	
1 month follow-up	5.7	10.8	11.5	19.7	5.2	9.1	1.4	3.3	<0.01
3 months follow-up	12.1	18.1	23.7	33.7	11	15.2	2.3	4.7	<0.05
6 months follow-up	14.1	22.4	26.5	42.2	14.7	18.8	2.5	5.7	<0.01
12 months follow-up	14.1	27.5	25.4	48.8	11.7	22	2.5	6.5	<0.01

WL = Weight Loss; EWL = Excess Weight Loss; TBWL = Total Body Weight Loss; BAROS = Bariatric Analysis and Reporting Outcome System.

## P1547 ENDOSCOPIC RESECTION OF NON-AMPULLARY DUODENAL POLYPS: A RETROSPECTIVE SINGLE CENTRE EXPERIENCE

Gunasigam N.<sup>1</sup>, Patel M.<sup>1</sup>, Gulati S.<sup>1</sup>, Haji A.<sup>2</sup>, Hayee B.<sup>3</sup>

<sup>1</sup>King's Institute of Therapeutic Endoscopy, Gastroenterology, London, United Kingdom, <sup>2</sup>King's College Hospital, Colorectal Surgery, London, United Kingdom, <sup>3</sup>King's College Hospital, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** nishmi@gmail.com

**Introduction:** Current literature estimates that complete endoscopic resection (ER) of duodenal adenomas can be achieved in 79-100% of cases, but complication rates are high and adenoma recurrence is encountered in up to 37% of cases (Basford & Bhandari, 2012). We present our retrospective experience.

**Aims & Methods:** Data from the electronic patient record was analysed for all patients who underwent duodenal polyp resection from June 2013 were included (excl. familial polyposis cases). Procedures were performed by either one of two endoscopists with experience in endoscopic resection. Accepted definitions of technical success, major adverse events and recurrence were used.

**Results:** 31 patients (15F; mean age 67.9±10.4 y) were included. The mean polyp size was 38.8±23.6 mm, with most (n = 26) located within D2. More than half were laterally spreading lesions (n=16). The main method of resection was with piecemeal EMR (n=24), with 5 removed by en-bloc EMR and 2 by ESD. Histology revealed tubular adenoma low grade dysplasia (n = 12), tubulovillous adenoma with low grade dysplasia (n = 11) and neuroendocrine tumour (n = 3). ER was successful in 28 / 31 cases (90.3%). Mean size in 3 incomplete resections was 93mm, with 1 patient referred for surgery, 1 repeat ER and 1 did not proceed due to a more pressing medical diagnosis.

3/31 had peri-procedural complications: endoscopically-treated perforation in 2 (6%) and minor bleeding in 1. 2/31 patients (6%) experienced delayed bleeding, with one patient requiring a repeat OGD but no intervention and the other requiring transfusion of packed red blood cells and observation in hospital. There was no procedure related mortality. At time of writing 4 patients had not yet had surveillance OGD and to date 5 patients (20.8%) had recurrence all treated endoscopically.

**Conclusion:** ER of duodenal polyps is feasible and safe. Our single centre experience is on par with what is published in the literature in regards to technical success and adverse events. A prospective analysis would be of value to guide patient selection, optimal treatment and surveillance protocols.

**Disclosure:** Nothing to disclose

## P1548 LONG-TERM OUTCOMES OF GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION IN ENDOSCOPIC CURABILITY CRITERIA

Konishi H., Kuwai T., Moriuchi R., Wada K., Tao K., Miura R., Tamaru Y., Kusunoki R., Yamaguchi A., Kouno H., Kohno H.  
National Hospital Organization Kure Medical Center and Chugoku Cancer Center, Gastroenterology, Kure, Japan

**Contact E-Mail Address:** hirox2x4@gmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early gastric neoplasms, and its indication is becoming expansive. The absolute-indication criteria for gastric ESD have been expanded in the Japanese gastric cancer treatment guidelines 2018. According to the new guidelines, endoscopic curability A (eCura A) is 1) lesions of any size without UL, differentiated-type, and pT1a or 2) lesion size  $\leq 3$ cm with UL, differentiated-type, and pT1a; whereas endoscopic curability B (eCura B) is 3) lesion size  $\leq 2$ cm without UL, undifferentiated-type, and pT1a or 4) lesion size  $\leq 3$ cm, differentiated-type, and pT1b(SM1,  $<500\mu\text{m}$ ). The eCura A cases are recommended to be followed up by annual EGD, whereas the eCura B cases are recommended to be followed by CT or US in addition to annual EGD. However, few studies have compared the short-/long-term outcomes of gastric ESD between the new endoscopic curability criteria.

**Aims & Methods:** This study aimed to evaluate and compare the clinical outcomes of ESD in early gastric cancers with eCura A and B lesions. The participants included 476 patients with 554 early gastric cancers, diagnosed as having eCura A or B lesions. All patients underwent ESD at our hospital between June 2007 and August 2018. The patients were divided into 2 groups: eCura A lesions (Group A, 419 patients with 483 lesions) and eCura B lesions (Group B, 70 patients with 71 lesions). We evaluated the clinicopathological findings; short/long-term outcomes including the local, distant, and metachronous recurrence rates, and the overall and disease-specific survival (OS and DSS) rates.

**Results:** The mean ages of Groups A and B were 72.9 and 68.5 years, respectively, and the male-to-female ratios in Groups A and B were 319/100 and 56/14, respectively. The mean tumor sizes in Groups A and B were 15.5 and 13.6mm, respectively. From the histopathological findings, the rates of differentiated-type were 100% (483/483) in Group A and 62.0% (44/71) in Group B ( $p < 0.01$ ). Regarding the tumor depth, intramucosal carcinomas were 100% (483/483) in Group A and 38.0% (27/71) in Group B ( $p < 0.01$ ), and shallow submucosal invasive carcinomas ( $< 500\mu\text{m}$ ) were 62.0% (44/71) in Group B. The *en bloc* resection rates and curative resection rates were 100% in both groups. Adverse events included the incidence of postoperative hemorrhages of Group A and B were 3.11% (15/483) and 5.63% (4/71), respectively, and perforations during ESD for Group A and B were 0.21% (1/483) and 1.41% (1/71), respectively. Regarding the long-term outcomes, the local and distant recurrence rates were 0.41% (2/483) and 0% (0/483) in Group A, and 0% (0/71) and 0% (0/71) in Group B, respectively (n.s.). The metachronous recurrence rates in Group A and B were 6.83% (33/483) and 5.63% (4/71), respectively (n.s.). Regarding the survival analysis (using the Kaplan-Meier method and long-rank test), the mean follow-up periods for Group A and Group B were  $51.6 \pm 35.2$  and  $49.9 \pm 35.3$  months, respectively. The 3 and 5 y OS rates were 93.1% and 90.0% in Group A, and 100% and 90.6% in Group B, respectively. The 5-year DSS rates were 100% in both groups. There were no significant differences observed for the survival rates.

**Conclusion:** The eCura B lesions have an excellent long-term prognosis equivalent to that of eCura A lesions. Therefore, the new endoscopic curability criteria are considered apt, and there is a possibility that eCura B lesions could be treated in the same manner as eCura A lesions.

**Disclosure:** Nothing to disclose

## P1549 SEQUENTIAL THERAPEUTIC APPROACH FOR PERSISTENT GASTRO-CUTANEOUS FISTULAS AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) REMOVAL IN CANCER PATIENTS

Currais P.<sup>1</sup>, Faias S.<sup>2</sup>, Francisco F.<sup>3</sup>, Sousa L.<sup>3</sup>, Gramancho J.<sup>3</sup>, Pereira A.D.<sup>3</sup>  
<sup>1</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, Gastroenterologia, Lisboa, Portugal, <sup>2</sup>Ipo Lisboa, Gastroenterology, Almada, Portugal, <sup>3</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal

**Contact E-Mail Address:** pedro\_currais@live.com.pt

**Introduction:** PEG removal in head and neck cancer patients (HNCPs) is required after completion of treatment, in case of tumor remission and after adequate oral intake is resumed. The PEG tract usually closes spontaneously within 48 to 72 hours. Persistent gastro-cutaneous fistula (PGCF) is a rare complication after PEG tube removal. The diagnosis is established in case of persistent gastric leakage through the fistulous tract for more than 30 days after PEG removal.

**Aims & Methods:** Our goal was to evaluate the incidence and treatment algorithm of PGCF in HNCPs.

This is a retrospective unicentric study of HNCPs referred for PEG removal between 2014-2018. The patients with PGCF were evaluated and their sequential treatment (medical, endoscopic and surgical) was reviewed, and technical and clinical success were assessed.

**Results:** During the study period, 331 PEG tubes, all with 24 French were removed. There were 313 (94.7%) male patients, with a mean age of  $59 \pm 11$  years (18-85), with 19 PGCF (5.7%). Medical therapy (proton-pump inhibitors, prokinetics and antibiotics in case of infection, for 2 to 8 weeks) was performed with clinical success (definitive closure of the PGCF) in 12 (63.2%) patients. The remaining 7 patients required endoscopic or surgical treatment. In 4 (21.1%), endoscopic treatment had technical and clinical success (3 patients with fulguration of the gastric leak edges with argon plasma coagulation (APC), silver nitrate in the path and external orifice, and closure of the internal orifice with hemoclips: mean number =  $6.33 \pm 0.47$  (range: 6 to 7), and 1 (5.3%) with an over-the-scope-clip (OTSC)). Only 3 patients underwent surgery, 1 due to clinical failure of sequential endoscopic therapy (hemoclips + OTSC) and 2 underwent direct surgery (one required surgery for another condition and one had a PEG-site herniation).

**Conclusion:** PGCF is a rare complication after PEG removal. Medical therapy is usually effective and should be maintained for at least 8 weeks. Endoscopic therapy is an effective second-line option and surgery is rarely required.

**Disclosure:** Nothing to disclose

## P1550 ENDOSCOPIC TREATMENT FOR ZENKER'S DIVERTICULUM WITH THE STAG BEETLE KNIFE (SB KNIFE) - PRELIMINARY RESULTS FROM A SINGLE-CENTER EXPERIENCE

Devani M.<sup>1</sup>, Reati R.<sup>2</sup>, Bezzio C.<sup>3</sup>, Saibeni S.<sup>4</sup>, Omazzi B.<sup>5</sup>, Arena I.<sup>6</sup>, De Nucci G.<sup>7</sup>, Della Corte C.<sup>6</sup>, Manes G.<sup>8</sup>  
<sup>1</sup>ASST-Rhodense, Milano, Italy, <sup>2</sup>ASST-Rhodense, Garbagnate, Italy, <sup>3</sup>ASST-Rhodense, Gastroenterology, Milano, Italy, <sup>4</sup>ASST-Rhodense, Gastroenterology, Rho, Italy, <sup>5</sup>Ospedale Rho, Gastroenterology, Rho, Italy, <sup>6</sup>ASST-Rhodense, Rho, Italy, <sup>7</sup>ASST-Rhodense, Gastroenterology and Endoscopy Unit, Milano, Italy, <sup>8</sup>ASST-Rhodense, Gastroenterology, Garbagnate, Italy

**Contact E-Mail Address:** massimo.devani@gmail.com

**Introduction:** Flexible endoscopic treatment of symptomatic Zenker's diverticulum (ZD) is an established treatment option. Over the years, various techniques have been developed and many devices have been tested with varying results. We report our experience with a scissor-shaped, rotating device with two insulated monopolar blades (SB knife) designed primarily for endoscopic submucosal dissection. Little data are reported about its use for endoscopic treatment of Zenker diverticulum.

**Aims & Methods:** From February 2014 to April 2019, n=20 patients (pts) were treated at ASST-Rhodense with the SB knife junior. The two insulated blades allowed to avoid the use of the overtube. The procedures were performed with a cap to better evaluate the diverticulum and the septum. All patients underwent an esophagram before the procedure and post-procedure, to rule out perforation and to assess esophageal transit. Symptoms (dysphagia, regurgitation, and respiratory symptoms) were analyzed

before and at the follow up using a validated scale. Procedure duration, rate of complications, symptom changes after the procedure and rate of relapsing patients during follow up were also recorded.

**Results:** The procedure was carried out successfully in all patients. The mean size of ZD was 3 cm (1-6 cm). Eighteen out of 20 (90%) patients received one treatment session. The mean procedure time was 28 min (18-60 min). In 4 procedures (20%), one to two clips were prophylactically placed at the bottom of the resection line. Two patients (10%) required a second treatment after a mean of 14 months (2-26) due to symptomatic recurrence; both patients were at the very beginning of our experience (pts n.2 and n.3) and the recurrence of dysphagia was likely to be as a result of an incomplete division of cricopharyngeal fibers of the septum. Two minor intraprocedural bleedings were easily treated by the "coagrasper" use of the device. No major bleeding or late-onset bleeding developed. One minor perforation occurred (minimum free air in the mediastinum, no mediastinitis, no leak of hydrophilic medium per os) and was successfully treated with medical therapy.

During a mean follow-up of 27 months (1-60), a significant symptom improvement was achieved in all the scores (dysphagia; regurgitation; respiratory symptoms).

**Conclusion:** Flexible endoscopic treatment of ZD with the SB knife is safe, effective, and has lasting effects on symptoms also at long term follow up, with a relatively low recurrence rate.

**Disclosure:** Nothing to disclose

### **P1551 PERSISTENT GASTRO CUTANEOUS FISTULAS AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY TUBE REMOVAL IN HEAD AND NECK CANCER PATIENTS WITH EARLY FEEDING AND DOUBLE-DOSE PPI: A PROSPECTIVE COHORT STUDY WITH A HISTORICAL CONTROL GROUP**

Currais P.<sup>1</sup>, Saraiva S.<sup>1</sup>, Cortez-Pinto J.<sup>2</sup>, Castela J.<sup>3</sup>, Francisco F.<sup>4</sup>, Sousa L.<sup>4</sup>, Gramancho J.<sup>4</sup>, Faia S.<sup>5</sup>, Pereira A.D.<sup>4</sup>

**Introduction:** Percutaneous endoscopic gastrostomy (PEG) removal is required in head and neck cancer patients (HNCP), after chemoradiotherapy ends and adequate oral intake is reacquired. The PEG tract usually closes spontaneously within 48-72 hours. Persistent gastro-cutaneous fistula (PGCF) is an uncommon complication of PEG removal.

**Aims & Methods:** Our aim was to compare the incidence of PGCF in two groups of HNCP removing PEG under distinct protocols.

We performed a prospective cohort study with a historical control group. Group A, with 86 patients who removed PEG in 18-month period (May15-Dec16) and Group B, a historical control group, with 102 patients who removed PEG in a 14-month period (Jan14-Apr15). There were two different PEG tube removal protocols. Group A had 4h of rest and fasting, followed by cold liquid diet 4/4h and omeprazole 40mg bid for 4 weeks. Group B rested for 6h and initiated oral diet 12h after PEG removal. The study primary end-point was the incidence of PGCF in both groups and secondary end-points were to evaluate predictors and treatment of PGCF.

**Results:** Demographics were identical in Group A and B, 84.9% male with a mean of 56±9 years old and 86.3% male with a mean of 53±11 years old, respectively. In Group A: 67.4% were smokers; 6.9% had diabetes mellitus (DM) and 2.3% used corticosteroids. Median body mass index (BMI) reduction of 2.25 (0.73-4.11) Kg/m<sup>2</sup>. PEG complication rate of 13.9%, predominantly minor infections. Mean PEG placement time was 8.2±4.5 months, use PEG for nutrition for 2.4 months on average, with 11.6% of the patients not using PEG. Only 2 (2.3%) patients had PGCF after PEG removal, one closure with medical therapy (PPI+prokinetic+antibiotic) and other with through-the-scope (TTS) clips.

In Group B: 50% smokers; 5.9% with DM and 2.9% used steroids. Median BMI reduction of 2.39 (0.71-4.14) Kg/m<sup>2</sup>. PEG complication rate of 33.3%, most frequently infections. Mean PEG time was 8.5±4.6 months, use PEG for nutrition for 4.75 months on average, 9.8% of patients not using PEG. PGCF occurred in 9 (8.8%) patients, with 7 closures with medical therapy, 1 with an over-the-scope clip (OTSC) and 1 with surgery.

By multivariable analysis, PEG time (p=0.006; CI95% 1.05-1.26) and presence of early leak (4h) after PEG removal (p=0.002; CI95% 4.10-9.63) were independent predictors of PGCF. The new protocol reduced the number of PGCF (2 cases versus 9 in the historical control group), nearly reaching statistical significance (p = 0.056, IC95% 0.87-19.57).

**Conclusion:** The new PEG removal protocol showed a tendency to reduction of PGCF, with less of time in hospital and fewer fasting hours. As PEG time is a predictor of PGCF, early removal of PEG is recommended. Patients with early leak post-PEG removal should be informed that, if PGCF installs, medical treatment is effective, and endoscopy or surgery are rarely required.

**Disclosure:** Nothing to disclose

### **P1552 A SUBMUCOSAL FLUID CUSHION PREVENTS MUSCLE LAYER DAMAGE DURING MUCOSAL ARGON PLASMA COAGULATION**

**Introduction:** Thermal damage to the muscle layer of the gastrointestinal wall can occur during mucosal application of argon plasma coagulation (APC). This injury may be mitigated by creating a fluid cushion within the submucosal layer. This can be achieved during endoscopy by injecting fluids directly into the submucosa, thus creating a cushion effect, using a needle and syringe or a high pressure needleless injection system. The fluid cushion physically separates the mucosal layer from the muscle layer and suppresses unwanted tissue temperature elevation. This in turn protects the muscle layer from thermal damage. The coagulative threshold of muscle proteins is known to be about 60°C, but there are no published systematic assessments of the minimum injection volume needed nor the ideal injectate to prevent thermal damage to the muscle layer during mucosal APC ablation.

**Aims & Methods:** Our aims were, firstly, to measure the final temperature inside the fluid cushion after mucosal ablation with APC and then to determine any differences in the final temperature between various injectable solutions. Secondly, we sought to determine the minimum volume of injectate required to protect the muscle layer from thermal damage.

All experiments were performed in an ex-vivo porcine gastrointestinal tract model. Five different fluids (normal saline, Glyceol, Gelafundin, Voluven and Eleview) of different volumes (range 0 - 5mL) were injected into the submucosa of the esophagus, stomach (fundus) and rectum to create a fluid cushion. APC was applied to the mucosa for a fixed duration (3s) at different power settings (ranging from 30 - 120W). Immediately after APC treatment, the final temperature was measured by placing a contact thermometer inside the fluid cushion, just on top of the muscle layer. The minimum volume of fluid needed to protect the muscle layer from thermal damage was also determined.

**Results:** There was no significant difference in the temperature measured at the surface of the muscle layer between elevation with normal saline, Glyceol, Gelafundin, Voluven and Eleview at all 3 tissue locations at equal injection volumes and power settings. The experiments showed that the temperature rose for each injectate with heightened power settings but also decreased with increasing volume of injected fluid. The minimum amount of fluid needed to protect the muscle layer from thermal damage was 2mL for the esophagus, stomach and rectum in the case of a power setting between 30 to 90W and 3mL in the case of 90 to 120W.

**Conclusion:** Normal saline and four commercially available submucosal injectates possess similar thermoregulatory effects in terms of acting as an insulator of the muscle layer during APC treatment. As opposed to the choice of injectate or anatomic location treated, the volume of fluid injected is the main determinant of the final temperature at the level of the muscularis propria. To reduce the likelihood of thermal damage to deeper layers of the GI tract when APC is applied, a minimum injection volume of 2mL is recommended if < 90W of power is utilized.

**Introduction:** Esophageal epiphrenic diverticula are infrequently associated with achalasia and major disorders of esophageal peristalsis. The mainstay of treatment is laparoscopic myotomy and diverticulectomy with anterior fundoplication. However, in case of contraindication and/or disapproval of the procedure by the patient, there are limited ways of alternative treatment. S-POEM (salvage POEM) has gained some evidence as a eligible treatment for achalasia and esophageal epiphrenic diverticula. However, the effectivity of the procedure has yet been demonstrated only in case reports and the data based on the series of patients are lacking.

**Aims & Methods:** We present a case series of 7 symptomatic patients with achalasia or spastic motility disorders and large epiphrenic diverticulum that have been treated by S-POEM. In these patients Eckhardt score was calculated, barium contrast study was performed and the posture and the size of the diverticulum was recorded before the procedure. High resolution manometry (HRM) was performed and in case of the detection of major disorder of peristalsis according to the Chicago classification v3.0 POEM procedure was performed. Generally, the myotomy was guided on the site opposite to the diverticular sack. After 3 months patients were invited for checkup, during which the general well-being and Eckhardt score was evaluated, upper endoscopy and HRM was performed.

**Results:** 7 patients (3 men, 4 women) met the inclusion criteria. Mean age was 69 years (range 43-80 y.). HRM revealed achalasia in 6 patients, I. type in 5 patients, II type in 1 patient. In one patient we were not able to classify the motility disorder due to previous intervention. Mean radiological size of diverticula was 6 x 4,8cm (range 4x4 - 11x9 cm). The most common complaint was dysphagia (mean partial Eckhardt score for dysphagia 2), followed by regurgitation (mean partial Eckhardt score for regurgitation 2). Posterior POEM procedure was performed in 6 patients, anterior procedure in 1 patient. In 3 months follow up we observed significant decrease of Eckhardt score (6.6 vs. 0.6,  $p < 0.0001$ ). There was a significant improvement in dysphagia and regurgitation (2 vs. 0.17  $p < 0.01$ , 2 vs. 0.33  $p < 0.01$ ). A dramatic decrease of IRP was also observed (31.8 vs. 8.8,  $p < 0.0001$ ). The average weight gain was 6.8 kg. There were neither complications related to the procedure, nor any aspiration event detected at 3 months follow up. **Conclusion:** S-POEM provided effective symptomatic improvement and significant decrease of the LES relaxation pressure in patients with esophageal epiphrenic diverticula associated with achalasia or spastic motility disorders. However, long term follow up in a large cohort of patients is required before it is considered equivalent treatment alternative for these patients. Supported by U01 DK116311 and VEGA 1/0304/19

## P1554 QUALITY IN UPPER GASTROINTESTINAL ENDOSCOPY: IMPACT OF CLINICAL PRACTICE GUIDELINES PUBLICATION

João M., Alves S., Taveira F., Areia M., Elvas L., Brito D., Saraiva S., Cadime A.T.

Portuguese Oncology Institute of Coimbra, Gastroenterology, Coimbra, Portugal

**Contact E-Mail Address:** mafaldacaine@gmail.com

**Introduction:** Upper gastrointestinal (UGI) endoscopy is the gold standard for the diagnosis and treatment of most esophageal, gastric, and small-bowel disorders. The European Society of Gastrointestinal Endoscopy (ESGE) has identified quality of endoscopy as a major priority and has published performance measures in the field of a quality improvement initiative.

**Aims & Methods:** Our aim was to evaluate ESGE's performance measures for UGI endoscopy in a tertiary center and assess the effect of their publication on improving the quality of procedures.

Retrospective cohort study included all UGI endoscopies performed in a single center between 2016 and 2018. We performed a global evaluation of performance measures defined by ESGE guideline and a comparative analysis between the period previous (2016) and subsequent (2017-2018) to their publication using Chi<sup>2</sup> test.

**Results:** A total of 3289 procedures were evaluated. Regarding key performance measures, proper fasting instructions were received in 99.9%; procedure duration was documented in 97.5%; accurate photo documentation was reported in 70.6%; standardized terminology was used in 35.9%; Seattle protocol in Barrett's surveillance was adopted in 55.9% and immediate and delayed complications were monitored in 99.4% and 77.6%, respectively. As far as minor performance measures are concerned, inspection time in the stomach was appropriate in 72.4%; lugol staining in esophagus for patients at risk of squamous cell cancer was used in 88.9%; biopsy protocol according to MAPS guidelines was applied in 76.1% and 55.6% of Barrett's patients entered a registry to monitor the incidence of dysplasia. Considering comparative analysis between 2016 and 2017-2018, we have verified statistically significant improvement in the accurate photo documentation (56.6% vs. 76.7%;  $p < 0.01$ ); in the standardized terminology use (24.1% vs. 42.7%;  $p < 0.01$ ) and in the inspection time in the stomach (70.7% vs. 76.3%;  $p < 0.01$ ).

**Conclusion:** In our center minimum standards are fulfilled to fasting instructions, documentation of procedure duration and registration of immediate and delayed complications after therapeutic endoscopies. The remaining measures require improvement and subsequent auditing. Disclosure of performance measures, followed by auditing and correction, may allow Gastroenterologists to improve UGI endoscopy quality.

**Introduction:** Endoscopic diagnosis of gastric cancer at an earlier stage is the single most effective strategy for reducing gastric cancer mortality. Magnifying narrow-band (M-NBI) imaging endoscopy significantly improves the diagnostic accuracy of gastric epithelial neoplastic lesions [1]. However, effective application of M-NBI endoscopy is difficult due to the presence of various changes of gastric mucosal patterns, and therefore requires appropriate training. Computer-aided decision support systems based on endoscopic image analysis are being designed to assist an endoscopist in enhancing the diagnosis and mastering advanced techniques that require a high level of expertise [2].

Recently convolutional neural networks have become one of the most popular and effective approaches in different fields of endoscopic image analysis.

**Aims & Methods:** The aim of this study was to develop a system for automatic identification of gastric cancer on M-NBI images using deep learning through convolutional neural networks (CNN). The database of 1293 M-NBI endoscopic images was created. It consisted of 357 M-NBI images of cancerous lesions and 936 M-NBI images of non-cancerous lesions (Olympus Exera II, GIF Q160Z, Lucera GIF, Q260Z, EXERA III, GIF HQ 190). The developed image analysis algorithm was based on the application of the SSD (Single Shot Multibox Detector) architecture of convolutional neural network. The network architecture was implemented using the Caffe framework. The neural network was pre-trained on the ImageNet [3] image database which was used to initialize part of the weights. The weights of the remaining layers were initialized using Xavier initialization. Neural network training was done simultaneously with 8 GPU video cards of the NVIDIA DGX-1 supercomputer. For numerical experiments 100 images were randomly selected from the endoscopic image database: 24 images of cancer and 76 images non-cancerous lesions. The videodata of M-NBI endoscopic procedures (415 frames which were not presented in the database) was blindly analyzed by the designed system and an expert endoscopist to compare it with the doctor's diagnosis. Spatial correlation between automated results and experts opinion was assessed.

**Results:** Average precision for “cancer” class was 0,827, average precision for “non-cancer” class was 0,923, mean average precision was 0,875. Average intersect over union (IoU) score (area of intersection the expert frame and the frame obtained using algorithm / total area combining these frames) was 0,767 which corresponds to high concordance between automated and expert marking of gastric cancer areas.

**Conclusion:** The proposed algorithm of image analysis based on deep learning through SSD convolutional neural network allowed to design the automated system for NBI-M endoscopic diagnosis of gastric cancer. The designed system is able to analyze videodata and can be implemented in endoscopic electronic data collecting system for further testing in daily clinical practice.

**Introduction:** Endoscopic intravariceal injection of cyanoacrylate, especially of N-2-butyl cyanoacrylate (NBC) is the treatment of choice for bleeding from type 2 gastro-esophageal varices (GOV 2) and isolated gastric varices (IGV), whether in acute phase or in a secondary prophylaxis setting. This endoscopic therapy has not been evaluated in our country. In this study, we evaluated the efficacy of this technique in the secondary prophylaxis of bleeding from GOV 2 and IGV and we have also estimated hemostasis rates and either complications of this technique and predictive factors for recurrence.

**Aims & Methods:** A prospective analysis of clinical, biological, endoscopic and evolutive parameters was carried out in patients recruited and treated consecutively, which we divided into two non-comparative groups: a group 1 (G1) of patients treated in secondary prophylaxis and a group 2 (G2) of patients treated in acute bleeding phase. Statistical analyses were performed using SPSS software (version 22.0; SPSS Inc., Chicago, IL, United States). Descriptive data are reported as mean  $\pm$  SD or as percentage. The Student's t test and the  $\chi^2$  test were used to assess differences between groups. Forward stepwise logistic regression analyses, both univariate and multivariate, and receiver operating characteristic curve (ROC) analysis were used to determine the correlation between factors and clinical outcomes; The actuarial survival curve was established by the Kaplan-Meier method. The comparisons of survival curves were made using the Logrank test. A P value  $< 0.05$  was considered statistically significant.

**Results:** 75 patients (37 males, 38 females), sex\_ratio=0.9 with a mean age of  $54.23 \pm 3.46$  years were enrolled and followed for an average duration of  $16.27 \pm 2$  months, 44 patients were G1 and 31 G2. Gastric varices (GV) were GOV 2 in 96% of cases and were related to cirrhosis in 55 patients (73%). Immediate and initial hemostasis rates in the G2 were 95% and 90%, respectively, and the failure rate was about 10% (N=3) in the same group. Minor complications were observed in 38.7% in the G2 (N=12) and 29.5% cases in the G1 (N=12). Major complications were seen in 9.7% in the G2 (N=3), including a case of pulmonary embolism and in 2.3%, in the G1 (N=1)

represented by a single case of spontaneous bacterial peritonitis. Mortality was estimated at 9.7% in the G2 (N=3) and 0% in the G1 (N=0). The G1 bleeding recurrence rate was estimated at 0% at six weeks and at 9.1% at 1 year (N=4) and the mean survival without recurrence was evaluated at 22.7 months  $\pm 1.24$  [20.26-25.13]. In multivariate analysis only the presence of ascites at the time of endoscopic treatment was a predictive factor of recurrence with an adjusted OR: 13.89 CI 95% [1.07-17.915].

**Conclusion:** Our study confirms the efficacy and relative safety of NBC injection in the treatment of GV either in secondary prophylaxis and acute haemorrhage setting. We confirm its feasibility in our environment with satisfactory hemostasis and bleeding recurrence rates and acceptable complications.

**Disclosure:** Nothing to disclose

## P1557 COATING OF METALIC STENTS WITH ACCELLULAR BIOMATRIX AND NANOFIBERS BASED SCAFFOLD CONTAINING A STEROID IN PREVENTING ESOPHAGEAL STRICTURE AFTER CIRCUMFERENTIAL ENDOSCOPIC DISSECTION - AN EXPERIMENTAL STUDY

**Contact E-Mail Address:** dolezelrad@uvn.cz

**Introduction:** The major drawback of circumferential endoscopic submucosal dissection (CESD) in the esophagus is development of refractory stricture in almost 100% of cases. We have previously shown that a self-expandable metallic stent (SEMS) covered with acellular biomatrix from pig's dermis resulted in reduced stricture severity and improved quality of healing (Dolezel et al. *GIE* 87.6 (2018): AB266-7).

**Aims & Methods:** To assess the effect of a newly developed drug eluting SEMS coated with acellular biomatrix and with a nanofibers-based scaffold (from a polymer solution) containing a steroid (Depomedrol 104 mg) in preventing the post-CESD esophageal stricture.

An experimental controlled study. CESD were performed in the mid-esophagus in 14 pigs (control group, A, n=6; interventional group, B, n=8). After completing CESD, SEMS were placed alongside the post-CESD defect and fixed with a lasso technique. SEMS were removed 21 days after CESD. Pigs were euthanatized when a significant stricture developed.

**Results:** The mean length of the defect was  $54 \pm 15$  mm. Significant strictures developed in all pigs after a mean of  $12.8 \pm 4.3$  days. The length of stricture was  $26.6 \pm 14.9$  mm in the control group and  $17.0 \pm 10.4$  mm in the B group, (p=0.19). The narrowest stricture diameter did not differ between the groups ( $8.8 \pm 4.0$  mm (A) vs.  $8.6 \pm 2.1$  mm (B), p=0.45). Macroscopic re-epithelization was not detected in 66% (4/6) of pigs in the control group, while it was always present in the B group, p=0.06. The re-epithelization length (measured as the longest distance of new epithelization from the edge of the defect) was  $1100 \pm 935$   $\mu$ m in the control group vs.  $679 \pm 489$   $\mu$ m in the interventional group (p=0.39). The re-epithelization width was  $105 \pm 115$   $\mu$ m (A) and  $236 \pm 202$   $\mu$ m in the B group, p=0.24. Thickness of fibrosis was  $2.3 \pm 1.1$  mm (A) and  $2.0 \pm 0.1$  mm (B), p=0.36. Histologically, severe inflammation was present in all pigs in the control A group, while in no pig in the B group (only mild inflammation), p=0.0008.

**Conclusion:** Depomedrol eluted from SEMS covered with acellular biomatrix was unable to effectively prevent post-CESD esophageal stricture in the experimental model. However, it significantly improved microscopic healing quality in terms of re-epithelization and less severe inflammation. The stent may be a suitable candidate for further development.

## P1558 UNSEDATED UPPER GASTROINTESTINAL ENDOSCOPY: DOES TOPICAL PHARYNGEAL ANESTHESIA MAKE IT MORE TOLERABLE?

Ferchichi L., Sabbah M., Trad D., Ouakaa A., Bibani N., Elloumi H., Gargouri D.

Habib Thameur Hospital, Department of Gastroenterology, Tunis, Tunisia

**Contact E-Mail Address:** ichrakferchichi.if@gmail.com

**Introduction:** In many countries, upper gastrointestinal endoscopy (UGIE) is commonly performed without sedation, which avoids the cost and risk of procedural sedation altogether. Adequate patient tolerance is essential for successful completion of a safe examination. As a result, endoscopists tend to use a topical pharyngeal anesthesia (TPA) as a pretreatment for unsedated UGIE. However its efficiency has not been established.

**Aims & Methods:** The purpose of this study is to assess the tolerance of unsedated UGIE and to determine whether TPA has an impact on patients' tolerance level. A prospective study during a period of 6 months (November 2018 - April 2019) was conducted. Patients who underwent unsedated UGIE were included and randomly divided into two groups: with and without TPA administration (xylocaine spray).

A comparison of UGIE tolerance between the two groups was performed. Patients who were under psychotropic or analgesic treatment were excluded from this study. The UGIE tolerance evaluation was based on a primary criterion: the patient's acceptance to undergo the examination again under the same conditions.

The secondary criteria were: the occurrence of a suffocation sensation, the occurrence of nausea and the level of pain/discomfort measured using the visual analog scale (VAS) (0 = no pain/discomfort encountered to 10 = extremely painful/uncomfortable).

**Results:** Seventy patients (female=36, male=34, mean age 50 years [18-82]) were included. UGIE was mostly performed for epigastralgia (48.6%) and iron deficiency anemia (17%). UGIE was well tolerated in 65.7% of patients: forty-six out of seventy accepted to undergo the same procedure. The refusal to repeat the examination was significantly related to suffocation sensation ( $p < 0.01$ ), nausea ( $p < 0.01$ ) and the level of pain/discomfort ( $p < 0.01$ ).

There was no significant difference between the 2 groups in terms of tolerance according to the primary and the secondary criteria. The VAS score was 4.66/10 for patients who received TPA versus 5.49/10 for those who didn't receive TPA. Unsedated UGIE was less tolerable in female patients ( $p < 0.01$ ) and in less than 40 year-old patients but with no statistical significance ( $p = 0.08$ ). Previous endoscopic experience and longer examination time didn't seem to interfere with patient's tolerance level.

**Conclusion:** The use of a Topical pharyngeal anesthesia appears to be beneficial for male and for over 40 year-old patients. Otherwise, TPA doesn't seem to improve unsedated UGIE tolerance.

**Disclosure:** Nothing to disclose

## P1559 COMPARISON OF PERORAL ENDOSCOPIC MYOTOMY (POEM) IN ESOPHAGEAL ACHALASIA FOR NAIVE PATIENTS AND PATIENTS WHO FAIL OTHER TREATMENTS. RESULTS OF A MULTICENTER STUDY ON 105 PATIENTS

**Contact E-Mail Address:** raphael.olivier0714@orange.fr

**Introduction:** Peroral Endoscopic Myotomy (POEM) is part of the modern therapeutic arsenal for the management of achalasia. Its effectiveness has been widely demonstrated and it is now often offered as a first-line treatment. Nevertheless, the overall impact of previous processing operations on the results of this intervention remains to be determined in current practice. The purpose of our study was therefore to compare the feasibility, morbidity and efficacy of POEM in naïve and naïve patients.

**Aims & Methods:** Clinical, manometric and endoscopic data from patients treated for esophageal achalasia with POEM in 2 tertiary centers were collected prospectively and analyzed retrospectively. Esophageal motor disorders were defined according to the Chicago Classification v3.0. Symptoms were assessed using Eckardt's score before POEM, then at 1 and 6 months post-procedure. Esophageal manometry data (before the procedure and at 6 months), gesture data (procedure duration, myotomy length, number of clips), per and postoperative complications (bleeding, infection, hospitalization duration) and efficacy (defined by an Eckardt score  $\leq 3$ ) were collected. The data were compared by matched and unpaired t-test or by Chi2 test.

**Results:** A total of 105 patients (40 females, 38.1%, median age = 51.2[38.2-64.8] years) were included between July 2015 and October 2018. Twenty-five patients (23.8%) had type I achalasia, 63 (60.0%) type II achalasia, 13 (12.4%) type III achalasia and 4 (3.8%) a variant. Fifty-two (49.5%) patients were naïve to any treatment and fifty-three (50.5%) had previous treatment, (49 patients, had at least one pneumatic dilation, 7 had Heller's myotomy and 4 had botulinum toxin injection). The characteristics of the 2 groups were comparable in terms of sex, age, type of achalasia, Eckardt score, resting pressure of the lower esophageal sphincter (LES) and integrated relaxation pressure (IRP) before POEM.

With regard to the feasibility and the safety of the gesture, no significant differences were found between the two groups concerning: the duration of the intervention (naïve = 45[36-60] minutes vs non naïve = 50[35-65] minutes;  $p = 0.1647$ ), the length of the myotomy (naïve = 10[8-10]cm vs. non naïve = 9[8-10]cm;  $p = 0.4275$ ) or the number of clips used to close the submucosal tunnel (naïve = 6[5-7] vs. naïve = 6[6-7];  $p = 0.3221$ ). There was no significant difference concerning per and postoperative complications notably for severe complications. Two patients (1.9%) (1 naïve et 1 non naïve, no statistical difference  $p = 1.00$ ) had a mediastinitis of favourable progression after endoscopic treatment; associated with surgical drainage for one and radiological drainage for the other, without esophagectomy.

Myotomy treatment was considered successful (Eckardt score  $\leq 3$ ) in 77/87 patients (88.5%) at 6 months. The efficacy of POEM at 6 months was comparable between the 2 groups: 39/44 patients (92.9%) in the naïve group and in 38/43 (84.4%) in the non naïve group ( $p = 0.1288$ ). Esophageal manometry data were available for 66/87 patients. There was no significant difference in the post-POEM IRP and lower esophageal sphincter resting pressure between the 2 groups.

**Conclusion:** This study, conducted on a large number of patients under conditions of routine clinical practice, shows that the feasibility, morbidity and efficacy of POEM in achalasia at 6 months are comparable between naïve and non naïve patients. This technique can therefore be offered to patients with severe esophageal achalasia resistant to other therapies.

## P1560 SHOULD ROUTINE DUODENAL BIOPSIES ALWAYS BE PERFORMED IN ELDERLY PATIENTS WITH ANEMIA WITHOUT ENDOSCOPIC SIGNS OF BLEEDING?

Coluccio C.<sup>1</sup>, Lahner E.<sup>2</sup>, Angeletti S.<sup>3</sup>, D'ambra G.<sup>3</sup>, Ruggeri M.<sup>3</sup>, Annibale B.<sup>4</sup>, Di Giulio E.<sup>3</sup>, Corleto V.D.<sup>3</sup>

<sup>1</sup>Sant'Andrea Hospital, Gastroenterology, Rome, Italy, <sup>2</sup>University Sapienza, Dept Medical-surgical Sciences and Translational Medicine, Rome, Italy, <sup>3</sup>Sant'Andrea Hospital, Sapienza University of Rome, Endoscopy Department, Rome, Italy, <sup>4</sup>Sant'Andrea Hospital, Medical and Surgical Sciences, Rome, Italy

**Contact E-Mail Address:** chicol87@hotmail.it

**Introduction:** Anemia, a multifactorial condition, occurs in 12.7% of men and 30.2% of non-pregnant women worldwide. Specifically, iron-deficiency anemia (prevalence 2-5% of men and postmenopausal women in developed countries) is considered a warning sign especially in elderly

(colonic or gastric neoplasia), but it may be also due to benign conditions (coeliac disease (CD), duodenal intraepithelial lymphocytosis (DIL), chronic atrophic gastritis or *H. pylori*, poor dietary intake, non-steroidal anti-inflammatory drugs. Multimorbidity and polypharmacy may play an additional role. Anemia is found in 80-90% of CD, but the need for routine duodenal biopsies, independently from age or coeliac serology status, is debated. Guidelines from British Society of Gastroenterology recommend duodenal biopsies in individuals undergoing upper endoscopy (EGDS) in whom CD or alternative mucosal cause of malabsorption is suggested.

**Aims & Methods:** To determine diagnostic yield of routine duodenal biopsies in adult and elderly patients with anemia whose EGDS failed to reveal macroscopic causes of bleeding and to identify predictive features of duodenal histopathological findings. Single center cross-sectional study; between 2015-2018, among consecutive 7968 EGDS performed in our Endoscopy Unit, 744 were for anemia. Patients with manifest GI bleeding or no gastric/duodenal biopsies were excluded. In 469 (F 68%; median age 60yrs), both gastric and duodenal biopsies, were taken.

Clinical, endoscopic and histological features were collected and separately analyzed in the groups with or without histopathological changes of duodenal mucosa (DM). Univariate/multivariate analyses were performed (dependent variable: normal or pathological DM; independent variables: gender, outpatient/inpatient, age, endoscopic findings in stomach or duodenum). Different cut-offs for age were considered (>50, >60, >70, >80yrs).

**Results:** Of 469 included patients, 40(8.5%) had histopathological changes in DM: 12(2.6%) CD, 25(5.3%) DIL, 3(0.6%) others (2 *Giardia Lamblia* infection, 1 hypereosinophilia). Compared to patients with normal DM, they were younger (median age 47.5 yrs, range 20-90 vs 62 yrs, range 17-93,  $p=0.0005$ ) and showed more frequently duodenal endoscopic findings (22.5% vs 6.7%,  $p=0.0014$ ), while the stomach was endoscopically normal in all cases (0 vs 14.7%,  $p=0.0182$ ). The frequency of histopathological findings in the DM showed a significantly decreasing trend with increasing age, in patients aged < 40, 41-50, 51-60, 61-70, 71-80, and >80yrs, they were observed in 25%, 30%, 20%, 12.5%, 10%, and 2.5%, respectively ( $p=0.0010$ ).

Logistic regression models showed that endoscopically normal DM and age >50, >60, and >70yrs were significantly associated with normal DM biopsies. Anemic patients aged >60, >70, or >80yrs with endoscopically normal DM had a 3- to 4-fold higher probability of having normal duodenal histology (OR3.5, 95%CI 1.5-8.2, OR3.6 95%CI 1.6-8.5, OR4.1, 95%CI 1.8-9.4). The strength of association increased with increasing age. Other independent variables (gender, outpatient/inpatient, gastric findings) were not associated.

**Conclusion:** In anemic patients without endoscopic signs of bleeding, predictors for histologically normal DM were age and endoscopically normal DM appearance. In over 70yrs anemic patients infrequent or negligible pathological findings in DM were found.

These results suggest that taking routine duodenal biopsies is questionable in elderly anemic patients especially in absence of macroscopic duodenal alterations of other suspected signs of related intestinal diseases.

<sup>2</sup>Cleveland Clinic, Cardiac and Thoracic Surgery, Cleveland, United States,

<sup>3</sup>Cleveland Clinic, Hematology-Oncology, Cleveland, United States, <sup>4</sup>National Cancer Center, Endoscopy, Tokyo, Japan

**Contact E-Mail Address:** mehtan5@ccf.org

**Introduction:** Esophageal endoscopic submucosal dissection (ESD) can be technically challenging due to the narrow lumen and thin wall of the esophagus. Device and technique innovation is needed to make esophageal ESD easier to perform, especially in the West where experience and procedure volumes are less. The loose submucosa of the esophagus allows easy entry of the entire ceramic tip of an insulated tip (IT) knife within it. This allows for the backside chip (electrocautery blade on the backside of the ceramic tip) to dissect the submucosa, while the ceramic tip protects the muscle layer from injury as the knife is advanced.

This technique is called IT knife tunneling technique and has been described in Japan for esophageal ESD. We evaluated the safety and efficiency of the IT knife tunneling technique for esophageal ESD at our Western endoscopy center.

**Aims & Methods:** A single center study evaluating consecutive patients who underwent esophageal ESD with IT knife tunneling technique between July 2016-November 2017. This technique was not used on lesions with expected severe fibrosis. All ESDs were performed by a single ESD expert (AB). Primary aim was to determine safety of the technique, particularly regarding perforation, intraprocedural (>2-gram hemoglobin drop < 48 hours after procedure), and delayed (active bleeding from a post-ESD ulcer diagnosed by emergency or planned follow-up endoscopy) bleeding. Procedure time, resection speed, *en-bloc*, R0 (negative vertical and horizontal margins), and curative (R0 resection, well to moderately differentiated histology, absence of lymphovascular invasion, absence of budding, and absence of invasion beyond superficial submucosa (< 500 microns) for adenocarcinoma or no submucosal invasion for squamous cell cancer) resection rates were measured.

**Results:** 19 patients underwent esophageal ESD with IT knife tunneling technique [Table]. Median lesion size was 3 cm [25-75 IQR: 2.5-3.3], median procedure time 70 min [60.5-96.5], and median resection speed 0.364 cm<sup>2</sup>/min [0.269-0.482]. No esophageal perforations, strictures, or delayed bleeding. One case with intraprocedural bleeding requiring blood transfusion of one unit. *En-bloc*, R0, and curative resection rate 100% (19/19), 94.7% (18/19), and 73.7% (14/19), respectively. 4/5 of the non-curative lesions were known high-risk lesions; ESD performed because these patients were deemed non-surgical candidates. 17 patients had Barrett's-related neoplasms (5 high-grade dysplasia, 12 adenocarcinoma). Two had squamous cell cancer; these two large resections >2/3 esophageal circumference (6 and 7 cm) were injected with Kenalog and prescribed oral fluticasone to prevent stricture formation.

IT Knife Tunneling Technique	
N=19	
Factor	Statistics
Histology	
1) Barrett's Associated Neoplasm	17/19 (89.5%)
a) Esophageal Adenocarcinoma	12/17
b) High grade dysplasia	5/17
2) Squamous Cell Cancer	2/19 (10.5%)
Size of resected lesion (cm)	3 [2.5, 3.3]
En-bloc resection rate	70 [60.5, 96.5]
R0 resection rate	0.364 [0.269, 0.482]
Curative resection rate	14/19 (73.7%)
Perforations/Strictures	0/0 (0%/0%)
Significant Intraprocedural Bleed	1/19 (5.3%)
Significant Delayed Bleed	0/19 (0%)

[Table 1. Safety and Efficiency of IT Knife Tunneling Technique ESD Resection]

**Conclusion:** IT knife tunneling technique allowed for safe esophageal ESD of non-fibrotic lesions at our endoscopy center. Further use of this technique in the West is warranted.

**Disclosure:** Nothing to disclose

## P1562 THE EFFECT OF ENDOSCOPIC MUCOSAL RESECTION (EMR) VS ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) TECHNIQUE ON HISTOLOGIC MARGINS FOR ENDOSCOPICALLY TREATED EARLY ESOPHAGEAL ADENOCARCINOMA

Mehta N.<sup>1</sup>, Li F.<sup>1</sup>, Young A.<sup>2</sup>, Robertson S.<sup>3</sup>, Chahal P.<sup>1</sup>, Jang S.<sup>1</sup>, Cruise M.<sup>3</sup>, Vargo J.<sup>1</sup>, Stevens T.<sup>1</sup>, Bhatt A.<sup>1</sup>

<sup>1</sup>Cleveland Clinic, Gastroenterology and Hepatology, Cleveland, United States,

<sup>2</sup>Cleveland Clinic, Internal Medicine, Cleveland, United States, <sup>3</sup>Cleveland Clinic, Pathology, Cleveland, United States

**Contact E-Mail Address:** mehtan5@ccf.org

**Introduction:** Both endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) techniques are used for the treatment of early esophageal cancers. ESD has potential advantages including higher en

bloc and RO resection rates, which have been demonstrated for squamous cell carcinomas (ESCC) but data for esophageal adenocarcinoma (EAC) is more limited. Histologic determination of the horizontal and vertical margins is important to determine the completeness of resection and risk of recurrence. Larger tumors, especially those that spread laterally may exceed with limits of en bloc resectability using standard EMR techniques.

#### Aims & Methods:

**Aim:** To determine the effect of EMR vs ESD techniques on the histologic margins in endoscopically treated early EAC.

**Methods:** Our institution's endoscopy and pathology databases were queried for patients undergoing endoscopic treatment of early EAC. Endoscopic and histologic characteristics were collected. Pathology slides were re-reviewed by a blinded pathologist to determine status of horizontal and vertical margins. All statistical analyses were performed using SAS (version 9.4, The SAS Institute, Cary, NC) and a  $p < 0.05$  was considered statistically significant.

**Results:** A total of 52 patients with early EAC were analyzed. 23 patients underwent ESD and 29 had EMR. Tumors that underwent ESD were significantly larger compared to those resected with EMR technique (20.0 mm [20.0,28.0] vs 11.0 mm [9.0,13.0],  $p < 0.001$ ). Rates of endoscopic en bloc resection were not statistically different (EMR 89.7% vs ESD 100%,  $p = 0.25$ ). On the other hand, EMR specimens were significantly more likely to have positive lateral margins compared to ESD specimens (48.3% vs 8.7%,  $p = 0.003$ ) as well as have lower confidence in determining lateral margins. The reason for lower confidence in the EMR group included cautery artifact (37.9%) and difficulty in orientation (20.7%). Interestingly, EMR and ESD had similar rates of positive vertical margins (7.1% vs 8.7%,  $p = 0.33$ ).

**Conclusion:** EMR and ESD had similar rates of positive vertical margins but rates of positive horizontal margins were significantly higher in the EMR group, despite a smaller size of lesion resected in the EMR group. We postulate that this is a limitation of the EMR technique and there is a certain lateral size threshold or Paris classification that is unsuitable for EMR as the standard EMR cap assisted technique may not be able to resect enough of a "normal" margin to the tumor compared to ESD. Further analysis is needed to determine if early EAC below a certain size threshold or tumor morphology may be more amenable to EMR technique while other types of tumors should undergo ESD to ensure higher rates of negative margins.

## P1563 WHAT IS THE CAUSE OF MISSED GASTROINTESTINAL CANCERS AND DELAYS IN DIAGNOSIS?

Hayes B.<sup>1</sup>, Bjarnason I.<sup>2</sup>, Logan R.<sup>1</sup>, Hayee B.<sup>1</sup>, Dubois P.<sup>1</sup>, Haji A.<sup>2</sup>, Barker L.<sup>2</sup>, Chung-Faye G.<sup>1</sup>, Srirajaskanthan R.<sup>1</sup>, Kent A.<sup>1</sup>

<sup>1</sup>King's College Hospital, Gastroenterology, London, United Kingdom, <sup>2</sup>King's College Hospital, London, United Kingdom

**Contact E-Mail Address:** bradley.hayes@nhs.net

**Introduction:** A delay in diagnosis in Upper Gastrointestinal Cancer (UGIC) and Colorectal Cancer (CRC) are associated with poor outcomes. Multiple studies have looked at rates of missed cancers at endoscopy, but few have looked at other factors that delay the time to endoscopy. This study looks at systematic factors responsible for this delay, and identifies ways in which we can reduce this delay in both UGIC and CRC.

**Aims & Methods:** We looked at all patients diagnosed with an UGIC or CRC at King's College Hospital (KCH), London between 2011-2018 inclusive. From this group we identified all patients who were seen by a Gastroenterologist or a Colorectal Surgeon in the 36 months prior to diagnosis, either in clinic or at endoscopy. Each of these cases was looked at in detail to determine whether the cancer was missed due to a 'Systematic Factor' or was a 'Post Endoscopy Cancers' (PEC).

**Results:** 1,073 cases of GI Cancer were diagnosed in the study period. 60 of 797 (7.5%) cases of CRC and 28 of 276 (11.3%) UGICs had been seen in the last 36 months. 61 patients (5.7%) were determined to have a 'missed cancer'. From this group 10 UGICs and 23 CRCs were determined to be 'Post Endoscopy Cancers' (PEC). The remaining 28 cases were determined to be missed secondary to 'Systematic Factors'. Specific causes of delay in diagnosis are shown in Table 1.

The mean length of delay was longer in the 'Systematic Factors' group versus the 'PEC' group (430 vs. 264 days). The 'Systematic Factors' group also showed a more advanced TNM staging compared the 'PEC' group; pT 2.14 vs. 1.39, pN 0.57 vs. 0.45, pM 0.07 vs 0.12. The 'Systematic Fac-

tors' group also showed a higher percentage of patients referred routinely, rather than via an emergency cancer pathway, compared to the PEC group (74.1% vs. 53.8%).

Factor leading to delay	Number of patients
Post Endoscopy Cancers	33
Inadequate Investigation	10
Incomplete endoscopy	2
Poor bowel preparation	5
Missed on radiological investigation	2
Delayed investigation	4
Incomplete Follow up	4
Histology not reviewed	1

[Table 1. Factors leading to Delay of Diagnosis in Gastrointestinal Cancers]

**Conclusion:** Post Endoscopy Cancers are well-established concept, leading to delays in diagnosing gastrointestinal cancers. However it is important to identify Systematic Factors which also impact on speed to diagnosis. Higher proportions of missed cancer in the routine pathway imply that we are more likely to miss cancers without the pathway driven approach we see in Two Week Wait referrals. Systematic Factors are also more likely to contribute to a longer delay to diagnosis and a more advanced clinical picture as shown by the TNM staging. Therefore, if we are to improve diagnosis of Gastrointestinal Cancers we should focus equally on the Systematic Factors leading up to diagnosis as well as the quality of endoscopy.

**Contact E-Mail Address:** yosrasaid10@yahoo.fr

**Introduction:** Ingesting foreign bodies (FB) can be accidental or deliberate. It can be serious because of the location or nature of the FB, which makes their endoscopic extraction urgent. Prisoners represent a population particularly affected by this pathology.

**Aims & Methods:** The purpose of our study was to describe the modalities of this endoscopic technique as well as to highlight its particularities in the inmates. We conducted a comparative retrospective study of consecutive patients who had undergone upper digestive endoscopy for foreign body extraction between January 1982 and December 2018. We have compared prisoners to non incarcerated patients.

**Results:** We included 99 patients (74 men and 25 women) with a mean age of 29 years [6 months-66 years]. Endoscopy was performed for all patients. Of these patients, 30.3% were inmates. A psychiatric history was found more frequently among prisoners than non prisoners (90% versus 24.6%,  $p < 0.001$ ). The FB's ingestion circumstance was more voluntary for the detainee (90%, OR = 29,  $p < 0.001$ ). FBs were more numerous among inmates (43.3% versus 13%,  $p < 0.001$ ), with a higher frequency of metallic FB (70% versus 13%,  $p < 0.001$ ) and larger dimensions than non-incarcerated patients (63.6% versus 37.7%,  $p = 0.02$ ). The success rate of the extraction was 78% with no statistically significant difference between the two groups. Recurrence of FB ingestion was higher in the case of incarceration (13.3% versus 5.8%,  $p = 0.038$ ).

**Conclusion:** The multiple number, the large size of the ingested body and the predominance of metallic ones testify the severity of FB ingestion in the inmates. These are characteristics to be considered by the practitioner before extraction and also for better management of a fragile population in order to reduce the recidivism rate.

**Contact E-Mail Address:** kuvaev\_roman@mail.ru

**Introduction:** Gastric intestinal metaplasia (GIM) is considered as a premalignant condition and associated with a high risk for the development of gastric cancer [1]. However, conventional white light imaging endoscopic features of GIM has a high rate of interobserver variability and correlates poorly with the histology. Uedo et al. first described “light blue crest” (LBC) sign as highly accurate sign of the presence of histological GIM using magnifying endoscopy and narrow band imaging (NBI) system with a monochrome CCD and rotary RGB filter (Lucera, Olympus) [2]. LBC was defined as an optical phenomenon caused by the reflectance of narrowed spectrum light on the ciliated surface of the epithelium that can be seen at the tangential observation of edge of the surface. However the possibility of LBC detection and its efficacy in diagnosis of GIM with other narrowed spectrum technologies were not fully investigated.

**Aims & Methods:** The aim of this study was to evaluate the diagnostic efficacy of LBC in diagnosis of GIM with magnifying i-scan optical enhancement endoscopy (PENTAX Medical, Japan). 86 gastric lesions in 46 patients (mean age 52.1 years, SD=10.2, 54% male, 46% female) were observed with magnifying i-scan optical enhancement endoscopy (EPK-i7010, endoscope EG-2990Zi, PENTAX Medical). Presence of LBC were assessed by two endoscopists (R.K. and S.K.), cases with low confidence of LBC diagnosis was consulted with developer of the LBC concept (N.U.). LBC was defined as a fine, blue-white line on the crests of the epithelial surface/gyri[2]. Forceps biopsy was performed for a histological evaluation of lesions.

**Results:** From 86 gastric lesions complete GIM was confirmed in 14 cases, incomplete GIM - in 8 cases, mixed GIM - in 9 cases. LBC was diagnosed in 22 cases (all lesions with confirmed GIM). Sensitivity, specificity, accuracy, positive predictive value, negative predictive value for LBC sign in diagnosis of GIM were 0.71, 1.00, 0.90, 1.00, 0.86, respectively.

**Conclusion:** Magnifying endoscopy with i-scan optical enhancement technology provides accurate diagnosis of GIM by using LBC sign. Further studies are needed to evaluate the efficacy of different previously described endoscopic features of IM using new optical technologies.

**Introduction:** Endoscopic resection of Superficial Colorectal lesions in close proximity to the Appendiceal Orifice (L-PAO) was shown to be feasible but is still considered impossible in case of deep invasion into the appendix (Toyonaga type 3). We report here a series of Endoscopic Submucosal Dissection with double clip and rubber band traction (DCT-ESD) of L-PAO to determine the outcomes.

**Aims & Methods:** We reviewed retrospectively all the consecutive DCT-ESD resections of L-PAO in 3 french centers. Toyonaga's classification was described for each lesion and type 0 lesions which are not in contact of appendiceal orifice were excluded. Our primary outcome was En bloc and R0 resection rates for L-PAO. Morbidity (bleeding, perforation and acute appendicitis) and salvage surgery were recorded.

**Results:** 32 patients underwent DCT-ESD (mean age 67). 11 patients had previous appendectomy (28.6%). Toyonaga's type of lesion was type 3 (enter deeply in appendiceal orifice) for 22 lesions (68.8%) including 11 (34.4%) without history of appendectomy and 11 (34.4%) with previous appendectomy, 7 type 2 (enters orifice, and transition to normal appendiceal mucosa is discernible on inspection of the appendiceal lumen) (21.9%) and 3 type 1 lesions (reaches border of the appendix orifice) (9.4%). Median diameter of the specimen was 35 mm (10-110mm) and median resection duration was 47 min (10-230 min). En bloc resection was achieved in all cases exclusively with DCT-ESD. Histology confirmed R0 resection in 29 cases (90.6%) and R1 in 3 cases but only with lateral contact with low grade dysplasia. Finally, 11 perforations occurred per-procedure and were all immediately closed with clips. In post-operation, 3 patients (10.7%) underwent delayed surgery without stoma for remaining leakage in 2 cases for complications related and in 1 case for incomplete resection. No death occurred.

**Conclusion:** DCT-ESD is effective and safe for resection of lesion developed into appendiceal orifice. Most procedures allowed En Bloc curative resection by endoscopic means only avoiding surgery in 90.6% of cases.

**Introduction:** Endoscopic resection allows treating intramucosal colorectal cancer with a low morbidity and no mortality. However, lymph node involvement is found in about 10% of submucosal colorectal carcinomas, indicating additional surgical resection. According to the Japanese (JSCCR) and European (ESGE) guidelines, the presence of a deep submucosal infiltration (beyond 1000µm), poor differentiation, lympho-vascular invasion, or grade 2-3 tumor budding should lead to complementary surgery. The aim of this study was to assess the safety and long-term outcome of endoscopic resection for T1 colorectal carcinoma in a Western population.

**Aims & Methods:** We conducted a retrospective study, from a prospectively collected database including all patients with endoscopic mucosal resection or endoscopic submucosal dissection performed at a single French tertiary referral center. We included 68 consecutive patients with T1 colorectal cancer between February 2014 and May 2018. All patients were discussed in a dedicated multidisciplinary meeting for superficial gastrointestinal cancers.

We collected demographic data, procedural histological data and follow-up data in order to determine the local and distant recurrence rates and overall, progression free and cancer specific survival.

**Results:** The mean age of the population was 71.5 +/- 11.8. 44/68 (64.7%) lesions were in the colon and 24/68 (35.3%) in the rectum. 14/68 (20.6%) lesions were pedunculated. 26/68 (38.2%) patients had an endoscopic mucosal resection (EMR), 22/68 (32.4%) an endoscopic submucosal dissection (ESD), 8/68 (11.8%) a hybrid technique, 7/68 (10.3%) a conventional polypectomy and 5/68 (7.4%) a full-thickness resection using a dedicated device (FTRD). En bloc resection rate was 49/68 (72.1%), histologically resection rate was 45/68 (66.2%) and curative resection rate was 11/68 (16.2%). Overall, 49/68 (72.1%) patients had an indication for complementary surgery.

However, only 29/68 (42.6%) actually underwent the surgery: eight were lost to follow-up, seven declined surgery and five were not fit for the surgical procedure. Among the patients who underwent surgery, 6/29 (20.7%) actually had lymph node metastases. The median follow-up was 32 months (15-41 months). Nine patients were lost to follow-up. During follow-up, 3/59 (5.1%) patients had cancer relapse: one patient developed a metachronous colorectal cancer with distant metastases, one patient developed distant metastases after declining complementary surgery, and one patient developed lymph node metastasis although the initial endoscopic resection was thought to be curative, and was ultimately treated with chemoradiotherapy and then surgery. 3/59 (5.1%) patients died, one from a distant metastatic relapse of his colorectal cancer and the two others from non cancer related other causes.

Finally, among the 59 patients followed after endoscopic resection for T1 colorectal cancer, 8 (13.4%) were metastatic: 6 (10.2%) had lymph node metastasis on the surgical specimen and 2 (3.4%) developed distant metastases during follow-up.

**Conclusion:** Our data support the validity of the JSCCR guidelines in a French monocentric cohort with long-term follow-up: endoscopic resection of T1 colorectal cancer can be considered safe and curative in the vast majority of cases. Given the high proportion of surgical specimens free of lymph node metastases, additional criteria to assess the risk of lymph node involvement associated with early colorectal cancer are needed.

## P1568 BIOPOTENTIALS FOR CLINICIAN SATISFACTION WITH SEDATION IN COLONOSCOPY

Hann A.<sup>1</sup>, Götze S.<sup>1</sup>, Mehlhase N.<sup>1</sup>, Gruss S.<sup>2</sup>, Walter S.<sup>2</sup>

**Introduction:** Nurse-administered propofol sedation (NAPS) with intermittent bolus applications has become the standard procedure for colonoscopy in Germany. Although patient satisfaction with this method is high, little about the satisfaction of the examiner and factors that might negatively influence this satisfaction are available.

**Aims & Methods:** In this ongoing study we hypothesized that the number of movements or paralinguistic noises during sedation correlate with lower overall scores in the Clinician Satisfaction with Sedation Instrument (CSSI). Further we aimed to measure different biopotentials of the patient in order to accurately identify movements and paralinguistic noises that result in administration of sedating drugs.

Consecutive patients scheduled for a colonoscopy or sigmoidoscopy were prospectively enrolled. Biopotentials including electromyography of different facial muscles, skin conductance level and body temperature were obtained during the procedure. Additionally, events like movements, paralinguistic noises, dosages of sedatives were recorded with the corresponding event time. Clinician Satisfaction with Sedation Instrument (CSSI) was filled out by the examiner after the procedure. Correlation between the

number of movements and paralinguistic noises and the global values of CSSI were calculated. Additionally, biopotentials were evaluated for their relationship with the recorded events. ClinicalTrials.gov number: NCT03860779.

**Results:** 94 patients were enrolled. Biopotentials were available for 76 patients. Mean global satisfaction with the sedation was 84 (95% CI: 81-88) of 100 points. Combined events of movements and paralinguistic noises were mean 7 (95% CI: 6-9) per examination. Lower global satisfaction with the sedation values significantly correlated with higher values of movements and paralinguistic noises ( $p < 0.001$ ). Skin conductance level was available for 71 patients. Changes in the conductance level show a first relationship between body movements, paralinguistic noises and the application of sedatives in 53 (75%) examinations.

**Conclusion:** In this ongoing trial we were able to present that movements and paralinguistic noises of the patient during colonoscopy are associated with a lower satisfaction with the sedation using the CSSI. Simultaneously measured biopotentials - in combination with machine learning algorithm - might help to overcome this problem by helping to identify the right timing for the application of sedatives.

**Introduction:** Endoscopic submucosal dissection (ESD) can be considered for en-bloc resection of early cancers in the gastrointestinal tract. A major drawback of the current technique is its inability to perform bimanual tasks. We have recently designed and evaluated a 3D-printed platform that was successfully tested in the living pig model (Zizer et al., *Endoscopy* 2015). Nevertheless, we also experienced that complex procedures in an angulated position might be difficult to perform using such a system.

**Aims & Methods:** On the basis of an automated design process for the flexible manipulator structures as well as additive manufacturing by means of selective laser sintering the overtube manipulator system for ESD was further modified. Several subtypes were printed that included a single- and dual-arm version, as well as a version for pediatric scopes and standard gastroscopes, respectively. Furthermore, manipulators were either small or long.

Focus of the study was to evaluate the feasibility of endoscopic submucosal resection with the new systems. ESD was performed in a porcine ex-vivo model. 30mm lesion in size were resected located in the upper and lower GI tract (corpus, antrum; cecum, rectum).

**Results:** In total, 24 ESD's were performed (6 antrum, 6 corpus in inversion, 6 cecum, 6 rectum) with one-arm and two-arm manipulators or small (8 5mm) or standard scopes (8 10mm), respectively. ESD was feasible in 13 cases. Mean procedure time (min±SD) for ESD was 17.5(±7.1) for the corpus, 19.2(±8.5) for antral lesions, 20.5(±12.3) for the rectum, and 30.1(±8.5) for the cecum. Pediatric scope manipulators were too frail for sufficient resection working in inversion and for lesions located in the cecum. Resection was also impaired in the corpus and rectum using longer sized manipulator-arm systems. Single-arm manipulator equipped standard endoscopes offered best results in optimal traction-countertraction during ESD for all locations. ESD was feasible in all those 4/4 cases. Mean procedure time was rather short with 16.5(±4.6).

**Conclusion:** Based on our preliminary data we conclude that ESD is feasible using a customizable manipulator system designed for standard endoscopes with a monolithic design in an ex-vivo model. A single-arm manipulator system attached onto a standard gastroscope appears to offer the optimum utilization of traction and counter traction during endoscopic resection even in difficult locations.

**Contact E-Mail Address:** ambilymck@gmail.com

**Introduction:** The Irish public endoscopy service is facing unprecedented pressure in terms of a huge increase in endoscopy referrals over the past 10 years with currently over 20,000 patients on the Inpatient/Daycase National GI Endoscopy waiting list. Despite established referral guidelines many patients are referred inappropriately from both primary and secondary care for urgent and non-urgent endoscopies with high non-attendance and cancellation rates. There is a lack of data assessing the impact of consultant triage and endoscopy nurse triage on endoscopy referrals.

**Aims & Methods:** To prospectively compare the effect of consultant triage alone (which is relatively less labour intensive) with combined consultant and endoscopy nurse triage (which is relatively more labour intensive) on endoscopy referrals to our endoscopy unit.

**Methods:** All endoscopy referrals including GP letters, direct access and Surgical, Medical and ED referrals received over a 28 day period in February 2019 were included in this prospective study. Referrals were stratified pre-triage into urgent/priority 1 (P1) within 4 weeks, non-urgent/priority 2 (P2) within 3 months and surveillance groups before being triaged by 4 GI consultants based on established HIQA and BSG endoscopy referral guidelines. Any referrals with missing data, alarm symptoms, prior endoscopy/histology data were subsequently validated by telephone triage by our Endoscopy Triage Nurse. Outcomes were compared between pre-triage, consultant triage and combined consultant and endoscopy nurse triage. Statistical analysis was performed using student *Chi Square* test.

**Results:** Out of 312 endoscopy referrals during the study period, 12 patients were excluded as they had already undergone consultant triage. Of the 300 patients enrolled (median age 50, range 17-88, M:F 150:150). 142 (47%) were directly referred from their GP, 101 (34%) from the Surgical department, 31 (10.4%) from other Medical departments and 26 (8%) from the Emergency Department. Prior to triage 159 patients were referred for urgent P1 endoscopy, 125 for non-urgent P2 endoscopy and 16 for surveillance endoscopy. Consultant triage alone reduced P1 endoscopies by 16% from 159 to 133 (p=0.02) and combined consultant and endoscopy nurse triage reduced P1 endoscopies by a total of 30% to 112 (p=0.0003). Consultant triage increased overall P2 endoscopies marginally from 125 to 129 and subsequently to 124 after endoscopy nurse triage (P=0.5(nonsignificant)). Consultant triage alone reduced all endoscopy referrals by 11% (p< 0.05) redirecting referrals to HP testing/OPD/GP follow-up/CT colonography while combined consultant and endoscopy nurse triage reduced all endoscopy referrals by 21% (p=0.01).

**Conclusion:** Consultant triage alone significantly reduced 16% of urgent endoscopy referrals and 11% of all endoscopy referrals while combined consultant and endoscopy nurse triage significantly reduced 30% of urgent endoscopy referrals and 21% of all endoscopy referrals. Both consultant triage alone and combined consultant and endoscopy nurse triage can achieve significant reductions and cost savings in endoscopy referrals.

**Introduction:** The majority of large ( $\geq 20$ mm) colorectal laterally spreading lesions (LSLs) are benign and can be effectively managed by piecemeal endoscopic mucosal resection (EMR). However, a subgroup harbor submucosal invasive cancer (SMIC) and require en bloc resection by an alternative resection technique. Accurately predicting SMIC by optical evaluation is critical to inform therapeutic decisions. It is unknown whether LSL morphology, specifically nodular versus flat morphology, and LSL topography influence the performance of SMIC prediction.

**Aims & Methods:** Colorectal LSLs  $\geq 20$ mm referred for endoscopic resection, within a prospective multi-center observational cohort, were considered for inclusion. As per protocol, optical evaluation was performed prior to endoscopic resection and included lesion morphology (Paris classification), topography (granular, non-granular, mixed), surface pit pattern and surface vascular pattern characterization. SMIC prediction was based on the identification of established surface pit pattern and vascular pattern features consistent with invasive neoplasia. Rigid/fixed/non-lifting lesions and those with a Paris 0-IIc component were excluded, as these features are strongly associated with SMIC and are established predictors of it.

Sensitivity, specificity, accuracy\* and miss rates were calculated for SMIC prediction with histology as the reference gold standard. Outcomes were then stratified by nodular (Paris 0-Is and 0-IIa+Is) versus flat (Paris 0-IIa and 0-IIb) morphology and topography

\*Accuracy = correctly predicted lesions for histology (including SMIC and non-SMIC) divided by total number of lesions.

**Results:** From July 2013 - March 2019, 1808 colorectal LSLs were identified. 258 serrated lesions, 39 rigid/fixed/non-lifting lesions, and 79 lesions with a Paris 0-IIc component were excluded from analysis. Of the remaining 1432 LSLs (mean size 37.2mm; range 20-120; 665 nodular, 767 flat), SMIC was identified in 92 (6.4%). Overall sensitivity, specificity, and accuracy of SMIC prediction were 43.5% (95% CI 33.7%-53.7%), 98.4 (95% CI 97.6%-98.9%) and 94.8% (95% CI 93.5%-95.8%), respectively.

Sensitivity decreased when comparing nodular LSLs (37.5%; 95% CI 25.9%-50.0%) vs. flat LSLs (57.1%; 95% CI 37.4%-74.9%) and non-granular LSLs (58.6%; 95% CI 40.6%-75.0%) vs. granular LSLs (32.6%; 95% CI 20.4%-46.9%). The overall miss rate was 3.6%. This was significantly higher amongst nodular vs. flat LSLs (6.4% vs. 1.6%; p< 0.001) with flat granular LSLs having the lowest SMIC miss rate (0.7%; 95% CI 0.2-1.9) amongst all LSL sub-populations.

Variable	Nodular Lesions % (95% CI)	Flat Lesions % (95% CI)	P-value
Sensitivity All Lesions	37.5 (25.9-50.0)	57.1 (37.4-74.9)	
Sensitivity Granular	30.0 (17.6-45.2)	50.0 (16.7-83.3)	
Sensitivity Non-Granular	55.6 (25.4-82.7)	60 (38.4-78.9)	
Sensitivity Mixed	46.7 (23.9-70.6)	50 (6.1%-93.9)	
Specificity All Lesions	97.3 (95.6-98.4)	99.0 (97.9-99.5)	
Specificity Granular	98.1 (96.5-99.0)	100	
Specificity Non-Granular	94.3 (88.0-97.8)	97.5 (95.2-98.9)	
Specificity Mixed	95.3 (85.9-99.0)	100	
Accuracy	91.6 (89.3-93.5)	97.5 (96.2-98.5)	< 0.001
SMIC Missed	6.4 (4.4-8.0)	1.6 (0.9%-2.8%)	< 0.001

[Submucosal Invasive Cancer Prediction Performance and Miss Rates]

**Conclusion:** The sensitivity of predicting SMIC by pit pattern and vascular pattern is limited in large colorectal LSLs, specifically nodular lesions. Given their SMIC miss rate, nodular LSLs, in the absence of concerning features on optical biopsy, require further risk stratification to accurately

identify optimal candidates for en bloc resection techniques. Alternatively, flat granular lesions, in the absence of optical features of SMIC, need only be removed by EMR.

<sup>2</sup>University of Sydney - Westmead Clinical School, Sydney, Australia,

<sup>3</sup>Westmead Hospital, Gastroenterology and Hepatology, Gent, Belgium

**Contact E-Mail Address:** drmsidhu16@gmail.com

**Introduction:** No formal training pathways for endoscopic mucosal resection (EMR) currently exist and training is often ad-hoc and sporadic. As such many endoscopists practice EMR without formal training. This may contribute to incomplete polyp resection and referral of large benign colorectal neoplasia to surgery. We aimed to investigate the impact of a dedicated 12-month EMR training program on trainee competency.

**Aims & Methods:** Prospective data, relating to technical aspects of EMR and outcomes, was collected from consecutive directly-supervised procedures commenced by five trainees over a 12-month period at a tertiary endoscopic resection centre. All trainees had achieved appropriate competency in colonoscopy (at least 200 independent procedures prior to their training year of which at least 50 procedures involved diminutive polypectomy) and undertook a four-week observation period prior to starting cases. Data was analysed in two cohorts divided by procedures performed in the first or second six months of their training period.

**Results:** Five trainees (median age - 31yrs) performed 98 EMRs in 98 patients over 12 months. Median lesion size in the first half was 30mm (interquartile range [IQR] 25-40) and 35mm (IQR 25-50) in the second. The complexity of LSL increased in the second half of the cohort [SMSA 4 LSL 2nd half vs 1st half, 47.2% (26/55) vs. 32.5% (14/43)]. Other important lesion characteristics did not vary between the halves of the cohort.

The ability to competently perform dynamic submucosal injection and specimen retrieval after EMR was significantly more likely in the second six months of training as compared to the first (86.8% vs 54.8%, p=0.001 and 88.9% vs 60.5%, p=0.002 respectively).

Trainees were significantly more likely to independently complete greater than 50% of the EMR procedure in the second six months of their training as compared to first (81.8% vs 51.2%, p= 0.001, OR - 4.3 (1.7-10.7), p= 0.002). The need for consultant intervention was also significantly less likely in the second half of the training period (62.8% vs 40%, p=0.004). Despite the involvement of a trainee and the complexity of the lesions attempted the overall technical success was 96.9% and not statistically different between the two cohorts. There was also no significant difference in the rate of adverse events including bleeding and deep mural injury (see Table 1).

Table 1	First Half	Second Half	Total	p	OR (95% CI) 1st vs 2nd Half	p
Median Size, mm (IQR)	30 (25-40)	35 (25-50)				
SMSA Level 2/3/4	13/16/14	12/17/26	25/33/40	0.33		
SMSA-EMR Level: Low Risk/ High Risk	15/28	25/30	40/58	0.30		
Dynamic submucosal injection	17 (54.8)	46 (86.8)	63	0.001	5.6 (1.7-18.0)	0.005
Percentage of resection performed independently <50% v. >50%	21 (48.4) vs. 22 (51.2)	10 (18.2) vs. 45 (81.8)	31 vs. 67	0.001	4.3 (1.7-10.7)	0.002
Consultant takeover	27 (62.8)	22 (40)	63	0.04	2.53 (1.1-5.8)	0.03
Technical success (%)	41 (95.3%)	54 (98.2%)	95 (96.9)	0.42		
CSPEB	3	7	10	0.35		
Total	43	55	98			

[Lesion Characteristics, Trainee and Procedure Outcomes; CSPEB - clinically significant endoscopic bleeding, SMSA - size, morphology, site and access]

**Conclusion:** Endoscopists competent in diminutive polypectomy can be trained to perform EMR of complex colorectal lesions safely and without detriment to overall outcomes. Key aspects of this programme include a focussed, intensive period of training (>6 months) with competency-based teaching and introduction of sequentially more complex lesions (identified using the SMSA score [1]).

This study may provide a foundation for the development of a structured, competency based training program for endoscopists learning advanced tissue resection.

**Introduction:** Large ( $\geq 20$ mm) laterally spreading lesions (LSLs) at the anorectal junction are most commonly referred for surgery due to the unique anatomical, sensory and physiological characteristics of this area. More recently, it has been argued that these lesions, if treated endoscopically, should be managed by endoscopic submucosal dissection (ESD) or transanal endoscopic microsurgery (TEM). Endoscopic mucosal resection (EMR) is well established as a definitive therapy for colorectal LSLs, however, it is unknown whether it is an effective and durable treatment for LSLs at the ARJ (ARJ-LSLs).

**Aims & Methods:** We evaluated the technical success, short-term and long-term outcomes of EMR for ARJ-LSLs (defined as distal margin either crossing or within 20mm of the dentate line) in comparison to rectal LSLs within a prospective multi-center observational cohort of LSLs  $\geq 20$ mm.

Technical success was defined as complete removal of all neoplastic tissue during index EMR. Safety was evaluated by the frequency of intra-procedural bleeding, deep mural injury, delayed bleeding and perforation. Long-term efficacy was defined by the absence of either endoscopic or histological recurrence at surveillance colonoscopy (SC) at recommended intervals of 6, 12, 36 and 60 months (SC1 - SC4, respectively).

**Results:** Between July 2008 - April 2019, 109 ARJ-LSLs and 351 rectal LSLs were considered for endoscopic resection. Twenty (5 ARJ, 15 rectal) LSLs had endoscopic features consistent with deep submucosal invasive cancer (SMIC) and were referred directly to surgery.

One rectal lesion had a concomitant sigmoid cancer and went to surgery. Recently, 39 (18 ARJ, 21 rectal) LSLs were enrolled in a selective ESD protocol and were excluded from analysis. The remaining 86 ARJ-LSLs (mean size 48.3mm, range 20 - 100mm) were removed by EMR. Technical success was 97.7%. SMIC was present in 3 (3.5%) lesions.

The frequency of recurrence was 14.9%, 4.7%, 5.3% and 0.0% at SC1-SC4 and surgery was avoided in all. Amongst 24 ARJ-LSLs which underwent margin snare-tip soft coagulation (STSC) to mitigate the risk of recurrence, no recurrence was identified at SC1 (0.0% vs. 23.3%; p=0.01), nor at SC2 - SC4. The frequencies of technical success, adverse events and recurrence were not different between ARJ-LSLs and rectal LSLs.

**Conclusion:** EMR is a safe, efficient, effective and durable therapy for ARJ-LSLs. EMR should be considered as the primary therapeutic modality for the majority of these lesions.

**Disclosure:** Nothing to disclose

Variable	ARJ-LSLs n=86(%)	Rectal LSLs n=314(%)	p-value

**Introduction:** Linked color imaging (LCI) is one of image-enhanced endoscopies and can visualize gastrointestinal lesions better. We previously reported that LCI improved the visibility of various colorectal lesions including diminutive polyps and sessile serrated adenoma and polyps (SSA/P) using videos and pictures [1,2].

In this study, we analyzed the efficacy of LCI for improving flat polyp's visibility in various situations including fast-withdrawal or large-monitor observation utilizing endoscopist's visibility scoring and color difference (CD) value in a multicenter study.

**Aims & Methods:** We recorded videos of flat polyps 2-20 mm in white light imaging (WLI), blue laser imaging-bright (BLI-b), and LCI from July 2017 to December 2017 according to inclusion criteria. All videos were evaluated by 8 endoscopists according to a published polyp visibility score from four (excellent) to one (poor). Additionally, 1.5-times-faster videos and 1.7-times-larger-sized videos were also evaluated. Moreover, we calculated color difference (CD) value in three modes between each polyp and surrounding mucosa.

**Results:** The mean scores of LCI (3.11±0.95) were significantly higher than WLI (2.55±1.04, p< 0.001), and were not significantly higher than BLI-b. With respect to right-sided location, < 10mm size, and serrated lesions, the scores of LCI were significantly higher than WLI. Additionally, the scores of faster videos were significantly lower than normal videos in each mode. The scores of faster videos in LCI (3.0±1.1) were also significantly higher than WLI (2.0±1.0, p< 0.001) and BLI-b (2.8±1.1, p=0.03). The scores of larger-sized videos weren't significantly higher than normal monitor's videos in each mode. The CD value of LCI was significantly higher than WLI (18.0±7.7 vs. 11.7±7.0, p< 0.001) and BLI-b (15.8±9.6, p=0.04).

**Conclusion:** Our study showed that LCI significantly improved visibility of colorectal polyps in various situations such as faster withdrawal or a larger-sized monitor observation with multicenter study. Moreover, we proved LCI's increase of objective CD value as an objective indicator for polyp vis-

ibility compared to WLI and BLI-b. According to these results, we thought LCI is promising for polyp detection. Prospective randomized control studies are expected in the future for proving this hypothesis.

**Contact E-Mail Address:** mdlsk75@gmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) is a well-established technique that allows for en bloc removal of superficial gastro-intestinal cancer. To improve the efficacy, safety of endoscopic submucosal dissection techniques the quality and duration of the submucosal lift is key. Currently available agents are not satisfactory. The objective of this study is to assess the safety and efficacy of an injectable, poly(amidoamine)s based hydrogel to lift the submucosa in comparison with standard lifting solution for colorectal ESD in an in vivo porcine study.

**Aims & Methods:** Prior to ESD proper preparation of the colon was carried out.

ESD of similar size (2x2cm) were performed in the colon 20 to 30cm from the anal verge by an experienced endoscopist. Two types of solutions were used for submucosal lifting: saline solution in the control group and hydrogel. Procedure time, dissection speed, and complications were recorded and compared between the two groups.

**Results:** 22 procedures were performed in the colorectum of thirteen pigs (10 ESDs in control group and 12 ESDs in hydrogel ESD group). Effective procedure times were 2744 seconds in control group and 1496 seconds in hydrogel ESD group. In the hydrogel ESD group the dissection speed improved significantly after the first five cases (26.77 mm<sup>2</sup>/min in first five cases vs 49.88 mm<sup>2</sup>/min in later seven cases) and the mean dissection speed in last seven cases was significantly faster than that in control group (49.83 mm<sup>2</sup>/min vs 29.13 mm<sup>2</sup>/min, p=0.019). Perforation occurred in 3 cases in the control group and in 1 case in the hydrogel ESD group.

**Conclusion:** The use of poly(amidoamine)s based hydrogel as a lifting agent significantly improved dissection speed compared to standard saline solution in colorectal ESD. Further randomized studies should confirm the lower rate of perforation observed in the hydrogel group.

## P1576 ENDOSCOPIC-LIKE MAXIMUM-MAGNIFYING EVALUATION WITH CMOS LASER ENDOSCOPY FOR COLORECTAL LESIONS IS CLINICALLY USEFUL

Yasuda M.<sup>1,2</sup>, Naito Y.<sup>2</sup>

<sup>1</sup>Uji-Tokushukai Medical Center, Dept. of Gastroenterology and Hepatology, Kyoto, Japan, <sup>2</sup>Kyoto Pref University of Medicine Gastroenterology, Dept. of Gastroenterology, Kyoto, Japan

**Contact E-Mail Address:** koutoku7@fa2.so-net.ne.jp

**Introduction:** As an endoscopic diagnosis of neoplastic lesions of the colon and rectum, an endoscope capable of ultra-magnifying 520 times has been put on the market and is spreading. Developed by Kudo et al., this is

an extremely excellent and epoch-making endoscope system that allows real-time observation similar to microscopic HE staining by contacting a lens of a colonoscope with a lesion after staining the lesion with methylene blue and crystal violet.

However, the endoscope is limited in that it is a little expensive, that it is used by a system made by Olympus, and that it requires a little techniques to be contacted and observed.

Therefore, we examined how close the conventional magnifying endoscope can be to the above-mentioned super-magnifying endoscope Endocytoscope even by non-contact observation, and how much Endocyte-like evaluation can be observed with the widely marketed and widespread endoscope with laser light source, which is equipped with CMOS image center manufactured by FujiFilm Co., optical 135 times, electronic 270 times magnification.

**Aims & Methods:** From March 2018 to December 2018, we studied 40 cases in which colorectal lesions were observed on Endocyte and CMOS laser source endoscopy at our hospital.

The Endocyte system used Olympus's CF-H 290 ECI endoscope and EVIS Elite 290 light source system.

The CMOS laser source endoscope used the Fujifilm endoscope EC-L 600 ZP and the light source system LASEREO 4450.

When lesions were observed, they were compared by methylene blue-crystal violet staining with 520 fold magnification for CF-H 290 ECI and 270 fold magnification for EC-L 600 ZP.

In addition, the established EC classification at the end site was made the golden standard, and it was examined in comparison with EC1a, EC1b, EC2, EC3a, EC3b, pathology after the lesion cutting.

Observation with a CMOS laser endoscope at a maximum magnification of 270 times is classified into ECL, a classification similar to EC classification. Classified as (Meaning of EC-like classification or EC-Laser classification). As in the EC classification, ECL 1a, ECL 1b, ECL 2, ECL 3a, and ECL 3b were determined according to the shape of the gland lumen and the state of nuclear staining.

**Results:** The concordance rate between EC classification and ECL classification was 100% for EC1a and ECL 1a, 100% for EC1b and ECL 1b, 95% for EC2 and ECL 2, 95% for EC3a and ECL 3a, and 100% for EC3b and ECL 3b. However, the EC classification was superior in confidence and strength of diagnosis.

**Conclusion:** Endocytoscopy-like maximum-magnifying evaluation with CMOS laser endoscopy for colorectal lesions is clinically useful.

Endocytoscopy for colorectal neoplastic lesions is currently the highest point of magnification endoscopy, but equipment deployment is still slow. When CMOS LASER endoscopes, which are already in wide use to some extent, are used at the limits of specifications, it has been found that approximate results can be obtained to some extent.

## P1577 COMPARISON OF LONG TERM CLINICAL OUTCOMES BETWEEN COLD ENDOSCOPIC MUCOSAL RESECTION (C-EMR) AND COLD SNARE POLYPECTOMY (CSP) FOR COLORECTAL POLYP LESS THAN 15MM IN SIZE

Moon J.R., Kim H.G., Jeon S.R., Jung Y., Ko B.M., Kim J.O.  
Soonchunhyang University Hospital, Internal Medicine-GI/Hepatology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** ukino816@gmail.com

**Introduction:** Incomplete resection rate of small polyp was reported as 6.8% in the CARE study. Several methods of cold polypectomy including cold snare polypectomy (CSP) and cold endoscopic mucosal resection without electrocautery (C-EMR) have been used for routine polypectomy practice. The aim of this study was to assess the long-term efficacy and safety of CSP versus C-EMR for colorectal polyps less than 15 mm in size.

**Aims & Methods:** Total 472 patients underwent polypectomy with cold methods from July 2015 to December 2017. In this retrospective study, 112 patients who underwent surveillance colonoscopy after colon polypectomy with cold methods were included for analysis. Clinical parameters including recurrence, polyp size and shape, complication between two groups were compared.

**Results:** Total, 331 colorectal polyps were removed with CSP (n=148) or C-EMR (n=183) from 112 patients. Mean age was  $60.9 \pm 11.1$  years old, and mean surveillance interval was  $458.3 \pm 237.3$  days. Regarding polyp shape, pedunculated polyps (65.4% vs. 34.6%) and flat polyps (69.9% vs. 30.1%)

were tended to resected by C-EMR more frequently than CSP ( $p=0.053$ ). Mean size was larger in C-EMR group ( $8.46 \pm 1.97$  mm) than CSP ( $6.80 \pm 1.21$  mm) group ( $p < 0.001$ ). In histology, 92.3% (12/13) of sessile serrated adenoma and two high-grade dysplasias were removed by C-EMR method. Recurrence rates were 6.1% (9/148) in CSP group, and 2.2% (4/183) in C-EMR group, respectively ( $p=0.070$ ). Regarding complication, immediate bleeding was 4.4% (8/183) in C-EMR group and 2.0% (3/148) in CSP group ( $p=0.237$ ), and delayed bleeding was occurred in one patient after C-EMR (0.5%).

**Conclusion:** Both cold methods were feasible in terms of recurrence rate and safety. C-EMR was performed more in the flat or pedunculated polyps, and larger sized polyp than CSP method with relatively lower recurrence rate. Further large-scaled prospective study with long-term surveillance is required.

## P1578 BODY MASS INDEX AND THE RISK OF COLONIC POLYPS

Popescu A., Chisevescu D., Foncea C.G., Suseanu D., Danila M., Sirli R., Sporea I.  
Victor Babes University of Medicine, Department of Gastroenterology and Hepatology, Timisoara, Romania

**Contact E-Mail Address:** alinamircea.popescu@gmail.com

**Introduction:** Colorectal cancer (CRC) screening is associated with a decreased incidence and mortality from CRC. However, patient adherence to screening is less than desirable and resources are limited even in developed countries. Better identification of individuals at a higher risk could result in improved screening efforts. Some studies suggest that body mass index (BMI) could be associated with higher frequency of colonic polyps and consequently CRC [1]. The aim of this study is to assess whether there is a relationship between BMI and the presence of colonic polyps.

**Aims & Methods:** A retrospective study was performed including 424 patients whom underwent colonoscopy for various reasons between January 2018-December 2018 in a private endoscopy unit. BMI was calculated as  $\text{weight/height}^2$  ( $\text{kg/m}^2$ ). Normal weight was defined as BMI 18.5-24.9  $\text{kg/m}^2$ , overweight 25 to 29.9  $\text{kg/m}^2$  and obesity  $> 30 \text{ kg/m}^2$ . The frequency of polyps diagnosed at colonoscopy was assessed.

**Results:** From the 424 patients included in the study, 60%(256/424) female and 40%(168/424) male, mean age  $53 \pm 12$  years, mean BMI  $26.8 \pm 4.8 \text{ kg/m}^2$ . Considering BMI, 33.2% (141/424) were normal, 38.6%(164/424) overweight and 28%(119/424) obese. 18% (77/424) patients presented colonic polyps: 13%(18/141) in the normal patients, 18%(29/164) in overweight patients and 25%(30/119) in obese patients, with significant difference between normal and overweight plus obese patients ( $p < 0.0001$ ). Considering BMI  $> 25 \text{ kg/m}^2$  as a threshold for the risk of developing colonic polyps, the risk was significantly higher for overweight and obese patients OR 1.79 CI 95% (1.01-3.18)  $p=0.043$ .

**Conclusion:** Subjects with BMI  $> 25$  have a significantly higher risk of association with colonic polyps, therefore, BMI as a measure of obesity can be a valuable and easy to use tool for optimizing screening methods.

**Contact E-Mail Address:** roberta.maselli@humanitas.it

**Introduction:** In Asian countries, the safety and efficacy of endoscopic submucosal dissection (ESD) is well-established for the minimally invasive treatment of early colorectal cancer. Large retrospective studies have shown favorable long-term outcomes with a disease free survival of 94.6% and 92.1% at 3 and 5 years, respectively [1]. On the other hand, the role of ESD for colorectal lesions in Western communities is unclear. This may be attributed to the limited adoption of ESD in Western centers and disappointing technical outcomes in preliminary studies. In addition, the lack of long-term data for Western-based colorectal ESD generates uncertainty as to the clinical relevance of such a procedure.

**Aims & Methods:** The aim of this study is to assess the long-term outcomes of a large cohort of patients treated with colorectal ESD in a tertiary Western endoscopy centre. Between 2011 and 2018, a retrospective analysis of a prospectively maintained procedure database was conducted on patients treated by ESD for colorectal lesions at Humanitas Research Hospital in Milan, Italy. Both conventional ESD and hybrid-ESD cases were included. Short-term outcomes of interest were en-bloc, R0 and curative resection rates as well as the occurrence of adverse events. Long-term outcomes of interest were adenoma and carcinoma recurrence rates. Uni- and multivariable logistic regressions were applied to identify factors associated with resectional outcomes and adenoma recurrence.

**Results:** Over the study period, 244 consecutive patients with colorectal neoplasia underwent colorectal ESD. Conventional ESD was performed in 80.3% of cases. Overall, 189 (77.4%) lesions were adenomas and 55 (22.6%) were cancers (52 adenocarcinomas and 2 neuroendocrine and 1 squamous carcinoma). Rates of en bloc and R0 resection were 87.3% and 82.8%, respectively. On multivariate analysis, only hybrid-ESD technique was negatively related to en bloc resection (OR 0.02 vs standard ESD 95% CI: 0.01-0.08) yet for R0 resection only standard ESD technique (vs hybrid-ESD) was predictive (OR 4.61 95% CI: 1.41-18.58).

Nine perforations occurred: 7 (77.8%) were managed endoscopically; 2 (22.2%) required surgery. Intra- and post-procedural bleeding occurred in 9 (3.7%) and 1 (0.4%) patient(s), respectively; all cases were managed endoscopically. No ESD-related deaths occurred. In total, 39 patients underwent surgical consultation and/or subsequent resection due to non-curative ESD (37 patients) or adverse events (perforation in 2 patients). Thus, the follow-up analysis included 205 patients with a median follow-up of 2.9 years (range 0.5-8.0).

Adenoma recurrence was detected in 5 (2.6%) patients (3 at 6 months, 2 at 1 year and none at 3 or 5 years). The risk of recurrence was higher for patients in the piecemeal resection group than for those in the en-bloc resection group (p=0.05). The adenoma recurrence-free probability at 6 and 12 months from resection was 98.5% (95% CI: 97.0%-100.0%) and 97.4% (95% CI: 95.2%-99.7%), respectively. No carcinoma recurrences were observed.

**Conclusion:** Colorectal ESD is a safe and effective approach for managing advanced colorectal neoplasia. Furthermore, in expert hands, colorectal ESD can be performed in a Western setting with outcomes comparable to published Eastern series.

## P1580 DRUG DELIVERY THROUGH COLONIC TRANSENDOSCOPIC ENTERAL TUBING: A REAL WORLD STUDY AND MULTIFACTORIAL ANALYSIS

Zhang T., Long C., Ji G., Zhang F.

The Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China

**Contact E-Mail Address:** tzhang@njmu.edu.cn

**Introduction:** Colonic transendoscopic enteral tubing (TET) as a new colon-ic interventional method has been frequently used for complete delivery of fecal microbiota transplantations (FMTs) or whole-colon administration of drugs.

**Aims & Methods:** To evaluate the possible factors affecting methodology, feasibility and safety of colonic TET. We prospectively recorded patients who underwent colonic TET for FMT or medications in our center from October 2014 to November 2018. The success rate, adverse events and patients' satisfaction, as well as the retaining time of TET tube were evaluated.

**Results:** Totally 224 patients were included for analysis in this real-world study. The success rate of TET procedure was 100% (224/224). The median retaining time of TET tube was 8.5 (IQR 7 - 11) days in 158 patients with the tube falling out naturally. These patients were divided into the short-retaining group ( $\leq 8.5$  days) and the long-retaining group ( $> 8.5$  days). Univariate and multivariate analysis demonstrated that titanium clip type (p = 0.001) was an independent influencing factor for the retaining time of tube. The number of large titanium clips with longer arms significantly affected the retaining time (p = 0.013). No severe adverse event was observed during and after TET.

	Titanium clip number	Frequency	TET retaining time	P-value
Small titanium clip	3	7	6 (4 - 7)	0.498
	4	9	7 (6.5 - 7.5)	
	5	10	7.5 (5 - 10.5)	
	6	9	7 (5.5 - 9.5)	
Large titanium clip	2	14	7.5 (6 - 11)	0.013
	3	72	9 (7 - 11)	
	4	35	11 (8 - 12)	

[Table 1. Correlation between the titanium clip number and TET retaining time.]

**Conclusion:** Colonic TET is a feasible, practical, and safe technique with a high degree of patients' satisfaction for multiple FMTs or frequent colonic medication administration. Generally, two to four large titanium clips are recommended to ensure the fixation of the TET tube onto the colonic wall and maintain it for 7-10 days.

**Disclosure:** Nothing to disclose

## P1581 IS POOR BOWEL PREP EVER ACCEPTABLE AND WHAT IS THE EFFECT OF INDICATION FOR THE TEST?

Archer T.<sup>1</sup>, Riley S.<sup>1</sup>, Thoufeeq M.<sup>2</sup>, YORKER Yorkshire Endoscopy Research Group

<sup>1</sup>Sheffield Teaching Hospitals, Gastroenterology, Sheffield, United Kingdom,

<sup>2</sup>Hull Royal Infirmary, Endoscopy/ Gastroenterology, East Yorkshire, United Kingdom

**Contact E-Mail Address:** thomas.p.archer@outlook.com

**Introduction:** Bowel preparation is recognised as a key quality indicator for colonoscopy. It correlates with the adenoma detection rate (ADR) and is used to guide subsequent surveillance period after a normal investigation. It is also a perennial bug bear of endoscopists, leading to prolonged as well as incomplete procedures. The Boston Bowel Preparation Scale (BBPS) is a commonly used metric for assessing bowel cleansing and a score of 6 is generally regarded as adequate. Evidence demonstrates that a score of 6 or higher is associated with a higher ADR and fewer missed polyps. However, few studies have addressed the relationship between a BBPS of less than 6 and the need for repeat colonoscopy by indication.

The aim of this study was to evaluate association between indication for colonoscopy and the perceived need of repeat colonoscopy in the setting of poor bowel preparation.

**Aims & Methods:** Endoscopists of varying experiences and grades were invited to take part in the study during a regional endoscopy research meeting. All participants were shown videos of approximately 1 minute duration which demonstrated bowel preparation quality in 3 segments of the bowel; right, transverse and left. They were informed that no abnormalities were seen, and were asked to grade the bowel preparation on a dichotomous scale of "adequate for indication" or "inadequate, requiring repeat colonoscopy". All participants also documented their colonoscopy experience and whether they were bowel cancer screening programme (BCSP) accredited.

Indications are detailed in the table. 2 videos were presented per indication in a random order, each with a BBPS of between 3 and 5. Chi squared tests were used to assess differences.

**Results:** 19 endoscopists participated. 18 of whom graded 10 videos and 1 who graded 5 videos. 8 were consultants, 7 registrars, 2 fellows and 2 were nurses. 4 of the consultants were BCSP accredited. Overall 42.2% of cases were recorded as inadequate, requiring a rescope. The number of cases which the reviewers felt were inadequate ranged from 0/10 to 7/10 with a median of 4/10 and interquartile range of 3 to 5. 11.1% of the scores for case 1 were graded as inadequate, compared with 49.0% for all the other cases combined ( $p < 0.0001$ ). No other indication reached statistical significance. The mean number of inadequate cases rated by BCSP accredited endoscopists was 4.75, compared with 3.93 in the non BCSP group ( $p = 0.35$ ). There was no significant difference between consultants, registrars and nurses.

**Conclusion:** All of the videos were chosen to demonstrate bowel preparation which was inadequate, as defined by the BBPS  $< 6$ . However, only 42% of examinations were considered sufficiently poor to require a rescope. Furthermore there is a considerable variation between endoscopists as to whether a patient required a rescope. The indication for colonoscopy, however, had little influence on judgement of the adequacy of bowel preparation, other than a young patient with possible inflammatory bowel disease, whose suboptimal prep was accepted by most. These results suggest that suboptimal bowel preparation as defined by a BBPS  $< 6$  is often accepted in clinical practice.

Case	Indication
1	18 year old female with a history of diarrhoea and a family history of ulcerative colitis
2	62 year old male patient with positive faecal occult blood in BCSP
3	74 year old female with rectal bleeding mixed with stool
4	60 year old male with 3 small polyps at index colonoscopy 3 years ago
5	80 year old male patient with iron deficiency anaemia

[Indications for cases]

**Contact E-Mail Address:** lasse.pedersen@rn.dk

**Introduction:** Established markers of good colonoscopy quality such as the Cecum Intubation Rate (CIR) and the Polyp Detection Rate (PDR) are known by most colonoscopists and performance goals are readily available. Factors such as patient sex, patient age and colonoscopy indication have the potential to affect the CIR or the PDR<sup>1</sup>. Colonoscopists might not perform examinations on an identical casemix. Different casemix could result in performance goals being too easy or nearly impossible to reach.

**Aims & Methods:** The primary aim was to introduce a benchmark (based on CIR and PDR) that accounted for differences in casemix between colonoscopists. The secondary aim was to see if colonoscopist performed different than the benchmark.

Individual colonoscopist casemix (patient age, patient sex and colonoscopy indication) were registered on all colonoscopies in a 7-week period at Aalborg University Hospital, Denmark ( $n = 894$ ). Colonoscopists performing  $>40$  colonoscopies were analyzed individually. Colonoscopist performing  $<20$  colonoscopies and 21-40 colonoscopies were grouped in a *very low volume* and a *low volume* group, respectively.

Statistical analysis were conducted using Stata MP 15.1 and R 3.5.1.

Difference in patient age, patient sex and indication were analyzed using univariate analysis.

Predicted CIR and predicted PDR with 95% CI was calculated using bootstraps. A permutations test was performed to identify whether deviation from predicted performance represented low colonoscopy quality or statistical uncertainty.

**Results: Univariate casemix analysis:**

Mean age, [range 61 - 67], Diff.  $p = 0.36$ .

Male sex [range 44% - 72%], Diff.  $p = 0.25$ .

Indication (% of screening), [range 1% - 70%], Diff.  $p < 0.01$ .

**Individual colonoscopists actual and predicted performance:**

Colonoscopist	n	Measured CIR%	Predicted CIR%(95% CI)	Measured PDR%	Predicted PDR%(95% CI)
A	123	87.0	85.9 (83-88)	20.3	26.5 (23-29)
B	96	81.3	85.9 (83-88)	26.0	27.9 (25-31)
C	85	74.1	85.8 (83-88)	22.4	32.4 (29-35)
D	83	92.8	85.9 (83-88)	26.5	26.9 (24-30)
E	81	96.3	88.9 (87-91)	45.7	41.9 (38-46)
F	62	87.1	86.6 (84-89)	40.3	27.9 (25-31)
G	49	91.8	86.0 (84-88)	36.7	36.8 (34-40)
H	47	83.0	88.0 (86-90)	44.7	39.9 (36-44)
I	43	86.0	89.8 (87-92)	55.8	49.0 (44-54)
Low vol. (n 20-40)	98	87.8	89.0 (87-91)	37.8	41.6 (38-46)
Very low vol. (n <20)	127	90.6	87.5 (85-90)	37.8	33.0 (30-36)

[Actual and predicted cecum intubation rate (CIR) and poly detection rate (PDR)]

The permutation test did not find evidence to support that overall deviation from the predicted performance were related to inferior performance (PDR:  $p = 0.11$ , CIR:  $p = 0.81$ ).

**Conclusion:** Predicted performance allow each colonoscopist to see if he/she performs better or worse than the department average performance given his/her unique casemix.

Actual performance deviated from 95 CI of predicted performance among some colonoscopist, but the deviation was not significant.

Our study found little variation in predicted CIR [range 85.8-89.8] and larger variation in predicted PDR [range 26.5-49.0]. The large variation indicates that numeric performance goals should be applied with caution when there is a large variations in casemix among colonoscopists. A low PDR could simply be related to casemix. Casemix analysis could easily be extended too include additional variables available from Electronic Health records for more precise estimates.

**Introduction:** Endoscopic polypectomy is the standard of care for most of colorectal polyps and has expanded to include larger and sessile polyps. We compared the role of clip placement after polypectomy of pedunculated or sessile polyps larger than 2 cm in diameter to prevent postpolypectomy bleeding.

**Aims & Methods:** Patients who underwent polypectomy of sessile or pedunculated polyps larger than 2 cm were randomized to clip versus no clip placement at the base of the polyp. Patients with obvious bleeding or visible vessel after polypectomy were excluded from the study. The patients were followed-up for any signs of postpolypectomy bleeding for one month after the therapeutic procedure.

**Results:** In total 50 subsequent patients who underwent polypectomy of sessile or pedunculated polyps larger than 2 cm were studied (30 males, median age 67 years, range 28-86 years, 32 with sessile polyps, 18 with pedunculated polyps). Half of the patients were randomly treated with clip placement after the procedure. The aim of the clip was either to strangulate the peduncle of pedunculated polyp or close the open wound left after the resection of the sessile polyp. None of the patients bled in the group of clip placement, while 4 of the 25 patients bled in the group of no clip placement ( $P < 0.05$ ). All bleeding episodes were managed conservatively with endoscopy, adrenaline solution injection and clip placement.

**Conclusion:** Clip placement after resection of pedunculated and sessile polyps larger than 2 cm can prevent postpolypectomy bleeding. In cases of bleeding subsequent endoscopic treatment was effective in all cases.

## P1584 ROOT CAUSE ANALYSIS OF 424 POTENTIAL POST COLONOSCOPY COLORECTAL CANCERS USING THE WORLD ENDOSCOPY ORGANIZATION ALGORITHM

Nielsen A., Pedersen L.

Aalborg University Hospital, Department of Surgical Gastroenterology, Aalborg, Denmark

**Contact E-Mail Address:** andersnielsen1991@gmail.com

**Introduction:** Root cause analysis of post colonoscopy colorectal cancer (PCCRC) is essential to understand and prevent cases of PCCRC. The World Endoscopy Organization (WEO) has recently proposed a common method when conducting root cause analysis of PCCRC<sup>1</sup>. The aim of this study was to test the feasibility of the WEO algorithm on a large PCCRC dataset and to perform sub analysis in each WEO category to identify factors that could help avoid PCCRC in the future.

**Aims & Methods:** All colorectal cancers (CRCs) (ICD-10: C.18-C.20) diagnosed in North Region, Denmark from 2010-2018 were included in the root cause analysis. CRCs were cross-referenced with colonoscopies occurring from 6 months until 4 years from CRC diagnosis. A total of 424 colo-

noscopies on 330 individuals were investigated in journal records and the pathology database. Cause was assigned according to the WEO algorithm with the most plausible explanation.

Currently, the root cause analysis is based on 100 out of the 424 potential PCCRCs. With later inclusion of the remaining PCCRCs in a complete root cause analysis.

**Results:** Exclusion criteria and the distribution of PCCRC-cases according to the most plausible cause are found below.

Exclusion (n=42)	
Examination cancelled upon scope insertion (solid stool)	4
Metastatic CRC recurrence recurrence outside the colon	21
CRC date not registered correctly	13
Incorrect colonoscopy procedure code	3
Appendix tumor	1
Total	42

WEO PCCRC cause (n = 58)	n (%)
Missed lesion, prior examination adequate	25 (43)
Missed lesion, prior examination inadequate	23 (40)
Detected lesion not resected	2 (3)
Incomplete resection of detected lesion	6 (10)
Deviation from planned management pathway	2 (3)

[Exclusion criteria and WEO PCCRC causes of PCCRC cases]

The location of missed lesions (adequate and inadequate examinations) were: Rectum 33%, Sigmoid: 14%, Descending colon: 0%, Splenic flex: 2%, Transversal colon: 2%, Hepatic flex: 10%, Ascending colon: 9% and the Cecum: 31%.

The main reason for inadequate examinations was the lack of documented cecal intubation (18/23).

**Conclusion:** Missed lesions were predominantly located in the rectum or the cecum. The cecum can be technically challenging to visualize adequately, and previous studies have found higher risk of missed lesions in the cecum.<sup>2,3</sup> The high proportion of missed lesions located in the rectum may be related to local practices. Mandatory looping in the rectum is not required in North Region, Denmark, and rectal looping was only recorded in one case of a missed rectal lesion.

In cases with a previous inadequate examination, lack of evidence for cecal intubation was the dominant factor. In North Region, Denmark photo documentation is not required, but no evidence of terminal ileum intubation nor visualization of the ileocecal valve, the appendix orificium or an ileocolonic anastomosis were documented.

Incomplete resections were usually related to difficult polypectomies with multiple colonoscopies, polypectomies and short surveillance intervals before a final CRC diagnosis. Only one case of unexpected recurrence was identified.

Deviation from the planned pathway was mostly related to insufficient and unclear journal recording.

The WEO algorithm provides a useful framework to categorize PCCRC. In our study 82% of cases are related to missed lesions which are probably avoidable. The WEO algorithm is a valuable tool to identify areas in the colonoscopy service that could be improved in an attempt to avoid PCCRC.

## P1585 COLONOSCOPY FREQUENCY IN DIFFERENT SOCIOECONOMIC GROUPS BEFORE AND AFTER IMPLEMENTATION OF COLORECTAL CANCER SCREENING IN STOCKHOLM-GOTLAND REGION: A NATIONWIDE REGISTER-BASED STUDY IN SWEDEN, 2006-2015

Thulin T.<sup>1</sup>, Hultcrantz R.<sup>1</sup>, Holmén A.<sup>2</sup>, Strömberg U.<sup>3</sup>, Forsberg A.<sup>1</sup>

<sup>1</sup>Karolinska Institutet, Medicine, Stockholm, Sweden, <sup>2</sup>Region Halland, Varberg, Sweden, <sup>3</sup>Gothenburg University, Medicine, Gothenburg, Sweden

**Contact E-Mail Address:** torbjorn.thulin@ki.se

**Introduction:** Colorectal cancer (CRC) screening programmes are used to prevent CRC by detection of precancerous lesions or CRCs in less advanced stages. From 2008 and onwards, inhabitants aged 60-69 years in the Stockholm-Gotland Region (SGR) have been invited to participate in a faecal occult blood test (FOBT) based screening. Individuals with a positive FOBT were invited to a colonoscopy. In the rest of Sweden, organised CRC screening has not been implemented. We hypothesize the implementation of the screening programme in the SGR has accentuated socioeconomic disparities in colonoscopy frequency.

**Aims & Methods:** The aim was to study time trends in the colonoscopy frequency in different socioeconomic groups and geographical areas, with special consideration to the implementation of CRC screening in the SGR in 2008, within the age group 60-69 years. All registered colonoscopies in Sweden 2006-2015 were collected from Swedish in- and outpatient registers. In total 576,598 colonoscopies were included. From this cohort we selected colonoscopies performed on persons 60-69 years old. Data about sex, age, marital status, immigrant status and number of school years were collected from Statistics Sweden and linked to each colonoscopy (using unique personal identification numbers). Groups were categorized according to educational level (low, < 9 years in school; intermediate, 10-12 years; and high, >12 years), immigrant status (Swedish- vs. foreign-born) and sex. We compared colonoscopy frequencies in the population aged 60-69 years before (2006-2007) and after (2010-15) implementation of the screening programme.

**Results:** In the pre-screening period, the absolute frequency per 1000 was slightly higher in the SGR (8.9 for men, 9.9 for women) than in the rest of Sweden (7.5 for men, 8.6 women). In the SGR, the colonoscopy frequency was markedly higher among people with high educational level, 14.0 per 1000 such persons. By contrast, in the rest of Sweden, the frequency was somewhat lower among people with high educational level, 5.9 per 1000. Between the pre- and post-screening periods the absolute frequency increased by 14.6 units for men and 11.5 for women in the SGR. In the rest of Sweden, the corresponding frequency increases were less pronounced; 4.7 and 5.2, respectively. Comparing the frequency increases for different population groups according to educational level revealed the following patterns: 7.5 (low educational level), 7.0 (intermediate) and 10.7 (high) in the SGR; 4.9, 5.1 and 6.7 in the rest of Sweden. Comparing the frequency increases with regard to immigrant status revealed less pronounced disparities: 13.3 (Swedish-born) and 11.3 (foreign-born) in the SGR; 5.0 and 4.6 in the rest of Sweden.

**Conclusion:** In the pre-screening period, colonoscopy within the population aged 60-69 years in the SGR was more common among women and among people with high educational level. In the rest of Sweden, colonoscopy was not more common among people with high educational level. The frequency of colonoscopy have increased most pronouncedly in men and in highly educated individuals after the implementation of the CRC screening programme in the SGR. The frequency increase was similar in Swedish- and foreign-born individuals. Prerequisites for a screening programme that creates more equal conditions for attendance need to be addressed in further studies.

## P1586 MEASURES TO REDUCE POST-POLYPECTOMY BLEEDING IN PEDUNCULATED POLYPS - DOES A CLIP HELP?

Patel R.N., Moledina S., Hall R., Canda R., Besherdas K.

Royal Free London NHS Trust, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** Immediate and delayed post-polypectomy bleeding (PPB) is a serious complication after endoscopic removal of large pedunculated polyps. Options to decrease the risk of bleeding include injecting the stalk with adrenaline, placing endoscopic clips across the stalk (before or after

the polypectomy) and placement of a nylon loop around the stalk. The principle of closing a defect to reduce complications is well established but the cost effectiveness of prophylactic clipping remains controversial. There are currently no consensus guidelines.

**Aims & Methods:** We aimed to investigate the use of endoscopic clips during polypectomy of pedunculated polyps >10mm and assess its association with PPB. We performed a large retrospective study across two sites at a tertiary London-based hospital Trust. Endoscopy software (Unisoft GI reporting tool) was used to identify pedunculated polyps >10mm in size during a 5 year period (January 2014 to March 2019). Patients that did not undergo polypectomy were excluded.

**Results:** 657 polypectomies were performed for pedunculated polyps during the study period (mean age 65.2 (range 22 - 94), Female 240 (36.5%)). Mean pedunculated polyp size 16.4mm (10 - 60mm). 431 (65.6%) in sigmoid colon. 636 (96.8%) hot snare polypectomy; 264 (40.2%) injected with adrenaline. Endoscopic clip used in 191 (29%). Total immediate (< 6hrs) and delayed bleeding (6hrs to 2 weeks) events were 11 (1.7%) and 14 (2.1%), respectively.

	Endoscopic Clip (n = 191)	No Endoscopic Clip (n = 466)	p value*
Size (mm)	18.1	15.7	0.0002
Hot Snare (%)	183 (95.8)	453 (97.2)	0.35
Adrenaline injection (%)	115 (60.2)	149 (32.0)	<0.0001
Immediate bleeding (%)	9 (4.7)	2 (0.4)	0.0001
Delayed bleeding (%)	4 (2.1)	10 (2.1)	0.97

[Table 1. Bleeding complications according to use of endoscopic clip]

**Conclusion:** Endoscopic clip use was associated with more immediate bleeding events suggesting that it is being used as a treatment strategy (not prophylactically) to achieve haemostasis in high risk patients. Endoscopic clips are being deployed more often with larger polyps and in combination with adrenaline injection. Overall PPB rates in our cohort remain low. There remains considerable variation in practice and the type / size of clip to use and the method of clipping remain unanswered questions. Whilst there is clear guidance from national and international bodies on how to remove sessile polyps, the optimal technique for resection of pedunculated polyp is less clear and this may account for the variability in clinical practice.

**Disclosure:** Nothing to disclose

## P1587 POST-COLONOSCOPY COLORECTAL CANCERS - SHOULD WE BE ASPIRING TO BETTER TARGETS?

Patel R.N., Kumar R., Khurram R., Ang K.M., Hickmott L., Besherdas K.

Royal Free London NHS Trust, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** The British Society of Gastroenterology (BSG), the UK Joint Advisory Group (JAG) on GI Endoscopy and the Association of Coloproctology of Great Britain and Ireland (ACPGBI) have developed quality assurance measures and key performance indicators for the delivery of colonoscopy within the UK. One of these includes aspiring to a target of < 5% post-colonoscopy colorectal cancers (PCCRC) at 3 years.

**Aims & Methods:** We performed a retrospective study across two sites at a tertiary London-based hospital Trust. Endoscopy software (Unisoft GI reporting tool) was used to identify all new colorectal cancers diagnosed during colonoscopy during a 16 month period (May 2017 to September 2018). Interrogation for a prior colonoscopy within 3 and 5 years of the date of each colorectal cancer diagnosis was then performed. PCCRC rate was defined as the proportion of PCCRC diagnoses amongst all CRC cases within a 3 year period.

We also analysed demographics, time interval (initial to diagnostic colonoscopy) and colonoscopist performing the procedure (physician vs. surgeon). Quality of bowel preparation was scrutinised in the PCCRC cases (excellent, good, fair, inadequate).

**Results:** We identified 282 cases of colorectal cancer diagnosed during colonoscopy in the study period. There were a total of 8 cases of PCCRC within 3 years giving our Trust a PCCRC rate of 2.8%. Mean age of patients with a PCCRC diagnosis was 75.8 (64 - 88). Mean interval from initial to diagnostic colonoscopy in PCCRC cases was 2.08 years (0.92 - 3). Of the 8 pa-

tients with PCCRC; 1 was Dukes' A, 4 were Dukes' B2, 2 were Dukes' C1 and 1 was Dukes' C2. 7 of the 8 cases (87.5%) were colonoscopies performed by surgeons or external agency endoscopists. 4 of the 8 cases (50%) had less than good bowel preparation. Retroflexion in the rectum was not performed in 6 of the 8 cases (75%). When PCCRC diagnoses were extended to within 5 years the PCCRC rate was 4.3%.

**Conclusion:** Our study shows that our Trust is within the quality standards set by the relevant governing bodies. Root cause analyses identified caecal, sigmoid and anastomotic lesions as high risk sites for missed cancers as well as omission of retroflexion in the rectum. Accepting less than good bowel preparation is also a factor in half of PCCRC cases. Only 1 patient had an endoscopically resectable lesion at diagnostic colonoscopy but there were no patients with distant metastases. In view of the advances made in the quality of colonoscopy training and enhanced endoscopic technology, we suggest raising the bar with regards to acceptable PCCRC by either lowering the target or increasing the time frame to 5 years.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** marcoalgo@gmail.com

**Introduction:** Up to 20% of bowel preparations for colonoscopy are considered inadequate and the colonoscopy is not valid. The consequences are missed lesions, cancelled procedures, diagnostic delays, and increased risks and costs. The most important predictor of inadequate bowel preparation is a previous failure. There are no standardized recommendations to prepare those patients. An educational intervention through a telephone call has demonstrated to improve the efficacy of bowel preparation in the general population.

**Aims & Methods:** The aim of this study was to analyze the efficacy of a nurse-led educational intervention by telephone within the 48 hours before the colonoscopy, in patients with previous bowel preparation failure. This was a multicentre randomized clinical trial with parallel groups (control and educational intervention), endoscopist-blind. The study was approved by each of the 11 participant hospitals. Consecutive patients with inadequate bowel preparation were included. A sample size of 650 participants was calculated to show a 10% improvement in bowel preparation adequacy. Both groups received the same bowel preparation protocol including 4 liters of PEG in split dose regimen. The main outcome was adequate bowel preparation defined as all segments of the Boston Bowel Preparation scale with 2 or 3 points. Participants with no efficacy data were considered bowel preparation failures. Intention to treat (ITT) analysis included all randomized participants and per protocol (PP) analysis included participants that could be contacted by telephone and control cases. Clinicaltrials identifier: NCT03055689

**Results:** The investigators included, 651 consecutive participants (329 control and 321 intervention) without differences in the baseline characteristics. In the ITT analysis bowel preparation was inadequate in 97 (29.6%) control cases and in 77 (23.9%) intervention cases, risk difference 5.7%,  $p=0.1$ . Attendance to colonoscopy was 296 (91.4%) and 297 (92.2%),  $p=0.68$  in control and intervention groups. Adenoma detection rate was 39.2% and 44.4%,  $p=0.21$  in the control and intervention groups respec-

tively. In the intervention group 267 (82.9%) participants could be reached by telephone. In the PP analysis the bowel preparation was inadequate in 45 cases (16.9%) in the intervention group, with a risk difference with the control group of 12.7%,  $p>0.001$ .

**Conclusion:** In patients with previous failure of bowel preparation a nurse-led telephone education in the 48 hours before the colonoscopy is not effective as intention to treat, due to a limited applicability. However that intervention is clearly effective when the patient can be reached by telephone.

## P1589 THE ROLE OF KEY PERFORMANCE INDICATORS IN THE SURVEILLANCE OF POST-RESECTION COLORECTAL CANCER PATIENTS

Richardson-Thibodeau J.<sup>1</sup>, Norton B.<sup>2</sup>, Monahan K.J.<sup>3</sup>

<sup>1</sup>Imperial College London, Faculty of Medicine, London, United Kingdom,

<sup>2</sup>Imperial College London, Department of Genomic Medicine, London, United Kingdom, <sup>3</sup>West Middlesex Hospital, Family Cancer Clinic, London, United Kingdom

**Contact E-Mail Address:** jr1515@ic.ac.uk

**Introduction:** Between 2013 and 2014, 63-66% of all patients with newly diagnosed colorectal cancer (CRC) in the UK underwent a surgical resection for their tumour<sup>1</sup>. Post-resection surveillance colonoscopy for metachronous CRC has become standard practice, as patients with a previous CRC may be at greater risk of a secondary CRC diagnosis than age and sex-matched controls are of a primary CRC diagnosis<sup>2</sup>. However, the protection offered by surveillance colonoscopy may in fact be limited by the quality of the colonoscopy performed, and in particular, the ability of the colonoscopist conducting the procedure. Key performance indicators (KPIs) are markers of colonoscopy quality, and include adenoma detection rate (ADR), caecal intubation rate (CIR) and polyp retrieval rate (PRR). Unfortunately, the utility of KPIs for surveillance colonoscopy in patients who have undergone surgical resection for CRC is not well described.

**Aims & Methods:** Using KPIs, we aimed to assess the quality of colonoscopy in a cohort of patients with previous CRC who underwent surveillance post-resection at West Middlesex University Hospital (WMUH), and compare these to non-surveillance KPIs by the same colonoscopists to assess the relationships between them. We retrospectively assessed colonoscopy data for post-resection CRC surveillance at WMUH between 2010 and 2019. Patient demographic and colonoscopy data was collected alongside colonoscopist non-surveillance KPI data and analysed using the software SPSS. All flexible-sigmoidoscopies which did not aim to completely intubate the bowel were excluded. We assessed for correlation between surveillance and non-surveillance KPIs from the same colonoscopists at the trust, and tested for any differences in KPIs between the two cohorts.

**Results:** In total, 641 surveillance colonoscopies for post-resection CRC were performed by over 50 colonoscopists. The overall ADR in the 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> surveillance colonoscopies was 22.0%, 27.0%, 36.8% and 38.5% respectively, with an ADR of 26.0% across all colonoscopies. 7 colonoscopists performed at least 20 surveillance colonoscopies in our cohort. For these 7 colonoscopists, the total ADR was 25.9% (range 13.6%-45.0%), the total CIR was 97.4% (range 95.0%-100%), and the total PRR was 90.3% (range 76.9-100%). Non-surveillance ADRs correlated with surveillance ADRs ( $R^2=0.650$ ,  $p<0.05$ ), but non-surveillance CIRs did not correlate with surveillance CIRs ( $R^2=0.270$ ,  $p=0.232$ ), nor did non-surveillance PRRs correlate with surveillance PRRs ( $R^2=0.532$ ,  $p=0.153$ ). There were no significant differences between the surveillance and non-surveillance ADRs observed in these colonoscopists ( $p=0.115$ ).

**Conclusion:** Even with a relatively small sample size, we found a clear association between surveillance and non-surveillance colonoscopist ADRs (the primary marker of colonoscopy quality) in our cohort. Although other KPIs including CIR and PRR did not correlate between surveillance and non-surveillance cohorts, there may be practical reasons for this, including the presence of short bowels in post-resection CRC patients and the exclusion of flexible-sigmoidoscopies in our study.

**Introduction:** Adenoma detection rate (ADR) and mean adenoma per colonoscopy (APC) are established quality indicators in colonoscopy. Yet they are not generally used in European countries. This may be because it is rather difficult to obtain them in terms of time and personnel. To improve the compliance of endoscopists with quality control, it is essential to simplify the entire monitoring process. Polyp detection rate (PDR) is a user friendly alternative of ADR that can be easily evaluated from administrative data.

**Aims & Methods:** The aim of our study was to assess whether PDR correlates with ADR and with APC. Our effort was to determine minimal marginal value for APC. Prospective multicenter study included asymptomatic individuals aged 45-75 who underwent preventive colonoscopy in 2012-2016 as part of Czech study monitoring metabolic risk factors of colorectal cancer. Individuals with incomplete colonoscopy and endoscopists with less than 30 colonoscopies and/or no detected adenoma in the observed group were excluded from the study. Spearman's correlation coefficient was used to assess the relation between individual PDR/ADR and PDR/APC resp. The resulting conversion factors to predict ADR (APC) from PDR were obtained by linear regression.

**Results:** In total, the study included 1,614 preventive colonoscopies performed by 16 endoscopists. Correlation between PDR and both indicators in all preventive colonoscopies was strong and statistically significant (PDR/ADR: Rs 0.82; p < 0.001; PDR/APC: Rs 0.70; p = 0.0027). We used the same methodology to determine gender-specific and indication-specific PDR/ADR and PDR/APC correlations. In all cases, we demonstrated a strong and statistically significant correlation between PDR and ADR (APC resp). We obtained conversion factors for both quality indicators: PDR to ADR 0.7185, resp. PDR to APC 0.0123.

**Conclusion:** There is a strong correlation between PDR/ADR as well as between PDR/APC. Because of better availability, PDR may replace ADR and APC in colonoscopy quality assessment. Using our conversion factor we obtained minimal marginal value of APC 0.5 based on 40% minimal marginal value of PDR as recommended by ESGE.

PDR has the potential to increase compliance of endoscopists to quality control, at least until data processing is fully automated.

**Introduction:** The effectiveness of bowel cleansing is essential for a quality colonoscopy as it affects diagnostic accuracy and adenoma detection rate. Inadequate cleansing remains a major challenge, with a suboptimal bowel preparation observed in 25% of procedures.

Among all factors contributing to inadequate preparation, age has been shown to be an independent risk factor for poor bowel cleansing. Nevertheless, factors affecting bowel cleansing in the elderly are not fully known, and current guidelines do not provide a specific recommendation for optimisation of preparation in these patients.

**Aims & Methods:** This study aimed to assess the difference in bowel cleansing in elderly compared to younger patients and to evaluate independent factors associated with a cleansing success.

We retrospectively reviewed a prospective cohort of 1289 in- and out-patients undergoing a colonoscopy after a standard (afternoon-only) or a split (afternoon-morning) preparation with a 1, 2 or 4L PEG-based solution consecutively enrolled from September 2018 to February 2019 in 5 Italian centres. The elderly population was defined by an age ≥65 years. Bowel cleansing was assessed through the Boston Bowel Preparation Scale (BBPS) and a cleansing success was defined as a total BBPS≥6 with a partial BBPS≥2 in each segment. Tolerability was evaluated by a semi-quantitative scale with a score ranging from 0 to 10.

**Results:** All 1289 patients were included in the analysis. Overall 52.8% of subjects were male, the mean age was 60.5±14, and 44.6% of patients were older than 65 years.

Bowel preparation was performed with a 4L, 2L and 1L PEG solution in 38.0%, 43.9% and 18.1% of cases, in the absence of serious adverse events. Bowel cleansing by BBPS was 6.6±1.4 and 6.3±1.6 (p = 0.006) in the groups of patients aged < 65 and ≥65 years and colonoscopy was completed with cecal intubation in 97.5% and 95.5% (p=0.05) of patients, respectively. Compared to patients < 65 years, patients ≥65 years achieved a lower cleansing success: 70.3 vs 77.3% overall, 61.2% vs 69.5% in the subgroup of standard preparation and 84.9% vs 90.2% in the subgroup of split preparation.

At multivariate analysis, split regimen (OR=2.49, 95% CI=1.38-4.48; p=0.002), adequate cleansing at previous colonoscopy (OR=3.28, 95% CI=1.40-7.68; p=0.006) and tolerability score (OR=1.14, 95% CI=1.03-1.26; p=0.006) were independently associated with a cleansing success in the group of patients aged < 65 years. In the group of patients aged ≥65 years, split regimen (OR=2.43, 95% CI=1.34-4.38; p=0.003), adequate cleansing at previous colonoscopy (OR=2.29, 95% CI=1.14-4.73; p=0.02), tolerability score (OR=1.29, 95% CI=1.16-1.44; p< 0.001), low-fiber diet for at least 3 days preceding colonoscopy (OR= 2.45, 95% CI=1.42-4.24; p=0.001) and colonoscopy within 5 hours after preparation (OR= 2.67, 95% CI=1.28-5.56; p=0.008) were independently associated with a bowel cleansing success.

**Conclusion:** Compared to younger patients, achieving adequate cleansing in the elderly is more challenging, and it is influenced by a higher number of external factors. Among these, split preparation, timing of colonoscopy within 5 hours after preparation, low-fiber diet for at least 3 days preceding colonoscopy, adequate cleansing at previous colonoscopy and tolerability of preparation were independently associated with a cleansing success. These factors play a crucial role in achieving a proper bowel cleansing and need to be properly addressed to optimise the quality of preparation in elderly, thus avoiding the discomfort and the risks deriving from the repetition of the exam.

## P1592 SNARE TIP SOFT COAGULATION OF THE MUCOSAL DEFECT MARGIN FOLLOWING COLONIC ENDOSCOPIC MUCOSAL RESECTION (EMR) REDUCES RECURRENCE IN A "REAL LIFE" SETTING

Abu Arisha M.<sup>1,2</sup>, Half E.<sup>1</sup>, Maza I.<sup>1</sup>, Muaalem R.<sup>2</sup>, Bana S.<sup>2</sup>, Awadie H.<sup>2</sup>, Klein A.<sup>2,3</sup>

**Contact E-Mail Address:** m\_abu-arisha@rmc.gov.il

**Introduction:** Large (>20 mm) colonic lateral spreading lesions (LSL) while uncommon, are high risk precursors of CRC, and require Endoscopic Mucosal Resection (EMR) for their safe and efficacious removal. EMR is the treatment of choice due to its high success rates, good safety profile and multiple advantages compared with surgery.

A recent randomized study demonstrated that ablation of the post-EMR mucosal defect margin significantly reduced polyp recurrence at surveillance. Also, recently studies have shown that endoscopic assessment of recurrence is very accurate with a NPP of 99%-100%.

We aimed to determine the efficacy of this technique for reducing polyp recurrence in a "real life" setting.

**Aims & Methods:** Analysis of a prospectively collected database of LSL ≥ 20 mm was performed in two hospitals in Israel. Standard EMR technique was used in all cases emphasizing complete snare excision followed by thermal ablation of the entire defect margin. Surveillance colonoscopy was performed 4-6 month after resection. Recurrence was assessed endoscopically with High Definition White Light (HDWL), Narrow Band Imaging (NBI) and magnification. Normal appearing scars were randomly biopsied as were any scars suspicious for recurrence. The primary endpoint was lesion recurrence at first surveillance colonoscopy.

**Results:** Over 34 months 313 LSL in 303 patients were removed by EMR. 249/313 (81.7%) were removed piecemeal. 233/249 (93.5%) lesions were treated with ablation of the margin. 176/233 (75.5%) completed first surveillance colonoscopy. Recurrence was suspected endoscopically and confirmed histologically in 4/176 cases. One histological recurrence was detected in a biopsy from a normal appearing scar. Overall recurrence occurred in 5/176 (2.8%) cases. Compared to the final histology, endoscopic diagnosis was accurate in 98%. We had 6/249 (2.4%) cases of clinical significant delayed bleeding all treated conservatively and two cases of deep mural injury treated by clips only.

**Conclusion:** Ablation of the mucosal defect margin following EMR in a "real life" setting results in very low recurrence rates and low rates of complication. STSC should be performed routinely following piecemeal colonic EMR.

## P1593 QUANTIFYING EMERGENCY ADMISSIONS AFTER DAYCASE ENDOSCOPY USING ROUTINE DATA

Crooks C.J.

University of Nottingham, Nottingham Digestive Diseases Centre / NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom

**Contact E-Mail Address:** colin.crooks@nottingham.ac.uk

**Introduction:** Detailed stratified estimates of adverse events after endoscopy would inform clinical decision making about appropriate investigations in those at higher risk. This is important due to the ever increasing proportion of the population undergoing diagnostic endoscopy. This abstract identified the adjusted total and excess risk of cardiovascular, respiratory, gastrointestinal and symptom events in both primary and secondary care following low risk day case diagnostic gastroscopy, colonoscopy, sigmoidoscopy and double upper and lower procedures.

**Aims & Methods:** Patients undergoing day case diagnostic endoscopy were identified in the English population from the Clinical Practice Research Datalink hospital data using OPCS-4 coding. Each endoscopy procedure was frequency matched with replacement on decade of birth to at 4 controls alive and registered at the time of the endoscopy including those who might have an endoscopy at a later date. Follow up was censored on; 30 days or the earliest diagnosis of cancer, a subsequent gastrointestinal event, a subsequent interventional procedure, after the first emergency hospital admission, any transfer out the study population, or death.

The first acute event was defined as either the primary reason for the first emergency admission after an endoscopy or a primary care consultation. This was coded broadly by their ICD 10 chapter; and more specifically as a cardiac, cerebrovascular, respiratory, gastrointestinal bleeding, perforation or peritonitis event; or as having an episode coding symptoms of nausea, vomiting or abdominal pain without a gastrointestinal diagnosis. Gastrointestinal events or symptoms recorded both prior and post procedure were censored as likely to be the indication for the procedure. Outcomes were identified in the 30 days after the index date, from either linked primary care consultations, the underlying cause from death certificates, or the main diagnosis from emergency hospital admissions.

The age stratified risk of each type of event following each type of day case diagnostic endoscopy was estimated in a Cox regression model adjusted for age, gender, and a previously developed measure of pre-existing co-morbidity<sup>1</sup>. Then the stratified absolute excess risks were calculated, adjusting for censored and competing events, by using the cumulative incidence functions derived from the Cox model.

**Results:** 277,535 gastroscopies, 172,862 colonoscopies, 22,995 dual procedures and 73,195 flexible sigmoidoscopies were recorded in the linked data between 1998 and 2016. Of the outcome events 118,089 were coded as cardiorespiratory, 1,463 as gastrointestinal, and 4,213 as pain, nausea or vomiting. The absolute excess cardiovascular risk compared to the general population decreased with age for colonoscopy and double procedures, but increased following gastroscopies and flexible sigmoidoscopies, possibly reflecting the different case mix of patients referred for these procedures. There was no reduction in the risk of a post procedure event over the time course of the study after adjusting for age and co-morbidity. The largest annual relative change was for a slight increase in cardiovascular events after diagnostic gastroscopy (HR=1.005 (1.001-1.009)) with an average 30 day risk of 5% for patients over 80 years.

**Conclusion:** This study showed the potential of linked routine data to provide a comprehensive population based measurement of post endoscopic events in primary and secondary care. Cardiovascular events predominate, and despite improvements in sedation practice there was no observable reduction in post procedure events.

**Contact E-Mail Address:** marcello.maida@hotmail.it

**Introduction:** The effectiveness of bowel cleansing is a key element for a quality colonoscopy as it affects diagnostic accuracy and adenoma detection rate. A very-low-volume 1L PEG solution NER1006 (Plenvu® Norgine, Harefield, UK) has been recently introduced after the publication of three phase 3 randomized controlled trials showing non-inferiority respect to comparators<sup>1-3</sup>. Despite its proven effectiveness, the safety of NER1006 in the elderly has never been assessed in a real-life setting.

**Aims & Methods:** This study aimed to assess the difference of NER1006 safety profile in elderly compared to younger patients in a real-life setting. We performed a post-hoc analysis of data from a cohort of 1289 patients undergoing a colonoscopy after a standard (afternoon-only) or a split (afternoon-morning) preparation with a 1, 2 or 4L PEG-based solution

consecutively enrolled from September 2018 to February 2019 in 5 Italian centres. The elderly population was defined by an age  $\geq 65$  years. Tolerability was evaluated through a semi-quantitative scale with a score ranging from 0 to 10. Safety was monitored through adverse event (AE) reporting.

**Results:** Among 1289 patients, 233 subjects undergoing a bowel preparation with NER1006 were included in the analysis. The mean age was  $59.5 \pm 15.9$  years, 52.4% of patients were male, and 43.5% were older than 65 years old. Mean age was  $48.6 \pm 11.9$  years (range 18-64) in the group of patients aged  $< 65$  years, and  $73.7 \pm 6.3$  years (range 65-91) in the group of patients aged  $\geq 65$  years, while prevalence of hypertension, diabetes and obesity was 13.7 vs 32.7% ( $p=0.03$ ), 3.1 vs 9.9% ( $p=0.001$ ) and 12.2 vs 13.9% ( $p=0.7$ ) in the two groups, respectively. Overall incidence of adverse events was 19.8% and 10.9% ( $p=0.06$ ) in the group of patients aged  $< 65$  and  $\geq 65$  years. Incidence of nausea, vomit, abdominal pain, dehydration and headache was 3.1 vs 3.0% ( $p=0.9$ ), 9.9 vs 5.9% ( $p=0.2$ ), 0.8 vs 0.0% ( $p=0.3$ ) 2.3 vs 0.0% ( $p=0.1$ ) and 2.3 vs 0.0% ( $p=0.1$ ), in the group of patients aged  $< 65$  and  $\geq 65$  years, respectively. No serious adverse events or deaths occurred in any of the two groups.

**Conclusion:** In this post-hoc analysis, we did not find any substantial difference in the safety profile of NER1006 in the elderly compared to younger patients. Given the observational nature of our study, an assessment of blood electrolyte or creatinine was not feasible. Nevertheless, no clinical event attributable to electrolyte imbalance or dehydration was observed in any patient. These results confirm the safety of this product even in the elderly and in a real-life setting.

## P1595 EFFICACY OF ENDOSCOPIC TREATMENT FOR ADENOMA RECURRENCE AFTER PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION OF LESIONS LARGER THAN 20MM

Currais P.<sup>1</sup>, Saraiva S.<sup>1</sup>, Marques I.<sup>2</sup>, Mão Ferro S.<sup>3</sup>, Pereira A.D.<sup>2</sup>

<sup>1</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, Gastroenterology, Lisboa, Portugal, <sup>2</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal, <sup>3</sup>IPO Lisboa, Gastroenterology, Amadora, Portugal

**Contact E-Mail Address:** pedro\_currais@live.com.pt

**Introduction:** Endoscopic mucosal resection (EMR) is a safe and effective technique for the resection of large colorectal lesions, but is associated with a high risk of local recurrence (LR). Data on the ideal methods and outcomes of endoscopic treatment of LR after EMR are scarce, with no formal recommendations.

**Aims & Methods:** We intended to evaluate the efficacy, safety and endoscopic clearance rate following treatment of LR after piecemeal EMR (pEMR).

Retrospective unicentric study based on the analysis of LR after pEMR of lesions with  $\geq 20$  mm between January/2010 and December/2017, registering its endoscopic, histological, treatment, complications and surveillance features.

**Results:** A total of 226 pEMR of lesions measuring  $\geq 20$ mm (Median 25mm, IQR 20-35mm) were evaluated. LR was observed in 71 patients (31.4%). Mean age of  $66 \pm 10$  years, male in 45%, 42.2% located distal to the hepatic flexure.

LR was small ( $< 5$ mm) and unifocal in 76% and 86% of cases, respectively. It was objectified in the first 6 months after index pEMR in 60.5% and submitted to en-block resection in 63.1% of the cases. The modalities used to resect recurrence were cold snare (49.3%), hot snare (25.4%), cold snare and cold-forceps avulsion (11.3%), cold-forceps avulsion alone (3%) and endoscopic full-thickness resection (3%). 8.5% ( $n = 6$ ) of the patients were referred for surgery due to an inability to resect recurrence. Histology: 50.7% displayed tubulovillous adenoma at histopathology and 38.1% high

grade dysplasia. A second LR was observed in 12.3% ( $n = 8$ ) patients, all of whom underwent piecemeal resection of the first relapse. 1 patient was referred for surgical resection due to nonresectability of the second relapse. An endoscopic clearance of recurrent adenoma of 91.1% was obtained.

**Conclusion:** LR after pEMR is often small and can be effectively treated using conventional endoscopic techniques with long-term remission rates greater than 90%. More complex endoscopic techniques (endoscopic full-thickness resection/endoscopic submucosal dissection) and surgery are only necessary in a small number of patients.

**Disclosure:** Nothing to disclose

## P1596 MANAGEMENT OF COLORECTAL POLYPS IN A DEVELOPING COUNTRY: IS THERE ANY DIFFERENCE?

Mrabti S., Seddik H., Boutallaka H., Sair A., Berraida R., Sentissi S., El kotli I., Benkirane A.

Military Instruction Hospital Mohammed V, Gastroenterology II, Rabat, Morocco

**Contact E-Mail Address:** doc.mrabti@gmail.com

**Introduction:** Colorectal polyps are very common in general population. Endoscopy allows the diagnosis and characterization of the polyp which is fundamental to determine the modalities of polyp removal.

**Aims & Methods:** The aim of our study is to determine the incidence of rectocolic polyps in our department and thus their adequate management. This is a retrospective descriptive and analytical study conducted over a period of 19 years from January 2000 to April 2019 in our department of gastroenterology II of the military teaching hospital of Rabat. We included all patients over 18yo whom had less than 4 colorectal polyps of more than 3mm each, discovered during a total colonoscopy with a complete polyp characterization using white light and narrow band imaging, and whom underwent a complete endoscopic removal and retrieval. For all patients, we assessed the endoscopic devices used for polypectomies, and for complications management. We then performed a statistical analysis using SPSS software 24.0.

**Results:** 3,23% ( $n=214$ ) of patients who had undergone total colonoscopies performed during the study period ( $n=6607$ ) underwent one or multiple polypectomies. The mean age of our patients was  $55.89 \pm 14.45$  years old [18-90], with a sex ratio M/F of 2,17 and a history of operated rectocolic cancer in 13,2% ( $n=27$ ). The mean number of polyps in each patient was  $1.32 \pm 0.66$ . Colonoscopies indications were dominated by rectal bleeding which represented 22,9% ( $n=47$ ), followed by constipation in 12,2% ( $n=25$ ), iron deficiency anemia in 5% ( $n=10$ ) and abdominal pain in 5% ( $n=10$ ). During the procedure, the major part of polyps were located in left colon in 45,1% ( $n=93$ ) and rectum in 27,7% ( $n=57$ ), followed by transverse colon in 17,6% ( $n=36$ ), right colon in 15,1% ( $n=31$ ) and coecum in 5,4% ( $n=11$ ). All colorectal polyps were staged according to Paris classification with a predominance of sessile polyps (Is) which represented 73,83% ( $n=158$ ), followed by pedunculated ones (Ip) which represented 37,38% ( $n=80$ ). stages IIa , IIb and IIc of Paris classification were less frequent with respectively 0,46% ( $n=1$ ), 7,47% ( $n=7$ ) and 0,46% ( $n=1$ ).

42,05% ( $n = 90$ ), polyps were removed by forceps, 32,24% ( $n = 69$ ) had polypectomies using cold snare, 22,89% ( $n = 49$ ) had endoscopic mucosal resection (EMR), and 28,03 % ( $n = 60$ ) were biopsied and resected later. Early complication rate defined by the occurrence of bleeding after polypectomy was 2% ( $n = 2$ ), and there was no late complication noted.

**Conclusion:** Endoscopic resection of recto-colic polyps is currently an alternative to radical surgery, leading to a significantly lower cost and morbidity and allowing a decrease of the incidence and mortality due to recto-colic cancer. The therapeutic choice depends on good endoscopic characterization in real time. Monitoring after polypectomy is necessary and depends mainly on histological findings

**Contact E-Mail Address:** barbara.majcher@meduniwien.ac.at

**Introduction:** After investigating the impact of a quality improvement conference on screening colonoscopy in 2016, we wanted to analyze if attending a second conference one year later has an influence on quality parameters. Thus, our aim of the study was to assess differences in quality measures according to the endoscopist's participation in the conference.

**Aims & Methods:** 69 902 screening colonoscopies from 213 endoscopists performed within the Austrian Certificate of Screening Colonoscopy were evaluated. The second one-day quality improvement conference on screening colonoscopy was also organized within the framework of the certificate on September 9<sup>th</sup>, 2017. We investigated the following quality parameters: the adenoma detection rate (ADR), advanced adenoma detection rate (AADR) and cecal intubation rate (CIR).

**Results:** Data from the year before (September 2016 to August 2017) and the year after the conference (October 2017 to September 2018) were compared.

No statistical significance was found in mean ADR, AADR and CIR from the year before and after the conference among participants of the certificate attending the conference for the second time, first time and those who did not participate (table 1).

		Before conference	After conference	p-value
Endoscopists participating for 2nd time; N= 24 (11,27%)	ADR % (SD)	30,49 (9,39)	32,45 (9,85)	0,2022
	AADR % (SD)	7,83 (6,05)	8,33 (5,87)	0,6064
	CIR % (SD)	97,2 (3,15)	97,46 (2,71)	0,4597
Endoscopists participating for 1st time; N=15 (7,04%)	ADR % (SD)	27,37 (12,82)	28,59 (12,59)	0,5056
	AADR % (SD)	5,81 (3,94)	4,39 (3,0)	0,2621
	CIR % (SD)	98,82 (1,53)	97,71 (3,9)	0,2349
Non-participants; N= 174 (81,69%)	ADR % (SD)	24,39 (12,79)	24,38 (12,43)	0,9930
	AADR % (SD)	5,6 (5,02)	5,11 (4,51)	0,1421
	CIR % (SD)	97,51 (3,15)	97,41 (3,19)	0,6520

[Table 1]

**Conclusion:** This study did not show any change in the investigated quality parameters among endoscopists who attended the quality improvement conference and the ones who did not participate. Endoscopists attending the conference had higher quality parameters than non-participants already before the conference. Therefore, it is important to reach those endoscopists who need more improvement and encourage them to take part in training.

**Contact E-Mail Address:** rameshshan777@yahoo.co.uk

**Introduction:** Intra procedural and post polypectomy bleeding is a recognised complication of large broad -based or pedunculated polyp resection. Several endoscopic techniques have been applied to prevent bleeding with variable success. Furthermore, piecemeal endoscopic mucosal resection could lead to incomplete resection and future recurrences.

**Aims & Methods:** We report our preliminary experience in achieving a complete en bloc, Endoscopic Sub mucosal Dissection (ESD) using a scissor type SB knife.

A prospective database was analysed including 26 consecutive patients (median age 66 years, range 34-80) with 28 broad-based colorectal neoplasms resected by ESD between 2015 and 2017.

**Results:** ESD technique Once a broad-based polyp was detected, the surface was scrutinised with white light and NBI. Firstly, the base was injected with submucosal injection of 0.1% hyaluronate and methylene blue and ESD was performed using SB knife junior (monopolar ESD knife, Sumius, Tokyo, Japan). Following an initial mucosal incision, submucosal (SM) dissection was performed. SM blood vessels (BV) were grasped and coagulated to prevent bleeding. A sequence of coagulation and cutting was performed repeatedly until the polyp was resected completely. Polypectomy base was examined and any oozing BV's were treated with SB knife and the base was closed using haemostatic clips. Polyp tissue were retrieved and sent for histology.

The median (IQR) polyp size was 3.25cm (2-6cm). 89% (25/28) of the polyps were in either rectum or sigmoid colon. Histology showed adenoma with low grade dysplasia in 12/28(42.8%), high grade dysplasia in 28.6%(n=8), T1 adenocarcinoma in 10.7%(n=3), hamartomas in 7.1%(n=2), serrated lesions without dysplasia in 7.1% (n=2) and lipoma in 3.6%(n=1) of endoscopically resected lesions. Intra procedural bleeding was treated either with haemostatic function of SB knife or with snare tip soft coagulation. Base of all polyps, following resection were closed with multiple clips. There were no episodes of perforation or delayed post polypectomy bleeding. 3 patients (11.5%) were electively admitted post procedure for overnight observation and discharged on the following day. The en-bloc, histological complete and curative(R0) resection rates were 100%, 89% and 85%. Three patients (11.5%) at risk of lymph node metastasis underwent additional radical surgery. 20/25(80%) of ESD cases had endoscopic follow up data over a median duration of 12 months (range 6-36 months) and none of them had local recurrences.

**Conclusion:** ESD using scissor type SB knife is efficient and safe in treating broad-based or stalked polyps. Our series highlighted a favourable short and medium-term outcome.

**Disclosure:** None declared

**Contact E-Mail Address:** giulia.gibiino@gmail.com

**Introduction:** Even if the barriers to the adoption of Endoscopic Submucosal Dissection (ESD) in the current practice in Western countries are falling, it remains, especially for colonic lesions, challenging and with a high risk of adverse events. ESD for residual/recurrent colonic lesions on scar is even more technically difficult and it has significant rate of perforations even in Japanese expert hands. Nevertheless, in Japanese tertiary referral centers ESD represents the standard of care in such lesions. Full thickness resection (FTR) with a over-the-scope device (FTRD - Ovesco Endoscopy) is a minimally invasive endoscopic technique recently introduced in Western countries. Even if with some limitations (the major limitation is the maximum size of the lesion, 30 mm), it showed to be safe and effective in the resection of residual/recurrent colonic lesions on scar and, being less technically demanding than ESD, it is more applicable among Western endoscopists.

**Aims & Methods:** This study sought to compare, therefore, outcomes for endoscopic resection of such lesions between a Japanese and an Italian tertiary referral centre. From January 2017 to December 2018 a total of 17 and 48 residual/recurrent colorectal lesions on scar were respectively treated by FTR (in the Italian Centre) and ESD (in the Japanese Centre). En-bloc and R0-resection rates were recorded as primary outcomes and retrospectively analysed. Adverse events, median procedure time and residual lesions at 3-months follow-up were assessed as secondary outcomes.

**Results:** The proportions of R0 resections were 86.7% in the FTR group vs 97.9% in the ESD group. En-bloc resection rate was achieved in 100% in both groups. Adverse events were not reported in the first group. ESD group Intraoperative perforations rate was 20.8%, all managed conservatively; no delayed perforations were reported and 1 case of bleeding occurred, managed endoscopically. There was no significant difference in median procedure time (56 min vs 67.5 min). At 3-months follow-up relapse was evident in one patient of the FTR group, treated with hybrid ESD while no relapse was reported for ESD group. Mean size of specimens was 21 mm for FTR (20/35) vs 37 mm (12/48) for ESD group. Histological analysis revealed: low-risk adenocarcinoma or adenoma (16 FTR, 46 ESD), high-risk adenocarcinoma (1 FTR, 2 ESD group).

**Conclusion:** Despite the few numbers of preliminary data and clear limitations when comparing two techniques with different advancement in asiatic and non-asiatic endoscopic centres, FTR showed to be a safe and effective procedure in residual/recurrent colonic lesions on scar and could become the standard of care in such lesions in Western Countries.

## P1601 FEASIBILITY OF HYBRID ENDOSCOPIC SUBMUCOSAL DISSECTION WITH MULTIFUNCTIONAL SNARE 'SOUTEN'

Minato Y., Ohata K., Matsuhashi N.

NTT Medical Center Tokyo, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** yoheiminato55925@gmail.com

**Introduction:** Colorectal endoscopic submucosal dissection (ESD) provides complete en bloc resection and precise pathological evaluations. However, ESD is still technically difficult and time required. Therefore, as an alternative option, Hybrid ESD may shorten the procedure time and enable to achieve an en bloc resection for relatively large lesions. Recently, a novel multifunctional snare (SOUTEN; Kaneka Medics, Tokyo, Japan) was intro-

duced to enable successful hybrid ESD procedures. Since the knob-shaped tip helps to stabilize the needle-knife, making it less likely to slip during circumferential incision and partial submucosal dissection, all the processes can be completed using 1 device.

**Aims & Methods:** The aim of this study is to evaluate the safety and efficacy of colorectal hybrid ESD. In this retrospective study, we applied Hybrid ESD using the "SOUTEN" for relatively large (20-30mm), non-pedunculated colorectal tumors. From June 2016 to December 2018, 46 lesions were removed by Hybrid ESD. Lesions involving the ileocecal valve and/or appendiceal orifice were excluded from this study. In addition, lesions with polypoid growth or converging fold and those suspected of exhibiting severe fibrosis were also excluded. The clinical characteristics and outcomes were evaluated. To assess the efficacy and safety of the hybrid ESD, we extracted the clinical data for patients who received conventional ESD randomly from our ESD database performed within the previous year adjusted for tumor size, morphology, and location.

**Results:** The patient age was 63.9±8.5 years. All the lesions were successfully resected with the hybrid ESD procedure. The tumor locations were 8, 10, and 28 in the rectum, left-sided colon, and right-sided colon, respectively. The mean procedure time was 16.6±4.8 minutes. The mean diameter of the resected specimen was 28.5±4.7mm, and the mean tumor size was 22.3±3.4mm. The histological assessment revealed low-grade dysplasia in 24 lesions, high-grade dysplasia in 20 patients and SM invasion in 2 lesions. En bloc resection was achieved in all the lesions and R0 resection was 89.1%(41/46). Delayed bleeding occurred in 1(2.2%) patient and Perforation occurred in 1(2.2%) patient. These complications were controlled by endoscopic treatment. No significant differences in the rates of R0 resection, curative resection, or adverse events were seen between ESD and Hybrid ESD. However, the hybrid ESD group had a significantly shorter procedure time than the conventional ESD group (16.6±4.8 minutes vs. 37.5±21.1 minutes, P>0.001).

**Conclusion:** Hybrid ESD using a multifunctional snare may enable easy and safe resection of relatively large colorectal tumors. In addition, a cutting device and additional snare are usually required for hybrid ESD. But we could perform all the hybrid ESD steps using the "SOUTEN" snare. Therefore, multifunctional snare also may provide cost benefit.

**Contact E-Mail Address:** ukino816@gmail.com

**Introduction:** Sessile serrated adenoma/polyp (SSA/P) is known as high risk lesion of incomplete resection. However, there have been very limited evidence about how to immediately detect of remnant lesion of SSA/P right after the endoscopic resection. We compared Narrow band imaging (NBI) and white light endoscopy (WLE) for detection of remnant lesion of SSA/P right after the endoscopic resection of SSA/P.

**Aims & Methods:** Prospective randomized multi-center study was done. All target lesions were suspicious SSA/P lesions which had 3 or more than 3 scores out of WLE criteria assigned 1 point on each criterion by observing WLE; non-protruding and non-excavated shape, larger than 1 cm in size, right colon location, being covered by mucus cap, and varicose vessels presence on the surface of the lesion after submucosal injection. After endoscopic resection, we performed NBI or WLE inspection by randomization for detection of remnant tissue, if detected, additional resection was performed. Four directional biopsies for checking the incomplete resection were performed on the resection margin after endoscopic resection including additional resection for remnant lesion. Primary aim was comparing the detection rate of remnant lesion, the diagnosis rate of SSA/P in the

remnant lesion after additional resection, and the incomplete resection rate between two groups. Secondary aim was finding accuracy of endoscopic WLE criteria for SSA/P diagnosis.

**Results:** Total 145 lesions (NBI inspection group, n=69, WLE inspection group, n=76) were removed. The diagnosis rate of SSA/P was 87.6% (127/145) by criteria. There were no significant differences of remnant tissue detection rate (14.5% vs. 13.2%,  $p>0.05$ ), proportion of SSA/P of remnant tissue after additional resection (10.1% vs. 10.5%,  $p>0.05$ ), and the incomplete resection rate (5.8% vs. 9.2%,  $p>0.05$ ) between NBI and WLE groups. The positive predictive value (PPV) of the individual criteria for diagnosis of SSA/P were 95.2% (mucus cap), 92.2% (ascending colon and cecum location), 92.1% (varicose vessel), and 86.6% (non-protruding and non-excavated morphology). In ROC curve analysis, the sensitivity of the endoscopic criteria by WLE was 93.7% at the cut-off of 2.5 with 0.741 (95% confidence interval 0.588–0.895) of the area under the ROC curve.

**Conclusion:** There was no significant difference for detecting remnant lesion and for checking incomplete resection between NBI and WLE after endoscopic resection of SSA/P. WLE criteria showed moderate performance in diagnosing SSA/P.

**Disclosure:** Nothing to disclose

## P1604 FEASIBILITY AND ACCEPTABILITY OF NOVEL COLONOSCOPY WITH COMPUTER AIDED EARLY DIAGNOSIS OF BOWEL CANCER

Dolwani S.<sup>1</sup>, Brain K.<sup>1</sup>, Ye X.<sup>2</sup>, Gubala V.<sup>3</sup>, Howe R.W.<sup>4</sup>, Davies G.-L.<sup>5</sup>, Smits S.<sup>1</sup>

<sup>1</sup>Cardiff University, Population Medicine, Cardiff, United Kingdom, <sup>2</sup>University of Lincoln, Computer Science, Lincoln, United Kingdom, <sup>3</sup>University of Kent, Medway School of Pharmacy, Kent, United Kingdom, <sup>4</sup>Lostwithiel Surgery, Primary Care, Exeter, United Kingdom, <sup>5</sup>University College London, Materials Chemistry, London, United Kingdom

**Contact E-Mail Address:** dolwanis@cardiff.ac.uk

**Introduction:** Patients with low risk bowel symptoms often triaged to a non-urgent pathway have longer diagnostic intervals and later detection of cancer. Resource and workforce constraints in delivery of secondary care colonoscopy contribute to these delays

**Aims & Methods:** This study presents preliminary data to investigate the acceptability and feasibility of a novel type of semi-automated robotic colonoscopy (portable with disposable probes not requiring reprocessing or decontamination) to potentially overcome delays between presentation, referral, diagnosis and treatment decision.

Participants referred by their GP for direct colonoscopy underwent the new procedure (semi-automated robotic colonoscopy) and a parallel (back to back design) standard colonoscopy and were later interviewed via telephone to explore their experience and comparison between the two procedures. Comfort scores and colonoscopy quality indicators and outcomes were compared. An online GP survey exploring feasibility of the new procedure in a primary care setting was also conducted. We also analysed the feasibility and accuracy of developing a machine learning tool to interpret findings at both novel and standard colonoscopy.

**Results:** Participants (6 M, 9 F) perceived the value, usefulness and purpose of the new procedure, with favourable comparisons made to standard colonoscopy, particularly previous experience of pain and recovery. Lack of requirement for sedation was a key benefit of the new procedure. Primary care was endorsed as a location, with proximity and familiarity viewed favourably, particularly in overcoming negative aspects of bowel preparation and recovery (e.g. not wanting to travel far). Those feeling they would not need sedation also viewed primary care positively. Others were indifferent, with feelings that it was such an undesirable procedure that location would not matter. Twenty-nine GPs completed the online survey. Barriers to the new procedure in GP practices included perceived lack of expertise to interpret findings (74% agreement) and not enough space for equipment (59% agreement). Nearly all participants felt the new procedure had the potential to impact quicker diagnosis (97% agreement), and all participants felt it had the potential to achieve early diagnosis in low risk bowel symptoms not meeting 2 week wait criteria (100% agreement).

**Conclusion:** Target users found the new procedure acceptable and viewed it favourably compared to standard colonoscopy. GPs perceived uses for the new procedure in primary care, particularly for low risk patients, however expertise and space were a concern. These findings are positive as the new procedure has the potential to improve issues with colonoscopy capacity and diagnostic workforce in the NHS, with a larger scale study now need-

ed. We have previously published on the training requirements and learning curve for the novel colonoscopy procedure and will also present data on computer aided analysis and interpretation of findings at colonoscopy.

## P1605 ENDOSCOPIC TREATMENT OF LARGE SYMPTOMATIC COLON LIPOMAS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Vandenbroucke A.-M.<sup>1</sup>, Bronswijk M.<sup>2</sup>

<sup>1</sup>University Hospitals Leuven, KU Leuven, General Internal Medicine, Leuven, Belgium, <sup>2</sup>University Hospitals Leuven, Gastroenterology and Hepatology, Heverlee, Belgium

**Contact E-Mail Address:** mjh.bronswijk@gmail.com

**Introduction:** Various techniques have been described for endoscopic resection of large symptomatic colon lipomas. Relying on spontaneous intraluminal expulsion following partial snare resection, lipoma unroofing might provide a safer, more cost effective and easier technique, compared to dissection-based techniques, endoscopic mucosal resection (EMR) or loop-assisted resection.

**Aims & Methods:** The aim of this systematic review was to compare efficacy and safety of these four endoscopic techniques. A systematic review was performed by AMVB and MB in March 2019, using PubMed, Embase, the Cochrane Library and Clinicaltrials.gov. As most outcomes were binary in nature and several outcomes did not occur in some studies, routine calculation of standard errors in outcome probability was not possible. Therefore, original patient data were extracted, after which complete resolution rate, recurrence rates and adverse events were compared.

**Results:** Twenty seven studies between 1979-2019 met selection criteria. In total, 119 lesions were identified (45.5% female, mean age 63 years, mean lesion size 47.9mm). In total, 5 retrospective analyses, 21 case reports and 1 prospective study were included. As no higher quality studies were found, possible publication bias should be taken into account. Heterogeneity was not assessed as most studies were not controlled. Ten patients underwent unroofing (8.4%), whereas 27 patients (22.7%), 33 patients (27.7%) and 48 patients (40.3%) underwent dissection-based technique, EMR or loop-assisted-snare resection respectively. Complete resolution rate was 80%, 100%, 100% and 95.8% respectively. A statistically significant increased rate of complete resolution was seen only amongst patients receiving EMR (OR 19.71 (0.86-450.00 95% CI),  $p=0.0498$ ), compared to unroofing. As expected, no recurrence was detected in all four groups. More importantly, no adverse events were identified in patients receiving endoscopic treatment by unroofing. Amongst patients who underwent dissection-based resection, EMR or loop-assisted techniques, adverse events were identified in 7.4%, 12.1% and 6.3% respectively.

**Conclusion:** Compared to unroofing, dissection-based techniques and loop-assisted resection did not provide an increased complete resolution rate which was statistically significant. Owing to the superior safety profile, our data suggest that unroofing should be considered as the primary endoscopic technique for resection of giant colonic lipomas, before resorting to EMR, dissection-based or loop-assisted techniques. However, due to the nature of the studies included, possible publication bias should be taken into account

**Disclosure:** Nothing to disclose

**Introduction:** Chromoendoscopy, CE, is the optimal choice of surveillance for dysplasia in the inflammatory bowel, IBD, disease cohort, particularly for primary sclerosing cholangitis, PSC. However, with the pressure of waiting list and busy endoscopy list, CE can be perceived as a cumbersome task.

**Aims & Methods:** To review the IBD colonoscopy surveillance practice in a tertiary centre of IBD and PSC patients with regard to CE, highlighting obstacles and perceived barriers. We performed a retrospective review of 121 surveillance colonoscopies for inflammatory bowel disease in a teaching tertiary hospital over a 12month period. Patient demographics including age, IBD phenotype and medication were recorded. Endoscopy settings such as bowel preparation, withdrawal time and endoscopist expertise were recorded along with pre-endoscopy faecal calprotectin. Mode of examination by CE, targeted biopsies or quadrantic biopsies every 10cm were noted.

**Results:** 121 surveillance colonoscopies were performed over 12months. Median cohort age: 48years. Male:71(58.6%). 58, 25, 2 and 36 patients had Crohn's Disease, Ulcerative colitis, IBD undetermined and PSC-IBD respectively. CE, white band light, WBL, targeted biopsies and quadrantic biopsies at 10cm intervals were performed in 30, 74, and 12 patients respectively. 5 patients had no biopsies taken due to failed procedures/poor preparation. 49/121(40.5%) had active disease at time of assessment, 9/121(7%) having moderate to severe disease. 41 patients had a faecal calprotectin, FCP, within the 12 months prior to endoscopy, 11/41(27%) of which were >200. 69/121(57%) patients had excellent bowel preparation. However, 52/121(42.9%) had reported adequate or poor preparation, not compatible with EC.

Amongst the CE cohort, there was no significant predominance in expertise of endoscopist, fellow 17/30, consultant 13/30. Average withdrawal time for consultants for non-chromo v CE was insignificant; 15.4 v 21 minutes (p value= 0.0571). Average withdrawal time for fellows for non-chromo v CE was significant; 19 v 30 minutes (p value 0.0020). 25/30 patient were reported to have excellent bowel preparation. There was a significant difference between the incidence of CE amongst hepatologist and gastroenterologist endoscopists; 1/17 v 29/91 (p value 0.0020).

Amongst the PSC-IBD cohort, 8/36 patients received chromoendoscopy in equal measuring from fellow and consultant endoscopists. 11/36(30%) patients were reported to have poor bowel preparation not compatible with CE. 6/36(17%) patients had active disease not compatible to EC.

**Conclusion:** The quality of surveillance endoscopy is influenced by the degree of bowel preparation, remission of disease and mode of inspection. Poor bowel preparation was found to be a significant obstacle to CE, particularly in the PSC-IBD cohort. Few patients had a recent FCP to ensure remission prior to colonoscopy. Both these factors can be optimised pre-endoscopy to facilitate EC performance. While it may be perceived to be a longer procedure, no significance in withdrawal time was seen amongst consultant endoscopy performing EC and standard white light colonoscopy suggesting initial delays seen amongst fellow endoscopist reflects a learning curve.

**Disclosure:** Nothing to disclose

## P1607 CORRELATION BETWEEN SURROGATE QUALITY INDICATORS FOR ADENOMA DETECTION RATE (ADR) AND ADENOMA MISS RATE (AMR) IN QUALIFIED COLONOSCOPY, CORE STUDY; KASID MULTI-CENTER STUDY

Moon J.R.<sup>1</sup>, Kim H.G.<sup>1</sup>, Jeon S.R.<sup>1</sup>, Cha J.-M.<sup>2</sup>, Kwak M.S.<sup>3</sup>, Jung Y.<sup>1</sup>, Shin J.E.<sup>4</sup>, Cho Y.S.<sup>5</sup>

**Contact E-Mail Address:** ukino816@gmail.com

**Introduction:** Adenoma detection rate (ADR) has been known as a key quality indicator of colonoscopy. However, ADR cannot reflect every adenoma detection during colonoscopy and still it is unclear that ADR can properly reflect adenoma missing rate (AMR). We evaluated the correlation between AMR and ADR, and other surrogate quality indicators.

**Aims & Methods:** We performed a cross-sectional study of asymptomatic examinees aged 50~75 years who underwent back-to-back screening colonoscopies by 8 endoscopists. The polyp detection rate including adenoma (PDR), the total number of adenomas per colonoscopy (APC), the additional adenomas found after the first adenoma per colonoscopy (ADR-Plus), the total number of adenomas per positive participant (APP), and ADR were calculated for prediction of AMR.

**Results:** Total 371 back-to-back colonoscopies were performed. ADRs were 64.6% in male, and 51.1% in female examinees (p=0.009). Because there was a significant difference in the gender of the examinees by each endoscopist (p< 0.001), and also was a significant difference of ADRs (65.6, 44, 64.3, 75.4, 54, 48, 52, and 60%, p=0.024), ADRs were separately obtained by gender. There were no significant differences of ADRs of each endoscopist obtained separately for male (p=0.335) and female (p=0.218) examinees. AMRs not differed between endoscopists (31.3, 9.1, 21.9, 22.1, 10.9, 12.5, 19.2, 22.9%, p=0.462) for male examinees and for female examinees (27.8, 8.7, 0, 18.2, 46.4, 0, 31.8 and 23%, p=0.052). There was no related quality indicators with AMR in both male and female examinees. Overall, PDR was significantly correlated with ADR (rho 0.826, p=0.011). In female participants, PDR (rho 0.904, p=0.002) and APC (rho=0.838, p=0.009) were significantly correlated with ADR.

**Conclusion:** High ADRs endoscopists showed varied AMRs. PDR and APC may be surrogate quality indicators for ADR. However, further studies for surrogate quality indicators to discriminate meticulous endoscopists should be performed.

**Disclosure:** Nothing to disclose

**Introduction:** Bowel preparation is one of the important factors to ensure a high quality colonoscopy. Efforts to improve bowel preparation level through traditional communication routines have proven to be useful. However, the impact of WhatsApp reminder on the bowel preparation level of screening colonoscopy is still unknown.

**Aims & Methods:** We aimed to investigate the effectiveness of WhatsApp reminder in bowel preparation level of screening colonoscopy. Subjects recruited and randomized from a population based CRC screening program. All subjects would receive both verbal and written instructions of bowel preparation by a healthcare professional on the day of appointment making. For subjects randomized to the WhatsApp reminder group, they will receive a WhatsApp reminder with same content of the written instruction and a video of detailed bowel preparation instruction 4 days prior colonoscopy. For subjects randomized to usual care group, they will not receive any reminder.

	WhatsApp reminder	Usual Care	p-value
	N = 333	N = 333	
Male Gender (%)	197 (59.2)	195 (58.6)	0.875

Chronic obstructive pulmonary disease (%)	4 (1.2)	3 (0.9)	1
Cirrhosis (%)	2 (0.6)	1 (0.3)	1
Renal impairment (%)	2 (0.6)	5 (1.5)	0.451
Fatty liver (%)	8 (2.4)	5 (1.5)	0.401
Caecal intubation (%)	328 (98.5)	327 (98.2)	0.761
	N = 328	N = 327	
Median withdrawal time in minutes (IQR)	11 (7-17)	10 (7-16)	0.399
Median intubation time in minutes (IQR)	6 (4-9)	6 (4-9)	0.579
Satisfactory bowel preparation level (%)	283 (86.3)	257 (78.6)	0.01
Adenoma detection (%)	240 (72.9)	227 (69.4)	0.318

[Demographics and colonoscopy findings between WhatsApp reminder and usual care groups]

**Results:** From June 2017 to April 2019, 667 subjects scheduled for screening colonoscopy because of positive fecal immunochemical test were recruited. They were randomized to WhatsApp reminder and usual care groups in 1:1 ratio. Demographics between two group was similar. 12 subjects with incomplete colonoscopy were excluded. No difference can be observed in median intubation and withdrawal time between two groups. When compared to usual care group, more subjects significantly achieved satisfactory (excellent or good) bowel preparation level (86.3% vs 78.6%,  $p=0.01$ ) during screening colonoscopy. However, adenoma detection rate was similar between two groups (72.9% vs 69.4,  $p=0.318$ ).

**Conclusion:** WhatsApp reminder shows significant improvement in the bowel preparation level of screening colonoscopy.

**Disclosure:** Nothing to disclose

## P1609 TIME'S UP: FATIGUE NEGATIVELY IMPACTS COLONOSCOPY ADENOMA DETECTION RATE

Wu T.<sup>1,2</sup>, Vandeleur A.<sup>3</sup>, Rahman T.<sup>2,3</sup>

<sup>1</sup>The Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia, Department of Gastroenterology, Newstead, Australia, <sup>2</sup>University of Queensland, Medicine, Brisbane, Australia, <sup>3</sup>The Prince Charles Hospital, Gastroenterology & Hepatology, Brisbane, Australia

**Contact E-Mail Address:** t.hong.wu@gmail.com

**Introduction:** The quality of colonoscopy is influenced by patient and operator factors. Various studies on timing of colonoscopy and effect of operator fatigue on adenoma detection (ADR) have yielded conflicting results (1-3). This study aims to compare adenoma detection and complication rates between elective colonoscopies performed first and last in the list, across multiple operators (n=12) in a tertiary public hospital.

**Aims & Methods:** We conducted a case-control study on patients who underwent elective colonoscopies from 2012 to 2017 at the Prince Charles Hospital. Time of endoscopy was used as a surrogate marker for operator fatigue, whereby colonoscopies performed after 11am on the morning list and after 4pm on the afternoon list were identified as cases, and matched with those performed before 9am and at or before 1pm as controls. Clinical, endoscopic and histological databases were analysed for baseline patient characteristics, colonoscopy quality markers, and adverse events from a 30-day follow up survey.

**Results:** We report on preliminary analysis of 1216 patients who underwent colonoscopies between April and June 2017. The patients were booked in no particular sequence and have similar baseline characteristics. Colonoscopies done later in the list had lower adenoma detection rates (39.7% vs 55.7%, OR 0.5,  $p=0.007$ ) and lower mean adenoma count (1.2 vs 1.9,  $p=0.04$ ). No statistically significant difference was found in SSA detection rates, quality of bowel preparation, and complication rates.

**Conclusion:** Preliminary data suggests a significant deterioration in colonoscopy quality associated with operator fatigue. Further analysis with stratified data for individual operators, and on extended dataset between 2012-2017 will be carried out to confirm these findings.

**Contact E-Mail Address:** philippoppong@doctors.org.uk

**Introduction:** Endoscopic tattooing is a safe technique useful for localisation of small colorectal lesions, especially in the laparoscopic setting. However, many studies have reported variation in tattooing practice, resulting in inaccuracies in diagnosis and management. The aim of this study was to review tattooing practice in all patients with colorectal cancer and high grade dysplastic polyps who were discussed at the colorectal multidisciplinary team meeting (MDT) at Nottingham University Hospitals (NUH) in 2016.

**Aims & Methods:** Minutes and colonoscopy reports for all new cases discussed at the colorectal MDT in 2016 were analysed. Cases discussed at the MDT were those with colorectal cancer, polyps with cancer, high grade dysplasia, or suspicious for malignancy. Tattooing practice was evaluated against the local NUH colon tattoo protocol. This states that all suspected cancers identified, excluding those located at the caecum and rectum, should be tattooed at 3 radial sites, 3 cm anal to the lesion. Colonic polyps >2 cm (excluding caecum and rectum) and/or suspicious for malignancy, should be tattooed at least 1 site 3 cm anal to the lesion. Tattoos and their relationship to the lesion should be photo-documented. Cases discussed at the colorectal MDT were excluded if they had been previously discussed, the endoscopy report was unavailable, the cancer was identified at emergency surgery or on CT only or there was no cancer/polyp at colonoscopy.

**Results:** The results are shown in table 1.

	n	Tattooed (%; 95% CI)	Tattooed as per protocol (%; 95% CI)
Colonic cancer	133	96 (72.2, 63.7-79.1)	49 (51.0, 40.6-61.4)
Malignant polyp	14	10 (71.4, 41.9-91.6)	23 (52.3, 36.7-67.5) [all polyps]
HGD polyp	55	24 (43.6, 30.3-57.7)	
LGD or other polyp	21	10 (47.6, 25.7-70.2)	
Suspected rectal cancer	116	17 (14.7, 8.8-22.4)	
Suspected caecal cancer	24	7 (29.2, 12.6-51.1)	

[Table 1: Results]

Rates of tattooing were similar across males and females. There was some variation by patient age, location of the cancer and who did the index colonoscopy. For example, only 59.1% of patients had a tattoo if the index colonoscopy was performed by consultant surgeon compared to over 70% by other professionals ( $p>0.05$ ). With regards to tattooing as per local protocol, the lowest rate (33%) was seen with independent trainee colonoscopists ( $p>0.05$ ). No variables however were identified to have statistically significant associations with increased rate of tattooing polyps.

**Conclusion:** How and when to tattoo colonic lesions is becoming increasingly pertinent in the age of minimally invasive surgery. This audit highlights the need for improvement in this area and serves as a reminder for us to align routine clinical practice with local guidelines. Given these findings, we believe there is a role for regular standardised teaching on endoscopic tattooing for endoscopists.

We acknowledge the limitations inherent in our study, including the small sample size of the study. However, we are undergoing a re-audit for year 2019 of similar qualitative study to ascertain improvements. As conclusion, we consider our findings an important first step towards effective clinical management, and prevention of colorectal cancers.

**Contact E-Mail Address:** anna.hinterberger@meduniwien.ac.at

**Introduction:** Colorectal cancer can arise from nonadvanced adenomas or advanced adenomas. Patients with advanced adenomas have higher risk to develop CRC (Brenner et al., Gut. 2007).

Aim of this study was to see if patients redevelop advanced- or nonadvanced lesions by comparing diagnosis of baseline colonoscopy with diagnosis of surveillance colonoscopy.

**Aims & Methods:** In this retrospective study 5175 patients underwent two colonoscopies within 1-10 years. Data stem from the Austrian certificate of screening colonoscopy. Diagnosis of patients in first screening colonoscopy got compared with diagnosis of surveillance colonoscopy with a Chi-square-test.

**Results:** Mean surveillance interval was 4 years. 372 patients (7,19%) got diagnosed with advanced adenomas, 1384 (26,74%) had nonadvanced adenomas and 3419 (66,07%) had no pathological findings in first screening colonoscopy. Diagnosis of surveillance colonoscopy per baseline colonoscopy are shown in table 1. (p=0,0001). Most patients who got diagnosed with advanced adenomas in screening colonoscopy had no pathological findings or nonadvanced adenomas in surveillance colonoscopy. Patients who got diagnosed with nonadvanced adenomas in screening colonoscopy had mostly no pathological findings or got diagnosed with nonadvanced adenomas again.

	Advanced adenomas in surveillance colonoscopy	Nonadvanced adenomas in surveillance colonoscopy	No pathological findings in surveillance colonoscopy
Advanced adenomas in screening colonoscopy	77 (20,70%)	135 (36,29%)	160 (43,01%)
Nonadvanced adenomas in screening colonoscopy	93 (6,72%)	580 (41,91%)	711 (51,36%)
No pathological findings in screening colonoscopy	208 (6,08%)	680 (19,89%)	2531 (74,03%)

[Table 1]

**Conclusion:** Most of the patients who had advanced- or nonadvanced lesions in screening colonoscopy had no pathological diagnosis in surveillance colonoscopy. Nevertheless, results demonstrate that patients, who got diagnosed with advanced- or nonadvanced adenomas, redeveloped adenomas, which shows the importance of accurate surveillance colonoscopy. Chi-square test was significant (p=0,0001).

**Introduction:** Moon phases, in particular full moon, are often discussed to have an impact on sleep and activity behavior as well as various other functions of the human body.

**Aims & Methods:** The aim of the present study was to investigate the impact of moon phases on bowel preparation quality. Therefore, we analyzed bowel preparation quality according to a modified Aronchick Score in screening colonoscopies performed between 08/2008 and 12/2018 within a national quality assurance program in Austria. Preparation quality rated as excellent, good or fair were considered sufficient.

**Results:** 207,593 screening colonoscopies were included in the study. 50,74% of screenees were woman, mean age was 60.9 years (SD 9.1). Bowel preparation quality was sufficient in 95.94% of examinations. Overall bowel preparation quality differed significantly between moon phases (new/waning/waxing/full moon, p=0.014). 3.12% (n=6,480) of colonoscopies were performed the day after a full-moon night. Those patients had a significantly higher rate of inadequate bowel preparation as compared to other moon phases (relative risk 1.18 [95% CI 1.06-1.32], p=0.004). Notably, this effect was only significant in men (5.32% vs. 4.22% insufficient preparation; p=0.003%, women p=0.26%).

**Conclusion:** If screening colonoscopy is scheduled on a day after a full moon night, patients, particularly male patients, should be intensely instructed to follow bowel preparation guidelines.

**Disclosure:** Nothing to disclose

## P1613 PREVALENCE OF ADENOMAS AMONG DIMINUTIVE UNRESECTED POLYPS IN LEFT COLON

**Contact E-Mail Address:** daniela.penz@meduniwien.ac.at

**Introduction:** The American Society for Gastrointestinal Endoscopy (ASGE) recommends that diminutive polyps located in the distal colon can be left in place without any resection if they are predicted to be nonadenomatous with a negative predicting value of >90%. However, we know that approximately 30% of adenomas are located in the left colon. Therefore, aim of our study was to assess the prevalence of adenomas among unresected diminutive polyps in the distal colon.

**Aims & Methods:** 315,822 screening colonoscopies between 2007 and March 2019 performed by 355 endoscopists were analyzed within the Austrian quality assurance program. Histopathologic diagnosis of polyps under 5mm located in the left colon that were not resected but where endoscopists took biopsies to ensure were assessed. Further the negative predictive value for adenomatous lesions among those polyps was analyzed.

**Results:** Overall In 39,24 % (n= 123,942) polyps were detected. 14,18% (n=17581) were diminutive and located in the left colon. 3,22% (n=566) of those lesions remained unresected but a biopsy was taken. Among those 566 unresected diminutive polyps 2,83% (n=16) were advanced and 21,91% (n=124) nonadvanced adenomas. In 0,35% (n=2) those lesions were characterized as SSA and in 0,53% (n=3) as TSA. 421 (74,38%) of all unresected left sided diminutive lesions were classified as hyperplastic polyps.

**Conclusion:** In our study cohort there was a high prevalence of adenomas (24,74%) among unresected diminutive polyps in the left colon were a biopsy was performed. The negative predictive value for adenomas, SSAs, as well as TSAs was 74,38% which is lower than recommended. Therefore left-sided diminutive lesions that macroscopically appear to be hyperplastic but were the endoscopist decided to take a biopsy should be resected. Only in case the endoscopists can characterize the adenomatous lesions with high confidence, predict and leave behind strategy may be used.

**Introduction:** Therapeutic endoscopic retrograde cholangiopancreatography (ERCP) is the first approach in the management of bile duct stones. It is estimated that bile ducts can be cleared in 90% of the cases with conventional endoscopic methods. Large stones, however, can be sometimes challenging to remove.

**Aims & Methods:** The aim of our study was to investigate the management and the complications associated with large common bile duct stones. We realized a retrospective study including all patients that underwent an ERCP between 2013 and January 2018. The patients who had common bile duct stones were divided into two groups:

- First group: those who had large common bile duct stones ( $\geq 10$ mm).
- Second group: patients with smaller common bile duct stones.

**Results:** During the study period, 424 ERCPs were performed to remove common bile duct stones. The mean age of the patients was 61,3 years old (13-98) with a sex ratio (F/M) of 2. Large stones have been found in 22,16% of the procedures (n=94). In both groups of patients, an acute biliary pancreatitis or cholangitis was associated in 5,3% of the cases. Bile duct clearance was obtained respectively in 95,74% and 90,6% within the first and second group. Nine patients from the first group needed more than one ERCP. When it came to large stones, lithotripsy was performed in 5 patients, we placed a nasobiliary catheter once and a biliary endoprosthesis in 12 patients. Among the second group, a biliary endoprosthesis was needed 5 times and one patient had a nasobiliary catheter placed. No difference was found in terms of short term ERCP complications between the two groups (p=0,349).

**Conclusion:** Large common bile duct stones may require additional techniques while ERCP to be removed but do not cause more short term complications than smaller bile duct stones.

**Disclosure:** Nothing to disclose

## P1615 EFFICACY OF INTRAMUSCULAR DICLOFENAC IN THE PREVENTION OF POST-ERCP PANCREATITIS: A PROSPECTIVE, RANDOMIZED, PLACEBO-CONTROLLED STUDY

**Introduction:** Rectal nonsteroidal anti-inflammatory drugs (NSAIDs) reduce the risk and the severity of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP). However, rectal NSAIDs are not available in some countries including Korea. Recently, two contrary studies about the effect of intramuscular NSAIDs to PEP had been reported. The aim of this study was to evaluate the efficacy of intramuscular NSAIDs in prevention of PEP.

**Aims & Methods:** This is prospective, randomized, placebo-controlled clinical trial. Patients who underwent ERCP with naïve papilla received single dose of intramuscular diclofenac (75mg) or placebo immediately before

ERCP. The primary outcome was PEP, which was defined as followings; newly developed abdominal pain, elevation of serum amylase or lipase at least three times the upper normal limits 24 hours after ERCP, and prolongation of hospitalization at least 2 days.

**Results:** Total 171 patients were randomized, and 168 patients were finally enrolled in study. Demographic and clinical factors, comorbidities, ERCP findings, and types of treatment were similar between two groups. The PEP developed in 6 of 73 patients (8.2%) in the diclofenac group and in 5 of 95 patients (5.3%) in placebo group (p=0.443). While most of PEP had mild severity (90.9%), moderate case was only 1 patient of PEP in diclofenac group (p=0.338). There was no case of severe PEP in both groups. In multivariate logistic regression analysis, factor associated with prevention of PEP was endoscopic retrograde pancreatic drainage (odds ratio 0.012; 95% confidence interval 0.001-0.184; p-value=0.002) and not intramuscular diclofenac (odds ratio 0.565; 95% confidence interval 0.114-2.798; p-value=0.565).

**Conclusion:** Intramuscular diclofenac does not seem to be effective in prevention of PEP.

**Disclosure:** Nothing to disclose

## P1616 WEIGHT-BASED DOSING STRATEGY IN RECTAL DICLOFENAC USE IS FEASIBLE FOR PREVENTION OF POST-ERCP PANCREATITIS IN A REAL-WORLD JAPANESE POPULATION

**Contact E-Mail Address:** track800ryo@icloud.com

**Introduction:** Acute pancreatitis is a common complication after endoscopic retrograde cholangiopancreatography (ERCP) and called post-ERCP pancreatitis (PEP). It is, however, difficult to completely prevent it. ESGE guideline 2014 says that nonsteroidal anti-inflammatory drugs (NSAIDs) routine rectal administration of 100mg of diclofenac or indomethacin immediately before or after ERCP in all patients without contraindication. 100 mg of diclofenac is higher than the normal single dose used for the Japanese population. However, there are still few evidence of the efficacy of a low dosage of rectal diclofenac in a real-world Japanese population. The aim of this study was to evaluate the efficacy of low-dose diclofenac use based on weight for prevention of PEP.

**Aims & Methods:** This study was a retrospective single-center cohort study of consecutive patients underwent ERCP or ERCP-related procedures from January 2016 to March 2019. During the study period, procedures were conducted to prevent PEP using either 50mg or 25mg of rectal diclofenac in patients weighing  $\geq 50$ kg or  $< 50$ kg and intensive intravenous fluid administration when post ERCP 2-hour serum amylase level was more than 2 times of upper limit of normal. Before the study period, we conducted the PEP prevention strategy using prophylactic antibiotics and protease inhibitor for 3 days without the use of NSAIDs. The PEP rate was 3.9% (95% CI: 3.02-5.07) in 1403 patients as historical control (World J Gastrointest Endosc. 2016). In the present study, we evaluated the PEP rate of weight-based dosing strategy in rectal diclofenac use. The following conditions were excluded: 1) gallstone pancreatitis, 2) unreachable to papilla, 3) no use of diclofenac.

**Results:** A total of 1241 patients (median age 76, female 43%) were enrolled. Of them, 181 cases were excluded. Finally, 1060 cases were analyzed (native papilla: 514, 48%, diclofenac 25mg: N=561, 53%, 50mg: N=499, 47%). The median cannulation time was 1 min (range 1-82), and the median procedure time was 30 min (range 3-120min). PEP developed in 26 patients (2.4%, 95%CI: 1.7-3.6) including 4 severe acute pancreatitis, and perforation and bleeding occurred 0 and 2 patients, respectively. PEP rates were similar in both diclofenac 25 mg and 50 mg (2.7% and 2.2%, respectively).

**Conclusion:** Low dose rectal diclofenac use and intensive intravenous fluid administration strategy is relatively lower PEP rate than our historical control. It seems to be better compared with the strategy using protease inhibitor without the use of NSAIDs.

**Disclosure:** Nothing to disclose

## P1617 MANAGEMENT OF PANCREATICOJEJUNAL ANASTOMOTIC STENOSIS FOLLOWING PANCREATODUODENECTOMY WITH SINGLE-BALLOON ENTEROSCOPY ASSISTED ENDOSCOPIC RETROGRADE PANCREATOGRAPHY (SBE-ERP)

Shimizu S., Takaki R., Kobashikawa K.

Urasoe General Hospital, Department of Gastroenterology, Okinawa, Japan

**Contact E-Mail Address:** murasachi1004@hotmail.com

**Introduction:** Pancreaticojejunal anastomotic stenosis (PAS) is recognised as one of the long-term complications post pancreatoduodenectomy (PD). PAS can cause acute pancreatitis and associated complications such as stone formation. Balloon-assisted enteroscopy (BAE) has been available since 2003. Its primary use has been for therapy post hepato-biliary surgery. However, data pertaining to efficacy, safety, and long-term outcomes of the optimal enteroscopic approach for PAS is lacking.

**Aims & Methods:** Our aim is to assess the efficacy, safety, and long-term outcomes of single-balloon enteroscopy for PAS related acute pancreatitis post PD. 8 patients between November 2013 and March 2017 were enrolled from our center. The pancreaticojejunal anastomosis was assessed with a single balloon enteroscope, using a 3/0 prolene suture for identifying the site. We then proceeded to followed by replacing the plastic stent. Follow up stent removal were performed at 3 months. We recorded;

- 1) the duration of the onset of acute pancreatitis after operation,
- 2) success rate of endoscopic treatment,
- 3) procedure time,
- 4) complication rate, and
- 5) recurrence rate of pancreatitis.

**Results:** The median age in these 8 patients are 66 years old, and male/female are 4/4. All 8 patients underwent pylorus-preserving pancreaticoduodenectomy (PPPD) for malignancy. The average total observation period since PD was 94 (41-151) months, while the period since first treatment was 41 (14-61) months.

- 1) The mean to time of onset of acute pancreatitis after PD was 45 months (8-129) months.
- 2) 7 out of 8 patients had a successful endoscopic result (88%).
- 3) The average procedure time was 86 (56-124) minutes.
- 4) Two patients (25%) who had hyper amylasemia and one patient (13%) experienced the recurrence of acute pancreatitis due to stent migration. However, there were no serious complications in these 8 patients.
- 5) 3/7 (42%) cases had recurrence of pancreatitis after recurrent PAS.

For these 3 recurrent cases, the average duration of recurrent pancreatitis was 19 (11-35) months. Despite repeated endoscopic treatment, all three patients experienced multiple episodes of acute pancreatitis.

**Conclusion:** The previous reports have mentioned that the rate of pancreatitis was 3% after PPPD, with surgical management considered as first line therapy. Evidence for BAE-ERP treatments for PAS have been limited to case reports. However, reported issues include difficulty in identification of the pancreaticojejunal anastomosis and thus success rate varies. In our study, the success rate was as high as 88% due to using 3/0 prolene sutures as an indicator for locating pancreaticojejunal anastomosis. We had shorter procedure times without significant adverse events. Therefore, endoscopic treatment is safe, and less invasive technique in this small case series. Further prospective, multi-centre studies are required to validate our findings.

**Disclosure:** Nothing to disclose

## P1618 ENDOSCOPIC MANAGEMENT OF MINOR AMPULLARY TUMORS: A MULTICENTER CASE SERIES

Aslam R.<sup>1</sup>, Ahsan N.<sup>2</sup>, Inamullah M.<sup>2</sup>, Ayub K.<sup>3</sup>

<sup>1</sup>Silver Cross Hospital, Gastroenterology, New Lenox, United States,

<sup>2</sup>Southwest Gastroenterology, Oak Lawn, United States, <sup>3</sup>Silver Cross Hospital, Medicine, Oak Brook, United States

**Contact E-Mail Address:** raslam01@nyit.edu

**Introduction:** Ampullary and duodenal carcinoma are aggressive cancers with poor 5 year survival rates. Like colorectal cancer, ampullary and duodenal carcinomas are also thought to follow the adenoma-carcinoma sequence. Ampullectomy is a well-established treatment for adenoma and early stage carcinoma of major ampulla. Several studies have established its safety and efficacy in the management of major ampullary adenomas. However, adenomas arising in the minor ampulla are relatively rare and

there are no good case series on endoscopic management of these tumors. We report a multicenter case series of endoscopic ampullectomy in the management of minor ampullary tumors.

**Aims & Methods:** To establish the safety and efficacy of endoscopic ampullectomy in the management of minor ampullary adenomas. Consecutive patients undergoing ampullectomy for minor ampullary tumor at four hospitals were included in this study over a period of 5 years. A total of 6 patients were included in the study and all six patients underwent ERCP for purpose of minor ampullectomy. MRCP and EUS was performed on all patients prior to ERCP to rule out invasion. Pancreatic stents were placed after ampullectomy in 5 patients, 3 F x 8 cm single pigtail stents in 4 patients, and 5 F x 5 cm straight stent in one patient. All stents were removed in approximately 2 weeks.

**Results:** Ampullectomy was technically successful in all 6 patients. One patient required two ERCPs for complete ampullectomy. The adenomas varied in size from 1 cm to 3 cm. Pathology revealed adenoma in three patients, adenoma with high grade dysplasia in one patient, carcinoma in one patient, and carcinoid tumor in one patient. One patient (16%) developed post ERCP pancreatitis; this patient was kept in the hospital for 2 days. No other major complications were noted. Two patients had abdominal pain for one day post ERCP; this was considered a minor complication. Follow-up for these patients ranged from 2 to 5 years with EGD using duodenoscope at 3 months, one year and yearly thereafter. One patient had recurrence at 2 years which was thought to be recurrent adenoma (4 mm). This patient was treated with repeat ampullectomy. The patient with carcinoma had endoscopies every 3 months for a year followed by yearly endoscopy; no recurrence was noted during the 3 years of follow-up. An EUS, MRI and PET scans were also performed at 1 year per oncology advice; all tests were negative. Two out of six patients (33%) had Familial Adenomatous Polyposis (FAP). Two patients had Pancreas Divisum, one with Type 1, and other with type 3 Divisum.

**Conclusion:** In our pilot study, endoscopic ampullectomy appears safe and effective in the management of minor ampullary adenomas.

**Contact E-Mail Address:** ali494@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) carries potential for procedure-related adverse events. Several clinical variables have been identified in prior studies that increase risk for such events. We are reporting data from our ERCP experience to compare adverse events post-ERCP between post-orthotopic liver transplant (pOLT) patients and patients with native anatomy (nOLT).

**Aims & Methods:** A retrospective review was conducted with prospectively maintained patient data at a single, high-capacity ERCP center. ERCP encounters between Dec 2017 and Oct 2018 were identified from endoscopy software. During this time outpatients were contacted within 72 hours of ERCP to assess for adverse events. Individual patient demographics, clinical

cal and endoscopy data, and reported outpatient and inpatient adverse events were recorded from the electronic medical record. Fisher's exact test was utilized to determine significance between rates of adverse events between pOLT patients and nOLT patients.

**Results:** 312 nOLT patients underwent 415 ERCPs and 43 pOLT patients underwent 66 ERCPs. 75.6% and 62.8% of nOLT and pOLT patients, respectively, underwent only one ERCP during the study time period; 17.6% and 20.9% had two ERCP encounters and 6.7% and 16.3% had three or more ERCP encounters. The average age of nOLT and pOLT patients was 60 and 55 with both groups being mostly male (71.4% and 54%, respectively). 12.1% of nOLT had cirrhosis prior to ERCP. Leading etiologies of liver disease in the transplant group included non-alcoholic steatohepatitis (28.6%), hepatitis C (21.4%), and alcohol-related (19%). Chronic kidney disease  $\geq$  stage III was found in 4.5% (nOLT) and 11.9% (pOLT) of patients. 13.4% nOLT and no pOLT patients had comorbid pancreaticobiliary malignancy. 19.5% and 4.8% of nOLT and pOLT patients reported a history of acute pancreatitis prior to ERCP. The pOLT group had a greater rate of bile duct strictures than the nOLT group (54.5% vs. 28.4%,  $p = 0.0001$ ) while the rate of choledocholithiasis was similar (30.3% vs 34.4%,  $p = 0.58$ ). Stent manipulation was performed in a majority of cases (nOLT 69.6% and pOLT 90.9%,  $p = 0.0002$ ). Rectal indomethacin was used more often in native anatomy (14.7% vs 1.5%,  $p = 0.0012$ ). Total adverse event rates were similar in both groups (10.1% nOLT and 10.6% pOLT,  $p = 0.83$ ) and rates of post-ERCP pancreatitis in nOLT was 1.9% and in pOLT was 6.1%,  $p = 0.068$ . Additional ERCP data is described in Table 1.

**Conclusion:** While pOLT status does not appear to independently predict overall increased rate of adverse events after ERCP, we observed in our cohort that pancreatitis occurs nearly three times more frequently. The transplant group also received indomethacin much less often. A larger prospective study with to further analyze these differences is recommended.

<sup>2</sup>University of Helsinki, Helsinki, Finland

**Contact E-Mail Address:** vilja.koskensalo@helsinki.fi

**Introduction:** Transpancreatic biliary sphincterotomy (TPBS) is an advanced cannulation method for access to common bile duct (CBD) in endoscopic retrograde cholangiopancreatography (ERCP). If CBD cannulation is difficult, endoscopist can open the septum between the pancreatic and the biliary duct with a sphincterotome to gain the access. Long-term results of this procedure are not well-known. We wanted to evaluate the short- and the long-term complications of TPBS on patients with native papilla.

**Aims & Methods:** ERCPs performed during years 2007 to 2013 in Helsinki University Hospital Endoscopy unit were reviewed. After exclusion of primary sclerosing cholangitis, chronic pancreatitis (CP), biliary or pancreatic malignancies and deceased patients, there were 170 consecutive TPBS patients with native papilla and a benign indication for ERCP. For these TPBS patients we searched 170 consecutive age- and sex matched controls with same inclusion criteria, but with successful biliary access by primary wire-guided cannulation. Of these groups, 143 (84.1%) patients and 140 (82.6%) controls participated the phone survey  $\geq 4$  years after first ERCP. Data of patient demographics, acute post-ERCP pancreatitis (PEP), recurrent pancreatitis, CP or symptoms related to CP, upper abdominal pain, new ERCP procedures and surgical treatments was collected from patient records.

**Results:** PEP developed to seven patients (4.9%) in TPBS and one patient (0.7%) in control group ( $p=0.067$ ). Other acute complications (cholangitis, perforation, bleeding) were not significantly different between the groups (Table 1). ERCP ended with no access to biliary tract in four cases (2.8%)  $p=0.122$  in TPBS group and all ERCPs in control group were successful. Three patients (2.1%) in TPBS and six patients (4.3%) in control group ( $p=0.238$ ) suffered from acute recurrent non-ERCP related pancreatitis during the follow-up period. Only one (0.7%) patient in control group developed CP and there were no patients with CP in TPBS group. Upper abdominal pain was as common in both groups: 10 patients (6.9%) in TPBS group and 12 patients (8.6%) in control group suffered from abdominal pain daily and six patients (4.2%) in TPBS group and 12 patients (8.6%) in control group weekly.

	TPBS group (n=143)	Control group (n=140)	p-value
Age* at ERCP	59 (18-93)	62 (21-89)	0.418
Female	106 (74.1)	99 (70.7)	0.595
BMI* (kg/m <sup>2</sup> )	26.0 (16.9-70.3)	27.9 (16.0-74.0)	0.222
Indication for ERCP			
Biliary stones	112 (78.3)	104 (74.3)	0.485
Biliary pancreatitis	18 (12.6)	24 (17.1)	0.318
Bile duct injury after cholecystectomy	15 (10.5)	16 (11.4)	0.851
Biliary stricture (non-malignant)	15 (10.5)	11 (7.9)	0.485
Post-ERCP pancreatitis	7 (4.9)	1 (0.7)	0.067
Cholangitis	1 (0.7)	1 (0.7)	1.000
Perforation	3 (2.1)	1 (0.7)	0.622
Bleeding	2 (1.4)	2 (1.4)	1.000
No acute pancreatitis in follow-up period	140 (97.9)	134 (95.7)	0.238
Chronic pancreatitis	0 (0)	1 (0.7)	0.495
Abdominal pain during previous year	58 (40.5)	50 (35.7)	0.463
daily	10/143 (6.9)	12/140 (8.6)	
weekly	6/143 (4.2)	12/140 (8.6)	
once a month/seldom	42/143 (29.4)	26/140 (18.6)	
Medication for abdominal pain in previous year	30 (21.1)	22 (15.7)	0.283

[Table 1. Patient and procedure characteristics (n=283). Numerical data are presented as median (range)\* or number of patients (%)]

**Conclusion:** TPBS is a useful procedure with acceptable complication rates. There was no significant difference between groups when evaluating the short-term or long-term complications. Additionally, there were no significant difference during the follow-up period in upper abdominal pain, usage of painkillers, recurrent pancreatitis or development of CP.

## P1621 WITHDRAWN

## P1622 CONSCIOUS SEDATION IN ERCP: A UK PERSPECTIVE FROM A GENERAL HOSPITAL

Mohammed O., Raees K., Mahmood Z.

Stepping Hill Hospital, Gastroenterology, Stockport, United Kingdom

**Contact E-Mail Address:** omarkadem@yahoo.com

**Introduction:** Despite the fact, it has been more than 8 years since the release of the UK guidelines for the use of propofol for deep sedation of adult patients undergoing Endoscopic Retrograde Cholangiopancreatography (ERCP) (1), yet the lionshare of UK based centres consider conscious sedation as the preferred way of sedation.

**Aims & Methods:** The goal of this project is to evaluate ERCP under conscious sedation and compare quality indicators with the benchmark stated by British society of Gastroenterology (BSG).

In our centre, we retrospectively analysed all ERCP procedures data from hospital-based registry carried out under conscious sedation and general anaesthesia (GA) during the period (2016, 2017, and 2018), and reviewed related complications during the study period.

Total number of cases 602, 579 were done under conscious sedation, while 23 cases were done under GA.

**Results:** A total 579 patients had ERCP under conscious sedation during these 3 years, Male 42.1% (241), mean age 71.7, and range (17-99), physical health was assessed via ASA score; 76.1% of our cohort were classified as ASA II-III. 100% of the procedure was intended for therapy. Deep cannulation was achieved in 97.4% (564), and procedure was successfully completed in 93.2% (540), incomplete procedure was 4.14% (24), and failed 2.6% (15). Complications; Pancreatitis was 2.9% (17), no patient had serious bleeding requiring blood transfusion, perforation rate 0.34% (2), and mortality related to the procedure 0.17% (1). Sedation wise, mean sedation rate for Midazolam for age below 70 was (3.2 mg), while for age above 70 was (2.3 mg). Regarding Fentanyl for age below 70, the mean rate is (81.8 mg), while above the age of 70, the rate was (57.84 mg), and

mean comfort score was (2.5). Antibiotic for incomplete decompression of bile duct was given in 100%. While the cases that needed ERCP under GA (N=23), 65% of the cases were classified as ASA score 2-3. These cases formed 3.8% of the whole ERCP pool during the period of the study.

**Conclusion:** In a summary, we concluded that ERCP under conscious sedation is still safe and effective in vast majority of the cases, and on pars with the guidelines (4, 5). However a small number of cases still require GA or propofol, this would need discussion and collaboration between gastroenterologists and anaesthetists base on each case due to the peculiar situation in the UK where propofol should be given only by anaesthetist (1).

## P1623 PLACE OF ERCP IN HEPATIC HYDATID DISEASE WITH CYSTOBILIARY COMMUNICATION: A 17 YEARS EXPERIENCE

Boutallaka H., Seddik H., Mrabti S., Sair A., Berraida R., Elkoti I., Loubaris K., Sentissi S., Benkirane A.

*Military Instruction Hospital Mohammed V, Gastroenterology II, Rabat, Morocco*

**Contact E-Mail Address:** hanaeboutallaka@gmail.com

**Introduction:** Hydatid disease is an infectious disease caused by Echinococcus Granulosus, it affects most commonly the liver. Intrabiliary fistulisation is one if its rare and severe complications which remains frequently unrecognized.

**Aims & Methods:** The aim of our study is to evaluate the efficacy and safety of ERCP in management of hepatic hydatid cysts with cystobiliary communication based on our experience.

We conducted a retrospective bi-centric descriptive and analytical study, from January 2002 to March 2019 in both the departments of gastroenterology of military teaching hospital, and Cheikh Zayed Hospital in Rabat, including 50 patients with hepatic hydatid cyst communicating with biliary tract. Endoscopic retrograde cholangiopancreatography with endoscopic sphincterotomy were performed in all our patients. Global success was defined by the final clearance of bile ducts and drying up of biliary fistula. IBM SPSS software 24.0 was used for statistical analysis of our data.

**Results:** The mean age of our population was 46,2 $\pm$ 14,9 years old with a sex ratio M/F of 2,06. Of the 50 patients enrolled in the study, ERCP was performed before surgery in 52,2% cases and post-operatively in 47,8% cases. Indications of ERCP included cholangitis due to biliary obstruction in 43,5%, and persistent external biliary fistula in 34% of cases. During ERCP, mean diameter of common bile duct (CBD) was 10,7 $\pm$ 4,06 millimeters, and median diameter of cyst of 35mm [20-60] measured by leakage of contrast into cyst cavity. CBD was filled by defect of varying size in 82,1%, and we noted a distal stenosis in 28,6%. Endoscopic sphincterotomy was performed in all cases, so that we could empty out hydatid cysts and daughter cysts encountered in bile duct using biliary occlusion balloon and/or Dormia basket in 87% of cases. Nevertheless, 21,7% required nasobiliary drainage and 8,7% required biliary stenting due to CBD stricture. Global success defined by the final clearance of bile ducts was obtained in 100%. Regression of jaundice was noted in 5 to 10 days after ERCP and biliary fistula healed in a median of 10 days.

**Conclusion:** ERCP is a safe, effective and conservative procedure to manage hepatic hydatid disease with cystobiliary communication. Endoscopic sphincterotomy allows the treatment of associated cholangitis and biliary obstruction most frequently. It leads to decrease the duration of hospital stay and to avoid a heavy surgery in some cases.

**Disclosure:** Nothing to disclose

## P1624 RETROSPECTIVE COMPARISON OF EFFICACY AND COST-EFFECTIVENESS OF SELF-EXPANDABLE METAL STENTS AND PLASTIC BILIARY STENTS IN THE MANAGEMENT OF MALIGNANT BILIARY OBSTRUCTION

Hungary, <sup>3</sup>University of Szeged, Department of Medical Physics and

Informatics, Szeged, Hungary, <sup>4</sup>University of Szeged, First Department of Szeged, Szeged, Hungary

**Contact E-Mail Address:** bor.reni86@gmail.com

**Introduction:** Self-expandable metal (SEMS) and plastic stents (PS) placement are the two alternative therapeutic options for the palliative endoscopic management of unresectable malignant biliary obstruction. The longer stent patency might compensate for the substantially higher cost of SEMS compared to PS. Current guidelines recommend the use of SEMS if the patient's life expectancy is more than four months. **The aims** of this study were to compare the therapeutic efficacy and cost-effectiveness of SEMS and PS in the treatment of malignant biliary obstruction.

**Aims & Methods:** 135 consecutive patients were retrospectively enrolled who underwent endoscopic stent placement due to unresectable malignant biliary obstruction between 2011 and 2017 at University of Szeged. Patients were divided into PS (41 patients), primary SEMS (39 patients), and secondary SEMS (55 patients) subgroups. The efficacy and cost-effectiveness of stents were determined on basis of technical and functional success rate, stent patency and cumulative cost of treatment.

**Results:** The 135 enrolled patients underwent 111 SEMS and 153 PS placement with similarly high technical (100% vs. 98.69%) and functional success rate (90.10% vs. 86.27%) during the study period. The average patency of SEMS was significantly higher compared with PS (22.16 vs. 10.28 weeks;  $p < 0.001$ ). In the PS subgroup multiple stent implantation and larger stent diameter increased the stent patency compared with the 7 Fr stents (10.88 vs. 10.55 vs. 7.63). The mean survival of patients was substantially higher in the secondary SEMS subgroup (47.07 weeks, range 1-134, med. 40) compared with the primary SEMS (24.46 weeks, range 2-72, med. 17) and PS groups (18.27 weeks, range 3-76, med. 12). There was no difference in the average cost of treatment per month between the PS, primary and secondary SEMS groups (892.12 EUR vs. 939.12 EUR vs. 788.46 EUR). The cumulative cost of first two-months' treatment was substantially lower in the PS group compared with primary and secondary SEMS groups (1645.19 EUR vs. 1937.82 EUR vs. 1755.82 EUR), however, if the patients' survival time was more than two months, the cost-effectiveness of SEMS was better than plastic stents: 4-months cumulative cost was 2325.14 EUR in SP, 1898.96 EUR in primary SEMS and 2009.02 HUF in secondary SEMS group.

**Conclusion:** Considering the cost of treatment, the burden of patients and health care system we recommend the SEMS implantation if the life expectancy of patients is more than two months. In short survival cases or if the SEMS not available the multiple plastic stent implantation is recommended.

**Disclosure:** Nothing to disclose

## P1625 TREATMENT STRATEGY FOR CHOLEDOCHOLITHIASIS IN VERY ELDERLY ( $\geq 85$ YEARS) PATIENTS

Suzuki A., Nakase K., Mandai K., Tanaka K., Uno K., Yasuda K.

*Kyoto Second Red Cross Hospital, Department of Gastroenterology, Kyoto, Japan*

**Contact E-Mail Address:** azmaked@gmail.com

**Introduction:** Endoscopic sphincterotomy with stone extraction is a widely accepted standard therapy for choledocholithiasis. Use of endoscopic therapy in very elderly patients with common bile duct (CBD) stones has increased with the aging society. However, it is sometimes difficult to perform lengthy or frequent procedures in elderly patients because of poor physical status or comorbidities. Several studies have reported that long-term biliary stenting is safe and effective for the elderly.

**Aims & Methods:** This study aimed to evaluate strategies for endoscopic management of choledocholithiasis in very elderly patients.

This is a retrospective cohort study of very elderly patients (age,  $\geq 85$  years) who had undergone endoscopic retrograde cholangiopancreatography (ERCP)-related procedures for CBD stones at Kyoto Second Red Cross Hos-

pital between 1998 and 2018. Patients who failed biliary cannulation or presented with biliary stricture, post Billroth II reconstruction, Roux-en-Y reconstruction, and biliary reconstruction were excluded. 477 very elderly patients were analyzed and divided into two groups according to the management strategy: stone extraction group (n=304), patients who underwent endoscopic CBD stone removal; and stent group (n=173), patients who underwent endoscopic bile duct stenting without stone removal. Patient characteristics, treatment, clinical outcomes, long-term outcomes, and complications were compared between the groups.

**Results:** There were significant differences between the stone extraction and stent group with regard to age (88.7 vs. 91.1 years,  $p < 0.001$ ), presence of multiple ( $\geq 5$ ) CBD stones (19.7% vs. 37.6%,  $p < 0.001$ ), and presence of large stone (28.7% vs. 53.3%,  $p < 0.001$ ). There was no significant difference in presence of comorbidities and antithrombotic therapy between the groups.

Significantly more ERCP sessions were required during hospital stay in the stone extraction group than in stent group (1.7 vs. 1.2,  $p < 0.001$ ). Total procedure time were significantly longer in the stone extraction group than in the stent group (66.9 vs. 42.2 min,  $p < 0.001$ ). The rate of complete stone removal was 88.7% in the stone extraction group.

There was no significant difference in the rate of complications during and after ERCP between the groups. Kaplan-Meier analysis showed a significantly lower rate of CBD stone and/or cholangitis recurrence in the stone extraction than in the stent group ( $p < 0.001$ ).

**Conclusion:** In terms of long-term outcomes, endoscopic stone extraction is recommended as the first choice even in very elderly patients. For difficult common bile duct stones, long-term biliary stenting is a feasible option and appropriate in patients with short life expectancy due to old age and comorbidities.

**Disclosure:** Nothing to disclose

## P1626 PREVALENCE AND RISK FACTORS FOR ERCP ADVERSE EVENTS

Morais R., Rodrigues-Pinto E., Silva M., Coelho R., Costa-Moreira P., Santos A., Gaspar R., Peixoto A., Silva J., Dias E., Vilas-Boas F., Moutinho-Ribeiro P., Pereira P., Macedo G. Centro Hospitalar São João, Gastroenterology, Porto, Portugal

**Contact E-Mail Address:** ruimorais20@gmail.com

**Introduction:** Since its first description, endoscopic retrograde cholangiopancreatography (ERCP) has evolved into a leading modality in the treatment of the pancreas and biliary tract conditions. Its enormous therapeutic potential also carries the possibility of adverse events (AEs) that may be associated with a significant morbidity and mortality. Numerous studies have helped determine the expected rates of ERCP-related AEs and possible methods for improving the safety of ERCP, but many of them are limited by nonuniformity of definitions, small sample sizes or analyse each AE separately.

**Aims & Methods:** The aim of our study was to evaluate the AEs' prevalence after ERCP, and risk factors for its occurrence.

Retrospective cohort study of all patients who underwent ERCP between January 2012 and December 2017, in a single tertiary center. Demographic and clinical data, including post-procedural AEs, were analysed. Risk factors for global and individual AEs occurrence were identified using multivariate logistic regression analysis.

**Results:** During the study period a total of 2002 ERCPs were performed on 1492 consecutive patients, 51.4% male, with a median age of 68 years (IQR 56-79). The main indications for ERCP were choledocholithiasis (37.0%), jaundice (11.1%), biliary stenosis (11.4%) and imaging abnormality of the bile duct (8.6%).

The overall AE rate was 15.3% [Planned bile duct cannulation with naive papilla - 210/1339 (15.7%); Planned bile duct cannulation with previous sphincterotomy - 55/499 (11.0%); Planned pancreatic duct cannulation with naive papilla - 18/83 (21.7%); Planned pancreatic duct cannulation with previous sphincterotomy - 21/70 (30%)]. The main post-ERCP AE was pancreatitis (7.5%), followed by cholangitis (4.9%), hemorrhage (1.3%), perforation (1.0%), cardiopulmonary events (0.9%) and cholecystitis (0.3%). ERCP AE-related mortality rate was 1.0%.

In the multivariate analysis, ERCP difficulty degree (III/IV vs I/II: OR 1.842,  $p < 0.001$ ), difficult biliary cannulation (OR 1.992,  $p < 0.001$ ), imaging abnormality of the bile duct (OR 1.636,  $p = 0.025$ ), periprocedural haemorrhage (OR 3.656,  $p < 0.001$ ) and ampulectomy (OR 4.681,  $p = 0.018$ ) were

independently associated with an increased risk of AEs. Naïve papilla (OR 2.170,  $p = 0.008$ ), pancreatic duct cannulation (OR 1.923,  $p = 0.026$ ), imaging abnormality of the bile duct (OR 2.035,  $p = 0.009$ ), choledocholithiasis (OR 0.535,  $p = 0.01$ ), previous post ERCP-pancreatitis (OR 3.434,  $p = 0.003$ ), periprocedural haemorrhage (OR 2.432,  $p = 0.022$ ) were independently associated with pancreatitis.

Periprocedural haemorrhage (OR 9.747,  $p < 0.001$ ), anti-aggregation plus anticoagulant therapy (OR 11.832,  $p = 0.028$ ), sphincteroplasty (OR 3.545,  $p = 0.013$ ) and distal common bile duct stricture (OR 8.767,  $p = 0.003$ ) were independently associated with postprocedural haemorrhage. Hilar stricture was the only independent factor associated with cholangitis (OR 8.685,  $p = 0.006$ ). Altered anatomy (OR 9.391,  $p = 0.014$ ) and peripapillary diverticulum (OR 3.813,  $p = 0.019$ ) were associated with perforation. Post-ERCP AEs-related mortality was independently associated with difficult biliary cannulation (OR 3.160,  $p = 0.020$ ), jaundice (OR 5.071,  $p = 0.006$ ), anticoagulation with NOACs (OR 26.660,  $p = 0.007$ ) and ASA score (4 vs 1-3, OR 5.273,  $p = 0.008$ ).

**Conclusion:** ERCP AEs' prevalence is significant. Patient-related risk factors assume a non-negligible role for its occurrence. Adequate stratification, considering potentially modifiable risk factors, with identification of high-risk patients and targeted prophylactic management may be important to prevent or minimize their occurrence.

**Introduction:** Post-cholecystectomy iatrogenic biliary injuries, though more uncommon than in the early years of laparoscopic surgery still represents an important burden of morbidity and mortality. When discovered during surgery the injuries can be easily managed, otherwise endoscopic retrograde cholangiopancreatography (ERCP) represents the first choice of treatment.

**Aims & Methods:** The aim of this study is to evaluate the role of ERCP in the management of biliary laparoscopic induced lesions after cholecistectomy. We conducted a retrospective study which enrolled the patients with iatrogenic biliary injuries after laparoscopic cholecystectomy hospitalized in the Clinical Emergency Hospital Bucharest, who underwent ERCP from January 2014 to March 2019.

**Results:** The study included 48 patients diagnosed with post laparoscopic cholecystectomy iatrogenic injuries or who had a high clinical and imaging suspicion of biliary lesion, and were mainly referred to our tertiary center for ERCP. The mean age was 54,5 years (range 20 to 84).

According to S.M. Strasberg classification 72, 91% of the patients had a type A lesion, which was associated in half of the cases with main bile duct lithiasis. ERCP with plastic stent insertion was used in 22 patients, the stent was extracted on average after 30 days with full recovery, while for 13 patients only sphincterotomy was performed also with full recovery. A type D lesion was described during ERCP for 5 patients, 4 of whom were treated surgically after an initial ERCP with sphincterotomy, while one patient had a full recovery after plastic stent placement.

More complex type E lesions where described in 8 patients (E1-3 patients; E2 - 4 patients; E3- 1 patient), and in all except one patient the first ERCP had failed to treat the lesion.

One patient with type E2 lesion had a plastic stent inserted via ERCP in the surgery room and need it another 6 ERCP's with multiple plastic stent exchange for 18 months until full recovery.

**Conclusion:** ERCP remains a useful treatment tool for iatrogenic biliary lesions after laparoscopic cholecystectomy. Therapeutic ERCP can successfully treat low complexity lesions and in some cases can be used in rendez-vous procedures in the surgery room for very complex injuries.

**Introduction:** Single-operator cholangioscopy (SOC) has been a major advance in indeterminate biliary stricture (IDBS) diagnosis because it has made direct visualization and optically guided biopsy of these lesions. However, SOC-guided biopsies have shown limited sensitivity. In order to overcome this limitation, identifying the cholangioscopic features that most strongly suggest malignancy is an interesting way to improve SOC diagnostic capabilities; however, no systematic analysis of SOC findings has been conducted to date. The aim of our study is to establish endoscopic criteria allowing to distinguish between benign and malignant lesions.

**Aims & Methods:** 4 referral centers included 98 Spyglass DS cholangioscopy recordings performed for indeterminate biliary strictures (IDBS) whose final diagnosis was known by histology or follow-up for more than 1 year. 7 experts in cholangioscopy participated in the development of a consensus reading grouping 20 semiological criteria. The videos were analyzed individually by each expert after randomization according to the reading grid. A hypothesis diagnosis was issued for each examination. After a statistical analysis a second meeting with the same methodology were held for criteria validation.

**Results:** 98 IDBS videos from 95 patients of mean age 66 years (13 - 89) were analyzed; there were 38 benign and 60 malignant strictures. The Sensitivity ranged from 68% to 81% and specificity from 55 to 71%. The univariate and multivariate analysis identified 4 significant criteria. One for benign lesions: the presence of endobiliary material odds ratio (OR)= 0.649; 95% confidence interval (CI), 0.427 - 0.988. Three for malignant lesions: villous pattern OR = 1.477; 95% CI, 0.98 - 2.21; irregular vessels OR = 2.042; 95% CI, 1.35 - 3.08; redish aspect OR = 1.67; 95% CI, 1.09 - 2.53.

**Conclusion:** Simple criteria's could assist malignancy diagnosis and enhance The performance of cholangioscopic visual diagnosis of IDBS.

**Contact E-Mail Address:** filipe.desousa.damiao@gmail.com

**Introduction:** ERCP is a technically challenging and high-risk procedure requiring focussed training and experience to maximize technical success and minimize adverse outcomes. Quality indicators in ERCP are useful to evaluate and monitor technical performance and adverse outcomes.

**Aims & Methods:** The objective of this study was to evaluate the technical performance and the fulfillment of quality indicators in ERCP practice in a tertiary center.

We retrospectively evaluated 941 consecutive ERCPs that were performed at a tertiary hospital between October 2016 and January 2019 and were prospectively registered.

We excluded 92 procedures due to lack of an attempt to cannulate the papilla of Vater (mainly due to duodenal obstruction often due to malignant stricture and altered small intestinal anatomy with Roux en Y anastomosis) and in 13 procedures due to inadequate post procedure follow-up data. Finally, the study cohort included 836 procedures. Intravenous hydration with Ringer's lactate and prophylactic diclofenac suppository were performed in all procedures. Prophylactic post ERCP antibiotic prophylaxis was prescribed when indicated.

The technical performance was compared with the quality indicators for ERCP recommended by the American Society of Gastrointestinal Endoscopy (ASGE) and the European Society of Gastrointestinal Endoscopy (ESGE).

**Results:** The mean age of the study sample was 71 ± 15.8 years and 51% (426) of the procedures were performed in men.

The indications for ERCP were as follows: Choledocholithiasis 57% (476); malignant biliary stricture 27% (226); benign biliary stricture 6% (48); biliary fistula 4% (30); acute gallstone pancreatitis 2% (17); ampuloma 0.2% (2) and others 4.4% (37).

The overall rate of deep cannulation of the main bile duct was 97.8% (818/836) and in patients with intact papilla of Vater was 97% (543/560). The incidence of post ERCP pancreatitis (PEP) was 2.5% (21), post sphincterotomy haemorrhage 1.1% (9) and perforation 0.2% (2). The technical performance indicators of ERCPs compared to those recommended by ASGE and ESGE are presented in table 1.

The following variables were not documented in the study: the use of prophylactic antibiotic therapy and the success rate of bile duct stent placement.

	ASGE	ESGE	Technical performance
1)Appropriate indication for ERCP	>90%		100%
2)Native papilla deep cannulation rate	>90%	>90% (>95% ideal)	97%
3)Extraction rate of <1cm common bile ducts stones	≥90%	>90%	100%
4)Successful biliary stent placement rate	≥90%	>95%	Not recorded
5)Post-ERCP pancreatitis rate	Yes	<10% (<5% ideal)	2.5%

[Table 1. Evaluation of technical performance when compared to quality indicators of ERCP recommended by ASGE and ESGE]

**Conclusion:** The awareness and use of a prospective database allowed a detailed analysis of the performance indicators in ERCP as recommended by ASGE and ESGE and may have contributed to the good technical outcomes and low incidence of adverse outcomes.

**Disclosure:** Nothing to disclose

## P1630 INCIDENCE OF POST ERCP ADVERSE EVENTS AND PREDICTORS OF POST-ERCP PANCREATITIS - ANALYSIS OF A PROSPECTIVE DATABASE

Damião F.<sup>1</sup>, Noronha Ferreira C.<sup>1</sup>, Freitas C.<sup>1</sup>, Marques A.<sup>1</sup>, Palma R.<sup>1</sup>, Moura M.<sup>1</sup>, Costa P.<sup>1</sup>, Carvalho J.<sup>1</sup>, Almeida A.<sup>2</sup>, Carrilho-Ribeiro L.<sup>1</sup>, Marinho R.T.<sup>3</sup>

<sup>1</sup>Centro Hospitalar Universitário Lisboa Norte, Serviço de Gastroenterologia e Hepatologia, Lisbon, Portugal, <sup>2</sup>Centro Hospitalar Universitário Lisboa Norte, Serviço de Anestesia, Lisbon, Portugal, <sup>3</sup>Hospital de Santa Maria, Medical School of Lisbon, Lisbon, Portugal

**Contact E-Mail Address:** filipe.desousa.damiao@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is one of the endoscopic techniques with the highest rate of adverse events. The expected rate of post-ERCP pancreatitis (PEP) varies between 1% and 7% for most average-risk patients, haemorrhage post endoscopic sphincterotomy varies between 0.8% to 2% and perforation varies between 0.1% to 0.6%

**Aims & Methods:** The objective of this study was to evaluate the incidence of adverse events after ERCP and determine risk factors for post-ERCP pancreatitis (PEP).

We retrospectively evaluated 941 consecutive ERCPs that were performed in a tertiary hospital between October 2016 and January 2019. Data related to the procedures was prospectively registered. The indication for ERCP,

incidence and predictors of PEP were evaluated. We excluded 92 procedures wherein cannulation of papilla of Vater was not attempted (mainly because of duodenal obstruction due to neoplastic stricture, altered small intestinal anatomy with Roux en Y anastomosis) and 13 procedures due to inadequate follow-up data. The final study sampled included 836 ERCP procedures. All patients received intravenous Ringer's lactate and rectal diclofenac 100mg suppository for prophylaxis of PEP.

Patients at high risk for PEP were defined by intact papilla of Vater and time to cannulation of the main bile duct > 5mins or ≥2 cannulations of the pancreatic duct. Descriptive statistical analysis, chi square and logistic regression were realized (SPSS<sup>®</sup> 21).

**Results:** The average age of the study sample was 71±15.8 years with 51% (426) being men. The main indications for ERCP were: Choledocholithiasis 57% (476); Malignant stenosis 27% (226); Benign stenosis 6% (48). The cannulation rate of intact papilla of Vater was 97% (543/560). Guide wire assisted cannulation was used in 72% (591) and precut papillotomy in 13.3% (111). The time to main bile duct cannulation was < 5mins in 65% (546) patients. The pancreatic duct was cannulated in 24% (202) patients. Contrast was injected into the pancreatic duct in 6.2% (52) and a prophylactic 5Fr stent placed in the pancreatic duct in 9.1% (76) patients. The high-risk group for PEP represented 33% (275) of ERCPs. The overall incidence of complications after ERCP was 4.3% (36) with PEP occurring in 2.5% (21) patients as shown in table 1.

PEP was associated with time until cannulation of main bile duct > 5mins ( $p = 0.01$ ); ≥1 pancreatic duct cannulations ( $p < 0.01$ ) and pancreatic duct contrast injection ( $p < 0.01$ ). The only predictor of PEP was ≥2 cannulations of the pancreatic duct (OR: 4.7; 95% CI, 1.29-17.1,  $p = 0.019$ ).

	Overall study sample (n=836)	Native papilla of Vater (n=560)	Prior sphincterotomy (n=276)
Main bile duct cannulation rate	97.8% (818)	97% (543)	99.6% (275)
PEP	2.5% (21)	3.4% (19)	0.7% (2)
Hemorrhage	1.1% (9)	1.4% (8)	0.4% (1)
Cholangitis	0.5% (4)	1.4% (2)	0.4% (1)
Perforation	0.2% (2)	1.4% (2)	0%

[Table 1. Cannulation rate and incidence of post ERCP adverse events]

**Conclusion:** In our prospective registry, the incidence of ERCP adverse events was low with a PEP rate lower than that usually described in published literature. The only independent predictor of PEP were ≥2 cannulations of the pancreatic duct.

**Disclosure:** Nothing to disclose

### P1631 SERUM AMYLASE LEVEL AT 2 HOURS AFTER ERCP CAN BE A PREDICTIVE FACTOR FOR THE SEVERITY OF POST-ERCP PANCREATITIS; MULTICENTER PROSPECTIVE STUDY, SOSUI

**Contact E-Mail Address:** toshifumi-doi@kyoto1-jrc.org

**Introduction:** The severity of post-ERCP pancreatitis (PEP) is a major problem because of its occasional lethality. However, no predictor of the severity has been identified. In the present multicenter prospective study, SOSUI, we investigated potential predictive factors for the severity of PEP.

**Aims & Methods:** We prospectively followed 3,914 patients who underwent ERCP between February 2015 and May 2017 at five high-volume centers in Kyoto or Shiga prefecture in Japan. 3,661 patients were included after 253 those who had been complicated by pancreatitis, undergone biliary tract reconstruction, or had papilla not reached were excluded.

Of the 3,661 patients, we evaluated 263 patients who developed PEP. We compared between the mild and severe cases to examine potential predictors for the severity of PEP. PEP was diagnosed when patients presented with at least two of three following manifestation: (1) serum amylase elevation (above the upper limits of each center) on the following day, (2) abdominal pain lasting for longer than 24 hours and (3) pancreatitis on CT. The severity of PEP was assessed based on the severity criteria of the Japanese Ministry of Health, Labour and Welfare.

**Results:** 35 (0.9%) and 228 (6.5%) patients developed severe and mild PEP. A significant difference was found between patients with severe and mild PEP with regard to the serum amylase level at 2 hours after ERCP ( $P = 0.0016$ ), abdominal pain immediately and 24 hour after ERCP ( $P = 0.011$  and  $0.0024$ ) and performing lithotomy ( $P = 0.031$ ). ROC analysis was conducted on the serum amylase level at 2 hours as a predictive factor for severe PEP, demonstrating that the cutoff value was 3.6 times higher than the upper limits of each center (sensitivity: 60%; specificity: 68%; and AUC: 0.63). In multivariate analysis using logistic regression by dividing the amylase level at 2 hours after ERCP into 3.7 times higher or lower than the reference values of each center, abdominal pain immediately after ERCP and AMY values at 2 hours after ERCP were identified as independent factors.

**Conclusion:** In the present study, abdominal pain immediately after ERCP and serum amylase level at 2 hours were identified as predictive factors for the severity of PEP. They can be useful for facilitating urgent therapeutic intervention. We have to investigate more to identify appropriate treatment for preventing PEP.

**Disclosure:** Nothing to disclose

### P1632 DIAGNOSTIC ACCURACY AND THERAPEUTIC EFFICACY OF DIGITAL SINGLE-OPERATOR CHOLANGIOSCOPY FOR BILIARY LESIONS AND STENOSIS

Weigand K.<sup>1</sup>, Küchle M.<sup>1</sup>, Zuber-Jerger I.<sup>1</sup>, Müller-Schilling M.<sup>2</sup>, Kandulski A.<sup>1</sup>

<sup>1</sup>University Hospital Regensburg, Department of Internal Medicine, Regensburg, Germany, <sup>2</sup>University Hospital Regensburg, Department of Internal Medicine I, Regensburg, Germany

**Contact E-Mail Address:** Arne.Kandulski@klinik.uni-regensburg.de

**Introduction:** Digital single-operator cholangioscopy (dSOC) has revolutionized bile duct visualization during endoscopic retrograde cholangiography (ERC). Visual inspection of suspicious areas and targeted biopsies have become possible quick and easy, as well as interventions like electrohydraulic or laser lithotripsy. One main indication for dSOC is the evaluation of indeterminate biliary strictures.

**Aims & Methods:** In this study 180 dSOCs performed 2016 till 2017 in a high volume tertiary center have been retrospectively analyzed to evaluate sensitivity, specificity as well as positive and negative predictive values for indeterminate strictures and lesions. Furthermore technical success and complications were analyzed.

**Results:** In 92-97% the region of interest was reached and visualized and in 83-100% successful biopsies were taken in the biliary tract in this study. Only the distal bile duct was less successful with only 84% and 62%, respectively. The procedure was safe with cholangitis as main complication. Regarding the diagnostic accuracy of dSOC of indeterminate biliary lesions and strictures we found a sensitivity of 0.87 and specificity of 0.88. The investigators assessment directly after dSOC had a positive predictive value of 0.63 and a very high negative predictive value of 0.97.

**Conclusion:** Our study demonstrates that dSOC has a very high diagnostic efficacy as well as a favorable safety profile. Therefore, it should be discussed as standard of care in addition to ERC for indeterminate biliary lesions.

## P1633 ENDOSCOPIC TREATMENT OF COMPLICATIONS OF HYDATID CYSTS IN THE LIVER BROKEN IN THE BILE DUCTS: EXPERIENCE OF A MOROCCAN DEPARTMENT

Jamal S., Seddik H., Loubaris K., El Koti I., Benkirane A.  
Military Training Hospital Mohammed V of Rabat, Morocco, Hepatology and Gastroenterology, Rabat, Morocco

**Contact E-Mail Address:** jamalsara24@gmail.com

**Introduction:** The Hydatid cyst of the liver is a parasitic disease due to the development of the larval form of the Taenia of the dog Echinococcus granulosus. By its clinical latency, the Diagnosis is most often at the stage of complications. Fistulization of the cyst hydatid in the bile ducts is the most common complication. Endoscopy is necessary because of the therapeutic problems and risks associated with surgery.

**Aims & Methods:** The objective of our study was to evaluate and analyze the effectiveness of ERCP in the diagnosis and treatment of Hydatid cysts of the liver broken in the pathways ducts.

This is a 15-year retrospective and descriptive study, ranging from January 2003 to October 2018, focused on patients with fistulized Hydatid cyst in the pathways bile duct. ERCP and endoscopic biliary sphincterotomy were performed in all patients, 18 times pre-operatively and 21 times post-operatively.

**Results:** 39 patients with broken Hydatid cyst in the biliary duct, 2.4% of the indications ERCP in our series were included. The average age of patients was 47, with male predominance in 65% of cases. KHF broken in the ways galls were complicated by persistent external biliary fistula post operatively in 34% of cases. Sphincterotomy was performed in all patients allowing removal of Hydatid material by extraction balloon or Dormia basket. The evolution was marked by the disappearance of jaundice after 5 to 12 days in average after endoscopic gesture and dryness of external biliary fistula after 10 to 12 days.

**Conclusion:** The results of our study confirm the efficacy and safety of ERCP and the endoscopic sphincterotomy in biliary complications of echinococcosis hepatic. It makes it possible to shorten the post-operative stay and to avoid are operation, often difficult and haemorrhagic.

**Disclosure:** Nothing to disclose

## P1634 THE ROLE OF RECTAL EUS BIOPSY IN PRE-SACRAL UNDEFINED LESIONS IN PATIENTS WITH HISTORY OF LOWER GI NEOPLASIA

Clinico Humanitas Rozzano Dept. of Gastroenterology, Dept. of Gastroenterology, Milano, Italy

**Contact E-Mail Address:** francesco.auriemma.1987@gmail.com

**Introduction:** Colo-rectal neoplasia is one of the most commonly diagnosed malignancies, representing in Italy the second cause of overall malignan-

cies in the man, after prostate neoplasia, and in woman, after breast neoplasia, with 373.000 new diagnosis/years in 2018. Pre-sacral lesions may arise in the follow up after colo-rectal surgery, after adjuvant chemotherapy (CT), or neo-adjuvant chemo-radiotherapy. CTscan and pelvic RM are the two most used diagnostic tool in these patients, but they can be inconclusive in the diagnosis of pre-sacral lesions. PET scan adds more information but, in presence of inflammation, can show false positive results.

**Aims & Methods:** The aim is to critically evaluate the role and the efficacy of endoscopy ultrasound (EUS) and Fine Needle Aspiration or Biopsy (FNA/FNB) in the multimodal restaging of suspected local recurrence or progression disease in patients with history of rectal cancer. Procedures were performed with linear EUS scope. The number of EUS FNA/FNB passes was decided by the endoscopist based on the gross morphology of the specimen (if core was visible) and or rapid on-site evaluation if available.

**Results:** From September 2015 to March 2019 we retrospective enrolled eight patients referred to our units for pre-sacral lesions undergoing endoscopy ultrasound (EUS) and Fine Needle Aspiration or Biopsy (FNA/FNB). In all cases the radiological findings (CT scan and or PET/MRI) were inconclusive for a final diagnosis. Table 1 summarizes patients' lesions' and procedures' results. In 6 of 8 patients pathological evaluation confirmed the suspicion of local recurrence and they were referred for oncological re-treatment.

In two patients EUS-FNB of lymph-node yielded a diagnosis of inflammation (at histology) with no tumoral cells at cytology. Radiological follow-up for these two patients confirmed benign characteristics. In only two cases both cytology and histology were performed, and in both tissue acquisition by EUS-FNB allowed to reach a diagnosis. All lesions resembling masses resulted in local recurrence. In only one of three cases in which lymph-nodes were targeted, cytology evaluation on an EUS-FNB of 15 mm lymph-node showed tumoral cells. Procedures were performed in out-patient setting. All patients underwent antibiotic prophylaxis with intra-venous cefalosporine one shot before the biopsy. No adverse events or infection were observed.

**Conclusion:** EUS plus FNA/FNB should be a mandatory diagnostic tool in patients with a history of lower GI neoplasia in case of pre-sacral lesions supposed to be local recurrence. EUS-FNB seems to offer a higher diagnostic power. High diagnostic accuracy allows to redefine oncologic treatment and follow-up strategy. Further and wider retrospective cohort studies are warranted to offer more significative results.

**Disclosure:** Nothing to disclose

**Introduction:** EUS-guided tissue acquisition (EUS-TA) is crucial step in the differential diagnosis and management of patients with gastrointestinal subepithelial lesions (GI-SELs).

**Aims & Methods:** The aim of the study was to evaluate the adequacy of EUS-TA performed with standard needles (SN) and with fine needle biopsy needles (FNB needles), using a standardized protocol for the management of specimens in the diagnosis of GI-SELs.

This retrospective, single center study enrolled patients who underwent EUS-TA of upper or lower GI-SELs. A macroscopic on-site evaluation (MOSE) was performed by the endoscopist after every needle pass. All specimens obtained using either standard or histology needles were processed in the same way according to the MOSE.

Specimens were defined as "diagnostic" when sufficient material for histologic or cytologic evaluation was present. If the biopsies did not allow a complete evaluation, the specimens were considered as "not adequate". If the patient underwent surgical resection of the SEL, the EUS TA findings were compared with the final pathological diagnosis.

**Results:** 86 patients were included in the study (45 males, 52.3%), with mean age 64.0 years (SD = 11.6 years). The average size of the lesions was 36.3 mm (SD = 23.2 mm). 61.2% of lesions were detected in stomach, 19.8% in the duodenum, 15.1 % in the esophagus and cardias, and 4.7% in the rectum. FNB was used in 53 patients (61.6%), in the remaining 33 (38.4%) a SN was used. Adequate samples were obtained in 65 patients (75.6%): 59 had adequate histologic samples, 19 had an adequate cytology and 13 patients had both adequate histology and cytology samples.

In terms of adequacy, no statistically significant difference was found between standard and FNB samples (69.7% versus 80.0%, respectively,  $p=0.306$ ). (69.7% versus 80.0%, respectively  $p=0.306$ ). The mean number of needle passes was 2.2 (SD = 0.8 passes, range: 1-4 passes). It did not differ between the standard needle and the FNB groups ( $2.2 \pm 0.9$  passes versus  $2.3 \pm 0.8$  passes, respectively,  $p=0.431$ ), nor the adequacy of the specimens not affected by the mean number of needle passes ( $2.3 \pm 0.8$  passes for adequate samples vs  $2.1 \pm 0.9$  passes for inadequate samples  $p=0.400$ ).

A histological sample was, however, more frequently obtained with FNB needles than with standard needles [74.0% versus 60.0%, respectively ( $p=0.008$ )]. The adequacy of histological samples was higher than the adequacy of cytological specimens (85.3% versus 65.3%, respectively,  $p=0.015$ ). No early adverse events or technical difficulties were registered in either group.

Fifty-three patients (61.6%) underwent surgical resection, of which 40 had a diagnostic EUS-TA. In all of them, the final diagnosis confirmed that obtained with EUS-TA. Considering EUS and surgical findings, the final diagnosis was: GIST in 68 patients (79.6%), leiomyoma in 6 (6.9%), schwannoma in 2 (2.3%) and desmoid tumor in 1 (1.2%). Inadequate specimens were obtained, and no subsequent surgery was performed in 8 patients (9.6%): considering the lesion characteristics (< 20 mm, without worrisome features) and/or age >75 years, clinical and imaging follow up alone was proposed to these patients.

**Conclusion:** using a standardized protocol based on MOSE for the management of specimens from the endoscopy suite to the pathology department in an expert center, EUS-TA had a high rate of diagnostic accuracy and concordance between biopsy and surgical specimens, with no difference between FNBs and SN. FNB needles guaranteed a higher rate of histological specimens for ancillary analysis.

**Contact E-Mail Address:** peter.uhrík@yahoo.com

**Introduction:** Endoscopic ultrasound (EUS) is a specific endoscopic examination used to diagnose various types of gastrointestinal tumors. An important role of the EUS was found in the diagnostics of neuroendocrine tumors of the gastrointestinal tract (GEP NETs). In recent years, other modalities have been developed which, in combination with the EUS, improve diagnostics, give detailed description about invasion into surrounding structures, and allow prediction of the tumor's biological behavior. Such methods include elastography (EG). EG is based on demonstrating the difference in tissue stiffness between tumor and reference area. Strain EG measures tissue response to external or internal application of a certain force. It is based on the fact that the stiffer tissue has a lower elasticity and therefore is less deformed upon exposure to pressure. Tissue characteristics are analyzed based on a color qualitative method, or using one of the semi-quantitative methods: strain ratio (SR), strain histogram (SH). SR is the difference in elasticity between two regions in one region of interest (ROI). SH represents the average elasticity value in the defined area.

**Aims & Methods:** The aim of our study was to find a typical image, SR and SH of GEP NET in endoscopic elastographic measurement using strain qualitative and semi-quantitative methods. In our prospective pilot study, patients with subepithelial tumors of the stomach, duodenum and pancreas were examined. The lesions were displayed on an endoscopic ultrasonography using a convex probe with 7.5-10 MHz. The elastographic image contained the entire tumor in the region of interest and the same amount of comparison region. For the evaluation of the qualitative picture we used the 4-stage EG image rating scale according to WFUMB (World Federation for Ultrasound in Medicine and Biology) 2015. SH and SR were obtained by three different measurements in each case. The selected reference area for SR was chosen non-standard. SR was obtained by comparing subendothelial tumor with the stomach or duodenal wall, pancreatic NETs were compared with the unaffected pancreatic tissue.

**Results:** 30 patients (20 females and 10 males) with histologically confirmed GEP NET from 2017 to 2019 were included in the study. The mean age of subject was 53.7 years (17 to 74 years). We observed EG qualitative image of GEP NETs homogeneous hard, heterogeneous hard, heterogeneous soft, homogeneous soft 73.3%, 20.0%, 3.3%, 3.3%, respectively. The mean SR observed was 5.17 (95% CI; 5.41 - 10.61) and SH 26.6 (95% CI; 21.35 - 35.02). Sufficient correlation coefficient in the group with qualitative image - homogeneous hard between SR and SH was reached  $r=-0.613$  (95% CI; -0.8 to -0.2585;  $p=0.0024$ ).

**Conclusion:** Endoscopic ultrasonography with elastography allows to evaluate changes in tissue elasticity in otherwise poorly accessible locations. Gastroenteropancreatic neuroendocrine tumors exhibit considerable homogeneity in qualitative endoscopic elastographic images. The relatively small range of strain ratio and strain histogram measured between tumor and healthy tissue in our study, indicates the possibility of using these semi-quantitative methods in GEP NETs differential diagnostics.

**Contact E-Mail Address:** doc\_hobafaheem@yahoo.com

**Introduction:** The assessment of bile duct dilatation can be carried out using many diagnostic modalities including abdominal ultrasonography (US), computed tomography (CT), and magnetic resonance cholangiopancreatography (MRCP). However, failure to identify the cause of CBD dilatation has been observed in subjects with normal liver function tests and nonspecific abdominal symptoms. EUS has emerged as an important tool for evaluation of biliary disease. Some literatures suggest its impact in detection of a potential biliary pathology, despite a low pre-test clinical suspicion.

**Aims & Methods:** The aim was to assess the diagnostic value of EUS in patients with normal liver blood tests and unexplained dilatation of common bile duct following other diagnostic modalities including US, CT, and MRCP. Methods: we conducted a retrospective study on 56 patients referred to TBRI (Theodor Bilharz Research Institute) over the period of 2 years. The patients who had dilated CBD, but evaluation with US, and CT or MRCP did not provide a specific cause with normal liver biochemistry {alkaline phosphatase, or AST, or ALT} were included in our study. The patients in whom a diagnosis had been provided by prior imaging (CT/MRCP/US), those with obscure etiology on CT and/ or US alone, and those with previous ERCP or pancreaticobiliary surgery were excluded from this study. There were 11 patients had normal alkaline phosphatase (45-120 IU/L), 21 patients had normal aspartate aminotransferase {AST} (20-40 U/L), and 24 patients had normal alanine aminotransferase {ALT} (20-50 U/L). All patients were enrolled to determine the diagnostic yield of endoscopic ultrasound in this condition.

**Results:** Our study revealed that among 11 subjects with normal alkaline phosphatase, there were 5 males and 6 females, with a mean ( $\pm$ SD) age of 45.18 ( $\pm$ 14.58). The diameter of CBD dilatation by abdominal ultrasound was 9.96 ( $\pm$ 1.13). EUS findings were as follows: 6 cases (54.55%) had stone, 2 cases (18.18%) had benign stricture, another 2 cases (18.18%) had prominent CBD no obstruction, and 1 case (9.09%) had malignant stricture. Among 21 subjects with normal AST, there were 12 males and 9 females, with a mean ( $\pm$ SD) age of 50.19 ( $\pm$ 11.11). The diameter of CBD dilatation by abdominal ultrasound was 11.55 ( $\pm$ 2.53). EUS findings were as follows: 8 cases (38.10%) had stone, another 8 cases (38.10%) had malignant stricture, 3 cases (14.29%) had benign stricture, and 2 cases (9.52%) had prominent CBD no obstruction. Among 24 subjects with normal ALT, there were 11 males and 13 females, with a mean ( $\pm$ SD) age of 50.75 ( $\pm$ 13.16). The diameter of CBD dilatation by abdominal ultrasound was 11.79 ( $\pm$ 2.59). EUS findings were as follows: 11 cases (45.83%) had stone, 8 cases (33.33%) had malignant stricture, 3 cases (12.50%) had benign stricture, and 2 cases (8.33%) had prominent CBD no obstruction.

		Alkaline phosphatase (45-120 IU/L)	AST (20-40 U/L)	ALT (20-50 U/L)
		N (%)	N (%)	N (%)
EUS	Stone	6 (54.5%)	8 (38.1%)	11 (45.8%)
	Benign stricture	2 (18.1%)	3 (14.2%)	3 (12.5%)
	Malignant stricture	1 (9.09%)	8 (38.1%)	8 (33.3%)
	Prominent CBD dilatation without obstruction	2 (18.1%)	2 (9.5%)	2 (8.3%)
Total		11(100%)	21 (100%)	24 (100%)
CBD diameter	Mean $\pm$ SD	9.96 $\pm$ 1.13	11.55 $\pm$ 2.53	11.79 $\pm$ 2.59
Age	Mean $\pm$ SD	45.18 $\pm$ 14.58	50.19 $\pm$ 11.11	50.75 $\pm$ 13.16

[Table 1. Descriptive data of the study]

**Conclusion:** In our study we revealed firstly that CBD dilatation with normal liver chemistry is not always a benign condition. Secondly the importance of EUS as a diagnostic modality in patients with normal liver blood tests and dilated CBD and negative prior imaging tests.

**Disclosure:** Nothing to disclose

## P1640 DIAGNOSTIC YIELD OF A NEW MICRO-BIOPSY FORCEPS IN THE ASSESSMENT WORK OUT OF PERITONEAL CARCINOMATOSIS: A PRELIMINARY EXPERIENCE

**Introduction:** Peritoneal carcinomatosis (PC) is the metastatic seeding of malignant cells to peritoneal cavity. It is associated with a dramatic prognosis worsening, with limited therapeutic options. Although cumbersome in diagnosing, due to its presentation variability, it should be ruled out before starting any invasive treatment modality. Recently, a new through-the-needle micro-biopsy forceps (Moray Forceps, US Endoscopy) have been proposed, allowing micro-histology cores.

**Aims & Methods:** With this novel application, we aimed to evaluate the feasibility of MF in the assessment of PC to complete patient diagnostic work out.

All procedures were conducted under moderate sedation, by 2 expert endosonographers. After a complete EUS evaluation, ascites was punctured, with a 19G FNA needle. Before suction, the MF was introduced through-the-needle, and the suspected carcinomatosis nodule was sampled. Micro-histology specimens were collected in formalin and evaluated by a dedicated pathologist.

**Results:** 3 consecutive patients (2 F, 1 M; mean age 72 yo), with ascites and suspicion of PC, referred to our center for EUS staging, were sampled with MF. Tissue sampling with MF was feasible in all patients, with a technical success of 100%. Sample quality was medium-high, in all the cases, giving the opportunity for immuno-histochemical staining, when necessary. No adverse events were observed both during and after the procedure in all cases.

**Case 1** A 75 yo man underwent investigations for abdominal pain and weight loss. A CT scan showed a 70 mm solid lesion of the pancreas tail. A subsequent EUS confirmed the lesion and showed the presence of ascites, with hypoechoic nodules, suspicious for PC. A FNB of the pancreatic lesions was performed, together with ascites sampling and nodules biopsy with MF. Pathology evaluation reported extended necrotic carcinoma on nodules biopsies, compatible with PC.

**Case 2** A 64 yo woman underwent US and CT scan, showing PC, with unknown primary lesion. After negative EGD and colonoscopy, pt underwent EUS, showing ascites with omentum nodules, biopsied with MF. Pathology evaluation reported malignant cells on peritoneal nodules. Supplemental analysis for immunohistochemistry showed CK7, WT1 positivity and CK20 negativity, compatible with ovarian primitivity.

**Case 3** A 77 yo woman underwent staging EUS for a focal solid lesion of the pancreatic tail, with abundant peri-hepatic and pelvic fluid. Since the finding of ascites with irregular peritoneal nodular-like lesions, with hypo-enhancement after contrast medium injection, a MF biopsy was performed, for micro-histology. Pathology evaluation of both pancreatic lesion FNA and MF biopsy showed pancreatic ductal adenocarcinoma.

**Conclusion:** This is the first experience reporting a micro-histology forceps in the ascites work-out to rule out PC. The technique, using this through-the-needle device, is feasible and safe, with technical success rate of 100%. It allowed to sample peritoneal irregularity, with high quality tissue fragments in all the cases, giving the opportunity for additional assessment, as immunoistochemical staining.

**Introduction:** Pseudoachalasia is an infrequent secondary form of achalasia which can result from malignant or benign tumors, postoperative complications or paraneoplastic syndromes. Management can be vastly different between achalasia and pseudoachalasia, making it important to exclude the latter condition. Esophago-gastro-duodenoscopy (EGD), high resolution manometry (HRM), barium esophagram, CT scan and EUS play complementary roles to procure a diagnosis of achalasia and exclude pseudoachalasia. This is one of the few studies that aims to evaluate the role of EUS in excluding pseudoachalasia for patients referred for achalasia workup.

**Aims & Methods:** Data was collected retrospectively from hospital electronic records from 2008 to 2015. Our study group comprised 77 patients (female=44, male=33) with a mean age of 62 years. All cases had a prior EGD and EUS performed. Only cases with a non-diagnostic EGD (including negative esophageal biopsies) were included. Cases with obvious mass seen on EGD were excluded. Work up included the following: (A) classic achalasia symptoms, (B) normal EGD, (C) positive HRM +/- barium for achalasia/gastro-esophageal junction outflow obstruction (GEJ-OO) and (D) had CT scan performed. Yield of excluding pseudoachalasia with addition of EUS was analysed in 4 groups: (1) A+B, (2) A+B+C, (3) A+B+D and (4) A+B+C+D. Cases referred without information on manometry, barium or CT findings were excluded appropriately in the subgroup analysis. Surveillance was performed within 6-12 months to detect any missed cases of pseudoachalasia. Statistical analysis was performed using SPSS V20 using the McNemar Chi-Square and Cochran's Q.

**Results:** Almost all patients (98.7%) had dysphagia as one of the main symptoms. EGD was non-diagnostic in all cases. EUS was performed in all patients. Number of pseudoachalasia cases detected in Group (1)[n=77], Group (2)[n=53], Group (3)[n=38] and Group (4)[n=26] were 0, 0, 3 and 0 respectively. With addition of EUS (Table 1), incremental detection of pseudoachalasia in these respective cohorts were 7.8% (p=0.031), 1.9% (p=NS), 0% (p=NS) and 0% (p=NS). EUS showed a sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 85.7%, 100%, 100% and 98.6%. There was only 1 case of pseudoachalasia that was not picked up which manifested 2 years later. Other modalities (B, C and D) complemented each other to give excellent values of sensitivity, specificity and NPV (Table 2).

**Conclusion:** In excluding pseudoachalasia, addition of EUS to a well complemented workup (typical symptoms, EGD, HRM and/or CT scan) may not yield statistically significant benefit. However, EUS demonstrated good sensitivity and excellent specificity, PPV and NPV for pseudoachalasia detection clinically and should be considered on a case-by-case basis especially in any diagnostic dilemma.

**Disclosure:** Nothing to disclose

## P1642 THE THICKNESS OF THE FNA NEEDLE CONTRIBUTING TO THE PROCEDURES AND HISTOLOGICAL RESULTS BY EUS-FNA

Masaki Y., Kawakami Y., Ishigami K., Ito A., Akutsu N., Motoya M., Sasaki S., Nakase H.

Sapporo Medical University, Gastroenterology and Hepatology, Sapporo, Japan

**Contact E-Mail Address:** yoshiharu.masaki@gmail.com

**Introduction:** Recently, the newly franseen shaped EUS-FNA needle has been used in worldwide. However, it remains unclear which gauge needles are optimal for the improvement of the diagnostic yield with biopsy specimens.

**Aims & Methods:** The aim of this study is to whether the thickness of the FNA needle affects procedures of EUS-FNA or histopathological diagnosis. We retrospectively enrolled the patients whose EUS-FNA were performed in our hospital between December 2017 and May 2019. Thirty-two and fifty-one patients underwent EUS-FNA by using 19G and 22G franseen shaped

needle, respectively. We investigated the difference in the success rate of histopathological diagnosis between these two groups. Additionally, we analyzed clinical characteristics (age, sex, clinical diagnosis, target site, puncture tract, the number of punctures, the success rate of string like tissue sampling, the success rate of histopathological diagnosis) to identify the factors contributing to an accurate diagnosis. The Pearson  $\chi$  test or the Fisher exact test was used for the categorical variables, whereas Student's t-test or Mann-Whitney U test was used for continuous data. Multivariate analysis was performed for the factors which showed  $p \leq 0.20$  by univariate analysis.

**Results:** With regard to clinical characteristics, there were no statistical differences in age, sex, clinical diagnosis, and target site ( $p = 0.55, 0.10, 0.70, 0.06$ , and  $0.06$ , respectively). In the 19G group, the mean number of punctures was significantly lower than that in the 22G group (1.81 vs 2.21,  $p = 0.04$ ). The success rate of string like tissue sampling and histopathological diagnosis didn't show significant differences between these two groups ( $p = 0.94$  and  $0.21$ , respectively). We could not identify the significant factors by multivariate analysis, while younger age could contribute to accurate diagnosis by univariate analysis ( $p = 0.036$ ).

**Conclusion:** EUS-FNA using 19G franseen shaped needle could have the advantage of achieving the accurate histopathological diagnosis by a significantly smaller number of punctures in comparison with the 22G franseen needle.

## P1643 CYTOLOGICAL ANALYSIS BY ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE BIOPSY IN SAMPLING SOLID GASTROINTESTINAL LESIONS: A FEASIBILITY STUDY

Grech M.G., Saliba G., Azzopardi N., Gerada J.,  
Mater Dei Hospital, Gastroenterology, Msida, Malta

**Contact E-Mail Address:** jurgen.gerada@gov.mt

**Introduction:** Anecdotal results suggest FNB (fine needle biopsy) needles, used for tissue acquisition during endoscopic ultrasound (EUS), yield just as good results when cytological evaluation was performed, as it does with histological analysis.

**Aims & Methods:** We studied the feasibility of FNB needle (ProCore®, Cook) to obtain samples for cytology analysis. 29 randomly selected patients who underwent EUS-guided FNB of a solid gastrointestinal lesion, with sampling taken for both cytological and histological analysis, between 2016 and 2018, were retrospectively enrolled. Positive cytology was defined as adequate material for interpretation, following either of these cytological techniques: rapid on-site evaluation, sample in fixative or cell block. Data was collected through the medical notes.

**Results:** 29 patients (59% males, mean age 66) had EUS-FNB of a gastrointestinal lesion (pancreas 80%; others 20%). Positive cytology was obtained in 24/29 cases (83% sensitivity), 23 of which had correct diagnosis (23/24; 96% specificity). Positive histology was obtained in 20/29 cases (69% sensitivity), 19 of which had correct diagnosis (19/20; 95% specificity). Analysing malignant cases only (20), sensitivity was 90% (18/20) and 65% (13/20) for cytology and histology respectively. 5 cases were diagnosed cytologically but not histologically.

**Conclusion:** This small feasibility study confirms that EUS-FNB needle samples can be sent for cytological analysis. The high sensitivity and specificity of cytology, which in this cohort were even higher than histology, suggests that cytology should be included when EUS-FNB is performed. Sending samples for cytology and histology using 1 needle would increase the yield, while remaining cost-effective. Larger studies are however needed to confirm this.

**Contact E-Mail Address:** giovanna.del.vecchio.blanco@uniroma2.it

**Introduction:** Endoscopic ultrasound (EUS) with fine needle aspiration (FNA) is a well-established technique for assessing lesions of the pancreas and biliary tract. Diagnostic yield of EUS-FNA varies according to the expertise of endosonographer ranging from 65% to >90%. ESGE guideline suggests to perform a formal training in EUS before starting supervised EUS-FNA. At least 20 to 30 EUS-FNAs with rapid on-site cytopathological examination (ROSE) are recommended to reach a diagnostic accuracy of 80%. Whether the absence of ROSE prolongs the learning period required to achieve a diagnostic accuracy ≥90% has not yet been defined.

**Aims & Methods:** Aim of the study was to evaluate the factors, including the absence of ROSE, influencing diagnostic accuracy of EUS-FNA in patients with suspected pancreato-biliary tumors in a tertiary center. From 2010 to 2018, 557 consecutive EUS-FNAs were carried out by a single operator under conscious/deep sedation using an echo endoscope (Olympus GFUCT140 or GFUCT180). EUS FNAs were carried out using a needle of different type (Echotip ProCore, Wilson-Cook, Expect TM Boston Scientific, Shark Core TM FNB Medtronic, Acquire Boston Scientific) and with different size (19, 20, 22 Gauge). All samples were fixed in formalin solution for histopathological assessment. In case of absence of clear findings of neoplasm, the sample was deemed as not diagnostic. All clinical data, sex, age, type and size of the needle, site of the lesion, number of passes, and sampling technique (with/without stilet) were prospectively recorded in an electronic database. EUS-FNA performance was defined on the basis of sensitivity, specificity and diagnostic accuracy calculated according to kind and size of the needle, site of the lesion, and progressive experience expressed in the number of procedures grouped in blocks of 50. Variables associated with diagnostic accuracy were evaluated by multivariate logistic regression analysis.

**Results:** Of 557 EUS-FNA, 308 were carried out for pancreato-biliary neoplasms. The final diagnosis was pancreatic cancer in 253 patients, cystic pancreatic lesion in 8 patients, primary and metastatic liver cancer in 5 patients, and cholangiocarcinoma in 17 patients. Overall sensitivity of EUS-FNA was 66% (95% CI: 60.8 - 71.8), specificity 100%, and diagnostic accuracy 69% (95% CI: 64.0 - 74.4). When tissue sampling was performed using a new fine needle biopsy (FNB) (Acquire/Shark needles), the diagnostic accuracy increased up to 90.5% (95% CI: 80.7 - 99.3). When EUS-FNA was targeted to both primary and metastatic lesions (33 patients) sensitivity raised to 98% (95% CI: 93.9 - 100). Diagnostic accuracy was influenced by the experience of the operator, reaching 87.5% after 250 procedures (95% CI: 78.8 - 96.2). Variables associated with diagnostic accuracy were FNB needle (OR 3.06; 95% CI: 0.94 - 9.94), operator expertise (OR 1.21; 95% CI: 1.02 - 1.43) and EUS-FNA of primary and metastatic sites (OR 9.67; 95% CI: 1.27 - 73.75). No EUS-FNA-related complication occurred during the study period.

**Conclusion:** EUS-FNA is a safe procedure with high diagnostic accuracy in pancreato-biliary neoplasms. The diagnostic accuracy increases during the learning curve period, being necessary at least 250 EUS-FNAs to achieve a good (>85%) value in the absence of ROSE. The new FNB needles seem to strongly improve EUS performance.

## P1645 STUDY ON COMPLICATIONS OF EUS-FNA IN CASES TAKING ANTITHROMBOTIC DRUGS

Tsunevoshi K., Iwaya H., Hashimoto S., Tanoue S., Ido A.  
Kagoshima University Graduate School of Medical and Dental Sciences,  
Digestive and Lifestyle Diseases, Kagoshima, Japan

**Contact E-Mail Address:** t-kengo@m3.kufm.kagoshima-u.ac.jp

**Introduction:** Endoscopic examinations under antithrombotic medication have been performed with increasing frequency in recent years, and there have been a few reports of bleeding after EUS-FNA [Endoscopic Ultrasound-Fine Needle Aspiration]. We retrospectively examined bleeding and complications after EUS-FNA among users of antithrombotic drugs in our institution.

**Aims & Methods:** The subjects were 665 consecutive patients (February 2013 to January 2019) who underwent EUS-FNA according to the BSG and ESGE guidelines 2016 for users of antithrombotic drugs.

(1) We divided the patients into two groups according to the preoperative intake condition, (antithrombotic drug group and non-antithrombotic group) and examined the bleeding rate and technique related factors.

(2) The antithrombotic group was further divided into four groups: a continuation group, a withdrawal group (a withdrawal of more than 24 hours before surgery), an aspirin or cilostazol substitution group, and a heparin substitution group.

Direct oral anticoagulants (DOAC) are recommended to be discontinued for more than 48 hours according to the guidelines, and were included in the withdrawal group.

The definition of hemorrhage was a decrease of Hb  $\geq 2$  g/dl within 24 h after the operation according to the guidelines of the International Society for Thrombosis and Hemostasis.

**Results:** The puncture site of the lesion was pancreas in 474, liver in 7, lymph node in 67, digestive tract in 83, and other organs in 34.

A total of 98 patients in the antithrombotic group, and 567 in the non-antithrombotic group, had a significantly higher proportion of men in the group ( $p = 0.002$ ), had a significantly higher proportion of the age in the group ( $p < 0.001$ ). There were no significant differences in the number of punctures, in the puncture sites between the 2 administration groups ( $P = 0.228$ ,  $P = 0.248$ ). The overall incidence of FNA complications was 16 cases (2.4%), 4 cases of bleeding, 6 cases of hematoma, 2 cases of pseudocyst, 1 case of pancreatitis, 2 cases of peritonitis, and 1 case of intraabdominal abscess. There were 1 case (1.0%) and 3 cases (0.53%) of bleeding in the antithrombotic and non-antithrombotic groups, and there was no association ( $P = 0.472$ ).

(2) The antithrombotic drugs consisted of antiplatelet drugs in 69, anticoagulants in 25, and concomitant medication in 4. There were 28 patients in the continuation group, 34 in the drug holiday group, 18 in the aspirin or cilostazol substitution group, and 18 in the heparin substitution group. The bleeding rates in the continuation group, withdrawal group, aspirin or cilostazol substitution group, and heparin substitution group were 0% (0 case), 0% (0 case), 5.6% (1 case), 0% (0 case) being highest in the aspirin or cilostazol substitution group ( $P = 0.213$ ). No bleeding was observed in patients taking direct oral anticoagulants.

**Conclusion:** Rates of bleeding and complications after EUS-FNA were similar to those previously reported. Hemorrhaging was more frequent in the aspirin or cilostazol replacement group than in the other groups but improved with conservative treatment. Even in patients taking antithrombotic drugs, the risk of bleeding is low, and it may be possible to safely perform EUS-FNA.

**Disclosure:** Nothing to disclose

## P1646 INCIDENCE AND RISK FACTORS ASSOCIATED WITH BLEEDING POST ENDOSCOPIC ULTRASOUND FINE NEEDLE ASPIRATION/BIOPSY (EUS-FNA/FNB) OF SOLID AND CYSTIC PANCREATIC MASSES

Razpotnik M., Bota S., Essler G., Weber-Eibel J., Peck-Radosavljevic M. *Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt am Wörthersee, Austria*

**Contact E-Mail Address:** marcel.razpotnik@gmail.com

**Introduction:** Endoscopic ultrasound fine needle aspiration/biopsy (EUS-FNA/FNB) is an established technique for pancreatic tumor evaluation and considered a high risk bleeding procedure.

**Aims & Methods:** The aim of this study was to assesses the bleeding rate of EUS-FNA/FNB of solid and cystic pancreatic masses according to use of antithrombotic agents and coagulations parameters (platelet count and prothrombin time).

Our retrospective analysis included EUS-FNA/FNB of solid and cystic pancreatic masses performed between 01/2017-03/2019 in our newly established GI-Department, which features a centralized endoscopy-service in a University affiliated tertiary care teaching hospital.

Bleeding rate was assessed separately for solid pancreatic masses and pancreatic cysts. Parameters analyzed regarding the occurrence of bleeding were: age, use of acetylsalicylic acid (ASA), low molecular heparin (LMWH) or other antithrombotic/anticoagulant agents, platelets count, prothrombin time, and use of EUS-FNB needles.

**Results:** 115 patients were included into this analysis (76 with solid and 39 with cystic pancreatic masses). Only EUS-FNA was used for pancreatic cysts. EUS-FNA was used in 88.1% of cases with solid pancreatic masses. No bleeding was observed by EUS-FNA of pancreatic cysts. ASA was present in medication at EUS-FNA in 9/39 (23.1%) of these patients and LMWH in 3/39 (7.7%) cases. Platelets were lower than 100.000/mm<sup>3</sup> in one case (2.5%) and prothrombin time < 60% in 5/39 (12.8%).

Bleeding with hemodynamic instability was not observed in our cohort of EUS-FNA/FNB of solid pancreatic masses. In one case (1.3%) bleeding from a vessel from the duodenal wall was observed with Doppler-US and immediately treated with a hemoclip. In 8/76(10.5%) cases slight intraluminal bleeding with spontaneous termination was registered.

The use of EUS-FNB needles and biopsy in ASA-users trend to increase the bleeding rate in patients with solid pancreatic masses.

Factor	Patients without bleeding (n=67)	Patients with any type of bleeding (n=9)	p value
Age (years)	65.6±14.1	64.8±16.9	0.88
Use of antithrombotics			
- Acetylsalicylic Acid (%)	16.4	44.4	0.12
- LMWH (%)	13.4	11.1	0.73
Platelets (cells/mm <sup>3</sup> )	260.9±78.7	266.7±76.7	0.83
Prothrombine time (%)	90.1±15.9	81.3±18.9	0.13
Use of FNB needles (%)	8.9	33.3	0.08

[Table: Risk Factors associated with Bleeding post EUS-FNA/FNB of Solid and Cystic Pancreatic Masses]

**Conclusion:** No bleeding was observed post EUS-FNA of pancreatic cysts. Slight bleeding was observed in 11.8% of EUS biopsies of solid pancreatic masses, but no hemodynamic relevant bleeding occurred. Only in one case a hemoclip was needed to stop bleeding. Use of EUS-FNB needle and ASA trend to increase the bleeding rate.

**Disclosure:** Nothing to disclose

## P1647 GASTROINTESTINAL SUBEPITHELIAL LESIONS (GI SELS): OPTIMIZING UNNECESSARY SURVEILLANCE AND PATIENT CARE WITH ENDOSCOPIC ULTRASOUND (EUS)

Chia C.T.W.<sup>1</sup>, Lim W.C.<sup>2</sup>, Vu C.<sup>2</sup>

<sup>1</sup>Tan Tock Seng Hospital, Gastroenterology & Hepatology, Novena, Singapore,

<sup>2</sup>Tan Tock Seng Hospital, Gastroenterology & Hepatology, Singapore, Singapore

**Contact E-Mail Address:** tzechris@gmail.com

**Introduction:** Upper GI subepithelial lesions (SELs) are commonly found during oesophagogastroduodenoscopy (OGD) and most are <2cm on average. Management of these small SELs are often variable by different centres. Many patients are routinely brought back for frequent 1-2 yearly surveillance despite being asymptomatic and this significantly escalates health care cost without benefit to patients or actual improvement in clinical management if the SELs are small and stable.

**Aims & Methods:** We aim to determine the outcome of these small but frequently seen SELs based on a retrospective analysis of a cohort of SEL cases followed prospectively. Patients with SELs < 2cm and no change in GI symptoms from 2007 up to 2016 with OGD and EUS done were analyzed in terms of demographic characteristics and size progression of SEL, lymph node presence and eventual change in management from first detection right up to the last OGD/EUS surveillance. Cases with less than 3 years of follow up were excluded for meaningful analysis. Analysis using paired sample T-test for mean SEL size was done using SPSS.

**Results:** There was 210 patients ranging from 29-83 years of age, 61% being female. Average follow up range from 3 to 11 years with mean of 6 years. SEL size on index EUS and final EUS range from 3-19mm and 2-20mm respectively. The SEL distribution comprised 72% gastric and 18% esophageal origin.

Of all cases, 62% , 28% and 10% were found on EUS to arise from muscularis propria (MP), muscularis mucosa (MM) and submucosa of the GI tract respectively. About 10% underwent fine needle aspiration (FNA) with none being malignancy. Only 1 case demonstrated an increase in size of more than 50% but less than 100% over 3 years. All other SELs had fluctuations in mean size of < 33% or size regression and was deemed overall stable by endosonographer.

There was no significant difference between the initial mean size of these SELs on index EUS compared to final mean size on the last EUS (p=0.288). There was 0% mortality related to all these SELs.

**Conclusion:** This study suggests small GI SELs < 2cm can generally adopt a longer interval surveillance from baseline and may not need continuous yearly/biyearly surveillance if the initial repeat EUS is stable compared to the index scope, done within 3 years. A reasonable surveillance sequence proposed include 1 year followed by 3 years and then every 5-10 yearly if SEL remains stable and patient has no new GI symptoms. This has potential to reduce health care cost and growing endoscopy burden without sacrificing important clinical outcomes for patients.

**Introduction:** Endoscopic ultrasound (EUS)-guided biliary drainage (BD) is gaining a primary role for endoscopic palliation of malignant common bile duct obstruction. Lumen apposing fully covered metal stents (LAMS) are now replacing self-expandable metal stents (SEMS), commonly used for this procedure in the past.

**Aims & Methods:** The aim of this systematic review and meta-analysis was to evaluate the efficacy and safety of LAMS vs SEMS for biliary drainage via endoscopic ultrasound-guided choledochoduodenostomy.

A meta-analysis was performed using the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) protocols. Three databases (PubMed, EMBASE and Google Scholar) were searched for studies containing data on EUS-guided choledochoduodenostomy. English language articles from inception to 03 February 2019 were checked against our predetermined eligibility criteria. Odds ratios (OR) and mean differences (MD) were pooled using the random effects model with the DerSimonian-Laird estimation and displayed on forest plots.

**Results:** A total of 29 studies were included containing data on 960 patients. LAMS and SEMS were evaluated in 4 and 25 studies, accounting for 174 and 786 patients, respectively. Overall, the pooled rate of clinical success was 82.1% [95% CI 76.3-86.7], and significantly higher for LAMS than SEMS (91.5% [95% CI 86.2-94.9] vs. 71.4% [95% CI 61.2-79.9,  $p < 0.001$ ). The overall technical success rate was 78.2% [95% CI 70.8-84.2], and significantly higher for LAMS than SEMS (93.4% [95% CI 60.5-79.0] vs. 70.6% [95% CI 61.2-79.9],  $p < 0.001$ ).

Both the procedure-related adverse events (AEs) and re-intervention rates were lower for LAMS than SEMS, although the rate of overall AEs was significantly higher for LAMS than SEMS (18.4% [95% CI 11.3-28.5] vs. 11.2% [95% CI 8.5-14.6],  $p < 0.001$ ).

**Conclusion:** LAMS outperformed SEMS in terms of efficacy of EUS-guided choledochoduodenostomy for biliary drainage. Their use was associated with less procedural AEs and fewer re-interventions when compared to SEMS placement, however, more post-procedure AEs occurred with LAMS when compared to SEMS. This most critical point requires further investigation.

**Introduction:** Endoscopic ultrasound guided fine needle biopsy (EUS-FNB) represents the current standard for obtaining a histological diagnosis of a pancreatic mass. 19G stainless steel needles are relatively rigid and technical difficulties due to the inability to advance the needle out of the endoscope often prevent tissue collection, especially for the transduodenal puncture route. Nitinol-based needles are more flexible and might decrease technical difficulties and thus increase diagnostic accuracy. In this prospective, multicenter, randomized, partially blinded study we compared the diagnostic value of those two needle types in patients with a solid pancreatic lesion.

**Aims & Methods:** Consecutive patients with a solid pancreatic mass were diagnosed with EUS-FNB using one puncture with each needle in a randomized fashion. Olympus EZ Shot 2 19G were used as steel needles and EZ Shot 3 Plus 19G were used for nitinol-based needles. Final diagnosis was made by histology and diagnostic procedures during follow up. Primary endpoint was diagnostic accuracy of each needle. Secondary endpoints included time for puncture, amount of tumor tissue obtained, and technical failure. Histological specimen were centrally reviewed by a pathologist blinded to the final needle type and final diagnosis. ClinicalTrials.gov Identifier: NCT02909530.

**Results:** Out of 46 prospectively recruited patients central pathological examination was available for 41. Diagnostic accuracy for the two needles combined was 87.8%. Diagnostic accuracy was 66% and 68% using the stainless steel and nitinol-based needle respectively. Analysis of diagnostic accuracy divided by transduodenal and transgastric route furthermore presented no significant difference. Time spent for puncturing was 137 +/- 61 seconds (mean +/- SD) for the stainless steel and 111 +/- 53 seconds for

the nitinol-based needle ( $p < 0.001$ ). Technical failure occurred in 3 (6.5%) cases using the stainless steel and in none using the nitinol-based needle. Postprocedural self-limited bleeding occurred in 2 (4%) cases.

**Conclusion:** Usage of a nitinol-based 19G needle failed to present a significant difference regarding diagnostic accuracy compared with a stainless steel needle in EUS-FNB of solid pancreatic lesions. Usage of a nitinol-based needle was faster and resulted in no technical failures.

**Disclosure:** Nothing to disclose

## P1650 ENDOSCOPIC ULTRASOUND GUIDED BIOPSY USING FRANSEEN NEEDLE: COMPARISON WITH EUS GUIDED FINE NEEDLE ASPIRATION

Shah R., Banka N.H., Patel T., Udawat P., Dhir V.

S L Raheja Hospital, Gastroenterology, Mumbai, India

**Contact E-Mail Address:** rahulshah@hotmail.com

**Introduction:** Current guidelines suggest that the EUS-FNB is equivalent to FNA and both tissue acquisition techniques may be utilised for cytopathological analysis. With the FNB technique there is a possibility of assessing tissue adequacy macroscopically obviating the need for ROSE. Possibility of immunohistochemistry in these samples aids classification of the neoplasia particularly in difficult cases. Reduction in number of passes would lead to fewer complications.

**Aims & Methods:** We performed a retrospective cohort study of patients with solid masses or lesions needing EUS-guided core biopsy between January 2018 and November 2018. All core biopsies were obtained using an Acquire™ Fine Needle Biopsy Device- 22 gauge (Boston Scientific Corporation, Natick MA, USA). This data was compared to the matched population in the previous year using the standard 22-25 gauge needle for FNAC. All patients having EUS-FNAC/FNB were evaluated for the study. Patients with cystic lesions based on EUS and other cross-sectional imaging data were excluded from the study. Details of the location of the lesion, size of the lesion, endoscopic ultrasound findings, type of tissue acquisition (transesophageal, transgastric, trans duodenal), tissue acquisition techniques (slow pull, fanning vs. suction), technical success, operator visual satisfaction on tissue acquisition, pathologist satisfaction, average passes, size of the core in FNB and final cytopathologist or histopathologic diagnosis with or without IHC were recorded.

**Results:** A total of 207 patients, 134 (64.7%) male and 73 (35.3%) female were included in this study. The mean age of the study population was 54.3 ± 11 years. 83 of these patients has FNB and 124 had FNAC. 148 (71.4%) of the biopsied lesions were located in the pancreas and 59 (28.6%) were extrapancreatic in location. Only 3/83 needed repeat biopsy for diagnosis in the FNB group vs. 17/124 in the FNAC group with average pass of 1 and 2.7 respectively. Notably 2/3 repeat biopsies in the FNB group were gastric wall thickening? Linitus plastica and the third was a retroperitoneal tumour with extensive necrosis. There were no significant complications in either group.

**Conclusion:** FNB sampling provides intact cores that provide better characterization of malignancy and improve the diagnostic accuracy for benign lesions. With extrapancreatic lesions (especially gastrointestinal stromal tumors, lymphoma, and neuroendocrine tumors), histology is crucial for reaching a diagnosis, as cytology alone cannot uniformly provide adequate architecture and cellular configuration. We encountered no procedure-related complications. In this large, single-center study, EUS-FNB performed with a novel Franseen-type biopsy needle proved to be an effective modality for tissue acquisition from all solid lesions. EUS FNB should replace FNAC in our opinion.

**Disclosure:** Nothing to disclose

## P1651 EUS-GUIDED SAMPLING OF PANCREATIC ADENOCARCINOMA: STANDARD VERSUS CORE NEEDLE WITHOUT ON-SITE CYTOPATHOLOGY

**Introduction:** With the development of the new core needles, fine needle biopsy (FNB) has emerged as an alternative to standard fine needle aspiration (FNA) for procurement of larger amounts of tissue. Several studies have been published so far on core needles, most of them coming from expert centers. Our aim was to compare the diagnostic adequacy and yield of a core versus standard needle, in a center without on-site cytopathology.

**Aims & Methods:** We enrolled all patients with a diagnosis of pancreatic adenocarcinoma admitted in our clinic over a period of 16 months, who underwent endoscopic ultrasound (EUS) guided tissue sampling using either standard EchoTip, or ProCore needle (Cook Medical). EUS examinations were carried out using a Pentax-Hitachi system using a linear probe. Final diagnosis was set by FNA/FNB, repeated FNA/FNB, surgery or long-term outcome. We compared the diagnostic adequacy of samples and the diagnostic yield for malignancy between the two groups - FNA versus FNB needle.

**Results:** Altogether 58 patients were enrolled, median age 62 years, 63.8% males. FNB using the core needle was done in 19/58 (32.8%) of patients, while the other 67.2% were punctured using FNA needle. Mean tumor size was 33 mm in the FNA group, and 33.9 mm in the FNB group. More pancreatic head tumors were sampled using an FNA needle - 51.3% versus 31.6%. Also, more 22G needles were used in the FNA group (46% vs. 37%). Diagnostic adequacy was achieved in 89% of FNA samples and 94% of FNB. Diagnostic yield for malignancy was slightly better for FNB - 89.5%, compared to FNA - 82.1%.

**Conclusion:** In our study, high diagnostic performance was achieved with both needles without on-site cytopathology, but the core one proved to be slightly better.

**Disclosure:** Nothing to disclose

## P1652 THE ON- DEMAND NUMBER OF NECROSECTOMY SESSIONS DURING LUMEN APPOSING METAL STENTS DRAINAGE IN WALLED-OFF PANCREATIC NECROSIS CANNOT BE PREDICTED

**Contact E-Mail Address:** andradaseicean@gmail.com

**Introduction:** The fully-covered stents lumen apposing metal stents (LAMS) are designed for one step placement and facilitates the direct endoscopic necrosectomy into the walled-off pancreatic necrosis (WOPN). However, the prediction of the number of necrosectomy sessions in these patients is not known.

**Aims & Methods:** To assess the possible prediction for the need of necrosectomy according to the amount of necrosis inside the WOPN assessed during endosonography (EUS).

This is a single center prospective analysis at a single tertiary referral center. There were enrolled patients with symptomatic WOPN (pain, infection or gastric or biliary outlet obstruction) with more than 4 weeks after the onset of acute pancreatitis. The amount of necrosis was assessed by EUS in the session of LAMS placement. There were noted the clinical success regarding LAMS placement, the number of necrosectomies, the need for additional drainage (pigtail stents), the complications and the survival rate. The need for necrosectomy was performed on-demand when fever or inflammatory biological markers raised after LAMS placement. The patients were discharged when the inflammatory markers normalized and they were followed-up monthly by abdominal ultrasound and by CT scan at three months.

**Results:** There were 28 patients included and more than half were infected. The median size of the WOPN was 108mm (IQR: 81-146). LAMS was successfully placed in all patients, without immediate complications following the procedure. Necrosis was present in all patients and one third of them had more than 50% of the WOPN cavity with necrosis. Necrosectomies were performed in 25/28 (89.2%) patients. The median number of endoscopic debridement sessions was 2 (IQR: 1-4). There was no statistically significant association between the size of the WOPN and number of necrosectomies performed (Spearman's  $r$  coefficient =153,  $p=0.427$ ) or between the amount of necrosis and the number of necrosectomies ( $p>0.05$ ). The median duration until stent removal was 36 days (IQR: 24 - 55 days). Overall, WOPN resolution at 3 months follow up was noted in 24/28 (85.7%) patients. Two patients died, one due to pseudoaneurysm bleeding and another with bleeding from gastric collateral circulation.

**Conclusion:** The size of WOPN and the amount of necrosis prior LAMS drainage of WOPN cannot predict the need for on-demand necrosectomy sessions.

**Disclosure:** Nothing to disclose

## P1653 OVER THE SCOPE CLIPS FOR EUS DUODENAL PERFORATION

El Bacha H.<sup>1</sup>, Prat H.<sup>2</sup>

<sup>1</sup>Hopital Ibn Sina / Université Mohamed V / Faculté de Medecine, Gastroenterologie et Hepatologie, Rabat, Morocco, <sup>2</sup>Hôpital Cochin Dept. of Gastroenterology, Paris, France

**Contact E-Mail Address:** elbachahicham@hotmail.fr

**Introduction:** EUS represent nowadays an essential tool the identification, staging sampling and follow-up of benign and malignant bilio-pancreatic lesions. Diagnostic endosonography has traditionally been associated with a very low rate of complications Perforation stay one of the most deemed complication in endoscopy and in EUS, although surgery allows simultaneous treatment of the perforation and of an associated biliary or pancreatic disorder, surgery is an invasive treatment carrying its own morbidity and mortality, especially when undertaken in a context of emergency. We wanted to assess the feasibility, efficacy and safety of the immediate endoscopic repair of EUS-induced duodenal perforations with over-the-scope clips and report our experience to determine whether this procedure can be recommended in such cases.

**Aims & Methods:** We performed a retrospective study of patients with EUS related iatrogenic perforation observed in our unit from 2011 to 08/2018. We included all consecutive patients with EUS related perforation with immediate diagnosis, and receiving a conservative endoscopic management. Patients with primary surgical management and conservative, non-interventional management, as well as perforation resulting from an endoscopic intervention (eg endoscopic sphincterotomy, cyst fenestration, etc), were excluded.

**Results:** 13 perforations in 8504 EUS procedure occurred (0.15%).

Two patients were excluded, one for a large duodenal tear requiring immediate surgery, the other one for misdiagnosing the perforation leading to early discharge and readmission 24h later with peritonitis and emergency surgery.

A total of 11 patients were included, all women. The mean patient age was 75 (range 68-88) years. 8/11 (72.7%) perforations were due to a radial probe. All procedures were performed at a diagnostic end.

Perforations were located in the superior flexure of the duodenum in 9/11 (81%), in the descending part of the duodenum 1/11(9%), and in the inferior duodenal flexure 1/11 (9%). The size of the defect was ranged from 10-15mm. All clipping procedures experienced a technical and clinical success. 3/11(27%) had a stay in intensive care unit for less than 72h, total hospital stay ranged from 3-22 days.

**Conclusion:** Although bearing a low rate of specific complications, diagnostic EUS is not adverse event-free and observing proper indications is necessary, especially in elderly patients. Duodenal perforation is a potentially serious adverse event, but conservative endoscopic treatment with over-the-scope clips represents a feasible, efficient and safe treatment that can prevent surgery in most instances.

**Disclosure:** Nothing to disclose

## **P1654 COMPARISON OF DIAGNOSTIC OUTCOMES OF TWO DIFFERENT CORE NEEDLES FOR EUS GUIDED TISSUE ACQUISITION: 22-GAUGE REVERSE BEVEL VERSUS 22-GAUGE FRANSEEN NEEDLE**

**Contact E-Mail Address:** jeevinesh@outlook.com

**Introduction:** Endoscopic Ultrasound (EUS) guided tissue acquisition of lesions adjacent to the gastrointestinal tract has been previously achieved by fine needle aspiration (FNA). Recently, core biopsy from EUS guided approach has been successfully performed with the new tip-modifying needles, known as fine needle biopsy (FNB) needles. The first of these was the reverse bevel needle known as ProCore™ (Cook Medicine). The more recently developed core needles include the franseen-tip needle (Acquire™, Boston Scientific) and fork-like tip needle (Sharkcore, Metronics). Although the use of these core needles obtained more tissue and is associated with a better diagnostic yield than the FNA needles, data on diagnostic outcome between these core needles are lacking.

**Aims & Methods:** To compare diagnostic outcomes of EUS guided tissue acquisition between the 22-gauge Cook ProCore™ and the 22-gauge Boston Scientific Acquire™ needles.

This is a prospective evaluation of consecutive patients who were referred for EUS tissue acquisition of lesions of at least 1cm adjacent to the upper GI tract. Biopsy was performed without the presence of on-site cytology and two needle passes were taken from each lesion, with one pass from a 22-gauge ProCore needle and one pass from a 22-gauge Acquire needle. The order of the needle was randomized. Macroscopic On-Site Evaluation (MOSE) was performed to examine the adequacy of the acquired tissue and the samples from each needle were sent in separate pots for histology. Core was defined as whitish tissue and the length of the core was measured to be 3 times that of the width. Final diagnosis was based on either surgical specimen or from biopsy specimen with at least 6 months clinical follow up.

**Results:** A total of 78 needle passes were taken from 39 lesions, including 24 pancreatic lesions, 6 lymph nodes, 4 subepithelial lesions, 3 biliary masses, 2 liver lesions and 1 GB mass. The mean size of the lesions was 27±9mm. Overall, tissue diagnosis was achieved in 38/39 lesions, giving a diagnostic accuracy of 97%, which included 21 pancreatic cancers, 8 metastatic cancers, 2 pancreatic neuroendocrine tumour, 2 GIST, 2 leiomyoma, 1 focal pancreatitis, and 3 reactive nodes. There was no difference in diagnostic yield between the two needles (Procore = 90% (35/39) vs. Acquire = 95% (37/39); P=0.97). In 3 patients, the Acquire needle provided a diagnostic sample whereas the ProCore did not. In one patient, the ProCore needle provided a diagnostic sample whereas the Acquire did not. Both needles were unable to obtain an adequate sample for a retrocardiac lymph node. Based on MOSE, the core length of tissue taken from the Procore needle was longer than that of the Acquire needle (14.6mm vs. 12.8mm, P=0.038). This, however, this did not contribute to an increase in diagnostic yield

**Conclusion:** This tandem EUS guided biopsy study showed that, even in the absence of rapid on-site cytology, the diagnostic accuracy from 2 passes of FNB needles is high (97%), and there is no difference in the diagnostic yield between the reverse bevel and franseen tip needles. These findings support the use of these new FNB needles in routine EUS guided tissue acquisition.

**Contact E-Mail Address:** catarina.rib.gomes@gmail.com

**Introduction:** Currently, a validated scale for grading small-bowel cleansing in capsule endoscopy (CE) is lacking. The computed assessment score of the small-bowel cleansing (CAC) is based on objective measurements of color intensities (red over green) in the Rapid Reader® of the PillCam® CE system. Areas of adequate mucosal visibility should be associated with high values of red intensity and areas of inadequate mucosal visibility associated with low values of green intensity. The CAC score was adapted to Mirocam® MC1200 system by Ponte et al, being considered an objective and feasible score in the assessment of small-bowel cleansing. About Ali et al, considered a CAC score cut-off of 1.6 to best discriminate adequately from inadequately cleansed frames. Recently, Mirocam® system created a new informatic software (MC1600) which enables capturing around 6 frames per second, comparing with the 3 frames per second in MC1200.

**Aims & Methods:** This study aimed to adapt the CAC score to the Mirocam® MC1600 system and evaluate the correlation of this computed score with Brotz grading scales (Quantitative Index - QI and Qualitative Evaluation - QE) in the old CE MC1200 and in the new CE MC1600. The authors performed a retrospective single-center analysis of CE Mirocam® MC1200 and MC1600. Patients with active bleeding and whose capsule did not reach the cecum were excluded from the study. The first duodenal image and the first cecal image were selected from all CE videos, and all the remaining findings were deleted. Map View function displays a bar circumscribed by a blue line which represents the small bowel images. The histogram function of GIMP® was used to measure the mean intensity value of the green and red channels. Afterwards, these values were entered into a database and the CAC score were determined according to the Weyenberg et al formula. The correlation between the CAC scores and the 10 points QI was performed using Spearman's correlation coefficient. The CAC scores and the 4 grades QE were compared using the intra-class correlation coefficient (ICC).

**Results:** 73 CE videos were analyzed referring to 73 patients, 53.4% were male (n=39), with a mean age of 54.2 (± 18.8) years-old. 58.9% (n=43) of the CE videos were performed with the MC1600, and 41.1% (n=30) with the MC1200. The main indication was OOGIB in 61.6% (n=45), followed by suspected Crohn's disease (CD) in 32.9% (n=24). The sex, age and indication to perform CE did not show to be different between the 2 softwares (p=0.23, p=0.06 and p=0.29, respectively). The QI (New: 8.16 vs. Old: 7.87, p=0.44) and a poor QE (New: 11.6% vs. Old: 6.7%, p=0.89) did not differ between the 2 softwares. On the other hand, the CAC score was higher with the MC1600 version (5.62 vs. 4.95, p=0.03). With the MC1600 version, a poor correlation between QI and CAC score was found with a Spearman's Rho of 0.36 (p< 0.05), and a poor correlation between QE and CAC score was found with an ICC of 0.15 (CI 95% = -0.11 to 0.44, p = 0.01). With the MC1200 version, a fair correlation between QI and CAC score was found with a Spearman's Rho of 0.48 (p< 0.01), and a poor correlation between QE and CAC score was found with an ICC of 0.21 (CI 95% = -0.18 to 0.56, p = 0.03).

**Conclusion:** The new software (MC1600) presented higher CAC scores, which could be of great importance since this score allows a more objective assessment of small-bowel cleansing. With this new software version, the authors were not able to verify a better correlation between this computed assessment and the Brotz grading scales.

**Contact E-Mail Address:** hanyee99@hanmail.net

**Introduction:** Although small bowel capsule endoscopy (SBCE) has become the best diagnostic modality for small bowel lesion, time-consuming and tedious review process leads to low diagnostic yield.

**Aims & Methods:** The aim of this study was to develop a convolutional neural network (CNN) algorithm for automatic detection of various small bowel lesions. A total of 3,313 still images containing pathology findings were collected from 389 SBCE videos. These were classified into two categories by expert readers: vascular lesion (red spot/angioectasia/active bleeding) and depressed lesion (erosion/ulcer/stricture). A VGG-like CNN [1] (14 convolutional, 7 max-pooling and 2 fully-connected layers) was implemented to extract features which carry principal characteristics of an input image in both categories. Then we combined the two different binary classification models (normal-vascular and normal-depressed) not only to detect two types of lesions from each model, but also to yield conservative negative. Furthermore, we visualized where the detected lesions are, class activation map (CAM), by calculating contributions of each pixel in a feature to the classification result [2].

**Results:** The algorithm for detection of vascular lesions yielded a sensitivity of 88.3%, a specificity of 97.3%, a positive predictive value of 97.0%, a negative predictive value of 89.3%, and an accuracy of 92.8%. The algorithm for detection of depressed lesions revealed a sensitivity of 88.9%, a specificity of 95.6%, a positive predictive value of 95.2%, a negative predictive value of 89.6%, and an accuracy of 90.0%. We combined these two algorithms in the way that a normal image was defined when it was not classified as a pathology image by either vascular or depressed lesion detection algorithm. As a result, the combined algorithm yielded a sensitivity of 91.4%, a specificity of 93.2%, a positive predictive value of 93.1%, a negative predictive value of 91.6%, and an accuracy of 92.3%. Furthermore, CAM accurately pinpointed lesion parts from the pathology images, which means that it colored the lesion parts red but non-lesion parts blue.

**Conclusion:** Our CNN algorithm showed high diagnostic performances for detecting various lesions of SBCE. Visualization of the relevant lesions by CAM could help to reduce missed detection with the naked eye.

**Introduction:** Visualization of the mucosa in Small bowel capsule endoscopy (SBCE) is frequently impaired by intestinal contents (e.g. food residue, air bubbles and unclear turbid intraluminal fluid), more often in the lower small intestine where we tend to encounter more endoscopic and pathological findings. A meta-analysis had shown that small-bowel purgative preparation (polyethylene glycol solution or sodium phosphate) improves the diagnostic yield (Am J Gastroenterol 2009; 104: 219-227). The Canadian Association of Gastroenterology (CAG) and the European Society of Gastro-

intestinal Endoscopy (ESGE) does recommend the use of a bowel preparation (Gastroenterology. 2017 Feb;152(3):497. Endoscopy 2010; 42: 220-227.), but no specific preparation regimen is shown.

**Aims & Methods:** The aim of this study was to seek an appropriate preparation for SBCE. We reviewed a consecutive 340 patients (201:139/ male:female) who underwent SBCE from Jul. 2009 to Sep. 2017 in Okayama Saiseikai General Hospital and assessed retrospectively from the clinical record. SBCE was performed using the Given Imaging PillCam SB2 and SB3. For each SBCE, two segments of 10 minutes were selected, one at the last 10 minutes of the small intestine transit and one at the start of the last quartile of the small intestine transit time. Visibility of the SBCE image was assessed based on percentage of (or proportion) of 5 elements: (1) visualized mucosa, (2) fluid and debris, (3) bubbles, (4) bile/chyme staining, and (5) brightness.

Among 340 subjects, Group A followed the conventional overnight fast (n=58, 17.1%). Group B received 0.9L of magnesium citrate (MC) solution after the overnight fast, 2 hours prior to the endoscopy (n=84, 24.7%). Group C received 1-2L of polyethylene glycol (PEG) solution after the overnight fast, 2 hours prior to the endoscopy (n=29, 8.5%). Group D received 1-2L of PEG solution after the overnight fast before colonoscopy, and SBCE was performed immediately after the negative colonoscopy, but the duration was not assessable (n=117, 34.4%).

Group E received 0.18L of MC solution before the overnight fast (n=24, 7.1%). 28 subjects were excluded, 24 because the visibility was not assessable due to massive bleeding, unreached cecum, recording failure and 4 because of preparation unknown.

**Results:** The use of 0.9L of MC solutions led to a significant improvement in (4) bile/chyme staining (P=0.0101) and (5) brightness (P=0.0014). Also, (1) visualized mucosa (P=0.0826), (2) fluid and debris (P=0.0515), and (3) bubbles (P=0.0592) seemed to show a trend toward visibility improvement. All the patients in Group B were able to ingest the whole 0.9L solutions before the SBCE.

**Conclusion:** Comparatively low volume (0.9L) MC solution improves visual quality of SBCE and was feasible.

**Disclosure:** Nothing to disclose

## P1658 CAPSULE ENDOSCOPY FOR SMALL BOWEL CROHN'S DISEASE - SHOULD WE TRUST IN MAGNETIC RESONANCE ENTEROGRAPHY?

Xavier S.<sup>1,2,3</sup>, Boal Carvalho P.<sup>1,2,3</sup>, Dias de Castro F.<sup>1,2,3</sup>, Magalhães J.<sup>1,2,3</sup>, Rosa B.<sup>1,2,3</sup>, Moreira M.J.<sup>1,2,3</sup>, Cotter J.<sup>1,2,3</sup>

**Contact E-Mail Address:** smaxavier@gmail.com

**Introduction:** Currently, both small bowel capsule endoscopy (SBCE) and magnetic resonance enterography (MRE) can be used to assess small bowel involvement in Crohn's disease (CD). However, SBCE appears to be more sensitive in the detection of mild and proximal lesions.

**Aims & Methods:** We aimed to compare the diagnostic yield for SBCE and MRE.

Adult patients with either confirmed or suspected Crohn's disease who were submitted to both SBCE and MRE were retrospectively reviewed. Only patients performing SBCE and MRE within 3 months were included and patients with changes in CD therapy during this period were excluded. Presence of ulcers, villous edema and stenosis were assessed in SBCE, and patients with Lewis Score (LS)  $\geq 135$  were considered to have significant inflammation. SB wall thickening, hyperenhancement, edema, comb sign or presence of ulcers were considered signs of active CD in MRE.

**Results:** Included 30 patients (53.3% suspected and 46.7% confirmed CD) with a median age of 31 $\pm$ 11 years, 56.7% of which were females. Comparing SBCE and MRE, SBCE had a significantly higher diagnostic yield (90.0% vs 53.3%, p=0.007), with higher detection of ileal lesions (83.3% vs 53.3%, p=0.022).

Even more importantly, only SBCE identified jejunal inflammatory activity (46.7% vs 0.0%, p< 0.001). Despite the fact that statistical significance was not attained, SBCE identified 2 traversable strictures that were not identified by MRE (6.7% vs 0.0%, p=0.500) and out of 14 patients with suspected Crohn's disease, SBCE identified significant inflammation in 4 patients with negative MRE (85.7% vs 57.1%, p=0.289). MRE was more

likely to detect findings when SBCE showed moderate to severe inflammatory activity (LS  $\geq 790$ ) compared with those with mild inflammatory activity (LS 135-790) (72.7% vs 30.8%,  $p=0.041$ ).

**Conclusion:** In our cohort, SBCE showed a significant overall higher diagnostic yield than MRE, with higher detection of distal lesions and, more importantly, SBCE identified proximal lesions in nearly half of examination while MRE was unable to identify any case. MRE diagnostic yield was more heavily influenced by the severity of inflammatory activity, being significantly inferior to SBCE in patients with mild inflammatory activity.

**Disclosure:** Nothing to disclose

# P1659 VIDEO CAPSULE COLONOSCOPY: MAY THERE BE PREDICTORS OF COLORECTAL POLYPS FINDINGS AFTER INCOMPLETE CONVENTIONAL COLONOSCOPY?

Macedo Silva V.<sup>1,2,3</sup>, Magalhães R.<sup>1,2,3</sup>, Rosa B.<sup>1,2,3</sup>, Boal Carvalho P.<sup>1,2,3</sup>, Moreira M.J.<sup>1,2,3</sup>, Cotter J.<sup>1,2,3</sup>

<sup>1</sup>Hospital Senhora da Oliveira, Gastroenterology Department, Guimarães, Portugal, <sup>2</sup>Life and Health Sciences Research Institute, University of Minho, Braga/Guimarães, Portugal, <sup>3</sup>ICVS/3B's, PT Government Associate Laboratory, Braga/Guimarães, Portugal

**Contact E-Mail Address:** rui.magalhaes.med@gmail.com

**Introduction:** Even though conventional colonoscopy remains as the first line approach in colorectal polyps detection, Video Capsule Endoscopy (VCE) may play an important role on further investigation after an incomplete colonoscopy.

**Aims & Methods:** Our aim was to evaluate the existence of predictive factors for colorectal polyps detection by VCE on patients with previous incomplete conventional colonoscopy.

For that, a retrospective monocentric study of patients who underwent VCE after previous incomplete colonoscopy between April 2015 and January 2019 was carried out. Analyzed variables included age, gender, capsule's transit time in colon, previous hemoglobin, positive fecal occult blood test, personal history of colorectal polyps, familiar history of colorectal cancer, smoking habits, obesity, progression level on the incomplete colonoscopy and existence of previous complete colonoscopy. Mann-Whitney test was used for evaluation of continuous variables and Chi-square test for categorical variables.

**Results:** 59 patients were included, 49 being females (83.1%), with a median age of 68 (interquartile range of 18). Colorectal polyps were documented in 18 patients (30.5%), with sessile polyps prevailing (88.9% of the patients with positive findings). 17 of these patients (94.4%) presented polyps in locations not previously approached by the incomplete colonoscopy. Smoking habits (former or current) were significantly associated with the detection of colorectal polyps after incomplete colonoscopy (66.7% vs 26.0%;  $p=0.041$ ). Other analyzed variables did not show any statistically significant differences ( $p>0.05$ ).

**Conclusion:** VCE is a very useful technique to be used on further investigation of patients with previous incomplete conventional colonoscopy, allowing to detect colorectal polyps in around one-third of the evaluated patients. There was a significant association between smoking habits and colorectal polyps on VCE.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** jeanphilippe.lemouel@wanadoo.fr

**Introduction:** Small bowel (SB) capsule endoscopy (CE) is a standard for the examination of the SB in patients with occult gastrointestinal bleeding (OGIB) or suspicion of Crohn's disease. The detection of lesions in CE may be dependent on the quality of the visualization of the SB. Brotz et al. developed 3 different scores to assess the SB cleanliness: one quantitative score named Qualitative Index (QI); and two qualitative scores named Qualitative Evaluation (QE), and Overall Adequacy Assessment (OAA). After internal validation these 3 scores were considered as a reference. However, no external validation of any of these score has been performed to date. The aim of our study was to assess their reproducibility.

**Aims & Methods:** One hundred and fifty-five complete, third-generation SB-CE videos were analysed. These videos were extracted from a recent, randomized, controlled multicenter trial (PREPINTEST, NCT01267981); which evaluated three different modalities of preparation of SB, in 834 patients with OGIB; by selecting third-generation SB-CE from the 5 largest inclusion centres. All 155 videos were read twice, in a random order, at six-week interval, by three SB-CE expert readers. The 3 scores (QI, QE, OAA) were determined by each expert independently, using the definitions of the initial study:

- QI was based on a 10-point scale, with 2 points allotted to each of five items amongst mucosa visibility, fluid and debris, bubbles, bile/chyme staining, brightness;
- QE based on QI items but simplified, grading the cleansing of the SB as poor, fair, good and excellent;
- OAA was defined by the "adequacy" or "inadequacy" of the preparation. Linear weighted Cohen's Kappa were calculated to assess intra-observer and inter-observer reproducibility for each score.

**Results:** Intra-observer reproducibility was fair to moderate, with Kappa coefficients varying between 0.37-0.46, 0.41-0.51 and 0.41-0.50 for QI, QE and OAA, respectively.

Inter-observer reproducibility was fair to substantial correlation, with Kappa coefficients between experts varying between 0.40-0.64, 0.29-0.65 and 0.52-0.71 for QI, QE and OAA, respectively (Table 1).

	Qualitative index (QI) Mean (range)	Qualitative evaluation (QE) Mean (range)	Overall Adequacy Assessment (OAA) Mean (range)
First Reading (at week-0, random order)			
Expert 1 vs 2	0.49 (0.41 - 0.58)	0.48 (0.37 - 0.59)	0.52 (0.27 - 0.77)
Expert 1 vs 3	0.57 (0.49 - 0.66)	0.53 (0.42 - 0.64)	0.70 (0.48 - 0.91)
Expert 2 vs 3	0.55 (0.47 - 0.63)	0.65 (0.55 - 0.75)	0.66 (0.45 - 0.88)
Second Reading (at week-6, random order)			
Expert 1 vs 2	0.40 (0.30 - 0.49)	0.29 (0.17 - 0.40)	0.52 (0.34 - 0.71)
Expert 1 vs 3	0.46 (0.37 - 0.54)	0.43 (0.32 - 0.54)	0.67 (0.51 - 0.82)
Expert 2 vs 3	0.64 (0.57 - 0.71)	0.53 (0.42 - 0.65)	0.71 (0.57 - 0.86)

[Table 1: Inter-observer reproducibility of three scores assessing small bowel cleanliness in capsule endoscopy]

Specifically, some of the 5 QI items were poorly reproducible, and particularly the evaluation of the amount of bile and chime, with Kappa coefficient varying from 0.21 to 0.29 and from 0.16 to 0.34, for intra and inter-observer reproducibility, respectively.

**Conclusion:** One of the main preparation score used in research studies proved to be poorly reproducible whenever the same or a different reader was used as comparator. There is a major need for improved preparation scores to allow satisfying data analysis in small bowel capsule endoscopy.

## P1661 ACCURACY OF ARTIFICIAL INTELLIGENCE AIDED REPORTING IN VIDEO CAPSULE ENDOSCOPY

Hong Y.Y.<sup>1</sup>, Ninh A.<sup>2</sup>, Corbett G.<sup>1</sup>

<sup>1</sup>Cambridge University Hospital, Department of Gastroenterology, Cambridge, United Kingdom, <sup>2</sup>Docbot, California, United States

**Contact E-Mail Address:** hyouyi@yahoo.com

**Introduction:** Video Capsule Endoscopy (VCE) is primarily used for diagnostic examination for the area of small bowel, which cannot be assessed by conventional gastroscopy or colonoscopy. VCE offers a variety of advantages like being non-invasive, easily tolerable with small swallowed capsule, painless, sedation free, potentially avoidance of harmful radiation and invasive investigations.

However, the reviewing and examination of each VCE can be a tedious and time-consuming process, potentially taking up to 1-2 hours (depending on experience) of a Gastroenterologist time. A new Artificial Intelligence (AI) algorithm - Docbot CapsuleAI version 1.3, which consists of a multi-class convolutional neural network and pHash post-processing algorithms, was developed to highlight and present the potential clinically significant frames, with the aim to reduce the reviewing time and improve the accuracy of VCE reporting.

**Aims & Methods:** To examine the accuracy of this new AI aided reporting system (Docbot CapsuleAI version 1.3) in VCE.

50 anonymized VCEs (pre-reported by Gastroenterologists, inclusive of 40 VCEs with abnormal findings and 10 VCEs with normal findings) were selected to test the diagnostic accuracy of the new AI algorithm (Docbot CapsuleAI version 1.3) in aiding the reporting process. All the frames highlighted by AI, will be subsequently reviewed by 2 Gastroenterologists, to determine the sensitivity, specific and accuracy of the AI aided diagnostic system, against the gold standard of human reporting by Gastroenterologist.

**Results:** Out of the total 50 VCEs, the AI algorithm picked up an average total frame of 190 per VCE (Min=27, Max =417). There were lower number of average total frames picked up by AI for the normal VCEs = 168 Vs abnormal VCEs =195. For the abnormal VCEs, the average number of abnormal frames picked up by AI were 22.

Overall, this AI algorithm has the sensitivity of 95%, specificity of 100% with the accuracy of 96%, in picking up the clinically significant frames, for the final diagnostic reporting of VCE.

The AI algorithm has successfully highlighting clinically significant frames (ranging from normal, vascular lesion, ulcer, erosion, tumour, stricture, and inflammation) in 48 out of 50 VCEs. 2 VCEs with abnormal finding which were not picking up by the AI algorithm were small duodenal polyp and sub-mucosal lipoma.

**Conclusion:** The new AI algorithm has high sensitivity, specificity and accuracy in highlighting clinically significant frames to clinician, helping to improve time spent and accuracy of VCE reporting.

## P1662 WORLD'S LARGEST SERIES WITH CAPSOCAM®. FEASIBILITY, COMPLETION AND DETECTION RATE OF THE NEW GENERATION OF CAPSULE ENDOSCOPE WITH A 360° LATERAL PANORAMIC VIEW - A SINGLE CENTER RETROSPECTIVE STUDY

Pachofszky T., Holzmüller P., Madl C.

KA Rudolfstiftung, IV. Department of Internal Medicine with Gastroenterology, Hepatology, Endoscopy and Oncology, Vienna, Austria

**Contact E-Mail Address:** thomas.pachofszky@gmx.at

**Introduction:** Capsule endoscopy started in 2000 a revolution in diagnosing small bowel diseases. The first capsule endoscope was M2A® with one camera at one end of the capsule (Given Imaging, Yoqneam, Israel). It was the first time that direct visualization of the entire small bowel was possible. From this year onwards, we can see a rising number of examina-

tions and indications for capsule endoscopy. The drawback of the endview capsule is the limited view - PillCam SB3® (Medtronic, Dublin, Ireland) 156°, MiroCam® (IntroMedic, Seoul, Korea), 170°.

With the introduction of CapsoCam® (CapsoVision, Saratoga, CA, USA) with a lateral panoramic view of 360°, now we have a total view on the mucosa. Because of this 360° lateral panoramic view, we have the chance to get a better detection rate for capsule endoscopy.

**Aims & Methods:** The aim of this single center retrospective study was to compare the different capsule systems used at the KA Rudolfstiftung, Vienna, Austria (CapsoCam®, PillCam®, MiroCam®), in respect to visibility of the Papilla of Vater, completion rate, detection rate (defined as pathology identified according to the indication), loss of data because of technical problems, image quality, download and reading time of the 360° lateral panoramic view of CapsoCam® and the endview systems including PillCam® and MiroCam®.

Included are examinations from 2012 to 2018 with the CapsoCam® system including the three generations of SV1®, SV2® and CapsoCam Plus®: 852 (CapsoCam Plus®:516), and the PillCam SB2® and SB3®: 803 and MiroCam®: 315 - a total of 1970 examinations.

**Results:** Visibility of Papilla of Vater: CapsoCam® 81.7%; Endview 9.6%

Complete examination: CapsoCam® 97.4%; Endview 84.8%

Detection rate: CapsoCam® 51.3%; Endview 44.6%; p-value: 0.003901

Loss of data: CapsoCam® 3.1%; Endview 6%

Download time: CapsoCam® 15 min; PillCam SB3® 90 min; MiroCam® 35 min  
Reading time: CapsoCam® 15-20 min; PillCam SB3® 30-40 min; MiroCam® 30-40 min

**Conclusion:** CapsoCam® showed an excellent visibility of the Papilla of Vater at more than 80% and a complete examination of the small bowel at more than 97%. These numbers are the highest published data to this time. In our series, the CapsoCam® is superior in finding relevant pathologies according to the indication with a p-value of 0.0039

The main fear of experts about the loss of data because of the inability to retrieve the excreted CapsoCam® can be rejected. In our study we found twice the data loss in the endview group because of problems with the data recorder, SD-card or the sensor belt. With CapsoCam Plus® we have the same image quality as with the PillCam SB3®. Because of these data, the fastest download and reading time CapsoCam Plus® have a clear benefit compared with the established endview systems.

**Disclosure:** Consultant for Medtronic, Boston Scientific, CapsoVision

## P1663 HIGH-RISK FACTORS FOR GASTRIC RETENTION IN SMALL BOWEL CAPSULE ENDOSCOPY. A SINGLE CENTRE RETROSPECTIVE COMPARATIVE STUDY

O'Riordan F.<sup>1</sup>, Reidy M.<sup>1</sup>, Sim Yan En S.<sup>1</sup>, McNamara D.<sup>1,2</sup>, Wong J.<sup>1</sup>, Manoharan T.<sup>1</sup>, Semenov S.<sup>1,2</sup>, Omorogbe J.<sup>1</sup>, Ryan B.<sup>1,2</sup>, O'Connor A.<sup>1,2</sup>, Breslin N.<sup>1,2</sup>

<sup>1</sup>Tallaght Hospital/Trinity College Dublin, Gastroenterology, Dublin, Ireland,

<sup>2</sup>Trinity Academic Gastroenterology Group, Clinical Medicine, Dublin, Ireland

**Contact E-Mail Address:** fionaoriordan85@gmail.com

**Introduction:** Certain conditions and medications have been identified as risk factors for gastric capsule retention (GCR). ESGE guidance recommends the use a real-time viewer to guide appropriate early preventative intervention such as prokinetic administration when delayed gastric emptying occurs.

**Aims & Methods:** To examine the prevalence and associations of GCR in an Irish cohort and to compare findings against a control group. Patients with video confirmation of gastric retention for the duration of the study were identified from a small bowel capsule endoscopy (SBCE) database of 3078 cases. Using this database, we also retrospectively identified patients who underwent a SBCE immediately after each GCR patient without retention. These patients were used as controls. Demographic and clinical data was extracted from medical records. Cases and controls were compared using a chi<sup>2</sup> test, a p value of < 0.05 was considered significant.

**Results:** A total of 70 GCR cases were identified giving an occurrence rate of 2.3%. Data was available for 61 GCR and 55 control patients. There were more females than males in both groups; 36/61 (59.1%) GCR group and the 34/55 (61.8%) control group. The mean age was 58 years in both groups. In keeping with standard SBCE practice, the commonest indications for SBCE were iron deficiency anaemia [32/62(52%) GCR group and 20/55(36%) control group] and suspected Crohn's disease [15/61(25%) GCR group and 17/55(31%) control group].

There was significantly more patients with hypothyroidism in the GCR group 12/61 (20%) vs 4/55 (7%) than in the control group [ $P = 0.0438$ ]. There was no difference in the rate of diabetes [10/61(16%)] GCR group vs 9/55(16%) control group [ $P = 1.000$ ] nor psychotropic medication use [14/61 (23%) GCR group vs 16 (29%) control group [ $P = 0.4630$ ]]. While there were over twice as many patients 14/61 (23%) in the GCR group with more than one associated risk factor vs the control group 6/55 (11%) this was not statistically significant [ $P = 0.0894$ ]. Interestingly, there were significantly less current or ex-smokers 18/61 (30%) in the GCR group versus 28/55 (51%) in the control group [ $P = 0.0217$ ].

**Conclusion:** GCR was a relatively frequent occurrence in our large capsule population. In our cohort, only hypothyroidism was associated with an increased risk of GCR. Contrary to published data, older age, female gender, smoking, diabetes and use of psychotropic medications were not predictive. Our data suggests current predictive measures of GCR are inadequate and unlikely to accurately select patients for real time monitoring and appropriate early intervention. The role of multiple risk factors for GCR prediction warrants further evaluation.

**Disclosure:** Nothing to disclose

### P1664 EFFECT OF INTRAVENOUS METOCLOPRAMIDE ON SMALL BOWEL TRANSIT TIME DURING MAGNETIC CAPSULE ENDOSCOPY EXAMINATION: A PROSPECTIVE, RANDOMIZED STUDY

Schmiedt P.<sup>1</sup>, Lovasz B.D.<sup>2</sup>, Szalai M.<sup>1</sup>, Kiss E.<sup>3</sup>, Oczella L.<sup>1</sup>, Dubravcsik Z.<sup>4</sup>, Madacsy L.<sup>1</sup>

<sup>1</sup>Endo-Kapszula Health Center and Endoscopy Unit, Székesfehérvár, Hungary,

<sup>2</sup>Semmelweis University, 1st Department of Medicine, Budapest, Hungary,

<sup>3</sup>Szent Imre Hospital, Budapest, Hungary, <sup>4</sup>Bacs-Kiskun County Hospital, Gastroenterology & Endoscopy, Kecskemét, Hungary

**Contact E-Mail Address:** endomabt1@gmail.com

**Introduction:** Diagnostic yield with capsule endoscopy (CE) is limited by incomplete study due to slow small-bowel transit and poor view quality in the distal bowel. Prokinetics may increase gastric transit time, but currently, there are conflicting results regarding the effect of metoclopramide on small bowel transit time and optimal preparation protocol during CE.

**Aims & Methods:** aim of our present study was to investigate whether intravenous metoclopramide accelerates small bowel transit time and increases the completion rate of CE examination.

191 patients who underwent magnetic capsule endoscopy (MACE) after 6 hours of fasting period were randomized to receive either 5 mg intravenous metoclopramide (metoclopramide (MC) group: 103 cases) or no prokinetic treatment at all (control (C) group: 88 cases), after the completion of a 30 min automated gastric mucosal surface robotic examination protocol. During the small bowel examination period all patients in each group received 1000 ml PEG solution to improve visibility of the distal small bowel.

**Results:** PEG administration during CE resulted in an excellent small bowel and distal ileal mucosal visibility which was demonstrated in both patient groups without significant differences. Complete small bowel examination was detected in 100/103 (97%) in the MC group, and 87/88 (98%) of the C group, without significant differences. However, we demonstrated significant differences in the small bowel transit time between the MC and the C group, 3:07:41±1:57:47 vs. 4:03:01±1:52:19 ( $p=0.00007$ ), respectively.

**Conclusion:** Intravenous metoclopramide proved to have a significant effect on shortening the small bowel transit time, but it has no effect on the completeness of the entire small bowel visibility, which is due to the fact of long-lasting operation time and possibility of active pyloric passage of MACE. One liter of PEG administration during the small bowel transit period might improve the quality of distal ileal mucosal visibility and have an additive effect on the high success rate to accomplish combined gastric and small bowel MACE examinations.

### P1665 PREVALENCE AND RISK FACTORS FOR DUODENAL PERFORATION DUE TO MIGRATED BILIARY PLASTIC STENTS

Stassen P.M.C., de Jong D.M., Poley J.W., Bruno M.J., de Jonge P.J.F. Erasmus MC, University Medical Center Rotterdam, Department of Gastroenterology & Hepatology, Rotterdam, Netherlands

**Contact E-Mail Address:** p.stassen@erasmusmc.nl

**Introduction:** Transpapillary biliary drainage by stent placement through endoscopic retrograde cholangiography (ERC) is a well-established treatment for bile duct obstruction. Migrated stent-induced perforation of the duodenal wall can be a potentially life-threatening complication. The actual prevalence of this complication is however unknown and risk factors for perforation are unclear.

**Aims & Methods:** We aimed to analyze the prevalence, risk factors and clinical course of migrated stent-induced duodenal perforation (MSDP). All consecutive patients who underwent an ERC with biliary plastic stent placement during the study period January 1<sup>st</sup> 2014 till December 31<sup>st</sup> 2017 in our center were retrospectively analyzed. Data on demographic factors, medical history, indication for ERC, biliary stricture and stent characteristics were systematically collected in all patients. In addition, for patients who were diagnosed with a MSDP, date of perforation, clinical presentation at diagnosis, type of treatment of perforation and outcome of treatment were reviewed.

**Results:** During the study period, a total number of 2487 ERCs were performed in 1228 patients (mean age 59 years, 59% male). In 630 patients (51%), a biliary plastic stent was placed; in 304 patients (25%), one or more stents were placed for perihilar strictures.

A total of 14 MSDPs were diagnosed in 13 patients (mean age 63 years, 79% male). All perforations occurred in patients with a perihilar stricture. The overall prevalence of MSDP was 1.1% in all patients who underwent an ERC, 2.2% for patients who underwent ERC with biliary stent placement and 4.6% for patients with a biliary stent for a perihilar stricture.

The median length of the stents was 15 cm (IQR 12-15 cm), perforation did not occur with stents shorter than 12 cm. Perforation occurred both with 7 and 10 French stents (21% and 79% resp.), and with either center or duodenal bend type stents (42% and 58% resp.). The stenosis was malignant in 8 patients (57%). The majority of perforated stents were deployed with the proximal tip in the left intrahepatic ducts (57%). Biliary sphincterotomy and stricture balloon dilation were not significantly associated with MSDP. Median time to diagnosis of perforation was 13 days (IQR, 4-66 days). In 71% of the patients (n=10) duodenal perforation was clinically suspected due to presentation with abdominal pain, fever and/or laboratory abnormalities. 4/14 patients were asymptomatic and MSDP was diagnosed at elective stent retrieval. Treatment was either conservative by removal of the stent, endoscopic closure with an over the scope clip (OTSC) or surgery in respectively 36% (n=5), 57% (n=8) and 7% (n=1) of the patients. Two patients died due to ongoing abdominal sepsis (14%), despite repeated endoscopic, percutaneous and surgical interventions.

**Conclusion:** This is the first study to report on the prevalence of MSDP in patients who undergo ERC. Despite the overall low risk of MSDP, it represents a potentially life threatening complication of ERC after transpapillary drainage for perihilar biliary strictures. The risk of MSDP needs to be acknowledged for this indication and warrants consideration in symptomatic patients after ERC.

### P1666 STENT SELECTION FOR PREOPERATIVE DRAINAGE OF A DISTAL MALIGNANT BILIARY OBSTRUCTION

Kohisa J., Yoshikawa S., Miida S., Hojo Y., Azumi M., Takeuchi M. Nagaoka Red Cross Hospital, Nagaoka, Japan

**Contact E-Mail Address:** jun-g2588@angel.ocn.ne.jp

**Introduction:** For stent placement in cases of unresectable distal malignant biliary obstruction, self-expandable metallic stents (SEMS) are recommended, as they have a longer patency period than plastic stents (PS). However, there has been no consensus on the types of stents that should be recommended for preoperative drainage. In recent years, preoperative adjuvant therapy has been increasingly adopted in the clinic, and the preoperative waiting periods have lengthened in an increasing number of cases. This study examined the selection of stents for preoperative drainage.

**Aims & Methods:** For stent placement in cases of unresectable distal malignant biliary obstruction, self-expandable metallic stents (SEMS) are recommended, as they have a longer patency period than plastic stents (PS). However, there has been no consensus on the types of stents that should be recommended for preoperative drainage. In recent years, preoperative adjuvant therapy has been increasingly adopted in the clinic, and the preoperative waiting periods have lengthened in an increasing number of cases. This study examined the selection of stents for preoperative drainage.

**Results:** The median patient age was 72 years, and the sex breakdown was 37 men and 11 women. The causative diseases included pancreatic cancer in 26 cases, bile duct cancer in 14 cases, papillary cancer in 7 cases, and intraductal papillary-mucinous carcinoma in one case. Stent malfunction was observed in one case in the SEMS group (6.7%) and in eight cases in the PS group (24.2%). The mean estimated patency periods that were obtained through the Kaplan-Meier method were 136 days in the SEMS group and 74 days in the PS group, and the mean period was significantly longer in the SEMS group ( $p=0.043$ ). The median technical costs were 359,340 JPY in the SEMS group and 170,710 JPY in the PS group, which indicates that the cost was higher in the SEMS group. On the other hand, in patients who received multiple treatments, the median technical cost in the PS group was 331,580 JPY, and there was no significant difference from that in the SEMS group ( $p=0.220$ ). Procedural accidents included acute pancreatitis in two cases in the SEMS group (13.3%) and acute cholangitis in one case in the PS group (3.0%), and both cases were mild. The mean estimated preoperative waiting periods were 28 days in the non-NA group and 131 days in the NA group.

**Conclusion:** As preoperative waiting periods were shorter in the non-NA group, the patency period of PS was sufficient for this group. Since the cost that is incurred by the use of PS is low, PS is recommended for patients in the non-NA group. On the other hand, preoperative waiting periods are long in the NA group, and the use of PS for this group would likely require multiple treatments. Therefore, from the perspectives of cost and invasiveness, SEMS is recommended for patients in the NA group.

### P1667 CONCOMITANT MALIGNANT DUODENAL AND BILIARY STENOSIS: DUODENAL STENTING AND HEPATICOGASTROSTOMY DURING THE SAME PROCEDURE IS A SAFETY PROCEDURE (SAMETIME STUDY)

Debourdeau A.<sup>1</sup>, Caillol F.<sup>2</sup>, Ratone J.P.<sup>2</sup>, Zemmour C.<sup>1</sup>, Decoster C.<sup>1</sup>, Winkler J.<sup>1</sup>, Pesenti C.<sup>2</sup>, Bories E.<sup>1</sup>, Giovannini M.<sup>2</sup>

<sup>1</sup>Institute Paoli Calmettes, Marseille, France, <sup>2</sup>Institute Paoli Calmettes, Endoscopy, Marseille, France

**Contact E-Mail Address:** antoinedebourdeau@hotmail.com

**Introduction:** The concomitant biliary and duodenal malignant stenosis is a rare event, reflecting a locally advanced neoplastic process. Endoscopic management is usually an association of duodenal and biliary retrograde stenting. EUS biliary drainage is an alternative drainage for these patients with inaccessible papilla. We conducted a single retrospective study to evaluate EUS biliary drainage in association duodenal stenting.

**Aims & Methods:** Patients were included from 01.01.2011 to 31.12.2017. Patients were included if they had palliative endoscopic management with biliary drainage and duodenal stenting in the same time or within 7 days or less for concomitant bilio-duodenal malignant stenosis. Patients were extracted from our database with ConSore soft.

Patients were divided into several groups for statistical analysis.

First, according to the timing of biliary drainage: in the SAMETIME drainage group if the two procedures were done on the same day and in the DEFERRED drainage group if the two procedures were done in different days ( $< 7$  days).

And secondly, depending on the biliary drainage method used: EUS-HG if hepaticogastrostomy or DUODENALACCESS if the drainage was done by ERCP, radiological or choledoduodenostomy.

**Results:** From 01.01.2011 to 31.12.2017 31 patients were included (19 women, mean age=66). Stenosis was related to pancreatic cancer for 17 patients (54%), colorectal cancer for 4 (12.9%), breast cancer metastases for 3 (9.7%), vesicular adenocarcinoma for 3 (9.7%), duodenal adenocarcinoma for 1 (3.2%), uterine sarcoma for 1 (3.2%), ovarian cancer metastases for 1 (3.2%) and one gastric adenocarcinoma (3.2%). Patients had an average Karnofsky index of 72%, the average preoperative bilirubin was 143 $\mu$ mol/L.

Sixteen (52%) patients were in the SAMETIME group, 15 in the DEFERRED: 11 (35%) with biliary drainage after duodenal stenting and 4 (13%) with biliary drainage before duodenal stenting.

Biliary drainage was done by EUS-HG for 11 (35%) patients, by DUODENALACCESS for 20 (65%): percutaneous path for 11 (35%) patients, by ERCP for 8 patients (26%) and choledoduodenostomy for 1 patient.

30 of 31 patients died during follow-up. Median survival was 76 days (mean 152 days  $\pm$  206).

Patients in the group SAMETIME had significantly shorter hospitalization than the DEFERRED group: 7.47 days vs 12.5 days ( $p=0.035$ ). The SAMETIME group trended to have a lower rate of significant postoperative complications (27% VS 56%;  $p=0.0953$ ).

The EUS-HG group trended to have lower rate of significant postoperative complications Dindo-Clavien classification  $> III$  (18% VS 55%  $p=0.065$ ) and less biliary endoscopic revision (9% VS 30%  $p=0.37$ ).

**Conclusion:** In case of double biliary and duodenal obstruction, SAMETIME drainage is associated with a halved hospitalization time and probably with less adverse events than a two procedures drainage. In case of double stenosis EUS-HG should be preferred. No more complication were described in our study than others drainage and on the contrary a tendency to better patency, less complication, and in current practice an easier re-intervention for stent obstruction.

**Disclosure:** Nothing to disclose

### P1668 WITHDRAWN

### P1669 THE EFFECTIVENESS AND SAFETY OF ENDOSCOPIC TRANSPAPILLARY GALLBLADDER STENTING FOR PATIENTS WITH ACUTE CHOLECYSTITIS

Seikine K., Doi S., Kuniyoshi N., Tsujikawa T., Mabuchi M., Yasuda I.  
Teikyo University Mizonokuchi Hospital, Gastroenterology, Kanagawa, Japan

**Contact E-Mail Address:** hawaiiintuberider@gmail.com

**Introduction:** The gold standard definitive therapy for acute cholecystitis is cholecystectomy. However, it is not possible to perform cholecystectomy all the time, especially in poor performance status patients. In those cases, the Endoscopic transpapillary gallbladder stenting (EGBS) is more effective rather than other drainage methods. EGBS is relatively new gallbladder drainage method for acute cholecystitis. Therefore, the effectiveness and safety of EGBS has not been considered enough.

**Aims & Methods:** We evaluate the effectiveness and safety of EGBS for acute cholecystitis.

This retrospective cohort study included the patients which had diagnosed for acute cholecystitis and underwent EGBS at our institution between September 2012 and January 2018. The primary endpoint of this study was a technical success rate of EGBS. The adverse events of EGBS and recurrence of the cholecystitis after undergoing EGBS were also considered.

**Results:** A total of 111 patients (77 men and 34 women; median age 66 years) underwent EGBS. The severity assessments of acute cholecystitis were 46 mild, 60 moderate, and 5 severe. The technical success rate for EGBS was 80.0% (89/111). Among them, 36 patients had common bile duct and were performed for endoscopic lithotripsy. The adverse events of EGBS were observed in 6 patients. Of these, 3 patients were penetration of cystic duct, 2 patients were pancreatitis, and 1 patient was bleeding during Endoscopic sphincterotomy. No recurrence of acute cholecystitis was observed during waiting periods for cholecystectomy after EGBS.

**Conclusion:** The success rate of EGBS was relatively high and recurrence of cholecystitis was not observed. In addition, the adverse event rate was also low. Therefore, we consider that EGBS is effectiveness and safety, and becomes one of the effective treatments for acute cholecystitis.

**Contact E-Mail Address:** hamid.asadzadeh@gmail.com

**Introduction:** Needle-knife Fistulotomy (NKF) is a commonly used rescue method for biliary cannulation in challenging ERCP cases. The type of Major Duodenal Papilla (MDP) is suggested to be an effective factor in selection of patients suitable for NKF. However, data from clinical studies is scarce. In this study we aim to compare the success and complication rates of NKF between three types of MDP.

**Aims & Methods:** The study samples were patients who experienced difficult cannulation during an elective ERCP procedure conducted in an affiliated university hospital between September 2017 and March 2018. The success and complication rates of NKF administered for these patients were compared by the patients' type of MDP. Three categories of MDP (small, bulging, long) were defined based on the anatomical characteristics observed during endoscopy.

**Results:** A total of 72 patients (35 men, 37 women; mean  $\pm$  SD age 62.3 $\pm$ 15.5 years) underwent NKF and were classified into 3 groups of small (N=24), bulging (N=20) and long (N=28) MDP. The overall success rate of NKF was 70.8%, which was highest in patients in the bulging MDP group (90%), followed by the small (75%), and long (53.6%) MDP groups (P=0.02). The total complication rate was 59.7%, including post ERCP Pancreatitis (13.9%), bleeding (19.4%), perforation (4.2%) and asymptomatic hyperamylasemia (25%). Overall complication rates were lowest among patients in the small MDP (45.8%) followed by bulging MDP (55%) groups and highest in the long MDP groups (78.6%) (P=0.03).

**Conclusion:** Characteristics of MDP is an important factor for selection patients for NKF. The best outcome for NKF (highest success and lowest complication rate) was achieved in patients with bulging MDP and the worst outcome (lowest success and highest complication rate) was observed in patients with long MDP.

**Disclosure:** Nothing to disclose

## P1671 INTRADUCTAL VS. TRANSPAPILLARY FULLY COVERED METAL STENT PLACEMENT FOR MALIGNANT BILIARY STRICTURES

Taniguchi Y.

Kobe city Medical Center General Hospital / Japan, Gastroenterology, Kobe, Japan

**Contact E-Mail Address:** guuguuyouhei@hotmail.com

**Introduction:** Endoscopic transpapillary placement of a metal stent (MS) for treatment of a malignant biliary stricture has been widely accepted as a standard palliative biliary drainage technique. A conventional fully covered metal stent is placed across the duodenal papilla. Duodenobiliary reflux though a biliary stent placed across the major duodenal papillary is considered to be a predisposing factor for stent occlusion and cholangitis. Intraductal placement of a biliary stent above the duodenal papilla (inside stent) may be associated with longer stent patency and a lower occlusion rate because of reduced duodenobiliary reflux.

**Aims & Methods:** The aim of this study was to determine whether intraductal fully covered metal stent placement (IP) or transpapillary fully covered metal stent placement (TP) is a better therapeutic technique for malignant biliary strictures.

From January 2016 to December 2018, a total of 79 patients with malignant biliary strictures were retrospectively enrolled in this study. The patients were divided into an IP group (n=30) and TP group (n=49). Technical and clinical success, complication, and stent patency were compared between the two groups.

**Results:** There were no significant differences between the IP and TP groups in the rates of technical success (100% vs. 100%), clinical success (100% vs. 100%), early complications (10.0% vs. 6.1%), late complications (0% vs. 4.1%), or stent occlusion (23.3% vs. 20.6%). The average

patency periods in the IP and TP groups were 150.0 and 103.7 days, respectively. Cumulative stent patency also did not differ significantly between the two groups (P=0.680).

**Conclusion:** TP for malignant biliary strictures showed a high technical success rate, low complication rate, and no difference in stent patency when compared with IP. Long-term follow-up and prospective comparative studies are needed to evaluate the usefulness of IP.

**Contact E-Mail Address:** ayla.turan@radboudumc.nl

**Introduction:** Percutaneous transhepatic cholangiography and biliary drainage (PTCD) is used for treatment for biliary obstruction after failed endoscopic biliary cannulation.

**Aims & Methods:** Our aim was to evaluate complication rates and risk factors for adverse outcome of PTCD in a real-world population. We performed a multicenter (4 Teaching and 1 University hospitals) cohort study in the period 2011-2016.

Our primary outcome was the incidence of infectious (sepsis, cholangitis, abscess or cholecystitis) and non-infectious complications (bile leakage, catheter blockage, severe hemorrhage, etc.) and mortality within 30 days of a PTCD procedure. Intra Class Correlations (ICC) were calculated to determine variance of outcomes between the five hospitals. Multilevel logistic regression analysis was performed to identify risk factors for predefined outcomes.

**Results:** In total, 331 patients with PTCD were analyzed, 251 of whom had malignant biliary tract obstruction. Two-hundred-twenty-six patients (68.3%) developed a complication after PTCD.

In 224 patients without pre-existent infection, 114 developed one or more infectious complications (40.6%), i.e. cholangitis in 26.3%, sepsis in 24.6%, abscess in 2.7% and cholecystitis in 1.3%. Non-infectious complications were seen in 167 of 331 patients (50.5%). PTCD-related 30-day mortality was 8.5%.

Risk factors for infectious complications were internal drainage (OR 2.12, 95% CI 1.03-3.38) and drain obstruction (OR 2.60, 95% CI 1.39-4.88), while multiple re-interventions were related to non-infectious complications (OR 2.11, 95% CI 1.64-2.71). No risk factors for mortality were identified.

**Conclusion:** This multicenter study shows that PTCD is associated with a high number of adverse events and substantial mortality. Infectious complications, in particular cholangitis and sepsis, are common and appear to be caused by drain malfunction and internalized drainage. These high complication rates should stimulate the search for alternative strategies for biliary drainage.

**Disclosure:** Nothing to disclose

## P1673 UNCOVERING CLINICAL GAPS IN THE MANAGEMENT OF CHRONIC LIVER DISEASE-ASSOCIATED THROMBOCYTOPENIA IN ADULTS REQUIRING ELECTIVE INVASIVE PROCEDURES: A CLINICAL PRACTICE ASSESSMENT

Fisher G.<sup>1</sup>, Voorn S.<sup>1</sup>, Guneseckera D.<sup>1</sup>, Peck-Radosavljevic M.<sup>2</sup>

<sup>1</sup>Medscape, Global Medical Education, London, United Kingdom, <sup>2</sup>Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology, Klagenfurt, Austria

**Contact E-Mail Address:** geoff@geofishmedicalmarketing.com

**Introduction:** Optimal implementation of emergent thrombopoietin receptor agonists (TPO-RA) such as lusutrombopag and avatrombopag is anticipated to require significant changes to the treatment paradigm for patients with Chronic Liver Disease (CLD)-associated thrombocytopenia (TCP) requiring elective invasive procedures (EP). In order to provide clinical

cians with optimum education, guidance and support to achieve the best outcomes with these agents in routine practice, it is important to identify current knowledge and clinical gaps that need to be addressed.

**Aims & Methods:** This study determined the readiness of clinicians to implement TPO-RA in practice by exploring understanding of current patient selection criteria, the limitations of platelet infusions and the scientific rationale and supporting efficacy and safety data for emergent TPO-RA, including considerations related to practical application. A 25-question, online, continuing medical education (CME) survey was developed that included a range of demographic, knowledge and practice-based questions. The activity launched on December 20, 2018 and data collected through February 6, 2019.

**Results:** 31 gastroenterologists, 47 hematologists, and 30 other physicians completed the survey. All were required to be involved in the management of patients with CLD-associated TCP undergoing EP. 47% of participants were from community hospitals, 30% from teaching hospitals and the remainder from solo/group community practices. Delay to invasive procedures due to TCP was common: 25% of participants reported a delay >40% of the time, 22%, 21-40% of the time, and 41%, 1-20% of the time. Only 13% never experienced delays. Lack of awareness/availability of newer treatment options (45% participants), lack of evidence-based guidelines (20%), and insufficient time to manage TCP before the procedure (12%) were identified as the current most significant barriers to optimal management of patients. Participants were currently only slightly (32%) or moderately (39%) confident in application of TPO-RA in practice. Only 16% were mostly/very confident. Only 49% of participants correctly identified 50,000/mL as the platelet threshold for considering intervention for TCP. Participants were familiar with the role of TPO in the pathophysiology of TCP (79%) and the mechanism of action of TPO-RA (75%). However, participants generally lacked knowledge on a range of questions that explored understanding of the clinical evidence for avatrombopag and lusutrombopag including identification of eligible patients in terms of type of EP and bleeding risk, magnitude and type of efficacy benefit, safety profile, duration of use, and monitoring requirements. 62% failed to identify that portal vein thrombosis occurred at a similarly low level in patients receiving lusutrombopag or placebo in the LPLUS1/2 trials. Only 22% of participants correctly identified that platelet counts should be monitored for 4 weeks after initiating treatment with TPO-RA.

**Conclusion:** The findings reveal significant current knowledge and clinical gaps amongst clinician specialties involved in the management of CLD-associated TCP in patients undergoing EP. Whilst this highlights some of the key issues and challenges in current practice, and may reflect the current lack of access to and clinical experience with TPO-RA, this strongly points to a need for education to establish a better understanding of the impact of TPO-RA on practice. Clinicians require support with the implementation of the paradigm shift that is needed for effective and safe routine application of TPO-RA to achieve the best patient outcomes.

## P1674 EMERGING TREATMENTS FOR CHRONIC LIVER DISEASE-ASSOCIATED THROMBOCYTOPENIA IN ADULTS REQUIRING ELECTIVE INVASIVE PROCEDURES: EFFECT OF ONLINE EDUCATION ON CLINICIAN KNOWLEDGE, AND CONFIDENCE

Fisher G.<sup>1</sup>, Voorn S.<sup>2</sup>, Gunsekera D.<sup>2</sup>, Peck-Radosavljevic M.<sup>3</sup>

<sup>1</sup>Medscape, Global Medical Education, London, United Kingdom, <sup>2</sup>Medscape Global Medical Education, London, United Kingdom, <sup>3</sup>Klinikum Klagenfurt am Wörthersee, Abteilungsvorstand Gastroenterologie & Hepatologie, Endokrinologie und Nephrologie, Klagenfurt, Austria

**Contact E-Mail Address:** geoff@geofishmedicalmarketing.com

**Introduction:** Thrombopoietin Receptor agonists (TPO-RA) such as lusutrombopag and avatrombopag are emerging as alternative treatment options to platelet transfusions for patients with Chronic Liver Disease (CLD)-associated thrombocytopenia requiring elective invasive procedures. Optimal implementation of these agents is anticipated to require significant changes to the treatment paradigm, so education of clinicians on the rationale and supporting data as well as practical application of these agents will be important.

**Aims & Methods:** This study determined whether online continuing medical education (CME) could improve clinicians' knowledge of the rationale behind the development of TPO-RA and the supporting clinical evidence, and improve clinician confidence with application of these agents in practice. A 30-minute online video discussion between 2 experts was launched for countries in Europe in December 2018, with data collected until February 2019. Educational effect was assessed with a repeated-pairs pre-/post-assessment study design, where individual participants served as his/her own control. 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale (confidence) question were analyzed. Chi-squared test assessed pre- to post-assessment change (5% significance level,  $P < .05$ ). Magnitude of change in total number of correct responses overall, and for each question, were determined with Cramer's V (effect size:  $< 0.05$  modest;  $0.06-0.15$  noticeable,  $0.16-0.30$  considerable,  $> 0.30$  extensive).

**Results:** 78 gastroenterologist and 72 hematologists completed both pre- and post-assessments. An overall positive extensive education effect was observed for both specialties ( $V = .306$ ,  $p < .001$  and  $V = .281$ ,  $p < .001$ , respectively).

For both specialties significant improvements were observed between pre- and post-assessment for all 3 questions which covered identification of the complications of platelet infusions, identification of the correct platelet count defining eligibility for the ADAPT-1 and ADAPT-2 Phase 3 trials of avatrombopag and identification of the correct efficacy and safety data from the L-PLUS1 and L-PLUS2 Phase 3 trials of lusutrombopag. Average % of correct responses improved from 28% to 88% pre- and post-assessment for gastroenterologists and from 43% to 68% for haematologists.

Both specialties had only modest baseline knowledge of the key data for both agents (24-47% gastroenterologists and 49-56% hematologists), with significant improvement post-assessment. Improved confidence in the ability to treat thrombocytopenia in patients with CLD requiring an elective invasive procedure was demonstrated post-assessment, with a total average confidence improvement of 35% for gastroenterologists and 25% for haematologists.

**Conclusion:** This on-demand, online video discussion resulted in a highly positive educational effect with improvements in clinician knowledge and confidence. However, the study revealed that there is currently only a modest baseline understanding of key data supporting the implementation of TPO-RA in practice. In addition, despite the positive educational gains, there are persistent knowledge gaps evident post-assessment for a significant proportion of clinicians.

Further education is merited given the important implications of these agents to the treatment paradigm. Online medical education is valuable in supporting the interpretation of new data and practical application of new agents in practice, as well as identifying areas of continued educational need

## P1675 WITHDRAWN

## P1676 COMBINED ULTRASOUND- AND FLUOROSCOPY GUIDED TRANSHEPATIC BILIARY DRAINAGE IS SUPERIOR TO CONVENTIONAL RADIOGRAPHY GUIDED TECHNIQUE

Hollenbach M.<sup>1</sup>, Schaumburg T.<sup>1</sup>, Feisthammel J.<sup>1</sup>, Mössner J.<sup>1</sup>, Michl P.<sup>2</sup>, Rosendahl J.<sup>2</sup>, Hoffmeister A.<sup>1</sup>

<sup>1</sup>University of Leipzig, Department of Internal Medicine, Neurology and Dermatology; Division of Gastroenterology and Rheumatology, Leipzig, Germany, <sup>2</sup>Martin-Luther-University Halle-Wittenberg, Department of Medicine, Clinic for Internal Medicine I, Halle, Germany

**Contact E-Mail Address:** marcus.hollenbach@web.de

**Introduction:** Difficult biliary cannulation (DBC) is a common condition in endoscopy and often remains challenging. DBC is related to benign, malignant or iatrogenic diseases. In case of unsuccessful ERCP, EUS-guided or percutaneous transhepatic biliary drainage (PTCD) are standard procedures for alternative bile duct access. PTCD is often performed by ultrasound guided puncture (US-PTCD) but also conducted without sonography (non-US-PTCD). However, there is no comparative data showing any supe-

priority for the use of US-PTCD with regard to technical success or complications. Thus, we performed a retrospective two-center study comparing US-PTCD with non-US-PTCD.

**Aims & Methods:** Data of 269 patients who underwent PTCD between 2002 and 2018 were collected and retrospectively analyzed. Indications, outcome, technical efficacy, comorbidities and procedural characteristics were analyzed. Fisher's exact test, Student's t-test and Chi-Square-test were used to identify dispersions between both groups.

**Results:** We identified 200 patients, who were treated by US-PTCD and 69 by non-US-PTCD. Mean age was 66.3 (US-PTCD) and 67.4 years (non-US-PTCD) and PTCD was performed mostly in men (64.5% and 66.7%). In both groups, right-sided PTCDs were conducted more often than left sided (78% and 79%). Main indications for PTCD were palliative (63.5% and 62.2%) bile duct drainage due to prior abdominal surgery or unsuccessful ERCP. US-PTCD resulted in technical efficacy of 81% compared to 79.7% in non-US-PTCD ( $p>0.05$ ). Internal duodenal drainage was achieved in 50.5% (US-PTCD) and 36.2% (non-US-PTCD) patients ( $p=0.05$ ). Interventions could be performed without sedation in 19% of patients in US-PTCD but only in 3% in non-US-PTCD group ( $p<0.001$ ). Minor complications (severe pain, dislocation, bleeding, cholangitis and other) occurred in 18.5% of US-PTCD and 20.3% of non-US-PTCD ( $p>0.05$ ) but severe complications (pleural or cardiac injuries, perforation and fistula) occurred significantly less in US-PTCD (2% vs. 6.2%,  $p=0.04$ ).

**Conclusion:** US-PTCD and non-US-PTCD showed comparable technical efficacy but US-PTCD resulted in improved internal duodenal biliary drainage, less necessity of sedation and less severe complications compared to non-US-PTCD.

### P1677 DOES ENDOSCOPIC OBSTRUCTION IN COLORECTAL CANCER REQUIRE URGENT SURGERY AND RESULT IN POOR PROGNOSTIC FACTORS?

Wilasrusmee C., Supsamutchai C., Jirasiritham J.

Faculty of Medicine Ramathibodi Hospital, Mahidol University, Surgery, Bangkok, Thailand

**Contact E-Mail Address:** chumpon.wil@mahidol.ac.th

**Introduction:** Colonoscopy is an endoscopic tool for evaluation of colorectal cancer, and there is no conclusive evidence of a connection between clinical gut obstructions and obstructed seen in endoscopy (obstructed colonoscopy). Unplanned urgent operations in obstructed colorectal cancer by endoscopic processes may increase mortality and the possibility of poor outcome. The suitable waiting time to complete staging and prepare patients before surgery has not been reported.

**Aims & Methods:** The aim of the study is to determine the suitable waiting times, incidence of emergency surgery during waiting times, and outcomes of obstructed colonoscopy.

Retrospective cohort of obstructed colonoscopies in colorectal cancer was analyzed. Patients who refused surgery or failed to attend follow up appointments were excluded. Data was collected from both emergency and elective operation groups, including incidences of emergency surgery, waiting times, staging, level of obstruction and outcome.

**Results:** The total of 4,017 colonoscopies were analyzed. There were 211 (5.25%) unsuccessful procedures due to tumor obstruction. Twelve patients (7.3%) had emergency operations during waiting for surgery. The average waiting time was 25 days. No perioperative deaths were reported. 5-year survival rate was lower in stage II and III cancer.

**Conclusion:** In this study, we found low incidence (7.3%) of emergency surgery in unsuccessful colonoscopy from obstructed colorectal cancer. Patients are able to wait 2-3 weeks after the date of colonoscopy without risk of increased mortality.

**Disclosure:** Nothing to disclose

### P1678 LONG TERM HEALTH RELATED QUALITY OF LIFE FOLLOWING COLORECTAL CANCER SURGERY: PATIENT REPORTED OUTCOMES IN A REMOTE FOLLOW-UP POPULATION

Malcolm F.<sup>1</sup>, Banerjee A.<sup>1</sup>, Whitehead D.<sup>1</sup>, Gupta A.<sup>1</sup>, Adiamah A.<sup>1</sup>, West J.<sup>2</sup>, Humes D.J.<sup>3</sup>

**Contact E-Mail Address:** francesca.malcolm@nhs.net

**Introduction:** Remote follow-up (RFU) after colorectal cancer (CRC) surgery allows delivery of surveillance tests without the need for regular clinical review. However little is known about long term health related quality of life (HRQoL) in RFU patients.

**Aims & Methods:** The aim of this cross sectional survey was to investigate HRQoL in this patient group. EQ-5D and QLQ-C30 questionnaires were sent to all CRC enrolled into RFU between 2011-2016. Primary outcomes were HRQoL scores. We analysed HRQoL scores with respect to year of RFU, demographics, operation type and stoma.

**Results:** In total 428 of 722 patients responded (59.3%) with a median RFU time of 2.6 years. 26.6% of patients reported 'perfect health'. The median EQ-5L index score was 0.785 (IQR: 0.671-1) and QLQ-C30 Global HRQoL score was 75 (IQR: 58.3-83.3). HRQoL scores were similar in different years of follow up. Lower HRQoL score were related to having a stoma ( $p<0.003$ ), cancer recurrence ( $p=0.009$ ), female gender ( $p=0.009$ ) and right-sided resection ( $p=0.03$ ). Right-sided resection patients reported higher pain severity compared with those who underwent left-sided resections ( $p=0.037$ ).

**Conclusion:** HRQoL is good in remotely followed up CRC patients. Predictors of lower scores will be a useful in service planning and holistic needs assessment. Despite an abundance of literature describing morbidity related to anterior resection, right-sided resection patients in this cohort reported worse HRQoL and symptoms.

**Disclosure:** Nothing to disclose

### P1679 ILEOANAL POUCH CANCER: A CASE SERIES

Patel R., Worley G., Allison L., Evans S., Sasikumar A., Jenkins J.T., Antoniou A., Faiz O., Corr A., Clark S.K., Latchford A.  
St Mark's Hospital, London, United Kingdom

**Contact E-Mail Address:** roshani.patel@nhs.net

**Introduction:** There are few data detailing management and outcomes of ileoanal pouch cancer.

**Aims & Methods:** We aimed to determine the clinical presentation, management and outcomes for patients with ileoanal pouch cancer with Familial Adenomatous Polyposis (FAP) and Ulcerative Colitis (UC). Patients were identified by a search of two prospectively maintained institutional databases: UC pouches (2006-2019) and the Polyposis Registry (1978-2019). Endoscopic surveillance and cancer staging and management data were retrieved from hospital records.

**Results:** Thirteen cases were identified; three=FAP, nine=UC, one both. Two patients were referred to our centre following a diagnosis of pouch cancer locally. Five patients were diagnosed at our centre with pouch cancer following a referral to our centre for other reasons such as fistula, pouch sepsis, and stricture.

Six patients were diagnosed at our centre whilst on annual surveillance; median time to diagnosis of pouch cancer from previous surveillance endoscopy was 11.5 months (range 6- 18 months). 3/6 on surveillance at our centre had UC; none of whom had any adenomatous or dysplastic lesion visible on prior surveillance endoscopy.

Eleven patients had cuff cancer, one pouch body cancer (FAP) and one had an anal canal squamous cell carcinoma (UC). The median time since pouch formation was 12 years (3-30) for UC and 30 years (12-34) for FAP. Seven (58%) patients were undergoing active annual surveillance.

Five UC cases had dysplasia (n=3) or cancer (n=2) in their proctocolectomy specimen. Five UC patients developed anal fistulae before cancer diagnosis. Pre-operative imaging was available for review on 11 patients, all of whom had margin threatening disease at diagnosis.

Ten patients had/will be undergoing pouch excision (seven exenteration, three abdominoperineal excision). Ten underwent neoadjuvant chemoradiotherapy. Two had non-operative management (one complete clinical response after neoadjuvant therapy; one palliative chemotherapy). One patient was lost to follow-up. Kaplan Meier one-year survival: 86% (SE 0.132).

**Conclusion:** There should be a high index of suspicion for pouch cancer in pouch patients with dysplasia or carcinoma at proctocolectomy or late-developing fistulae in patients who have had a pouch for UC. Surveillance does not abolish the risk of developing pouch cancer and adequate cuff examination can be challenging. Ileoanal pouch cancers usually are diagnosed when they are already locally advanced.

**Disclosure:** Nothing to disclose

## P1680 EVALUATION OF EXTENDED LATERAL PELVIC SIDEWALL EXCISION [ELSIE] FOR LOCALLY ADVANCED & RECURRENT RECTAL CANCER (RCC) INVOLVING THE LATERAL PELVIC SIDEWALL

Pring E.<sup>1</sup>, Gould L.<sup>2</sup>, Fletcher J.<sup>3</sup>, Taylor C.<sup>3</sup>, Hona T.<sup>3</sup>, Hellawell G.<sup>3</sup>, Corr A.<sup>4</sup>, Burling D.<sup>5</sup>, Aston W.<sup>3</sup>, Antoniou A.<sup>3</sup>, Jenkins J.T.<sup>5</sup>

<sup>1</sup>St Mark's Hospital and Imperial College London, Surgery and Cancer, London, United Kingdom, <sup>2</sup>St Mark's Hospital, Academic Institute, London, United Kingdom, <sup>3</sup>The Complex Cancer Clinic, St Marks Hospital, London, United Kingdom, <sup>4</sup>St Mark's Hospital, Academic Institute, Middlesex, United Kingdom, <sup>5</sup>St. Marks Hospital, London, United Kingdom

**Contact E-Mail Address:** etpring@doctors.org.uk

**Introduction:** In the context of locally advanced or recurrent rectal cancer, disease extension to the lateral pelvic sidewall is associated with lower rates of complete resection and poorer survival overall. Adaptions to surgical approach may improve complete resection rates but whether improvement in survival will follow is unclear.

**Aims & Methods:** We aimed to assess the outcomes following surgery for locally advanced and recurrent rectal cancer with disease extension into the pelvic side wall using a novel surgical approach termed ELSIE (Extended Lateral Pelvic Sidewall Excision)

304 consecutive National Health Service (NHS) patients underwent exenterative surgery in a single UK specialist centre. Where pretreatment MRI indicated pelvis sidewall or sciatic notch extension ELSIE was offered as a component of the pelvic exenteration surgery (n=111). Retrospective analysis of a prospectively maintained database assessed R0 rates, Clavien-Dindo morbidity and overall specific survival (OSS - assessed using Kaplan-Meier analysis).

**Results:** 304 patients underwent pelvic exenteration surgery, 111 of these were offered and underwent ELSIE. R0 rate in the ELSIE group was 85.3% compared to 82.2% non-ELSIE group. 53% of ELSIE procedures were for recurrent or re-recurrent rectal cancer compared to 36% in the non-ELSIE group. 47% of those who underwent ELSIE had en-bloc Total Perineal Excision whilst 27% did in the non-ELSIE population. En-bloc sacrectomy rate in ELSIE was 32.4% (15.5% non-ELSIE). Major-morbidity in the ELSIE group 41.4% and 30% in the non-ELSIE. Morbidity without sacrectomy in ELSIE was 35% as opposed to 24% in non-ELSIE. 90-day mortality was 4.5% ELSIE and 5.0% non-ELSIE. Survival analysis revealed that 70% of patients were alive at 1000-days post-operatively with no differences in OSS between either group.

**Conclusion:** ELSIE as an adjunct to exenteration surgery for pelvic sidewall disease extension in locally advanced, recurrent and re-recurrent rectal cancer increased R0 rates with relative improvements in OSS. Morbidity remains high in ELSIE and methods to reduce this are required. External validation of the ELSIE technique is now required.

**Disclosure:** Nothing to disclose

## P1681 DEVELOPMENT OF PATIENT SPECIFIC 3D VIRTUAL MODELS FOR PLANNING BEYOND-TME RESECTIONS IN ADVANCED RECTAL CANCER

Fletcher J., Gould L., Pring E., Sahnun K., Burling D., Corr A., Antoniou A., Lung P., Miskovic D., Jenkins J.T.  
St Mark's Hospital, London, United Kingdom

**Contact E-Mail Address:** jordan.fletcher@nhs.net

**Introduction:** Advanced rectal cancer is defined by invasion into surrounding structures. Complete tumour clearance (R0), requires radical resections going beyond the usual TME plane. Operative approaches are bespoke and pre-operative planning essential. Patient specific 3D models may be a useful adjunct and enable a personalised operative "roadmap".

**Aims & Methods:** The following complex cases were selected; Extended Lateral Side-wall Excision (ELSIE), High Subcortical Sacrectomy (HiSS) and posterior exenteration.

Standard axial and sagittal T2-weighted MRI sequences were obtained. DICOM images were imported into open-source software ITK-SNAP<sup>1</sup> and key anatomical structures were manually segmented and exported into 3D software, Blender for processing.

**Results:** Segmentation took approximately 60-180 minutes and 20-60 minutes for mesh processing. Advanced rendering techniques were employed enabling ultra-realistic anatomical visualisation. Surgeons can manipulate models in 3D space, hide/reveal or change transparency of different structures of interest. In each case the precise anatomical relationship of the tumour to surrounding structures was clearly visualised.

**Conclusion:** Surgeons currently use a combination of MRI scans, reports and discussion with radiologists to better understand anatomy. The use of these reconstructions in the MDT, in clinic and in the operating theatre could be useful to better communicate complex rectal anatomy, identify areas of difficulty and aid surgical planning.

**References:** Yushkevich PA, Piven J, Hazlett HC, et al. User-guided 3D active contour segmentation of anatomical structures: Significantly improved efficiency and reliability. *Neuroimage*. 2006;31(3):1116-1128. doi:10.1016/j.neuroimage.2006.01.015

## P1682 UTILITY OF HIGH SUBCORTICAL SACRAL RESECTION [HISS] FOR LOCALLY ADVANCED & RECURRENT RECTAL CANCER EXTENDING ONTO L5/S1/2

Pring E.<sup>1</sup>, Gould L.<sup>2</sup>, Fletcher J.<sup>3</sup>, Taylor C.<sup>3</sup>, Hona T.<sup>3</sup>, Aston W.<sup>3</sup>, Corr A.<sup>4</sup>, Burling D.<sup>5</sup>, Holloway I.<sup>3</sup>, Antoniou A.<sup>3</sup>, Jenkins J.T.<sup>5</sup>

<sup>1</sup>St Mark's Hospital and Imperial College London, Surgery and Cancer, London, United Kingdom, <sup>2</sup>St Mark's Hospital, Academic Institute, London, United Kingdom, <sup>3</sup>Complex Cancer Clinic, St Marks Hospital, London, United Kingdom, <sup>4</sup>St Mark's Hospital and Academic Institute, Middlesex, United Kingdom, <sup>5</sup>St Marks Hospital, London, United Kingdom

**Contact E-Mail Address:** etpring@doctors.org.uk

**Introduction:** In locally advanced and recurrent rectal cancer disease extension onto the lower lumbar spine and sacrum at L5/S1/2 is regarded as surgically unsalvageable, en-bloc bony cortex excision, High Subcortical Sacral resection [HiSS], may offer the chance of salvage in patients regarded as unsuitable or at high risk of incomplete resection with conventional surgical approaches.

**Aims & Methods:** We aimed to assess whether this technique improved outcomes in this group of patients who have been thought to have surgically unsalvageable disease.

Consecutive National Health Service (NHS) patients undergoing exenterative surgical procedures at a single centre were assessed and those with disease extension onto L5/S1/2 assessed for suitability for HiSS. Patients suitable for mid-distal S1-S1/2 sacrectomy were preferentially offered this option.

A prospective database of these patients was maintained and retrospective analysis performed. Outcomes including R0 rates, Clavien-Dindo morbidity, length-of-stay and OSS (Kaplan-Meier survival analysis) were assessed.

**Results:** 304 consecutive exenterations were performed, of these 30 were HiSS procedures and 66 were sacrectomies, 46 classified as high sacrectomies [HS] (above S2/3) and 20 as distal sacrectomies [DS]. 60% of HiSS;

28% HS and 50% DS had the diagnosis of primary rectal cancer extending beyond the TME (PRbTME). Ro rates were HiSS 81%; HS 87%; DS 75% and 83% for the non-sacral resection cohort.

Major-morbidity, classified as Clavien-Dindo grades 3 and 4, occurred in HiSS 36%; HS 48%; DS 45% and 28% in the non-sacrectomy group.

Median LOS [IQR] varied significantly between the groups  $p=0.00005$ : non-sacral exenteration 19 days [IQR 11-29]; HiSS 24 days [IQR 13-45]; HS 35 days [IQR 23-62]; DS 21 days [IQR 11-42]. Survival analysis confirmed no differences in OSS between groups  $-p=0.829$ , the OSS for HiSS was 70% at 1000 days.

**Conclusion:** HiSS may offer an opportunity for radical treatment and improve outcomes for patients previously regards as unsalvageable. The data presented here demonstrate that options to optimise Ro rates and reduce morbidity are needed these could include 3D reconstruction & image-enhanced surgery.

**Disclosure:** Nothing to disclose

### P1683 SURGICAL REPAIR OF ENDOSCOPY INDUCED COLONIC PERFORATIONS: A CASE-MATCHED STUDY OF SHORT-TERM MORBIDITY AND MORTALITY

Daniel F.<sup>1</sup>, Jabak S.<sup>1</sup>, Hosni M.<sup>1</sup>, Tamim H.<sup>2</sup>, Mailhac A.<sup>2</sup>, Khalife M.<sup>3</sup>, Faraj W.<sup>3</sup>, Jamali F.<sup>3</sup>

<sup>1</sup>American University of Beirut Medical Center, Division of Gastroenterology, Department of Internal Medicine, Beirut, Lebanon, <sup>2</sup>American University of Beirut Medical Center, Biostatistics Support Unit, Clinical Research Institute, Beirut, Lebanon, <sup>3</sup>American University of Beirut Medical Center, Surgery, Beirut, Lebanon

**Contact E-Mail Address:** fd21@aub.edu.lb

**Introduction:** Iatrogenic perforation of the gastrointestinal tract is mainly caused by endoscopic procedures. Surgical repair of endoscopy induced colonic perforation have only been evaluated in small case series.

**Aims & Methods:** To study the short-term morbidity and mortality associated with surgical repair of endoscopy induced colonic perforations, and to compare these outcomes to those of similar surgeries performed for other indications on elective or emergency basis.

We studied all patients with endoscopic colonic perforation (ICD 9-10 codes) who underwent surgical intervention from the 2014-2017 National Surgery Quality Improvement Program (NSQIP) participant use data specific file. NSQIP data base includes prospective validated outcomes and anonymized data for patients undergoing major surgery in more than 500 hospitals. The primary outcome in this study was short term surgical morbidity (including wound, cardiac, respiratory, urinary, neurological, thromboembolism, and sepsis) and mortality.

Outcomes were compared between 3 groups of surgical interventions: Suturing, open segmental colectomy, and laparoscopic segmental colectomy. Then, based on surgery CPT codes, patients (group 1) were matched with 1:2 ratio to control patients undergoing same surgical interventions for other indications on elective (group 2) or emergency basis (group 3).

We used the chi square test or Fisher's exact to compare categorical variables. We used the independent t-test for continuous variables. We performed multivariate analysis to adjust for confounders of 30-day postoperative outcomes between the 3 matched groups. We included confounders into the models based on both clinical and statistical significance.

**Results:** Over 4 years, 590 patients underwent surgical intervention to repair endoscopy induced colonic perforation. The average age of the patients was  $66.5 \pm 13.6$  with female gender predominance (381, 64.7%). The majority underwent open colectomy (365, 61.8%) while 85 patients (14.4%) underwent laparoscopic colectomy and 140 patients (23.7%) underwent surgical suturing.

Overall mortality occurred in 25 patients (4.2%). No statistically significant difference in mortality was found between open colectomy, laparoscopic colectomy, and suturing (4.0%, 2.6%, and 5.9% respectively,  $p=0.48$ ). Composite morbidity occurred in 163 patients (27.6%). It was significantly lower in laparoscopic colectomy (14.1%) compared to 30.2% and 29.4% in open colectomy and suturing approaches ( $p=0.014$ ).

Group 1 patients were shown to have better 30-day outcomes compared to group 3, regarding mortality (OR=0.66, 95% CI [0.51-0.85],  $p=0.001$ ), sepsis (OR=0.54, 95%CI[0.66-0.91],  $p=0.002$ ), and bleeding (OR=0.70, 95% CI [0.58-0.85],  $p=0.0003$ ). Compared to group 2, group 1 patient showed significantly fewer bleeding complications (OR=0.54, 95% CI [0.35-0.84],  $p=0.0055$ ).

**Conclusion:** Open segmental colectomy was the most frequent approach used to repair endoscopy induced colonic perforation in our series. Laparoscopic repair was associated with lower composite morbidity. Post-operative mortality, sepsis and bleeding complications were found to be significantly lower than in controls matched for the same procedures performed for other indications on emergency basis.

**Contact E-Mail Address:** stassorogin@gmail.com

**Introduction:** Laterally spreading lesions, which are traditionally treated surgically, may be amenable to endoscopic mucosal resection (EMR), often using a piecemeal method and Endoscopic submucosal dissection (ESD). Appropriate selection of lesions and a careful technique may enhance the efficacy of EMR and ESD for polyps more 10 mm in diameter without compromising safety. The aim of this study was to identify the factors that may predict the risk of polyp recurrence.

**Aims & Methods:** A retrospective analysis was conducted on the outcome of 101 polyps more/20 mm in diameter, treated by piecemeal EMR at a single centre using the "lift and cut" technique or ESD. All records were reviewed for polyp size, site, morphology and histology.

Polypectomy technique, patient treatment, polyp recurrence and surgical interventions were also recorded.

**Results:** Over THE 3-year period, 101 colonic polyps measuring more 10 mm were removed by EMR and ESD. Follow-up data WAS available for 83 cases (82%) with a mean polyp diameter of 42.9 mm; the total success rate of endoscopic polyp removal was 98%.

There was no statistically significant relationship between the site and recurrence.

Two patients (2%) underwent surgical intervention after EMR or ESD because of failed clearance. There were no post-EMR or post-ESD perforations and significant bleeding was revealed among only six patients (5.9%). Based on clinicopathological analyses of LSTs, the indication for colorectal ESD is an LST non-granular type (LST-NG) >20 mm. LST granular type (LST-G) >30 mm or 40 mm are possible candidates for ESD because they have a higher submucosal (SM) invasion rate and are difficult to treat even by endoscopic piecemeal mucosal resection (EPMR). En bloc ESD reduces the local recurrence rate for large colorectal neoplasias. Piecemeal resection is the most important risk factor for local recurrence regardless of the ER method used.

**Conclusion:** With careful attention to technique, piecemeal EMR or ESD is a safe option for the resection of most sessile and flat colorectal polyps more/20 mm in size. A stricter treatment may be required for larger lesions because of the higher risk of recurrence.

**Disclosure:** Nothing to disclose

## P1685 RECTAL CANCER IN ADOLESCENTS AND YOUNG ADULTS (AYA): PRESENTATION PATTERN AND OUTCOMES

**Contact E-Mail Address:** caterina.foppa@gmail.com

**Introduction:** Rectal cancer in AYA ( $\leq 39$  years) is rare but increasingly diagnosed. The aim of our study was to analyze presentation pattern, and outcomes in AYA operated for RC.

**Aims & Methods:** Data on rectal cancer resections from 2008 to 2018 were collected from the prospectively maintained databases of 3 European referral centers and compared to a control group of consecutive patients over 40 (n=500).

**Results:** 87 patients in AYA group (mean age: 33.5, range 18-39; 53% males) were compared to 500 patients in the control group (500). In AYA tumors were significantly more advanced (locally advanced 12% vs 4%; p=0.005; metastatic 37% vs 14.3%; p< 0.0001). Accordingly, neoadjuvant and adjuvant treatment (69% vs 32%, p< 0.0001; 76.2% vs 48.7%; p< 0.001), more complex and staged surgical procedures (9.3%), open surgery (31.1% vs 4.7%; p< 0.0001) and stomas (68% vs 47.6%; p=0.004) were more commonly performed in AYA patients. No differences in perioperative outcomes were reported. At a mean follow-up of 5 years no difference in overall survival (p=0.651), while a significantly lower cancer free survival was observed in AYA (p< 0.0001).

**Conclusion:** AYA patients undergoing resection for RC are rare, but more advanced at presentation, resulting in more complex operations, a faster cancer progression and lower cancer free-survival. Our data call for increasing awareness on rectal cancer in AYA population.

**Introduction:** Deep infiltrating endometriosis invading the intestine occurs in 8 to 12% of women with endometriosis. Surgery is indicated in patients with pelvic pain that do not respond to medical therapy.

**Aims & Methods:** To access the results of laparoscopic surgical treatment of bowel endometriosis in a single referral center. A retrospective analysis of medical records of patients with intestinal endometriosis submitted to laparoscopic surgical treatment. Number of surgeries, conversion rates, surgical time, length of hospital stay and complications were evaluated.

**Results:** One-hundred and thirteen patients were included. The mean age was 34.6 (ranging from 19 to 53), 62.8% of the patients have previous surgeries, the mean body mass index (BMI) was 25.2kg/m<sup>2</sup>. The main surgical indication was chronic pelvic pain (84.9%), followed by infertility (73.5%) and dyspareunia (54.9%). All procedures were done by laparoscopy. Surgeries performed: retosigmoidectomy (n=49, 43.4%), discoid anterior rectum resection (n=35, 31.0%), rectum shaving (n=26, 23.0%), appendectomy (n=11, 9.7%), and colon and ileal resection or ileal resection (n=8, 7.1%). Hysterectomy was performed in eleven patients (9.7%) and bladder

or ureteral lesions with need of resection in 7 patients (6.2%). Thirty-five patients (31.0%) had more than one resection at the same laparoscopic procedure. The mean surgical time was 122 minutes (retosigmoidectomy: 149minutes, anterior discoid rectum resection 114minutes and shaving 87minutes). When more than one procedure was performed at the same laparoscopy the mean surgical time increased to 161minutes.

The mean hospitalization time was 1.5 days (retosigmoidectomy: 1.8 days; discoid anterior resection: 1.4 days; shaving 1.0 day; more than one procedure at same laparoscopy 2.2 days). The conversion rates was 1.8% (n=2). Three patients needed temporary stoma (2.6%). The postoperative complication rates were 23% including rectal bleeding (n=18, 15.9%; only one case needed blood transfusion), wound infection (n=2, 1.8%), anastomotic leakage (n=0, 0%), nonsurgical site infection (n=3, 2.6%), need for reoperation (n=2, 1.8%, due to thermal injury; these two patients need provisory colostomy), readmission at 30 days (n=3, 2.6%, one due thermal injury and other two patients due to abdominal pain and diarrhea), deep vein thrombosis (n=1, 0.9%), and mortality at one year (n=0, 0%). Surgical recurrence occurred in four patients (3.5%) with need of new intestinal resection.

**Conclusion:** Laparoscopic surgery is safe and should be offered as the first surgical option in patients with deep endometriosis with intestinal involvement.

## P1687 COMPARATIVE RESULTS OF ENDOSCOPIC OPERATIONS FOR ZENKER'S DIVERTICULUM

Shumkina L.<sup>1</sup>, Nedoluzhko I.<sup>2</sup>, Pavlov I.<sup>2</sup>, Shishin K.<sup>2</sup>

<sup>1</sup>A.S. Loginov Moscow Clinical Science Center, Operative Endoscopy, Moscow, Russian Federation, <sup>2</sup>MCSC, Dept. of Operative Endoscopy, Moscow, Russian Federation

**Contact E-Mail Address:** kvshishin@gmail.com

**Introduction:** The best option of treatment of Zenker's diverticulum is still controversial. Recent data shows that same effectiveness of flexible endoscopy and traditional surgery. The only drawback of endoscopic technique is the limitation of myotomy level, which can result in the relapse of symptoms. Driven by new technologies we started to utilize the tunnel technique in patients with Zenker's diverticulum.

**Aims & Methods:** To evaluate the effectiveness of endoscopic cryopharyngoesophagomyotomy using a different techniques in the treatment of patients with Zenker's diverticulum.

In the period from July 2014 to April 2019, endoscopic surgery in MCSC A.S. Loginov for Zenker's diverticulum was performed in 113 patients. The average age of patients was 65 (from 34 to 86 years). According to the traditional method, 35 patients were operated on (I group). The average operative time was 42 minutes. According to the tunnel technique, 37 patients were operated on (group II). The mean operative intervention time was 50 minutes. According to the combined method, 42 patients were operated on. The average operative time was 32 minutes.

**Results:** The peculiarity of the patients who underwent surgery using the new combined method was the almost complete absence of the residual cavity of the diverticulum during the X-ray control examination.

Two patients in the group of traditional endoscopic treatment were re-operated because of complaints recurrence; each of them underwent two re-interventions. In two more cases the traditional endoscopic treatment was completed in two stages due to the large size of diverticulum. No recurrence of symptoms was observed after tunnel or combined technique.

**Conclusion:** Combined and tunneled endoscopic surgery for Zenker's diverticulum allows to successfully expand the scope of surgical intervention by performing an extended myotomy and dissection of the mucous membrane of the septum. This allows you to create conditions for the prevention of recurrence of the disease, thereby providing the best result of treatment.

**Introduction:** Anastomotic leak (AL) after low anterior rectal resection represents dreadful complication, which is associated with significant morbidity, morbidity and affects oncological and functional outcomes. Some of recently developed minimal invasive techniques are potentially suitable for the treatment of early diagnosed AL. TAMIS (Transanal Minimally Invasive Surgery) which was primarily introduced for local rectal excisions is one of those. Another option may be to use endoscopic suturing system (Over-Stitch; Apollo Endosurgery, Inc) providing full thickness closure in hollow viscera.

**Aims & Methods:** The aim of our study was to compare feasibility and efficacy of two different minimal invasive techniques for early repair of anastomotic leak on animal model.

Model of low colorectal anastomotic leak was introduced in 42 male pigs. Laparoscopic low anterior resection was performed with anastomosis created with 28 mm circular stapler after removing half of the staples. Two days later, the animals were randomized for endoscopic closure, TAMIS repair or control group with no treatment.

In endoscopic group a double-channel endoscope was introduced and anastomotic defect closed with 2/0 prolene and secured with original knotless fixation.

In TAMIS group a special port (GelPOINT) was inserted transanally and pneumorectum established. Standard laparoscopic instruments and 5mm camera were then used to close the defect by interrupted 3/0 vicryl suture. Three - grade scale (I - closed completely, II - closed with visible gaps, III - closure not possible) was introduced to assess the completion of closure. The signs of intraabdominal septic complications (IASC) and anastomotic healing including the burst test were evaluated after animals being sacrificed on 9th postoperative day. Chi square and Mann-Whitney tests were used to compare interventional and control groups.

This project was approved by local ethical committee in accordance with the European Convention on Animal Protection and supported by health research grants (AZV 16-31806A, MO 1012)

**Results:** Closure was technically possible in all 28 cases (grades I/II/III - 11/3/0 in endoscopic and 9/5/0 in TAMIS group;  $p>0.005$ ). Two animals after endoscopic closure died due to peritonitis on 8<sup>th</sup> and 9<sup>th</sup> postoperative day. There was no difference in operating time - 31 (19-70) min in endoscopic and 43 (20-70) min in TAMIS group ( $p=0.357$ ).

Overall IASC rate was lower after both endoscopic (5/14;  $p=0.022$ ) and TAMIS (4/14;  $p=0.0079$ ) repair compared to control (11/14). Healed anastomosis with no visible defect was observed in 10/14 ( $p=0.0023$ ) and 11/14 ( $p=0.0068$ ) in endoscopic and TAMIS groups respectively vs. 2/14 in control group. The burst test confirmed sufficient closure with mean pressure of 200 (80-300) mmHg in endoscopic and 235 (25-300) mmHg in TAMIS group ( $p=0.619$ ).

**Conclusion:** Evaluated techniques were proved to be suitable for closure of anastomotic defect with similarly high success rates. Both interventions reduced intraabdominal septic complications. Endoscopic closure seems to require more training since initial procedures were associated with peritoneal soiling and peritonitis.

**Disclosure:** Nothing to disclose

## P1689 SURGERY THROUGH STOMA-SITE INCREASES THE RISK OF PARASTOMAL HERNIA IN THE FIRST 6-MONTHS

Wickramasinghe D.<sup>1,2</sup>, Twum-barima C.<sup>3</sup>, Alkizwini E.<sup>1</sup>, Zafar N.<sup>4</sup>,

Lanka, <sup>3</sup>Nhs, Colorectal, Harrow, United Kingdom, <sup>4</sup>Consultant General,

Emergency, Laparoscopic Surgeon, London North West Hospitals Healthcare

NHS Trust, London, United Kingdom, <sup>5</sup>St Mark's Hospital and Academic

Institute, Surgery, London, United Kingdom

**Contact E-Mail Address:** marmaduke007@hotmail.com

**Introduction:** The overall reported rate of parastomal hernias (PSH) in literature ranges from 44- 56%, and is highest in end colostomies (48%) followed by loop colostomies (30.8%), end ileostomies (28.3%) and lowest in loop ileostomies (6.2%-16%) [1,2]. Although several risk factors contributing to the development of PSH have been identified, manipulation of the stoma site during surgery has not been studied.

**Aims & Methods:** The primary aim of this study was to identify the influence of manipulation of the marked stoma-site during surgery (e.g. laparoscopic port placement) on the subsequent development of parastomal hernia (PSH).

We analysed data of consecutive patients who underwent colorectal surgery for benign and malignant pathology between January 2017 and December 2018 at a single tertiary care centre.

**Results:** A total of 408 patients were analysed. Their mean age at surgery was 54.6 (SD-17.9) years. Forty-nine(12.0%) developed PSH after surgery. The median time to developing a hernia was 222(25 and 75 percentile 147 and 363, respectively) days.

Laparotomy was performed in 233 while 127 and 48 had laparoscopy and single-incision surgery, respectively. One-hundred-and-ten (28.7%) had instrumentation placed through the stoma site during surgery.

A log-rank test was run to determine if there were differences in developing a PSH if the stoma site was being used as a port site. When the first 180-days were considered, the PSH formation was significantly different ( $\chi^2(2)=9.4, p=.002$ ). When the entire follow-up period was considered, however, there was no statistically significant difference in PSH formation ( $\chi^2(2)=1.13, p=.28$ ).

**Conclusion:** Using the stoma site as a port site increases the risk of early PSH formation, but this does not lead to an increased risk of PSH formation in the long run.

<sup>1</sup>St Marks Hospital and Academic Institute, Harrow, United Kingdom, <sup>2</sup>Faculty

of Medicine, University of Colombo, Department of Surgery, Colombo, Sri

Lanka, <sup>3</sup>Nhs, Colorectal, Harrow, United Kingdom, <sup>4</sup>St Mark's Hospital and

Academic Institute, Surgery, London, United Kingdom, <sup>5</sup>Consultant General,

Emergency, Laparoscopic Surgeon, London North West Hospitals Healthcare

NHS Trust, London, United Kingdom

**Contact E-Mail Address:** marmaduke007@hotmail.com

**Introduction:** The overall reported rate of parastomal hernias (PSH) in the literature ranges from 44- 56% and is highest in end colostomies (48%) followed by loop colostomies (30.8%), end ileostomies (28.3%) and lowest in loop ileostomies (6.2%-16%) [1,2]. Single Incision Laparoscopic Surgery (SILS) uses a port that is larger than standard laparoscopic ports (35-50mm) and therefore exerts a much higher radial force at the stoma site compared to other techniques. The short and medium-term effects of this have not been studied.

**Aims & Methods:** The primary aim of this study was to identify the incidence of PSH in patients who underwent SILS.

We analysed data of consecutive patients who underwent colorectal surgery for benign and malignant pathology between January 2017 and December 2018 at a single tertiary care centre. Patient and procedural data were retrieved from a prospectively maintained database.

**Results:** A total of 408 patients were analysed. Their mean age at surgery was 54.4 (SD=17.9) years. A total of 45 (11.3%) developed PSH after surgery. The median time to developing a hernia was 220 (25 and 75 percentile 146 and 368, respectively) days.

Two-hundred-and-thirty-three patients underwent laparotomy while 127 and 48 had laparoscopy and SILS, respectively, with 27(11.5%), 19(14.9%) and 3(6.3%) patients developing PSH. Univariate analysis did not identify a statistically significant difference between different surgical techniques (Chi-square 2.59,  $p=0.27$ ).

A log-rank test was run to determine if there were differences in developing a PSH and the different types of surgery. The survival distributions for the surgeries were not statistically significantly different,  $\chi^2(2) = 3.06$ ,  $p=0.22$ , but there was a non-significant reduction in PSH in SILS patients.

**Conclusion:** Single Incision Laparoscopic Surgery did not increase the risk of PSH. A study with a larger sample size may show a statistically significant risk reduction in SILS compared to other techniques.

**Contact E-Mail Address:** sauid.ishaq@dgh.nhs.uk

**Introduction:** Flexible endoscopic septum division (FESD) is an established treatment for Zenker's diverticulum, however, data on long term outcomes are sparse. In addition, treatment of recurrences after surgery stapling can be technically challenging and little is known about role of FESD of recurrence after surgical recurrence. In this prospective study we aimed to evaluate long-term efficacy data for FESD and identify predictors of sustained symptom remission (treatment naïve and surgical recurrence).

**Aims & Methods:** Successive patients undergoing FESD for ZD between 2014-2018 were enrolled in this prospective study. Procedures were performed by a single operator under propofol sedation without endotracheal intubation. Symptom severity pre- and post-FESD was recorded using the Dysphagia, Regurgitation, Complications (DRC) scale. Symptom remission was defined as a total DRC score of  $\leq 1$  after index FESD or the latest attempt after planned multi-stage procedures. Symptom-free remission was measured using a Kaplan-Meier approach, with univariable analyses performed using Cox-regression models.

**Results:** 69 patients (mean age 74.4 years, SD 11.8, 61% male) were included for analysis, of which 60% were categorised American Society of Anaesthesiologists (ASA) Grade III or IV. 19 patients (28%) had undergone previous stapling treatment. The median cricopharyngeal muscle length was 24mm (IQR 17-30mm). The median procedure time was 20 minutes (IQR 19-25). The mean number of sessions of FESD therapy per patient was 1.4 (SD 0.7). In total, 75.4% of patients achieved symptom remission after the last planned FESD procedure. Kaplan-Meier estimated rates of symptom recurrence at 12, 24, 36 months were 12.6%, 36.3%, 46.5% respectively. The median time from the latest planned FESD procedure to symptom recurrence was 46.7 months (95% CI 18.4-75.0). On univariable

analysis, factors associated with symptom recurrence included previous stapling (hazard ratio [HR] 2.88;  $P=0.33$ ) and younger age (HR 0.959 per year,  $P=0.030$ ), but not significantly by gender ( $P=0.699$ ), cricopharyngeal muscle length ( $P=0.059$ ), procedural duration ( $P=0.241$ ) or combined DRC score ( $P=0.080$ ).

**Conclusion:** Using Kaplan-Meier estimates, the majority of patients develop recurrent ZD symptoms beyond 12 months post-FESD. This risk is higher in patients with recurrent ZD and in younger patients. All patients undergoing FESD for ZD should have either regular or open access follow-up arrangements in case symptoms recur.

## Paediatric: Endoscopy, Imaging and Surgery

09:00-14:00 / Poster Exhibition - Hall 7

## P1693 ERCP SAFETY AND EFFICACY IN THE PEDIATRIC POPULATION: A SINGLE TERTIARY CARE CENTER EXPERIENCE

Ligresti D., Martino A., Granata A., Barresi L., Tarantino I., Traina M. IRCCS - ISMETT, Endoscopy Service, Department of Diagnostic and Therapeutic Services, Palermo, Italy

**Contact E-Mail Address:** dligresti@ismett.edu

**Introduction:** Experience with endoscopic retrograde cholangiopancreatography (ERCP) in the pediatric setting is still limited especially in infant population. Wide heterogeneity of reported safety and efficacy profile and lack of systematic and standardized methodologies use exist, thus limiting pediatric ERCP use even in specialized centers.

**Aims & Methods:** The aim of this study was to evaluate the efficacy and safety of pediatric ERCP and to identify factors associated with procedure-related adverse events. All consecutive ERCPs performed for any indication in patients under the age of 18 from 2005 to 2018 at our single tertiary referral center were included in the study. Demographic characteristics of patients, indications, technical and clinical success, findings and procedure-related adverse events were retrospectively analyzed. The grade of technical complexity of each ERCP and the procedure-related complications were assessed according to the American Society for Gastrointestinal Endoscopy (ASGE) criteria.

**Results:** A total of 117 ERCPs were performed in 57 children (median age 7.6 (1-17) years; median weight 23.2 kg) by three ERCP expert endoscopists under general anaesthesia. The most frequent indications of ERCP were as follows: recurrent or chronic pancreatitis (33), post-surgical bile duct injury (19), suspected choledocholithiasis (14), and primary sclerosing cholangitis (PSC) (9). Therapeutic techniques performed were biliary sphincterotomy (32/117), biliary stenting (42/117), biliary stone extraction (21/117), pancreatic sphincterotomy (7/117), pancreatic stone extraction (5/117) and pancreatic stenting (10/117). Technical success was achieved in 112/117 (96%) cases and clinical success in 52/57 (92%) patients. ERCP-related complications consisted of seven episodes of mild pancreatitis (6% post-ERCP pancreatitis (PEP) rate) all resolved following conservative treatment. No procedure-related mortality was recorded.

**Conclusion:** When performed in experienced hands the use of ERCP in newborns, children and adolescents is safe and effective, with complication rates comparable to those reported in adults.

However well designed prospective studies are needed to better define outcomes.

**Disclosure:** Nothing to disclose

## P1694 COHORT ANALYSIS OF PEDIATRIC INTUSSUSCEPTION SCORE TO DIAGNOSE INTUSSUSCEPTION

Rukwong P.<sup>1</sup>, Phewplung T.<sup>2</sup>, Vejchapit P.<sup>3</sup>, Sintusek P.<sup>1</sup>

**Introduction:** Intussusception is a serious cause of intestinal obstruction in young children and delayed diagnosis increases morbidity. Ultrasonography (USG) is the gold standard for diagnosis but operator dependence and unavailable worldwide.

**Aims & Methods:** The aims of the present study are to study the clinical characteristics and treatment outcomes and to evaluate the diagnostic accuracy of abdominal radiography (AR) with and without promising parameters to diagnose intussusception.

Children with suspected intussusception who underwent abdominal USG investigation in our center from 2006 to 2018 were recruited. Clinical and investigation were evaluated and compared between intussusception and non-intussusception groups. AR images were interpreted by a pediatric radiologist. Diagnosis of intussusception is composed of compatible USG and response with reduction.

**Results:** Ninety-seven children were diagnosed with intussusception (2.06±2.67 years, 62.9% male), 37.1% of whom were referrals and 74% were < 2 years old. The common manifestations of intussusception were irritable or abdominal pain (86.6%), vomiting (58.5%), abdominal distension (39.2%) and bloody stool (36.1%). The classic triad of intussusception (abdominal pain, bloody stool and palpable mass) had specificity of 100% but sensitivity of 11.3%. Children with no clinical fever and no palpable abdominal mass could discriminate intussusception from other mimics ( $P < 0.05$ ). The referral cases had more clinical lethargy, bilious vomiting, bloody stool and more failure to reduce intussusception than non-referral cases ( $P < 0.05$ ). In the multivariate model, clinical irritability and abdominal distension were the significant factors for failure to reduce intussusception. The pathologic leading of intussusception were identified in 28.8% including lymphoma, diverticulum, polyp, Crohn's disease, appendicolith, and enlarged intra-abdominal lymph nodes. AR to diagnose intussusception had sensitivity, specificity, PPV, NPV and accuracy of 73%, 63.6%, 67%, 70% and 68.4%, respectively. However, a combination of clinical irritability or abdominal pain, vomiting and age < 2 years with compatible AR (the Pediatric Intussusception Score model) had a high diagnostic value with a specificity of 93.33%

**Conclusion:** AR had a poor diagnostic value to diagnose intussusception. Apart from the well-known triad, the Pediatric Intussusception Score could increase the diagnosis accuracy leading to timely specific management.

**Introduction:** There is paucity of literature on portal cavernoma cholangiopathy (PCC) in children and there are a number of unanswered questions regarding the outcome of PCC especially after porto-systemic shunt surgery.

**Aims & Methods:**

**Objectives:** To assess the effect of portosystemic shunt surgery on PCC in children with EHPVO.

**Methods:** Children with EHPVO deemed unfit for Meso-Rex shunt with splenomegaly-related issues and presence of PCC (symptomatic or asymptomatic) underwent Magnetic resonance cholangiogram (MRC) and

Magnetic resonance portovenogram (MRPV) just before non-selective portosystemic shunt surgery. PCC was graded as per modified Llop classification.[1] Those with patent shunt were re-evaluated for PCC at least 6 months after surgery with repeat MRC and compared with pre-shunt images. Pre and post shunt assessment of peribiliary collateral density was made on MRPV and correlated with the vascular anatomy.

**Results:** Twenty five children underwent portosystemic shunt surgery (central end to side splenorenal shunt with splenectomy in 24, mesocaval shunt in 1). Their duration of disease, age at surgery (pre-surgery PCC assessment) and age at re-assessment (post-surgery PCC) were 77 (15-144) months, 156 (72 - 210) months, 192 (78 to 216) months respectively. All showed shunt patency and adequate flow velocity. Pre-surgery MRC showed PCC grade I in 11, grade II in 1 and grade III in 13. MRPV showed SMV block in 20. Re-assessment for PCC 18 (6 to 54) months after surgery showed grade I in 6 and grade III in 19. The overall change in grade of PCC pre and post-surgery was significant ( $p=0.04$ ). Thus, PCC was progressive in 6 and static in 19 children. Regression was seen in none. The density of peribiliary collaterals decreased in 5, increased in 3 and remained unchanged in 17. Decrease in peribiliary collaterals was seen only in those with SMV patency ( $n=5$ ) and their PCC was static. Splenomegaly-related issues, gastroesophageal varices on endoscopy and other intrabdominal (esophageal, perisplenic and perigastric) collaterals ameliorated in all.

	Pre-surgery (n=25)	Post-surgery (n=25)	p-value
Grade I	11	6	
Grade II	1	0	
Grade III	13	19	
Wavy changes	19	17	0.16
Angulations	10	10	1.0
Indentations	7	9	0.56
Strictures	14	19	0.02
Upstream dilatation (Intrahepatic)	12	18	0.01
Upstream dilatation (Extrahepatic)	8	13	0.06

[Comparison of MRC features pre and post-portosystemic shunt surgery]

**Conclusion:** Non-selective porto-systemic shunt surgery decompresses the portal hypertension in esophago-gastro-splenic venous circuit effectively but fails to ameliorate the cholangiopathy and peribiliary collaterals. The persistence of cholangiopathy is attributable to SMV block.

**Contact E-Mail Address:** joan.amoedo@goodgut.eu

**Introduction:** *Clostridium difficile* infection (CDI) incidence has increased in recent years and it is the major cause of antibiotic-associated diarrhoea. Its manifestations have many similarities to exacerbations of Inflammatory Bowel Disease (IBD). Dysbiosis, a deviation from the normal microbial composition, has been widely reported in both CDI and IBD patients.

**Aims & Methods:** The aim of this study was to compare the abundances of different bacterial markers in stool samples of CDI and IBD patients, which might be used to develop bacterial biomarkers for IBD in symptomatic

patients. A cohort consisting of 20 CDI and 22 IBD patients were recruited by the Gastroenterology department from Beth Israel Deaconess Medical Center (Boston, USA). All CDI and IBD patients presented an active clinical represented by the presence of depositional alteration and abdominal pain. The relative abundance of all bacterial markers by qPCR: *Faecalibacterium prausnitzii* (Fpra), *Escherichia coli* (Eco), *F. prausnitzii* phylogroup I (PHG-I), *F. prausnitzii* phylogroup II (PHG-II), *Akkermansia muciniphila* (Akk), *Ruminococcus sp.* (Rum), *Lactobacillus sp* (Lac), Bacteroidetes (Bac) and *Methanobrevibacter smithii* (Msm) was determined on faecal samples. **Results:** The relative abundances of Fpra, PHG-I, PHG-II, Rum, Eco and Msm were significantly different between CDI and IBD patients. While Fpra, PHG-I, PHG-II and Rum were significantly lower in CDI patients when compared with IBD patients, the abundance of Eco and Msm were significantly higher in CDI patients. No significant differences were found in Akk, Lac and Bac.

**Conclusion:** CDI patients exhibit a lower abundance of anaerobic bacterial markers such as *Ruminococcus*, *F. prausnitzii* and its phylogroups, which are considered to be beneficial maintaining gut homeostasis. Instead, species with inflammatory properties such as *E. coli* were increased in CDI. These results indicate that conditions with similar phenotypes (symptoms, endoscopic appearance) may display significant differences in faecal bacterial.

## P1697 ESTABLISHMENT OF CHRONIC INFLAMMATION MODEL USING HUMAN SMALL INTESTINAL AND COLONIC ORGANOID

Hibiya S., Tsuchiya K., Katsukura N., Shirasaki T., Watanabe S., Nishimura R., Okamoto R., Watanabe M.

**Introduction:** Patients with inflammatory bowel disease (IBD) mainly present with ulcerative colitis (UC) or Crohn's disease (CD). Recently, it has been recommended that mucosal healing is therapeutic goal of IBD. Furthermore, histological healing is becoming new target to treat IBD, because dysfunction of epithelial cells such as goblet cell depletion and crypt distortion might cause frequent relapse. However, the mechanism for cell transformation of intestinal epithelial cells by chronic inflammation remains unknown.

**Aims & Methods:** We have previously reported the irreversible transformation of intestinal epithelial cells after long-term chronic inflammation for over a year by using mice colonic organoids<sup>1</sup>. We therefore aimed to establish human in vitro chronic inflammatory model using human small intestinal and colonic organoid because human model might be useful to assess the molecular mechanism of pathogenesis. Human small intestinal and colonic organoids were isolated from non-inflamed lesion of small intestine and colon, respectively. The expression of inflammatory related receptors in both organoids were assessed by RT-PCR. Inflammatory response of the organoids by each inflammatory reagent was assessed by IL-8 expression. The mixture of inflammatory reagents were added into medium every other day for 12 weeks. The expression of NF-κB target genes IL-8, DUOXA2 was assessed every 3 weeks during 12 weeks stimulation. Microarray analysis was performed at 5 weeks of inflammatory stimulation in colonic inflammatory organoids. This study was approved by the ethics committee.

**Results:** We identified the difference of the inflammatory related receptors expressed in between human small intestinal and colonic organoids. Inflammatory response by each inflammatory reagent was also different between small intestinal and colonic organoids. The mixture of inflammatory reagents for small intestinal and colonic organoids has therefore been decided respectively for suitable inflammatory response. The stimulation by inflammatory reagents showed the significant induction of IL-8 and DUOXA2 in both small intestinal and colonic organoids. IL-8 was immediately downregulated during 12 weeks stimulation following rapid increase at 3 hours stimulation in both small intestinal and colonic organoids. In con-

trast, the expression of DUOXA2 gene was persistently increased from 3 hours to 12 weeks stimulation in both organoids. Microarray analysis in colonic organoids showed that the highest induced gene was claudin-18 (CLDN18), which has been reported to be increased in UC patients. The expression of CLDN18 were gradually increased at the late phase of inflammatory stimulation for 12 weeks in both organoids, indicating that the expression pattern of inflammatory induced genes was classified by 3 types; tentative, persistent and gradual.

**Conclusion:** Chronic inflammation into the human small intestinal and colonic organoid might mimic the phenotype of IBD. The establishment of in vitro human model for IBD might be useful for the identification of chronic inflammatory specific genes and developing effective therapy targeted mucosal healing. Moreover, the analysis of genes gradually upregulated at the late phase of inflammatory stimulation might be useful for understanding the pathogenesis of epithelial cell transformation during IBD disease duration. Furthermore, the identification of the differences between in vitro small intestinal and colonic organoids might be necessary for the investigation of differences between UC and CD.

**Contact E-Mail Address:** jesus.cosin@uv.es

**Introduction:** Crohn's disease (CD) is a chronic inflammatory disorder of the gastrointestinal tract characterized by initial transmural inflammation, commonly associated with complications, such as stenosis, abscesses and fistulas. The development of fistulas has been associated with the epithelial-mesenchymal transition (EMT) which is the process that allows to change the phenotype of the epithelial cells to a fibrotic behavior. Under inflammatory conditions, the metabolite succinate accumulates and its receptor, called SUCNR1, activates EMT.

**Aims & Methods:** The objective of this study is to analyze the pathway activated by succinate in epithelial cells. Intestinal resections from CD's patients (subdivided in B2 and B3 according Montreal's classification) were obtained. Healthy resections from colon carcinoma patients were used as controls and succinate levels were measured by using a colorimetric kit. HT-29 intestinal epithelial cells were treated with a constant concentration of 1mM succinate during different times (0 min, 15min, 30min, 1h, 6h and 24h). We analyzed the expression of p-ERK with respect to total ERK by means of Western Blot. The expression of the EMT markers (*Snail*, *Vimentin* and *E-Cadherin*) as well as the expression of Wnt ligands and Wnt targets (*Wnt1*, *Wnt4* and *Wnt10a*, *c-myc*, *Igr5*) were analyzed by qPCR after treatment with succinate. In some cases cells were treated with an inhibitor of the ERK pathway (V0126 10 μM). Results are expressed by mean ± SEM (n≥3) and as fold induction vs vehicle. Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test.

**Results:** The succinate concentration is higher in intestinal resections from B3 (208.9 ± 26.03) than B2 (127.2 ± 21.66) CD patients. In HT-29 cells, succinate induces an increase in the expression of p-ERK at 15 min (195.5% ± 72.83). It also produces an increase in the mRNA expression of *Vimentin* (fold induction of 1.60 ± 0.20), *Snail1* (2.12 ± 0.09), *Wnt1* (4.76 ± 1.05), *Wnt4* (2.32 ± 0.52), *Wnt10a* (3.69 ± 0.34), *c-myc* (1.14 ± 0.10) and *Igr5* (1.28 ± 0.12) and a decrease in E-cadherin (0.63 ± 0.08). The treatment with V0126 revert these changes to values that do not differ from that obtained in vehicle-treated cells.

**Conclusion:** Succinate is increased specifically in B3 patients. In addition, succinate induces the activation of the ERK pathway and the expression of Wnt ligands in epithelial cells, which could be involved in the effects of succinate on EMT.

## P1699 ASSOCIATION OF CX3CR1 EXPRESSION IN THE PERIPHERAL BLOOD WITH MUCOSAL INFLAMMATION IN IBD: A NATURAL KILLER STORY?

Uniken Venema W.T.C.<sup>1</sup>, Visser F.<sup>1</sup>, Hagting M.<sup>1</sup>, Voskuil M.<sup>2</sup>, Jansen B.H.<sup>1</sup>, Weersma R.K.<sup>2</sup>, Festen E.A.M.<sup>3</sup>

**Contact E-Mail Address:** w.t.c.uniken.venema@umcg.nl

**Introduction:** CX3CR1 is a chemokine receptor expressed on various (immune) cell types, and involved in adhesion on and migration of leukocytes through epithelial and endothelial cells (1,2). The proportion of CX3CR1+ cells within the blood CD4 effector T cell population, has been found to be correlated with clinical disease activity in IBD (3). Moreover, blocking CX3CR1 has been shown to reduce colitis in mice. This renders CX3CR1 a promising drug target for IBD and a potential biomarker for disease activity. We assessed expression of CX3CR1 on a variety of cell types in the blood of IBD patients and healthy controls to find potential target cells for CX3CR1-blockade therapy in humans, and questioned whether expression of CX3CR1 is associated with histologically proven disease activity in the gastrointestinal tract in patients with IBD.

**Aims & Methods:** Peripheral blood from patients with Crohn's disease (CD, n=11), ulcerative colitis (UC, n=11) and healthy controls (HC, n=11) was collected prior to endoscopy. Whole blood was isolated using washing and lysis of red blood cells, stained with a panel containing various antibodies (CD3, CD8, CD19, CD16, CD14, CD15, CX3CR1, CD56) and subsequently analyzed using an LSR II FACS analyzer. Disease activity was assessed through evaluation of biopsies of macroscopically inflamed areas by a pathologist. Using flow cytometry, the proportion of CX3CR1-positive cells as well as the level of CX3CR1 expression in a variety of cell types was evaluated. Differences between CD, UC and HC, as well as between patients with and patients without disease activity in the gastrointestinal tract were assessed.

**Results:** We noted CX3CR1 expression on blood (NK) T cells, NK cells, monocytes and granulocytes, but not on B cells. Neutrophils constitute the largest proportion of CX3CR1+ cells in the blood (median 3.7% [IQR 3.3]), whereas within the subpopulations, non-classical monocytes (median 98% [IQR 2.6]) and NK cells (median 90.3% [IQR 8.7]) had the highest proportion of CX3CR1 positive cells. In blood derived from patients with histologically active UC, intermediate monocytes showed a significantly higher proportion of CX3CR1+ cells (p=0.036), whereas CD4+ NK T cells showed upregulation of CX3CR1 on the cell surface (p=0.013), compared to patients with UC in remission. In CD, the proportion of CX3CR1+ CD8+ NK T cells was higher in patients with inflammation versus patients without inflammation (p=0.05).

**Conclusion:** CX3CR1 is expressed on a wide variety of peripheral blood cells. Although the proportion of CX3CR1+ cells within the CD4 T cell population has previously been reported to be associated with *clinical disease activity* in IBD, we do not find an association between the proportion of CX3CR1+ CD4 T cells and *histologically proven disease activity* in IBD. We do find an association between inflammation and CX3CR1+ CD8+ NK T cells in CD and CX3CR1+ intermediate monocytes in UC, which highlights the role of these cells in IBD. These results provide a baseline for follow-up studies on the role of CX3CR1 in IBD.

## P1700 NO DIFFERENCE IN THE DISTRIBUTION OF PATHOGENIC FACTORS FOUND IN *ESCHERICHIA COLI* ISOLATES FROM PATIENTS WITH CROHN'S DISEASE AND HEALTHY INDIVIDUALS

Siniagina M., Markelova M., Laikov A., Boulygina E., Khusnutdinova D., Kharchenko A., Fedorova M., Romanova V., Grigoryeva T. Kazan Federal University, Kazan, Russian Federation

**Contact E-Mail Address:** marias25@mail.ru

**Introduction:** Dysbiosis of the gut microbiome in Crohn's disease (CD) patients is associated with reduced bacterial diversity and higher relative abundance of Proteobacteria phylum, in particular *Escherichia coli*. In recent decades, *E. coli* is thought to be implicated in CD pathogenesis and considered as one of the possible causes of the disease occurrence and progression.

**Aims & Methods:** The aim of the study was to characterize *E. coli* strains obtained from diagnosed CD patients and individuals (controls), and to evaluate their contribution to the pathogenesis of CD.

*E. coli* strains were isolated from stool samples of 14 patients and 18 controls. Fecal suspensions were inoculated on selective Endo medium and colonies were identified by MALDI Biotyper and serological test. Based on quadruplex PCR identification according to Clermont *et al.* (2013), the colonies were assigned to phylogenetic groups. Ninety seven selected isolates were sequenced on MiSeq platform. Reads were assembled using SPAdes v.3.11.1 followed by assemblies' annotation using Prokka v.1.9. Serotypes were assigned using SerotypeFinder-2.0 tool. Using MLT ENTEROTest 24N kit, the strains were tested for the production of H<sub>2</sub>S and the ability to utilize various sugars, polyhydric alcohols, glycosides, and amino acids.

**Results:** Out of 97 sequenced isolates, 33 duplicates were revealed using the comparative genome analysis, i.e. isolates sequenced more than once due to varying colony phenotypes. Sixty four strains had unique genomes - 27 isolates from CD patients, and 37 isolates from the control group.

The phylogenetic group distribution did not differ significantly between CD patients and controls. However, *E. coli* strains belonged to phylogroups E/ clade 1 and F were identified only in healthy donors. Clinical significance of strains belonging to these groups is not well understood.

The pathogenicity and virulence of *E. coli* strains were explored by searching for 61 previously reported genes of adhesion and invasion system in their genomes. We found no statistically significant difference in these genes distribution when comparing isolates from both CD and control groups. So, there was no evidence for the association between CD status and the presence of pathogenic or virulent genes in *E. coli* strains. According to the classification of *E. coli* serotypes, among isolated strains 3 enteroaggregative types (EAEC: O17/O44:H18, O15:H18, O126:H27), 3 enteropathogenic types (EPEC: O128ac:H12, O88:H25, O154:H9), and 1 enteroinvasive type (O112ac:H16) were found. The distribution of these types did not differ significantly between CD and control groups, either, though strains of these serological subgroups prevailed in fecal samples from individuals with CD and constituted a smaller proportion in healthy ones. Prevalence of these strains in CD patients may be associated with the development of the disease.

Strains from studied cohorts showed no significant difference in ability to catalyze sugars, polyhydric alcohols, glycosides and amino acids. It is of interest to note, 3 different strains from one CD patient showed ability to produce H<sub>2</sub>S. It is supposed that hydrogen sulfide involves in IBD development by disrupting the integrity of the intestinal mucosa.

**Conclusion:** The whole genome analysis of *E. coli* strains in CD patients and healthy controls did not reveal any connection between *E. coli* virulence and pathogenicity and disease status. It may be assumed that the development of the disease is associated with altered interaction between the bacteria with certain serotypes and human immune system and their balance in community.

**Introduction:** The intestinal mucosa inhabits the largest pool of phagocytes that fails to be constantly replenished from circulating monocytes in the absence of the gut microbiota and to some extent in response to antibiotics. Understanding this paradigm is of importance as long-term compositional changes in the gut microbiome has been linked to the initiation and progression of either inflammatory or neoplastic lesions even later in life. We herein investigated whether bacterial muramyl dipeptide (MDP), which occurs physiologically in high concentrations within the intestinal lumen, may interfere on the functional specialization of circulating monocytes into either dendritic cells or macrophages for intestinal homeostasis. **Aims & Methods:** The *NOD2* gene expression levels of 427 colorectal cancer patients was respectively compared to outcome using the cancer genome atlas database. The transcriptomic data from *NOD2*<sup>hi</sup> and *NOD2*<sup>low</sup> tumors were further analysed for identifying gene pathways that were differentially enriched. We next performed multiparametric cell cytometry and gene expression analysis by making use of the Azoxymethane (AOM)/Dextran Sulfate Sodium (DSS) model of mouse colorectal cancer. A mouse model of colitis and competitive bone-marrow chimera mice were used for evaluating the anti-inflammatory properties and the long-term autonomy of M-CSF-derived phagocytes from *Nod2*-deficient mice respectively. This fate mapping of *Nod2*-deficient bone marrow derived precursors was addressed by reconstituting *Nod2*-deficient CD45.2<sup>+</sup> animals with an equal mixture of wild-type CD45.1<sup>+</sup> and congenic *Nod2*-deficient CD45.2<sup>+</sup> cells. After these *in vivo* systems, we used *in vitro* culture approaches to study the impact of MDP on human monocytes differentiation into either dendritic cells or macrophages.

**Results:** A shorter median survival time of patients was observed for those with the lowest transcript levels of *NOD2*. Such tumors were markedly characterized by a lowered expression of several genes involved in phagocytosis and antigen presentation. Conversely, the intratumoral abundance of monocyte-derived phagocytes (CD11b<sup>+</sup> CCR2<sup>-</sup> Ly6C<sup>-</sup> MHCII<sup>+</sup>) was lowered in tumours from *Nod2*-deficient animals. Quantitative RT-PCR analysis further argued for a specific decrease in the accumulation of antigen presenting cells derived from circulating monocytes despite similar abundance of macrophages. The shift towards monocyte-derived dendritic cells was also found when treating human peripheral blood monocytes with MDP. Adoptive transfer of M-CSF-derived phagocytes alleviated the severity of DSS-induced colitis, while the absence of *NOD2* gave a lowered advantage on the expansion of such cells as determined by competitive chimera experiment.

**Conclusion:** Herein, we identified a key role of the major Crohn's disease predisposing *NOD2* gene on the ontogeny of monocyte-derived dendritic cells that may account for the greater survival of colorectal patients with high levels of intratumoral *NOD2*.

**Introduction:** There is mounting evidence to suggest that vitamin D levels are associated with important clinical parameters and outcomes in patients with inflammatory bowel disease (IBD). In recent years, additional IBD cohort studies have emerged that further support an association between vitamin D deficiency and clinical disease activity (1-4). However, the causal relationship remains unclear. To our knowledge, this is the first study in adult patients with IBD to report the influence of vitamin D binding protein (VDBP) on the association between circulating total, free, and bioavailable 25(OH)D and inflammation in IBD.

**Aims & Methods:** This study aimed to provide a better understanding of this relationship by more closely examining the relation between inflammation and different vitamin D parameters. A comparative, single-centered, cross-sectional study was conducted in 108 adults with IBD. Blood count, transferrin, albumin and CRP were determined by routine assays. CRP levels  $\geq 5$  mg/dL were considered biochemical evidence of inflammatory activity. 25(OH)D and VDBP levels were determined by ELISA. Free vitamin D and bioavailable vitamin D levels were calculated with the validated formula (5). Statistical analysis was performed using IBM SPSS version 25.0.

**Results:** 108 subjects with IBD (54 male, 59 female; 68 CD, 45 UC) with a mean age of  $41.08 \pm 12.84$  years were recruited to the study. Of these patients, 32/108 had inflammatory activity (14 male, 18 female; 22 CD, 10 UC;  $39.69 \pm 13.89$  years) while 76/108 had no inflammation (36 male, 40 female; 44 CD, 32 UC;  $41.54 \pm 12.43$  years). The albumin levels were negatively correlated with CRP ( $-0.303$ ,  $p=0.002$ ) and significantly lower in the presence of inflammation ( $p<0.05$ ). Average serum 25(OH)D levels were found to be similar in inflammatory and non-inflammatory conditions ( $25.37 \pm 11.38$  and  $23.46 \pm 10.12$  ng/mL respectively,  $p>0.05$ ). However, VDBP levels were significantly higher when inflammation was present ( $364.26 \pm 63.26$  mg/L in inflammatory vs.  $335.27 \pm 67.51$  mg/L in non-inflammatory conditions,  $p<0.05$ ) and also showed a positive correlation with CRP levels ( $0.288$ ,  $p=0.003$ ). The free/total 25(OH)D ratio was negatively correlated with CRP levels ( $-0.260$ ,  $p<0.05$ ). Neither free 25(OH)D nor bioavailable 25(OH)D levels were correlated with CRP or albumin levels and no significant inflammation-related variance in levels was found for either of these parameters.

**Conclusion:** Although no association between total, free and bioavailable 25(OH)D and inflammation was observed, high levels of circulating VDBP were associated with increased levels of inflammation. Confirming this association, the free/total 25(OH)D ratio showed an inverse association with inflammation. These findings suggest that VDBP may play a bigger role than previously thought in the modulation of the complex relation between vitamin D and inflammation. Thus, we propose that the simultaneous detection and investigation of total, free and bioavailable 25(OH)D and VDBP levels in plasma can provide valuable information when studying the relationship between vitamin D and IBD-related inflammation.

**Contact E-Mail Address:** javier.condearanda@usz.ch

**Introduction:** Inflammatory bowel disease (IBD) is caused by a complex interaction among genetic, immunological, bacterial and environmental factors. In this scenario, protein tyrosine phosphatase non-receptor type-2 (PTPN2) has been recognized as a risk factor for the development of IBD and functional studies revealed a major role for this protein in the development of experimental colitis through the regulation of the inflammasome, among other processes. Similar, the immunoregulatory cytokine interleukin-10 (IL-10), which is a master regulator of innate immune cell function and controls excessive inflammatory cytokine release, e.g. that of the inflammasome product IL-1 $\beta$ , has also been considered a relevant player in the control of intestine inflammation.

**Aims & Methods:** Here we aimed to elucidate the interaction between IL-10 and PTPN2 dysfunction in the development of intestinal inflammation, at cellular and molecular level, in order to contribute to the identification of new and novel prevention and/or therapeutic approaches.

DSS colitis and the IL-10<sup>-/-</sup> immune cell-driven colitis models were performed in mice lacking PTPN2 in myeloid cells (PTPN2<sup>fl/fl</sup>xLysMCre mice or PTPN2<sup>fl/fl</sup>xCD11cCre mice). After that, histology studies, flow cytometry, expression analysis, ELISA and barrier function experiments were performed. Bone marrow derived macrophages (BMDMs) were used for *ex vivo* studies.

**Results:** *Ex vivo* experiments using BMDCs showed that recombinant IL-10 was able to ameliorate the expression of IL1 $\beta$  induced by LPS in WT but not in PTPN2<sup>CD11cCre</sup> BMDCs. The same experiments using BMDMs from WT and PTPN2<sup>LysMCre</sup> mice revealed no differences in the expression of IL1 $\beta$ . However, IL-10-induced reduction of the production of mature IL1 $\beta$  was impaired in BMDMs from PTPN2<sup>LysMCre</sup> mice as compared with their WT littermates. Analysis of different well-known signalling pathways involved in the regulation of the inflammasome and IL1 $\beta$  expression revealed that NF $\kappa$ B, Erk and Jnk activation were dysregulated in PTPN2<sup>LysMCre</sup> BMDMs. Colitis models using IL-10<sup>-/-</sup> and IL-10<sup>-/-</sup>xPTPN2<sup>LysMCre</sup> mice also revealed differences in prolapse incidence, histology scores and myeloperoxidase activity, being all these parameters increased in the mice lacking PTPN2 in myeloid cells.

**Conclusion:** PTPN2 contributes to IL-10-related effects on innate immune response and development of colitis. These results unravel a novel molecular mechanism, by which the beneficial effects of IL-10 on intestinal inflammation depends on the genetic host factors.

**Disclosure:** Nothing to disclose

## P1704 GREATER REDUCTIONS OF GUT T LYMPHOCYTES WITH COMBINED BLOCKADE OF $\alpha$ 4 $\beta$ 7 AND $\alpha$ E $\beta$ 7 INTEGRINS VERSUS INDIVIDUAL BLOCKADE ALONE

Dai B., Ichikawa R., Elstrott J., Gogineni A., Keir M.E., McBride J., Yi T. Genentech, Inc., Discovery Immunology and Discovery Biomarkers, South San Francisco, United States

**Contact E-Mail Address:** dai.bingbing@gene.com

**Introduction:** Therapeutic approaches to treating inflammatory bowel diseases (IBD) include targeting integrins that mediate adhesion and migration of inflammatory lymphocytes to the gastrointestinal (GI) tract. In the era of anti-integrin therapies in IBD, it is important to understand the relative contributions of integrin family members to lymphocyte migration and retention in the GI tract.

**Aims & Methods:** To dissect the role of  $\beta$ 7 integrins in lymphocyte trafficking, we used the KikGR transgenic mouse model which ubiquitously expresses a green-to-red photoconvertible protein. After treatment with antibodies against  $\alpha$ 4 $\beta$ 7,  $\alpha$ E $\beta$ 7,  $\beta$ 7 (which targets both  $\alpha$ 4 $\beta$ 7 and  $\alpha$ E $\beta$ 7), or a control, mesenteric lymph nodes (MLNs) were surgically exposed to violet light to photo-convert cells from KikG (green fluorescence) to KikR (red fluorescence). Frequency of KikR<sup>+</sup> CD8<sup>+</sup> T cells in the colon lamina propria was then analysed by flow cytometry. Statistical testing was conducted using Student's unpaired *t* tests.

**Results:** Individual blockade of either  $\alpha$ 4 $\beta$ 7 or  $\alpha$ E $\beta$ 7 integrin reduced CD8<sup>+</sup> T cell localization to the colon lamina propria from mesenteric lymph nodes, whereas blockade of both led to a greater reduction in CD8<sup>+</sup> T cells (Table). Further, we demonstrate superior reductions in both polyclonal and antigen-specific effector T cell accumulation in the intestinal mucosa following concurrent inhibition of both  $\beta$ 7 integrins as compared with single blockade of either  $\alpha$ 4 $\beta$ 7 or  $\alpha$ E $\beta$ 7. Additional experiments using intra-vital two-photon microscopy to image mucosal CD8<sup>+</sup> T cells from the luminal side of the small intestine showed that  $\alpha$ E $\beta$ 7-expressing T cells actively migrate within the epithelium and can travel across the basement membrane between subepithelial regions and lamina propria compartments. Importantly, blockade of  $\alpha$ E $\beta$ 7 or its ligand E-cadherin reduces T cell interactions with the basolateral epithelial surface. Lastly, blockade of  $\alpha$ E $\beta$ 7, but not  $\alpha$ 4 $\beta$ 7, reduces the retention time of activated effector T cells in the intestinal mucosa.

Comparison	Mean $\pm$ SEM (% of migration relative to control)
Anti- $\alpha$ E $\beta$ 7 vs control	54.6% $\pm$ 9.5% vs 100%*
Anti- $\alpha$ E $\beta$ 7 vs control	52.1% $\pm$ 6.7% vs 100%*
Anti- $\alpha$ E $\beta$ 7 + anti- $\alpha$ 4 $\beta$ 7 vs control	29.1% $\pm$ 6.7% vs 100%***
Anti- $\alpha$ E $\beta$ 7 + anti- $\alpha$ 4 $\beta$ 7 vs anti- $\alpha$ E $\beta$ 7	29.1% $\pm$ 6.7% vs 54.6% $\pm$ 9.5%*
Anti- $\alpha$ E $\beta$ 7 + anti- $\alpha$ 4 $\beta$ 7 vs anti- $\alpha$ 4 $\beta$ 7	29.1% $\pm$ 6.7% vs 52.1% $\pm$ 6.7%*
Anti- $\beta$ 7 vs control	26.4% $\pm$ 6.4% vs 100%**
Anti- $\beta$ 7 vs anti- $\alpha$ E $\beta$ 7	26.4% $\pm$ 6.4% vs 54.6% $\pm$ 9.5%*
Anti- $\beta$ 7 vs anti- $\alpha$ 4 $\beta$ 7	26.4% $\pm$ 6.4% vs 52.1% $\pm$ 6.7%*

MLN, mesenteric lymph node; SEM, standard error.

Data were calculated as percentage of KikR<sup>+</sup> CD8<sup>+</sup> cells migrated from MLN relative to that of the control group. \**P* < 0.05, \*\**P* < 0.01, \*\*\**P* < 0.001. Data are representative of five independent experiments.

[Table. Trafficking of CD8<sup>+</sup> T Cells from MLNs to the Colon Is Reduced by Dual Blockade of  $\alpha$ 4 $\beta$ 7 and  $\alpha$ E $\beta$ 7]

**Conclusion:** Taken together, our results suggest a model in which cell migration to the gut mucosa is mediated through  $\alpha$ 4 $\beta$ 7 while activated effector T cells are retained in the lamina propria and intra-epithelial space via  $\alpha$ E $\beta$ 7:E-cadherin interactions. Co-blockade of  $\alpha$ 4 $\beta$ 7 and  $\alpha$ E $\beta$ 7 leads to increased reduction of T cell accumulation in GI tissues through a stepwise inhibition of T cell migration and subsequent tissue retention. Our data also suggest that a therapeutic blockade of both  $\alpha$ 4 $\beta$ 7 and  $\alpha$ E $\beta$ 7 such as that provided by etrolizumab may provide more efficient inhibition of T cell trafficking to the gut and potentially their inflammatory effects on the gut lining, which could alter the pathogenesis of IBD, than blockade of one integrin alone.

## P1705 INTRACELLULAR SURVIVAL AND REPLICATION OF ADHERENT-INVASIVE *ESCHERICHIA COLI* (AIEC) AND NON-AIEC WITHIN TWO MACROPHAGE CELL LINES

Camprubí-Font C., Caballero-Moya A., Pont-Redondo N., Martinez Medina M. Universitat de Girona, Biology Department, Girona, Spain

**Contact E-Mail Address:** c.camprubi4@gmail.com

**Introduction:** Adherent-invasive *Escherichia coli* (AIEC) have been associated with Crohn's disease pathogenesis. AIEC pathotype is constituted by *E. coli* able to adhere to and invade intestinal epithelial cells, and able to survive and replicate within macrophages without inducing cell death. Identification of AIEC is based on *in vitro* models of infection and lacks standardisation. Besides, scarce data exist about the intramacrophage survival and replication abilities of non-adherent and non-invasive *E. coli* colonizing the gut mucosa (non-AIEC).

**Aims & Methods:** We aimed to compare the intracellular survival and replication abilities of AIEC and non-AIEC strains in two different cell lines previously used for AIEC identification. We tested 13 AIEC and 29 non-AIEC strains isolated from the intestinal mucosa of Crohn's disease patients and controls using gentamicin protection assays in triplicate. The cell lines tested were the murine macrophages J774 and the human monocytes THP-1, the latter was differentiated to macrophages. The results are expressed as the percentage of intracellular bacteria after 24h of infection. Indices >100% indicate intracellular survival.

**Results:** In J774, AIEC strains clearly showed higher indices of intracellular survival/replication than non-AIEC (1143±750% vs 282±175%,  $p < 0.001$ ). However, 85% of non-AIEC were indeed able to survive and replicate within this cell line, what can represent an issue in AIEC screening. We suggest a new threshold value that could be of assistance, as 85% of AIEC strains and only 7% of non-AIEC showed indices over 500% ( $p < 0.001$ ). In THP-1, the indices of survival/replication were lower than in J774 and no differences were found between strains (AIEC: 90±52%, non-AIEC: 119±72%). No correlation was found between the data obtained by the two models.

**Conclusion:** In conclusion, we suggest that the human cell line THP-1 is not suitable for AIEC screening and that a higher threshold value of intracellular survival/replication in J774 may be of assistance in AIEC screening. Additional studies using more realistic models such as non-tumour human cell lines would be of interest.

**Introduction:**  $\beta$ -glucan consumption is known for its beneficial effects in reducing inflammation. Humans lack the required enzymes to digest  $\beta$ -glucans, but certain intestinal microbiota species can digest  $\beta$ -glucans and thus trigger gut microbial changes, improving human health.

**Aims & Methods:** In this study, we determined curdlan (bacterial  $\beta$ -glucan) induced microbial changes, and followed its influence on the course of intestinal inflammation in the Dextran Sodium Sulfate (DSS) colitis. C57BL/6 mice were pre-treated with vehicle (5% glucose) or curdlan (10 mg/ml) through oral gavage for 14 days. Subsequently, mice were taken off curdlan and colitis was induced by administering 2% fresh DSS daily to the drinking water for 7 days. Control (non-colitis) groups received normal drinking water. To determine inflammation, colon weight and length was measured and histology scoring and gene expression study were performed. Colon content was collected for 16S amplicon (V3-V4) sequencing of microbiota composition. Differences in amplicon sequence variance (USEARCH) composition were visualized based on the Bray-Curtis-Dissimilarity Index. Fold differences were studied using DESeq2.

**Results:** In colitis condition, disease activity index, weight loss and inflammation score of the curdlan pre-treated group were improved compared to the vehicle treated group. Concomitant with improved colitis, the bacterial populations exhibited a higher alpha diversity of the curdlan fed animals compared to vehicle. Beta diversity analysis indicated large differences ( $R^2 = 0.46$ ) in the bacterial community structure (Bray-Curtis) between the colitis and non-colitis condition. While curdlan feeding did not induce any global community changes, specific taxa did show significant differences in relative abundance. Interestingly, a specific *Bifidobacterium* was observed to be 10 to 100-fold more prevalent in the curdlan fed group in both colitis and non-colitis conditions respectively.

**Conclusion:** Curdlan feeding improved DSS-induced colitis and our data suggests that alterations in the gut microbiome may mediate the observed beneficial effects.

**Contact E-Mail Address:** margamartinez@udg.edu

**Introduction:** Variations in the expression and/or the sequence of outer membrane proteins (OMPs) may modulate bacterial virulence. Increased OmpC expression and particular mutations in OmpA sequence have been related to a better interaction of adherent-invasive *Escherichia coli* (AIEC) strain LF82 with intestinal epithelial cells (IECs).

**Aims & Methods:** We aimed to study in a collection of AIEC and non-adherent and non-invasive *E. coli* colonizing the gut mucosa (non-AIEC): i) the variability of OMPs sequence to look for new variants associated with AIEC, and ii) to study the differential gene and protein expression of OMPs between the two groups of strains to gain knowledge about the role of OMPs in AIEC pathogenicity.

Fourteen AIEC and 30 non-AIEC strains were included in the study. The *ompA*, *ompC* and *ompF* genes were sequenced by Sanger method. Differential expression of OMPs was studied at the protein level by urea-SDS-PAGE in strains growing LB medium, and for the first time, at the gene level during *in vitro* infection of intestine-407 cells by RT-qPCR. Two fractions were analysed: i) the bacteria present in the supernatants of infected cultures and ii) the bacteria interacting with IECs (either the adhered or the intracellular ones).

**Results:** Sequence variants were mostly associated with the phylogenetic origin of the strains rather than with the AIEC phenotype. Nonetheless, OmpA-A200V, and OmpC-S89N, -V220I and -W231D amino acid substitutions were more frequently found in AIEC than in non-AIEC strains. OMPs protein levels were also similar between AIEC and non-AIEC growing in conventional culture. However, AIEC showed increased expression of *ompA* and *ompF* in comparison with non-AIEC when growing in the supernatants of infected IECs cultures ( $p < 0.030$ ). Interestingly, reduced OMPs expression was observed in AIEC strains infecting IECs ( $p < 0.032$ ), whereas non-AIEC strains did not significantly alter OMPs expression under this condition ( $p > 0.577$ ).

**Conclusion:** In conclusion, despite no particular OMPs sequence variants have been found as a common and distinctive trait in AIEC, a general trend has been observed in terms of OMPs gene expression using *in vitro* infection models. This supports the hypothesis that differential expression of OMPs proteins could play an important role in AIEC virulence.

## P1708 ELTANEXOR RAPIDLY DECREASES INFLAMMATION AND IMPROVES OUTCOMES IN A DSS MODEL OF IBD

Stakenborg M.<sup>1</sup>, De Simone V.<sup>2</sup>, Widman D.G.<sup>3</sup>, Gornisiewicz S.<sup>3</sup>, Tamir S.<sup>3</sup>, Baloglu E.<sup>3</sup>, Matteoli G.<sup>2</sup>

<sup>1</sup>KU Leuven, *TARGID, Leuven, Belgium*, <sup>2</sup>KU Leuven, *Translational Research Center for Gastrointestinal Disorders, Leuven, Belgium*, <sup>3</sup>Karyopharm, *Newton, United States*

**Contact E-Mail Address:** gianluca.matteoli@kuleuven.be

**Introduction:** Crohn's disease and ulcerative colitis are inflammatory bowel diseases (IBD) leading to abdominal pain, severe diarrhea, fatigue and weight loss. Over 1 million Americans and 2.5 million Europeans are estimated to have IBD, with incidence rates rising exponentially in industrialized nations. To date, there is no cure for IBD, making patients dependent on lifelong symptomatic treatment aimed to reduce recurrence of intestinal inflammation. Thus, novel and effective treatments for IBD are an urgent and unmet medical need. Selective Inhibitor of Nuclear Export (SINE) compounds, that inhibit exportin 1 (XPO1)-mediated nuclear export of over 200 cargoes, may represent a novel option to treat inflammation, such as NFκB and PPAR-γ. Eltanexor (KPT-8602), an oral SINE compound, has a broad therapeutic window and minimal brain penetration in preclinical species associated with reduced toxicities while maintaining efficacy. The safety, tolerability, and efficacy of eltanexor is currently being evaluated in patients with relapsed/refractory cancer indications (NCT02649790). Our preliminary data indicated that eltanexor also has potent anti-inflammatory and cytoprotective effects both *in vitro* and *in vivo*, providing clear rationale for its utility as a promising therapeutic agent for IBD. This study sought to determine the effects of eltanexor during intestinal inflammation using a dextran sulfate sodium (DSS)-induced colitis mouse model, as well as its impact on cytokine expression in bone marrow-derived (BMD) macrophages (Mφs).

**Aims & Methods:** Colitis was induced in C57BL/6J mice by 2.5% dextran sodium sulfate (DSS) in drinking water for 5 days. Disease progression was assessed by a standardized disease activity index (DAI) including body weight loss, stool consistency and blood in the faeces. Myeloid cells infiltrating the colonic mucosa were analyzed via flow cytometry. To assess the therapeutic potential of eltanexor *in vivo*, 10 and 15 mg/kg of the SINE compound were orally administered every other day starting at day 5 of DSS colitis. To study the anti-inflammatory effect of eltanexor at gene expression level, BMDMφs were pre-treated with eltanexor before stimulation with LPS (100 ng/ml) and IFNγ (50 ng/ml).

**Results:** To test the therapeutic potential of eltanexor, mice treatment was started at the peak of intestinal inflammation, namely day 5 after DSS. Oral administration of 15 mg/kg eltanexor resulted in a rapid and potent reduction of DAI within 48 hours of administration. Eltanexor treatment resulted in recovery of body weight loss, reduced blood in the faeces and normalization of stool consistency. This anti-inflammatory effect was accompanied by a decreased infiltration of colonic inflammatory myeloid cells including neutrophils and monocytes, followed by an increase in mature Mφ. *In vitro*, eltanexor pre-treatment suppressed expression of pro-inflammatory cytokines (IL-1b, IL-1a, NOS2, IL-6 and TNFα) in LPS/IFNγ treated BMDMφs. In parallel, eltanexor was able to induce a rapid increase (within 2 hours post dosage) in LPS+IFNγ stimulated BMDMφs of IL-10 compared to the vehicle pointing towards a strong anti-inflammatory effect.

**Conclusion:** Eltanexor was able to significantly improve the course of murine DSS-induced colitis. Both *in vitro* and *in vivo*, eltanexor demonstrated the ability to rapidly decrease inflammation and prevent myeloid cell activation. These data suggest that blockage of XPO1-mediated nuclear export may be a promising therapeutic strategy to favor a rapid remission in IBD and further research is warranted.

**Introduction:** The dysbiosis displayed by patients with Crohn's Disease (CD) and ulcerative colitis (UC) are different [1]. Although the location of the disease is a parameter relevant to clinical practice [2], few studies have shown the changes in the microbial community among the subtypes of inflammatory bowel disease (IBD) that affect the colon (E1, E2, E3, C-CD and IC-CD).

**Aims & Methods:** Our aim was to analyse the richness, diversity and composition of the microbiota associated to the colonic mucosa of IBD patients with disease located in the colon in order to identify bacterial markers that allow their discrimination.

Colonic biopsies were obtained from 21 patients with UC (5 E1, 6 E2 and 10 E3) and 22 with CD (12 C-CD and 10 IC-CD). Mucosa-associated microbial community was analysed by sequencing the V4 region of the 16S rRNA gene by the Illumina MiSeq method (depth 23,611 seqs/sample). Differences between IBD subtypes according to location have been sought by analysing alpha diversity (richness and diversity) and the relative abundance of taxa at different taxonomic levels (phylum-genus). The receiver operating characteristic (ROC) curve analysis was performed for the significant taxa, and accuracy to discriminate amongst disease locations was measured by the area under the ROC curve (AUC). Besides, and given the compositional nature of microbiome data [3], a linear discriminant analysis was performed with *selbal* [4]. The groups of taxa whose relative abundance allowed the best discrimination between diseases was selected to calculate a balance to differentiate conditions, using a k-fold cross-validation algorithm.

**Results:** Richness (Sobs=55-288) and diversity (InvSimp=1.9-38.9) of the bacterial community were similar among all the disease locations compared. Six indicators, that determine a differential microbiological signature between IBD locations, have been identified (relative abundance=0.16-20.91%). The abundances of sequences corresponding to indicators 36 and 75 were significantly lower in patients with C-CD compared to those with UC of any location ( $p \leq 0.040$ ,  $AUC \geq 0.726$ ). Besides, indicators 2, 11 and 69 showed significant differences between E3 and C-CD ( $p \leq 0.015$ ,  $AUC \geq 0.829$ ). Indicators 2 and 11 also showed differences between UC locations ( $p \leq 0.017$ ,  $AUC \geq 0.861$ ) while the relative abundance of indicators 51 and 19 is higher in C-CD compared to IC-CD ( $p \leq 0.007$ ,  $AUC \geq 0.846$ ). On the other side, using the compositional approach, a ratio of two indicators resulted in the best balance to discriminate between diseases, which had an apparent  $AUC=0.857$  when measured on the whole dataset (cross-validation  $AUC=0.665$ ).

**Conclusion:** Richness and diversity of the microbiota associated to the colonic mucosa of IBD patients with colonic disease location is similar. However, differential bacterial indicators have been identified and a ratio to discriminate between UC and CD with colonic location is proposed. The quantification of these taxa would allow to refine the use of microbiomarkers to

(i) support the diagnosis between IBD that affect the same location and/or (ii) assess the risk of disease extension.

**Introduction:** N-acyl homoserine lactones (AHLs) are molecules involved in quorum sensing, a bacterial communication network, which can also impact the host's physiology. We recently showed the presence of AHLs in the human gut ecosystem and identified a new AHL, named 3-oxo-C12:2. This molecule was decreased in inflammatory bowel disease subjects during flare and its absence was associated with dysbiosis, thus suggesting a beneficial role if this new AHL. However, 3-oxo-C12:2 is structurally very close of the well-studied AHL 3-oxo-C12, produced by the opportunistic pathogen *P. aeruginosa*, which is known to impair epithelial barriers.

### Aims & Methods:

In this context, we aimed to investigate the effects of the 3-oxo-C12:2 AHL on the intestinal barrier function, and compare them to those of the 3-oxo-C12.

Human Caco-2/TC7 enterocytic cells were exposed on their apical side to 3-oxo-C12:2 or 3-oxo-C12 AHLs. These treatments were combined or not with pro-inflammatory cytokines Interferon- $\gamma$  and Tumor Necrosis Factor- $\alpha$ , known to have deleterious effects on the barrier function. We assessed paracellular permeability by measuring the passage of FITC-dextran 4 kDa and analyzed tight junctions (TJ) integrity by immunofluorescence and Proximity Ligation assays.

**Results:** Upon exposure to 3-oxoC12, the paracellular permeability is increased and the signal of Occludin and Tricellulin, bicellular and tricellular TJ proteins respectively, is decreased. In contrast, 3-oxo-C12:2 AHL modifies neither permeability nor tight junctions integrity. While 3-oxo-C12 potentiates the increase in permeability induced by the pro-inflammatory cytokines, 3-oxo-C12:2 does not exacerbate cytokine effects on permeability. Moreover, 3-oxo-C12:2 attenuates the deleterious effects of cytokines on Occludin and Tricellulin, as well as on their interaction at the plasma membrane with their cytoplasmic partner ZO-1. Preliminary results show that Occludin and Tricellulin interact with the E3-ubiquitin ligase Itch and that the increase in ubiquitination levels of Occludin and Tricellulin caused by cytokines is suppressed in the presence of 3-oxo-C12:2, suggesting that it prevents their endocytosis or degradation.

**Conclusion:** Our results show that 3-oxo-C12:2, a major AHL in the human gut, exerts a protective role on the intestinal barrier function in pro-inflammatory conditions. Given its loss in inflammatory bowel disease patients, the beneficial role of the 3-oxo-C12:2 AHL in the gut ecosystem leads to interesting perspectives to better understand host-microbiota interactions in this digestive tract pathology.

**Introduction:** Vitamin D has traditionally been known as a regulatory factor in bone metabolism and homeostasis, but emerging evidence suggests that it also plays an important role in immune regulation, as indicated by the fact that vitamin D deficiency has been associated with the pathogenesis of inflammatory bowel disease (IBD) (1). While it is possible that vitamin D affects the severity of inflammation and the disease course in patients with IBD, the causal relationship remains uncertain due to the com-

plexity of the interrelationship between vitamin D and inflammation (2-4). Most studies have relied on immunoassays measuring 25-hydroxyvitamin D (25(OH)D<sub>3</sub>), which may be less accurate than the accepted gold standard of liquid chromatography tandem mass spectrometry (LC-MS/MS). Circulating 25(OH)D<sub>3</sub> is hydroxylated to the metabolically active 1,25(OH)<sub>2</sub>D<sub>3</sub> by CYP27A1. The alternative pathway involves hydroxylation to the inactive 24,25(OH)<sub>2</sub>D<sub>3</sub> via the 24-hydroxylase CYP24A1 prior to elimination (5).

**Aims & Methods:** Based on the hypothesis that the ratio of 25(OH)D to 24,25(OH)<sub>2</sub>D<sub>3</sub> may be a more accurate measure of vitamin D status than 25(OH)D alone, our study aimed to characterise vitamin D metabolism in patients with active and inactive IBD using LC-MS/MS. The study was conducted as a cross-sectional prospective cohort study. Patients with inflammatory disease had definite endoscopic evidence of ulceration, and either CRP >5mg/L or faecal calprotectin >200mg/kg in stool. Patients who had taken medications with corticosteroids or vitamin D supplementation in the preceding 4 weeks were excluded. Serum was tested for 25(OH)D<sub>3</sub>, 1,25(OH)<sub>2</sub>D<sub>3</sub> and 24,25(OH)<sub>2</sub>D<sub>3</sub> using an LC-MS/MS assay. Spearman's correlation coefficient was used to test correlations and unpaired t-tests to test differences between inflammatory and non-inflammatory IBD patient groups.

**Results:** Up to November 2018, 87 consecutive patients with IBD (39 CD; 48 UC) were recruited; 55% were male. Median age was 36 years (range 23 to 72 yrs). Fewer patients in the active group were on immunomodulators (40% vs. 61%,  $p=0.05$ ) or TNF inhibitors (25% vs. 49%,  $p=0.05$ ). There was no difference in serum 25(OH)D<sub>3</sub>, or 1,25(OH)<sub>2</sub>D<sub>3</sub> between the groups. Serum 24,25(OH)<sub>2</sub>D<sub>3</sub> levels were significantly lower in the active group (mean 1.9 vs. 2.7ng/mL,  $p<0.001$ ) and thus the ratio of 25(OH)D<sub>3</sub>: 24,25(OH)<sub>2</sub>D<sub>3</sub> was higher (49.4 vs. 26.1,  $p<0.001$ ). There was an inverse correlation between active disease and 24,25(OH)<sub>2</sub>D<sub>3</sub> levels ( $r^2=0.39$ ;  $p=0.01$ ). Dietary vitamin D intake and sunlight exposure did not differ between the groups.

**Conclusion:** In the context of inflammation, levels of 1,25(OH)<sub>2</sub>D<sub>3</sub> are maintained by shifting the metabolism of 25(OH)D to 1,25(OH)<sub>2</sub>D<sub>3</sub> rather than 24,25(OH)<sub>2</sub>D<sub>3</sub>, suggesting a reduction in 24-hydroxylase activity to maintain the active metabolite. The ratio of 25(OH)D<sub>3</sub>:24,25(OH)<sub>2</sub>D<sub>3</sub> is increased in active disease and may be a more sensitive marker of vitamin D status in patients with CD.

**Introduction:** South Asians (SA) with Crohn's disease (CD) display a different disease phenotype and course (1), as well as a different urinary metabolic profile (2). Metabolic profiling of faecal water has distinguished CD from controls previously, but only in Caucasian (Cau) cohorts, characterised by a reduction in short chained fatty acids.

**Aims & Methods:** The aim of this study was to compare the metabolic profiles of faecal water in CD patients and healthy controls (H) from Caucasian and South Asian backgrounds.

Samples from 28 CD patients (15 Cau and 13 SA) and 44 healthy controls (20 Cau and 24 SA) were analysed by <sup>1</sup>H NMR spectroscopy. Data was assessed using orthogonal partial least squares discriminant analysis (OPLSDA). Hypothesis-led univariate analysis was also performed using metabolites that have been previously shown to distinguish CD from controls (2). These metabolites were as follows: acetate, butyrate, propionate, lactate, methylamine, glutamine, alanine, taurine, valine, and 2-hydroxybutyrate (2HIB).

**Results:** Multivariate analysis (Table 1) demonstrated that the faecal metabolites driving the separation between CD and controls were similar regardless of ethnicity, although statistically significant separation could not be achieved by multivariate analysis in the smallest group (CD v H in Caucasians).

Univariate analysis demonstrated a statistically significant reduction in butyrate, acetate, 2HIB, and methylamine (p < 0.05) in Cau CD patients compared to controls consistent with previous studies, but only a reduction in 2HIB and methylamine was seen with statistical significance in SA patients. When directly comparing Cau and SA patients with CD, butyrate and 2HIB were significantly different (p = 0.034 and 0.035 respectively) between these ethnic groups.

Model OPLSDA	n	R <sup>2</sup> X	Q <sup>2</sup>	P value CV-ANOVA	Metabolites driving separation in CD
CD : HC All	72 (28:44)	0.145	0.197	<0.001	acetate↓ butyrate↓ glutamine↓ alanine↓ creatine↓ tryptophan↓ 2HIB↓ methylamine↓
CD : H Caucasian	35 (15:20)	0.122	0.126	0.117	acetate↓ butyrate↓ glutamine↓ alanine↓ creatine↓ tryptophan↓ 2HIB↓ methylamine↓
CD : H South Asians	37 (13:24)	0.196	0.290	0.024	acetate↓ butyrate↓ glutamine↓ alanine↓ creatine↓ tryptophan↓ 2HIB↓ methylamine↓

[Table 1]

**Conclusion:** Despite observing consistent changes in the metabolites driving separation between Caucasian and SA patients compared to controls, univariate analysis reveals differences relating to ethnicity, showing that ethnicity influences faecal water metabolic profiles. The effect of ethnicity is likely to be a combination of genetics, diet and environment. Ethnicity therefore must be accounted for as a potential confounder in this type of analysis.

**Introduction:** Tumor progression locus 2 (TPL2, also known as MAP3K8) is a mitogen-activated protein kinase kinase kinase and the primary regulator of ERK-mediated gene transcription downstream of multiple proinflammatory stimuli.<sup>1</sup> Converging lines of evidence suggest a critical role for TPL2 in IBD. TPL2 RNA is upregulated in IBD patient colon biopsies and a TPL2 gain-of-function single nucleotide polymorphism (SNP) is associated with the development of IBD.<sup>2-4</sup> Furthermore, TPL2 deficiency has been demonstrated to attenuate disease pathology in murine models of IBD, including TNF<sup>ΔARE</sup> and DSS-induced mouse colitis models.<sup>5,6</sup> As such, TPL2 inhibition represents a potential strategy to modulate inflammation in IBD.

**Aims & Methods:** The objective of this work was to determine the effect of a highly selective TPL2 inhibitor on chronic intestinal inflammation in a severe combined immunodeficient (SCID) T cell transfer model of colitis. A highly selective TPL2 inhibitor (TPL2i) was dosed in a SCID T cell transfer model. In this model, SCID mice develop chronic intestinal inflammation following the transfer of naïve CD4+CD45RBhi T-cells.<sup>7</sup> Animals were randomized into treatment groups at day 21 (N=15 vehicle, N=15 20 mg/kg TP-

L2i, N=15 60 mg/kg TPL2i) and orally dosed BID for 28 days. On day 21, prior to treatment initiation, 5 naïve and 5 T-cell transferred mice were sacrificed to confirm disease initiation. Following 4 weeks of treatment animals were randomized into necropsy groups and sacrificed at 2, 8, or 12h post-last dose. Plasma TPL2i levels were assessed to estimate target coverage. The effect of TPL2 inhibition on colitis was evaluated based on multiple histopathological endpoints at necropsy. Three independent transverse colon sections (proximal, middle and distal) were scored to assess histology sum score (tabulated from independent inflammation, gland loss, erosion and hyperplasia scores), edema (μm), percent PMN, and neutrophil score. To assess the effects of TPL2i treatment on TPL2 signaling and proinflammatory cytokine levels in the colon, flash frozen colon tissue was analyzed by western blot and MesoScale Discovery, respectively. Statistics were performed using a 2-sided Wilcoxon Rank sum test.

**Results:** Plasma TPL2i levels demonstrated that the 60 mg/kg dose achieved plasma concentrations sufficient to inhibit TPL2 activity by 50% at trough. Treatment with both 20 mg/kg and 60 mg/kg doses of TPL2i improved colitis at day 49 as demonstrated by a significant improvement in colon weight/length. A statistically significant improvement in multiple histopathological endpoints was also observed with 60 mg/kg TPL2i treatment, including an improvement in histology sum, inflammation, gland loss, percent PMN and neutrophil scores. Modulation of TPL2 activation and a reduction in proinflammatory cytokines were demonstrated in the colon of TPL2i treated animals with a significant reduction in phospho-TPL2 levels (a marker of TPL2 kinase activation) and a clear trend towards reduced TNFα, IL-1β, IL-6, KC, IL-12, IFNγ and IL-17 levels in the colon.

**Conclusion:** This work demonstrates that a highly selective TPL2i improves colitis and reduces multiple inflammatory markers in a SCID T cell transfer model of colitis.

**P1716 GS-4875, A FIRST-IN-CLASS TPL2 INHIBITOR SUPPRESSES MEK-ERK INFLAMMATORY SIGNALING AND PROINFLAMMATORY CYTOKINE PRODUCTION IN PRIMARY HUMAN MONOCYTES**

Warr M., Hammond A., Park G., Cui Z.-H., Wright N., Taylor J. *Gilead Sciences, Inc., Foster City, United States*

**Contact E-Mail Address:** matthew.warr@gilead.com

**Introduction:** Tumor progression locus 2 (TPL2, also known as MAP3K8) is a mitogen-activated protein kinase kinase kinase and the primary regulator of ERK-mediated gene transcription downstream of multiple proinflammatory stimuli including bacterial products (eg, LPS and bacterial peptidoglycans), damage-associated molecular patterns (DAMPs), TNFα, and IL-1β.<sup>1</sup> TPL2 regulates the expression of several proinflammatory cytokines, including TNFα, IL-1β, IL-6 and IL-8. As TPL2 acts on both the production of and response to TNFα and IL-1β, it acts to amplify proinflammatory signaling. Dysregulated signaling downstream of these inflammatory signals can drive uncontrolled immune cell activation and inflammation, associated with IBD and other chronic inflammatory and autoimmune diseases. As such, TPL2 inhibition represents a strategy to modulate inflammation in IBD and other disease states.

**Aims & Methods:** We evaluated the effect of a highly selective TPL2 inhibitor (GS-4875) on inflammatory signaling and cytokine production in LPS and TNFα-stimulated primary human monocytes and monocyte-derived dendritic cells. A rat LPS-TNFα acute inflammation model was used to establish a PK/PD relationship. A TPL2 kinase assay was used to assess GS-4875 biochemical IC<sub>50</sub>. GS-4875 selectivity was screened using a KINOMEScan™ selectivity assay (ScanMAX, DiscoveRx, San Diego, CA) at 1μM GS-4875. Monocytes or monocyte-derived dendritic cells were pre-cultured with a GS-4875 and stimulated with LPS or TNFα, and phospho-signaling and cytokine production was then evaluated at 30 minutes and 4 hours post stimulation. A431 cells (human epidermoid carcinoma cell line) were stimulated with TNFα or EGF and phospho-ERK was evaluated after 30 minutes. In vivo PK/PD relationship was established using a rat LPS-TNFα model of acute inflammation. In this model, female lewis rats

were dosed orally with 3, 10, 30 or 100 mg/kg doses of GS-4875 or 1 mg/kg dexamethasone followed by IV dosing of 0.01 mg/kg LPS 2 hours later. Animals were bled for plasma at multiple time points between 0 and 5h after compound dosing and plasma concentrations of TNF $\alpha$  and GS-4875 were measured.

**Results:** GS-4875 inhibits the TPL2 kinase with an IC<sub>50</sub> = 1.3 nM with no significant off-target binding activity. GS-4875 selectively inhibited LPS and TNF $\alpha$ -stimulated phosphorylation of TPL2, MEK, and ERK, with little to no inhibition of phosphorylated p38, JNK or p65 observed. Both the RNA production and secretion of TNF $\alpha$ , IL-1 $\beta$ , IL-6, and IL-8 following LPS stimulation in primary human monocytes was similarly inhibited with GS-4875. In monocyte-derived dendritic cells GS-4875 inhibited the secretion of TNF $\alpha$  and IL-6 following LPS stimulation. To confirm TPL2 requirement for inflammatory, but not Ras-mediated (growth factor stimulated) ERK signaling, A431 cells were stimulated with either TNF $\alpha$  or EGF. Although TPL2 inhibition reduced TNF $\alpha$ -stimulated pERK, no effect on ERK activation downstream of EGF was observed. In vivo activity and PK/PD relationship was established using a rat LPS-TNF $\alpha$  model of acute inflammation. GS-4875 treatment showed dose and exposure dependent inhibition of LPS-stimulated TNF $\alpha$  production at all time points with an estimated EC<sub>50</sub> ( $\pm$ SD) of 667  $\pm$ 124 nM. Inhibition of TNF $\alpha$  production at the highest dose tested inhibited TNF $\alpha$  levels at levels equivalent to that of dexamethasone.

**Conclusion:** This work demonstrates the selective effects of TPL2 inhibition on ERK-mediated signaling and proinflammatory cytokine production and highlights the potential for TPL2 inhibition to treat IBD and other chronic inflammatory and autoimmune diseases.

**Contact E-Mail Address:** michel.neunlist@univ-nantes.fr

**Introduction:** Enteric glial cells (EGCs) are involved in the modulation of intestinal motility, permeability and inflammation. We have shown that these regulations involve the production and release of soluble mediators, including omega-3 and -6 derivatives such as prostaglandins. Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) participates in the control of intestinal functions, but studies focusing on the effects of PGE<sub>2</sub> released specifically by EGC are still lacking. We have evaluated *in vivo* the impact of mPGES1 (PGE<sub>2</sub> producing enzyme) deletion induced specifically in EGC, on intestinal functions and intestinal inflammation.

**Aims & Methods:** mPGES1 deletion was induced in 10 to 20 weeks old male or female S100b<sup>Cre-ERT2</sup>-mPGES1<sup>fl/fl</sup> by a daily injection of tamoxifen (tamo) for 5 days. Two weeks after the onset of the induction of deletion, we induced, or not, the development of colitis by adding dextran sodium sulfate (DSS 4%) in the drinking water during 4 days. The intestinal functions measured at the end of the protocol are: (i) the paracellular permeability (sulfonic acid flux), (ii) the total transit time (expulsion time of carmine red given in gavage) and (iii) the disease Activity Index (DAI = presence of blood in the stool and weight loss of the animals). An immunohistological analysis enabled us to verify the induction of mPGES1 after inflammation in the EGC of wild type mPGES1 mice (mPGES1<sup>fl/fl</sup> mice treated with tamoxifen), and its deletion in mPGES1  $\Delta$ <sup>EGC</sup> mice (S100b<sup>Cre-ERT2</sup>-mPGES1<sup>fl/fl</sup> treated with tamoxifen).

**Results:** The increased expression of mPGES1 in glial cells was observed after exposure to DSS in the myenteric and submucosal ganglia of male and female wild type mPGES1 mice. This induction was absent in mPGES1  $\Delta$ <sup>EGC</sup> mice. In female, DSS treatment induced increases in permeability and DAI, and reduction of transit time only in mPGES1  $\Delta$ <sup>EGC</sup> mice. In contrast, mPGES1 deletion has had no impact on intestinal function or inflammation in males that behaved like mPGES1  $\Delta$ <sup>EGC</sup> female mice.

**Conclusion:** This work represents the first *in vivo* evidence of a direct involvement of glial-derived PGE<sub>2</sub> in the pathophysiology of the intestine. In addition it suggests that the resistance to colitis development observed in female could be due to an increase PGE<sub>2</sub> production.

## P1718 MATERNAL EXPOSURE TO GOS/INULIN MIXTURE FOSTERS COLITIS DEVELOPMENT IN OFFSPRING MICE

[Le A.](#)<sup>1</sup>, Selle A.<sup>2</sup>, Aubert P.<sup>1</sup>, Brosseau C.<sup>2</sup>, Durieu E.<sup>1</sup>, Oullier T.<sup>1</sup>, Neunlist M.<sup>3</sup>, Bodinier M.<sup>2</sup>, Rolli-Derkinderen M.<sup>4</sup>

<sup>1</sup>Inserm U1235, TENS, Nantes, France, <sup>2</sup>INRA, BIA, Nantes, France, <sup>3</sup>Inserm U1235, Nantes, France, <sup>4</sup>Inserm, TENS, Nantes, France

**Contact E-Mail Address:** amelie.le@etu-univ-nantes.fr

**Introduction:** An alteration of the gut microbiota is involved in the pathogenesis of inflammatory bowel disease (IBD) and several probiotic strains and/or non-digestible food ingredients such as prebiotics are already used as dietary supplements to improve intestinal health. One alternative to prevent or reduce colitis development could consist of modulating maternal immunity and microbiota through prebiotics. For this purpose, we studied the effects of prebiotics given to Balb/c mice during gestation on the development of colitis in their offspring.

**Aims & Methods:** 8-10 weeks old offspring mice from mothers exposed to the GOS/inulin prebiotics mixture (9/1, 4% w/w) during gestation or fed with a control diet, were submitted or not to 3 cycles of dextran sodium sulfate (DSS) which induces colitis. A cycle consists of 2 days of 4% DSS in drinking water followed by 5 days of water. At day 4, 11 and 18 of the protocol, the total transit time, the fecal pellet output, the intestinal permeability and the disease activity index (stool consistency, weight loss, and gross bleeding) were measured in the 4 groups of mice. At day 18, the offspring mice were sacrificed and further measurements of intestinal segment permeability, tissue remodelling, systemic and intestinal inflammation as well as microbiota sequencing were performed.

**Results:** Offspring from mothers that received GOS/inulin prebiotics presented no changes in the humidity percentage of feces or total transit time before or after DSS cycles. Nevertheless when treated with DSS, offspring from mothers that received GOS/inulin prebiotics presented an increased disease activity index compared to the DSS group of offspring from mothers with control diet.

**Conclusion:** The enrichment of pregnant mice with non-digestible GOS/inulin prebiotics promotes a long-term effect in their offspring that is, unexpectedly, not a protective one but a sensitization to colitis development. Molecular mechanisms involved are under investigation, but our results already question about the "health benefit" that GOS/inulin should confer.

**Introduction:** Inflammatory bowel disease (IBD) comprises two distinct diseases: Crohn's disease (CD) and ulcerative colitis (UC). Both are chronic diseases with a relapsing course of inflammation in the digestive system. The aetiology of these diseases has not been fully elucidated but is currently presumed to result from a complex interplay among genetic, environmental, microbial and immune factors. Intestinal homeostasis also depends on genetic, environmental, microbial and immune factors, while dysbiosis has been considered an important immunologic aetiology factor in IBD with quantitative and qualitative changes in the microbial composition. Short chain fatty acids (SCFAs) such as acetic, propionic and butyric acids, arise from bacterial fermentation of carbohydrates, proteins, peptides and glycoprotein precursors and its levels differ between healthy subjects and IBD patients as a results from dysbiosis presented by IBD patients. Endoscopy and histopathology are the golden standard methods for detection and assessment of IBD, but a distinct increase of faecal calprotectin level can be a useful marker for the diagnosis of IBD. Calprotectin is a calcium- and zinc-binding protein, which for practical purposes can be considered to be neutrophil-specific. The amount of calprotectin reflects the number of participating neutrophils in this inflammation. This aspect has been widely confirmed in intestinal inflammatory diseases by significant correlation between faecal calprotectin levels and other measures of acute inflammation.

**Aims & Methods:** Based on this, the aim of this work was to analyse and correlate faecal calprotectin levels with acetic, propionic and butyric acids production in faeces samples from patients with UC (n=55) or CD (n=35). For that, calprotectin levels were measured using Quantum Blue® fCAL Extended kit (Bühlmann Laboratories) and SCFAs were dosed by chromatographic analysis using a GC-MS Thermo Scientific, model FOCUS equipped with an automatic liquid sampler (Thermo - triplus DUO), and coupled to a Thermo - ISQ 230ST mass detector. All results are represented by mean± SEM and statistical significance were considered for p≤0.05

**Results:** Calprotectin value were 401.1±56.66 µg/ml for UC and 276.6±52.90 µg/ml for CD patients. Acetic, propionic and butyric acid levels were 0.1367±0.006 mg/ml, 0.2345±0.005mg/ml and 0.069±0.003mg/ml respectively, for UC and 0.1338± 0.006 mg/ml, 0.2500±0.006 mg/ml and 0.07±0.003 mg/ml for CD patients. There is no correlation between calprotectin and SCFAs values, but, when compared UC and DC SCFAs levels, we found major levels of propionic acid in DC patients compared with UC ones (p≤0.05). This result could represent the discovery of a new biomarker useful for IBD subtypes differentiation.

**Conclusion:** Based on this, SCFAs cannot be used as substitute for calprotectin dosage in IBD patient's diagnosis; however, SCFAs can represent a new biomarker for IBD subtypes differentiation. Additional experiments should be performed in order to evaluate SCFAs levels in healthy subjects and compare to IBD patients.

**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) are main clinical forms of inflammatory bowel disease. IBD is a chronic inflammatory disorder of the intestine and its pathogenesis remains unclear.

The cause of IBD is unknown, but it is suggested that an aberrant immune response toward the commensal microbiota is responsible for the disease in genetically predisposed individuals.

**Aims & Methods:** The purpose of the study is to analyze the serum level of several proinflammatory cytokines and standard inflammatory biomarkers (C reactive protein (CRP) and calprotectin) in patients with CD and UC. A total of 286 patients with IBD (156 with UC and 130 with CD) were included into the study. 67 healthy volunteers were included into the control group. UC patients included 61% females, 39% males, average age was 41.6±12.8; 43.9% had pancolitis, 36.5% was with left-sided colitis and 19.5% presented symptoms of proctitis. CD patients included 52.7 % females, 47.2% males with average age 34.5±11.7; 25% of patients had localized form, 75% - distant form. Serum cytokine levels were analyzed using multiplex immunoassay. CRP was measured in serum by ELISA test. Calprotectin was analyzed in stool samples. Statistical analysis was performed using STATISTICA 6.0 Software Package.

**Results:** Statistically significant increase of CRP (mg/L) both in UC (8.51±8.17) and CD (15.2±24.55) patients compared to controls (1.23±1.61) was revealed (p < 0.001). The same trend was observed for calprotectin (mg/kg) in UC (572,6190±501,0668) and CD (539,80±674,7079) patients compared to controls (34,5±30,98) (p < 0.001).

Besides statistically significant increase of IL1b, IL8, IFNγ serum levels was observed in UC patients both in acute stage and remission compared to control group (p < 0.001). Serum level of proinflammatory IL-6 was not increased in UC patients compared to controls (p < 0.001). It was noticed statistically significant increase of IL1b, IL6, IFNγ in CD patients both in acute stage and remission compared to controls (p< 0,05). It was also re-

vealed a correlation between CRP & IL6 (RS=-0.4, p=0.007), CRP & IL8 (RS=0.34, p=0.02), calprotectin&IFNγ (RS=0.3, p=0.04), calprotectin&IL1a (RS=0.35, p=0.02) in UC patients. Analysis of CD patients showed correlation between CRP&IL12p70 (RS=0.3, p=0.04), CRP&IL1b (RS=0.5, p=0.003), calprotectin&IL-4 (RS=0.35, p=0.03), calprotectin & fractalkine (RS=0.5, p=0.0009).

**Conclusion:** Thus, proinflammatory cytokines contribute to chronic inflammation in IBD both in acute stage and remission correlating with inflammatory biomarkers CRP and calprotectin.

**Disclosure:** Nothing to disclose

## P1721 GUT-BRAIN AXIS IN INFLAMMATORY BOWEL DISEASES: EMERGENT ROLE OF INTESTINAL PERMEABILITY

Petito C.<sup>1</sup>, Petito V.<sup>2</sup>, Ferrarese D.<sup>1</sup>, Laterza L.<sup>1</sup>, Schiavoni E.<sup>1</sup>, Napolitano D.<sup>1</sup>, Gasbarrini A.<sup>1,2</sup>, Scaldaferrì F.<sup>1,2</sup>

**Contact E-Mail Address:** claudia.petito93@gmail.com

**Introduction:** Inflammatory bowel diseases (IBD) are characterized by chronic inflammation of the intestine, malabsorption and loss of protein and micronutrients. The pathogenesis of these disorders is not yet defined, but numerous evidences allow to hypothesize that it is due to a dysregulation of the mucosal immune response to the antigenic components of the intestinal flora. Factors like depression and chronic psychosocial distress seem to represent a risk factor for the arise of disease, as well as showing an influence on the course of the disease.

Stress can increase intestinal permeability, probably as a result of alterations in the cholinergic nervous system and mucosal mast cell functions.

**Aims & Methods:** The aim of this study is to investigate whether the alterations of the intestinal barrier are associated with psychometric alterations. We enrolled 33 IBD patients: 20 CD and 13 UC, with a mean age of 45 years. Serum samples were collected for determination of the ZO-1, TNF alpha and LPS proteins by ELISA assay to study the alterations of the intestinal barrier. Each patient completed a specific questionnaire for mood disorders: Minnesota Multiphasic Personality Inventory-2 (MMPI-2), State-Trait Anxiety Inventory (STAI Y1 - Y2), Hospital Anxiety and Depression Scale (HADS), Connor-Davidson Resilience Scale (CD-RISC), Barrat Impulsiveness Scale (BIS), Aggression Questionnaire (AQ). All study participants gave written informed consensus before sampling and data collection.

**Results:** The 61% of patients suffered from anxiety, and 37% from depression. Despite this, patients maintained good resilience: 94% have CD RISC scores > 40. Moreover 88% of patients are positive for some MMPI-2 items, in particular Schizophrenia (Sc), Psychastenia (Pt), Paranoia (Pa), hypomania (Ma), depression (D) and hysteria (Hy). Patients were divided by disease activity and no significant psychometric profile differences were found. The levels of ZO-1 and TNF were elevated in patients with high scores in anxiety scales (STAI Y1 and Y2 and HADS) but high LPS levels did not seem to be significantly associated with any of the variables examined.

**Conclusion:** This study showed that the prevalence of psychometric alterations in patients with IBD is significant, although the possible alterations of behavior are independent of disease activity. Furthermore, the increase of intestinal permeability could have a role in the worsening of anxiety. Further studies and more patients are necessary to better understand the development of mood disorders in course of IBD, and the role of Gut-Brain Axis in the medium-long term reactivation of patients, especially in terms of response and adherence to therapy.

**Contact E-Mail Address:** danilagua77@gmail.com

**Introduction:** Microscopic colitis (MC), comprising both collagenous colitis (CC) and lymphocytic colitis (LC), currently constitute an emergent cause of chronic watery diarrhea. Previously considered as a rare disease, several epidemiological studies have documented an increasing incidence of MC in Western countries.

However, there seems to be a significant variation in the reported incidence and prevalence rates among countries. Furthermore, a good estimation of the proportion of MC in patients presenting with chronic diarrhea is unclear.

**Aims & Methods:** To provide accurate estimates on the incidence and prevalence rate of MC and the frequency of MC in patients presenting with chronic diarrhea through a systematic-review and meta-analysis.

MEDLINE and EMBASE databases were searched for studies exploring on the epidemiology of MC up to December 2018. A pre-determined protocol following the PRISMA criteria was used.

The pooled incidence and prevalence rates, the pooled frequency of MC in chronic diarrhea patients and the geographical distribution of MC were calculated with random-effects models. Female/male odds ratios were estimated with a random-effects model. Heterogeneity between studies was assessed with the chi-square test (Cochran Q statistic) and quantified with the *I*<sup>2</sup> statistic.

**Results:** Of the 1,446 citations retrieved, 26 population-based studies from North-America and Europe were included for calculating incidence and prevalence rates, showing high heterogeneity and most of them (80%) providing high quality methodologies. The pooled overall incidence and prevalence rates of MC were estimated to be 11.9 (95%CI,9-14.8; *I*<sup>2</sup>=99.73%) new cases per 100,000 person-year (N=21 studies) and 119 (95%CI,73-166; *I*<sup>2</sup>=97.1%) per 100,000 persons (N=5 studies), respectively.

For CC, the pooled overall incidence and prevalence rates were 5.2 (95%CI,4.2-6.2; *I*<sup>2</sup>=98.3%) new cases per 100,000 person-year (n=25 studies) and 50.1 (95%CI,13.7-76.5; *I*<sup>2</sup>=98.4%) cases per 100,000 persons (n=6), respectively. For LC, this was 5.2 (95%CI,4.1-6.4; *I*<sup>2</sup>=97.7%) new cases per 100,000 person-year (n=21 studies) and 61.7 (95%CI,48.2-75.3; *I*<sup>2</sup>=80.6%) per 100,000 persons (n=5), respectively.

There are geographical variations in the incidence of MC (table 1). However, the relative low number of studies from Southern Europe compared to Northern Europe in combination with the different time periods studied, impedes direct comparisons.

Geographic regions	CC(95%CI)	LC(95%CI)	MC(95%CI)
Northern Europe	5.9(4.6-7.4)	4.9(3.5-6.2)	12.1(8.3-15.8)
Southern Europe	2.4(0.6-4.1)	3.1(1.4-4.7)	7.5(5.2-9.8)
North America	5.5(3.4-7.4)	8.0 (5.0-11.0)	14.3(8.9-19.8)

[Table 1]

Subgroup analyses on the incidence of MC by sex was possible in 18 studies and demonstrated that female sex is significantly associated with an increased risk of MC (OR 2.5;95%CI,2.3-2.9; *I*<sup>2</sup>=86.7%) as well as for CC and LC (OR 3.2;95%CI,3-3.5 and OR 2.0;95%CI,1.8-2.3, respectively) independently of the setting, study fashion (retrospective or prospective), level (national, regional or local) and geographical region considered.

The pooled frequency of MC in patients with chronic diarrhea was estimated to be 12.8% (95%CI:9.9-15.9; *I*<sup>2</sup>=93.6%), considering only studies with a moderate/high quality and sample size of ≥100 patients (n=14).

**Conclusion:** The population-based incidence and prevalence of MC vary widely across individual studies and geographical areas, probably due to differences in background populations, environmental exposure, genetic

background and differences in the awareness on the disease. More prospective, large-scale, and population-based studies are needed to better evaluate MC epidemiology.

**Introduction:** Inflammatory bowel disease (IBD) impacts on the physical and mental wellbeing of patients. Addressing and quantifying disability in IBD as part of Patient Reported Outcomes (PROs) is a major therapeutic target in IBD.

The IBD-Disk is a visual self-administered, abbreviated version of the IBD Disability Index which gives a rapid over view of disability in patients with IBD.

**Aims & Methods:** The aim of our study was to assess for correlation between disability reported by patients with IBD, their endoscopy findings and IBD therapy using the IBD Disk. A prospective study was conducted over 3 months between July to September 2018. Patients attending the IBD clinic were invited to complete the 10 item IBD-Disk questionnaire. Patient demographics, endoscopy findings and IBD therapy were also recorded.

**Results:** 58 patients completed the questionnaire. 59% (34) male, age range 19-85 years. 59% (34) had ulcerative colitis (UC) and 41% (24) Crohn's disease. Low energy levels was the commonest disability reported affecting 57% (33), followed by difficulty sleeping at 53% (31). Dissatisfaction with body image, followed by sexual dysfunction accounted for lowest levels of disability at 24% (14) and 22% (13) respectively. 10% (6) of patients had no disability and were receiving either 5-aminosalicylate (5-ASA) monotherapy or combination with an immunomodulator. 40% (23) used 5-ASA alone, 31% (18) used immunomodulators and 26% (15) were receiving biologics. 6% (2) had a Mayo Endoscopic score of 3.

**Conclusion:** In our study difficulty sleeping and poor energy levels accounted for the greatest disability among our patients. There was no correlation between the degree of disability, endoscopic scores and IBD treatments. Disabilities reported were variable, but the IBD Disk rapidly highlights patient concerns allowing health care professionals adequately address them.

**Introduction:** Studies since early 1980s have shown the presence of sub-clinical gut inflammation in up to 60% of the patients with axial spondyloarthritis, 6% of which proceed to become inflammatory bowel disease (IBD) in 10 years. Here we aim to further explore the presence of gut inflammation using acute inflammatory markers in stool and serum and correlate the results with disease characteristics.

**Aims & Methods:** A collaborative group comprising of gastroenterologists and rheumatologists was formed between 2 healthcare trusts in UK. Clinic lists and electronic operating systems were interrogated with appropriate ethical approval to identify patients with axSpA with or without IBD (axSpA-IBD and axSpA not-IBD, respectively) and psoriatic arthritis as disease controls. Eligible patients were called prior to their clinic appointments and were sent stool containers. On the day of their clinic appointments,

patients were consulted for 15-30 minutes where their disease was carefully phenotyped, drug history obtained and they were consented in to the study. Stool and blood samples were collected and analysed for faecal calprotectin (FC) and ESR and CRP respectively.

**Results:** 116 patients with axial spondyloarthritis (79 axSpA-not IBD, 22 axSpA-IBD and 15 psoriatic axSpA [axSpA-PsA]) and 22 patients with psoriatic peripheral spondyloarthritis (pPsA) were recruited.

Total of 81 stool samples were analysed. Faecal calprotectin (FC) was elevated to above 50ug/g in 36 stool samples; 21 out of 44 (48%) patients with axSpA-not IBD (median 72, range 51- 587), 9 out of 18 (50%) patients with axSpA-IBD (median 224.5, range 51->2000), 2 out of 7 (29%) patients with axSpA-PsA (median 69, range 51-87) and 6 out of 14 (43%) patients with pPsA (median 61.5, range 57- 122). Of the elevated FC samples, only one patient with known Crohn's disease had significant GI symptoms.

10 out of 36 (28%) patients with elevated FC were taking daily NSAIDs compared to 4 out of 48 (8%) patients with normal FC. Daily NSAID users did not have higher mean FC.

9 out of 11 (82%) patients who had disease duration of more than 10 years had elevated FC.

13 out of 28 (46%) patients with BASDAI index (axSpA disease activity score) of > 4 had elevated FC and 13 out of 33 (39%) with BASDAI < 4. BASDAI of above 4 reflects active disease.

Patients on biological therapy were equally distributed across all cohorts.

**Conclusion:** Significant proportion of axSpA-not IBD patients have gut inflammation as evidenced by raised faecal calprotectin however median level in axSpA-not IBD is still lower than axSpA-IBD. NSAIDs have relatively little impact. There is a correlation between gut inflammation and age of symptoms onset, disease duration and serum inflammatory markers. There is no correlation between gut inflammation and joint disease activity. Based on this study, further work is required to delineate at risk population with a view to determining those in whom a colonoscopy would be a helpful tool.

<sup>3</sup>London North West Healthcare, Harrow, United Kingdom

**Contact E-Mail Address:** uma.selvarajah@nhs.net

**Introduction:** Up to 40% of the patients with inflammatory bowel disease (IBD) have MRI evidence of axial spondyloarthritis compared to 1.5% in the non IBD population. Here we aim to distinguish axial spondyloarthritis associated with IBD (axSpA-IBD) from axSpA without IBD (axSpA-not IBD) and psoriatic axSpA (axSpA-PsA).

**Aims & Methods:** A collaborative group comprising of gastroenterologists and rheumatologists was formed between 2 healthcare trusts in UK. Clinic lists and electronic operating systems were interrogated with appropriate ethical approval to identify patients with axSpA-IBD, axSpA-not IBD and axSpA-PsA. Patients were contacted prior to their clinic appointments and were sent stool containers. On the day of their clinic appointments, they were consulted for 15-30 minutes where their diseases were carefully phenotyped, drug history obtained, and informed consent taken. Stool and blood samples were collected and analysed for faecal calprotectin and acute inflammatory markers.

**Results:** 62 patients were analysed for this study; 22 patients (10 Crohn's/ 12 UC) with axSpA-IBD, 24 with axSpA-not IBD and 16 patients with axSpA-PsA. Of the patients with IBD, 13 out of 22 (59%) were diagnosed with IBD first. Median duration of IBD before the diagnosis of axSpA was 3.5 years. Remaining 9 patients who were diagnosed with axSpA first, the median duration of disease before the diagnosis IBD was 3.5 years as well.

Median age of onset for joint disease in axSpA-IBD is 30 years compared to 27 and 22 in axSpA-not IBD and axSpA-PsA cohorts.

All three cohorts had gender predominance towards the male sex with 82% in axSpA-IBD, 86% in axSpA-not IBD and 94% in axSpA-PsA. There was no ascertainment bias with the male gender when the diagnosis of axSpA was given first.

Association with HLA B\*27 is stronger in the axSpA-not IBD group with 76% patients possessing the polymorphism compared to 50% in axSpA-IBD and 40% in axSpA-PsA. Median BASDAI (ankylosing spondylitis disease activity score) for axSpA-IBD, axSpA-not IBD and axSpA-PsA are 4.3, 3.95 and 3.2 respectively. Scores of above 4 indicate active disease.

Mean faecal calprotectin in axSpA-IBD is 233.7ug/g compared to 99.1 and 28.2 in axSpA-not IBD and axSpA-PsA.

Pearson correlation coefficient between faecal calprotectin and BASDAI scores was 0.0451.

**Conclusion:** In our cohort, we have shown that IBD related axial spondyloarthritis is different to axSpA-not IBD in terms of its weaker association with HLA B\*27 antigen, higher degree of gut inflammation and increased age of onset for joint disease. Mean faecal calprotectin in axSpA-not IBD was still significantly higher than axSpA-PsA.

Weaker association with HLA B\* 27 antigen in axSpA-IBD points to the possibility of a different genetic loci or mode of aetiopathogenesis.

Contrary to what we had expected, male gender predominance is similar across both axSpA-IBD and axSpA-not IBD group. We've found similar joint disease activity and functional disability across all cohorts. Further work is required to compare this study population with previously studied population.

## P1726 EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS, AND RESPONSE TO TREATMENT, IN PATIENTS WITH MICROSCOPIC COLITIS

Rojo E., Casanova M.J., P. Gisbert J.  
Gastroenterology Department from Hospital Universitario de La Princesa, Instituto de Investigación Sanitaria Princesa (IIS-IP) and Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERED), Madrid, Spain

**Contact E-Mail Address:** mjcasanova.g@gmail.com

**Introduction:** Microscopic colitis (MC) is a common cause of chronic diarrhea with an increasing incidence. However, its etiology and pathogenesis are not fully understood.

**Aims & Methods:** i) To describe the main epidemiological and clinical characteristics of the patients with MC; ii) to evaluate the efficacy of the different treatments for MC; and iii) to determine the relapse rate in patients who achieved clinical remission with budesonide. All patients aged over 18, diagnosed with collagenous colitis (CC) or lymphocytic colitis (CL) at the Gastroenterology Department from Hospital Universitario de La Princesa from January 1, 2010 to June 31, 2018, were included. Efficacy and loss of response to budesonide were evaluated by Kaplan-Meier analysis.

**Results:** 113 patients diagnosed with CC or CL were included (78% female, mean age at diagnosis 65 years, 59% had CC). The median time from symptoms to diagnosis was 4 months (IQR 2-7). The most frequent symptoms were: diarrhea (98%), weight loss (43%), and abdominal pain (31%). 3% had a family history of inflammatory bowel disease, 44% history of smoking, and 19% cancer antecedents. 31% suffered from depression and 48% had at least one autoimmune disease associated, the most frequent being thyroid disease (19%), allergic asthma (10%), type 1 diabetes mellitus (5%) and celiac disease (4%). At diagnosis, 43% of the patients were on proton-pump inhibitors, 34% on statins, 29% on non-steroidal anti-inflammatory drugs, 25% on selective serotonin reuptake inhibitors and 20% on beta blockers. The diagnostic colonoscopy showed mucosal abnormalities in 16% of the patients, the most frequent being: erythema (13%), edema (10%), loss of vascular pattern (5%) and spontaneous bleeding (5%). Only in 12% of all colonoscopies biopsies were taken by colon segments and the mean number of biopsies per colonoscopy was 6. At the onset of the disease, 30% of the patients experienced a spontaneous clinical remission. Of the remaining, 75% received budesonide, 27% 5-aminosalicylic acid (5-ASA), 7% systemic steroids and 3% thiopurines.

93% achieved remission with budesonide, 43% with 5-ASA, 7% with loperamide and 100% with systemic steroids (60% became steroid-dependent). 2 patients received thiopurines due to lack of response to other treatments and both achieved clinical remission. Of the patients treated with budesonide at diagnosis, 19% were unable to discontinue the drug and received maintenance therapy. Of the 51 patients who achieved remission with budesonide at diagnosis, 39% relapsed. Of them, 90% responded again to budesonide. A second relapse after budesonide withdrawal occurred in 28% and all of these patients achieved remission after restart of budesonide. There was no difference in response to budesonide between patients with CC and CL ( $P>0.05$ ). The cumulative incidence of loss of response after achieving remission with budesonide at diagnosis (median follow-up time of 55 months) was 39% (95% CI 26–54%): 20% at 1 year, 32% at 2 years, and 46% at 3 years of follow-up. The rate of adverse events of the patients treated with budesonide was 4%, leading to drug discontinuation in all cases.

**Conclusion:** MC is more frequent in elderly women. Diarrhea, weight loss and abdominal pain are the most common symptoms at diagnosis. MC frequently appears in patients with autoimmune disorders, smoking history and under treatment with certain drugs. The vast majority (93%) of the patients treated with budesonide at diagnosis achieved remission, however, almost 40% of them lost response subsequently. Retreatment with budesonide after relapsing was effective in most cases.

## P1727 TOP LIST OF MALIGNANCIES OBSERVED IN THE HUNGARIAN POPULATION WITH ULCERATIVE COLITIS

Molnár T.<sup>1</sup>, Szántó K.<sup>1</sup>, Milassin Á.<sup>2</sup>, Farkas K.<sup>2</sup>

<sup>1</sup>University of Szeged, First Department of Internal Medicine, Szeged, Hungary, <sup>2</sup>University of Szeged, First Department of Medicine, Szeged, Hungary

**Contact E-Mail Address:** molnar.tamas@med.u-szeged.hu

**Introduction:** Ulcerative colitis (UC) is associated with an increased risk of colorectal cancer (CRC) and the second most common cause of death among UC patients is CRC. An increased risk for extraintestinal malignancies are also observed among IBD patients.

**Aims & Methods:** Our aim was to recognize malignancy pattern associated with UC using the National Health Insurance Fund social security databases including inpatient-, outpatient care between 2010 and 2016. This is an epidemiological study based on a Hungarian national database. Hungarian UC patients were enrolled. Patients were classified as having a certain kind of cancer if they have at least two appearances in the in- or outpatient care with the corresponding ICD codes.

**Results:** 37795 patients with UC were included in the study during the observational period. Investigating all malignant neoplasms of the UC population, colorectal cancer (CRC) was found to be the most frequently observed cancer. 1424 patients, 3.7% of the total UC population were diagnosed with CRC. Colonic localisation (2.16%) was more frequent than rectal localisation (1.7%). The second most common malignancy was non-melanotic skin cancer, in 1.48% of the patients, the third was prostate cancer in 0.99% of the patients. Malignant neoplasm of the urogenital tract and the breast were diagnosed in 0.54–0.46% of the patients. Malignant melanoma of the skin was the fifteenth most common malignancy, 0.21% of the patients were diagnosed with malignant melanoma. Among our patients intestinal non-Hodgkin lymphomas were observed in 0.092% of the patients. Malignancies with the least incidence were malignant neoplasm of the uvula and testis and bone and articular cartilage, 10–10 UC patients were diagnosed with these malignancies.

**Conclusion:** Our results underly that colorectal carcinoma is still a real danger in UC patients, highlight that surveillance need to be improved in national level. The most common extracolonic malignancies were non-melanotic skin cancer.

## P1728 USEFULNESS OF NATURAL LANGUAGE PROCESSING (NLP) COMBINED WITH DEEP MACHINE LEARNING AS A TOOL FOR CLINICAL RESEARCH IN CROHN'S DISEASE. PREMONITION-CD STUDY

Fernandez-Nistal A.<sup>1</sup>, Martínez V.<sup>1</sup>, Gomollon García F.<sup>2</sup>, Tagarro I.<sup>1</sup>, Medrano I.<sup>3</sup>, Montoto Otero C.<sup>1</sup>

**Contact E-Mail Address:** alonso.fernandez@takeda.com

**Introduction:** Natural Language Processing (NLP) is a technology that uses computer-based linguistics and artificial intelligence to identify and extract information from free-text data sources such as progress notes, procedure and pathology reports, and laboratory and radiologic test results<sup>1</sup>. NLP can accurately and efficiently use the vast data resources that have been relatively unavailable for meaningful clinical or research use until now. However, it is still unknown the full potential and applicability of NLP in clinical practice and research<sup>2</sup>. In this study, we have tried to understand if NLP could become another alternative of generating evidence in Crohn's Disease.

**Aims & Methods:** This is a data-driven, observational, retrospective, non-interventional, study using secondary data captured in Electronic Medical Records (EMRs). A data-driven system based on Natural Language Processing (NLP) and big data techniques, has been used to conduct the study, using the EHRead technology (Savana). Natural Language was extracted from EMRs and captured as free text. Medical concepts were detected by using computational linguistic techniques and comprehensive clinical contents, scientifically validated (like SNOMED Clinical Terms, CT). This unstructured data has been treated as big data and analysed with artificial intelligence. The results presented here belong to an interim analysis of data from 3 Spanish hospitals participating in PREMONITION-CD study (NCT03668249). The period for extracting the data has been bounded to the last available five years of clinical practice contained in the EMRs available at each site.

**Results:** Using this innovative technology, we have been able to extract data from 877 EMRs from Crohn's Disease (CD) patients. NLP has allowed us to determine some of the main descriptive characteristics of these patients and Health Care Resources Utilization (HCRU). Therefore, we have learned that 50.6% of patients were female and, out of those patients with available data about faecal calprotectin, CRP and hemoglobin, mean (SD) were 532 (638.8) µg/g, 460.6 (133.4) mg/L and 12.8 (2.1) g/dL respectively. Regarding previous medical history, the most common conditions were disorders of cardiovascular system (20.3%) and disorder of lipoprotein/lipid metabolism (13.3%).

Additionally, NLP also allowed us to gather information about HCRU. For example, the average (SD) number of visits/year to GI units has been relatively stable along last years, ranging between 1.5 (2.4) and 2.1 (2.9). However, the average number of visits to the hospital day have steadily increased over the last years from 6.4 (7) visits in 2013, to 8.3 (8.9) in 2017; with a similar trend regarding visits to other specialists: from 6.6 (8.6) in 2013 to 8.3 (9.7) in 2017.

**Conclusion:** NLP seems to be a promising tool that can be used in specific situations to accurately provide meaningful information in patients with Inflammatory Bowel Disease. We anticipate it will become more widely used within clinical, research, and administrative roles. Quality of clinical data contained within EMRs and validation of data extraction process must be taken into consideration in order to let NLP become a key resource to answer questions that otherwise would be too expensive or time consuming to address with a traditional research methodology.

**Introduction:** Crohn's disease (CD) is a progressive disease with variable rate of acceleration. An increase in the incidence of CD is evident in Asia and specifically in India. Data on clinical presentation and course in the Indian population is lacking.

**Aims & Methods:** The Indo-Israeli IBD GastroEnterology paRtnership (TiiGER) aimed to assess patterns of early disease among Indian and Israeli patients with newly diagnosed CD. Prospective observational inception cohorts were recruited in two large referral centers in India and Israel between May 2013 and December 2017. Adults (>18 years) suspected of CD or patients with newly diagnosed CD were included. Disease acceleration was defined by the first CD-related surgery, hospitalization or recommendation to start steroids, immunomodulators or biologic therapy.

**Results:** Two hundreds sixty patients were included, 104 Indians and 156 Israelis. Indian patients had male predominance compared with the Israeli cohort (65.4% vs. 50.6%,  $p=0.019$ ). At diagnosis Indian patients were older ( $37.8\pm 12.8$  vs.  $31.8\pm 12.8$ ,  $p<0.0001$ ) and were less likely to be active smokers (8.7% vs. 22.4%,  $p<0.0001$ ). Indian patients had significantly more colonic and upper gastrointestinal disease location (35.6% vs. 19.2%,  $p=0.003$  and 13.5% vs. 5.1%,  $p=0.018$ , respectively), more stenotic behavior (36.6% vs. 6.5%,  $p<0.0001$ ) and lower rate of perianal disease involvement (5.8% vs. 23.7%,  $p<0.0001$ ), compared to Israeli patients. Furthermore, Israeli patients had higher body mass index ( $23.4\pm 4.5$  vs.  $19.9\pm 4.3$ ,  $p<0.0001$ ) and significantly more family history of CD (22.4% vs. 3.8%,  $p<0.0001$ ).

Overall during a follow-up period of up to 43 months, disease acceleration rate was 50% (52/104) in Indian and 66.7% (104/156) in Israeli patients, with median time to disease acceleration of 7.6 (interquartile range [IQR] 1.9-25.6) and 3.4 (IQR 1.3-23) months,  $p=0.05$ , respectively. In multivariate cox regression model, Indian compared to Israeli patients were less likely to have disease acceleration or to be treated with steroids, immunomodulators or biologic therapy (hazard ratio [HR] 0.598; 95% CI, 0.4-0.8;  $p=0.011$  and HR 0.563; 95% CI, 0.373-0.851,  $p=0.006$ ).

**Conclusion:** In a first indo-Israeli inception cohort of patients with newly diagnosed CD more than half of the patients experienced early disease acceleration. Distinct demographic and phenotype characteristics at CD diagnosis and different rates of disease acceleration were identified. Ethnic variations in disease phenotype may help to identify key genetic, environmental & behavioral factors contributing to the development of IBD.

## P1730 COMPARISON OF DIETARY PATTERNS IN IBD PATIENTS BETWEEN THE NORTHERN AND SOUTHERN PROVINCES OF THE NETHERLANDS

Peters V.<sup>1,2</sup>, Spooren C.<sup>3</sup>, Weersma R.K.<sup>1</sup>, van Dullemen H.M.<sup>1</sup>, Festen E.A.M.<sup>1</sup>, Visschedijk M.<sup>1</sup>, Masclee A.A.<sup>3</sup>, Hendrix E.<sup>3</sup>, Pierik M.J.<sup>4</sup>, Dijkstra G.<sup>1</sup>, Jonkers D.M.<sup>3</sup>, Campmans-Kuijpers M.<sup>1</sup>

<sup>1</sup>University Medical Centre Groningen and University of Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands, <sup>2</sup>University Medical Centre Groningen and University of Groningen, Department of Epidemiology, Groningen, Netherlands, <sup>3</sup>University Medical Centre Maastricht and University of Maastricht, Division Gastroenterology-Hepatology, Maastricht, Netherlands, <sup>4</sup>Maastricht University Medical Center, Department of Gastroenterology and Hepatology, Maastricht, Netherlands

**Contact E-Mail Address:** v.peters@umcg.nl

**Introduction:** Evidence-based dietary guidelines are not available for patients with Inflammatory Bowel Disease (IBD). Therefore, patients tend to follow their own "unguided" dietary habits, often leading to unbalanced intakes that may further impact disease course. Hence, we aimed to identify dietary patterns in post-diagnosis habitual dietary intake in 2 separate cohorts of Dutch IBD outpatients.

**Aims & Methods:** 489 IBD patients (286 Crohn's Disease (CD), 203 Ulcerative Colitis (UC)) from Groningen and 236 IBD patients (154 CD, 82 UC) from Maastricht with data on demographics and disease phenotype were included. Dietary intake, including nutrients and 22 food groups, was obtained via semi-validated food frequency questionnaires. Dietary differences in macronutrients and food groups, and baseline characteristics were analysed between the cohorts using a students' t-test or X<sup>2</sup>-test when appropriate. A preliminary principal-components analysis (PCA) was conducted on 22 food groups to identify relevant dietary patterns.

**Results:** Compared to the Maastricht cohort, patients in the Groningen cohort had a lower age at inclusion and diagnosis, disease duration, and less men (all  $p<0.05$ ); no differences were observed in phenotype, BMI or smoking. The total energy intake including energy from all separate macronutrients was significantly lower in the Groningen cohort. Moreover, patients in Groningen consumed less legumes, grains, red and processed meat, poultry, fish, confectionery, coffee, oils, alcoholic beverages and condiments, but more potatoes, dairy, non-alcoholic beverages and prepared meals than patients in Maastricht.

First, a PCA was run in the Groningen cohort to identify dietary patterns. This PCA, with an overall Kaiser-Meyer-Olkin (KMO) measure of 0.624 revealed 8 components with eigenvalue >1. Visual inspection of the scree plot (Cattell, 1966) and interpretability criteria, indicated that two components should be retained, explaining 22.0% of the total variance. The interpretation of the data was in line with the western and prudent components as described before (Stricker, 2013). Condiments, grain products, potatoes, oils, processed and red meat, snacks and confectionery contributed to a western component; whereas fruits, vegetables, fish, tea, eggs and nuts loaded positively, and snacks and non-alcoholic beverages loaded negatively on the prudent component. To confirm the above patterns, a PCA was also run on the Maastricht data, with an overall KMO of 0.602 and revealing 9 components with an eigenvalue >1. Here, visual inspection of the scree plot and interpretability criteria also indicated that two components should be retained. These explained 21.8% of the total variance and were also consistent with the western and prudent component. The same food groups loaded on the western component and prudent component, except for snacks and fruits to the prudent component. This might be due to smaller sample size in the Maastricht cohort.

**Conclusion:** Our study shows that IBD patients in the Groningen cohort mainly use a western or prudent-based diet after diagnosis. These findings were confirmed in the geographical distinct Maastricht cohort; as mainly the same patterns were extracted. Since, adapting a western dietary pattern may contribute to potentially unintended effects on disease course, dietary intervention in these patients might be beneficial.

**Introduction:** The number of individuals affected by inflammatory bowel diseases (IBD) has been globally increasing. We have described a low incidence of Crohn's disease in our area in the past. The aim of this extended study was to investigate and update the incidence and prevalence of IBD and its subtypes (UC, CD, IBD unclassified) in Epirus which is a well-defined geographical area of Greece with a 30-year observation period of these diseases.

**Aims & Methods:** The epidemiological study was conducted in the region of Epirus, one of the 13 prefectures of Greece, and in the two neighboring islands of the Ionian Sea, Corfu and Lefkada. The study was conducted in two periods, 1982-2002 and 2003-2015 so that we could trace any changes in the incidence and behavior of IBD during time in our area.

**Results:** The overall incidence of Crohn's disease was 1.16/100,000 inhabitants (95% C.I. 0.62 - 1.60) [1.41 (95% C.I. 0.75 - 2.15) for males vs 1.02 (95% C.I. 0.39 - 1.23) for females] on the first period (1982-2002) and 2.75/100,000 inhabitants (95% C.I. 1.53 - 3.46) [3.67 (95% C.I. 1.96 - 4.71) for males vs 1.85 (95% C.I. 0.77 - 2.64) for females] of the second period (2003-2015). These observations showed a significant increase of Crohn's disease in both genders in our area. In addition, the prevalence of ulcerative colitis per age group showed a decrease of the incidence of UC in older ages during the most recent time period compared to the past. This decrease was more prominent to male patients over 70 years of age. Regarding the age distribution of ulcerative colitis, it appears that there is a significantly increasing trend to affect younger ages during the second time period (the recent one). At the same time, as mentioned, a noteworthy decrease in the incidence of ulcerative colitis after the age of 70 years has been documented during the second period of the study.

**Conclusion:** The results of our study confirm the continuing change of epidemiology of IBD in our area, with increasing incidence of Crohn's disease and decreasing incidence of ulcerative colitis in elderly patients. In addition, based on international multicenter studies, patients with IBD and particularly CD are expected to increase within the next decades. Awareness of the disease, early diagnosis and consistent and prompt monitoring from the time of diagnosis will provide them with a better quality of life and prevent complications.

**Disclosure:** Nothing to disclose

### P1732 PREVALENCE AND PREDICTORS OF SEXUAL AND ERECTILE DYSFUNCTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Domislovic V.<sup>1</sup>, Brinar M.<sup>2</sup>, Barišić A.<sup>3</sup>, Vujčić L.<sup>4</sup>, Novosel M.<sup>4</sup>, Krznaric Z.<sup>5</sup>

<sup>1</sup>University Hospital Centre Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia, <sup>2</sup>University Hospital Centre Zagreb, Department of Gastroenterology, Zagreb, Croatia, <sup>3</sup>University Hospital Center Zagreb, Clinical Nutrition, Zagreb, Croatia, <sup>4</sup>Zagreb School of Medicine, Zagreb, Croatia, <sup>5</sup>KBC Zagreb, Gastroenterology, Zagreb, Croatia

**Contact E-Mail Address:** viktor.domislovic@gmail.com

**Introduction:** Inflammatory Bowel Disease (IBD) has a negative impact on quality of life (QOL), and sexuality is one of its major determinants. The impact of disease characteristics on sexuality and intimacy is one of the main concerns of IBD patients. Despite the obvious relevance of this problem, knowledge of the extent and the determinants of sexual dysfunction in persons with IBD is limited.

**Aims & Methods:** The main goal of the study was to determine the prevalence of sexual dysfunction (SD), erectile dysfunction and association with quality of life (QOL) and its components in patients with IBD, and to search for predictors of SD and ED.

In this cross-sectional study patients fulfilled anonymous validated questionnaire on their sexual function. In International Index of Erectile Function (IIEF) for males, five domains were evaluated through questions on erectile function, orgasmic function, sexual desire, intercourse satisfaction and overall satisfaction. In women were six domains assessed, desire, arousal, lubrication, orgasmic function, satisfaction and pain. For both scores, higher scores indicated a better function. Patients also fulfilled IBDQ-32, a validated questionnaire for assessing quality of life in IBD patients. IBDQ-32 score is ranging from 32 to 224 with higher scores representing better quality of life and consists of four main components (social, emotional, systemic and bowel function). Disease activity was defined as Crohn's Disease Activity Index (CDAI) >150 or Partial Mayo Score ≥3 for CD and UC, respectively.

**Results:** In this study we have enrolled 202 patients who fulfilled the questionnaire (133 CD, 69 UC). Among them 122 were men and 80 women. Average age of included patients was 39.2±11.02. In women, SD rates were 75% (N=60), and were significantly higher than 18% (N=22) in men (p<0.001). QOL was significantly lower in patients with SD, in which IBDQ-32 score amounted 167.47±30.4 vs. 182.8±31.9, p=0.01. ED was reported by 30% (N=37) of male IBD patients. Patients with ED had lower IBDQ-32 score comparing to patients without ED (161.4±35.4 vs. 186.6±27.5, p<0.001). In univariate analysis, significant positive predictors for SD in total IBD population were female gender, UC and impaired social, emotional, systemic and bowel function components of IBDQ. Multivariate analysis showed that the significant predictors for SD were female gender (OR=17.5, 95% CI 8.3-37.2) and emotional component of IBDQ (OR=3.5, 95% CI 0.7-17.05). Disease duration, disease activity, history of lower abdominal surgery, presence of stoma, perianal disease and current biological treatment were not significant predictors of SD.

**Conclusion:** The results show that SD is highly prevalent in IBD patients, with women to man ratio of almost 4 to 1. Erectile dysfunction is present in approximately every third male patient. Patients with both SD and ED have lower QOL. Significant and strong predictors for SD are female gender and emotional component of IBDQ, which consists of questions regarding frustration, depression, tension, worry about surgery, irritation, anger, fear of not finding a toilet, being tearful or upset, feel lack of understanding and satisfaction with personal life. Improvement of QOL is one of the main goals in treating IBD patients. Because of its strong connection with sexual function and satisfaction, it is important to identify those problems and to provide proper psychological support, medical treatment and educational information.

### P1733 ERECTILE DYSFUNCTION IN MEN WITH NEWLY DIAGNOSED INFLAMMATORY BOWEL DISEASE

Ait Errami A.<sup>1</sup>, Samlani Z.<sup>2</sup>, Oubaha S.<sup>3</sup>, Krati K.<sup>3</sup>

<sup>1</sup>Mohammed VI, Hepatogastroenterology, Marrakech, Morocco, <sup>2</sup>UHC Marrakech, Hepatogastroenterology, Marrakech, Morocco, <sup>3</sup>UHC Marrakech, Marrakech, Morocco

**Contact E-Mail Address:** adil.ae@hotmail.fr

**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) are chronic inflammatory bowel diseases (IBDs) that often present between the second and fourth decades of life, when sexual identity and relationships are developing. Sexual function is one of the top concerns expressed by patients with IBD yet remains poorly explored by researchers and clinicians.

**Aims & Methods:** Cross-sectional studies on sexual function in men with inflammatory bowel disease (IBD). Using a prospective incidence cohort, we aimed to describe sexual function at baseline and over time and to identify factors associated with impaired sexual function in men with IBD. 18 years and older enrolled between April 2016 and January 2019 in our centre with a minimum three months of follow-up were eligible for study. Male sexual function was assessed using the International Index of Erectile Function (IIEF), a self-administered questionnaire that assesses 5 dimensions of sexual function over the most recent 4 weeks. To assess changes in the IIEF per various demographic and clinical factors, linear mixed effects models were used.

**Results:** Fifty two of 73 eligible men (71 %) completed the questionnaire (19 Crohn's disease, 33 ulcerative colitis). The mean age (SD) of the cohort at diagnosis was 29.4 years. At baseline, 28 % of men had global sexual dysfunction, and 85% had erectile dysfunction. Independent factors associated with erectile dysfunction are older age and lower physical and mental component summary scores on the Short Form Health Survey (SF-36). **Conclusion:** In an incident cohort of IBD patients, most men had erectile dysfunction. Physicians should be aware of the high prevalence of erectile dysfunction and its associated risk factors among men with newly diagnosed IBD to direct multidisciplinary treatment planning.

### P1734 OBESITY AND OSTEOPOROSIS IN INFLAMMATORY BOWEL DISEASE PATIENTS: A NATIONWIDE ANALYSIS

Enofe I.<sup>1</sup>, Aluko A.<sup>2</sup>, Yam J.<sup>3</sup>, Khan N.N.<sup>1</sup>

<sup>1</sup>Michigan State University, Internal Medicine, Lansing, United States, <sup>2</sup>Michigan State University, East Lansing, United States, <sup>3</sup>Michigan State University, Gastroenterology, East Lansing, United States

**Contact E-Mail Address:** enofeik@yahoo.com

**Introduction:** Osteoporosis is a major health problem in patients with inflammatory bowel disease (IBD) with reported prevalence ranging from 30-60% among this population in the United States. Obesity on the other hand has conflicting evidence as it relates to osteoporosis especially among IBD patients with some studies reporting a protective effect while others demonstrate worsening bone mass effect. Given the rising global prevalence of obesity and the poorly understood consequences in IBD patients, we aimed to examine the relationship between obesity and osteoporosis in IBD patients using the largest repository of discharges in the United States. We hypothesize that obesity will be associated with osteoporosis in IBD patients.

**Aims & Methods:** We performed a retrospective study using the 2014 National Inpatient Sample database. All adult patients with a primary or secondary discharge diagnosis of inflammatory bowel disease were included in this study. Data on patient and hospital level characteristics, sociodemographic factors, and outcomes were obtained. Diagnosis of both obesity and osteoporosis diagnosis were identified using ICD 9 codes. Descriptive and inferential analysis was performed. Patient and outcome characteristics were compared using chi-square and logistic regression. We controlled for sociodemographic factors and patient comorbidities.

**Results:** A total of 273,905 discharge records with inflammatory bowel disease met our inclusion criteria for this study. The prevalence of obesity was significantly higher in patients with Ulcerative colitis compared to Crohn's disease (10.64% versus 10.03 % p-value < 0.05). Using multivariable analysis to control for patients age, sex and comorbidities, obese patients with Crohn's disease were 43% significantly less likely to have osteoporosis compared to their non-obese counterparts (AOR 0.57, 95% CI 0.46 - 0.71).

Obese patients with Ulcerative colitis were 16% less likely to have osteoporosis compared to non-obese patients (AOR 0.84, 95% CI 0.69 - 1.14), however this relationship was not statistically significant.

**Conclusion:** Our study demonstrates a protective effect of obesity against osteoporosis in patients with Crohn's disease but not in patients with Ulcerative colitis. Although prior studies have shown conflicting results concerning the role of obesity in IBD, our study further adds to the literature demonstrating different effects of osteoporosis in Crohn's disease versus ulcerative colitis. The mechanism by which obesity may possibly protect against osteoporosis is poorly understood, more so, in light of studies that associate obesity predominantly with active Crohn's disease, prospective studies are needed to understand these findings better and provide higher level evidence as well as a molecular basis for this interaction.

### P1735 THE OMIS (OCULAR MANIFESTATIONS IN IBD SCREENING) QUESTIONNAIRE: A TOOL FOR CLINICIANS FOR EARLY DETECTION OF OCULAR INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE

Scrive B.<sup>1</sup>, Vadalà M.<sup>2</sup>, Giuffrida E.<sup>1</sup>, Davì C.<sup>3</sup>, Ingrassia Strano G.<sup>3</sup>, Ventura N.<sup>2</sup>, Cillino S.<sup>1</sup>, Cammà C.<sup>1</sup>, Cappello M.<sup>1</sup>

<sup>1</sup>University of Palermo, Gastroenterology and Hepatology Section, ProMiSe Department, Palermo, Italy, <sup>2</sup>University of Palermo, Biomedicine, Neuroscienze and Advance Diagnostic Department, Palermo, Italy, <sup>3</sup>University of Palermo, Palermo, Italy

**Contact E-Mail Address:** barbara.scrive@gmail.com

**Introduction:** Extraintestinal manifestations (EIM) are common in Inflammatory Bowel Disease (IBD) being reported in up to 50% of patients. Among EIMs ocular manifestations are less frequent (less than 15%) but may be associated with significant morbidity, including blindness. They may be related to active inflammation or have an independent course or represent adverse events of pharmacological therapies. Ocular complaints are often non specific and are frequently ignored from both physicians and patients. Biological therapies, especially anti-TNFs, have been shown effective on some eye EIMs, probably reducing their prevalence.

**Aims & Methods:** Our aim was to assess the accuracy of a dedicated questionnaire in patients with IBD treated with biological drugs for the detection of ocular EIMs in a tertiary IBD referral clinic. We developed a questionnaire, OMIS (Ocular Manifestations in IBD Screening), after agreement between gastroenterologists and ophthalmologists. The questionnaire was administered by a non-ophthalmologist physician to 96 IBD patients treated with biological drugs (anti-TNFs) in the Gastroenterology clinic during infusion or in the waiting room.

**Results:** Out of 96 interviewed patients, EIMs were reported in 55 persons (57%), mainly as joint manifestations (36%). Thirty-five patients (36.5%) tested positive for ocular involvement at screening and were selected for ophthalmologic examination. Red eye (12 patients, 34.28%), ocular pain (10 patients, 28.57%), photophobia (14 patients, 40%) and visual fogging (18 patients, 51.42%). On ophthalmological visit, ocular EIMs were confirmed in 29 of 35 patients (82.85%): 4 cases of uveitis (11.42%), all dated before the beginning of biologics, 12 cases of dry eye (34.28%) and 13 cases of cataracts (37.14%), in progress or already treated with surgery.

**Conclusion:** The OMIS questionnaire is a useful tool for non-ophthalmologist physician in everyday practice during the outpatient visit, in order to select patient to be addressed to ophthalmological visit, creating a real integrated multidisciplinary clinical equipe, to improve management of IBD, to prevent visual disability and guarantee quality of life.

**Introduction:** It's common knowledge that the risk of colorectal cancer in patients with ulcerative colitis (UC) is greatly increased compared with the general population. Pseudopolyps (PP) are considered as a part of UC manifestation, in the same time, they can mask adenomatous polyps that may become malignant. In case of multiple PP, differential diagnosis with the precancerous is subjective by endoscopist evaluation, besides, biopsy of all PP and is financially and technically difficult process.

**Aims & Methods:** The aim of the study was to optimize the identifying potential precancerous polyps among the multiple PP.

For a 10 years study, 80 patients with moderate to severe UC with endoscopic and histologic established multiple PP were undergone CT of abdomen, pelvis and enterography on TOSHIBA Aquilion 64 Slice CT Scanner with dual contrast (intravenous and oral). Based on conclusion results, they were divided into two groups. Group 1 included 28 patients with PP that were determined on CT. Other 52 patients were included in Group 2 as they had no evidence of polyps on CT. Then, all patients were received conventional and immunobiological treatment up to achieve clinical and laboratory remission (in general 54 patients: 23 (82.1%) in Group 1 and 31 (59.6%) in Group 2). After that, they were undergone colonoscopy.

**Results:** 1. Group 1 had before treatment the mean size of polyp 1.7+/-0.4 cm and the affected by PP area 30 +/- 5 % per bowel segment. After treatment, 20 patients (87%) had the same size and affected area ( $p < 0.05$ ). Other 3 patients (13%) got improvement - mean size of polyp decreased to 1.2+/-0.3 cm ( $p < 0.05$ ), affected area left the same. After biopsy of the largest PP in each subject, the different type adenoma was found in 10 (43.5%), hyperplastic in 3 (13%) and chronic inflammation in 10 (43.5%) cases.

2. Group 2 had before treatment the mean size of polyp 1.0+/-0.4 cm and the affected by PP area 27% +/- 4 % per bowel segment. After treatment, 24 patients (77.4%) had disappearance of PP ( $p < 0.05$ ). Other 7 patients (22.6%) got improvement - mean size of polyp decreased to 0.6+/-0.2 cm ( $p < 0.05$ ), affected area to 23 % +/-3%. After biopsy of the largest PP in each subject only chronic inflammation was observed.

Thus, the most polyps that were determined on CT after biopsy (56%) were precancerous, versus polyps that were not (chronic inflammation) ( $p < 0.05$ ). The using of CT is allowed to decrease number of biopsies and more accurately determine precancerous polyps.

**Conclusion:** The CT, in the aggregate with standard methods, could be used for verification of precancerous polyps among PP.

**Introduction:** The presence of antinuclear antibodies (ANA) in serum of inflammatory bowel disease (IBD) patients has been associated with a worse response to treatment with anti-TNF agents including infliximab (IFX). An association between ANA and the development of paradoxical cutaneous and rheumatological manifestations in IBD patients under IFX has also been reported. However, there is limited data on the direct correlation of ANA with the pharmacokinetics of IFX.

**Aims & Methods:** The aim of this study is to investigate the potential association of serum ANA with IFX trough levels (IFX-TLs) and IFX antibodies (ATIs) in IBD patients treated with IFX. We studied IBD patients under

maintenance treatment with IFX retrospectively in whom we had at least one IFX-TLs and ATIs measurement and one ANA measurement in the serum. IFX and ATIs as well as clinical disease activity scores (HBI or SCAI), biomarkers (CRP) and development of adverse events were compared between patients with positive and negative ANA.

**Results:** Fifty IBD patients under maintenance therapy with IFX were enrolled. Of these, 28 had positive ANA [men 15 (54%), median age 46.8 ± 12.1 years, 20 with Crohn's disease (71.4%), median disease time 14.1±11 years, median IFX therapy time 62.5±51 months, 11 smokers and 7 ex-smokers, 15 under combination therapy with an immunomodulator AZA/MTX (53.5%)] and 22 had negative ANA [men 17 (77.2%) mean age 41.8 ± 17.9, 18 Crohn's disease (81.8%), median disease time 12.2±7.9 years, median IFX therapy time 51.9±36.8 months, 7 smokers and 7 ex-smokers, 12 under combination therapy with AZA/MTX]. The median IFX-TLs (IQR) in serum of group 1 was 3.51 µg / ml (1.26-6.74), significantly lower than those of group 2 [7.38 µg / ml (4.85-10.18)],  $P = 0.017$ .

In addition, the median ATIs in the 1st group (ANA +) were 2.65 U / mL (2.41-3.21) significantly higher than the median ATIs of the 2nd (ANA-), [2.35 U / mL (2.12-2.81)],  $P = 0.031$ . No significant differences in regards of clinical activity scores, CRP levels or the development of adverse events between positive and negative ANA patients was found ( $P > 0.05$ ).

Eight patients of the first group also showed positive anti-ds-DNA. Positive anti-ds-DNA patients did not have a statistically significant difference in IFX-TLs versus patients with negative anti-ds-DNA ( $P > 0.05$ ). There was also no difference in ATIs levels between patients with positive or negative anti-ds-DNA ( $P > 0.05$ ).

**Conclusion:** In IBD patients under maintenance treatment with IFX the presence of positive ANA is associated with lower IFX-TLs and higher ATIs compared to those with negative ANA. Further study is needed in a larger population to evaluate the significance of this finding.

## P1738 PREVALENCE AND RISK FACTORS FOR NON-ALCOHOLIC FATTY LIVER DISEASE IN CROHN'S DISEASE

Ben Mohamed A., Medhioub M., Khsiba A., Mahmoudi M., Hamzaoui L., Azzouz M.M.

Faculty of Medicine of Tunis, Tunis, Tunisia

**Contact E-Mail Address:** asmabenmed2014@gmail.com

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is responsible for up to 40% of hepatic alterations diagnosed in inflammatory bowel diseases (IBD).

**Aims & Methods:** We aimed to evaluate the prevalence and risk factors for NAFLD in patients with Crohn's disease (CD).

**Methods:** This is a comparative retrospective study of 86 cases of CD (42 men and 44 women, sex-ratio of 0.95) with a mean age of 42.47 years (18-88 years). We used as a control group, 50 patients consulting for an intestinal functional disorder (29 women and 21 men) whose average age was 42 years.

In both groups, hepatic steatosis was sought by abdominal ultrasound as well as calculation of the HSI score (Hepatic Steatosis Index). Patients with chronic liver disease whose etiology is different from NAFLD, or daily alcohol consumption greater than 20 g/day for women and 30 g/day for men were excluded.

**Results:** We collected 86 patients followed for CD, the median duration of follow-up was 54 months; 44.2% (36) of patients were smokers, 12% had a family history of CD, 25.6% (22) were overweight with an average BMI of 22.45 kg/m<sup>2</sup> (15-30.47kg/m<sup>2</sup>), 44.2% (38) had ileal disease, 14% (12) a colonic disease and 38.6% (33) ileocolic localization.

CD was inflammatory in 38.4% of cases, stenotic in 34.9% of cases, fistulizing in 7% of cases and both stenosing and fistulizing in 17.4% of cases. NAFLD based on abdominal ultrasound data and HSI score calculation was observed in 21 (24.7%) patients with CD versus 8 cases in the control group (16%) ( $p = 0.04$ ).

The prevalence of diabetes and overweight was comparable between the two groups. Among patients with CD, those with NAFLD were more likely to be women (14 women versus 7 men) with an average age greater than 45 years. BMI was higher in patients with hepatic steatosis. Factors associated with the presence of hepatic steatosis during CD were overweight (BMI > 25 kg/m<sup>2</sup>) ( $p = 0.026$ ), smoking ( $p = 0.006$ ), and cortico- steroid therapy ( $p = 0.032$ ). There was no significant association between history of surgery and the concept of fatty liver.

**Conclusion:** Hepatic steatosis is the most common hepatobiliary event during CD. Its screening should be systematic in order to introduce preventive measures avoiding its progression towards fibrosis.

**Disclosure:** Nothing to disclose

### **P1739 A SCREENING TOOL FOR THE EARLY DIAGNOSIS OF EXTRAINTESTINAL MANIFESTATIONS IN INFLAMMATORY BOWEL DISEASE: THE EMAIL QUESTIONNAIRE**

Ingrassia Strano G.<sup>1</sup>, Busacca A.<sup>1</sup>, Giuffrida E.<sup>1</sup>, Guida L.<sup>1</sup>, Carrozza L.<sup>1</sup>, Scrivo B.<sup>2</sup>, Calvaruso V.<sup>3</sup>, Cappello M.<sup>4</sup>

**Contact E-Mail Address:** anitabusacca05@gmail.com

**Introduction:** Data on prevalence of extraintestinal manifestations (EIMs) in inflammatory bowel disease (IBD) range from 6% up to 47%. Recently, several red flags and questionnaires have been proposed for early diagnosis of articular manifestations.

**Aims & Methods:** Our aim was to analyze the prevalence of EIMs in a single center prospective cohort, using a comprehensive questionnaire developed by our group to detect all EIMs (Extraintestinal MANifestations in Inflammatory boweL disease, EMAIL). Patients with IBD attending our Clinic from November 2017 to January 2019 were interviewed using a two-part questionnaire, the first part for clinical-demographic data and the second part for EIMs (date of diagnosis, pharmacological therapies at onset and for EIMs, response to therapy, relationship with disease activity). Patients positive to screening were referred for multidisciplinary approach.

**Results:** 206 IBD patients were interviewed, 114 (55,3%) Crohn's disease (CD) and 92 (44,7%) ulcerative colitis (UC), 52,4% male, mean age 46,7 years (SD± 15,2). Familial predisposition for IBD was reported in 28,2% (47/206). Smokers were 63 (30,6%). 60 (53%) CD patients and 48 (52%) UC patients, in total 108, had history of at least one EIM. 37 patients (18%) had more than one EIM. The maximum number of EIMs was 4. Articular EIMs were found in 49 pts (24%), 36 (31,6%) with CD; peripheral arthritis was found in 14% (29/206), axial arthritis in 9,7% (20/206): 7 pts (3,4%) had ankylosing spondylitis, 13 (6,3%) sacroiliitis. Mucocutaneous EIMs were detected in 39 pts (19%), 27 (23,7%) with CD; erythema nodosum in 15 pts (7,3%), pyoderma gangrenosum in 9 (4,4%), psoriasis in 15 (7,3%), folliculitis in 7 (3,4%). Ocular EIMs were observed in 35 pts (17%), 19 (16,6%) with CD: uveitis in 7 pts (3,4%), conjunctivitis in 8 (3,9%), optic neuritis in 2, glaucoma in 2 pts, cataract in 13 (6,3%), dry eye in 4 (1,9%), central serous chorioretinopathy in 1. Hepatobiliary EIMs were observed in 31 pts (15%), 19 with UC: 26 steatosis (12,6%), 5 (2,4%) primary sclerosing cholangitis. 4 (2%) pts had DVT. There was a significant correlation between CD and articular EIMs ( $p=0,001$ ), between axial arthritis and IBD related surgery ( $p=0,001$ ) and age at IBD diagnosis between 16 and 40 years ( $p=0,042$ ). Skin manifestations were more frequent in female ( $p=0,002$ ) in CD ( $p=0,032$ ), in pts without perianal disease ( $p=0,019$ ). There was a strong correlation between skin manifestations and IBD activity ( $p<0,001$ ). Ocular manifestations were more frequent in pts without perianal disease ( $p=0,042$ ). Hepatobiliary manifestations were more frequent in male ( $p=0,017$ ) and in UC ( $P=0,044$ ). There was a significant correlation between DVT and IBD activity ( $p=0,016$ ). 59,6% of patients with EIM (64/108) were treated with biologics, immunomodulators were used in 25/108 patients (23%). Combo Therapy was used in 11/108 pts (10%).

**Conclusion:** The questionnaire developed by our group proved to be a sensitive screening tool since the prevalence of EIMs in our cohort was higher than that reported in the literature. Articular and cutaneous EIMs are more frequent in CD, hepatobiliary EIMs are more frequent in UC. A gender difference has been found since cutaneous EIMs are more frequent in females, hepatobiliary more in males. Cutaneous EIMs and DVT are related with IBD activity. EIMs require a multidisciplinary approach and the frequent use of biologics and immunomodulators, early diagnosis could improve response to therapy and positively impact on quality of life.

### **P1740 PREDICTORS OF NEGATIVE C-REACTIVE PROTEIN IN ACTIVE CROHN'S DISEASE**

Ben Mohamed A., Medhioub M., Khsiba A., Mahmoudi M., Hamzaoui L., Azzouz M.M.

Faculty of Medicine of Tunis, Tunis, Tunisia

**Contact E-Mail Address:** asmabenmed2014@gmail.com

**Introduction:** Due to its wide accessibility, fast availability and proven correlation with disease activity, C-reactive protein (CRP) remains an essential tool in the management of Crohn's disease (CD). However, the correlation of CRP with CD activity is not perfect. It is therefore of great importance to identify the group of patients with active disease and negative CRP.

**Aims & Methods:** We performed a retrospective case-control study, with inclusion of CD patients with proven active disease as demonstrated by endoscopic and/or radiologic examinations. The CRP's cut-off value used to separate patients in two groups (cases and controls) was 1 mg/dl. Demographic, phenotypic and clinical characteristics were collected. Statistical analysis was performed with SPSS 20.0.

**Results:** We included 77 patients (38 men, 39 women) with a mean age of 40.21 years (18-88 years) and median duration of disease of 58 months (24-310 months). Twenty seven (35%) of these patients had negative CRP. There weren't statistically significant differences in CD activity between cases and controls, as evaluated by Best index. Upon exploratory analysis, there were statistically significant differences regarding gender as 47.36% of men vs. 23.07% of women had a negative CRP ( $p=0,04$ ). Even though location was not a significant predictor, all patients with a negative CRP had ileal involvement. On multivariate analysis, gender remained a significant predictor ( $p=0,02$ ). There was also a tendency to a higher probability of negative CRP in isolated ileal disease ( $p=0,058$ ). There were no differences in age, behaviour, disease duration, previous abdominal surgery or smoking status.

**Conclusion:** Despite being a useful tool, CRP has some limitations and it can be negative in cases of active disease. In patients with the identified characteristics: men with ileal disease, other methods should be used to exclude with confidence the presence of inflammatory activity.

**Disclosure:** Nothing to disclose

### **P1741 DEGRADATION AND FORMATION OF TYPE III, IV AND V COLLAGEN ARE ASSOCIATED WITH DISEASE ACTIVITY, DISEASE SEVERITY AND DISEASE EXTENSION IN PATIENTS WITH ULCERATIVE COLITIS**

Mortensen J.H.<sup>1</sup>, Domislovic V.<sup>2</sup>, Karsdal M.A.<sup>1</sup>, Brinar M.<sup>2</sup>, Krznarić Ž.<sup>2</sup>, Manon-Jensen T.<sup>1</sup>

**Contact E-Mail Address:** viktor.domislovic@gmail.com

**Introduction:** Ulcerative colitis (UC) is an idiopathic chronic inflammatory bowel disease, where increased matrix metalloproteinases are the major contributor to the intestinal tissue remodelling. The intestinal basement membrane (main constituent is type IV collagen) is directly positioned underneath the epithelial cells. The supportive interstitial matrix (main constituent are type I, III and V collagens) is mainly produced by fibroblasts. Both matrices are important for intestinal health and are highly affected in UC.

**Aims & Methods:** We investigated serum biomarkers of collagen degradation and formation of the respective extracellular matrix (ECM) compartments and their association with disease activity, severity and extension in 29 UC patients and 29 healthy donors (HD) were included as a control group. A combination of the partial mayo score and biochemical activity was used to determine disease activity (pMayo>1 and CRP>5). Disease severity and extension was assessed by Montreal classification. Biomarkers of type III collagen degradation (C3M) and formation (PRO-C3), type IV collagen degradation (C4M) and formation (PRO-C4), type V collagen formation (PRO-C5) and C-reactive protein (CRP) were measured in serum by ELISA. One-way ANOVA (Tukey's multiple comparisons test), and Spearman rho correlations were applied for statistical analyses.

**Results:** C4M was significantly elevated in active UC compared to UC in remission ( $P<0,05$ ) and HD ( $P<0,001$ ), and PRO-C4 was also significantly elevated in active UC and UC in remission compared to HD ( $P<0,01$ ). C3M

was significantly elevated in active UC compared to UC in remission ( $P < 0.05$ ) and HD ( $P < 0.05$ ), whereas PRO-C3 was significantly elevated in active UC and UC in remission compared to HD ( $P < 0.001$ ). PRO-C5 was elevated in active UC compared to HD ( $P < 0.01$ ) (figure 1). In addition, C3M ( $r=56, P < 0.01$ ), C4M ( $r=0.41, P < 0.05$ ), PRO-C4 ( $r=58, P < 0.001$ ), PRO-C5 ( $r=49, P < 0.01$ ), and CRP ( $r=47, P < 0.01$ ) correlated with disease severity, and PRO-C4 ( $r=48, P < 0.01$ ), PRO-C5 ( $r=0.38, P < 0.05$ ), and CRP ( $r=45, P < 0.01$ ) correlated with disease extension.

**Conclusion:** The biomarkers C3M and C4M were associated with disease activity in UC and disease severity in addition to PRO-C4 and PRO-C5. PRO-C4 and PRO-C5 also correlated with disease extension. These data demonstrated that ECM remodelling of the intestinal basement membrane and interstitial matrix are associated with disease status and progression, which can be used to optimize treatment strategies for UC patients.

**Contact E-Mail Address:** tmj@nordicbio.com

**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) is marked by inflammation of the gastrointestinal tract and characterized by intermittent periods of active disease (flares) and inactive disease (remission) resulting in impaired intestinal epithelial barrier and induced tissue damage and remodeling. Methods for assessment of the intestinal permeability can be used to evaluate the disease burden, however, there are only a few non-invasive biomarkers available. The epithelial cells are positioned directly on top of the basement membrane, which is remodeled extensible in IBD. The transmembrane collagens connect the epithelial cells to this extra cellular matrix (ECM).

**Aims & Methods:** Since transmembrane collagens have an important role in epithelial cell homeostasis, we sought to determine whether type 23 collagen, a transmembrane collagen expressed in epithelial cells as associated with the basement membrane, could serve as surrogate for disease activity in patients with CD and UC active disease.

We developed an enzyme-linked immunosorbent assay (ELISA, named PRO-C23) to detect the ectodomain of type 23 collagen in serum, followed by evaluation of its levels in both rat dextran sulfate sodium (DSS) model and human UC and human CD cohorts. Serum from 44 CD and 29 UC patients with active and inactive disease based on the simple endoscopic score for CD (SES-CD) and on the Mayo score for UC (pMayo), respectively were included in this study.

**Results:** In patients, serum levels of PRO-C23 were elevated in CD ( $p < 0.05$ , Fig. 1A) and UC ( $p < 0.001$ , Fig. 1B) patients with active disease compared to healthy donors. In the DSS induced rat colitis model, PRO-C23 level was significantly increased in the rats with active disease (Fig. 1C) and returned to normal level after disease remission.

**Conclusion:** This is the first study that showed type 23 collagen levels were elevated in IBD, and consequently that transmembrane collagens and the basement membrane axis is important for the pathology of IBD. We demonstrated that biomarker, PRO-C23, was elevated in rats with active colitis (proving accuracy) and in CD and UC patients with active disease. This indicates that PRO-C23 is associated with a compromised interstitial mucosa, and epithelial cell dysfunction. PRO-C23 may potentially be used as non-invasive surrogate of disease activity in CD and UC patients and thus aid in the diagnosis and monitoring patients, in combination with other biomarkers.

**Disclosure:** JHM, MAK, SS, ML, and TMJ are full time employees at Nordic Bioscience. MAK and TMJ hold stocks in Nordic Bioscience.

## P1744 INSIGHTS FROM A MULTIDISCIPLINARY REFERRAL CLINIC FOR DERMATOLOGICAL COMPLICATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES: IBD-DERMA-CLINIC

**Introduction:** Dermatological manifestations are common among patients with inflammatory bowel diseases (IBD). They may be driven by the inflammatory process, nutritional deficiencies, or medications. As the diagnosis and treatment of dermatologic manifestations is often challenging, we established a multidisciplinary referral clinic (IBD-DERMA) for joint decision making and patient care.

**Aims & Methods:** We aimed to estimate the impact of multidisciplinary care in the IBD-DERMA clinic. The clinic functions since 2018. It is conducted by an IBD expert and a dermatologist with expertise in immunological disorders. Consecutive patients with IBD who have developed a dermatological complication and were referred for consultation by either gastroenterologists or dermatologists were included. Joint decision making was driven by the status of the IBD, past medical history, exposure to medications, and the dermatological diagnosis. Mann Whitney or Chi-square tests were employed to compare continuous or categorical variables, accordingly.

**Results:** Overall 92 patients were included: 50 males (54.3%), median age 34 years (IQR 29-44), and median disease duration of 8 years (IQR 3-13). Crohn's disease - 75 patients, most with small bowel involvement, and a form of bowel damage (L1- 50%, L3-37%, B2 -24%, B3 27%, B2/3-17%), and 43% with perianal involvement. Ulcerative colitis -16 patients, of whom 71% had pancolitis. In 23% of the cohort there was a history of IBD-related surgery, and 48% had at least one extra-intestinal manifestation in addition to IBD and dermatologic manifestations. Only 20% of patients had a history of dermatological condition prior to IBD diagnosis (mostly psoriasis [63%]). Sixty percent of patients were experienced with thiopurines, 12% with methotrexate, and 78.5% with anti-tumor necrosis factor agents (ATNFs). At referral 80% of patients had quiescent IBD, most (92%) controlled with medications. The most prevalent dermatologic diagnosis was skin eruptions induced by ATNFs, complicating 45.6% of the cohort: 28/42 patients with psoriasiform dermatitis (PD), and 14/42 patients with dominant inflammatory alopecia (IA). Characteristics of patients with PD and dominant IA were comparable, however therapeutic strategies differed. Intervention strategies were: (i) topical therapy (steroid ointments/injections or phototherapy), systemic steroids, combination with methotrexate - without discontinuation of the offending ATNF, (ii) discontinuing the ATNF, (iii) a biologic switch. Altogether 88% significantly improved. Topical treatments were effective in 60.7% of patients with PD but only 21.4% of those with IA ( $p=0.023$ ). Discontinuation of the offending ATNF was necessary in 93% of the patients with IA compared to 36% of patients with PD ( $p < 0.001$ ). A switch to a different biologic class was needed in order to control either the skin condition and/or the IBD in 57.1% of the IA patients, compared to only 10.7% of patients with PD ( $p=0.002$ ).

**Conclusion:** An IBD-DERMA clinic provides expert care for patients with IBD and dermatological manifestations. Paradoxical skin eruptions were the most prevalent diagnoses. Almost a third of the patients presented with dominant IA secondary to ATNF, a condition that has a distinct course, and may represent a different pathophysiologic process. Joint decision making resulted in improvement in 88% of dermatologic manifestations. The IBD-DERMA clinic is a platform enabling professional and personalized approach to treat patients with IBD and dermatological manifestations.

**Introduction:** Crohn's disease (CD) is generally found in the ileum and/or colon, albeit, since the 1960s it has become evident that this chronic inflammatory disorder of unknown etiology can affect the whole gastrointestinal tract from mouth to anus. In 0.5-13% of patients with ileocolonic CD, upper gastrointestinal tract is affected, with 0.2 to 1.8% of cases being mainly located in the lower third of the esophagus, however, should a systematic esophageal biopsy be performed in all patients with IBD?

**Aims & Methods:** The aim of this study is to evaluate the interest of systematic esophageal biopsy in every IBD patient's case, as well as the prevalence of esophageal Crohn's disease in our series.

We conducted a prospective and descriptive study including 64 patients with IBD supervised within our department, and who have had an upper endoscopy. Epidemiological, clinical, endoscopic and histological data were collected. These patients systematically underwent biopsy esophageal.

**Results:** A total of 64 patients were included, 35 men (54.68%) and 29 females (45.32%), with an average age being 39.32 years (range: 22-76 ans). Among them, 39 patients (60.9%) had Crohn's disease, 19 patients (29.6%) had ulcerative colitis, and 5 patients (7.8%) had indeterminate colitis. Upper endoscopy was systematically performed on 58 (90.6%) patients and was indicated to investigate an upper gastrointestinal disorder in 9.3% (6 patients) of cases. It was normal for 55 patients (85.9%) and revealed: Esophagitis in five cases (grade A of Los Angeles (three patients), grade B (one patient), and grade C (one patient), typical manifestations evoking an esophageal localization of Crohn's disease were found in 2 patients: superficial ulcerations scattered in the lower third of the esophagus and an oval ulcer of 6 mm. These 2 patients are females whose respective ages are 35 and 31 years old, they have a low localization of Crohn's disease (L2 and L1 according to the Montreal classification), one of them, had an upper gastrointestinal tract symptom: epigastralgia. Histological findings were nonspecific, indicating ulcerative esophagitis for both patients. For the other patients, histological findings showed chronic and hyperplastic esophagitis in 33 cases (51.5%), normal esophageal mucosa in 22 cases (34.3%), congestive mucosa in 3 cases (4.6%), and reflux esophagitis in 3 cases (4.6%).

**Conclusion:** Our study showed that a systematic esophageal biopsy performed on all IBD patients is far from being profitable, while a systematic upper GI endoscopy might be more useful.

**Disclosure:** Nothing to disclose

## P1746 SEROLOGICAL BIOMARKERS OF TYPE VI COLLAGEN REMODELLING REFLECT ENDOSCOPICALLY AND CLINICALLY ACTIVE CROHN'S DISEASE

Lindholm M.<sup>1</sup>, Godskesen L.E.<sup>2</sup>, Kjeldsen J.<sup>2</sup>, Krag A.<sup>2</sup>, Pehrsson M.<sup>1</sup>, Manon-Jensen T.<sup>1</sup>, Karsdal M.A.<sup>1</sup>, Mortensen J.H.<sup>1</sup>

<sup>1</sup>Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, <sup>2</sup>University of Southern Denmark, Department of Medical Gastroenterology, Odense, Denmark

**Contact E-Mail Address:** mpe@nordicbio.com

**Introduction:** The relapsing and transmural inflammation of Crohn's disease (CD) may cause intestinal tissue damage that eventually may result in surgery. Disease activity in CD patients is assessed by clinical symptoms and macroscopic findings of intestinal inflammation at endoscopy. Type VI collagen is positioned in the interface of the interstitial matrix and basement membrane in the intestine. It affects epithelial cell-fibronectin interaction that is important for cell proliferation, adhesion, and migration. Collagens hold signalling potential, and endotrophin that is released from the pro-peptide of type VI collagen during enzymatic processing can itself stimulate fibroblasts to produce more extracellular matrix (ECM).

**Aims & Methods:** Type VI collagen is more than just a structural protein and we investigated if serum biomarkers of its remodelling could serve as surrogate of disease activity in CD patients.

Serum from 17 CD patients with active (n=10) and inactive (n=7) disease based on the simple endoscopic score for CD (SES-CD) were included in this study. Two competitive ELISAs were used to estimate serum levels of degradation and formation of type VI collagen, respectively. One for a neo-epitope of matrix metalloproteinase (MMP)-9 mediated degradation of type VI collagen  $\alpha 3$  chain (C6Ma3) and one for endotrophin; C-terminus of released C5 domain of type VI collagen  $\alpha 3$  chain (PRO-C6).

**Results:** Serum levels of C6Ma3 were elevated in CD patients with a SES-CD above 2 compared to patients with a SES-CD of 0-2. A receiver operating characteristic (ROC) analysis showed an area under the curve of 1 for C6Ma3 with specificity and sensitivity both at 100%. The area under the ROC curve for CRP and Fc $\alpha$  were 0.87 and 0.81, respectively. Serum levels of PRO-C6 were lower in CD patients with active disease compared to patients in remission based on the Harvey-Bradshaw Index (HBI) and serum PRO-C6 demonstrated an inverse correlation to HBI.

**Conclusion:** Our data show that biomarkers of tissue remodelling reflect endoscopically and clinically active CD. MMP mediated destruction of type VI collagen (C6Ma3) was associated with endoscopically active CD and could separate endoscopically active and inactive patients with 100% sensitivity and specificity. Decreased levels of endotrophin (PRO-C6) was associated with clinically active CD and showed an inverse relationship with HBI. This indicates that remodelling of type VI collagen measured by C6Ma3 and PRO-C6 can be used as surrogate markers of endoscopically and clinically active CD, and fragments and signalling molecules released from type VI collagen are associated with pathological features of CD.

## P1747 A SEROLOGICAL BIOMARKER OF TYPE VIII COLLAGEN THAT CONTAINS THE ANTI-ANGIOGENIC SIGNALLING MOLECULE, VASTATIN, IS ASSOCIATED WITH THE EXTENSION OF DISEASE IN ULCERATIVE COLITIS

Lindholm M.<sup>1</sup>, Godskesen L.<sup>2</sup>, Pehrsson M.<sup>1</sup>, Kjeldsen J.<sup>2</sup>, Krag A.<sup>2</sup>, Karsdal M.A.<sup>1</sup>, Manon-Jensen T.<sup>1</sup>, Mortensen J.H.<sup>1</sup>

<sup>1</sup>Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, <sup>2</sup>University of Southern Denmark, Department of Medical Gastroenterology, Odense, Denmark

**Contact E-Mail Address:** mpe@nordicbio.com

**Introduction:** Ulcerative colitis (UC) is characterized by superficial inflammation that starts in the rectum and can extend proximally to affect the entire colon. Endoscopy is used to diagnose patients in terms of extension of disease, however this is invasive and cannot always be completed e.g. if the colon is too severely inflamed. The epithelial and endothelial basement membrane (BM) is an abundant extracellular matrix (ECM) of the intestine. Type VIII collagen is directly associated with the BM and the C-terminus of this collagen contains the anti-angiogenic signalling molecule, vastatin.

**Aims & Methods:** Due to the abundant vasculature in the intestine, we investigated if a serum biomarker that targets the vastatin site of type VIII collagen was associated with the degree of inflammation in UC.

Serum was collected from 61 UC patients that were endoscopically recorded for extension of disease: remission, proctitis, left-sided, pancolitis, and unknown. Endoscopy could not be completed in patients with unknown extension of disease, however, five out of six unknown patients had at least left-sided colitis, but most possibly pancolitis. Rat serum from acute (n=10) and chronic dextran sulfate sodium (DSS) colitis (n=39) were included. A competitive ELISA for the C-terminus of type VIII collagen (PRO-C8) was used to estimate serum levels of type VIII collagen/vastatin.

**Results:** Serum levels were elevated in UC patients with proctitis (P=0.003), left-sided (P=0.008), pancolitis (P=0.002) and unknown (P=0.0003) extension of disease compared to patient in endoscopically remission. In addition, PRO-C8 serum levels were elevated in unknown (P=0.036) and pancolitis (P=0.03) patients compared to proctitis. The levels were also elevated in unknowns (P=0.04) compared to left-sided, for which pancolitis patients had a tendency (P=0.065) of higher PRO-C8 levels. Serum PRO-C8 was confirmed to be increased in both acute and chronic DSS colitis.

**Conclusion:** PRO-C8, containing the anti-angiogenic signalling molecule vastatin, was associated with extension of disease in UC patients and was elevated in patients for which endoscopy could not be completed. Increased PRO-C8 was shown to originate from intestinal inflammation in DSS colitis in rats. Thus, PRO-C8 may be a serological biomarker that reflects intestinal tissue inflammation based on extension of disease. This

also indicates that UC patients with broad tissue involvement may have an altered collagen signalling and that ECM signals are part of the disease pathology.

**Disclosure:** ML, MP, JHM, MAK, and TMJ are full time employees at Nordic Bioscience. MAK and TMJ hold stocks in Nordic Bioscience.

## P1748 MUCOSAL CAPILLARY PATTERN RECOGNITION BASED ON AUTOMATED IMAGE ANALYSIS DURING ENDOSCOPY ACCURATELY DETECTS HISTOLOGICAL REMISSION IN ULCERATIVE COLITIS

Bossuyt P.<sup>1,2</sup>, De Hertogh G.<sup>3</sup>, Eelbode T.<sup>4</sup>, Vermeire S.<sup>5</sup>, Bisschops R.<sup>6</sup>

**Contact E-Mail Address:** peter.bossuyt@imelda.be

**Introduction:** A treat to target strategy in ulcerative colitis (UC) requires an objective evaluation tool to assess remission. The Mayo endoscopic subscore (MES) and the ulcerative colitis endoscopic index of severity (UCEIS) have important inter-rater variability mainly in evaluating remission. Histological remission is the best predictor for sustained clinical remission in UC. The infiltration of neutrophils is associated with morphological irregularities of the pericryptal capillaries.

**Aims & Methods:** The aim was to develop a new objective automated tool for a prototype colonoscopic system to assess histological remission based on the evaluation of the morphology of the pericryptal capillaries during endoscopy.

We used a prototype endoscopic system enabling activation of a short wave-length monochromatic light through adaptation of a LED system. This enables to evaluate in real time the mucosal architecture (crypts, pericryptal capillaries, bleeding) up to a depth of around 200µm. In initial observations histological non-remission was associated with bleeding (mucosal/luminal) and capillary congestion. For this, an image analysis algorithm was applied to provide a score that quantifies the specific morphology of the mucosal capillaries. The algorithm included two steps. First, bleeding (mucosal/luminal) was assessed by pattern recognition. Samples with bleedings were automatically classified as non-remission. In case of non-bleeding (mucosal/luminal), the degree of congestion of the capillaries was measured (maximal localized density estimation after morphological hessian based vessel recognition) to assess an ideal cut off value to identify histological remission (Geboes score (GBS) < 2B.1; no neutrophils in the lamina propria). Consecutive UC patients at the University of Leuven were evaluated with the MES, UCEIS, visual capillary evaluation based on short wave-length monochromatic light and the automated image analysis algorithm. To test the reliability of the algorithm and scores, the results were correlated with the GBS. Biopsies were taken in the matching area of the endoscopic evaluation.

**Results:** Fifty eight patients with UC (53% male, median age 41y IQR 38-56, disease duration 7.1y IQR 2.4-16.4) with 113 evaluable segments (89% rectum or sigmoid) were included. The correlation between GBS and MES, UCEIS and visual short wave-length was good (r= 0.76, 0.75, 0.74, respectively). The automated image analysis algorithm detected histological remission with a high performance (sens 0.79, spec 0.90) compared to UCEIS (sens 0.95, spec 0.69) and MES (sens 0.98, spec 0.61), resulting in a positive predictive value of 0.83, 0.65 and 0.59 for the automated image analysis algorithm, UCEIS and MES respectively. The algorithm detects histological remission with high accuracy (86%). (table 1)

	Mayo endoscopic sub score	Ulcerative colitis endoscopic index of severity	Visual capillary score	Image analysis algorithm
n	113	113	113	113
accuracy	0.743	0.788	0.876	0.858
sensitivity	0.976	0.952	0.810	0.786
specificity	0.606	0.690	0.915	0.901
Positive predictive value	0.594	0.645	0.850	0.825
Negative predictive value	0.977	0.961	0.890	0.877

[Table 1: performance of the different evaluation tools]

**Conclusion:** Mucosal capillary pattern recognition based on image analysis with short wave-length monochromatic light detected histological remission with high accuracy in UC. This technique provides an objective and quantitative tool to assess histological remission, and excludes inter-reader variability.

**Introduction:** Hepatic disorders associated with IBD are frequent and varied according to the type of IBD (Crohn's disease or ulcerative colitis). The abnormalities of biochemical liver tests observed may be transient or lasting. The most specific of these is primary sclerosing cholangitis (PSC) with a risk of degeneration.

**Aims & Methods:** The objective of our study was to evaluate the prevalence of various hepatic histological lesions, especially PSC in patients operated for ulcerative colitis or Crohn's disease, and to discuss the value of systematic perioperative liver biopsy.

Descriptive and analytical prospective study including 14 patients who had surgery for severe acute colitis or complicated Crohn's disease, consent was previously obtained by the patients to have their agreement to perform a liver biopsy.

**Results:** Fourteen patients (6 women, 8 men) were included in the study. 9 patients with Crohn's disease and 5 patients with ulcerative colitis. The various histological lesions discovered are: chronic hepatitis in 6 patients associated with fibrosis in 5 cases, including 4 cases F1 and one case F2 according to the Metavir score, nonspecific inflammatory lesions compatible with lesions of small duct cholangitis or chronic portitis in 7 patients, 2 patients had hepatic steatosis and one patient had a hepatic capillary haemangioma. Liver biopsy was normal in only one case. However, no patient presented histological lesions suggestive of primary sclerosing cholangitis.

**Conclusion:** Our study (preliminary results) proves that performing a systematic perioperative liver biopsy can be cost-effective by allowing the diagnosis of early-stage histological abnormalities such as hepatic steatosis and small channel cholangitis in order to initiate treatment. adequate and regular follow-up to avoid complications.

**Introduction:** Therapeutic Drug Monitoring (TDM) is a useful tool to help physicians managing patients with Inflammatory Bowel Disease treated with anti-tumor necrosis factor (TNF) drugs. Different techniques are currently available to evaluate serum drug concentration (TL), and various studies found an association between drug TL, evaluated either with ELISA or HMSA, and IBD activity. However, these techniques are time consuming. Recently, a point-of-care (POC) method has been proposed to evaluate drug TL and overcome the limitations inherent to other methodologies.

**Aims & Methods:** The aim of our study was to evaluate the capability of POC to discriminate between IBD relapse and remission, and to evaluate the concordance of drug TL measured with POC and HMSA.

We analyzed with Quantum Blue® (Bühlmann Laboratories AG, Schönenbuch, Switzerland) (POC) 200 Adalimumab (ADA) and 200 Infliximab serum samples of 46 Crohn's Disease (CD) patients previously assessed with HMSA. Blood samples were drawn at standardized time points during anti-TNF treatment (2, 6, and every 8 weeks), before anti-TNF administration. Disease activity was assessed by the Harvey-Bradshaw Index (HBI, remission defined by HBI < 5).

**Results:** We evaluated 46 CD patients who responded to anti-TNF induction with ADA (n= 25, 54.3%) and IFX (n= 21, 45.6%), with a median follow-up of 83 weeks (range 16-144 weeks).

At week 16, median ADA TL of patients in remission were significantly higher as compared to patients in disease relapse using both HMSA [12.7 mcg/mL (range, 8.9-23.6 mcg/mL) vs 6.6 mcg/mL (range, 0.7-9.6 mcg/mL), P=0.0001] and POC [17.8 mcg/mL (range 7.6-35.0 mcg/mL) vs 9.8 mcg/mL (range 5.8-11.4 mcg/mL), P=0.0003]. The concordance between the two different techniques has been assessed as 0.76 by Cohen Kappa. Considering IFX TL, patients in remission had higher serum drug concentration using both HMSA [7.0 mcg/mL (range, 0.0-21.8 mcg/mL)] and POC [6.2 mcg/mL (range 0.4-14.3 mcg/mL)] as compared to patients who experienced disease relapse [HMSA, 0.1 mcg/mL (range, 0.0-4.1 mcg/mL), P=0.019; POC, 0.45 mcg/mL (range 0.4-3.3 mcg/mL), P=0.0072]. The concordance between the two different test for IFX TL was 0.81.

At the end of follow up, median ADA TL of patients in remission were significantly higher as compared to patients who experienced disease relapse, using both HMSA and POC [respectively, 10.7 mcg/mL (range, 4.6-18.3 mcg/mL) and 16.2 mcg/mL (range 5.7-35.0 mcg/mL) vs 5.6 mcg/mL (range, 3.1-9.9 mcg/mL) and 6.5 mcg/mL (range 1.3-17.1 mcg/mL) P=0.001 and P=0.0012] with a concordance of 0.75.

Lastly, considering IFX TL, patients in remission had numerically higher serum drug concentration [4.7 mcg/mL (range, 0.1-18.6 mcg/mL) and 2.4 mcg/mL (range 0.4-11.1 mcg/mL)] compared to patients who experienced disease relapse [0.2 mcg/mL (range, 0.1-6.7 mcg/mL) and 0.5 mcg/mL (range 0.4-4.8 mcg/mL)] (P=0.13 and P=0.25) using HMSA and POC, respectively. The concordance between the two different test we used to calculate TL was 0.70.

**Conclusion:** In conclusion, we observed that both POC and HMSA are TL tests able to differentiate relapse and remission in IBD patients. The association between anti-TNF TL and disease status (remission/relapse) was better in ADA-treated patients rather than patients treated with IFX. Lastly, we demonstrated a good concordance between HMSA and POC. Anti-drug antibody concentrations while available on HMSA were not available on POC. This would limit the identification of anti-TNF non-responders on the POC test if a percentage of those were anti-drug antibody positive.

**Disclosure:** Nothing to disclose

**Introduction:** Calprotectin, a calcium and zinc binding protein present in the cytosol of granulocytes neutrophils, monocytes, and macrophages. Fecal calprotectin (FC), a marker of colonic inflammation, can be used as first diagnostic tool and in the follow up of inflammatory Bowel Diseases (IBD). Many studies show that fecal calprotectin is useful in IBD diagnosis and in specialist settings but its benefit in the clinical practice of general practitioners is still not clear.

**Aims & Methods:** Our aim was to analyze the usefulness of fecal calprotectin indication in a north - east Italy population with lower GI symptoms of mild to moderate severity. A cohort of 2487 laboratory exams of fecal Calprotectin were selected from January 2018 to December 2018. 2388 of these were requested by the General Practitioner (96.0%) and the other 99 exams by a Gastroenterologist (4.0%), which were excluded from the

analysis. The study population was thus composed of 937 men (39.2%) and 1451 women (60.8%), mean age 49.48 years (range 18-96). According to the literature, 3 cut off values were selected for this exam: 0-49 µg/g was considered negative, 50-149 µg/g was considered indeterminate and ≥150 was considered positive.

285 of these patients were sent to a Colonoscopy by general practitioners.

**Results:** The results of 2037 fecal calprotectin was divided into: negative (0-49 µg/g): n. 1735 (72.7%), indeterminate (50-149 µg/g) n. 493 (20.6%) and positive (≥150 µg/g) n. 160 (6.7%).

The patients who underwent colonoscopy after FC testing were 285 (14.0% of the total number of requested FC tests): 155 with negative FC, 81 with indeterminate FC, and 49 with positive FC.

Colonoscopic findings in patients with negative FC were: normal in 89 cases (57.4%), diverticular disease in 33 cases (21.3%), polyps in 10 patients (6.5%), IBD in 16 cases (10.3%), other types of colitis (ischemic and non-specific) in 6 patients (3.9%), and colorectal neoplasia in 1 patient (0.6%). Colonoscopic findings in patients with indeterminate FC were: normal in 37 cases (45.7%), diverticular disease in 27 patients (33.3%), polyps in 6 cases (7.4%), IBD in 3 patients (3.7%), other types of colitis in 7 cases (8.6%) and, colorectal neoplasia in 1 case (1.2%).

Colonoscopic findings in patients with positive FC were: normal in 19 (38.8%) cases, diverticular disease in 4 (8.2%) cases, polyps in 2 patients (4.1%), IBD in 17 patients (34.7%), other types of colitis in 5 cases (10.2%) and neoplasia in 2 patients (4.1%).

**Conclusion:** Although positive FC values are more frequently associated with organic disease, especially IBD, and should therefore prompt colonoscopic evaluation, the latter, as well as diverticular disease and even colorectal neoplasms can be present with normal FC values. We notice a high rate of indeterminate FC in diverticular disease patients, suggesting that an early treatment and subsequent FC retesting might be an optimal approach.

Considering FC in association to some clinical data (such as age) can increase the usefulness of the test. Despite the high number of false positive cases, Calprotectin alone can be useful in the clinical practice for the general practitioner in the management of patients with low GI symptoms, to avoid diagnostic delay and to restrict unnecessary invasive and expensive exams.

**Introduction:** Crohn's disease (CD) is characterized by episodes of relapse and remission and therefore requires continuous evaluation of disease activity. Extra Cellular Matrix (ECM) consists of basement membrane (BM) and interstitial matrix (IM). BM is positioned directly underneath the epithelial cells and consists mainly of type IV collagen, while IM consists mainly of type I, III and V collagen, and is produced by fibroblasts. Pathological environment, such as inflammation and fibrosis, leads to impaired remodeling, structure, quality and function of the collagen in the ECM.

**Aims & Methods:** Our aim was to investigate biomarkers of collagen degradation and formation and their association with disease activity and in patients with CD.

In this cross-sectional study we measured five biomarkers of ECM remodeling in 75 patients with CD (60% males, age 35(IQR 26.5-43.5)), and 29 healthy controls matched by age and gender. Biomarkers of type III collagen degradation (C3M) and formation (PRO-C3), type IV collagen degradation (C4M) and formation (PRO-C4), type V collagen formation (PRO-C5) and C-reactive protein (CRP) were measured in serum by ELISA. Inflammatory activity was defined as combination of clinical or biochemical disease activity (CDAI≥150 or CRP>5). Disease behavior was assessed by Montreal classification. One-way ANOVA (Tukey's multiple comparisons test), and ROC analysis was applied in statistical analysis.

**Results:** Biomarkers of interstitial matrix remodelling showed that C3M was significantly elevated in active CD compared to inactive CD ( $P < 0.05$ ) and HD ( $P < 0.05$ ), whereas PRO-C3 and PRO-C5 were significantly elevated in active CD and inactive CD compared to HD ( $P < 0.001$ ,  $P < 0.05$ ). (Figure 1) Turnover type III collagen showed highest diagnostic accuracy for active disease (AUC=0.74). Area under curve was for C3M 0.63, PRO-C3 0.36 and PRO-C5 0.52.

Biomarkers of basement membrane remodelling showed significantly higher C4M in active CD compared inactive ( $P < 0.05$ ) and HD ( $P < 0.001$ ), whereas PRO-C4 was significantly elevated in active and inactive CD compared to HD ( $P < 0.01$ ). Area under curve was for C4M 0.64, C4M/PRO-C4 ratio 0.57 and PRO-C4 0.56.

**Conclusion:** Both biomarkers of interstitial matrix (C3M) and basement membrane (C4M) were associated with disease activity. PRO-C3, PRO-C5 and PRO-C4 were associated with CD regardless of disease activity. Interstitial matrix biomarkers of turnover type III collagen C3M/PRO-C3 showed highest diagnostic accuracy for disease activity. In conclusion, these biomarkers may be used in monitoring and prediction of disease activity and in differentiation between patients with CD and healthy individuals.

**Introduction:** Faecal Calprotectin (FCP) has been found to be an accurate surrogate marker for post-operative recurrence in Crohn's disease (CD). However, the use of FCP to monitor disease activity in patients with an ileostomy due to CD has not been established. The aim of this study was to assess the performance characteristics of FCP in patients with CD and an ileostomy and to compare this to patients with CD post ileo-colonic resection.

**Aims & Methods:** Post-operative patients with CD attending a single academic centre were identified using a prospectively maintained database of >4000 Inflammatory Bowel Disease (IBD) patients. These were cross-referenced with the local hospital endoscopy reporting system to identify patients with small bowel endoscopic assessment from 2014 onwards. Endoscopic CD activity was classified using the Rutgeert's score (RS) and RS $\geq 2$  was used to define endoscopic recurrence. A FCP cut-off 150 $\mu$ g/g was used to define disease activity. MRE assessment was used to classify patients as active or inactive CD.

**Results:** 1,896 surgeries for CD were identified from our IBD database. A total of 80 (ileostomy: n=27, anastomosis: n=53) contemporaneous endoscopic and FCP results in 74 patients were analysed. Median age was 46.9 (IQR 37.0-57.1) and did not significantly differ between the two groups. Similar numbers of male (n= 30) and female (n=44) were identified in both groups. Patients with an ileostomy had significantly higher rates of negative disease predictors including younger age at diagnosis ( $p < 0.05$ ), longer disease duration ( $p=0.001$ ) and a higher proportion of perianal disease ( $p=0.01$ ). Patient demographics, disease characteristics and baseline biochemistry are outlined in Table 1.

72% had i0-1 disease, and 28% i2-4 disease in the ileostomy group compared to 47.2% and 52.8% respectively in the anastomosis group, with a trend towards more active disease in the anastomosis group ( $p=0.052$ ). No significant correlation was identified between endoscopic scores and FCP results in patients with an ileostomy ( $p=0.109$ ,  $R=0.328$ ). In the anastomosis group, there was a significant correlation between level of FCP and RS $\geq 2$  ( $p=0.012$ ,  $R=0.343$ ), particularly in patients with FCP >150 ( $p=0.008$ ,  $R=0.371$ ).

**Conclusion:** Our study confirms the strong correlation between FCP and endoscopic activity in post-operative CD and in particular shows a high degree of accuracy when 150 $\mu$ g/g is used as a cut off in these patients.

There was, however, poor correlation in CD patients with an ileostomy. FCP is best used with caution in this patient cohort and in conjunction with other validated objective tools.

### P1754 THE SYSTEMIC IMMUNE-INFLAMMATION INDEX PREDICTS DISEASE SEVERITY OF ULCERATIVE COLITIS

Yan J.<sup>1</sup>, Deng F.<sup>1</sup>, Tan Y.<sup>1</sup>, Liu D.<sup>2</sup>

<sup>1</sup>The Second Xiangya Hospital of Central South University, Gastroenterology, Changsha, China, <sup>2</sup>Second Xiangya Hospital, Gastroenterology, Changsha, China

**Contact E-Mail Address:** liudeliang@medmail.com.cn

**Introduction:** Ulcerative colitis (UC) is an intractable chronic inflammatory disease characterized by diffuse inflammation of the colonic mucosa. Current indexes to evaluate the severity of UC include blood routine (BR), ESR and clinical grading system such as Mayo score and Baron endoscopic score[1]. But there is still lack of reliable objective index to assess disease severity. Systemic immune-inflammation index (SII) is a newly developed composite index based on BR, which is defined as platelet $\times$ neutrophil/lymphocyte[2]. It has been proved to be both convenient and feasible in predicting treatment effect and prognosis of small cell lung cancer[3], pancreatic cancer[4], colorectal cancer[5] and hepatocellular carcinoma[6]. Hence, we analyze the correlation between SII and severity of UC patients, and estimate its value in UC diagnosis.

**Aims & Methods:** We retrospectively include patients in our department from January 2013 to December 2018. UC patients were diagnosed according to Third European Evidence-based Consensus on Diagnosis and Management of Ulcerative Colitis. The exclusion criteria include coronary heart disease, diabetes, chronic renal failure, hematopathy, hypersplenism, autoimmune disease, pregnancy, carcinoma, radiotherapy, infection, antiplatelet or NSAID drug intake. The control group was selected from patients who received colorectal polyps ESD. Their medical and family history were clear and pathological results of ESD samples were hypertrophic polyps. Their baseline information, BR, ESR, CRP and Mayo score were recorded. Statistical analyses were performed using Graphpad prism 8.

**Results:** There were 79 UC patients and 79 age and sex matched controls. The disease duration of UC patients was 45.78 $\pm$ 65.31 months. Most patients suffered from pancolitis (n=50), while the number of left sided and distal colitis patients were 17 and 12, respectively. Mesalazine (n=52) was most commonly used in these patients, others were glucocorticoid (n=7), salazosulfapyridine (n=6), azathioprine (n=3), infliximab (n=2) and thalidomide (n=1). There were 18 patients who have never used any anti-immune, anti-inflammatory medicine or have been suspended for over 3 months. According to Mayo scoring system, the patients were classified into remission (n=8), mild (n=8), moderate (n=48) and severe (n=15).

There were significant differences between UC patients and controls in PLR, NLR and SII ( $p < 0.0001$ ). Notably, SII was significantly lower between remission/mild group and severe group ( $p=0.012$ ). Moreover, PLR, NLR and SII were associated with Mayo score, ESR and CRP. Among them, SII and Mayo score are most relevant ( $r=0.505$ ,  $p < 0.0001$ ). This revealed the outstanding ability of SII in estimating disease severity of UC.

NLR and SII shows excellent ability in UC diagnosis (Table). The AUC of NLR and SII was 0.808 and 0.858, separately, with cut-off values of 2.535 ( $p < 0.0001$ , SE=0.034, 95% CI [0.742, 0.874]) and 619.1 ( $p < 0.0001$ , SE=0.030, 95% CI [0.800, 0.917]). Similarly, PLR can diagnose UC with a cut-off value of 174.5 (AUC=0.755,  $p < 0.0001$ , SE=0.030, 95% CI [0.800, 0.917]).

**Conclusion:** This is the first report to demonstrate that SII has great potential in evaluating UC severity and diagnosis. Properly designed prospective studies are needed for further investigation.

## P1755 THE RISK OF COLORECTAL CANCER IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Zhou W.<sup>1</sup>, Chen H.<sup>1,2</sup>, Sha W.<sup>1,3</sup>, Luo Y.<sup>1</sup>

<sup>1</sup>Guangdong Provincial people's Hospital and Guangdong Academy of Medical Sciences, Gastroenterology, Guangzhou, China, <sup>2</sup>Guangdong general hospital, Guangdong general hospital, Guangzhou, China, <sup>3</sup>Guangdong General Hospital Dept. of Gastroenterology, Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** 464695938@qq.com

**Introduction:** Inflammatory bowel disease (IBD) is associated with a higher risk of colorectal cancer (CRC). However, studies have investigated this risk and reported widely varying rates.

**Aims & Methods:** This meta-analysis aims to estimate the risk of colorectal cancer in inflammatory bowel disease from multiple aspects. A literature search using Medline and Pubmed was conducted for terms related to colorectal cancer in inflammatory bowel disease from 1988 to 2018. All the full-text articles were searched and studies should meet our inclusion criterias, in which no country restricted, the number of patients was over 500 and the follow up time was over 5 years. Overall pooled incidence rate, with 95% confidence intervals (CI), of colorectal cancer was obtained using a random-effects model as well as a cumulative risk at 10 years, 20 years, and 30 years of disease.

**Results:** Of 3620 studies, 46 articles were included and the total number of inflammatory bowel disease patients was 142190 in which 38672 were Crohn's disease (CD) and 103518 were ulcerative colitis (UC). The overall prevalence of CRC in IBD patient was estimated to be 1.17% (95% CI 1.03-1.31%). The CRC incidence of 71.03/100000 person year duration (pyd) in CD patients yielded differently to the incidence of 122.56/100000 pyd in UC patients. The CRC incidence rate in CD patients varied in intestinal site, being 34/100000 pyd in colon, 31.2/100000 pyd in caecum and 25.26/100000 pyd in rectum. The CRC incidence rate in UC also varied in intestinal site, being 60.88/100000 pyd in colon, 44.61/100000 pyd in cecum and 34.61/100000 pyd in rectum. The worldwide CRC incidence rate varied regionally, being 169.03/100000 pyd in North America, 95.05/100000 pyd in Europe, 95.05/100000 pyd in Asian, 235.12/100000 pyd in Australia and 139.78/100000 pyd in South Africa. The risk for CRC was 0.91% (95% CI 0.63-1.20%) at 10 years, 3.66% (95% CI 2.42-4.90%) at 20 years, and 12.58% (95% CI 5.92-19.23%) at 30 years after IBD diagnosis. Subgroup analysis by stratifying the studies according to data source, study design and gender of the study did not reveal any significant differences.

**Conclusion:** Using the meta-analysis we determined the incidence of CRC in IBD patients was 1.17% and the highest incidence rate was found in Australia in 5 continents. UC patients had a higher risk of CRC than CD patients. No matter UC or CD, colon had a higher risk of developing CRC. Hence, adherence to colonoscopy is essential. A larger prospective study is needed to obtain a better incidence of CRC.

**Disclosure:** Nothing to disclose

## P1756 NORMALISATION OF FAECAL CALPROTECTIN WITHIN 12 MONTHS OF DIAGNOSIS IS ASSOCIATED WITH REDUCED LONG-TERM DISEASE PROGRESSION IN CROHN'S DISEASE

Plevris N., Fulforth J., Jenkinson P., Lyons M., Arnott I., Jones G., Lees C.W. NHS Lothian, Gastroenterology, Edinburgh, United Kingdom

**Contact E-Mail Address:** n.plevris12@gmail.com

**Introduction:** Faecal calprotectin (FC) is a reliable surrogate marker of mucosal inflammation in Crohn's disease (CD). Recent data suggest a FC-directed treat-to-target approach results in superior mucosal healing compared to a symptom-based treatment approach.<sup>1</sup> However, it is unknown whether normalisation of FC within the first 12 months of diagnosis improves long-term outcomes in CD.

**Aims & Methods:** We performed a retrospective cohort study to establish if normalisation of FC within 12 months of diagnosis was correlated with disease progression. Inclusion criteria were: (a) diagnosis of CD between 2009-2017; (b) measurement of FC at diagnosis or +/- 2 months and prior to any initiation of treatment; (c) a FC value  $\geq 250 \mu\text{g/g}$  at diagnosis; (d) at least 1 additional FC within 12 months after diagnosis; (e) >12 months follow up.

The primary endpoint was a composite of progression in Montreal disease behaviour (B1-B2/3, B2-B3 or new perianal disease), resectional IBD surgery or disease related hospitalisation 12 months post-diagnosis onwards.<sup>2</sup> Normalisation of FC was defined as < 250  $\mu\text{g/g}$ . When >1 FC was performed in the 12 month post-diagnosis period, the last FC was used to determine normalisation. Survival analysis was performed using Kaplan Meier curves and groups compared via the log-rank test. Multivariable Cox-regression analysis was used to determine independent factors associated with disease progression.

**Results:** A total of 200 patients met inclusion criteria with a median follow up of 4.9 years (IQR 2.9-7.3 years). 46% (92/200) of patients normalised FC within 12 months of diagnosis. Normalisation of FC within the first 12 months of diagnosis was associated with a significantly lower rate of the composite endpoint of disease progression (Table 1, log-rank  $p < 0.001$ ).

There was no difference in disease characteristics at diagnosis (sex, age, Montreal location/behaviour, perianal disease, smoking status, FC) between patients who normalised FC versus those that did not. FC-normalisation was associated with a higher rate of biologic use (37.0% vs 18.5%,  $p < 0.001$ ). Correcting for age, sex, disease location / behaviour and FC value at diagnosis; smoking (Hazard Ratio 1.8, 95% CI 1.1-3.0,  $p = 0.03$ ), biologic use within 12 months of diagnosis (Hazard Ratio 2.7, 95% CI 1.6-4.6,  $p < 0.001$ ) as well as normalisation of FC within 12 months of diagnosis (Hazard Ratio 0.2, 95% CI 0.1-0.4,  $p < 0.001$ ) were independently associated with disease progression.

**Conclusion:** This study demonstrates that normalisation of mucosal inflammation in the first year of CD will substantially impact long-term outcomes. The data indicate that FC is an excellent surrogate marker for this purpose and are of immediate clinical utility.

Status at 12 months	Cumulative progression rates after first 12 months from diagnosis		
	1-Year	3-Years	5-Years
FC normalised (<250 $\mu\text{g/g}$ )	7.0%	18.7%	24.4%
FC not normalised ( $\geq 250 \mu\text{g/g}$ )	28.1%	43.2%	63.8%

[Table 1. Cumulative progression rates (composite of progression in Montreal disease behaviour or new peri-anal disease/ surgery/ IBD hospitalisation)]

**Introduction:** Ulcerative colitis is a mucosal inflammatory disease of the colon. Depending on the extent and degree of mucosal involvement there may not be signs of systemic inflammation like high CRP values. Although fecal calprotectin can predict mucosal remission in ulcerative colitis, data about CRP level in this context is insufficient

**Aims & Methods:** The aim of this study is to define a CRP level to predict mucosal remission in ulcerative colitis. We retrospectively reviewed colonoscopy reports of ulcerative colitis patients (who are not on any steroid treatment) between December 2016 and March 2019 and also their CRP levels which were obtained at the same week of the colonoscopy examination. Mucosal remission was defined as Mayo score 0 or 1 at colonoscopy. The best CRP level for mucosal remission prediction was assessed by ROC curve analysis and also by positive and negative predictive values

**Results:** A total of 289 patients were involved. CRP levels which predicts mucosal remission is shown at the table. At the ROC curve analysis we found that CRP levels between 2.69-2.78 mg/dl can predict mucosal remission with a 80% sensitivity and specificity. For subgroups with Montreal E2 and E3 ROC curve analysis suggested 2,1 mg/dl (sen. 80%, spe. 80%) and 2,95 mg/dl (sen. 83% , spe. 85%) CRP levels can be used for prediction of mucosal remission respectively

Crp Level mg/dl	Mayo 0-1 group	Mayo 2-3 group
<5	131	61
>5	7	89
Sens: 0,94; Spec: 0,59; PPV: 0,68; NPV: 0,92		
<3	117	30
>3	21	120
Sens: 0,84; Spec: 0,80; PPV: 0,79; NPV: 0,85		
<2	94	20
>2	44	130
Sens: 0,68; Spec: 0,86; PPV: 0,82; NPV: 0,74		

[Table 1. Sensitivity and specificity values for predicting mucosal remission.]

**Conclusion:** CRP cutoff level of approximately 2.7 mg/dl can predict mucosal remission in ulcerative colitis better than standard cutoff of 5 mg /dl

**Disclosure:** Nothing to disclose

## P1758 FECAL EOSINOPHIL-DERIVED NEUROTOXIN/EOSINOPHIL PROTEIN X (EDN/EPX) SHOWED HIGH SPECIFICITY AND POSITIVE PREDICTIVE VALUE AS A BIOMARKER FOR DETECTING DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE COMPARE TO FAECAL CALPROTECTIN

**Contact E-Mail Address:** ivan.lyutakov@gmail.com

**Introduction:** Colonoscopy with histological analysis with multiple biopsies represents the accepted procedure used to find the diagnosis of patients with chronic diarrhea and to assess disease activity and severity. However, it is invasive and costly. Fecal calprotectin (FC) is used as a biomarker for intestinal inflammation in inflammatory bowel disease (IBD) but there is always a search for new biomarker for microscopic colitis (MC). Moreover, the best biomarker for distinguishing functional from organic intestinal disorders is elucidated. In some studies is demonstrated that, mucosal inflammation in IBD and MC is done by eosinophil activation and this need to be evaluated in future bigger studies.

**Aims & Methods:** The AIM is to evaluate the diagnostic accuracy of faecal eosinophil-derived neurotoxin/eosinophil protein x (EDN/EPX) and to compare it to FC in patients with chronic diarrhoea. In this prospective study, we enrolled 109 adult patients with chronic diarrhoea who underwent standard laboratory test, CRP, colonoscopy, faecal EDN/EPX and FC at 'Tsaritsa Yoanna - ISUL' University Hospital, Sofia, Bulgaria. We divided the patients into six groups: 30 patients with active IBD, 21 patients with IBD in remission, 21 patients with IBD after surgery (IBD-IL), 23 patients with IBS-D, 14 patients with MC and 11 healthy control subjects. We used ELISA to detect EDN/EPX and quantitative immunochromatographic to evaluate FC. **Results:** Of these 109 (90,9%) patients with chronic diarrhea included in the analysis, elevated levels of EDN/EPX above 366 ng/ml was confirmed in 51 patients (46,8%) and lower levels of 58 patients (53,2%) as using cut-off level of disease activity compare to 11 (9,1%) healthy controls (p=0,002). We found a EDN/EPX cut-off level of 366 ng/ml for IBD active group with sensitivity of 80% (95% CI 61,43% to 92,29%), specificity 90,9 % (95% CI 58,72% to 99,77%), negative predictive value 62,5% (95% CI 44,3% to 77,74%) and positive predictive value (PPV) of 96% (78,6% to 99,37%) (p=0,001), compare to FC with sensitivity 78% and specific 72,2%. Mean FC levels among the 6 groups were IBD Active (750 µg/g) vs IBD in remission (81 µg/g) vs IBD after surgery (375 µg/g) vs IBS-D (47 µg/g) vs MC (221 µg/g) vs healthy controls (43 µg/g), respectively (p= 0,002). Mean EDN/EPX levels among the 6 groups were IBD Active (2777 ng/ml) vs IBD in remission (412 µg/g) vs IBD after surgery (1425 µg/g) vs IBS-D (524 µg/g) vs MC (187 µg/g) vs healthy controls (179 µg/g), respectively (p= 0,002). We found correlation between EDN/EPX and FC to be moderate (Pearson's r=0,6, p-value < 0,01). We estimate higher median levels of EPX/EDN in IBD patients with active disease, IBD patients after surgery and lower levels of EPX/EDN in MC group and no difference between IBD in remission and IBS-D group.

**Conclusion:** EPX/EDN fecal biomarker could be used as surrogate markers for assessing disease activity in IBD patients with active disease and provided additional discrimination from IBD in remission. EDN/EPX showed higher specificity and PPV for detecting disease activity in IBD patients compared with FC. Combination of EDN/EPX and FC should be used for identifying patients with active IBD and they could possibly be used as biomarkers for differentiating IBD and MC from IBS-D or healthy subjects with high diagnostic accuracy. Both EDN/EPX and FC can be used as a screening and monitoring surrogate markers for non-invasive disease activity. Furthermore, bigger studies are needed to establish the efficacy of EDN/EPX.

## P1759 BONE MINERAL METABOLISM IN INFLAMMATORY BOWEL DISEASE: A CROSS-SECTIONAL STUDY

Tulewicz-Marti E.M., Korcz T., Rydzewska-Wyszkowska G.  
*Centralny Szpital Kliniczny MSWiA w Warszawie, General Medicine and Gastroenterology with Inflammatory Bowel Disease Subdivision, Warsaw, Poland*

**Contact E-Mail Address:** e.tulewicz@gmail.com

**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) are the main forms of inflammatory bowel disease (IBD), chronic relapsing-remitting inflammatory conditions of uncertain origin affecting the gastrointestinal tract. Vitamin D plays a key role in gut immunity and maintenance of the mucosal barrier and also may be a predictive factor of bone mineralisation.

**Aims & Methods:** The objective of our study was to determine the prevalence of vitamin D deficiency and the levels of biochemical markers of bone mineral metabolism in patients with IBD. A total of 87 patients with IBD were included. Serum calcium, albumin, phosphorus, parathyroid hormone, 25-hydroxyvitamin D (25-OHD), Beta-crosslaps (CTX), osteocalcin and urine phosphorus levels were evaluated.

**Results:** 57 patients with CD (32% were women) and 30 patients with UC (55% women) were enrolled in the study. The mean calcium level was  $2.32 \pm 0.13$  mmol/L in CD patients and  $2.31 \pm 0.34$  mmol/L in UC patients. Albumin level was  $4.14 \pm 0.52$  g/dL in CD and  $4.26 \pm 0.45$  in UC group. Interestingly 21% of UC patients and 5% of CD had hypophosphatemia ( $p < 0.05$ ). Mean phosphorus in urine was  $59.6 \pm 48.1$  mg/dL in CD and  $44.6 \pm 36.1$  mg/dL in UC patients ( $p = 0.179$ ). Deficiency of 25-OHD was very high, with a prevalence of 86% in patients with UC and 83% in patients with CD. Hyperparathyroidism, defined as a parathyroid hormone level  $> 56.9$  pg/mL was present in 18% of patients with CD and 14% of patients with UC. Whatmore CTX was elevated in 22% of CD patients and 40% of UC. Mean osteocalcin level in CD was  $23.12 \pm 9.8$  and  $20.74 \pm 11$  in UC patients. No significant differences were observed between CD and UC ( $p = 0.865$  for PTH;  $p = 0.140$  for CTX and  $p = 0.891$  osteocalcin).

**Conclusion:** Bone mineral metabolism disorders were common in UC and CD patients. Hypophosphatemia and bone turnover markers were more frequent in UC group. Vitamin D deficiency was likely to occur in IBD patients, therefore it should be monitored and supplemented to avoid bone damage.

**Disclosure:** Nothing to disclose

## P1760 VITAMIN D DEFICIENCY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IS ASSOCIATED WITH INCREASED DISEASE ACTIVITY

Kubesch A., Hausmann J., Amiri M., Sprinzl K., Blumenstein I.  
*University-Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt am Main, Germany*

**Contact E-Mail Address:** irina.blumenstein@kgu.de

**Introduction:** Vitamin D has an inhibitory role in the inflammatory signaling pathways and supports the integrity of the intestinal barrier. Due to its immunomodulatory effect, vitamin D appears to play a role in the course of chronic inflammatory bowel disease (IBD) and a corresponding deficiency is associated with an increased risk of a flare.

**Aims & Methods:** The aim of this study was to investigate to what extent the 25(OH)D<sub>3</sub> level correlates with clinical and laboratory parameters of disease activity and whether a cut-off value for prediction of remission could be defined. Patients with IBD treated in the outpatient department of the University Hospital Frankfurt were included and analyzed retrospectively. The 25(OH)D<sub>3</sub> levels were measured and correlated with clinical and laboratory chemical activity parameters. Vitamin D deficiency was defined as 25(OH)D<sub>3</sub> levels  $< 30$  ng/ml.

**Results:** A total of 481 (218 male, 45.5%) patients with IBD were included, 274 (58.1%) with Crohn's disease (CD), 198 (41.9%) with ulcerative colitis (UC). The median age of the patients was 41.65 (17-84). In 294 patients (61%) a vitamin D deficiency was detected. CD patients had significantly more vitamin D deficiency than UC patients ( $p = 0.04$ ). 217 (46.6%) patients received oral vitamin D substitution. However, 165 of these patients (76%) still had a relevant vitamin D deficiency. In the logistic regression analysis of the HBI (Harvey Bradshaw Index) in CD patients was inversely associated with the 25(OH)D<sub>3</sub> serum concentration. A 25(OH)D<sub>3</sub> serum concentration of 27.5 ng/mL seems to be the optimal cut-off value to predict remission in our cohort.

**Conclusion:** In our study, vitamin D levels were inversely associated with disease activity. Thus, especially in high-risk patients, close monitoring should be established in clinical routine and, if necessary, optimized substitution should be considered.

**Disclosure:** Nothing to disclose

## P1761 MMP-2 AND -8 DEGRADED AND CITRULLINATED-VIMENTIN (VICM) CORRELATES TO DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASES

**Introduction:** Vimentin is a type III intermediate filament protein that stabilises cell architecture, but might be more active involved in intestinal inflammation during Crohn's disease (CD) and ulcerative colitis (UC). In lamina propria vimentin is found in mesenchymal cells like fibroblast and myofibroblasts, but are also produced by activated macrophages in inflammatory diseases. Protein fragments from vimentin turnover can be measured by competitive enzyme-linked immunosorbent assay (ELISA) targeting MMP-2 and -8 degraded and citrullinated-vimentin (VICM) and thereby maybe act as serological biomarker of intestinal inflammation.

**Aims & Methods:** The aim of this study is to evaluate how VICM correlates to clinical and endoscopic disease activity in CD and UC. We included 63 CD patients, 107 UC patients and 20 healthy controls in a prospective study aimed at biomarker evaluation. 35% (n=24) of CD patients and 49% (n=52) of UC patients with active disease. We recorded Harvey-Bradshaw Index (HBI) or Simple Clinical Colitis Activity Index (SCCAI), and measured VICM, C-reactive protein (CRP) and faecal calprotectin (FC). 17 CD and 63 UC patients were evaluated with sigmoidoscopy or colonoscopy from where we recorded Simple Endoscopic Score for Crohn's disease (SES-CD) or Endoscopic Mayo Score.

**Results:** VICM was significantly elevated in CD and UC patients compared to healthy controls ( $p = 0.0001$ ). VICM correlated positively to SES-CD, SCCAI and Endoscopic Mayo Score and, and had a tendency to correlate to HBI. VICM had a stronger correlation to the endoscopic scores than CRP but not as strong a correlation as FC.

**Conclusion:** VICM is significantly elevated in IBD patients in remission and IBD patients with active disease compared to healthy controls. Furthermore, VICM correlates significantly to endoscopic disease activity in CD, to clinical and endoscopic activity in UC, and have a tendency to correlate to clinical disease activity in CD. VICM correlates more to the endoscopic scores compared to CRP. This might reflect the fact that VICM is produced locally in the inflamed gut, whereas CRP is a systemic inflammation marker produced in the liver. VICM might act as a serological biomarker of inflammation in the intestinal wall in IBD.

**Contact E-Mail Address:** danilova.natalya.87@mail.ru

**Introduction:** Short-chain fatty acids (SCFA) play an important role in maintaining colon homeostasis, provide optimal levels of acidity and are probably involved in the pathogenesis of various bowel diseases.

**Aims & Methods:** The aim of the study was to determine the level of fecal SCFA in patients with ulcerative colitis (UC) and Crohn's disease (CD). Seventy seven IBD patients, including 42 UC and 35 CD patients were included into the study. The control group consisted of 42 healthy volunteers. Determination of fecal SCFA in IBD patients and control group volunteers was carried out by gas-liquid chromatographic analysis.

**Results:** In our study, the ratio of major SCFA was as follows: in the control group - C2 (68.5%), C3 (11.8%), C4 (19.7%), in the group of CD patients - C2 (62.2%), C3 (17.4%), C4 (20.4%), in UC patients - C2 (63%), C3 (18%), C4 (19%). The C2-C4 profile showed an increase of the relative content of propionic acid in CD - (0.16±0.07 units) and UC patients - (0.16±0.07 units), compared to the control group - (0.13±0.03 units), p=0.0188, p=0.0079, respectively, with the unchanged relative content of acetic and butyric acids. However, UC and CD patients showed a decrease in the absolute content of acetic acid - (3.07±2.02 and 3.65±2.75 mg/g) and butyric acid - (0.93±0.81 and 1.20±1.15 mg/g) compared to the control group - (6.32±4.81 and 1.82±1.56 mg/g, respectively), p< 0.05. Besides we found that CD and UC patients had reduced absolute content of isobutyric (IC4) - (0.20±0.23) mg/g, (0.18±0.18) mg/g and isovaleric (IC5) acids - (0.25±0.23) mg/g, (0.23±0.26) mg/g, as well as isocaproic acid (IC6) level was decreased in UC patients - (0.011±0.016) mg/g compared to the control group - (0.33±0.34) mg/g for IC4, (0.41±0.39) mg/g for IC5, (0.006±0.018) mg/g for IC6, p< 0.05. The sum of all SCFA (C2+C3+C4+C5+C6+IC4+IC5+IC6) was lower in UC - (5.51±3.89) mg/g and CD patients - (6.58±5.08) mg/g compared to the control group - (10.35±7.7) mg/g, p=0.0018, p=0.0194. There was also a tendency to the shift of the anaerobic index to a more negative side in UC (-0.56±0.24) u. and CD patients - (-0.55±0.26) u, compared to the control group - (-0.47±0.18) u.

**Conclusion:** Reduced absolute content of butyric acid in IBD patients allows to suppose the presence of the link between decreased butyrate level and gut inflammation. A shift in the anaerobic index to a more negative side indicates the activation of opportunistic bacteria in IBD patients. A decrease in the absolute content of particular SCFA and their total number in IBD patients may indicate the inhibition of functional activity and the number of anaerobic microbiota and/or an increase of the SCFA utilization by colonocytes.

**Contact E-Mail Address:** nada.abedin@kgu.de

**Introduction:** Fecal biomarkers are important non-invasive means for the diagnosis, measurement of disease activity and evaluation of treatment efficiency in inflammatory bowel disease (IBD), but endoscopy remains the gold standard for the diagnosis and determination of state of inflammation and disease activity in inflammatory bowel disease (IBD).

**Aims & Methods:** Here, we evaluate the significance of fecal Eosinophil Cationic Protein (fECP) and compare it to the most studied fecal biomarker calprotectin (fCal). fECP and fCal were analyzed in fecal samples of patients with Crohn's disease (CD, n = 144), Ulcerative colitis (UC, n = 70), clostridium difficile infection (CDI, n = 9), primary food allergy (PFA, n = 11), secondary pollen-associated food allergy (SFA, n = 25) and non-inflammatory controls (total n = 78; healthy controls n = 37; disease controls n = 13; irritable bowel syndrome n = 28). In IBD patients, results were correlated with serum CRP and both clinical and endoscopic activity scores. Endoscopy was performed in 83 IBD patients (CD n = 42; UC n = 41).

**Results:** Compared to controls, fECP was significantly elevated in CD, UC, CDI and PFA. fCal was increased in CD, UC and CDI, but not PFA. fECP correlated with disease activity markers in IBD patients; however, ROC analyses shows a lower diagnostic accuracy to differentiate between endoscopically active and inactive IBD patients (AUC = 0.77) than for fCal (AUC = 0.88). In contrast to fCal, fECP correlated negatively with age. fECP elevation in IBD patients below the age of 45 years was independent of clinical and endoscopic activity (endoscopically inactive IBD vs controls; AUC for fECP = 0.86; AUC for fCal = 0.62). Furthermore, in IBD patients < 45 years and low inflammatory activity (fCal < 250 mg/kg), fECP is a prognostic marker indicating the necessity of change of treatment or surgery (fECP < 200 µg/kg = 22 %; 200 - 600 µg/kg = 44 %; > 600 µg/kg = 82 % at month 48 of follow-up).

**Conclusion:** fECP could serve as a diagnostic marker and indicates disease progression in young IBD patients in remission.

**Disclosure:** Nothing to disclose

## P1764 IL-33/ST2 LEVELS AND GUT MICROBIOTA CHARACTERIZATION CAN PREDICT MUCOSAL RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

**Introduction:** It is now well-established that IL-33/ST2 axis and gut microbiota are important factors in the pathogenesis of IBD with a potential reciprocal influence. Recent evidence has shown that tumor necrosis factor

(TNF) inhibitors (anti-TNF) are able to modulate the IL-33/ST2 axis as well as gut microbiota in inflammatory conditions. Anti-TNF are considered to be effective in inducing mucosal healing in patients with moderate-to-severe Ulcerative Colitis (UC).

**Aims & Methods:** The aim of our study was to explore the potential role of the IL-33/ST2 axis and gut microbiota in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic MAYO score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 26 UC patients (MAYO score at T0  $\geq 2$ ), grouped into 14 responders with mucosal healing (MAYO score  $\leq 1$ ) and 12 non-responders to anti-TNF at T2 (MAYO score  $\geq 2$ ) were enrolled. 10 healthy controls undergoing routine colonoscopy for tumor screening were also enrolled. At each time point, serum and fecal samples were collected. ELISA and western blot were performed to assess IL-33/ST2 protein levels and to evaluate protein isoforms, respectively. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization. Genomic DNA was extracted from fecal samples and V3-V4 regions of the 16S rRNA gene were sequenced by MiSeq Illumina platform for microbiota characterization.

**Results:** IL-33 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, while no differences between groups were found at T2. Among responders, ST2 levels were dramatically reduced at T2 vs. T0. No significant differences were found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared with other groups. Full-length, bioactive IL33 (31 kDa), ST2L (76 kDa) and sST2 (52 kDa) were expressed in all experimental groups; the cleaved, less active form of IL33 (24 kDa) was increased in only non-responders vs. responders and healthy controls.

IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. Little to no staining for both IL-33 and ST2 was present in healthy controls. Microbiota analysis showed an increased biodiversity at T0 in responders vs. non responders. At T0, non responders showed lower levels of Verrucomicrobia (Akermansia muciphila) and Firmicutes, with an increased abundance of Bacteroidetes vs. responders.

**Conclusion:** Our results suggest a possible role for IL-33/ST2 and gut microbiota in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF. IL-33/ST2 axis and gut microbiota could thus represent a useful diagnostic tool to evaluate therapeutical options in IBD patients. Further studies are underway to determine mechanisms of action that support these findings.

**Introduction:** Immune mediated diseases (IMIDs) include a heterogeneous group of chronic diseases that are characterized by the loss of the immune system tolerance causing inflammation and tissue damage in different organs. Inflammatory bowel diseases (IBD) belong to IMIDs group together with other autoimmune diseases. Literature data showed a IMIDs prevalence of 9-15% in IBD, depending of the region studied.

**Aims & Methods:** The aim of our study is to describe the prevalence and influence of IMIDs in IBD.

A retrospective and descriptive study was designed to evaluate the influence of IMIDs in IBD. 1448 IBD patients were studied to evaluate the different clinical characteristics and evolution course of the disease depending on the associated IMIDs.

**Results:** We included 1448 patients of whom 46.96% (n=680) were diagnosed with Crohn's Disease, 48.34% (n=700) with Ulcerative Colitis and 4.7% (n=68) with IBD Unclassified. A IMIDs prevalence of 25.69% was present in IBD patients compared to 74.31% (n=1076) of IBD patients without IMIDs. The most prevalent IMIDs were intrinsic asthma and skin psoriasis following rheumatoid conditions. An increased risk of IMIDs was observed in IBD women (OR 1.48 (IC 95%: 1.17 - 1.87) p=0.001). Furthermore, more proportion of IMIDs patients was observed in Crohn's Disease compared to Ulcerative Colitis (OR 1.35 (IC 95%: 1.07-1.70) p=0.02). It is important to highlight that IMIDs required more immunomodulator (OR 1.61 (IC 95%: 1.27 - 2.03) p< 0,01) and biological therapy (OR 1.89 (IC 95%: 1.47 - 2.43) p= < 0,01).

### Conclusion:

1. There is an increased IMIDs prevalence in IBD patients.
2. Crohn's Disease patients and women have a higher risk of associated IMIDs to their IBD.
3. IBD patients with associated IMIDs require more immunomodulator therapy or biological therapy to control their disease, probably caused by a more aggressive course of IBD.
4. More studies are necessary to increase the knowledge in IBD patients with associated IMIDs.

	IBD with IMIDs associated (% , n)	IBD without IMIDs (% , n)	OR (IC)	p
Gender: men	44.64% (168)	52.34%	1.48 (1.17 - 1.87)	0.001*
Type of Disease: Crohn's Disease	52.21% (201)	45.06% (478)	1.35 (1.07-1.70)	0.026*
Immunomodulator Therapy: yes	48.31% (186)	36.78% (391)	1.61 (1.27 - 2.03)	<0.000*
Biological Therapy: yes	36.36 % (140)	23.24% (247)	0.89 (1.47 - 2.43)	<0.000*
Surgery: yes	21.04%(81)	19.59% (208)	1.1 (0.82 - 1.46)	0.536

[Odds ratio of clinical characteristics and therapy.]

**Introduction:** Prevalence of overweight and obesity is increasing worldwide, as well as of Inflammatory Bowel Disease (IBD). However, there is lack of evidence about the nutritional habits of patients with IBD and also about the relationship between the course of the disease and the body mass index (BMI).

### Aims & Methods:

- 1) To determine the healthy and nutritional habits of patients with IBD and their adherence to Mediterranean diet (MD).
- 2) To analyze the course of the disease, regimens of treatment and quality of life depending on body mass index (BMI).

We performed a prospective cohort study that included consecutive patients with IBD attending our adult IBD clinic in a one-month period. Demographic characteristics and disease related factors were obtained from Spanish ENEIDA database. Health-related quality of life was measured using the disease-specific Inflammatory Bowel Disease Questionnaire (IBDQ-9)<sup>1</sup> and anxiety and depression were estimated by the Goldberg Anxiety and Depression Scale (GADS). Adherence to MD was evaluated using the 14-point Mediterranean Diet Adherence Screener from PREDIMED study<sup>2</sup>. The variables were analyzed depending on the BMI (underweight  $\leq 18.4$ , normal 18.5-24.9, overweight 25-29.9, obesity  $\geq 30$ ). Statistical analysis was performed using SPSS version 22.0.

**Results:** A total of 104 patients were included in our study. Mean age was 47.0±14.4 years and 56.7% of patients (59/ 104) were females; 53.8% (56/104) of patients had ulcerative colitis and 46.2% (48/104) Crohn's disease. More than half of patients were diagnosed of overweight (41.3% (43/104)) or obesity (15.4% (16/104)) with a significantly increase in BMI as age does (mean age 41.6±14.7 years in normal-underweight, 49.7±12.3 years in overweight and, 55.1±13.2 years in obesity;  $p=0.001$ ). There were more former smokers in the group of obese and overweight patients than in normal-underweight ones (62.5% (10/16), 55.8% (24/43), 33.3% (15/45), respectively,  $p=0.034$ ). Since IBD diagnosis, 42.3% (44/104) of patients have modified their diet with weight changes in 61.4% (27/44) of them (55.6% (15/27) of patients lost weight and 44.4% (12/27) gained weight). No statistically significant differences were observed between the physical activity and the BMI ( $p=0.269$ ).

47.1% (49/104) of patients had a good adherence to MD, decreasing adherence as the BMI increases, but without reaching statistical significance (55.6% (25/45), 41.9% (18/43) and 37.5% (6/16) in normal-underweight, overweight and obese; respectively,  $p=0.308$ ).

There were no significant differences neither in the disease related factors (type, location, extension, activity of the disease, extraintestinal manifestations or complications) nor in the IBD treatments depending on BMI.

Concerning quality of life, the mean mark in the IBDQ-9 questionnaire was 44.8±10 (equivalent to 61.5 in the 0-100 scale) without significantly differences between BMI groups. More than half percent of patients (59.6% (62/104)) had probably depression based on Goldberg questionnaire.

**Conclusion:** Nearly 50% of patients modify their diet after the diagnosis of IBD and there is a low adherence to MD, specially in those with obesity. No differences were shown in the course of IBD, treatment and outcomes depending on BMI. A high number of patients have probably depression and quality of life could be improved.

**Contact E-Mail Address:** vanilla16@mail.ru

**Introduction:** Spondyloarthritis (SpA) is one of the most common extraintestinal manifestations (EIM) of Inflammatory bowel diseases (IBD). The diagnosis of SpA in patients with IBD is challenging, treatment strategy should be often revised when IBD and SpA coexist.

**Aims & Methods:** The aim of the study is to evaluate factors associated with higher risk of axial SpA in patients with IBD. The single-center observational cross-sectional study included patients with a definite diagnosis of IBD and chronic back pain (duration > 3 months). Inflammatory Back Pain (IBP) was determined according to ASAS criteria (2009). If suspected with SpA, patients underwent X-ray and/or MRI of sacroiliac joints. SpA was diagnosed according to ECCO recommendations. All patients diagnosed with SpA also fulfilled ASAS criteria for axial SpA. Univariate and multivariate logistic regression analysis was performed to assess the factors associated with higher risk of being diagnosed with axial SpA.

**Results:** The study included 91 patients (males - 47 (51.6%), mean age - 40.2±11.7 years, duration of IBD - 7.7±7.6 years) with IBD: 52 (57.1%) with ulcerative colitis (UC), 39 (42.9%) with Crohn's disease (CD). IBP was present in 39 (42.9%) patients with IBD, 26 (28.6%) patients were diagnosed with axial SpA, among them 14 (15.4%) patients with radiographic axial SpA. In the univariate logistic regression model, 4 factors were associated with a higher chance of SpA diagnosis: presence of arthritis, arthralgia, CD and IBP. The associations remained statistically significant when mul-

tivariate logistic regression model was constructed (Table 1). In particular, patients with CD had higher chance of being diagnosed with axial SpA compared with UC 3.51 (1.04-11.82).

Parameter	Univariate analysis, OR (95% CI)	Multivariate analysis; OR (95% CI)
Male sex	0.57 (0.23-1.44)	
HLA-B27	4.00 (0.55-29.17)	
Smoking	0.91 (0.26-3.25)	
Arthritis	10.77 (2.26-44.2)	20.03 (3.05-131.69)
Crohn's Disease	2.92 (1.14-7.48)	3.51 (1.04-11.82)
Arthralgia	4.12 (1.55-10.95)	
Inflammatory back pain	8.07 (2.8-23.23)	16.41 (3.99-67.34)

[Table 1. Factors associated with a higher chance of axial spondyloarthritis]

**Conclusion:** Presence of CD was associated with higher chance of being diagnosed with axial SpA compared to UC. Arthritis, arthralgia and IBP were also associated with a higher chance of axial SpA diagnosis.

**Disclosure:** Nothing to disclose

## P1768 DOES HISTOLOGICAL REMISSION (NANCY INDEX) PREDICT RELAPSE-FREE SURVIVAL IN PATIENTS WITH ULCERATIVE COLITIS IN ENDOSCOPIC REMISSION?

**Contact E-Mail Address:** marouabenabbes88@gmail.com

**Introduction:** During the last decades, treatment goals in patients with ulcerative colitis (UC) have shifted from clinical remission only to clinical remission combined with mucosal healing. However, yet, the value of achieving histological remission remains unclear.

**Aims & Methods:**

**Aim:** To examine whether histological healing could be a predictor of sustained remission in UC patients with mucosal healing and to investigate risk factors for relapse.

**Methods:** This was a retrospective monocentric study conducted in the Departments of Gastroenterology and Pathology of Mohamed Taher Maamouri Hospital, between January 2012 to December 2018. Patients diagnosed with UC who had been in clinical remission for at least 6 months were evaluated for endoscopic remission. Those in endoscopic remission (Mayo score ≤1) underwent colonic biopsies. Histological findings were analyzed according to Nancy index. Histological remission was defined as a Nancy index of 0 or 1. Clinical demographics including age, sex, smoking status, history of appendectomy, disease extent and use of medications were collected.

**Results:** Sixty one patients had a sustained clinical remission with a duration ranged from 9 months to 25 years. Of these 61 patients, 28 were in endoscopic remission, 18 were female with a median age of 50.82 years. Medical therapy included 5-aminosalicylic acid (78.6%) and immunosuppressive treatments (21.4%). According to the affected areas, proctitis type accounted for 21.4% of the patients, left-sided type for 21.4%, and pancolitis type for 57.1%. Histological remission was noted in 60.7% (17/28) of the patients, while 11 (39.1%) patients still had histologically active disease. The remission maintenance rate was higher in the histological healing group, without reaching statistical significance (88.3% VS 45.5%,  $p=0.2$ ). Histological remission did not depend on the disease duration ( $p=0.5$ ). Endoscopic findings were graded as Mayo score 0 in 57.1% of the patients ( $n=16$ ) and 1 in 33, 9% ( $n=12$ ). The remission maintenance rate was higher in the Mayo score 0 group ( $p=0.04$ ). Others factors as age, gender, and duration of clinical remission were not found to be statistically significant in predicting relapse.

**Conclusion:** In our study histological remission failed to reach statistical significance to predict relapse but it showed that patients with Mayo score 1 may need examination of histological inflammation to improve UC patients outcomes.

## P1769 COST-UTILITY ANALYSIS OF MRI AND CT IN RADIATION-INDUCED NEOPLASMS IN INFLAMMATORY BOWEL DISEASE

Low D.J.<sup>1</sup>, Chawla T.<sup>2</sup>, Nguyen G.C.<sup>1</sup>

<sup>1</sup>Mount Sinai Hospital, Medicine, Toronto, Canada, <sup>2</sup>Mount Sinai Hospital, Medical Imaging, Toronto, Canada

**Contact E-Mail Address:** danielj.low@mail.utoronto.ca

**Introduction:** Given the chronic nature of IBD, frequent imaging with CT and MRI is often used to assess disease activity and complications. The advantages of CT scans include greater accessibility, lower cost and better spatial resolution. However, its major disadvantage is ionizing radiation. On the other hand, MRIs do not contain ionizing radiation and have improved soft tissue resolution, but are costlier, more time-intensive and are less accessible. Currently, CT scans are used more commonly in the management of IBD, despite recent studies demonstrating similar sensitivity and specificity in the two imaging modalities. This is of importance, given that the lifetime attributable risk of neoplasm and mortality related to radiation is directly related to the cumulative radiation exposure. As a result, a Markov model was created to ascertain the cost utility of utilizing MRI rather than CT in preventing radiation-induced neoplasms in patients with inflammatory bowel disease.

**Aims & Methods:** A provincial (Ontario) database of 72 933 IBD patients from 1999-2016 was examined. Quarterly rates of CT/MRI utilization were extrapolated from this database. The lifetime attributable risk of malignancy related to radiation was taken from the BEIR VII study from the National Academies Press (2006). Cost considerations for MRI/CT were taken from the American College of Radiology and mortality rates were taken from Statistics Canada. A hypothetical population of patients aged 40 was examined over a 30 year period. An analysis was conducted with Markov modeling to examine whether use of MRIs rather than CTs was cost effective with regards to increased health utility from reduced rates of malignancy and malignancy-related death in IBD patients.

**Results:** In the female group, the aggregate cost of CT and MRI scans was \$7291.05 and \$11023.88, respectively. This represents a \$3732.84 cost difference. The total QALY in the MRI group compared to the CT group was 29.32 and 29.27, respectively. This represents a difference of 0.049 QALY, and an ICER of \$75782.53/QALY. A sensitivity analysis was conducted in this group and demonstrated that the ICER was < \$100000/QALY after 26 years, and < \$50000/QALY after 35 years. In the male group, the total cost of CT and MRI scans was \$7257.22 and \$10971.06, respectively. There was a cost difference of \$3713.84. The total QALY in the MRI group compared to the CT group was 29.11 and 29.08, respectively. This represents a 0.036 QALY difference, and an ICER of \$102473.35/QALY. A sensitivity analysis demonstrated that the ICER was < \$100000/QALY after 31 years and < \$50000/QALY after 39 years.

**Conclusion:** A hypothetical Markov model was constructed to evaluate the cost-effectiveness of using MRIs rather than CTs in IBD patients, given the increased health utility from reduced rates of malignancy and malignancy-related death. In our analyses, use of MRIs was cost-effective to CTs in females and males after 26 and 31 years of imaging, respectively, starting at the age of 40. As a result, there may be a role in using MRIs over CT scans in patient populations requiring frequent imaging given the cost-effectiveness of the intervention.

## P1770 FECAL CALPROTECTIN AND FECAL IMMUNOCHEMICAL TEST HAVE DIFFERENT VALUES DEPENDING ON MUCOSAL STATUS IN PATIENTS WITH ULCERATIVE COLITIS

Kim H.W., Ryu D.G., Park S.B., Choi C.W., Kang D.H., Kim S.J., Nam H.S.  
Pusan National University Yangsan Hospital, Internal Medicine, Yangsan-si, Korea (Republic of)

**Contact E-Mail Address:** mdkhwook@gmail.com

**Introduction:** Although fecal calprotectin (Fcal) and fecal immunochemical test (FIT) have been to be associated with endoscopic disease activity in ulcerative colitis (UC), the values of each marker depending on the mucosal status are not well known.

**Aims & Methods:** This study evaluated the differences between two fecal markers depending on the mucosal status in UC. A total of 174 results, obtained in simultaneous examination with endoscopy and fecal tests, were

retrospectively evaluated for 127 UC patients from March 2015 to February 2018. The usefulness of fecal markers as a surrogate marker of endoscopic disease activity and the difference between fecal markers depending on the mucosal status was statistically evaluated. Endoscopic disease activity was divided into Mayo endoscopic subscore (MES) and ulcerative colitis endoscopic index of severity (UCEIS).

**Results:** Both fecal markers showed statistically significant correlation with MES ( $r = 0.678$  for Fcal ( $p < 0.001$ ) and  $r = 0.635$  for FIT ( $p < 0.001$ )) and UCEIS ( $r = 0.711$  for Fcal ( $p < 0.001$ ) and  $r = 0.657$  for FIT ( $p < 0.001$ )). Fcal was significantly superior to FIT in predictive accuracy for endoscopic disease activity (AUC; 0.863 versus 0.765 in MES ( $p < 0.001$ ) and AUC; 0.847 versus 0.757 in UCEIS ( $p < 0.001$ )). FIT was significantly superior to Fcal in sensitivity for complete mucosal healing (98.0% versus 78.4% in MES, 94.9% versus 74.6% in UCEIS).

**Conclusion:** Both Fcal and FIT were well correlated with endoscopic disease activity in UC patients. Fcal was more accurate correlation with endoscopic disease activity in patients with active inflammation, while FIT was more sensitive in predicting the achievement of complete mucosal healing.

**Disclosure:** Nothing to disclose

**Introduction:** Early detection of postoperative recurrence (POR) remains a major concern in patients with Crohn disease (CD).

**Aims & Methods:** We aimed to assess the performances of serial faecal calprotectin monitoring within the three first months following ileocolonic resection to predict CD endoscopic POR at 6 months.

In this multicenter prospective study, all the patients with CD who underwent ileocolonic resection were consecutively enrolled. Stools samples were collected at baseline, at one month (M1) and M3 to measure faecal calprotectin level. The stools samples were collected in the morning the day before the endoscopy to reduce intraindividual variation, and immediately stored at 4 °C. Faecal calprotectin was measured using quantitative immunoassay. Ileocolonoscopy was performed at M6. The endoscopic severity was graded independently according to the Rutgeerts' index by two experienced central readers, blinded from clinical or biological data. Endoscopic POR was defined as Rutgeerts' index  $\geq$  i2b.

**Results:** Overall, 48 patients were included.

Among them, 18 patients (36%) presented with endoscopic POR (Rutgeerts score  $\geq$  i2b) 6 months after surgery. We did not observe any significant difference between patients with or without early endoscopic POR (M6), respectively, regarding the level of faecal calprotectin at baseline (100 [50-190] vs 166 [89-312]  $\mu$ g/g;  $p=0.15$ ), at M1 (93 [48-104] vs 100 [50-180]  $\mu$ g/g;  $p=0.44$ ) and at M3 (100 [68-328] vs 99 [50-100]  $\mu$ g/g;  $p=0.28$ ). Faecal calprotectin kinetics during the first three months after surgery was significantly different between the patients with or without POR at M6 ( $p=0.021$ ). The relative variation (median) between the level of faecal calprotectin at baseline and M3 ( $\Delta$ Fcal M3-M0) was significantly higher in patients with endoscopic POR +60% IQR [-47%; +217%] compared to those without POR -38% IQR [-64%; 0%].  $\Delta$ Fcal M3-M0  $>$  +10 % demonstrated the best performances to predict endoscopic POR at M6 (AUC=0.73, sensitivity = 64.7% CI [41.1-82.7], specificity = 87.5% CI [68.0-96.3], negative predictive value = 77.8% CI [57.5-91.4] and positive predictive value = 78.6% CI [49.2-95.3]).

**Conclusion:** Faecal calprotectin variation within the first months after ileocolonic resection is an accurate predictor of early endoscopic POR in CD patients.

### **P1772 CUTTING EDGE TECHNOLOGIES PIMS MOLECULAR FINGERPRINT AND NPOT MOLECULAR NETWORK IN DETERMINATION OF RESPONSE TO VEDOLIZUMAB IN A PROSPECTIVE TREATMENT OF ULCERATIVE COLITIS (UC) AND CROHN'S DISEASE (CD)**

Eftekhari P.<sup>1</sup>, Bredert M.<sup>2</sup>

<sup>1</sup>Inoviem Scientific, Departement Clinical Developement, Illkirch Graffenstaden, France, <sup>2</sup>Waid. Zuerich. Hospital, Department of Gastroenterology and Hepatology, Zürich, Swaziland

**Contact E-Mail Address:** p.eftekhari@inoviem.com

**Introduction:** The complexity of underlying pathophysiology of IBD and the difficulty to understand the relevance of, “-omics” have prompted us to asses alternative approaches and technologies. Physiological intermolecular modulation spectroscopy (PIMS), and nematic protein organization technic (NPOT) two cutting edge label free technologies that have been used to reconcile these “omics” with the clinical relevance. PIMS, stratifies patients to responder and non-responder in regard to a treatment. NPOT identifies the functional molecular network in responder patients, thus paving the way to identify success biomarkers.

We have therefore in a prospective study used PIMS and NPOT to predict responder IBD patients prone to be treated with Vedolizumab and isolated their underling functional molecular network.

**Aims & Methods:** In a prospective clinical study, protein extracts of peripheral blood mononuclear cells (PBMC) of 31 outpatients (female = 17, mean age= 55.6 years and men=14, mean age=41.7) diagnosed with UC or CD (UC=13, CD= 18) prone to be treated with Vedolizumab were subjected to PIMS analysis.

PIMS analysis were performed blinded on isolated PBMCs from 4 different treatment period (week 0, 2, 6 and 14). Patient's data were blinded. One microgram of total protein from each patient's PBMC was challenged with 1µM of Vedolizumab.

After determination of base line, the samples were frozen at -17°C. Dynamic changes in macromolecular interaction were registered from -17 to 5°C. After deblinding IBD patients from each group of responder (n=3) and non-responder (n=3) were subjected to Nematic protein Organization technique (NPOT) in order to identify the signaling pathways in both group respectively.

**Results:** PIMS predictions were in accordance with clinical response to Vedolizumab from treatment on set (week 0) to last treatment (week 14) as follow 14 CD 77-92% and UC, 78-100% respectively. NPOT revealed the presence of proteins ITGB7, ITGAV, ITG3, PF-4 and ASGH in Vedolizumab responder patients whereas no distinct signaling pathway was observed in non-responder patients.

**Conclusion:** PIMS could predict responder from non-responder and NPOT highlighted the signaling pathway required for positive clinical response to Vedolizumab. The combination of these two technologies can pave the way in identification of success and resistance biomarkers.

**Introduction:** Retrospective and prospective treat-to-target studies have shown biological and endoscopic remission are superior to clinical remission in achieving improved long-term clinical outcomes in patients with inflammatory bowel diseases (IBD). Stricter, more rigorous therapeutic targets may require higher drug levels.

**Aims & Methods:** We aimed to study whether higher maintenance adalimumab drug levels are associated with clinical, biological and endoscopic remission. Demographic, clinical, laboratory and endoscopic data were collected retrospectively from 66 consecutive IBD patients treated with adalimumab who had a C-reactive protein (CRP) and/or stool calprotectin measured and endoscopic evaluation within 12 weeks of adalimumab serum trough levels. We defined clinical remission as HBI< 5 or MAYO < 2 for Crohn's disease (CD) and ulcerative colitis (UC), respectively; biologic remission as CRP < 0.5 mg/dL and/or calprotectin < 250; endoscopic remission as SESCD ≤3 (for ileal disease) or SESCD ≤4 for a more extensive CD or endoscopic Mayo ≤1 for UC. Data was analyzed using STATA statistical analysis software. This study was approved by the local IRB.

**Results:** Sixty-six consecutive patients were included in our study. Median age was 37 years (range 20 to 79), 50% were male, most patients (86%) had CD. Patients who achieved clinical, biologic and endoscopic remission had higher serum trough adalimumab levels (ug/mL±StdErr, 8.9±0.9 Vs. 5.7±1, p=0.016; 8.2±0.8 Vs. 6.6 ±1.1, p=0.023; 9.2±1.0 Vs. 6.1±0.7, p=0.019, respectively).

Increased levels of adalimumab were required to reach deeper levels of remission, reaching significance comparing clinical and deep (clinical, biologic and endoscopic) remission (ug/mL±StdErr, 5.9±1 Vs. 11.7±1.5, p=0.04).

Patients who achieved remission had lower odds ratio of developing disease-related complications (OR=0.4, p=0.04). Lower complications rate was also associated with higher maintenance adalimumab serum trough levels (8.4±0.8 Vs. 5.7±0.9, p=0.04).

**Conclusion:** Higher adalimumab trough levels may be required to achieve better disease control. This study provides additional data to guide therapeutic drug monitoring with adalimumab.

**Disclosure:** Nothing to disclose

### **P1774 ULCERATIVE COLITIS PATIENTS WITH LOW SERUM LEVELS AFTER THE INDUCTION OF ANTI-TNF DRUGS DO NOT ACHIEVE MUCOSAL HEALING AT ONE YEAR. A PROSPECTIVE STUDY**

<sup>1</sup>University of Pisa, Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy, <sup>2</sup>Pisa University Hospital, General Surgery and Gastroenterology, Pisa, Italy

**Contact E-Mail Address:** lorenzobertani@gmail.com

**Introduction:** Anti-Tumor Necrosis Factors (TNF) are currently the most commonly used drugs for moderate to severe ulcerative colitis (UC). Therapeutic drug monitoring (TDM) is a promising strategy to optimize the health care resources in case of loss of response during antiTNF treatment, but a proactive management of TDM is being debated.

**Aims & Methods:** The aim of this prospective study was to evaluate the use of Trough Levels (TL) of Infliximab (IFX), Adalimumab (ADA) or Golimumab (GOL) at the end of the induction phase as predictors of mucosal healing (MH) in patients with UC.

All the patients who started anti-TNF treatment with IFX, ADA or GOL in monotherapy at Pisa University Hospital since November 2017 were prospectively enrolled. At the end of the induction (week 6 for IFX or GOL, week 8 for ADA) TL were evaluated on serum samples drawn before drug administration, by using an ELISA test (Promonitor®, Grifols, Spain). At week 54, MH (defined as Mayo Endoscopic Score< 2) and clinical remission (CR, defined as a Partial Mayo Score< 2) were evaluated. Statistical correlation between TL and MH or CR was performed using Wilcoxon signed-rank test and ROC curves.

**Results:** At present, 61 patients were enrolled: 32 treated with IFX, 15 with ADA, 14 with GOL. MH was reached in 30 patients (14 with IFX, 9 with ADA, 7 with GOL). A collective correlation between TL and MH was found (p < 0.01), which was confirmed when the 3 drugs were considered separately: in particular, patients with low TL were less likely to achieve MH. ROC curve analysis, currently performed for IFX, identified a cut-off of 5.4µg/ml (AUC 0.885, p< 0.001) in predicting the probability of non-achieving MH.

**Conclusion:** TL in UC patients after the induction of anti-TNF treatment were predictors of endoscopic response. For all the drugs evaluated, high TL showed a correlation with MH. For IFX, TL less than 5.4µg/ml predicted with good accuracy the lack of MH at one year.

**Disclosure:** Nothing to disclose

## P1775 SAFETY OF USTEKINUMAB IN INFLAMMATORY BOWEL DISEASES: INTEGRATED SAFETY ANALYSIS OF RESULTS FROM PHASE 2 AND 3 STUDIES IN CROHN'S DISEASE AND ULCERATIVE COLITIS

**Introduction:** Ustekinumab (UST) is a well-established therapy in Crohn's disease (CD) and psoriatic diseases. Recently presented phase 3 data showed that UST was safe and effective in ulcerative colitis (UC). Phase 3 induction and maintenance studies of UST in CD (UNITI, IMUNITI) and UC (UNIFI) had similar designs, which allows for integrated analysis across both inflammatory bowel disease (IBD) indications.

**Aims & Methods:** We present an analysis of integrated safety data of UST in IBD. Data from 6 phase 2/3 CD and UC studies were pooled, and safety was evaluated through 1 year of follow-up. In phase 3, CD and UC pts received a single IV placebo (PBO) or UST (130mg or ~6mg/kg) induction dose followed by SC maintenance doses of PBO or UST (90mg q8 or q12 wks). Concomitant immunomodulators (IMM) and corticosteroids were permitted. All pts who received ≥ dose of UST were included. Safety outcomes through 1 year are presented as the number of pts with events per 100 pt-years (PY) of follow-up

**Results:** At induction baseline (2370 pts in pooled phase 3 IBD studies), median age was 38.0 years, 46.9% were receiving corticosteroids, 30.8% were receiving IMM, 53.0% had failed biologics, and 37.1% were naïve to biologics.

In phase 3 IBD studies, through Wk8 of PBO-controlled induction, 1582 pts were treated with UST. Pts with ≥1 event (PBO vs UST) were 55.8% vs 53.9% with AEs, 6.2% vs 4.4% with SAEs, 19.9% vs 19.3% with infections, and 1.3% vs 1.1% with serious infections.

Through 1 year in pooled phase 2/3 IBD studies, 2574 pts were treated with UST with 1733 PY. The number of patients per 100 PY with AEs (PBO 165.99 vs UST 118.32), SAEs (27.50 vs 21.23), infections (80.31 vs 64.32), serious infections (5.53 vs 5.02), malignancies including non-melanoma skin cancer (NMSC) (0.50 vs 0.81), and discontinuations of study agent because of an AE (13.41 vs 7.73) were similar between UST and PBO. The most frequently occurring AEs (excluding diseases under study) were arthralgia (PBO 16.93 vs UST 16.56), headache (16.43 vs 16.50), nausea (13.25 vs 11.94), and abdominal pain (14.59 vs 11.54), and infections were nasopharyngitis (16.26 vs 18.11) and upper respiratory tract infection (11.40 vs 11.36). Results were similar for the CD and UC studies separately (Table shows key safety events).

	CD Studies <sup>a</sup>		UC studies <sup>b</sup>	
	PBO <sup>c</sup> (n=943)	UST <sup>d</sup> (n=1749)	PBO <sup>c</sup> (n=446)	UST <sup>d</sup> (n=825)
Total PY of follow-up	347	1106	250	627
Adverse events	197.97 (686)	131.52 (1455)	121.65 (304)	95.03 (596)
Serious adverse events	34.05 (118)	25.94 (287)	18.41 (46)	12.91 (81)
Infections	95.52 (331)	72.59 (803)	59.23 (148)	49.75 (312)
Serious infections	6.64 (23)	6.06 (67)	4.00 (10)	3.19 (20)
Discontinuation of study agent because of an adverse event	13.56 (47)	9.76 (108)	13.21 (33)	4.15 (26)
Malignancies (including NMSC) <sup>e</sup>	0.58 (2)	0.63 (7)	0.40 (1)	1.12 (7)

a. NCT00265122, NCT00771667, NCT01369329, NCT01369342, and NCT01369355

b. NCT02407236

c. The PBO group includes data up to the first UST dose for patients who were initially treated with PBO and data at or after 16 wks from the first UST dose for patients who were randomized to placebo maintenance.

d. The UST group includes data up to 16 wks from the first UST dose for patients who were randomized to placebo maintenance.

e. Malignancies that occurred in patients receiving UST included colon cancer, papillary renal cell carcinoma, squamous cell carcinoma, basal cell carcinoma, prostate cancer, small intestine adenocarcinoma and incidental carcinoid tumor, and rectal adenocarcinoma.

[Number of pts with key safety events through 1 year of treatment per 100 PY of follow-up (number of patients with events) in phase 2/3 CD & UC studies]

Regarding serious infections, the CD-specific manifestation of anal abscess occurred in PBO 2.02 and UST 0.90 pts per 100 PY in CD pts. When CD-specific events were excluded, overall rates of serious infections were similar between UC and CD populations.

In pooled phase 2/3 studies, the only malignancy (excluding NMSC) reported in >1 UST-treated pt was prostate cancer; no lymphomas were reported through 1 year. Two pts receiving UST (0.12 per 100 PY; both had UC) died from events that investigators considered to be unrelated to study agent (esophageal varices hemorrhage and acute respiratory failure during thyroid surgery).

**Conclusion:** The safety profile of UST in pts with UC and across integrated IBD indications through 1 year was favorable and consistent with the established safety profile in pts with CD and psoriatic disease.

**Disclosure:** Drs. Ghosh, Sands, Sandborn, and Danese were investigators in clinical trials sponsored by Janssen. Drs. O'Brien, Tikhonov, Zhou, Volger, Marano, Ott, and Gasink are employees of Janssen.

## P1776 DOES ANTI-TNF MAKES DIFFERENCE IN OSTEOARTICULAR MANIFESTATIONS ASSOCIATED TO INFLAMMATORY BOWEL DISEASE?

Santos A.L.<sup>1,2,3</sup>, Lopes S.<sup>1,2,3</sup>, Gaspar R.<sup>2,3,4</sup>, Andrade P.<sup>1,2,3</sup>, Corte-Real Nunes A.<sup>2,3,5</sup>, Macedo G.<sup>1,2,3</sup>

Porto, Porto, Portugal, <sup>4</sup>Hospital São João, Gastroenterology, Porto, Portugal,

<sup>5</sup>Centro Hospitalar de São João, Porto, Portugal

**Contact E-Mail Address:** anaasantos89@gmail.com

**Introduction:** Among the extraintestinal manifestations (EIM) related to inflammatory bowel disease (IBD), which occur in 15-40% of patients, the most prominent are those of osteoarticular spectrum, due to their high prevalence (30%) and impact in quality of life.

**Aims & Methods:** With this study, the authors intended to evaluate the prevalence of osteoarticular manifestations (OAM) in patients undergoing biological therapy and the main factors associated with their development. Retrospective and unicentric study, with inclusion of patients followed in referral outpatient care of IBD, under anti-TNF at time of the study. Demographic characterization with determination of OAM [mechanical complaints (MC), OAM secondary to therapy and IBD-related arthropathy (AD)] and the predictor factors related to their development.

**Results:** A total of 422 patients were included [337 with Crohn's disease (CD) and 85 with ulcerative colitis (UC)], with median age of 40 years (IQR 29-50), 54% of female gender. The OAM prevalence was 23% (89% in DC). A higher prevalence of OAM was associated, with statistic significance, to female gender in ulcerative colitis (p=0.045) and to age higher than 40 years in DC (p=0.018). MC were identified in 20% of cases and OAM secondary to therapy in 18% (15 osteopenia/osteoporosis and 2 cases of arthritis caused by IFX). Among AD's patients, 56% presented manifestations of axial predominance (30% of ankylosing spondylitis, 21% of axial spondylarthritis related to IBD and 15% sacroileitis), 35% of peripheral spondylarthritis and 7% with an enthesopathic component. In 21%, the OAM occurred before IBD's diagnosis.

The absence of therapy with anti-TNF was risk factor for AD manifestations (p<0.001) and, in cases of DC, the higher rate of AD was associated, with statistic significance, to a clinical active disease when it appeared (p=0.001). The presence of OAM led to therapeutic changes in 86% of patients, the most leading to the initiation or dose optimization of anti-TNF.

**Conclusion:** The OAM present higher prevalence in CD patients conditioning, frequently, changes in therapeutic strategy. The absence of anti-TNF therapeutic and, in CD, absence of clinical remission, was related to AD.

**Disclosure:** Nothing to disclose

## P1777 ELEMENTAL DIET THERAPY PLAYS A SIGNIFICANT ROLE IN AVOIDING POSTOPERATIVE SURGICAL RECURRENCE IN PATIENTS WITH CROHN'S DISEASE IN THE ERA OF BIOLOGICS

Shinozaki M., Takahashi R.  
University of Tokyo, Surgery, Tokyo, Japan

**Contact E-Mail Address:** mshino@ims.u-tokyo.ac.jp

**Introduction:** Postoperative recurrence affects most patients with Crohn's disease. Novel therapies have been introduced, including anti-tumour necrosis factor-alpha agents, integrin antagonists, and endoscopic balloon dilatation. However, little is known about their efficacy in the long term.

**Aims & Methods:** We aimed to clarify which therapies could decrease postoperative surgical recurrence in patients with Crohn's disease. Seventy operations in 46 patients with Crohn's disease were included in this retrospective study. Survival curves were created, and univariate and multivariate analyses were performed.

**Results:** Smokers were significantly more likely to develop recurrences ( $p=0.023$ ). Patients who were administered anti-tumour necrosis factor-alpha therapy had significantly better prognoses than those who did not receive it ( $p=0.028$ ). Patients who underwent endoscopic balloon dilatation procedures had significantly better prognoses ( $p=0.017$ ). Immunomodulators were significantly more effective at preventing surgical recurrences ( $p=0.046$ ). Patients who maintained an elemental diet (greater than 900 kcal/day) had significantly better prognoses than those who did not or those whose diets were lower in quantity ( $p<0.001$ ). However, multivariate analysis indicated that the only significant factor for controlling postoperative surgical recurrence was nutritional therapy ( $p=0.0058$ ).

**Conclusion:** Univariate analyses showed that smoking, anti-tumour necrosis factor-alpha therapy, immunomodulator therapy, endoscopic balloon dilatation therapy, and elemental diet therapy exerted significant effects on postoperative recurrence in patients with Crohn's disease. However, the multivariate analysis revealed that only elemental diet therapy was significantly associated with surgical recurrence rates. Elemental diet therapy can play a significant role in the management of Crohn's disease even in the era of biological therapies.

**Disclosure:** The author received grant support from Mitsubishi Tanabe Pharma Co. Ltd

**Introduction:** Methotrexate (MTX) is an immunomodulator that has shown efficacy in Crohn's disease (CD). Its use is mainly recommended to maintain remission in patients with steroid-dependency and failure of, or intolerance to, thiopurines. Data on its use as monotherapy in patients with failure of anti-TNF- $\alpha$  drugs are limited.

**Aims & Methods:**

- (1) To determine the short and long term efficacy of MTX monotherapy in CD patients with previous failure and/or intolerance to anti-TNF- $\alpha$ .
- (2) To evaluate the safety profile in this scenario.
- (3) To identify factors associated to short- and long-term efficacy.

Multicentre, observational, and retrospective study on the Spanish National IBD Registry ENEIDA. Patients with CD who were treated with MTX for active disease, defined by Harvey-Bradshaw index (HB)  $\geq 3$ , with previous failure and/or intolerance to at least one anti-TNF- $\alpha$  were included. Patients with MTX as part of a combined therapy regimen were excluded. Short-term results were evaluated between 12 and 16 weeks of therapy. Remission was defined as HB  $< 3$ , and response as a decrease of 3 points, at least, in the HB score, without achieving remission. Long-term success was defined as continuation on steroid-free monotherapy at the maximum follow-up. Adverse events were specifically registered.

**Results:** 110 patients were included. Demographic and disease-related characteristics are reflected in Table 1. A 77.2% had been exposed to thiopurines. All patients had received at least one anti-TNF- $\alpha$ , infliximab (IFX) in 73.6% and adalimumab (ADA) in 26.4%, 44.5% had received two anti-TNF- $\alpha$  (ADA and IFX), and 1.8% three anti-TNF- $\alpha$  (IFX, ADA, and certolizumab). Induction of MTX therapy was done with 25 mg in 80.9% of cases, and with SC injection in 93.6%. On induction, mean HB score was  $6.6 \pm 3$ , and C-reactive protein (CRP)  $12.2 \pm 10$  mg/L. Steroids were associated in 42.6%

of cases. In the short term analysis (week 12-16), percentages of remission, response, and failure, were 33.0, 31.1%, and 35.9%, respectively. Mean CRP at this point was  $7.7 \pm 6\text{mg/L}$ . Partial or complete steroid withdrawal was achieved in 96.3% at week 12-16. Long-term success was 36.4% with a median therapy duration of 36 months (range 4-300). Long-term MTX withdrawal was necessary in 73.6%, due to failure (44.5%), adverse events (29.1%), or both. Adverse events were registered in 41.2% of cases, mainly digestive intolerance (15.5%), weakness/malaise (10.9%), and liver injury (7.3%). In 22.7%, these adverse events resulted in drug withdrawal. In the multivariate analysis non-smoking status (OR 1.56, CI 1.05-2.33), and the use of only one anti-TNF- $\alpha$  before MTX therapy (OR 1.25, CI 1.01-6.08) were factors significantly associated to short term remission/response. No predictors of long-term response could be identified.

Gender (M/F)	43/67 (39.1/60.9%)
Age (years)	47 $\pm$ 14
Tobacco use (No/Yes/Former)	53/30/27 (48.1/27.2/24.5%)
Obesity (No/Yes)*	99/11 (90/10%)
Liver disease (No/Yes)**	103/7 (93.6/6.4%)
Duration of disease (years)	16 $\pm$ 10
Disease localization (L1/L2/L3/L4)	41/22/47/29 (37.2/20.4/27.6/4%)
Disease behaviour (B1/B2/B3)	55/30/25 (50.2/27.3/22.7%)
Perianal disease (No/Yes)	62/48 (55.4/44.6%)
Previous surgery (No/Yes)	39/71 (35.5/64.5%)

[Table 1. Demographic and disease-related characteristics. \*BMI>30, \*\*viral hepatitis/steatosis/cirrhosis]

**Conclusion:** MTX has an acceptable short-term efficacy and safety profile in a group of CD patients with previous anti-TNF- $\alpha$  failure or intolerance. Although treatment discontinuation due to lack of efficacy and/or side effects is frequent, a long-term therapeutic benefit is obtained in one third of patients.

**Disclosure:** Nothing to disclose

## P1779 BIOLOGIC USE IN ADULT PATIENTS NEWLY DIAGNOSED WITH ULCERATIVE COLITIS IN THE UNITED STATES, 2010-2013 AND 2014-2016

**Contact E-Mail Address:** naegelian@lilly.com

**Introduction:** The objective of this research was to characterize treatment patterns and sequences of biologic initiation in adult patients newly diagnosed with Ulcerative Colitis (UC) in the United States in 2010-2013 and 2014-2016.

**Aims & Methods:** Adult (18+ years) patients with  $\geq 2$  UC diagnosis codes (ICD-9: 556.x; ICD-10:K51.x) from October 1, 2010 to September 30, 2016 were included in this retrospective analysis of medical and pharmacy claims data from the IBM MarketScan Commercial, Medicaid, and Medicare-Supplemental Claims database. Patients were excluded if they were < 18 years old, had a Crohn's disease (CD) diagnosis two years pre- or post-index, had a dual UC and CD diagnosis, or did not have treatment throughout the study period. Pathway visualization techniques and subgroups analyses were conducted for the 2 years post diagnosis to compare biologic use following first diagnosis during 2010-2013 and 2014-2016. Two-sample t-tests were conducted to compare continuous variables and two-sample proportion tests were used to compare categorical variables in two time periods of diagnosis.

**Results:** A cohort of 7,794 UC patients were identified with 4,637 (59.5%) diagnosed with UC during 2010-13 and 3,157 (40.5%) diagnosed during 2014-16. Overall, during both periods of diagnosis, patients were more likely to be female (55%). Patients diagnosed during 2014-16 tended to be younger when compared to 2010-13 (mean age at diagnosis: 49.2 vs. 46.2 years;  $p < .00001$ ). In general, the majority of patients initiated conventional treatment (aminosalicylates, immunomodulators, and/or corticosteroids)

at the time of diagnosis (99%). 231 (5.0%) diagnosed 2010-13 and 304 (9.6%) diagnosed 2014-16 initiated at least one biologic treatment during the 2 year follow-up. The median time to biologic treatment in the 2 years post diagnosis was 289 days for those diagnosed 2010-13 versus 223 days for those diagnosed during 2014-16 ( $p < 0.00001$ ). On average, patients initiated biologic treatment 66 days earlier when receiving a UC diagnosis during 2014-16. Infliximab was more frequently identified as the first-line biologic in the 2 years post diagnosis for those diagnosed 2010-13, while adalimumab was the first-line biologic for those diagnosed 2014-16. However, pathway visualization Sankey diagrams illustrated limited switching from one biologic to another after initiation of biologic therapy during the 2 years post diagnosis for 2010-13, with no predominant sequence identified. This trend remained for the 2014-16 cohort (data not shown).

Characteristic:	Diagnosis in 2010-2013 (N=4,637)	Diagnosis in 2014-2016 (N=3,157)	P-value
Gender			
Male; n (%)	2,064 (44.5%)	1,434 (45.4%)	0.427
Female; n (%)	2,573 (55.5%)	1,723 (54.6%)	0.427
Age (years); mean (standard deviation)	49.2 (15.8)	46.2 (16.5)	<.00001
Treatment at Diagnosis			
Conventional Treatment; n (%)	4,620 (99.8%)	3,137 (99.6%)	0.92
Biologic Treatment; n (%)	9 (0.2%)	14 (0.4%)	0.046
Time to Biologic Treatment (days)*			
Median* (Q1, Q3)	289 (132, 495)	223 (89.5, 389)	<.00001
Min-Max	0-715	0-727	

\*Wilcoxon rank test, Q1=first quartile, Q3=third quartile, Min=Minimum; Max=Maximum

### [Patient Demographics and Clinical Characteristics]

**Conclusion:** Despite recent authorization of safe and effective biologic treatments for UC, updated clinical guidelines, and initiatives to treat patients more aggressively to delay disease progression, conventional treatment is still more common at the time of diagnosis. Biologic use in UC remains limited; however, the time to biologic initiation after diagnosis is decreasing.

**Introduction:** Thiopurines are drugs used as maintenance therapy in patients with ulcerative colitis (UC). There are dissimilar results regarding the relationship between adherence to treatment and risk of relapse.

**Aims & Methods:** To evaluate the percentage of adherence to thiopurines, its repercussion in the evolution of the disease and the factors related to it. Analytical, observational and retrospective study of patients with UC followed at University Clinic Hospital of Valencia under treatment with thiopurines from October 2017 to October 2018. Adult patients registered in the ENEIDA database in clinical remission at the beginning of the study were included. The adherence was evaluated with an electronic pharmaceutical prescription system (GAIA), considering adherence to the dispensation of

≥80% of the prescribed medication. The study analyzed, according to the degree of adherence, clinical variables (age, gender, comorbidity, smoking habit, disease extent, time of evolution, extraintestinal manifestations, number and severity of relapses) and therapeutic variables (number of tablets, dose, concomitant treatment).

**Results:** Forty-six patients with UC (67.4% males) were included with a median of 43 (IQR 32-55) years old. The adherence was of 74% and no correlation with fewer disease relapses was found. A lower dose of thiopurines was considered as a predictor of non-adherence. A tendency to higher risk of relapse was observed in the non-adherent group after the 30th week of follow-up in the Kaplan-Meier curve. Mesalazine and biologic therapy was prescribed in 74% and 24% of patients, respectively. The adherence to mesalazine correlates with the adherence to thiopurines.

Variables	NO adherence	YES adherence	p-value
Gender, n (%): Males // Females	6 (19.4) // 6 (40)	25 (80.6) // 9 (60)	0.135
Extraintestinal manifestations, n (%)	5 (31.2)	11 (68.8)	0.560
Adverse reaction to thiopurines, n (%)	5 (38.5)	8 (61.5)	0.230
Concomitant treatment related to IBD, n (%)	9 (25.7)	26 (74.3)	0.918
Concomitant treatment not related to IBD, n (%)	5 (26.3)	14 (73.7)	0.976
Comorbidity, n (%)	6 (28.6)	15 (71.4)	0.725
Relapse, n (%) // Mild relapse, n (%) // Moderate/severe relapse, n (%)	5 (38.5) // 2 (28.6) // 3 (50)	8 (61.5) // 5 (71.4) // 3 (50)	0.230 // 0.871 // 0.153
Dose/day (mg), x (sd) // No of tablets/day, x (sd)	90 (49) // 2 (1)	132 (51) // 3 (1)	0.015 // 0.050
Adherence to mesalazine, n (%)	0 (0)	20 (76.9)	<0.001

#### [Results]

**Conclusion:** The adherence to thiopurines evaluated by the electronic prescription system was of 74%. No relation between adherence and number and severity of disease relapse was observed during one year follow-up. Dose and adherence to mesalazine were factors related to adherence to thiopurines. It may be necessary to extend the follow-up period.

**Disclosure:** This abstract has been previously presented as a poster at a national scientific meeting, in the 22th annual meeting of the Spanish Gastroenterology Group (AEG).

### P1782 SEVERE FATIGUE IS COMMON AND ASSOCIATED WITH LOW QUALITY OF LIFE AND WORK PRODUCTIVITY LOSS IN IBD: THE WORK-IBD STUDY

**Contact E-Mail Address:** s.vangennep@amc.uva.nl

**Introduction:** More than 40% of inflammatory bowel disease (IBD) patients suffer from fatigue, even during quiescent disease. Associations have been reported between anti-TNF use and severe fatigue in IBD,<sup>1</sup> which can be related to the mode of action, side-effect profile or indirectly to more severe disease.

**Aims & Methods:** One of the aims of the prospective WORK-IBD study was to determine the prevalence and burden of severe fatigue and identify predictors for severe fatigue in IBD. All Crohn's disease (CD) and ulcerative colitis (UC) patients that attended the outpatient clinic of two non-academic and two academic hospitals between May 1<sup>st</sup> and August 31<sup>st</sup> 2017 were invited. Only (self-) employed patients were eligible to participate. Fatigue, quality of life, work productivity and disease activity were measured using the Multidimensional Fatigue Inventory (range 0-100), Short Inflammatory Bowel Disease Questionnaire (range 10-70), Work Productivity and Activity

Impairment questionnaire, patient-reported Harvey Bradshaw Index and Simple Clinical Colitis Activity Index, respectively. Severe fatigue was defined as a general fatigue score above the 95<sup>th</sup> percentile of the general population adjusted for gender and age.<sup>2</sup> Factors with p-value below 0.1 in univariable analysis, or that were considered clinically relevant, were entered into multivariable logistic regression analysis using backward elimination (likelihood ratio).

**Results:** In total, 1590 IBD patients were invited out of which 768 (48%) responded (119 not eligible, 86 declined participation), and 536 were included (58% female, 53% CD) with a median (IQR) age of 45 (33-53) years, respectively (table 1). Severe fatigue was reported in 252 patients (47%). Considering type of treatment, severe fatigue was reported in 42/113 (37%) of patients receiving mesalamine (5-ASA), 51/112 (56%) receiving immunomodulators (thiopurines, methotrexate), 45/86 (52%) on anti-TNF monotherapy, 23/42 (55%) on anti-TNF combination therapy, 15/29 (52%) using vedolizumab, 12/16 (75%) using ustekinumab and in 64/138 (46%) of patients without maintenance treatment. Patients from academic centers were more likely to report severe fatigue compared to non-academic patients (53% vs 38%, p=0.001). Clinical disease activity (OR 3.6, 95% CI 1.9-6.8) and arthralgia (OR 1.8, 95% CI 1.0-3.3) were independent risk factors for severe fatigue and patients treated with 5-ASA had a significant lower risk to report severe fatigue (OR 0.3, 95% CI 0.1-0.8). Patients suffering from severe fatigue reported significantly lower quality of life (median (IQR) 50 (43-55) vs 60 (55-64), p<0.001) and significantly higher percentages work productivity loss (median (IQR) 30% (0-60) vs 0% (0-10), p<0.001).

Severe fatigue, n (%)	252 (47)	64 (46)	42 (37)	51 (46)	68 (53)	15 (52)	12 (75)

[Table 1. Baseline characteristics]

**Conclusion:** In this large IBD cohort, 47% of patients reported severe fatigue. Clinical disease activity and arthralgia were significantly associated with severe fatigue, whereas 5-ASA treatment was associated with a lower incidence. The latter may be due to the favorable safety profile or a mild disease course. In contrast to prior studies, no higher risk for severe fatigue was found for patients treated with anti-TNF. Severe fatigue was associated with reduced quality of life and higher percentage of work productivity loss.

**Introduction:** Therapeutic drug monitoring is being incorporated into everyday clinical management with anti-TNF therapy; however, measurement of serum drug and antibody levels of vedolizumab (VDZ) is less clear to guide drug dosing in the clinical practice. According to all available data, serum trough levels alone seem to be inadequate to predict clinical response with VDZ therapy. At present, no data is available on the potential correlation between mucosal or fecal VDZ concentration and therapeutic response to VDZ.

**Aims & Methods:** The aim of this study is to assess the correlation between serum, mucosal and fecal VDZ concentrations to get a better view on the pharmacokinetic-pharmacodynamic relationships of the drug in inflammatory bowel disease (IBD-Crohn's disease [CD], ulcerative colitis [UC]) patients receiving maintenance therapy.

**Patients and methods:** Patients with luminal CD and UC receiving maintenance VDZ therapy were enrolled in the study. Clinical disease activity was assessed, blood samples and fecal specimens were collected and colonoscopy with biopsy samples was performed in every patient. Biopsy samples were obtained from inflamed and uninfamed tissue from the colon. Serum, mucosal and fecal VDZ levels were determined by ELISA assay.

**Results:** Data of 26 patients (8 CD, 18 UC) have been available so far. The mean duration of VDZ therapy was 5.8 months. Seven patients were naive to biological therapy at induction. Twenty patients had endoscopic activity during colonoscopy. Mucosal drug level did not show difference between either samples obtained from the inactive vs. active part of the bowel (0.54 vs. 0.39 µg/g, p=0.28), or between samples obtained from patients with endoscopic activity vs. mucosal healing (0.44 vs. 0.86 µg/g, p=0.11). Similarly, median serum trough level did not differ significantly between patients with endoscopic activity and remission (31.96 µg/ml vs. 28.99 µg/ml, p=0.3). However, median fecal concentration of VDZ was significantly lower in patients with endoscopic activity compared to those showing mucosal healing (0.22 µg/ml vs. 0.55 µg/ml, p< 0.001). Fecal drug level showed significant correlation with tissue drug levels obtained from both inflamed and uninfamed region of the colon (r=0.80, p=0.001 and r=0.78, p=0.0003), however no correlation was shown between serum and fecal and between serum and tissue drug levels.

**Conclusion:** Our study would be the first that simultaneously examine serum, mucosal and fecal concentrations of VDZ comparing with endoscopic activities. Our data suggest that determination of fecal drug concentration may be promising in the evaluation of endoscopic response to VDZ therapy and may help to identify a useful surrogate marker of tissue drug concentration.

## P1784 SAFETY AND EFFICACY OF ENDOSCOPIC DILATATION OF SMALL BOWEL CROHN'S DISEASE STRICTURES BY BALLOON-ASSISTED ENTEROSCOPY: A POOLED ANALYSIS OF INDIVIDUAL DATA FROM 219 PATIENTS

**Introduction:** Strictures are a common complication of Crohn's disease (CD). While colonoscopy has been proven suitable and effective for dilatation therapy of CD-associated strictures of the ileocecum, the published evidence on safety and efficacy of balloon-assisted enteroscopy (BAE) for balloon dilation therapy of CD strictures of the small intestine is scarce.

**Aims & Methods:** In the present study we performed a pooled safety and efficacy analysis based on individual patient data. Therefore, a systematic literature review was performed to assess all relevant citations found in Embase, Medline and the Cochrane library regarding BAE used for EBD of small intestinal CD strictures. In addition, conference proceedings including DDW, ECCO, UEGW, A-IBD, AGA and German Gastroenterology Congress were screened for additional data. Study authors were contacted to provide individual patient data. Descriptive statistics were used to summarize patients' characteristics. Univariate cox proportional hazards regression model was applied to find out possible risk factors for need for re-dilatation and surgery. Backward model selection procedure was used and multi-variate cox model were built.

**Results:** 19 publications with a total of 468 CD patients and 1194 performed dilation procedures were included. 25.1% of strictures were anastomotic strictures (74.9% de novo, respectively). Technical success rate was 88.1%, resulting in clinical efficacy in 78% of patients. Major complications defined as perforation, bleeding or dilation-related surgery occurred in 3.7% of all procedures. During a mean follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilatation and 27.5% required surgical intervention.

Multivariate analysis of 219 individual patients identified a 73% higher hazard of re-dilatation in CD patients with clinical symptoms compared to asymptomatic patients and a 40% lower hazard in patients with prestenotic dilation compared with patients with no prestenotic dilation. Additionally, increased CRP values at dilation (elevation of CRP per 0.1 increased the hazard for surgery by 8.6%) and inflamed mucosa at dilation (2.8 times increased hazard as compared with non-inflamed mucosa) were identified as risk factors for the need for surgery.

**Conclusion:** Balloon-assisted enteroscopy for dilatation therapy of CD-associated strictures of the small intestine possesses a high rate of short-term technical and clinical success with acceptable complication rates. Main predictors for intermediate therapeutic failure are clinical symptoms, non-stenotic dilation, increased CRP values and mucosal inflammation at the time of dilation. Endoscopic dilation by BAE is a valuable alternative to surgery in selected patients with small bowel CD associated strictures.

**Introduction:** For patients with non-responding or refractory to standard treatment ulcerative colitis (UC), tofacitinib and biologic agents pose an additional alternative. Emerging evidence suggest that fecal microbiota transplantation (FMT) can also induce remission of UC.

**Aims & Methods:** We performed a systematic review and network meta-analysis to compare FMT to current therapies with regard to safety and efficacy in induction of remission of UC. We searched Medline, Embase, CENTRAL and grey literature sources up to November 2018. We included randomized controlled trials (RCTs) in patients with active UC that compared FMT, infliximab, adalimumab, golimumab, vedolizumab and tofacitinib to each other or placebo as induction therapies. Efficacy outcomes included clinical remission, clinical response and endoscopic remission. Safety was assessed with the incidence of any adverse event (AE), serious AEs and infections. We conducted random-effects network meta-analysis and ranked treatments based on the surface under the cumulative ranking (SUCRA) probabilities. We estimated Predictive intervals (PrIs), which indicate the interval within which the relative effect of a future study is expected to be, to facilitate interpretation of the results in the light of the magnitude of heterogeneity.

**Results:** Twenty placebo-controlled trials (FMT 5 trials) with 4634 patients were included in the network meta-analysis. FMT was superior to placebo in clinical remission (OR 2.80; 95% CI 1.46-5.36) and response (OR 2.53; 95% CI 1.52-4.23), however there was no difference in terms of endoscopic remission (OR 1.91; 95% CI 0.62-5.86). No indirect comparisons between FMT and licensed treatments reached statistical significance in any efficacy outcome. Results remained stable when PrIs were applied. On SUCRA analysis, infliximab (SUCRA 0.94, 0.73 and 0.87) and tofacitinib (SUCRA 0.79, 0.86 and 0.87) were ranked highest while adalimumab (SUCRA 0.28, 0.25 and 0.28) was ranked lowest in terms of response, clinical and endoscopic remission, respectively. FMT (SUCRA 0.64, 0.60 and 0.53) had comparable SUCRA values with golimumab (SUCRA 0.45, 0.56 and 0.46) and vedolizumab (SUCRA 0.40, 0.49 and 0.46). Regarding safety, there was no increase in the rates of any AEs for FMT and licensed therapies (data on infliximab were not available) and no differences in indirect comparisons. Vedolizumab (SUCRA 0.78) was the safest option, followed by tofacitinib (SUCRA 0.57). FMT (SUCRA 0.38) had comparable SUCRA values with adalimumab (SUCRA 0.38) and golimumab (SUCRA 0.49). Only tofacitinib increased the incidence of infections compared to placebo (OR 1.51; 95%CI 1.05-2.19, SUCRA 0.06), but the risk was not retained when PrIs were included in the analysis. Based on SUCRAs, FMT (SUCRA 0.85) was safest in terms of infections followed by golimumab (SUCRA 0.55), adalimumab (SUCRA 0.52) and vedolizumab (SUCRA 0.49). There was no difference between treatments regarding incidence of serious AEs, however FMT was ranked lowest (SUCRA 0.10). Lack of efficacy data in FMT trials based on prior anti-TNF exposure precluded evidence synthesis separately for anti-TNF naïve and anti-TNF experienced patients.

**Conclusion:** Preliminary evidence suggest that FMT could be an alternative induction therapy for ulcerative colitis with comparable efficacy and safety to licensed pharmacological treatments. Nevertheless, due to the absence of head-to-head trials, the short duration of studies and the limited size of FMT trials (277 patients) conclusions must be interpreted with caution.

**Introduction:** Crohn's disease (CD) is an inflammatory bowel disease characterized by chronic inflammation of the gut. As new treatments become available, analyses of the cost to healthcare systems, patients, and their caregivers incurred by CD are increasingly important. The aim of this systematic literature review (SLR) was to identify and summarize the costs and healthcare resource utilization associated with CD in Europe from a societal perspective.

**Aims & Methods:** An SLR was conducted to identify studies reporting healthcare resource use and direct and indirect costs associated with CD, published in English from 1 January 2012 to 22 June 2018. Literature searches were conducted using MEDLINE, Embase, EconLit, and the Cochrane library databases. Conference abstracts from the past 2 years were reviewed, and bibliographic lists of relevant SLRs were interrogated. Study selection was guided by prespecified inclusion and exclusion criteria. Currency values were adjusted using purchase price parity values and inflation data using EU28 values (OECD, 2019).

**Results:** A total of 40 studies presenting resource use, productivity and/or cost data were identified. Twenty-seven studies reported healthcare resource use data, 23 studies assessed direct costs, and 15 studies estimated indirect costs/lost productivity, 3 of which specifically assessed caregiver economic burden.

Various methodologies including prospective questionnaires, database claims analysis, surveys, observational studies, and randomized controlled trials were used to estimate the direct cost of CD. Medication use (n = 20) and hospitalizations (n = 15) were the most frequently reported resources. The proportion of patients hospitalized ranged from 9.3% in patients on a biologic to 66% in patients with perianal disease. In addition, the mean hospital length of stay ranged from 2 days reported for a patient population in which only 14% of patients presented with active disease to 23 days in a study of patients with perianal disease. Total annual direct costs per patient varied widely across Europe, ranging from €4639 for a newly diagnosed patient population in Italy to €24 374 for a Spanish patient population receiving 12 months of biologic treatment.

Before the introduction of biologics, the main components of the direct cost of CD across European healthcare systems were related to surgery and hospitalizations: after the introduction of biologics, the main cost driver was that associated with anti-tumor necrosis factor (TNF) therapies. Indirect costs such as productivity loss, sick leave, travel expenses, and out of pocket expenses contributed between €665 and €7591 per patient per year to the economic burden of CD.

**Conclusion:** This systematic review indicates that the direct costs and healthcare resource use associated with CD present a considerable economic burden in Europe. Although surgery and hospitalizations can have a substantial impact on costs, more recent studies show that the cost of biologics is now the main cost driver in CD patients across Europe.

**Contact E-Mail Address:** s.kousgaard@rn.dk

**Introduction:** Pouchitis is a common long-term complication after restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) in the surgical treatment of Ulcerative Colitis (UC) (1). Many theories have been proposed, but the exact disease mechanism of pouchitis is still uncertain. Current evidence suggest that the gut microbiota could be a significant factor in the aetiology of pouchitis (2). During the last decades, interest in faecal microbiota transplantation (FMT) has grown rapidly.

This intervention as a new 'ecological' therapy for several diseases including chronic pouchitis. Studies have shown that FMT may restore the intestinal microbial balance in treated patients - re-establishing an almost normal intestinal microbial environment (3-4). However, evidence to use repeated FMT for treatment of chronic pouchitis is still lacking.

**Aims & Methods:** To investigate the clinical effect of FMT in treatment of patients with chronic pouchitis, we performed a 2-week FMT treatment pilot study. The study was designed as an open-label cohort study with a 2-week intervention period and a 6-month follow-up period. Patients diagnosed with chronic pouchitis were included in the study. All patients were allocated to treatment with FMT delivered by enema daily for two consecutive weeks. FMT material was obtained from healthy faecal donors recruited from the Blood Bank and screened according to international guidelines (5).

Disease severity was accessed before and after FMT using the Pouchitis Disease Activity Index (PDAI) score. A PDAI score < 7 was considered equivalent to clinical remission. The clinical PDAI score (cPDAI) was used in the 6-month follow-up period. Quality of life was measured using the Short Inflammatory Bowel Disease Questionnaire (SIBDQ) before and after FMT.

**Results:** Ten patients were included of whom one was excluded before the FMT intervention. Nine patients completed the 2-week FMT treatment period. At 30-day follow-up, 44% of the patients had clinical remission with a PDAI score < 7. A non-significant improvement of the PDAI score was found between inclusion and 30-day follow-up, mean 7.0 (SD 3.13) before FMT and mean 5.2 (SD 4.02) after FMT, p=0.81. The clinical effect lasted to end of follow-up at 6 months in 33% of the patients. The cPDAI score improved from mean 2.7 (SD 1.25) at inclusion to mean 0.7 (SD 0.47) at 6-month follow-up, p=0.07. The SIBDQ score showed a non-significant improvement between inclusion (mean 43.0 (SD 13.43)) and 30-day follow-up (mean 48.0 (SD 8.37)), p=0.29.

**Conclusion:** In this study, we found that FMT induced clinical remission in 44% of patients with chronic pouchitis with improvement of symptoms and quality of life. Although our study showed no significant clinical remission of pouchitis symptoms after FMT, we still believe that FMT can be a new treatment of chronic pouchitis. Several factors might influence the effect of FMT, such as the route used for FMT administration and duration of FMT treatment. Approaches in FMT treatment of chronic pouchitis need to be explored. This includes length of treatment, use of maintenance treatment, FMT donor-mix versus single donor, and if antimicrobial therapy should be administered prior to FMT treatment. Finally, a randomized controlled study is required to examine the true role of FMT in treating chronic pouchitis.

**P1788 ECONOMIC EVALUATIONS OF BIOLOGICAL TREATMENTS FOR MODERATE-TO-SEVERE CROHN'S DISEASE: FINDINGS FROM A SYSTEMATIC LITERATURE REVIEW**

Purser M.<sup>1</sup>, Bhaila R.<sup>2</sup>, Hartley L.<sup>2</sup>, Earnshaw S.<sup>1</sup>, Nag A.<sup>3</sup>  
<sup>1</sup>RTI Health Solutions, Research Triangle Park, United States, <sup>2</sup>RTI Health Solutions, Manchester, United Kingdom, <sup>3</sup>Shire, a Takeda Company, Lexington, United States

**Contact E-Mail Address:** arpita.nag@takeda.com  
**Introduction:** Moderate-to-severe Crohn's disease (CD) is a chronic, progressive disease characterized by inflammation of the lining of the gut. Treatment options include targeted biological therapies such as tumor necrosis factor (TNF)-alpha inhibitors (e.g. infliximab, adalimumab) and anti-integrin and anti-IL-23 treatments (vedolizumab, ustekinumab). With increasing treatment options, understanding economic evaluations of different therapies is crucial to inform clinical practice. The aim of this systematic literature review (SLR) was to summarize published economic evaluation models of biologic treatments for CD in Europe.  
**Aims & Methods:** An SLR was conducted to identify studies (economic analyses, systematic literature reviews, meta-analyses, and health technology assessments [HTAs]) of biological therapies in patients with moderate-to-severe CD, published in English from 1 January 2012 to 22 June 2018. Literature searches were performed in MEDLINE, Embase, EconLit, and the Cochrane library databases. Conference abstracts from the past 2 years were reviewed, along with key HTA websites. Bibliographic lists of relevant SLRs were also interrogated. Study selection was guided by prespecified inclusion and exclusion criteria.  
**Results:** Thirteen economic analyses were identified, of which 10 compared biological treatment with biological and/or conventional therapy, 1 compared biological treatment with surgery and 2 focused on clinical management of CD. Biologics considered included infliximab, infliximab biosimilar, adalimumab, vedolizumab, and ustekinumab. Ten analyses were performed from a health systems perspective while three studies presented data from a societal perspective. Economic models utilized in the studies included decision tree models, Markov models, or hybrid decision tree-Markov approaches. The models were built around key endpoints of response and remission. Efficacy of first- and second-generation biologics when compared with one another was estimated primarily using network meta-analyses. The time horizon of analyses ranged from 48 weeks to lifetime. Key health states considered include remission, mild disease, moderate/severe disease, surgery, and death. The value of second-generation biologics (vedolizumab and ustekinumab) was examined separately in anti-TNF naïve and anti-TNF failure patient populations in five studies. These biologics were more cost effective in the anti-TNF failure population than the anti-TNF naïve group. Sequencing of biologics was considered in two analyses.  
**Conclusion:** Several modelling structures have been used to model CD using various time horizons. As treatment options for CD increase in Europe, economic evaluations comparing biologics to each other has become increasingly important. In addition, as more treatments are approved, the impact of sequencing of biologics may need to be considered and may in turn dictate analyses of longer time horizons.

**Contact E-Mail Address:** mariagvivo@gmail.com  
**Introduction:** Vedolizumab (VDZ) is a humanized monoclonal antibody targeting the  $\alpha 4\beta 7$  integrin in ulcerative colitis (UC). So far, no VDZ response biomarker has been identified.  
**Aims & Methods:** Aim: to assess whether baseline circulating CD4<sup>+</sup> and CD8<sup>+</sup> memory T lymphocytes subpopulations could be biomarkers of response to VDZ treatment in patients with UC. Prospective study, n=15 patients with active UC defined as Ulcerative Colitis Disease Activity Index (UCDAI) >3, Mayo endoscopic subscore >1 and fecal calprotectin >250 mcg/g. Treatment with VDZ (300mg iv) was scheduled as standard induction regime. Peripheral blood samples were obtained before the first dose of VDZ. Purification of circulating memory T cells (CD45RO<sup>+</sup>) and simultaneous analysis of CD4<sup>+</sup> and CD8<sup>+</sup> lymphocytic subpopulations ( $\alpha 4\beta 7$ +, HLA-DR<sup>+</sup>, IL23R<sup>+</sup>, CCR9<sup>+</sup>, IL17A<sup>+</sup>, IL-23R<sup>+</sup>, IL-9<sup>+</sup>,  $\beta 7$ +) by flow cytometry were performed.  
Clinical response and remission, faecal calprotectin levels and Mayo endoscopic subscore were evaluated at week 14.  
**Results:** 8 females, median of age was 45 (IQR=32) years, disease extent (Montreal - E1: 2 patients, E2: 8 patients, E3: 5 patients), 7 severe colitis (UCDAI > 9). Most patients (14) had prior failure to anti-TNF- $\alpha$ : primary non-response in 8 patients and loss of response in 6.  
Washout period were: 1 month for infliximab, 2 weeks for adalimumab. Vedolizumab treatment combined with steroids (prednisone 1 mg/kg/day PO) was started in 13 patients.  
At week 14: 10 patients achieved steroid-free clinical remission, 9 patients had fecal calprotectin levels < 250mcg/g and 9 patients achieved biochemical and/or endoscopic remission (calprotectin levels < 250 mcg/g and/or Mayo endoscopic subscore < 1).  
Patients with steroid-free clinical remission presented baseline absolute account of CD8  $\alpha 4\beta 7$ + memory T cells significantly higher when compared with patients with no VDZ response (table 1). Patients with biochemical and/or endoscopic remission at week 14 presented baseline absolute account of CD8  $\alpha 4\beta 7$ + T cells significantly higher and CD8 CCR9+ T cells significantly lower than non-responders.  
No differences were identified according to flare severity, the extent of disease or the type of anti-TNF- $\alpha$  failure. No statistically differences were found in the other lymphocyte subpopulations included in the study.

Baseline lymphocytes (absolute account/ml)	CLINICAL REMISSION 14Wk	NON CLINICAL REMISSION 14Wk	p value
CD4	394,47	327,66	0,026
CD8 $\alpha 4\beta 7$ +	19,265	11,4	0,026
Baseline lymphocytes (absolute account/ml)	BIOCHEMICAL AND/OR ENDOSCOPIC REMISSION 14W	NON BIOCHEMICAL AND/OR ENDOSCOPIC REMISSION 14W	p value
CD8CCR9+	0,33	1,12	0,041
CD8 $\alpha 4\beta 7$ +	24,1	10,57	0,007

[Analysis of baseline T cells subpopulations]

**Conclusion:** The absolute account of CD8  $\alpha 4\beta 7$ + memory T cells before starting VDZ therapy could be an early biomarker of remission and therefore help us to select a subset of responders.  
**Disclosure:** Investigator Initiated Sponsored Research by Takeda

## P1790 COMBINATION OF BIOMARKERS REFLECTING TYPE IV COLLAGEN DEGRADATION AND CITRULLINATED VIMENTIN PREDICTS RESPONSE TO ADALIMUMAB WITH HIGH DIAGNOSTIC ACCURACY, IN PATIENTS WITH CROHN'S DISEASE

**Introduction:** In inflammatory bowel diseases (IBD), up to 40% of patients do not respond to biologic treatment, e.g. anti-TNF $\alpha$  antibodies. A personalized medicine approach may facilitate the best possible treatment option for IBD patients. Currently, no biomarkers have sufficient sensitivity to separate responders from non-responders within the first weeks of anti-TNF $\alpha$  therapy, which limits the personalized medicine approach for IBD patients.

**Aims & Methods:** We investigated serum biomarkers that reflect basement membrane degradation (C4M: MMP mediated degradation of type IV collagen) and citrullinated vimentin (VICM: activated macrophages), and their ability to predict response to anti-TNF $\alpha$  treatment in Crohn's disease.

This was a single-centre cohort study. We measured clinical responses to adalimumab at week 8 after treatment induction in 22 patients with Crohn's disease, using the Harvey Bradshaw Index (HBI). Response was defined as clinical remission (HBI < 5) at week 8. ELISA was applied to quantify the degradation of type IV collagen (C4M) and macrophages activity (VICM). Inflammation was estimated by C-reactive protein (CRP). The biomarkers were combined in a backwards multivariate regression model to increase the prediction value for non-response to anti-TNF.

**Results:** At baseline, C4M serum levels was significantly higher in non-responders compared with responders (AUC: 0.81 [CI: 0.58-1.00],  $p=0.027$ ). VICM serum levels were not significantly different at baseline between responders and non-responders but was modulated in patients who responded to anti-TNF and was significantly lower at week 1 compared with non-responders (AUC=0.89 [CI: 0.69-1.00],  $p=0.007$ ). CRP did not demonstrate any predictive value at baseline (AUC=0.65 [CI: 0.42-0.89],  $p=0.301$ ) or week 1 (AUC=0.66 [CI: 0.38-0.94],  $p=0.282$ ). C4M and VICM were included in the final model. The combination of C4M and VICM increased the predicted value to identify patients that do not respond to anti-TNF treatment (AUC=0.94 [CI: 0.75-1.00],  $p=0.005$ ), with an odds ratio of 22 (CI: 2.70-313).

**Conclusion:** The combination of baseline serum levels of C4M and week 1 serum levels of VICM demonstrated high accuracy to predict who will respond to anti-TNF $\alpha$  treatment in Crohn's disease, and was superior to CRP. Thus, baseline levels of C4M in combination with week 1 levels of VICM may be used to predict response to anti-TNF and may therefore aid in a more personalized treatment approach.

**Introduction:** Although clinical efficacy of combination therapy with infliximab (IFX) and thiopurine has been demonstrated in Crohn's disease (CD), it remains uncertain when to add thiopurine in CD patients treated with IFX. The present study aimed to clarify appropriate timing for the addition of thiopurine in CD patients treated with IFX.

**Aims & Methods:** We performed a retrospective analysis of CD patients treated with IFX as the first-line biologic during the period between June 2002 and July 2018 at our institution. Patients were classified into early combination (EC) group and late combination (LC) group; EC group includes patients who were initiated thiopurine prior to IFX or simultaneously. LC group includes patients who were initiated IFX monotherapy or those who were added thiopurine after losing response to IFX. We then

compared continuation rate of IFX between EC and LC groups using the Kaplan-Meier method and the log-rank test. We also compared adverse events (AEs) rates between the two groups.

**Results:** A total of 176 patients were included in the present study [64% men, median age, 23 (10-75) years], and the mean observation period was 76.8 months [range; 1-182 months]. 49 patients were classified into EC group and 127 patients were into LC group. The mean observation period and CRP level at the start of IFX were not significantly different between the two groups (64 months vs. 71 months;  $p=0.61$ , 0.55 mg/dl vs. 0.47 mg/dl;  $p=0.77$ ). The mean period of taking thiopurine were significantly longer in EC group than LC group (53 months vs. 0 months;  $p<0.0001$ ). The cumulative IFX continuation rates showed no significant difference between the two groups ( $p=0.25$ ). 19 patients (38.7%) in the EC group and 28 patients (22%) in the LC group experienced AEs, and the rate was significantly higher in the EC group compared to LC group ( $p=0.03$ ). Serious AEs including pneumonia and pancreatitis requiring hospitalization were identified in 4 cases (8.2%) in the EC group, and 6 cases (4.7%) in the LC group, whereas the rate was not different between the two groups ( $p=0.36$ ).

**Conclusion:** The addition of thiopurine after loss of response to IFX monotherapy might be an alternative to the early combination therapy in CD when considering safety profile during treatments, whereas more precise analysis with regard to disease control should be necessary.

**Introduction:** Vedolizumab, an antibody against  $\alpha 4\beta 7$ -integrin capable of blocking immune cell migration across intestinal endothelia expressing MADCAM-1, is a second-line biological treatment for moderate-to-severe inflammatory bowel disease (IBD). Because of moderate response rates to this drug, there is an urgent need for predictive markers to identify patients who are likely to benefit from vedolizumab. Our aim was to explore the predictive value of selected serum inflammatory biomarkers regarding response to vedolizumab induction therapy.

**Aims & Methods:** 76 IBD patients (Crohn's disease (CD),  $n=33$ , ulcerative colitis (UC),  $n=43$ ) completed vedolizumab induction therapy and 10 serum inflammatory biomarkers were quantified prior to vedolizumab treatment (CRP, SAA, TNF- $\alpha$ , IFN- $\gamma$ , IL-6, IL-8, IL-10, IL-17A, eotaxin-1 and eotaxin-3). Eosinophils were quantified in serum and in non-inflamed colon tissue (numbers per High Power Field (HPF 0.24 mm<sup>2</sup>)) prior to treatment. Eosinophil numbers were quantified up to 60/HPF and when  $\geq 60$  were set at 60. Clinical response was defined as a decrease of at least 3 points in the Harvey Bradshaw Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC.

**Results:** Baseline serum eotaxin-1 levels were significantly higher in vedolizumab responders, compared to primary non-responders (0.31 [0.22-0.46] vs. 0.20 [0.16-0.29] ng/mL,  $P<0.05$ ). Doubling of baseline serum eotaxin-1 levels was significantly associated with increased odds of attaining clinical response or remission at week 14 (adjusted OR: 3.28,  $P<0.05$ ). The final prediction model based on serum eotaxin-1 levels showed an adjusted area under the receiver operating characteristics curve (AuROC) of 0.81, with an optimally balanced cut-off value for serum eotaxin-1  $>0.49$  ng/mL with a sensitivity of 75.0% and specificity of 76.7% (Youden's index 0.52). A significant inverse correlation was observed between serum eotaxin-1 levels and serum eosinophil count ( $P<0.01$ ). As eotaxin-1 regulates the migration of eosinophilic granulocytes into the intestinal mucosa, we also analyzed mucosal eosinophilic granulocyte abundance in a subset of 24 IBD patients (10 CD and 14 UC) prior to treatment. Baseline median eosinophil numbers in non-inflamed tissue were significantly higher in responders compared to non-responders ( $60 \pm 12$  vs.  $25 \pm 7.5$  eosinophils/HPF,  $P<0.001$ ). Patients with  $>30$  eosinophils/HPF achieved clinical response in 83.3% of cases ( $n=12$ ), whereas only 8.3% of patients with

< 30 eosinophils showed therapy response (n=12). Preliminary analyses (in 15 patients) revealed a positive correlation between serum eotaxin-1 and mucosal eosinophil abundance, though this was not significant yet in this small sub cohort. None of the other tested serum biomarkers showed significant predictive value for response or non-response to vedolizumab in this patient cohort.

**Conclusion:** Serum eotaxin-1 and mucosal eosinophil abundance in non-inflamed colon tissue are reliable predictors for vedolizumab response in IBD patients. Our findings await further validation in an independent patient cohort.

**Introduction:** It is now well established that response to anti-tumor necrosis factor (antiTNF) biologics in inflammatory bowel disease (IBD) is dependent on their pharmacokinetics. Azathioprine (AZA) co-medication has been associated with higher rate of therapeutic levels of antiTNF biologics. Vedolizumab (VDZ) has recently enriched the therapeutic options for IBD and the data on its pharmacokinetics, especially in the setting of AZA co-medication are scarce.

**Aims & Methods:** Therefore, the aims of this study were first, to determine the association of vedolizumab trough levels with clinical response to vedolizumab. Second, to analyze the impact of azathioprine co-medication on vedolizumab pharmacokinetics.

All IBD patients treated with vedolizumab for at least 6 months in two referral IBD centra between September 2015 and October 2019 were included. Sera were collected in a prospective manner from each patient prior the first maintenance infusion. VDZ levels were determined by ELISA (Ridascreen®, Biopharm) and the differences in VDZ levels between responders and non-responders as well as between patients with AZA co-medication vs. patients on VDZ monotherapy were analyzed statistically.

**Results:** In total, 42 IBD patients (28 with Crohn's disease and 14 with ulcerative colitis) were included. There were 25 (59.5%) responders at 6 months of the treatment. Responders had significantly higher VDZ levels compared with non-responders (respective means±SEM - 15.08±2.475 µg/ml vs. 6.853±0.982 µg/ml; p=0.0118). The clinical response rate did not significantly differ between patients with AZA co-medication and patients on VDZ monotherapy (67% vs. 55%, p=n.s.). There was no difference in VDZ levels between these two groups of patients (13.2±2.859 µmol/l among AZA users vs. 11±2.26 µmol/l in VDZ monotherapy group; p=n.s.).

**Conclusion:** Clinical response to vedolizumab is associated with higher trough levels of vedolizumab during the maintenance phase of treatment. In contrast to antiTNF biologics, vedolizumab pharmacokinetics do not seem to be influenced by azathioprine co-medication.

**Introduction:** Reflect study has been carried out to assess in real life the use of CT-P13, the first monoclonal antibody biosimilar to infliximab (IFX) approved in France. Long-term real-life data on CT-P13 use are limited in patients (pts) suffering from Inflammatory bowel diseases and rheumatic diseases.
