**Results:** In this study, we found that the serum miR-23b-3p level was elevated in PC patients along with upregulation of phosphoinositide 3-kinase (PI3K) and phospho-protein kinase B (p-Akt), suggesting the possible involvement of miR-23b-3p and PI3K/Akt signaling in PC development. In addition, miR-23b-3p was induced in response to interleukin-6 (IL-6), which is involved in PC progression. Overexpression of miR-23b-3p by an miR-23b-3p mimic, on the other hand, activated PI3K/Akt signaling in PC cells, as evidenced by miR-23b-3p-induced upregulation of phosphatidylinositol (3,4,5)-trisphosphate (PIP3) and p-Akt as well as downregulation of phosphatase and tensin homolog (PTEN). MiR-23b-3p downregulated PTEN through directly targeting the 3'-untranslated region (3'UTR) of PTEN mRNA. Importantly, overexpression of miR-23b-3p by a miR-23b-3p agomir promoted PC cell-derived tumor growth and liver metastasis in a xenograft mouse model, along with activated PI3K/Akt signaling. In contrast, knockdown of miR-23b-3p by an miR-23b-3p antagomir suppressed tumor growth and metastasis as well as PI3K/Akt signaling activity. Furthermore, the mice in vivo imaging experiment showed over expression of miR-23b-3p can enhance the total fluorescence signals from regions of interest (ROI), and it was demonstrated that the fluorescence signals were stronger in the lung and heart when compared with control.

**Conclusion:** These results suggest that miR-23b-3p enhances PC cell tumorigenesis and metastasis at least partially through the PTEN/PI3K/Akt signaling pathway. Therefore, targeting miR-23b-3p or PTEN/PI3K/Akt signaling may be a potential therapeutic strategy against PC.

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) exhibit one of the worst survival rates of all cancers. For the majority of patients, a "curative" intended resection is not feasible and the response rates to palliative therapeutic approaches remain highly unsatisfactory. One hallmark of PDAC is a profound desmoplastic stroma reaction consisting of fibroblasts, endothelial and immune cells essentially contributing to therapy resistance of PDAC. It is known that inflammation and tumorigenesis are functionally connected and controlled by the NF-kB signaling pathway, mediating apoptosis resistance.

**Aims & Methods:** Analyzing the role of NF-kB controlled chemokine signaling in apoptosis resistance of PDAC using unbiased expression profiling followed by translational functional analysis.

**Results:** By using a genome wide unbiased approach we were able to establish the chemokines CCL20 and CX3CL1 as central NF-kB target genes mediating therapy resistance. Both chemokines are acting in a paracrine fashion, leading to an increased recruitment of inflammatory cells which in turn mediate apoptosis resistance of PDAC cells. By the use of an orthotopic syngeneic transplantation PDAC model, we further dissected the relevance of the observed cancer-immune cell interaction and strengthen the value of such onco-immuno-crosstalk to tailor novel precise therapeutic interventions.

**Conclusion:** In conclusion, our data show a functional role of NF-kB-controlled chemokine pathways in PDAC TRAIL resistance.

The demonstrated therapy induced cross-talk of cancer cells with immune cells impairs the intended treatment response, pointing out the need of novel bi-specific treatments, which target tumor cells as well as immune cell.

**Introduction:** Reactive Oxygen Species (ROS) and oxidative defense systems are believed to play a pivotal role in pancreatic cancer development. Recent results show the driving force of ROS in the development of pancreatic ductal adenocarcinoma (PDAC), yet the role of key regulators of ROS remains elusive. We set out to investigate the impact of mitochondrial Thioredoxin reductase (Txnrd2) deletion on mitochondrial ROS (mtROS) and Kras<sup>G12D</sup> - driven pancreatic carcinogenesis in a mouse model.

**Aims & Methods:** Genetically engineered mice (GEM) were kept in appropriate housing facilities according to German animal welfare law until tumor development or designated time points, respectively. Sections from pancreas and primary metastatic sites as well as macroscopically pathological organs were fixed and processed by H&E staining and immunohistochemistry. Also, tumor cells were isolated and further experiments were performed in cell culture. Methods such as qRT-PCR, Western Blot analysis, cellular oxygen consumption analysis, protein activity pull-downs, proliferation and colony formation assays, *in vivo* stainings, Flow cytometry and others were performed to investigate the objective.

**Results:** At 12 weeks and, to a lesser degree, also in 24 weeks, we observed an increase in ADM (acinar-to-ductal metaplasia) and PanIN (pancreatic intraepithelial neoplasia) lesions in Kras<sup>G12D</sup>; Txnrd2<sup>ΔPanc</sup> mice compared to Kras<sup>G12D</sup> control mice. Despite this initial increase in precursor lesions, tumor incidence was significantly lower compared to Kras<sup>G12D</sup> control mice. In order to gain insight into the mechanism behind this apparent discrepancy, we investigated cancer cell lines isolated from these GEM. We observed impaired proliferation and colony formation. This reduced proliferation could be linked to impairments in cell cycle, concerning mainly the S-Phase. ROS and some antioxidant enzymes were increased, however, the oxidative state of the cells remained balanced. Although we also detected a higher mitochondrial copy number in Txnrd2-deficient cells, measurement of mitochondrial bioenergetics showed no impairment of mitochondrial function and comparable O<sub>2</sub>-consumption and extracellular acidification rates, respectively.

Interestingly, we found slightly decreased levels of mRNA-levels of RAS-isoforms, which led us to investigate RAS abundance and activity, where we could observe significant alterations in cell lines deficient of Thioredoxin Reductase 2.

**Conclusion:** Although there are further experiments to be pursued, we believe to have gained insight into the mechanisms behind the observed phenotype of reduced tumor incidence in Kras<sup>G12D</sup>; Txnrd2<sup>ΔPanc</sup> mice.

**Introduction:** The reduced expression in immortalized cells (REIC)/Dkk-3 gene is down-regulated in various malignant tumors. Previous study revealed that the REIC/Dkk-3-expressing adenoviral vector (Ad-REIC) was found to induce cancer-selective apoptosis, and anti-tumor immunity.

**Aims & Methods:** We applied Ad-REIC to treatments of pancreaticobiliary carcinoma. The cell proliferation and the apoptotic effect of Ad-REIC were evaluated by MTT assay in the pancreatic cancer cell lines (ASPC1 and MIA-PaCa2) and cholangiocarcinoma cell lines (TFK-1 and G-415). Ad-LacZ was used as a control. The apoptosis signal was assessed by western blotting. Additionally, the effect of combined therapy with Ad-REIC and chemotherapy agents (gemcitabine, and cisplatin) was assessed in vitro. We also established the drug-resistant cancer cells (gemcitabine-resistant ASPC1, cisplatin-resistant TFK-1), and assessed the therapeutic effects of Ad-REIC therapy for drug-resistant cancer cells. The effects of Ad-REIC in vivo were assessed using the mouse xenograft model.

**Results:** Ad-REIC inhibited cell growth in pancreaticobiliary cancer cell lines (ASPC1: 31.9±8.8%, MIA-PaCa2: 39.7±11.6%, TFK-1: 64.5±1.7%, G-415: 48.4±4.1%). Anti-tumor effect of Ad-REIC was further enhanced in combination with chemotherapy agents (ASPC1: 29.1±6.8%, MIA-PaCa2: 19.7±3.1%, TFK-1: 50.0±5.3%, G-415: 22.0±2.0%). Ad-REIC also induced apoptosis in the gemcitabine-resistant ASPC1 (62.7±1.3%), and the cisplatin-resistant TFK-1 (58.0±1.3%). The anti-tumor effect may be caused by the stimulation of c-Jun-N-terminal kinase pathway. Ad-REIC also achieved tumor growth inhibition in the mouse xenograft model (ASPC1: 60.7±9.9%, G-415: 43.8±22.6%).

**Conclusion:** Ad-REIC induced apoptosis and inhibited tumor growth in the pancreaticobiliary cancer including drug-resistant cancer cells. REIC/Dkk-3 gene therapy could be an attractive therapeutic tool for the pancreaticobiliary cancer.

**Introduction:** Pancreatic cancer is a lethal disease partly due to poor drug delivery and acquired resistance to therapy. Nanotechnology have shown promise in a wide range of biomedical applications. In particular, nanoparticles have been used to achieve controlled drug delivery and to improve treatment efficacy. The protein kinase B, also known as Akt, is overexpressed in many types of cancers, including pancreatic cancer. This protein plays a key role in multiple cellular processes such as cell proliferation and cell death. Targeting Akt is a highly attractive anti-cancer strategy and different Akt inhibitors are now in clinical development for cancer therapy.

**Aims & Methods:** In this project, we have developed novel polymeric nanoparticles formed by elastin-like recombinamers (ELRs) carrying a small peptide inhibitor of the protein kinase Akt. We have evaluated the kinetic uptake and subcellular localisation of these carriers by flow cytometry and confocal microscopy, respectively. Moreover, we have determined the effectiveness of the loaded nanoparticles to inactivate both established pancreatic cancer cell lines and clinically relevant patient-derived cells by MTT assays and LIVE/DEAD staining. The specific inhibition of phospho-Akt and the activation of cell death pathways after incubation with the loaded nanoparticles were evaluated by western blot analysis and protein array-based approaches.

**Results:** We corroborated that the ELR polymer was able to self-assemble into smart nanoparticles with a mean diameter of 72 nm when the temperature was increased above 16°C. Accumulation of nanoparticles into the

cells was validated by flow cytometry. Confocal microscopy showed a lysosomal localisation of these nanoparticles. Cell viability and metabolic activity were significantly reduced after incubation with loaded nanoparticles in a time- and concentration-dependent fashion. Moreover, nanoparticles inhibited phosphorylation of Akt protein, blocked NFκB signalling pathway and triggered caspase 3-mediated apoptosis.

**Conclusion:** Hence, the use of these novel polymeric nanoparticles could lead to the development of more effective pancreatic cancer treatment options focused on the inhibition of Akt. The combination of these inhibitors with other treatment strategies could improve treatment outcomes.

**Contact E-Mail Address:** quilbea@gmail.com

**Introduction:** We have previously described in a humanized mouse model of nasopharyngeal carcinoma that an anti-Galectin-9 (Gal-9) monoclonal antibody (mAb) is able to significantly limit tumor growth by specifically inhibiting the suppressive activity of human natural Tregs (Patent WO: WO2015185875). Herein, we propose to use this new specific active immunotherapy in a pancreatic cancer mouse model (KRAS<sup>G12D</sup>), insofar as a high Treg prevalence has been described and correlated to the tumor progression of pancreatic cancer.

**Aims & Methods:** Gal-9 expression was analysed by immunohistochemistry on pancreas isolated from the KRAS<sup>G12D</sup> mouse model. Treg infiltration was analyzed by flow cytometry after digestion (GentleMACS) of pancreas isolated from the KRAS<sup>G12D</sup>

For in vitro study we used four PDAC cancer cell lines Capan-1, Capan-2, MIA-PaCa-2, Panc-1 and performed RT-qPCR, Immunofluorescence, Western-blot, flow cytometry and ELISA to validate Gal-9 expression and secretion.

**Results:** Gal-9 expression was confirmed by immunohistochemistry on pancreas isolated from the KRAS<sup>G12D</sup> mouse model. This Gal-9 expression level has been correlated to the progression of pre-cancerous lesions. Furthermore, an increase of Tregs prevalence has been observed in this transgenic model at a systemic and intratumoral level. Very interestingly, we also showed that

- (i) murine Tregs expressed Gal-9 (flow cytometry, immunofluorescence and western-blot),
- (ii) anti-Gal9 mAb neutralized the immunosuppression induced by recombinant murine Gal-9 (proliferation assays) and
- (iii) anti-Gal9 mAb neutralized the suppressive activity of murine Tregs (MLR assay).

Further investigations performed on four human pancreatic cancer cell lines (Capan-1, Capan-2, MIA-PaCa-2, Panc-1) have also confirmed the Gal-9 expression at a genomic (RT-qPCR), proteomic (Immunofluorescence, Western-blot and flow cytometry) and secreting (ELISA) level. Moreover public data from 'Gene Expression Omnibus' showed a high level of Gal-9 transcript in the pancreas of PDAC patients which is associated with decreased overall survival.

**Conclusion:** Our preliminary results suggest that the use of an anti-Gal-9 mAb could be considered as a new anti-tumoral immunotherapy targeting Tregs in the pancreatic cancer.

**Disclosure:** Presented at: 5th European Congress of Immunology (ECI), September 2-5, 2018 in Amsterdam

## P0125 DNA SEQUENCING OF CYTOPATHOLOGICALLY INCONCLUSIVE EUS-GUIDED FINE NEEDLE ASPIRATES FROM SOLID PANCREATIC LESIONS SUSPICIOUS FOR MALIGNANCY CONFIRMS EUS DIAGNOSIS

**Introduction:** Endoscopic ultrasound (EUS) with fine-needle aspiration (FNA) is inconclusive in up to 10-15% of patients with solid pancreatic lesions (SPLs). We aimed to investigate whether supplementary genetic analyses with whole exome sequencing add diagnostic value in patients with SPLs suspicious of malignancy but inconclusive EUS-FNA.

**Aims & Methods:** Thirty-nine patients, who underwent EUS-FNA of a SPL were retrospectively included. Three groups were defined: 16 (41.0%) had suspected malignancy on EUS confirmed by cytology (malignant), 13 (33.3%) had suspected malignancy on EUS but benign cytology (inconclusive), and 10 (25.6%) had benign EUS imaging and cytology (benign). Areas with highest epithelial cell concentrations were macro-dissected from the FNA smears from each patient, and extracted DNA was used for whole exome sequencing by Next Generation Sequencing of a selected gene panel including 19 genes commonly mutated in cancer. Final diagnosis was verified by surgery or clinical follow-up.

**Results:** Pathogenic mutations in *KRAS*, *TP53*, and *PIK3CA* differed significantly between the three groups ( $p < 0.001$ ,  $p = 0.018$  and  $p = 0.026$ , respectively). Pathogenic mutations in *KRAS* and *TP53* were predominant in the inconclusive (54% and 31%, respectively) and malignant groups (81.3% and 50%, respectively) compared to the benign group (0%). Malignant and inconclusive diagnoses correlated strongly with poor overall survival ( $p < 0.001$ ).

**Conclusion:** Whole exome sequencing of genes commonly mutated in pancreatic cancer may be an important adjunct in patients with SPLs suspicious for malignancy on EUS but with uncertain cytological diagnosis.

**Contact E-Mail Address:** stephan\_schorn@yahoo.de

**Introduction:** The worldwide number of people aged older than 60 years will more than triple by the year 2050. As a consequence, the absolute and relative number of elderly patients requiring oncological therapy for malignant diseases will rise leading to the question whether currently practiced treatment regimes can be applied in patients of higher age or should be adopted to age. Here, data on the impact of neoadjuvant therapy (NTx) in elderly patients with pancreatic cancer is lacking.

**Aims & Methods:** For this purpose, the RESPECT-study - a multinational, retrospective database - was screened for patients receiving either FO-FIRINOX (FFx) or Gemcitabine/nab-paclitaxel (GNP). Subsequently, patient outcomes were compared between young and elderly patients using a cut-off age of 63 years (Comparison 1) and 70 years (Comparison 2).

**Results:** 48.5% and 23.7% of all patients receiving NTx were older than 63 and 70 years. In both groups younger patients preferably undergo FFx (Comparison 1: 83.1% vs. 69.7%;  $p = 0.063$ ;

Comparison 2: 81.8% vs. 57.6%;  $p = 0.005$ ) with more NTx cycles (Comparison 1: 6.58 vs. 5.66;  $p = 0.057$ ). Although dose reduction of NTx was more common in elderly patients in Comparison 1 ( $n = 10/11.2\%$  vs.  $n = 23/23.9\%$ ;  $p = 0.003$ ), resectability (Comparison 1:  $n = 71/79.8\%$  vs.  $n = 57/75.0\%$ ;  $p = 0.575$ ;

Comparison 2:  $n = 102/77.3\%$  vs.  $n = 26/78.8\%$ ;  $p = 1.000$ ) did not differ between both groups. Importantly, median survival (Comparison 1: 29.867 vs. 23.1;  $p = 0.406$ , Comparison 2: 28.0 vs. 21.0;  $p = 0.499$ ), overall survival of resected patients (Comparison 1: 36.0 vs. 28.0;  $p = 0.453$ ,

Comparison 2: 35.0 vs. 26.0;  $p = 0.378$ ) and progression-free-survival time (Comparison 1: 22.0 vs. 19.0;  $p = 0.730$ , Comparison 2: 23.0 vs. 15.0;  $p = 0.095$ ) did not relevantly differ.

**Conclusion:** Results suggest that NTx is also feasible in elderly patients suffering from pancreatic cancer with an adequate resection rates, oncological response and overall survival.

**Disclosure:** Nothing to disclose

## P0129 CAN DIGITAL SKELETAL MUSCLE INDEX PREDICT PALLIATIVE CHEMOTHERAPY UPTAKE BEFORE PATIENTS UNDERGO ENDOSCOPIC PANCREATIC BIOPSY?

Jalal M.<sup>1</sup>, Campbell J.<sup>2</sup>, Wadsley J.<sup>3</sup>, Hopper A.<sup>4</sup>

**Contact E-Mail Address:** mustafa.jalal@nhs.net

**Introduction:** An endoscopic ultrasound guided biopsy (EUS-B) is required prior to treatment with palliative chemotherapy for patients with suspected pancreatic ductal adenocarcinoma (PDAC). Given the urgency of treatment, EUS-B is often done prior to oncological assessment after which a significant proportion of patients do not take up chemotherapy. Low skeletal muscle index (SMI), termed sarcopenia, is common in PDAC and has been associated with poor outcomes.

**Aims & Methods:** We aimed to assess if novel digital software can calculate SMI using a computerised tomography (CT) image to predict palliative chemotherapy uptake in patients with suspected PDAC, and streamline EUS-B. Patients who underwent an EUS-B showing PDAC between Jan 2016 and Dec 2017 with a CT scan performed within a month prior to biopsy were included in the study. SMI was calculated by a single slice CT image taken at the level of the third lumbar vertebra.

Software was used to identify skeletal muscle (sliceOmatic, Tomovision). Sarcopenia was defined as  $SMI < 41$  (female) and  $< 53 \text{ cm}^2/\text{m}^2$  (male). Body mass index (BMI), performance status, demographic data were also compared between patients that went on to receive chemotherapy and those who did not.

**Results:** EUS-B confirmed PDAC in 85 eligible patients during the study (median age 70; 41-84 years). A total of 61/85 (71%) of patients received at least one dose of chemotherapy. Sarcopenia was present in 57/85 (57.6%). Despite a raised BMI of  $> 25$  in 41/85 (48.1%) of the patients, sarcopenia was present in 25 (61.0%) of them.

Patients who did not take up chemotherapy had a lower SMI ( $40.5$  vs  $45.2 \text{ cm}^2/\text{m}^2$ ,  $p = 0.04$ ) and a poorer mean performance status ( $1.25$  vs  $0.7$ ;  $t$ -test  $p = 0.002$ ). There was no difference in BMI ( $26.8$  vs  $24.6$   $p = 0.10$ ) in patients that did and did not take up chemotherapy. No patients with a performance status of 3 ( $n = 3$ ) or age  $> 80$  ( $n = 5$ ) proceeded to chemotherapy. In those having chemotherapy, survival was higher in non-sarcopenic patients compared to sarcopenic patients ( $11.8$  vs  $7.7$  months,  $p = 0.04$ ). Survival was similar in sarcopenic patients having chemotherapy and non-sarcopenic patients who did not have chemotherapy ( $7.7$  vs  $7.4$  months  $p = 0.5$ ). Patients with performance status  $\geq 2$  and sarcopenia were much less likely to receive chemotherapy compared to those with performance status 0-1 without sarcopenia ( $83.9\%$  vs  $37.5\%$ ,  $p = 0.02$ ).

**Conclusion:** Patients with PDAC and a performance status of  $\geq 2$  and low SMI were significantly less likely to take up chemotherapy and had poorer survival. SMI measurement could act as part of a decision tool to assess suitability of patients to triage patients for rapid EUS-B, or clinical assessment prior to considering chemotherapy.

**Introduction:** There is increasing evidence that adipose tissue-derived hormones may significantly influence the growth and proliferation of tumor cells. We recently demonstrated the potential diagnostic role of changed adipokines levels in patients with pancreatic cancer (PC). However, the role of adiponectin in tumor proliferation in PC patients has not been well studied before.

**Aims & Methods:** The aims of the study were to analyze plasma concentrations of adiponectin in PC patients and to compare these concentrations to clinicopathological parameters. Baseline levels of serum adiponectin were determined in 50 consecutive patients with PC and followed up for the median period of 18 months. 50 Control subjects were matched to case patients by age, sex and BMI. The association between variables were evaluated using nonparametric Spearman's correlation test. Logistic regression analysis was used to evaluate the association of independent variables with one dependent variable. Receiver operating characteristics (ROC) analysis was employed to calculate the area under the curve (AUC). Survival analysis used the Kaplan-Meier curve.

**Results:** Overall median adiponectin concentrations were lower in PC patients versus control subjects (3.33 vs 6.62 mg/L,  $p < 0.001$ ). Strong inverse correlation between adiponectin concentrations and tumor size ( $r = -0.934$ ,  $p < 0.01$ ) and Ca 19-9 levels ( $r = -0.495$ ,  $p < 0.01$ ) in PC patients were observed. Logistic regression analysis demonstrated that low adiponectin levels were independent predictors of tumor size ( $\beta = -0.018$ ,  $p < 0.001$ ) and metastatic disease ( $OR = 0.573$ ,  $p < 0.005$ ). At ROC analysis the diagnostic profiles of adiponectin for detecting metastatic disease (AUC 0.924; sensitivity 82%; specificity 93%) among PC patients was high. Kaplan-Meier global survival analysis revealed that low adiponectin levels were associated with poorer survival compared to patients with high adiponectin levels (log-rank ( $\chi^2$ ): 5.02,  $p < 0.001$ ).

**Conclusion:** This study identified, for the first time, an inverse correlation between adiponectin levels, tumor size and Ca 19-9 levels suggesting a potential role of adiponectin as an indicator of disease progression. Furthermore these results suggest, that serum adiponectin levels might provide prognostic information in predicting survival in PC patients. The potential role of adiponectin levels as an adjunctive indicator of advanced PC disease requires further evaluation.

**Disclosure:** Nothing to disclose

**Introduction:** Recent advances in treatment of pancreatic adenocarcinoma are leading to an increasing use of neoadjuvant therapy before surgery,

even in borderline resectable disease. This could increase the number of patients who need pancreatic biopsy, until now reserved to unresectable pancreatic cancer or metastatic disease.

Current guidelines suggest that an histological diagnosis of adenocarcinoma of the pancreas can be made using fine-needle aspiration (FNA) biopsy with either endoscopic ultrasonography (EUS) guidance (preferred) or computed tomography (CT). EUS-FNA is highly sensitive and specific for solid lesions and provides the benefit of additional staging information at time of biopsy: lymph node staging, vascular invasion, and prediction of resectability. Although effective, EUS-FNA requires narcosis and is an expensive procedure. Percutaneous ultrasound-guided fine needle Biopsy (US-FNB) is a widely accepted procedure to study retroperitoneal and various abdominal lesions but it is not recommended for diagnosis of pancreatic cancer.

We aimed to assess the sensitivity, specificity, accuracy, safety and effectiveness of US-FNB in patients with suspected pancreatic lesions

**Aims & Methods:** In our prospective study we enrolled consecutive patients with a solid pancreatic lesion suspected for malignancy. All patients underwent, if possible, US-FNB and diagnosis of malignancy was confirmed at follow-up, either at surgery or by the evolution of disease (eg: systematic therapy, death, development of metastatic lesions). Sensitivity, specificity and side effects were estimated.

**Results:** Out of 90 patient, US FNB was technically feasible in 81 patients. 60 patients were diagnosed with malignancy lesions (in detail 55 were pancreatic adenocarcinomas, 2 metastasis, 3 neuroendocrine tumor). 6 patients had mass growing pancreatitis. The sensitivity of US-FNB was 80%, specificity was 100% and accuracy 82%. Only 2 adverse effects were registered: a case of mild abdominal pain and a case of self-limiting abdominal bleeding.

**Conclusion:** In our study the sensitivity, specificity and accuracy in pancreatic lesions of US-FNB are equal to EUS-FNA. US-FNB is safe and effective. We do not registered any important side effect and procedure was usually well tolerated by patient. Not requiring narcosis and using simple disposable equipment US-FNB is also a cheaper technique than EUS-FNA. We suggest to evaluate its use as a valid alternative to endoscopic biopsy.

**Disclosure:** Nothing to disclose

### P0132 PATIENT-REPORTED BURDEN OF INTENSIFIED SURVEILLANCE AND SURGERY IN HIGH-RISK INDIVIDUALS UNDER PANCREATIC CANCER SURVEILLANCE

**Introduction:** Worrisome features detected in high-risk individuals participating in a pancreatic cancer surveillance program, warrant for intensified surveillance or, occasionally, surgery.

**Aims & Methods:** Our aim was to determine the patient-reported burden of such intensified surveillance and/or surgery, and to assess post-operative quality of life. In the course of our pancreatic cancer surveillance program, participants completed questionnaires including the Hospital Anxiety and Depression Scale (HADS, subscales range 0-21) and the Cancer Worry Scale (CWS, ranges 8-32). For individuals who underwent intensified surveillance (without leading to surgery), questionnaires before intensified surveillance, during, and  $\geq 3$  weeks after the decision to return to regular follow-up were analyzed. In addition, those who underwent intensified surveillance in the last 3 years, or surgery at any time, were invited for a semi-structured telephone interview.

**Results:** 34 individuals underwent intensified surveillance, of which 20 returned multiple questionnaires (response rate 59%) and 12 were invited for an interview, to which eight consented (response rate 67%). Of those who underwent surgery, 10 were interviewed (response rate 91%). The total cohort consisted of 31 individuals (12 (39%) male, median age 52 (IQR 13) years), 16 (52%) familial pancreatic cancer kindreds and 15 (48%) gene mutation carriers.

During the intensified surveillance period, cancer worries increased significantly (median CWS 14, IQR 7), as compared to before (median 12; IQR 9,  $P=0.007$ ) or after (median 11, IQR 7,  $P=0.014$ ), but eventually returned back to baseline ( $P=0.823$ ). General anxiety and depression scores were low (both median 5, IQR 5) and not significantly influenced by the intensified surveillance period ( $P>0.100$ ).

Of the 8 interviewed participants, 5 (63%) had perceived the extra visits as more burdensome or stressful than the regular visits, and 5 still experienced increased worries. They regarded intensified surveillance as something positive (2), neutral (2), negative but necessary (3) or negative (1).

Of the 10 operated patients (median 43 months since surgery, IQR 63), 5 underwent a pancreatoduodenectomy and 5 a distal pancreatectomy. Pathology revealed one T1 pancreatic ductal adenocarcinoma, 7 premalignant lesions (PanIN 1-2 or IPMN with low-moderate grade dysplasia), and 2 cases of benign disease (neuroendocrine tumor and autoimmune pancreatitis).

Afterwards, 20% developed diabetes and 70% steatorrhea. Patients judged their recovery as good (fast, no complications, 20%), fair (minor complications and/or longer recovery time than anticipated, 50%), or poor (major complications, 30%). Median quality of life scores (SF-12 PCS 56 and MCS 52) were not different from age-matched reference data from the general population.

After surgery, patients' attitude towards surveillance was unchanged (60%) or became more positive (40%), but never more negative. Knowing the pathological outcome, when asked if surgery had been justified, only 20% disagreed and all would again have chosen to undergo surgery.

**Conclusion:** In individuals at high risk for pancreatic cancer, intensified surveillance transiently increased cancer worries, without affecting general anxiety or depression.

Although pancreatic surgery led to substantial co-morbidity, quality of life was similar to the general population, and surgery did not negatively affect the attitude towards surveillance.

### P0133 LARGER-DIAMETER PLASTIC STENT PLACEMENT FOR PREOPERATIVE BILIARY DRAINAGE IS SIGNIFICANTLY ASSOCIATED WITH LONGER PATENCY IN PATIENTS RECEIVING NEOADJUVANT CHEMORADIATION FOR PANCREATIC CANCER

Ikezawa K.<sup>1</sup>, Takada R.<sup>1</sup>, Takahashi H.<sup>2</sup>, Kiyota R.<sup>1</sup>, Imai T.<sup>1</sup>, Abe Y.<sup>1</sup>, Fukutake N.<sup>1</sup>, Nawa T.<sup>1</sup>, Ashida R.<sup>3</sup>, Katayama K.<sup>1</sup>, Ohkawa K.<sup>1</sup>

**Contact E-Mail Address:** ikezawa-ke@mc.pref.osaka.jp

**Introduction:** Neoadjuvant therapy has been investigated in the patients with resectable and borderline resectable pancreatic cancer (PC). In neoadjuvant chemotherapy, self-expandable metallic stents (SEMS) was reported to be superior to plastic stents for endoscopic biliary decompression. However, preoperative biliary drainage in PC patients receiving neoadjuvant chemoradiotherapy (NACRT) has not been fully examined. We mainly used plastic stents for biliary drainage in PC patients receiving NACRT because metallic stent placement during external irradiation could cause infiltration of inflammatory cells and fibrosis due to scattering of X-ray. In this study, we examined recurrent biliary obstruction (RBO) of preoperative biliary drainage and evaluated how the diameter of plastic stents impacts on time to RBO.

**Aims & Methods:** We retrospectively reviewed the data regarding 131 PC patients who received NACRT using gemcitabine or TS-1 at our institution between August 2012 and July 2017. We excluded the patients who did not receive preoperative biliary drainage and those who did not receive surgery. The definition of time to RBO was the period from the stent placement to the recurrence of biliary obstruction according to TOKYO criteria 2014. Analysis of time to RBO was performed using the Kaplan-Meier method and differences were evaluated with the log-rank test.

**Results:** 58 patients (pts) were included. Median age was 66; 62.1% were male; median tumor size was 22mm. All biliary obstruction was caused by pathologically-proven pancreatic head cancer. Operative procedures were pancreaticoduodenectomy (n=51), total pancreatectomy (n=2) and bypass surgery (n=5). Median time from the initial biliary drainage to surgery was 133 days. The study patients received preoperative biliary drainage in 2.9 times on average (once 10 pts; twice 12 pts; three times 20 pts; four times 8 pts; five-seven times 10 pts). Biliary drainage were plastic stents in 128 cases (75.7%), endoscopic nasal biliary drainage (ENBD) in 37 cases (21.9%), SEMS in 2 cases (1.2%) and percutaneous biliary drainage in 2 cases (1.2%). SEMS was placed after radiotherapy was completed. The ERCP-related complication rate was 1.8% (mild pancreatitis 2; bile duct injury 1). These complications were relieved with conservative treatment. Two mild pancreatitis was observed in the cases of 7-Fr plastic stent placement.

RBO occurred in 80 times (occlusion 70; distal migration 10). Cholangitis was observed at the time of RBO in 66.3% (53/80). 33.9% (20/58 pts) experienced the delay of chemotherapy due to RBO. 11.9% (7/58 pts) suffered from the delay of radiation due to RBO. Surgery was not delayed because of RBO. Median time to RBO of plastic stents was significantly longer in 10 Fr (107 days) than 49 days in 7 Fr ( $p=0.005$ ) and 62 days in 8.5 Fr ( $p=0.030$ ).

**Conclusion:** In this study primarily using plastic stents, PC patients receiving NACRT experienced preoperative biliary drainage in 2.9 times on average. 10Fr plastic stents were significantly associated with longer patency compared with smaller-diameter plastic stents. Larger-diameter plastic stents could decrease RBO and the delay of chemotherapy and radiation without increasing adverse events.

**Introduction:** The neuroendocrine neoplasia (NEN) were considered an heterogeneity disease in term of somatostatin receptor expression, uptake contrast enhancement in CT scan evaluation, FDG uptake, and heterogeneity of proliferative index especially for patients with multiple metastases. Tumor heterogeneity can be difficult to capture and quantify with traditional imaging tools. The recent tendency of radiology is to research reproducible parameters, extracted from the images and standardized. The technical term to explain this strand is "Radiomics". It is possible to obtain an objective evaluation in addition to traditional subjective evaluation, using TexRAD, software of CT-Texture Analysis, that refers to mathematical methods used to analyze the attenuation value of each voxel and their distribution within the region of interest (ROI) to obtain a measure of the intralésional heterogeneity.

**Aims & Methods:** Compare CT-texture analysis and CT features of liver metastases (mets) in pancreatic and non-pancreatic NENs according to tumor grading. CE-CT images of liver mets in NEN patients were analysed by 3D CT texture analysis. These parameters were evaluated during arterial and portal phase: mean attenuation, standard deviation, skewness, kurtosis, entropy, mean of positive pixels and Tx\_sigma. Lesions delta enhancement was also calculated. The CT exams were performed before the beginning of any medical treatment. All patients had G1 or G2 a tumor according with WHO classification.

**Results:** Twenty-five patients non pancreatic NENs (NP-NENs) and 23 patients pancreatic (PNENs) were included in the study.

Comparing liver mets from pNENs and non-pNENs, CT texture analysis showed that the parameter "skewness" was significantly higher in non-pNENs ( $p$ -value < 0.05). This data was also confirmed when subgroup analysis according with grading system (G1 vs G2) was performed. The parameter "mean" was significantly higher in pNENs compared with non-pNENs ( $p$ =0.0066). Furthermore, the "delta enhancement" was significantly higher ( $p$ -value < 0.05) in liver mets from pNENs. "Entropy" and "Kurtosis" assessed during arterial phase were associated with higher risk of death by Cox analysis ( $p$  < 0.05).

**Conclusion:** This study shows that liver metastases from pNENs and non-pNENs have different CT features in terms of texture parameters. The use of radiomics in NENs could be used by the physician to plan the therapy strategy.

**Contact E-Mail Address:** hjs\_snu@naver.com

**Introduction:** Contrast-enhanced harmonic endoscopic ultrasonography (CEH-EUS) can be used for differential diagnosis of pancreatic lesions by evaluating microvascular circulation and patterns of contrast enhancement<sup>1-3</sup>. However, routine use of CEH-EUS is limited by its high cost, the lack of contrast agent availability and expertise with this technique. Directional eFLOW (D-eFLOW) (Aloka Co., Ltd., Tokyo, Japan) was introduced as a new high-definition modality for blood flow that detects blood flow in microvessels<sup>4</sup>. Since it uses built-in functions, it needs no additional cost and takes less time for examination.

**Aims & Methods:** The purpose of this study was to investigate the usefulness of D-eFlow compared with CEH-EUS for differential diagnosis of pancreatic solid lesions, especially neuroendocrine tumors. From January 2016 to February 2019, a total of 34 patients who received EUS and D-eFLOW examination to evaluate pancreatic and peripancreatic masses were analyzed, retrospectively.

**Results:** Of 34 patients, D-eFLOW was performed in 34 patients and CEH-EUS was performed in 32 patients. Histological diagnosis was confirmed in 19 patients by EUS-FNA and/or surgery. Concerning the detection of the neuroendocrine tumors, D-eFLOW had higher sensitivity to CEH-EUS (100% vs. 91.7%), lower specificity (33.3% vs. 50.0%), lower positive predictive value (76.5% vs. 78.6%), higher negative predictive value (100% vs. 75%) and higher accuracy (78.9% vs. 77.8%). There was a good correlation between the D-eFLOW and CEH-EUS to evaluating the vascularity of tumors (correlation coefficient 0.683,  $p$  < 0.05).

**Conclusion:** In conclusion, D-eFLOW can be considered as an alternative method to CEH-EUS for the evaluation of pancreatic and peripancreatic solid tumors.

**Introduction:** We previously reported in a prospective multicenter trial that endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) using 25-gauge needles with a core trap provides histological samples of adequate quality for diagnosing and grading pancreatic neuroendocrine tumors (PNET) (UMIN00010021).

**Aims & Methods:** Since the number of surgical cases increased thereafter, we conducted further detailed examination in this study. Consecutive patients with hypervascular solid pancreatic masses, suspected as PNET on imaging modalities, who presented to ten Japanese referral centers from June 2016 to November 2017 were prospectively recruited. All patients underwent EUS-FNB using 25-gauge needles with a core trap (EchoTip ProCore, Cook Medical, Bloomington, Indiana, USA). After the mass was punctured, the slow-pull technique was used for biopsy. The specimen obtained by first pass was used for this study. The entire specimen was inserted into a formalin bottle and processed for histological analysis. All tissue samples were brought to a single facility where experienced pathologists reviewed them.

**Results:** A total of 52 patients (male/female: 24/28, median age: 63 years) were enrolled in this study. The technical success rate of EUS-FNB was 100% and tissue acquisition rate for histological analysis was 86.5%. There were no complications related to EUS-FNB. Thirty-six patients subsequently underwent pancreatic resection, and 31 patients were diagnosed as PNET (G1=28, G2=3, tumor size: 3 to 26 mm, median tumor size: 11 mm) by evaluation of the surgical specimen. The sensitivity, specificity and accuracy of EUS-FNB for the histological diagnosis of PNET were 82.1%, 100% and 84.8%, respectively. Sensitivity of EUS-FNB was 80% for tumors smaller than 10 mm, 91.7% for tumors 10 to 20 mm in size, and 80% for those larger than 20 mm. Sensitivity of EUS-FNB via transgastric access (median tumor size: 11 mm) was 84.6%, that via transduodenal bulb access (median tumor size: 15.5 mm) was 50%, and that via transduodenal 2<sup>nd</sup> portion access (median tumor size: 11 mm) was 90%. Although the sensitivity of EUS-FNB via transduodenal bulb access was low, the tumors were not smaller than those for the other route. The concordance rate of PNET grading by EUS-FNB with grade of the resected tumor was 82.6%.

**Conclusion:** EUS-FNB using a 25-gauge needle with a core trap via a single pass offers high accuracy for diagnosing and grading small PNET.

**Disclosure:** Nothing to disclose

### P0137 UNAWARENESS OF HYPOGLYCAEMIA IN PATIENTS WITH INSULINOMA

Nosáková L.<sup>1</sup>, Banovcin P.<sup>1</sup>, Ďuriček M.<sup>1</sup>, Uhrík P.<sup>2</sup>, Hyrdel R.<sup>1</sup>  
<sup>1</sup>Jessenius Faculty of Medicine, Gastroenterology Clinic, Martin, Slovakia, <sup>2</sup>Clinic for Internal Medicine and Gastroenterology, University Hospital Martin, Gastroenterology and Internal Medicine, Martin, Slovakia

**Contact E-Mail Address:** lenka.bubernakova@gmail.com

**Introduction:** Insulinoma is rare, but definitely most common functional neuroendocrine tumor of pancreas. In almost all cases there are benign

and sporadic. Clinical manifestation include various symptoms of hypoglycaemia, which is the result of insulin overproduction. Paradoxically, there is some patients without any clinical sign of hypoglycaemia. This patients suffer from unawareness of hypoglycaemia. In our work, we focus on presence of this syndrom in patients with insulinoma. Our aim was identify these patients, because unawareness hypoglycaemia is serious condition, which has a great influence life, and can be even life threatening.

**Aims & Methods:** Analysis of retrospective clinical and biochemical data was used to create file of patients. We evaluated every patient with confirmed insulinoma (biochemically, with localization technique) from 1996 to 2019 hospitalized in our department. During admission we asked patient about clinical presentations, duration of hardships and presence of spontaneous loss of consciousness. After admission, every patient underwent 72-hour fasting test on intensive unit care with monitoring vital signs, levels of blood glucose level, C-peptid and IRI. From this file of patients we selected and focus on patients with documented episode of clinically silent hypoglycaemia. After reaching the blood glucose level under 2,2 mmol/l, we took blood for examination of C-peptid and IRI levels, gave patient glucose parenterally and stopped fasting test. These patient was monitoring closely during whole diagnostic procedure, and were referred to surgical treatment as soon as it was possible

**Results:** From 1996 to 2019 there were overall 23 patients with confirmed diagnosis of insulinoma. The number of patients with unawareness hypoglycaemia events was 7 (30,43%), 4 men and 3 women. The mean age of our patients was 50 years (from 30 to 69 years). All of these patients suffer from severe episodes of hypoglycaemia without any accompanying symptoms during hospitalization in our department. We detected hypoglycaemia either accidentally during measurement profile of glucose or when patient loss of consciousness. Mean levels of blood glucose during fasting test was 1,79 mmol/l (from 2,4 to 1). Paradoxically, none of these patients had increased levels of C-peptid and IRI during fasting test.

**Conclusion:** Until now, unawareness of hypoglycaemia was described only in patients with diabetes mellitus. In our work, we found presence of this syndrom in patients with insulinoma. These patients suffered from severe episodes of hypoglycaemia without any accompanying symptoms and they are also at risk of sudden death.

## P0138 PROGNOSTIC AND SURVIVAL FACTORS OF INTESTINAL AND PANCREATIC NEUROENDOCRINE TUMORS (IP-NETS): THE EXPERIENCE OF A TERTIARY REFERRAL CENTER

Saraiva M.<sup>1</sup>, Brozzi L.<sup>2</sup>, Dias E.<sup>3</sup>, Cardoso H.<sup>4</sup>, Macedo G.<sup>5</sup>

<sup>1</sup>Centro Hospitalar São João, Gastroenterology, Porto, Portugal, <sup>2</sup>The Pancreas Institute, G.B. Rossi University Hospital, Department of Medicine, Gastroenterology and Digestive Endoscopy Unit, Verona, Italy, <sup>3</sup>Centro Hospitalar São João, Porto, Portugal, <sup>4</sup>Centro Hospitalar São João, Baguim do Monte, Portugal, <sup>5</sup>World Gastroenterology Organisation, Milwaukee, United States

**Contact E-Mail Address:** miguelmascarenhassaraiva@gmail.com

**Introduction:** Intestinal and pancreatic neuroendocrine tumors (IP-NETs) represent a rare group of neoplasias, with an incidence of approximately 0.5 in 100,000 inhabitants, constituting a small percentage of intestinal and pancreatic neoplasias. The clinical presentation and biological behavior is extremely variable, reflecting large differences in survival, depending on the location, type of primary tumor, metastization and other multiple factors.

**Aims & Methods:** In this study, we evaluated the location, type of primary tumor as well as other relevant clinical and pathological aspects with impact on the global and disease-free survival. We retrospectively evaluated 89 patients with intestinal and pancreatic neuroendocrine tumors with a confirmed pathological diagnosis between 2008 and 2019. Patients with MEN1 (Type1 Multiple Endocrine Neoplasia) or Von Hippel-Lindau syndrome were excluded.

**Results:** The most frequent primary site was pancreatic (47% -57%) and intestinal (42 patients-47%). The majority of patients were female (60%). The mean age at diagnosis was 53.8 years (range 22-87 years). The median survival was 138 months. Regarding the existence of metastases at the time of diagnosis (synchronous or metachronous), they were present in 37 patients (42%). Regarding the therapeutic approach, patients underwent surgery (54%), surgery + chemotherapy (40%) or chemotherapy alone (6%), Survival was higher in patients submitted to surgery ( $P < 0.001$ ). It

should be noted, that the patient's age  $>65$  years at diagnosis ( $P < 0.001$ ), primary tumor size greater than 25 mm ( $P = 0.02$ ), the presence of synchronous metastases ( $P = 0.03$ ) and the presence of a Ki67  $> 5\%$  ( $P = 0.04$ ) were evidenced as independent factors of adverse prognosis.

**Conclusion:** The clinical presentation and biological behavior of IP-NETs is considerably variable. Consistent with previously published series of cases, age less than 65 years, primary tumor size and absence of locoregional disease, angioinvasion and metastases are associated with a better prognosis.

**Disclosure:** Nothing to disclose

### P0139 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION VERSUS LAPAROSCOPIC RESECTION FOR GASTRIC STROMAL TUMORS LESS THAN 2 CM

Meng Y., Liu S.

Guangdong Provincial Key Laboratory of Gastroenterology, Department of Gastroenterology, Nanfang Hos, Department of Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** 1031294787@qq.com

**Introduction:** Gastrointestinal stromal tumors (GISTs) is the most common mesenchymal gastrointestinal tumor, which accounts for about 2% of all the gastrointestinal tumors. The age-adjusted yearly incidence rate of GISTs was about 6.8 per million, with 54% men and 46% women.

**Aims & Methods:** Laparoscopic resection (LAP) and endoscopic submucosal dissection (ESD) is commonly used to remove small gastrointestinal stromal tumors (GISTs). However, whether LAP or ESD has more efficient outcome for small GISTs is controversial. Therefore, our Aim was to evaluate the efficacy of ESD and LAP for small GISTs and provided long-term outcomes of the two methods.

**Methods:** All data from 398 patients who underwent ESD or LAP for small GISTs (between 2008 and 2019) were collected from Nanfang hospital, Guangzhou, China. We made telephone calls to collect information about their recurrence rate. Clinicopathological characteristics, recurrence rate and surgical outcome were collected and blindly measured for each procedure.

**Results:** Among the 398 patients, 234 (58.79%) received ESD treatment, and 164 (41.21%) received LAP treatment. The clinicopathological characteristics of the patients were well balanced. There was no significant difference between LAP and ESD groups according to gender, age, tumor size and location. There was also no significant difference in follow-up time (6.65 $\pm$ 1.84 years in ESD vs. 6.19 $\pm$ 1.53 years in LAP group,  $P=0.24$ ). However, there was a significant difference between the two groups in operating time (61.42  $\pm$  32.85min vs. 78.68  $\pm$  39.76 min,  $P=0.03$ ), estimated blood loss (6.58  $\pm$  12.16 ml vs. 16.35  $\pm$  17.06 ml,  $P=0.02$ ) and hospital stay (5.07  $\pm$  2.15 days vs. 9.84  $\pm$  3.80 days,  $P < 0.001$ ). The complication rate (defined as perforation or massive hemorrhage) showed no significant difference among ESD and LAP group (2.14% vs. 1.22%;  $P=0.85$ ). The recurrence rate of ESD and LAP group was 2.56% and 1.22%;  $P=0.56$ . Meanwhile, Kaplan-Meier curves for disease-free survival test showed no significant difference between two groups ( $P=0.86$ ).

**Conclusion:** Long-term follow-up showed that ESD can be a more preferable technique for resection of small gastric stromal tumors compared with LAP. However, long-term randomized controlled trials are further needed.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** crfrasca@hotmail.com

**Introduction:** Endoscopic mucosal resection (EMR) has proven to be a safe and effective technique to locally remove lesions confined to the mucosa, with the advantage of providing a complete specimen for histological analysis.

**Aims & Methods:** We aim to report our 22-year outcome data to measure resection success and complication rates in EMR procedures performed in a single center.

We retrospectively reviewed 176 EMR procedures (157 patients) performed in our endoscopic department from March 1, 1997 to December 10, 2018. Procedures were performed using Olympus and Fujinon singlechannel or dual-channel endoscopes with a cap or band-ligation. Endoscopic ultrasound was performed with linear scopes, radial scopes, or miniprobes in most patients. Recurrent cancer was re-treated (with additional EMR) when necessary.

**Results:** Of 157 patients, 93 (59.2%) were men. Mean patient age was 66.7 (SD, 11.0) years. Fourteen patients underwent more than 1 EMR procedure, for a total of 176 EMRs analyzed. Mean follow-up was 52.3 months. Gastric adenocarcinoma was diagnosed in 31.8% of patients (50/157), followed by esophageal squamous cell carcinoma in 17.8% (28/157), esophageal adenocarcinoma (Barrett esophagus) in 14.0% (22/157), and duodenal adenocarcinoma in 8.9% (14/157). Figure 1 shows a case of esophageal adenocarcinoma (Barrett esophagus) treated with EMR using band-ligation. The remaining 43 patients were diagnosed with benign lesions, including neuroendocrine tumors, hamartomas, granular cell tumors, and gastric heterotopia in the esophagus. En bloc resection was possible in 88.5% (139/157) of patients; the remaining 18 patients underwent piecemeal EMR. Eleven (7.0%) patients had recurrent lesions during follow-up: 3 esophageal adenocarcinomas (Barrett esophagus) and 8 gastric adenocarcinomas. Bleeding occurred in 21 (13.3%) patients, successfully controlled with hemoclips. Perforations occurred in 3 (1.9%) patients; 2 of them required surgery. No procedure-related death was observed during the follow-up period.

**Conclusion:** Our long-term outcome data demonstrate that EMR is a safe and effective therapy for high-grade dysplasia and early upper gastrointestinal neoplasia. However, careful follow-up is particularly necessary in cases of local recurrence, when additional EMR is required.

**Contact E-Mail Address:** luikalu@hk.hk

**Introduction:** Accurate endoscopic prediction of the histology of a sessile gastric lesion requires training and expertise, which may not be widely available. The use of artificial intelligence (AI) assisted image classifier has been shown to have high accuracy on endoscopic diagnosis. We evaluated the potential training effects of our recently developed AI assisted image classifier on histological prediction of gastric lesions by junior endoscopists.

**Aims & Methods:** An AI image classifier was built on a convolutional neural network with 5 convolutional layers and 3 fully connected layers Resnet backbone. It was first trained by 2,000 endoscopic images of both non-neoplastic and neoplastic gastric lesions, as verified by final histology of either multiple biopsies or total endoscopic resection. The endoscopic images were all obtained by high-definition endoscopy series (Olympus GIF-HQ290 and CV-290 video system). Gastric pathology was based on the WHO classification with neoplastic lesions defined as the presence of gastric dysplasia, adenoma or carcinoma in the most severe histology of the lesion. For each gastric lesion, around 10 regions of interest (ROI) were randomly selected in a pixel of at least 300 x 300 dpi. The independent validation set consisted of 1000 endoscopic NBI images from 100 gastric lesions. The validation set was also reviewed by six junior endoscopists who had performed more than 1,000 upper endoscopies and with training on NBI. The first part of validation set was first commented by all endoscopists and then the prediction of AI was disclosed to three of them (Group A endoscopists) while the remaining three (Group B endoscopists) were not provided this information. All the endoscopists then reviewed the 2<sup>nd</sup> part of the validation set.

**Results:** The overall accuracy of AI was 90.4% (95%CI: 88.6%-92.2%) with sensitivity 97.3% (95%CI: 95.8-98.7%), specificity 84.1% (95%CI: 80.9-87.2%), PPV 84.9% (95%CI: 81.8-87.8%), NPV 97.1% (95%CI: 95.6-98.7%) and area under the ROC (AUROC) 0.91 (95%CI: 0.89-0.93). AI was more confident in the prediction of non-neoplastic lesions than neoplastic lesions (84.5% vs 81.6%, p < 0.01). AI was superior to all junior endoscopists in term of accuracy and AUROC in both validation sets. (Table 1) The performance of the 3 endoscopists who had been revealed the AI finding of 1<sup>st</sup> validation set (Group A endoscopists), significantly improved on the 2<sup>nd</sup> validation set (69.3% to 74.7%; p = 0.003). However, there was no significant improvement on performance for those who were not disclosed the AI findings (Group B endoscopists).

**Conclusion:** The trained AI image classifier based on non-magnified NBI images can accurately predict the presence of neoplastic component of sessile gastric lesions. The use of AI image classifier can also hasten the learning curve of junior endoscopists on histologic prediction of gastric lesions.

## P0142 THE SEARCH, COAGULATION AND CLIPPING (SCC) METHOD TO PREVENT DELAYED BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

Azumi M., Takeuchi M., Miida S., Hojo Y., Yoshikawa S., Kohisa J.  
Nagaoka Red Cross Hospital, Gastroenterology, Niigata, Japan

**Contact E-Mail Address:** az2948@yahoo.co.jp

**Introduction:** Delayed bleeding is an important complication after gastric endoscopic submucosal dissection (ESD). Post-ESD coagulation (PEC) involving prophylactic cauterization of visible blood vessels at the ulcer floor is widely performed to prevent delayed bleeding after endoscopic therapy. The bleeding rate with this approach has been reported to be 3-5.5%. The search, coagulation, and clipping (SCC) method, which involves observing the ulcer floor, identifying blood vessels, and cauterizing and clipping respective blood vessels, appears to be a good approach to prevent bleeding after ESD. However, its safety and efficacy are unclear. We compared the SCC method with post-ESD coagulation (PEC) to clarify the safety and efficacy of the SCC method for preventing delayed bleeding after gastric ESD.

**Aims & Methods:** This retrospective study included 601 consecutive patients (669 lesions) who underwent gastric ESD. 97 patients treated with anti-thrombotic therapy (97/601 16.1%). Delayed bleeding was defined as clinical post-ESD bleeding with hematemesis, melena, or anemia progression that required endoscopic examination aside from the one scheduled during second-look endoscopy. Multivariate analysis was performed to identify the significant independent factors associated with delayed bleeding and we performed propensity score matching (PSM) to reduce the effect of procedure-selection bias of SCC method. Explanatory variables consisted of location, specimen size, antithrombotic agents, procedure time, and heparin placement.

**Results:** Of the 601 patients, 217 underwent PEC and 384 underwent SCC. According to the clinical pathway, the second-look endoscopy was performed for all cases. One patient presented bleeding in the stomach during second-look endoscopy. Delayed bleeding was significantly less common in the SCC group than in the PEC group (10/384 2.6% vs. 16/217 7.4%;  $P = 0.011$ ). Among 97 patients treated with antithrombotic therapy, the delayed bleeding rate was lower in the SCC group than in the PEC group; however, the difference was not significant (4/61 6.6% vs. 5/36 13.9%;  $P = 0.285$ ). Multivariate logistic regression analysis indicated that SCC methods and heparin placement were independent and significant factors affecting the delayed bleeding (SCC methods:  $P = 0.011$ ; heparin placement:  $P = 0.004$ ). PSM was performed in 154 patients in the PEC group and SCC group. There was a significant difference in the incidence of bleeding in the PEC and SCC groups (2/154 1.3% vs. 12/154 7.8%;  $P = 0.011$ ). No patient had perforation/bleeding associated with the SCC method.

**Conclusion:** Our findings suggest that the SCC method is a simple, safe, and effective approach for preventing delayed bleeding after gastric ESD.

**Contact E-Mail Address:** hzhzhkhk@yahoo.com

**Introduction:** The aim of this study was to compare the performance of different scoring systems (Rockall scoring system, Glasgow-Blatchford score and AIMS65) in predicting outcomes in patients with acute variceal bleeding.

**Aims & Methods:** Data were collected prospectively over a 6-month period in the emergency department of a university hospital. Adult patients with upper GI bleeding from variceal sources were included. Clinical outcomes

were re-bleeding, duration of hospitalization, need for blood transfusion and death. Patients who required blood transfusions or suffered composite clinical outcomes were considered high-risk patients. Rockall scoring system, Glasgow-Blatchford score (GBS) and AIMS65 scores were calculated for each patient. The sensitivity and specificity of the scoring systems were calculated. The areas under the receiver operating characteristic curve (AUC) of the scores were compared.

**Results:** There were 100 patients in the study; of whom 76 were men and 24 were women. The mean age was 59.39±7.7 years. Endoscopy was done for all of them and the three scores were calculated. Rebleeding was observed in 35 patients. A total of 83 patients received blood transfusions and 19 patients unfortunately died within 1-month follow up period. The three scores were compared to each other as regards our outcomes by using the ROC curves as shown in figures.

**Conclusion:** AIMS65 was superior for predicting the re-bleeding, GBS score was superior for predicting the need for blood transfusion and no significant difference was detected as regard duration of hospitalization and mortality among the three scores.

**Contact E-Mail Address:** prabinsharmaa@hotmail.com

**Introduction:** Curved linear-array [CLA] echoendoscopes and forward-viewing linear [FVL] echoendoscopes are used in sampling and draining of upper GI subepithelial lesions and pancreatic lesions. FVL echoendoscopes were designed to overcome the limitations of the CLA echoendoscopes. Only a few prospective studies have compared the 2 types of endoscopes in terms of safety, efficacy, procedure duration and ease of the procedure.

**Aims & Methods:** We aimed to review the currently available data that compare the CLA echoendoscope with FVL echoendoscope in terms of technical success rates, diagnostic yield, diagnostic accuracy and procedure time.

**Results:** A total of 3 prospective studies met the inclusion criteria for this meta-analysis. A total of 260 procedures were analyzed, which included 130 FVL and 130 CLA. There were no significant differences in the technical success rates and diagnostic yield (OR, 0.77; 95% CI, 0.14-4.40,  $P = 0.77$  and OR, 1.21, 95% CI, 0.6-2.44,  $p = 0.6$ ). Similarly, there was no significant difference in diagnostic accuracy (OR, 0.81; 95% CI, 0.38-1.71,  $p = 0.57$ ). However, procedure time was significantly less for the FVL group compared to CLA (MD, -2.88, 95% CI -4.53 - -1.22,  $p = 0.0006$ ).

**Conclusion:** Both forward-viewing and curved linear-array echoendoscopes have similar technical success rate, diagnostic yield and accuracy in sampling and draining upper GI sub-epithelial and pancreatic lesions. FVL echoendoscopes provide the benefit of shorter procedural time.

**Disclosure:** Nothing to disclose

## P0145 HYBRID ENDOSCOPIC SUBMUCOSAL DISSECTION VS CONVENTIONAL ENDOSCOPIC SUBMUCOSAL DISSECTION IN THE TREATMENT OF EARLY GASTRIC NEOPLASMS: A MULTI-CENTER RETROSPECTIVE ANALYSIS

Esaki M.<sup>1,2,3</sup>, Suzuki S.<sup>1,2</sup>, Horii T.<sup>1,2</sup>, Ichijima R.<sup>1</sup>, Kusano C.<sup>1,2</sup>, Ikehara H.<sup>1</sup>, Ihara E.<sup>3</sup>, Gotoda T.<sup>1</sup>

**Contact E-Mail Address:** esaki\_saiseikai@yahoo.co.jp

**Introduction:** Endoscopic submucosal dissection (ESD) is a technically difficult and time-consuming procedure. Hybrid ESD (H-ESD) combines circumferential incision with partial submucosal dissection and subsequently

snaring using a single device. H-ESD is potentially a simpler and shorter procedure. Here, we report the short-term outcomes of H-ESD for early gastric neoplasms.

**Aims & Methods:** The aim of this study is to compare short-term outcomes of H-ESD for early gastric neoplasms with those of conventional ESD (C-ESD). In this multi-center retrospective study, we reviewed the charts of patients with early gastric neoplasms within 20 mm in diameter treated with H-ESD or C-ESD between January 2017 and October 2018 at three hospitals. Propensity score matching was performed to reduce biases. Short-term outcomes including the procedure time, the en-bloc resection rate, the complete resection rate, and the rate of adverse events (perforation/delayed bleeding) were evaluated.

**Results:** Among 215 patients, 29 were in the H-ESD group and 186 were in the C-ESD group. Twenty-nine pairs were created by propensity score matching. In the H-ESD group, 82.8% of lesions met the original absolute indication (limited to 20 mm in diameter dominated by differentiated adenocarcinoma without ulcer) for endoscopic resection. As a result, H-ESD required a significantly shorter median procedure time (H-ESD: 20 [interquartile range, 12-27] min vs C-ESD: 40 [30-50] min;  $P < 0.001$ ). Other outcomes were similar among two groups and no significant differences were observed (En-bloc resection rate; 100% in both groups, Complete resection rate; 100% vs 93.1%,  $P = 0.49$ , Adverse event rate; 0% vs 3.4%,  $P = 1$ ).

**Conclusion:** H-ESD achieved significantly shorter procedure time with high curability without increase in adverse events. Therefore, H-ESD should be selected for gastric neoplasms within original absolute indication.

**Disclosure:** Nothing to disclose

## P0146 USEFULNESS OF 3-DIMENSIONAL FLEXIBLE ENDOSCOPY IN THE DIAGNOSIS OF GASTRIC EPITHELIAL NEOPLASIA

Higuchi K., Kaise M., Koizumi E., Kiritani K., Noda H., Umeda T., Akimoto T., Omori J., Goto O., Iwakiri K.

*Nippon Medical School, Department of Gastroenterology, Bunkyo-ku, Japan*

**Contact E-Mail Address:** k-higuchi@nms.ac.jp

**Introduction:** 3-dimensional (3D) visualization offers better depth recognition than 2-dimensional (2D) visualization. There are some reports that 3D rigid endoscopy in surgical fields can shorten the procedure time and reduce the complications. In contrast, the prototype of 3D flexible endoscopy has already been developed, and we have reported that it has reduced technical complications during endoscopic submucosal dissection (ESD), especially in trainees. 3D visualization might be effective in the diagnosis of cancer extent because it facilitates more clearly the recognition of ruggedness and shape of lesions than 2D.

**Aims & Methods:** To explore the feasibility of 3D visualization in the endoscopic diagnosis, we conducted a study to compare 2D and 3D endoscopy in the diagnosis of early gastric cancers (EGCs) and gastric adenomas. Study participants (3 experts and 6 trainees) who do not know clinical information of target lesions performed pre-ESD endoscopic assessment of EGCs and adenomas under 2D and 3D observation. In the 3D endoscopy system, 2D and 3D visualization under white light imaging or narrow band imaging are quickly changed by a food pedal. In the next, they made electrocautery markings on a half of demarcation line of EGCs and adenomas under 2D images at first, and on other half under 3D.

The markings under 2D and 3D were performed in half of the anterior and posterior wall side respectively, which side they would be on was randomly assigned. Thereafter, target lesions were resected by ESD. After procedure, participants answered visual analog scaled (VAS; 0-10, worst to best) questionnaire on ease of recognition of lesion morphology / lesion extent / total endoscopic cognition and technical ease of electrocautery marking under 2D and 3D visualization.

The main endpoint was accuracy of ESD marking, which derived from the pathological distance between the demarcation line and the markings in the excised specimens. This study was conducted after an approval of the institutional review board of our hospital.

**Results:** Enrolled 24 EGCs and 2 adenomas (median tumor size, 13 mm, range 3 - 32 mm) were 4 of type 0-Ia, 3 of type 0-IIb and 19 of type 0-IIc, and the types of histology of EGCs were 20 well differentiated adenocarcinomas, 3 signet-ring cell carcinomas and a poor differentiated adenocarcinoma. The distance between the demarcation line and electrocautery marking under 3D visualization was significantly shorter than under 2D ( $1.04 \pm 0.79$  mm vs  $1.93 \pm 1.92$  mm, respectively,  $P = 0.040$ ). In VAS, the

recognition of lesion morphology under 3D was easier than 2D ( $8.54 \pm 1.10$  vs  $4.96 \pm 1.56$ , respectively,  $P < 0.001$ ), and that of lesion extent under 3D was easier than 2D ( $8.00 \pm 1.20$  vs  $5.12 \pm 1.66$ , respectively,  $P < 0.001$ ). And ease of total endoscopic cognition under 3D ( $8.15 \pm 1.26$ ) was significantly higher than 2D ( $5.35 \pm 1.72$ ) ( $P < 0.001$ ). Additionally, technical ease of electrocautery marking under 3D was higher than 2D ( $7.35 \pm 1.32$  vs  $5.27 \pm 1.40$ , respectively,  $P < 0.001$ ).

**Conclusion:** 3D endoscopy was more accurate than 2D in the endoscopic diagnosis of extent of EGCs and adenomas. Furthermore, 3D visualization enhanced the quality of recognition of ruggedness and extent of lesions, and facilitated technically electrocautery marking before ESD. In flexible endoscopy, not only the efficiency and accuracy of procedure but also the quality of diagnosis is very important. Combined with previous results on 3D-enhanced improvement of ESD performance, 3D endoscopy is the key technological innovation in diagnosis and treatment of GI.

**Disclosure:** Nothing to disclose

## P0147 COMPLICATIONS OF THE SHARP-POINTED FOREIGN BODY INGESTION: A PREDICTIVE MODEL

Xiao X., Huang Z., Wu H.

*West China Hospital, Sichuan University, Gastroenterology Department, Chengdu, China*

**Contact E-Mail Address:** xxuenk@gmail.com

**Introduction:** Foreign body ingestion is a common emergency with little complication, but with the penetrating nature, sharp-pointed objects have a high risk in making esophageal perforation and subsequent death. Emergency endoscopy is the recommended treatment and sharp-pointed foreign body retrieval is a challenge for even highly experienced gastroenterologist. To date, there is no clear risk algorithm available for sharp-pointed foreign body ingestion. It is important to identify the risk factors in order to mitigate potential morbidity and improve prognosis.

**Aims & Methods:** In this single-center, retrospective study, 190 consecutive patients complained of sharp-pointed foreign body ingestion, and referred to gastroenterology department of West China Hospital between August 2018 and February 2019 were included. Patients data, include age, gender, foreign body type, ingestion duration (from ingestion to taking endoscopy), computed tomography (CT) features and gastroscopy findings were recorded and analyzed with univariable analysis. Logistic regression and conditional inference tree were applied to develop a predictive model. Complications of sharp-pointed foreign body ingestion were classed into four ordered categories, including none or edema, erosion, ulcer and perforation. We aimed to recognize risk factors for the complications of sharp-pointed foreign body ingestion, and help clinicians to decide the role and timing of endoscopic intervention.

**Results:** Of the 190 patients, 182 had taken gastroscopy (96%). The width of sharp-pointed foreign body was identified as an independent risk factor for complications (OR=3.10, 95%CI: 2.33-5.55,  $P < 0.001$ ). Conditional inference tree analysis was used to construct a risk stratification algorithm for complications. The sharp-pointed foreign body width of 1.9cm was the key discriminator ( $P < 0.001$ ), and the subsequent split was ingestion duration of 24 hours ( $P = 0.003$ ). Therefore, patients could be stratified into four risk groups: low risk (width  $\leq 1.9$ cm), moderate risk I ( $2.5\text{cm} \geq \text{width} > 1.9\text{cm}$  and duration  $\leq 24$ hours), moderate risk II (width  $> 2.5\text{cm}$ , duration  $\leq 24$ hours), and high risk (width  $> 1.9\text{cm}$ , duration  $> 24$ hours). To test the accuracy of conditional inference tree in predicting complications, receiver operating characteristic curve was drawn, and the area under the curve was 0.703 (95%CI: 0.543-0.862,  $P = 0.009$ ). In high risk group, the specificity in predicting perforation was 83.2% and sensitivity was 60%. We also examined the accuracy of CT in recognizing perforation, the specificity was 95.2%, and the sensitivity was 20%.

**Conclusion:** The width of sharp-pointed foreign body is the main risk factor for complications. Our predictive model including width and ingestion duration could help to differentiate the patient with a high risk in perforation.

## P0148 CLINICAL SIGNIFICANCE OF URGENT ENDOSCOPY FOR GASTRODUODENAL PERFORATION

Asayama N., Nagata S., Shigita K., Aoyama T., Fukumoto A., Mukai S.  
Hiroshima City Asa Citizens Hospital, Hiroshima, Japan

**Contact E-Mail Address:** a-s-ayama@hotmail.co.jp

**Introduction:** Gastroduodenal perforation, a condition representative of acute abdomen, is potentially life-threatening if left unattended, and thus early diagnosis and treatment are necessary. The standard treatment for gastroduodenal perforation is surgery. In some cases, however, operative findings reveal spontaneous closure where the perforation site is already sealed, indicating that surgery was not necessary. An accurate diagnosis by urgent endoscopy is therefore required before choosing between surgical and conservative management.

There is presently no consensus regarding the role of urgent endoscopic examination for gastroduodenal perforation in Japan.

**Aims & Methods:** The aim of the study was to evaluate the clinical significance of urgent endoscopy for gastroduodenal perforation. We retrospectively investigated 156 cases of gastroduodenal perforation in 154 patients (111 men, 45 women; mean age 59±19 years) at Hiroshima City Asa Citizens Hospital between December 2005 and December 2018.

We performed urgent endoscopy for the sole purpose of identifying the location of perforation and confirming the size of the perforation in order to shorten the examination time. All procedures were performed using CO<sub>2</sub> insufflation with a surgeon standing by in case of complications.

**Results:** The primary location of gastroduodenal perforation was the stomach in 42 cases and the duodenum in 114 cases. For 40 of the 42 cases of gastric perforation (95.2%) and 100 of the 114 cases of duodenal perforation (87.7%), urgent endoscopy was performed on admission to diagnose the primary disease and confirm the exact perforation site. For gastric perforation, the endoscopic diagnosis was gastric ulcer in 32 cases, gastric carcinoma in 5, malignant lymphoma (ML) in 1, and perforation due to fish bone ingestion in 1.

Regarding the clinical course of the 42 gastric perforation cases, 31 (73.8%) underwent surgery (25 gastric ulcers, 5 gastric cancer, and 1 ML) and 11 (26.2%) were managed conservatively (8 gastric ulcers, 1 terminal case of gastric cancer, 1 ML, and 1 perforation due to fish bone ingestion).

Of these 11 cases managed conservatively, 9 cases were successful while 2 cases required delayed emergency surgery because of progression of peritonitis. It is necessary to rule out the presence of malignant tumor for cases of gastric perforation. For duodenal perforation, the endoscopic diagnosis was duodenal ulcer in all 114 cases. For the clinical course of these 114 cases, 62 cases (54.4%) underwent surgery while 52 cases (45.6%) were managed conservatively.

Of the 52 cases managed conservatively, 48 cases (92.3%) were successful while 3 cases (7.7%) required delayed emergency surgery because of progression of peritonitis. There was 1 fatal case where the patient had presented in shock on admission.

We compared clinical factors between the cases of successful conservative management and those that required surgery plus the fatal case. Multivariate analysis revealed that localized abdominal pain (with no peritoneal signs) (odds ratio [OR] 0.25; 95% confidence interval [CI] 0.08-0.75; p<0.01) and perforation diameter ≤ 5 mm (OR 0.13; 95% CI 0.04-0.36; p<0.01) were significant independent clinical factors associated with successful conservative management of duodenal ulcer perforation. No complications of urgent endoscopy were observed.

**Conclusion:** Urgent endoscopy in gastroduodenal perforation enabled diagnosis of the primary disease and determination of the perforation site, and was considered useful in deciding the management strategy.

## P0149 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR UNDIFFERENTIATED EARLY GASTRIC CANCER, BEYOND EXPANDED CRITERIA

Ryu C.B.<sup>1</sup>, Lee M.S.<sup>2</sup>, Bae J.Y.<sup>3</sup>, Lee J.Y.<sup>2</sup>

<sup>1</sup>Soon Chun Hyang University School of Medicine, Department of Internal Medicine, Bucheon, Korea (Republic of), <sup>2</sup>Soonchunhyang University College of Medicine, Department of Internal Medicine, Bucheon, Korea (Republic of), <sup>3</sup>Seoul Medical Center, Department of Internal Medicine, Seoul, Korea (Republic of)

**Contact E-Mail Address:** ryuchb@gmail.com

**Introduction:** Expanded indication of endoscopic submucosal dissection (ESD) for intramucosal undifferentiated early gastric cancer (EGC) up to 2 cm without lymphovascular invasion have been accepted. However, pre-operative measurement of the tumor was completely not as same as post-operative one and if the postoperative tumor size would be a little more than 2 cm with R0 resection, additional surgery recommended absolutely. Without Intramucosal undifferentiated early gastric cancer (EGC) up to 2cm in size without ulceration has been treated by endoscopic submucosal dissection (ESD) because the incidence of lymph node metastasis negligible.

**Aims:** The aim of this retrospective study was to analyze the long-term outcomes of ESD carried out to treat undifferentiated EGC in two groups (group A: up to 2 cm, group B: 2-3 cm)

**Patients and methods:** Between January 2001 and March 2015, 104 patients with undifferentiated early gastric cancer (EGC) including poorly differentiated adenocarcinoma (PD, n=66) or signet ring cell carcinoma (SG, n=38) on preoperative biopsy underwent ESD (group A: 71cases, group B: 33cases), Total ESD specimens were evaluated en bloc resection, R0 resection, and curative resection (CR) and to evaluate long term outcome, annual endoscopic surveillance with biopsy and CT scan were done.

Long-term outcomes analyzed in the 79 patients with undifferentiated EGC who had undergone ESD between 1999 and 2008.

Short-term outcomes were evaluated in the remaining 97 patients with undifferentiated EGC.

**Results:** M/F was 40/31 and 17/16. Mean follow up period in group A and B were 61.10 ± 38.12, 60.79 ± 47.75. Mean age in group A and B were 52.90 ± 13.62, 57.00 ± 12.25.

En bloc in group A and B were achieved in 92.9%, 90.9 % of patients, respectively (NS).

R0 resection in were achieved in 87.3 %, 51.5 % of patients, respectively (p< 0.05).

Curative resection was 83.0 % in group A and group B was not include this definition.

Postoperative bleeding, perforation during the procedure, and delayed perforation were no significantly different in both groups, respectively.

Recurrence in group A and B were 5.6 % (n=4), 18.1 % (n=6), retrospectively (p< 0.01). All cases with lateral margin positive required additional ESD (n=2), desctructive therapy (n=3), or surgery (n=4) and no recurrence happened. No patient died of gastric cancer.

**Conclusion:** In group B, R0 resection rate was lower than group A but R0 resection in both group were not different recurrence rate with long term follow up. Carefully, undifferentiated EGC with 2 to 3 cm in a size recommended ESD.

**Disclosure:** Nothing to disclose

## P0150 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARISPROPRIA

Ryu C.B.<sup>1</sup>, Lee M.S.<sup>2</sup>, Bae J.Y.<sup>3</sup>

<sup>1</sup>Soonchunhyang University School of Medicine, Department of Internal Medicine, Bucheon, Korea (Republic of), <sup>2</sup>Soonchunhyang University College of Medicine, Department of Internal Medicine, Bucheon, Korea (Republic of), <sup>3</sup>Seoul Medical Center, Department of Internal Medicine, Seoul, Korea (Republic of)

**Contact E-Mail Address:** ryuchb@gmail.com

**Introduction:** Endoscopic resection for gastric subepithelial tumors (SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection.

**Aims & Methods:** The aims of this study were to compare endoscopic submucosal dissection (ESD) with surgical resection for the removal of GSET-PM. This study involved 17 patients with GSET-PM removed by ESD

and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound(EUS) finding.

**Results:** ESD group were more likely to have upper portion(10/17, 58.8%) and surgery group were more likely to have mid portion(41/76, 53.8%) ( $p=0.039$ ). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm,  $p=0.037$ ) and higher endoluminal ratio (58.5±9.1 % vs 45.8±15.4 %,  $p=0.002$ ). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%)( $p<0.001$ ). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%,  $p<0.001$ ). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group ( $p=0.006$ ), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two group.

**Conclusion:** ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

**Introduction:** Anastomotic leakage, which is one of the complications of surgical operations, sometimes causes a refractory fistula despite conservative therapy, including local drainage and decompression of the digestive tract. If a refractory fistula cannot be healed, a highly invasive reoperation may be performed in the end. Fistulas can occur after not only anastomotic leakage but also other situations, including cancer chemoradiation therapies (CRT). Polyglycolic acid (PGA) sheets (Neoveil; Gunze, Kyoto, Japan) with fibrin glue (Berioplast P Combi-Set; CSL Behring Pharma, Tokyo, Japan) have been reported to be useful for preventing perforations and delayed bleeding after endoscopic treatment [1,2]. Although it can be useful for closure of fistulas related to gastrointestinal cancer operation or chemoradiation therapies [3], large-scale multicenter treatment outcomes have not been reported.

**Aims & Methods:** Patients with GI fistulas endoscopically closed using PGA sheeting with fibrin glue between April 2013 and March 2018 in 18 institutions in the PGA study group, which is the affiliated study group of the Japanese Gastroenterological Endoscopy Society, were identified and retro-

spectively analyzed. Fistula is defined as the communication between the digestive tract and other areas (thoracic cavity, mediastinum, bronchus, abdominal cavity, etc.). Fistulas were filled with one or several pieces of PGA sheets followed by spraying fibrin glue using an endoscopic catheter. The procedure was repeated several times at 1- or 4-week intervals before fistula closure, and accompanied by nasal or percutaneous drainages, and endoscopic clipping as appropriate for each case.

**Results:** Fistula: Forty-five cases (hypopharyngeal/esophageal cancer 21, gastric cancer 3, pancreatic cancer 1, colon cancer 3, prostate cancer 1, and communicating organs: chest cavity 5, mediastinum 4, bronchus 10, abdominal cavity 6, and others 20) were extracted. The median fistula diameter was 5 mm (range 1-20 mm). Thirty-six cases were related with operations; and 9, with other conditions, including CRT. PGA sheets were filled at a median of 2 times (range 1-10). CRT was performed before surgery in 13 cases (29%). Infections caused by fistulas were suspected in 12 cases (22%) because pus was observed in the fistulas. Percutaneous drainage was performed in 26 cases (58%); nasal drainage, in 14 (31%); and endoscopic clipping, in 16 (36%). Complete closure was attained in 25 cases (56%). The median period until resuming diet after starting sheeting was 16 days (range 1-222 days) in the closed cases. No statistically significant differences in total protein level, fistula size, performance status, accompanying drainage, and the period between fistula occurrence and start of sheeting and fistula closure. Eleven deaths occurred, which were not related to PGA sheeting.

**Conclusion:** Endoscopic PGA sheeting can be expected to achieve conservative closure and inhibit highly invasive reoperation for more than half of fistula cases.

**Introduction:** Endoscopic submucosal dissection(ESD) is a standard treatment of intramucosal gastric neoplasms. However, still only highly skilled operators can perform ESD safe. One of those reason is that there is no proper counter-traction during procedure. Recently, our research team devised revolutive joint-based auxiliary transluminal endoscopic robot (REXTER). In this study, we evaluated the clinical feasibility of our REXTER in a live porcine model and identify the safety and efficacy of unskilled operator performing ESD.

**Aims & Methods:** We perform ESD was performed to imaginary gastric lesions in nonsurvival porcine models using our novel robotic assistive device. EAR can be mounted on GIF-Q260 endoscope and can be passed through overtube to porcine stomach, making it possible for clinical use. We divided two groups, conducted by experts and novice. We measured the time required to complete the ESD and complications involving perforation and significant bleeding in each group.

**Results:** Total 16 cases of ESD were done. 6 cases were conducted by experienced endoscopist and 10 cases by unskilled endoscopist. Procedure time between operator groups was similar. There was no significant time difference between operator group. There was no incidence of perforation and significant bleeding.

**Conclusion:** Our endoscopic assistive robot showed feasibility and its safety. Our robotic device could be helpful, especially in unskilled endoscopist.

## P0153 CLINICAL OUTCOMES OF ENDOSCOPIC INCISIONAL THERAPY FOR TREATING BENIGN ESOPHAGEAL STRICTURE: COMPARISON WITH BALLOON DILATION AND STENT PLACEMENT

Pih G.Y., Kim D.H., Na H.K., Lee J.H., Ahn J.Y., Jung K.W., Choi K.D., Song H.J., Lee G.H., Jung H.-Y.

Asan Medical Center, Gastroenterology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** lalila721@gmail.com

**Introduction:** Benign esophageal stricture has been treated with endoscopic methods including balloon dilation, stent placement. Despite these treatment modalities, recurrent refractory esophageal stricture impairs patient's quality of life. Recently endoscopic incisional therapy was reported as another treatment option for benign esophageal stricture.

**Aims & Methods:** We investigated the efficacy and safety of endoscopic incisional therapy (EIT) compared to balloon dilation (BD) and stent placement in treating benign esophageal stricture. Subjects who underwent balloon dilation, stent placement and EIT as a first-line treatment for benign esophageal stricture between January 2009 and December 2017 were eligible. Patients treated with different treatment modality from initial event for recurrent stricture were excluded. In addition, combination treatment more than two modalities concurrently were also excluded. All the patients were administered the same treatment modality as first when the stricture recurred. The medical records were retrospectively reviewed and clinical characteristics were investigated. Stricture was defined as an inability to pass a conventional endoscope.

**Results:** Of total 49 patients, 31 were in BD group, 7 were in stent group and 11 were in EIT group. There was no significant difference among three groups in median age and procedure time. Most common indications for BD group and EIT group was esophagojejunostomy anastomotic stricture, 10 patients (32.3%) and 4 patients (36.4%), respectively. In stent group, radiation therapy induced stricture of 4 patients (57.1%) was most common indication of procedure. Among three groups, there were no significant difference in re-stricture rate ( $p=0.697$ , 41.9% in BD group, 28.6% in stent group and 27.3% in EIT group) and interval to the second stricture ( $p=0.239$ , median 46 days in BD group, 215 days in stent group and 46 days in EIT group). Median follow up period was 699 days in BD group, 540 days in stent group and 395 days in EIT group. Subgroup analysis of esophagojejunostomy anastomotic stricture group showed lower recurrence rate in EIT group compared to BD group (0% vs. 30%,  $p=0.505$ ). There was no procedure related complication reported including bleeding, perforation and pneumothorax in three groups.

	Balloon dilatation group (n=31)	Stent group (n=7)	EIT group (n=11)	P value
Age (median, IQR)	62 (51-69)	61 (55-66)	67 (56-73)	0.680
Sex (male/female)	23/8	6/1	6/5	0.316
Procedure time, minutes	8 (7-12)	9 (8-15)	6 (2-14)	0.243
Restricture rate	13 (41.9%)	2 (28.6%)	3 (27.3%)	0.697
Interval to the 2nd stricture, days	46 (13-90)	215 (133-297)	46 (14-93)	0.239
Recurrence number (median, IQR)	0 (0-2)	0 (0-1)	0 (0-1)	0.589
Follow up period, days	699 (219-1752)	540 (305-774)	395 (86-552)	0.123
RT-induced stricture	2 (6.5%)	4 (57.1%)	2 (18.2%)	
Short segment stricture	25 (80.6%)	2 (28.6%)	8 (72.7%)	0.024

[Table 1. Baseline patient characteristics and treatment outcome]

**Conclusion:** EIT is a feasible, safe and effective treatment modality with acceptable long term patency for benign esophageal strictures especially in short segment stricture such as anastomotic stricture and expected to be an alternative treatment to balloon dilation or stent placement.

**Disclosure:** Nothing to disclose

## P0154 WHITE LIGHT IMAGING MORPHOLOGICAL FEATURES AND MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING FOR THE OPTICAL DIAGNOSIS OF SUPERFICIAL NONAMPULLARY DUODENAL EPITHELIAL TUMORS

Kakushima N., Yoshida M., Takizawa K., Yabuuchi Y., Kawata N., Kishida Y., Ito S., Imai K., Hotta K., Ishiwatari H., Matsubayashi H., Ono H. Shizuoka Cancer Center, Division of Endoscopy, Shizuoka, Japan

**Contact E-Mail Address:** kakushin-ky@umin.ac.jp

**Introduction:** Optical diagnosis of superficial nonampullary duodenal epithelial tumors (SNADETs) is important in guiding the treatment strategy.

**Aims & Methods:** The aim of this study was to compare the treatment outcomes based on optical diagnosis using white light imaging (WLI) morphological features and magnifying endoscopy with narrow band imaging (MNBI). We retrospectively analyzed endoscopic and pathological data on SNADETs treated at a tertiary cancer center between Feb. 2010 to Jan. 2019. We made a decision tree model for WLI and MNBI diagnosis. Optical diagnosis of high-grade dysplasia (HGD) or carcinoma with WLI were defined based on WLI scoring system (WLS) [1] as total score of 3 points or higher; 1 point for lesion diameter >10mm, heterogeneous/no lobulation, mixed type morphology/presence of depression, isochromatic, respectively, and 2 points for red color. Diagnosis of HGD/carcinoma using MNBI was based on MNBI pattern diagnosis [2]: >2 patterns of MNBI within a lesion or presence of the pattern of obscure surface structure with abnormal vessels. Ideal treatments were cold snare polypectomy (CSP) for low-grade dysplasia (LGD) < 10mm, endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) or surgery for lesions >10mm or HGD/carcinoma. We compared the ideal treatment based on optical diagnosis to actual treatment results.

**Results:** A total of 197 patients with 218 lesions who were pre-operatively diagnosed as SNADETs were included for analysis. Final histology included non-tumor 12(5%), LGD 53 (24%), HGD 20(9%), intramucosal carcinoma 124 (57%) and submucosal invasive carcinoma 9 (4%). Proportions of ideal treatment for LGD < 10mm based on WLS, MNBI and WLS with MNBI were 89%, 79% and 97%. For HGD/carcinoma, they were 89%, 90% and 96%. Diagnostic accuracy of WLS and MNBI was 84% and 80%, respectively. When the diagnosis was similar between WLS and MNBI, the accuracy was 94%.

**Conclusion:** Both WLI and MNBI were useful to select appropriate treatment for SNADETs. A high diagnostic accuracy was achieved when both WLI and MNBI showed similar results.

## P0155 CIRCULARITY IN ENDOSCOPIC ULTRASONOGRAPHY IMAGING AS A USEFUL DIAGNOSTIC INDICATOR OF GASTROINTESTINAL STROMAL TUMOURS: A RETROSPECTIVE ANALYSIS IN 51 GASTRIC CASES

Goto O.<sup>1,2</sup>, Akimoto T.<sup>1,2</sup>, Koizumi E.<sup>1</sup>, Higuchi K.<sup>1</sup>, Noda H.<sup>1</sup>, Omori J.<sup>1</sup>, Kaie M.<sup>1</sup>, Yahagi N.<sup>2</sup>, Iwakiri K.<sup>1</sup>

<sup>1</sup>Nippon Medical School, Department of Gastroenterology, Tokyo, Japan, <sup>2</sup>Keio University, School of Medicine, Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Tokyo, Japan

**Contact E-Mail Address:** o-goto@nms.ac.jp

**Introduction:** Gastrointestinal stromal tumour (GIST) should be accurately diagnosed to determine the treatment strategy for submucosal tumours (SMTs). Although endoscopic ultrasonography (EUS)-guided fine-needle aspiration is a standard option to diagnose SMTs, it is more or less invasive and less satisfactory due to technical difficulties or possible insufficient volume of specimen. Therefore, a non-interventional diagnostic method using imaging modality is still expected.

**Aims & Methods:** We hypothesise that GISTs can be distinguished from other SMTs based on the shape of the tumours in EUS images because GISTs generally appear round, whereas leiomyoma, a counterpart of differential diagnosis in gastric SMTs, appear craggy. Therefore, this study aims to investigate the potential diagnostic ability of EUS findings by using

tumour circularity. A total of 51 gastric cases with SMTs 20-50 mm in diameter, diagnosed as possible GISTs by EUS and surgically removed thereafter, were retrospectively collected at two institutions. In each lesion, one EUS still image showing the maximal area was selected, and the circularity of each lesion, a surrogate indicator of roundness calculated as four pi times the area divided by the perimeter squared ( $0-1$ ,  $1 =$  a true circle), was assessed using ImageJ (ver. 1.50e; National Institutes of Health, USA) by tracing the rim of the lesion. The mean circularity between GISTs and other SMTs were compared, and its diagnostic utility, by investigating a receiver operating characteristics (ROC) curve, as well as diagnostic accuracy were evaluated. In addition, circularity between GISTs and leiomyoma was compared as a sub-analysis.

**Results:** In 51 SMT cases, 31 GISTs were included. The mean circularity in GISTs and others were  $0.85 \pm 0.07$  and  $0.69 \pm 0.11$ , respectively, with statistical significance ( $p < 0.01$ ). In the ROC curve, a cut-off value of 0.83 with 0.91 in the area under the curve showed maximum diagnostic accuracy (84.3%), with sensitivity and specificity of 80.6% and 90.0%, respectively. The mean circularity in eight cases of leiomyomas was significantly lower than the mean circularity in GISTs ( $0.63$ ,  $p < 0.01$ ).

**Conclusion:** These retrospective data suggest that circularity calculated using EUS imaging can be used as a non-invasive diagnostic discriminator in gastric GISTs with high accuracy rate, particularly from leiomyomas. However, further prospective analysis is expected.

**Introduction:** Atrophic gastritis (AG) and intestinal metaplasia (IM) are established premalignant gastric lesions. Many studies using conventional white-light endoscopy (CWLE) documented a poor correlation between esophagogastroduodenoscopy (EGD) and histopathological (HP) findings for detection of precancerous gastric lesions. However, in daily practice, CWLE is still used.

**Aims & Methods:** Bridging the gap between endoscopy and HP in detection of chronic gastritis, AG and IM. This was a prospective single-center study involved 150 patients with endoscopic criteria of chronic gastritis, AG or IM selected from 300 patients with upper gastrointestinal symptoms who were referred for Upper GI endoscopy and met the criteria of chronic gastritis, AG or IM. They were classified into 3 groups according to HP results of gastric biopsies from targeted lesions (GI chronic non-atrophic gastritis  $n=86$ , GII AG  $n=42$  and GIII IM  $n=26$ ). Routine HP using updated Sydney system and *H.pylori* detection in gastric biopsies using Giemsa stain were done. We correlated the endoscopic criteria of chronic gastritis, AG and IM with the HP results.

**Results:** The sample included (73 males & 75 females) with ages ranged 17-75 years and mean  $\pm$  SD was  $41.96 \pm 15.95$ . GI, GII & GIII were [42 patients (28%), 82 patients (54.7%) and 26 patients (17.3%)], respectively. Smoking, DM, chronic NSIDs use, current *H.pylori* infection, and family history of *H. pylori* were highly statistically significant among the 3 groups with higher incidence of AG and IM in patients who had positive family history of *H.pylori* infection ( $p$  value  $< 0.001$ ). However, age and previous *H.pylori* therapy were not significant among the groups. We correlated the standardized endoscopic findings in each group, diffuse mottling was more common in GI (74.3%,  $P < 0.001$ ), visible submucosal vessels, atrophic mucosa and atrophic gastric folds predominated in GII (75.6, 82.3 & 73.1% ( $P$  0.005, 0.4 &  $< 0.01$ )), respectively. Whitish raised lesions were more specific in GIII (85.7%) with highly statistically significant difference between the groups ( $P < 0.001$ ). *H.pylori* was the most etiologic agent in all groups 132/150 patients (90%) ( $p < 0.001$ ). EGD could truly diagnose 36 out of 42 patients diagnosed by HP in GI, 71/82 in GII and 14/26 in GIII, the sensitivity

and specificity of endoscopic suspicion of chronic gastritis was (86 & 88% in GI), (87 & 85% in GII) and (54% & 100% in GIII) with statistically significant difference between the 3 groups ( $p < 0.001$ ). The logistic regression model for risk factors was statistically significant,  $\chi^2 = 25.74$  and  $49.32$  respectively,  $p < 0.001$ . The model explained 61.0 and 70% (Nagelkerke  $R^2$ ) of the variance in AG or IM and correctly classified 86.3, 85.3% of cases respectively. Smokers were 36.72 and 23.73 times more likely to exhibit AG or IM. Current *H. Pylori* infection was associated with an increased likelihood of exhibiting AG.

**Conclusion:** CWLE has a high sensitivity and specificity for suspicion of chronic gastritis and AG, but low sensitivity and very high specificity for IM and can be used as a bridge or an alternative to HP especially with high-definition endoscopy. Targeted biopsies with image enhanced endoscopic techniques may be more practical than updated Sydney protocol.

**Disclosure:** Nothing to disclose

## P0157 THE APPLICATION OF ARTIFICIAL INTELLIGENCE USING A CONVOLUTIONAL NEURAL NETWORK FOR DETECTING HEAD AND NECK CANCER IN ENDOSCOPIC IMAGES

**Introduction:** Head and neck squamous cell carcinoma is typically diagnosed at an advanced stage, and the prognosis for patients is poor. Recently, image-enhanced endoscopy (IEE) has become popular as a new diagnostic modality for the early detection of superficial head and neck cancer. However, it is difficult for inexperienced endoscopists to detect superficial head and neck cancer because the observation of the laryngopharyngeal sites is not a standard procedure with esophagogastroduodenoscopy. Image recognition using artificial intelligence (AI) with deep learning through convolutional neural networks (CNNs) has dramatically improved and been applied increasingly frequently to medical fields for diagnostic imaging.

**Aims & Methods:** The aim of this study is to investigate the utility of AI for diagnosing head and neck cancers. A CNN-based diagnostic system was constructed based on the Single Shot MultiBox Detector architecture and trained using 5163 endoscopic images of laryngopharyngeal cancer. To evaluate the diagnostic accuracy, an independent test set of 1775 laryngopharyngeal images collected from 68 consecutive patients with 75 laryngopharyngeal cancer lesions was applied to the constructed CNN.

**Results:** The CNN correctly diagnosed 72 of 75 laryngopharyngeal cancer lesions with an overall accuracy of 91.4%, and 4 of 6 non-cancerous lesions were diagnosed as benign. The two missed benign lesions were papilloma and lymphoid follicles. The three missed malignant lesions were superficial hypopharyngeal cancer ( $n=2$ ) and laryngeal cancer ( $n=1$ ). The sensitivity, specificity, positive predictive value, and negative predictive value in terms of the lesions were 96.0%, 66.7%, 97.3%, and 57.1%, respectively, and the accuracy, sensitivity, and specificity in terms of the endoscopic images were 83.0%, 83.3% and 79.2%, respectively. The CNN required 47 seconds to analyze 1775 test images.

**Conclusion:** This CNN system for detecting laryngopharyngeal cancer was able to process numerous stored endoscopic images in a very short time with clinically relevant diagnostic ability. It may be applicable to daily clinical practice, where it can help reduce the burden on endoscopists.

**Disclosure:** Nothing to disclose

## P0158 ENDOSCOPIC GRADING OF GASTRIC INTESTINAL METAPLASIA (EGGIM) USING NARROW BAND IMAGING ENDOSCOPY WITH NON-MAGNIFIED AND MAGNIFIED OBSERVATION

**Contact E-Mail Address:** dq8m-kwmr@asahi-net.or.jp

**Introduction:** Gastric intestinal metaplasia (GIM) is known to associated with a risk of gastric cancer. Recent studies suggest the endoscopic findings with narrow band imaging (NBI) (light-blue crest (LBC), white opaque substance (WOS)) correlate to histological GIM, and are useful markers for a cancer risk according to the classification of endoscopic grading of GIM (EGGIM). However LBC, WOS are originally reported under magnified endoscopic observation, it is unknown the difference in classifying EGGIM between non-magnified NBI (non-M-NBI) and magnified NBI (M-NBI) observation.

**Aims & Methods:** To investigate the difference in classifying EGGIM between non-M-NBI and M-NBI observation, 100 consecutive patients who underwent NBI endoscopy were enrolled. Helicobacter pylori (HP) infection and the endoscopic grading of gastric atrophy were investigated. Using a high resolution endoscopy (Model GIF-H260Z or H290Z, OLYMPUS Co.), four areas in each stomach (greater and lesser curvature in each corpus and antrum) were evaluated under non-M-NBI and M-NBI (with moderate-high magnification) observation. The presence of LBC and WOS were defined into three groups (score 0 (none), 1 (focal,  $\leq 30\%$ ), or 2 (extensive,  $>30\%$ )). Furthermore, using the combination of presence of LBC, WOS, or tubulo-villous pattern, endoscopic GIM score was classified according to above three groups. Resulting from the sum of endoscopic GIM score in each of the four areas, EGGIM was defined into stage 0/I/II/III/IV according to total score 0/1-2/3-4/5-6/7-8. The concordance rate and the weighted kappa value of LBC, WOS and EGGIM were analyzed between non-M-NBI and M-NBI observation.

**Results:** Fifty-nine patients were defined as present positive for HP infection, 20 were past infected, 21 were uninfected subjects. Endoscopic grading of atrophy were none-mild in 46 patients, moderate in 38 and severe in 16. Of total evaluated 400 areas, LBC score 0, 1 and 2 were found in 202 (50.5%), 148 (37.0%) and 50 (12.5%) areas with non-M-NBI, while 223 (55.7%), 131 (32.8%) and 46 (11.5%) areas with M-NBI observation, respectively. WOS score 0, 1 and 2 were found in 315 (78.7%), 53 (13.3%) and 32 (8.0%) areas with non-M-NBI, while 322 (80.4%), 47 (11.8%) and 31 (7.8%) areas with M-NBI observation, respectively. Several cases with whitish mucus or marginal of tubulo-villous surface structure (marginal turbid band (MTB)) were misdiagnosed as presence of LBC with non-M-NBI. The concordance rate between non-M-NBI and M-NBI were 75.8% in LBC score and 94.5% in WOS score. The strength of agreement showed good reproducibility between non-M-NBI and M-NBI observation (weighted kappa value of 0.77 in LBC score and 0.90 in WOS score). The EGGIM were classified as follows: stage 0, I, II, III and IV were 18, 26, 26, 21 and 9 patients with non-M-NBI, while 27, 21, 32, 15 and 5 patients with M-NBI, respectively. Several cases with a discordance in the EGGIM were found because of difference in a capability of evaluated field between non-M-NBI and M-NBI observation. The concordance rate of EGGIM were 76%, and the weighted kappa value showed substantial agreement with 0.72 between non-M-NBI and M-NBI observation.

**Conclusion:** Using high resolution NBI endoscopy, non-M-NBI and M-NBI observation showed good agreement on evaluation of the endoscopic findings associated with GIM (LBC, WOS, EGGIM). Non-M-NBI observation for EGGIM, with capability of a wide range view, may have a similar potential for assessment of an individual risk of gastric cancer as M-NBI observation.

## P0159 PREVENTIVE EFFECT OF PPIS ALONE, PPIS PLUS CYTOPROTECTIVE AGENT, AND H2RA PLUS CYTOPROTECTIVE AGENT ON BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

Lee J.Y., Jang J.S.  
Dong-A University, Gastroenterology, Busan, Korea (Republic of)

**Contact E-Mail Address:** ljyhateo@gmail.com

**Introduction:** ESD is the most effective treatment for early gastric cancer or gastric adenoma. However, the major complication of ESD is postoperative bleeding from ulcers after the procedure.

**Aims & Methods:** This study aimed to evaluate the preventive effect of using a proton pump inhibitor (PPI) alone, a PPI+rebamipide combination therapy, and an H2 receptor antagonist (H2RA)+rebamipide combination therapy on bleeding after endoscopic submucosal dissection (ESD).

In total, 210 patients who underwent ESD from April 2015 to July 2016 in Dong-A University Hospital were randomly assigned to the PPI-alone therapy group, the PPI+rebamipide combination therapy group, or the H2RA+rebamipide combination therapy group. We excluded patients who were lost to follow-up or who had diagnoses other than early gastric cancer or gastric adenoma. Twenty-eight days after ESD, we evaluated the ulcer bleeding ratio, gastric pH, ulcer residual ratio, and ulcer stage.

**Results:** This study included 149 patients (PPI-alone group: 43 patients, PPI+rebamipide group: 61 patients, H2RA+rebamipide group: 45 patients). The post-ESD bleeding ratio was not significantly different among the three groups ( $p=0.264$ ). The ulcer residual ratios were  $34.5\pm 21.4\%$ ,  $24.8\pm 18.8\%$ , and  $27.6\pm 20.2\%$  in the PPI alone, PPI+rebamipide, and H2RA+rebamipide groups, respectively ( $p=0.05$ ).

**Conclusion:** There was no difference in delayed bleeding after ESD among the PPI-alone, PPI+rebamipide, and H2RA+rebamipide groups at 28 days; however, PPI+rebamipide was significantly more effective in reducing the ulcer residual ratio.

**Disclosure:** Nothing to disclose

## P0160 OPPORTUNISTIC DETECTION OF OESOPHAGOGASTRIC NEOPLASTIC AND PRE-NEOPLASTIC LESIONS DURING SCREENING COLONOSCOPY PROGRAM - A WORTHWHILE STRATEGY?

Lau W.L.L.<sup>1</sup>, Khoo M.J.W.<sup>2</sup>, Leong X.H.<sup>2</sup>, Lim T.Z.<sup>3</sup>, Shabbir A.<sup>4</sup>, Yeoh K.-G.<sup>5</sup>, Koh C.J.<sup>5</sup>, So J.B.Y.<sup>4</sup>

<sup>1</sup>National University Hospital, General Surgery, Singapore, Singapore, <sup>2</sup>Yong Loo Lin School of Medicine, Singapore, Singapore, <sup>3</sup>National University Hospital, Singapore, Singapore, <sup>4</sup>National University Health System, Department of Surgery, Singapore, Singapore, <sup>5</sup>National University Health System, Division of Gastroenterology & Hepatology, Singapore, Singapore

**Contact E-Mail Address:** joellauwenliang@hotmail.com

**Introduction:** Endoscopic screening for colon cancer is generally accepted for screening for colorectal cancer, whereas endoscopic screening for oesophagogastric (EG) cancer alone is not cost-effective in countries with low to intermediate incidence of gastric cancer. The utility of offering an opportunistic upper endoscopy during a screening colonoscopy was evaluated as a potential strategy for detection of early EG neoplastic and pre-neoplastic lesions.

**Aims & Methods:** A retrospective review of a prospective database in a tertiary hospital was performed. Patients with age  $>40$  who underwent opportunistic screening upper endoscopy and colonoscopy in the same session from January 2015 to December 2017 were included. Patients who underwent upper endoscopy for indications such as dyspepsia, weight loss and anaemia were excluded. EG neoplastic lesions were defined as EG carcinomas, and pre-neoplastic lesions were defined as Barrett's oesophagus, intestinal metaplasia (IM), or atrophic gastritis.

**Results:** Out of 9,566 patients who underwent simultaneous upper endoscopy and colonoscopy, we identified 1,414 patients who underwent screening upper endoscopy. On colonoscopy, 491 (34.7%) patients had adenomatous polyps detected, and colorectal malignancy was detected in 20 patients (1.4%).

From our cohort, 179 (12.7%) patients undergoing opportunistic screening upper endoscopy had EG neoplastic and pre-neoplastic lesions. Of these, IM was found in 146 (10.3%) patients with 112 (7.9%) focal IM while 21 (1.4%) had extensive IM. Atrophic gastritis was detected in 23 (1.6%) patients. Also, 19 (1.3%) patients were found to have Barrett's oesophagus

with one high-grade dysplasia which was resected endoscopically. Early stage gastric cancers were diagnosed in three patients (0.2%) who underwent surgery. Two were T1bN0 and one was T2N0. Another patient was diagnosed with early MALT lymphoma.

On multivariate regression, independent risk factors for upper GI neoplastic and pre-neoplastic lesions in this population include age > 50 (Risk Ratio (RR) 2.18, 95%CI 1.15 - 4.14),  $p = 0.018$  and having a family history of first-degree relative with gastric cancer (RR 1.60, 95% CI 1.03 - 2.48,  $p = 0.035$ ).

Hence, using this strategy, the number needed to detect an incidental neoplastic or pre-neoplastic EG lesion is 7.90. At a cost of USD\$500/upper endoscopy, it would cost \$3950 per lesion detected.

Patient Group	Number Needed to Scope	Cost per diagnosis (\$USD)
All opportunistic OGDs	7.90	3,950
Age above 50	7.42	3,710
Family History of Gastric Cancer (1st Degree)	5.65	2,825
Any one risk factor	7.74	3,870

[Table 1]

**Conclusion:** This observational cohort suggests the potential utility of incorporating upper endoscopy into an established screening colonoscopy program, for the purpose of detecting EG neoplastic and pre-neoplastic lesions in countries with intermediate risk. All pathologies detected are early lesions. In addition, this strategy may be more acceptable to patients as they are already planned for colonoscopy. Further studies are worthwhile to verify these observations.

## P0161 PERORAL ENDOSCOPIC MYOTOMY AS RESCUE-THERAPY AFTER INEFFECTIVE HELLER MYOTOMY: A SINGLE CENTRE RETROSPECTIVE EXPERIENCE

Quarta Colosso B.M., Shimamura Y., Ikeda H., Abad M.R.A., Nishikawa Y., Ueno A., Tanabe M., Sumi K., Tomida H., Onimaru M., Inoue H.  
Showa University Koto Toyosu Hospital, Digestive Diseases Center, Tokyo, Japan

**Contact E-Mail Address:** quarta.colosso@gmail.com

**Introduction:** Heller Myotomy has been the treatment of choice for patients with achalasia for the past decades. Since 2008, Peroral Endoscopic Myotomy (POEM) has demonstrated excellent outcome and became the primary form of minimally invasive treatment in many centers. Although Heller myotomy is still being performed worldwide with excellent results, there are patients who are refractory to the surgical procedure.

**Aims & Methods:** The aim of this study is to assess the safety and efficacy of POEM as a rescue therapy in those cases in which Heller myotomy was not effective. This is a retrospective study from a prospective database in a tertiary referral single center from April 2015 to April 2019. All patients included in the study had undergone POEM after ineffective Heller myotomy. All underwent gastroscopy, barium esophagogram, and high resolution manometry, as well as CT Scan to rule out obstructive lesions at the junction prior to POEM. The approach during POEM was either anterior or posterior depending on patient's anatomy and scar of surgical myotomy. To rate the effectiveness of the procedure, we used Eckardt score and Satisfaction scale (a numeric scale from 1 to 10, 10 to express maximum satisfaction) upon second month follow up. Symptomatic patients were defined as those with Eckardt score  $\geq 3$  or those who complained of high intensity symptoms even with Eckardt score  $< 3$ . Outcome measures were as follows:

1. Clinical Success: post-POEM Eckardt score  $< 3$  or Satisfaction scale  $\geq 7$ ;
2. Technical Success: complete execution of myotomy;
3. Major Adverse Events: vital-sign instability, intensive care unit (ICU) stay, hospital readmission, conversion to open surgery, invasive postoperative procedure, blood transfusion, or prolonged ( $> 5$  days) hospitalization for functional impairment.

**Exclusion Criteria:** patients who did not present for routine second month follow-up post POEM.

**Results:** Thirty-six patients underwent POEM after ineffective Heller myotomy. Three patients were excluded because of exclusion criteria and a total of 33 patients were analyzed. Twenty-two patients had laparoscopic approach and 11 patients with open approach in previous Heller myotomy.

Thirty patients presented with Eckardt score  $> 3$  and 4 patients had high intensity symptoms. Based on Modified Chicago Classification, the type of achalasia seen were as follows: Type I/II/III = 21/2/2, and 8 unclear cases. We distinguished Straight Type from Sigmoid Type (1 vs 32) based on barium esophagogram.

All cases achieved Technical Success. Clinical Success was observed in 81.8% of patients. Eckardt score and Satisfaction scale were as follows: Eckardt score  $< 3$  in 23 patients (69.6%),  $\geq 3$  in 2 patients (6.0%), and  $> 3$  in 7 patients (21.2%), Unknown in 1 patient (3.0%). Satisfaction scale  $\geq 7$  in 19 patients (57.5%),  $< 7$  in 2 patients (6.0%), Unknown in 12 patients (36.3%). No patients experienced Major Adverse Events. There were few cases with discrepancy in Eckardt score and Satisfactory scale: 2 patients with Eckardt score = 3 and Satisfaction scale = 9, 1 patient with Eckardt score = 4 and Satisfaction scale = 7, 1 patient with Eckardt score = 2 with Satisfaction scale = 6.

**Conclusion:** According to our study, POEM can be considered a safe and effective rescue therapy in symptomatic patients with prior history of surgical myotomy. In addition, there seems to be no differences in risks in performing POEM after either laparoscopic or open Heller myotomy and clinical success was achieved in majority of patients.

**Disclosure:** Inoue H is an advisor of Olympus Corporation and Top Corporation. He has also received educational grants from Olympus Corp., and Takeda Pharmaceutical Co. All other authors have no conflict of interests to declare.

## P0162 ESOPHAGEAL CLEANSING BEFORE POEM - A SIMPLE AND EFFECTIVE TECHNIQUE

Desai P.N.<sup>1</sup>, Kabrawala M.V.<sup>2</sup>, Patel C.<sup>3</sup>

<sup>1</sup>Surat Institute of Digestive Sciences, Endoscopy, Surat, India, <sup>2</sup>Surat Institute of Digestive Sciences, Gastroenterology, Surat, India, <sup>3</sup>Surat Institute of Digestive Sciences, Surat, India

**Contact E-Mail Address:** drp\_desai@hotmail.com

**Introduction:** Pre - procedural preparation varies from center to center. No standard method prescribed.

Conventionally, patients are put on clear liquids for 48 to 72 hours pre POEM. Then an endoscopic lavage is given the previous day. This is very cumbersome and we need a better less cumbersome preparation method

**Aims & Methods:** To devise a simple yet effective method for pre-procedural preparation for poem.

**Methods:** 100 cases between 2017 and 2019 with Achalasia Cardia were included. A Pre POEM Score for the condition of oesophageal mucosa was devised.

### Pre POEM Score:

Grade 1: Clean esophagus

Grade 2: Presence of fluid and froth + crumpled / puckered but normal mucosa

Grade 3: Presence of fluid and froth, no food residue + intermittent esophageal candidiasis

Grade 4: Presence of fluid and froth with minimal food residue +/- esophageal candidiasis

Grade 5: Extensive food residue with candidal infection

Patients divided in two groups: A and B

Group A: 50 patients: Prepared with 48 hours clear liquids, 24 hours nil orally and endoscopic lavage the day before.

Group B: Our new preparation. Warm water and a carbonated drink alternately every 15 to 20 minutes for 12 hours prior to 6 hours before the procedure. No pre procedure lavage.

To assess anesthesia aspiration risk, while intubation in POEM, we devised an 'Anesthesia Risk Score'

1. Normal risk with no fluid regurgitation
2. Minimal fluid regurgitation requiring suction once
3. Significant fluid regurgitation requiring continuous suction
4. Food and fluid regurgitation needing emergency measures

Using this we compared Group A and B in terms of requirement of lavage - procedure time

- anaesthesia aspiration risk
- Length of hospital stay
- adverse events and
- cost effectiveness

**Results:** In the patients who had Grade 2 and Grade 3 pre-POEM score, the lumen clearance at the time of POEM procedure was found to be optimum in both the groups

- In patients with Grade 4 score
- Group A : two patients required additional wash prior to POEM
- Group B : all patients had good luminal clearance
- In patients with Grade 5 score
- Group A: all four patients required an additional wash prior to POEM
- Group B: one of the patients required wash prior to POEM.
- All patients had successful esophageal clearance with both approaches.
- Group B patients had
- Avoidance of an additional endoscopic procedure for esophageal lavage
- Decreased risk of aspiration.
- Decreased exposure to anesthesia/ sedation.
- Decrease in the total POEM procedure time
- Total cost to the patient was significantly decreased
- Duration of the hospital stay was reduced

**Conclusion:** The new simple protocol of giving warm water and a carbonated drink just 12 hours before keeping the patient nil orally for anaesthesia

- reduces the starvation time for the patient to 6 hours and hence, improves compliance.
- reduces one more procedure for esophageal lavage
- reduces the anaesthesia risk of aspiration during induction
- reduces the exposure to anaesthesia
- and reduces the hospital stay and is cost effective

We can have a randomised trial to prove the effectiveness of this simple protocol in a larger study.

Characteristics	Group A	Group B
Duration Of Symptoms, Median, months	4(1-60)	6(1-60)
Mean IRP mm Hg (Median)	17.6 (10.4-52.2)	24.2 (12.4- 65.6)
Type I Achalasia; n (%)	22 (44)	35 (70)
Type II Achalasia; n (%)	18 (36)	10 (20)
Type III Achalasia; n (%)	10 (20)	5 (10)
Grade I Mucosa; n (%)	14 (28)	12 (24)
Grade II Mucosa; n (%)	13 (26)	21 (24)
Grade III Mucosa; n (%)	13 (26)	21 (42)
Grade IV Mucosa; n (%) Gr V; n (%)	6 (12) 4 (8)	7(12) 4 (8)

**Contact E-Mail Address:** rui.magalhaes.med@gmail.com

**Introduction:** Gastric cancer is a major health concern worldwide, with significant morbidity and mortality rates. In western society, screening remains controversial regarding cost-efficiency issues. NBI (narrow-band-imaging) is a virtual chromoendoscopy tool that has been associated with higher detection of gastric premalignant conditions in comparison with white-light endoscopy (WLE). Endoscopic grading of gastric intestinal metaplasia (EGGIM) is a NBI grading score for metaplasia.

**Aims & Methods:** Assess the correlation between NBI and histological diagnosis of gastric dysplasia.

Retrospective, single center study, including consecutive patients that underwent upper endoscopy complemented with NBI for gastritis surveillance, from October 2016 to Jan 2019. Our cohort was analyzed by descriptive, parametric and non-parametric SPSS tools.

**Results:** We included 71 upper endoscopies complemented with NBI evaluation, 40 men (56.3%) with a mean age of 62 years old. Gastric dysplasia was detected, histologically, in 23 cases (32.4%).

The correlation between NBI targeted biopsies and histological findings was statistically significant ( $p < 0.001$ ) with a Kappa coefficient of 0.81.

EGGIM was associated with an increase of NBI diagnosis of dysplasia (odds 1.384;  $p=0.025$ ). However, as EGGIM increases the odds of correlation between NBI and histological dysplasia decreases in 42% (odds 0.58;  $p = 0.041$ ).

We report 15 gastric non polypoid lesions (Paris classification 0-IIa, 0-IIb and 0-IIc). Applying NBI, we established a concordance with histological dysplasia diagnosis of 100%.

**Conclusion:** NBI targeted biopsies presented a statistically significant correlation with histological findings, acknowledging an almost perfect agreement with a Kappa coefficient of 0.81. Applying NBI on non-polypoid lesions identified in WLE increases the rate of histological concordance, we report a 100% concordance. NBI is an accurate tool that, in the hands of experienced endoscopists, can lead to an easy identification of gastric dysplasia, with high concordance with histological findings.

## P0164 ENDOSCOPIC SUBMUCOSAL DISSECTION OF THE OESOPHAGUS AND OESOPHAGOGASTRIC JUNCTION FOR EARLY NEOPLASIA: WILL IT BE THE FUTURE?

Félix C., Mendo R., Pereira I., Rodrigues J.P., Barreiro P., Chagas C. Centro Hospitalar Lisboa Ocidental, Gastroenterology, Lisbon, Portugal

**Contact E-Mail Address:** sfelixcatorina@gmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) is an endoscopic technique widely employed in Asia for resection of oesophagus and oesophagogastric junction (EGJ) neoplasms. In the West, ESD of these locations is limited to a very few centres.

**Aims & Methods:** This study aims to report the feasibility, safety and effectiveness of ESD for the treatment of oesophagus and EGJ early neoplasms in a Western centre.

We conducted a prospective data analysis of all consecutive oesophageal and EGJ lesions treated by ESD from October 2014 to November 2018. Location, en bloc, pathological complete resection (R0) and curative rates, procedure time, complications and local recurrence were evaluated.

**Results:** Thirty lesions were included from 28 patients (65-year-old [39-84]; M/F=23/5): 9 squamous cell neoplasms, 6 neoplasms in Barrett's oesophagus, 12 gastric cardia neoplasms, 2 granular cell tumours and 1 oesophageal papilloma (proximal oesophagus n=3, medial oesophagus n=8, distal oesophagus n=6, EGJ n=13). The median size of the resected specimen was 42mm (12-88). En bloc resection was achieved in all resected lesions (29/29; 1 resection was considered non-feasible due to invasion detected during the procedure). Circumferential dissection was performed in 6/29 lesions (21%). R0 was accomplished in 24/29 (83%) and resection was considered curative in 19/29 (66%). Reasons to non-curative resection were: poorly differentiated cardiac gastric adenocarcinoma (n=1), R1 (n=1), deep submucosal invasion (n=6) and Rx (n=2). There were no immediate complications such as bleeding or perforation; in the curative resected group, stenosis was diagnosed in 1 patient submitted to a circumferential resection and was managed endoscopically. No recurrence was observed within a mean follow-up of 18 months (3-53).

**Conclusion:** This study represents one of the largest series of oesophageal and EGJ ESD in the West. Although representing the initial experience, ESD for oesophageal and EGJ lesions was efficient and extremely safe.

## P0165 A STUDY OF IMPROVING IMAGE PROCESSING TO REDUCE COLOR NOISES IN OXYGEN SATURATION IMAGING ENDOSCOPY

Nishihara K.<sup>1</sup>, Hori K.<sup>1</sup>, Saito T.<sup>2</sup>, Omori T.<sup>2</sup>, Yoda Y.<sup>1</sup>, Sunakawa H.<sup>1</sup>, Minamide T.<sup>1</sup>, Suyama M.<sup>1</sup>, Yamamoto Y.<sup>1</sup>, Shinmura K.<sup>1</sup>, Ikematsu H.<sup>1</sup>, Yano T.<sup>1</sup>

<sup>1</sup>National Cancer Center Hospital East, Gastroenterology and Endoscopy, Kashiwa, Japan, <sup>2</sup>Imaging Technology Center, FUJIFILM Corporation, Tokyo, Japan

**Contact E-Mail Address:** kenishih@east.ncc.go.jp

**Introduction:** Oxygen saturation (OS) imaging (FUJIFILM Corporation, Tokyo, Japan) is a novel endoscopic technology which can directly measure the tissue oxygen saturation (Sto2) of the surface of gastrointestinal tract

without any additional drugs or devices. Its principle is recognizing the difference in optical absorption spectra between oxy- and deoxy-hemoglobin by emitting two kinds of lasers from endoscopy. This imaging technology is expected to contribute to research into cancer biology which leads to clinical benefit such as prediction to efficacy of chemotherapy or radiotherapy. OS imaging supply the StO<sub>2</sub> mapping in real time, however, the measurement of StO<sub>2</sub> is difficult in some cases of advanced gastrointestinal cancer due to covered blood or necrotic tissue.

Therefore, the algorithm for discrimination between tumors and noises due to blood or necrotic tissue on tumors is necessary to measure the precise StO<sub>2</sub> in OS imaging.

**Aims & Methods:** To construct the algorithms for discriminating between tumors and its adhered substances using white light imaging (WLI) of gastrointestinal cancer, and validate the utility of it in OS imaging.

We classify color of tumors and its adhered substances in WLI into following 2 classes of 4 types (red points: red tumors (83 points) and blood (68 points); white area: white tumors (79 points) and white coat (89 points)), and plotting is made at each place in 50 endoscopic tumor images in upper digestive tract. As a result, we create scatter diagram using color data (RGB value) in WLI, which its X axis is  $\ln(R/G)$  value and Y axis is  $\ln(B/G)$  value. The minimum and maximum value of the X and Y axes of each classes, and linear function as discriminating algorithm for each types of areas is constructed by calculating scatter diagram to adjust color noises. Discriminating algorithms are verified by using validation datasets prepared separately from 15 images out of 50 images in this study, and classified each datasets into tumor and color noises. In addition, the comparison of StO<sub>2</sub> value of the tumors and that of its adhered substances is conducted in the images of gastrointestinal tumors captured using OS imaging.

**Results:** We randomly selected 50 cases consisting of advanced gastric cancer (n=30) and advanced esophageal cancer (n=20) who are simultaneously evaluated with WLI and SO imaging, and images are analyzed. The calculated algorithms for each areas were as follows: algorithm for red area;  $0.388 \leq x \leq 2.610$ ,  $-0.842 \leq y \leq 0.157$ ,  $Y < 0.77X - 1.440$ ; algorithm for white area;  $0.119 \leq x \leq 1.079$ ,  $-0.577 \leq y \leq 0.172$ , and  $Y < -0.32X + 0.10$ . In validation datasets of 15 images, each algorithms showed the discriminating accuracy between noise due to ad and tumor in red and white area of 87.8% and 86.0%, respectively.

The analysis resulted that StO<sub>2</sub> values (median, [range]) of the area recognized as tumor and adhered substances by algorithms are follows: all captured red area; 75.9%, [44.6-100.0], red adhered substances; 77.6%, [44.6-100.0], red tumor; 74.9%, [62.0-86.9], all captured white area; 66.1%, [42.1-100.0], white adhered substances; 71.4%, [42.1-100.0], white tumor; 64.8%, [54.2-71.4]. Analysis of StO<sub>2</sub> revealed that the values of tumors except for adhered substances were distributed more specific comparing with that of whole tumor.

**Conclusion:** The algorithm for discriminating between tumors and its adhered substances based on the annotated information using WLI can be useful for precisizing StO<sub>2</sub> measurement of gastrointestinal cancer in OS imaging.

## P0166 COMPARISON BETWEEN ENDOSCOPIC BAND LIGATION AND ARGON PLASMA COAGULATION FOR THE TREATMENT OF GASTRIC ANTRAL VASCULAR ECTASIA: A SYSTEMATIC REVIEW WITH META-ANALYSIS

Cubisino R.<sup>1</sup>, Losurdo G.<sup>1</sup>, Scalisi G.<sup>2</sup>, Perri F.<sup>3</sup>

<sup>1</sup>University of Bari, Section of Gastroenterology, Dept. Emergency and Organ Transplantation, Bari, Italy, <sup>2</sup>Presidio Osp Garibaldi Nesima, Gastroenterology, Catania, Italy, <sup>3</sup>Casa Sollievo della Sofferenza Hospital, Gastroenterology, San Giovanni Rotondo, Italy

**Contact E-Mail Address:** rossellacubisino@gmail.com

**Introduction:** Gastric antral vascular ectasia (GAVE) is a condition characterized by diffuse mucosal vascular ectasia causing chronic gastrointestinal blood loss and anemia. It is more common in patients with cirrhosis as well as chronic kidney disease, hematologic malignancies, scleroderma, systemic lupus erythematosus and other autoimmune diseases. Since GAVE is a cause of anemia in the above mentioned chronic illnesses, it is important to ensure a treatment that may reduce the morbidity related to GAVE in such patients. Argon plasma coagulation (APC) is one of the

most widespread endoscopic technique for GAVE, however endoscopic band ligation (EBL) has gained increasing interest. Therefore we aimed to perform a meta-analysis of studies comparing EBL versus APC.

**Aims & Methods:** A literature search was performed in February 2019 using the following string: (GAVE OR gastric antral vascular ectasia OR watermelon stomach AND band ligation AND APC). We selected only studies in which a direct comparison of EBL and APC was performed. For dichotomic variables, odd ratios (OR) and 95% confidence intervals (95% CI) were calculated according to the Mantel-Haenszel method. For continuous variables we calculated mean differences (MD). Heterogeneity was estimated by chi-square test and, if present, a random effect model was chosen, otherwise a fixed effect model was used. Statistical significance was set at  $p < 0.05$  and the RevMan 5.3 software was used. All procedures followed PRISMA guidelines.

**Results:** Five studies were selected, enrolling overall 207 patients (93 EBL and 114 APC). Pooled effectiveness of EBL was 91.4%, statistically greater than 57.9% of APC (OR=8.4; 95% CI 3.45-20.43;  $p < 0.001$ , no heterogeneity, fixed effect). Complication rate was 27.2% and 13.0% for EBL and APC respectively, not statistically different (OR=3.09,  $p=0.28$ ). EBL allowed a fewer number of endoscopy sessions than APC with a  $p$  value close to significance (MD=-1.28 95% CI -2.62-0.05;  $p=0.06$ ). With EBL, the mean number of transfused blood units was lower than for APC (MD=-1.55; 95% CI -3 to -0.09;  $p=0.04$ ; random effect for high heterogeneity). Post-treatment hemoglobin levels were higher in the EBL group than in APC group (MD=0.43; 95% CI 0.11-0.75;  $p=0.009$  fixed effect, no heterogeneity) and, in comparison to baseline hemoglobin, EBL showed a significantly higher increase in levels than APC ( $p=0.02$ ).

**Conclusion:** EBL was more effective than APC in treating GAVE since a better control of anemia, a fewer number of red cell transfusions, and a higher rise in hemoglobin levels were achieved. A non significant trend showed that less endoscopic sessions were required with EBL which could be proposed as a potential cost-effective modality compared to APC. However, the low number of patients enrolled in this analysis prompts the development of further randomized trials aiming to evaluate EBL and APC for GAVE treatment.

## P0167 ROBOT CONTROLLED MAGNET-ASSISTED CAPSULE GASTROSCOPY IS BETTER TOLERATED AND ACCEPTED BY PATIENTS THAN FLEXIBLE GASTROSCOPY

Tai F.W.D.<sup>1</sup>, Ching H.L.<sup>1</sup>, McAlindon M.<sup>2</sup>

<sup>1</sup>Royal Hallamshire Hospital, Academic Unit of Gastroenterology and Hepatology, Sheffield, United Kingdom, <sup>2</sup>Royal Hallamshire Hospital, Dept. of Gastroenterology, Sheffield, United Kingdom

**Contact E-Mail Address:** david.tai@nhs.net

**Introduction:** Gastroscopy is performed commonly but often poorly tolerated. Capsule endoscopy is well tolerated. Robot controlled magnet assisted capsule endoscopy (MACE) allows control of a capsule endoscope resulting in a non-invasive endoscopic examination of the upper GI tract. No controlled comparisons of patient tolerance and acceptability between MACE and gastroscopy have been performed. Post procedure Endoscopy Concerns Scale (ECS) scores correlate with patient acceptance after gastroscopy [Condon 2008, Can J Gastro]. We assess tolerance and acceptability of MACE compared to OGD using the ECS.

**Aims & Methods:** Patients referred for the endoscopic investigation of dyspepsia were recruited. Upper GI MACE examinations were performed followed by oral or transnasal gastroscopies. Questionnaires examined patients' tolerance to and acceptability of the endoscopies. Paired differences between median distress and ECS scores are reported ( $p < 0.0001^{***}$ ,  $p < 0.01^{**}$ )

**Results:** Thirty eight (oral n=33, transnasal n=5) patients were recruited (median age 50, female 74%, sedated in 36.4% of oral gastroscopy). All patients tolerated MACE adequately with minimal discomfort in 16%. Gastroscopy was adequately tolerated in 63% with the remaining reporting moderate or severe discomfort. There was less distress (1 - 10: not at all - extremely) caused by: discomfort during (1 vs 5<sup>\*\*\*</sup>), discomfort after (1 vs 2<sup>\*\*\*</sup>) and pain during (1 vs 2<sup>\*\*\*</sup>) the procedures, gagging (1 vs 6<sup>\*\*\*</sup>), choking (1 vs 4.5<sup>\*\*\*</sup>), bloating (1 vs 2<sup>\*\*</sup>) and swallowing the capsule vs. insertion of the scope (1 vs 4<sup>\*\*\*</sup>) with MACE compared to gastroscopy. The overall pre-procedure ECS score (28 vs 50 points<sup>\*\*\*</sup>) and post-procedure ECS score (13 vs 32 points<sup>\*\*\*</sup>) was lower after MACE compared to gastroscopy.

copy suggesting patients are more accepting of MACE before and after the procedure compared to gastroscopy. There was a reduction in pre-procedure ECS after both MACE (median difference -15 \*\*\*) and gastroscopy (-18 \*\*\*) suggesting procedures are not as distressing as initially anticipated, however 32% of patients report a higher ECS after gastroscopy whereas all patients reported a lower ECS after MACE.

All patients would undergo, or advise a friend to undergo MACE again given the same medical circumstances compared to 71% and 79% of patients when undergoing gastroscopy. All patients would have MACE as a screening test for cancer compared to 79% of patients when undergoing gastroscopy. If biopsies were required after MACE, patients would require a further gastroscopy. When asked, in retrospect after having both procedures, if the chance of requiring biopsies was 1:20, 1:10, 1:5, 1:4 and 1:2, 91%, 91%, 82%, 73% and 73% of patients respectively would prefer to have initial MACE.

**Conclusion:** Patients better tolerate, are more accepting of and prefer MACE over gastroscopy. Where biopsies are required, patients would still prefer capsule endoscopy initially. Cost effectiveness of this approach should be examined.

**Contact E-Mail Address:** giulio.antonelli@gmail.com

**Introduction:** Endoscopic ultrasound (EUS)-guided gastro-enteric anastomosis using lumen-apposing metal stents (LAMS) is emerging as an alternative, minimally invasive therapy for treating gastric outlet obstruction (GOO), as well as restoring bowel continuity in patients with surgically altered anatomy. Literature on this subject is heterogeneous, with variable reporting of techniques and outcomes.

**Aims & Methods:** Our aim was to perform a meta-analysis of published data on EUS-guided enteric anastomosis, providing a pooled estimate of technical and clinical outcomes.

The protocol was registered in PROSPERO (Reg. no. CRD42018111110). PubMed, Embase, Scopus, and Web of Science databases were searched until February 2019 for studies describing at least 5 patients undergoing EUS guided enteric anastomosis. Screening of titles/abstracts, full-text review, and data extraction was performed independently by two of the authors. Data regarding indication, technique, technical and clinical success, adverse events, and follow-up were collected. PRISMA methodology was used. Pooled technical and clinical success rates as well as pooled adverse events rates were calculated. Study quality, publication bias, and heterogeneity were explored.

**Results:** Twelve studies including 290 patients were included, published between 2016 and 2019. All studies but one were retrospective. The main procedure indication was GOO (62.4%), followed by need for ERCP (27.9%) in patients with gastric bypass surgery. Direct puncture technique was the most frequently adopted (68.2%). The pooled technical success rate (12 studies, 290 patients) was 93.5% [95% confidence interval (CI) 89.7-6.0%; I<sup>2</sup>:0%], while the clinical success rate (11 studies, 260 patients) was 90.1% [95% CI 85.5-93.4%; I<sup>2</sup>:0%]. The pooled total adverse events rate was (11 cohorts, 261 patients) was 11.7% [95% CI 8.2-16.6; I<sup>2</sup>:0%]. When stratified for adverse event severity, the mild/moderate pooled adverse event rate was 10.6% [95% CI 7 -15.6; I<sup>2</sup>:3.4%], while the severe/fatal adverse event rate was 2.9% [95% CI 1.4-6; I<sup>2</sup>:0%]. Mean procedure time was 63.5±35.7 minutes, and mean length of hospital stay was 4.9±2.7 days.

No publication bias or significant heterogeneity was found, although some included studies were graded as low quality.

**Conclusion:** EUS-guided enteric anastomosis, when performed by expert endoscopists in tertiary referral centres, has a high rate of technical and

clinical success. The procedure appears to be relatively safe, and a minimally invasive alternative to surgery in expert hands. Further prospective studies and technique standardisation are warranted to generalise these results.

**Introduction:** Superficial non-ampullary duodenal epithelial tumors (SNADET) are relatively rare. In a few studies, the association between clinicopathological features and mucin phenotypes was analyzed, and they reported that the gastric phenotype of SNADET showed more aggressive biological behavior than those of the intestinal phenotype [1-3]. However, the association between mucin phenotypes and endoscopic features in SNADET has not been well elucidated.

**Aims & Methods:** We aimed to clarify the clinicopathological and endoscopic features including conventional white-light imaging (WLI) and magnifying endoscopy with narrow-band imaging (M-NBI) findings based on the mucin phenotypes. We collected 65 lesions of SNADET which were resected by endoscopic procedures at our hospital between February 2013 and November 2017. Eleven lesions were excluded as follows; 3 lesions with insufficient histopathological evaluation due to specimen damage, 1 lesion diagnosed cancer arising from juvenile polyp, and 7 lesions with unclassifiable mucin phenotype. The remaining 54 lesions were classified into two groups immunohistochemically: the gastric predominant phenotype (GPP) and the intestinal predominant phenotype (IPP). Endoscopic and clinicopathological findings were compared between the two groups.

**Results:** There were 11 lesions of the GPP and 43 lesions of the IPP. All lesions of the GPP were located in the first portion (100%, 11/11), while lesions of IPP were located more often in the second portion (72.1%, 31/43) ( $p < 0.01$ ). The mean tumor size of the GPP was larger than that of the IPP (14.4 mm [range: 7-25] vs. 10.2 mm [2-30],  $p < 0.05$ ). Type 0-I (72.7%, 8/11 vs. 5/43, 11.6%,  $p < 0.01$ ), reddish color (72.7%, 8/11 vs. 16/43, 37.2%,  $p < 0.05$ ), lobular/granular pattern (81.8%, 9/11 vs. 4.7%, 2/43,  $p < 0.01$ ), category 4/5 (mucosal high-grade neoplasia/submucosal invasion by carcinoma) in Vienna classification (81.8%, 9/11 vs. 30.2%, 13/43,  $p < 0.01$ ) were observed more frequently in the GPP than in the IPP. No significant differences were observed in terms of the mean age (GPP vs. IPP=67.3 years vs. 65.2 years,  $p=0.72$ ), gender (male/female=9/2 in GPP, 26/17 in IPP,  $p=0.29$ ), operative method (EMR/ESD=8/3 in GPP, 30/13 in IPP,  $p=1.00$ ). M-NBI findings were assessed in 48 lesions. All lesions showed demarcation line (DL) clearly (100%, 48/48). White opaque substance (WOS) (22.2%, 2/9 vs. 89.7%, 35/39,  $p < 0.01$ ) and light blue crest (LBC) (0%, 0/9 vs. 43.6%, 17/39,  $p < 0.05$ ) were less frequently observed in the GPP than in the IPP. Vessels within epithelial circle pattern (VEC) (66.7%, 6/9 vs. 17.9%, 7/39,  $p < 0.01$ ), dense pattern (55.6%, 5/9 vs. 2.6%, 1/39,  $p < 0.01$ ), and dilatation of intervening part (DIP) (100%, 9/9 vs. 12.8%, 5/39,  $p < 0.01$ ) were more frequently observed in the GPP than in the IPP.

**Conclusion:** Endoscopic and clinicopathological features of the GPP were as follows: located in the first portion, reddish color, type 0-I, lobular/granular pattern, VEC, dense pattern, DIP, and high frequency of the category 4/5 in Vienna classification. On the other hand, those of the IPP were as follows: located in second or third portion, whitish color, type 0-IIa or IIc, WOS, LBC, and high frequency of the category 3. These features are useful to distinguish the mucin phenotypes of SNADET.

## P0170 COMPARISON OF MEDICAL COST BETWEEN DUODENAL AND GASTRIC ESD

**Mizutani M.**<sup>1,2</sup>, Kato M.<sup>1,2</sup>, Tsutsumi K.<sup>2</sup>, Kiguchi Y.<sup>2</sup>, Akimoto T.<sup>2</sup>, Takatori Y.<sup>2</sup>, Fukuhara S.<sup>3</sup>, Nakayama A.<sup>2</sup>, Maehata T.<sup>2</sup>, Kanai T.<sup>1</sup>, Yahagi N.<sup>2</sup>  
<sup>1</sup>Keio University School of Medicine, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Tokyo, Japan, <sup>2</sup>Keio University School of Medicine, Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Tokyo, Japan, <sup>3</sup>Keio University School of Medicine, Center for Diagnostic and Therapeutic Endoscopy, Tokyo, Japan

**Contact E-Mail Address:** marimizutani6@gmail.com

**Introduction:** Duodenal ESD (D-ESD) is reported to be technically difficult and at high risk of adverse events such as bleeding and perforation. Thus, it is expected D-ESD would require more medical cost than gastric ESD (G-ESD), however, actual costs of D-ESD are still unknown, since there are only few studies.

**Aims & Methods:** The aim of this study was to analyze the actual cost of D-ESD and compare with G-ESD, including analysis according to the elements of procedure. This is a single-center, retrospective cross-sectional survey. Medical costs were calculated among patients who underwent D-ESD or G-ESD from July 2016 to June 2017. Medical costs were calculated in summation of the costs of anesthesia, costs of devices for procedure, costs of materials to prevent adverse events, costs of intervention for adverse events, and hospitalization costs. Hospitalization costs were extracted in reference to the "diagnosis procedure combination" reimbursement system in Japan. The costs of devices and materials were calculated from the number of items actually used from medical records. We analyzed by using Wilcoxon rank sum test and a *p* value < 0.05 was considered statistically significant.

**Results:** A total of 49 cases of D-ESD and 107 cases of G-ESD were included in the study. Total medical costs in D-ESD group was significantly higher than in G-ESD group. As for the breakdown, the costs of the anesthesia, costs of materials to prevent adverse events, and hospitalization costs were significantly higher in D-ESD group than in G-ESD group, whereas there was no difference between two groups for costs of devices used for treatment and the additional treatment for the adverse events (Table1).

Costs (€)	G-ESD (N=107)	D-ESD (N=49)	P value
Median costs of anesthesia, Eur [range]	55 [8-1,079]	142 [27-3,230]	<0.001
Median costs of devices for procedure, Eur [range]	328 [208-584]	328 [208-584]	0.338
Median costs of prevention for adverse events, Eur [range]	0 [0-697]	86 [0-839]	<0.001
Median costs of intervention for adverse events, Eur [range]	0 [0-756]	0 [0-3416]	0.904
Median hospitalization costs of, Eur [range]	1,800 [1,297-14,546]	2,086 [1,420-15,119]	<0.001
Median total medical costs, Eur [range]	2,498 [1,795-12,971]	3,232 [2,243-22,219]	<0.001

[Table1: Actual medical costs during hospitalization for ESD]

**Conclusion:** The medical costs of D-ESD are more expensive than G-ESD, especially for the anesthesia and prevention for adverse events.

## P0171 DRUG ADMINISTRATION WITH PERCUTANEOUS ENDOSCOPIC GASTROJEJUNOSTOMY: A NOVEL TREATMENT OPTION FOR PARKINSON'S DISEASE

Yamashita K.<sup>1</sup>, Tsuboi Y.<sup>2</sup>, Fujioka S.<sup>3</sup>, Okada H.<sup>1</sup>, Mishima T.<sup>2</sup>, Shiwaku H.<sup>1</sup>, Ohmiya T.<sup>1</sup>, Hasegawa S.<sup>1</sup>

<sup>1</sup>Fukuoka University Faculty of Medicine, Department of Gastroenterological Surgery, Fukuoka, Japan, <sup>2</sup>Fukuoka University Faculty of Medicine, Department of Neurology, Fukuoka, Japan

**Contact E-Mail Address:** matubara666@gmail.com

**Introduction:** The incidence of Parkinson's disease (PD) sharply increases with age and, due to the progressive aging of the world's population, the number of affected individuals is likely to exponentially increase in the near future. However, it is difficult to maintain therapeutic plasma concentrations of levodopa after oral levodopa administration in patients with advanced PD due to the narrow therapeutic range and delayed gastric emptying. Levodopa-carbidopa intestinal gel (LCIG) therapy, a new drug delivery system for patients with advanced PD, has been covered by insurance in Japan since September 2016. LCIG is administered by using a percutaneous endoscopic gastrojejunostomy (PEG-J) system and helps maintain therapeutic plasma concentrations of levodopa. However, the LCIG administration cannot be achieved without PEG-J, which is the main hindrance to its introduction. Additionally, close collaboration between neurologists and gastroenterologists is very important.

LCIG therapy was introduced in our hospital in January 2017. This study investigated the usefulness and safety of the LCIG treatment system.

**Aims & Methods:** In LCIG therapy, a nasojejunal (NJ) feeding tube is indwelled and a test administration of LCIG is performed. After confirming reactivity and tolerability, gastrostomy is performed by the "pull" method and a PEG-J tube is inserted. We examined 11 patients who underwent LCIG therapy at our hospital from January 2017 to September 2018. The initial six cases used PEG-J tube insertion with the standard procedure, while the more recent five cases used it with the modified procedure. The modified procedure for placement of the PEG-J tube is as follows: after guiding the PEG-J tube to the jejunum with the grasping forceps using an endoscope, pull back only the endoscope to the stomach leaving the PEG-J tube with grasping forceps at the jejunum. Then, release the PEG-J tube and pull back the grasping forceps to the stomach. This method will prevent interference between the PEG-J tube and the endoscope.

**Results:** Out of the 11 patients, three were male and eight were female, and the mean age was 69.5±6.4 years old. Placement of the NJ tube was performed in eight patients, and, in three patients, the NJ tube placement was skipped, and gastrostomy and PEG-J were performed. The operation time for the placement of the NJ tube was 13.1±4.8 minutes (9 to 20 minutes), and for gastrostomy and the placement of the PEG-J, it was 45.6±28.4 minutes (20 to 120 minutes). PEG-J could be safely performed in all patients. The operation time for gastrostomy and the placement of the PEG-J of the modified procedure (27±6.7 min) was significantly shorter than that of the standard procedure (61.0±30.7 min) (*p* < 0.05). All patients responded well to LCIG regarding neurological outcomes.

**Conclusion:** Although there are differences among the currently used PEG-J systems, the LCIG treatment system could be used without major problems. Moreover, the modified procedure could shorten the operation time for gastrostomy and the placement of the PEG-J. For its introduction, the close collaboration between the neurologist and the co-medical staff proved to be important. The LCIG treatment system is a new and useful treatment option for PD and requires understanding and cooperation on the part of endoscopists.

**Disclosure:** Nothing to disclose

## P0172 POSTOPERATIVE BLEEDING RISK AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION DURING ANTITHROMBOTIC THERAPY

Yamauchi K., Nagahara T., Suto K., Seki H., Yasuhara H., Jinno H., Moriya A., Nakatsu M., Ando M.  
Mitoyo General Hospital, Gastroenterology, Kanonji, Japan

**Contact E-Mail Address:** yamauchi.kenji@hotmail.com

**Introduction:** Little is known about the safety of gastric endoscopic submucosal dissection (ESD) during antithrombotic therapy. In 2017, after several guideline updates, the Japan Gastroenterological Endoscopy Society recommended ESD under the continuation of aspirin/warfarin for patients with high thrombotic risk.

**Aims & Methods:** We aimed to evaluate the post-ESD bleeding rate and risk factors in patients receiving antithrombotic therapy. The medical records of 622 patients with gastric neoplasms treated by ESD at Mitoyo General Hospital between April 2009 and December 2018 were retrospectively analysed. The following patient/tumour clinical parameters were analysed: age, sex, comorbidities, antithrombotic drug type, antithrombotic drug management (complete cessation, continued, or heparin replacement), macroscopic findings, location, invasion depth, resected specimen diameter, and operative time. Post-ESD bleeding was defined as an episode of hematemesis/melena or a decrease in haemoglobin ( $>2$  g/dL).

**Results:** Of 622 patients, 140 underwent ESD during antithrombotic therapy. The post-ESD bleeding rate was significantly higher in patients receiving therapy than in those not receiving therapy (22.4% vs 5.4%,  $P=0.009$ ; log-rank test). In a multivariate analysis, the combined use of antiplatelet and anticoagulant drugs (odds ratio [OR] 13.1, 95% confidence interval [95%CI] 1.3-132) and tumours in the lesser curve (OR 0.28, 95%CI 0.08-0.99) were significant risk factors for post-ESD bleeding, while antithrombotic therapy continuation/cessation was not.

**Conclusion:** Gastric ESD under the continuation of aspirin/warfarin is acceptable. However, the combined use of antiplatelet and anticoagulant drugs is associated with a higher risk of post-ESD bleeding.

**Contact E-Mail Address:** sara.cococcia@gmail.com

**Introduction:** Percutaneous endoscopic gastrostomy with jejunal extension (PEG-J) is currently the gold standard for delivering levodopa-carbidopa duodenal infusion therapy in patients suffering from Parkinson's disease (PD). Data regarding the safety and durability of PEG-J are still lacking. Aim of this study was to review short- and long-term safety of PEG-J first positioning and any tube replacement in a cohort of patients with PD referred to our Endoscopy Unit.

**Aims & Methods:** We retrospectively collected data from 58 patients (53 with PD and 5 with other neurological conditions) with a PEG-J referred to our Endoscopy Unit between March 2010 and August 2018 (53 underwent PEG-J placement in our Unit, 5 patients elsewhere). We used descriptive statistics to define prevalence of short- and long-term adverse events (AEs) related to PEG-J placement or after any tube replacement. As many substitutions were performed electively, as suggested by the PEG-J manufacturers, Chi-square with Yates' correction was used to compare the number of AEs following tube replacement on either a programmed or on an urgent basis.

**Results:** Fifty-eight patients (mean age 71.5 years, F/M ratio 1.5:1) have been evaluated over the study period. Of 53 patients undergoing PEG-J placement at our Unit, no immediate AEs were reported. Short-term (within 30 days) AEs (1 kinking, 3 dislocations, and 1 obstruction of the jejunal extension) occurred in 5 patients (9.43%); while delayed (after 30 days) AEs (2 obstructions, 3 tube malfunctions, and 1 pyloric ulcer) were registered in 6 patients (11.32%). The median duration of the original PEG-J was 10.66 months (range 1-24 months).

Of the 113 tube replacement performed, no immediate AEs were registered and only in 2 cases (1.76%) a second procedure was necessary within the first 30 days due to dislocation of jejunal extension. A delayed AE occurred in 21 cases (18.58%; 6 obstructions, 2 buried bumper syndromes, 6 dislocations, 7 malfunctions). The median duration was 10.96 months (range 1-34 months).

The risk of developing an AE was not reduced if tube replacement was performed electively ( $p=0.96$ ). No serious complications were reported.

**Conclusion:** Differently from what is stated in previous literature (Devos, French Duodopa Study Group, 2009), PEG-J placement is a safe procedure, particularly in patients with PD. An elective tube replacement after one year is not strictly recommended, since the durability is variable among patients and an elective replacement does not significantly reduce the number of following AEs.

**Contact E-Mail Address:** rcannizzaro@cro.it

**Introduction:** Bowel obstruction represents a common condition of gynaecological cancer. The aim of this study was to evaluate the efficacy of a combined treatment with the somatostatin analogue Lanreotide and percutaneous endoscopic gastrostomy (PEG) in the clinical management of advanced ovarian cancer with intestinal occlusion.

**Aims & Methods:** 93 consecutive patients with advanced abdominopelvic carcinomatosis were enrolled in the study between November 1998 and December 2012. In particular, we investigated safety and efficacy of somatostatin analogue lanreotide, 30 mg every 10-14 days, alone or in combination with PEG.

**Results:** Seventy-seven patients were treated with Lanreotide, and 27 of them underwent also PEG. The median age was 52.3 years, and the median follow-up was 13 months. After 2 lanreotide administrations, we observed reduction of nausea in 56.3% of patients, of vomiting in 52.7%, of abdominal distension in 60%, and of colic pain in 67.2%. In no cases, drug-related side effects were observed. In patients who received lanreotide and PEG, there was a significant reduction in gastrointestinal secretions, with a real benefit for the patient also during the home care.

**Conclusion:** The integrated and combined treatment with Lanreotide 30 mg and PEG is effective in patients with advanced abdominopelvic cancers. A constant overall benefit for the quality of life was observed and the control of symptoms, which is very important especially during the home care follow-up of terminal patients.

## P0175 RISK FACTORS FOR BACTEREMIA AFTER LOW RISK ENDOSCOPIC PROCEDURES WITH A FOCUS ON NEUTROPENIA

Isenberg Y.<sup>1</sup>, Zamstein N.<sup>2</sup>, Horesh N.<sup>3</sup>, Bar-Yoseph H.<sup>4</sup>

<sup>1</sup>Rambam Medical Center, Internal Medicine, Haifa, Israel, <sup>2</sup>MDCI, Beer Sheva, Israel, <sup>3</sup>Rambam Medical Center, Hematology, Haifa, Israel, <sup>4</sup>Rambam Health Care Campus, Gastroenterology, Nofit, Israel

**Contact E-Mail Address:** yoniisenberg15@gmail.com

**Introduction:** risk for bacteremia following endoscopic procedures varies among studies. A low neutrophil count is considered by some to be a risk factor. We assessed risk factors for bacteremia in low risk endoscopic procedures and risk for post procedural complications in neutropenic patients.

**Aims & Methods:** A retrospective analysis of all inpatients undergoing low risk endoscopic procedure (esophago-gastro-duodenoscopy (EGD), short colonoscopy and colonoscopy) between 2005-2018 with a neutrophil level taken within 72 hours prior to procedure at our hospital. Data was retrieved using MDCI's query engine and was manually validated. Neutropenia was defined as neutrophil level < 1000 cell/μl. Primary outcome was new onset bacteremia within 48 hours after the procedure. Secondary composite endpoints in patients with neutropenia included mortality within 7 days of the procedure, new onset of fever, bacteremia or hemodynamic instability within 48 hours following the procedure. As a comparator invasive procedure, rate of new onset bacteremia was estimated following bronchoscopic procedures. Mean comparison for numerical variables was done using t-test. Categorical variables were compared using either a Chi-squared test or Fisher's exact test. The multivariate logistic regression models were built by using stepwise forward selection and backward elimination.

**Results:** 13168 patients were included, out of which 167 procedures were performed in the setting of neutropenia. The mean age was 61 years and EGD was the most common procedure (56%). Post-procedural bacteremia was recorded in 103 (0.8%) and 7 (4.2%) of the general cohort and patients with neutropenia, respectively. Neutropenia (OR 3.2), low albumin level (OR 0.33), male gender (OR 1.71), older age (OR 1.02), fever before procedure (OR 2.09) and ICU/hematologic department settings were associated with increased risk for bacteremia in the general study population, in both univariate and multivariate analysis. A multivariate model including these factors was predictive of bacteremia (AUC 0.82, 95% CI 0.78-0.88). Bacteremia was associated with increased risk of mortality. Among patients with neutropenia, secondary composite endpoints were more frequent in patients admitted to the hematology department and with low albumin level. Antibiotics or granulocyte stimulating factor before procedure were not associated with a decreased risk for adverse outcomes. In comparison with GI endoscopic procedure, the risk for bacteremia was significantly higher among patients that underwent bronchoscopy (1.85% vs. 0.78%, respectively), but not significant among neutropenic patients undergoing these procedures (1.8% vs. 4.2%, respectively).

**Conclusion:** we report a low incidence of post-endoscopic bacteremia in our center. Low neutrophil level was found to be a risk factor for bacteremia. A model highly predictive of bacteremia was developed. Further studies to assess these factors are needed.

## P0176 INTRAGASTRIC ADJUSTABLE BALLOON: USING THE DEVICE IN ORDER TO PROMOTE THE MOST EFFECTIVE WEIGHT LOSS-A BRAZILIAN STUDY

Hoff A.<sup>1,2</sup>, Barrichello S.<sup>3</sup>, Galvao M.<sup>4</sup>, Queiroz Sander B.<sup>5</sup>, Fittipaldi-Fernandez R.J.<sup>6</sup>

<sup>1</sup>Angioskope, Bariatric Endoscopy, São Paulo, Brazil, <sup>2</sup>Angioskope, Bariatric Endoscopy, São José dos Campos, Brazil, <sup>3</sup>Healthme Clinic, Endoscopy, São Paulo, Brazil, <sup>4</sup>ABC Medical School, São Paulo, Brazil, <sup>5</sup>Sander Medical Center, Bariatric Endoscopy, Belo Horizonte, Brazil, <sup>6</sup>Endogastro Med Service, Digestive Endoscopy, Rio de Janeiro, Brazil

**Contact E-Mail Address:** nathoff@yahoo.com

**Introduction:** Adjustable Balloon Therapy (ABT) is an effective minimal invasive technique for weight loss, proven widely. However, there is no published study comparing results using: 1- Non-modified volume during the 12-month treatment; 2- Submitted to upward adjustment with a fixed volume; 3- Associated with Liraglutide and 4- A combination of items 2 and 3.

**Aims & Methods:** From December 2016 to December 2017 were analyzed 159 patients (mean age 37.96±22.15, female 77.85%) who underwent and completed the 12-month therapy. 40 patients maintained initial volume until retrieval (IGB group). 35 received Liraglutide daily, initiated one month after implant, mean dose 2.18±0.53 mg for 9 consecutive months (LG group). 53 underwent the upward adjustment with 200 ml of sterile saline (mean 166days ±17.11 after placement) (UP group). 34 were submitted to both Liraglutide and upward adjustment (LGUP group). 3 in the UP and 1 in the LGUP group excluded. Percentage Total Body Weight Loss(%TBWL), Percentage Excess Weight Loss(%EWL), Body Mass Index (BMI) difference analyzed after balloon retrieval by the Kruskal-Wallis and the Wilcoxon test. The p set to ≤.005

**Results:**

	IGB GROUP	LG GROUP	LGUP GROUP	UP GROUP
(F)BMI-(I)BMI	6.14±1.99	7.72±2.42	7.69±1.84	5.97±2.21 #
%TBWL	18.18±3.66	22.53±3.64 ****	22.1±3.31****	17.14±4.68
%EWL	71.66±18.45	86.62±25.09*	80.56±15.96	61.82±16.34**

[Results]

#p=0.0205;\*\*\*\*p<0.0001;\*p=0.0252;\*\*p=0.0392

**Conclusion:** The LG and the LGUP group presented the highest %TBWL, %EWL and BMI difference and had no statistical difference between, emphasizing Liraglutide efficiency. However, complications regarding upward adjustment should be considered. Liraglutide costs should be summed up.

**Disclosure:** Nothing to disclose

## P0177 FULL-FIELD OPTICAL COHERENCE TOMOGRAPHY OF THE NORMAL DIGESTIVE MUCOSA: A PROMISING TOOL FOR THE STUDY OF THE DIGESTIVE BARRIER

Quénéhervé L.<sup>1,2</sup>, Olivier R.<sup>2,3</sup>, Mosnier J.-F.<sup>4</sup>, Brochard C.<sup>2,5</sup>, Bossard C.<sup>4</sup>, Neunlist M.<sup>2</sup>, Coron E.<sup>1,2</sup>

<sup>1</sup>University Hospital of Nantes, Digestive Disease Institute, Nantes, France, <sup>2</sup>Nantes University, Inserm U 1235 TENS, Nantes, France, <sup>3</sup>University Hospital of Poitiers, Gastroenterology, Poitiers, France, <sup>4</sup>University Hospital of Nantes, Pathology Unit, Nantes, France, <sup>5</sup>CHU Rennes, Services des Maladies de L'Appareil Digestif, Rennes, France

**Contact E-Mail Address:** lucille.queneherve@gmail.com

**Introduction:** Full-field optical coherence tomography (FF-OCT) is a non-invasive imaging technique, based on interferometry, allowing dynamic acquisition of images of ex vivo specimens on a microscopic scale.

**Aims & Methods:**

The aim of this study was to demonstrate the feasibility of imaging normal digestive biopsies using FF-OCT.

We enrolled adult subjects scheduled for an endoscopy with biopsies, who had no history of digestive disease. We *a posteriori* excluded patients, whose biopsies showed abnormal aspects at pathological examination. Four biopsies were sampled, 2 for pathological examination, 2 for immediate FF-OCT analysis, from 5 different locations: esophagus, gastric antrum, gastric fundus, duodenum or colon. Fresh biopsies were scanned using the LL-Tech benchtop scanner in order to perform an optical slicing beneath the tissue surface at selected depths (static mode) and a measurement of intracellular activity data (dynamic mode). Biopsies were then fixed in formaldehyde, sliced in a longitudinal plane parallel to the surface and stained using hematoxylin-eosin. FF-OCT images and pathological slides were then reviewed with the assistance of a senior pathologist.

**Results:** We enrolled 25 patients with normal biopsies of the esophagus (n=5), gastric fundus (n=10), gastric antrum (n=10), duodenum (n=7) and colon (n=6). Specific histological structures of each organ were clearly identified in 100% of FF-OCT images. For instance, the cellular structure of esophageal squamous epithelium with papillae, gastric crypts and glands, duodenal villi and colonic crypts was clearly seen at a 1μm resolution.

**Conclusion:** FF-OCT allows a morphological and functional analysis of digestive tissues on fresh routine endoscopic biopsies, at a subcellular scale. It is a promising tool for the study of the digestive barrier.

**Disclosure:** Nothing to disclose

<sup>1</sup>Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Aparato Digestivo, Sabadell, Spain, <sup>2</sup>Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Oficina Técnica de Cribado de Cáncer, Sabadell, Spain, <sup>3</sup>Universidad Autónoma de Barcelona, Departamento de Medicina, Barcelona, Spain, <sup>4</sup>Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Servicio de Estadística, Sabadell, Spain

**Contact E-Mail Address:** machlab@gmail.com

**Introduction:** To improve participation in the population screening program for colorectal cancer, to guarantee the quality of the exploration and to reduce its impact on the patient, it is necessary to provide the safest and most tolerable preparation. Although numerous studies have been conducted to determine which is the best purgative preparation and its administration regimen, no randomized study has been published regarding the number of days of low residue diet. Both the European and American guidelines give little concrete and low quality recommendation regarding the number of days stating "no more than 24 hours" and "several days" respectively.

**Aims & Methods:** To assess the efficacy and tolerance to a low-residue diet during a day in a comparison with three days in participants referred to screening colonoscopy. An equivalence margin of 5% was defined and a low diet was assigned during a day (Group A) or three days (Group B, control) without other differences in preparation. Participants with chronic constipation were given bisacodyl 10mg the night before the colonoscopy. Boston scale was used to determine the bowel cleansing. Inadequate preparation was defined as a punctuation lesser than 2 in any segment. A Likert scale was used for assessing the tolerance to the diet. We present the results of an intermediate analysis of the study.

**Results:** We included 210 participants in group A and 211 in group B. An adequate randomization was achieved without observing differences in age, sex, BMI, treatment with antidepressants, cirrhosis, reduced mobility or constipation. Neither in the time elapsed from the end of the preparation until the start of the colonoscopy. In group A 2 participants had an inadequate preparation versus 10 (4.7%) in group B. This is a difference of -3, 78% (-6, 88, -1.12% CI 90% unilateral) ( $p < 0.05$ ). In terms of tolerance to diet, group A obtained a maximum tolerance score (Likert 1) in 48.5% against 29.9% in B ( $p < 0.05$ ), while there were no significant differences in tolerance to the evacuating preparation, Likert 1 36.9% Vs. 29.4% ( $p > 0.05$ ). There were also no differences in the adenoma detection rate, 66.7% vs. 67.8%, nor in the withdrawal time with a median of 13 minutes vs. 14 ( $p > 0.05$ ). In group B, cecal intubation was not achieved due to poor cleansing in 5 participants, whereas that did not occur in group A.

**Conclusion:** The results of this intermediate analysis show that for the preparation of the screening colonoscopy a low residue diet for 1 day is noninferior to 3 days and offers a better tolerance.

**Disclosure:** Nothing to disclose

## P0180 THE UTILITY OF SELF-EXPANDABLE METALLIC STENT AS A BRIDGE TO SURGERY AGAINST MALIGNANT COLORECTAL OBSTRUCTION

Akabane M., Kuroda T., Nagaoki Y., Fukuhara T., Hirata D., Tamura T. Mazda Hospital, Gastroenterology, Hiroshima, Japan

**Contact E-Mail Address:** makisky1110@yahoo.co.jp

**Introduction:** Self-expandable metallic stent (SEMS) placement for malignant colorectal obstruction has been available from 2012 in Japan. On the other hand, SEMS placement as a bridge to surgery (BTS) is not recommended as a standard treatment of symptomatic left-sided malignant colonic obstruction in the European Society of Gastrointestinal Endoscopy Clinical Guideline. This is because there have been some concerns that SEMS placement has association with worse disease-free and overall survival. Therefore, we retrospectively investigated the treatment results.

**Aims & Methods:** Data collection was performed on the clinical outcomes from the patients who underwent colorectal resection against malignant colorectal obstruction between January 2012 and June 2018. A total of 22 patients were included in this analysis. Eleven patients received SEMS placement as BTS (Group A), and 11 patients received nasal ileus tube or emergency surgery (Group B). We retrospectively investigated the technical and clinical success rates of SEMS placement, the short-term outcomes (postoperative complication rate and 30-day mortality rate) and the long-term outcomes (progression free survival and overall survival).

**Results:** The mean age of the patients was 71 years (group A) and 77 years (group B), respectively. The male-to-female ratios were 3:8 (group A) and 9:2 (group B). Tumor sites (cecum/ ascending/ transverse/ descending/ sigmoid/ rectum) were 0/1/1/2/5/2 (group A) and 5/0/3/1/1/1 (group B). The pStages (I/II/III/IV) were 0/4/4/3 (group A) and 0/1/5/5 (group B), which were no significant differences between the two groups ( $p=0.308$ ). In group A, the technical and clinical success rates for SEMS was 100% (11/11) and 91% (10/11). There was one case of stent perforation, but it was coincidentally detected during the elective operation. Regarding the short-term outcomes, the postoperative complication rate was 9% ( $p=0.269$ ), and the postoperative 30-day mortality rate was 0%. As for long-term outcomes, there were no significant statistical differences between the two groups in progression free survival ( $p=1.000$ ) and overall survival ( $p=0.768$ ), using the Kaplan-Meier method and long-rank test.

**Conclusion:** In our institute relatively high technical and clinical success rates were observed after SEMS placement. There were no significant differences of short-term and long-term outcomes between the two groups. These findings may suggest that the SEMS as BTS might be one of the options as long as the placement is successfully performed.

**Disclosure:** Nothing to disclose

## P0181 ADENOMA DETECTION WITH CHROMO-ENDOSCOPY USING ORAL INDIGO CARMINE

Kawanishi K., Maekita T., Kitano M. Wakayama Medical University, Second Department of Internal Medicine, Wakayama, Japan

**Contact E-Mail Address:** amurosyaa218@yahoo.co.jp

**Introduction:** Colonoscopy is currently the reference method to detect colorectal neoplasia, yet some adenomas remain undetected. Indigo carmine staining with various methods has shown interesting results for reducing this miss rate.

**Aims & Methods:** The aim of this study was to determine if the standard colonoscopy prep followed by oral indigo carmine intake shows the increase in the adenoma detection rate (adenoma and adenocarcinoma; ADR) and the mean number of adenomas per patient (MAP).

We introduced the oral indigo carmine technique to every subject and prospectively collected the data, and also performed retrospective review of endoscopic reports and medical charts of consecutive patients who underwent colonoscopy before introducing this technique to compare the results.

**Results:** 211 subjects were included in the study (105 in indigo group). The ADR was not significantly different between the groups; 44.8% in the indigo group versus 41.5% in the standard colonoscopy group (odds ratio, 1.15; 95% confidence interval, 0.9 - 1.52,  $p = 0.33$ ). MAP was significantly greater in the indigo group (1.1) than in the standard colonoscopy group (0.81;  $p = 0.008$ ). For advanced adenomas, the results were 10 (9.5%) and 7 (6.6%), respectively ( $p = 0.13$ ).

**Conclusion:** The routine use of oral indigo carmine does not lead to higher ADR regardless of higher MAP.

**Disclosure:** Nothing to disclose

## P0182 A 10-YEAR EXPERIENCE WITH BOWEL PREPARATION: PREDICTORS AND COLONOSCOPY OUTCOMES OF INADEQUATE BOWEL CLEANSING. A LARGE COHORT STUDY

Abu Baker E.<sup>1</sup>, Mari A.<sup>2</sup>, Gal O.<sup>1</sup>, Suki M.<sup>1</sup>, Ovadia B.<sup>1</sup>, Kopelman Y.<sup>1</sup>

<sup>1</sup>Hillel Yaffe Medical Center, Gastroenterology and Hepatology, Hadera, Israel,

<sup>2</sup>Nazareth EMMS Hospital, Department of Gastroenterology, Nazareth, Israel

**Contact E-Mail Address:** fa\_fd@hotmail.com

**Introduction:** The last decade brought in an outstanding advancement in endoscopic equipment and awareness of colonoscopy quality indicators. However, inadequate bowel preparation is still the main obstacle for a complete, thorough and quality procedure in a sizable mass of patients, constituting one of the most leading indications for repeated procedures. In the current study we aimed to identify risk factors associated with inadequate bowel preparation and better characterize these patients in our practice.

**Aims & Methods:** a retrospective, large cohort, single centre study. Electronic reports of colonoscopy procedures over a 10-year period were revised. Patients were divided based on the quality of bowel preparation into adequate and non-adequate bowel preparation groups. Multivariate analysis was performed to identify variables associated with inadequate bowel preparation including age, sex, setting (inpatient/outpatient), preparation regimen and procedures' indications. We also examined the effect of inadequate preparation on colonoscopy outcome and quality indicators.

**Results:** 28725 patients were included in the study. Of these, 6702 (23.3%) had inadequate bowel preparation. In multivariate analysis, increased age (OR= 1.015, 95% CI= 1.013-1.017; P< 0.01), male gender (OR =1.353, 95% CI=1.286-1.423; P< 0.01) and minority population (OR =1.635, 95%CI=1.531-1.746; P< 0.01) were significantly associated with inadequate bowel preparation. Inpatient setting was among the most prominent factors associated with poor bowel preparation (OR= 2.018, 95%CI 1.884-2.163; P value< 0.01). In regard to procedures' indications, significant associations with inadequate preparation were recorded for constipation (OR =1.373, 95%CI=1.24-1.519; P< 0.01), rectal bleeding (OR = 1.473, 95%CI= 1.355-1.602) and surveillance procedures after colonic resection (OR = 1.266, 95%CI= 1.089-1.472). Evaluation of procedure's outcome and quality indicators revealed that adequate bowel preparation was associated with enhanced polyp detection rate (26.8% vs 23.6%; OR= 1.22, 95% CI= 1.109-1.347; P< 0.01), increased colorectal cancer detection rate (2.8% vs. 2.4% OR= 1.402, 95% CI=1.146-1.716; P< 0.01), as well as increased cecal (96.4% vs. 73.5%; OR= 2.243, 95% CI= 2.095-2.403) and terminal ileum detection rates (8.1% vs. 5.4%; OR= 1.243, 95% CI= 1.088-1.434), when compared to inadequate preparation.

**Conclusion:** In this large cohort study we outlined various factors associated with inadequate bowel preparation. Further study is underway to examine tailored preparation regimens in this population.

**Disclosure:** Nothing to disclose

## P0183 FEASIBILITY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR RECURRENT RECTAL LESIONS THAT AFTER TRANSANAL ENDOSCOPIC MICROSURGERY

<sup>1</sup>Kobe University Hospital, Division of Gastroenterology, Dept. of Internal Medicine, Kobe, Japan, <sup>2</sup>Kobe University Hospital, Dept. of Endoscopy, Kobe, Japan, <sup>3</sup>Akashi Medical Center, Akashi, Japan, <sup>4</sup>Kishiwada Tokushukai Hospital, Kishiwada, Japan, <sup>5</sup>St Mark's Hospital, Middlesex, HA UJ, United Kingdom, <sup>6</sup>Kings College Hospital, Colorectal Surgery, London, United Kingdom

**Contact E-Mail Address:** nobuikezawa@gmail.com

**Introduction:** Transanal endoscopic microsurgery (TEM) is a well-established local resection method. Although TEM is a useful and less invasive treatment, it has been reported to be associated with local recurrence rates of 3% to 19%. Occasionally surgical treatment such as low anterior resection or abdominal perineal resection may be required for such recurrent rectal lesions, however, they can have severe effects on patients' postoperative quality of life. Recently, several studies have demonstrated the usefulness of endoscopic submucosal dissection (ESD) for residual or

locally recurrent colorectal lesions after endoscopic treatment. However, the utility of ESD for recurrent rectal lesions after TEM has not been fully investigated.

**Aims & Methods:** Aim of this study was to evaluate the feasibility and safety of ESD for recurrent rectal lesions after TEM. This study was performed at Kobe University Hospital and Kishiwada Tokushukai Hospital, which are tertiary referral centers in Japan. It examined the outcomes of 10 consecutive lesions in 9 patients, who underwent ESD between January 2006 and March 2018 for recurrent rectal lesions after TEM. The target lesions were preoperatively assessed via conventional and magnified chromoendoscopic examinations. As ESD technique, after TEM procedures involving full-thickness resection, the resultant fibrosis can be so severe that the border between the submucosa and muscle layer, and sometimes even that between the inner circular and outer longitudinal muscles, is invisible. In such cases, dissecting at the assumed level of the submucosal layer would carry a risk of cutting into the lesion, so we employed the previously reported peranal endoscopic myectomy (PAEM) technique.

**Results:** All lesions were successfully resected en bloc, and the R0 resection rate was 90%. The median sizes of the resected specimens and tumors (range) were 44 mm (21-70) and 27.5 mm (5-60), respectively. In present study, the PAEM technique was used to treat 4 lesions, and all of them had negative vertical margins. The pathological diagnoses included 4 adenomas and 6 cancerous lesions. The cancerous lesions included 5 cases of mucosal cancer and 1 case of SM1 cancer. No adverse events occurred. There was no recurrence during the follow-up period (median duration: 25 months).

**Conclusion:** ESD for recurrent rectal lesions after TEM achieved en bloc resection for all lesions without any complications. ESD appears to be a safe and feasible treatment for recurrent rectal lesions after TEM.

## P0184 FACTORS INVOLVED IN ENDOSCOPISTS' CHOICE FOR PROPHYLACTIC CLIPPING AFTER EMR TO PREVENT DELAYED BLEEDING: A DISCRETE CHOICE EXPERIMENT

Turan A.<sup>1</sup>, Didden P.<sup>2</sup>, Siersema P.D.<sup>1</sup>, Van Geenen E.J.M.<sup>1</sup>

<sup>1</sup>Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands,

<sup>2</sup>University Medical Center Utrecht, Utrecht, Netherlands

**Contact E-Mail Address:** ayla.turan@radboudumc.nl

**Introduction:** Flat and sessile colorectal adenomas are often resected endoscopically using endoscopic mucosal resection (EMR). Delayed bleeding after EMR occurs in up to 10% of patients. Recently, a multicenter study reported a significant decreased delayed bleeding (DB) rate after prophylactic clipping (PC) in right sided colonic lesions >2cm. As PC is associated with significant costs, its use is considered not cost-effective for small (<2cm) polyps and left sided polyps. The practice of PC is not yet widely adopted in guidelines and clinical practice.

**Aims & Methods:** Our aim was to determine which predefined variables contribute to using PC in an international group of endoscopists. We performed an international survey study among endoscopists, structured as an online discrete choice experiment (DCE) with a choice based conjoint analysis. The survey was conducted in 428 gastroenterologists of the Dutch Association of Gastroenterology and Hepatology. Additionally, 69 international EMR experts were contacted and invited to forward the survey to other colleagues with EMR experience. Relevant variables hypothesized to influence decision-making for PC were selected by a panel of four EMR experts and included previous DB, periprocedural anticoagulant use, polyp size, morphology, location, intra-procedural bleeding and visible vessel(s) in the wound surface. Respondents answered ten sets of three hypothetical case scenarios with various option combinations of all of these variables, each time choosing only one scenario for PC. Alternatively, it was possible to choose a 'none'-option if they wouldn't use PC in any of the scenarios. Part-worth utility scores and importance weights were calculated for each level of the variables with a Hierarchical Bayes regression analysis and compared between subgroups using a T-test. Subsequently, considerations that were posed by participants in the comment section of the survey were analyzed quantitatively.

**Results:** The survey was completed by 190 endoscopists with experience in EMR from 17 different countries. In total, 6.8% of respondents would not use PC in any of the simulated situations, whereas 30.9% never chose the none-option in the survey. Except for polyp type (flat, sessile, mixed type), all tested variables were significant in the decision-making for PC with  $P < 0.01$ .

The most important factor was anticoagulant use, accounting for 22.5% in decision-making, followed by intra-procedural bleeding (16.3%), polyp size (16.2%), polyp location (15.9%), visible vessel(s) (13.5%) and previous DB (10%). Small polyps  $< 2$  cm were considered eligible for PC by 14% of the responders in the presence of high-weighting factors such as anticoagulant use. In a subgroup analysis, no significant differences in importance weights were found when comparing high with low to moderately experienced EMR endoscopists.

Qualitative analysis showed that other variables, not included in the survey, were also considered in clinical decision making, such as technical possibility of clipping, prophylactic coagulation of visible vessels and distance of patient's residence to the hospital.

**Conclusion:** PC after EMR is commonly considered useful by endoscopists, usually based on known risk factors for DB.

Anticoagulant use was the most important factor in decision-making to perform PC, independent of the experience of the endoscopist. Nonetheless, although not considered cost-effective, 1 in 7 EMR endoscopists also apply PC for adenomas  $< 2$  cm.

## P0185 EFFICACY OF COUNTER TRACTION USING A CLIP WITH A LOOPED THREAD FOR COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

Indo N., Anami T., Kitamura Y., Watanabe A.

**Contact E-Mail Address:** inchan0701@gmail.com

**Introduction:** Colorectal endoscopic submucosal dissection (ESD) remains a difficult endoscopic procedure. Several traction methods have been reported that enable an appropriate view of the submucosal layer; however, almost all these methods have limitations regarding preparation, delivery, ease or cost. We have reported a treatment strategy for colorectal ESD using a clip with a looped thread, which has been developed to resemble a ring-shaped thread counter traction.

Our original counter traction does not require any special tools or devices and can be carried out without the removal and reinsertion of a scope. Additionally, this method is very easy and only requires thirty seconds to make one looped thread.

**Aims & Methods:** This study was performed to evaluate the efficacy of our traction method.

A 3-0 nylon suture and a clip (HX-610-135; Olympus, Tokyo, Japan) were used as the material. Between January 2017 and November 2018, colorectal ESD was carried out on 90 lesions. These lesions were allocated either to the group before introduction of the looped thread counter traction (non-looped thread; NLT) ( $n=66$ ) or to the group after introduction (looped thread; LT) ( $n=24$ ). We retrospectively investigated the background factors, treatment outcomes and complications.

**Results:** We achieved en bloc resections of all lesions. No significant differences were detected in the background factors or in the procedure time ( $P=0.298$ ). The median time of the LT group (65 min) was shorter than that of the NLT group (80 min). There were 3 cases of perforation during ESD in the NLT group compared to 0 cases in the LT group ( $P=0.287$ ). There were 4 cases of post-ESD bleeding (1-7 days after ESD) in the NLT group compared to 2 cases in the LT group ( $P=0.749$ ).

**Conclusion:** No significant differences were detected in the treatment outcomes and complications in this study. But we think this traction method is useful, and we suggest that this counter traction method may be a superior method for colorectal ESD because the length of the thread can be adjusted and more clips or looped thread can be added as needed to maintain an appropriate view of the submucosal layer. Good visualization of the submucosal layer can prevent perforation and bleeding during ESD. The greatest advantages of this traction method include the low cost and ease. This method is readily available not only in high-volume centres but also in general hospitals. In this report, we demonstrate how to make the looped thread, how to tie the thread to a clip and how to carry out this traction method.

**Contact E-Mail Address:** roupen.rd@gmail.com

**Introduction:** Optical real-time diagnosis (=resect-and-discard strategy) is an alternative to histopathology for diminutive colorectal polyps. However, clinical adoption of this approach seems sparse and we were interested in evaluating potential clinical uptake and barriers for implementation of this approach.

**Aims & Methods:** We conducted an international survey using the "Google forms" platform. Nine endoscopy societies distributed the survey. Survey questions measured current clinical uptake and barriers for implementing the resect-and-discard strategy, perceived cancer risk associated with diminutive polyps and potential concerns with using CT-colonography as follow-up, as well as non-resection of diminutive polyps.

**Results:** 808 endoscopists participated in the survey. 84.2% (95% CI 81.6%-86.7%) of endoscopists are presently not using the resect-and-discard strategy and 59.9% (95% CI 56.5%-63.2%) do not believe that the resect-and-discard strategy is feasible for implementation in its current form. European (38.5%) and Asian (45%) endoscopists had the highest rates of resect-and-discard practice, while Canadian (13.8%) and American (5.1%) endoscopists had some of the lowest implementation rates. 80.3% (95% CI 77.5%-83.0%) of endoscopists believe that using the resect-and-discard strategy for diminutive polyps will not increase cancer risk. 48.4% (95% CI 45.0%-51.9%) of endoscopists believe that leaving diminutive polyps in place is associated with increased cancer risk. This proportion was slightly higher (54.7%; 95% CI 53.6%-60.4%) when asked if current CT-colonography screening practice might increase cancer risks.

**Conclusion:** Clinical uptake of resect-and-discard is very low. Most endoscopists believe that resect-and-discard is not feasible for clinical implementation in its current form. The most important barriers for implementation are fear of making an incorrect diagnosis, assigning incorrect surveillance intervals and medicolegal consequences.

**Introduction:** Cold forceps polypectomy (CFP) is often used to remove diminutive colorectal polyps. It has few adverse events and can be implemented using routine biopsy techniques. In addition, jumbo biopsy forceps are considered superior to standard ones in removing colorectal polyps. Examining the margin of resected regions using narrow band imaging (NBI)-enhanced endoscopy can also improve complete resection rate. However, even in such cases using jumbo forceps in NBI-enhanced endoscopy, local recurrence occurs in few cases. In such cases, lesions have to be treated again and clinical outcomes are still unknown.

**Aims & Methods:** We investigated clinical outcomes of treatment for patients with local recurrence of diminutive polyps resected by jumbo forceps biopsy in NBI endoscopy. This multicenter, prospective, single-arm observational study was conducted at 11 institutes of the National Hospital Organization in Japan between January 2015 and September 2018 (UMIN000015969). In total, 503 patients, aged 20-75 years, with diminutive polyps ( $\leq 5$  mm) were prospectively assessed, and 1015 polyps were resected by jumbo forceps biopsy in NBI endoscopy. Among these, 955 lesions from 471 patients were followed-up 1 year post-CFP to examine local recurrence in the polypectomy sites (follow-up rate; 94.1%). Finally, local recurrence occurred in 18 patients (20 lesions, 2.1%), who were enrolled in this study. We analyzed clinicopathological characteristics of primary and local recurrent lesions, as well as short- and long-term clinical outcomes of treatment for local recurrent lesions including resection rates, adverse events, and re-recurrence rate.

**Results:** The patients consisted of 12 men (67%) and 6 women (33%) with a median age of 68.5 years (49-74). The mean primary polyp size was  $3.9 \pm 0.9$  mm. The number of resected primary polyps in the right and left colon were 12 (60%) and 8 (40%), respectively. The histological diagnoses of the primary resected polyps were low-grade adenomas in all cases, and the rate of one-bite polypectomy was 55% (11/20). Immediate bleeding occurred in 1 case; delayed bleeding or perforations were not observed. The mean size of local recurrent polyps was  $1.5 \pm 0.6$  mm; all were less than 3 mm. Re-CFP successfully managed local recurrent polyps in all cases, and the rate of one-bite polypectomy was 90% (18/20). The histological diagnoses of local recurrent polyps were low-grade adenomas in all cases; no adverse events occurred in any cases. Additionally, 16 of 18 patients (18/20 lesions) were subjected to a 1-year follow-up examination with colonoscopy (follow-up rate; 88.9%), and no re-recurrence occurred in any cases (0/18).

**Conclusion:** The local recurrence rate of diminutive polyps in CFP by jumbo forceps biopsy in NBI endoscopy was acceptable. When local recurrence occurred, the size was small, and it could be treated using re-CFP.

**Disclosure:** Nothing to disclose

**Introduction:** The Colonoscopy vs. Fecal Immunochemical Testing (FIT) in Reducing Mortality from Colorectal Cancer (CONFIRM) Study, a randomized study comparing annual FIT vs. colonoscopy in average risk adults aged 50-75, recently completed enrollment and is now following participants for cancer outcomes.

**Aims & Methods:** To determine 1) findings on baseline colonoscopy, 2) factors associated with baseline neoplasia and 3) 30 day complication rate. Advanced adenoma (AA) was defined as any adenoma  $\geq 1$ cm, with high grade dysplasia or with villous histology. Univariable logistic regression was used to determine the association between baseline variables and findings of adenomas, advanced adenomas, and sessile serrated lesions (SSLs). See table for full variable list. Variables found to be significant at  $p \leq 0.1$  were included in a multivariable logistic regression model, stratified by site. Participants found to have colorectal cancer were excluded from this analysis as this study is ongoing. Coordinators reviewed medical records and telephoned participants to determine complications. All serious adverse events (SAEs) were recorded, as were non-serious adverse events (AEs) deemed to be at least possibly related to colonoscopy.

**Results:** 15,806/17,340 colonoscopies were complete with cecal intubation (97.3%) and adequate preparation (92.4%). Polyps were found in 66.0%. Among those without polyps, mean withdrawal time was 11.1 minutes. Non-gastroenterologists were less likely to detect polyps (0.65; 95% CI 0.58-0.77) and adenomas (Table). Trainee involvement was associated with higher polyp detection (1.24; 95% CI 1.14, 1.35). Factors associated with adenoma and AA are shown in the table. Factors associated with AA included age, male sex, smoking and alcohol use. Black race, college degree, NSAIDs and prior colonoscopy were inversely associated with AA. Independent predictors of SSLs included BMI and smoking; while Blacks had 62% reduced odds of SSLs. Former aspirin use was associated with adenomas, but this finding was modified by age.

There were 235 SAEs reported (1.3%), with 52 related (0.36%) and 38 possibly related (0.25%) to colonoscopy, including 31 serious bleeding events (.18%), 31 cardiovascular events (.18%) and 5 perforations (.03%). 585 AEs were reported (2.9%), most (84%) were mild, 15% were moderate and 0.1% were severe.

**Conclusion:** Our study confirms the importance of several demographic and environmental risk factors for adenomas, AA and SSL. AEs and SAEs related to colonoscopy occur in approximately 3% and 0.5% of colonoscopies, respectively.

The first two authors are co-first authors.

## P0189 USEFULNESS AND SAFETY OF COLORECTAL HYBRID ESD AND PRECUTTING EMR USING A NOVEL MULTIFUNCTIONAL SNARE FOR SSPS

Tamaru Y., Kuwai T., Moriuchi R., Wada K., Konishi H., Tao K., Miura R., Kusunoki R., Yamaguchi A., Kouno H., Kohno H.  
National Hospital Organization Kure Medical Center and Chugoku Cancer Center, Gastroenterology, Kure, Japan

Contact E-Mail Address: tamaru.yuzuru.vh@mail.hosp.go.jp

**Introduction:** Precutting endoscopic mucosal resection (EMR) and hybrid endoscopic submucosal dissection (ESD) have the advantages of decreased procedure time and perforation risk. Recently, a novel multifunctional snare (SOUTEN; Kaneka Medics, Tokyo, Japan) to enable easy and time-efficient hybrid ESD, involving circumferential incision and partial submucosal dissection, followed by snare resection, was introduced. The SOUTEN snare combines an 18.5-mm snare loop with a 1.5-mm needle-knife and a knob-shaped tip attached to the top of the snare loop. Sessile serrated polyps (SSPs) are increasingly recognized as a significant contributor to the epidemiologic burden of colorectal cancer; therefore, it is desirable that SSPs are resected en bloc for reliable histologic assessment of the resected specimen. We sometimes experience difficult SSP cases for en bloc EMR, in which the polyps are more than 20 mm in size or in which the border of the lesion is difficult to identify. Until now, there have been few reports regarding the outcomes of precutting EMR and hybrid ESD using SOUTEN for SSPs.

**Aims & Methods:** The aim of this study was to evaluate the usefulness and safety of colorectal hybrid ESD and precutting EMR for SSPs using SOUTEN. We analyzed 14 SSPs in 12 patients (2 male and 10 female, mean age: 69.1 years) who underwent hybrid ESD or precutting ESD using SOUTEN at our hospital between May 2018 and March 2019. The clinicopathological characteristics, en bloc resection rate, histological complete resection rate, curative resection rate, tumor size, specimen size, procedure time, and adverse event rate were evaluated.

**Results:** Of the 14 lesions, 1 (7%) was located in the cecum, 6 (43%) in the ascending colon, 6 (43%) in the transverse colon, and 1 (7%) in the descending colon. All lesions had a 0-IIa macroscopic polyp morphology, and all lesions were histopathologically identified as SSPs (low grade). Among the treatment methods, the hybrid ESD-to-precutting EMR ratio was 8/6. The mean tumor and specimen sizes were 18.2 mm, and 24.5 mm, respectively. The en bloc, histological complete, and curative resection rates were 100% (14/14), 100% (14/14), and 100% (14/14), respectively. The median procedure time was 16.5 minutes. There was no bleeding, perforation, or stricture postoperatively.

**Conclusion:** Hybrid ESD/precutting EMR using SOUTEN for SSPs is a safe and effective treatment option because of sufficient submucosal swelling after injection of the submucosal layer. A prospective study with a large number of cases should be conducted in the future to validate our results.

**Disclosure:** Nothing to disclose

## P0190 COLON CLEANSING EFFICACY AND SAFETY OF 1L NER1006 IN PATIENTS WITH MILD TO MODERATE RENAL IMPAIRMENT: POST HOC ANALYSIS OF RANDOMISED PHASE 3 CLINICAL TRIALS

Alvarez Gonzalez M.A.<sup>1</sup>, Mokashi S.<sup>2</sup>, Hassan C.<sup>3</sup>

<sup>1</sup>Hospital del Mar, Barcelona, Spain, <sup>2</sup>Norgine, Medical, Harefield Middlesex, United Kingdom, <sup>3</sup>Nuovo Regina Margherita Hospital, Gastroenterology, Rome, Italy

Contact E-Mail Address: marcoalgo@gmail.com

**Introduction:** Only polyethylene glycol (PEG) bowel preparations are recommended for patients with renal failure. This post hoc analysis of randomised phase 3 clinical trials assessed the colon cleansing efficacy of the first 1L PEG, NER1006, in renally impaired versus non-renally impaired patients [1-3].

**Aims & Methods:** Patients received split dosing regimens of NER1006, either day-before (PM/PM), overnight (PM/AM), or morning-only (AM/AM). Cleansing efficacy was assessed by treatment blinded central readers using the Harefield Cleansing Scale (HCS). The efficacy analysis included patients with a documented renal status and colonoscopy data. Patients were stratified into creatinine clearance rate (CrCl) groups: normal renal function (≥90 mL/min), mild renal insufficiency (≥60 to < 90 mL/min), or

moderate renal insufficiency ( $\geq 30$  to  $< 60$  mL/min). Patients with severe renal insufficiency were excluded.

**Results:** Among 1134 randomised patients, 1016 were assessed for efficacy (renal status; 692 mild/moderate, 324 normal). No significant difference was observed in the overall cleansing success rates in mild and moderate versus normal (Table). Safety was assessed in 1028 patients. The types of TEAEs were generally consistent between mild and moderate and normal. The most common TEAEs in all patient groups were gastrointestinal i.e. nausea, vomiting and dehydration. There were numerically more TEAEs in patients with moderate renal insufficiency versus normal. However, this may reflect the patients' disease state.

**Conclusion:** The current efficacy and safety findings support the use of NER1006 as a bowel preparation in patients with mild to moderate renal impairment.

Successful overall colon cleansing using the HCS	Mild to moderate renal impairment: CrCl 30-90 mL/min	Normal renal function: CrCl 90+ mL/min	P value
MORA PM/AM N=262	96% (183/190)	97% (69/71)	0.63
MORA AM/AM N=270	91% (182/200)	91% (62/68)	0.52
DAYB PM/PM N=236	64% (91/142)	67% (61/91)	0.68
NOCT PM/AM N=255	92% (147/160)	94% (88/94)	0.69

[Percentage of NER1006 patients with successful overall colon cleansing using the HCS in patients with renal-impairment vs normal renal function.]

### P0191 FEASIBILITY OF ILEAL INTUBATION IN COLONOSCOPY WITH ENDOCUFF: A PROSPECTIVE OPEN LABEL COMPARISON

**Sawatzki M., Borovicka J., Baumeler S.**  
Kantonsspital, Gastroenterology, St. Gallen, Switzerland

**Contact E-Mail Address:** sawatzki@sunrise.ch

**Introduction:** Endocuff (EC) is a mucosal exposure device attached to the distal tip of the colonoscope. Adenoma detection rate (ADR) can be improved with EC and the examination time (without reducing the ADR) can be reduced (1,2). The use of EC influencing the ileum intubation rate (IIR) has been investigated in only two studies as secondary endpoint with contradictory results (3,4).

**Aims & Methods:** We prospectively analysed the use of an EC and ileum intubation at the Kantonsspital St. Gallen in Switzerland between January to December 2018 performed by 3 experienced endoscopists and 1 trainee. Scientific data security were approved by the local ethics commission (EKSG14/099). EC was only applied for screening or follow-up colonoscopy. The withdrawal time had to be at least 6 minutes. Significance was calculated with the Fishers Exact Test. Adenoma detection rate (ADR) was determined.

**Results:** We included 570 patients, median age 60 years (range 21-94), 51% were male. Of the 570 colonoscopies, 63% were performed with EC (n=359). Colonoscopy with EC and intubation of the terminal ileum was achieved in 85.8% (308 of 359 patients). Without EC, the ileum was intubated in 82% (173 of 211 patients). There was no significant difference (p=0.234). ADR with EC was 45% and without EC 43%, p<0.00001. IIR for the trainee (n=87) was 71% with EC and 76% without EC (p=0.81).

**Conclusion:** Colonoscopy with the use of Endocuff achieved the same ileum intubation rate as without Endocuff. The need of ileum intubation therefore is not an argument against the use of Endocuff. In contrast, the ADR significantly improves with the use of an EC.

### P0192 1L NER1006 IMPROVES HIGH-QUALITY COLON CLEANSING VERSUS STANDARD BOWEL PREPARATIONS: POST HOC ANALYSIS OF PHASE 3 CLINICAL TRIALS USING REAL-WORLD CLEANSING ASSESSMENT BY SITE ENDOSCOPISTS

**Gschossmann J., Amlani B., Repici A.**  
<sup>1</sup>Klinikum Forchheim, Dept. of Internal Medicine, Forchheim, Germany, <sup>2</sup>Norgine, Medical Affairs, Harefield, United Kingdom, <sup>3</sup>st. Clinico Humanitas Rozzano, Dept. of Gastroenterology, Milano, Italy

**Contact E-Mail Address:** juergen.gschossmann@klinikum-forchheim.de

**Introduction:** Colonoscopy requires bowel cleansing; high-quality cleansing facilitates lesion detection. NER1006 is a 1L polyethylene glycol (PEG) bowel preparation. This post hoc analysis of three randomised trials investigated cleansing efficacy assessed, as in clinical practice, by site endoscopists [1-3].

**Aims & Methods:** Patients received either a 2-day evening/morning regimen of NER1006 (N2D), 2L PEG+ascorbate (2LPEG), or oral sulfate solution (OSS); or day-before NER1006 (NDB) or sodium picosulfate plus magnesium citrate (SPMC). Morning-only NER1006 (N1D) dosing was also evaluated. Cleansing was assessed by treatment-blinded site endoscopists using the Harefield Cleansing Scale (HCS). This analysis included only patients with self-reported 100% treatment adherence. Overall cleansing success (HCS grade A or B), overall high-quality cleansing success (HCS grade A), and the proportion of high-quality segments (HCS 3-4) per treatment population were analysed.

**Results:** Among 1985 randomised patients, 1367 were included (Table). Overall cleansing success was higher with N2D than 2LPEG (97.5% vs 93.0%) and more patients had overall high-quality cleansing with N2D and N1D than 2LPEG (72.1% and 68.4% vs 56.0%). N2D delivered more overall high-quality cleansing than OSS (77.3% vs 69.8%). Overall cleansing success was higher with NDB than SPMC (74.5% vs 62.9%) and more patients achieved HCS Grade A with NDB than SPMC (29.0% vs 12.0%). More high-quality segments were demonstrated with N2D and N1D versus 2LPEG (87.1% and 84.4% vs 76.3%), with N2D versus OSS (89.5% vs 84.4%) and with NDB than SPMC (60.3% vs 47.0%).

**Conclusion:** When assessed by site-endoscopists NER1006 delivers greater high-quality, HCS grade A, cleansing than 2LPEG, OSS, or SPMC.

Phase 3 trial	MORA			NOCT		DAYB	
Cleansing success	N2D	N1D	2LPEG	N2D	OSS	NDB	SPMC

**Introduction:** Endoscopic mucosal resection (EMR) with submucosal injection is widely performed to remove colorectal polyps, and underwater EMR (UEMR) without submucosal injection has been reported to be useful for large colorectal polyps. We recently reported the results of a multicenter randomized controlled trial that compared RO resection rates of 10-20-mm colorectal polyps between UEMR and conventional EMR (CEMR)<sup>1</sup>.

**Aims & Methods:** This study aimed to reveal independent predictors for RO resection by post hoc analysis of the multicenter randomized controlled trial conducted at five Japanese institutions (UMINO00018989). Patients aged ≥20 years with 10-20-mm colorectal mucosal lesions (adenoma, intramucosal adenocarcinoma, or sessile serrated adenoma/polyp) were randomly assigned to the UEMR or CEMR group. Only the most proximal lesion was registered. Exclusion criteria were as follows: pedunculated lesions, residual lesions after endoscopic resection, inflammatory bowel disease, familial polyposis, electrolyte abnormality, coagulopathy, or severe organ failure. In the CEMR group, mucosal resection was performed with submucosal injection in an environment of air or carbon dioxide. In the UEMR group, the colonic lumen was filled with water and EMR was performed without submucosal injection. The intergroup difference in RO resection rates was the primary endpoint. Multivariate logistic regression analysis was used for comparison of the RO and non-RO groups.

**Results:** A total of 214 patients were enrolled between February 2016 and December 2017. Finally, 108 in the UEMR group and 102 patients in the CEMR were analyzed in an intention-to-treat analysis. The RO resection rate of the UEMR group (69% [74/108; 95% confidence interval (CI), 59-77%]) was significantly higher than that of the CEMR group (50% [51/102; 95% CI, 40-60%]) (p = 0.011). There was no significant intergroup difference in median procedure time (165 vs. 175 s) or adverse events rate (2.8% vs. 2.0%). Multivariate analysis revealed that procedure (UEMR vs CEMR: odds ratio, 2.24 [95% CI, 1.24-4.03]) and tumor diameter (≥15 mm vs < 15 mm: odds ratio, 0.56 [95% CI, 0.31-0.99]) were independent factors of RO resection rate (Table).

		Odds ratio [95% CI]	P value
Procedure	UMER/EMR	2.24 [1.24, 4.03]	0.007
Endoscopist	Non-expert/expert	0.83 [0.46, 1.49]	0.530
Sex	Male/female	1.21 [0.65, 2.24]	0.550
Tumor diameter	≥15 mm/<15 mm	0.56 [0.31, 0.99]	0.048
Morphology	Superficial/sessile	0.95 [0.50, 1.81]	0.890
Age	≥70 y/<70 y	0.80 [0.44, 1.45]	0.460
Location	Rectum	1.00	0.244
	Right-sided colon	0.93 [0.30, 2.87]	
	Left-sided colon	1.70 [0.52, 5.52]	

[Results of multivariate analysis for RO resection]

**Conclusion:** UEMR featured an improved RO resection rate of 10-20-mm colorectal polyps without increasing procedure time or the adverse event rate. UEMR procedure and polyp size < 15 mm were independently related to RO resection.

**Introduction:** Detection and diagnosis of colon adenoma have long been emphasized in reducing colon cancer incidence. Since confirmation of the colon cancer diagnosis is by pathology, there has been lots of efforts to find and diagnose the colonic lesion more precisely before histological analysis. To spot the polyp and predict its pathology more accurately, there has been not only promising imaging technique development but also several studies using artificial intelligence for polyp recognition and its classification. The aim of this study is to develop computer-aided diagnostic system for colon adenoma.

**Aims & Methods:** We labeled the colonoscopic data into 4 classes according to the final pathology; Normal, Low-grade dysplasia, High-grade dysplasia, and Adenocarcinoma. The total number of colonoscopic pictures was 2507; Normal, 903; Low-grade dysplasia, 738; High-grade dysplasia, 459; and Adenocarcinoma, 407, and we separated them into the train set and the test set. We removed unnecessary black pads from the original images, and we resized our data into 224 by 224 for modeling.

**Results:** We used a ResNet50 model pre-trained with Imagenet data to classify the adenoma. The model we used classified the class with 86% accuracy. We used a few data augmentation methods to improve the data and utilized heatmap technique to explain the results. We also compared our data with the classification pilot test results from 6 endoscopists.

**Conclusion:** The trained model successfully distinguished the colon adenoma pathology. There should be follow up studies to detect and diagnose the colon adenoma in real-time practice.

**Contact E-Mail Address:** t-murakm@juntendo.ac.jp

**Introduction:** Sessile serrated adenoma/polyp (SSA/P), an early precursor lesion in the serrated neoplasia pathway [1], is now considered a major contributor to the failure of colonoscopy in the prevention of colorectal cancers, known as "interval cancer" [2]. Therefore, accurate diagnosis of SSA/P and its dysplastic components is endoscopically important. However, the usefulness of magnifying endoscopy for serrated lesions with dysplastic changes has not yet been fully elucidated.

**Aims & Methods:** The aim of this study was to verify the usefulness of magnifying narrow-band imaging (NBI) endoscopy and magnifying chromoendoscopy for the diagnosis of SSA/P with dysplasia/carcinoma. Among the endoscopically or surgically resected lesions pathologically diagnosed as SSA/P with dysplasia or invasive carcinoma at Juntendo University Hospital (Tokyo, Japan) between 2011 and 2018, 73 (from 73 patients), including 44 low-grade dysplasia (LGD), 17 high-grade dysplasia (HGD), and 12

submucosal invasive carcinoma (SIC), were assessed. We retrospectively evaluated magnifying NBI endoscopic and magnifying chromoendoscopic findings using the Japan NBI Expert Team (JNET) system [3] and Kudo's pit pattern classification [4], respectively.

**Results:** The clinicopathological and endoscopic characteristics of the studied lesions are summarized in Table 1. All the groups were more frequently located in the proximal colon. The SSA/P-SICs tended to be larger than the SSA/P-LGDs and SSA/P-HGDs. As for the JNET classification with magnifying NBI endoscopy, 63 SSA/P lesions (86%) exhibited type 1 and type 2A, 2B, or 3, corresponding to SSA/P and dysplasia/carcinoma, respectively. The pit pattern analysis revealed that 61 SSA/P lesions (84%) had a combination of types II (including type II-open) and III<sub>L</sub>, IV, V<sub>L</sub>, or V<sub>N</sub> pit patterns, corresponding to SSA/P and dysplasia/carcinoma, respectively. Furthermore, both magnifying NBI endoscopy and magnifying chromoendoscopy had high sensitivity (90%) for diagnosing SSA/P with dysplasia/carcinoma.

**Conclusion:** Our findings suggest that the use of magnifying NBI endoscopy and magnifying chromoendoscopy might be useful for the diagnosis of SSA/P with dysplasia/carcinoma. This increased awareness may also improve recognition and complete resection of SSA/Ps with dysplasia or invasive carcinoma, and reduce the rates of interval cancer.

**Contact E-Mail Address:** marcello.maida@hotmail.it

**Introduction:** The effectiveness of bowel cleansing is essential for a quality colonoscopy since it affects diagnostic accuracy and adenoma detection rate. Recently, a very-low-volume 1L PEG-ASC solution (Plenvu®; Norgine, Harefield, UK) has been introduced on the evidence arising from three parallel phase 3 randomized controlled trials showing non-inferiority respect to comparators [1-3].

**Aims & Methods:** This study aimed to assess the effectiveness and tolerability of novel 1L PEG preparation compared to 4L and 2L PEG solutions in a real-life setting and to evaluate independent factors associated with a bowel cleansing success.

All in- and out-patients aged 18 years and over scheduled for a screening, surveillance or diagnostic colonoscopy, after an afternoon only or afternoon/morning 1, 2 or 4L PEG-based preparation were consecutively enrolled from September 2018 to February 2019 in 5 Italian centres. Bowel cleansing was assessed through the Boston Bowel Preparation Scale (BBPS), a bowel cleansing success was defined as a total BBPS≥6 with a partial BBPS≥2 in each colon segment and a high-quality cleansing of the right colon as a partial BBPS=3. Tolerability was evaluated through a semi-quantitative scale with a score ranging from 0 to 10. Safety was monitored through adverse event (AE) reporting.

**Results:** 1289 patients meeting inclusion criteria were enrolled in the study. The mean age was 60.5±14.1 years with an equal gender balance, and the main indications of colonoscopy in 58% of cases were screening and surveillance for CRC. Overall, 490 patients performed a 4L PEG preparation (Selgesse®), 566 a 2L PEG cleansing (Moviprep® or Clensia®) and 233 a 1L PEG preparation (Plenvu®).

Overall, bowel cleansing by BBPS was 6.3±1.5, 6.2±1.5 and 7.3±1.5 (p<0.001) while right colon cleansing was 1.7±0.6, 1.6±0.6 and 2.1±0.6 (p<0.001) for 4L, 2L and 1L PEG preparation respectively. A bowel cleansing success was achieved in 72.4%, 74.5% and 90.1% (p<0.001), while an high-quality cleansing of the right colon in 15.5%, 11.7% and 39.5% (p<0.001) for 4L, 2L and 1L PEG preparation groups, respectively.

The 1L preparation was the most tolerated compared to the 2 and 4L PEG solutions, with an average score of 7.8±1.7 vs 7.1±2.0 and 7.3±2.0 (p<0.001) respectively, in the absence of serious adverse events within any of the three groups.

At multivariate analysis, age (OR = 0.98, 95% CI = 0.97-0.99; P = 0.02), absence of diabetes (OR = 1.51, 95% CI = 1.01-2.25; P = 0.04), adequate cleansing at previous colonoscopy (OR = 2.37, 95% CI = 1.37-4.09; P = 0.002), afternoon-morning split regimen (OR = 2.52, 95% CI = 1.65-3.83; P < 0.001), low-fiber diet for at least 3 days preceding colonoscopy (OR = 2.31, 95% CI = 1.61-3.31; P<0.001), colonoscopy within 5 hours after the end of the preparation (OR= 2.16, 95% CI = 1.30-3.60; P= 0.003) and tolerability score (OR = 1.22, 95% CI = 1.14-1.31; P<0.001) were independently associated with a bowel cleansing success.

**Conclusion:** The novel 1L PEG-ASC solution (Plenvu®) presents greater effectiveness compared to higher-volume PEG preparation in terms of overall bowel cleansing and high-quality cleansing of the right colon with the advantage of a higher adherence and a significantly better tolerability profile respect to comparators. In the next future, this new very-low-volume solution will be useful to improve the tolerability of bowel preparation, increasing at the same time the adherence to CRC screening and surveillance programs.

**Contact E-Mail Address:** hormati@yahoo.com

**Introduction:** The current study aimed at comparing the effects of diltiazem gel, an antispasmodic drug with local pain-reducing effects, with lidocaine gel in patients undergoing flexible rectosigmoidoscopy.

**Aims & Methods:** This double-blinded, randomized, clinical trial was performed on 80 patients who were potential candidates for rectosigmoidoscopy. After obtaining the informed consent, the patients randomly assigned to one of the lidocaine gel (2 mL) or diltiazem gel (2 mL) group, 10 minutes prior to rectosigmoidoscopy. The level of pain in the patients during the procedure was measured using the visual analogue scale (VAS) and the results were recorded. The data were analyzed using paired samples t-test and independent t-test as well as analysis of covariance (ANOVA) with SPSS version 18. P-value < 0.05 was considered the level of significance.

**Results:** Of 80 patients, 35 (43.75%) were male and 45 (56.25%) female with a mean age of  $51.45 \pm 15.21$  years. The most frequent indications for rectosigmoidoscopy were abdominal pain (46.3%) and rectorrhagia (31.3%). The mean VAS score for pain reported by the patients in the lidocaine and diltiazem groups were  $3.97 \pm 2.89$  and  $2.60 \pm 2.36$ , respectively. The VAS score for pain in the diltiazem group was significantly lower than of the lidocaine group ( $P = 0.023$ ).

**Conclusion:** The application of local diltiazem gel around the anus, in spite of no side effects, can effectively reduce the pain and discomfort in patients during rectosigmoidoscopy.

**Contact E-Mail Address:** cai.mingyan@qq.com

**Introduction:** Endoscopic submucosal dissection (ESD) has a higher rate of en bloc resection rate, more accurate histological evaluation and lower rate of local recurrence compared with endoscopic mucosal resection (EMR). However, the technical difficulty limits its use in western country. To overcome the drawback, various modified techniques have been applied. Among them, ESD with snaring (by the name of hybrid ESD) is the most commonly used technique.

**Aims & Methods:** We designed a new multifunctional snare to simplify hybrid ESD procedure. The new rotatable device has the following functions: submucosal injection, needle knife, snare and argon plasma coagulation (APC). Animal study on porcine model was used to test its feasibility and safety in gastric and colorectal hybrid ESD. Artificial colorectal lesions of proximately 10mm and artificial gastric lesions of about 15mm were created by APC function of the new device. Hybrid ESD was done as following: initial mucosal pre-cut, submucosal injection, circumferential cutting, snare and APC the wound. The wound was checked one week after hybrid ESD. Then, pigs were sacrificed and necropsy performed.

The primary outcome is the en bloc resection rate. The secondary outcomes are the intra- and postoperative adverse event rate (bleeding and perforation). The wound healing one week after resection was also assessed by pathology.

**Results:** Fifteen colorectal hybrid ESD procedures were conducted successfully in three pigs (five hybrid ESD each). The en bloc resection rate of colorectal hybrid ESD was 100% (15/15). The average size of the colorectal hybrid ESD is  $10.00 \pm 1.86$  mm. No adverse event was found during the procedure or one week after resection. The endoscopic examination one week after the resection showed all wound being healing. In the pathology evaluation, superficial muscularis propria damage was found in one case (1/15, 6.67%), which was covered with exudate.

Other fourteen postoperative wounds showed healing of the ulcer. Eleven gastric hybrid ESD procedures were performed. The en bloc resection rate of gastric hybrid ESD was 100% (11/11). The average size of the gastric hybrid ESD was  $17.18 \pm 9.00$  mm. No procedure related adverse event was found.

**Conclusion:** The new all in one snare is feasible and safe in gastric and colonic hybrid ESD in porcine model. It can save the numbers of endoscopic accessories using during hybrid ESD procedure and simplify the ESD procedure. Further study in human is awaited

**Disclosure:** Nothing to disclose

**Introduction:** The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously described in posters presented at United European Gastroenterology Week, 2015 and 2016.

**Aims & Methods:** To investigate the factors associated with adequate bowel preparation using questionnaire responses from across Europe. Data collection is an ongoing process. We analysed data collected between 2/6/16 and 30/4/18.

A stepwise multivariable logistic regression analysis was performed to investigate which factors are associated with achievement of adequate bowel preparation, defined as a Boston Bowel Preparation Scale (BBPS) score  $\geq 6$ . Analysis was performed on the following variables: age over or under 50; gender; body mass index (BMI) categories; inpatient/outpatient status; reason for procedure; use of bowel preparation; whether the patient followed instructions; proportion of bowel preparation consumed; total volume of fluid consumed; time period since last dose of bowel preparation; dosing regimen; time of day colonoscopy was performed.

**Results:** Data were collected on 6455 procedures, of which whether bowel preparation was adequate (BBPS  $\geq 6$ ) or not could be determined in 6236. Of these, there were 2884 procedures where the results of all selected variables were known: adequate bowel preparation was achieved in 86.96% of these procedures.

The first five variables most associated with adequate bowel clearance were, in order:

1. Patient following instructions (89.1% vs. 54.3%,  $p < 0.0001$ ).
2. Split-dosing or same-day regimen (89.5% split-dosing and 90.8% same-day vs. 77.9% evening,  $p = 0.004$ ).
3. Outpatient status (88.4% vs. 77.3% inpatient,  $p < 0.0001$ ).
4. Age < 50 years (93.3% vs. 85.3% > 50 years,  $p < 0.0001$ ).

5. Lower time period between procedure and last intake of bowel preparation (mean 6.1 hours vs. 8.0 hours in those with inadequate bowel preparation,  $p=0.0030$ ).

**Conclusion:** Patients following instructions is the most important factor associated with achieving adequate bowel clearance followed by using a split-dosing or same-day regimen.

Klinikum Ludwigshafen, Ludwigshafen, Germany, <sup>14</sup>Chairman, LebensBlicke Foundation for the Prevention of Colorectal Cancer, Ludwigshafen, Germany, <sup>15</sup>Norgine, Harefield, Middlesex, United Kingdom, <sup>16</sup>Fondazione Poliambulanza, Brescia, Italy

**Contact E-Mail Address:** pedro.amaro1967@gmail.com

**Introduction:** The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously presented at United European Gastroenterology Week, 2015 and 2016.<sup>1,2</sup> Management of pathology is a domain of colonoscopy quality according to European Society of Gastrointestinal Endoscopy (ESGE) performance measures.<sup>3</sup>

**Aims & Methods:** To assess the endoscopic interventions performed in procedures where a non-diminutive polyp was recorded. Data collection is an ongoing process: we analysed data collected between 2/6/16 and 30/4/18. **Results:** Of 6445 procedures, 2621 reported a polyp (40.7%). Polyp size was missing in 35 procedures, leaving 2586 procedures with at least one polyp of known size.

**Polyps >5 mm:** 1294 procedures reported at least one polyp >5mm: 1156 reported an endoscopic intervention (89.3%), 136 reported that there was no endoscopic intervention (10.5%) while 2 did not answer (DNA, 0.15%). Of the 138 procedures with a polyp >5mm that did not report an endoscopic intervention, there was one procedure in which an immediate complication (vascular syncope) was reported (132 stated there were no immediate complications, 5 DNA), and 37 who reported a requirement for a non-routine (immediate) repeat procedure (no 93, DNA 8). The reasons for a repeat procedure were: 20 further treatment or intervention required, 8 insufficient bowel preparation, 3 pathology encountered, 2 adjustment of blood-thinning medication required prior to intervention, and one case each of refused consent for polypectomy, referral to specialised hospital, pain and unsafe procedure.

**Polyps ≥20 mm** (polyp size ≥20 mm is a subset of >5 mm): There were 280 procedures with a polyp ≥20 mm recorded. Of these procedures 227 (81.1%) reported an endoscopic intervention while 53 (18.9%) reported that they did not perform an endoscopic intervention. Tattooing was only reported in 28 procedures (10%).

Of the 53 reporting no endoscopic intervention, one reported an immediate complication (vascular syncope), while 50 reported no immediate complication and 2 DNA. A requirement for an immediate (non-routine) repeat procedure was reported in 19 procedures (no 33, DNA 1): 9 further treatment or intervention required, 5 insufficient bowel preparation, 3 pathology encountered, one referral to specialised hospital for endoscopic mucosal resection and one unsafe procedure.

**Conclusion:** In procedures reporting non-diminutive polyps, no immediate endoscopic intervention was reported in over 1 in 10 procedures, rising to nearly one in five for procedures reporting a polyp ≥20 mm. The ESGE specifies that "In patients undergoing removal of colorectal nonpedunculated lesions 20mm in size or larger, or with suspicious macroscopic features regardless of size, the resection site should be tattooed to improve future re-location of the resection site". This should be done in 100% of cases.<sup>3</sup> Our findings indicate that tattooing rates are very low, being reported in only 10% of procedures recording a polyp ≥20 mm.

Type of endoscopic intervention	Polyp size >5 mm, Number, N=1156	Polyp size ≥20 mm, Number, N=227
Endoscopic mucosal resection	154	58
Endoscopic submucosal dissection	14	6
Polypectomy (complete)	1012	159
Polypectomy (incomplete)	18	10
Argon plasma coagulation	4	1
Biopsy	41	21
Tattooing	40	28

Note: Biopsies performed were not necessarily related with polyp resection.

[Endoscopic interventions in procedures with non-diminutive polyps (multiple options possible). Note: polyp size ≥20 mm is a subset of >5 mm.]

## P0201 SESSILE SERRATED LESIONS DETECTION WITH ENDOCUFF-ASSISTED COLONOSCOPY - A RANDOMIZED CONTROLLED TRIAL

Costa Santos M.P., Palmela C., Gouveia C., Gomes C., Roque Ramos L.M., Fidalgo C., Nunes J., Loureiro R., Barjas E., Oliveira H., Torres J., Cravo M., Oliveira Ferreira A.

Hospital Beatriz Ângelo, Gastroenterology, Loures, Portugal

**Contact E-Mail Address:** mariapiacostasantos@gmail.com

**Introduction:** Sessile serrated lesions (SSL) have been associated with interval colorectal cancer (CRC) since they present a faster carcinogenesis and are more difficult to detect than adenomas. Several techniques have been developed to increase the sensitivity of colonoscopy, namely the Endocuff. Studies demonstrated that Endocuff-assisted colonoscopy improves adenoma detection rate. Still, the available data of its' effectiveness in detecting SSL is very limited. The aim of this study was to compare the effectiveness in SSL detection of Endocuff-assisted colonoscopy versus conventional colonoscopy.

**Aims & Methods:** We performed a randomized controlled trial that included patients undergoing elective colonoscopy between June 2018 and March 2019. Patients were randomly assigned in two groups before the procedure: 1) Endocuff-assisted colonoscopy; 2) Conventional colonoscopy. The procedures were performed with high definition endoscopes. The primary endpoint was the mean number of SSL with ≥ 10 mm per colonoscopy.

**Results:** 170 patients were included, 57% male, with mean age of 62.4±9.9 years. In *per protocol analysis*, 81 (48%) patients performed Endocuff-assisted colonoscopy and 89 (52%) conventional colonoscopy. There were no differences in cecal intubation rate (99% vs 94%,  $P=0.214$ ), in mean cecal intubation time ( $7.3 \pm 4.1$  vs  $8.0 \pm 4.3$  minutes,  $P=0.260$ ) nor in withdrawal time ( $12.3 \pm 5.3$  vs  $13.1 \pm 6.7$  minutes,  $P=0.373$ ) between procedures with and without Endocuff. SSL detection rate was higher in Endocuff-assisted colonoscopy group (9% vs 2%,  $P=0.027$ ), as well as the mean number of SSL detected per colonoscopy ( $0.2 \pm 0.5$  vs  $0.02 \pm 0.1$ ,  $P=0.021$ ). There were no differences in the mean number of SSL  $\geq 10$  mm between groups ( $0.04 \pm 0.2$  vs  $0.02 \pm 0.1$ ,  $P=0.577$ ). There were also no differences in adenoma detection rate (72% vs 67%,  $P=0.554$ ) nor in the mean number of adenomas detected per colonoscopy ( $1.8 \pm 2.4$  vs  $1.7 \pm 2.2$ ,  $P=0.785$ ). The rate of adverse events was similar between groups (1% vs 1%,  $P=0.999$ ).

**Conclusion:** Endocuff-assisted colonoscopy increases SSL detection rate and the mean number of SSL per colonoscopy, but not the mean number of SSL  $\geq 10$  mm.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** ervin.toth@med.lu.se

**Introduction:** The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously described.<sup>1,2</sup>

**Aims & Methods:** To assess the patient factors associated with flat and protruded lesion reporting, as defined by Paris classification. Data collection is an ongoing process: we analysed data collected between 2/6/16 and 30/4/18. Adequate bowel clearance was defined as a Boston Bowel Preparation Score (BBPS)  $\geq 6$ .

**Results:** Of 6445 procedures, 2621 reported a polyp in at least one segment (40.7%). Protruded lesions were reported in 2160 procedures and flat lesions were reported in 692 procedures. In procedures with polyps reported, the proportion with flat lesions was significantly lower in the left colon segment than either transverse or right colon segments ( $p < 0.0001$ ).

	Right	Transverse	Left	Any segment
Any polyp	1328	723	1645	2621
Flat lesion	346	181	329	692
Protruded lesion	1012	544	1346	2160

[Table. Procedures in which a polyp was reported by type and colon segment]

Reporting of both flat and protruded lesions varied by age (generally increasing with increasing age,  $p < 0.0001$  overall and in all individual segments). Reporting also increased for both flat and protruded lesions in those who had received a previous total colonoscopy within the last 5 years ( $p < 0.0001$ , significant in all segments): flat lesions 13.8% vs 9.8%; protruded lesions 38.7% vs 29.2%. Flat lesion reporting was not associated with body mass index (BMI, kg/m<sup>2</sup>) ( $p=0.667$  overall, not significant in

any individual segment), while protruded lesion reporting was generally higher in higher BMI groups ( $p < 0.0001$  overall and in all individual segments): BMI  $< 18.5$  17.9%,  $18.5 < 25$  30.5%,  $25 < 30$  40.0%,  $30 < 35$  45.6%,  $\geq 35$  42.8%.

Flat lesions were more commonly reported in inpatients (inpatients 16.2% vs 10.7% outpatients,  $p < 0.0001$ ), this was significant in the left ( $p=0.004$ ) and right ( $p < 0.0001$ ) segments but not the transverse segment ( $p=0.256$ ). Protruded lesions were more common in outpatients (inpatients 29% vs 33.4% outpatients,  $p=0.023$ ), however, this was not significant in any individual segments.

The reporting of flat lesions was significantly higher in procedures reporting adequate bowel clearance (11.4% vs 8.0%,  $p=0.004$ ), this was significant in the left ( $p=0.016$ ) and right ( $p=0.01$ ) segments but not the transverse segment ( $p=0.354$ ). Conversely, reporting of protruded lesions was not changed according to bowel cleansing adequacy ( $p=0.317$ ).

**Conclusion:** Flat lesions are less commonly reported than protruded lesions. They are significantly less likely to be reported than protruded lesions in the left colon segment compared with the transverse and right segments. Reporting of flat lesions was not associated with BMI, while higher BMI was associated with increased reporting of protruded lesions. Flat lesions were more likely to be reported in inpatients while protruded lesions were more likely in outpatients. Reporting of protruded lesions was not affected by adequacy of bowel clearance while flat lesion reporting was higher in procedures reporting adequate bowel clearance.

## P0203 IS ADENOMA DETECTION RATE INCREASING IN PATIENTS YOUNGER THAN AGE 50?

Wonaga A., Gutierrez B., Cassella F., Graciano J., Fernandez J.L., Viola L.A. Centro Integral de Gastroenterología, Gastroenterology, Buenos Aires, Argentina

**Contact E-Mail Address:** awonaga@gmail.com

**Introduction:** Some data in the literature suggest that adenoma detection rate (ADR) in patients younger than age 50 has increased with the passage of years, with figures ranging between 4.7% and 24.1%. These observation gives cause for the start of colorectal cancer (CRC) screening at earlier ages.

**Aims & Methods:** Aim: To compare the ADR in two populations belonging to two periods separated by eight years.

**Methods:** We retrospectively studied patients younger than 50 years old who underwent a colonoscopy in an endoscopy center from Buenos Aires, Argentina; 204 from May to October 2009 (group 1) and 709 from January 2016 to May 2017 (Group 2). We recorded the following data: age, sex, indication of colonoscopy [low risk screening, high risk screening (family antecedents of CRC) and due to symptoms or surveillance], ADR and adenocarcinoma detection rate (ACDR). Detection rates were compared using a  $\chi^2$  or a Fisher test as appropriate.

**Results:** Ninety six (47.1 %) patients from group 1 and 337 (47.5%) from group 2 were men (NS). Mean age was  $40.4 \pm 7.5$  years in group 1 and  $39.1 \pm 7.5$  years in group 2 ( $P = 0.03$ ). In group 1, the indication of colonoscopy was low risk screening in 45 patients, high risk screening in 41, and symptoms or surveillance in 118. In group 2, the indication of colonoscopy was low risk screening in 116 patients, high risk screening in 97, and symptoms or surveillance in 496. In the total population, 20 adenomas were detected in group 1 (ADR 9.8%) and 66 in group 2 (ADR 9.3%) ( $P = 0.93$ ). No adenocarcinoma was detected in group 1 (ACDR 0%) and 5 were detected in group 2 (ACDR 0.7%) ( $P = 0.59$ ). In low risk screening patients, 7 adenomas were detected in group 1 (ADR 15.6%) and 22 in group 2 (ADR 19.0%) ( $P = 0.81$ ). In high risk screening patients, 5 adenomas were detected in group 1 (ADR 12.2%) and 12 in group 2 (ADR 12.3%) ( $P = 1.00$ ).

In patients who underwent endoscopy due to symptoms or surveillance, 8 adenomas were detected in group 1 (ADR 6.8%) and 32 in group 2 (ADR 6.4%) (P = 0.83).

**Conclusion:** We did not find significant differences in the ADR of both groups, independently of the indication of colonoscopy, suggesting that ADR has not increased with the passage of years. ACDR neither differs but we cannot reach any conclusion due to the very low prevalence of CRC.

**Disclosure:** Nothing to disclose

#### **P0204 SALINE-IMMERSION THERAPEUTIC ENDOSCOPY (SITE) COMBINED WITH THE POCKET-CREATION METHOD (PCM) FOR ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) OF GASTRIC AND COLORECTAL LESIONS: EXPERIENCE FROM A TERTIARY REFERRAL CENTRE IN LONDON**

Despott E.J., Coppo C., Lazaridis N., Costa D., Koukias N., Murino A. *Royal Free Hospital & UCL School of Medicine, Royal Free Unit for Endoscopy & Centre for Gastroenterology, UCL Institute for Liver & Digestive Health, London, United Kingdom*

**Contact E-Mail Address:** claudiacoppo@icloud.com

**Introduction:** Endoscopic submucosal dissection (ESD) is now widely accepted as a potentially curative, minimally invasive alternative to major surgery for the endoscopic management of superficial gastric and colorectal neoplasms. Due to its several advantages, in our institution, we use the pocket-creation method (PCM) for ESD as described by Yamamoto H. et al. (1). Since 2017, we have combined this with saline-immersion therapeutic endoscopy (SITE), since in our experience, this further facilitates PCM ESD by improving view quality (through refractive magnification, and minimal lense fogging) and lesion lifting, through buoyancy.

**Aims & Methods:** The aim of our study is to review our centre's experience of SITE-PCM-ESD cases. Demographic, endoscopic, histopathological data of patients treated by SITE-PCM-ESD were prospectively collected from July 2017 to April 2019.

**Results:** ESDs were performed in 35 patients (15 women), mean age: 64.8 years. Three lesions (8.6%) were removed from the stomach, 1 from the caecum (2.86%), 6 from the ascending colon (17.14%), 14 from the sigmoid colon (40%) and 11 from the rectum (31.40%). En-bloc pure SITE-PCM-ESD resection was achieved in 23 patients (65.7%); in 3 patients (8.6%) the procedure was not completed due to the suspicion of invasive malignancy and these patients were referred for surgery. Finally, in 9 cases (25.7%) the technique was converted in an endoscopic mucosal resection (EMR) due to time constraints. One of the 3 patients who were referred for surgery did not undergo any further intervention due to risks associated with underlying comorbidities. In 1 of the other 2 cases the histopathology after surgery confirmed our suspicion of malignancy.

Details of the cases managed by pure SITE-PCM-ESD are described as follows. Median specimen size was of 45,1 mm (12-100mm). Histopathological examination showed: 1) 1 villous adenoma with low grade dysplasia, 2) 8 tubular adenoma with low grade dysplasia, 3) 3 tubular adenoma with high grade dysplasia, 4) 1 tubulovillous adenoma with high grade dysplasia, 5) 10 tubulovillous adenoma with low grade dysplasia, 6) 1 adenocarcinoma, 7) 4 neuroendocrine tumors (2 G1 rectal NET, 1 G1 gastric NET and 1 G2 gastric NET), 8) 1 serrated adenoma with low grade dysplasia 9) 1 hyperplastic gastric polyp and 10) 1 sessile serrated lesion without dysplasia. RO resection rate was 90.32 %. Lymphovascular infiltration was suspected in the one case of malignancy (3.12%). Two patients suffered from early post-procedural rectal bleeding, warranting further endotherapy (clip placement and haemospray application); no further complications were identified. To date, 16 patients (51.6%) have completed 3 months' and 12 patients (38.7%) have completed 6 months' endoscopic follow-up respectively; none of these patients have had any evidence of disease recurrence.

**Conclusion:** Our series of SITE-PCM ESD showed favorable results in term of efficacy and safety. Further comparative randomised control studies are required to further evaluate potential advantages of this technique.

#### **P0205 EFFICACY, SAFETY AND RESECTION OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF SUPERFICIAL COLORECTAL NEOPLASIA IN AN ENDOSCOPY REFERRAL CENTER**

Fiori G., Bravi L., Ravizza D., Trovato C., De Roberto G., Giunta M., Crosta C.

*European Institute of Oncology, IRCCS, Division of Endoscopy, Milan, Italy*

**Contact E-Mail Address:** ivana.bravi@ieo.it

**Introduction:** Endoscopic submucosal dissection (ESD) is the preferred resection technique in eastern countries for superficial colorectal neoplasia larger than 2 centimeters in size and/or suspicious of submucosal superficial invasion. Only few data on ESD for colorectal neoplasia have been published in western countries.

**Aims & Methods:** We aimed to assess the safety, efficacy and resection outcomes of ESD for the treatment of large colorectal lesions in our center. We retrospectively collected medical data of consecutive patients who underwent colorectal ESD between 2015 and 2018 from a prospectively recorded database. Patients with inflammatory bowel diseases and familial polyposis were excluded.

**Results:** Ninety five lesions in 94 patients were included in the study (42 males, median age 69 years). Median lesion size was 30 mm. 82 (86.3%) were naïve lesions, whereas 13 (13.7%) were recurrent or remnant lesions. 24 (25.3%) lesions were located in the right colon, 21 (22.1%) in the left colon, 50 (52.6%) in the rectum. Naïve lesions were defined as laterally spreading tumors (LSTs) granular homogeneous, 2 (2.4%), LSTs granular mixed, 26 (31.7%), LSTs non granular, 37 (45.1%), sessile polyps, 17 (20.7%). Histology revealed 77 (81%) benign adenomatous lesions (with high grade dysplasia in 87%), while submucosal invasive cancer (SMIC) was present in the remaining 18 (19%) lesions. All SMICs were deeply invasive (>1000 µm).

En-bloc resection was possible in 71 (74.7%) lesions: 65/82 (79.3%) naïve and 6/13 (46.1%) non naïve. In 21(22.1%) lesions piecemeal ESD had to be performed. In the remaining 3 lesions (2 naïve), resection was stopped because of non-lifting.

Complications occurred in 13/95 (13.7%) lesions: 6 (6.3%) post-procedural bleedings (no one needed blood transfusion) and 7 (7.4%) intra-procedural perforations. Only one patient (1.05%) underwent surgical management for complication (i.e. perforation).

RO resection was obtained in 58/71 lesions: 54/60 (90%) adenomas and 4/11 (36.4%) SMICs. R1 was due to positive vertical margins in 2/60 (3.33%) adenomas and in 7/11 (63.6%) SMICs, positive lateral margins in 3/60 (5.0%) adenomas, both vertical and lateral positive margins in 1/60 (1.7%) adenomas.

14/18 (77.8%) patients with SMIC underwent surgery; in 10/14 (71.4%) of them surgical specimen was negative for neoplasia. The remaining 4 patients were not operated for comorbidities or refusal.

57 patients had 1-4 surveillance colonoscopies (SCs): 43 of the en-bloc resection group (EBG) and 14 in the piecemeal resection group (PMG). Recurrence was observed in 2/43 (4.6%) EBG patients and in 3/14 (21.4%) PMG patients. Recurrence occurred in 2/47 (4.2%) naïve lesions and in 3/10 (30%) non naïve lesions. All recurrences were successfully treated endoscopically.

**Conclusion:** In our experience ESD is a safe technique for the treatment of large superficial colorectal neoplasia, with an acceptable risk of complications and a low recurrence rate considering benign lesions. Despite our adherence to the current guidelines for ESD in the treatment of superficial colorectal neoplasia, none of the SMICs of our series had a curative treatment because all of them were deep invasive cancers.

**Disclosure:** Nothing to disclose

#### **P0206 RECTAL RETROFLEXION: IS IT REALLY NECESSARY?**

Giunta M., Tamayo D., Trovato C.M., Ravizza D., Bravi L., de Roberto G., Fiori G., Crosta C.

*European Institute of Oncology, Division of Endoscopy, Milan, Italy*

**Contact E-Mail Address:** mariangela.giunta@ieo.it

**Introduction:** Rectal retroflexion (RR) is a commonly performed maneuver during lower gastrointestinal (GI) endoscopy even if poor evidence supports its diagnostic and clinical value and international guidelines do not agree to consider it as a key performance measure.

**Aims & Methods:** The aim of this study was to assess the diagnostic yield of RR for neoplastic and non-neoplastic ano-rectal lesions, compared with straight view examination. The RR complications rate and the variables associated with complications were also evaluated. We prospectively enrolled all consecutive patients undergoing lower diagnostic GI endoscopy between June 2018 and February 2019 in our Institute. In all patients the endoscopist performed first straight view examination of rectum and anal canal and then RR. Major complications included perforation and bleeding needing endoscopic treatment. Mucosal injury without bleeding or with self-limited bleeding and pain during and after the maneuver were considered minor complications.

**Results:** A total of 1600 patients (woman, 59%), undergoing 1419 colonoscopies and 181 proctosigmoidoscopies were included. RR was successful in 1572 patients (98%). In 28 patients (2%) RR was unsuccessful or not performed because of narrow rectum or because the maneuver was not tolerated by the patients.

One hundred and seventeen lesions were detected in 117 patients (7.4%): 91 lesions were identified on both retroflexion and straight view (77.7%), 23 lesions only on retroflex view (19.6%) and 3 lesions only on straight view (2.5%). The 117 identified lesions were: 13 malignant anal or rectal lesions (3 squamous anal cancers, 2 distal rectal adenocarcinoma, 1 melanoma, 1 distal rectal gastrointestinal stromal tumor, 5 ano-rectal infiltrations by gynecologic cancer and 1 rectal infiltration by urologic cancer) (0.8%), 4 high-risk adenoma (0.3%), 7 low-risk adenoma (0.4%), 25 high-grade anal intraepithelial neoplasia (AIN) (1.6%), 20 low-grade AIN (1.3%), 27 hyperplastic polyps (1.7%), 21 non-neoplastic lesions -ulcerations, angiodysplasia, mucosal findings of ulcerative proctitis- (1.3%).

Lesions identified only by RR were 2 out of 13 (15%) malignant anal and rectal lesions (1 squamous anal cancer and 1 rectal infiltration by gynecologic cancer), 1 out of 4 (25%) high-risk adenoma, 2 out of 7 (16%) low-risk adenoma, 4 out of 25 (16%) high-grade AIN, 6 out of 20 (30%) low-grade AIN, 6 out of 27 (22%) hyperplastic polyps and 2 out of 21 (9%) non-neoplastic lesions. No major complications occurred. There were 161 (10%) minor complications which consisted of mild or moderate pain during RR (78%) and self-limited bleeding associated with mild or moderate pain (22%). Multivariate analysis identified age < 61 years and endoscope diameter as factors correlated to the presence of minor complications (p-value respectively 0.007 and 0.037) while sex and previous pelvic surgery and/or radiotherapy did not correlate to the occurrence of complications.

**Conclusion:** In our experience RR identified a low but significant number of neoplastic lesions undetected by straight view. Thus, considering that RR has a low rate of not significant complications and it is fast, repeatable and low cost, its use should be recommended in the clinical practice during lower GI endoscopy.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** ono.akiko@gmail.com

**Introduction:** European Society of Gastrointestinal Endoscopy (ESGE) guidelines recommend the routine use of high-definition (HD) white light colonoscopy for detection of colorectal neoplasia in the average population.<sup>1</sup> The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously described.<sup>2,3</sup>

**Aims & Methods:** To assess how aspects of a procedure associate with reporting of flat and protruded lesions, according to Paris classification. Data collection is an ongoing process: we analysed data collected between 2/6/16 and 30/4/18.

**Results:** Of 6445 procedures, 2621 reported a polyp in at least one segment (40.7%). Protruded lesions were reported in 2160 procedures and flat lesions in 692 procedures. In procedures with polyps reported, the proportion with flat lesions was significantly lower in the left colon segment than either transverse or right colon segments ( $p < 0.0001$ ).

Use of HD equipment significantly increases reporting of both flat lesions (13.2% vs 5.5%,  $p < 0.0001$ ) and protruded lesions (35.8% vs 23.6%,  $p < 0.0001$ ). HD equipment significantly increases the proportion of flat lesions in procedures where polyps are reported ( $p < 0.0001$ ): significant in right ( $p = 0.004$ ) and left ( $p = 0.0054$ ) segments, but not the transverse segment ( $p = 0.0933$ ).

Chromoendoscopy was increasingly used when both flat lesions (23.4% vs 7.9%,  $p < 0.0001$ ) and protruded lesions (61.4% vs 27.2%,  $p < 0.0001$ ) were reported. Where polyps are detected, the proportion of flat lesions increases with the use of chromoendoscopy ( $p = 0.0005$ ): significant in transverse ( $p = 0.0172$ ) and left ( $p = 0.0337$ ) segments, but not the right segment ( $p = 0.1176$ ).

The use of assistive technology significantly increases flat lesion reporting (21.3% vs 10.3%,  $p < 0.0001$ ), significant in all segments. Higher rates were seen with the use of Endocuff (38.5%) and cap-assisted (23.9%) versus when other assistive technologies were used (19.8%). Assistive technology does not influence reporting of protruded lesions ( $p = 0.712$ ).

The reporting of flat ( $p = 0.019$ ) and protruded ( $p = 0.015$ ) lesions varies according to the time of day the procedure was performed. Flat lesion reporting was highest in the morning (07:00-11:59): 13.9% vs 11.3% afternoon (12:00-17:59) vs 8.4% evening (18:00-19:59). However, this was not significant in individual segments: right ( $p = 0.321$ ), transverse ( $p = 0.063$ ) and left ( $p = 0.069$ ). Conversely, protruded lesion reporting was higher in the evening and afternoon than morning: morning 30.1% vs afternoon 33.8% vs evening 39.2%. This was significant in the transverse segment ( $p = 0.008$ ), but not the right ( $p = 0.62$ ) and left ( $p = 0.065$ ) segments.

**Conclusion:** Use of HD equipment improves the reporting of both flat and protruded lesions. Furthermore, its use relatively increases the reporting of flat lesions, particularly in the left colon segment, where flat lesions are less reported. Chromoendoscopy was increasingly used when both types of lesion were reported, and also relatively increased the proportion of flat lesions. Use of assistive technology improves detection of flat but not protruded lesions. Reporting of flat lesions is higher in the morning, while protruded lesions are more commonly reported in the afternoon and evening.

## P0208 WITHDRAWN

## P0209 TIME PLANNING AND LEARNING CURVE OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN THE COLORECTUM: RESULTS FROM AN EXPERT WESTERN CENTER

**Dang H.**, Dang Q., van der Kraan J., Dekkers N., Hommes D.W., Langers A.M.J., Hardwick J.C.H., Boonstra J.J.  
*Leiden University Medical Center, Gastroenterology and Hepatology, Leiden, Netherlands*

**Contact E-Mail Address:** h.dang@lumc.nl

**Introduction:** Endoscopic submucosal dissection (ESD) in the large bowel has gained considerable popularity in Asian countries. However, ESD has been slow to be taken up by Western endoscopists due to the technical complexity and time-consuming nature of the procedure. We have evaluated the learning curve and time planning outcomes of ESDs in an expert Western center.

**Aims & Methods:** Medical records of all patients undergoing ESD at Leiden University Medical Center till 1 January 2019 were retrospectively reviewed. We used multiple linear regression to identify independent risk factors for longer ESD duration.

**Results:** In total, 97 ESDs were performed by two expert endoscopists. The median size of the resected lesions was 45 mm (range 8-130). Median dissection speed was 8.5 cm<sup>2</sup> per hour (range 0.3-31.8) and did not significantly differ between the two endoscopists. Dissection speed significantly increased per 10 ESDs by 0.8 cm<sup>2</sup> per hour on average ( $p = 0.003$ ).

The amount of time scheduled for the procedure was  $\leq 120$  minutes in 31 patients, 121-239 minutes in 32 patients and  $\geq 240$  minutes in 34 patients. Median ESD duration was 160 minutes (range 30-720); scheduled time was exceeded  $> 1$  hour in 12 cases (3, 4 and 5 in the  $\leq 120$ , 121-239 and  $\geq 240$  minutes planning group respectively).

Time exceeding of  $> 1$  hour was associated with a higher rate of conversion to piecemeal resection (5/12 vs. 7/85;  $p = 0.006$ ). Size of the lesion was the only independent risk factor for longer ESD duration ( $\beta = 23.0$ ;  $p < 0.001$ ).

**Conclusion:** Although the dissection speed gradually increases with the amount of ESDs performed, ESD planning should mainly be based on the size of the lesion to be resected. Accurate time scheduling of ESDs may eventually lead to higher en bloc resection rates and easier implementation of ESD in Western endoscopy centers.

<sup>2</sup>National Hepatology and Tropical Medicine Institute, Gastroenterology,

Cairo, Egypt, <sup>3</sup>National Cancer institute, Biostatistics, Cairo, Egypt

**Contact E-Mail Address:** drshima202@yahoo.com

**Introduction:** Colonoscopy is the 'gold standard' investigation for assessment of the large bowel which detects and prevents colorectal cancer, as well as non-neoplastic conditions. The Joint Advisory Group (JAG) on GI Endoscopy suggests monitoring key performance indicators such as ce-

cal intubation rate (CIR) and the adenoma detection rate (ADR)<sup>2,3</sup>. There has been a drive to increase utilization of endoscopy units nationwide by offering out of hours (OOH) endoscopy to deal with increasing service demands. Our aim was to investigate the quality of colonoscopies carried out during evening and Saturday lists in our unit and compare against BSG standards of quality for colonoscopies.

**Aims & Methods:** We retrospectively collected and analyzed demographical and procedure related data for non- screening colonoscopies performed between January 2016 and April 2018. Procedures were grouped according to the day of the week and timing of session (weekday, evening and Saturday). We also compared those performed by advanced colonoscopist and non-advanced colonoscopist. Advanced colonoscopist was defined as a BCSP colonoscopist or an advanced EMR colonoscopist.

**Results:** There were a total of 17653 colonoscopies that were carried out, 56.8% (n=10025) were less than 70 years. Table 1 summarizes the differences between weekdays, evening and Saturdays' colonoscopies regarding the CIR and ADR. We noted that the KPIs (ADR, CIR) met the JAG standards. Advanced colonoscopists had better KPIs when compared to the non-advanced colonoscopists. (Table1)

		Weekdays		Evenings		Saturdays		P Value
		No.	Rate%	No.	Rate%	No.	Rate%	
Total	ADR	14200	28.9	1391	24.4	2062	24.2	<0.001a
	CIR		90.5		90.7		91.3	0.508
Advanced colonoscopist	ADR	1728	44.2	135	32.6	334	34.7	<0.001a
	CIR		94.5		97		95.2	0.411
Non-advanced colonoscopist	ADR	12472	26.7	1256	23.5	1728	22.1	<0.001a
	CIR		89.9		90.0		90.5	0.741
Advanced vs. Non-advanced colonoscopist	p value ADR	<0.0001		0.019		0.001		
	P value CIR	<0.0001		0.007		0.005		

[Table 1]

**Conclusion:** JAG standards were maintained during colonoscopies done on weekdays, evening and Saturdays. Advanced colonoscopists had higher CIR and ADRs. Other units should explore the options of doing planned OOH colonoscopies to meet service demands.

**Contact E-Mail Address:** sato\_yahaya@hotmail.com

**Introduction:** Cold snare polypectomy (CSP) has been performed worldwide as a safe endoscopic treatment for colorectal neoplasms compared with EMR and conventional polypectomy. However, in post-cold polypectomy, it is considerably difficult to evaluate pathological examination because of failed polyp retrieval and unclear cut margin. Incomplete resection is one of the most common causes that results in local recurrence after endoscopic treatment for colorectal neoplasms. The aim of this study is to assess the safety, efficacy, bleeding risk and problems of CSP compared with EMR and conventional polypectomy for small colorectal neoplasms.

**Aims & Methods:** We retrospectively analyzed a total of 5,991 lesions in 3548 consecutive patients who underwent CSP, EMR or conventional polypectomy for non-pedunculated polyps up to 10 mm in size at the Akashi Medical Center, Hyogo, Japan, from May 2013 to July 2017.

When lesions were found, we used chromoendoscopy and narrow band imaging (NBI) in all cases and included a magnifying examination if magnifying endoscopy was possible to use. Endoclip was performed when the oozing did not decline even after one minute of observation in CSP, on the other hand in EMR or conventional polypectomy it depended on operator's decision. We evaluated patient characteristics, clinicopathological features of the polyps, complications, polyps retrieval, and pathological complete resection rates for neoplasm lesions. The data were statistically analyzed.

**Results:** CSP was performed on (n=1381; 2518polyps), EMR was performed on (n=1820; 2888polyps), conventional polypectomy was performed on (n=347; 584polyps). Patient characteristics and clinicopathological features of the polyps did not show significant differences in three groups. Polyp size was significantly smaller in CSP group compared with the EMR group ( $3.89 \pm 1.39$  vs  $6.40 \pm 2.04$  mm,  $p < 0.01$ ), and conventional polypectomy group ( $3.89 \pm 1.39$  vs  $5.19 \pm 2.18$  mm,  $p < 0.01$ ). The retrieval rate for polyps was significantly lower in CSP group compared with EMR and conventional polypectomy group at (n=2035; 94.4 % vs n=2786; 99%  $p < 0.01$ ), and (n=2035; 94.4 % vs n=547; 97.3%  $p = 0.01$ ), respectively. Pathological complete resection rate of the neoplasm lesions was significantly lower in CSP compared with EMR at (73 % vs 86%  $p < 0.01$ ), but were identical to conventional polypectomy group (73 % 76%  $p = 0.15$ ). No significant difference in delayed bleeding requiring endoscopic hemostasis in CSP group compared with EMR and conventional polypectomy group at (n=1; 0.05 % vs n=6; 0.21%  $p = 0.12$ ), and (n=1; 0.05 % vs n=1; 0.31%  $p = 0.31$ ), respectively. The rate of using endoclip was significantly lower in CSP compared with EMR and conventional polypectomy at (n=51; 0.2 % vs n=1884; 67%  $p < 0.01$ ), and (n=51; 0.2 % vs n=51; 9.1%  $p < 0.01$ ), respectively.

**Conclusion:** CSP tended to conduct for significantly smaller lesions with lower polyp retrieval rate and lower rate of using endoclip compared with EMR and conventional polypectomy in this study. Delayed bleeding in CSP required endoscopic hemostasis was seen in only one case and perforation was not observed. Thus, CSP could be a safer and more convenient method for small colonic neoplasia compared with EMR and conventional polypectomy. On the other hand, pathological complete resection rates were significantly lower compared with EMR. Consequently, these findings highlight the importance of meticulous inspection of the remnant tumor via endoscopy after CSP to avoid unnecessary future local recurrence.

**Introduction:** Colonoscopy is the gold standard diagnostic method for colorectal cancer screening. The quality of such procedure depends on different factors, including endoscopist's skills and caecal intubation rate. Despite the progress in the endoscopy technology field, a small percentage of colonoscopies is still incomplete. The reasons for that are mostly associated to anatomic features, such as fixed, angulated, long and looped colon, intra-abdominal adhesions and female gender. To overcome such difficulties, the usefulness of scopes different from conventional colonoscope, such as paediatric colonoscope, gastroscope, single and double balloon enteroscope (SBE and DBE), has been shown in literature.

**Aims & Methods:** Our retrospective study aims to evaluate the caecal intubation rate using a push enteroscope (PE) without the overtube in patients who previously underwent an incomplete procedure with a standard colonoscope.

47 adult patients, mostly female (77%), who previously underwent an incomplete colonoscopy with a standard colonoscope, were retrospectively enrolled through the analysis of a dedicated database. The enteroscope used was the Olympus Enteropro Single Balloon SiF-Q180 with no overtube. Complete colonoscopy was defined as successful caecal intubation.

**Results:** The use of PE led to a complete procedure in 91% of patients (43 over 47). The most frequent reason (75%) for an incomplete procedure even with the use of PE was a fixed and angulated colon (3 over 4 patients).

**Conclusion:** Colonoscopy performed with PE was safe and no adverse events during and/or after the procedure occurred. Compared to standard colonoscope and paediatric colonoscope, PE is longer, thinner and more flexible and these features make it more suitable to complete a colonoscopy in tricky patients. Moreover, PE is a less expensive option compared to SBE and DBE (which require the overtube-balloon equipment and patient's X-ray exposure during fluoroscopic guidance) and it allows to perform operative endoscopy compared to less invasive alternatives, such as computed tomographic virtual colonoscopy and capsule endoscopy. Our results suggest that PE is a useful and valid alternative to standard scope in difficult cases, especially those related to fixed/angulated colon and in female gender.

## P0213 DIFFERENT RISK FACTORS FOR DELAYED POSTPOLYPECTOMY BLEEDING IN PATIENTS WITH A SINGLE POLYPECTOMY VERSUS MULTIPLE POLYPECTOMIES DURING A ONE-TIME COLONOSCOPY

Chen C.-W.<sup>1</sup>, Lin W.-R.<sup>1</sup>, Chiu C.-T.<sup>2</sup>

<sup>1</sup>Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan, <sup>2</sup>Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan

**Introduction:** Colorectal cancer (CRC) is a common and lethal disease. Polypectomy can prevent the development of CRC. Although polypectomy is a safe procedure, there is still 1% bleeding rate after polypectomy. During screening colonoscopy, patients may have more than one colon polyp to remove in one-time colonoscopic procedure.

However, data on the rate of delayed postpolypectomy bleeding (PPB) and risk factors for multiple polypectomies during a one-time colonoscopic procedure are limited.

**Aims & Methods:** The aim of the study was to evaluate the risk of delayed PPB of multiple polypectomies in a one-time colonoscopy. From Jan 2015, to Jan, 2017, patients who underwent snare polypectomy in a referral center of northern Taiwan for polyp's size between 6 and 20 millimeters (mm) were enrolled in this study. The PPB event was defined as the presentation of a bloody stool 14 days after the polypectomy and followed by repeat colonoscopic interventions. The demography of patients and the polyp characteristics were recorded. Descriptive statistics and frequency distributions were calculated. The data were analyzed by using either the Mann-Whitney U test for continuous variables or chi-square test for categorical variables. Univariate and multivariate logistic regressions were used to examine the risk factors of delay PPB. Statistical significance was defined as  $p$  value  $< 0.05$ .

**Results:** A total of 1188 patients were enrolled in this study. 888 (74.8%) patients underwent a single polypectomy during one-time colonoscopy, and 300 (25.2%) patients underwent  $\geq 2$  polypectomies during a one-time colonoscopy. There were 616 (69.4%) male patients in the single polypectomy group and 231 (77.0%) in the multiple polypectomies group. The median age in the single polypectomy group was 59 years (range: 19-96 years) and 61 years (range:20-96 years) in the multiple polypectomies group.

The mean polyp size in both groups was 8 millimeters without statistically difference. The overall delay PPB was 1.1 %. Compared to the single polypectomy group, the bleeding rate in the multiple polypectomies group was significantly higher. (3.3% vs 0.3%;  $p=0.02$ ) In the univariate regression analysis for bleeding risk factors, increases in the polyp size were significantly associated with delayed PPB in the single polypectomy group. (OR: 1.3, 95% CI:1.03-1.65,  $p=0.02$ ).

In the multiple polypectomies group, female was significantly associated with delayed PPB (OR: 3.7, 95% CI:1.05-12.93,  $p=0.04$ ) and a history of anti-platelet/coagulant agent use was a borderline factor for delayed PPB (OR: 4.85, 95% CI:0.99-23.69,  $p=0.05$ ). The patients' age, polyp location, polyp morphology, polyp pathology, prophylactic hemoclipping, and the endoscopists' experience were not found to be significant risk factors for delayed PPB in either group.

By adjusting for sex, polyp size and history of anti-platelet/coagulant agent use in the multivariate regression analysis, polyp size was still an independent factor for delayed PPB in the single polypectomy group. (OR: 1.30, 95% CI:1.02-1.65,  $p=0.03$ ) Female and history of anti-platelet/coagu-

lant agent use were independent factors for delayed PPB in the multiple polypectomies group (OR: 4.07, 95% CI:1.14-14.47,  $p=0.03$ ; OR: 5.54, 95% CI:1.09-27.94,  $p=0.03$  respectively).

**Conclusion:** When performing  $\geq 2$  polypectomies during a one-time colonoscopic procedure, the rate of delayed PPB significantly increases. Polyp size was a risk factor for delayed PPB in single polypectomy. Female and history of anti-platelet/coagulant agent use were risk factors for delayed PPB in multiple polypectomies.

## P0214 CLINICAL AND PATHOLOGICAL CHARACTERISTICS OF ADENOMATOUS POLYPS IN LYNCH SYNDROME

Hatamori H., Chino A., Ide D., Saito S.

Cancer Institute Hospital of Japanese Foundation for Cancer Research, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** kyoen\_miss2009@hotmail.co.jp

**Introduction:** Lynch Syndrome (LS) is an autosomal dominant disorder caused by germline mutations in DNA mismatch repair genes such as *MLH1*, *MLH2*, *MSH6* and *PMS2*, and patients with LS have an increased risk of developing colorectal cancer. While adenoma-carcinoma sequence is accelerated in patients with LS, the characteristics of adenomatous polyps in patients with LS are not precisely known.

**Aims & Methods:** A total of 325 consecutive adenomatous polyps in patients with LS removed by colonoscopy between June 2005 and May 2018 were retrospectively reviewed. In addition, we defined adenomatous polyps with advanced pathological features including high grade adenomas, intramucosal carcinomas, and superficial submucosal invasive carcinomas (submucosal invasion depth  $< 1000 \mu\text{m}$ ) as index lesions and compared the prevalence and clinical characteristics of the index lesions between patients with LS and a control group. As the control group, the adenomatous polyps in patients without LS, Familial Adenomatous Polyposis, or Inflammatory Bowel Disease removed by colonoscopy between January 2015 and December 2015 at our institute were reviewed.

**Results:** One hundred and fifty five polyps (48%) were located in proximal colon, 114 polyps (35%) at distal colon and 56 polyps (17%) at rectum. The median polyp size was 5 mm (range 2-40 mm) and 229 polyps (71%) were non-polypoid type. The percentage of carcinomas were 1%, 7%, 69% and 86% for polyps of diameter  $< 5$  mm,  $5 \leq X < 10$  mm,  $10 \leq X < 20$  mm and  $20 \leq$  mm, respectively.

The percentage of the index lesions was significantly higher in LS group (26%) than in the control group (15%) ( $P < 0.0001$ ). The percentage of the index lesions according to the location (proximal colon, distal colon and rectum) was 32%, 33% and 41%, respectively in LS group. The mean age  $\pm$  SD at the index lesions removal was significantly younger in LS group ( $59 \pm 13$  years) than in the control group ( $67 \pm 11$  years) ( $P < 0.0001$ ). The median polyp size of the index lesions was significantly smaller in LS group (7 mm, range, 3-30 mm) than in the control group (10 mm, range, 1-120 mm) ( $P < 0.0001$ ), which was applicable to the size of each histology including high grade adenoma, intramucosal carcinoma and superficial submucosal invasive carcinoma. Non-polypoid polyp was significantly more common macroscopic type of the index lesions in LS group (63%) than in the control group (30%) ( $P < 0.0001$ ).

**Conclusion:** The adenomatous polyps in patients with LS, especially greater than 10 mm, showed higher degree of dysplasia than sporadic ones. The index lesions in patients with LS were smaller and more often non-polypoid morphology than sporadic ones. The percentage of index lesions was comparable at any part of the colon in patients with LS and this result suggest the adenoma-carcinoma sequence in patients with LS should be similarly accelerated between proximal and distal colon.

**Disclosure:** Nothing to disclose

## P0215 ENDOSCOPIC ANALYSIS OF MICROSTRUCTURES OF THE COLON MUCOSA ON THE EDGE OF THE POST-RESECTION DEFECT AS A MEASURE OF PREVENTING RECURRENCE OF POLYPS AFTER A COLD POLYPECTOMY

Ageykina N.<sup>1</sup>, Fedorov E.<sup>2,3</sup>, Oleynikova N.<sup>3</sup>, Malkov P.<sup>3</sup>, Danilova N.<sup>3</sup>, Kharlova O.<sup>3</sup>

**Introduction:** To identify the residual tissue after the cold snare polypectomy, it is necessary to know an endoscopic view of the unchanged structure on the edge of the post-resection defect. This is the prevention of tumor recurrence.

**Aims & Methods:** To assess the usefulness of endoscopic removal of small (less than 10 mm) colon polyps with a cold snare on the basis of endoscopic microstructural analysis of the edges of the post-resection defect. In 74 patients (22 men and 52 women) aged 28 to 84 years ( $59.3 \pm 3.6$  years), 103 colon polyps were detected. These were up to 10mm in size and no more than 5mm in height, without endoscopic signs of severe dysplasia or cancer. Most of the polyps (81/103; 78.7%) were of flat-elevated form, type 0-IIa, of which 10 (9.7%) had a depression, type 0-IIa+c; and were of polypoid form 21/103; 20.3%.

The polyps were resected with a cold snare and in all cases the edges of the defect were evaluated for the absence of residual tissue. A complete endoscopic analysis of the microstructures and the capillary vessels of the mucosa was performed on the edge of the post-resection defect, and was then compared to the histological image.

**Results:** The endoscopic criteria followed post cold snare resection in order to check its success were: endoscopic visualization on the edge of the post-resection defect of 1) parallel crypts and 2) the pit pattern of only type I (S. Kudo).

This was observed in 93 (90.3%) cases. In 10 (9.7%) cases, single extended modified crypts were found, with violation of their parallelism, which was a sign of residual tissue. In these cases, a combined removal technique was used - a cold snare, supplemented with biopsy forceps for the purpose of radical intervention.

During endoscopic examination of the post-resection defects in the rectum, we noted differences in the location of the crypts of the rectum in the anorectal junction and in the range of 1-2 cm proximity to it, compared to the orderly arrangement of crypts in the colon. In this area, the loss of parallelism of the crypt is determined; the irregularity of the structure giving the impression of "falling crypts" It is noted that this feature of the structure complicates the differential diagnosis of normal and residual tumor tissue.

An endoscopic assessment of the capillary network of the colon mucosa was performed, as a result of which it was determined that the possibilities of endoscopic analysis in vivo have advantages over histological examination, where it is difficult to trace the course of blood vessels. Flat-elevated polyps have capillary vessels that are small in diameter, which significantly reduces the risk of bleeding when removed by a cold snare resection when up to 10 mm in size. This was confirmed by a slight capillary leakage of blood in 101 (98.1%) cases, which stopped independently, on average, after 2-3 minutes. In 2 (1.9%) cases, due to the reception of anticoagulant therapy, the period of capillary thrombosis varied from 5 to 10 minutes. In these patients, the defects were clipped to prevent delayed bleeding.

Follow-up colonoscopies were performed on 11 (10.7%) patients: neither advanced adenomas, nor interval cancers were detected.

**Conclusion:** A detailed assessment of the edges of the post-resection defect of the mucosa after cold snare resection provides a reliable diagnosis of the complete success of the endoscopic intervention and the possibility of removing residual tumor tissue (if present) immediately after its completion, and therefore reduces the number of recurrence of tumors.

**Disclosure:** Nothing to disclose

**Introduction:** A previous meta-analysis has shown that approximately 26% of neoplastic diminutive polyps are missed in single colonoscopies. We have developed a computer-aided detection (CAdE) system assisted by artificial intelligence (AI) to reduce this failure and the resulting deaths from cancer. Research on CAdE has been increasing in recent years, but most of it focuses on learning and analysis of still images. We think that the use of spatio-temporal data is essential for learning, improving, and evaluating AI systems. In this study, we compiled a database of many endoscopic videos and used it to develop a CAdE system. We then evaluated its performance.

**Aims & Methods:** To develop the CAdE system, we retrospectively collected colonoscopy videos from study participants who underwent colonoscopies in our institution from April 2018 to August 2018. We collected 1,089 colonoscopy videos with a total duration of 2,716,720 frames (514,240 polyp-positive frames and 2,202,480 polyp-negative frames) and constructed a new algorithm based on 3D convolutional neural networks with residual blocks. To evaluate our system, we also retrospectively collected 96 colonoscopy videos from 96 consecutive participants between August 2018 and October 2018. The exclusion criteria were advanced colorectal cancer and inflammatory bowel disease. Expert endoscopists annotated the presence of polyps in each frame of each video, and this annotation was treated as the gold standard for the presence of polyps to determine the sensitivity and specificity.

**Results:** Seventy-one patients had a total of 152 polyps and 25 patients were free from polyps. The median polyp size was 4(3-5) mm, the CAdE's sensitivity was 89% and the specificity was 75%. The sensitivity to polyps under 5 mm was 88%. Morphologically, the sensitivity to protruded polyps was 90% and to flat polyps was 88%. There was no significant difference between the sensitivities to protruded and flat polyps.

**Conclusion:** The CAdE we developed by learning spatio-temporal data had a high sensitivity regardless of the size and morphology of the polyp, and may improve the adenoma detection rate.

**Disclosure:** Nothing to disclose

## P0218 ENDOCYTOSCOPY COMBINED WITH NARROW-BAND IMAGING FOR PREDICTION OF CLINICAL RELAPSE IN PATIENTS WITH ULCERATIVE COLITIS

**Introduction:** Some patients with ulcerative colitis (UC) clinically relapse in the short term despite white light endoscopic mucosal healing was achieved. We developed a novel index using endocytoscopy (EC: x520 ultramagnifying colonoscopes providing both microvascular and crypt sharpness visualization of colorectal mucosa after application of the narrow-band imaging).

**Aims & Methods:** The aim of this retrospective cohort study was to evaluate clinical efficacy of endocytoscopy for prediction of future clinical relapse in patients with sustained remission. The study cohorts were including previ-

ously established UC patients in sustained corticosteroid-free ( $\geq 6$  months) clinical remission (defined as partial Mayo score of  $\leq 1$ ) and mucosal healing (defined as Mayo endoscopic subscore of 0 or 1) undergoing endoscopic evaluation using EC between October 2016 and September 2018 at the Digestive Disease Center of the Showa University Northern Yokohama Hospital. Exclusion criterion was patients with medical history of any previous surgical colon resection. The EC images to evaluate were selected by an endoscopist (M.O.) who was blinded to clinical, histological, and endoscopic information. Another expert endoscopist (Ya. M.) evaluated the images according to endocytoscopic findings, and the cohorts were classified into either 'Healing' or 'Active' group according to endocytoscopic findings. The main outcome measure was the difference of clinical relapse-free rates compared between 2 groups. The differences of clinical relapse-free rates depending on the extent of disease (extensive colitis, left-sided colitis, and proctitis) were also investigated as sub-analysis. Cohorts were followed until the end of the study in March 2019 or until relapse. Clinical relapse was defined as the presence of rectal bleeding together with any treatment intervention.

**Results:** A total of 178 patients were included as the study cohorts. 6 were not completed to be followed until the end of the study. 172 patients, who were followed for 12 months on average, were analyzed. 104 being classified in the 'Healing' group, and 68 in the 'Active' group. In the follow up period, 3.8% (4/104) relapsed in the 'Healing' group, and 22.1% (15/68) in the 'Active' group. The 'Healing' group had a significantly higher clinical relapse-free rate compared with the 'Active' group (Log rank test:  $P < 0.01$ ). In sub-analysis, it also revealed that the 'Healing' group had a significantly higher clinical relapse-free rate with the 'Active' group in extensive colitis, and left sided colitis ( $P < 0.01$ , and  $P = 0.02$ , respectively) and not significantly in proctitis. ( $P = 0.59$ ).

**Conclusion:** Endocytoscopy has potential to predict short-term relapse in patients with clinical and endoscopic remission.

## P0219 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR RECTAL NEOPLASIA: SAFETY AND EFFICACY IN A EUROPEAN CENTRE

Félix C., Mendo R., Pereira I., Chivia J., Rodrigues J.P., Barreiro P., Chagas C.

Centro Hospitalar Lisboa Ocidental, Gastroenterology, Lisbon, Portugal

**Contact E-Mail Address:** sfelixcatarina@gmail.com

**Introduction:** The efficacy of endoscopic submucosal dissection (ESD) has been well documented, however Western data on colorectal ESD is limited and its role for colorectal lesions is, at present, not well defined. Nevertheless, the rectum is recognized as a particular segment and ESD may play an important role in avoiding a major surgery.

**Aims & Methods:** This study aims to report the feasibility, safety and effectiveness of ESD for treating premalignant and early malignant rectal lesions in a Western centre.

We conducted a prospective data analysis of all consecutive rectal lesions treated by ESD between 2013 and 2019. En bloc, pathological complete resection (R0) and curative rates, procedure time, complications and local recurrence were evaluated.

**Results:** Included 114 lesions from 111 patients (mean age 69.0 $\pm$ 9.8 years old; M/F=71/40). Morphologically, lesions were laterally spreading tumour (LST) granular homogeneous (n=19), LST granular mixed (n=61), LST non-granular (n=15) and protruded lesions (n=19). Median size of the resected specimen was 50mm (13-156) and mean resection time was 107 $\pm$ 89.1min. En bloc resection was achieved in 91.9% (102/111) of the resected lesions (3 resections were considered non-feasible). R0 resection was accomplished in 81 cases (73%) and resection was considered curative in 78 cases (70%). Complications occurred in 15 procedures (13%): 7 immediate minor bleedings, 1 immediate perforation and 7 delayed bleedings. In the resected group, asymptomatic stenosis was diagnosed in 2 patients whose resection was >90% of the rectal circumference. All complications were managed conservatively or endoscopically. Of the 78 curative resections, 53 were followed up and median follow-up time was 12 months (1-74) revealing 1 recurrence (2%).

**Conclusion:** To the best of our knowledge, this study represents the third largest series of rectal ESD in the West, showing that rectal ESD can achieve a high rate of en bloc and R0 resection, safely.

**Disclosure:** Nothing to disclose

## P0220 THE ACCURACY OF WAVSTAT VERSION 4 OPTICAL BIOPSY FORCEPS IN CHARACTERIZING COLORECTAL POLYPS LESS THAN 10 MM: A PROSPECTIVE BLINDED STUDY

**Introduction:** WavSTAT Version 4 (WavSTAT4) Optical biopsy (designed by SpectraScience Inc, California, USA) represents a novel means of predicting histology based on laser-induced autofluorescence spectroscopy. Potentially, this could replace standard histological assessments of colonic polyps < 10mm in size. We present our final findings following the preliminary study in 2016.

**Aims & Methods:** The primary aim of this study was to demonstrate the accuracy of WavSTAT4 in characterizing colorectal polyps < 10mm. The secondary aim looked at comparing the real time diagnostic performance of WavSTAT version 4 with endoscopic assessment and a combination of both. Patients attending the endoscopy unit for lower gastrointestinal endoscopy as requested by their responsible physician were approached to participate in the study. Adult patients aged above 18 years were included. Patients with known active inflammatory bowel disease or colorectal cancer were excluded from the study. Polyps < 10mm were assessed in real time by high definition white light, NBI and WavSTAT4 optical biopsy forceps. Standard techniques were used for polypectomy. Histopathological specimens were read separately by two expert GI pathologists blinded to the results of the NBI and WavSTAT4 assessments. The primary outcome measure was the negative predictive value in distinguishing adenomatous from non-adenomatous colorectal polyps. The secondary outcome measure was the accuracy of on-site recommended surveillance intervals.

**Results:** 136 patients participated in this study. A total of 211 polyps (199 < 10mm, 12 >10mm) were found in 79 patients (51 males, 28 females). The mean age was 65 (range 28-95 years). 50 patients were excluded from the study (no polyps in 38 patients, device failure in 8 patients, 4 polyps not retrieved). A further 7 patients were not included due to missing data. 15 polyps were not included in the final analysis due to discrepancies between the histological analysis of the two pathologists.

	WavSTAT 4 alone % (95% CI)	WLE + NBI assessment % (95% CI)	Algorithmic approach % (95% CI)
Sensitivity	93.8 (86.0-97.9)	86.2 (76.7-92.3)	93.8 (86.0-97.9)
Specificity	45.4 (35.6-55.8)	82.2 (73.3-89.0)	77.2 (67.8-85.0)
NPV	90.2 (79.3-95.7)	88.3 (81.2-92.9)	94.0 (86.9-97.4)
PPV	57.7 (53.0-62.2)	79.3 (71.4-85.4)	76.5 (69.4-82.4)
Surveillance interval (% correctly coded)	67.9	88.5	87.2
Surveillance interval (% of patients called earlier)	32.1	11.5	12.8

[Diagnostic performance of Wavstat4, Endoscopic assessment and combined algorithmic assessment for characterization of colorectal polyps less than 10mm]

WavSTAT4 had a high NPV of 90.2% and was more sensitive (93.8%) compared to endoscopic assessment (NPV 88.3%, sensitivity 86.3%). WavSTAT4 however lacked specificity and was poor for hyperplastic recto-sigmoid polyps and only accurately predicted surveillance intervals in 67.9% of patients. Due to this we implemented an algorithmic approach where pol-

yps proximal to the recto-sigmoid were classified according to WavSTAT4, whereas the endoscopic classification used only if Wavstat4 prediction was as an adenomatous polyp in the recto-sigmoid area. With this combined algorithmic approach the NPV was 94.0% which met the PIVI thresholds and improved correctly predicted surveillance intervals to 87.2% of patients.

**Conclusion:** This study has shown that WavSTAT4 reached the threshold to "resect and discard" however only correctly predicted surveillance intervals in 67.9% of patients. When utilizing an algorithmic approach combining WavSTAT4 and endoscopic assessment a higher NPV was achieved with 87.2% achieving accurate surveillance intervals.

**Introduction:** Evidences have shown that automatic polyp detection system using deep learning can achieve both high sensitivity and specificity in colonoscopy images and videos, and with real-time assistance of this CAde system, the ADR/PDR can be improved in realistic colonoscopy settings. However, the detection performance of this system on colon laterally spreading tumor and sessile serrated adenoma, which are with higher miss rate and malignancy potential, has not been specifically investigated.

**Aims & Methods:** A real-time automatic polyp detection system based on deep learning was validated on colonoscopy images and videos from a large-scale of consecutive patients in a previous study<sup>1</sup>, in which the system has the sensitivity and specificity both above 94%. In this study, the system was validated exclusively on laterally spreading tumor (LST) and sessile serrated adenoma (SSA). 1451 LST images from 182 patient (92(50.55%) female; age, mean(s.d.):63.21(11.52)) are collected between July 2015 and January 2019, 82 SSA videos from 26 patients (7(26.92%) female; age, mean(s.d.):50.81(10.07)) were collected between September 2018 and January 2019. The per-frame sensitivity and per-lesion sensitivity were calculated.

	LST Image Dataset	SSA Video Dataset
Data acquisition*	July2015-January2019	September2018- January 2019
Content* *	1451 images containing LST	82 colonoscopy video clips, each with a SSA appearing from the beginning until the end. 12.59 min in total and 17.99s per polyp on average
Device* * *	Olympus and Fujifilm	Olympus and Fujifilm
Patient demographics	182 patients,92(50.55%) female; age, mean(s.d.):63.21(11.52)	26 patients,7(26.92%) female; age, mean(s.d.):50.81(10.07)
Polyp histology	Total LST number 194(100%) Carcinoma 23(11.86%) SSAP 14(7.22%) Adenomatous 147(75.77%) Advanced Adenoma 135(69.59%) Hyperplastic and Inflammatory 10(5.15%)	Total SSA number42(100%) SSAP 42(100%)
Polyp location	Rectum 74(38.14%) Sigmoid colon 24(12.37%) Descending colon, including splenic flexure 10(5.15%) Transverse colon 29(14.95%) Ascending colon, including hepatic flexure 43(22.16%) Cecum 14(7.22%)	Rectum 9(21.43%) Sigmoid colon 11(26.19%) Descending colon, including splenic flexure 3(7.14%) Transverse colon 11(26.19%) Ascending colon, including hepatic flexure 7(16.67%) Cecum 1(2.38%)
Polyp size (cm)	size, mean(s.d.):2.33(1.11)	Small(≤0.5) 29(69.05%) Moderate (>0.5&≤1) 12(28.57%) Large (>1) 1(2.38%)

\* All datasets were acquired from the Endoscopy Center of Sichuan Provincial People's Hospital of China. \* \* Resolution of images and videos are 704×576, 1,920×1,080 or 1,280×1,024. \* \* \* Olympus EVIS LUCERA CV260 (SL)/CV290 (SL) and Fujifilm 4400/4450 HD. NA, not applicable.

[Patient demographics and polyp characteristics for the validation datasets]

**Results:** 1) For LST image dataset, the system achieved an overall sensitivity of 94.28% (1368/1451). the sensitivity for LST-G(H), LST-G(M), LST-NG(F), LST-NG(PD) was 94.24% (360/382), 98.41% (681/692), 86.56% (322/372) and 100% (5/5) respectively. 2) for SSA video dataset, the system achieved an overall per-frame-sensitivity of 84.10% (15883/18885). This real-time system processed 25 frames per second.

**Conclusion:** This study demonstrated that a local feature oriented automatic polyp detection system could detect laterally spreading tumor and sessile serrated adenoma with high sensitivity comparable with general polyps. This CADE system has a higher sensitivity on granular lesions compared to flat lesions and the per-frame sensitivity in videos for small SSAP should be further improved.

**Introduction:** The clinical significance of a family history (FH) of colorectal cancer (CRC) in first-degree relatives (FDRs) as a risk factor for colorectal neoplasia is still inconclusive.<sup>1</sup> Several recent studies have suggested that the influence of an FH of CRC in FDRs as a risk factor in CRC screening weakens as the age of the screened population increases ( $\geq 55$  years)<sup>2</sup>. Even for younger screened populations ( $< 55$  years), the relationship between an FH of CRC in FDRs and the risk of colorectal neoplasia remains incompletely understood.

**Aims & Methods:** This study was performed to investigate the relationship between an FH of CRC in FDRs and the presence of advanced colorectal neoplasia (ACN) in asymptomatic screened individuals aged 40 to 54 and 55 to 69 years. Data from screened individuals aged 40 to 54 years ( $n=2,263$ ) and 55 to 69 years ( $n=2,621$ ) who underwent their first-ever screening colonoscopy at our institution from February 2004 to March 2013 were used. None of the screened individuals had an FH of hereditary CRC. Data on the following baseline characteristics of the study participants were extracted: age; sex; history of smoking, drinking, and nonsteroidal anti-inflammatory drug use; body mass index; and presence of diabetes mellitus. The relationship between the presence of FDRs with CRC and the presence of ACN was examined using the chi-square test. A multivariate logistic regression analysis incorporating all of the above-mentioned factors was also performed to calculate the odds ratio (OR) of an FH of CRC in FDRs for the presence of ACN adjusted by the other factors.

**Results:** Of 2,263 screened individuals aged 40 to 54 years, 249 (11.0%) had FDRs with CRC. No significant difference in the baseline characteristics was observed between these 249 individuals and the other 2,014 individuals without affected FDRs. The prevalence of ACN was significantly higher among the individuals with than without affected FDRs (5.6% vs. 1.6%, respectively;  $P < 0.01$ ). Despite this significant relationship, no statistically significant association was observed between the presence of ACN and the number of affected FDRs or presence of younger affected FDRs ( $< 60$  years). The OR of the presence of affected FDRs for ACN, which was adjusted by all other baseline characteristics, was 3.6 [95% confidence interval (CI), 1.9-6.8;  $P < 0.01$ ] in the screened population aged 40 to 54 years. Among the 2,621 screened individuals aged 55 to 69 years, 291 (11.1%) had FDRs with CRC, and the prevalence of ACN was not significantly different between these 291 individuals and the other 2,330 individuals without affected FDRs (5.8% vs. 5.8%, respectively;  $P=0.95$ ). The adjusted OR of the presence of affected FDRs for ACN was 1.0 (95% CI, 0.6-1.7;  $P=0.94$ ). Despite this lack of a significant association, individuals with two affected FDRs ( $n=23$ ) showed a significantly higher prevalence of ACN (17.4%) than those with one or no affected FDRs (5.7%) in the population aged 55 to 69 years ( $P=0.04$ ). In this population, no significant association was found between the presence of affected FDRs aged  $< 60$  years and ACN.

**Conclusion:** This study demonstrated the clinical significance of an FH of CRC in FDRs as a risk factor for ACN in a younger asymptomatic screened population aged 40 to 54 years. This result reemphasizes the importance of careful attention to an FH of CRC in FDRs, especially in CRC screening of younger populations. In contrast, an FH of CRC in FDRs may have a weaker impact for relatively older screened populations aged 55 to 69 years, except for those with two or more affected FDRs.

## P0223 DIAGNOSTIC YIELD OF EARLY SURVEILLANCE AFTER INADEQUATE BOWEL PREPARATION ON SCREENING COLONOSCOPY

Baile Maxía S., Medina Prado L., Mangas Sanjuan C., Compañy Catalá L., Ruiz Gómez F., Aparicio Tormo J.R., Martínez Sempere J., Casellas Valdes J.A., Jover Martínez R.  
Hospital General Universitario de Alicante, Gastroenterology, Alicante, Spain

**Contact E-Mail Address:** sandrabm\_92@hotmail.com

**Introduction:** Current guidelines regarding surveillance after screening colonoscopy assume adequate bowel preparation. Management and follow-up intervals of patients with suboptimal or inadequate cleansing is unknown, with early surveillance being recommended especially after colonoscopy with poor preparation.

**Aims & Methods:** To determine the diagnostic yield of early repeat colonoscopy in patients with suboptimal bowel preparation in screening colonoscopy, regarding adenoma detection rate (ADR), advanced adenoma detection rate (AADR) and colorectal cancer detection rate (CRCDR). Also, to identify which factors existing on index colonoscopy are associated with the presence of advanced adenomas or colorectal cancer on repeat colonoscopy.

We performed an observational cross-sectional study by collecting data from men and women who underwent screening colonoscopy with suboptimal bowel preparation and then repeat colonoscopy within one year from May 2012 to August 2017 at Hospital General Universitario of Alicante. Adequate bowel preparation was defined as a score of 2 or 3 in every colonic segment according to the Boston Bowel Preparation Scale (BBPS). Patients with a score of 1 at any segment were considered to have a suboptimal preparation. Patients with a BBPS score of 0 at any segment or incomplete examination were excluded. Adenoma detection rate, advanced adenoma detection rate and colorectal cancer detection rate were analyzed at both index and repeat colonoscopy.

**Results:** Of the 2474 patients who underwent screening colonoscopy at our center during this period, 314 (12.7%) were reported to have a suboptimal preparation, with an initial adenoma detection rate of 65%, advanced adenoma detection rate of 48% and colorectal cancer detection rate of 3.8%. Of the 259 (82.5%) patients who underwent repeat colonoscopy, suboptimal cleansing persisted in 22 (9%). Among these patients, adenoma detection rate was 38.9%, advanced adenoma detection rate was 15% and no colorectal cancer was detected.

After index colonoscopy, 155 (49.4%) patients had post-polypectomy surveillance recommendation in 3 years and 159 (50.6%) in 10 years. However, after repeat colonoscopy, recommendation changed from 10 to 3 years in 15% of the patients with previous 10 years surveillance recommendation. The number of colonoscopies needed to repeat to change a surveillance recommendation was 15.

Total BBPS or presence of advanced adenoma at index colonoscopy were not associated with the presence of advanced adenoma at repeat colonoscopy. In the per-segment analysis, only the left colon was found to have a higher advanced adenoma detection rate at repeat examination in those patients with suboptimal preparation in that segment at index study ( $p=0.036$ ).

**Conclusion:** Patients with suboptimal bowel preparation in screening colonoscopy present a high rate of advanced adenomas in repeat colonoscopy, with major changes in post-polypectomy surveillance recommendations. These findings support a recommendation for early repeat (within 1 year) colonoscopy in patients with a BBPS of 1 in any colonic segment at screening colonoscopy.

**Introduction:** The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously described in posters presented at United European Gastroenterology Week, 2015 and 2016.

**Aims & Methods:** To investigate the quality of colonoscopy in current clinical practice, through the use of online questionnaires, compared with recently published European Society of Gastrointestinal Endoscopy (ESGE) key performance measures. Data collection is an ongoing process. We analysed data collected between 2/6/16 and 30/4/18.

**Results:** 6445 colonoscopies were documented by 84 practitioners across 12 European countries.

Adequate bowel preparation was defined as Boston Bowel Preparation Scale score  $\geq 6$  (ESGE minimum standard  $\geq 90\%$ ). From our data (data unavailable for 209, 3.2%), 84.2% ( $n = 5427$ ) of procedures had adequate bowel cleansing.

Caecal intubation rate (ESGE minimum standard of  $\geq 90\%$  of all diagnostic and screening colonoscopies visualise the whole caecum, where indication exists). The caecum was the intended endpoint in 69.4% of procedures (ileum 28.1%, anastomosis 1.3%, data unavailable 1.2%). For those colonoscopies where the caecum was the intended endpoint ( $n = 4473$ ), 94.7% reported reaching the caecum but only 77.5% (3281/4234) of those stated endpoint photo-documentation.

Polyp detection rate (PDR) (ESGE minimum standard  $\geq 40\%$  of screening and diagnostic colonoscopies performed in those aged 50 years or older). At least one polyp was detected in 40.7% (1357/3335) of qualifying procedures.

Withdrawal time from caecum to anal canal and inspection of the entire bowel mucosa at negative (no biopsy or therapy) screening or diagnostic colonoscopy (ESGE minimum standard mean 6 minutes). Of the 1150 qualifying procedures providing data, the overall mean ( $\pm$  SD) withdrawal time was  $7.8 \pm 3.1$  minutes, the median withdrawal time was 7 minutes.

**Conclusion:** Our findings indicate that while minimum standards for PDR and withdrawal time are being met, they are not achieved for adequate bowel clearance, or photo-documentation of caecal intubation.

## P0225 THE SIGNIFICANCE OF CLOSURE OF THE MUCOSAL DEFECT AFTER COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

Takita M., Ohata K., Nobuyuki M.  
 NTT Medical Center Tokyo, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** mycopiasm@mail.goo.ne.jp

**Introduction:** Because of the technical difficulty of colorectal endoscopic submucosal dissection (ESD), injury to the muscularis layer or perforation might occur during the procedure. The efficacy of closure of the mucosal defect after colorectal ESD is unknown. We investigated the significance of mucosal defect closure after colorectal ESD.

**Aims & Methods:** We investigated 403 consecutive cases of colorectal ESD performed between January 2016 and March 2019 by an expert with an experience of >500 colorectal ESD procedures. We divided the patients into two groups; one for which mucosal defect closure was done (group C), and another for which mucosal defect closure was not performed (group N), and investigated their clinical outcomes. The closure was defined as the closure of the entire mucosal defect.

**Results:** Because of muscularis layer injury or perforation, 49 patients (12.2%) underwent closure of the mucosal defect and were classified into group C. Of these cases, 40 (81.6%) were closed using conventional clip and 9 (18.4%) were closed using over-the-scope clip (OTSC), respectively. The closure time was significantly shorter in conventional clip cases ( $6.7 \pm 3.2$  vs.  $22.4 \pm 7.3$  min,  $P < 0.01$ ) compared with OTSC cases.

On the other hand, all OTSC cases had a perforation or a widely exposed muscularis layer. One group C patient and 3 group N patients had delayed perforation (2.0% vs. 0.8%,  $P = 0.41$ ).

The one case in the group C patient was closed with OTSC. The clinical outcomes were not significantly different between groups, as follows: maximum temperature after the procedure (C vs. N:  $37.2 \pm 0.5^\circ\text{C}$  vs.  $37.2 \pm 0.5^\circ\text{C}$ ,  $P = 0.91$ ), white blood cell count on postoperative day 1 (POD1) ( $8055 \pm 2708/\mu\text{L}$  vs.  $8252 \pm 2419/\mu\text{L}$ ,  $P = 0.60$ ), and C-reactive protein level on POD1 ( $1.22 \pm 1.39$  vs.  $1.19 \pm 1.66$  mg/dL,  $P = 0.89$ ). However, the incidence of abdominal pain was lower in group C than in group N (16.3% vs. 17.8%,  $P = 0.80$ ).

**Conclusion:** Our results suggest that when perforation or muscularis layer injury occurs in colorectal ESD, a favorable course, similar to that of cases without such complications, can be obtained if the mucosal defect is closed.

**Disclosure:** Nothing to disclose

## P0226 ENDOBILIARY RADIOFREQUENCY ABLATION FOR REFRACTORY BENIGN STRICTURE: A PILOT BICENTRIC STUDY

**Introduction:** Endoscopic treatment of benign biliary stricture (BBS) remains challenging with 15% of recurrence after metallic or multiple plastic stenting. We experimented endobiliary radiofrequency ablation (ERFA) with the aim to eradicate biliary fibroplasia endoscopically. We report our first experience of ERFA in the management of refractory BBS.

**Aims & Methods:** 8 patients with BBS (5 postoperative strictures, 2 chronic inflammatory strictures and 1 post stenting stricture) were treated from august 2014 to march 2018. All had previously unsuccessful endoscopic treatment with dilatations (1,75 [0-3]) and plastic or metallic stenting during a median of 18 months (9-48). Bipolar ERFA was delivered at power of 10 W for 90 seconds per stricture segment, followed by a 10 mm balloon dilatation without stent placement. Data were collected on technical success (ERFA delivery), clinical success (stricture resolution), adverse events and follow-up.

**Results:** ERFA was performed in 8 patients (7 men) with a median age of 56 years (range 20-81). All patients had stricture resolution after ERFA. No severe adverse event occurred with only a case of short abdominal mild pain. The median follow-up is 31 months.

BBS resolution without the need for further stenting was achieved in 6 patients. The 2 patients with inflammatory stricture had BBS relapse after initial resolution at 10 and 12 months, one underwent surgery, the other metallic stenting for 9 months with no further relapse at 2 years.

**Conclusion:** ERFA appears to be a safe and effective treatment for refractory BBS, especially for postoperative strictures. Further studies are warranted.

## P0227 ASSESSMENT OF ERCP USING A SHORT-TYPE SINGLE-BALLOON ENTEROSCOPE FOR PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY

Tanisaka Y., Ryozaawa S., Mizuide M., Harada M., Fujita A., Ogawa T.  
 Saitama Medical University International Medical Center, Gastroenterology,  
 Saitama, Japan

**Contact E-Mail Address:** tanisaka@saitama-med.ac.jp

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered anatomy is technically challenging. We performed ERCP in such patients using a short single-balloon enteroscope (Short-SBE, Olympus), which has a 3.2-mm working channel and a 152-cm working length and for which conventional accessories are available. This study aimed to assess the efficacy and safety of ERCP using a Short-SBE in patients with surgically altered anatomy.

**Aims & Methods:** The present retrospective study included 144 patients (range, 32-93 years) and 236 procedures comprising Roux-en-Y reconstruction (105 patients and 141 procedures), Billroth II gastrectomy (21 patients and 40 procedures), and reconstruction by the modified Child method (18 patients and 55 procedures) performed using a Short-SBE. The success and complication rates of each procedure were evaluated.

**Results:** The blind end was reached in 95.3% of procedures (225/236). Of the failed procedures, five were caused by jejunum invasion. Among 225 procedures in which the blind end was reached, cholangiography was successfully performed 92.9% of procedures (209/225). Treatment was successful in 87.3% of procedures (206/236). Successfully performed therapeutic interventions included nasobiliary drainage (n = 3), plastic stent placement (n = 51), self-expandable metallic stent placement (n = 27), and stone extraction (n = 102) using endoscopic sphincterotomy (n = 5) endoscopic papillary balloon dilation (n = 11), endoscopic papillary large-balloon dilation (n = 39), and anastomosis dilation (n=22). Complications that occurred in 6.8% of procedures (16/236) included intestinal perforation (n = 1), mucosal laceration (n = 1), mild pancreatitis (n = 8), and mild cholangitis (n = 6).

**Conclusion:** ERCP using a short-SBE is effective and safe in patients with surgically altered anatomy.

**Disclosure:** Nothing to disclose

## P0228 TO CUT OR NOT TO CUT - CLINICAL EFFICACY OF ENDOSCOPIC SPHINCTEROTOMY IN RECURRENT ACUTE PANCREATITIS FROM FUNCTIONAL BILIARY SPHINCTER OF ODDI DISORDER - A SYSTEMATIC REVIEW AND META-ANALYSIS

**Contact E-Mail Address:** harmeeet.mashiana@unmc.edu

**Introduction:** Functional biliary sphincter of Oddi disorder, previously referred to as sphincter of Oddi dysfunction, is an established cause of recurrent acute pancreatitis which is defined as two or more episodes of documented acute pancreatitis per year. Data on the efficacy of endoscopic sphincterotomy in preventing future episodes of pancreatitis is limited.

**Aims & Methods:** We performed a systematic review and meta-analysis to evaluate the clinical efficacy of index endoscopic sphincterotomy in patients with recurrent acute pancreatitis secondary to manometrically proven functional biliary sphincter of Oddi disorder. Our goal was to assess reduction in episodes of pancreatitis following sphincterotomy, and not to assess chronic pain in these patients. We conducted a search of

several databases including PubMed, EMBASE, Google-Scholar, Scopus and Cochrane Review (from 1960 to October 2018). Random-effects model was used for analysis. Heterogeneity between study-specific estimates was calculated using Cochran Q statistical test and I<sup>2</sup> statistics. Publication bias was ascertained, qualitatively, by visual inspection of funnel plot and quantitatively, by the Egger test.

**Results:** Our initial search yielded 3201 results. After excluding non-english literature and duplicates, 1936 studies were screened and 12 met inclusion criteria. A total of 396 patients with recurrent acute pancreatitis and abnormal manometry findings were included from these studies in the final analysis. The interventions performed were as follows: endoscopic biliary sphincterotomy in 212 (53.5%), endoscopic pancreatic sphincterotomy in 19 (4.8%) and dual biliary and pancreatic sphincterotomy in 165 (41.6%) patients. Technical success ranged from 99 to 100%. The pooled estimate for clinical success following index sphincterotomy was 68.4% (95% CI 57.6-77.4; I<sup>2</sup>=71.4%). Lone endoscopic biliary sphincterotomy was successful in 43/60 (71.6%) patients. The pooled estimate for proportion of patients with post-ERCP pancreatitis was 23.2% (95% CI 16.6-31.4; I<sup>2</sup>=44.4%). The follow up duration ranged from 6 months (the shortest) to 120 months (the longest). There was no evidence of publication bias, based on funnel plot analysis and Egger's test.

**Conclusion:** Our study highlights the utility and clinical efficacy of endoscopic sphincterotomy in patients with recurrent acute pancreatitis secondary to functional biliary sphincter of Oddi disorder. We conclude that 68.4% of patients improved after endoscopic sphincterotomy and that it can be considered in patients with recurrent acute pancreatitis.

**Disclosure:** Nothing to disclose

## P0229 WITHDRAWN

## P0230 ASSESSMENT OF THE HOUSE CLASSIFICATION FOR GRADING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY COMPLEXITY

Leal T., Gonçalves B.M., Ferreira A., Costa R.S., Arroja B., Gonçalves R.  
 Hospital de Braga, Gastroenterology, Braga, Portugal

**Contact E-Mail Address:** tiago.afleal@gmail.com

**Introduction:** In order to grade the complexity of Endoscopic Retrograde Cholangiopancreatography (ERCP) there are many scores available, the most used being the one developed by the American Society of Gastroenterology Endoscopy (ASGE).

**Aims & Methods:** The aim of this study was to evaluate a new classification (HOUSE) and to compare it with ASGE's. The ERCPs performed between 2015 and 2018 in our center were retrospectively reviewed. Repeated procedures in the same hospital admission and ERCPs in which cannulation was not attempted were excluded. We assessed HOUSE and ASGE classification scores, complications (pancreatitis, cholangitis, bleeding and perforation) and global technical success (GTS) - cannulation of the duct of interest, complete stone clearance and drainage of the duct of interest.

**Results:** A total of 900 ERCP were selected (mean age 71,6 ± 21,9 years; 51,4% women), comprising 673 patients. According to the HOUSE classification, 765 (85%) ERCP were class 1, 86 (9,6%) class 2 and 49 (5,4%) class 3. The distribution by the ASGE classification was the following: 137 (15,2%) grade 1, 425 (47,2%) grade 2, 320 (35,6%) grade 3 and 18 (2%) grade 4. The GTS rate was significantly higher in less complex procedures according to the HOUSE (1 - 91,0%; 2 - 82,6%; 3 - 81,6%; p=0,009) and ASGE classification (1 - 98,5%; 2 - 92,7%; 3 - 83,4%; 4 - 61,1%; p < 0,01). The overall complication rate was 10,0%, with an increasing complication incidence observed in more complex procedures as determined by the HOUSE (8,8%; 15,1%; 20,4%; p=0,008) and ASGE classification (5,8%; 8,2%; 13,8%; 16,7%; p=0,019). The correlation between the two scores was poor (p=0,239; p < 0,01).

**Conclusion:** Both scores accurately graded the complexity of ERCP. As complexity of procedures rises, GTS decreases while complications increase. These scores may be useful to compare technical success and complications between centers and endoscopists according to complexity as well as to stratify endoscopy training.

**Disclosure:** Nothing to disclose

## P0231 ENDOSCOPIC TREATMENT STRATEGIES FOR BILIARY JEJUNAL ANASTOMOTIC STENOSIS

Hosono K., Kurita Y., Hasegawa S., Sato T., Kubota K., Nakajima A.  
Yokohama City University Hospital, Department of Gastroenterology and Hepatology, Yokohama, Japan

**Contact E-Mail Address:** hiro1017@yokohama-cu.ac.jp

**Introduction:** Although treatment by balloon endoscopy for benign biliary duct jejunal anastomotic stenosis after biliary reconstruction has been reported useful, there is currently no standardized treatment strategy. In this report, we have examined the treatment strategy and results at our facility.

**Aims & Methods:** We examined a total of 248 cases in 99 patients who underwent ERCP during single balloon endoscopy (SBE) with a diagnosis of cholangitis after biliary reconstruction from March 2013 to March 2019 in our hospital. After reaching the anastomotic site, direct-viewing observation was performed for diagnosis of benign or malignant disease, and biopsy was performed if malignancy was suspected.

A practical classification of endoscopic and retrograde cholangiographic appearance of hepaticojejunostomy strictures (K. Mönkemüller et al. WJG 2011; 3: 213-9) was used to evaluate the biliary-jejunal anastomotic site. The strictures were classified into Type A (small opening), B (large), C (normal), D (2 holes) and S (constriction upstream from the anastomotic site) according to endoscopic findings at the anastomosis site, and combined with the cholangiogram Type 0 (no stenosis), 1 (short stenosis), 2 (long stenosis), 3 (intrahepatic bile duct stenosis).

As a treatment strategy, only balloon dilatation was performed for Type A1 and S1, and balloon dilatation plus plastic stent placement was done for A2 and S2; cases of Type B / C / D without stenosis were left untreated. In cases of stent placement, replacement was repeated every 2-3 months, and the stent was removed, if expansion was good. If endoscopic treatment was not possible, percutaneous transhepatic biliary drainage (PTBD) or EUS-guided biliary drainage (EUS-BD) was performed.

**Results:** The overall arrival rate to the bile duct jejunal anastomosis site was 97/99 (97.9%). Malignant recurrence at the anastomotic site was found in 15/97 (15.4%) among the achieved cases. A total of 82 benign cases were observed, and the classification of anastomotic findings was A1: 30 cases, A2: 10 cases, B / C / D: 1/30/5 cases, S1: 3 cases, S2: 1 case and complete stenosis. 2 cases showed dissection of the bile duct jejunal anastomosis. The endoscopic treatment completion rate was 80/82 (97.5%) and balloon dilatation was performed in 44/80 cases (55%). Among the A1 and S1 cases, intrahepatic stones were present in 16/33 cases (48.8%). Stent placement was performed in 12/80 cases (15%), and 10 cases (83.3%) succeeded in having the stent removed. PTBD was performed in 2 cases and EUS-BD in 2 cases.

**Conclusion:** Balloon endoscopy enables direct observation of biliary jejunal anastomoses and is useful for diagnosis, differentiation and treatment of benign and malignant cases.

However, the classification and treatment consensus of anastomotic stenosis are still inadequate, so in the future it would be desirable to study a larger number of cases.

**Disclosure:** Nothing to disclose

## P0232 A RETROSPECTIVE ANALYSIS TO ASSESS THE IMPORTANCE OF DOING A BILIARY SPHINCTEROTOMY AS A METHOD TO INCREASE AND SIMPLIFY CANNULATION SUCCESS RATE OF THE MAIN PANCREATIC DUCT

**Introduction:** MPD cannulation is the prime requisite for any pancreatic endotherapy during an ERCP.

Lot of techniques are described for difficult bile duct cannulation, but very few for pancreatic duct cannulation. Usually in cases with chronic pancreatitis, acute on chronic pancreatitis or cases of acute pancreatitis followed by ductal leaks, the duodenum and peri ampullary region are edematous and makes MPD cannulation difficult.

We found that in difficult cases where MPD could not be cannulated easily and if we could get the wire into the CBD first, doing a wide biliary sphincterotomy improved the success of cannulation of the MPD without using any more sophisticated techniques.

**Aims & Methods:** Aim was to prove that doing a biliary sphincterotomy improves PD cannulation success.

Data of all cases (1206) for pancreatic ERCP from October 2008 to May 2018 in our tertiary care centre was studied.

All cases done by a single operator always using the wire guided technique. When MPD could not be cannulated in three attempts, or MPD not cannulated directly in 10 minutes or wire going in CBD first were studied. In failed MPD cannulation - we attempted to cannulate the CBD first or when wire went in CBD first inadvertently during an MPD cannulation, we did a biliary sphincterotomy wide enough to separate the biliary and pancreatic orifices and then cannulated the MPD with a cannula and a glide wire.

**Results:**

Number of ERP	1206
Successful direct MPD cannulation	982 ( 81.4%)
Difficult Cannulation	224 (18.6%)
CBD cannulated first inadvertently	199 out of 224 ( 88.9%)
Biliary Sphincterotomy done	199 (100%)
Successful MPD Cannulation after biliary sphincterotomy	185 (92.9%)
Failed MPD cannulation after biliary sphincterotomy	14 (7.03%)
Pancreas Divisum found	10 out of 14 failed cannulations (71.4%)
Failed MPD cannulation overall	25 out of 1206 (2.07%)

[Table 1]

**Conclusion:** If direct MPD cannulation is difficult, cannulating the CBD first and doing a prior biliary sphincterotomy improves the MPD cannulation success rate - from 81.4% to 92.9%.

Of those cases with failed MPD cannulation after biliary sphincterotomy, 71.4% cases had pancreas divisum which was not detected on MRCP or prior imaging.

Those who could not be cannulated at all were subjected with either EUS guided drainage or surgery.

**Disclosure:** Nothing to disclose

**Introduction:** Hypoxemia is the most frequent adverse effect of sedation during endoscopic procedures [1]. Hypoxemia can lead to unexpected cardiac arrest and/or brain injury. It has been reported that hypoxemia follows apnea during sedation, and as such, early detection of apnea might decrease hypoxemia [2]. However, the ESGE guideline recommended that capnography should be considered during non-anesthesiologist administration of Propofol in specific situations including high risk patients, intended deep sedation, and long procedures [3]. A previous report revealed that the detection of EtCO<sub>2</sub> during full endoscopic procedures using the available sidestream capnometer was difficult because of blockage of the sampling tube with saliva, undetectable shallow breathing, or tachypnoea. Many previous studies reported that severe adverse events could not be prevented using the unreliable capnometer [4-6]. Thus, we developed a novel mainstream capnometer bite block system (cap-ONE

bite block, YG-227T; Nihon Kohden Corporation, Tokyo, Japan) designed to detect either nasal or oral tidal flow, with the EtCO<sub>2</sub> detector placed on the bite block without a sampling tube. The detector was not dislodged during the endoscopic procedure because the bite block was tightly fixed. A small-scale pilot study revealed the reliable detection of end-tidal EtCO<sub>2</sub> using our system [7]. This is a feasibility study for the novel mainstream capnometer system in a larger cohort.

**Aims & Methods:** Non-intubated patients undergoing ERCP and EUS-related procedures with CO<sub>2</sub> insufflation under intravenous sedation with midazolam 0.25mg and pethidine 35mg were enrolled retrospectively during 2017 to 2018. EtCO<sub>2</sub> was monitored continuously during the procedure using a mainstream capnometer system. The accuracy of total respiratory count using wave form analysis was evaluated using software (Nihon Kohden Tokyo, Japan).

**Results:** We enrolled 125 patients (age, 65.4±12.8; American Society of Anesthesiologists [ASA] class 1, n=81 and ASA 2, n=44; ERCP, n= 31 and EUS, n=94). Measurement of EtCO<sub>2</sub> concentration was possible from the start to the end of the procedure in all 125 cases. No measurement failure, bite block disruption, or adverse event related to the capnometer was found. Of the patients, 53.6% (67/125) had an apnoea episode. The mean time to the first apnoea episode was 9:56±1:47 min after sedation. The incidence of apnoea episode within 5 min after sedation was 52.3% (35/67). No relationship was found between the incidence of apnoea episode and comorbid diseases, smoking habit, alcohol consumption, or sleep medication addition in the univariate analysis.

**Conclusion:** The detection rates of respiration and apnoea episodes were higher than those in previous reports. The novel mainstream capnometer system is reliable and feasible for use during EUS- and ERCP-related procedures even under CO<sub>2</sub> insufflation.

## P0235 VALUE OF PANCREATIC JUICE CYTOLOGY USING ENDOSCOPIC RETROGRADE PANCREATOGRAPHY IN PATIENTS SUSPECTED OF MALIGNANT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM

Yokode M., Hanada K., Kurihara K., Shimizu A., Minami T.  
*Onomichi General Hospital, Gastroenterology, Onomichi, Japan*

**Contact E-Mail Address:** ykdmstk0428@gmail.com

**Introduction:** Pancreatic juice cytology (PJC) can provide strong evidence of malignant intraductal papillary mucinous neoplasm (IPMN), resulting in appropriate management. However, routine endoscopic retrograde pancreatography (ERP) for PJC is not recommended in IPMN patients because of the low sensitivity and the risk of post-ERP pancreatitis (PEP).

**Aims & Methods:** We aimed to elucidate what types of IPMN gain benefit of PJC using ERP. From April 2007 to April 2018, we reviewed medical records of 76 IPMN patients who underwent PJC using ERP in our hospital. IPMN-derived pancreatic ductal adenocarcinoma (PDAC) was suspected in 55 patients (Group A); 21 patients were suspected of having concomitant PDAC (Group B). Group A patients were further classified as having high-risk stigmata (HRS) (n=16), worrisome features (WF) (n=33), and non- WF (n=6) according to the International Consensus Guidelines 2012. We evaluated the cytology results, rate of malignant IPMN, PEP frequency and post-operative prognosis.

**Results:** In Group A, the rates of cytologic malignancy were as follows: non-WF, 0% (0/6); WF, 9.1% (3/33); and HRS, 56.3% (9/16). In 4 patients with HRS, PJC was negative but surgery was performed, leading to definitive diagnosis of IPMC. Finally, the rate of malignant IPMN in the patients with HRS was 81.3% (13/16). Notably, the sensitivity and accuracy of PJC in patients with WF were 100% and 100%, respectively, because the patients with negative PJC could be observed without progression. In Group B, ERP was performed in the cases with main pancreatic duct (MPD) stenosis or hypoechoic lesion that was separately detected by endoscopic ultrasound (EUS) or magnetic resonance cholangiopancreatography. The rates of cytologic malignancy in Group B was 23.8% (5/21). In 3 patients, PJC was negative but EUS-guided fine needle aspiration revealed PDAC. Therefore, the concomitant PDAC rate was 38.1% (8/21) (3, Stage 0; 4, Stage IA; 1, Stage IV). PEP frequency was 7.3% (4/55) and 23.8% (5/21) in Group A and Group B, respectively. All 9 patients were composed of branch duct (BD)-IPMN without MPD dilatation. Except for 4 patients who died of other diseases, all patients in the two groups were alive after surgery at a median follow-up of 15 months (range 2-120 months).

**Conclusion:** In patients suspected of IPMN-derived PDAC with WF, PJC might have important roles in determining the appropriate treatment choice. In patients suspected of concomitant PDAC, careful follow-up examinations of the whole pancreas are needed for the early PDAC diagnosis regardless of IPMN type. Nevertheless, we should consider BD-IPMN without MPD dilatation as a risk factor of PEP.

<sup>2</sup>*Kitasato University Hospital, Endoscopy & Gastroenterology, Sagami-hara, Japan*

**Contact E-Mail Address:** m-kida@kitasato-u.ac.jp

**Introduction:** Nowadays Endoscopic treatment of Bile duct stones in patients with surgically altered anatomy have become popular with enteroscopy-ERCP. We have retrospectively investigated surgically altered patients with bile duct stones which were treated by Electrohydraulic lithotripsy(EHL) under direct single balloon enteroscopy(SBE).

**Aims & Methods:** We have reviewed medical records from 2009 to 2018 and finally found consecutive 159 cases of bile duct stones with surgically altered anatomy. Averaged age is 71.5y/o and male: female is 117(75%): 42(25%). The group of Roux-en-Y(R-Y) with gastrectomy were 95 cases which included gastric cancer 87cases and 8 others, R-Y without gastrectomy were 29 cases which included biliary cancer 12 cases, maljunction 8 cases, and 9 others, PD were 35 cases(53 sessions) which included pancreas cancer 20 cases, biliary cancer 7 cases and 8 others. Generally we started to treat these patients with enteroscopy-ERCP which were mainly short-type single-balloon enteroscopy(SBE). In case of large stone, we dilate the papilla by 15-18mm CRE balloon, then directly insert SBE into bile duct and crash the stones by EHL under SBE guidance.

**Results:** The rate of blind reach end and success rate were 88/95 cases(92.6%) and 79/81 cases(97.6%) in the Roux-en-Y(R-Y) with gastrectomy group, 28/29 cases(96.6%) and 28/28 cases(100%) in R-Y without gastrectomy, 34/35 cases(94.3%), and 33/33 cases(100%) in pancreato-duodenectomy, respectively. Totally 140/159 cases(88%) were treated by SBE which included 13 cases(8%) of EHL treatment by directly inserted SBE and remained 6 cases by surgery, 4 cases by PTBD, 2 cases by EUS-HGS, and conservative 7 cases. The adverse events were 3.1% in pancreatitis, 0.7% in bile leakage, 1.7% in perforation, and 1.1% in bleeding.

**Conclusion:** We concluded that EHL under direct cholangioscopy performed safely in 13/159(8%) and totally 140/159(88%) of bile duct stones were treated by enteroscopy-ERCP in surgically altered anatomy cases,

## P0238 DIAGNOSTIC UTILITY OF A NEW ENDOSCOPIC SCRAPER FOR BILIARY STRICTURES

Akao L., Itoh T., Nagao K., Tahara J., Takayama Y., Shimizu K., Tokushige K.  
Tokyo Women's Medical University, Gastroenterology, Shinjuku-Ku, Japan

**Contact E-Mail Address:** akao.junichi@twmu.ac.jp

**Introduction:** The endoscopic transpapillary bile duct brushing cytology and biliary forceps biopsy with endoscopic retrograde cholangiopancreatography are generally performed for pathological diagnosis of biliary strictures. The sensitivity of the conventional cytology and biopsy was reported to be 30% to 81%. The diagnosis of biliary strictures is difficult, especially of those caused by pancreatic cancer. Therefore, endoscopic transpapillary pancreatic juice cytology and endoscopic ultrasound-guided fine needle aspiration are performed for diagnosis.

**Aims & Methods:** The *Trefle* (Piolax Medical Devices, Yokohama, Japan) is a new device that consists of looped metallic wires to scrape and aspirate the tissue along with bile juice. The aim of the study was to compare the diagnostic performance of the new device with that of conventional cytology and biopsy. A total of 196 cases with biliary stricture underwent transpapillary biopsy and cytology between 2012 and 2018, of which 74 were diagnosed using the new device. We retrospectively analyzed the diagnostic utility of the new device compared with that of conventional cytology and biopsy.

**Results:** The locations of biliary strictures were perihilar in 56 cases and distal in 140. Of the 196 cases, 138 were diagnosed with a malignant stricture. Ninety-two cases had biliary cancer, whereas 46 had pancreatic cancer. The sensitivity of the new device and the conventional cytology and biopsy was 61% and 52%, respectively. Seven cases were diagnosed with malignant strictures using the new device, although they were not diagnosed during the conventional cytology and biopsy. In the cases with biliary strictures caused by pancreatic cancer, the sensitivity of the new device and the conventional cytology and biopsy was 59% and 32%, respectively.

**Conclusion:** Our study suggests that the new device was more useful than conventional cytology and biopsy for the pathological diagnosis of biliary strictures, especially those caused by pancreatic cancer.

**Contact E-Mail Address:** hayashishiro1976@yahoo.co.jp

**Introduction:** Medical radiation provides us many benefits not only in diagnosis but also therapeutic procedure. On the other hand, its adverse effect becomes non-negligible concerns. Even a low dose exposure can affect the carcinogenesis in proportion to radiation exposure (RE) dose according to the Linear no-threshold model. Likewise, it is also important for medical staffs. Therefore, we have to recognize the proper use of medical radiation. In the field of gastroenterology, ERCP represents the major procedures under fluoroscopic guidance. However, we gastroenterologist do not know enough about the basis of RE nor how much we actually use in each ERCP.

**Aims & Methods:** The aim of this study is to assess the actual RE dose in ERCP and its affecting factors.

This is a retrospective, single-center cohort study of consecutive patients who underwent ERCP with the fluoroscopic unit (EXAVISTA, Hitachi..co) between Oct 2012 and Mar 2018. All ERCP procedures were categorized by disease sites into 4 types: common bile duct stone (CBDS), distal malignant biliary obstruction (DMBO), proximal malignant biliary obstruction (PMBO), and the Others. A total of 1543 ERCP procedures excluding procedures with missing data, were analyzed. We measured total fluoroscopy time (FT, sec), dose area product (DAP, mGycm<sup>2</sup>) and air kerma (AK, mGy).

**Results:** The mean age was 73.9±10.8 years, and 663 patients were female (43%). 729 patients (47%) had a native papilla. ERCP procedures were performed for the purpose of treating CBDS (N=761, 49%), DMBO (N=275, 18%), PMBO (N=324, 21%), or other diseases (N=183, 12%). Median AKs in all case/ CBDS/ DMBO/ PMBO were 133/ 139/ 100/ 166 mGy, respectively.

In a similar fashion, median DAPs were 15.1/ 15.2/ 12.2/ 20.0 Gycm<sup>2</sup>, and median FTs were 639/ 623/ 526/ 794 sec. Dunn's multiple comparison test revealed that PMBO showed significantly the largest DAP, AK, and FT, compared with DMBO (p<.0001/ p<.0001/ p<.0001, respectively) and, compared with CBDS (p=.0006/ p<.0001/ p<.0001, respectively). Among them, DMBO showed significantly the smallest DAP, AK and FT (p=.0015/ p=0.012/ p=.0068 than CBDS). Among all procedures, the highest level of AK was 2.1 Gy in a PMBO case. Twelve cases (0.8%) were over 1Gy. Of them, 8 cases were PMBO including 3 cases with CBDS.

**Conclusion:** DAP, AK and, FT in PMBO were significantly larger than CBDS and DMBO. The disease sites significantly influenced the RD during ERCP. Some cases mainly in PMBO showed extremely high level of RE.

**Disclosure:** Nothing to disclose

## P0240 HYDRATION WITH LACTATED RINGER'S SOLUTION COMBINED WITH RECTAL DICLOFENAC IN THE PREVENTION OF PANCREATITIS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

Del Olmo Martinez L.<sup>1</sup>, Velayos Jiménez B.<sup>2</sup>, Almaraz Gomez A.<sup>3</sup>

<sup>1</sup>Hospital Clínico, Gastroenterology, Valladolid, Spain, <sup>2</sup>Hospital Clínico Universitario, Gastroenterology, Valladolid, Spain, <sup>3</sup>Facultad de Medicina, Medicina Preventiva y Salud Pública, Valladolid, Spain

**Contact E-Mail Address:** ldelolmo@yahoo.es

**Introduction:** Pancreatitis after retrograde cholangiopancreatography (PEP) is one of the most frequent and serious complications of this exploration. It has been reported that rectal diclofenac, aggressive hydration with lactated ringer's solution alone or together with rectal indomethacin prior to exploration decreases the number of PEP.

We conducted a retrospective study in consecutive patients who underwent ERCP and were given rectal diclofenac prior to exploration or lactated ringer during and after or both interventions (lactated ringer's solution plus diclofenac) to assess whether there is reduction in the number of PEP in the treated groups.

**Aims & Methods:** All consecutive patients who have undergone ERCP since 2009 have been included. Until June 2012, they did not receive any type of prophylactic treatment (Group I). As of this date, rectal diclofenac 100 mg was placed before the start the exploration (Group II). Since January 2016 they were treated with intravenous infusion of lactated Ringer 200 ml / hour during the procedure and 4 hours after the procedure. In those patients in whom the pancreas was cannulated, they also received 500 ml of lactated Ringer in 30 minutes postexploration (Group III). Subsequently, from January 2017, patients received the same IV infusion of lactated Ringer during and after the exploration plus diclofenac 100 mg rectal before the procedure (Group IV). 1,896 ERCPs were included: 725 patients group I, 530 Group II, 227 Group III and 414 Group IV. The risk factors for PEP and PEP cases that were defined by consensus criteria were recorded.

**Results:** The average age of the patients was 70.7 years. 53.1% were male and 46.9% female. There were 65 PEP (3.4%), 3.4% of which corresponded to group II, 2.9%, to group I, 3.5% to group III and 4.3% to group IV (p, 640). 38.4% of all patients had one or more risk factors for PEP. The bivariate analysis relating the influence of the various factors under study on the likelihood of PEP development no differences were seen according to diclofenac administration status, acute hydration with lactated ringer nor with both treatments. Wirsung stent placement had no influence. PEP risk was increased by pancreatic duct cannulation and biliary sphincterotomy increased risk by a factor of 1.13 (95% CI: 0.55-2.34). In the logistic regression analysis the variable found to be significantly associated with PEP included Wirsung cannulation (with guidewire, contrast or both - OR 3.09 (95% CI: 1.45-6.58), OR 2.05 (95% CI: 0.81-5.17), and OR 4.57 (95% CI: 2.47-8.45), respectively), 83). Age younger than 75 years would increase risk by a factor of 2.35 (95% CI: 1.14-4.83). Hydration plus diclofenac played no role in our cohort

**Conclusion:** In this study hydration with lactated ringer's solution combined with rectal diclofenac does not prevent the occurrence of PEP in our patients.

**References:** Lactated Ringer's solution in combination with rectal indomethacin for prevention of post-ERCP pancreatitis and readmission: a prospective randomized, double-blinded, placebo-controlled trial. ## P0241 EVALUATION OF A NEW METAL BILIARY STENT OF 12-MM DIAMETER: A CASE CONTROL STUDY

Decoster C.<sup>1</sup>, Caillol F.<sup>1</sup>, Pesenti C.<sup>1</sup>, Ratone J.P.<sup>1</sup>, Zemmour C.<sup>2</sup>, Bories E.<sup>1</sup>, Winkler J.<sup>1</sup>, Debourdeau A.<sup>1</sup>, Giovannini M.<sup>1</sup>

<sup>1</sup>Institute Paoli-Calmettes, Endoscopy, Marseille, France, <sup>2</sup>Institute Paoli-Calmettes, Statistics, Marseille, France

**Contact E-Mail Address:** claire.decoester@hotmail.fr

**Introduction:** Biliary stent allows pre-operative or palliative drainage of malignant biliary stenosis, and biliary calibration in case of benign stenosis. Currently, by expert agreement, the diameter is 10-mm for metal stent. Since 2017, larger stent have been marketed in France and are approved for the biliary drainage of benign and malignant biliary stricture. These new 12-mm diameter stent could reduce the risk of recurrent biliary obstruction (RBO) and therefore increase the stent patency. The aim of our study was to compare whether the patency of 12-mm diameter stent was better than a conventional 10-mm.

**Aims & Methods:** From April 2017 and April 2018, 2 patients per month with benign or malignant biliary stricture were treated with metallic biliary stent, covered or uncovered, of 12-mm diameter (length 4 or 6-cm). Control patients treated with stent of 10-mm diameter were identified in our center database over the same period. These patients were paired based on age (per decade), stricture etiology (i.e., benign or malignant) and type of stent (i.e., covered or non covered). Primary endpoint was time before RBO. Secondary endpoints were technical success rate and adverse events rate (< 1 month).

**Results:** From April 2017 to April 2018, we included 24 patients in the 12-mm group (sex ratio 1.8/1; mean age 71 years) and 48 patients in the control group (sex ratio 1.6/1; mean age 68.8 years).

In each group, 75% of patients were treated for malignant stricture, mainly due to pancreatic adenocarcinoma. There was no statistically significant difference between the two groups in terms of sex, Karnofsky index and initial total bilirubin level. The median follow-up time was 7.49 months in the 12-mm group compared to 8.8 months in the 10-mm group (p=0.042). Technical success rate was 95.8% and 100% in the 12 and 10-mm groups respectively. The only failure was due to a stent dysfunction during the placement requiring its immediate replacement. Median time to RBO was 5.9 months in the 12-mm group vs. 8.3 months in the 10-mm group (p=0.27). In the malignant stricture subgroup, RBO occurred after 6.1 months and 17.1 months in the 12 and 10-mm group respectively (p=0.05). The adverse events rate in the month following the biliary stent placement was 25% (n=6/24) in the 12-mm group and 2% (n=1/48) in the control group without significant difference. In the 12-mm group, there were two grade II, one grade IIIa and three grade V adverse events according to the Dindo-Clavien classification. The only adverse event in the 10-mm group was grade II (acute pancreatitis). When new biliary drainage was required, it was done endoscopically in 100% of cases for both groups.

**Conclusion:** This case-control study does not show better permeability of 12-mm diameter metal biliary stent. This result seems to be true regardless of the etiology of biliary stricture and particularly in the group of malignant strictures. The placement of 12-mm diameter stent in benign stricture should be better evaluated. New prospective studies must be conducted to investigate the efficacy and safety of these stent.

**Disclosure:** Nothing to disclose

## P0242 LAPARO-ENDOSCOPIC RENDEZ-VOUS MANAGEMENT OF GALLSTONES AND COMMON BILE DUCT STONES: A LARGE CASE SERIES

Lauri A.<sup>1</sup>, Lattanzio R.<sup>2</sup>, Vittorini V.<sup>3</sup>, Navarra L.<sup>3</sup>, Caterino G.<sup>3</sup>, Rando G.<sup>1</sup>

<sup>1</sup>Gastroenterology and Digestive Endoscopy Unit, Department of Medicine, Pescara, Italy, <sup>2</sup>Surgical Endoscopy Unit, Surgery, Pescara, Italy, <sup>3</sup>General Surgery Unit, Surgery, Pescara, Italy

**Contact E-Mail Address:** adrianolauri1@gmail.com

**Introduction:** Biliary lithiasis is an endemic condition in both Western and Eastern countries, affecting 20% of the general population. In up to 20% of cases, gallstones are associated with common bile duct stones (CBDS), which are asymptomatic in up to one half of cases.

The ideal management of CBDS in the era of laparoscopic cholecystectomy is still controversial: multiple modalities have been applied with success.

The aim of our study is to evaluate the success rate, clinical results and length of hospital stay of single stage treatment of gallstones and CBDS by laparo-endoscopic rendez-vous.

**Aims & Methods:** From April 2000 to April 2019 a total of 495 elective patients (mean age 65 years, range 18-92, M/F 235/260) underwent single stage treatment of gallstones and CBDS by laparo-endoscopic rendez-vous technique. All patients were diagnosed preoperatively by MRCP or EUS and informed about alternative methods of treatment and potential complications related to laparo-endoscopic rendez-vous technique.

**Results:** Cholecystectomy and common bile duct drainage were achieved in 494 cases of 495.

The transcystic-transpapillary guidewire access was achieved in 448 of 495 (90.5%). In 46 of 495 patients (9.3%) we successfully performed intraoperative ERCP. We registered one case in which it was necessary a percutaneous drainage due to distal biliary stenosis (0.2%).

The conversion rate to an open cholecystectomy was 1.8% (9/495) because of previous abdominal surgery (7 pts) and unknown gallbladder cancer (2 pts). The mean ERCP operative time was 35 minutes (range 15-120 min). A biliary plastic stent was placed in 61 patients (12.3%) due to anatomic alteration of biliary tract (1 pt, 0.2%), not complete stone extraction (40 pts, 8%), giant lithiasis in elderly patients (17 pts, 3.4%) or biliary fistula (2 pts, 0.4%). One patient died after the procedure for severe acute pancreatitis. Of the 495 patients who underwent laparo-endoscopic rendez-vous 6 patients (1.2%) suffered by major complications (lesions of the biliary tract=5 (1%); severe acute pancreatitis=3 (0.6%); retroperitoneal bleeding=2 (0.4%). Eleven patients (2.2%) underwent minor complications (bleeding=11). The mean length of hospitalization was 3 days.

**Conclusion:** Single stage treatment of gallstones and CBDS by laparo-endoscopic rendez-vous technique is a safe and effective method with low risk of postoperative pancreatitis. One-step treatment is more comfortable for patients and also shortens the mean hospital stay.

**Disclosure:** Nothing to disclose

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) plays major role in pancreaticobiliary disorders, however; its use in acute biliary pancreatitis (ABP) is a very debatable issue.

The aim of this work was to study the safety and efficacy of ERCP in ABP.

**Aims & Methods:** Patients presented with ABP were prospectively included and subjected to ERCP procedure after full clinical and investigational work up as per the policy of Qena university hospital. Diagnosis of AP was based on presence of deep-seated epigastric pain, at least triple-fold rise of pancreatic amylase and/or lipase, and radiologic findings of AP including edema, fluid collection or necrosis as detected by abdominal ultrasound (US) and computerized tomography (CT). Biliary aetiology of AP was confirmed by a triple-fold rise of ALT with detection of CBD stone(s) or mud in abdominal imaging.

To distinguish patients with concomitant cholangitis from those without cholangitis, the included patients were then classified into two groups: group (A) with concomitant cholangitis as defined as right upper quadrant pain, serum bilirubin  $\geq 3$  mg/dl and temperature  $\geq 38$  C, and group (B) patients without cholangitis who did not fulfill these criteria. ERCP procedures were performed by experienced ERCP endoscopist with more than 500 procedures performed.

**Results:** A total of 78 ABP patients were included, mean age: 40.7 $\pm$ 13, 42 (54%) were females.

Clinical presentations on admission were; abdominal pain in 78 (100%), nausea in 55 (70.5%), jaundice in 44 (56.4%), vomiting in 43 (55 %) and fever in 35 (44.9%).

All patients were subjected to ERCP within 24 hours from the onset of pain. The cannulation technique was: wire-guided cannulation (WGC) in 56 patients (72%), transpapillary fistulotomy (TPF) in 18 (23%) and transpapil-

lary papillotomy in 4 patients (5%) with impacted stone at the papillary orifice. Definite stones were extracted in 74 patients (94%) while the rest of patients had only debris. The mean cannulation time was 13.6 minutes and the mean total procedure time was 68.4 minutes.

Our result showed a statistically significant difference among means of all biochemical parameters at baseline, 24-hours post-ERCP and at the time of discharge. The mean values of ALT, AST, ALP, total bilirubin, direct bilirubin, pancreatic amylase and lipase were: 261 U/L, 178 U/L, 252.5 U/L, 5.1 mg/dl, 3.3 mg/dl, 1013 U/L, 1404 U/L at baseline versus 180, 105, 178, 2.7, 1.7, 367, 918 one-day post-ERCP and 98, 69, 137, 1.6, 0.5, 84, 716 at discharge time.

At baseline; 18 patients had mild abdominal pain, 52 had moderate and 8 had severe while after ERCP 76 patients were pain-free, 1 patient had worsening of her pain from mild to moderate and another patient had the same moderate intensity pain. Both patients were young-age females with serum bilirubin < 3 mg/dl, BISAP score of 2 at admission, and without cholangitis. Biliary access was achieved via WGC after a relatively-long cannulation time of 17 and 23 minutes, and prolonged total procedure time of 98 and 103 minutes respectively. Both were managed medically for 5 and 7 days then were discharged.

No reported serious complications in our study.

**Conclusion:** In the setting of acute biliary pancreatitis, either with or without cholangitis, ERCP is safe and efficient procedure when performed by experienced hands and at the optimal time.

**Disclosure:** Nothing to disclose

## P0244 A POPULATION-BASED ANALYSIS: WHO DOES RECTAL INDOMETHACIN IN POST-ERCP PANCREATITIS HELP?

**Introduction:** Pancreatitis (PEP) post endoscopic retrograde cholangiopancreatography (ERCP) is a severe complication, with an incidence rate ranging between 1.3 - 24.4%. Many studies have shown that indomethacin effectively decreases post-ERCP pancreatitis (PEP). However, it is unclear which demographics are effected most, and the role of indomethacin in these populations. Additionally, large population-based studies reporting the effectiveness of rectal indomethacin are limited. This study aims to report populations who pose a higher than average-risk of PEP, and describe the role of indomethacin in these patients.

**Aims & Methods:** A population-based study was conducted using a cloud-based, HIPPA-enabled web platform called Explorys (IBM, New York) to collect aggregated de-identified electronic health records. At the time of the study, Explorys had access to over 62 million unique records. Data was obtained using ICD-9 code criteria for ERCP's, acute pancreatitis (pancreatitis within 7 days of ERCP), and inclusion of rectal indomethacin formulations. Relative risk (RR) with 95% confidence intervals (CI) in a random effect model was used for aggregated subgroup outcome data based on associated factors or patient characteristics to identify populations who may benefit most from rectal indomethacin.

	PEP [n=23,920]	PEP with Rectal Indomethacin [n=3,320]	Relative Risk [95% CI]	P
Age, n [%]				
18-65	12,150 [51]	1,920 [58]	1.11 [1.04, 1.18]	0.0011
> 65	11,630 [49]	1,390 [42]	0.68 [0.63, 0.72]	< 0.0001
Gender, n [%]				
Female	13,560 [57]	2,020 [61]	0.96 [0.90, 1.02]	0.1660
Male	10,360 [43]	1,300 [39]	0.76 [0.71, 0.81]	< 0.0001
Race, n [%]				
Caucasian	18,890 [79]	2,820 [85]	1.50 [1.37, 1.64]	< 0.0001
African-American	2,840 [12]	340 [10]	0.25 [0.22, 0.27]	< 0.0001
Hispanic	1,509 [7]	220 [7]	1.05 [0.93, 1.20]	0.4150

[Role of Rectal-Indomethacin in Post-ERCP Pancreatitis (PEP)]

**Results:** A total of 112,290 patients underwent ERCP, of which 23,920 (21%) developed PEP. We found a higher risk of PEP development in younger patients (18-65), African-Americans and Hispanics (P< 0.001). Rectal indomethacin decreased rates of PEP in patients > 65 [RR 0.68 (95% CI: 0.63-0.72), P< 0.0001] and African-Americans [RR 0.25 (95% CI: 0.22-0.27), P< 0.0001]. Indomethacin did not affect the risk of PEP in the younger population and Caucasians.

**Conclusion:** Rectal indomethacin decreases rates of post-ERCP pancreatitis in the elderly, and African-Americans. Given our study found African-Americans have higher rates of PEP, clinicians need to be aware and vigilant to provide rectal indomethacin in these populations, where benefit was greatest.

**Introduction:** Endoscopic sphincterotomy (ES) is the standard therapy in common bile duct (CBD) stones extraction. Large stones (≥ 10 mm) or multiple stones extraction may be challenging after ES alone. Endoscopic sphincterotomy followed by large balloon dilation (ESLBD) has been described as an alternative to ES in these indications.

The aim of this study was to determine the therapeutic outcomes and safety of ESLBD compared with ES for large CBD stone extraction.

**Aims & Methods:** This is a retrospective study in which 323 consecutive patients who presented with choledocholithiasis >10 mm from January 2011 to December 2018 have been analyzed. In 249 ES was performed and the extraction of the stones was attempted. 74 patients were treated with ESLBD. Data for each patient and exploration were collected in an Excel sheet, and later analyzed using the IBM SPSS Statistics 20 software package. Simple statistical applications were applied in order to determine whether significant differences exist in comparison groups. We used chi-square test to compare proportions and categorical variables. Non-parametric Mann-Whitney U-test was applied in order to compare continuous variables. All comparisons were deemed to be statistically significant if P values were less than 0.05.

**Results:** The comparison of variables of two groups are expressed in Table 1.

VARIABLES	ES n=249	ESLBD n=74	p
Mean Age	75,81	75,82	0,828
Older than 75 Years(%)	59,3	60,8	0,893
Mean Number Stones	2,9	3,45	0,154
Size Major Stone (mm)	11,91	13,26	0,029
Male/Female (%)	52,2/47,8	50/50	0,792
Dilatation bile duct (%)	89,6	95,9	0,107
Full extraction stones (%)	68,7	69,9	0,887
Adverse Events (%)	2	0	0,593

[Comparison variables of ES and ESLBD groups]

78 (31.3%) of patients in ES group required repeat ERCP for stone clearance and in 70 large biliary dilation (LBD) was performed. In 22 (30.1%) of ESLBD group it was not possible to extract the stones and 11 had repeat LBD for complete duct clearance. Larger stone size (12.7 mm vs 16.3 mm, P < 0.001), multiple stones (3 vs 4 P < 0.06) were significant predictors of failed duct clearance at ERCP. Procedure related adverse events included 5 cases (2%) in ES group and none in ESLBD group (P< 0.593).

**Conclusion:** In our study ESLBD and ES clear bile stones with equal efficacy. However, ESLBD achieves the removal of larger stones in the initial ERCP with few adverse effects.

**Introduction:** Endoscopic ultrasound guided biliary drainage (EUS-BD) is a useful method after failed ERCP yet need expertise in performing the procedure. Hands on model for EUS-BD training has been developed to improve trainee's skill but previous models required fluoroscopy and included ex-vivo animal organs. We reported an all-synthetic interventional EUS training model (TAGE-1) and now a newer model (TAGE-2) has been developed.

**Aims & Methods:** This study aims to evaluate TAGE-2 model during the hands on workshop. We developed a non-fluoroscopy, all-artificial model for EUS-BD which included both hepaticogastrostomy (HGS) and choledochoduodenostomy (CDS). We launched TAGE-2 in two international EUS hands on workshops and gave a questionnaire to the participants. 10 aspects of EUS-BD was assessed scored from 1 to 4, with score 1 = poor, 2 = fair, 3 = good, 4 = excellent, by both the expert (> 300 experiences of EUS FNA) and the trainee during the workshop. The trainees were divided into a beginner (< 50 cases of EUS) and an experienced (≥50 cases of EUS FNA).

**Results:** The evaluation scores for EUS guided HGS and CDS are shown in table 1. Almost all items were graded as good to excellent, especially for the needle visibility, guidewire manipulation and stent deployment. However, the puncture sensation in EUS-CDS and contrast visibility in EUS-HGS are still graded fair to good by the experienced and the expert, respectively.

**Conclusion:** We developed a non-fluoroscopic, all-artificial model for EUS BD training which provided good training hands on for therapeutic EUS, especially for the steps and maneuverability of the instruments.

Evaluated items	HGS beginner (23)	HGS experienced (2)	HGS expert (3)	HGS overall (28)	CDS beginner (36)	CDS experienced (5)	CDS expert (4)	CDS overall (45)
Anatomical correlation	3	3	3	3	3	3	3	3
Bile duct identification	4	3	3	3	3	3	3.5	3
Needle visibility	4	3	4	4	4	4	4	4
Puncture sensation	3	3	3.5	3	3	3	2.5	3

**Contact E-Mail Address:** francescbas15@gmail.com

**Introduction:** The endoscopic band ligation (EBL) without resection combined with a single-incision needle-knife (SINK) biopsy is a little reported option in the management of subepithelial tumours (SET).

**Aims & Methods:** The main aim was to determine the efficacy of this technique. Secondary aims: to evaluate its safety and the diagnostic yield of biopsy.

**Methods:** Prospective multicenter study. Inclusion criteria: SET≤15-mm, confirmed by endoscopic ultrasound (EUS). Technical success: complete EBL of the SET plus SINK biopsy. Clinical success: total disappearance of the SMT. Clinical controls: recovery at first 6 hours, calling at 48 hours and 7 days. EUS control at 4-6 weeks and 12 months. Clinical-Trials.gov register: NCT03247231.

**Results:** Seventy-two cases (49% of the sample calculation); EUS control 4-6 weeks n=59. Esophagus n=5, stomach n=52, duodenum n=14, rectum n=1. SET medium size: 9.6-mm (4.5-15 mm). EBL technical success: 85% (n=61/72). Clinical success at 4-6 weeks: 93% (n=55/59), overall clinical success: 79% (n=55/70). SET dependence of superficial vs deep layer subanalysis: technical success 90% vs 71%; overall clinical success 86% vs 62%. SET≤10-mm vs >10-mm: technical success 100% vs 63%; overall clinical success 98% vs 52%. Pathological diagnosis: 64% (35/55); no differences between SET-size, SET-layer, or number of biopsies. Three mild adverse events (4%): bleeding, pain, mucosal intraprocediment laceration. Incidences: epigastralgia (6h: 29%; 24-48h: 26%; 7-days: 13%; 4-6 weeks: 2%).

**Conclusion:** Preliminary results in the short-medium follow up term indicate that EBL of small SET, supplemented with SINK biopsy, seems to be a feasible and safe technique. The limitations of its technical and clinical success seem to be associated with the SET size and deep layers dependence.

	Superficial layer	Deep layer	SET ≤10-mm	SET >10-mm
<b>YES technical success</b>	46 (90%)	15 (71%)	42 (100%)	19 (63%)
<b>NO technical success</b>	5 (10%)	6 (29%)	0 (0%)	11 (37%)
<b>YES clinical success</b>	42 (95%)	13 (87%)	40 (98%)	15 (83%)
<b>Overall NO clinical success</b>	7 (14%)	8 (38%)	1 (2%)	14 (48%)

[Technical and clinical success subanalysis]

**Introduction:** Endoscopic ultrasound (EUS) is useful for obtaining high-resolution images of pancreaticobiliary diseases but is not readily available for a physical checkup. Recently, a new ultrasonic endoscope (EG-580UR; FUJIFILM) capable of simultaneously performing esophagogastroduodenoscopy (EGD) and EUS was developed. In this study, we evaluated the safety and efficacy of single-session EGD and EUS for the detection of upper-gastrointestinal and pancreaticobiliary diseases using this newly developed ultrasonic endoscope.

**Aims & Methods:** A total of 148 patients scheduled to undergo upper-gastrointestinal screening using an endoscope were prospectively included. All patients were examined using EUS together with EGD using EG-580UR. The primary endpoint was the safety of the procedures, and the secondary endpoints were the prevalence of diseases, basal imaging capability of EUS, correlation between the prevalence of pancreatic diseases and backgrounds, and procedure time. Imaging capability was scored as 0 (invisible) to 2 (sufficient visualization to evaluate the organs clearly) in each region.

**Results:** Intraoperative hypotension occurred as an adverse event of intravenous anesthesia in one patient, however her hypotension was reversed rapidly with the administration of ephedrine, and she recovered from anesthesia without further symptoms. The prevalence of pancreaticobiliary diseases was as written below; pancreatic cysts: 32 patients, early chronic pancreatitis: 25 patients, gallbladder polyps: 22 patients, adenomyomatosis: 9 patients, gallbladder stone: 13 patients, bile duct stone: one patient. The prevalence of upper-gastrointestinal diseases was as written below; esophagitis: 51 patients, esophageal polyp: 3 patients, chronic gastritis: 69 patients, gastric ulcer scar: one patient, gastric polyp: 23 patients, gastric submucosal tumor: 8 patients, duodenal ulcer scar: 8 patients, duodenal submucosal tumor: 2 patients. There were no features of malignancy of pancreaticobiliary and upper-gastrointestinal findings in any patients. Swollen abdominal lymph nodes were detected in one patient incidentally, and EUS-guided fine-needle aspiration was performed, which revealed the lesion to be follicular lymphoma. The mean EUS imaging scores of each section were 1.95 (pancreatic head and papilla), 2.0 (pancreatic body), 1.99 (pancreatic tail), and 1.89 (common bile duct and gallbladder). The age, history of diabetes mellitus, and smoking history were significantly associated with the prevalence of pancreatic diseases. Median procedure time was 21 minutes.

**Conclusion:** Performing EGD and EUS simultaneously using the new ultrasonic endoscope is tolerable and safe for upper-gastrointestinal and pancreaticobiliary screening.

**Disclosure:** Nothing to disclose

## P0249 THE "TWIST-NEEDLE" - A NEW CONCEPT FOR ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE-BIOPSY

**Introduction:** Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) represents a standard method for tissue acquisition of lesions adjacent to the gastrointestinal wall. 19-gauge needles acquire more tissue than needles with a smaller diameter, but are often unable to penetrate solid, rigid masses. In this study we evaluate a novel prototype that links forward movement of the needle to rotation of the needle tip.

**Aims & Methods:** Two needle-models that generate either a regular axial movement or a combination of axial movement with rotation of the needle tip were compared ex vivo for measurement of pressure needed to penetrate artificial tissue. Furthermore, a standard 19-gauge EUS-FNB needle was compared to a modified model ("Twist Needle") in an ex vivo model to measure the amount of tissue obtained.

**Results:** Pressure measurements using the rotating needle revealed that significantly less pressure is needed for penetration compared to the regular axial movement (mean  $\pm$  SEM;  $3.7 \pm 0.3$  N vs.  $5.5 \pm 0.3$  N). Using the modified 19-gauge "Twist Needle" did not diminish tissue acquisition measured by surface amount compared to a standard needle ( $37 \pm 5$  mm<sup>2</sup> vs.  $35 \pm 6$  mm<sup>2</sup>).

**Conclusion:** The method of rotation of an EUS-FNB needle tip upon forward movement requires less pressure for penetration but does not diminish tissue acquisition. Hence, the concept of our "Twist Needle" may potentially reduce some of the current limitations of standard EUS-FNB.

## P0250 DOES ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE BIOPSY USING A FRANSEEN NEEDLE REALLY OFFER HIGH DIAGNOSTIC ACCURACY AND POOR PUNCTURE PERFORMANCE?

Fujita A., Ryozaawa S., Mizuide M., Tanisaka Y., Harada M., Ogawa T.

**Contact E-Mail Address:** a.fujita0628@gmail.com

**Introduction:** Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) was first reported in 1992 and is now used for a wide range of lesions. This widely used non-surgical biopsy procedure provides safe, consistent results under ultrasound guidance.

A recent meta-analysis of pancreatic lesions showed that EUS-FNA was a modality producing excellent diagnostic accuracy, and EUS-FNA has now been established as an important modality for the histopathologic diagnosis of pancreatic lesions. This modality is not, however, without unresolved issues, including the need for by-lesion needle selection, the need for availability of rapid onsite evaluation (ROSE), and the need for skilled endoscopists.

New clinical applications for biopsies are on the horizon, such as genetic diagnostics and anticancer drug-sensitivity assays in addition to conventional diagnostics. Such applications will inevitably require collection of an adequate tissue volume to achieve better diagnostic accuracy. In EUS-FNA, 19-G needles are useful for histologic diagnostics, providing sufficient sample for immunostaining, but the greater puncture resistance encountered at this size increases the difficulty of the procedure. This has left users wanting smaller-gauge needles that could collect comparable volumes of tissue. In 2016, the Franseen needle emerged as a fine needle biopsy (FNB) device with the potential to provide better histologic diagnostic accuracy than conventional FNA needles. This device, however, remains under-researched.

We recently evaluated the diagnostic accuracy and utility of EUS-FNB performed with a 22-G Franseen needle for solid pancreatic lesions, comparing the results to those obtained through EUS-FNA with conventional needles.

**Aims & Methods:** This study aimed to investigate the diagnostic accuracy and utility of EUS-FNB performed using a Franseen needle on solid pancreatic lesions.

This study included 132 consecutive lesions sampled by EUS-FNA using a 22-G conventional needle and 93 consecutive lesions evaluated by EUS-

FNB using a 22-G Franseen needle to evaluate solid pancreatic lesions at our medical center between July 2013 and October 2018. Patient data were analyzed retrospectively.

**Results:** Diagnostic accuracy was significantly higher in the Franseen needle group (Group F; 91.4%, 85/93) than in the conventional needle group (Group C; 80.3%, 106/132;  $P=0.02$ ). In Group F, diagnostic accuracies for pancreatic head lesions, lesions sampled by transduodenal puncture, and relatively large lesions  $>20$  mm in diameter were 97.9% (47/48), 97.8% (45/46), and 93.3% (70/75), respectively. These values were significantly higher than in Group C ( $P < 0.001$ , 0.002, and 0.04, respectively). In terms of differentiating benign from malignant lesions, Group C showed 78.3% sensitivity (94/120), 100% specificity (12/12), 100% positive predictive value (94/94), and 31.6% negative predictive value (12/38), while Group F showed values of 89.9% (71/79), 100% (14/14), 100% (71/71), and 63.6% (14/22), respectively. Sensitivity and negative predictive value were better in Group F.

**Conclusion:** Using a Franseen needle for EUS-FNB of solid pancreatic lesions offers superior diagnostic accuracy to conventional FNA regardless of the lesion site.

**Disclosure:** Nothing to disclose

## P0251 THE SENSITIVITY AND NEGATIVE PREDICTIVE VALUE OF EUS-FNA OF PANCREATIC MASSES IN PRACTICE: CAN WE RULE OUT PANCREATIC CANCER?

Faigel D., Pannala R., Nguyen C., Villa N., Fukami N.  
Mayo Clinic, Gastroenterology, Scottsdale, United States

**Contact E-Mail Address:** faigel.douglas@mayo.edu

**Introduction:** EUS-FNA is commonly performed to establish a tissue diagnosis of pancreatic cancer. Performance metrics for FNA of solid masses include diagnostic yield  $\geq 70\%$  and sensitivity for malignancy  $\geq 85\%$ . (1) These benchmarks were based on a meta-analysis of 33 studies from 1997-2009 reporting an average sensitivity of 85% but with a range among these studies of 54-95%. (2) Our previously published threshold analysis suggests that this level of sensitivity may have inadequate negative predictive value (NPV) to affect management. (3)

**Aims & Methods: Objective:** Review a tertiary center's clinical experience with EUS-FNA of pancreatic masses and calculate the sensitivity and NPV for pancreatic cancer.

**Methods:** This study was granted an IRB exemption from review. As part of our quality assurance program, all EUS-FNA procedures of solid pancreas masses from calendar years 2013 and 2014 were identified. All procedures were performed by 1 of 3 experienced endosonographers using Olympus echoendoscopes and processors and 22g or 25g FNA needles (Boston Scientific, Cook Medical) using a no suction technique. Rapid on-site evaluation for adequacy was performed by trained cytotechnicians after staining with toluidine blue. Final pathology was determined by cytopathologists after review of pap stained slides and cell block material. Only cytology that was diagnostic was considered a true positive (suspicious was considered negative). Follow-up was done by chart review. False negatives had subsequent biopsy or clinical follow-up diagnostic of pancreatic cancer. True negatives either had an alternative diagnosis established at FNA, by resection or biopsy, or adequate clinical follow-up indicative of a benign condition.

**Results:** 120 patients underwent EUS-FNA for pancreatic masses. Patients with a preprocedure or a pre-FNA endosonographic diagnosis of a cystic lesion without a solid mass were excluded. 102 (85%) were positive for malignancy. 18 patients with a negative cytology had median follow-up of 695 days. Of these 18, 4 were subsequently diagnosed with cancer (3 adenocarcinoma, 1 NET). The EUS-FNA was diagnostic of a benign etiology in 6 (AIP, ectopic spleen, 4 benign cystic lesions). Of the 8 without cancer and with a non-diagnostic EUS-FNA (median follow-up 830 days), 3 had surgical resections with pathology revealing benign cystic lesions, 2 had resolution of the lesion on repeat imaging, and 3 had chronic pancreatitis with no progression on at least 2 years of follow-up. The sensitivity of EUS FNA for cancer was 102/106 = 96%. The NPV was 14/18 = 78%.

**Conclusion:** EUS-FNA of pancreatic masses using modern techniques and rapid on-site evaluation has improved in the last 10 years. Our previously published threshold analysis indicated that if the post-test probability of cancer was  $\geq 43\%$  then surgery should be done. (3) With a NPV=78% and a post-test probability of 22%, a negative FNA should prompt additional testing and follow-up as opposed to proceeding with surgical resection in

most cases. Given the high sensitivity for cancer in clinical practice, our results also suggest that quality benchmarks for EUS-FNA should be re-evaluated.

**Introduction:** The aim of the diagnostic evaluation of bile duct obstruction is to differentiate benign from malignant lesions and to stage the tumor in cases of malignancy. Endoscopic retrograde cholangiopancreatography (ERCP) helps in detecting the stricture location especially in the lower parts of biliary tract. Endoscopic ultrasound (EUS) is another modality which is safe when performed at a center with an experienced endosonographers. Isolated dilated CBD on abdominal ultrasound (US) is still in need to be probably assessed.

**Aims & Methods:** Our aim was to compare the accuracy of endoscopic ultrasound (EUS) to endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis of dilated common bile duct of undetermined etiology detected by abdominal ultrasound. **Methods:** we conducted a retrospective study on 139 patients referred to TBRI (Theodor Bilharz Research Institute) over the period of 2 years. 80 patients were included in the study and 59 were excluded due to insufficient endoscopic details. All patients with dilated CBD of indeterminate etiology by US who underwent EUS and ERCP were enrolled to compare between the accuracy of both as a diagnostic tool.

**Results:** Our study included 43 (53.7%) males and 37 (46.2%) females, with a mean ( $\pm$ SD) age of 52.01 ( $\pm$ 12.15). The mean ( $\pm$ SD) of CBD diameter detected by US was 12.38 ( $\pm$ 2.65). In comparison between ERCP and EUS in diagnosing pathological causes of CBD dilatation. EUS was statistically significant than ERCP with ( $p$  value  $< 0.001^*$ ). Diagnosis of CBD dilatation by EUS was as follows: 40 cases had malignant stricture, 28 cases had stones, 10 cases had benign stricture, and prominent CBD with no obstruction was in only 2 cases. While diagnosis of CBD dilatation by ERCP was as follows: 26 cases had indeterminate stricture, 24% cases had stones, another 24% cases had malignant stricture, 4 cases had prominent CBD with no obvious obstruction, and 2 cases had benign stricture.

FNA-EUS/biopsy sample was conducted on 44 cases only and the results were as follows: 36 cases had malignant stricture, 5 cases had chronic nonspecific inflammation, and 3 cases had benign non inflammatory stricture. In relation between FNA \ Biopsy sample results and pathological causes of CBD dilatation diagnosed by EUS and ERCP, there was statistically significant relation between FNA \ Biopsy sample results and findings of EUS and ERCP (with  $p$ -value  $< 0.001^*$  in both), while diagnosis of CBD dilatation by EUS on those 44 cases was as follows: 36 cases (81.82 %) had malignant stricture, 6 cases (13.64%) had benign stricture and 2 cases (4.55%) had microlithiasis. While the diagnosis of CBD dilatation by ERCP was as follows: 21 cases (47.73%) had benign stricture, 19 cases (43.18%) had indeterminate stricture, 2% cases (4.55%) had stones, 1 case (2.27%) had benign stricture, and another 1 case had prominent CBD with no obvious obstruction.

	ERCP	EUS	Chi-Square		FNA / Biopsy (only 44 cases)	EUS	ERCP	Chi-Square	
	N (%)	N (%)	X2	P-value	N (%)	N (%)	N (%)	X2	P-value
Stone	24 (30%)	28 (35%)				2 (4.5%)	2 (4.5%)	FNA / Biopsy and EUS	
Indeterminate stricture	26 (32.5%)	0 (0%)					19 (43.1%)	68.444	<0.001*
Benign stricture	2 (2.5%)	10 (12.5%)	36.308	< 0.001*	3 (6.8%)	6 (13.6%)	1 (2.2%)	FNA / Biopsy and ERCP	
Malignant stricture	24 (30%)	40 (50%)			36 (81.8%)	36 (81.8%)	21 (47.7%)	33.868	<0.001*
Prominent CBD no obstruction	4 (5%)	2 (2.5%)					1 (2.2%)		
Chronic non-specific inflammation					5(11.3%)				
Total	80 (100%)	80 (100%)			44 (100%)	44 (100%)	44 (100%)		

[Table (1): Descriptive data of the study]

**Conclusion:** Our study revealed the superiority of EUS over ERCP in diagnosing CBD dilatation of undetermined etiology detected by abdominal US.

**Introduction:** Biliary self-expandable metal stents (SEMS) are a palliative therapy for malignant biliary obstruction (MBO); however, acute cholecystitis is a described adverse event. Tumor involvement to the orifice of the cystic duct (OCD) is a major predictive factor for acute cholecystitis after SEMS placement. Endoscopic ultrasound guided gallbladder drainage (EUS-GBD) have been reported for the acute cholecystitis treatment; however, the role of primary EUS-GBD for acute cholecystitis prophylaxis remains unknown.

**Aims & Methods:** A single-center, randomized control-trial. Primary EUS-GBD was performed using a 3.8 mm therapeutic echoendoscope and a lumen apposing metal stent (Hot Axios™ Stent and Electrocautery Enhanced Delivery System, Boston Scientific, MA) after conventional biliary drainage with SEMS. In the other arm, patients were submitted to conventional biliary drainage using SEMS without primary EUS-GBD. A sample size of 11 patients per group was estimated, considering the clinical success of EUS-GBD vs. percutaneous transhepatic gallbladder drainage (92% vs. 86%) and, a type I & II errors of 10% and 20%, respectively. Baseline characteristics were described and compared with their corresponding hypothesis testing. The primary outcome of the study was the occurrence of acute cholecystitis after randomization and asessed-up to 12 months or death. Secondary endpoints were the length of hospitalization and the median relative survival. Time-to-event analysis for acute cholecystitis and relative survival were estimated through Competing Risk Analysis and Cox Regression, respectively. A p-value < 0.05 was considered statistically significant. Data analysis was performed using R.

**Results:** 23 patients were included: 12/23 in the primary EUS-GBD group and 11/23 in the control group. No reintervention was required in the primary EUS-GBD group; whereas, four patients from the control group developed acute cholecystitis: three patients were treated via laparoscopic cholecystectomy at the day 16, 7 and 1, after randomization. One patient in control group developed acute cholecystitis and was rejected to surgery at the day 100, being switched and treated with EUS-GBD. The median length of hospitalization in days was inferior in patients treated with primary EUS-GBD. The one-year acute cholecystitis-free survival rate was 91.7% for primary EUS-GBD compared to 36.4% in the control group (HR 0.117;

0.014-0.958, p=0.016). No difference in the median relative survival was detected among groups 2.4 months for primary EUS-GBD vs 2.8 months in the control group (HR 0.837; 0.308-2.272, p=0.727) (table 1).

	Primary EUS- GBD (n = 12)	Control group (n = 11)	p-value
Age (years), median (IQR)	63.9 (52.4 - 71.9)	71.6 (67.9 - 81.7)	0.037
Sex (female), n (%)	9 (75.0)	7 (63.6)	0.444
Primary tumor, (cholangiocarcinoma/malignant pancreas tumor)	8/4	8/3	0.555
Middle-distal common bile duct tumor obstruction, n (%)	5 (41.7)	1 (9.1)	0.112
Size of the lesion (mm), median (IQR)	27.5 (15 - 30)	23.5 (20 - 35)	1.000
Covered/Uncovered metal stent, n (%)	8/4	6/5	0.543
Hospitalization days, median (IQR)	1 (1-3)	3 (0-27)	0.054
One-year acute cholecystitis-free survival rate, n (%)	11/12 (91.7)	4/11 (36.4)	0.016
One-year relative survival rate, n (%)	8/12 (66.7)	9/11 (81.8)	0.727

[Table 1. Baseline characteristics & study outcomes per groups.]

**Conclusion:** Primary EUS-GBD prevent the development of acute cholecystitis after SEMS placement in patients with MBO and tumor involvement of the orifice of the cystic duct.

**Introduction:** Gastric varices (GV) are less common and rupture less often than esophageal varices (EV). However, once ruptured, GV bleeding is difficult to control and carries a higher mortality than EV bleeding in the setting of portal hypertension. Treatment options include direct endoscopic (END) glue injection and endoscopic ultrasound (EUS) guided glue and/or coil injection. The role of EUS in the treatment of GV is not established.

**Aims & Methods:** We conducted a comprehensive search of several databases (inception to Dec 2018) to identify studies that evaluated the use of END and EUS in the treatment of GV. Our goals were to estimate and compare the pooled rates of treatment efficacy, GV obliteration, GV recurrence, early re-bleeding (< 120hrs), and late re-bleeding (>120hrs) with END and EUS. Our secondary goals were to analyze the adverse events with these two modalities in the treatment of GV.

**Results:** Total of 44 studies (2777 patients) were included. 26 studies (2196 patients), 8 studies (231 patients), 7 studies (303 patients), and 3 studies (47 patients) were treated with END-glue, EUS-glue, EUS-glue/coil, and EUS-coil respectively. Mean age range was between 40 and 65 years, with 68% of males. N-butyl-2-cyanoacrylate and 2-octyl-cyanoacrylate were the most commonly used glue. 28% had GOV1, 49% had GOV2, and 23% had IGV1 (Sarin classification). 63% of the patients had cirrhosis. 30% were due to alcohol, 31% due to viral hepatitis, and the rest were due to other causes. 11% of the included patients had hepatocellular carcinoma. Complete GV obliteration was significantly higher with EUS-coil/glue as compared to END-glue [(89% (95% CI 66.3-97.1, I<sup>2</sup>=62.4) vs 57.1% (38.2-74.1, I<sup>2</sup>=94.3), p=0.03]. GV recurrence was significantly lower with EUS-coil/glue as compared to END-glue [(3.1% (95% CI 0.9-10.3, I<sup>2</sup>=0) vs 22.6% (95% CI 13.8-34.9,

(95% CI, I2)	All EUS modalities	EUS-glue	EUS-coil	EUS-coil/glue	END-glue
Immediate treatment efficacy	93.6% (85-97.4, 59.5), p=0.17	92.3% (74-98, 54.4), p=0.44	86.2% (38.4-98.4, 6.5), p=0.99	96.5% (85.3-99.2, 61.5), p=0.1	86.4% (75.3-93, 96.1)
Complete GV obliteration	84.7% (66.8-93.8, 84.2), p=0.03	89.8% (57.4-98.3, 28.8), p=0.07	NC	89% (66.3-97.1, 62.4), p=0.03	57.1% (38.2-74.1, 94.3)
GV recurrence	6.1% (2.6-13.7, 51.4), p=0.006	12.4% (4-32.3, 18.8), p=0.29	NC	3.1% (0.9-10.3, 0), p=0.002	22.6% (13.8-34.9, 77.1)
Early rebleeding (<120 hrs)	6.8% (4.1-11.1, 13.2), p=0.43	5.9% (2.8-12, 0), p=0.83	NC	9% (4.1-18.4, 64.2), p=0.25	5.4% (4.2-6.8, 17.8)
Late rebleeding (>120hrs)	10.6% (6.3-17.3, 45.7), p=0.03	14.2% (6.6-27.9, 68.2), p=0.39	14.7% (4-42, 0), p=0.63	6.4% (2.7-14.7, 0), p=0.01	20% (14.7-26.6, 89.3)
Total adverse events	16.5% (9.7-26.9, 83.1), p=0.48	27.4% (13.8-47, 81.7), p=0.07	5.5% (0.9-26.8, 0), p=0.3	11.7% (5-25.3, 79.5), p=0.79	13% (8.5-19.5, 87.7)
Sepsis	2.5% (1.3-4.9, 0), p=0.91	2.8% (1.1-7.3, 0), p=0.65	4% (0.7-20.4, 0), p=0.53	1.7% (0.5-5.4, 0), p=0.74	2.4% (1.5-3.8, 53.6)
Distant organ embolism	4.1% (1.9-8.6, 40.6), p=0.22	3.4% (1-10.5, 0), p=0.52	4% (0.5-26.4, 0), p=0.92	4.9% (1.5-14.9, 70.8), p=0.27	2.2% (1.2-4.1, 70.9)
Fever	2.9% (1.3-6.2, 0), p=0.57	3.5% (1.1-10.5, 0), p=0.95	4% (0.5-24.9, 0), p=0.92	2% (0.5-6.9, 0), p=0.4	3.8% (2.1-6.7, 84.3)
Pain	4.3% (2.1-8.6, 29.9), p=0.3	4% (1.3-11.5, 0), p=0.51	4% (0.5-24.5, 0), p=0.68	4.7% (1.6-13.2, 67.9), p=0.36	2.7% (1.5-4.7, 73.4)
Death due to GV rebleeding	6% (3.3-10.6, 28.9), p=0.3	8.8% (3.7-19.5, 62), p=0.13	4.7% (0.9-21, 0), p=0.87	4% (1.5-10.3, 0), p=0.97	4.1% (2.7-6.2, 57.5)

EUS: endosonography, END: direct endoscopy, GV: gastric varices, All p-values are in comparison to END-glue. NC: not calculated due to limited data

#### [P0254 Table. Summary of pooled results.]

$I^2=77.1$ ,  $p=0.002$ ]. Late re-bleeding was significantly lower with EUS-coil/glue as compared to END-glue [(6.4% (95% CI 2.7-14.7,  $I^2=0$ ) vs 20% (14.7-26.6,  $I^2=89.30$ ,  $p=0.01$ )]. The pooled rates of immediate treatment efficacy and early re-bleeding were comparable between the treatment modalities. The pooled rate of all adverse events, sepsis, distant embolism, fever, pain, and death due to GV rebleeding were similar between the groups. No difference was noted between EUS-glue and END-glue. (Table)

**Conclusion:** EUS guided treatment of GV with simultaneous use of coil/glue seems to give superior long term clinical benefits as compared to END-glue with comparable immediate treatment efficacy and similar risk to early-rebleeding. Well-conducted studies are warranted to further establish the role of EUS-coil/glue treatment in GV.

**Introduction:** Endoscopic Ultrasound (EUS)-guided fine needle aspiration (FNA) sensitivity for malignancy in parenchymal masses of patients with concurrent chronic pancreatitis (CP) has been reported to be unsatisfactory.

**Aims & Methods:** The aim of the present study was to directly compare the diagnostic accuracy of EUS-FNA and EUS-fine needle biopsy (FNB) in differentiating between inflammatory masses and malignancies in the setting of CP. We performed a retrospective analysis of prospective, multicentric databases of all subjects with pancreatic masses and clinical-radio-logical-endosonographic features of CP who underwent EUS-FNA or FNB.

**Results:** Among 1124 with CP, 210 patients (60% males, mean age 62.7 years) with CP and pancreatic masses met the inclusion criteria and were enrolled. In the FNA group (110 patients), a correct diagnosis was obtained in all but 18 cases (diagnostic accuracy 83.6%, sensitivity 69.5%, specificity 100%, PPV 100%, NPV 73.9%); by contrast, among 100 patients undergoing FNB, a correct diagnosis was obtained in all but 7 cases (diagnostic accuracy 93%, sensitivity 86.8%, specificity 100%, PPV 100%, NPV 87%) ( $p=0.03$ , 0.03, 1, 1 and 0.07, respectively). At binary logistic regression, focal pancreatitis (OR 4.9;  $p<0.001$ ), higher Ca19-9 (OR 2.3;  $p=0.02$ ) and FNB (OR 2.5;  $p<0.01$ ) were the only independent factors associated with a correct diagnosis.

**Conclusion:** EUS-FNB is effective in the differential diagnosis between pseudotumoral masses and solid neoplasms in CP, showing higher diagnostic accuracy and sensitivity than EUS-FNA. EUS-FNB should be considered the preferred diagnostic technique for diagnosing cancer in the setting of CP.

**Contact E-Mail Address:** gimanese@tin.it

**Introduction:** Endoscopic ultrasound-guided fine needle aspiration (FNA) is the standard choice to sample gastrointestinal/pancreatic lesions. EUS-FNA is accurate when rapid on-site evaluation (ROSE) is performed, but ROSE is not always available. EUS-guided fine needle biopsy (EUS-FNB) can give a better chance to reach a diagnosis providing more tissue. It is not simple to use 19-gauge needles especially in transduodenal settings for risk of complications. A new needle for EUS-FNB, the Acquire needle is available from 2016. Data for pancreatic and non pancreatic solid lesions are available but these are based only on small sample size studies.

**Aims & Methods:** The aim of our study is to perform a retrospective evaluation of all sampling procedures performed using the 22/25 gauge Acquire needle in patients with solid lesions. We performed a retrospective analysis

sis of prospective, multicentric databases in 5 Italian Endoscopic centres, including all consecutive patients with solid lesions who underwent EUS between June 2016 and October 2018. All lesions localized at pancreas, nodes, biliary, kidney/liver masses, periduodenal/perigastric abdominal masses were enrolled in the study. Features of masses and technical details of FNB were recorded.

**Results:** 450 patients (60.2% males, mean age 64.3) were enrolled. EUS-FNB was performed using the 22 and 25 gauge Acquire needle. The biopsies were done transgastrically in 190 (42%) cases and transduodenally in 260 (58%) cases. A mean of  $2.2 \pm 0.32$  passes per lesion site were performed, without any complication. A tissue core biopsy sample for histological evaluation was obtained in 438 (97%) cases. In all the cases, the specimens were useful for cytological analysis too. Acquire sensitivity, specificity and diagnostic accuracy were 98.8%, 100% and 98.7% respectively.

**Conclusion:** EUS-FNB using the 22 and the 25-gauge Acquire needle has a very high accuracy and is useful to achieve histological sample in almost all the patients.

**Disclosure:** Nothing to disclose

## P0257 EUS-GUIDED THROUGH-THE-NEEDLE MICROFORCEPS BIOPSY FOR THE DIAGNOSIS OF PANCREATIC CYSTIC LESIONS: HOW MANY SPECIMENS SHOULD BE RETRIEVED?

**Contact E-Mail Address:** lorenzo.brozzi89@gmail.com

**Introduction:** Accurate diagnosis of pancreatic cystic lesions (PCLs) is of paramount importance to guide the decision-making process and reduce the rate of inappropriate resection.

Endoscopic ultrasound (EUS)-guided through-the-needle biopsy (TTNB) has been reported to improve diagnostic yield compared with cytology [1-3]. However, TTNB technique is not yet standardized and the minimum number of visible specimen to be retrieved is unknown.

**Aims & Methods:** The aim of this single center retrospective study was to evaluate the diagnostic yield of TTNB according to the number of macroscopically visible samples acquired.

All consecutive patients with PCLs with risk features (cyst >3 cm, thickened wall, 5-9 mm main pancreatic duct, increased size during follow-up, and mural nodules) who underwent TTNB between May 2016 and July 2018 were included. TTNB procedures were performed following an internal protocol established with the pathologists whereby the acquisition of three samples, when possible, was set as a standard. Each acquired specimen was placed separately in formalin vials.

Diagnostic yield of one, two, or three TTNB macroscopically visible specimens was analyzed and compared with fluid cytology at four levels: capa-

bility of differentiating mucinous vs nonmucinous cysts, ability to obtain a cyst-lining epithelium, definition of the grade of dysplasia, and definition of specific cyst histotype.

**Results:** Sixty-one patients (M/F 14/47; mean age  $50.2 \pm 14.7$  years) were included. PCLs were located in the head, body, and tail in 18 (29.5%), 23 (37.7%), and 20 (32.8%) cases, respectively. The mean size was  $40.7 \pm 14.2$  mm. Overall, 179 TTNB specimens were evaluated (in four cases, intracystic bleeding impeded collection of the third specimen). Specimens were judged adequate for histological evaluation in 164 (91.6%) cases. A 100% histological adequacy was reached by two samples ( $p=0.05$  versus one). In the cytological samples, cyst epithelium was present in 27 (44.2%), the distinction between mucinous and nonmucinous cysts was possible in 30 (49.2%), the grade of dysplasia was established in 25 (41%), and a specific diagnosis of cyst type was achieved in 5 (7.9%) cases.

Compared with cytology, one TTNB specimen improved only the possibility of defining cyst histotype ( $p<0.0001$ ), whereas two specimens increased all four diagnostic categories ( $p<0.003$ ). Two specimens also increased diagnostic yield compared with one sample ( $p<0.085$ ). The collection of a third sample did not improve the value of any diagnostic level (Table 1). A specific diagnosis was reached in 74% of patients with two histological samples. The diagnostic reliability of TTNB compared with surgical histology was 90% (18/20 patients). The two TTNB nonconcordant cases were mucinous non-neoplastic cysts according to TTNB, resulting in mucinous cystic neoplasms with surgical histology. The rate of adverse events was 22.9% (10 cases of intracystic bleeding, 2 mild acute pancreatitis, 1 peripancratic bleeding and 1 transitory fever).

**Conclusion:** Two TTNB macroscopically visible specimens allowed reaching a 100% histological adequacy and a specific diagnosis in 74% of patients. The collection of a third specimen did not add any additional information, and should be avoided in order to possibly decrease the risk of adverse events.

## P0258 CASE SERIES OF EUS GUIDED BILIARY DRAINAGE AS A NEWLY ADOPTED TECHNIQUE FOR BILIARY OBSTRUCTION IN A TERTIARY CARE CENTER

Hoppmann N.<sup>1</sup>, Harris P.<sup>1</sup>, Hingorani N.<sup>1</sup>, Mitchell R.<sup>1</sup>, Ahmed A.<sup>2</sup>, Kyanam Kabir Baig K.R.<sup>1</sup>

**Contact E-Mail Address:** nhoppmann@uabmc.edu

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is often the procedure of choice for drainage of biliary obstruction; however, this technique may not be feasible in all patients. Percutaneous transhepatic biliary drainage (PTBD) is another option but is associated with high morbidity and post procedural complications. Endoscopic ultrasound (EUS), initially a diagnostic procedure, has evolved into a therapeutic option in patients with failed ERCP. EUS can be performed immediately after attempted ERCP, thereby providing a potentially immediate solution. This project focuses on the implementation of EUS guided biliary drainage (EUS-BD) as a new technique for relieving biliary obstruction in patients with failed ERCP in a tertiary care center.

**Aims & Methods:** A prospective analysis of patients with biliary obstruction and failed ERCP requiring EUS-BD was conducted between November 2017 to February 2019. Indication for intervention and reason for failed ERCP were noted. Patients' clinical improvement, laboratory data, and procedural complications were documented 1 month after the procedure.

**Results:** Twenty-six patients (M/F, 14/12; median age 68) underwent EUS-BD. Twenty-five patients required drainage secondary to a malignancy while 1 was for choledocholithiasis. ERCP failure was due to clinical instability in 1 patient with severe aortic stenosis (4%), inaccessible papilla in 13 patients (50%), and inability to cannulate the papilla in 12 patients (46%).

The procedure was technically successful in 20 patients with the remaining 6 requiring PTBD. In patients with successful EUS-BD, there was one complication with a patient requiring ICU admission for Klebsiella bacteremia. Clinical success, in the form of reduced total bilirubin or improvement of obstructive symptoms, was noted in 100% of patients following successful EUS-BD.

**Conclusion:** Our study shows that EUS-BD is a technique that offers high clinical and technical success rates and low complication rates. The learning curve is short when performed in the hands of an experienced endoscopist. Furthermore, EUS-BD provides immediate solution for failed ERCP rather than investigating other therapeutic options.

Further studies are required to establish outcomes in patients with EUS-BD and comparison of this technique to potential alternative solutions such as PTBD or surgery. One limitation of this case series is the majority of cases are specific to distal biliary obstruction caused by malignancy.

## P0259 COMPARING MODIFIED WET SUCTION VERSUS DRY SUCTION TECHNIQUES IN EUS-FNA FOR SOLID LESIONS: A PROSPECTIVE, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

Wang R., Wang Y., Cheng B.

Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Gastroenterology and Hepatology, Wuhan, China

**Contact E-Mail Address:** wangrh1988@126.com

**Introduction:** The optima sampling techniques for endoscopic ultrasound (EUS) -guided fine-needle aspiration (FNA) are not standardized. We conducted a prospective, multicenter, randomized controlled trial comparing the modified wet suction technique (MWST) and the dry suction technique (DRST) for sampling the solid lesions in the pancreas, mediastinum and abdomen.

**Aims & Methods:** A total of 296 patients from 4 endoscopic centers were randomized in a ratio of 1:1 to receive either DRST or MWST as the first pass during EUS-FNA procedure. For Group A (n=134), the pass sequence was DRST - MWST - DRST - MWST versus MWST - DRST - MWST - DRST for Group B (n=135). The outcome measures were the diagnostic yield and specimen quality.

**Results:** We demonstrated that the MWST group had a significantly better histological diagnostic accuracy (84.85%) than DRST group (73.19%,  $P=0.0013$ ). In subgroup analysis, the MWST group reached a 91.59% histological diagnostic accuracy for non-pancreatic masses and achieved a significantly superiority for all lesions >20 mm. Furthermore, the MWST provided a better specimen adequacy and less blood contamination whether it was chosen as the first pass or not.

**Conclusion:** In this prospective study of sampling solid masses, we found using MWST resulted in significantly better histology than DRST, especially for the masses >20 mm. Two passes of MWST provided adequate tissue for non-pancreatic lesions. The specimen quality collected by MWST was superior to DRST regardless of sequence selection bias. Trials registration: NCT02789371.

**Disclosure:** Nothing to disclose

	DRST group % (95% CI)	MWST group % (95% CI)	P value
Overall diagnostic accuracy			
All lesions (n=269)	89.22 (84.89-92.66)	92.94(89.19-95.69)	0.13043
Pancreatic (n=161)	86.34 (80.05-91.23)	91.30(85.84-95.16)	0.15714

**Introduction:** There are a few reports on the use of double guidewire (DGW) technique to facilitate multiple drainage placement for EUS-guided drainage of pancreatic fluid collections (PFC). However, this technique can provide advantages other than multiple drainage placement during interventional EUS, such as scope stabilization, support for stone extraction or device insertion.

**Aims & Methods:** Consecutive patients who underwent interventional EUS between Feb 2012 and Apr 2019 were retrospectively reviewed. The rate and purposes of DGW technique, and clinical outcomes were evaluated. A double lumen cannula (UDLC: Uneven Double Lumen Cannula, Piolax Medical, Kanagawa, Japan) was used to achieve DGW technique. UDLC has two separate lumens (0.025" and 0.035") with a tip diameter of 3.6 Fr. DGW technique was performed as follows; Puncture using a 19-gauge FNA needle under EUS guidance, insertion of a 0.025" guidewire (GW), followed by UDLC insertion, preloaded with a 0.035" GW, over the 0.025" GW, and then, advancement of a 0.035" GW. A 0.035" stiff GW was used when multiple drainage placement is planned or when support for scope stabilization, antegrade stone extraction or device insertion is needed, while a 0.035" hydrophilic GW was used when negotiation of the stricture is necessary. After achieving DGW insertion, EUS-guided interventions were completed.

**Results:** During the study period, 252 interventional EUS procedures were performed: 51 pancreatic cyst drainage (PCD), 82 hepaticogastrostomy (HGS), 8 choledochoduodenostomy (CDS), 37 gallbladder drainage (GBD), 36 rendezvous (RV), 19 antegrade stone treatment (AG), 13 pancreatic duct drainage (PD) and 6 abscess drainage (AD). Among those 252 cases, DGW technique was used in 82 cases (32.5%). The reasons for DGW technique were multiple drainage placement in 61 cases (21PCD, 32 GBD, 5 HGS, 2 AD, 1 PD), scope stabilization in 10 (5 HGS, 3 PD, 1 GBD, 1 AD), support for stone removal in 4 AG, support for device insertion in 8 (4 HGS, 2 PD, 1 AG, 1 RV) and safety GW placement in 5 (3 guidewire manipulation for stricture passage and 2 stent placement). DGW technique was utilized as a salvage technique after single guidewire procedure in 17 (20.7%) and as a primary technique in 65 (79.3%). Insertion of UDLC and DGW were

both successful in 100%. Adverse events related to DGW technique were not observed. Preplanned intervention was technically successful in 75 cases (91.5%). The reasons for preplanned procedure failure were failed multiple drainage placement in 3 and failed GW passage in 4 (3 rescue transmural drainage and 1 technical failure). Among 17 cases with salvage DGW technique, preplanned intervention was achieved only after DGW technique in 13 (76.5%).

**Conclusion:** DGW technique using UDLC during interventional EUS was useful for multiple drainage placement as well as support for stone removal and device insertion.

## P0261 FOCUSED ENDOSCOPIC ULTRASOUND RESULTS IN PATIENTS WITH UNEXPLAINED DILATATION OF COMMON BILE DUCT AND OR PANCREATIC DUCT

Parihar V.<sup>1</sup>, Offiah G.<sup>2</sup>, Bashir Y.<sup>2</sup>, Karl H.<sup>3</sup>, Ryan B.<sup>4</sup>

<sup>1</sup>Tallaght Hospital, Gastroenterology, Dublin, Ireland, <sup>2</sup>Trinity College Dublin, Dublin, Ireland, <sup>3</sup>James Connolly Memorial Hospital, Gastroenterology, Dublin 15, Ireland, <sup>4</sup>Adelaide and Meath Hospital, Department of Gastroenterology, Dublin 24, Ireland

**Contact E-Mail Address:** vikpar37@yahoo.com

**Introduction:** Unexplained dilation of the common bile duct (CBD) and pancreatic duct (PD) or both on abdominal imaging are amongst the most common indications for endoscopic ultrasound (EUS).

**Aims & Methods:** Patients referred for EUS for dilated CBD and/or PD from 2012 to 2016 for whom LFTs were available, were included in the study. CBD dilatation was defined as CBD diameter greater than 7mm at any place while PD diameter more than 4 mm in the head and 3 mm in the body and tail was considered dilated. To investigate if derangement of liver function tests (LFTs) is associated with positive findings on EUS to explain the cause for the dilated ducts.

**Results:** We examined a total of 2179 EUS procedures, of which 404 patients met the study criteria. 293/404 had elevated LFTs [defined as elevation of one of these: bilirubin, ALT, ALKP or GGT] and 111/404 had normal LFTs. 74% of patients had more than one imaging modality before the EUS. EUS found a cause of dilated duct in >50% of cases in both the groups. In patients with CBD dilatation alone, elevated bilirubin was associated with finding a significant finding on EUS ( $p < 0.027$ ) (66%). In those with CBD and PD dilatation, raised bilirubin ( $p < 0.022$ ) and Alkaline Phosphatase ( $p < 0.018$ ) were associated with positive findings (39% and 62% respectively).

**Conclusion:** The presence of raised bilirubin +/- concurrent ALKP rise was statistically more likely to have a cause found for the dilated duct on EUS. EUS detected undiagnosed pathology in unexplained duct dilation even in the presence of normal LFTs. We recommend early access to a diagnostic EUS in the diagnostic pathway of patients with dilated CBD and or PD.

**Introduction:** Non-hypovascular (i.e., isovascular or hypervascular) patterns can be observed in solid pancreatic lesions (SPLs) with different diagnoses with different prognosis and management.

**Aims & Methods:** The primary aim was to identify lesion features on endoscopic ultrasound (EUS) associated with malignancy/aggressiveness in this setting of patients. Secondary aims were EUS-tissue acquisition (EUS-TA) outcome and safety. In a prospective observational study we included consecutive patients with one or more non-hypovascular SPLs detected on cross-sectional imaging and referred for EUS-TA. Exclusion criteria were hypovascular pattern on contrast-harmonic EUS, concomitant chronic pancreatitis, and lesion of nonpancreatic origin. Lesion features (size, site, margins, echotexture, vascular pattern, and upstream dilation of the main pancreatic duct) were recorded. Malignancy/aggressiveness was determined by one or more of the follows: a) evidence of carcinoma at biopsy/surgical histology; b) signs of local aggressiveness (perineural invasion, lymphovascular invasion, microscopic tumor extension/infiltration or evidence of metastatic lymph nodes) at surgical specimen; c) radiologic detection of lymph nodes or distant metastases; d) tumor growth >5mm/12 months. Uni- and multivariate analyses were performed to assess the primary aim.

**Results:** Among 174 patients evaluated, 154 (M/F 70/84, mean age 58.7 years  $\pm$  13.1) with 161 SPLs were enrolled. SPLs were located in the head/uncinate, body, and tail in 50 (31.1%), 55 (34.1%), and 56 (34.8%) cases, respectively. Mean lesion size was 18.8 mm  $\pm$  10.6. Fifty-six lesions (34.8%) were resected and 105 (65.2%) underwent follow-up for a median period of 20 months (range 12-32 months). Overall, 40 (24.8%) lesions were defined malignant/aggressive and 121 (75.2%) benign. Irregular margins and size >20mm were independent factors associated with aggressiveness in multivariate analysis ( $p < 0.001$ , OR=5.2 and  $p=0.003$ , OR=2.1, respectively). Irregular margins and size >20mm predicted malignancy/aggressiveness with an accuracy of 81% and 74%, respectively. A subgroup analysis evaluating neuroendocrine tumors (NET) (N=92) and non-NETs (N=60) was performed (Table 1) revealing that in non-NET group only irregular margins were associated with malignancy/aggressiveness.

EUS-TA sensitivity, specificity and accuracy were 91.6%, 100%, and 92%, respectively. The rate of adverse events was 4%.

**Conclusion:** Our study demonstrated that irregular lesion margins are an independent factor useful in predicting malignancy/aggressiveness of isovascular and hypervascular SPLs. Size >20mm should be considered a warning feature only when a diagnosis of NET is confirmed. EUS-TA is safe and highly accurate in this setting and should be largely adopted for the differential diagnosis of these lesions.

**Introduction:** Accurate tumor staging guides the choice of treatment modality and suggest the prognosis of rectal cancer. EUS and magnetic resonance imaging (MRI) are used indistinctly in the pretherapeutic workup of rectal cancer. Post neoadjuvant therapy interpretation of response in both MRI and EUS retains some difficulty due changes seen in the peritumoral region because of the effects of chemoradiation such as edema, inflammation, necrosis, and fibrosis lead to a hypoechoic appearance which mimics the primary tumor, leading to frequent overstaging.

**Aims & Methods:** To compare the performance of EUS and MRI in assessment of locoregional staging of anorectal cancer after neoadjuvant therapy. Up till now, we have twenty-eight (16 male, 12 female) were included in the study. Histopathological staging after surgery were used as reference for comparing the yield of locoregional staging for EUS and MRI. EUS and MRI were done 1 month after completion of neoadjuvant therapy.

**Results:** Regarding Post-Surgical T staging, there were eight patients with early tumor (T2=6 and T1=2) and twenty patients with locally advanced tumor (T3= 20 and No T4), while N staging, there were sixteen patients with negative nodes and twelve with positive nodes (N1= 7 and N2= 5). Regarding T staging; The sensitivity, specificity and accuracy of EUS (95%, 72%, 89.29%) was significantly higher than MRI (70%, 50%, 64.29%) for detecting early and locally advanced tumor. Also, EUS had a high statistical significant difference for detection of lymph nodes across MRI (sn 83.33%, sp 62.5% and acc 71.43% vs 54.55%, 52.94%, 53.57 ).

**Conclusion:** EUS appears more accurate in locoregional staging of rectal carcinoma after neoadjuvant therapy compared to MRI in rectal carcinoma.

**Contact E-Mail Address:** jerome.winkler@hotmail.fr

**Introduction:** Biliary drainage is the main palliative therapeutic measure for unresectable malignant hilar biliary strictures (MHS) and survival is highly correlated to the volume of drained liver<sup>1</sup>. Endoscopic ultrasound-guided biliary drainage (EUS-BD) has emerged as an alternative technique for primary drainage or as rescue technique after failed endoscopic retrograde cholangiography (ERCP).

**Aims & Methods:** The aim of this study was to demonstrate the feasibility of EUS-BD in MHS, both as the initial and rescue procedure.

This study is a single center retrospective work based on prospective data of patients included between January 2015 and September 2018 for biliary drainage of inoperable malignant hilar obstruction. For this analysis, only

patients with EUS-BD drainage were included. It could be a drainage by EUS-BD alone or in combination with another technique, for initial drainage or re-intervention. Clinical characteristics of patients, stenosis and drainage were collected. The percentage of liver drained, the complication rate in the month following the procedure using Clavien-Dindo classification, the number of re-interventions, the length of hospitalisation were analyzed.

**Results:** Among the 139 patients of the registry, 20 patients were included (10 women and 10 men). The mean patient age was 68 years. 7 patients had an obstruction by cholangiocarcinoma and 13 by metastasis. 4 patients had type II stenosis according bismuth classification, 7 type IIIA, 2 IIIB and 7 type IV. The mean invasion of liver was 24%.

No patient had ascites or duodenal stenosis but 2 patients had a modified anatomy. EUS-hepaticogastrostomy (EUS-HGS) was the only one EUS-BD technique used. 16 patients had EUS-HGS for initial drainage: 2 EUS-HGS alone due to a right liver invasion and 14 combined with another technique : 11 combined with ERCP, 2 with Percutaneous transhepatic drainage (PCTD) and 1 with ERCP and PCTD.

The mean percentage of drained liver was 86%. The average number of stents was 2.8. The early complication rate was 31% (n=5) mainly angiocholitis (n=4) with 3 grade II and 2 grade III. The mean hospital length was 8 days.

The EUS-HGS combined with PCTD was performed in 2 patients with modified anatomy. One of this patient had a right-left drainage by hepaticogastrostomy combined without complication.

For EUS-HGS/ERCP combined drainage , 5 were performed during the same session and 6 in two sessions .Hospitalisation length was 7,4 days and 8,3 days respectively. It was mainly type IIIa (n=5) and type IV (n=5) stenosis. There was no difference between the complication rate (n=1), the number of endoscopic reintervention (n=3) and the percentage liver drainage (96% vs 97% respectively).

4 patients had EUS-HGS as re-intervention with 3 situations : One patient had rescue drainage by EUS-HGS because of pancreatitis associated with angiocholitis. Two patients had an EUS-HGS in the follow-up because of the progression of the disease (Day 183 and day 303) and 1 patient needed EUS-HGS to drain the left liver not initially drained. In the registry, 11 patients had an undrained left liver due to ERCP failure or left liver atrophy. Only this patient needed additional drainage.

**Conclusion:** EUS-BD is a feasible and safe technique for initial drainage and for re-intervention procedures. EUS-HGS/ERCP combination seemed to be useful in cases of complex stenosis, especially type IIIa , and could be performed in one or two sessions.

**Contact E-Mail Address:** ishigakikazunaga@yahoo.co.jp

**Introduction:** Recently, EUS-guided fine-needle biopsy (EUS-FNB) of pancreatic solid lesions has been developed in the hopes of obtaining core tissue samples for histological evaluation. However, data with regard to the adverse events (AEs) of EUS-FNB are scarce.

**Aims & Methods:** We conducted a retrospective study to identify the AE rate of EUS-FNB and compare with that of EUS-FNA in patients with pancreatic solid lesions. Consecutive patients who underwent EUS-FNA/B for pancreatic solid lesions between Jan 2017 and Aug 2018 at the University of Tokyo Hospital were retrospectively studied. Inclusion criteria were patients who underwent EUS-FNA using mainly 22-gauge FNA needle (Expect, Boston Scientific Japan, Tokyo, Japan) and EUS-FNB using mainly 22-gauge FNB needle (Acquire, Boston Scientific Japan) for pancreatic solid lesions.

About 10-20 strokes after application of 10-cc suction were similarly performed during EUS-FNA/B. The frequency of AEs after EUS-FNA/B of pancreatic solid lesions were compared and a multivariate logistic regression

analysis for AE rate was performed to clarify the risk factors of AE. AEs were graded according to the ASGE lexicon's severity grading system.

**Results:** A total of 221 patients were included to this study. The median age was 69 (24-91) years, and 148 patients were male. The median diameter of lesions was 20 (3-72) mm and location was in the head in 85 (38%). The median number of passes were 4 (2-8). The final diagnoses were pancreatic cancer in 122 (55%), neuroendocrine tumor in 16 (7%), autoimmune pancreatitis in 33 (15%). The rate of patients with tumor size >20mm was significantly higher in the FNB group (FNA: 39%, FNB: 67%,  $P < 0.01$ ), and the rate of patients who had been punctured through the normal pancreatic parenchyma was higher in the FNA group (FNA: 69%, FNB: 42%,  $P < 0.01$ ). Ten (4.5%) patients out of 221 patients had AEs (pancreatitis in 8 and pancreatic fistula in 2). Five patients had asymptomatic hyperamylasemia. The AE rates was 5.2/4.2 % in the FNA/B group and there was no statistically significant difference between these two groups. According to the ASGE lexicon's severity grading system, 6 cases were mild and 4 cases were moderate. The median extended length of hospital stay in patients with AEs was 3.5 (2-7) days. In one case of EUS-FNA group, endoscopic naso-pancreatic drainage was performed for moderate pancreatic fistula which had improved in 4 days. In a multivariate logistic regression analysis for AE rate, the head location of the lesions was the only statistically significant factor for AEs of EUS-FNA/B (HR 4.3, 95% CI 1.05-17.4,  $P = 0.04$ ). EUS-FNB (HR 1.2, 95% CI 0.31-4.85,  $P = 0.76$ ), the puncture through the normal pancreatic parenchyma (HR 1.3, 95% CI 0.30-5.96,  $P = 0.71$ ) and tumor size >20mm (HR 0.30, 95% CI 0.06-1.32,  $P = 0.11$ ) were not the statistically significant factors for AEs.

**Conclusion:** In our retrospective analysis, the total AE rate of EUS-FNA/B was 4.5%, and EUS-FNB was not the statistically significant factor for AE in patients with pancreatic solid lesions.

**Contact E-Mail Address:** dinimobolivar@gmail.com

**Introduction:** Biopsy by Fine-Needle Aspiration guided by ultrasonography (EUS-FNA) with rapid on-site evaluation (ROSE) by cytopathologists improves diagnostic capacity of the EUS. We have investigated the usefulness of ROSE performed by endoscopists with cytopathology training to assess whether the samples were adequate or not adequate.

**Aims & Methods:** Between March and October 2015, 49 patients with solid or cystic lesions of the gastrointestinal tract were taken to EUS-FNA. Two endoscopists with short training in cytopathology performed the ROSE and they categorized samples obtained as adequate or not adequate; the results were compared with the evaluation of a pathologist, using the same criteria to assess concordance.

**Results:** A high concordance of a proper reading between the endoscopist and pathologist in first EUS-FNA (EUS-FNA 1) (Kappa agreement measure 81%, sig = 0.000) and second EUS-FNA (EUS-FNA 2) (Kappa agreement measure 78%, sig = 0.001) was found.

**Conclusion:** Endoscopists can acquire basic skills in cytopathology to perform the ROSE, and the findings are consistent with those made by a pathologist. This strategy can contribute to obtaining adequate samples for cytopathology diagnosis and improve EUS-FNA diagnostic capacity. Basic cytopathology should be included as a subject in endosonography and endoscopy programs.

**Contact E-Mail Address:** fcaillol@free.fr

**Introduction:** Pancreatic metastasis (PM) from renal cell carcinoma (RCC) are rare but associated with good prognosis. The usual management of PM is surgery or tyrosine kinase inhibitor (TKI) with sides effects. Endoscopic radiofrequency ablation (ERFA) is a very innovative approach to focally treat deep metastasis and could be a relevant technic to control PM from RCC.

**Aims & Methods:** We report a monocentric, prospective analysis for local control and toxicity in patients treated by ERFA for progressive PM from RCC. ERFA was performed under general anesthesia, with a linear EUS scope and a 19 G RFA needle; time of ablation was short (30sec to 1 mn), 1 or 2 shots were needed to ablate a 2 cm lesion.

**Results:** 7 pts from Paoli-Calmettes Institute (France) were recruited between May 2017 and December 2018. Median age was 72y [69-73], 4/7 female, ECOG 0-1 (100%). The median time from diagnosis to PM was 14 years [9.98-22.18], median number of PM was 2 [1-3], 5/7 was documented by histology and all were classified as progressive before ERFA. PM localizations was: head in 40%, body 40%, tail 20% and average size was 14 mm before treatment [4 - 35]. 86% of pts (6/7) had other mRCC spread, 5/7 received systemic treatment and 2 of them were on therapy at ERFA time (1 TKI, 1 Nivolumab). Two pts had ERFA as the only treatment for oligometastatic RCC. We performed 17 ERFA procedures over 14 PM. Median number of ERFA sessions was 2/patient [1-3]. With a median follow up of 18 months [4.6-35.6], 50% of treated PM displayed a complete response, 15% a partial response and 20% a stable disease at the last CT-evaluation. Only two patients were considered as progressive disease revealing 86% of PM focal control. One patient treated by TKI during procedure, developed a paraduodenal abscess 2 months after ERFA and was drained endoscopically and one with biliary prosthesis developed hepatic abscesses few days after ERFA. Acute side effects like pancreatitis or life-threatening bleeding was not experienced. PM with size <20mm had the best focal control rate. **Conclusion:** ERFA is feasible and displays an excellent local control for PM without any major side effect. However, TKI should be stop before the procedure to avoid complications. ERFA could be a valuable option, less morbid than pancreas resection for progressive PM.

## P0268 LONG-TERM OUTCOMES OF TREATMENT DECISION BASED ON THE SEVERITY OF SMALL BOWEL CAPSULE ENDOSCOPY FINDINGS IN PATIENTS WITH CROHN'S DISEASE: A SINGLE-CENTRE COHORT STUDY IN JAPAN

Nasuno M., Tanaka H., Nakamura K., Sugiyama K., Miyakawa M., Motoya S.  
Sapporo Kosei General Hospital, IBD Center, Sapporo, Japan

**Contact E-Mail Address:** nasunomasanao@gmail.com

**Introduction:** There are few reports on the impact of small bowel capsule endoscopy (SBCE) findings on clinical outcomes in patients with Crohn's disease (CD). In particular, the relevance of SBCE findings to the treatment decision in patients with CD has not been adequately evaluated. Likewise, an appropriate SBCE score to support treatment decision has not been determined.

**Aims & Methods:** The aim of this study was to better understand the long-term outcomes of treatment initiative based on the severity of SBCE findings and compare with the routinely used SBCE scores in patients with CD. We retrospectively compiled the data on patients with CD who underwent an initial SBCE between January 2015 and December 2017. Patients with ileostomy or colostomy, without lesions in the small intestine together with

those who received new medications within three months after SBCE were excluded. SBCE findings were evaluated using the Lewis and Capsule Endoscopy CD Activity Index (CECDAI) scores. Intervention was defined as an additional treatment involving budesonide, prednisolone, elemental diet, immunomodulators, anti-tumor necrosis factor agents or intestinal resection. The rate of treatment intervention within one year since the initial SBCE was assessed. Receiver operating characteristic (ROC) curves were constructed, and the area under the ROC curve (AUC) was calculated to determine the cut-off values for the Lewis and CECDAI scores at baseline that required treatment intervention within one year. Further, the cumulative rates of treatment intervention, following the initial SBCE, were estimated using the Kaplan-Meier method. Further, the rates of treatment intervention within one year and the cumulative rates of treatment intervention were compared using univariate analysis, stratified according to the determined cut-off value of Lewis and CECDAI scores.

**Results:** A total of 94 patients were included in this study (median age, 26.1 years; 22 female). The median CD activity index was 111, and the median C-reactive protein was 0.10 mg/dL. The median Lewis and CECDAI scores were 258.5 and 6.0, respectively. The rate of treatment intervention within one year was 11.7%. The ROC curve showed that the cut-off values of Lewis and CECDAI score were 645.0 (AUC = 0.803; 95% confidence interval [CI] 0.677 to 0.930; 85.5% specificity, 63.6% sensitivity) and 8.0 (AUC = 0.831; 95% CI 0.742 to 0.921; 66.3% specificity, 100.0% sensitivity), respectively. There was no significant differences between the AUC of Lewis scores and that of CECDAI scores ( $P = 0.705$ ). The rates of treatment intervention within one year with Lewis score  $\geq 645.0$  and CECDAI score  $\geq 8.0$  were significantly higher than with Lewis score  $< 645.0$  (36.8% vs. 5.3%,  $P = 0.001$ ) and CECDAI score  $< 8.0$  (28.2% vs. 0%,  $P < 0.001$ ), respectively. The 1-, 2- and 3-year cumulative rates of treatment intervention were 12%, 27% and 31%, respectively. The 3-year cumulative rates of treatment intervention according to the Lewis score were  $< 645.0$ , 22% and  $\geq 645.0$ , 61%, respectively ( $P < 0.001$ ). Similarly, the 3-year cumulative rates of treatment intervention according to the CECDAI score were  $< 8.0$ , 15% and  $\geq 8.0$ , 52%, respectively ( $P < 0.001$ ).

**Conclusion:** Both, the Lewis and the CECDAI scores had moderate accuracy to allow decision making in the treatment of patients with CD following the initial SBCE. However, the Lewis and CECDAI scores equally predicted the therapeutic intervention. A cut-off value of Lewis score  $\geq 645.0$  and CECDAI score  $\geq 8.0$  significantly predicted the long-term outcomes of treatment intervention.

**Contact E-Mail Address:** nicolas.benech@chu-lyon.fr

**Introduction:** Colon capsule endoscopy (CCE) allows non-invasive exploration of colon mucosa. It has been proposed as an alternative to colonoscopy for average-risk colorectal cancer (CRC) screening patients with contraindications or unwilling to undergo colonoscopy and/or with an incomplete colonoscopy.<sup>1,2</sup> However relevance of CCE in a real-life practice and its short and long-term impact on clinical decisions have never been described. A prospective national cohort of CCE, the ONECC cohort, has been developed to assess these questions.

**Aims & Methods:** All patients that underwent a CCE (PillCam 2, MedTronics, United States) in France have been enrolled from January 2011 to May 2016 in a prospective manner in the ONECC cohort. All CCE and colonoscopy reports have been systematically collected and data analysis has been only performed on complete data. All enrolled patients had an annual phone-call during the study with a standardized questionnaire until May 2017.

**Results:** The results of CCE in 689 patients from 14 different medical centers (7 teaching hospitals, 7 general hospitals) were analyzed. The median time of follow-up was of 3 years (0-7). The median age was of 70 years old (min 16- max 96). The main indication for CCE was represented by anaesthesia or colonoscopy contraindication ( $n=307$ ; 44.6%). Bowel cleansing was considered satisfying (Excellent or Good) in 69.2% of CCE ( $n=477/689$ ). CCE were considered complete in 442 cases (64.2%) and 337 examinations (48.5%) were both complete and associated with a satisfying bowel preparation. A polyp was identified in 295 CCE (42.8%) among which 189 (27.4%) were classified as significant (i.e.  $\geq 6$ mm or  $\geq 3$  polyps). Following CCE, a colonoscopy was indicated in 40.5% of patient (279/689) and performed for 32.7% (225/689). The main indications to perform a colonoscopy following CCE were the diagnosis of a significant polyp on CCE (139/279; 49.8%), an incomplete examination or with unsatisfying bowel preparation (73/279; 26.1%) or the diagnosis of a non-significant polyp (30/279; 10.7%). The 2 main reasons for failure to perform colonoscopy for patients with a significant capsule were the refusal of the patient (19/52, 36.5%) and anesthesia contraindication (16/52, 30.8%). Twenty-two CCE (4.6%) were followed by the diagnosis of an advanced adenoma with high-grade dysplasia or CRC. Colonoscopy and CCE were concordant for the diagnosis of polyp with advanced dysplasia (location and size) in 84.4% of cases (27/32). Discrepancies were mainly explained by an incomplete CCE associated with a distal lesion of the sigmoid colon or rectum identified in the colonoscopy (4/5 of non concordant observations; 80%). At the end of follow-up, 115 patients were dead (16.7%) and a total of 40 advanced dysplasia were diagnosed. Performing a colonoscopy after a CCE with a significant polyp or an incomplete CCE would allow the diagnosis of 97.5% (39/40) of all advanced adenoma in the ONECC cohort.

**Conclusion:** In patients with a satisfying preparation and complete colonic examination a normal CCE is a reassuring result to exclude adenoma with advanced dysplasia. This real-life practice cohort shows that the decision after a positive colon capsule endoscopy takes into account patient status and the nature of capsule abnormalities in mostly old patients.

**Contact E-Mail Address:** xavier.dray@aphp.fr

**Introduction:** Nomenclature and description of small bowel (SB) ulcerative and inflammatory (UI) lesions in capsule endoscopy (CE) are scarce in the medical literature. Interobserver variability in interpreting the findings remains a major limitation for the assessment of severity of mucosal lesions with a potential negative impact on clinical care, training and research regarding SBCE. Our aim is to establish a consensus on the nomenclature and the description of UI lesions seen in SBCE in Crohn's Disease (CD).

**Aims & Methods:** An international panel of experienced SBCE readers was formed during the 2016 UEGW meeting. A core group of 5 CE and inflammatory bowel disease (IBD) experts established an internet-based three-round Delphi consensus, but did not participate in voting process. The core group built illustrated questionnaires including various still frames of SB UI CE lesions obtained from CD patients. A group of 27 other experts was asked to rate and comment different proposals on the nomenclature and the description of the most frequent SB UI lesions. A 6-point rating scale (varying from 'strongly disagree' to 'strongly agree') was used in successive rounds. The consensus was reached when at least 80% voting members scored the statement within the 'agree' or 'strongly agree'.

**Results:** A 100% participation rate was obtained for all rounds. Consensual nomenclature and descriptions were reached for the seven following UI lesions: aphthoid erosion, deep ulceration, superficial ulceration, stenosis, edema, hyperemia and denudation.

Nomenclature	Description	% Nomenclature/description
Aphthoid erosion	Diminutive loss of epithelial layering with a white center and a red halo, surrounded by normal mucosa	85.2/96.3
Deep ulceration	Frankly deep loss of tissue compared to the surrounding swollen / oedematous mucosa, with a whitish base	96.3/85.2
Superficial ulceration	Mildly depressed loss of tissue with a whitish bottom, whose features fit neither with that of aphthoid erosion nor with that of deep ulceration, as previously defined	81.5/85.2
Stenosis	Narrowing of the intestinal lumen withholding or delaying the passing of the videocapsule (therefore, to be evaluated on a video)	100.0/88.9
Edema	Enlarged / swollen / engorged villi	85.2/81.5
Hyperemia	Area of reddish villi	96.3/81.5
Denudation	Reddish (but not whitish) mucosal area where villi are absent	81.5/81.5

[International Delphi Consensus on the nomenclature and descriptions of ulcerative and inflammatory lesions seen in IBD during SBCE.]

**Conclusion:** Consensual nomenclature and descriptions of the most frequent SB UI lesions seen in CD in CE have been reached by an international group. These terms and descriptions are useful in daily practice, for teaching and for medical research purposes.

**Disclosure:** Xavier Dray has acted as a consultant for Alfasigma; Bouchara Recordati; Boston Scientific, Fujifilm, Medtronic, and Pentax

## **P0271 COLON CAPSULE ENDOSCOPY: AN EFFICIENT COMPLEMENT FOR INCOMPLETE COLONOSCOPIES**

**Introduction:** Colonoscopy is the gold standard for visualization of the colon during colorectal cancer screening. A colonoscopy is considered complete when cecum is reached. Completion rates, on some series, are described as low as 81% for mixed indications. Colon capsule endoscopy (CCE) is approved for complementing incomplete colonoscopies, with completion rates up to 90%, and it could help to detect additional relevant colonic and extracolonic findings.

**Aims & Methods:** To assess the value of CCE on incomplete colonoscopies: complementation rates and incremental diagnostic yields. Retrospective, single center study, including consecutive patients that underwent CCE for incomplete colonoscopy, from April 2015 to October 2018. Our cohort was analyzed by descriptive and parametric SPSS tools.

**Results:** We included 55 patients submitted to CCE after an incomplete colonoscopy. Included 46 women (83.6%) with a mean age of 67 years old. CCE were complete in 64% of the patients, however, in almost 90%, we reach total colon visualization, considering both exams. The three main indications for primary colonoscopy were colorectal carcinoma screening (49.1%), followed by positive fecal occult blood test (14.5%) and post-polypectomy surveillance (14.5%). Significant endoscopic findings were identified in 44 (80%) CCE, namely, colon diverticula (61.8%) followed by polyps (29.1%), angiectasias (9.1%) and erosions (9.1%). From the 16 CCE with diagnosis of colon polyps, three lesions (18.5%) had more than 10mm. Polyps were mainly found on left colon (12.7%). Seven patients performed colonoscopy after CCE (12.7%), and in 6 (85.7%) the intended lesions were identified and treated: 5 polypectomies and 1 fulguration with argon plasma. Therefore, 87.3% of the patients won't need additional investigation after CCE. There were no CCE retentions or other complications associated to the procedure.

**Conclusion:** CCE is useful and well tolerated, an important tool to be used to increase colonic diagnostic yield with direct impact on therapeutic interventions.

**Disclosure:** Nothing to disclose

**Introduction:** Colorectal cancer (CRC) screening programs have been implemented in many countries in order to decrease CRC incidence and mortality. Primary colonoscopy and fecal immunochemical testing (FIT) are the most commonly used screening modalities. An alternative screening instrument is second generation colon capsule endoscopy (CCE). Although the accuracy of CCE has already been proven in several trials, information on its performance in a screening population remains scarce.

**Aims & Methods:** We therefore performed the first systematic review on the role of CCE as a CRC screening tool. A systematic search was conducted until November 2018 to retrieve studies from Embase, Web of Science, Medline Ovid and Cochrane Central according to the PRISMA guideline. Studies with patients participating in a population colorectal screening were included. Studies using first generation CCE were excluded.

**Results:** Literature search retrieved 499 studies, of these 11 studies met the inclusion criteria. The included studies focused on FIT-positive screening populations (n=7) or opportunistic screening populations (n=4). In total 1792 subjects were included. The participation rate ranged between 4.2% and 17.4% (Table 1). The polyp detection rate of CCE varied from 63% to 74%. Complete CCE led to detection of 16/17 (94%) CRCs. Sensitivity of CCE for polyps ranged between 75% and 92.8% and specificity between 65.3% and 99%. Bowel preparation was adequate in 70% to 92% and completion rate varied from 57% to 88%. No adverse events with CCE were reported in the included studies.

**Conclusion:** CCE is a safe and effective diagnostic tool for the detection of cancer and polyps in a screening population. Bowel preparation is adequate in most studies, but the low completion rates affect the performance of CCE. More studies are needed to determine the role of CCE as screening instrument.

**Disclosure:** Nothing to disclose

## P0273 POLYETHYLENE GLYCOL PURGATIVES PRIOR TO SMALL BOWEL CAPSULE ENDOSCOPY IMPROVE DISTAL SMALL BOWEL VISUALISATION

Tai F.W.D.<sup>1</sup>, Wray N.<sup>1</sup>, Healy A.<sup>1</sup>, Thurston V.<sup>1</sup>, Hookey L.<sup>2</sup>, McAlindon M.<sup>3</sup>

**Contact E-Mail Address:** david.tai@nhs.net

**Introduction:** Bowel purgatives are common practice prior to small bowel capsule endoscopy (SBCE). The use of Polyethylene glycol (PEG) laxatives is suggested to improve SB visualisation quality and diagnostic yield [Kotwal, Eur J Gastro Hep 2014]. However, this finding is not completely consistent, with other studies suggesting no clear benefit of PEG preparation over clear fluids only [Hookey, GIE 2017]. Therefore, unlike colonoscopy where the routine use of split dose bowel preparation to improve right colon cleansing has become a standard of care [Flemming, GIE 2012], the benefit and timing of purgatives prior to SBCE is unknown. We report the interim results from a clinical trial comparing the use of split dose PEG and single dose PEG against clear fluids only.

**Aims & Methods:** Adult patients referred for SBCE were invited to participate and subject to exclusion criteria, were randomised to control (clear fluids only), single dose PEG (2L PEG at 6am on the day of the exam) and split dose PEG (1L PEG at 7pm the day before and 6am on the day of the exam). Briefly, the mean red to green colour intensity from SBCE procedure colour bars were used to calculate a computed assessment of cleansing (CAC) scores described elsewhere [Van Weyenberg, Endoscopy 2011]. The CAC is a validated 10 point scoring system (0-10; least - most clean) used to assess small bowel visualisation quality. CAC scores are reported as mean  $\pm$  SEM and student t-tests performed to compare the means.

**Results:** A total of 78 patients (35% male, mean age 48 $\pm$ 2.0) were included (split n=28, single n=24 and control n=26). Intention to treat analysis show that split dose PEG preparation results in significantly greater mean CAC score in the distal quartile (5.58 $\pm$ 0.16) of the small bowel compared to control (4.78 $\pm$ 0.30; p=0.02). No differences in the overall, first, second and third quartile CAC score of the small bowel was found between control and PEG groups. Complete ingestion of PEG preparation occurred in 88% and 77% of single vs split dose (p=0.33). Subgroup analysis showed that amongst patients that completed preparation successfully, those randomised to both split dose (5.52 $\pm$ 0.20; p=0.01) and single dose (5.64 $\pm$ 0.18, p=0.003) PEG had a significantly greater mean CAC score in the distal quartile of the small bowel compared to control (4.58 $\pm$ 0.28).

**Conclusion:** The use of split dose laxatives improves the visualisation quality of the distal small bowel. Initial results may suggest that the PEG dose in the morning of the procedure improves distal quartile visualisation.

**Introduction:** Angiodysplasias of the small intestine is reported to be the most common cause of obscure gastrointestinal bleeding (OGIB). The aim of our study was to identify whether it is possible to treat the bleeding due to angiodysplasias found in patients with OGIB subjected to small bowel capsule endoscopy (SBCE).

**Aims & Methods:** Retrospective analysis of prospectively collected data [March 2003 - March 2019] from 5771 patients that were subjected to SBCE in our Department, which is a tertiary referral centre for this test. Among these patients, 3403 were subjected to the test for the investigation of OGIB. All these patients were referred to our Department for OGIB after a reported negative gastroduodenoscopy and a negative colonoscopy.

**Results:** By SBCE angiodysplasias were found in 1652 of 3403 patients (48.5%). Of these lesions 224 (13.5%) were actively bleeding at the time of testing and were localized in the proximal gastrointestinal tract (stomach or the first/second part of the duodenum) (n=12, 5.3%), the proximal jejunum (n=62, 27.6%), the distal jejunum (n=49, 21.8%), the proximal ileum (n=41, 18.3%), the distal ileum (n=42, 18.7%), and the right colon (n=18, 8.0%).

Therapeutic intervention by Argon-Plasma Coagulation (APC) cauterization was possible in 6 patients with gastric or duodenal angiodysplasias, in 7 patients with angiodysplasias in the right colon, and in 31 patients with angiodysplasias in the proximal jejunum (using a push enteroscopy), since in the remaining patients angiodysplasias were not seen during repeat endoscopy.

Therefore, in total, angiodysplasias were endoscopically treated in 44 patients (2.6%), among the 1652 initially revealed through SBCE.

**Conclusion:** Angiodysplasias are seen in the majority of patients with obscure gastrointestinal bleeding subjected to SBCE; however therapeutic intervention is possible only in a small minority of them, especially if double balloon endoscopy is not available.

**Disclosure:** Nothing to disclose

## **P0275 NEGATIVE SMALL BOWEL VIDEO CAPSULE ENDOSCOPY FOR OCCULT GASTROINTESTINAL BLEEDING PREDICTS A LOW RISK OF SUBSEQUENT INPATIENT ADMISSION WITH UPPER GASTROINTESTINAL BLEEDING**

Rajagopalan A., Venugopal K.  
*Royal Perth Hospital, Gastroenterology and Hepatology, Perth, Australia*

**Contact E-Mail Address:** arvind.raja@gmail.com

**Introduction:** Small bowel video capsule endoscopy (SBVCE) is the investigation of choice for occult gastrointestinal bleeding (OGIB) following a negative gastroscopy and colonoscopy. Approximately 50-55% of these tests are negative, however the long-term outcome of this cohort of patients is not well described.

**Aims & Methods:** **Aim:** To assess the long-term clinical impact of a negative SBVCE in patients with OGIB.

**Methods:** A retrospective review of all patients who underwent SBVCE at an Australian tertiary health service between 1<sup>st</sup> January 2012- 31<sup>st</sup> December 2017 was performed. The gastrointestinal Procedure Reports database was reviewed for listed indications of 'anaemia' or 'iron deficiency'. Demographic data (including medication history) was determined by reviewing the medical record.

Primary outcome measure was hospital admission secondary to gastrointestinal bleeding within 1 year of negative SBVCE, with secondary outcome measure being further endoscopic investigation of iron deficiency anaemia or gastrointestinal bleeding within 1 year. Statistical analysis was performed using GraphPad Prism software (version 8.02).

**Results:** 429 cases were initially identified. 13 were excluded due to capsule retention in upper gastrointestinal tract, whilst a further 209 excluded due to either additional presence of overt gastrointestinal bleeding or a positive capsule result (Significant angioma burden, ulcers, small bowel Crohn's Disease and small bowel tumors).

207 cases were included for final assessment. 110 (53%) female, median age 61 years (range 17-91). 18 (9%) had a history of non-steroidal anti-inflammatory use, 41 (20%) reported aspirin use, 17 (8%) other antiplatelet agents and 15 (7%) were using other anticoagulation at the time of SBCE. Regarding the primary outcome measure, 7 (3%) of patients were admitted to hospital within 1 year of negative SBVCE. 11 (6%) of patients had repeat endoscopic investigation (8 patients had negative studies, 2 patients had gastric antral vascular ectasia and 1 patient had a duodenal angioma). 3/62 patients receiving antiplatelet or anticoagulant therapy were admitted to hospital compared to 4/145 not receiving these therapies. The odds ratio for readmission when on anticoagulation was 1.7 (95% confidence interval 0.44-6.8), when compared to patients not on anticoagulation - although this did not reach statistical significance (p = 0.44). No patient had multiple admissions.

**Conclusion:** Negative SBVCE for occult GI bleeding carries a low risk for subsequent hospital admission due to overt GI bleeding within 1 year of the study. In addition, there is a low risk of requiring further endoscopic investigations.

**Disclosure:** Nothing to disclose

**Introduction:** Capsule Endoscopy (CE) is a first-line diagnostic test in patients with suspected small bowel bleeding (SSBB). One of the main limitation of CE is reading that might be time consuming. In order to overcome such limitation, innovative types of reading software have been developed. A new generation reading algorithm (Express-View by MiroCam) has recently released with the aim to reduce CE reading time by removing images based upon their similarity and effectively reducing the number of images for the review, without affecting the diagnostic yield. Accuracy and impact on reading time are unknown.

**Aims & Methods:** Primary aim was to evaluate the accuracy of the new generation Express View in patients with SSBB. Secondary objective was to evaluate the reading time with the Express View compared to standard reading. This is a per patient, interim analysis including 48 patients with SSBB prospectively enrolled in 5 centers. All patients underwent small-bowel CE (MC 1200, Intromedic, Republic of Korea). CE reading was initially performed in the standard mode according to the ESGE capsule endoscopy technical guidelines. A second reading was performed using the Express View (EV) mode by an external, blinded reader. For each lesion,

the time of visualization, nature, and relevance according to the Saurin classification were collected. For the accuracy evaluation, the Express View reading was compared to the standard reading (SR) that was considered gold standard. In case of discrepancies between SR and EV reading, accuracy parameters were re-evaluated after a consensus reading that was performed by two experienced investigators (>500 cases) and that was considered the gold standard. Reading time (gastric + small bowel) was also evaluated after selection of the first gastric, duodenal and cecal landmarks. In case of incomplete enteroscopy, the last recorded image was considered as landmark.

**Results:** On a total of 48 patients, 47 performed VCE examination while one patient had gastric capsule retention. Enteroscopy was complete (i.e. cecal visualization) in 43 patients (91.5%). In 33 out of 47 patients (70.2%) both SR and EV mode were in agreement for type of lesion and localization, while in the remaining 14 patients (29.8%) the EV reading was discordant compared to the gold standard (i.e. SR). Sensitivity, specificity, PPV, and NPV of EV reading after the initial evaluation were 71.8%, 66.6%, 82%, 52.6%, respectively. After the consensus reading, in 12 out of 14 patients with discordant reports (n=5 SR-EV+, n=4 SR-EV-, n=3 SR-EV+ but no comparable lesions) EV was reclassified to be able to properly detect the lesion and the disagreement was considered related to a reader-misinterpretation. In the remaining 2 patients (4.2%), EV mode missed relevant lesions (1 patient with significant ileal erosions and 1 with a vascular malformation).

After consensus reading reclassification, EV mode sensitivity, specificity, NPV and PPV were 94.6%, 100%, 83.3% and 100% respectively. The mean reading time at SR and EV was 84.13 ± 53.63 min and 14.79 ± 11.2 min, respectively (p< 0.001).

**Conclusion:** The preliminary results of this study suggest that the new generation Express View algorithm shows excellent accuracy and significantly reduces CE reading time.

**Contact E-Mail Address:** catarina.rib.gomes@gmail.com

**Introduction:** The European Society of Gastrointestinal Endoscopy recommends that a solution such as polyethylene glycol (PEG) should be used prior to a capsule endoscopy (CE), since it allows a better mucosal visualization and increases the diagnostic yield. However, it is still controversial which is the best enteric preparation. In the current literature, some series showed similar results between a PEG solution and a clear liquid diet on the day before the CE.

**Aims & Methods:** The aim of this study was to compare Brotz's enteral cleansing scales between two enteric preparation protocols in patients undergoing CE. The authors performed a retrospective single-center analysis of CE. Patients with active bleeding and whose capsule did not reach the cecum were excluded from the study. The enteric preparation protocols were (1) clear liquid diet on the previous day plus 8 hour fasting, (2) 2 liters of PEG solution plus simeticone. The CE videos were graded regarding the level of cleanliness according to 2 grading scales developed by Brotz *et al* previously described: a) quantitative index (QI), which grades the level of cleanliness with a score ranging from 0 to 10 and b) qualitative evaluation (QE), which grades the degree of cleanliness as excellent, good, fair and poor. The diagnostic yield between the 2 protocols was also evaluated.

**Results:** 110 CE were analyzed, 52.7% (n=58) were female, with a mean age of 56.1 years-old (± 18). 52.7% (n=58) of the patients had the clear liquid diet protocol and 47.3% (n=52) the PEG protocol. Sex, age and indication for CE were not significantly different between the two protocols. In addition, there were no significant differences between the PEG and the

liquid diet in relation to the QI (8.13 ± 1.56 vs. 7.47 ± 1.97, p=0.05) and the QE cleansing grades (excellent: 15.4% vs. 13.8%, good: 48.1% vs. 39.7%, reasonable: 25% vs. 27.6%, poor: 11.5% vs. 19%, p = 0.67). The diagnostic yield was not different between the 2 protocols (PEG: 58.8% vs Clear liquid diet: 55.2%, p=0.7).

**Conclusion:** The use of a PEG solution did not show to affect the small-bowel cleansing in CE when evaluated by QI and QE Brotz scales, and did not affect the diagnostic yield of CE.

**Disclosure:** Nothing to disclose

## P0278 COMPARING THE EFFICACY AND SAFETY OF METAL VERSUS PLASTIC STENTS IN PREOPERATIVE BILIARY DRAINAGE

Roberts A.<sup>1</sup>, Jaya J.<sup>2</sup>, Thakur U.<sup>2</sup>, Aldridge O.<sup>3</sup>, Pilgrim C.<sup>3</sup>, Wong E.<sup>4</sup>, Tan E.<sup>4</sup>, Fox A.<sup>4</sup>, Le S.T.T.<sup>5</sup>, Croagh D.<sup>2</sup>

<sup>1</sup>Monash Health, Gastroenterology, Clayton, Australia, <sup>2</sup>Monash Health, Surgery, Melbourne, Australia, <sup>3</sup>Alfred Health, Surgery, Melbourne, Australia, <sup>4</sup>Eastern Health, Surgery, Box Hill, Australia, <sup>5</sup>Monash Medical Centre Gastroenterology and Hepatology, Gastroenterology, Melbourne, VIC, Australia

**Contact E-Mail Address:** atr444@gmail.com

**Introduction:** There is conflicting evidence regarding whether routine pre-operative biliary drainage (PBD) should be performed if clinically warranted prior to a pylorus-preserving pancreaticoduodenectomy (PPP) for resectable pancreatic head cancer. In addition, there are limited studies that investigated whether PBD with metal or plastic biliary stents have differing impacts on PBD-related complication rates, post PPP surgical outcomes, and healthcare resource utilisation.

**Aims & Methods:** An Australian multicentre retrospective cohort study was conducted which included patients who underwent PBD prior to PPP from 2010 to 2019. Patients included received PBD based on one or more of: cholangitis defined by revised Tokyo guidelines, level of total bilirubin ≥40 µmol/L, expected time to operation ≥7 days, or receiving neoadjuvant chemotherapy.

The aim of this study was to compare PBD with fully covered self-expandable metal stent (FCSEMS) compared to plastic stents in terms of the rate of endoscopic reintervention, stent related complication and surgical complications in patients with resectable pancreatic head cancer who later underwent a PPD.

**Results:** 106 patients underwent PBD. 32 patients (30.19%) received a FCSEMS versus 74 (69.81%) with plastic). The mean age was 66.75 ± 9.79 years, 47.17% were male and the baseline bilirubin was 184.91 ± 113.59 µmol/L. Both FCSEMS and plastic effectively reduced bilirubin (Δ140.04 ± 113.04 µmol/L from baseline) with no difference between the FCSEMS arm and the plastic arm (Δ134.56 ± 108.35 µmol/L vs Δ152.19 ± 123.74 µmol/L, p-value=0.47).

There was no difference in the PBD complication rates in the FCSEMS and plastic stent groups respectively: readmission (p-value=0.40), pancreatitis (p-value=0.25), cholangitis (p-value=0.35), haemorrhage (p-value=0.51), stent occlusion without cholangitis (p-value=0.09), and reintervention with either ERCP or PTC (p-value=0.21). There were no cases of stent related perforation. There was also no difference in the post-operative complication rates including surgical or biliary leaks, infection, haemorrhage or return to theatre in the FCSEMS and plastic stent groups.

On multivariate logistic regression analysis, the stent type was not an independent risk factor of endoscopic or post-operative complication or death. On multivariate linear regression analysis, the stent type was not an independent risk factor for increased length of stay for those readmitted for a stent related complication. The resection histopathology showed pancreatic adenocarcinoma (69.81%), neuroendocrine (2.83%), autoimmune pancreatitis (0.94%) and other primary malignancy (26.42%).

**Conclusion:** Both FCSEMS and plastic PBD stents were comparable in normalising bilirubin pre-PPP. There were no statistically significant difference in pre or post-operative complications or healthcare resource utilisation between the two groups apart from the increased upfront cost of the FCSEMS. The cost benefit in using plastic stents in preference to FCSEMS may be an important consideration where there are clinical indications for PBD or long wait times for surgical management of resectable pancreatic head cancer.

**Disclosure:** Nothing to disclose

**Introduction:** Forward-viewing echoendoscope (FV-ES) was originally designed for therapeutic procedures, particularly for pseudocyst drainage. The advantage of FV-ES is that it enables the axial application of force during needle insertion and accessory device deployment. Although other big advantage of FV-ES is its easier manipulation throughout the GI tract due to forward viewing, a wider angulation range, and short length of the hard tip, there are few reports on EUS-guided transjejunal anastomotic drainage for the patients with altered anatomy. The advantages of this technique are that we can approach both biliary systems and it is a 1-step procedure (no need for Rendezvous method) and it is not performed through the abdominal cavity.

**Aims & Methods:** We evaluated the feasibility of the EUS-guided choledochojunostomy (EUS-CJS) and pancreaticojejunostomy (EUS-PJS) with FV-ES (TGF-UC260; Olympus, Tokyo, Japan) for the patients with surgically altered anatomy from Feb 2015 through Mar 2019 in our institution, retrospectively.

**Results:** A total of 7 cases with surgically altered anatomy were received transjejunal anastomotic drainage with FV-ES. All of them were after pancreaticoduodenectomy with modified Child reconstruction. The indication for drainage was complete stricture of the hepaticojejunal anastomosis in 6 cases and the pancreaticojejunal anastomosis in one case. The success rate of reaching the target site at afferent limb is 100% (7/7) and median reaching time was 6 min (4-17). EUS-CJS and bile duct stent placement was succeeded in 66.7% (4/6). Erroneous puncture of unintended bile duct in one case and impossibility to pass by mechanical dilatation device in one case, in which cautery dilation catheter was not applied due to major vessels close to the puncture site on EUS. Both were rescued by percutaneous transhepatic biliary drainage. EUS-PJS and pancreatic duct stent placement was succeeded in one case (1/1). No adverse events related to the procedure were happened such as severe bile or pancreatic juice leakage.

**Conclusion:** EUS-CJS and PJS with FV-ES is feasible in the patients with modified Child's reconstruction after pancreaticoduodenectomy and they can be safe and effective method in case of complete stricture of the anastomotic site.

**Disclosure:** Nothing to disclose

## P0280 DOUBLE STENTING HAS BETTER OUTCOMES THAN DOUBLE SURGICAL BYPASS IN THE CASE OF COMBINED MALIGNANT DUODENAL AND BILIARY OBSTRUCTION: A META-ANALYSIS AND A SYSTEMATIC REVIEW

**Introduction:** Data about efficacy of palliative double stenting of malignant duodenal and biliary obstruction are limited.

**Aims & Methods:** Systematic literature search was performed to assess feasibility and optimal method of double stenting of malignant duodenal and biliary obstruction compared to surgical double bypass in terms of technical and clinical success, adverse events, reinterventions, and sur-

vival. Seventy-two retrospective and 8 prospective studies published until July 2018 were enrolled. Event rates with 95% confidence intervals were calculated.

**Results:** Technical and clinical success rates of double stenting were 97% (95-99%) and 92% (89-95%), respectively. Clinical success of endoscopic biliary stenting was higher than that of surgery (97% [94-99%] vs 86% [78-92%]) in an older population (67.9 years [67.0-68.9 years] vs 63.7 years [62.3-65.0 years]). Double stenting was associated with less adverse events (13% [8-19%] vs 28% [19-38%]) but more frequent need for reintervention (21% [16-27%] vs 10% [4-19%]) than double bypass. No significant difference was found between technical and clinical success and reintervention rate of endoscopic retrograde cholangiopancreatography (ERCP), percutaneous transhepatic drainage (PTD) and endoscopic ultrasound guided biliary drainage (EUS-BD). ERCP was associated with the least adverse events (3% [1-6%]), followed by PTD (10% [0-37%]) and EUS-BD (23% [15-33%]).

**Conclusion:** Substantially high technical and clinical success can be achieved with double stenting also in elderly. ERCP is recommended as first choice for biliary stenting as part of double stenting. Prospective comparative studies with well-defined outcomes and cohorts are needed.

**Introduction:** Endoscopic ultrasound (EUS)-guided drainage is considered the gold standard for the treatment of symptomatic peripancreatic fluid collections (PFCs). Both lumen-apposing metal stents (LAMS) and double pigtail plastic stents (DPPS) can be deployed once access in the collection is achieved.

**Aims & Methods:** In this retrospective study we aimed to evaluate the efficacy and safety of EUS-guided drainage of PFCs. Data from consecutive patients undergoing drainage in 8 European centers were retrospectively retrieved. Characteristics of PFC, type of stent, technical success (successful stent deployment), clinical success (satisfactory drainage), rate of early adverse events, drainage duration and complications on stent removal were evaluated.

**Results:** 96 patients [69 men (72%), 57.8±12.8yrs] underwent drainage from 2016 to 02.2019. A pancreatic pseudocyst (PC) and a walled-off necrosis (WON) was drained in 62 and 34 patients, respectively. LAMS were used in 76 (79.2%) patients; DPPS in 20 (20.8%) of them. In 75 patients (78.1%) PFC was located in the body or tail of the pancreas with a mean diameter of 12±5cm. In 86 cases (89.6%) the transgastric approach was used to access the PFC. For all above characteristics no difference was detected between PC and WON (p>0.1). Among LAMS, the 15mm diameter was chosen in 57 (75%) of the cases. Overall, 30 DPPS were used [median 2(1-3)]; the most common diameters were 10Fr (15/30, 50%) and 7Fr (12/30, 40%). A successful deployment was possible in 92 (95.8%) of the cases with no difference regarding either the PFC type (p=0.13) or the type of stent (p=1). Clinical success was achieved in 88 (92%) of the patients; PC had better response than WON (62/62 vs. 6/32, p=0.001, respectively). Type of stent did not affect the rate of clinical success (p=0.61).

An early complication was evident in 16 (16.8%) of the cases. The most common adverse event was bleeding (n=5, 5.2%) followed by obstruction of the stent causing inflammatory reaction (n=4, 4.2%), perforation (n=3, 3.1%) and migration necessitating stent replacement (n=3, 3.1%). More complications were noted in the LAMS group (n=14, 18.7%) compared to DPTS group (n=2, 10%) but this difference did not reach statistical significance (p=0.51). PFC type was also not related to the rate of early complications [9/62, 14.5% vs. 7/33, 21.2% for PC and WON, respectively (p=0.41)]. 10/16 adverse events were handled conservative while 6 patients received further intervention to treat the adverse event. All 5 bleeding episodes were recorded in the LAMS group with 4 patients undergoing embolization. All but one patients recovered completely. The mean duration of drainage was 61.1±67 days, but was significantly longer for the DPTS group compared to that of LAMS [98.5±47.7 vs. 54±68.2; p=0.007, respectively]. In LAMS group, stent removal was intended in all cases while in the DPPS group 4 cases received indwelling stent placement. On stent removal 9 (11.8%) complications were recorded in the LAMS group compared to none in the DPPS. Buried stent syndrome (n=6, 7.9%) was the most common complication on stent removal followed by bleeding (n=3, 3.9%). PFC type did not affect the complication rate on removal.

**Conclusion:** EUS-guided drainage of PFCs using LAMS or DPPS is associated with high percentages of technical and clinical success. Early adverse events are similar between the two types of drainage and not affected by the type of collection. Drainage using LAMS is of shorter duration, but severe complications occur more frequently on stent removal, regardless of the type of PFC.

**Introduction:** Inoperable biliary cancer with hilar biliary stenosis has a poor prognosis and requires multiple drainage of complicated stenoses. Radiofrequency ablation (RFA) for the bile duct was recently reported to be effective in ensuring the long-term stent patency and affording a good prognosis. Many reports on biliary RFA have been retrospective studies of distal biliary obstruction including a variety of etiologies, such as a pancreatic cancer, biliary cancer, and metastasis of the lymph node and other organ cancers.

**Aims & Methods:** We prospectively evaluated the feasibility and short-term outcomes of endoscopic biliary RFA for malignant hilar biliary obstruction (MHBO) caused by biliary cancer. The primary outcomes of the study were the technical success of RFA with the bilateral placement of a self-expandable metallic stent (SEMS) and complications within 30 days after the procedures. Bilateral biliary stenting for MHBO was performed by the partial stent-in-stent method using a thin delivery system of the SEMS after RFA.

**Results:** Twelve patients (10 men; 70.8 ± 6.0 years of age) were enrolled in the study between May 2017 and March 2019. Hilar bile duct cancer was diagnosed in 11 patients (92%), while 1 had gallbladder cancer (8%). The Bismuth classification of biliary stenosis was III and IV in 7 (58%) and 5 (42%). The mean stricture length was 39.1 ± 14.6 mm. Before RFA, all patients underwent biliary drainage once in 2 patients (17%), twice in 9 patients (75%), and 3 times in 1 patient (8%). The technical success rate for RFA with SEMS placement was 100%. The mean number of ablations was 5.4 ± 1.1. Post-procedural adverse events occurred in 4 patients (33%; 3 with fever and 1 with cholecystitis). The patients with a fever improved immediately with conservative treatment. The case of cholecystitis required percutaneous aspiration of the gallbladder three days after the procedure and was suspected to have been influenced by the SEMS placement, as the stent was placed across the cystic duct without ablation of the duct.

**Conclusion:** The short-term outcomes of RFA for MHBO were suitable. Further preoperative studies are needed to confirm the efficacy of RFA with bilateral placement of a SEMS for MHBO.

**Disclosure:** Nothing to disclose

## P0283 REINTERVENTION FOR STENT OCCLUSION AFTER PLACEMENT OF MULTIPLE SELF-EXPANDABLE METALLIC STENTS FOR MALIGNANT HILAR BILIARY OBSTRUCTION

Kitamura H., Hijioka S., Hisada Y., Harai S., Yoshinari M., Maruki Y., Ohba A., Nagashio Y., Kondo S., Morizane C., Ueno H., Okusaka T.

**Introduction:** Endoscopic reintervention for stent occlusions following the placement of multiple self-expandable metallic stents (SEMS) for malignant hilar biliary obstruction (MHBO) is challenging, and the appropriate drainage method have not yet been clarified. We aimed to clarify a suitable reintervention method for stent occlusions following placement of multiple SMES for MHBO.

**Aims & Methods:** Between October 2017 and March 2019, 41 patients with MHBO underwent reintervention for stent occlusion after placement of multiple SEMS. We retrospectively evaluated the technical and functional success rates of the reintervention, and the time to recurrent biliary obstruction (RBO). The treatment strategy of reintervention was the first choice via ERCP, and EUS-BD was performed/co-administered in cases when transpapillary drainage was insufficient.

**Results:** Re-intervention was performed in 41 of 118 cases (34.7%) that were indwelled with multiple SEMS for hilar region stenosis. The median age of the patients was 59 ± 11.5 years, and the patients comprised of 27 men and 17 women. Etiologies included cholangiocarcinoma in 17 cases, gallbladder cancer in 6, pancreatic cancer in 5, and others in 13. Bismuth classification were type II in 15 patients (36.6%), type III in 17 patients (41.5%), and type IV in 9 patients (21.9%). Regarding the methods used for the placement of the initial SEMS, 28 cases (68.2%) underwent SBS and 13 cases (31.7%) underwent PSIS. In 24 (58.5%) and 17 (41.5%) cases, 2 and 3 areas were drained.

As a result, the technical and functional success rates of re-intervention were 82.9% (34/41) and 90.2% (37/41), respectively. In SBS group, the technical and functional success rates were 82.2% (23/28) and 92.3% (26/28), and in PSIS group, these were 84.6% (11/13) and 92.3% (12/13). In drainage for 2 areas group, the technical and functional success rates were 79.2% (19/24) and 91.7% (22/24), and in drainage for 3 areas group, these were 88.2% (15/17) and 94.1% (16/17). ERCP was performed in 25 cases, EUS-BD (all EUS-HGS) in 13, and ERCP+ EUS-BD in 3 (EUS-HGS in 2, EUS-HDS in 1). Stent for re-intervention was used Plastic stents (PS) for 3 cases, PS + SEMS for 2, and SEMS for 36. The median time to RBO was 109 days. The time to RBO tended to be longer in the EUS-BD group compared to that of the ERCP group (116 days vs. 78 days; long-rank test, p = 0.076). There was no significant difference in examination time (72.2 vs. 79.4, p = 0.52). In the ERCP group, mild acute pancreatitis was observed in 3 cases (12%). In the EUS-BD group, the stent straying into the gastric wall was observed in 1 patient (postoperative 59 days), intraabdominal abscess (CT-CAE v5.0 grade 3) in 1, and hemorrhage from the puncture site (CTCAE v5.0 grade 2) in 1.

**Conclusion:** When considering reintervention for MHBO, EUS-BD has a long patent period and can be used as a new reintervention method.

**Introduction:** Endoscopic gallbladder drainage is an alternative to percutaneous gallbladder drainage (PGBD) to treat acute cholecystitis in poor surgical candidates. Treatment is achieved through retrograde transpapillary gallbladder drainage (ERC-GBD) or endosonographic gallbladder drainage (EUS-GBD), and offers similar success rates with less adverse events. No cost-effectiveness analysis has compared these three strategies.

**Aims & Methods:** We aim to compare the clinical and cost determinants of three treatment alternatives for acute cholecystitis in subjects who were deemed poor surgical candidates for cholecystectomy.

A cost-effectiveness analysis compared three strategies: PGBD, ERC-GBD and EUS-GBD. A decision tree was created comparing clinical outcomes during the first three months after hospitalization. All subjects included were considered poor surgical candidates based on comorbidities, and subsequently managed with bowel rest, intravenous fluids and antibiotics without improvement.

Effectiveness was a composite of length of hospitalization plus additional hospital care due to adverse events or readmissions (measured in hospital days). Costs of care were obtained from the National Inpatient Sample and published literature. Outcomes estimates (e.g. procedure complications and readmissions) were obtained from published literature. Primary analysis was performed from the health care perspective.

Cost-effectiveness was compared to the national average cost of one hospital bed *per diem* as reference. One-way sensitivity analyses and Monte Carlo simulations were generated to evaluate effect modifying variables.

**Results:** Analysis of a hypothetical cohort of patients considered poor candidates for cholecystectomy showed that the cost effectiveness of endoscopic therapies was superior to PGBD. Compared to PGBD, ERC-GBD was a cost-saving strategy and EUS-GBD was cost effective, requiring \$1,312 per hospitalization day averted. Both interventions were acceptable under the cost of one-hospital-bed per diem (\$2,338 national average). Compared to ERC-GBD, EUS-GBD required spending \$8,950 more per hospitalization day averted.

Sensitivity analyses showed that our model was notably affected by LAMS price, length of stay for patients managed conservatively, and length of stay for patients requiring laparoscopic cholecystectomy. Cost effectiveness was minimally affected by variations in technical success rates of endoscopic procedures. One-way sensitivity analysis showed that a decrease of LAMS price (to \$780) could potentially make EUS-GBD the dominant strategy.

The Monte Carlo simulation included a variable range of therapeutic success rates. ERC-GBD was cost effective in the majority of simulation trials, and was under the cost of one hospitalization day. ERC-GBD ceased being cost effective when willingness to pay for a new intervention was greater than \$10,000. ERC-GBD remained more cost effective than EUS-GBD in the Monte Carlo simulation.

Analysis from a societal perspective added \$6,264 for PGBD, \$4,659 for ERC-GBD, and \$4,543 for EUS-GBD over 3 months. Loss of productivity days represented approximately 60% of the additional costs. Cost-effectiveness results did not change from the primary analysis; EUS-GBD remained cost effective, with \$762 per hospital day averted compared to PGBD.

**Conclusion:** Endoscopic treatment for acute cholecystitis is cost-effective compared to PGBD, favoring ERC-GBD over EUS-GBD. Further efforts are needed to make endoscopic treatments available in more medical centers, reduce equipment costs and shorten inpatient care.

**Introduction:** Image-guided percutaneous thermal ablation can be used for treatment of non-operable primary and metastatic lung tumors. These techniques are based on heating effect on the tissue around a percutaneous applicator causing coagulative necrosis of the tumor cells. Microwave ablation (MWA) is a commonly used locoregional interventional procedure in treatment of pulmonary tumors with satisfactory outcome.

**Aims & Methods:** To study the efficacy of MWA in treatment of colorectal pulmonary metastases.

**Patients and methods:** A total of 47 patients (22 men and 25 women; mean [± SD] age, 63.8 ± 14.6 years; range, 30-91 years) with 68 inoperable lung metastases of colorectal origin (Mean tumor size 15 ± 9.0 mm) were treated with MWA under guidance of CT-Fluoroscopy using conscious sedation according to the guidelines from November 2008 to October 2017.

Diagnosis of lung metastases relied on chest CT with contrast (Somatom Sensation 64; Siemens, Erlangen, Germany with scanning parameter: 5-mm collimation, 30 mAs, and 120 kV and 5-mm section thickness) and lung biopsy.

Follow-up post ablation by chest CT was done after 24 hours, three months, six months, one year and every 6 months onwards to determine treatment response. Patients were either adequately ablated (no residual tumor activity) or had local progression (residual tumor activity). Local progression was considered when the lesion became of larger size or expressed morphological changes in its shape such as protrusion or, irregular, scattered, nodular or eccentric focus arising from the margin in addition to de novo lesion showing contrast uptake. Survival rates were calculated from the time of the first ablation session, with the use of Kaplan-Meier and log-rank tests. Changes in the size and volume of the ablated lesions were measured using the Kruskal-Wallis method.

**Results:** Forty four lesions (64.7%) showed complete response to treatment and 24 lesions (35.3%) had local progression (residual activity). The median time to local tumor progression was 7.6 months. The median survival was 31.5 months for patient underwent MWA according to the Kaplan-Meier test. The overall survival rate at 1, 2, and 4 years was 83.5%, 68.2%, and 16.5%, respectively.

The progression-free survival rate at 1, 2, 3, and 4 years was 53.9%, 28.8%, 10.0%, and 1.0%, respectively.

Successful tumor ablation was significantly more frequent for lesions with a maximal axial diameter of 3 cm or smaller than for lesions greater than 3 cm in maximal axial diameter ( $P = .0001$ ). There were no deaths during the procedure and the mortality rate within 6 months after ablation was 0%. Early postablation complications included pneumothorax (10.3%), pain (8.8%), hydroneumothorax (5.8 %), pulmonary hemorrhage (5.8%) and postablation syndrome (2.9%). An intercostal chest tube was applied in one (14.2%) of the 7 sessions with pneumothorax. No significant long term complications were seen.

**Conclusion:** Pulmonary CT-guided microwave ablation therapy for management of pulmonary metastases of colorectal origin is safe and effective minimally invasive option and can improve local tumor control and survival rate in patients who are not candidate for surgical resection. The efficacy of the ablation is determined by the size and location of the tumor in relation to the hilar structures.

**Disclosure:** Nothing to disclose

## P0286 APPARENT DIFFUSION COEFFICIENT IN EVALUATING EARLY TREATMENT RESPONSE AFTER CT-GUIDED MICROWAVE ABLATION FOR INOPERABLE COLORECTAL PULMONARY METASTASES

**Introduction:** Microwave ablation (MWA) is a commonly used locoregional thermal ablation technique in treatment of primary and secondary pulmonary tumors. There is growing evidence that apparent diffusion coefficient (ADC) value can be used in evaluating early MWA therapeutic efficacy in treatment of pulmonary tumors and thus represent a reliable predictor of tumor recurrence after treatment.

**Aims & Methods:** To determine the early treatment response of lung MWA in patients with colorectal pulmonary metastases using ADC value.

**Patients and methods:** A total of 47 patients (22 men and 25 women; mean [± SD] age, 63.8 ± 14.6 years; range, 30-91 years) with 68 lung lesions of colorectal origin were retrospectively included, and were treated with MWA according to the guidelines during the period from November 2008 to October 2017.

All lesions were evaluated by diffusion weighted imaging (DWI) and ADC value measurement before and 24 hours after MWA. DWI was obtained using axial a single-shot echoplanar imaging with two *b*-values (50,400, 800 mm<sup>2</sup>/s) using 3 tesla MRI machine. Quantitative ADC maps were calculated using commercially available software and an imaging workstation.

Diagnosis of lung tumors relied on chest CT and/or MRI with contrast. Follow-up post ablation by chest CT and/or MRI with ADC value measurement

was done after 24 hours, three, six months, one year and every 6 months onwards to determine responsive cases (no residual tumoral activity) and local progression cases with residual tumor activity. Local progression was considered when the lesion became of larger size or expressed morphological changes in its shape such as protrusion or, irregular, scattered, nodular or eccentric focus arising from the margin in addition to denovo lesion showing contrast uptake. Immediate changes in ADC values were compared to the net response based on CT and/or MRI follow-up.

**Results:** Forty four lesions (64.7%) responded to ablation and twenty four lesions (35.3%) had shown local progression (residual tumor activity). ADC values were significantly higher in lesions that responded to MWA than in non-responding lesions.

The mean ADC value before treatment was  $0.8 \pm 0.2 \times 10^{-3} \text{ mm}^2/\text{s}$  (mean  $\pm$  SD), while after treatment it was  $1.7 \pm 0.3 \times 10^{-3} \text{ mm}^2/\text{s}$  with a statistically significant difference ( $P = 0.001$ ) for the responsive group.

The mean ADC of the local progression group before treatment was  $0.7 \pm 0.2 \times 10^{-3} \text{ mm}^2/\text{s}$ , and increased after treatment to reach  $1.4 \pm 0.3 \times 10^{-3} \text{ mm}^2/\text{s}$  with a statistically significant difference ( $P = 0.001$ ).

The mean ADC value before treatment didn't show significant difference between responding ( $0.8 \pm 0.2 \times 10^{-3} \text{ mm}^2/\text{s}$ ) and local progression group ( $0.7 \pm 0.2 \times 10^{-3} \text{ mm}^2/\text{s}$ ;  $P = 0.857$ ).

There is statically significant difference in mean ADC value between responsive group (was  $1.7 \pm 0.3 \times 10^{-3} \text{ mm}^2/\text{s}$ ) and local progression group ( $1.4 \pm 0.3 \times 10^{-3} \text{ mm}^2/\text{s}$ ) after ablation ( $P = 0.001$ ).

A cut-off ADC value (1.42) has been suggested as a reference point to predict the response after ablation with 66.67 % Sensitivity, 84.21% Specificity, 66.7% PPV & 84.2% NPV.

**Conclusion:** ADC value calculated from DWI performed 24 hours post treatment is a good quantitative measurement for early prediction of the therapeutic efficacy of MWA in treatment of patients with inoperable lung metastases of colorectal origin and can be used as good alternative to CT imaging in early immediate post ablation follow-up before morphological changes in tumor become detectable on conventional CT and/or MRI.

**Disclosure:** Nothing to disclose

## P0287 ROLE OF COMBINED PALLIATIVE LOCAL THERMAL ABLATION AND TRANSARTERIAL CHEMOEMBOLIZATION IN IRRESECTABLE INTRAHEPATIC CHOLANGIOCARCINOMA IN TERMS OF LOCAL TUMOR CONTROL AND OVERALL SURVIVAL

Elhawash E.<sup>1,2</sup>, Emara E.<sup>3,4</sup>, Naguib N.<sup>4</sup>, Eldin N.<sup>4</sup>, Hegab S.<sup>2</sup>, Abdel-Kerim A.<sup>2</sup>, Vogl T.<sup>4</sup>

**Contact E-Mail Address:** elsayedelhawash@yahoo.com

**Introduction:** Intrahepatic cholangiocarcinoma (ICC) constitutes around 30% of all hepatic malignant neoplasms and considered the second most common primary malignant hepatic tumor following hepatocellular carcinoma. ICC is often diagnosed at an advanced stage; associated with poor prognostic outcomes and 5-year survival less than 5%.

conventional transarterial chemoembolization (TACE) have been recently applied in cases of ICC. Microwave and radiofrequency are minimal invasive procedures have also been proved to be effective safe therapeutic modalities in case of various hepatic tumors including HCC and liver deposits aiming to decrease tumor burden by inducing local coagulative necrosis; still their therapeutic value in case of ICC not clearly defined. In the last 10 years, we implemented TACE, local thermal ablative methods, and combined treatment protocols as minimal invasive palliative procedures aiming to limit the disease process and improve survival rates.

**Aims & Methods:** To assess the combined role of local thermal ablation and transarterial-chemoembolization in cases of irresectable intrahepatic cholangiocarcinoma.

**Methods & Materials:** Retrospective analysis for 32 patients with CCC from Januar 2007 till December 2017, in which 11 males (34.4 %) and 21 (65.6 %) females with mean age 59.2 years (25-86) with either irresectable (22/32, 68.8%) or recurrent lesions (10/32, 31.3%) managed by at least three sessions of TACE (3-26, mean 9) with local thermal ablation for overall 73 lesions with mean size 21 mm (10-74) with either laser (9/73, 12.3%), radiofrequency (8/73, 11%) or microwave (56/73, 76.7%) devices. Follow

up using contrast enhanced MRI to evaluate local tumor control based on modified Response Evaluation Criteria for Solid Tumors (mRECIST) and the survival was evaluated using Kaplan-Meier method.

**Results:** The mean and median survival was 42.5 and 28 months (CI: 27.3-57.6 and 15.3-40.7 respectively). The initial local tumor response following 3 TACE was stable (10%), partial response (80%), progressive (10%) and complete remission (0%) and final effect was 13.3%, 16.7%, 63.3% and 6.7% respectively. Local lesion response following thermal ablation was complete resolution of the targeted lesion in 47/73 lesions (64.4%) and incomplete response at the rest. 6.2% (2/30) patients developed local complication following thermal ablation.

Significant correlation has been found between the size of the targeted lesion and the response with better results at diameter ranging from 10-50 mm. However no significant correlation was found between the device type and the ablation outcome.

**Conclusion:** Combined targeted local liver therapy has a potentiality to provide safe therapeutic option for irresectable or recurrent cholangiocarcinoma and may affect the overall patients' survival as well.

**Disclosure:** Nothing to disclose

## P0288 ENDOVASCULAR PRESSURE MEASUREMENTS TO ASSESS THE FUNCTIONAL SEVERITY OF MESENTERIC ARTERY STENOSIS IN PATIENTS SUSPECTED OF HAVING CHRONIC MESENTERIC ISCHEMIA

van Dijk L.<sup>1,2</sup>, Terlouw L.<sup>1,2</sup>, van Noord D.<sup>3</sup>, Bijdevaate D.C.<sup>2</sup>, Bruno M.J.<sup>1</sup>, Moelker A.<sup>2</sup>

<sup>1</sup>Erasmus MC - University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands, <sup>2</sup>Erasmus MC - University Medical Center, Radiology, Rotterdam, Netherlands, <sup>3</sup>Franciscus Gasthuis & Vlietland, Gastroenterology and Hepatology, Rotterdam, Netherlands

**Contact E-Mail Address:** l.terlouw@erasmusmc.nl

**Introduction:** Chronic mesenteric ischemia (CMI) is an invalidating disease causing severe complaints of postprandial abdominal pain and weight loss. CMI is most often caused by stenosis of one or more mesenteric arteries, a frequent finding in the general population with a prevalence rising to up to 67% in patients >80 years of age(1). The abundant collateral mesenteric circulation protects the bowel against ischemia, creating a diagnostic challenge since CMI only occurs when the collateral circulation is insufficient. Revascularization is performed after multidisciplinary group discussion amongst gastroenterologists, vascular surgeons and interventional radiologists of the patient's history, radiological imaging and result of a functional test. Treatment decisions are especially challenging in patients with a single vessel mesenteric stenosis, since 27% does not experience an improvement of symptoms after successful revascularization(2). An assessment of hemodynamic significance of a stenosis to determine clinical relevance and support treatment decision could be of great value in these patients. Endovascular pressure measurements to assess the severity and clinical relevance of a stenosis have been validated in coronary and renal arteries and are widely used to guide treatment decision in clinical practice(3,4). No conclusive data on clinical applicability of pressure measurements in the mesenteric arteries exist.

**Aims & Methods:** The aim of this single center, retrospective cohort study was to identify clinically significant mesenteric stenosis by correlating mesenteric pressure measurements with clinical success after stenting of the celiac artery (CA) or superior mesenteric artery (SMA). All consecutive patients planned for endovascular mesenteric artery treatment with pressure measurements between April 2015 and May 2017 were included. Pressure measurements were performed before and after intra-arterial administration of a vasodilator (nitroglycerin). For both series of measurements the pressure gradient over the stenosis and the pressure distal to the stenosis divided by the aortic pressure (Pd/Pa) were calculated. Clinical success was defined as an improvement of symptoms and or weight gain.

**Results:** In total 41 endovascular mesenteric procedures with pressure measurements were performed in 37 patients (mean age 67.7 $\pm$ 10.8 years, 62% female). The measured Pd/Pa without vasodilator in patients with an isolated CA or SMA stenosis or an inferior mesenteric artery and either CA or SMA stenosis (N=24), significantly differed between patients with clinical success after stenting (N=18), median 0.885 (IQR 0.735-0.904) versus patients without clinical success 0.923 (0.897-0.958),  $p=0.040$ . After administration of a vasodilator differences increased further with a Pd/Pa of 0.703 (0.598-0.769) in patients with clinical success and 0.827 (0.818-

0.906) in patients without,  $p=0.009$ . The pressure gradient showed similar differences, without vasodilator 17.5 (11.0-29.0) vs. 8.0 (4.0-15.0),  $p=0.047$  and after vasodilator 36.0 (21.0-40.0) vs. 20.0 (9.0-21.0),  $p=0.041$ . A Pd/Pa after vasodilator with a cut-off  $\leq 0.8$  proved to be the best predictor of clinical success with a sensitivity of 86% and specificity of 83% (AUC=0.869).

**Conclusion:** Endovascular pressure measurements seem a promising tool to assess the clinical relevance of mesenteric artery stenoses and hence may be helpful in making treatment decisions. Pressure measurements in a larger cohort are needed to verify the results of this study.

**Introduction:** Irreversible Electroporation (IRE) of the pancreas is an increasingly used method for unresectable pancreatic cancer that can be used in cytoreduction followed by surgical treatment and shows promising results in palliative care.

IRE is an ablative technique where electric pulses cause damage the cell membrane leading to apoptosis. It is claimed that IRE is not causing thermal effect comparing to radiofrequency and microwave ablation.

The early assessment of signal intensity changes after IRE could provide information on actual processes occurring in the ablation zone.

**Aims & Methods:** The study aims to assess the MR (Magnetic Resonance) images performed before and up to 7 days after IRE to evaluate the early post IRE changes in signal intensities in the ablation zone with a special emphasis on thermal effect and vascularization in the ablated zone.

We retrospectively analyzed the MRI studies of 24 patients (10 F, 14M, aged 35-71) with unresectable pancreatic cancer during or shortly after chemotherapy. IRE was performed under general anesthesia percutaneously or during open surgery with the use of 4-6 electrodes (AngioDynamics) placed in pairs at a maximum distance of 20mm between each other, 90 pulses of 90us (maximum 1500V/cm) were delivered per pair of electrodes. The MR images were performed on 1.5T and 3T scanners one day before IRE procedure, on the 1st and 7th day after. The standard protocol for pancreas was performed including T1-weighted images (T1W), T2-weighted images (T2W), Diffusion Weighted Images (DWI), ADC (Apparent Diffusion Coefficient) maps, Dynamic Contrast Enhancement (DCE) images with subtraction series. The qualitative and quantitative assessment of the obtained images was performed.

**Results:** The signal intensity in the ablated zone on T1 Fat Saturation (Fat-Sat) after contrast media administration with subtraction was in the range 0-6,25 (Mean 2,03, SD 1,83). The ADC values after IRE were significantly higher compared to pre IRE measurements. These trends were found likewise on different MR scanners (1,5, 3T).

The signs of thermal effect, e.g., areas of electrodes placement were found in 83,3% of patients. They were seen as small, hypointense zones close to electrodes on T1-weighted fat saturation contrasted enhanced images in the coronal plane.

**Conclusion:** Lower (close to zero) SI values in the ablated zones on T1 FatSat images after contrast media administration images with subtraction proves that vascular bed within the ablation zone was completely damaged. The

growth of ADC values after IRE is the effect of cellular water displacement to intercellular space what is a sign of cytolysis. IRE can create a thermal effect on exposed tissues.

**Contact E-Mail Address:** adagio@catholic.ac.kr

**Introduction:** The duodenal neuroendocrine tumors (dNETs) are arising from the cell of the mucosal layer and often small and confined to the superficial layer. Surgery and endoscopic resection are both considered appropriate; however, there are critical hurdles to both modalities in real practice. Laparoscopic surgery has a difficulty to determine precise tumor location, and endoscopic resection has high risks for bleeding, perforation, and incompleteness. In our study, we compared the treatment outcomes of endoscopic full-thickness resection assisted laparoscopic surgery (EFTRLS).

**Aims & Methods:** The electronic medical record database was reviewed at a university hospital (Yeouido St. Mary's Hospital), Seoul, Korea. A total of 33 patients were found to be diagnosed during the last 10 years, from June 2008 to Dec 2018.

**Results:** Among the 35 patients with dNETs, 12 were excluded, follow-up loss (3), transfer-out (2), treatment refusal (2), invisible after forceps biopsy (2), poorly differentiated histology (2), and the presence of metastatic lesion (1). Twenty-three patients who showed well-differentiated histology, less than 2 mitosis per 10 HPF and less than 3% of Ki-67 index, underwent excision of tumors. Sixteen were treated with endoscopic resection, 3 with surgery only and 4 with EFTRLS. Resection margin involvement was none in the EFTRLS group compare to other single modality groups (0% [0/4 cases] vs 19% [3/16 endoscopic resection] vs 33% [1/3 surgery only]). One endoscopically treated patient had a macroscopic residual tumor and needed additional surgery. Two patients of endoscopic resection group experienced perforation and underwent surgery. Tumor recurrence and metastasis were not reported during the study period in all patients.

**Conclusion:** EFTRLS provides a precise and secure safety margin of tumor resection and abolishes the risk of uncontrolled bleeding and perforation. EFTRLS has the advantage in the oncological completeness and patient safety over either endoscopic resection alone or surgery alone.

**Contact E-Mail Address:** rjwqrli@yahoo.com

**Introduction:** Achalasia (AC) is a clinically rare disease of lower esophageal inflammatory changes and myenteric plexus injury has been treated by medication, surgical and endoscopic methods. During the pathological process, the lower esophageal sphincter (LES) contracts, leading to food retention, and esophageal peristalsis, constriction and expansion. Clinical symptoms include dysphagia, food reflux, nausea, vomiting, chest pain,

and severe malnutrition. The drug and surgical treatments have many disadvantages such as, easy-to-relapse, high cost and complications, and the patient's intolerance. Contrary to the above-mentioned methods, the Peroral endoscopic myotomy (POEM), a new endoscopic treatment of AC has been affirmed with the short-term efficacy. However, there are few reports on long-term efficacy of POEM. The study aims to evaluate the short-term, medium- and long-term effects of POEM analyzing the clinical data of 59 patients with AC in the second hospital from 2012 to 2018.

#### Aims & Methods:

**Objective:** To explore the short-term and long-term clinical efficacy of peroral endoscopic myotomy (POEM) and its postoperative complications in the treatment of achalasia (AC).

**Methods:** The retrospective clinical study of 59 patients who underwent POEM was conducted from Jan. 2012–April 2018 in the Endoscopy Center of Lanzhou University Second Hospital. The short-term and long-term clinical efficacy, complications and changes in the clinical manifestations was comparatively analyzed according to the Eckardt scoring system before and after achalasia (AC) management by POEM.

**Results:** All the 59 patients underwent 100% successful POEM, in which the disorder duration ranges from 4–380 months. The follow-up times were 6–89 months, respectively. The pre-operative and post-operative Eckardt score was  $6.45 \pm 1.63$ ,  $0.52 \pm 0.56$  ( $P < 0.05$ ), respectively. The patients, who were follow-up 12 month, mean Eckardt score was 0.61. Post-operative weight gain was  $9.92 \pm 5.97$  kg. The post-operative complications were observed in 5 cases (8.4%) and 1 case (1.69%) was successfully treated conservatively, whereas 23 cases (38.9%) presented with gastro-esophageal reflux.

**Conclusion:** The short-term and long-term clinical efficacy of POEM is safe and effective in the treatment of achalasia (AC).

**Disclosure:** Nothing to disclose

## P0293 TREATMENT STRATEGY FOR LAPAROSCOPIC HIATAL HERNIA REPAIR

Yano E., Omura N., Tsuboi K., Hoshino M., Yamamoto S.R., Akimoto S., Masuda T., Fukushima N., Mitsumori N., Kashiwagi H., Yanaga K.  
*The Jikei University School of Medicine, Surgery, Tokyo, Japan*

**Contact E-Mail Address:** f-yano@jikei.ac.jp

**Introduction:** Based on the anatomy-function-pathology (AFP) classification, the recurrence rate of A2 and A3 hiatal hernia after laparoscopic fundoplication (LF) is higher than A1, a mesh is used to reinforce the esophageal hiatus.

**Aims & Methods:** The aim of this study is to report the surgical outcomes and treatment strategies in our institution. The subjects were 509 patients (mean age  $55.2 \pm 16.6$  years, 209 women) who underwent primary LF for hiatal hernia from January 1995 to November 2018. These patients were divided into the 3 groups by A factor of AFP classification (A1:A2:A3=285:148:76). We assessed the patients' background, pathological condition, surgical outcome, recurrence rate and changes in surgical procedure.

**Results:** The median age (years) of the patients in each group was A1:A2:A3=46:63:74 and the size of the hernia increased in proportion to the age ( $p < 0.001$ ). Female ratio was significantly higher in A3 ( $p < 0.001$ ). Preoperative reflux esophagitis was severe in A2 ( $p < 0.001$ ) and operation time (min) became longer by the hernia size (A1:A2:A3=135:165:191,  $p < 0.001$ ), but the amount of bleeding was minimum in each group ( $p = 0.753$ ). The incident rate (%) of intraoperative complications in A3 was significantly higher (A1:A2:A3=9:8:23,  $p = 0.005$ ). The recurrence rate of hiatal hernia after LF was 13% (68/509), and the recurrence rate (%) was increased by the hernia size (A1:A2:A3=12:18:24,  $p = 0.043$ ). Therefore, we introduced reinforcement of the hiatus using mesh since February 2011 for cases with A2 and A3, from 75 years old and above, BMI 28 or more. After that, the recurrence rate of A2 markedly decreased to 3% (1/37,  $p = 0.001$ ), but that of A3 was still high (8/34=24%) and no effect was obtained by mesh reinforcement ( $p = 1$ ).

**Conclusion:** Mesh reinforcement decreased the recurrence rate of A2 patient. Further improvement is necessary for A3 patients, and now the fixation of the anterior wall of the stomach and the abdominal wall is added.

**Disclosure:** Nothing to disclose

## P0294 A SINGLE CENTER EVALUATION ON IMPLEMENTATION OF SELECTIVE PATHOLOGIC EXAMINATION OF THE GALLBLADDER

Corten B.<sup>1</sup>, Leclercq W.K.G.<sup>1</sup>, Roumen R.M.H.<sup>1</sup>, van Zwam P.H.<sup>2</sup>, Slooter G.D.<sup>1</sup>

**Contact E-Mail Address:** bartcorten@gmail.com

**Introduction:** Historically, all gallbladders are sent for histopathologic examination following cholecystectomy to exclude presence of malignancy. Several hospitals switched to a selective histopathologic (Sel-HP) policy to reduce unnecessary pathological workload. Our aim was to evaluate the evolution of a Sel-HP policy and determine safety and cost reduction.

**Aims & Methods:** A single center retrospective study was conducted from January 2012 to December 2017 in a teaching hospital in the Netherlands. All gallbladders were macroscopically examined by the surgeon or resident. Consequently, they decided which cases required additional histopathologic evaluation. We reviewed the number of gallbladders sent for pathologic examination. To identify missed GBC we reviewed the Netherlands Comprehensive Cancer Organisation (IKNL) registry to detect GBC in patients of whom the gallbladder was not sent for histopathology.

**Results:** Out of the 2271 patients, 1083 (47.7%) were selected for additional histopathology to assess the presence of malignancy. Percentage of gallbladders selected for histopathologic examination decreased from 83% in the first year to 38% in the last year. Six (0.26%) gallbladder cancers (GBC) were discovered, 7 times (0.31%) a low grade dysplasia and 3 times (0.13%) an intestinal metaplasia of the gallbladder. During follow-up, no patient was found to have GBC recurrence after Sel-HP. Our policy implementation reduced medical cost and saved over €65 000.

**Conclusion:** The strategy of a Sel-HP policy decreased the number of referred gallbladders to the department of pathology by roughly 60%, while no GBC cases were missed and therefore appears to be safe and leads to significant cost reduction.

**Introduction:** Pancreatoduodenectomy is a high-risk surgical procedure, after which one complication may provoke a sequence of adverse outcomes. To improve quality of care after pancreatoduodenectomy, initiatives are required to mitigate the impact of separate complications. To allow prioritization of such initiatives, the aim of this study was to quantify the attribution of individual complications to postoperative mortality, organ failure, prolonged hospital stay and unplanned readmissions after pancreatoduodenectomy in a national cohort.

**Aims & Methods:** Data from all consecutive patients undergoing pancreatoduodenectomy from January 2014 to December 2017 were extracted from the mandatory nationwide Dutch Pancreatic Cancer Audit.

Using a modified Poisson regression model, adjusted risk ratios were calculated for the association of each of the individual complications (i.e. postoperative pancreatic fistula, postpancreatectomy hemorrhage, bile leakage, delayed gastric emptying, wound infection and pneumonia) with each of the study outcomes (i.e. in-hospital mortality, organ failure, prolonged hospital stay and unplanned readmission). Complications were defined according to the International Study Group of Pancreatic Surgery. Prolonged hospital stay was defined as exceeding the 75<sup>th</sup> percentile in this cohort (i.e. longer than 18 days).

Risk adjusted population attributable fractions (PAF) were calculated for each complication-outcome pair while adjusting for patient- and treatment related factors and the presence of other complications in individual patients. The PAF represents the percentage of an outcome that could be prevented in a theoretical scenario where a specific complication would be eliminated completely and is therefore particularly useful in prioritizing quality improvement initiatives.

**Results:** Overall, 2620 patients were analyzed. A total of 1672 patients (63.8%) experienced complications after pancreatoduodenectomy, leading to an in-hospital mortality of 3.6% (95 patients), organ failure in 7.6% (198 patients), and an unplanned readmission of 16.2% (427 patients). Post-operative pancreatic fistula and postpancreatectomy hemorrhage had the greatest independent impact on both mortality and organ failure. Complete elimination of these complications would lead to a 25.7% [95% CI 13.4-37.9%] and 32.8% [95% CI 21.9-43.8%] decrease in mortality and a 21.8% [95% CI 12.9-30.6%] and 22.1% [95% CI 15.0-29.1%] decrease in organ failure, respectively. Delayed gastric emptying had the greatest independent impact on prolonged hospital stay (risk adjusted PAF 27.6% [23.5-31.8%]).

The reasons of unplanned readmission remained largely unexplained in this analysis. The impact of other evaluated complications on the study outcomes was relatively small.

**Conclusion:** Interventions to improve clinical outcome after pancreatic resection may have the greatest effect when focused on prevention and treatment of postoperative pancreatic fistula and postpancreatectomy hemorrhage, because these complications have the most impact on both mortality and organ failure. To reduce prolonged hospital stay, initiatives to decrease delayed gastric emptying should be explored.

**Introduction:** A way to avoid the delay of surgery for patients with acute cholecystitis is to perform laparoscopic cholecystectomy 24/7. Existing data on the safety of out-of-hours operations are conflicting and large studies regarding this are few.

**Aims & Methods:** The aim of this study was to investigate if out-of-hours laparoscopic cholecystectomy is associated with a higher rate of complications.

We used the Swedish Registry of Gallstone Surgery and Endoscopic Retrograde Cholangiopancreatography (GallRiks). Data from patients registered for laparoscopic cholecystectomy due to acute cholecystitis, between 2006-2017 was collected. Out-of-hours surgery was defined as starting 7 pm - 7 am on weekdays or any time during weekends (Friday 7 pm - Monday 7 am). A multivariate logistic regression analysis was performed to assess the risk of complications, with time of procedure as independent variable.

We also analyzed the rate of conversion to open surgery and rate of procedures exceeding 120 minutes. Adjustments were made for sex, age, BMI and ASA score.

**Results:** Altogether 13165 procedures were included in the analysis. The adjusted Odds Ratio (OR) for complications, comparing the out-of-hours procedures compared to daytime surgery, was 1.14 (95% CI 1.01-1.27, p=0.03). OR for conversion to open surgery was 2.07 (1.89-2.27, p< 0.001) and OR for operative time exceeding 120 minutes was 0.50 (0.46-0.54, p< 0.001).

**Conclusion:** We found a small increased risk of per-/postoperative complications comparing out-of-hours surgery to daytime surgery. The conversion rate was significantly higher in the out-of-hours group. The operative time was significantly lower when surgery was performed out-of-hours.

<sup>2</sup>Universidad Industrial de Santander, Bucaramanga, Colombia

**Contact E-Mail Address:** caroline\_aqc@hotmail.com

**Introduction:** Prolonged postoperative ileus (PPOI) represents a frequent complication following colorectal surgery, affecting approximately 10%-15% of these patients(1).

**Aims & Methods:** This systematic review and meta-analysis aimed to evaluate the perioperative risk factors for PPOI.

Study conducted in accordance with the PRISMA Statement. Pubmed, Embase, Scielo and LILACS databases were searched from inception to November 2018 for studies that evaluated primary clinical data regarding the analysis of risk factors for PPOI after colorectal surgery. Heterogeneity was assessed with the I<sup>2</sup> measure of inconsistency. The Newcastle-Ottawa scale was used for bias assessment within studies, and the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach was used for quality assessment of evidence on outcome levels. According to the AMSTAR 2 tool, this meta-analysis was ranked with a high methodological quality.

**Results:** Fifty-six studies were included, of which forty-two were assessed in the meta-analysis, comprising a total of 131,034 patients that underwent colorectal surgery from 1997 to 2017. From these, 25838 (19.71%) developed PPOI. Significant risk factors for PPOI development were male sex (OR 1.56;95%CI 1.25-1.94), age (MD 3.17;95%CI 1.63-4.71), cardiac comorbidities (OR 1.65;95%CI 1.24-2.20), previous abdominal surgery (OR 1.44; 95%CI 1.19, 1.75) and open approach (OR 2.47;95%CI 1.77-3.44). Included studies evidenced a moderate heterogeneity. The quality of evidence was regarded as low-moderate according to the GRADE approach.

**Conclusion:** Multiple factors as demographic characteristics, past medical history and type of approach can increase the risk of developing PPOI in colorectal surgery patients. The knowledge of these will allow a more accurate assessment of PPOI risk in order to take measures to decrease its impact in this population.

## P0298 THE "TIME-OF-DAY" EFFECT ON 30-DAY MORTALITY FOR ELECTIVE ABDOMINAL SURGERY

Lee J.<sup>1</sup>, Kim M.H.<sup>1</sup>, Kim D.-R.<sup>2</sup>, Suh B.<sup>3</sup>, Oh H.-K.<sup>1</sup>

<sup>1</sup>Seoul National University Bundang Hospital, Department of Surgery, Seongnam, Korea (Republic of), <sup>2</sup>Seoul National University College of Medicine, Seoul, Korea (Republic of), <sup>3</sup>Seoul National University Graduate School of Convergence Science and Technology, Department of Transdisciplinary Studies, Seoul, Korea (Republic of)

**Contact E-Mail Address:** pippi0531@naver.com

**Introduction:** Emphasis on systematic approaches to patient safety has led to many studies demonstrating worse outcomes in the absence of supporting staff, especially during the night. This so called "time-of-day" effect has shown conflicting results based on the hospital setting, type of surgery, supporting system, or country studied.

**Aims & Methods:** The purpose of this study was to investigate the time-of-day effect on 30-day mortality for elective abdominal surgery patients in a tertiary care center. All patients receiving elective abdominal surgery between May 2003 and Feb. 2018 at Seoul National University Bundang Hospital were included in the study. Patients were evaluated by the starting time of the surgery received and grouped into first- surgery and non-first-surgery. To reduce the effects of confounding variables an inverse

probability treatment weighting (IPTW) propensity score analysis was done utilizing 51 variables. These variables included baseline characteristics (age, BMI, ASA class, residential and education status, alcohol and smoking status), baseline vital signs and lab results (blood pressure, pulse rate, body temperature, blood cell count, liver function tests, electrolyte tests), surgery type (minimal invasive surgery, cancer vs. non-cancer operation, anesthesia type), whether the patient underwent post-operative ICU care, and operation year. The primary outcome was 30-day mortality.

**Results:** Out of a total of 66,606 patients receiving abdominal surgery, 58,649 (88.1%) were elective procedures. There was a total of 110 (0.19%) 30-day mortalities (first-surgery: 20/15,285, 0.13%; non-first-surgery: 90/43,364, 0.21%). There were more cancer surgeries in the first-surgery group, and the patients were of older age and higher ASA class. The two groups were well rounded in the IPTW adjusted population. Undergoing first-surgery was found to be protective against 30-day mortality (Relative risk (first vs. non-first) = 0.58 95%CI[0.35-0.96], P = 0.033). In the numbers-needed-to-treat analysis, the calculated absolute difference was 0.088% and translated to 1 additional mortality for every 1,142 patients treated.

**Conclusion:** Receiving the first surgery may be protective for 30-day mortality in elective abdominal surgeries. Further large-scale population studies are needed to evaluate these findings.

**Disclosure:** Nothing to disclose

## P0299 CLINICAL IMPACT OF BACTERIAL CONTAMINATION OF INTRA-ABDOMINAL DISCHARGE ON THE INCIDENCE OF PANCREATIC FISTULA AFTER PANCREATODUODENECTOMY

Yamashita K., Kato D., Sasaki T., Ishii F., Okada H., Hirano Y., Hayashi T., Yamada T., Hasegawa S.

Fukuoka University Faculty of Medicine, Department of Gastroenterological Surgery, Fukuoka, Japan

**Contact E-Mail Address:** kanefumio519@yahoo.co.jp

**Introduction:** Pancreatoduodenectomy (PD) is one of the most technically demanding operations, and thus, a challenge for surgeons. Postoperative pancreatic fistula (POPF) is the most severe postoperative complication of pancreatic surgery, and is recorded in 6-16% of patients. Some studies have shown that bacterial contamination in abdominal discharge is associated with the development of pancreatic fistula after PD. Moreover, we previously found that retrograde infections can be prevented and the incidence and severity of pancreatic fistulae reduced by using a closed drainage system following PD [1]. In another study, we showed that infection with *Pseudomonas aeruginosa* during the perioperative period in PD activates pancreatic juice secretion and induces the progression of pancreatic fistulae to higher grade fistulae [2]. However, thus far, the clinical relationship between POPF and the bacterial strain involved remains unclear. Therefore, this study was performed to assess the relationship between POPF following PD and the bacterial strain involved in a clinical setting.

**Aims & Methods:** The data for 82 consecutive patients who had undergone PD at Fukuoka University Hospital between January 2009 and July 2014 were retrospectively analysed to review patient characteristics and perioperative and postoperative parameters. We compared the clinicopathologic features between patients with bacterial contamination of drainage fluid and those without bacterial contamination of drainage fluid. We also examined the relationship between POPF and bacterial contamination of drainage fluid, according to bacterial strain.

**Results:** In total, 82 patients who underwent PD were divided into 2 groups: 57 patients to the bacterial contamination negative group and 25 patients to the bacterial contamination positive group. The incidence of preoperative cholangitis was significantly higher in the bacterial contamination positive group ( $p=0.014$ ). The incidence of Grade B/C POPF was significantly higher in the bacterial contamination positive group than in the bacterial contamination negative group (44.0% vs. 0.0%;  $p<0.001$ ). Soft gland texture and bacterial contamination of intra-abdominal discharge were found to be risk factors for POPF (odds ratio: 9.00; odds ratio: 43.94, respectively). The incidence of Grade B/C POPF was significantly higher in patients harbouring *Pseudomonas aeruginosa* than in patients harbouring bacteria other than *Pseudomonas aeruginosa* ( $p=0.005$ ).

**Conclusion:** Our findings suggest that bacterial contamination of intra-abdominal discharge plays an important role in the risk for the development of pancreatic fistulae. Therefore, bacterial infection control is very important in the perioperative PD period. Herein, all cases involving *Pseu-*

*domonas aeruginosa* isolation progressed to POPF. These results suggest that *Pseudomonas aeruginosa* is related to POPFs. The results are consistent with our previous vitro research [2]. Therefore, such cases should be handled with extreme caution.

## P0300 ENDOSCOPIC VACUUM THERAPY (EVT) FOR TREATMENT OF ANASTOMOTIC DEHISCENCE AFTER COLORECTAL SURGERY

Milluzzo S.M.<sup>1,2</sup>, Lovera M.<sup>1</sup>, Cesaro P.<sup>1</sup>, Olivari N.<sup>1</sup>, Bizzotto A.<sup>1</sup>, Spada C.<sup>1,3</sup>

<sup>1</sup>Fondazione Poliambulanza Istituto Ospedaliero, Department of Medicine, Gastroenterology and Endoscopy, Brescia, Italy, <sup>2</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS - Università Cattolica del Sacro Cuore, Department of Gastroenterology, Rome, Italy, <sup>3</sup>Catholic University Rome, Digestive Endoscopy Unit, Rome, Italy

**Contact E-Mail Address:** sebastian.m.milluzzo@gmail.com

**Introduction:** Management of anastomotic dehiscence after colorectal surgery is a severe complication. EVT (Endoscopic Vacuum Therapy) is a promising therapeutic approach, being able to reduce both morbidity and mortality.

**Aims & Methods:** The primary endpoint of this series was to analyze efficacy and feasibility of EVT in the management of anastomotic leakage after colorectal surgery. This is a prospective single center study evaluating consecutive patients referred for EVT for anastomotic dehiscence. Patients were excluded in case of small cavity (i.e. < 1 cm) or circumferential anastomotic defect. All patients were treated with the same EVT. A preliminary endoscopic evaluation was performed in order to define size and shape of dehiscence. Then, the sponge was modeled to fit the cavity and advanced through a 12 mm overtube into the dehiscence. After removal of the overtube, the sponge was connected to a suction bottle at a 150 mmHg negative vacuum. After a mean 3-days interval, the sponge was removed and replaced until healing process was achieved (i.e. cavity < 1 cm covered by granulating tissue). In order to maintain the healing process, further endoscopic curettages were performed until full resolution of the cavity (disappearance of anastomotic leakage at endoscopy). Treatment failure was defined as persistence of cavity during follow up and/or no sign of tissue granulation and/or infection signs. Procedures were performed under conscious sedation, according to our internal safety protocol and ASA score. All patients signed the informed consent.

**Results:** 14 patients with low colorectal anastomosis dehiscence were evaluated between October 2017 and April 2019: 2 were excluded (< 1 cm defect) and treated with pig tail drainage. 12 patients (M=11; F=1) (median age of 70 y.o. - R 40-86) were included. Indications for EVT were Hartmann's stump insufficiency (n=6), anastomotic leakage after Laparoscopic Total Mesorectal Excision (Lap-TME) (n=3) and anastomotic dehiscence after Trans-anal Total Mesorectal Excision (TaTME) (n=3). A total of 169 sponges were placed in 12 patients with a median number of 12.5 (R 4-31) per patient. Overall, full resolution was achieved in 6 patients in a median time of 97 days (range, 15-160). 4 patients had an initial healing process followed by a subsequent deterioration requiring EVT reinsertion: 1 patient finally had a full resolution of the cavity, a treatment failure was observed in 1, while the remaining 2 patients died during EVT for neoplastic progression (n=1) and septic complications (n=1). The remaining 2 patients had a treatment failure. No EVT-related complications were observed.

**Conclusion:** EVT seems to be a feasible and safe treatment with a high success rate in patients with large colorectal anastomotic dehiscence. It represents a minimally invasive alternative to surgical re-treatment.

**Disclosure:** Nothing to disclose

## P0301 ENDOSCOPIC MANAGEMENT OF BARIATRIC SURGERY COMPLICATIONS: LONG-TERM RESULTS OF 830 CONSECUTIVE PATIENTS IN A SINGLE CENTER EXPERIENCE

**Introduction:** Surgery is the gold standard treatment of morbid obesity and its related co-morbidities. However early or late surgical related adverse events(AE) occurs in 4 to 25% of patients requiring, in most cases, re-interventions. Endoscopy is an effective treatment especially if it is performed soon after occurrence of AE. However a comprehensive evaluation of long-term results and need for revisional surgery after endoscopic management is lacking.

**Aims & Methods:** The aim of this study is to report overall results and long-term outcomes of patients underwent to endoscopic management for AE following bariatric surgery in a tertiary interventional endoscopic center. From January 2013 to April 2019, 830 consecutive patients(640F), average age 44(17 - 72), underwent upper GI endoscopy for suspected AE following obesity surgery.

651 patients underwent Sleeve Gastrectomy, 167 gastric-by-pass(98 Roux-en-Y and 69 Omega)(GBP)and 12 had lap-band. 168 patients presented an AE after revisional bariatric surgery.

358 patients were addressed for sepsis due to supposed leak(extravasation of medium contrast).

226 patients presented dysphagia due to GI stenosis.

201 subjects presented fistula(abnormal communication between two re-epithelized structures or skin due to previous placement of surgical drainage).

28 patients had a perigastric intra-abdominal collection.

12 patients had partial intragastric migration of gastric band.

5 presented weight regain following GBP for enlargement of G-J anastomosis. Endoscopic management according to the different type of AE were one or an association of the following: endoscopic internal drainage, septotomy, stenting with Lumen apposed metal stent, Argon plasma coagulation(APC) anastomotic remodeling and trans-oral lap band ablation.

Clinical success was defined as follows: leak and fistula: no medium contrast extravasation, no chemistry tests alterations no need for prolonged antibiotics therapy. Stricture: adequate passage of medium contrast at swallow study or easy crossing of the stricture with a standard gastro-scope. Lap band migration:uneventful removal. Loss of excess weight after G-J anastomotic remodeling with APC. Long term clinical success was considered after a minimum follow up of more than 18 months.

**Results:** 89 patients underwent endoscopy after one week from index surgery( $5.13 \pm 1.92$ days), 451 between 8 and 42days( $19.63 \pm 9.17$ ), 93 patients between 43 and 91days( $60.34 \pm 13.07$ ) and 197 after more than 91days( $854.93 \pm 1170.37$ ). Overall mean period was of 223days(0-2100) from index surgery.

70 patients(8.4%) presented normal findings at upper endoscopy.

An average of 6 endoscopic sessions(1-31) were needed to achieve AE resolution in 72%(598) of patients. At long follow up (more than 18 months) 16%(96 out 598) of patients healed were lost whereas. 8%(66) are still under treatment.

Overall mortality was of 0,6%(5 out 830) whereas overall AE related to endoscopic treatment was of 2%(15)namely bleeding, stent migration with/ or perforation. 3 patients with perforation required emergency surgery.

11.%(91 patients) underwent revisional surgery either for endoscopic treatment failure or poor quality of life after an average of 331days(15 - 1400).

**Conclusion:** According to this large case series endoscopy plays a pivotal role in the management of AE following bariatric surgery guaranteeing good results with low morbidity and mortality rates avoiding emergency surgery in 65% of cases. However several endoscopic sessions are needed. Long-term follow up showed that 11% of patients require, revisional surgery, either in case of endoscopic clinical success.

**Introduction:** Hybrid minimally invasive esophagectomy (HMIE) has been shown to reduce major postoperative complications compared with open esophagectomy (OE) for esophageal cancer.

**Aims & Methods:** The aim of this study was to compare short- and long-term health-related quality-of-life (HRQOL) following HMIE and OE within a randomized controlled trial.

We performed a multicentre, open-label, randomised controlled trial at 13 study centres between 2009 and 2012. Patients aged 18-75 years old with resectable cancers of the middle or lower third of the oesophagus were randomized to undergo either transthoracic OE or HMIE. Patients were followed-up every six months for three years postoperatively and global health assessed with EORTC-QLQ-C30 and esophageal symptoms assessed with EORTC-OES18.

**Results:** The short-term reduction in global HRQOL at 30-days specifically role functioning (-33.33 (HMIE) vs. -46.3 (OE);  $P=0.0407$ ) and social functioning (-16.88 (HMIE) vs. -35.74 (OE);  $P=0.0003$ ) was less substantial in the HMIE group. At two years, social functioning had improved following HMIE to beyond baseline (+5.37) but remained reduced in the OE group (-8.33) ( $P=0.0303$ ). At two years, increases in pain were similarly reduced in the HMIE compared with the OE group (+6.94 (HMIE) vs. +14.05 (OE);  $P=0.018$ ). However at three-years there were no statistical significant differences between treatment groups in changes from baseline HRQOL.

**Conclusion:** HMIE reduces the short-term adverse effects upon global health from esophagectomy compared to an open approach, with some persistence of these improvements up to two years. This HRQOL effect may be mediated by a reduction in postoperative complications following HMIE.

**Disclosure:** Nothing to disclose

## P0303 WITHDRAWN

## P0304 FIVE YEAR AUDIT OF ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) IN DAILY CLINICAL PRACTICE

Pytlík D.<sup>1</sup>, Netzer P.<sup>1,2</sup>

<sup>1</sup>GastroZentrum Netzer AG, Bern, Switzerland, <sup>2</sup>Lindenhofspital, Bern, Switzerland

**Contact E-Mail Address:** domip@students.unibe.ch

**Introduction:** ESD provides a modern endoscopic resection technique with a high rate of en bloc resections for lesions in the upper and lower gastrointestinal tract (GIT). It is recommended for high grade dysplasia (HGD) or superficial early cancer and other lesions with a diameter > 10 mm where common snare resection is difficult to perform.

**Aims & Methods:** Our aim was to report our experience and results of ESD in the GIT in daily clinical practice over a five year period in a Swiss private hospital. Therefore we retrospectively analysed 302 ESD cases (cs) of 268 patients (pts) that have had at least one ESD resection. All ESD were performed by one experienced endoscopist (PN).

**Results:** In the last 5 years 302 ESD in 268 pts were performed and now analysed (136 f, mean age 64.4). Further surgery after ESD was needed in 27 cs (9%). Of these, 19 cs (6.3%) were ESD-related: 15 (5%) ESD were not

completed due to technical problems (missing lifting sign, difficult anatomical situations, difficult pts conditions), 4 due to severe adverse event (SAE). 8 (2.6%) were not ESD-related: 6 due to unfavourable histology, 2 recurrences. Major SAE occurred in 15 cs (5%) and consisted of perforation (9 cs, 3%), delayed bleeding (4 cs 1.3%) or infection (2 cs, 0.7%). From the further analysis 18 (6%) cs with a not completed ESD were excluded.

Of these 18, 13 had subsequent surgical resections, 2 had a second ESD in the follow up and 2 snare resections were performed. 1 needed no further resection.

The definitive study population consisted of the remaining 284 ESD-cs in 254 pts. The median lesion size was 3 cm (0.8-8), median intervention time was 14 min (5-111).

Follow-up was performed according to current guidelines and took place between 1 and 59 months after ESD. So far, local recurrence was found in 11 cs (3.9%).

Esophagus: 23 ESD (8%) were performed (1x surgery due to unfavourable histology (histo)): 2 showed an adenocarcinoma. 9 showed Barret's mucosa, of which 6 had HGD. 2 showed superficial squamous cell carcinoma pT1a. In 10 other benign lesions were found.

Stomach: 76 ESD (27%) were performed (3x surgery: 1 due to unfavourable histo, 1 delayed perforation, 1 recurrence). 4 GIST. 11 hyperplastic polyps. 11 ectopic pancreatic tissue (1 combined with a hamartoma). 7 inflammatory fibroid polyps (Van Eek's Tumour). 3 NET. 1 solitary nodal malign lymphoma. 39 other benign lesions.

Duodenum: 14 ESD (5%) were performed (no further surgery). 4 adenoma, of which 1 with HGD. 1 NET. 1 Peutz-Jeghers Polyp. 8 other benign lesions. Colon above sigmoid: 79 ESD (28%) were performed (4x surgery: 2 due to delayed perforation, 1 unfavourable histo, 1 technical reasons). 1 had no histo (lost). 68 showed adenoma, of which 3 with HGD. 10 other benign lesions.

Sigma: 23 ESD (8%) were performed (1x surgery due to delayed perforation). 1 adenocarcinoma pT1 which was successfully treated by ESD. 21 adenoma, of which 6 with HGD. 1 retention "juvenile" polyp.

Rectum: 69 ESD (24% of all ESD) were performed, (4x surgery: 3 due to unfavourable histo, 1 due to recurrence). 5 showed adenocarcinoma. 1 showed squamous cell dysplasia AIN III. 48 adenoma, of which 19 showed HGD. 15 other benign lesions.

**Conclusion:** ESD is a safe technique in daily clinical practice if performed by experienced endoscopists. With a high rate of successfully treated HGD and carcinoma it appears to be a favourable choice of treatment for such lesions.

**Disclosure:** Nothing to disclose

## P0305 A CASE-MATCHED STUDY ON EUS-GUIDED DRAINAGE OF WALLED-OFF NECROSIS USING 20MM VS 15MM LUMEN APPOSING METAL STENTS: IS BIGGER BETTER?

**Introduction:** EUS-guided placement of lumen apposing metal stents (LAMS) for the drainage of walled-off necrosis (WON) has gained popularity due to ease of placement, wide bore and anti-migration properties. Traditionally, the 10mm and 15mm diameter LAMS have been used. The 20mm diameter LAMS was recently introduced and provides 300% and 78% greater cross-sectional area as compared to the 10mm and 15mm stents, respectively. Therefore, it is plausible that the 20mm stent may result in improved efficacy. Nonetheless, the larger flanges may theoretically increase risk of adverse events (AEs) (e.g. bleeding). It is currently unknown how the 20mm and 15mm LAMS compare in terms of efficacy and safety.

**Aims & Methods:** To compare the 15 mm and 20 mm LAMS for the treatment of symptomatic WON in terms of technical success, clinical success and AEs. This was a retrospective comparative study at 21 centers (16 US, 4 Europe, 1 South America) between 04/14 and 10/18. Adult patients with WON who underwent EUS-guided drainage with 15 mm or 20 mm LAMS were identified. Patients with 20mm LAMS were matched to those with 15mm LAMS by age, gender, and route of LAMS insertion (trans-gastric vs trans-duodenal) with a ratio of 1:2. Univariable analysis was performed to compare technical success, clinical success and AE rates between the two groups.

**Results:** A total of 306 patients (31% F; mean age 55.1 yr) underwent EUS-guided WON (mean size 107mm) drainage (204 with 15 mm LAMS; 102 with 20 mm LAMS). The most common etiology of WON was gallstone pancreatitis (39.2%), most common indication for drainage was abdominal pain (54.9%), and most common location was pancreas body (53.9%). Baseline characteristics of patients and WON in both groups were equivalent. The technical success of LAMS placement of the 15mm and 20mm stents were similar (100%). At 6-month follow-up, the rate of clinical success with resolution of WON was similar in the two groups (92.1% vs 91.6%;  $p=0.85$ ). The mean number of endoscopic necrosectomy sessions required for WON resolution was lower in the 20mm LAMS group compared with the 15mm LAMS group (0.8% vs 1.5%,  $p < 0.001$ ). The need for additional intervention for WON resolution, including nasocystic drainage and percutaneous drainage, was not significantly different (Table 1).

A total of 31 (15.2%) AEs events developed in patients with 15mm LAMS and 22 (21.6%) AEs developed patients with 20mm LAMS (mild AE 2% vs 2%, moderate AE 13.2% vs 17.6%,  $p=0.30$ , severe AE 0% vs 2%;  $p=0.11$ , 15 mm and 20 mm, respectively) and were comparable without significant difference (3.4% vs. 4.9% with bleeding, 1.5% vs. 1% with infection, 4.4% vs. 4.9% with stent occlusion; 6.4% vs. 6.9% with stent migration;  $p=0.61$ ).

**Conclusion:** The 20mm LAMS carries similar efficacy and safety profile to the 15mm stent, while requiring significantly less necrosectomy sessions.

	Total (N=306)	20 mm LAMS (N=102)	15 mm LAMS (N=204)	p-value
Technical Success, n (%)	306 (100)	102 (100)	204 (100)	
Clinical Success, n (%)	281 (91.8)	94 (92.1)	187 (91.6)	0.85
Total number of direct endoscopic necrosectomy	1.8 (8.2)	1.3 (0.8)	2.1 (1.5)	<0.001
WON recurrence requiring intervention, n(%)	25 (8.2)	8 (7.9)	17 (8.4)	0.22
Surgical necrosectomy	1 (0.3)	1(0.9)	0	0.24
Endoscopic stent placement	18 (5.8)	6 (5.8)	12 (5.8)	0
Percutaneous catheter placement	6 (1.9)	1 (0.9)	5 (2.4)	0.38
Length of hospital stay (days), mean (SD)	12.5 (25)	15.4 (27.6)	10.9 (23.2)	0.13
Follow-up duration	5.8	2.7 (SD, 2.6)	7.3 (SD 9.5)	<0.001

[Clinical Outcomes of WON drainage using 20mm LAMS vs 15mm LAMS]

**Introduction:** Pancreatic duct sphincterotomy, a technique referred also as transpancreatic pre-cut sphincterotomy, has been used to access difficult cannulation of CBD with an immediate success rate of 60-90%.<sup>1</sup> The aim of this study is to present a single center's experience of such technique along with its success rate, indications and identified complications.

**Aims & Methods:** Eighty three patients who underwent endoscopic retrograde cholangiopancreatography using pancreatic duct sphincterotomy technique to access the CBD was retrieved from the endoscopy unit's patient's record from January 2014 to December 2018. Only 72 were retrospectively analyzed due to the unavailability of charts. Pancreatic duct sphincterotomy was used on cannulations that were deemed difficult and when initial standard technique failed.

**Results:** The success rate of CBD cannulation was 96.4%, while failed access to CBD was only 3.6%. A periampullary diverticulum, an anatomic obstacle to sphincterotomy, was noted among 27% of successfully cannulated patients. Procedure-related complications was 18% in which bleeding (mild: 2.7%, moderate:4.1%) and pancreatitis (mild:8.3%, moderate:4.2%) were the only ones identified while 81.9% did not have any complications.

**Conclusion:** Pancreatic duct sphincterotomy is an effective technique for difficult bile duct cannulation with minimal mild to moderate bleeding and pancreatitis as the only procedure-related complication.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** 1031294787@qq.com

**Introduction:** The IBD includes Crohn's disease (CD) and ulcerative colitis (UC). The common characteristic of IBD is chronic relapsing of inflammation of the gastrointestinal tract. It is thought that IBD results from an aberrant and continuing immune response to the microbes in the gut, catalyzed by the genetic susceptibility of the individual. 2,4,6-trinitrobenzene sulfonic acid (TNBS) is known to induce inflammation through triggering the MAPK/NF-KB pathway and activation of T helper cells. Recently, sacral nerve stimulation (SNS) was reported to exert an anti-inflammatory effect on TNBS-induced colitis.

The aim of this study was to investigate whether the SNS anti-inflammatory effect was mediated via the MAPK/NF-KB signaling pathway and/or balancing Th1/Th17-Treg cells. Meanwhile, we also explored if SNS could alter self-renewal of neurons in myenteric plexus.

**Aims & Methods:** Forty male Sprague-Dawley (SD) rats were implanted wire electrodes unilaterally at sacral nerve (S3). One week later, the rats were administered with TNBS intra-rectally. Five days later, 20 of the rats were treated with SNS 1 hour daily for 10 days with the optimized parameters derived from previous studies and the other 20 rats were treated with sham-SNS (exactly the same setting but SNS at 0mA). Additional 20 rats were treated with intra-rectal injection of saline, serving as controls. Animal behaviors and various inflammatory factors were assessed by the disease activity index (DAI), macroscopic score, microscopic score, fluorescence-activated cell sorter and western blot. Longitudinal muscle myenteric plexus (LMMP) was studied by immunohistochemistry.

**Results:** 1) Compared with saline group, the TNBS treatment substantially induced inflammation, increased the percentage of Th1 cells (4.71% ± 1.18% vs. 8.87% ± 2.32%,  $P=0.03$ ), Th17 cells (8.78% ± 1.95% vs. 12.35% ± 1.61%,  $P=0.02$ ) and Treg cells (10.15% ± 3.57% vs. 15.73% ± 2.81%,  $P=0.04$ ); it also increased p-ERK/ERK by 3.3 folds ( $P<0.01$ ) and p-JNK/JNK by 21.7 folds ( $P<0.001$ ) and increased nuclear translation of NF-KB p65 by 4.5 folds ( $P<0.01$ ); 2) compared to sham-SNS, SNS significantly decreased DAI (area under the curve: 64.3 ± 3.8 vs. 49.5 ± 3.2,  $P<0.01$ ), microscopic scores (4.6 ± 1.1 vs. 2.7 ± 0.8,  $P=0.04$ ) and macroscopic scores (5.85 ± 0.9 vs. 2.55 ± 0.6,  $P=0.03$ ) and normalized the colon length (16.05 ± 1.6 cm vs. 14.33 ± 1.3 cm,  $P<0.05$ ); 3) in colon tissues, compared with sham-SNS, SNS reduced the percentage of Th1 cells (8.87 ± 2.32% to 5.40 ± 1.39%,  $P=0.04$ ) and Th17 cells (12.35 ± 1.61% to 9.75 ± 1.17%,  $P=0.04$ ) but increased Treg cells (15.73 ± 2.81% to 20.15 ± 2.24%,  $P=0.03$ ); 4) SNS reduced the percentage of the phosphorylation of MAPKs compared to Sham-SNS (p-ERK/ERK: 22.5%,  $P=0.03$ ; p-JNK/JNK: 25.6%,  $P=0.04$ ) and prevented the nuclear translocation of NF-KB p65 by 41.7% ( $P=0.02$ , vs. sham-SNS); 5) the percentage of choline acetyltransferase (ChAT) neurons were decreased by TNBS but reversed by SNS (19.06 ± 2.07% to 25.68 ± 3.56%,  $P=0.02$ ). The percentage of

nitric oxide synthase (NOS) neurons was increased by TNBS but decreased by SNS ( $17.21 \pm 1.27\%$  to  $13.34 \pm 1.63\%$ ,  $P=0.03$ ).

**Conclusion:** SNS is effective in inhibiting colon inflammation through the inhibition of the MAPK/NF- $\kappa$ B pathway, balancing of Th1/Th17-Treg cells, and also improving the LMMP neuronal self-renewal and regeneration.

**Introduction:** A herbal medicine, berberine (BBR), which is used as an anti-diarrhea medicine in Japan, is known as an AMPK activator to show various kinds of action such as diabetes control and anti-tumor response. Recently, BBR has been reported to elicit anti-inflammatory response of CD4<sup>+</sup>T cells resulting in improvement of experimental chronic inflammatory diseases such as multiple sclerosis and may be of potential therapeutic utility in the treatment of immune-mediated diseases. Inflammatory bowel disease (IBD) is also immune-mediated diseases characterized by a chronic inflammation of the gastrointestinal tract. Inflammatory lamina propria (LP) CD4<sup>+</sup>T cells are acknowledged as critical factors in the pathogenesis of IBD. Some reports showed the anti-inflammatory response of BBR against experimental colitis models, however, detailed analysis of BBR against LP CD4<sup>+</sup>T cells including anti-inflammatory mechanisms have not been performed.

**Aims & Methods:** To investigate the effect of BBR against LP CD4<sup>+</sup>T cells of IBD, we conducted a T cell transfer model of chronic colitis in which SCID mice were injected with CD4<sup>+</sup>CD45RB<sup>high</sup>T cells resulting in T cell mediated colitis. The excised colitic LP CD4<sup>+</sup>T cells were used for *in vitro* experiments (1) and the chronic colitis model mice were used for *in vivo* experiments (2).

(1) In *in vitro* experiments, we stimulated colitic LP CD4<sup>+</sup>T cells by PMA/Ionomycin to induce interferon (IFN)- $\gamma$  and interleukin (IL)-17A production. With this model, we investigated the effect of BBR connecting AMPK pathway and immune system activation. To investigate the effect of AMPK activation on immune system, AMPK agonist AICAR and antagonist Compound C were added to the culture.

(2) In *in vivo* experiments, the colitic mice were fed with BBR and subjected to the mechanism investigation.

**Results:** (1) When colitic LP CD4<sup>+</sup>T cells were cultured with BBR, the frequency of IFN- $\gamma$  and IL-17A producing cells reduced and the activation of AMPK was induced by Western blotting (WB). When colitic LP CD4<sup>+</sup>T cells were cultured with AMPK agonist, (AICAR) or antagonist, Compound C (C.C), AICAR significantly suppressed and C.C significantly increased inductions of IFN- $\gamma$  and IL-17A producing cells frequency. WB analysis showed AICAR significantly activated and C.C significantly inactivated AMPK activities. Metabolic assay showed BBR suppressed oxidative phosphorylation (OXPHOS) and ATP production in colitic LP CD4<sup>+</sup>T cells.

(2) The BBR fed mice showed reduced severity of colitis with significant reduction of IFN- $\gamma$  and IL-17A producing cells frequency. This effect was induced by AMPK activations of colitic LP CD4<sup>+</sup>T cells.

**Conclusion:** BBR elicited anti-inflammatory response in colitic LP CD4<sup>+</sup>T cells via AMPK activation possibly induced by OXPHOS inhibition. AMPK activation of LP CD4<sup>+</sup>T cells could be a new therapeutic target of IBD and BBR might be a good candidate.

**Introduction:** Diet is considered an important pathological trigger in inflammatory bowel diseases (IBD), as feeding habits can affect intestinal permeability and efficient clearance of bacterial antigens, consequently influencing the immune system. Moreover, high incidence of IBD was reported in western, developed countries which is likely related to the increasing environmental pollution, as well as "westernization" of the populations' diet and lifestyle (e.g. diet rich in animal fat and protein and low in fiber), all of which significantly affect individuals' immune response. Free Fatty Acid receptors (FFARs), expressed on the intestinal epithelial cells, belong to the family of luminal-facing receptors that are responsive to nutrients (nutrient-sensing receptors). They are possibly involved in the maintenance of gut function and implicated in IBD.

**Aims & Methods:** The objective of this study was to test the anti-inflammatory activity of synthetic agonists of FFARs in mouse models of colitis. Therapeutic activity of GW9508 (FFAR1 agonist), 4-CMTB (FFAR2 agonist), AR420626 (FFAR3 agonist) and GSK137647 (FFAR4 agonist) was investigated in two models of semi-chronic colitis: induced by trinitrobenzenesulfonic acid (TNBS) mimicking Crohn's disease as well as induced by DSS that recapitulates ulcerative colitis in humans. Body weight, macroscopic score, ulcer score, colon length, weight and thickness, as well as myeloperoxidase (MPO) activity were recorded. Expression of FFAR1, 2, 3 and 4 in the colon was compared between control and colitic animals.

**Results:** We found that expression of FFAR1 is significantly elevated while FFAR2 reduced in the inflamed colon. Systemic administration of GSK137647 (FFAR4 agonist; 1 mg/kg, twice daily) attenuated both TNBS-induced and DSS-induced colitis in mice, as indicated by significantly reduced body weight loss as well as macroscopic parameters and MPO activity. The action of GSK137647 was blocked by pretreatment with selective FFAR4 antagonist AH 7614 (5 mg/kg, twice daily).

**Conclusion:** This is the first investigation evaluating the anti-inflammatory activity of FFAR agonists and showing that pharmacological intervention targeting FFAR4, which is a sensor of medium and long chain fatty acids, attenuates intestinal inflammation. Further experiments evaluating the signaling pathways triggered by FFAR4 stimulation are pending.

**Introduction:** Inflammatory bowel disease (IBD) consists of 2 main disorders: ulcerative colitis (UC) and Crohn's disease (CD). IBD is characterized by chronic, uncontrolled inflammation of the intestinal mucosa. Although major advances have improved the understanding of the multifactorial influence of genetic, environmental, microbial, and inflammatory determinants of IBD, the etiology of the disease still confusing. The diagnosis is based on a combination of disease history, colonoscopy, inflammatory biomarkers, radiological and histological evaluation. Most biomarkers used are not disease specific and not reliable, but reflect generalized inflammation.

**Aims & Methods:** The aim of the work is to identify serum proteomic profiles of IBD cases and correlating this profile with the other diagnostic markers and activity of the disease. We performed a study with 101 serum samples collected from patients classified in 3 groups (31 Crohn's, 37 ulcerative colitis, 33 healthy controls) according to accredited criteria. They were subjected to: complete history taking, thorough clinical examination, Lab investigations (routine, fecal calprotectin, ANCA, ASCA), endoscopy (upper, lower), histopathology, imaging were done. Plasma proteomic pattern of IBD patients and control subjects was determined using matrix-assisted

laser desorption/ionization (MALDI) TOF MS analysis, all serum samples were subjected to solid-phase extraction (SPE). We analyzed the spectra obtained from all the samples using ClinProTool.

**Results:** There was a statistical significant difference of the serum proteome profiles of UC group in comparison to health volunteers. Also there was a statistical significant difference of the serum proteome profiles of crohn's group in comparison to health volunteers, we used Support Neural Network (SNN), Genetic algorithms (GA) to analyse proteomic profile of UC and CD cases versus control cases respectively. (64, 76) signals were identified by the ClinProt software with a statistically different area for UC, Crohn's disease respectively. There was a statistical significant difference between active versus inactive UC group and Crohn's disease group.

**Conclusion:** Advances in mass spectrometry and bioinformatics have allowed capturing and selecting the signal of thousands of small, low molecular weight peptides. The pattern of these peptides holds the promise of distinguishing disease states and providing clinically important information such as prognosis, response to therapy, or even targets of therapy.

**Contact E-Mail Address:** lopetusoloris@libero.it

**Introduction:** It is now well-established that IL-33 and its receptor, ST2, are important factors in the pathogenesis of IBD. Emerging evidence also suggests its critical role in epithelial proliferation and the potential contribution to inflammation-driven tumorigenesis that can lead to colorectal cancer (CRC).

**Aims & Methods:** The aim of our study was to characterize the precise contribution of IL-33/ST2 axis in the azoxymethane (AOM)/dextran sodium sulfate (DSS) model of colitis-associated CRC. C57/BL6 wild-type (WT), IL-33 KO, ST2 KO and CD73 KO mice were given a single dose of AOM (7.4 mg/kg) followed by two cycles of 3% DSS for 7d in drinking water. Disease Activity Index (DAI), as well as endoscopic and histological evaluation of colons were performed. IHC, immunofluorescence (IF) and qPCR were done on full-thickness colons for IL-33 and ST2 localization and identification, as well as mRNA expression, respectively. FACS analysis was performed on cell suspensions from resected, isolated polyps and qPCR for Vimentin, Desmin, αSMA, CD34, CD31, CD73 was completed on sorted cells in order to functionally characterize ST2+/IL-33 responsive cells.

**Results:** IL-33, ST2L, and sST2 mRNA transcripts were dramatically elevated in AOM/DSS-treated WT mice vs. controls. IHC of treated WT mice revealed localization of IL-33 to the colonic epithelium and to cells within the LP morphologically consistent with tissue macrophages. ST2 staining was localized to the intestinal epithelium in tissues immediately adjacent to tumors, while within the tumors themselves, ST2+ cells displayed a spindle/fibroblast-like morphology with a unique distribution throughout the polyps. Little to no staining for both IL-33 and ST2 was present in controls. Using IF, ST2 co-localized with αSMA in polyps; however, ST2 staining was not exclusive for αSMA+ cells. FACS analysis showed a distinct population of CD45+ hematopoietic cells consisting of CD3/CD8+ cytotoxic T cells (CTLs), CD19+ B-lymphocytes, CD11b+CD11c- and CD11b+CD11c+ myeloid cells. ST2 was mainly expressed by CTLs, and CD11b+CD11c- and CD11b+CD11c+ myeloid cells. Non-hematopoietic cells (CD45-) also expressed ST2. At qPCR, CD45-ST2+ and CD45+ST2+ expressed significantly elevated levels of CD73 vs. ST2- cells. AOM/DSS treatment in IL-33, ST2 KO and CD73KO mice resulted in a significant decreased polyp number and size vs. WT, with colonoscopy revealing the development of protruding lesions with abnormal

vascular patterns, suggesting pre-tumorous lesions in WT mice, while all KO mice showed their absence with a more impressive mucosal inflammation, likely due to reduced epithelial proliferation and repair caused by the deficiency of IL-33 signaling.

**Conclusion:** Our results suggest that the IL-33/ST2 axis promotes tumorigenesis in colitis-associated CRC through the activation of CD73.

**Disclosure:** Nothing to disclose

### P0312 REGULATION OF INTESTINAL EPITHELIAL HOMEOSTASIS BY THE IBD RISK GENE CCNY

Da Silva-Heil S., Koch S., Molinas A.

Wallenberg Centre for Molecular Medicine (WCMM) and Department of Clinical and Experimental Medicine (IKE), Linköping University, Linköping, Sweden

**Contact E-Mail Address:** stephanie.da.silva@liu.se

**Introduction:** Inflammatory bowel diseases (IBD) are recurring inflammatory disorders characterized by chronic dysregulation of the intestinal epithelium. The etiology of IBD is still unknown. CCNY, encoding Cyclin Y, has previously been identified as a putative risk gene in Crohn's disease and Ulcerative Colitis; however, the function of CCNY in the gut is unknown. We have shown that Cyclin Y is a critical activator of the Wnt/beta-catenin signalling pathway, which controls stemness and proliferation in intestinal epithelia<sup>2</sup>. We thus investigated whether CCNY regulates epithelial homeostasis and wound repair in the gut.

**Aims & Methods:** To address the role of CCNY in intestinal epithelia, we used a RNA interference based loss-of-function approach in model cell lines HEK 293T, SW48 and HCT 116 cells. Wnt signalling activity was assayed by a Topflash luciferase reporter assay following siRNA-mediated depletion of CCNY in model cell lines. In addition, we generated transgenic mice with deletion of Ccny specifically in intestinal epithelial cells. These animals were subjected to the dextran sulphate sodium (DSS) model of intestinal injury (acute, 5 days of DSS) and repair (recovery, 5 days of DSS followed by 5 days of plain drinking water), which mimics human Inflammatory Bowel Diseases<sup>3</sup>. In addition to the *in vitro* experiments, we determined daily colitis progression and epithelial homeostasis in mice using an established disease activity index, histopathological analyses (haematoxylin-eosin staining, crypt length measure) and proliferation markers. Animal were weighed daily.

**Results:** In contrast to non-intestinal model epithelial cells, loss-of-function of CCNY did not reduce Wnt signalling activity in intestinal HCT116 and SW48 cell lines. Accordingly, CCNY depletion did not impair epithelial proliferation or stemness *in vitro*. Ccny mutant mice did not present any changes compared to controls regarding proliferation, crypt length or histopathology. Moreover, markers of Wnt activity and cell proliferation were unchanged in Ccny mutant mice compared to their littermate controls, and we observed no changes in disease activity index or weight loss of the animals during both acute intestinal inflammation or after recovery.

**Conclusion:** Our results thus far suggest that IBD risk gene CCNY is dispensable for intestinal epithelial homeostasis. The apparent uncoupling of Cyclin Y from Wnt signalling in the gut is the subject of ongoing investigation in our lab. In addition, we continue to investigate the possible contribution of CCNY to epithelial regeneration following colitis.

**Introduction:** Fibrosis and fistula development constitute the main complications associated to Crohn's disease. Notch signalling has been implicated in lung, kidney, liver and cardiac fibrosis and in various disease conditions such as scleroderma.

**Aims & Methods:** We aim to analyse here the pattern of NOTCH ligands, receptors and effectors expression in surgical resections from stenotic and fistulizing CD patients and to determine the potential role of these ligands in favouring fistula and fibrosis. CD patients (n= 52) were categorized according to Montreal classification (age at diagnosis, location and behaviour). mRNA was isolated from resections of patients presenting a structuring (B2, n=26) or a penetrating (B3, n=15) behaviour or from unaffected mucosa of patients with colorectal cancer (control, n=15). The expression of Notch ligands, receptors, and effectors (HES1 and MATH1) was determined by RT-PCR or WB. The data are showed as mRNA expression of NOTCH ligands and receptors vs. the housekeeping gene  $\beta$ -ACTIN in intestinal mucosa and values correspond to mean  $\Delta$ CT (CT target - CT housekeeping)  $\pm$  SEM. Significant differences vs the respective Non-IBD patients are shown by \*P< 0.05 or \*\*P< 0.05 and vs B2 CD patients by #P< 0.05. Correlations between data were analysed using Pearson's correlation coefficient (\*p < 0.05).

**Results:** The expression of NOTCH3 and NOTCH4 receptors was significantly higher in intestinal samples from B3 CD patients (14.8 $\pm$ 0.3\*\*#, and 9.6 $\pm$ 0.9\*\*#, respectively) than in controls (17.4 $\pm$ 0.2, and 13.4 $\pm$ 0.3, respectively) or B2 CD patients (16.0 $\pm$ 0.3\*, and 11.5 $\pm$ 0.3\*, respectively), but only NOTCH3 expression was up-regulated in crypts in the penetrating group (Control:14.5 $\pm$ 0.5; B2: 15.3 $\pm$ 0.5; B3: 12.4 $\pm$ 0.3\*#). The fistulizing group presented a generalized overexpression of NOTCH ligands (JAG2, DLL3 and DLL4) compared with controls and among them, only DLL3 expression was up-regulated in the penetrating group (Control: 0.39 $\pm$ 0.05 A.U.; B2: 0.31 $\pm$ 0.04 A.U.; and B3:0.81 $\pm$ 0.18\*# A.U.). Similar levels of HES1 and MATH1 mRNA expression were detected between different groups while protein levels of HES1 were higher in the fistulizing group than in control or stenotic groups (3.4 $\pm$ 0.1 A.U\*#, 2.8 $\pm$ 0.2 A.U and 2.0 $\pm$ 0.1 A.U, respectively). The expression of DLL3 significantly correlated with FSP1 (r=0.77, P=0.04\*), DESMIN (r=0.80, P=0.03\*), and SMA11 (r=0.59, P< 0.04\*), only in intestinal tissue from the fistulizing CD group.

**Conclusion:** Activation of the Notch signalling pathway is detected in Crohn's disease patients with a penetrating (B3) behaviour compared with those with a structuring (B2) phenotype and it may be involved in fistula development over fibrosis.

**Disclosure:** Nothig to disclosure

## P0314 MICROBIAL METAGENOMIC SIGNATURES REVEAL DYSBIOTIC DIFFERENCES AND SIMILARITIES BETWEEN INFLAMMATORY BOWEL DISEASES

Dubinsky V.<sup>1</sup>, Reshef L.<sup>1</sup>, Rabinowitz K.<sup>2,3</sup>, Godny L.<sup>2,3</sup>, Yadgar K.<sup>2,3</sup>, Gophna U.<sup>1</sup>, Dotan I.<sup>3,4</sup>

**Contact E-Mail Address:** [dani.dubinsky@gmail.com](mailto:dani.dubinsky@gmail.com)

**Introduction:** The etiology of inflammatory bowel diseases (IBD) including Crohn's disease (CD) and ulcerative colitis (UC) involves an aberrant immune response towards the gut microbiome in genetically susceptible individuals. Approximately 25% of patients with UC may undergo total large bowel resection (proctocolectomy) followed by creation of a reservoir ("pouch") from the normal small bowel. Most will develop de-novo

inflammation of the previously normal small bowel comprising the pouch (pouchitis). Pouchitis may be a model for the development of intestinal inflammation with features resembling CD.

**Aims & Methods:** To compare the microbiome and its functions across different phenotypes of IBD, faecal samples were obtained from patients with a pouch, diagnosed according to accepted criteria and inflammatory biomarkers were detected. Shotgun metagenomics was applied and microbiome data was analyzed using specifically designed bioinformatics pipelines. Outcomes were compared to metagenomic data from two independent cohorts, PRISM and LifeLines DEEP-NLIBD both comprised of CD and UC patients and healthy-controls.

**Results:** Samples from 78 patients with a pouch (40 normal pouch, 38 pouchitis) were analysed and compared to data of 88 patients with CD 76 with UC and 56 healthy controls. PCoA analysis based on bacterial species and enzymes profiles showed substantial overlap between patients with a normal pouch, pouchitis and CD. Taxonomic and functional variation correlated (Spearman  $r=0.5$ ,  $P<0.05$ ) with inflammation (faecal calprotectin) and samples were stratified according to phenotype, from healthy controls to UC, CD, patients with a normal pouch and pouchitis (highest inflammation). Area under the curve of 0.9 (mean) was achieved for three IBD phenotypes classifier and was the highest for patients with a pouch. Most of the misclassified pouch patients' samples were labelled as CD. *Escherichia coli* and several *Streptococcus* and *Veillonella* species were significantly more abundant in IBD phenotypes compared to healthy controls, while patients with a pouch, especially with pouchitis presented the highest levels (median relative abundance of *E. coli*: 13% compared to 4% in CD, 2.7% in UC and 0.3% in healthy,  $P=4\times10^{-18}$ ). In contrast, beneficial bacteria such as *Eubacterium rectale*, *Roseburia inulinivorans*, *Faecalibacterium prausnitzii*, *Ruminococcus bromii* and *Bacteroides* species were depleted in patients with a pouch, especially in pouchitis (*E. rectale*: 1.2%, 6.9%, 5.5%, and 10.8%; *R. bromii*: 0.13%, 1.2%, 2.3% and 4.2%; *F. prausnitzii*: 2.7%, 3.3%, 7.3% and 6.5% in pouch, CD, UC, and healthy controls, respectively,  $P<0.05$ ). Microbial enzymes related to protection against oxidative stress: glutathione-disulfide reductase, peroxiredoxin and nitric-oxide dioxygenase were enriched in patients with a pouch. Moreover, numerous metabolic pathways were associated with IBD phenotypes. Specifically: heme biosynthesis with a pouch, CD and UC; NAD salvage with a pouch, aromatic amino-acid biosynthesis and starch degradation with healthy controls (lowest in patients with a pouch).

**Conclusion:** Major metabolic and microbial signatures common to IBD patients as well as several that are phenotype-specific were identified. Robust bacterial taxonomic and functional overlap supports resemblance between a pouch and CD. Oxidative stress and virulence pathways are associated with IBD, specifically with pouch, while beneficial metabolic pathways are decreased. Patients with pouchitis harbour a distinct signature characterized by intensified dysbiosis.

**Contact E-Mail Address:** [jesus.cosin@uv.es](mailto:jesus.cosin@uv.es)

**Introduction:** Intestinal fibrosis is a common complication of Crohn's Disease (CD) patients characterized by an obstruction of the intestinal lumen which requires surgery. Several single nucleotide polymorphisms in autophagy-related genes associated to CD have been identified. Although autophagy is impaired in CD patients, the relevance of autophagy in intestinal fibrosis is still not well elucidated.

**Aims & Methods:** We aim to analyze the effect of pharmacological modulation of autophagy in the development of murine intestinal fibrosis.

Murine intestinal fibrosis was induced using the heterotopic transplant model. Segments of 1cm colon from mice were subcutaneously transplanted into the neck of a recipient mice and collected after 7 days. Recipient mice were treated with a daily injection of 3-MA (10mg/kg) or rapamycin (1.25 mg/kg). Expression of intestinal inflammation, fibrosis and EMT markers were analyzed by qPCR and protein levels of autophagy markers by Western Blot. Collagen layer was evaluated by Sirius Red Staining. Intestinal resections from CD patients were obtained and expression

of p62, Col1a1,  $\alpha$ -SMA, Snail1 and Snail2 was analyzed by qPCR. Results are expressed as fold induction (mean $\pm$ SEM, n $\geq$ 5). Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test. Correlations were analyzed with the Spearman coefficient.

**Results:** Intestinal grafts 7 days after surgery exhibited a reduced autophagic flux since higher levels of p62 and lower levels of phospho-MTOR and LC3 were detected compared with intestinal grafts at day 0. The inhibition of autophagy by 3-MA and the activation of autophagy by rapamycin were also confirmed by WesternBlot. As shown in Table 1, grafts obtained 7 days after surgery from 3-MA-treated mice exhibited a significant increase in the expression of proinflammatory, profibrotic and EMT genes and a significant thicker collagen layer after Sirius Red Staining. Of interest, grafts 7 days after transplantation obtained from rapamycin-treated mice showed a significant reduction in the expression of proinflammatory, profibrotic and EMT genes and a significant reduction in the thickness of the collagen layer after Sirius Red Staining. In intestinal resections from CD patients, the expression of p62 positively correlates with the expression of Col1a1 ( $r_{\text{Spearman}}=0.6098$ ,  $P=0.004$ ),  $\alpha$ -sma ( $r_{\text{Spearman}}=0.5168$ ,  $P=0.041$ ), Snail1 ( $r_{\text{Spearman}}=0.4112$ ,  $P=0.0003$ ) and Snail2 ( $r_{\text{Spearman}}=0.4410$ ,  $P=0.0009$ ).

	TNF- $\alpha$	IL-1 $\beta$	COX-2	Col1a1	Col3a1	Col4a1	Snail1	Snail2	Itgb6
Graft day 0	1.1 $\pm 0.2$	1.6 $\pm 0.8$	1.1 $\pm 0.2$	1.2 $\pm 0.4$	2.6 $\pm 1.9$	1.1 $\pm 0.3$	1.0 $\pm 0.1$	1.0 $\pm 0.1$	1.1 $\pm 0.2$
Graft day 7	50.5 $\pm 7.5$	243.7 $\pm 35.9$	103.1 $\pm 22.3$	41.3 $\pm 9.3$	166.9 $\pm 61.4$	2.7 $\pm 0.8$	11.6 $\pm 1.5$	3.7 $\pm 0.7$	2.7 $\pm 0.4$
Graft day 7 + 3-MA	102.9 $\pm 22.9$	425.4 $\pm 84.9$	174.5 $\pm 46.2$	74.2 $\pm 9.2$	2005.0 $\pm 1229.0$	11.7 $\pm 1.7$	21.1 $\pm 4.6$	7.3 $\pm 1.8$	7.7 $\pm 1.9$
Graft day 7 + Rap	24.1 $\pm 6.2$	132.8 $\pm 33.5$	36.2 $\pm 9.3$	9.5 $\pm 1.9$	40.6 $\pm 17.9$	4.1 $\pm 1.1$	7.5 $\pm 1.3$	1.8 $\pm 0.5$	1.9 $\pm 0.5$

[Table 1: Expression of proinflammatory, profibrotic and EMT genes in intestinal grafts analyzed by qPCR.]

**Conclusion:** Pharmacological modulation of autophagy modulates intestinal inflammation and fibrosis since the inhibition of autophagy exacerbates intestinal inflammation and fibrosis whereas an autophagy activation reduces the intestinal fibrosis. In addition, in intestinal resections from CD patients the expression of autophagy markers correlates with the expression of pro-fibrotic and pro-EMT genes, which led us to suggest that pharmacological modulation of autophagy might be a new therapeutic option for intestinal fibrosis.

**Introduction:** Cigarette Smoke (CS) contains many compounds that exert biological effects, increasing the risk of cardiovascular and pulmonary diseases as well as carcinogenesis in exposed individuals. Moreover, smoking in Crohn's Disease patients is associated with greater disease activity, increased requirement for immunosuppressant, and early post-operative recurrence.

However, epidemiological and clinical evidence from robust case-controlled studies points to an inverse association between smoking and the onset and development of ulcerative colitis (UC). The biological mechanisms responsible of the underlined smoking effects on UC progression remain largely elusive. Several studies have demonstrated the anti-inflammatory action of cholinergic agonists, such as the main tobacco alkaloid, nicotine.

However, contrasting results have been observed in clinical and non-clinical studies addressing the role of nicotine in UC, opening new questions on the molecular mechanisms at the base of the intrinsic nicotinic anti-inflammatory activity and the possible involvement of other tobacco alkaloids in the observed reduced severity of UC.

In the present study, we aimed to investigate the potential anti-inflammatory activity of nicotine and another tobacco alkaloid (PM1001) in a full human immune system Hu-Mouse colitis model.

**Aims & Methods:** NOD/Shi-scid/IL-2R $\gamma$  null immunodeficient mice were engrafted with functional cord blood-derived human CD34<sup>+</sup> hematopoietic stem cells. During the 14 weeks following cell injection, the engrafted human stem cells developed fully functional human dendritic cells, granulocytes, NK cells, macrophages, and monocytes as well as B and T lymphocytes. After complete maturation, mice were treated with nicotine or PM1001 for two weeks. Colitis was induced by adding 3% dextran sulfate sodium (DSS) over seven days, and mouse necropsy was performed after DSS treatment (acute model) or five days after DSS removal (recovery model). Disease-specific endpoint analysis (global clinical score, colon length, body weight loss, diarrhea, rectal bleeding), immune-phenotyping, colon histopathological assessment, and colon transcriptomics were performed.

**Results:** Data analysis revealed that nicotine significantly reduces all the associated acute colitis symptoms (diarrhea, rectal bleeding, and body weight loss) and improves colitis-specific endpoints (colon length, global clinical score). Moreover, histopathological analysis confirmed a significant reduction of colon inflammation, tissue damage, and mononuclear cell infiltration upon nicotine treatment. Finally, nicotine significantly improved the survival of mice; no mortality was observed compared to the vehicle group. The tobacco alkaloid PM1001 showed a similar, although generally weaker, effectiveness trend. Further molecular analyses are ongoing to investigate the molecular mechanisms implicated in the disease progression.

**Conclusion:** The risks of smoking far outweigh any possible benefit, thus smoking cessation must be considered as a first step toward well-being and healthy status. However, tobacco constituents, such as nicotine or other alkaloids, may exert positive effects in the context of UC, thus representing molecules to further investigate. Using a full human immune system mouse models, the current study enabled the investigation of possible molecular mechanisms responsible for the attenuation of UC by tobacco alkaloids, providing therapeutic opportunities for the treatment of the various pathological conditions with an inflammatory component.

**Introduction:** We have developed and longitudinally characterized a non-human primate (NHP) macaque model of chemical colitis for the purpose of testing efficacy of mucosal healing therapies in a highly translational model.

**Aims & Methods:** Disease induction and progression was assessed by clinically relevant modalities, including white light colonoscopy, histopathology, and positron emission tomography/computed tomography (PET/CT). Utilizing four cynomolgus macaques, colitis was initiated and maintained with endoscopic application of the hapten 2,4,6-trinitrobenzenesulfonic acid (TNBS) on Day 0 (100mg), D7 (50mg), and D14 (50mg), and mucosal health was assessed and scored by colonoscopy at baseline (14 days before D0), D7, D14, D17, D21, D28, and D48. Histopathology from colonoscopy guided mucosal pinch biopsies was performed at baseline, D17, D28, and D42 and quantified using a modified Geboes score. To assess colonic mucosal inflammation non-invasively, we quantified maximum standardized uptake value (SUV-max) signals of the radio-ligand, 18F-fluorodeoxyglucose ([<sup>18</sup>F]FDG), a glucose metabolism marker, in two cynomolgus macaques at baseline, D17, D21, D28, and D42. To account for background signal, SUV-max values were collected from PET images that had been gated relative to the baseline PET image for each subject.

**Results:** Colonoscopy revealed ulcers, mucosal friability, luminal narrowing, and mucosal edema, which were significantly increased in severity relative to baseline (mean score=0.25) on D14 (mean score=6.6,  $p=0.029$ ), D17 (mean score=8.3,  $p<0.005$ ) and D21 (mean score=7.3,  $p<0.054$ ); however, mucosal changes assessed by colonoscopy were not significantly different on D28 (mean score=5.08,  $p=0.174$ ) or D42 (mean score 2.25,  $p=0.478$ ). Histological evaluation demonstrated epithelial changes com-

pared to baseline (mean score=0) including ulceration, loss of goblet cells, and epithelial hyperplasia, which were observed on D17 (mean score=5,  $p=0.005$ ) and D28 (mean score=2,  $p=0.120$ ). Inflammatory changes included increased numbers of neutrophils and eosinophils and increased occurrence of intra-epithelial leukocytes, which were observed on D17 (mean score=2.5,  $p=0.060$ ) and D28 (mean score=2.5,  $p=0.041$ ). By D42, epithelial and inflammatory changes had resolved. TNBS application increased [ $^{18}$ F] FDG, SUV-max signal on D17 by 6-fold and on D21 by 3-fold compared to baseline; however, SUV-max was not increased compared to baseline at D28 and D42.

**Conclusion:** The pathological features and feasibility for longitudinal and clinically relevant assessment demonstrate the translational strength of this NHP, TNBS colitis model. Further, the duration of significant, quantifiable pathology should provide a window for the immediate evaluation of therapeutic interventions, targeting mucosal healing and inflammation.

**Disclosure:** The design, study conduct, and financial support for the study were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication. **Introduction:** Crohn's disease (CD) is a multi-factorial disorder and familial aggregation of CD has long been recognized. In first-degree relatives of patients suffering from IBD, the relative risk for disease onset can be up to 5-fold higher than that in unaffected families<sup>1</sup>. The interplay between impaired host genetics, defective immune system components and altered gut microbiome composition is often pointed out as the main drivers of CD pathogenesis.

**Aims & Methods:** We included 112 individuals comprising adult CD patients in clinical remission ( $n=33$ ; time to diagnosis < 2 years), their healthy first degree relatives (HFDR;  $n=46$ ) and matched healthy controls (HC;  $n=33$ ). Our objectives were to identify microbial features within the microbiota composition of HFDR that were discriminant from CD and HC and to correlate them to host inflammatory markers such as faecal calprotectin. The faecal microbiota composition, diversity and estimated loads were assessed by 16S rRNA gene sequencing and quantitative PCR. Other CD-associated biomarkers (serum IgG and IgA ASCA and faecal calprotectin) and Adherent-Invasive *Escherichia coli* (AIEC) detection in stool samples and their respective phylotyping/invasiveness classification) were evaluated.

**Results:** Estimated bacterial loads were similar between the different groups (CD=9.8, HC=10.2, HFDR=10; log<sub>10</sub> CFU/g). Microbial diversity was not lower in CD or HFDR (CD=0.91, HC=0.90 and HFDR=0.93; Simpson index). Microbiota richness (number of observed OTUs) was higher in HFDR

(227.6) individuals as compared to CD (181.7) and HC (205.4) ( $p=0.01$ ). Eight bacterial genera displayed significantly different abundances across the groups. CD microbiome was characterized by higher abundances of *Bacteroides* and *Intestinibacter* and lower abundances of *Faecalibacterium* and *Odoribacter* than HC and HFDR microbiomes. The microbiota composition of HFDR harboured specific microbial features such as higher representation of *Coprococcus*, *Gemmiger* and *Clostridium* IV and an almost undetectable presence of *Haemophilus*. At the species level *Coprococcus catus*, *Coprococcus comes*, *Gemmiger formicilis*, *Eubacterium siraeum* and *Clostridium leptum* were significantly more abundant in the microbiota of HFDR as compared to CD and HC. *E. coli* strains isolated from CD patients and HFDR presented higher invasion ability to intestinal epithelial cells compared to *E. coli* strains isolated from HC. AIEC strains are mostly distributed among B2 phylogroup. No association was found between these microbiota features and ASCA measurements as well as fecal calprotectin levels.

**Conclusion:** Our study depicts the presence of specific microbial features within the microbiota of healthy individuals with higher risk of CD onset. Healthy relatives of CD patients exhibited higher microbiota richness and higher abundances of numerous bacterial taxa than CD patients but also healthy controls. These specific microbial features (mostly bacteria known to produce short-chain fatty acids, such as butyrate or formate) may counterbalance potential host impairments such as genetic predisposition. Furthermore, healthy relatives harbour more invasive *E. coli* strains than healthy controls. Since healthy relatives microbiome differ from that of healthy individuals, therapeutic approaches focusing on bacteria specifically associated with healthy relatives microbiome may be more appropriate to correct the microbiota dysbiosis in CD.

**Introduction:** Crohn's disease (CD) is a chronic inflammatory bowel disease engendering both psychological and physiological stresses. Our previous studies demonstrated that prolonged stress and chronic inflammation cause dysregulation of glucocorticoid (GC) signaling in different immune subsets, with consequent reduced sensitivity to GCs, so-called steroid resistance, and a shift towards a more aggressive immune response. The present study aims to identify and characterize patterns of steroid resistance in adult CD patients.

**Aims & Methods:** We analyzed leukocyte subset distribution, functionality and their responsiveness to GCs using peripheral blood mononuclear cells (PBMCs) isolated from CD patients (mean age 35 years, mild-moderate disease activity with a Harvey-Bradshaw Index in the range 6-15) and from age- and sex-matched healthy controls. PBMCs underwent stimulation with anti-CD3 without or with methylprednisolone (MP, 1-10,000 ng/ml) followed by measuring secreted levels of IL-2 (24 hours), IL-10 (48 hours), IFN- $\gamma$  (48 hours), and IL-17 (72 hours) with ELISA. In addition, PBMCs were activated with PMA/ionomycin for 6 hours and analyzed for cytokine production with flow cytometry. Finally, non-activated PBMCs were analyzed for lymphocyte subsets such as naïve, exhausted, regulatory (Tregs) and effector memory T cells.

**Results:** MP in increasing doses caused a progressive reduction of PBMC cytokine production; the effect was less in CD ( $n=8$ ) than in controls ( $n=8$ ). For IL2 and IL10 the difference became statistically significant at MP 1000 ng/ml (Table). MP in increasing doses caused a progressive reduction of TNF $\alpha$  producing cells in the CD8 population. The effect was less pronounced in CD ( $n=4$ ) than controls ( $n=4$ ). The difference became statis-

tically significant at MP 10000 and 100000 ng/ml (Table). Non-activated PBMCs analyzed for lymphocyte subsets such as naïve, exhausted, regulatory (Tregs) and effector memory T cells did not demonstrated differences between CD (n=4) and controls (n=4).

		Fold of steroid sensitivity decrease in CD patients					
		MP, ng/ml	1	10	100	1000	10000
IL2 production	mean (p)	1.040 (0.63)	1.306 (0.15)	1.587 (0.07)	2.391 (0.049)	2.2105 (0.049)	
IL1 production	mean (p)	1.191 (0.28)	1.328 (0.19)	1.379 (0.36)	1.462 (0.05)	1.341 (0.11)	
		Fold of steroid resistance in CD patients					
relative TNFα production by CD8	average(p)	1.129 (0.57)	1.905 (0.14)	1.241 (0.41)	1.049 (0.64)	8.445 (0.03)	3.031 (0.01)

[Cytokine production after MP stimulation]

**Conclusion:** In CD patients certain immune cell subsets demonstrated a loss of steroid sensitivity. This may be indicative of a dysregulated hypothalamus-pituitary-adrenal (HPA) axis, which phenomenon may contribute to the disease process itself and moreover augur an inadequate response to corticosteroid therapy.

**Disclosure:** Nothing to disclose

### P0320 ACTIVATION OF ARYL HYDROCARBON RECEPTOR ATTENUATES INTESTINAL INFLAMMATION BY ENHANCING IRF4 MEDIATED MACROPHAGE M2 POLARIZATION

Li L.<sup>1</sup>, Zhao X.<sup>2</sup>, Zhang H.<sup>2</sup>

**Introduction:** Inflammatory bowel diseases (IBDs) are characterized by a functional dysregulation of immune cells, among which macrophages play an indisputable role. Macrophages could undergo opposite polarization under different conditions thus exerting pro-/anti-inflammatory effects. Aryl hydrocarbon receptor (AhR), a ligand-dependent transcription factor, is implicated in intestinal inflammation by regulating both innate and adaptive immune response, but the relationship between AhR and macrophages in inflammatory bowel diseases has not been investigated.

**Aims & Methods:** We investigated the distribution of macrophages in colonic tissue of patients with active IBDs and assessed the effects of AhR activation in trinitrobenzenesulfonic acid (TNBS)-induced colitis in mice and on the polarization of bone marrow derived macrophages (BMDMs). Macrophage IRF4 expression was measured and IRF4 siRNA was used to explore the potential mechanism behind AhR mediated macrophage polarization.

**Results:** Compared with normal controls, there are fewer M2 macrophages in colonic tissue of patients with active IBDs. Experimentally, intra-colonic administration of 6-formylindolo [3,2-b] carbazole (FICZ), an AhR agonist, protected against TNBS-induced colitis, manifested by less frequency of diarrhea and bloody stool and less weight loss. This protection was associated with the increase of M2 macrophages and the release of IL-10 in the intestine. *In vitro*, FICZ enhanced the expression of M2 related hallmarks like Ym-1, Fizz1 and CD206, and increased the production of anti-inflammatory mediators. Furthermore, FICZ mediated M2 polarization was accompanied by an induction of IRF4 expression, and IRF4 silencing using siRNA significantly impaired M2 polarization.

**Conclusion:** In conclusion, AhR activation reduces the severity of colitis and the inflammatory process via enhancing macrophage M2 polarization, and this effect could be mediated by the induction of IRF4 expression. These findings provide insight into the mechanisms of colonic inflammation and could lead to new therapeutic strategies for IBDs.

### P0321 PLASMA CONCENTRATION OF LIPOPROTEIN (A) AND ITS RELATIONSHIP WITH INFLAMMATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Zhao X., Li J., Zhang H.

The First Affiliated Hospital of Nanjing Medical University, Department of Gastroenterology, Nanjing, China

**Contact E-Mail Address:** zhaoxj91718@163.com

**Introduction:** Inflammatory bowel disease (IBD) patients have increased risk of cardiovascular disease (CVD). Dyslipidemia is a confirmed risk factor for CVD. The purposes of this retrospective study were to examine the lipid and lipoprotein profiles in patients with IBD, investigate the relationship between disease severity and lipid and lipoprotein profiles, and also analyze influence factors.

**Aims & Methods:** Three hundred seven consecutive Crohn's disease (CD) patients and 235 consecutive ulcerative colitis (UC) patients were included in this retrospective study. We retrieved patients' clinical and laboratory parameters from their medical records. The control group (n=167) comprised clinically healthy subjects from the same geographic region as the IBD study group. Total cholesterol (TC), triglyceride (TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and lipoprotein (a) (Lp (a)) levels were analyzed in relation to disease activity. Tukey's post-hoc test, Mann-Whitney U test, and Pearson's or Spearman's coefficient were used in the statistical analyses.

**Results:** Compared to the controls, patients with CD and UC had lower TC, TG, HDL-C, and LDL-C levels. This lipid pattern was more prominent in patients with CD than in those with UC. Furthermore, TC, HDL-C, and LDL-C levels were negatively associated with the Crohn's Disease Activity Index (CDAI) and Mayo scores. Additionally, patients with CD had higher Lp (a) levels than in those with UC and the controls. Patients with active CD had higher Lp (a) concentrations than those with inactive CD, and the Lp (a) levels were positively associated with the CDAI, C-reactive protein level (CRP), and erythrocyte sedimentation rate (ESR).

**Conclusion:** Lower TC, TG, HDL-C, and LDL-C levels are demonstrated in patients with IBD (particular CD) compared to normal controls and are negatively correlated with the disease activity. Conversely, higher Lp (a) concentrations are observed in patients with CD, and they are positively correlated with CDAI. Inflammation may induce dyslipidemia in IBD. Furthermore, a more efficient method for diagnosing and treating dyslipidemia is warranted in patients with IBD.

**Introduction:** The caudal-related homeobox transcription factor 2 (CDX2) plays an important role in intestinal epithelial differentiation, proliferation, migration, and adhesion. Coskun and colleagues previously reported that CDX2 was downregulated in ulcerative colitis, showed that TNF-α reduces CDX2 mRNA and protein levels in cultured Caco-2 colon epithelial cells, in a dose-dependent manner, and this effect was significantly reduced by adding the anti-TNF-α drug infliximab to the culture medium (Biochim. Biophys. Acta. 2011;1812:283-9).

**Aims & Methods:** The aim of this study was to determine whether CDX2 is reduced in Crohn's disease (CD) and whether CDX2 levels are affected by anti-TNF-α treatment.

Sections of formalin-fixed paraffin-embedded ileocolonic biopsy tissues from 6 biologics-naïve patients with Crohn's disease (CD), 16 patients with CD treated with anti-TNF-α (CD-T), 7 biologics-naïve patients with ulcerative colitis (UC), and 7 biopsies without significant distortion or active inflammation (controls), were stained by immunohistochemistry (IHC) for CDX2. The inflammation activity was scored on a scale from 0 (no activity) to 3 (erosion/ulceration) using a modified Riley Histological Activity

Score (HAS). The level of CDX2 expression was determined using the image analysis software OTMIAS; the expression levels of CDX2 are given in OTMIAS Units (OU). Statistical analysis was performed using Prism statistical analysis software.

**Results:** There was no significant correlation between CDX2 levels and (HAS). Compared to the control group (mean 21.13), CDX2 expression was reduced in CD (mean 5.2,  $p = 0.0147$ ) and in CD-T (mean 8.137,  $p = 0.0176$ ). CDX2 expression was also reduced in UC, but this was not statistically significant (mean 11.89,  $p = 0.1625$ ). Biopsies from CD-T patients had only slightly higher mean CDX2 expression (8.137) compared to CD (5.2,  $p = 0.4797$ ).

**Conclusion:** CDX2 levels in ileocolonic epithelial cells are significantly reduced in biopsies from patients with CD compared to controls, confirming what has been previously reported in UC. However, treatment with anti-TNF did not significantly impact the levels of CDX2 expression in CD suggesting that other inflammatory mediators may be involved in CDX2 downregulation, in addition to TNF- $\alpha$ . Lack of correlation between CDX2 levels and HAS suggests that CDX2 downregulation may be more related to the chronic inflammation than a direct response to acute inflammation.

**Contact E-Mail Address:** doctoruday80@gmail.com

**Introduction:** Despite considerable progress in IBD therapies, at least half of the treated patients fail to reach remission. Monoclonal antibody therapies are associated with immunogenicity. Niclosamide is a salicylide which has been used as an anti-helminthic drug and minimally absorbed from the gastrointestinal tract. It has been shown to have anti-inflammatory properties and is currently repurposed for use in head and neck cancer. We aimed to study its effects on immune cells *ex vivo* and potential for repurposing in IBD.

**Aims & Methods:** Peripheral blood mononuclear cells (PBMCs) from the bloods of 6 IBD patients were cultured with or without stimulation with 0.5  $\mu$ g/ml antiCD3 (clone OKT3). Niclosamide was prepared in dimethyl sulfoxide (DMSO) and diluted into culture medium at 0.25mM and 0.5mM. Effect of niclosamide upon cell survival and T cell activation was measured at 1 day by flow cytometry analysis of activation markers CD69, CD25 and CTLA-4. At six days, cells were re-stimulated with PMA and ionomycin in the presence of Brefeldin A and expression of cytokines IL-17A, TNF $\alpha$ , IFN $\gamma$  and IL-2 measured by flow cytometry. Data was analysed by Flowjo and significance tested by Friedman Analysis.

**Results:** Niclosamide was not toxic to cells at the concentrations tested and did not alter the frequencies of CD4<sup>+</sup> and CD8<sup>+</sup> T cells, CD19<sup>+</sup> B cells or CD14<sup>+</sup> monocytes in unstimulated cells. However, niclosamide reduced CD4 and CD8 T cell activation indicated by a significant decrease in the frequency of CD4<sup>+</sup> cells expressing CTLA-4 and CD25 and CD69 and CD25 by CD8<sup>+</sup> cells. This resulted in a significant decrease in T cell number at six days ( $P=0.0120$ ). Furthermore, it significantly inhibited expression of pro-inflammatory cytokines IL-17, IFN $\gamma$ , TNF $\alpha$  and IL-2 by CD4 and CD8<sup>+</sup> T cells.

**Conclusion:** Niclosamide has a strong anti-inflammatory effect on T cells from IBD patients with no significant cell toxicity seen at concentrations used. The significant reduction in cytokine levels known to be involved in IBD make it a potential drug that could be used in IBD.

**Disclosure:** Nothing to disclose

#### Introduction:

Therapy with anti-TNF has improved notably the management of Crohn's disease (CD). However, 25-40% of patients treated with these drugs lose response long-term. In addition, these treatments are expensive and not without risk of adverse events. Therefore, it is essential to identify reliable markers that will select those patients who can benefit of anti-TNF drugs, thus improving their efficacy and safety.

**Aims & Methods:** A consecutive cohort of CD patients, who were naïve to anti-TNF therapy, were enrolled and followed up during 12 months. Demographic, analytical, nutritional and physiopathology were recorded. Patients were stratified according to clinical response as follows: a) Non-primary response (NPR) at 12 weeks post-treatment; b) loss of response (LR) within 12 months; c) sustained clinical response (SCR). In addition, plasma samples were collected previously to anti-TNF treatment and further analysed by SWATH proteomics, in order to identify potential biomarkers of response to anti-TNF. Anova or Kruskal-Wallis tests were used for analysis, according to data distribution. Functional pathways of identified biomarkers was analysed by DAVID Bioinformatics Resources 6.7.

**Results:** 54 CD patients were included. 77.3% showed a SCR. However, 4.5% of patients had NPR and 18.2 % LR. Patients with recent diagnosis of CD (< 12 months) were less likely to achieve SCR. Indeed, the interval from diagnosis to anti-TNF therapy was shorter in patients NPR ( $0 \pm 0$ ) as compared with LR ( $9.9 \pm 5.9$  years) and SCR ( $6.32 \pm 8.0$  years) ( $p=0.04$ ). We have identified as NPR factors, the early use of antiTNF during the first year of diagnosis (NPR:  $0 \pm 0$  vs LR:  $9.9 \pm 5.9$  and SCR:  $6.32 \pm 8.0$ ) ( $p=0.043$ ). Increased blood leucocytes count before treatment was also associated with NPR (NPR:  $13.7 \pm 2.1$  vs LR:  $8.4 \pm 2.3$  and SCR:  $7.6 \pm 2.9$ ) ( $p=0.018$ ). In addition, we have identified the overweight as a factor of losing response during the first year of treatment (BMI: NPR:  $24.5 \pm 7.5$ , LR:  $27.6 \pm 4.6$  vs SCR:  $23.4 \pm 3.6$ ) ( $p=0.036$ ). As potential biomarkers of primary response we have identified 18 proteins upregulated, related to hemostasis and metabolism of carbohydrates, all of them with  $p \leq 0.009$  and a fold change  $\geq 2.4$ . 17 of these proteins are regulated by acetylation.

In addition, 4 proteins were potential biomarkers of loss of response ( $p \leq 0.05$  and fold change from 0.5 - 1.4). 2 of them related to lipids metabolism.

**Conclusion:** Early need for anti-TNF and increased blood leucocytes count, probably related to a more severe disease, are associated with NPR. Overweight is associated with secondary loss of response to anti-TNF. In addition, hemostasis, metabolism of carbohydrates and lipids may be involved in the response to anti-TNF in CD.

### P0325 THE EFFECT OF PAI-1 ON ENDOPLASMIC RETICULUM STRESS IN RATS WITH INFLAMMATORY BOWEL DISEASE

Haitao H., Wen L., Xia W.

Hangzhou First People's Hospital, Department of Gastroenterology, Hangzhou, China

**Contact E-Mail Address:** hhtzhcn@126.com

**Introduction:** Studies have shown that long-term, severe endoplasmic reticulum stress (ERS) exceeds regulatory capacity of cells, and activation of the unfolded protein response (UPR) will cause a large number of unfolded and misfolded proteins to deposit in the endoplasmic reticulum. Induction of apoptosis leads to an immune response that causes an immune imbalance. Among them, cytokines TNF- $\alpha$ , IL-1, IL-6, IFN- $\gamma$  and BIP play a key role in the pathogenesis of IBD. Plasminogen Activator Inhibitor 1 (PAI-1) is an irreversible inhibitor of tissue-type Plasminogen Activator (tPA) and urokinase Plasminogen Activator (uPA).

Studies have shown that PAI-1 is involved in the inflammatory process of IBD [4], but the relationship between its specific gene expression and the involvement of related cytokines in the ERS process is still unclear.

**Aims & Methods:** In this study, we will investigate the effect of PAI-1 gene on ERS in rats with inflammatory bowel disease.

12 Wistar normal rats were randomly divided into 2 groups: Control group(n=6) and IBD group(n=6); 12 PAI-1 knock out rats were randomly divided into 2 groups: Knock out PAI-1 control group(n=6) and Knockout PAI-1+IBD group(n=6). The model of IBD was induced by 2,4,6-trinitrobenzene sulfonic acid (TNBS)/absolute ethanol; The pathological grade was evaluated using HE staining; The gene transcriptional levels of PAI-1, IL-6, IFN- $\gamma$ , BIP were measured by Quantitative Real-time PCR (qRT-PCR); The protein expression levels of PAI-1, IL-6, IL-10, IFN- $\gamma$ , BIP, p-IRE1 $\alpha$ , p-JNK, JNK were measured by western blot.

**Results:** 1.Pathological examinations showed severe changes of colonic tissue and inflammation in IBD rats whereas relieved symptoms were found in PAI-1 knock out rats with IBD.

2. Compared with the control group, the transcription levels of the inflammation-related factors IL-6, IL-10, IFN- $\gamma$  and BIP in the colon tissue of rats in the IBD group were significantly up-regulated ( $p < 0.01$ ), and the transcription level of PAI-1 gene was significantly up-regulated ( $p < 0.01$ ). Compared with the IBD group, the transcription levels of PAI-1, IL-6, IL-10, IFN- $\gamma$  and BIP genes in Knock out PAI-1+IBD group were significantly down-regulated ( $p > 0.01$ ).

3. Compared with the Control group, the PAI-1 protein expression in the colon tissue of the IBD group was significantly increased, and the protein expression levels of PAI-1, IL-6, IL-10, IFN- $\gamma$ , BIP, p-IRE1 $\alpha$ , p-JNK, JNK were significantly up-regulated. Compared with Knockout PAI-1 control group, there was no significant difference in PAI-1 protein expression of Knock out PAI-1+IBD group, the protein expression levels of PAI-1, IL-6, IL-10, IFN- $\gamma$ , BIP, p-IRE1 $\alpha$ , p-JNK, JNK of Knock out PAI-1+IBD group were significantly up-regulated. Compared with the IBD group, the protein expression levels of PAI-1, IL-6, IL-10, IFN- $\gamma$ , BIP, p-IRE1 $\alpha$ , p-JNK, JNK were significantly down-regulated in the Knock out PAI-1+IBD group.

**Conclusion:** This study explored the interaction of PAI-1 in inflammatory response and endoplasmic reticulum stress. It is concluded that the expression of PAI-1 gene is positively correlated with tissue inflammation and endoplasmic reticulum stress in IBD rats, which may promote the development of inflammatory bowel disease.

**Introduction:** Evidence for the role of the gut microbiota in the development and progression of Crohn's disease (CD) is increasing. So far, gut microbiome studies in patients with CD have focused on characterising the changes in bacterial abundances. Clinical, environmental factors and inflammation can influence not only the microbial composition in the gut but also its total bacterial biomass. However, the total number of bacteria in a sample is rarely considered when investigating the relation between microbiome and gastrointestinal diseases.

**Aims & Methods:** We hypothesize that combining sequencing data with absolute quantification of the gut microbiota (e.g. the number of bacteria per gram of feces) provides better insight in disease heterogeneity and improves the accuracy of gut microbiome studies in diseases such as IBD. We collected 140 fecal samples from a cohort of 70 patients with CD, taken at two time points with an interval of three weeks. Microbial densities were calculated by fluorescence in situ hybridization. Microbiota composition was estimated by shotgun metagenomic sequencing. Phenotypic data, such as medication use and surgery, was obtained from clinical records. PERMANOVA analysis was used to estimate the explained variance of each phenotype on the microbiome composition. Differences between disease phenotypes and microbial loads were calculated using a Wilcoxon-test. To estimate the confounding effect of absolute bacterial quantification, metagenome-wide associations were then recalculated adjusting for bacterial cell counts.

**Results:** Patients with CD showed a large variation in gut bacterial densities, which is independent of disease activity, measured as the level of fecal calprotectin ( $\rho = 0.05$ ,  $P = 0.53$ ). Differences in microbial loads explained most of the variation in microbiome composition between samples ( $R^2 = 10\%$ ,  $P = 0.0001$ ). Higher densities were related with an increased compositional abundance of beneficial bacteria, such as *F.prausnitzii* and *R.intestinalis*, while lower microbial loads were associated with an expansion of potentially pathogenic bacteria such as *E.coli* and *R.gnavus*. Patients with intestinal resections showed lower microbial loads ( $P = 5.94 \times 10^{-6}$ ), although the latest resection occurred, on average, 11 years before sample collection. Interestingly, by using the concentration of DNA extracted in combination with the bacterial richness per sample we can capture ~40% of the variation in the number of bacteria per gram of fecal material. Correcting for bacterial densities in the microbe-trait associations allowed us to increase the specificity of microbiome-wide association studies and therefore pinpoint relevant species in CD sub-phenotypes, such as the association between *F.prausnitzii* and clinical resections in the ileum.

**Conclusion:** The number of bacteria in the gut of patients with CD show a large variation between individuals. Lower microbial densities are correlated with the expansion of pathogenic bacteria and associated with intestinal resection. For specific conditions or sub-phenotypes in the context of IBD, adding bacterial quantification to metagenomics sequence data reveals potential false positive and false negative findings. The differences in bacterial loads should be considered when exploring the gut microbiota of patients with CD, both as a separate major indicator of gut health and as correction factor for microbe-phenotype association.

**Introduction:** Crohn's disease (CD) and ulcerative colitis, generally known as inflammatory bowel disease (IBD), are chronic, relapsing and refractory disorders of the intestine. The pathogenesis of IBD is still not clear. Autophagy is a required system to maintain cellular homeostasis by disassembling unnecessary or dysfunctional components in the cytoplasm, and plays an important role in recovery from inflammation and bacterial infection of intestinal epithelium. Involvement of autophagy-related genes such as Atg16L1, NOD2 and LRRK2 has also been reported in the onset of CD. Therefore, we investigate the effect of autophagy induction on the alleviation of colonic inflammation.

**Aims & Methods:** The modulators of autophagy were screened by *in vitro* screening assay from compound library derived from food and herbal medicine. Autophagy induction was examined using autolysosome formation in MEF cell line. The modulator of autophagy screened by *in vitro* assay was administered to the acute dextran sulfate sodium (DSS)-induced colitis model mice and the effect was evaluated by weight reduction, colon length and histopathological examination.

**Results:** From screening assay, 3 compounds showed autophagy induction and relieving colitis. The administration of one compounds derived from herbal medicine (named SO) significantly prevent weight loss, colonic shortening and infiltration of inflammatory cells. SO induced autophagosome formation in Caco2 (human intestinal epithelium cell line) by concentration dependency. Western blotting assay showed the expression of representative autophagy marker LC3 was high in the epithelium and enhanced by administration of SO. Immunohistological examination showed high expression of LC3- II in the intestinal epithelium after administration of SO in colitis model mice.

**Conclusion:** We identified 3 autophagy modulators which has effects of autophagy induction and relieving colitis. SO which has high activity for inducing autophagy induced the effect of alleviation colitis through autophagy induction of intestinal epithelium.

**Introduction:** Inflammatory bowel disease (IBD) and colorectal cancer (CRC) evoke response from circulating immune cells and analyzing gene expression patterns in whole blood, owing to its availability, might be advantageous over more relevant but less accessible bowel tissues. The effect

of bowel inflammation and cancer on the expression of the most popular internal controls: ACTB, GAPDH, and B2M in whole blood is unknown, although at least GAPDH occurred to be tightly regulated and suspected of supporting cancer growth, challenging its suitability as reference.

**Aims & Methods:** We designed our present study to find and validate optimal reference genes for whole blood transcriptome studies involving patients with CRC and IBD, active and non-active (1), and to examine and compare the effect, if any, bowel cancer and inflammation might have on the expression of popular HKG in whole blood (2). Stability of ACTB, B2M, GAPDH, HPRT1, SDHA, and TBP expression in blood from controls, colorectal cancer, and active inflammatory bowel disease patients was evaluated in RT-qPCR using NormFinder, geNorm, BestKeeper, and comparative  $\Delta\Delta C_t$  method and validated by comparison with absolute quantification of IL1 $\beta$  and CCL4.

**Results:** HPRT1, SDHA and TBP were superior normalizers for whole blood in CRC and IBD. The highest variability was in active IBD. B2M was significantly lower in CRC but higher in IBD. GAPDH was higher in CRC and IBD. ACTB and GAPDH corresponded with CRC advancement ( $p=0.52$  and  $p=0.53$ ) and with clinical activity in Crohn's disease ( $p=0.44$  and  $p=0.57$ ) and ulcerative colitis (GAPDH:  $p=0.72$ ). ACTB, B2M, and GAPDH correlated with circulating inflammatory/angiogenic indices, differently in IBD and CRC. In IBD, ACTB positively correlated with CRP, B2M with FGF2 and MIP1 $\alpha$ , and GAPDH with CRP, IL1 $\beta$ , IL4, IL8, IL12, G-CSF, and TNF $\alpha$ . In CRC, ACTB positively correlated with IL1 $\beta$ , IL6, IL8, FGF2, G-CSF, GM-CSF, MIP1 $\alpha$ , and TNF $\alpha$  and GAPDH with IL1 $\beta$ , IL6, FGF2, G-CSF, GM-CSF, MIP1 $\alpha$ , and TNF $\alpha$ , and B2M negatively with FGF2, G-CSF, and TNF $\alpha$ .

**Conclusion:** The expression of frequently used normalizers for whole blood transcriptomic analysis, that is, GAPDH, ACTB, and B2M, is directionally affected by bowel inflammation and cancer, rendering them unsuitable as reference in CRC and IBD. The expression of HPRT1, SDHA and TBP was stable across CRC and IBD patients allowing for their recommendation as normalizers in studies involving both groups of patients.

**Introduction:** Clinical trials suggest that vagus nerve stimulation presents an alternative approach to classical immune suppression in Crohn's disease. T-cells capable of producing acetylcholine (ChAT<sup>+</sup> T-cells) in the spleen are essential mediators of the anti-inflammatory effect of vagus nerve stimulation. Besides the spleen, ChAT<sup>+</sup> T-cells are found abundantly in Peyer's patches of the small intestine. However, the role of ChAT<sup>+</sup> T-cells in colitis pathogenesis is unknown.

**Aims & Methods:** The aim of this study was to investigate the role of ChAT<sup>+</sup> T-cells in experimental models of colitis. We made use of CD4<sup>cre</sup>ChAT<sup>fl/fl</sup> mice (CD4ChAT<sup>-/-</sup> mice), lacking ChAT expression specifically in CD4<sup>+</sup> T-cells. Littermates (ChAT<sup>fl/fl</sup> mice) served as controls. We used three experimental colitis models: 1) Acute dextran sulphate sodium (DSS)-induced colitis: 7 days of 2% DSS in the drinking water; 2) A resolution model of DSS-induced colitis: 5 days of 2% DSS in the drinking water followed by 7 days without DSS; 3) T-cell transfer colitis using CD4<sup>+</sup>CD45RB<sup>high</sup> T-cells as donor cells. Outcome measures included bodyweight loss, endoscopy and histology score, colon weight and intestinal cytokine levels.

**Results:** In acute DSS-induced colitis, CD4ChAT<sup>-/-</sup> mice showed attenuated colitis and lower intestinal inflammatory cytokine levels compared to ChAT<sup>fl/fl</sup> mice. In contrast, in the resolution model of DSS-induced colitis, CD4ChAT<sup>-/-</sup> mice showed a worsened colitis recovery and augmented colonic histological inflammation scores and inflammatory cytokine levels as compared to ChAT<sup>fl/fl</sup> mice. In the T-cell transfer model, T-cells from CD4ChAT<sup>-/-</sup> mice induced a similar level of colitis compared with ChAT<sup>fl/fl</sup> T-cells.

**Conclusion:** Our results indicate that ChAT<sup>+</sup> T-cells aggravate the acute innate immune response upon mucosal barrier disruption in a DSS-induced colitis model, while they are supporting the later resolution process of this innate immune driven colitis. Surprisingly, ChAT expression in T-cells seems redundant in the context of T-cell driven colitis.

**Introduction:** The family of Free Fatty Acid Receptors (FFARs), specific G protein-coupled receptors consist of four members: FFAR1-4, where each responds to different chain length fatty acids (FAs). It was reported that FFAR ligands may reduce inflammatory states, thus FFARs have become a potential new target in inflammatory bowel disease (IBD). IBD is a heterogeneous disorder characterized by chronic, relapsing, inflammation in the gastrointestinal tract, consisting of ulcerative colitis (UC) and Crohn's disease (CD). Neither CD nor UC are fatal diseases but both are debilitating with a wide range of symptoms. One of IBD symptoms is secretory diarrhea, which occurs when secretion of water and electrolytes into the intestinal lumen exceeds its absorption. The movement of fluid between the intestinal lumen and blood is driven by the active transport of ions, thus restoration of this process in IBD patients could be beneficial as the chronicity of symptoms leads to decrease in patient's quality of life.

**Aims & Methods:** The aim of this study was to evaluate the effects of FFAR1-4 agonists on epithelial ion transport in isolated mouse colon stimulated by Forskolin (FSK) and Veratridine (VER) and compare between groups comprising healthy control and 3% Dextran Sulfate Sodium (DSS)-treated mice.

Male c57 mice were randomly divided into healthy control group and group treated with 3% DSS in drinking water. Epithelial ion transport was examined using Ussing Chambers. Changes in ion flux were determined on the basis of short-circuit current ( $\Delta I_{sc}$ ) in isolated mouse colon exposed to FFAR1-4 and stimulated with FSK or VER.

**Results:**  $\Delta I_{sc}$  values were reduced in inflamed tissues as compared to controls in all colon samples stimulated with FSK. Incubation of healthy tissue with FFAR1 and FFAR2 agonists caused significant ( $p < 0.05$ ) reduction of  $\Delta I_{sc}$  induced by FSK. On the other hand, FFAR3 agonist caused significant  $\Delta I_{sc}$  decrease in inflamed colon tissue stimulated with FSK. FFAR1 and FFAR2 agonists lowered, but FFAR3 and FFAR4 agonists increased ion transport in control tissues stimulated with VER. Incubation of DSS-treated mouse colon tissue with FFAR1, 2 and 4 agonists diminished  $\Delta I_{sc}$  caused by VER.

**Conclusion:** FFAR agonists differentially affect the ion transport in healthy and inflamed colon tissue. The varying effects depend not only on the receptor but also on the modulator of ion flux (FOR or VER). These differences may be explained by the activation of various intracellular pathways by FFAR agonists, which need further investigation.

To summarize, we suggest that it is possible to develop treatment in a form of specialized diet enriched with specific FFAR ligands which could ameliorate symptoms of IBD associated with disrupted transport across intestinal epithelium.

### P0331 MOLECULAR RESPONSE TO USTEKINUMAB IN MODERATE-TO-SEVERE ULCERATIVE COLITIS BY SERUM PROTEIN AND COLON TRANSCRIPTOMIC ANALYSIS: RESULTS FROM THE UNIFI PHASE 3 MAINTENANCE STUDY

**Li K.**, Yang F., Hayden K., Strawn D., Wadman E., Bhagat S., Marano C., Friedman J.

**Contact E-Mail Address:** kli@its.jnj.com

**Introduction:** The cytokines IL-12 and IL-23 are elevated in ulcerative colitis (UC), and genetic association suggests that they play causative roles in the disease. Ustekinumab (UST), an anti-IL-12p40 monoclonal antibody that binds both cytokines, is an effective therapy for moderate-to-severe UC. We previously observed a partial normalization of UC disease signatures in colonic biopsy gene expression and serum protein levels following UST induction therapy.<sup>1</sup> However, the molecular effects of maintenance UST therapy in UC patients are unknown.

**Aims & Methods:** We evaluated the molecular effects of UST in the UNIFI Phase 3 maintenance study of UST in moderate-to-severe UC (n=961). Subjects in response to UST 8 weeks after intravenous induction were randomized to receive maintenance treatment with subcutaneous placebo, UST 90 mg every 8 (q8w) weeks, or UST 90 mg every 12 weeks (q12w). Colonic biopsy mRNA and serum samples from the first ~60% of patients treated in the UNIFI phase 3 induction study<sup>2</sup> were analyzed, with equal representation of patients with or without a history of biologic therapy failure (Table 1). Biopsy and serum samples from healthy subjects were analyzed as controls.

**Results:** At Week 44 after the start of maintenance therapy, the expression of colonic genes dysregulated in UC was altered towards normal levels in all treatment groups, with the greatest improvements among those receiving UST and those in clinical remission ( $p < 0.05$  for maintenance Week 44 versus start of maintenance). No dose effect was observed between q8w and q12w UST treatment arms, and no significant improvements in disease signature occurred in non-responders to placebo or UST. Ustekinumab maintenance therapy magnified the normalization of serum proteins following UST induction; among subjects receiving q8w UST who were in remission at Week 44, the proteins IFN $\gamma$ , IL-17A, MMP3, and SAA reached concentrations comparable to those seen in healthy controls. Similar trends occurred in subjects in remission following q12w UST and to a lesser degree among UST-treated subjects not in remission at Week 44. Among subjects receiving placebo maintenance therapy who were in remission at Week 44, the disease-associated serum proteins that decreased following UST induction were not further reduced during maintenance. As previously observed in the induction studies, UST maintenance did not reduce serum TNF levels.

**Conclusion:** UST maintenance therapy suppressed IL-12 and IL-23-related serum proteins and promoted normalization of the UC disease transcriptomic profile. These results provide insight into the molecular mechanisms associated with the efficacy of UST maintenance therapy.

**Contact E-Mail Address:** paolo.biancheri@gmail.com

**Introduction:** Biologic therapy is highly effective in inflammatory bowel disease (IBD), however a significant proportion of patients fail to respond, and mechanisms underlying primary non-responsiveness are unclear. We have previously observed that proteolytic degradation by MMP (matrix metalloproteinase)-3 and MMP-12, which are up-regulated in IBD inflamed mucosa, may contribute to primary non-responsiveness to anti-tumour necrosis factor (TNF)- $\alpha$  agents in IBD.<sup>1</sup> We hereby investigated the effect of other proteases on the integrity and function of anti-TNF- $\alpha$  and anti-integrin agents.

**Aims & Methods:** We co-incubated increasing concentrations of activated recombinant human MMP-7, MMP-13, and Cathepsin G with the anti-TNF- $\alpha$  agents Infliximab, Adalimumab, and Etanercept, or with the anti-integrin agent Vedolizumab, and we subsequently analysed the cleavage reaction products by Western blotting. Using a reporter cell line, we evaluated the effect of recombinant human proteases on the ability of anti-TNF- $\alpha$  agents to neutralise soluble TNF- $\alpha$ .

**Results:** Infliximab, Adalimumab and Vedolizumab were not degraded by MMP-7, MMP-13, or Cathepsin G. Etanercept was degraded in a concentration-dependent manner by MMP-7 and MMP-13, but not by Cathepsin G. Degradation by MMP-7 and MMP-13 did not significantly impair the ability of Etanercept to neutralise soluble TNF- $\alpha$ .

**Conclusion:** Despite being known to cleave immunoglobulins,<sup>2</sup> MMP-7 and MMP-13 do not appear to impair the integrity and function of Infliximab and Adalimumab. In keeping with our previous findings, Etanercept appears to be highly susceptible to the action of proteases.

**Introduction:** Distinct metabolic signatures have been detected in urine that differentiate Crohn's disease (CD) from controls in multiple studies, with consistent discriminatory metabolites derived from bacteria and co-bacterial pathways (1). Multiple other diseases have also been found to affect the urinary metabolome, and many of these relate to changes in bacterial associated metabolites (2).

**Aims & Methods:** The aim of this study was to examine whether the same metabolite changes that have been previously shown are present in a real life cohort of CD patients, and if these patients could be distinguished from controls despite the presence of co-morbidities. Nuclear magnetic

resonance (<sup>1</sup>H NMR) spectroscopy was used to acquire urinary metabolic data from 74 CD patients and 100 controls. 19 of the CD group and 48 of the controls had at least one significant co-morbidity (diabetes, asthma, hypertension). Multivariate analysis was performed using OPLSDA. Univariate analysis was also performed to assess whether bacterial associated metabolites, as demonstrated in previous studies (1), were significantly different in CD patients compared to controls. These metabolites were hippurate, alanine, citrate, P-cresol, phenylacetylglutamine (PAGn), and dimethylglycine (DMG).

**Results:** OPLSDA analysis showed statistically significant separation between CD patients and controls irrespective of the presence of co-morbidities. Model 1 compares CD patients to healthy controls (H). Models 2 and 3 include CD patients with at least one other co-morbidity (CDWC), and Model 3 includes non-CD patients with another co-morbidity in the control group (C).

Univariate analysis showed that the bacterial associated metabolites hippurate, citrate, P-cresol, DMG, and PAGn changed with statistical significance between CD groups and controls irrespective of the presence of co-morbidities.

**Conclusion:** The pattern of change in discriminating metabolites appear to be preserved in models separating CD from controls when patients with co-morbidities are included in the models, and these groups can be significantly separated with multivariate analysis. It is likely the effect of microbial disturbance is still measurable with this technique in a real world cohort.

Model	n	R <sup>2</sup> X	Q <sup>2</sup>	P value CV-ANOVA	Metabolites driving model in CD
1 CD : H	106 (54 : 52)	0.085	0.231	0.014	hippurate↓ alanine↓ citrate↓ P-cresol↑ PAGn↑ DMG↓ leucine↓ aspartate↓
2 CDWC : H	128 (74 : 54)	0.100	0.175	0.057	hippurate↓ alanine↓ citrate↓ P-cresol↑ PAGn↑ DMG↓
3 CDWC : C	174 (74 : 100)	0.037	0.093	<0.001	hippurate↓ alanine↓ citrate↓ P-cresol↑ PAGn↑ DMG↓ sucrose↑

**Contact E-Mail Address:** jonathan.evans@hcdconomics.com

**Introduction:** Ulcerative Colitis (UC) has a significant impact on quality of life, ability to work and making career choices and often a negative psychosocial impact on patients' lives. The wider implications to psychosocial well-being and activities of daily living challenge existing paradigms which are currently limited to clinical "remission" and regard surgery in some instances as being "curative". There is an urgent need for studies assessing health-related quality of life (HRQoL) even as modern biological therapies redefine our perceptions of disease control.

The Living with Ulcerative Colitis: Identifying the socioeconomic burden in Europe (LUCID) study was a descriptive, retrospective, cross-sectional, European (France, Germany, Italy, Spain, United Kingdom, Denmark, Norway,

Poland, Romania and Turkey), multi-site bottom-up prevalence-based Burden of Illness research study carried out by HCD Economics and the University of Chester in partnership with Crohn's and Colitis UK.

**Aims & Methods:** The aim of this study was to explore the impact of UC on patients' HRQoL and productivity. Patients were recruited through Gastroenterologists (surveyed between August 2018 - February 2019) and split into two population cohorts; Arm 1: Patients with moderate or severe UC status at initiation of documentation period (12 months prior the index date) and Arm 2: Patients with moderate or severe UC that achieved mild UC or remission at initiation of documentation period. Each patient was invited to complete a public patient involvement and engagement (PPIE) form. The PPIE included patient reported outcome measures (PROMs) to capture intangible costs using the work productivity and impairment (WPAI) questionnaire, which quantifies work time missed, work impairment and activity impairment, and HRQoL using the EQ5D. The EQ5D produces a utility score of the patients current HRQoL from five domains, with 1 denoting perfect health and 0 denoting death.

**Results:** 1,658 patients completed the PPIE form. Of these patients, 9 patients did not have their UC status recorded so could not be assigned to an arm. Out of these patients, 1,001 patients (60.7%) were categorised into arm 1 with 648 patients (39.3%) categorised into arm 2. 994 patients from arm 1 and 638 patients from arm 2 completed the EQ5D with a mean score of 0.81 (0.17 SD) and 0.86 (0.16 SD) respectively. The mean WPAI scores for arm 1 (n=602) were 0.11 (0.25 SD) for work time missed (absenteeism), 0.24 (0.21 SD) for impairment (presenteeism), 0.28 (0.24 SD) for work impairment and 0.27 (0.24 SD) for activity impairment. The mean WPAI scores for arm 2 (n=368) were 0.01 (0.19 SD) for work time missed (absenteeism), 0.24 (0.18 SD) for impairment (presenteeism), 0.2 (0.21 SD) for work impairment and 0.18 (0.2 SD) for activity impairment.

**Conclusion:** Our preliminary results show that UC has implications on HRQoL and work productivity for all patients with UC, ranging from those in remission or mild disease to those with moderate or severe UC, underpinning the need for more holistic and inclusive definitions of care and disease control. Further analysis, to understand the impact of ulcerative colitis on patients, is ongoing to address this important and unmet need.

**Contact E-Mail Address:** sarah.campbell-hill@takeda.com

**Introduction:** Perianal fistulas (PAF) in patients with Crohn's disease (CD) are associated with morbidity and impaired quality of life. Limited data is available on the risk of PAF among patients with CD and long-term PAF relapse rates.

**Aims & Methods:** To describe characteristics of patients with CD and PAF, and rates of PAF recurrence (a proxy for disease relapse including both relapse of previous fistula and development of new fistula). A retrospective cohort study on US adult patients with CD identified in an US administrative claims database (2001-2018) was conducted. Patients with PAF were identified using diagnosis or procedure codes in medical claims. A PAF episode, starting from the first PAF occurrence, was defined as consecutive PAF-related codes ≤120 days of each other. PAF recurrence was defined as a new PAF-related code occurring after a PAF-free period of ≥180 days (proxy for remission) following the end of the first PAF episode. Time from the 180-day PAF-free period to PAF recurrence was estimated using KM analyses. A similar analysis was conducted in CD patients with a PAF-free period of ≥360 days.

**Results:** 5,482 patients with a PAF-free period of ≥180 days after their first PAF episode were included (CD-PAF cohort; mean age=43.8 years and proportion of males=51.8%). Over a mean follow-up duration of 2.6 years, 28.8% had a PAF recurrence. Estimated rates of PAF recurrence in these CD-PAF patients were 23.7%, 32.0%, 42.1% and 47.8% at 1, 2, 5, and 10 years, respectively (Table 1).

In the 12 months before first PAF occurrence, 70.8% of CD-PAF patients received non-biologic therapies: corticosteroids (46.5%), antibiotics (44.4%), aminosalicylates (5-ASA) (32.5%) and immunomodulators (IMDs)/immunosuppressants (IMs) (21.1%); 25.3% used ≥1 biologic therapy; and 19.2% had ≥1 CD-related surgery. In the 4 months after first PAF occurrence, 66.5% of CD-PAF patients received non-biologic therapies: antibiotics (39.6%), corticosteroids (30.3%), 5-ASA (27.4%) and IMDs/IMs (22.1%); 31.8% used ≥1 biologic therapy; and 47.2% had ≥1 CD-related surgery. In patients with a longer PAF-free period of ≥360 days (CD-PAF360 cohort), a numerically lower proportion had a PAF recurrence (20.5%) and estimated rates of recurrence were numerically lower at every time point (32.6% at 5 years and 39.4% at 10 years) vs the CD-PAF cohort.

Cohort (N)	Duration of follow-up, mean [a]	Patients with PAF recurrence, N (%)	KM analyses [b,c]	3 months	6 months	1 year	2 years	5 years	10 years
CD-PAF (N=5,482)	2.6 years	1,578 (28.8%)	KM rates [b,c]	10.0%	16.0%	23.7%	32.0%	42.1%	47.8%
CD-PAF (N=5,482)	2.6 years	1,578 (28.8%)	Patients at risk, N	4,478	3,771	2,824	1,702	494	85
CD-PAF360 (N=3,764)	2.7 years	771 (20.5%)	KM rates [b,c]	5.2%	9.2%	14.5%	21.7%	32.6%	39.4%
CD-PAF360 (N=3,764)	2.7 years	771 (20.5%)	Patients at risk, N	3,236	2,824	2,162	1,360	422	67

[a] Duration of follow-up starts from the end of the PAF-free period following the first PAF episode

[b] KM rates of PAF recurrence from the end of the PAF-free period of 180 days (CD-PAF) or 360 days (CD-PAF360) following the first PAF episode. KM rates are estimated at given time points and represent cumulative incidence accounting for right censoring

[c] Similar findings were observed in the sensitivity analysis defining a PAF episode as all consecutive PAF within 180 days of each other (vs. 120 days)

[Table 1. Kaplan-Meier rates of recurrence of perianal fistulas among patients with Crohn's disease]

**Conclusion:** In this retrospective US claim database analysis, the 5-year and 10-year rates of PAF recurrence following PAF remission of ≥180 days were 42.1% and 47.8% among patients with CD, respectively. Patients achieving longer-term remission (≥360 days) had numerically lower rates of PAF recurrence. Future studies should examine the impact of disease severity and treatment on long-term rates of PAF recurrence.

**Introduction:** Updated data on the incidence, evolution and treatment strategies used in IBD management in South Europe is needed. This is the largest study on the recent epidemiology of IBD in Spain.

### Aims & Methods:

i) To assess the incidence of IBD in Spain; ii) to describe the main epidemiological and clinical characteristics of patients at diagnosis and the evolution of the disease; and iii) to explore the use of treatments in the biological era.

Prospective and population-based nationwide registry. Adult patients diagnosed with IBD <sup>3</sup>/<sub>4</sub> Crohn's disease (CD), ulcerative colitis (UC) or IBD unclassified (IBD-U) <sup>3</sup>/<sub>4</sub> during 2017 in the 17 Spanish regions were included and will be followed-up for 5 years after diagnosis. Treatment was grouped into 5 categories: mesalazine (oral or topical), steroids (intravenous, oral or topical), immunomodulators (thiopurines, methotrexate or cyclosporine), biologics (anti-TNF, vedolizumab or ustekinumab) and surgery. Cumulative incidence of exposure to each of the studied treatments was estimated by Kaplan-Meier curves.

**Results:** 3,627 incident cases of IBD diagnosed during 2017 from 108 centres covering over 22 millions of adult inhabitants (about 50% of the Spanish population) comprise the study cohort.

The overall incidence (per 100.000 person-years) of IBD was 16: 7.5 for CD, 8 for UC, and 0.5 for IBD-U. 46% of patients had CD and 50% UC. Diagnosis delayed was significantly longer in CD than in UC (5 vs. 2 months,  $p < 0.01$ ). The proportion of patients with symptoms at diagnosis was higher in UC (94 vs. 89%,  $p < 0.01$ ).

On the opposite, the proportion of patients with family history of the disease (18 vs. 13%,  $p < 0.01$ ), smoking habit (38 vs. 12%,  $p < 0.01$ ) and extraintestinal manifestations (12.5 vs. 6%,  $p < 0.01$ ) were significantly higher in CD than in UC. At diagnosis, 18% of CD patients had structuring or fistulising behaviour and 64% of UC patients had pancolitis or left-sided colitis. 27% of patients were hospitalized during a median follow-up of 10 months (35% of CD and 22% of UC patients,  $p < 0.01$ ).

During follow-up, 33 (2.4%) CD patients progressed to a more severe phenotype, and 2 (0.01%) UC patients to more extensive involvement. The cumulative incidences of the different treatments are shown in table 1.

**Conclusion:** The incidence of IBD in Spain is relatively high and similar to figures reported in Northern Europe. IBD patients require the use of substantial diagnostic and therapeutic resources, which are higher in CD than

in CU. One third of patients are hospitalized in the first year after diagnosis and over 5% undergo surgery. Our results highlight the high burden of IBD as well as the important challenges faced by health-care systems to manage this costly and complex disease.

Treatments	Cumulative incidence of exposure to treatments (%)					
	6 months			12 months		
	UC	CD	p	UC	CD	p
Mesalazine (%)	89	36	<0.01	99	40	<0.01
Steroids (%)	35	70	<0.01	40	75	<0.01
Immunomodulators (%)	7	38	<0.01	11	50	<0.01
Biologics (%)	7	13	<0.01	11	31	<0.01
Surgery (%)	1	8	<0.01	2	11	<0.01

[Table 1. Cumulative incidences of exposure to different therapeutic options in Crohn's disease (CD) and ulcerative colitis (UC) patients]

**Introduction:** Data from clinical trials suggest that biological drugs might improve the outcomes in Crohn disease (CD) by reducing the need for surgery or hospitalization. Data on the trends in biological drugs use and outcomes in CD patients are scarce.

**Aims & Methods:** The aim of this study was to evaluate the time-trends of the prescription of biological drugs and other treatments for Crohn's disease (CD), and its relationship with outcomes as surgery and hospitalization in Catalanian population.

All patients with CD included in the Catalan Health Surveillance System (including data on more than 7.5 million individuals) from 2011 to 2017 were identified. The exposures to different IBD treatments was retrieved from the electronic dispensation records. Time trends for surgery and hospitalization were also described and correlated with treatment. The statistical analysis was carried out using the statistical package R, version 3.4.3.

**Results:** The use of salicylates, corticosteroids and immunosuppressant treatment decreased from 2011 to 2017 from 28.8% to 17.1%, 15.8% to 13.7%, and 32.9 to 29.6%, respectively. Biological treatments increased from 15.0% to 18.7%. Adalimumab was the most prescribed (1604 patients, 52% of all biologics in 2017). Ostomy rates per 1000 patients/year decreased from 13.2 in 2011 to 9.8 in 2017. Corresponding figures for surgical resection decreased from 24.1 to 18.0. The rate of the CD-related hospitalizations per 1000 patients/year decreased from a 92.7 to a 72.2.

**Conclusion:** Use of biological drugs increased from 15.0% to 18.7% from 2011 to 2017. During the same periods we observed an improvement in the outcomes of CD patients.

**Introduction:** in general, IBD are diagnosed in subjects with gastrointestinal symptoms, despite this a diagnostic delay is often observed. However IBD may also be present in asymptomatic subjects. In these cases, diagnosis may be further delayed, incidentally done or missed.

**Aims & Methods:** we analyzed an electronic database of a regional colorectal cancer population screening program offered to subjects from 50 to 70 years old with faecal occult blood. From 1 September 2013 to 31 August 2018, among subjects who underwent colonoscopy in a single hospital, we identified subjects with endoscopic findings suggestive of IBD. Of these, we retrieved histological findings as well as information on other examinations and possible therapeutic decisions.

**Results:** 3972 subjects undergoing to colonoscopy were enrolled. In 46 (1.16%) subjects (24 men, mean age  $\pm$  SD 60.3  $\pm$  6.8 years) endoscopic findings suggestive of IBD were present: 35 of CD and 11 of UC; none of these subjects were taking oral anticoagulants or NSAIDs and reported gastrointestinal symptoms. After a median follow-up of 12 months (range 2-58), a definitive diagnosis of IBD was done in 13 subjects (0.33%). Of these, 3 already underwent to colonoscopy in the context of the same program and 1 showed familiarity for IBD. Nine were diagnosed with CD (7 men, 60.0  $\pm$  6.6 years) and 4 with UC (3 men, 59.1  $\pm$  6.9 years). In CD population, 4 patients showed colonic, 4 ileal and 1 ileo-colonic location; 1 was treated with steroids and then with vedolizumab, 1 with steroids and then with azathioprine, 1 with 5-ASA, 1 with Budesonide, while 5 did not receive any therapy. In UC population, 2 patients showed extension limited to rectum and 2 to rectum and sigmoid colon; all patients started therapy with 5-ASA, 1 with systemic steroids and Vedolizumab.

**Conclusion:** prevalence of IBD in a colorectal cancer population screening program is 0.33%. IBD diagnosis can be missed in asymptomatic subjects, but only 1 out of 4 subjects with endoscopic findings suggestive of IBD is eventually diagnosed as affected by CD or UC.

**Introduction:** The etiology of inflammatory bowel diseases (IBD), including ulcerative colitis (UC), has not been established. The role of microbiota in the development of intestinal wall inflammation is still unclear. Can dysbiosis be one of the causes of the disease, or is it a consequence of it? We still do not know.

**Aims & Methods:** Our study was prospective aimed to evaluate the composition of the gut transient and mucosal microbiome in various forms of UC by real-time polymerase chain reaction (RT-PCR). None of patients had received antibiotics or probiotics previously. Stool samples and mucosal biopsies were collected for each participant immediately frozen until analysis. 70 patients with UC were included. The median age was 40 $\pm$ 14.4 years (range 18-69). 43 were female (61.4%), 27 - male (38.6%). Duration of the disease was 7.22 $\pm$ 6.9 years (range 0.5-38). Extensive colitis was diagnosed in 78.6% cases (n=55), left-sided colitis - 21.4% (n=15). Acute UC was found in 3 (4.3%) patients, relapsing course of the disease in 29 (41.4%) and remitting course in 38 (54.3%) patients. The activity of the UC (Truelove-Witts classification) was variable: mild - 38 (54.3%), moderate - 14 (20%) and clinical remission - 18 (25.7%). PCR diagnostics of stud-

ied samples was carried out using a DT-96 amplifactor (DNA-Technology, Russia). The non-parametric Mann-Whitney test was performed to calculate the confidence.

**Results:** Using RT-PCR, the following bacterial phylotypes were isolated: *Firmicutes*, *Bacteroidetes*, *Actinobacteria*, *Euryarchaeota*, *Fusobacteriaceae*, *Verrucomicrobia*, and *Proteobacteria*. When comparing the microbial composition in stool samples and mucosal biopsies of the affected parts of the intestine in left-sided UC were revealed the following differences. The total bacterial mass of biopsies (4.736) is less compared to the total bacterial mass of fecal samples (7.240) ( $p < 0.05$ ). In stool samples the concentration of *Methanobrevibacter spp* ( $p < 0.05$ ), *Fusobacteriaceae* ( $p < 0.05$ ), *Akkermansia muciniphila* ( $p = 0.0441$ ), *Staphylococcus spp* ( $p = 0.0002$ ), *Anaerococcus spp* ( $p = 0.0308$ ), *Helicobacter spp* ( $p < 0.05$ ), *Bdelovibrio* ( $p = 0.0017$ ), *Suterella wadsworthensis* ( $p = 0.0295$ ), *Pseudomonas spp* ( $p < 0.05$ ), *Campylobacter spp* ( $p < 0.05$ ), *Mageebacillus indolicus* ( $p < 0.05$ ), *Clostridium leptum gr-* ( $p = 0.0025$ ) was significantly less. The number of *Lactobacillus spp* is reduced in the biopsy compared to stool samples ( $p = 0.0434$ ). The difference in the microbes' concentration in stool samples and biopsies from unaffected sections in left-sided UC is similar to the above data ( $p < 0.05$ ).

The content of *Clostridium leptum gr-* is significantly reduced in the inflamed part of the intestine ( $p = 0.03$ ). In patients with extensive UC, when comparing stool samples and biopsies, a significant decrease in the concentration of 15 species in stool samples ( $p < 0.05$ ) was found. The number of *Lactobacillus spp* is reduced in the biopsies compared to stool samples ( $p < 0.05$ ).

**Conclusion:** In any form of UC, stool samples significantly reduced microbes' concentration in types *Euryarchaeota*, *Fusobacteriaceae*, *Verrucomicrobia*, and *Proteobacteria*. The content of *Lactobacillus spp* in the affected areas of the intestine has been reduced. Transient microbiota differs in composition from the mucosal and does not reflect the real microbial diversity of mucosal microbiome. Its definition in routine practice is not diagnostically significant. The composition of mucosal microbiota of the right and left sections of large intestine in left-sided UC was not significantly different.

**Introduction:** Inflammatory bowel diseases (IBD) can be considered as systemic conditions for the possible involvement of extraintestinal manifestations (EIMs). Previous studies showed that patients with IBD in an active phase have an increased cardiovascular (CV) risk compared to healthy controls. Flow-mediated dilation (FMD) of brachial artery and carotid intima-media thickness (IMT) are ultrasound, validated techniques, which assess endothelial function and atherosclerosis. We aimed to assess CV risk in IBD patients with EIMs in order to evaluate a possible influence of extraintestinal inflammatory activity.

**Aims & Methods:** We enrolled 56 consecutive subjects with an established diagnosis of IBD associated with EIMs and 20 patients with IBD without EIMs as control group. The first group was subsequently divided into 4 subgroups on the bases of disease activity (patients with both active or inactive IBD and EIMs, patients with intestinal symptoms and no signs of EIM and vice versa). Patients were screened for common CV risk factors and underwent FMD and IMT evaluation.

We performed Kruskal-Wallis test, followed by Dunn's post-hoc test for multiple comparisons for analysis of continuous variables. Spearman's test was used for correlation analysis.

**Results:** FMD and IMT values showed no statistically significant difference in any group ( $P = 0.64$  and  $P = 0.65$ ) nor when we considered only the presence of active or inactive EIM (control group vs active or vs inactive EIM,  $P = 0.44$  and  $P = 0.29$ ). FMD showed no correlation with patients' and disease characteristics, while IMT correlated with BMI ( $p < 0.0001$ ).

**Conclusion:** Our study showed no difference in CV risk in IBD patients with a concomitant EIM. However, it cannot address definite conclusions, since the lack of statistically significant differences is probably due to the small sample size. Therefore, we should obtain a clear picture about the possible relationship between CV risk and EIM in IBD only when the results will involve an adequate sample size.

**Introduction:** Inflammatory bowel diseases (IBD) are frequently diagnosed in individuals who are in the reproductive period. Lack of fertility and pregnancy-related knowledge leads to subsequent voluntary childlessness, although pregnancy outcome is favorable in the majority of IBD patients that plan pregnancy when the disease is in remission.

**Aims & Methods:** The aim of the study was to investigate specific reproductive knowledge in patients with IBD. In this study 165 female IBD patients (aged 20 to 74) treated in the Clinic for Gastroenterology and Hepatology Clinical center of Serbia and Clinical center of Vojvodina completed a standardized questionnaire consisting of demographic characteristics, pregnancy, and abortion data, IBD phenotype and therapy. Disease-related pregnancy knowledge was assessed using Crohn's and colitis pregnancy knowledge score (CCPKnow). CCPKnow consists of 18 questions and scores lower than 7 are considered poor. Patients were divided according to the diagnosis into the group with ulcerative colitis (UC) and Crohn's disease (CD). These two groups were further stratified according to the occurrence of pregnancy after IBD diagnosis.

**Results:** We analyzed data from 165 IBD patients (73 UC, 92 CD). In UC group 23 (31.5%) and in CD group 32 (34.9%) were childless. After IBD was diagnosed a total of 48 pregnancies occurred. In 17 UC patients, there were 24 pregnancies while in CD patients a total of 18 women had 24 pregnancies. Statistically, a significant difference was shown in UC patients when the average number of children was compared between groups with and without pregnancy after IBD diagnosis (2.05 vs. 0.94,  $p < 0.001$ ). The average age at diagnosis in UC patients who gave birth after IBD diagnosis was  $24 \pm 6$  compared to  $37 \pm 13$  years in the group who did not give birth after IBD diagnosis ( $p < 0.001$ ). Average CCPKnow score surprisingly did not differ between the two groups (6.82 vs. 5.76  $p > 0.05$ ). CD patients who were pregnant after diagnosis were significantly younger ( $p < 0.001$ ) compared to those who did not ( $21 \pm 7$  vs  $33 \pm 12$ , respectively) and they had an average of 1.5 children compared to 0.96 in those who did not have children after IBD was diagnosed ( $p < 0.05$ ). The CCPKnow score was higher in patients that had children after IBD diagnosis although the difference did not reach statistical significance (7.61 vs. 5.31,  $p = 0.051$ ). The average number of children in mothers on biological therapy was 1.0 on infliximab (IFX) and 0.96 on adalimumab (ADA).

**Conclusion:** Our study confirmed that voluntary childlessness is common in female patients with IBD. The CCPKnow score is extremely low in the examined population and is not related to the decision to have children after IBD diagnosis. Patients who had children after IBD was diagnosed were significantly younger at diagnosis and had more children than those who remained childless after IBD was diagnosed. There is an urgent need to improve pregnancy and fertility-related knowledge in IBD patients in Serbia.

**Contact E-Mail Address:** johannes.stallhofer@med.lmu.de

**Introduction:** Vitamin D deficiency and iron deficiency are common comorbidities in inflammatory bowel disease (IBD) and linked to complications like osteoporosis and anemia, respectively<sup>1</sup>. There is emerging evidence that active vitamin D may enhance intestinal iron absorption and prevent iron deficiency and iron deficiency anemia by direct suppression of hepcidin mRNA transcription<sup>2,3</sup>.

**Aims & Methods:** To investigate a potential influence of vitamin D status on iron metabolism, iron deficiency and iron deficiency anemia in IBD, 25-hydroxyvitamin D levels, 1,25-dihydroxyvitamin D levels, hepcidin serum concentrations, biochemical markers of iron status (serum iron, ferritin, transferrin, transferrin saturation) and hemoglobin levels were measured in 104 adult patients with IBD (67 patients with Crohn's disease [CD] and 37 patients with ulcerative colitis [UC]). Multivariate logistic and linear regression models included age, gender, body mass index, smoking status, disease activity and C-reactive protein levels as covariables when assessing the association of vitamin D levels with iron deficiency, iron deficiency anemia, hemoglobin levels and biochemical markers of iron status. Patients, who were substituted with iron during the last 30 days, were excluded from the study. For iron substitutions dating back longer than 30 days (up to three months), a corresponding categorical covariable was introduced in a multivariate confirmatory model. For categorical considerations, vitamin D deficiency was defined as 25-OH-vitamin D  $< 20$  ng/ml. Iron deficiency and iron deficiency anemia in IBD were defined according to ECCO guidelines.

**Results:** In multivariate logistic regression models controlling for age, gender, body mass index, smoking status, disease activity and C-reactive protein levels, lower 25-hydroxyvitamin D levels were significantly associated with iron deficiency in patients with IBD ( $\beta$  [SE] = - 0.064 [0.030],  $P = 0.029$ ). In multivariate linear regression models, vitamin D deficiency was significantly associated with decreased levels of ferritin ( $\beta$  [SE] = 0.25 [0.11],  $P = 0.024$ ) and transferrin saturation ( $\beta$  [SE] = 8.41 [4.07],  $P = 0.044$ ) in IBD. IBD patients with lower 25-hydroxyvitamin D levels exhibited significantly lower serum iron levels ( $\beta$  [SE] = 0.94 [0.42],  $P = 0.029$ ) and ferritin levels ( $\beta$  [SE] = 0.013 [0.0059],  $P = 0.037$ ). Moreover, multivariate linear regression models showed a significant negative association of higher 1,25-dihydroxyvitamin D : 25-hydroxyvitamin D ratios with lower hepcidin serum levels in IBD ( $\beta$  [SE] = - 4.31 [1.67],  $P = 0.012$ ). For CD, multivariate linear logistic regression analysis revealed a significant association of increased concentrations of active 1,25-dihydroxyvitamin D with higher transferrin saturation levels ( $\beta$  [SE] = 0.43 [0.18],  $P = 0.027$ ). In CD patients, there was a significant positive correlation of 25-hydroxyvitamin D levels with iron (Kendalls Tau 0.17,  $P < 0.05$ ), ferritin (Kendalls Tau 0.18,  $P < 0.05$ ) and transferrin saturation (Kendalls Tau 0.21,  $P < 0.05$ ). Furthermore, levels of active 1,25-dihydroxyvitamin D correlated positively with transferrin saturation in patients with CD (Kendalls Tau 0.21,  $P < 0.05$ ).

**Conclusion:** Vitamin D deficiency in IBD patients correlates significantly with parameters indicating iron deficiency. An optimized vitamin D status may ameliorate iron deficiency in IBD, potentially by downregulation of hepcidin serum expression, suggesting a beneficial role for vitamin D substitution. Further interventional studies are warranted to prove this hypothesis.

## P0344 NEUROCOGNITIVE DEFICITS IN ADULT INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hopkins C.<sup>1</sup>, Powell N.<sup>2</sup>, Dumbrill J.<sup>3</sup>, Moulton C.<sup>4</sup>

<sup>1</sup>Berkshire Healthcare NHS Foundation Trust, Psychological Medicine Service, Reading, United Kingdom, <sup>2</sup>King's College London, Centre for Inflammation Biology & Cancer Immunology, London, United Kingdom, <sup>3</sup>University of Manchester, Faculty of Biology, Medicine and Health, Manchester, United Kingdom, <sup>4</sup>King's College London, Psychological Medicine, London, United Kingdom

**Contact E-Mail Address:** calum.moulton@kcl.ac.uk

**Introduction:** People with inflammatory bowel disease (IBD) are exposed to multiple risk factors for cognitive impairment, including inflammation, nutritional deficiencies, depression, pain and vascular damage. Furthermore, reduced productivity and subjective cognitive difficulties are highly prevalent in people with IBD. To date, however, the presence of neurocognitive deficits in people with IBD has not been systematically evaluated.

**Aims & Methods:** Using a PRISMA systematic review and meta-analysis, we tested for domain-specific neurocognitive deficits in people with IBD compared to healthy controls. We systematically searched EMBASE, Web of Knowledge, Medline, CINAHL, PsycINFO and grey literature from inception to 31 December 2018 for cross-sectional- and longitudinal studies comparing cognitive function in adults with IBD versus healthy controls. According to DSM-5 classification, cognitive measures were stratified by domains of executive function (including working memory), attention, perceptual-motor, learning and recall, language, social cognition, as well as premorbid IQ. For any cognitive domain reported by 3 or more studies, we performed random-effects meta-analysis using STATA 15.0 to calculate the standardised mean difference (SMD) between IBD and control groups; higher scores reflected better performance. Where a single study used multiple measures within a single domain, we averaged the effect sizes. Between-study heterogeneity was assessed using the  $I^2$  statistic; publication bias estimated using Egger's intercept test; and study quality assessed using the IBD-modified Newcastle-Ottawa scale. For significant findings, we used Monte-Carlo permutation tests for meta-regression to test the following potential moderators of cognitive impairment: age, sex (% female), IBD disease duration, depressive symptoms (% of maximum questionnaire score) and years of formal education.

**Results:** Of 8287 articles screened, 11 were included, of which 3-, 6-, and 1 were of high, moderate and low quality respectively. All studies were cross-sectional; none specifically recruited older adults; and 6-, 1-, and 4 recruited populations with Crohn's disease, ulcerative colitis and mixed IBD respectively. The sample (n=674 people) had mean age 39.9 years and 60.2% were female. Despite no difference between groups in premorbid IQ ( $p=0.13$ ), the IBD group showed deficits compared to healthy controls in attention (pooled effect size (ES) = -0.40 [95% confidence interval -0.69 to -0.10],  $p=0.009$ ,  $I^2=4.3\%$ ) and executive function (pooled ES = -0.38 [-0.70 to -0.07],  $p=0.017$ ,  $I^2=20.3\%$ ), including specifically in working memory (pooled ES = 0.73 [-1.09 to -0.37],  $p<0.001$ ,  $I^2=0\%$ ). By contrast, deficits in learning and recall were inconsistent (pooled ES = -0.50 [-1.08 to 0.08],  $p=0.089$ ,  $I^2=72.8\%$ ) and data for other cognitive domains insufficient for meta-analysis. There was no evidence of publication bias. Although there were no significant moderators of cognitive impairment, power of meta-regression was limited by low between-study heterogeneity.

**Conclusion:** Despite comparable premorbid IQ, people with IBD show small-to-moderate deficits in attention and overall executive function, including large deficits in working memory. Such deficits may impact adversely on productivity. Longitudinal studies are required to test the course of neurocognitive deficits - including specifically in older adults - whilst testing the biological and psychological pathways that can be modified to improve cognitive function in people with IBD.

## P0345 THE CHANGING PATTERN OF INFLAMMATORY BOWEL DISEASE INCIDENCE IN NORTHERN FRANCE: A CONTINUING INCREASE IN THE YOUNG WOMEN (1988-2014)

**Contact E-Mail Address:** thibaut.cretin@gmail.com

**Introduction:** Inflammatory Bowel Disease (IBD) incidence rates seem to be stabilised in adults in industrialised countries unlike in the paediatric population.

**Aims & Methods:** The aim of this study was to describe changes in incidence and phenotypic presentation of adult-onset IBD in northern France during a 27-year period. All adult-onset IBD patients ( $\geq 17$  years at IBD diagnosis) were issued from the EPIMAD population-based IBD registry in France between 1988 and 2014. Standardized incidence rates were calculated for Crohn's Disease (CD) and Ulcerative Colitis (UC) in the whole population, and separately according to age and gender. Digestive location was defined according to the Montreal classification.

**Results:** 17,686 incident IBD cases were recorded including 10,206 CD (58%), 6,839 UC (39%) and 640 IBD unclassified (IBDU) (4%). Median age at diagnosis was lower in CD (28 years, interquartile range (IQR) [22-40]) than in UC (36, IQR[27-49]) ( $p<0.0001$ ). Age at diagnosis was stable in time for both diseases ( $p=0.37$  in CD and  $p=0.52$  in UC). Females were younger at diagnosis than men, especially in UC : respectively 28 IQR[21-39] vs 29 IQR[22-40] in CD ( $p<0.0001$ ) and 33 IQR[26-45] vs 39 IQR[28-51] ( $p<0.0001$ ) in UC. The proportion of females were significantly higher in CD (females/males = 1.36) conversely to UC (females/males = 0.84) ( $P<0.0001$ ). Sex ratio was stable over time in CD ( $p=0.28$ ) and changed in UC with an inversion from 0.70 in 1988-1990 to 1.10 in 2012-2014 ( $p=0.001$ ). Median time between onset of symptoms and IBD diagnosis was consistently 3 months IQR[1-6]. Mean annual incidence was  $13.5/10^5$  95% Confidence Interval (95%CI) [13.3 - 13.7] for IBD overall,  $7.5/10^5$  95%CI[7.4 - 7.7] for CD,  $5.4/10^5$  95%CI[5.3 - 5.6] for UC and  $0.51/10^5$  95%CI[0.46 - 0.55] for IBDU. From 1988-1990 to 2012-2014, a continuous increase in incidence of CD was observed while that of UC stayed stable: for CD from  $5.5$  to  $7.9/10^5$  (+44%,  $p<0.0001$ ) and for UC at  $5.4/10^5$ . The most important increase of IBD incidence rate was in young women (17-39 years): average percent change of +1.9% per year in CD ( $p<0.0001$ ) and +1.7% per year in UC ( $p<0.0001$ ). In CD, over time, pure colonic location (L2) decreased from 41% (1988-1990) to 25% (2012-2014), while pure ileal (L1) and ileo-colonic (L3) locations increased from 20% to 26% and from 39% to 49%, respectively ( $p<0.0001$ ). During the same period, explorations of the small bowel increased from 76% to 86%. In UC, proctitis (E1) and left sided colitis (E2) represented 38% and 37% of the locations.

**Conclusion:** In this French population-based study, CD incidence increases continuously during a 27-year period, especially CD with ileal involvement, while UC incidence remains stable. These results highlight the difference in immunopathology between each CD phenotype. Moreover, CD and UC incidence rates rise mostly in young women (17-39 years), suggesting that one or more strong environmental factors may predispose the women to IBD.

**Disclosure:** Nothing to disclose

## P0346 INFLAMMATORY BOWEL DISEASE IS ASSOCIATED WITH A HIGHER RISK OF RENAL CANCER

Kochhar G.<sup>1</sup>, Syed A.<sup>2,3</sup>, El-Hachem S.<sup>2</sup>, Abdul-Baki H.<sup>2</sup>, Chintamaneni P.<sup>2</sup>, Thakkar S.<sup>2</sup>, Shen B.<sup>4</sup>, Dulai P.<sup>5</sup>

**Contact E-Mail Address:** drkochhar@gmail.com

**Introduction:** Inflammatory bowel disease (IBD) including ulcerative colitis (UC) and Crohn's disease (CD) has been implicated as a precursor to extra-intestinal cancers. Recent studies have shown an increased risk of renal cancer.

The aim of our study is to conduct a population-based study to explore the risk of renal cancer in IBD, and evaluate the role of IBD associated medications.

**Aims & Methods:** A population-based study was conducted using a cloud-based, HIPPA-enabled web platform called Explorys (IBM, New York) to collect aggregated de-identified electronic health records. At the time of the study, Explorys had access to over 62 million unique records. Data was obtained using ICD-9 code criteria for Crohn's disease, ulcerative colitis, and malignant neoplasm of the kidney. Each cohort was further evaluated for baseline patient characteristics and usage of IBD-associated medications, including corticosteroids, biologics, and immunomodulators. All-cause mortality was also reported. Comparisons were reported for relative risks (RR) with 95% confidence intervals (CI) in a random effect model.

**Results:** Renal cancer was more common in patients with both UC [RR 3.51 (95% CI: 3.29-3.74),  $P < 0.0001$ ] and CD [RR 3.45 (95% CI: 3.25-3.66),  $P < 0.0001$ ] vs. the general population. Patients over the age of 65, males, and Caucasians with CD had an increased risk of renal cancer. Patients over the age of 65, males, Caucasians and African-Americans with UC had an increased risk of renal cancer. In patients with CD, subsequent renal cancer had an increased risk in the setting of corticosteroids [RR 2.45 (95% CI: 2.12-2.82),  $P < 0.001$ ], biologics [RR 1.86 (95% CI: 1.65-2.10),  $P < 0.001$ ], and immunomodulators [RR 1.37 (95% CI: 1.19-1.58),  $P < 0.001$ ]. In patients with UC, renal cancer risk was elevated in patients on corticosteroids [RR 2.24 (95% CI: 1.92-2.62),  $P < 0.001$ ], biologics [RR 1.61 (95% CI: 1.41-1.83),  $P < 0.0001$ ] and immunomodulators [RR 1.44 (95% CI: 1.20-1.72),  $P < 0.001$ ]. All-cause mortality was higher in patients with renal cancer in patients with CD [RR 3.91 (95% CI: 3.35-4.56),  $P < 0.0001$ ] and UC [RR 3.55 (95% CI: 3.01-4.19),  $P < 0.0001$ ].

**Conclusion:** Risk of renal cancer is higher in patients with ulcerative colitis and Crohn's Disease. All-cause mortality risk is significantly higher in patients with UC and CD with renal cancer.

## P0347 PHENOTYPIC CHARACTERISTICS OF ULCERATIVE COLITIS IN LATIN AMERICANS VERSUS HISPANICS FROM THE UNITED STATES: A SYSTEMATIC REVIEW WITH META-ANALYSIS

Sativa J.<sup>1</sup>, Contreras A.<sup>2</sup>, Zuckerman M.<sup>3</sup>, Dodoo C.<sup>4</sup>, Dwivedi A.<sup>4</sup>, Avalos D.<sup>5</sup>

<sup>1</sup>University of Miami, Internal Medicine, Atlantis, United States, <sup>2</sup>Texas Tech University Health Sciences Center, Division of Internal Medicine, El Paso, United States, <sup>3</sup>Texas Tech University Health Sciences Center, Division of Gastroenterology, El Paso, United States, <sup>4</sup>Texas Tech University Health Sciences Center, Division of Biostatistics & Epidemiology, El Paso, United States, <sup>5</sup>Digestive Medicine Associates LLP, Miami, United States

**Contact E-Mail Address:** jinen19@gmail.com

**Introduction:** Latin America has been experiencing a rise in the prevalence and incidence of inflammatory bowel disease. Environmental and dietary changes may be contributing to this rise. Ulcerative colitis (UC) is more common than Crohn's disease in Latin America, but it is unclear whether the phenotype seen in Latin America is similar to the one seen in Hispanics residing in the United States (U.S.), two locations with distinct environmental and dietary exposures. In addition, it is yet to be determined whether there are major differences in the phenotype of ulcerative colitis across Latin America.

**Aims & Methods:** We conducted a systematic review with meta-analysis of population-based studies to compare the phenotypic characteristics of UC in Latin America with UC in Hispanic-Americans in the U.S. We also aimed to compare phenotype of UC across Latin American countries. Phenotype was defined using the Montreal classification. A systematic search was conducted using MEDLINE and EMBASE. Google Scholar was used to search for unpublished data.

**Inclusion criteria:**

(i) studies describing the phenotype of UC in Latin America and Hispanics in the U.S.

(ii) age equal to or greater than 18 years.

**Exclusion criteria:**

(i) prevalence or incidence studies not describing phenotype.

A random effects model was chosen "a priori" for analysis of pooled proportions.

**Results:** A total of 4,627 studies were screened. There were 34 studies from 9 countries in Latin America and 7 studies from Hispanics in the U.S. This included 4,082 patients with UC from Latin America and 390 Hispanic patients with UC in the U.S.

The predominant phenotype in Latin America was proctitis (E1) with a pooled proportion of 0.37 (95% CI 0.28-0.45,  $I^2$  98.2%), as compared with 0.08 (95% CI 0.05-0.11,  $I^2$  18%),  $p=0.003$ , in the U.S. Extensive colitis (E3) was present in two-thirds of Hispanics in the U.S. as compared with only one-third of Latin Americans,  $p<0.001$ . There was no difference in the prevalence of left-sided colitis (E2) in Latin America and the U.S., with nearly one-third of patients showing this phenotype in both regions,  $p=0.82$ . Among the Latin American countries, Cuba and Puerto Rico had the highest frequency of proctitis with nearly two-thirds of patients showing this phenotype. Left-sided colitis was more frequent in Colombia (0.39, 95% CI 0.34-0.45) and Peru (0.36, 95% CI 0.29-0.44), whereas, extensive colitis was more frequent in Argentina (0.67, 95% CI 0.59-0.75) and Mexico (0.54, 95% CI 0.51-0.57).

Variables	Countries of Origin	N	Prevalence	95 % Confidence Interval	I Squared	ES P Value (%)	Meta regression p value
E1: Proctitis	Latin America	33	0.37	0.28	0.45	98.2	0.003
	Hispanic Americans	6	0.08	0.05	0.11	18.06	
E2: Left-sided colitis	Latin America	30	0.27	0.23	0.32	91.11	0.815
	Hispanic Americans	5	0.26	0.15	0.38	82.01	
E3: Extensive Colitis	Latin America	34	0.38	0.32	0.44	95.26	<0.001
	Hispanic Americans	6	0.64	0.52	0.77	84.01	

[Phenotypic Characteristics of Ulcerative Colitis in Hispanics from Latin America versus the United States]

**Conclusion:** The phenotype of UC varies between Latin America and the U.S. Proctitis was more frequent in Latin America, whereas, extensive colitis was the predominant phenotype in Hispanics from the U.S. This may suggest that Hispanics that develop UC in the U.S. have a more aggressive form of the disease. In Latin America, Cubans and Puerto Ricans have a milder form of UC as compared with Argentinians and Mexicans who are more likely to have extensive disease. Further research is warranted to determine underlying genetic, environmental and dietary factors which may account for these differences.

**Contact E-Mail Address:** radislav.nakov@gmail.com

**Introduction:** Trefoil factors (TFFs) include a family of three mucin-associated peptides secreted by goblet cells in the intestinal mucosa. They have a key role in maintaining mucosal barrier integrity and are up-regulated at the site of mucosal damage. It has recently been suggested that serum levels of TFF3 can predict disease activity and reflect mucosal healing (MH) in ulcerative colitis (UC) patients with minimal disease activity. However, its potential to predict complete MH independently or in combination with other biomarkers has never been addressed.

**Aims & Methods:** In the current study we aimed to evaluate the role of trefoil factor 3 (TFF3) as a marker for complete MH in patients with UC. 116 consecutive UC patients were enrolled. TFF3 levels were measured by ELISA and were compared to clinical activity, assessed by Lichtiger Index, fecal calprotectin (FCP) and C-reactive protein (CRP) levels. Colonoscopy was performed in all the patients and the findings were graded according to Mayo endoscopic score (EMS) and UC endoscopic index of severity (UCEIS).

**Results:** TFF3 levels were significantly correlated with Lichtiger Index ( $r = 0.736$ ,  $p < 0.001$ ), EMS ( $r = 0.811$ ,  $p < 0.001$ ), UCEIS ( $r = 0.820$ ,  $p < 0.001$ ), FCP ( $r = 0.696$ ,  $p < 0.001$ ) and CRP ( $r = 0.405$ ,  $p < 0.001$ ). The TFF3 cut-off level of 6.74 ng/ml indicated complete MH (EMS = 0; UCEIS = 0) with a sensitivity and specificity of 0.879 and 0.869, respectively (area under the curve (AUC), 0.927; 95% confidence interval, 0.877-0.976). The DeLong's test revealed no significant difference between the AUC of TFF3+CRP and the AUC of FCP ( $Z = 1.717$ ,  $p = 0.086$ ), AUC of TFF3+FCP ( $Z = 1.908$ ,  $p = 0.056$ ), and AUC of TFF3+CRP+FCP ( $Z = 1.915$ ,  $p = 0.056$ ). However, the AUC of TFF3+CRP showed significant difference with the AUC of TFF3 ( $Z = 2.210$ ,  $p = 0.027$ ) and the AUC of CRP ( $Z = 3.145$ ,  $p = 0.002$ ) for predicting complete MH.

**Conclusion:** TFF3 levels correlated significantly with clinical activity, endoscopic indices, CRP and FCP. TFF3 is highly predictive marker of complete MH independently and in combination with CRP in patients with UC

**Disclosure:** Nothing to disclose

**Introduction:** Prevention of post-operative recurrence (POR) is a controversial field in Crohn's disease. Despite evidence for some clinical risk factors favoring POR (previous ileocolonic resections, extensive resection, penetrating disease, active smoking), there is no total agreement among guidelines<sup>[1-2]</sup> on initiation of postoperative prophylactic therapy, preferred drug as well as on the modality and timing of POR assessments.

**Aims & Methods:** Our aim was to obtain an international perspective on the current adopted therapies and strategies (immediate postoperative prophylaxis versus endoscopy-driven) with regard to prevention of POR. A 11-question anonymous survey was proposed to all gastroenterologists participating at various ECCO pre-meeting workshops in March 2019.

**Results:** Data from 168 participants were collected (participation rate 24%). Median gastroenterology experience was 8 years [IQR 4-14 years], 65% junior ( $\leq 10$  years of practice), 35% senior ( $> 10$  years). The majority were European (67%), while the remainder were representatives of 19 countries across all five continents. Most participants (60%) were working in an academic hospital.

Post-operative endoscopic evaluation to assess POR was routinely performed within 12 months by 87% of respondents. This was the same for patients who do or do not receive immediate postoperative prophylactic therapy. After a first endoscopy without POR, 89% of physicians reported following up patients with a combination of clinical examination, lab test and fecal calprotectin, and 45% considered endoscopy as a routine assessment modality. Comparison between young and senior gastroenterologists did not show any statistical difference ( $p > 0.05$ ).

Most respondents (60%) reported starting medical prophylaxis against POR in naïve patients if 1 or more risk factors are present, while 16% of respondents would prescribe immunoprophylaxis even in patients without risk factors. Only 20% of participants reported that they would wait for endoscopic proof of recurrence (Rutgeerts score  $\geq 2$ ) before starting immunomodulators. Data were similar between young and senior gastroenterologists ( $p > 0.05$ ).

In regard to the class of drug, the number of POR risk factors lead the majority (59%) to prescribe biologics over immunosuppressants. Among biologics, 98% of respondents having access to anti-TNF reported a routine use of them in this setting, while 62% and 56% of physicians with access to vedolizumab and ustekinumab respectively prescribed these drugs for POR prophylaxis.

In the specific clinical context of perianal disease, fistulizing phenotype or concomitant colonic disease, most of the participants reported adopting an immediate POR prophylaxis in 98%, 85% and 88% of cases, respectively. Conversely, a significant number of respondents were more prone to an endoscopy-driven treatment in the elderly (42%) and in long-standing disease after failure of thiopurines (51%). No significant difference ( $p > 0.05$ ) in post-operative approach was registered in these scenarios between young and experienced gastroenterologists.

**Conclusion:** Clinicians are well aware of the risk of POR in Crohn's disease and tight endoscopic control within twelve months is often proposed. After a first ileocolonoscopy without POR, most respondents reported relying on fecal calprotectin for routine monitoring. The surprisingly high rate of immediate postoperative prophylactic therapy with biologics, even in the absence of clear endoscopic recurrence or clinical risk factors for POR, highlights the need for a randomized trial comparing immediate prophylaxis with endoscopy-driven therapy.

**Contact E-Mail Address:** martavernero@gmail.com

**Introduction:** There is a rising interest in identifying easy to dose disease markers to predict response to therapy in inflammatory bowel disease (IBD) patients.

Several markers have been studied, but none of them has been validated.

**Aims & Methods:** The aim of our study was to understand the role of inflammatory interleukins in predicting the response to immunosuppressive or biological therapy. A monocentric prospective study was conducted. Forty IBD patients who needed to start immunosuppressive or biological drugs were included. For each patient serological levels of interleukin (IL)1-B, IL4, IL6, IL8, IL10, IL12p70, IL17, IFN-gamma, TNF-alfa, TGF-beta-1 were dosed at the time of enrollment (T0) and after three months of immunosuppressive or biological therapy (T3). To dose these cytokines, multiplex Bio-Plex® system was used.

**Results:** Among the 40 enrolled patients, 32 (80%) were suffering from Crohn's disease (CD) and 8 from Ulcerative Colitis (UC); the mean age was 46.6 years (18-79 years).

IL1-B T0 was detectable only in CD patients (mean value 0.05 pg/ml), with no difference due to illness localization.

Serological T0 TNF-a levels correlated with pre-treatment endoscopic activity: among patients with moderate or severe endoscopical activity median value was 20.94 pg/ml while among mild activity or remission group median value was 13 pg/ml ( $p=0.034$ ).

To IL8 levels correlated both with pre-treatment fecal calprotectin ( $p=0.03$ ;  $r=0.437$ ) and endoscopic activity (median value 28,07 pg/ml for moderate to severe activity vs 5,79 pg/ml median value for mild activity/remission;  $p=0.023$ )

To TGF-b1 levels were significantly lower in CD patients than in UC patients ( $p=0.0076$ ).

Low levels of IL6 at T0 ( $\leq 0.54$  pg/ml) predicted a negativization of fecal calprotectin after three months of adalimumab (ADA) administration (area under the curve [AUC] = 0.89;  $p=0.001$ ; sensitivity = 72.7%; specificity = 100%). Low levels (median value = 0.54 pg/ml) of T0 IL6 correlated with a higher probability to response to azathioprine (AZA) too ( $p=0.049$ ). To IL6  $\geq 0.9$  pg/ml correlated with higher response to vedolizumab (VEDO). Patients who responded to AZA had undetectable T0 serological levels of IFN-g, while the ones who did not respond had a median IFN-g level of 0.11 pg/ml ( $p=0.043$ ).

To serological levels of TGF-b1 correlated with response to AZA ( $< 4.7$  pg/ml) and to ADA ( $> 6.57$  pg/ml) ( $p=0.027$ ).

Low IL12p70 levels predicted a better response to therapy at all ( $p=0.0095$ ), but not for each drug separately.

To IL8 levels predicted response to vedolizumab therapy: at ROC curve analysis we observed for  $> 6.6$  pg/ml levels of IL8 a response to VEDO in all patients (AUC = 1; sensitivity 100%; specificity 100%;  $p=0.0001$ ).

**Conclusion:** IFN-g and TGF-b1 may be useful to identify AZA responders and IL8 and IL6 levels could be good predictors of response to both biological and immunosuppressive drugs. Our study is a first step for tailored therapy in IBD patients.

### P0351 MEASURING INFLIXIMAB DRUG LEVELS CONSISTENTLY: ALIGNMENT TO THE 1<sup>ST</sup> INTERNATIONAL STANDARD MATERIAL (NIBSC 16/170) USING IDKMONITOR® INFLIXIMAB DRUG LEVEL ELISA LEADS TO AN INCREASE IN THE MEASURED INFLIXIMAB CONCENTRATION

Nice R.<sup>1</sup>, Perry M.<sup>2</sup>

<sup>1</sup>Royal Devon and Exeter Hospital, Blood Sciences, Exeter, United Kingdom,

<sup>2</sup>Royal Devon and Exeter NHS Foundation Trust, Blood Sciences, Exeter, United Kingdom

**Contact E-Mail Address:** rachel.nice@nhs.net

**Introduction:** Measuring the concentration of infliximab drug levels in IBD patients is widely practiced. Variability between assays has previously been a problem as inconsistent results are obtained between different laboratories, depending on the methodology and manufacturer used.

Introduction of the 1st International Standard infliximab material (NIBSC 16/170) should allow for alignment of the methods for measuring infliximab, and ultimately more consistent results between laboratories.

Immundiagnostik has aligned the IDKmonitor® Infliximab drug level ELISA by re-calibrating with the International Standard infliximab material (NIBSC 16/170). The impact of this change upon clinical results is explored.

**Aims & Methods:** The aim of this work is to determine the change in the measured concentration of infliximab using the IDKmonitor® Infliximab drug level ELISA kit before and after alignment with the 1st International Standard infliximab (NIBSC 16/170).

Serum samples received through the routine infliximab monitoring service ( $n=80$ ) were measured using the IDKmonitor® Infliximab drug level ELISA, using kits manufactured before and after calibration with the 1st International Standard infliximab (NIBSC 16/170). Regression and correlation results were obtained.

**Results:** Regression analysis of results before and after the calibration provide are good ( $R^2 = 0.99$ ). Correlation of the data shows that when aligned to the 1st International Standard infliximab (NIBSC 16/170), the measured concentration of infliximab is higher than that obtained with the kit manufactured before the calibration (i.e. post calibration result =  $1.35x$  pre-calibration result  $+ 0.81$ ).

**Conclusion:** International standardisation of infliximab drug level concentrations is now possible due to the introduction of the 1<sup>st</sup> International standard infliximab. This is a step change towards consistency of measuring infliximab drug levels.

However, clinicians who are using this test for monitoring need to be aware of this change and consider patient results carefully in the light of this information.

### P0352 LEVELS OF SERUM FREE THIOLS ARE SUPERIOR TO FECAL CALPROTECTIN IN PREDICTING ENDOSCOPIC DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE

Bourgonje A.R.<sup>1</sup>, Gabriëls R.Y.<sup>1</sup>, de Borst M.H.<sup>2</sup>, Bulthuis M.L.C.<sup>3</sup>, Faber K.N.<sup>1</sup>, van Goor H.<sup>3</sup>, Dijkstra G.<sup>1</sup>

**Introduction:** Oxidative stress is considered to play a pivotal role in the pathogenesis of Inflammatory Bowel Diseases (IBD). Serum free thiol groups (R-SH) reliably reflect systemic oxidative stress, since they are readily oxidized by reactive species. Endoscopic examination is the gold standard to determine disease activity in IBD. In clinical practice, fecal calprotectin (FC) levels are most widely used as surrogate marker for endoscopically proven disease activity.

However, its diagnostic accuracy and applicability are still subject to de-

bate. Systemic biomarkers for disease activity are urgently sought to improve disease activity monitoring and to avoid repeated endoscopic examination.

**Aims & Methods:** In this study, we aimed to establish concentrations of serum free thiols in IBD and assessed their potential utility as a discriminating biomarker for different grades of endoscopic disease activity. Serum free thiol concentrations were measured in 78 IBD patients (31 patients with Crohn's disease (CD) and 47 patients with ulcerative colitis (UC)) and 50 healthy controls, adjusted for serum albumin. Albumin-adjusted serum free thiols were analyzed for associations with clinical and biochemical disease parameters. Endoscopic disease activity was assessed by the Simple Endoscopic Score for CD (SES-CD) and Mayo endoscopic subscore for UC, that were merged to create an IBD composite endoscopy score. Non-parametric ROC estimation with cross-validated areas under the curves (AUCs) was used to assess the discriminative value of serum free thiols regarding the degree of endoscopic disease activity (n=54) and to compare this to fecal calprotectin (n=28) in patients for which those data were available.

**Results:** Mean serum free thiol concentrations were significantly decreased in both CD and UC as compared to healthy controls ( $19.4 \pm 3.1$  and  $17.8 \pm 3.4$  vs.  $21.1 \pm 1.9$   $\mu\text{mol/g}$  of albumin,  $P < 0.001$ ). Albumin-adjusted serum free thiols significantly inversely associated with age ( $r = -0.49$ ,  $P < 0.01$ ), platelet counts ( $r = -0.29$ ,  $P < 0.01$ ) and fecal calprotectin levels ( $r = -0.32$ ,  $P < 0.05$ ). Patients with severe endoscopic disease activity demonstrated significantly lower serum free thiol concentrations compared to patients having mild disease activity ( $16.2 \pm 3.1$  vs.  $20.4 \pm 3.4$   $\mu\text{mol/g}$  of albumin,  $P < 0.01$ ). Finally, serum free thiols highly accurately discriminated between mild and moderate-to-severe disease activity, better than fecal calprotectin (FC) levels (AUC=0.87,  $P < 0.001$  vs. AUC=0.76,  $P < 0.05$ , respectively). After cross-validation, serum free thiols maintained their predictive accuracy (AUC=0.89,  $P < 0.001$ ).

**Conclusion:** Serum free thiols are reduced in IBD as compared to healthy controls and strongly correlate with the degree of endoscopic disease activity. Quantifying systemic redox status in IBD may be a promising, minimally invasive strategy to monitor IBD disease activity. Future studies are warranted to further explore free thiols as potential biomarker for IBD disease activity in larger, prospective patient cohorts and serially assess their predictive value in relation to disease course and therapeutic interventions.

## P0353 VALIDATION OF NOVEL FECAL INFLAMMATORY MARKER FOR ASSESSMENT OF INFLAMMATORY BOWEL DISEASE ACTIVITY

**Introduction:** Diagnosis of inflammatory bowel disease (IBD) require combination of patient history and physical examination in association with laboratory, endoscopic, histologic, and radiographic investigations. Although ileocolonoscopy is the preferred method of diagnosis, assessing disease extent, activity and follow up after therapy but repeated endoscopy is neither practical nor feasible, being invasive, time consuming, and not always well tolerated or accepted.

Therefore, employment of non-invasive biomarkers is needed. No single marker is ideal. Many studies focus on fecal calprotectin (FC) in IBD and confirm its value in diagnosis, disease activity evaluation, effect evaluation, and relapse monitor.

Neopterin, is a metabolite of cyclic guanosine monophosphate that is released by activated T lymphocytes and macrophages after induction by interferon  $\gamma$ . Neopterin release from activated macrophages may provide, at least theoretically by its intrinsic mechanism of release, an advantage over calprotectin which is not secreted and represents a neutrophil-derived protein.

**Aims & Methods:** to investigate the relation between fecal neopterin (fNeo) excretion and IBD clinical and endoscopic activity indices and compare its specificity to that of fecal calprotectin.

60 patients were included: 30 patients with ulcerative colitis (UC) (15 clinically in remission, 15 active) and 30 patients with Crohn's disease (CD) (15 clinically in remission, 15 active) and 20 healthy control subjects.

FC and fNeo were detected in stool samples by enzyme-linked immunosorbent assay (ELISA).

The following indices were calculated at enrollment: for Crohn's disease the Crohn's disease activity index (CDAI) and simple endoscopic score for Crohn's disease (SES-CD); for ulcerative colitis, Simple Clinical Colitis Activity Index (SCCAI) and ulcerative colitis endoscopic index of severity (UCEIS).

**Results:** Among UC patients, fNeo was higher in those with either clinically active or inactive disease than in control subjects ( $P=0.001$ ,  $P=0.040$ ; for active and inactive disease vs. controls respectively) but there was no significant difference between both UC groups ( $P=0.225$ ). For CD patients, fNeo concentration was higher in those with active disease than in those with inactive diseases ( $P < 0.001$ ) or healthy controls ( $P=0.001$ ). Nonsignificant trends toward greater fecal neopterin concentration were observed with increased colonic disease involvement. Neopterin was not found to be significantly correlated with all laboratory tests done (Hemoglobin, platelets, white blood cells, ESR, CRP, serum albumin, fecal calprotectin). fNeo was significantly correlated with CDAI ( $r=0.604$ ,  $P < 0.001$ ), SES-CD ( $r=0.600$ ,  $P < 0.001$ ) in CD patients but not with SCCAI, UCEIS in UC patients. fNeo was found to have comparable sensitivity and overall accuracy to FC in predicting endoscopic disease activity in CD patients but less in UC and combining both stool tests together increases the sensitivity and specificity of either alone.

**Conclusion:** Stool neopterin could be used to assess disease activity in CD but not in UC patients as it correlates positively with disease activity indices in CD but not in UC. Thus its measurement represents a novel reliable biomarker useful to detect and monitor the severity of mucosal affection in CD patients more than UC.

**Introduction:** Patients with upper (L4) and diffuse (L1 + L4) Crohn's disease (CD) may have a more aggressive and refractory disease course. However, evidence on this particular sub-type of patients is scarce. Clinical guidelines do not offer specific protocols on how to manage them.

**Aims & Methods:** To identify the clinical characteristics, therapeutic requirements and complications that are independently associated with an upper digestive tract CD involvement.

Retrospective study of cases and controls matched (1: 2) by sex and age in patients with CD (L4 or L1 + L4: cases; L1 or L3: controls) of the ENEIDA database (49 hospitals). The small intestine was evaluated with radiologic and/or endoscopic examination, and complex perianal disease was excluded. Clinical variables: pattern, severity, anaemia; Complications: stenosis, fistula, abscess, perforation and digestive bleeding; Therapeutic requirements: use of anti-TNF, second line biologic drug, 1 or more biological treatment, iv iron, blood transfusions, enteral nutrition, endoscopic/radiological treatments, surgeries and hospitalisations were investigated. A logistic regression analysis with those significant variables in univariate analysis (SPSS) was performed.

**Results:** 941 cases and 1882 controls were identified. Multivariate analysis showed that cases were independently associated to a stricturing pattern at disease diagnose (OR: 1.3 (95% CI: 1-1.6), p = 0.028), anaemia due to iron loss (OR: 1.9 (95% CI: 1.3-2.7), p < 0.002), more extensive involvement (> 30cm) (OR: 2.7 (95% CI: 2.2-3.3), p < 0.0001), and the use of anti-TNF

during follow-up (OR 1.3 CI 95% 1-1.6 p = 0.033). In contrast, they exhibit fewer abscesses (OR: 0.6 (95% CI: 0.5-0.9), p = 0.001) and have less familial history of inflammatory bowel disease (OR 0.7 CI 95% 0.6 -0.9 p = 0.008).

**Conclusion:** In the most extensive series of upper digestive tract involvement in CD, it is shown that they present a more evolved disease at CD diagnosis, suggesting that these patients may be diagnosed late on time. Consequently, they are more refractory to treatments, requiring more frequently anti-TNF treatment. Chronic anaemia due to iron loss in the absence of endoscopic findings should be suspicious of upper CD involvement. Diagnostic and specific treatment strategy for these patients must be considered including signs that allow a high rate of suspicion and a rapid therapeutic escalation.

**Introduction:** Up to onethird of patients with acute severe ulcerative colitis (ASUC) will fail intravenous steroid (IVS) treatment, requiring rescue therapy with cyclosporin (Cys), infliximab (IFX), or colectomy. Even with the best available therapy, over 1/3 of these patients will still require surgery. Long-term outcomes of steroid responsive (SR) patients have seldom been studied. We hypothesize that this subgroup of patients also presents an unfavorable short and long term prognosis.

**Aims & Methods:** We hypothesize that SR patients also presents an unfavorable short and long term prognosis.

Retrospective multicenter study including patients fulfilling Truelove and Witts criteria for ASUC. Response to IVS was determined by the attending physician between the 3rd and 5th day of admission. Patients were then classified as steroid nonresponders (SNR) or SR. A cohort of consecutive patients admitted with a flare of Ulcerative colitis but without criteria for ASUC served as a control group (CG). Endpoints included the need for biologics, surgery or both in the 5 years following discharge.

**Results:** 253 patients were included, 170 (67.2%) with ASUC (SNR: 47, SR: 123) and 83 controls. 53.4% were male with median age of 33 (18-80). Although SR patients presented lower surgical rates than SNR patients (13.9% vs 53.2%, P< 0.001) they were substantially higher than in the CG (0%, P< 0.001). Of note, 70.6% of surgeries in SR patients occurred within one year after discharge. Furthermore, 40.6% of SR patients were subsequently readmitted with a flare of colitis requiring biologics or surgery in 44.0% and 28.0% of cases, respectively. Concerning treatment escalation, SR patients required less biologic therapy than SNR (36.7% vs 91.5%, P< 0.001) but more so than patients in the CG (18.1%, P< 0.001). Likewise, a composite endpoint of any unfavorable outcome was more common in SR patients than in the CG (44.9% vs 18.1%, P< 0.001). Time to event analysis showed that SR patients reached an unfavorable outcome sooner than the CG (logrank test P< 0.001).

**Conclusion:** Patients with ASUC present an unfavorable prognosis, even after an adequate response to IVS. Early therapy intensification should strongly be considered in these patients as almost half develop unfavorable outcomes.

**Introduction:** There is increasing evidence supporting the use of therapeutic drug monitoring (TDM) of anti-TNF therapies in Crohn's disease (CD) following loss of response. However, the potential benefit of proactive TDM is still unknown <sup>1-4</sup>.

**Aims & Methods:** To study the pharmacokinetics and clinical benefits associated with a proactive TDM strategy in CD.

Patients completing Infliximab (IFX) induction were assigned to a proactive TDM protocol (pTDM). Before the 4<sup>th</sup> infusion and before every 2 infusions, IFX drug levels and anti-drug antibodies were measured using a drug sensitive assay (Theradiag®, Lisa Tracker). Treatment was proactively escalated aiming at a trough level of 3-7 µg/ml. A retrospective cohort of patients treated with IFX but without TDM was used as a control group (noTDM). Endpoints included the need for IBD-related surgery and hospitalization, treatment discontinuation, and mucosal healing (absence of ulceration in non-operated patients or Rutgeerts score < i2 in operated patients) at 2 years of follow-up. Patients with major bowel surgery, drug holiday and primary IFX non-response were excluded.

**Results:** 185 patients were included in the study (35 in the pTDM and 150 in the noTDM group); Baseline characteristics were non-significant between groups. A median (range) of 3 (1-7) drug/anti-drug measurements were collected in the pTDM group over the 2-year period. The median (range) IFX trough levels and anti-drug antibodies were 5.80 µg/ml (0.03-16.4) and 0 U/mL (0-200.0), respectively. Pharmacokinetic analysis showed a significant correlation between IFX trough levels and C-reactive protein ( $\rho = -0.197$ ,  $P = 0.01$ ), fecal calprotectin ( $\rho = -0.344$ ,  $P = 0.004$ ) and anti-drug antibodies ( $\rho = -0.220$ ,  $P = 0.003$ ). Higher trough levels were associated with higher rates of mucosal healing (7.25 µg/ml (1.9-14) vs 2.9 µg/ml (0.03-7);  $P = 0.02$ , AUROC = 0.83), magnetic resonance enterography normalization (7.25 µg/ml (3.75-14) vs 2.14 µg/ml (0.03-7);  $P < 0.001$ , AUROC = 0.92) and transmural healing (7.5 µg/ml (3.75-14) vs 2.6 µg/ml (0.03-7.66);  $P = 0.015$ , AUROC = 0.88).

After 2 years of follow-up, pTDM patients presented higher rates of treatment escalation (74.3% vs 20.7%,  $P < 0.001$ ) and mucosal healing (77.1% vs 46.7%,  $P = 0.01$ ), but similar rates of hospitalization ( $P = 0.534$ ), surgery ( $P = 0.241$ ) and treatment discontinuation ( $P = 0.212$ ). pTDM patients were less likely to reach any of the former outcomes (66.0% vs 45.7%,  $P = 0.033$ ). In regression analysis only proactive TDM (OR 0.44 95%CI 1.52-8.54;  $P = 0.04$ ) and immunomodulation (OR 0.35 95%CI 1.17-4.63;  $P = 0.016$ ) were independently associated with mucosal healing. Immunomodulation did not influence IFX trough levels ( $P = 0.456$ ) and anti-drug antibodies ( $P = 0.150$ ), and was not associated with improved rates of mucosal healing ( $P = 0.182$ ) in the pTDM group.

**Conclusion:** Higher IFX trough levels were associated with lower inflammatory biomarkers and higher rates of endoscopic and radiologic healing. In comparison with a cohort under conventional management, proactive TDM was unable to show a difference in the rates of surgery, hospitalization and treatment discontinuation but significantly improved the rates of mucosal healing at 2-years. As several studies have shown that mucosal healing reduces the rates of surgery and hospitalization in the long-term, we hypothesize that a longer follow-up would significantly improve our results.

In conclusion, improved IFX pharmacokinetics were associated with better disease control. Proactive TDM was associated with higher rates of mucosal healing than a conventional non-TDM based management.

**Introduction:** IBD-associated cancer and high grade dysplasia (HGD) are sometimes difficult to diagnose, because the patients with IBD-associated cancer do not have any characteristic symptoms and the tumor cannot be detected easily because of their inflammatory background. To overcome the weakness of the current methods for the diagnosis of IBD-associated cancer and HGD, we tried to develop "liquid biopsy" with blood based on the concept of non-invasive diagnostic method with circulating tumor DNA.

**Aims & Methods:** Ten patients with IBD-associated cancer and HGD were enrolled in this study. Tumors and paired non-tumor tissues obtained from 10 patients were analyzed for mutations of 48 oncogenes (Cancer panel; Haloplex, Agilent Technology) using next generation sequencing (NGS; Illumina, San Diego, CA, USA). Blood from 10 patients was also analyzed for the mutations with droplet digital PCR (ddPCR; BioRad, Hercules, CA, USA). Each sample was obtained prior to the treatment. As negative controls, 10 tissues and blood samples of IBD patients without neoplasia were analyzed for mutations of the 48 oncogenes in the same way.

**Results:** The median (range) age was 49 (34-83) years and the male/female ratio was 0.67 (4/6). Of the 10 cases, 7 were IBD-associated cancer and 3 were IBD-associated HGD. Five, three, and two patients were diagnosed as stage 0 (which contained HGD), stage I, and stage III, respectively. We set the cut-off value at 5% for rare mutation rate based on the results of control samples to avoid false positive. Seven of 10 (70%) tumor tissue samples were positive for the mutations. TP53, KRAS, and PIK3CA mutations were detected in 5/10 (50%), 1/10 (10%) and 1/10 (10%) respectively. The frequency of the amino acid changes in each gene were as follows: TP53 (20.9%; R136H), TP53 (25.0%; C110W), TP53 (8.5%; H140Q), TP53 (31.1%; R150W), TP53 (12.8%; R141H), KRAS (40.0%; G12V) and PIK3CA (34.1%; R88Q). In these seven patients, the same mutations were detected in all blood samples. On the other hand, blood samples of the remaining 3 patients without the mutations in tissue did not show any mutations either. Concordance rate with mutations between tissue and blood was 100%. Blood analysis for the mutations indicated that sensitivity, specificity, positive predictive value (PPV) and negative predict value (NPV) were 70%, 100%, 100% and 76.9%, respectively. None of negative control samples showed any mutations.

**Conclusion:** Mutations in tumor could be detected in blood using digital PCR with high PPV (100%). Liquid biopsy with blood may help us to diagnose IBD-associated cancer and HGD non-invasively.

**Introduction:** Leucine-rich alpha-2 glycoprotein (LRG) is an acute phase protein induced by various inflammatory cytokines. Naka *et al.* has recently reported that LRG is an effective biomarker for inflammatory diseases, such as inflammatory bowel diseases (IBD). In this study, we prospectively measured serum LRG in patients with ulcerative colitis (UC), who were treated with adalimumab. We also analyzed the correlation of serum LRG with other disease activity markers.

**Aims & Methods:** This is a multicenter prospective observational study [Predictor and Biomarker; LRG (leucine rich alpha-2 glycoprotein) for Inflammatory Bowel Disease Treatment with Adalimumab: PLANET study (UMIN00019958)]. Active UC patients with Mayo score of 6 or more were recruited for the standard adalimumab treatment. Serum LRG levels were measured by latex turbidimetric immunoassay before and at 12, 24 and 52 weeks after the initiation of adalimumab. Partial Mayo score (PMS), fecal calprotectin (fCP) and C-reactive protein (CRP) were evaluated at the same time point, and severity of colonic inflammation was evaluated by Mayo endoscopic subscore (MES) and Ulcerative Colitis Endoscopic Index of Severity (UCEIS) at 12 and 52 weeks. This study was funded by Eisai Co., Ltd.

**Results:** Forty-seven patients with UC (27 males, 20 females; age 40.6 ± 14.4; disease duration 6.9 ± 6.7 years; left-side colitis 16 cases, total colitis 30 cases, right-side/segmental colonic type 1 case) were registered. The serum LRG level was 23.6 ± 10.4 µg/ml before the treatment (n = 46), and was decreased to 13.9 ± 5.5 µg/ml at 12 weeks (n = 37), 12.5 ± 5.0 µg/ml at 24 weeks (n = 31), and 13.1 ± 5.0 µg/ml at 52 weeks (n = 27).

The levels of LRG and CRP were significantly correlated with pre-treatment PMS, MES and UCEIS (PMS, r = 0.503; MES, r = 0.534; UCEIS, r = 0.394 for LRG; PMS, r = 0.440; MES, r = 0.538; UCEIS, r = 0.365 for CRP). In addition, LRG and fCP were significantly correlated with MES (LRG, r = 0.429; fCP, r = 0.448) and UCEIS (LRG, r = 0.608; fCP, r = 0.512) at 12 weeks. LRG and fCP were significantly correlated with PMS at 52 weeks (LRG, r = 0.398; fCP, r = 0.494).

At week 52, however, fCP was the only parameter, which was significantly correlated with UCEIS (r = 0.640). When serial data were put into an analysis, LRG was the best correlated with PMS and UCEIS (PMS, r = 0.408; UCEIS, r = 0.301).

**Conclusion:** LRG is a novel serum biomarker which can reflect disease activity possibly better than CRP and fCP in UC patients with adalimumab treatment.

## P0359 CHROMOENDOSCOPY TO DETECT NEW DYSPLASIA IN THE SURVEILLANCE OF INFLAMMATORY BOWEL DISEASE WITH PREVIOUS DYSPLASIA

Villar Lucas C., Quiñones Castro R., Pérez Fernández R., Cano López V., González Nuñez R., Alcoba Vega L., Vaquero Ayala L., Sierra Ausin M. Complejo Asistencial Universitario de León, Gastroenterology, León, Spain

**Contact E-Mail Address:** ruben.perez.fernandez@outlook.es

**Introduction:** Inflammatory bowel disease (IBD) patients are in higher risk of developing colorectal cancer (CRC) than general population. Studies show that surveillance with chromoendoscopy (CE) detects a higher number of dysplastic lesions, allowing their endoscopic resection and therefore preventing CRC. It also saves costs by avoiding non-targeted biopsies. We aimed to assess the endoscopic results from follow-up CE in IBD patients with diagnose of dysplasia.

**Aims & Methods:** We carried out a retrospective data collection from IBD patients who have had dysplastic lesions in surveillance chromoendoscopy, which were performed in our hospital from January 2013 to November 2018. Demographic and clinical data were assessed at the time of the first CE, as well as endoscopic findings in this CE and in the first follow-up CE.

**Results:** 320 chromoendoscopies were performed, all of them using Indigo Carmine 0.2% and spray catheter Olympus.

41 patients show dysplastic lesions in the initial CE. Most of them were male (75.5%), with median age 58 years old (23.8-77.4) and familiar history of colorectal cancer was found on 26.7% of them. Ulcerative colitis was more frequent than Crohn's disease (84%), most patients had extensive colitis (79%) and an average age of evolution of the disease of 16 years. 17% were in treatment with biological drugs, 23.7% with immunomodulators and 80% with salicylates, at an average dose of 2.33 g/d. 12 patients (30%) had already had dysplasia in previous colonoscopies, all of them were visible lesions and they were treated endoscopically.

In the initial chromoendoscopy, an average of 2.89 dysplastic lesions with an average size of 8 mm was detected, 76.9% were flat lesions (0-IIa or 0-IIb from Paris classification) and 86% were completely removed endoscopically. Most of them were located distal to the splenic flexure (72%). 80% were tubular adenomas with low grade dysplasia (LGD); there were 2 cases of high grade dysplasia (HGD) and one case of adenocarcinoma. At this time we have performed 25 follow-up CE and new dysplastic lesions were found in 39% of them, with an average of 3.25 lesions, < 10 mm in size, 75% in distal location. 50% of the visible lesions were tubular adenomas LGD, 12.5% serrated adenomas LGD and 12.5% hyperplastic.

In our analysis we found that those patients with flat lesions 0-IIa in the baseline chromoendoscopy have more frequent dysplastic lesions in the revision compared to those with lesions 0-I (78.6% vs 0%, p=0.035). Bowel cleanliness also influenced the number of lesions detected, as we found that those patients whose Boston was < 8 in the baseline CE have a greater number of lesions in the next CE (16 vs. 8; p=0.005).

**Conclusion:** Surveillance with chromoendoscopy in IBD patients with previous dysplastic lesions detects new dysplasia in 30% of cases. Low grade dysplasia was the most frequent histology within the removed lesions. Finding higher number of lesions, 0-IIa lesions or worse bowel preparation (Boston < 8) in the first chromoendoscopy predicts having a higher number of lesions on the follow-up in our sample.

**Introduction:** Infliximab (IFX) increases the risk of infection in patients with inflammatory bowel diseases (IBD), but the relationship between drug ex-

posure, mostly estimated by the trough level of IFX (TLI), and infections remains controversial. The present study aimed to assess factors associated with infection among IFX-treated patients, including pharmacokinetic data.

**Aims & Methods:** All IBD patients receiving the IFX maintenance regimen from November 2016 to April 2017 were screened and prospectively followed. Patients during induction phase of treatment at baseline or who interrupted the treatment during the study period were excluded. Clinical and biological data, infectious events and the TLI were collected at each infusion visit. IFX exposure was estimated by the area under the curve (AUC) of the drug concentration using pharmacokinetic modelling, and then the individual exposure over the 6-month period was estimated by the sum of the AUC ( $\Sigma$ AUC). Independent risk factors of infection were identified by logistic regression.

**Results:** Among the 288 patients treated with infliximab during the study period, 209 patients were included: 102 men (49%), mean ( $\pm$ SD) age 39 ( $\pm$ 14) years old, 159 Crohn's disease (76%). A total of 54 (26%) patients received a combination therapy. The mean TLI was 5.46 mg/L and the mean  $\Sigma$ AUC was 3938 ( $\pm$ 1427) mg.d/L, corresponding to a mean period of IFX exposure of 24.7 ( $\pm$ 3.5) weeks. A total of 215 infections were collected from 640 infusion visits (63 [29%] bacterial infections, 143 [67%] viral infections and 9 [4%] fungal infections). At least one infection occurred in 123 patients (59%), more than one infection in 64 patients (30%), and 46 patients (22%) received antibiotics. Three factors were independently associated with infection after a multivariate analysis: smoking (OR=2.05,  $p=0.046$ ), IBD flare-up (OR=2.71,  $p=0.0060$ ) and a high  $\Sigma$ AUC of IFX ( $>3234$  mg.d/L) (OR=2.02,  $p=0.02$ ). The  $\Sigma$ AUC was higher in patients with infection than in patients without infection ( $p=0.04$ ) and correlated with the number of infections ( $p=0.04$ ). The trough concentration of IFX alone was not associated with infection.

**Conclusion:** Almost two-thirds of patients treated with IFX developed an infection over the 6-month follow-up, and this risk was individually related to increased cumulative drug exposure. These results encourage starting therapeutic de-escalation for patients in remission, guided by drug monitoring.

**Contact E-Mail Address:** naishikyoi@hph.pref.hiroshima.jp

**Introduction:** No biomarkers can effectively predict the clinical prognosis of Crohn's disease (CD) in remission. Capsule endoscopy (CE) is known as a direct examination that can detect minute lesions of the mucous membrane. However, the consensus on the relevance of CE findings and the subsequent course of disease remains to be determined.

**Aims & Methods:** CE was performed after the patency capsule (PC) procedure to verify the patency of the small intestinal tract in patients with CD in remission, and the relationship between CE findings and prediction of clinical prognosis was evaluated.

A total of 45 patients with small intestine type and small intestine-colon type CD in remission phase underwent CE after the PC procedure from October 2010 to December 2017 (27 men, 18 women; average age, 34.9 years). All patients had CD activity index (CDAI) of  $<150$  (average, 92.7). Patients were divided into "active group" with small or longitudinal ulcers detected by CE and "non-active group" without ulcer, and the relationship between the two groups was examined according to disease duration, CDAI value, and C-reactive protein (CRP) value. In addition, occurrence of "exacerbation" requiring change or strengthening of treatment was determined, and its relationship with CE findings was evaluated.

**Results:** Among the 45 patients, 35 (77.8%) were confirmed to have patent small intestines by PC and subsequently underwent CE. Incidents of capsule retention in the small intestine were not observed. Among the

35 patients who underwent CE, 12 (34.3%) were included in the "active group" and 23 (65.7%) in the "non-active group." The disease durations were 82.8 and 142.1 months and the CDAI values were 100.8 and 88.3 in the "active group" and "non-active group," respectively, without significant differences. CRP values were 1.04 and 0.53, respectively, which were significantly higher in the "active group" than those in the "non-active group" ( $p < 0.05$ ). "Exacerbation" occurred in 6 (50%) and 2 (8.7%) patients, respectively, which was significantly higher in the "active group" than those in the "non-active group" ( $p < 0.01$ ).

**Conclusion:** CE was safely performed in 77.8% of patients with CD in remission after performing the PC procedure. The CRP value was significantly associated with the active phase of the small intestinal mucosa as detected by CE. Exacerbation rate was significantly higher in the "active group" than those in the "non-active group." CD in remission may be exacerbated even in clinical remission when an active phase of small intestinal mucosa is detected by CE, and thus, the treatment should be strengthened. These findings suggested that CE is a useful examination procedure to predict the clinical prognosis in patients with CD in remission.

### P0362 DEMOGRAPHIC FEATURES OF ULCERATIVE COLITIS PATIENTS AS PREDICTORS OF RESPONSE TO ADSORPTIVE GRANULOMONOCYTOPHERESIS AS REMISSION INDUCTION THERAPY: A RETROSPECTIVE ASSESSMENT OF TREATMENT OUTCOMES

Tanaka T.<sup>1</sup>, Goishi H.<sup>2</sup>, Iiboshi T.<sup>2</sup>, Kajihara T.<sup>2</sup>, Miura T.<sup>2</sup>

<sup>1</sup>Akitsu Prefectural Hospital, Dept. of Gastroenterology, Hiroshima, Japan,

<sup>2</sup>Akitsu Prefectural Hospital, Hiroshima, Japan

**Contact E-Mail Address:** tomotaka@c.do-up.com

**Introduction:** Inflammatory bowel disease (IBD) is associated with elevated myeloid lineage leucocytes, which show activation behaviour<sup>1</sup> including the CD14+CD16+DR++ phenotype known as proinflammatory monocytes and a major source of tumour necrosis factor- $\alpha$ .<sup>2</sup> Accordingly selective depletion of myeloid leucocytes by granulomonocytapheresis (GMA) with an Adacolumn is expected to promote remission and enhance drug efficacy. However, hitherto studies in IBD have reported contrasting efficacy outcomes, ranging from an 85%<sup>3</sup> to statistically insignificant.<sup>4</sup> Patients' demographic features should guide to select responder patients.

**Aims & Methods:** In ulcerative colitis patients, we were interested to identify relevant demographic features, which potentially could indicate a favourable response to GMA. Therefore, in a retrospective setting, we looked at the baseline clinical and endoscopic features of responders and non-responders to adsorptive GMA in 146 consecutive ulcerative colitis patients who had undergone GMA as remission induction therapy, 74 steroid naïve, 70 steroid dependent, and 2 steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI)  $\leq 4$  was defined as remission. Biopsies from endoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.

**Results:** At entry, the average CAI was 12.8, range 10-17. Ninety-four patients (64.1%) had responded to GMA, 53 of 74 steroid naïve (71.6%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent cohort. Mucosal biopsies revealed that infiltrating leucocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leucocytes in the biopsies from the responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (100%), followed by steroid naïve patients. Further, a short duration of active UC prior to GMA marked a patient as a likely responder.

**Conclusion:** Patients who responded well to GMA attained a favourable long-term clinical course. GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by patients for its safety profile and for being a non-drug remission induction option. Patients with extensive deep ulcers, with long duration of UC refractory to multiple pharmacologies are unlikely to benefit from GMA. In therapeutic settings, knowing baseline features, which may identify responder patients should help to avoid futile use of medical resources.

**Introduction:** Leucine-rich alpha-2 glycoprotein (LRG) is an acute phase protein induced by various inflammatory cytokines. Naka T. *et al.* has recently reported that the serum level of LRG is an effective biomarker to reflect the activity of chronic inflammatory diseases, such as inflammatory bowel disease. In the present study, we prospectively analyzed the levels of serum LRG in patients with Crohn's disease (CD) who were treated with adalimumab. We also analyzed the correlation of LRG levels with conventional disease activity markers.

**Aims & Methods:** This is a multicenter prospective observational study [Predictor and biomarker; LRG (leucine rich alpha-2 glycoprotein) for inflammatory bowel disease treatment with Adalimumab: PLANET study (UMIN000019958)]. Active CD patients with Crohn's disease activity index (CDAI) score of 220 or more were recruited for the standard adalimumab therapy. Serum LRG levels were measured by latex turbidimetric immunoassay before and at 12, 24 and 52 weeks after adalimumab treatment. CDAI score, C-reactive protein (CRP) and fecal calprotectin (fCP) levels were evaluated at the same time point, and the severity of intestinal inflammation was evaluated by Simple endoscopic score for Crohn's disease (SES-CD) before and at 24 and 52 weeks after adalimumab treatment.

**Results:** Thirty-four patients with CD (24 males, 10 females; age 29.5 ± 14.0; disease duration 4.5 ± 6.6 years; ileocolitis 27 cases, ileitis 3 cases, colitis 4 cases) were registered. The serum LRG level was 32.5 ± 13.6 µg/ml before treatment (n = 34), and it decreased to 17.3 ± 9.4 µg/ml at 12 week (n = 33), 18.7 ± 11.7 µg/ml at 24 week (n = 31), and 15.8 ± 8.1 µg/ml at 52 week (n = 28).

LRG levels were significantly correlated with CDAI at 12, 24 and 52 weeks (12 week, r = 0.440; 24 week, r = 0.743; 52 week, r = 0.554). CRP levels were significantly correlated with CDAI before treatment, and at 24 and 52 weeks (pre, r = 0.375; 24 week, r = 0.622; 52 week, r = 0.597). fCP was correlated with CDAI only at 52 week (r = 0.600).

In addition, LRG was significantly correlated with SES-CD before treatment (r = 0.391). LRG, CRP and fCP were significantly correlated with SES-CD at 24 week (LRG, r = 0.563; CRP, r = 0.470, fCP, r = 0.659), and LRG (r = 0.697) and fCP (r = 0.593) were significantly correlated with SES-CD at 52 weeks. When serial data were put into an analysis, LRG was the most highly correlated with CDAI and SES-CD (CDAI, r = 0.660; SES-CD, r = 0.636).

**Conclusion:** LRG is a novel serum biomarker for CD, which specially represents endoscopic activity of the disease. LRG may be superior to CRP and fCP for monitoring CD under adalimumab treatment.

### P0364 MANAGEMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS IN THE EMERGENCY DEPARTMENT: A FRENCH NATIONAL CONSENSUS

Hebuterne X.<sup>1,2</sup>, Peyrin-Biroulet L.<sup>3,4</sup>, Hausfater P.<sup>5,6</sup>, Emergency IBD Group <sup>1</sup>Nice University Hospital, Nice, France, <sup>2</sup>University of Nice Sophia-Antipolis, Nice, France, <sup>3</sup>Nancy University Hospital, Nancy, France, <sup>4</sup>Lorraine University, Nancy, France, <sup>5</sup>Sorbonne University, Paris, France, <sup>6</sup>Pitié-Salpêtrière Hospital, APHP, Emergency Department, Paris, France

**Contact E-Mail Address:** hebuterne.x@chu-nice.fr

**Introduction:** Inflammatory bowel diseases (IBD) are conditions of unpredictable evolution. Despite recent therapeutic progress, particularly since the arrival of biologics, visits to the emergency department (ED) by IBD patients remain frequent and two-thirds of the ED visits lead to hospital admission.

There are currently no guidelines on the actions to be taken when an IBD patient visits the ED: urgent CT scan, hospitalization, or discharge. Certain situations can sometimes lead to unnecessary hospitalizations or, on the contrary, to an inappropriate discharge. The aim of this study was to define criteria to help in the decision-making process in IBD patients visiting ED.

**Aims & Methods:** To address this problem, after a systematic literature review, a Delphi consensus on the actions to be taken when an IBD patient visits the ED was organized in France. Three experts (2 gastroenterologists and 1 emergency physician) built an initial list of criteria which, if met, could lead either to an emergency CT scan prescription or to a hospitalization. An Internet-based two-round Delphi consensus was constructed and a panel of 119 healthcare professionals (68 gastroenterologists, 42 emergency physicians and 9 nurses) were asked to rate each criterion according to a 4-point rating scale (from 'strongly agree' to 'strongly disagree') and to propose additional criteria. Consensus was reached for one criterion when at least 75% of voting members scored the statements 'strongly agree' or 'agree'.

After the first round a national web conference was organized to present and discuss the results and to build the list of criteria for the second round. The first round took place between 21st November and 5th December 2018 and the second round between 19th December 2018 and 15th January 2019.

**Results:** 86 healthcare professionals took part in the first round of voting and 58 in the second round. For both Crohn's disease and ulcerative colitis, consensus was reached on 'IV morphine titration', 'fever', 'vomiting', 'laboratory-confirmed signs of dehydration', 'anorectal abscess', 'haemodynamic instability' as criteria for hospitalisation. The criteria 'suspect abdomen', 'bowel resection in the past 30 days' and 'bowel obstruction' reached consensus both for hospitalization and emergency CT scan. Regarding biological criteria, consensus was reached on 'haemoglobin < 9

g/dL or decrease of  $\geq 2$  g/dL' and 'acute renal failure' as criteria in favour of hospitalization and 'very high CRP' for an emergency CT scan. The final checklist is presented in Table 1.

**Conclusion:** A French group of experts reached a multidisciplinary consensus on a list of clinical and biological criteria which could be used in daily practice when an IBD patient is admitted to the ED. It is hoped that the use of this list will improve management of IBD patients visiting ED. Future studies will be conducted to evaluate the use and the impact of this new tool.

Criteria for immediate hospitalisation	
Clinical criteria	• Suspect abdomen
	• IV morphine titration
	• Fever
	• Vomiting
	• Laboratory-confirmed signs of dehydration
	• Bowel resection in the past 30 days
	• Anoperineal abscess
Laboratory criteria	• Bowel obstruction
	• Haemodynamic instability
Criteria for emergency CT scan	
Clinical criteria	• Haemoglobin $<9$ g/dL or decrease of $\geq 2$ g/dL
	• Acute renal failure
Laboratory criteria	• Suspect abdomen
	• Bowel resection in the past 30 days
	• Bowel obstruction
Laboratory criteria	• Very high CRP

[Final checklist]

## P0365 HEPATOBIILIARY MANIFESTATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Chabib F-Z, Benelbarhadi I., Ajana F-Z.

Ibn Sina University Hospital, Medical Unit C, Rabat, Morocco

**Contact E-Mail Address:** dr.chabib.fatimazahra@gmail.com

**Introduction:** Hepatobiliary manifestations in IBD (chronic inflammatory bowel diseases) are common. The most common is steatosis and the most specific is primary sclerosing cholangitis (PSC).

**Aims & Methods:** The objectives of the study are: to evaluate the frequency of these anomalies, and enumerate the different etiologies as well as their consequences on the management of IBD. This is a 26-year retrospective study [1990 -2016], which includes patients with IBD who presented with at least one biological and / or morphological hepatobiliary abnormality.

**Results:** Out of 1157 patients followed up, 109 patients had at least one liver anomaly, being an incidence of 9.42%. The average age of our patients was 37 years with extremes [13 years, 69 years], the female sex was predominant [68 women, 41 men] with a sex F / H ratio of 1.6. Crohn's disease was the predominant type of IBD (93 cases of Crohn's, 13 cases of UC, 3 cases of indeterminate colitis). Clinically, 89% of patients were asymptomatic. The biological assessment found cytotoxicity in 37% of cases, cholestasis in 21%, both in 6% of cases and normal in 36% of cases. Abdominal ultrasound was performed for all patients. Magnetic resonance cholangiopancreatography was performed in 15.6% of cases (17 cases) and found: an aspect suggestive of sclerosing cholangitis in 8 cases and normal in 9 cases. Puncture Biopsy of the liver was performed in 28.45% of cases (27 cases). The etiologies were as follows: hepatocellular toxicity in 30.25% (33 cases) (24 cases under thiopurines, 6 cases under methotrexate (MTX), 3 cases under salicylic agent and one case under anti bacillary), a steatosis in 26.21% (27 cases), an infectious origin in 15.6% (17 cases) (16 cases of viral hepatitis B or C, 1 case of hepatic abscess), primary sclerosing cholangitis (PSC) in 9.18% (10 cases), vesicular lithiasis (VL) in 11.9% (13 cases), autoimmune hepatitis type I in 2.75% (3 cases), hepatic angioma in 3.66% of cases (4 cases). ), 1 case (0.91%) of liver metastasis of adeno-

carcinoma in the retained rectum after colectomy for ulcerative colitis and undetermined origin in 5.42% (6 cases). transitory anomalies were noted in 6.42% of cases (7 cases). 13 cases of our patients associate 2 anomalies at the same time. Therapeutic drug hepatotoxicity led to the decrease of the dose in 42.4% (14 cases) and to stop definitely the medicament in question in 57.58% (19 cases) with either a therapeutic abstention in asymptomatic patients or a change to another therapeutic molecule: from one purine agent to another or to MTX, MTX or salicylic to a purinic agent. PSC cases were treated by ursodeoxycholic acid. The cases of steatosis improved once the disease stabilized. Treatment of autoimmune hepatitis was similar to that of IBD combined with corticosteroid therapy followed by azathioprine. The case of liver metastasis was followed by surgical resection followed by chemotherapy. For the other patients a specific treatment was applied. The evolution was good in all patients.

**Conclusion:** Hepatobiliary manifestations in patients with IBD are frequent, the incidence in our study is 9.42%. as it's showed it range from benign diseases and side effects of the treatment to malignant disorders. Early diagnosis by a monitoring of liver function at regular intervals is important because of the therapeutic implications for the overall management of patients. Additionally, we should not forget the search for common causes of liver disease as well as for the general population.

## P0366 THE INTRA-INDIVIDUAL VARIABILITY OF FECAL CALPROTECTIN IN PATIENTS WITH GI-SYMPTOMS

Netzer S.<sup>1</sup>, Behrouz S.<sup>1</sup>, Mehr-Rahimi S.<sup>1</sup>, Moriconi F.<sup>1</sup>, Wilhelmi M.<sup>1</sup>, Netzer P.<sup>1,2</sup>

<sup>1</sup>GastroZentrum Netzer AG, Bern, Switzerland, <sup>2</sup>Lindenhofspital, Bern, Switzerland

**Contact E-Mail Address:** serainanetzer@rocketmail.com

**Introduction:** Levels of faecal calprotectin (FC) are used to distinguish between functional and organic gastrointestinal disease. In routine clinical practice, we have observed intra-patient variability in FC measurements made during a short time period. This may indicate that the detection assay is not as reliable as originally presumed. To evaluate this variability more closely, we retrospectively analysed FC measurement data from a selected patient cohort.

**Aims & Methods:** Our aim was to systematically assess the variability in the levels of FC measured within a defined period of time in patients with either a functional or organic gastrointestinal disorder. We searched our electronic patient database for all patients with a gastrointestinal disorder, independent of diagnosis, who had at least three FC measurements made within a 10-day period.

**Results:** Of 404 patients who fulfilled the search criteria and were included in the study analysis, there were 284 women (70%) with a mean age (range) of 45.8 (11 to 90 years). Based on the commonly recommended cut-off value of 50 µg/g for most European countries, 144 patients (35.6%) had three values below the cut-off level and 150 (37.1%) had all three values above the cut-off. Therefore, 110 patients (28.1%) showed a variability in FC levels, which included values considered normal as well as pathological. The range analysis for this patient group showed: 48 patients (43.6%) with the range  $< 50$  µg/g; 33 (30%) within 50-99 µg/g; 11 (10%) within 100-199 µg/g; 9 (8.2%) within 200-500 µg/g; and 8 pts (7.3%) with values  $> 500$  µg/g. Large variability was also seen in a sub-analysis of three patient groups categorised either with an organic disease (232, 57.4%), functional disease (153, 37.9%) or uncertain diagnosis (19, 4.7%). In patients with an organic disease, 66 (28.4%) had FC values below and above the cut-off, whereas there were 30 (19.6%) and 11 (58%) patients with normal and pathological values in the groups defined with a functional disease and uncertain diagnosis, respectively. Further analysis showed variability in patients with three elevated values: 21 (14%) in the range  $< 50$  µg/g; 25 (16.7%) within 50-99 µg/g; 33 (22%) within 100-199 µg/g; 38 (25.3%) within 200-499 µg/g; 19 (12.7%) within 500-1000 µg/g; and 14 (9.3%) with levels  $> 1000$  µg/g. When the cut-off was increased to 100 µg/g, 92 patients (22.6%) had values below and above the cut-off. By applying a cut-off of 150 µg/g, the number of patients with both normal and pathological values decreased to 62 (15.4%). Age and gender did not have any significant influence on the data analysis.

**Conclusion:** We were able to show a relevant variability in FC values measured in our patients. More than one quarter of the patients (28%) had levels of FC deemed both normal and pathological within the sampling time

period. The range for patients with all three measured values above the cut-off of 50 µg/g was relatively large, which creates significant difficulties in analysing the results. By applying a higher cut-off of 100 or 150 µg/g, the number of patients with normal and elevated values was reduced, which suggests that a higher cut-off may be more pertinent. Our analysis also raises the question of whether a single measurement is sufficient to form the basis for clinical decision. We suggest that, as with occult blood, three measurements could be performed. All three values in conjunction with a clear picture of patient symptoms should enable the clinician to determine further treatment procedures. To clearly define recommendations for clinical practice, a large prospective study is needed.

**Introduction:** Since it started in 2012 in the USA, the Choosing Wisely campaign promoted by the American Board of Internal Medicine has rapidly spread all over the world, involving all medical subspecialties. The campaign aims at promoting the clinician-patient relationship, identifying procedures, tests, and treatments that are commonly used in routine practice, but necessity of which should be questioned or discussed. The Canadian inflammatory bowel disease (IBD) Network has recently carried out the first choosing wisely campaign for IBD. However, it was carried out with a top-down approach, involving only 14 expert gastroenterologists. A choosing wisely campaign conducted in a broader scientific community could promote a more rationale, clinically-oriented, management for patients suffering from IBD.

**Aims & Methods:** Between May 2018 and March 2019 we carried out the choosing wisely campaign involving regular members of the Italian Group for the Study of IBD (IG-IBD). Modified Delphi process was applied. All IG-IBD members were asked to submit through SurveyMonkey five statements starting with "Do not..." addressing any management strategy, procedure, or treatment the necessity of which should be questioned or discussed. As a second step, all the proposed recommendations were evaluated by a group of seven senior members and three young members (panellists) who prioritised each item, giving a score from 1 to 10 (1=lowest priority, 10=maximum priority). The ten recommendations with the highest score were prioritised again by all IG-IBD members with the same scoring system. The top five list of the IG-IBD choosing wisely campaign was identified.

**Results:** Overall, 101 members (mean age 42±12; 62 males), working in both academic (57%) and non-academic (43%) hospitals, participated in the campaign. Most participants were gastroenterologists (92%), followed by internists (4%), surgeons (2%), and paediatricians (2%). In the second step, before selecting the top ten recommendations, panellists merged together and rephrased similar statements, and consensus was reached after discussion through email. The top five "Do not..." recommendations are as follow: 1. Do not use corticosteroids for maintenance therapy, or without a clear indication (score 9.08); 2. Do not forget venous thromboembolism prophylaxis in hospitalised patients with active disease (score 8.9); 3. Do not treat perianal Crohn's disease with biologics without prior surgical evaluation (score 8.66); 4. Do not discontinue IBD-related medications during pregnancy unless specifically indicated (score 8.63); 5. Do not delay surgery (8.4).

**Conclusion:** The IG-IBD promoted a choosing wisely campaign with a bottom-up approach, thus reflecting the most compelling, but yet unmet, needs in the care of IBD across Italy. Despite the growing number of guidelines, uncertainties still exist in day-by-day clinical practice. We therefore

envisage that the top five recommendations will be a useful tool for enhancing patient-doctor relationship and provide a better care, especially among non-IBD experts.

### **P0368 OPPORTUNISTIC INFECTION IN PATIENTS WITH INFLAMMATORY DISEASE USING BIOLOGICAL THERAPY. (PROSPECTIVE STUDY)**

Bismara Cury D.H.

*Harvard, Gastroenterology, Campo Grande / MS, Brazil*

**Contact E-Mail Address:** didiacury@gmail.com

**Introduction:** Infection by clostridium difficile has been related in patients who were in hospital and making use of antibiotics therapy.

Up till now, such an infection has not been seen in patients making use of biological and without history preview of hospitalization or antibiotic and who are in remission.

**Aims & Methods:** We investigated the incidence of parasitosis as well as clostridium difficile in the faeces of patients with inflammatory bowel disease during the course of three years of monotherapy with TNF inhibitors (infliximab and adalimumab) or thiopurines (azathioprine). Prospective study with patients in follow-up at a referral center of inflammatory bowel diseases, who were in remission (endoscopic and clinical), with no previous hospitalisation or use of antibiotics, but undergoing treatment with biological therapy for at least six months. The results were compared with those of patients with inflammatory disease not using immunosuppressive agents.

**Results:** Of the total sample of 329 (212 Crohn's disease, 117 ulcerative colitis) patients undergoing biological therapy, 81.13% tested positive for clostridium B versus 18.87% of those only taking immunosuppressants ( $p < 0.0001$ ) OR 4.956 CI 1.96-8.39, demonstrating that patients on TNF inhibitors were four times more likely to be affected by clostridium ( $p = 0.0002$ ). In contrast, no positivity was observed for parasitosis.

No predominance was observed among the biologics (adalimumab/infliximab),  $p = 0.79$ .

**Conclusion:** Patients undergoing biological therapy are more susceptible to becoming infected with clostridium, and not only those hospitalised or receiving antibiotics. This study points to the importance of clostridium research in this specific group of patients.

<sup>5</sup>Univers.-Klinik Schleswig-Holstein, Campus Kiel, Kiel, Germany, <sup>6</sup>IKMB + First Medical Department, Kiel University, Kiel, Germany

**Contact E-Mail Address:** mark.ellrichmann@uksh.de

**Introduction:** Endoscopic quantification of inflammation in ulcerative colitis (UC) is limited to superficial criteria. Mucosal healing is only validated after 8 weeks of treatment and therefore cannot predict early therapy response in UC patients undergoing biological therapy with either anti-integrin or anti-TNF-alpha antibodies. Confocal Laserendoscopy (CLE) allows real-time visualisation of dynamic changes of the mucosal anatomy and might therefore be a reliable tool for an exact quantification of inflammation in UC.

**Aims & Methods:** To evaluate CLE for dynamic quantification of the level of inflammation in UC patients undergoing biological therapy (Vedolizumab (VDO) or Infliximab (IFX)) as a marker for early therapy response.

90 patients (54m) with active UC were recruited for probe based CLE (Cellvizio) in the sigmoid colon before and 2/4/6/14 weeks(wk) after initiation of therapy with IFX (46 patients) or VDO (44 patients). The following CLE criteria were quantified: Mucosal barrier dysfunction, vascular alteration, changes of crypt architecture, inflammatory cell infiltrate. Data were correlated to endoscopic Mayo scores and histological activity indices. Data are presented as mean $\pm$ SD.

**Results:** Response to therapy (defined as clinical remission at wk 14) was achieved in 73.9% (30/46) of IFX patients and 70.5% (31/44) of VDO patients. At baseline, fluorescein accumulated in the mucosa after 8.9 $\pm$ 6.1sec. In patients with later response to both therapies time to accumulation significantly decelerated within 2 wk to 14.8 $\pm$ 5.2sec compared to patients without response (9.6 $\pm$ 5.4sec.; p=0.03). Capillary diameters were dilated up to 16.3 $\pm$ 3.2 $\mu$ m prior to initiation of biological therapies. In case of therapy response a reduction in the capillary diameter of 20.2% (13.65 $\pm$ 3.2 $\mu$ m, p=0.001) was observed within the first two weeks of treatment.

Crypts were significantly enlarged up to an outer diameter of 114.1 $\pm$ 21.2 $\mu$ m at baseline and showed a significant shrinkage in response to therapy (92.9 $\pm$ 12.3 $\mu$ m; p=0.01). Endoscopic Mayo score revealed no significant differences at wk 2 between responders and non-responders.

In patients not responding to biological therapy pCLE criteria did not show significant changes after 2 wk of treatment.

Though both therapy groups exhibited significant changes of pCLE criteria between response and non-response patients, changes were markedly higher in the IFX group compared to the VDO groups after 2 wk of treatment. Thereafter, no significant changes were observed between the groups.

**Conclusion:** Dynamic pCLE criteria allow a reliable quantification of the level of inflammation in UC. The assessed criteria proved to be predictive for therapy response already after 2 wk of treatment and preceded mucosal healing by far. Of note, dynamic, intramucosal changes occur significantly earlier in patients undergoing IFX therapy compared to VDO.

**Disclosure:** Nothing to disclose

**Introduction:** The IBD-disk is a 10-item visual tool assessing the disease burden in patients with inflammatory bowel diseases (IBD) with no validation to date. In a cohort of patients with IBD, we aimed to determine the correlation between the IBD-disk and each of its components with the daily-life IBD burden.

**Aims & Methods:** A one-week cross-sectional cohort study has been conducted in 42 tertiary centers in France and Belgium affiliated to the GETAID in November 2019 recruiting all consecutive outpatients with IBD. Patients fulfilled a self-administered anonymous standardized questionnaire collecting data on patients', IBD and treatment characteristics. Patients were

asked to complete each component of the IBD-disk on 10-point Likert scales (0 = no burden ; 10 = maximal burden) assessing abdominal pain, body image, education and work, emotions, energy, interpersonal interactions, joint pain, regulating defecation, sexual functions, and sleep) ranging from 0 to 100 as well as a 10-point Likert scale assessing the daily-life IBD burden. The objective of the study was to determine the correlation between the IBD-disk score and the daily-life IBD burden, using Pearson's correlation coefficient.

Secondary objectives were to determine the correlation between each component of the IBD-disk score and the daily-life IBD burden. A multivariate linear regression was carried out to investigate the effect of each IBD-disk score component on daily life IBD burden scale. In addition, we evaluated completion rate as well as patient satisfaction for IBD-disk.

**Results:** A total of 2011 outpatients with IBD responded to the survey (930 men; median age 40.0 (29.0-52.0) yrs; median IBD duration 10.5 (4.5-18.5) yrs; 67.8% of patients with Crohn's disease). Patient global assessment of clinical remission was noted in 49.9%. Completion of the IBD-disk was complete in 1484 (73.8%) cases and partial (>5 items) in 220 (10.9%). It was considered as easy to complete by 88.4% of patients. The mean IBD-disk score was 39.0  $\pm$  23.2. After removing 29 outliers, a significant correlation was found between IBD-disk score and daily-life IBD burden scale (r=0.65, p<0.001).

A significant correlation was found between 5 IBD-disk score components (abdominal pain, regulating defecation, education/work, emotions and energy) and daily-life IBD burden (r>0.50). Based on multivariate linear regression analysis, we build a modified 5-item IBD-disk score (education and work x3 + regulating defecation x2 + abdominal pain + energy + emotions) ranging from 0 to 80 with the highest correlation with daily-life IBD burden (r=0.68, p<0.001).

The receiver operating characteristic (ROC)- curves analysis indicated a good performance to predict the absence of clinical remission (AUROC 0.70 95%CI[0.66-0.72], p<0.001) and a significant daily-life IBD burden (0.82 [0.80-0.84], p<0.001) with an optimal cut-off above 30.

Subgroup analysis of patients in clinical remission revealed a significant burden (score >5) in many dimension of burden: body image (33%), education/work (34%), emotions (40%), energy (55%), interpersonal interactions (17%), sexual functions (23%), and sleep (47%).

**Conclusion:** The IBD-disk had a good completion rate and demonstrated a close correlation with daily-life IBD burden in a large multicentre cohort of IBD patients. Our results suggest that the IBD-disk could be a valuable tool in routine practice to assess daily-life IBD burden. Although a simplified 5-item IBD-disk demonstrated better performance to assess IBD burden, the overall score, the IBD-disk allows to explore all dimensions of IBD burden.

**Disclosure:** This study was funded by a grant from Abbvie

## P0371 INCIDENCE AND SIGNIFICANCE OF FATIGUE IN PATIENTS WITH IBD

Kokkotis G., Bekiari D., Gizis M., Perlepe N., Gagas F., Athanasios V., Kounadis G., Xourafas V., Bamias G., Koutsounas I.

3rd Internal Medicine clinic, University of Athens, Gastroenterology, Athens, Greece

**Contact E-Mail Address:** gkokkot@gmail.com

**Introduction:** Fatigue is common in IBD patients, even in clinical remission and adversely affects the quality of life. For this reason, it has been suggested to use fatigue questionnaires as PROs (patient reported outcomes). We aimed to study the degree of fatigue in IBD patients and identify factors that are positively or negatively related to its presence.

**Aims & Methods:** Patients with IBD (men: 48.7%, Crohn's Disease: 65.8%, age: 39.7yrs median, 18.1-72 yrs range), with a regular f-up in our Department completed the Fatigue Severity Scale, IBD Fatigue self assessment 1 & 2, short IBDQ and Short Health Scale upon consensus. Two groups of patients were studied: Group A, patients attended the IBD outpatient clinic (111 patients / 127 questionnaires) and Group B, patients attended the infusion center for biological therapy (45 patients / 256 questionnaires). The SPSS-23 statistical program was used to identify correlations between fatigue and various clinical-laboratory parameters of patients.

**Results:** Problematic fatigue (FSS> 36) was reported by 45.9% of patients. No difference was observed between Crohn's disease and Ulcerative Colitis or between the two groups of patients. There were statistically significant correlations between fatigue and disease activity (R = 0.452, P

<0.001), HGB ( $R = -0.318$ ,  $P < 0.001$ ) and albumin ( $R = -0.172$ ,  $P = 0.039$ ). Fatigue was significantly associated with quality of life based on the short IBDQ and SHS questionnaires ( $R = -0.544$ ,  $P < 0.001$  and  $R = 0.426$ ,  $P < 0.001$  respectively). There was also a statistically significant relationship of both fatigue and quality of life with parameters such as female sex ( $P < 0.01$ ), arthralgia ( $P < 0.05$ ) and biological agent treatment ( $P < 0.05$ ). Sequential measurements showed that the quality of life and fatigue rate were consistently maintained in patients with remission under biological therapy.

**Conclusion:** In the group of IBD patients we studied, a significant correlation with various clinical characteristics was observed. The presence of fatigue is a factor associated with poor quality of life for patients.

**Disclosure:** Nothing to disclose

**Introduction:** Ulcerative colitis (UC) endoscopic scores decode and translate mucosal damage and into a numeric value to reach inter/intra-observer standardization and variability reduction. At this regard, we elaborated a new UC endoscopic score i.e. the "Extended Mayo Endoscopic Score (EMES)". In this study, we evaluated its inter-observer agreement within a multicenter IBD endoscopy experts team and compared EMES concordance with that of Mayo score.

**Aims & Methods:** Sixteen UC consecutive patients underwent follow-up colonoscopy. Sixteen videos were recorded during instrument withdrawal phase. They were anonymously loaded on a web platform realized by SEM web-service, FORMEDICA Scientific Learning srl, Lecce, Italy. Thirteen endoscopists were allowed to access by a personal account in order to evaluate UC activity using both Mayo and EMES scores from April to May 2018. EMES has the peculiarity to depict in every colon segment (ascending, transverse, descending, sigmoid and rectum) the following features: erythema (0: absent, 1: mild, 2: moderate, 3: severe); vascular pattern (0: normal, 1: reduction, 2: disappearance); erosions (0: absent, 1: from 1 to 5, 2: 6 to 10, 3:>10); ulcers (0: absent, 1: from 1 to 5, 2: 6 to 10, 3:>10).

The weighted Fleiss' kappa (k) with 95% confidence interval (CI) and the p-value defined the Interrater agreement for global EMES, for every colon segment EMES and for Mayo score. Agreement was considered poor if  $k < 0$ ; slight for  $k = 0-0.2$ ; fair for  $k = 0.21-0.4$ ; moderate for  $k = 0.41-0.6$ ; substantial for  $k = 0.61-0.8$ ; almost perfect for  $k = 0.81-1$ . STATA MP14 software was used.

**Results:** The interobserver agreement degree of EMES score was moderate even if statistically significant ( $k = 0.56$ ; 95% CI = 0.46 - 0.67;  $p < 0.001$ ). Every colon segment showed the following agreement degrees: ascending ( $k = 0.46$ ; 95% CI = 0.32 - 0.60;  $p < 0.001$ ); transverse ( $k = 0.48$ ; 95% CI = 0.29 - 0.67;  $p < 0.001$ ); descending ( $k = 0.49$ ; 95% CI = 0.35 - 0.64;  $p < 0.001$ ); sigmoid ( $k = 0.52$ ; 95% CI = 0.39 - 0.65;  $p < 0.001$ ); rectum ( $k = 0.55$ ; 95% CI = 0.42 - 0.69;  $p < 0.001$ ) (figure 1). Mayo score result was similar to EMES global agreement ( $k = 0.53$ ; 95% CI = 0.39 - 0.66;  $p = 0.001$ ).

**Conclusion:** EMES and Mayo score showed a moderate, but significant global agreement. Despite the evidence of the need of a further improve-

ment of the agreement for both scores, this study suggested that EMES could be a feasible diagnostic tool for disease activity assessment and tailored therapy.

**Introduction:** Patients with Crohn's disease (CD) struggle continuously with chronic somatic symptoms that could bring about emotional distress. Previous studies have mostly focused on the symptoms of depression and anxiety [1]. The present study evaluates a possible role of somatic distress (previously termed somatization) due to perceived bodily sensations (e.g., numbness, dizziness, chest pain), in addition to depression and anxiety, in exacerbating disease activity among adult patients with CD.

**Aims & Methods:** A cross-sectional analysis was performed on unselected CD patients (age >18years) attending for routine follow-up at a teaching hospital. Clinical disease activity was assessed by the Harvey-Bradshaw Index (HBI) [2]. Anxiety, depression and somatic distress symptoms were measured using the self-report Brief Symptom Inventory questionnaire [3]. Socio-economic status (SES) was self-declared on a Likert scale [4]. Path analysis models tested the contribution of depression, anxiety and somatic distress to disease activity, in the whole cohort and across socio-demographic groups.

**Results:** The cohort was composed of 494 CD patients, mean age 38.0 ±13.8 yr., women 58%. Declared SES was: bad 20%, medium 50%, high 30%. Among the three dimensions of distress symptoms, somatic distress was the only significant predictor of increased HBI for the entire sample (Table). The effect of somatic distress on HBI was stronger in men than women, but there were no gender differences in the effects of depression or anxiety on HBI. The effect of somatic distress on HBI was stronger for individuals with low SES (vs. medium SES) and for patients who had recently endured a stressful life event (vs. those who did not). In contrast, no such differences were found in the effect of depression or anxiety on HBI across these subgroups.

**Conclusion:** Somatic distress is more strongly related than depression and anxiety to disease activity in CD. The association between somatic distress and HBI was especially strong for men, for patients with a recent stressful life event and for patients with low SES. We suggest that screening for emotional distress arising from perceived bodily sensations should be part of CD care. Further investigation will determine whether somatic distress symptoms are causal for elevated markers of inflammation, and whether psychological interventions designed to manage somatic distress could improve outcomes for IBD patients.

	All	Gender		SES			Stressful life event

**Introduction:** Crohn's Disease (CD) is a chronic debilitating inflammatory intestinal disease causing lifetime medical problems. It was shown to affect patients' ability to work and perform everyday leisure activities. We assessed whether a specifically designed Cognitive Behavioral Mindfulness Intervention (CBMI) as an add-on treatment, could improve work productivity and leisure activities in CD patients.

**Aims & Methods:** Unselected adult CD patients with mild to moderate disease activity (4< HBI < 16) attending for routine follow-up at the outpatients' department of a university-affiliated tertiary hospital were enrolled consecutively into a prospective randomized controlled study. Patients were randomized to CBMI (Intervention group) or were wait-listed (Control group). CBMI was taught to Intervention group patients by trained therapists, using SKYPE in weekly hour-long sessions over an 8-week period. Medical details were collected by study physician and medical treatment was uninterrupted. Patients' clinical status was scored by the Harvey Bradshaw Index (HBI). Treating physicians were blinded to randomization. Patients completed the Work Productivity and Activity Impairment (WPAI) Questionnaire, which assesses their ability to work and perform leisure activities in the previous week while coping with their disease. The WPAI generates four scores: Absenteeism - missed work d/t CD; Presenteeism - reduced on-the-job effectiveness; Work productivity loss -overall work impairment; Activity Impairment - degree CD affected regular leisure activities. HBI and WPAI were again completed three months from baseline.

**Results:** The cohort consisted of 41 patients, 20 in the Intervention Group (IG) and 21 in the Control Group (CG). Of the IG and CG patients 65% and 62% were female, the mean (SD) age was 36 (14.4) and 34 (10.8) years, mean (SD) disease duration was 9.7 (10.1) and 9.7 (8.9) years, 10% and 14.3% were smokers, baseline mean HBI was 9.14 and 8.5, and employment rates were 71.4% and 85.0% respectively. Three months from baseline HBI decreased by 3.35 in the IG vs 1.95 in the CG. Absenteeism decreased from 25.4% to 4.6% in the IG (P=0.06) and increased from 15.1% to 21.8% in the CG (P=0.55). Presenteeism decreased from 52.1% to 24.3% in the IG (P=0.027) and from 43.3% to 38.0% in the CG (P=0.63). Work productivity loss decreased from 57.0% to 26.9 % in the IG (P=0.021) and from 49.8% to 45.2% in the CG (P=0.46). Activity impairment decreased from 47.0% to 29.0% in the IG (P=0.018) and from 51.9% to 48.6% in the CG (P=0.51).

**Conclusion:** Work productivity is significantly improved by a specifically designed CBMI. This intervention should be added to the treatment options for better outcomes in CD.

### **P0375 EVALUATION OF THE DIAGNOSTIC VALUE OF FECAL CALPROTECTIN IN THE MANAGEMENT OF CROHN'S DISEASE: MOROCCAN EXPERIENCE**

Chabib F-Z, Benelbarhdadi I., Ajana F-Z.  
Ibn Sina University Hospital, Medical Unit C, Rabat, Morocco

**Contact E-Mail Address:** dr.chabib.fatimazahra@gmail.com

**Introduction:** To limit the repetition of colonoscopies, which are not appreciated by patients, non-invasive tools have been developed. Among them, fecal calprotectin is the non-invasive reference biomarker for assessing endoscopic activity in Crohn's disease (CD).

**Aims & Methods:** The objective of our study is to evaluate the performance of fecal calprotectin for the detection of endoscopic activity in patients with Crohn's disease. This is a single-center retrospective study that includes patients with CD. Inclusion criteria: Patient with both fecal calprotectin and ileocolonoscopy. Fecal calprotectin was measured by ELISA and expressed in mg / kg. Criterion of judgment : Endoscopic remission: CDEIS < 6 and Rutgeert score < i2. Statistical analysis was performed using Medcalc V9 software. The diagnostic evaluation of (calpro) was performed by the ROC curve. For each value, the sensitivity (Se), the specificity (Spe), the positive predictive value (VPP) and the negative predictive value (VPN) were determined. The best threshold value of (calpro) corresponds to the value having a better sensitivity for a better specificity.

**Results:** A total of 70 patients were included in this study. There are 54 women and 16 men; the couple calprotectin-fecal-ileocolonoscopy was performed 90 times. According to the Montreal classification: the localization is distributed as follows: L1 = 17.8%, L2 = 20% , L3 = 62.2% and the phenotype is distributed as follows: B1 = 50%, B2 = 37.8%, B3 = 12 , 2%. Clinically: 76.6% were asymptomatic. The analysis of the area under the curve ROC revealed a diagnostic value estimated at 70% (confidence interval [0.589 - 0.788]). The best detection threshold for the endoscopic activity was 150 mg / kg. This threshold demonstrated the following performances: Se = 72.97%, Spe = 71.70%, VPP = 64.3%, VPN = 79.2%. If we take operated patients separately, the analysis of area under ROC curve found an estimated diagnostic value of 72% (confidence interval [0.544 - 0.859]). The best detection threshold for endoscopic activity was 127 mg / kg . This threshold demonstrated the following performance: Se = Se = 66.67%, Spe = 78.57%, VPP = 82.4%, VPN = 61.1%.

**Conclusion:** Measurement of fecal calprotectin have a diagnostic value acceptable for the diagnosis and monitoring of endoscopic remission in patients with Crohn's disease. In our study, the optimal threshold was 150 mg / kg and 127 mg/kg in operated patients. This threshold value presented a better sensitivity for a better specificity.

**Contact E-Mail Address:** igbakulin@yandex.ru

**Introduction:** Due to the lack of a "gold standard" in the diagnosis of IBD, the differential diagnosis between ulcerative colitis (UC) and Crohn's disease (CD) can be difficult. The complexity of the short-term diagnosis, but its extreme necessity, the lack of uniform criteria for diagnosis, but at the same time high social and medical significance, require the development of new algorithms and methods for identifying and differentiating the forms of IBD.

**Aims & Methods:** We have created an artificial neural network (ANN) of the multilayer perceptron type using the Neural Network Toolbox application from the MATLAB application package. Three types of images were used to train the ANN: the norm of the endoscopic picture of the colon, the endoscopic pictures of UC and CD. The first stage is the training of an

artificial neural network to distinguish the presence or absence of pathology (29 images of the "normal colon", 14 images of the CD, and 15 - UC). The second stage is the training of the network in the task of differentiating IBD. The network was trained on an array of 124 images (62 images of each class of pathologies). Each image was previously converted to grayscale mode, and then into a matrix of pixels. A vector with the number of elements equal to the size of the image was fed to the input of the perceptron. **Results:** To solve the problem of identifying pathology, a perceptron was built with 32,2784 input neurons, 10 hidden neurons and 2 output neurons, which represent the conclusion that the image belongs to one of two classes: norm or pathology. To solve the problem of differentiating CD and UC, a perceptron was created with 364500 input neurons (this value was determined by the image resolution) and 2 output neurons, representing the conclusion that the image belongs to one of two classes: ulcerative colitis or Crohn's disease. ANN studied no more than three times, because then there was a decrease in accuracy.

The best result in the differentiation of pathologies was shown by a neural network of the type MP 364500: 364500-20-2: 2, the overall recognition accuracy of which was 96.8%. However, on the control sample, the accuracy was 84.2%.

The effectiveness of the created artificial neural network in relation to the differentiation of the forms of IBD (UC / CD) can be judged by the criteria: specificity (Sp) 78.2%, sensitivity (Se) 93.1%, accuracy (Ac) 85.7%.

**Conclusion:** At present, it is planned to further refine the models obtained in order to increase the reliability of their estimates. In particular, it is planned to train the network on a larger array of endoscopic images, including those with higher resolution, as well as the use of other types of networks, in particular, the radial basis function. The resulting ANN can be used to solve the problems of classifying endoscopic images of the intestine for the presence of IBD, as well as to differentiate between Crohn's disease and ulcerative colitis.

**Disclosure:** Nothing to disclose

## P0377 SUBOPTIMAL ADHERENCE TO VACCINATION IN PREGNANT PATIENTS WITH INFLAMMATORY BOWEL DISEASE ON BIOLOGICS

Jubran B.<sup>1</sup>, Sharifi N.<sup>2</sup>, Seow C.<sup>3</sup>

<sup>1</sup>University of Calgary, Internal Medicine, Calgary, Canada, <sup>2</sup>University of Calgary, Calgary, Canada, <sup>3</sup>University of Calgary, Gastroenterology, Calgary, Canada

**Contact E-Mail Address:** bellal.jubran@ahs.ca

**Introduction:** Inflammatory bowel disease (IBD) affects 0.7% of the Canadian population[1]. Studies have suggested that preventative health services are received at a significantly lower rate for IBD patients than the general population[2]. Further, many IBD patients are young, female and of child-bearing age. Recent data has demonstrated that despite having multiple health care providers, post partum individuals with IBD have suboptimal health care maintenance rates, with lower self-reported rates of vaccination[3]. We determined adherence to vaccination in pregnant women with IBD by linking a provincial database to a dedicated IBD pregnancy registry.

**Aims & Methods:** To determine the proportion of pregnant women with IBD on biologics who received key vaccines, which included Hepatitis A and B, pneumococcal vaccines 13 and 23, the diphtheria, tetanus and acellular pertussis (dTdap) vaccine, human papilloma virus (HPV) vaccine, and the hemophilus influenza (HiB) vaccine. Adherence was based on serological documentation of immunity and/or electronic public health provincial vaccination records.

**Results:** Records of 115 IBD patients who were pregnant and on a biologic in the study period of 2012-2018 were reviewed. The median age of patients studied was 32 years (IQR 6). Of these patients, 23% had ulcerative colitis (UC), 2% had indeterminate colitis, and 75% had Crohn's disease (CD). 87% were on an anti TNF-alpha biologic (infliximab, adalimumab or golimumab), 7% were on vedolizumab and 6% on ustekinumab. Our results show that 70% had either serological evidence of immunity or registry reported vaccination to Hepatitis B. 37% had serological or registry reported evidence of Hepatitis A vaccination. With the pneumococcal vaccine, 2% had records of the Prevnar 13 vaccine with 35% having received the Pneumovax 23 vaccine. When it came to the dTap vaccine, 78% had evidence of vaccination. The recorded rate of a complete HPV vaccine was 4% while exposure to the hemophilus influenza (HiB) vaccine was 14%.

**Conclusion:** Our study suggests deficiencies in rates of vaccination in the pregnant IBD population on biologics, particularly hepatitis A, the pneu-

mococcal vaccines, HPV and HiB vaccines. These results will serve as a starting point for establishing determinants of suboptimal adherence within the studied population. Ultimately, targeted education programs can be developed.

## P0378 RELATION BETWEEN 6-THIOGUANINE NUCLEOTIDES AND RED CELL MEAN CORPUSCULAR VOLUME, WHITE BLOOD CELL, NEUTROPHIL AND LYMPHOCYTE COUNT IN PATIENTS TREATED WITH AZATHIOPURINE AND 6-MERCAPTUPURINE

Zad M.<sup>1</sup>, Do C.<sup>2</sup>, Mahy G.<sup>3</sup>

<sup>1</sup>Logan Hospital, Logan, Australia, <sup>2</sup>Princess Alexandra Hospital, Brisbane, Australia, <sup>3</sup>Mater Hospital, Brisbane, Australia

**Contact E-Mail Address:** ali6351@gmail.com

**Introduction:** Inflammatory bowel disease (IBD) is caused by dysregulated immune responses, thus thiopurine drugs, 6-mercaptopurine (6-MP) and prodrug Azathiopurine (AZA) are indicated in refractory and steroid-dependent patients. Due to narrow therapeutic ranges, risks of myelosuppression and liver toxicity, these drugs require therapeutic monitoring of metabolites. The 6-Thioguanine nucleotide (6-TGN) metabolite is predominant during therapeutic efficacy (235-460 pmol/8x10<sup>8</sup> erythrocytes), whereas 6-Methylmercaptopurine (6-MMP) correlates with toxicity. Monitoring is associated with significant laboratory costs and a more cost-effective surrogate marker is desirable. As thiopurines cause lymphopenia and increased mean corpuscular volume (MCV), it has been postulated that these may be clinically useful in determining 6-TGN levels, and thus therapeutic efficacy of immunomodulatory treatment.

**Aims & Methods:** To investigate the correlation between 6-TGN levels in relation to MCV, white blood cell count (WBC), neutrophil and lymphocyte count in patients treated with thiopurines.

We retrospectively analysed an electronic database of IBD and non-IBD patients from 2008 to 2017 who were treated with thiopurines (either 6-MP or AZA) in a regional Australian hospital. A total of 931 laboratory results were consecutively obtained, with some patients having repeated blood tests. Pearsons correlation was performed between 6-TGN and MCV levels. Laboratory results were grouped with those < 235 pmol/8x10<sup>8</sup> erythrocytes (below therapeutic level, n=403) and those ≥235 pmol/8x10<sup>8</sup> erythrocytes (above therapeutic level, n=528). Unpaired t-test was used to compare the MCV, WBC, neutrophil and lymphocyte levels of these two groups. The value of these surrogate markers to distinguish shunters (6-TGN < 260, 6-MMP > 5700) vs. non-shunters (6-TGN ≥ 260, 6-MMP ≤ 5700) was also assessed.

**Results:** Results showed that a positive statistically significant correlation existed between 6-TGN and MCV levels (r=0.3219, p< 0.0001) within our dataset. The odds ratio of therapeutic levels of 6-TGN (≥235 pmol/8x10<sup>8</sup> erythrocytes) found in patients with MCV ≥92 fl was 2.79 (95% CI 2.13, 3.67) (p< 0.0001), compared to patients with MCV < 92 fl. Patients above therapeutic 6-TGN level had a mean MCV of 92.66 fl, compared to MCV 89.1 fl (p< 0.0001) in patients below therapeutic 6-TGN (< 235 pmol/8x10<sup>8</sup> erythrocytes). Therapeutic patients also had a mean WBC of 6.59 x10<sup>9</sup>/L (p=0.0012), neutrophil count of 4.37 x10<sup>9</sup>/L (p=0.0211) and lymphocyte count of 1.53 x10<sup>9</sup>/L (p=0.033), which were statistically lower levels than non-therapeutic patients at 7.16 x10<sup>9</sup>/L, 4.73 x10<sup>9</sup>/L and 1.64 x10<sup>9</sup>/L respectively. The mean MCV (95 fl) and WBC (5.915 x10<sup>9</sup>/L) of shunters was statistically different to the mean MCV (90.91 fl) and WBC (6.885) of non-shunters (p=0.0001 and p=0.0131 respectively). The mean neutrophil and lymphocyte count between shunters and non-shunters was non-significant.

**Conclusion:** The results from this study show that there is a statistically significant correlation between 6-TGN and MCV levels. Patients with above therapeutic 6-TGN levels have statistically higher MCV levels and statisti-

cally lower levels of WBC, neutrophils and lymphocytes. Further, there are statistically significant odds that patients managed on thiopurines with MCV  $\geq 92$  fl have a therapeutic 6-TGN level. This indicates that it may be possible to use these markers as surrogates for expensive 6-TGN levels in patients treated with thiopurines. Further, this study suggests that shunters have a statistically higher mean MCV and WBC.

### P0379 BAMBOO JOINT-LIKE APPEARANCE IN STOMACH - AN ENDOSCOPIC BIOMARKER OF CROHN'S DISEASE. A PROSPECTIVE CASE CONTROL STUDY

Graca-Pakulska K.<sup>1</sup>, Dabkowski K.<sup>2</sup>, Zawada I.<sup>1</sup>, Starzynska T.<sup>2</sup>

<sup>1</sup>Pomeranian Medical University, Department of Gastroenterology, Szczecin, Poland, <sup>2</sup>Pomeranian Medical University, Department of Gastroenterology, Szczecin, Poland

**Contact E-Mail Address:** kgracapakulska@gmail.com

**Introduction:** Crohn's disease (CD) is a chronic inflammatory condition that typically involves the ileocecal region; but the whole gastrointestinal (GI) tract can be affected. Lesions in the upper GI tract are increasingly diagnosed. It was suggested that lesions in the stomach, with a bamboo joint-like appearance (BJA) might be an endoscopic biomarker for CD. However, the reported prevalence of upper GI tract involvement in CD varies greatly and diagnostic significance of BJA remains to be defined. A majority of European studies were retrospective and did not refer to the presence of BJA in stomach.

**Aims & Methods:** Our aim was to investigate the prevalence, characteristic and clinical importance of upper gastrointestinal involvement in a patients with CD, with special focus on the lesion named bamboo joint like appearance. A prospective, case control study was conducted. 144 patients were included into the study, 72 with CD (37 female, 35 male) and 72 gender and age matched non IBD controls. The endoscopy was performed by experienced physician using a high definition endoscope with narrow band imaging.

**Results:** The upper gastrointestinal tract was involved in 43 out of 72 (59.7 %) patients with CD. Most commonly stomach was affected (n=37; 51.4 %), followed by duodenum (n=21; 29.2 %) and esophagus (n=9; 12.5 %). 16 (22.2%) of CD patients had BJA in proximal part of gastric body or/and fundus. BJA was present irrespectively of the patient's sex, age, location of the disease, and medications taken. BJA was absent in control group (statistically significant difference with study group, p=0.00025).

**Conclusion:** The upper gastrointestinal involvement in Crohn's disease is common phenomenon. The most commonly affected area is the stomach with a specific lesion for CD, the bamboo joint like appearance. This finding may help to identify individuals at high risk for CD using only gastro-duodenoscopy.

**Contact E-Mail Address:** kmali@seznam.cz

**Introduction:** Telemedicine refers to the professional monitoring of patients and the transmission of medical information remotely via information technologies. The first Czech study of the remote monitoring of IBD patients called "IBD Assistant" was launched at the IBD Clinical & Research Centre ISCARE IVF in 2018. The inclusion criteria for the study were as follows: (1) a diagnosis of Crohn's disease or ulcerative colitis, (2) remission of the disease verified by endoscopy conducted during the 12 months prior to the start of the study, (3) age > 18 years, (4) user-level computer literacy with the possibility of regular use of an online smartphone, and (5) the subject's own email address.

The exclusion criteria were (1) lacking knowledge of the Czech language, (2) a diagnosis of IBD within the 3 months preceding the start of the study, (3) pregnancy, (4) ongoing biological treatment, and (5) hospitalisation in the preceding 3 months due to exacerbation of IBD symptoms. In addition to monitoring the patients' subjective complaints, the occurrence of defined clinical signs and treatment adherence, the best-known and most widely used biomarker of gut inflammation - fecal calprotectin (FC) measurement - were integral parts of the project.

**Aims & Methods:** Quality assessment of the home-based CalproSmart (CALPRO, Norway) FC test in the telemonitoring of patients with inflammatory bowel disease (IBD).

One hundred FC values were compared. The first data set was measured by patients using the home-based CalproSmart test, and the second data set was obtained using standard fluoroimmunoassay (FIA) in a clinical laboratory. The principle of CalproSmart measurement is lateral flow analysis. Its measurement range is 70-1,500 µg/g. Expert measurements were conducted by using the ELiA Calprotectin Phadia (Thermo Fisher Scientific, USA) diagnostic kit. The measurement range of the analysis is 0-6,000 µg/g.

**Results:** Spearman's correlation coefficient  $r = 0.895$  ( $p = 0.0004$ ) and weighted Cohen's kappa 0.835 indicate good correlation of two data sets measured by different measurement systems; see Table 1.

		LFA (CalproSmart)		
		LOW	MODERATE	HIGH
FIA (Phadia)	LOW	53	6	0
	MODERATE	2	32	1
	HIGH	0	1	5

FIA - fluoroimmunoassay; LFA - laminar flow analysis; LOW - concentrations of fecal calprotectin up to 200 µg/g; MODERATE - concentrations of fecal calprotectin between 201 and 500 µg/g; HIGH - concentrations of fecal calprotectin over 500 µg/g; Unweighted kappa = 0.814; Weighted kappa = 0.835; Standard error of kappa = 0.055; 95% confidence interval: from 0.706 to 0.923; The strength of agreement is considered „very good.”

[Table 1. LFA and FIA performance results in terms of Cohen's kappa coefficient]

**Conclusion:** The home-based FC test CalproSmart is well-suited to qualitative FC analysis in the telemonitoring of patients with IBD. It cannot replace standard laboratory FC measurements, but such performance is not required for the home-based kit.

## P0381 SERUM TROUGH SB5 LEVELS: A COMPARISON OF TWO DIFFERENT IMMUNOASSAYS FOR THE MONITORING OF BIOSIMILAR ADALIMUMAB TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Malícková K., Bortlík M., Ďuricová D., Machková N., Hrubá V., Lukáš M., Vašátko M., Mitrová K., Kostrejšová M., Lukáš M.  
ISCARE IVF & Charles University, Clinical & Research Center for Inflammatory Bowel Disease, Prague, Czech Republic

**Contact E-Mail Address:** kmali@seznam.cz

**Introduction:** SB5 is a biosimilar monoclonal antibody adalimumab for the treatment of patients with inflammatory bowel disease (IBD). Only minor differences in clinically inactive components are allowable in biosimilars compared to reference products. However, even a small difference in the molecular structure can lead to different behavior of the biosimilar drug in analytical systems for the detection of serum drug trough levels.

**Aims & Methods:** Although monitoring of adalimumab serum trough levels hold an important significance in treatment modalities and clinical outcome during the treatment, no data about monitoring of drug serum trough levels in IBD patients treated with SB5 are present to date. Therefore, we would like to compare recombinant human TNF $\alpha$ -based (rhTNF $\alpha$ ) ELISA kit for the adalimumab trough levels detection with results obtained from the system based on the monoclonal antibody towards an original adalimumab.

Sixty-two IBD serum samples from patients on maintenance treatment with SB5 (40 mg subcutaneously every two weeks) were analyzed. Sera from IBD Blood Bank established according to the Ethics Committee of ISCARE (Nr 2015/1a) were used. SB5 trough levels were measured by the standard enzyme immunoassay (ADALIMUMAB ELISA ImmunoGuide, REF: IG-AA103) based on recombinant human TNF $\alpha$  (rh TNF $\alpha$ ). Moreover, the same serum samples were analyzed by RIDAScreen ADM Monitoring (R-Biopharm, REF: G09043) based on the highly specific monoclonal antibody towards original adalimumab MA-ADM40D8 isolated and characterized at the KU Leuven.

Data were analyzed by Statistica 13.3. (TIBCO). The strength and direction of association between two variables were assessed by Spearman's rank order correlation coefficient. The Kruskal-H test was used for comparing two cohorts of concentration values.

**Results:** Of 62 serum samples, 54 were patients with Crohn's disease and 8 patients with ulcerative colitis, 36 were women and 26 were men, median age was 41.5 years. Excellent quantitative agreement was observed between adalimumab trough levels measured by rhTNF $\alpha$ -based, and monoclonal antibody-based kits,  $r = 0.804$ ,  $P < 0.0001$ . Non-parametric Kruskal Wallis test have shown that medians of trough levels concentrations in two data groups are not different,  $p = 0.363$ .

**Conclusion:** rh-TNF $\alpha$ -based ELISA kit and monoclonal antibody-based ELISA kit for measuring SB5 trough levels showed similar overall performance. and were in very good mutual quantitative agreement. This would provide valuable information on the possibility of using these assays as monitoring tools during treatment with biosimilar adalimumab.

## P0382 WITHDRAWN

## P0383 FACTORS CONTRIBUTING TO INDETERMINATE INTERFERON- $\gamma$ RELEASE ASSAY RESULTS IN INFLAMMATORY BOWEL DISEASE PATIENTS UNDERGOING PRE-BIOLOGIC TUBERCULOSIS SCREENING

Bi C.J.<sup>1</sup>, Sadler C.<sup>1</sup>, Makaranka S.<sup>1</sup>, Potter J.L.<sup>2</sup>, Samaan M.A.<sup>1</sup>, Parker H.<sup>1</sup>, Kettle R.<sup>1</sup>, Whitley L.<sup>1</sup>, Di Caro S.<sup>1</sup>, Rahman F.<sup>1</sup>, Mehta S.<sup>1</sup>, Vega R.<sup>1</sup>, Seward E.<sup>1</sup>, McCartney S.<sup>1</sup>, Bloom S.<sup>1</sup>

<sup>1</sup>University College London Hospital, Department of Gastroenterology, London, United Kingdom, <sup>2</sup>University College London Hospital, Department of Respiratory Medicine, London, United Kingdom

**Contact E-Mail Address:** claudia.sadler@nhs.net

**Introduction:** IFN- $\gamma$  release assays (IGRA) are routinely used in patients with Inflammatory Bowel Disease (IBD) prior to initiation of biologic monoclonal antibody treatment to screen for latent tuberculosis (TB) infection.

IGRA results are often indeterminate, resulting in the need for repeat testing and a potential delay in commencing appropriate management. Disease activity and corticosteroid treatment have previously been shown to be associated with indeterminate IGRA results. We hypothesise that there is a positive correlation between systemic inflammation and indeterminate IGRA results.

**Aims & Methods:** We performed a case-control study of 268 IBD (5 IBDU, 48 UC, 215 CD) patients who underwent pre-biologic IGRA testing at our tertiary IBD referral centre. We compared various phenotypic, disease activity and treatment characteristics of patients who had a determinate IGRA with those who had an indeterminate IGRA results. Biochemical disease activity was evaluated using CRP, platelet count and albumin measured within one week of IGRA testing. We also aimed to assess whether treatment setting (inpatient vs outpatient) affected IGRA results. The Mann-Whitney U and Chi-Square tests were used to compare the two groups.

**Results:** Of the 268 included patients, 42 (16%) had an indeterminate IGRA and the remaining 226 (84%) were determinate: 215 negative, 11 positive (table 1).

We observed that a significantly higher proportion of patients with an indeterminate IGRA results were on corticosteroid therapy (50% vs 15.5%,  $p < 0.0001$ ) and were inpatients (52% vs 5%,  $p < 0.0001$ ) at the time of testing. We also found that patients with an indeterminate result had a higher median CRP (25 vs 5mg/L,  $p < 0.0001$ ) and platelet count (412 vs 330x10<sup>9</sup>/L,  $p < 0.0001$ ) as well as a lower albumin (35 vs 44g/L,  $p < 0.0001$ ). There was no significant difference in the proportion of patients in each group who were receiving immunomodulators at the time of testing (55% indeterminate IGRA vs 61% determinate IGRA,  $p = 0.48$ ).

	Indeterminate IGRA (n=42)	Determinate IGRA (n=226)	p
Characteristic			
IBD phenotype, UC:CD:IBDU	15:24:3	33:191:2	
Use of immunomodulators	23 (55%)	137 (61%)	0.48
Use of steroids	21(50%)	35 (16%)	<0.0001
Treatment setting- inpatient	22 (52%)	12 (5%)	<0.0001
Disease activity			
Median CRP (mg/L)	25	5	<0.0001
Median albumin (g/L)	35	44	<0.0001
Median platelet count (x10 <sup>9</sup> /L)	412	330	<0.0001

[Table 1. Univariate analyses of associations with an indeterminate IGRA result]

**Conclusion:** Our results demonstrate that patients with more active IBD are significantly more likely to have an indeterminate IGRA test than those with less active disease. IGRA testing may be of limited diagnostic utility in the context of hospitalised patients and those receiving corticosteroids. These factors should be taken into account by clinicians when considering how to manage patients with indeterminate IGRA requiring escalation to a biologic. In patients with factors known to contribute to indeterminate IGRA testing, low risk of TB and a normal chest radiograph, clinicians may decide to proceed with biologic treatment rather than delay. If possible, IGRA testing should be carried out prior to the initiation of corticosteroid therapy.

## P0384 ADHERENCE TO THERAPY INFLAMMATORY BOWEL DISEASE OBSERVED IN MOSCOW CLINICAL SCIENTIFIC CENTER

Knyazev O.<sup>1,2</sup>, Babayan A.<sup>1</sup>, Kagramanova A.<sup>1</sup>

<sup>1</sup>The Loginov Moscow Clinical Scientific Centre, Department of Inflammatory Bowel Diseases, Moscow, Balaschiha, Russian Federation, <sup>2</sup>AbbVie, Department of Inflammatory Bowel Diseases, Moscow, Russian Federation

**Contact E-Mail Address:** kagramanova@me.com

**Introduction:** Inflammatory bowel diseases (IBD) are chronic autoimmune inflammatory diseases with intestinal lesions and external manifestations. The concept of permanent life-long medication is the cornerstone in the treatment of IBD. Depending on the dosage regimen prescribed, the patient is injected with a dose and an interval between doses.

**Aims & Methods:** To assess adherence to the treatment of diseases in patients with Crohn (CD) and ulcerative colitis (UC), observed in the department of inflammatory bowel disease.

**Materials and methods:** The study included 55 (45.8%) men and 65 (54.2%) women older than 18 years, 70 (58.3%) patients with UC, 50 (41.7%) with CD, who attend treatment and examination in the department of inflammatory bowel diseases. Patient adherence to therapy is evaluated using the Moriska-Green test, the results of which all patients were divided into two groups: the first group - patients with low adherence treatment (LAT); the second group - patients with high adherence to treatment (HAT).

**Results:** It was shown that patients with high adherence to therapy were 78 (65.0%) versus 42 (35.0%), respectively ( $p < 0.001$ ). In the group of patients with HAT, women predominate - 26 (61.9%) versus 16 (30.1%) men ( $p < 0.001$ ). In the group of HAT, patients with CD 30 (71.4%) also prevail against 12 (28.6%) patients with UC ( $p < 0.001$ ). It was established that in the group of HAT, patients receiving 5-aminosalicylic acid preparations (5-ASA) 23 (54.8%) and biological preparations (BP) - 15 (35.7%) predominate. In the LAT group, patients with the necessary immunosuppressors and glucocorticosteroids prevail - 54 (69.3%), against patients receiving 5-ASA and BP - 24 (30.7%) ( $p < 0.001$ ). The frequency of exacerbations of diseases was higher in the LAT group - 52 (66.6%), versus 13 (30.9%) in the HAT group ( $p < 0.001$ ). The frequency of surgical interventions in patients with CD was higher in the LAT group - 15 (75.0%) versus 5 (16.6%) in the HAT group ( $p < 0.001$ ). A significant difference between the groups was noted when it was possible to obtain drugs in the preferential provision (38.5%) in the HAT group versus 40 (51.3%) LAT groups ( $p < 0.001$ ). It was shown that the patient has no age, no educational and socio-economic status.

**Conclusion:** Among patients with IBD, examined in the department of inflammatory bowel diseases, 65% have a low commitment to taking prescribed medications. Low adherence of treatment is associated with factors such as the use of systemic immunosuppressants and glucocorticosteroids in therapy, complications during CD, the frequency of exacerbations of IBD. Female sex is reliably associated with high adherence to treatment, the presence of drugs in the preferential provision.

**Contact E-Mail Address:** jonathanmacdonald@nhs.net

**Introduction:** Anti-tumour necrosis factor  $\alpha$  (anti-TNF $\alpha$ ) drugs infliximab (IFX) and adalimumab (ADL) are effective treatments for inflammatory bowel disease (IBD) and have greatly improved outcomes for many individuals. However, treatment effects are not universally favourable with primary non-response (PNR) to treatment occurring in up to 30% and secondary loss of response (SLR) in up to 46% of IFX and ADL treated IBD cohorts (1,2). Therapeutic drug level and anti-drug antibody monitoring (TDM) has emerged as a useful tool for optimising the effectiveness of these drugs, identifying individuals who may benefit from dose or treatment frequency adjustments to regain control of disease after relapse, or even to prevent PNR or SLR.

**Aims & Methods:** Ensuring safe and effective use of biologic medicines has been identified as a key priority for NHS Scotland. Inequity and inconsistency of access to TDM across the nation was recognised as a barrier to delivering best practice and so a nationally commissioned TDM service was established in January 2018 to support clinical practice, providing universal access to TDM for IBD services across Scotland. A service webpage was developed to provide guidance on testing strategies and interpretation of TDM results (3). Preliminary data and initial clinical observations from the first year of the service have now been collated. Data collection and analysis of results regarding usage and clinical impact of the service were identified as key outcome measures to assess service success and sustainability.

An automated search of clinical data and test results recorded within the clinical biochemistry electronic results management system was conducted to identify all TDM tests performed between 01/01/2018 and 31/12/2018. Outcomes for descriptive analysis included the number of samples received and processed, overall testing population, service utilisation by Health Board, and the number and results of TDM tests performed per patient. TDM results were interpreted according to published guidance on the service webpage and comparison was made with previously published data (4).

**Results:** 3609 specimens were received for testing, from 13 of the 14 Scottish Health Boards. 3561 drug level (DL) tests were performed; 1786 IFX, 1775 ADL. 2717 total antidrug anti-body (TABT) tests and 681 free antidrug anti-body tests (FABT) were performed according to service protocol. 2791 individuals had one or more TDM tests during the 12-month period, of whom 541 were tested twice or more (range 2-5).

Drug level by category		INFLIXIMAB		ADALIMUMAB	
		Supratherapeutic DL > 8mcg/ml	546 (30.6%)	708 (39.9%)	Supratherapeutic DL > 10 mcg/ml
		Therapeutic DL $\geq 3 < 8.1$ mcg/ml	738 (41.3%)	636 (35.8%)	Therapeutic DL $\geq 5 < 10.1$ mcg/ml
		Sub-therapeutic DL < 3mcg/ml	502 (28.1%)	431 (24.3%)	Sub-therapeutic DL < 5 mcg/ml
TABT by category		Negative (<10 AU/ml)	791 (54.2%)	905 (71.9%)	Negative (<10 AU/ml)
		Positive (>10 AU/ml)	668 (45.8%)	353 (28.1%)	Positive (>10 AU/ml)
FABT by category		Negative (< 5AU/ml)	376 (82.8%)	176 (77.6%)	Negative (<10 AU/ml)
		Positive (> 5 AU/ml)	78 (17.2%)	51 (22.4%)	Positive (>10 AU/ml)

[Table 1 - IFX & ADL DL, TABT and FABT results by category as defined in service guidance (AU/ml = Arbitrary Units/ml)]

**Conclusion:** TDM has been enthusiastically embraced with rapid uptake of testing in IBD. It is estimated that > 50% of individuals treated with IFX or ADL have been tested at least once in the first year. DL results were found to be similar to previously published data, as were rates of antibody positivity. The large volume of data generated by the service may provide additional evidence regarding the utility of TDM in predicting clinical response. Next steps are to conduct a comparative effectiveness analysis where proactive vs reactive TDM testing strategies will be compared, with the primary outcome measure being the proportions of patients with SLR. **References:** 1. **Contact E-Mail Address:** leonardo.salese@pfizer.com

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Oral corticosteroids are an acknowledged induction therapy, but are associated with side effects including infections.<sup>1</sup>

**Aims & Methods:** We evaluated induction efficacy and infection risk with tofacitinib 10 mg twice daily (BID) treatment based on baseline corticosteroid use in tofacitinib UC induction studies. Remission (total Mayo score  $\leq 2$ , no individual subscore  $>1$ , rectal bleeding subscore 0), mucosal healing (Mayo endoscopic subscore  $\leq 1$ ) and clinical response (decrease from baseline total Mayo score of  $\geq 3$  points and  $\geq 30\%$ , and decrease in rectal bleeding subscore of  $\geq 1$  point or absolute rectal bleeding subscore of 0 or 1) were evaluated in two 8-week, Phase 3 tofacitinib induction studies (OCTAVE Induction 1 & 2; NCT01465763 & NCT01458951; pooled data). Induction studies allowed stably dosed corticosteroids (25 mg/day maximum). Efficacy and safety data were summarised by oral corticosteroid use at induction baseline (BLC-Yes/No). Infections of interest included herpes zoster (HZ), serious infections (SIs), and adjudicated opportunistic infections (OIs).

**Results:** Of 1139 patients (placebo: n=234; 10 mg BID: n=905) in OCTAVE Induction 1 & 2, 525 (46.1%) were on corticosteroids at baseline ( $< 15$  mg daily dose: 32.8%;  $\geq 15$  mg daily dose: 67.2%). A statistically significant treatment effect of tofacitinib 10 mg BID vs placebo was observed for remission, mucosal healing and clinical response at Week 8, for both subgroups of patients with and without baseline oral corticosteroid use (Table). Differences vs placebo were numerically greater for patients not receiving oral corticosteroids at baseline. In OCTAVE Induction 1 & 2, infections of interest occurred with similar frequency among both subgroups of patients: the proportion of placebo-treated patients with HZ was 0.8% for BLC-No vs 0.0% for BLC-Yes; and 0.2% for BLC-No vs 1.0% for BLC-Yes with 10 mg BID. The proportion of placebo-treated patients with SIs was 0.0% for BLC-No vs 0.0% for BLC-Yes; and 1.0% for BLC-No vs 0.2% for BLC-Yes with 10 mg BID. The proportion of placebo-treated patients with OIs was 0.0% for BLC-No vs 0.0% for BLC-Yes; and 0.2% for BLC-No vs 0.5% for BLC-Yes with 10 mg BID.

% (n/N)	Placebo (N=234)	Tofacitinib 10 mg BID (N=905)	Difference from placebo (95% CI)
Remission - oral CS use at baseline (No)	5.0 (6/121)	18.1 (89/493)	13.1** (7.9, 18.2)
Remission - oral CS use at baseline (Yes)	7.1 (8/113)	17.0 (70/412)	9.9** (4.0, 15.9)
Mucosal healing - oral CS use at baseline (No)	7.4 (9/121)	28.2 (139/493)	20.8*** (14.6, 26.9)
Mucosal healing - oral CS use at baseline (Yes)	20.4 (23/113)	32.0 (132/412)	11.7* (3.0, 20.4)
Clinical response - oral CS use at baseline (No)	26.4 (32/121)	54.0 (266/493)	27.5*** (18.5, 36.5)
Clinical response - oral CS use at baseline (Yes)	35.4 (40/113)	61.9 (255/412)	26.5*** (16.5, 36.5)

Data are FAS, NRI, central read endoscopy. 95% CI for differences from placebo are based on the normal approximation for the difference in binomial proportions

\*p<0.05; \*\*p<0.01; \*\*\*p<0.0001 vs placebo based on Cochran-Mantel-Haenszel chi-square test

BID, twice daily; CI, confidence interval; CS, corticosteroid; FAS, full analysis set; N, number of patients in treatment group; n, number of patients with efficacy response; NRI, non-responder imputation

[Table. Summary of efficacy at Week 8 in OCTAVE Induction 1 and 2 by oral CS use at baseline (yes/no)]

**Conclusion:** Tofacitinib demonstrated significant induction efficacy vs placebo for both subgroups of patients with and without baseline corticosteroid use. Proportions of HZ, SIs and OIs in OCTAVE Induction 1 & 2 were generally similar for both subgroups of patients with and without baseline corticosteroid use; however, the relatively small number of events and short duration of follow-up (8 weeks) are limitations of this analysis.

**Introduction:** Treatment options for inducing/maintaining clinical remission in moderate to severe ulcerative colitis (UC) include biologic therapies. Yet, in some patients, biologics are less effective over time due to immunogenicity and fail to maintain remission. Hence, dose escalations (dose intensifications or more frequent dosing) may be considered. Previous studies assessing dose escalations in biologic therapies have mainly focused on one biologic, predominantly adalimumab (ADA) or infliximab (INF); therefore, there is a need for data relating to other biologic therapies and also for comparative data.

**Aims & Methods:** This study aimed to estimate the frequency and extent of dose escalations in patients with UC in Germany initiated on biologic therapy. A retrospective, longitudinal cohort design was employed utilising de-identified German statutory health insurance (SHI) claims data within the Health Risk Institute database. Adult patients (18+ years of age) with UC (ICD-10 K51) but without Crohn's disease (ICD-10 K50) were indexed (Jan 2013-Dec 2015) on biologic therapy initiation (ADA, golimumab [GOL], INF or vedolizumab [VED]) with a 24-month follow-up. Patients had to be continuously insured by SHI and have no record of biologic therapy in the prior 12 months.

Daily doses (in milligrams [mg]) were calculated as a quotient of dose prescribed and duration between prescriptions/administrations (in days). Dose escalations were defined as an increase in daily dose of  $\geq 50\%$  compared with the recommended maintenance daily dose (ADA = 2.86, GOL = 3.57, INF = 6.25 [70 kg assumed], VED = 5.36) following induction period. De-escalations were defined as a daily dose equal to or below the recommended maintenance daily dose. Time to dose escalation (from start of maintenance) and subsequent de-escalation were calculated.

**Results:** In total, 304 patients were identified (mean age 42.9 years, 56.3% male), and 56% of patients had sufficient data to assess dose escalations. Of those, over half (59%) of patients received a dose escalation, occurring after a mean of 58.5 days (see Table). A significant difference ( $P < 0.0001$ ) in the frequency of dose escalations was observed across index biologics, with 73% of patients initiated on ADA receiving a dose escalation. Patients initiated on INF were escalated, on average, to over four times the

recommended dose. Patients initiated on VED were escalated to double the recommended dose. Two-fifths (41%) of patients who received a dose escalation received a subsequent de-escalation.

**Conclusion:** A large proportion of patients required dose escalations to manage their UC. The prevalence and timing of dose escalations differed significantly between biologic therapies, with the largest proportion of dose escalations observed for ADA. These data suggest that many patients may require dose escalations to achieve and maintain remission when being treated with current biologic therapies. Further advanced treatment options that remain effective for this patient population without the need for dose escalations may be warranted.

**Introduction:** Biologic therapies for the treatment of moderate to severe ulcerative colitis (UC) provide relevant options for achieving clinical remission. Yet, in some patients, they do not induce and/or maintain clinical response or remission as monotherapy. Thus, concomitant treatment with steroids and/or immunosuppressants (IMs) is required. Given the long-term safety profile associated with these therapies, it is important to

understand concomitant steroid/IM use in this patient population to determine how biologics are being used in combination with other therapies to achieve response/remission in UC.

**Aims & Methods:** This study explores the concomitant use of steroids and IMs in patients with UC in Germany initiated on biologic therapy. A retrospective, longitudinal cohort design was employed utilising de-identified German statutory health insurance (SHI) claims data within the Health Risk Institute database. Adult patients (18+ years of age) with UC (ICD-10 K51) but without Crohn's disease (ICD-10 K50) were indexed (Jan 2013-Dec 2015) on biologic therapy initiation (adalimumab [ADA], golimumab [GOL], infliximab [INF] or vedolizumab [VED]) with a 24-month follow-up (FU). Patients had to be continuously insured by SHI and have no record of biologic therapy in the prior 12 months (baseline).

Steroid use (oral only) and IM use were observed in the FU period and stratified by whether steroids/IMs had been received prior to biologic initiation or not (ie newly initiated). Descriptive statistics are reported and Chi-squared or Fisher's exact tests were used to assess statistical significance of outcomes across index biologics.

**Results:** In total, 304 patients were identified (mean age 42.9 years, 56.3% male). Only a quarter of patients (26%) did not require any treatment with steroids in the FU period (see Table). Prednisolone was the most frequently observed steroid (88%) among steroid users. Approximately two-fifths of patients (41%) received treatment with IMs in the FU period, with azathioprine being the most frequently observed IM (77%). Most IM users (72%) had received an IM in the baseline period, whilst 28% newly initiated an IM following biologic initiation.

**Conclusion:** Steroid use was high following biologic initiation, with only a quarter of patients being steroid-free. Over a quarter of IM users were newly initiated on IM treatment following biologic initiation. These data suggest that control with biologic monotherapy is often insufficient treatment, highlighting the need for further advanced treatment options for this patient population.

Outcomes, n (%)	Total (n=304)	ADA (n=125)	GOL (n=47)	INF (n=114)	VED (n=18)

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Faecal calprotectin (FCP) levels were shown to correlate with clinical and endoscopic outcomes at Week 8 in patients with moderately to severely active UC receiving tofacitinib in a Phase 2 study.<sup>1</sup>

**Aims & Methods:** In these post-hoc analyses, we aimed to determine if FCP levels, C-reactive protein (CRP) levels or partial Mayo score (PMS) can be early predictors of clinical or endoscopic outcomes in a Phase 2, randomised, double-blind, placebo-controlled, parallel group, multicentre study (NCT00787202).<sup>2</sup> FCP levels and PMS at baseline, Week 2 and Week 4, and CRP levels at baseline and Week 4, were analysed based on whether patients with moderately to severely active UC treated with tofacitinib 10 mg twice daily (BID) had clinical response, clinical remission, mucosal healing or endoscopic remission at Week 8. Univariate logistic regression analyses were performed to evaluate if FCP levels (log transformed), CRP levels (log transformed) or PMS were associated with clinical and endoscopic outcomes.

**Results:** In patients treated with tofacitinib 10 mg BID (N=28), numerically greater decreases from baseline were observed in FCP levels and PMS at Weeks 2 and 4 in patients who achieved clinical response, clinical remission, mucosal healing and endoscopic remission at Week 8 vs those who did not achieve these clinical or endoscopic outcomes. FCP levels at Week 2 were decreased by >50% from baseline in patients who achieved endoscopic remission. Furthermore, numerically greater decreases from baseline were observed in CRP levels at Week 4 in patients who achieved clinical response and mucosal healing at Week 8 vs those who did not achieve these clinical or endoscopic outcomes (Table).

[Table. FCP levels, CRP levels and PMS in patients treated with tofacitinib 10 mg BID, by Week 8 efficacy endpoints<sup>a</sup>]

In patients treated with tofacitinib 10 mg BID, logistic regression results showed that PMS at Week 2 (odds ratio [OR] [95% confidence interval (CI)] 0.496 [0.288, 0.856]; p=0.0117) and Week 4 (OR [95% CI] 0.463 [0.251, 0.853]; p=0.0135), and CRP levels at Week 4 (OR [95% CI] 0.582 [0.342,

0.990]; p=0.0460), were significantly associated with clinical remission at Week 8. In addition, PMS at Week 4 (OR [95% CI] 0.572 [0.345, 0.948]; p=0.0302) was significantly associated with clinical response at Week 8. **Conclusion:** These post-hoc analyses of a Phase 2 study showed that decreases as early as Week 2 in FCP levels and PMS, and as early as Week 4 in CRP levels, may be predictors of improved clinical and endoscopic outcomes in patients with moderately to severely active UC treated with tofacitinib 10 mg BID, although definitive conclusions cannot be drawn due to low patient numbers.

Contact E-Mail Address: peter.irving@gstt.nhs.uk

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Monitoring of liver enzymes, lipids, absolute neutrophil count (ANC), absolute lymphocyte count (ALC) and haemoglobin (Hb) is recommended in patients (pts) with UC treated with tofacitinib.<sup>1</sup>

**Aims & Methods:** We investigated the changes in laboratory parameters in pts with moderately to severely active UC treated with tofacitinib in OCTAVE Open, an ongoing Phase 3, open-label, long-term extension (OLE) study (NCT01470612; data as of Sep 2018, database not locked). Pts who had completed or demonstrated treatment failure in the OCTAVE Sustain maintenance study, or those who were non-responders after completing OCTAVE Induction 1 or 2, were eligible for inclusion in the OLE study. Pts who were in remission at the end of OCTAVE Sustain were assigned to tofacitinib 5 mg BID; all other pts were assigned to tofacitinib 10 mg BID in the OLE study. Changes from baseline values in the OLE study for liver enzymes, lipids, ANC, ALC and Hb at Month 36 were evaluated (observed data). The proportions of pts with laboratory values meeting protocol criteria for discontinuation (two sequential: aspartate aminotransferase [AST] or alanine aminotransferase [ALT] elevations ≥3× upper limit of normal [ULN] with ≥1 total bilirubin value ≥2× ULN or signs or symptoms consistent with hepatic injury; AST or ALT elevations ≥5× ULN; ANC < 750/mm<sup>3</sup>; ALC < 500/mm<sup>3</sup>; or Hb < 8.0 g/dL or >30% decrease from baseline) were assessed. The proportions of pts with investigator-defined hyperlipidaemia treatment-emergent adverse events (TEAEs), and with a change in lipid-lowering agent (LLA), were also reported.

**Results:** Changes from OLE study baseline in liver enzymes, lipids, ANC, ALC and Hb at Month 36 in pts treated with tofacitinib 5 and 10 mg twice daily (BID) are presented in the Table. With regard to meeting protocol criteria for discontinuation, 2.9% and 1.0% of pts treated with tofacitinib 5 and 10 mg BID, respectively, met the criteria for liver enzyme elevations; 0.6% and 1.4% of pts treated with tofacitinib 5 and 10 mg BID, respectively, met the criteria for ALC; 0 and 0.1% of pts treated with tofacitinib 5 and 10 mg BID, respectively, met the criteria for ANC; and 0 and 1.4% of pts treated with tofacitinib 5 and 10 mg BID, respectively, met the criteria for Hb. Hyperlipidaemia TEAEs were experienced by 1.7% of pts treated with tofacitinib 5 mg BID and 1.2% of pts treated with tofacitinib 10 mg BID. Furthermore, 8.0% and 6.6% of pts treated with tofacitinib 5 and

10 mg BID, respectively, had a new LLA added, and 2.3% and 1.7% of pts treated with tofacitinib 5 and 10 mg BID, respectively, had their LLA dose increased.

**Conclusion:** No major changes from OLE study baseline were observed in the laboratory parameters recommended for monitoring in pts treated with tofacitinib up to Month 36. In addition, the proportions of pts meeting protocol criteria for discontinuation for liver enzymes, ANC, ALC or Hg, with hyperlipidaemia TEAEs or with a change in LLA, were evaluated and were low in both tofacitinib treatment groups. Due to the dose assignment in the OLE study, the pt populations in the treatment arms differ in terms of their baseline remission status.

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). The effect of tofacitinib treatment on Inflammatory Bowel Disease Questionnaire (IBDQ) domains has been reported in patients with UC in OCTAVE Induction 1 & 2 and OCTAVE Sustain, with significant improvements observed in all domains vs placebo.<sup>1</sup> However, the effect of tofacitinib on the individual items within each IBDQ domain has not been analysed previously.

**Aims & Methods:** We examined the effect of induction treatment with tofacitinib 10 mg twice daily (BID) on individual IBDQ items in adults with moderate to severe UC. Data were pooled from OCTAVE Induction 1 & 2

(NCT01465763 & NCT01458951), which were identical, randomised, 8-week, double-blind, Phase 3 studies.<sup>2</sup> The IBDQ was self-administered by patients at baseline, Week 4 and Week 8, and has four domains, with individual items within each domain. The IBDQ domains are bowel symptoms (10 items), systemic symptoms (5 items), emotional function (12 items) and social function (5 items), with higher scores indicating better health-related quality of life (HRQoL).<sup>1,3</sup> Change from baseline in IBDQ items was analysed for tofacitinib 10 mg BID vs placebo using a linear mixed-effects model, with treatment, study, prior tumour necrosis factor inhibitor treatment, corticosteroid use at baseline, geographical region, week, treatment by week interaction, and baseline score as fixed effects, and patients as a random effect. No multiplicity adjustment was performed for this ad-hoc analysis.

**Results:** Significant improvements ( $p < 0.05$ ) were observed in all IBDQ items with tofacitinib 10 mg BID vs placebo at Weeks 4 and 8. The largest treatment differences within each domain were reported as follows: 'bowel movements been loose' at Weeks 4 and 8, and 'problem with rectal bleeding' at Week 8 (all 1.1), for the bowel symptoms domain; 'getting a good night's sleep' at Week 4 (0.8) and Week 8 (0.9), for the systemic symptoms domain; 'fear of not finding a washroom' at Week 4 (0.6) and Week 8 (0.8), and 'felt embarrassed' and 'felt angry' at Week 4 (both 0.6), for the emotional function domain; and 'avoid attending events' at Week 4 (0.8) and Week 8 (1.0), and 'difficulty doing leisure/sports' at Week 8 (1.0), for the social function domain (Table).

**Conclusion:** Tofacitinib treatment resulted in improvements vs placebo in all bowel-related symptoms, systemic symptoms, emotional functioning and social functioning IBDQ items, highlighting the broad impact of tofacitinib on all aspects of HRQoL. The greatest numerical improvements across all items were reported for 'bowel movements been loose' and 'problem with rectal bleeding'. This analysis provides an informative and useful perspective on which components of the IBDQ domains are the most improved following tofacitinib induction therapy, which may help to facilitate patient-physician dialogue.

IBDQ item, LSM (SE)	Week 4		Week 8	
	Placebo (N=231)	Tofacitinib 10 mg BID (N=881)	Placebo (N=218)	Tofacitinib 10 mg BID (N=849)

## P0392 CLINICAL COURSE AND DIETARY PATTERNS AMONG PATIENTS INCORPORATING THE AUTOIMMUNE PROTOCOL FOR MANAGEMENT OF INFLAMMATORY BOWEL DISEASE

Lee J.<sup>1</sup>, Pedretti C.<sup>2</sup>, Konijeti G.<sup>3</sup>

<sup>1</sup>Scripps Clinic, Department of Medicine, La Jolla, United States, <sup>2</sup>Pacific College of Oriental Medicine, San Diego, United States, <sup>3</sup>Scripps Clinic, Division of Gastroenterology & Hepatology, La Jolla, United States

**Contact E-Mail Address:** lee.joy@scrippshealth.org

**Introduction:** Elimination diets, including the autoimmune protocol (AIP), may improve symptoms among patients with inflammatory bowel disease (IBD), but limited data exist on diet efficacy and utilization.

**Aims & Methods:** The aim of our study was to examine clinical course and dietary patterns of patients with IBD utilizing AIP. We conducted an anonymous online survey sent through electronic newsletters and support groups utilizing AIP. The survey assessed demographics, IBD disease activity and medication use, including use of steroids and immunosuppression (biologics and/or immunomodulators). Participants were asked about AIP utilization and food group reintroductions. Symptom measures of abdominal pain, stool frequency, and rectal bleeding were compared at baseline (BL, prior to starting AIP), week 6 (after starting AIP), and present, separately for Crohn's disease (CD) and ulcerative colitis (UC).

**Results:** There were 78 respondents who attempted AIP for management of IBD. Mean age was 39.4 years (SD 11.4), with mean IBD duration 13.2 yrs (SD 11.4), 78% prior steroid exposure, and 35% currently on immunosuppression. Seventy-three percent perceived achieving clinical remission due to AIP, but this was more common among patients not on immunosuppression (76% vs. 24% on immunosuppression,  $p < 0.001$ ). After starting AIP, 32% reported being able to discontinue steroids. AIP was initiated according to protocol by 73%, while 27% modified it.

Compared to BL, 6 weeks after starting AIP more patients with CD reported no abdominal pain (47% vs BL 17%,  $P = 0.01$ ), normal stool frequency (53% vs BL 30%,  $P < 0.01$ ), and no rectal bleeding (90% vs 43%,  $P = 0.057$ ). Similarly, more patients with UC reported no abdominal pain (60% vs BL 14%,  $P < 0.01$ ), normal stool frequency (47% vs BL 14%,  $P < 0.01$ ), and no rectal bleeding (63% vs 30%,  $P < 0.01$ ) 6 weeks after starting AIP, compared to BL.

Food group reintroductions were started within 0-4 weeks of starting AIP among 8%, while 23% reintroduced within 5-8 weeks, 24% within 2-6 months, 23% within 6-12 months, and 13% after 12 months. Although success of food group reintroductions varied, this did not appear to affect symptom improvement, with majority of patients with IBD reporting no abdominal pain (80%), no rectal bleeding (72%), and normal stool frequency (64%) at present.

**Conclusion:** In this retrospective study, patients utilizing AIP for management of IBD report clinical benefit, with reduction of steroid use and improvement in IBD symptoms, including with food group reintroduction.

**Disclosure:** Dr. Konijeti has previously received honoraria from Takeda, Abbvie, Janssen, and Pfizer.

## P0393 TOFACITINIB FOR THE TREATMENT OF ULCERATIVE COLITIS: AN UPDATE ON THE ANALYSIS OF MALIGNANCY RATES FROM THE UC CLINICAL PROGRAMME

Lichtenstein G.R.<sup>1</sup>, Ciorba M.A.<sup>2</sup>, Rogler G.<sup>3</sup>, Quirk D.<sup>4</sup>, Thorpe A.J.<sup>4</sup>, Pedersen R.D.<sup>4</sup>, Lawendy N.<sup>4</sup>, Chan G.<sup>4</sup>, Panés J.<sup>5</sup>

<sup>1</sup>Perelman School of Medicine at the University of Pennsylvania, Division of Gastroenterology, Philadelphia, United States, <sup>2</sup>Washington University in Saint Louis, Division of Gastroenterology, Saint Louis, United States, <sup>3</sup>University of Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland, <sup>4</sup>Pfizer Inc, Collegeville, PA, United States, <sup>5</sup>Hospital Clínic de Barcelona, IDIBAPS, CIBERehd, Barcelona, Spain

**Contact E-Mail Address:** jpanes@clinic.ub.es

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). The safety of tofacitinib for the treatment of moderate to severe UC was evaluated in a randomised, placebo-controlled induction Phase (P) 2 study (NCT00787202),<sup>1</sup> 2 induction P3 studies (NCT01465763; NCT01458951), 1 maintenance P3 study (NCT01458574),<sup>2</sup> and an ongoing, open-label, long-term extension (OLE) study (NCT01470612).<sup>3</sup> Here, we present an update on the integrated analysis of adjudicated malignancies observed in the UC clinical development programme, as of Sep 2018.

**Aims & Methods:** Patients (pts) who received placebo, tofacitinib 5 or 10 mg twice daily (BID) were analysed as 3 cohorts: Induction (P2/P3 induction studies, N=1220), Maintenance (P3 maintenance study, N=592) and Overall (pts receiving tofacitinib 5 or 10 mg BID in P2, P3 or ongoing OLE studies, N=1157). Proportions and incidence rates (IRs; unique pts with events per 100 pt-years [PY] of exposure) were evaluated for malignancies (excluding non-melanoma skin cancer [NMSC]) and NMSC. For Overall Cohort analysis, pts were categorised based on the average daily dose of tofacitinib: predominant dose (PD) tofacitinib 5 mg BID (average total daily dose < 15 mg) and PD tofacitinib 10 mg BID (average total daily dose ≥ 15 mg). For P3 studies, an independent adjudication committee reviewed all potential malignancies. Overall Cohort data are as of Sep 2018.

	Induction Cohort <sup>a</sup>		Maintenance Cohort <sup>a</sup>			Overall Cohort
	Placebo (N=282; 44.8 PY)	Tofacitinib 10 mg BID (N=938; 156.2 PY)	Placebo (N=198; 100.4 PY)	Tofacitinib 5 mg BID (N=198; 146.2 PY)	Tofacitinib 10 mg BID (N=196; 154.3 PY)	Tofacitinib All (N=1157; 2403.6 PY)
Age (years), mean (SD)	41.4 (14.4)	41.3 (13.8)	43.4 (14.0)	41.9 (13.7)	43.0 (14.4)	41.3 (13.9)
Prior TNFi failure, n (%)	124 (53.0) <sup>b</sup>	465 (51.4) <sup>c</sup>	89 (44.9)	83 (41.9)	92 (46.9)	583 (51.9) <sup>d</sup>
Prior immunosuppressant failure, n (%)	158 (67.5) <sup>b</sup>	661 (73.0) <sup>c</sup>	129 (65.2)	143 (72.2)	141 (71.9)	813 (72.3) <sup>d</sup>
Prior immunosuppressant treatment, n (%)	160 (68.4) <sup>b</sup>	683 (75.5) <sup>b</sup>	134 (67.7)	149 (75.3)	144 (73.5)	838 (74.6) <sup>d</sup>
Disease duration (years), mean (SD)	8.2 (6.8)	8.2 (7.0)	8.8 (7.5)	8.3 (7.2)	8.7 (7.0)	8.2 (7.0)
Malignancies (excluding NMSC), n (%), IR [95% CI] <sup>e,f,g</sup>	0 (0.0)	0 (0.0)	1 (0.5), 0.97 [0.02, 5.39]	0 (0.0), 0.00 [0.00, 2.48]	0 (0.0), 0.00 [0.00, 2.35]	17 (1.5), 0.69 [0.40, 1.11]
NMSC, n (%), IR [95% CI] <sup>e,f</sup>	0 (0.0)	2 (0.2)	1 (0.5), 0.97 [0.02, 5.40]	0 (0.0), 0.00 [0.00, 2.48]	3 (1.5), 1.91 [0.39, 5.59]	19 (1.7), 0.78 [0.47, 1.22]

Data are as of Sep 2018 for the Overall Cohort (OLE study database not locked)

<sup>a</sup>As per the SCS analysis convention, only events occurring within 28 days after the last dose are included in this Table for calculation of proportion and IR; <sup>b</sup>N=234; <sup>c</sup>N=905; <sup>d</sup>N=1124;

<sup>e</sup>Data for the Induction Cohort are shown as n (%), due to the short duration (8 weeks) of the induction studies; <sup>f</sup>Adjudicated data do not include data from the P2 Study (A3921063; NCT00787202); <sup>g</sup>One case of breast cancer in the Maintenance Cohort (placebo arm); in the

Overall Cohort, 17 malignancy events (excluding NMSC), including two cases of cervical cancer, breast cancer and adenocarcinoma of the colon, and one case each of hepatic angiosarcoma, cholangiocarcinoma, leiomyosarcoma, diffuse large B-cell lymphoma, Epstein-Barr virus-associated lymphoma, malignant melanoma, renal cell carcinoma, lung cancer, invasive ductal breast carcinoma, essential thrombocythemia, acute myeloid leukaemia, plus secondary malignancies in the liver and peritoneum; <sup>h</sup>Of the 19 Overall Cohort pts with NMSC, most (17/19) had prior immunosuppressant failure, most (15/19) had prior treatment failure with TNFi, and seven had prior NMSC

BID, twice daily; CI, confidence interval; IR, incidence rate (patients with events per 100 patient-years of exposure); N, number of patients in the treatment group; n, number of patients in a specified category; NMSC, non-melanoma skin cancer; OLE, open-label, long-term extension; P, Phase; pts, patients; PY, patient-years; SCS, summary of clinical safety; SD, standard deviation; TNFi, tumour necrosis factor inhibitors

[Table. Demographics and summary of incidence of malignancies (all causality) among pts in the Induction, Maintenance and Overall Cohorts]

**Results:** The Overall Cohort comprised 1157 pts with 2404 PY of tofacitinib exposure and up to 6.1 years of treatment (median 623 days) who received  $\geq 1$  dose of tofacitinib 5 or 10 mg BID (Table). There were no pts with malignancy events (excluding NMSC) in the Induction Cohort, 1 pt with a malignancy event (excluding NMSC; placebo, breast cancer) in the Maintenance Cohort, and 17 pts with malignancy events (excluding NMSC) in the Overall Cohort (IR 0.69; 95% confidence interval [CI] 0.40, 1.11). There was no clustering of malignancy events (excluding NMSC) in the Overall Cohort (Table). Of the 17 pts with malignancy events (excluding NMSC), 3 had received a PD of tofacitinib 5 mg BID (IR 0.49; 95% CI 0.10, 1.45) and 14 a PD of tofacitinib 10 mg BID (IR 0.75; 95% CI 0.41, 1.27).

NMSC was reported in 2 (0.2%) tofacitinib-treated Induction Cohort pts, 4 Maintenance Cohort pts (3 tofacitinib 10 mg BID; IR 1.91; 95% CI 0.39, 5.59; and 1 placebo-treated pt; IR 0.97; 95% CI 0.02, 5.40) and 19 Overall Cohort pts (IR 0.78; 95% CI 0.47, 1.22; 4 had received a PD of tofacitinib 5 mg BID and 15 a PD of tofacitinib 10 mg BID).

**Conclusion:** In the UC clinical programme, malignancies (including NMSC) were observed with tofacitinib treatment. There was no clustering of types of malignancy (excluding NMSC). The IR of malignancies (excluding NMSC) reported here is similar to that previously reported (IR 0.7; 95% CI 0.3, 1.2),<sup>4</sup> suggesting no treatment duration impact on the IR of malignancies (excluding NMSC). The IRs for malignancies (NMSC, and excluding NMSC) were similar to those reported for tofacitinib in pts with rheumatoid arthritis<sup>5</sup> and in pts with UC treated with biologics.<sup>6,7</sup>

**Contact E-Mail Address:** markus.neurath@uk-erlangen.de

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). The efficacy and safety of tofacitinib was shown in 3 Phase 3, randomised, placebo-controlled trials in patients (pts) with moderately to severely active UC.<sup>1</sup> Pts who received tofacitinib 10 mg twice daily (BID) for 8 weeks in OCTAVE Induction 1 & 2 (NCT01465763 & NCT01458951) and did not achieve clinical response could enter an ongoing, Phase 3, multicentre, open-label, long-term extension (OLE) study (NCT01470612)<sup>2</sup> and receive tofacitinib 10 mg BID. Long-term maintenance data for up to 3 years of treatment in the OLE study for those who achieved clinical response with an additional 8 weeks of tofacitinib treatment (ie delayed responders) have been previously reported.<sup>3</sup>

**Aims & Methods:** We evaluated potential predictors of delayed response, ie a clinical response ( $\geq 3$ -point and  $\geq 30\%$  decrease from induction study baseline total Mayo score, plus  $\geq 1$ -point decrease in rectal bleeding subscore [RBS] or absolute RBS  $\leq 1$ ) after 16 weeks of tofacitinib 10 mg BID (8 weeks induction plus an additional 8 weeks in the OLE study). Potential predictors evaluated included characteristics at baseline of OCTAVE Induction 1 & 2 and the OLE study, and at Month 1 of the OLE study. Pts were analysed as 3 subgroups: induction responders (pts who demonstrated clinical response after 8 weeks of tofacitinib 10 mg BID); delayed responders; and complete non-responders (pts who did not respond to 16 weeks of treatment with tofacitinib 10 mg BID).

	Induction responders <sup>a</sup> (N=521)	Delayed responders <sup>b</sup> (N=148)	Complete non-responders <sup>c</sup> (N=106)
Prior TNFI failure at OCTAVE Induction baseline, n (%)	237 (45.5)	85 (57.4)	66 (62.3)
Total Mayo score			
- OCTAVE Induction baseline, mean (SD)	8.8 (1.4)	9.1 (1.4)	9.2 (1.3)
- Mean change from OCTAVE Induction baseline to OCTAVE Induction Week 8 (SD)	-5.6 (1.7)	-1.0 (1.2)	-0.4 (1.1)
PMS			
- OLE study Month 1, mean (SD)	N/A	2.9 (1.7) <sup>d</sup>	5.2 (1.7) <sup>e</sup>
- Mean change in PMS from OLE baseline to OLE Month 1 (SD)	N/A	-2.4 (1.7) <sup>d</sup>	-0.9 (1.6) <sup>e</sup>
Mayo endoscopic subscore			
- OCTAVE Induction baseline, mean (SD)	2.6 (0.5)	2.6 (0.5)	2.7 (0.5)
- Mean change from OCTAVE Induction baseline to OCTAVE Induction Week 8 (SD)	-1.0 (0.9)	0.1 (0.5)	0.1 (0.5)
Mayo stool frequency subscore			
- OLE study baseline, mean (SD)	N/A	2.2 (0.8)	2.5 (0.7)
- OLE study Month 1, mean (SD) [mean change from OCTAVE Induction baseline (SD)]	N/A	1.4 (0.9) [-1.2 (0.9)] <sup>f</sup>	2.4 (0.8) [-0.3 (0.7)] <sup>e</sup>
Mayo rectal bleeding subscore			
- OLE study baseline, mean (SD)	N/A	1.1 (0.8)	1.2 (0.7)
- OLE study Month 1, mean (SD) [mean change from OCTAVE Induction baseline (SD)]	N/A	0.5 (0.7) [-1.1 (0.7)] <sup>f</sup>	1.1 (0.7) [-0.4 (0.8)] <sup>e</sup>
C-reactive protein (mg/L)			
- OCTAVE Induction baseline, mean (SD)	10.0 (16.6) <sup>g</sup>	10.8 (16.2) <sup>i</sup>	14.6 (26.9)
- Mean change from OCTAVE Induction baseline to OCTAVE Induction Week 8 (SD)	-7.3 (16.4) <sup>h</sup>	-2.2 (18.8) <sup>j</sup>	-3.4 (29.4) <sup>j</sup>
- OLE study baseline, mean (SD)	N/A	8.3 (15.4)	11.2 (18.4)

OCTAVE Induction data are pooled data from OCTAVE Induction 1 and 2.

<sup>a</sup>Pts who demonstrated a clinical response following 8 weeks of tofacitinib 10 mg BID in OCTAVE Induction; <sup>b</sup>Pts who demonstrated a clinical response following 16 weeks of tofacitinib 10 mg BID;

<sup>c</sup>Pts who did not demonstrate a clinical response following 16 weeks of tofacitinib 10 mg BID; <sup>d</sup>N=143;

<sup>e</sup>N=104; <sup>f</sup>N=144; <sup>g</sup>N=511; <sup>h</sup>N=510; <sup>i</sup>N=146; <sup>j</sup>N=105

BID, twice daily; FAS, full analysis set; N, number of patients in the analysis population; n, number of patients in the category; N/A, not applicable; OLE, open-label, long-term extension; PMS, partial Mayo score; pts, patients; SD, standard deviation; TNFI, tumour necrosis factor inhibitor

[Table. Characteristics of induction responders, delayed responders and complete non-responders (FAS, observed case)]

**Results:** Characteristics at baseline of OCTAVE Induction 1 & 2 were generally similar between the 3 subgroups (Table). The proportion of pts with prior tumour necrosis factor inhibitor (TNFi) failure was numerically higher among complete non-responders than that among delayed responders (Table). Induction baseline mean C-reactive protein (CRP) was numerically higher in complete non-responders compared with induction responders and delayed responders (Table). A similar trend was observed at baseline of the OLE study; mean CRP value was numerically lower for delayed responders than complete non-responders (Table). At Month 1 of the OLE study, stool frequency subscore (SFS) and RBS were numerically lower in delayed responders compared with complete non-responders, and the reduction in partial Mayo score (PMS) from baseline of the OLE study was greater for delayed responders than complete non-responders (Table).

**Conclusion:** Numerically higher proportions of complete non-responders and delayed responders had prior TNFi failure vs induction responders. In pts with UC, changes in SFS, RBS and PMS during extended induction treatment with tofacitinib may be indicative of the likelihood of clinical response. Extended treatment with tofacitinib 10 mg BID beyond the initial 8-week induction period may be associated with clinical response in a subset of pts with UC who do not respond initially. This ad hoc analysis is limited by the small sample size and further evaluation is needed to confirm the findings.

**Introduction:** Approximately one half of the patients with Crohn's disease may develop intestinal strictures during their lifetime. The effectiveness of the currently approved drugs in these stricturing complications remains barely known. Our aim was to determine the effectiveness of anti-TNF therapy for symptomatic stenosis in Crohn's disease patients.

**Aims & Methods:** We included adult patients with symptomatic stricturing Crohn's disease receiving their first-line anti-TNF therapy. Strictures were defined as constant luminal narrowing with pre-stenotic dilatation. We excluded those patients with previous anti-TNF exposure, surgery or endoscopic therapy of the stenosis. The effectiveness of the anti-TNF agent

was defined as a composite outcome combining the persistence of the treatment and without dose or frequency intensification, with no new immunomodulators, surgery or endoscopic therapy during follow-up.

**Results:** A total of 262 patients from 32 IBD Units in Spain were included. The main characteristics of the cohort are summarized in Table 1. The median number of stenosis per patient was 1 (range 1-9). One hundred-forty one patients (54%) received infliximab and 121 (46%) adalimumab. The treatment was considered to be effective in 81% and 60% of patients after 6 and 12 months, respectively, while this outcome was fulfilled by 21% after a median follow-up of 40 months (IQR, 19-85). There were no radiological findings at baseline associated with the effectiveness or the rate of surgery. During follow-up, anti-TNF therapy required a dose or frequency adjustment in 39% of patients, 12% required a new immunomodulator or endoscopic therapy in 4%. The proportion of subjects requiring surgery was 15% after 1 year, and 21% after 2 years, with an overall rate of surgery of 32%. In the multivariate analysis, infliximab was associated with a higher rate of surgery as compared to adalimumab (OR 1.78; 95% CI, 1,025-3,09). The anti-TNF agent was discontinued in 131 patients (50%) after a median of 16 months (IQR, 7.5-37), mainly due to an absence or loss of response (56%). A total of 88 subjects (34%) required a switch to a new biologic drug (72% to a second anti-TNF, 24% to ustekinumab and to 5% to vedolizumab).

**Conclusion:** Anti-TNF agents are effective in approximately 20% of patients with Crohn's disease complicated with symptomatic strictures, avoiding surgery in a relatively high proportion of cases.

Characteristic	Infliximab N = 141	Adalimumab N = 121	All N = 262	p value
Age at diagnosis, years Median (IQR)	33 (25-47)	33 (23-46)	33 (25-46)	0.92

**Introduction:** Clinical trials have demonstrated that golimumab is effective in anti-TNF naïve patients with ulcerative colitis.

**Aims & Methods:** The aim of this prospective, multicentre cohort study was to assess the clinical effectiveness of golimumab in a real world setting. All patients with moderate-to-severe ulcerative colitis, defined as Mayo endoscopic subscore ≥2 who initiated golimumab between June 2014 and

June 2017 at 16 Swedish hospitals were eligible for inclusion after written consent. Clinical characteristics, treatment, clinical, biochemical, endoscopic activity and quality of life measures were recorded at baseline and prospectively, using an electronic Case Report Form, integrated with the Swedish National Quality Registry for IBD (SWIBREG). Primary objective was clinical effectiveness at 12 weeks and 52 weeks, i.e. clinical response (defined as a decrease in Mayo score by ≥3 points or 30% from baseline) and remission (defined as a score of ≤2 with no individual subscores >1.) Continuous data are presented as median (interquartile range). Differences between baseline and follow-up were assessed by Wilcoxon-signed rank test.

**Results:** 50 patients were included during the three-year study period. At study entry, 24/50 (48%) were on concomitant treatment with immunomodulators, 16/50 (32%) on oral corticosteroids and 27/50 (54%) on 5-ASA (table 1). In total, 35/50 (70%) had previously been exposed to at least one TNF-antagonist. The 12 and 52-week drug continuation rates were 37/50 (74%) and 23/50 (46%), respectively. The 12-week clinical response rate was 14/50 (28%), the remission rate, 8/50 (16%) and the corresponding figures at week 52 were 13/50 (26%) and 10/50 (20%). Among patients who continued golimumab, the median Mayo score decreased from 7 (6-9) at baseline to 1 (0-5) at 52 weeks (p< 0.01) and the median faecal calprotectin decreased from 862 (335-1759) µg/g to 90 (34-169) µg/g (p< 0.01). Consistently, quality of life improved in golimumab treated patients, with a significant reduction of the overall short health scale (SHS) score (p< 0.01).

Median age yr. (IQR)	41 (28-53)
Sex female no. (%)	25 (50)
Median disease duration yr. (IQR)	5 (2-11)
Extent no. (%)	
Proctitis (E1)	5 (10)
Left-sided colitis (E2)	19 (38)
Extensive colitis (E3)	26 (52)
Previous medications no. (%)	
Immunomodulators	46 (92)
Anti-TNF therapy	35 (70)

[Table 1. Baseline clinical and demographical characteristics of patients with ulcerative colitis]

**Conclusion:** In this prospective cohort study, golimumab-treated patients, in Swedish clinical practice, represented a treatment refractory patient-group, in which 70% previously were exposed to anti-TNF. Despite this, our results confirm that golimumab is an effective therapy in UC.

The study was financially supported by MSD.

## P0397 LUPUS-LIKE REACTIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH ANTI-TNFs ARE RARE BUT INSIDIOUS ADVERSE EVENTS: DATA FROM A LARGE SINGLE-CENTER COHORT

Macaluso F.S., Sapienza C., Ventimiglia M., Cottone M., Orlando A.  
'Villa Sofia-Cervello' Hospital, IBD Unit, Palermo (Pa), Italy

**Contact E-Mail Address:** fsmacaluso@gmail.com

**Introduction:** The occurrence of lupus-like reactions (LLRs) may complicate the management of patients with inflammatory bowel disease (IBD) treated with anti-TNFs. However, very few data on the incidence, predictors, and clinical outcomes of LLRs have been reported.

**Aims & Methods:** We aimed to describe all these features in a large cohort of IBD patients treated with anti-TNF drugs. All records of consecutive patients who started a treatment with an anti-TNF from January 2006 to June 2018 were retrospectively reviewed. Patients were defined as having LLR by the presence of immunologic abnormalities (positivity for ANA and/or anti-ds-DNA), along with clinical features that included at least two of the following: arthralgia, fatigue, fever, cutaneous manifestations, or serositis, which had a clear temporal association with exposure to the anti-TNFs, and resolved without recurrence once the drug was discontinued. Univariable and multiple Cox proportional hazard models were used to estimate the association between all variables at baseline and occurrence of LLRs.

**Results:** 760 patients (1059 total treatments with anti-TNFs) were included. Participants contributed a total of 2863.5 person-years of follow-up, during which 16 cases of LLRs (2.1% of patients) were reported, with an incidence rate of 5.6 per 1000 person-years. Female gender and being former smokers were more prevalent in the LLR group (75.0% versus 44.1%,  $p=0.02$ ; and 18.8% versus 5.4%,  $p=0.037$ , respectively), with a hazard ratio of 3.86 (95% CI: 1.21-12.38;  $p=0.023$ ) and 4.42 (95% CI: 1.20-16.24;  $p=0.025$ ), respectively, at Cox regression analysis adjusted for possible confounders. LLRs occurred after a mean of  $12.0 \pm 9.7$  months of therapy with anti-TNFs. Antinuclear antibodies were universally positive, and 10 out of 16 (62.5%) patients had also anti-ds-DNA. Arthropathy was the most frequent symptom (87.5%), followed by fatigue (81.2%), and fever (31.2%). Three cases presented with a concomitant autoimmune hepatitis-like syndrome. The diagnosis of LLR was further confirmed by a re-challenge with the culprit agent in half of the cases. All LLRs resolved following discontinuation of the drug after a mean of  $8.1 \pm 4.2$  weeks, even if 10 patients required corticosteroids for the control of symptoms. Five patients (31.2%) were switched to a second anti-TNFs, and one of them developed a second LLR.

**Conclusion:** In this very large cohort of patients treated with anti-TNFs, LLRs were rare adverse events, more common in women and former smokers. Clinical features are non-specific and insidious. All LLRs resolved following discontinuation of the drug, but the use of corticosteroids was required in most of the cases.

## P0398 EFFECTIVENESS AND SAFETY OF USTEKINUMAB FOR THE TREATMENT OF CROHN'S DISEASE IN REAL-LIFE STUDIES: A META-ANALYSIS

Macaluso F.S.<sup>1</sup>, Maida M.<sup>2</sup>, Ventimiglia M.<sup>1</sup>, Cottone M.<sup>1</sup>, Orlando A.<sup>1</sup>  
<sup>1</sup>'Villa Sofia-Cervello' Hospital, IBD Unit, Palermo, Italy, <sup>2</sup>'S.Elia-Raimondi' Hospital, Gastroenterology Unit, Caltanissetta, Italy

**Contact E-Mail Address:** fsmacaluso@gmail.com

**Introduction:** The real-life value of ustekinumab in Crohn's disease is under evaluation.

**Aims & Methods:** The aim of this single-arm meta-analysis was to estimate the effectiveness and safety of ustekinumab in real-life observational studies. PubMed Central/Medline and Embase, as well as reference lists of articles, were systematically searched through December 2018. Only real-life observational studies were included.

**Results:** Seven studies comprising 597 patients met the inclusion criteria. Almost all patients had been previously exposed to anti-TNFs. Ustekinumab was administered subcutaneously at induction in all studies except one. The pooled estimates rates of clinical response and remission at in-

duction were 72% (95% CI: 53-86%; range: 39-100%;  $I^2=92\%$ ) and 42% (95% CI: 20-68%; range: 15-84%;  $I^2=92\%$ ), respectively. At maintenance, the pooled estimates rates of clinical response, clinical remission, endoscopic response, and endoscopic remission were 69% (95% CI: 56-79%; range: 48-89%;  $I^2=86\%$ ), 47% (95% CI: 25-70%; range: 28-73%;  $I^2=93\%$ ), 60% (95% CI: 53-67%; range: 55-77%;  $I^2=0\%$ ), and 24% (95% CI: 19-31%; range: 15-31%;  $I^2=0\%$ ), respectively. The pooled estimate of incidence rates of total adverse events and infections were 15.3 (95% CI: 8.7-26.8; range: 7.2-34;  $I^2=89\%$ ) and 3.7 (95% CI: 2.0-6.9; range: 2.2-9.0;  $I^2=60\%$ ) per 100 persons-years, respectively.

**Conclusion:** Cumulative analysis of data from real-life studies confirmed that ustekinumab holds the potential to deserve a relevant role in the management of patients with Crohn's disease with a reassuring safety profile. Furthermore, its clinical effectiveness at induction seems to be higher in real-life observational studies compared with randomized controlled trials.

**Disclosure:** FSM served as advisory board member or received lecture grants from for AbbVie, Biogen, MSD, Takeda Pharmaceuticals. AO served as advisory board member for AbbVie, MSD, Takeda Pharmaceuticals, and received lecture grants from AbbVie, MSD, Sofar, Chiesi, and Takeda Pharmaceuticals.

## P0399 LONG-TERM EFFECT OF RISANKIZUMAB ON IMPROVED AND SUSTAINED HEALTH-RELATED QUALITY OF LIFE OVER 3 YEARS IN PATIENTS WITH MODERATE TO SEVERE CROHN'S DISEASE: INTERIM ANALYSIS OF A PHASE 2 OPEN-LABEL EXTENSION STUDY

Louis E.<sup>1</sup>, Bossuyt P.<sup>2</sup>, Panés J.<sup>3</sup>, Feagan B.<sup>4</sup>, Kalabic J.<sup>5</sup>, Wallace K.<sup>6</sup>, Chen N.<sup>6</sup>, Lee W.-J.<sup>6</sup>, Ferrante M.<sup>7</sup>

KG, Ludwigshafen, Germany, <sup>6</sup>AbbVie Inc., North Chicago, United States, <sup>7</sup>University Hospitals, KU Leuven, Leuven, Belgium

**Contact E-Mail Address:** edouard.louis@uliege.be

**Introduction:** The clinical and endoscopic efficacy of risankizumab (RZB), an IL-23 inhibitor, in patients with moderate to severe Crohn's disease (CD) have been reported in the phase 2 trials of induction<sup>1</sup> and maintenance phases over 52 weeks.<sup>2</sup> Longer term outcomes were assessed from an ongoing open-label extension (OLE) study (NCT02513459).

**Aims & Methods:** This study aims to evaluate the long-term effects of RZB on health-related quality of life (HRQoL) measured by the Inflammatory Bowel Disease Questionnaire (IBDQ) for up to 3 years from the ongoing phase 2 OLE study. Patients who achieved clinical response (decrease from baseline [BL] in CD Activity Index [CAI]  $\geq 100$ ) without remission (CAI  $< 150$ ) after Period 2 (Week 26) or clinical response and/or remission after Period 3 (Week 52) of the preceding study<sup>1,2</sup> were enrolled to receive open-label RZB 180 mg subcutaneous (SC) injections every 8 weeks for up to 216 weeks. Patients who lost clinical response or remission after completion of the preceding study were re-induced with open-label RZB 600 mg intravenous (IV) infusions at Weeks 0, 4 and 8. Patients could only receive subsequent RZB 180 mg SC maintenance treatment if they achieved response and/or remission following re-induction treatment. Percentages of patients with IBDQ response per minimal clinical important difference (MCID: increase in IBDQ total score from the induction BL  $\geq 16$ ); IBDQ remission (IBDQ total score  $\geq 170$ ); and mean change from induction BL in IBDQ total, domain, and selected individual scores were calculated at Weeks 0, 24, 48, 72 and 96 with a data cut-off date of February 4, 2019. Results were reported as observed, and additional non-responder imputation was applied for remission/response data.

**Results:** A total of 65 adults with CD were enrolled, including 4 patients who were re-induced. At BL of the preceding study, median (range) age 34 (19-67) years and median disease duration 10 (2-38) years; 60 (92%) patients were previously exposed to tumour necrosis factor antagonists. Over 96 weeks of OLE therapy with RZB,  $>90\%$  achieved IBDQ response and  $>58\%$  of patients achieved IBDQ remission (Table, as observed). Mean change from induction BL to Week 0 of the OLE study was 62.5 points for IBDQ total score and this improvement was maintained over 96 weeks. This maintenance effect was also observed across all four IBDQ domains, with a mean change per individual item scores improved by approximately 2 points (Table). Individual items with the greatest improvement at Week

96 from Induction BL were abdominal pain (2.7 points), abdominal cramps (2.7 points), bowel movement frequency (2.4 points), number of loose bowel movements (2.5 points), feeling unwell (2.8 points), quality of sleep (2.3 points) and fatigue (1.9 points).

Outcome	Week 0	Week 24	Week 48	Week 72	Week 96
N (as observed)	64	65	60	52	51
IBDQ response (increase of IBDQ total score $\geq 16$ from the Induction Baseline), n/N (%)					
As observed	60/64 (93.8)	59/65 (90.8)	57/60 (95.0)	47/52 (90.4)	47/51 (92.2)
NRI	60/65 (92.3)	59/65 (90.8)	57/65 (87.7)	47/65 (72.3)	47/65 (72.3)
IBDQ remission (IBDQ total score $\geq 170$ ), n/N (%)					
As observed	40/64 (62.5)	38/65 (58.5)	42/60 (70.0)	36/52 (69.2)	37/51 (72.5)
NRI	40/65 (61.5)	38/65 (58.5)	42/65 (64.6)	36/65 (55.4)	37/65 (56.9)
Total IBDQ score, mean change $\pm$ SD (mean change per item)*	62.5 $\pm$ 38.8 (1.95)	58.7 $\pm$ 35.6 (1.83)	64.1 $\pm$ 33.1 (2.00)	63.8 $\pm$ 43.4 (1.99)	62.4 $\pm$ 39.2 (1.95)
IBDQ bowel symptom domain, mean change $\pm$ SD (mean change per item)*	20.4 $\pm$ 11.7 (2.04)	18.3 $\pm$ 11.6 (1.83)	20.5 $\pm$ 10.7 (2.05)	20.5 $\pm$ 12.8 (2.05)	19.1 $\pm$ 13.1 (1.91)
IBDQ systemic symptom domain, mean change $\pm$ SD (mean change per item)*	11.0 $\pm$ 8.2 (2.20)	10.6 $\pm$ 7.7 (2.12)	11.7 $\pm$ 7.5 (2.34)	11.3 $\pm$ 9.0 (2.26)	10.6 $\pm$ 8.6 (2.12)
IBDQ social function domain, mean change $\pm$ SD (mean change per item)*	9.9 $\pm$ 6.7 (1.98)	9.1 $\pm$ 6.4 (1.82)	9.6 $\pm$ 6.1 (1.92)	10.1 $\pm$ 7.5 (2.02)	10.3 $\pm$ 5.8 (2.06)
IBDQ emotional function domain, mean change $\pm$ SD (mean change per item)*	21.1 $\pm$ 16.8 (1.76)	20.8 $\pm$ 15.6 (1.73)	22.3 $\pm$ 15.0 (1.86)	21.9 $\pm$ 18.3 (1.83)	22.4 $\pm$ 17.1 (1.87)

\*Total number of items in IBDQ is 32: 10 items in bowel symptom domain, 5 items in systemic symptom domain, 5 items in social domain, and 12 items in emotional domain.

[Table. IBDQ response, IBDQ remission and mean change in IBDQ total and domain scores from induction BL]

**Conclusion:** In patients with moderate to severe CD responding to RZB, improvements in HRQoL as measured by IBDQ were maintained over 3 years with RZB treatment. Bowel symptoms as well as patients' sleep quality and fatigue were found to have the greatest improvement with RZB therapy.

**Introduction:** Randomized clinical trials have confirmed that biological therapy with ustekinumab (UST- amonoclonal antibody targeting interleukins 12 and 23) is an effective treatment to induce and maintenance of remission in Crohn's disease (CD). UST using intravenous (iv) induction in CD was approved in Spain in June 2017 and limited data on the efficacy and safety of this drug in clinical practice are available.

### Aims & Methods:

**Aim:** To assess the efficacy and safety of UST, using iv induction, in a real world clinical setting.

**Methods:** A retrospective multicenter cohort study was performed on IBD patients receiving iv induction dose of UST between June 2017 and June 2018 in five tertiary hospitals from Canary Islands (Spain). Efficacy was defined as clinical remission (HBI  $\leq 4$ ) at 8 weeks and 3, 6 and 12 months and steroid withdrawal at 3 and 12 months. We examined previous use of anti-TNF agents, need of surgery, rate of treatment discontinuation and adverse effects during UST treatment.

**Results:** A total of 47 CD patients (22M/25F; mean age 29  $\pm$  11 years; A2 85.1%, L3 59.6%/ B1 44.7%/ p 44.7%) were included. Mean time from diagnosis to use of UST was 224  $\pm$  323 months and 17.4% of patients were naive to anti-TNF and 43% had received 3 previous biological treatment. UST was indicated for induction of remission in 47.7% patients. Remission was achieved in 51.6% and 42% of patients at 8 weeks and 12 months, respectively. Steroid withdrawal was obtained in 80% of patients at 3 months of UST treatment. Escalation treatment by administering UST every 8 weeks was indicated in 80% of cases and 91% received combination treatment with immunosuppressants (80% azathioprine). Number of previous anti-TNF agents, use of steroids when starting UST and combination treatment with immunosuppressants did not reach statistical significance to associate with clinical response to UST. The mean time of use of UST was 6.7  $\pm$  3 months. Biological treatment discontinuation occurred in 30% of patients predominantly owing to lack or loss of response. Surgery was underwent in 5 patients (10%). No adverse effects were reported and only one infection (infectious colitis) (2.1%) during follow-up.

**Conclusion:** UST is a safe treatment for IBD patients but the efficacy of UST might be distorted due to the complex profile of IBD patients in which we use in routine clinical practice.

**Disclosure:** Nothing to disclose

## P0401 LONG-TERM OUTCOMES OF INFLIXIMAB THERAPY FOR PATIENTS WITH CROHN'S DISEASE AT DIFFERENT TIMES OF INITIATION OF INFLIXIMAB ADMINISTRATION: A SINGLE-CENTRE COHORT STUDY IN JAPAN

**Contact E-Mail Address:** masaki0801\_3@marianna-u.ac.jp

**Introduction:** In Japan, infliximab was first approved for patients with Crohn's disease as an induction therapy in 2002. Subsequently, it was approved for maintenance therapy and dose escalation in 2007 and 2011, respectively. However, the comparative long-term effectiveness of infliximab treatments in patients with Crohn's disease at different times of initiation of infliximab administration is not fully established.

**Aims & Methods:** The aim of this study was to compare the rates of dose escalation of infliximab, intestinal resection and retention of infliximab among patients with Crohn's disease at different times of initiation of infliximab administration. Data for 338 patients with luminal Crohn's disease who were treated at our hospital with infliximab (5 mg/kg) for  $\geq 14$  weeks between January 2003 and May 2017 were retrospectively reviewed. The cumulative rate of the dose escalation of infliximab from 5 mg/kg to 10 mg/kg, the rate of intestinal resection and the rate of retention of infliximab following the initial infliximab administration were estimated using the Kaplan-Meier method. Patients were categorised into three groups according to the time of initiation of the infliximab therapy [A, 2003-2006 (n = 83); B, 2007-2010 (n = 146) and C, 2011-2017 (n = 109)]. Patient characteristics and the rates of dose escalation of infliximab, intestinal resection and retention of infliximab were compared among the three groups. Prognostic factors related to the outcomes were evaluated using the log-rank test.

**Results:** Of the 338 patients (median age, 29.7 years; 85 females), the median duration of the disease at initiation of infliximab therapy was 4.3 years. Of the total patients, 201 patients had ileocolitis, 75 had ileitis and 62 had colitis. In addition, 145 patients were diagnosed with non-stricturing, non-penetrating disease, 145 with stricturing disease and 48 with penetrating disease. Perianal disease was diagnosed in 156 patients. The median C-reactive protein was 1.01 mg/dL. Prior to initiation of the infliximab therapy, 108 patients had undergone at least one intestinal resection and 11 had been previously exposed to adalimumab. Concomitant treatment with immunomodulators (azathioprine or 6-mercaptopurine) and prednisolone was administered to 248 and 36 patients respectively. The 1-, 3-, 5- and 10-year cumulative rates of dose escalation of infliximab, intestinal resection and retention of infliximab in all 338 patients were 16.2%, 33.7%, 42.3% and 52.2%, 3.4%, 9.8%, 13.8% and 21.3% and 98.2%, 93.5%, 89.8% and 80.1%, respectively. Patients in group C had significantly shorter disease durations ( $P = 0.029$ ) and higher rates of concomitant treatment with immunomodulators ( $P < 0.001$ ) than those in group A. The 5-year cumulative rates of dose escalation of infliximab, intestinal resection and retention of infliximab were 54.2%, 17.1% and 88.5% in group A; 46.8%, 16.6% and 89.1% in group B and 27.3%, 6.5% and 92.2% in group C, respectively. The rates of dose escalation of infliximab ( $P < 0.001$ ) and intestinal resection ( $P = 0.043$ ) in group C were significantly lower than those in groups A and B.

**Conclusion:** The rates of dose escalation of infliximab and intestinal resection of patients with Crohn's disease who were administered infliximab after 2011 were lower than those of patients who were administered infliximab before 2010. Early induction of infliximab and a combined therapy with infliximab and immunomodulators in the 2011-2017 period may have contributed to the reduction in the rates of dose escalation of infliximab and intestinal resection.

**Introduction:** In Japan, a new auto-injection pen for self-administration of adalimumab, which differs in shape from the conventional auto-injection pen used worldwide, has been available since June 2018. This pen is filled with the same drug solution and fitted with the same 29-gauge needle as the prefilled syringe. However, there are no data comparing the new pen and the syringe in terms of preference among patients with Crohn's disease (CD). We report the results from the Comparison of Preference for New Auto-injection Pen Versus Prefilled Syringe in CD Patients Receiving Adalimumab Treatment (COMFORT).

**Aims & Methods:** The COMFORT study was to assess the patients' preference for the new pen in comparison with that of the syringe of adalimumab using a questionnaire survey. This study was a prospective cohort study conducted at a single centre in Japan. Patients with CD who agreed to switch from the adalimumab syringe to the new pen between September 2018 and January 2019 were enrolled. The inclusion criteria were as follows: 1) patients who were self-injecting 40 mg/0.4 mL of adalimumab using a syringe every other week, 2) those who were treated with adalimumab for  $\geq 6$  weeks and had  $\geq 1$  self-injections with a syringe and 3) those whose date of consent was within 2 weeks from the last date of self-injection with the syringe. The first questionnaire survey was conducted within 2 weeks from the last date of self-injection using the syringe, and the patient's impressions of the syringe during the final self-injection were assessed. All patients were instructed by a nurse on how to use the pen after the first survey was completed. The second and third surveys were conducted within 1 h after the first and seventh self-injection using the pen, and the patients' impressions of the pen were then investigated. Pain at the injection site was assessed using the visual analogue scale (VAS). In all surveys, VAS scores and the overall patients' satisfaction were examined. In the second and third surveys, pain, administration time, safe operability, simplicity, convenience and overall assessment were investigated to determine the patients' preference for the pen, syringe or neither.

**Results:** A total of 81 patients (median age, 33.6 years; female, 33.3%) were included in this study. All patients responded to the first survey, while 73 and 64 patients responded to the second and third surveys, respectively. The mean VAS score significantly decreased from 28.2 during the first survey to 16.7 ( $P < 0.001$ ) and 19.1 ( $P = 0.003$ ) during the second and third surveys, respectively. The proportion of patients who were satisfied increased sequentially from 66.7% in the first survey to 78.6% and 85.2% in the second and third surveys. The proportion of patients who reported that the pen was generally better than the syringe significantly increased from 69.9% in the second survey to 83.9% in the third survey ( $P = 0.012$ ). Similarly, the proportion of patients who reported that the pen caused milder pain, took less time to administer, had safer operability, was simpler and more convenient to use than the syringe increased from 61.6%, 82.2%, 76.7%, 83.6% and 69.9% in the second survey to 71.4%, 87.3%, 85.7%, 88.9% and 79.4% in the third survey, respectively.

**Conclusion:** The new pen for self-administration of adalimumab caused less pain than the syringe. Further, approximately 70% of patients answered that the new pen was generally better than the syringe at the first self-injection. In addition, the proportion of patients who preferred the new pen was higher at the seventh self-injection than at the first self-injection.

**Contact E-Mail Address:** severine.vermeire@uzleuven.be

**Introduction:** The efficacy of etrasimod, a once-daily, oral, selective, sphingosine-1-phosphate receptor modulator as induction therapy in adult patients with moderate to severe ulcerative colitis (UC) was previously demonstrated in the 12-week phase 2, randomised, placebo-controlled, double-blind (DB), OASIS study (NCT02447302). This open-label extension (OLE) study (NCT02536404) subsequently evaluated for an additional 34 weeks the safety and efficacy of etrasimod in achieving and maintaining response and/or remission in patients who completed OASIS.

**Aims & Methods:** All patients completing the OASIS DB study were eligible to enrol in the OLE and receive etrasimod 2 mg QD for up to 46 weeks from the DB baseline, irrespective of their response or treatment during the DB study. Efficacy was summarized in the modified intent-to-treat (mITT) population evaluable cohort, which included patients with required assessments who received etrasimod 2 mg throughout the OLE. Patients in the treat-through (TT) group received etrasimod 2 mg in both the DB and OLE studies. Endpoints were clinical remission (endoscopic score  $\leq 1$  [with absence of friability], rectal bleeding [RB] 0, and stool frequency [SF] score  $\leq 1$  with  $\geq 1$  point decrease from DB baseline), clinical response (clinical remission or decrease in 3-component Mayo Clinic score [endoscopy findings, RB, or SF] of  $\geq 2$  points and  $\geq 30\%$  decrease from DB baseline, with either a RB decrease of  $\geq 1$  or RB score of  $\leq 1$ ), and endoscopic improvement (subscore  $\leq 1$ ). All statistics are descriptive. End of treatment (EOT) was the last observation for each patient, occurring at week 46 (week 34 of OLE) for study completers or at last visit for patients who discontinued or had missing data.

	By previous treatment group in DB study			
	DB Study: Any treatment	DB Study: Etasimod 1 mg	DB Study: Etasimod 2 mg	DB Study: Placebo
	OLE: Etasimod 2 mg (N = 105)	OLE: Etasimod 2 mg (N = 35)	OLE: Etasimod 2 mg (N = 31)	OLE: Etasimod 2 mg (N = 39)
Patients with clinical response, %				
n	94	33	28	33
Week 12 (end of DB study)	40.4	39.4	57.1	27.3
End of treatment	70.2	75.8	64.3	69.7
Patients with clinical remission, %				
n	94	33	28	33
Week 12 (end of DB study)	21.3	9.1	50.0	9.1
End of treatment	35.1	33.3	39.3	33.3
Patients with endoscopic improvement, %				
n	96	34	29	33
Week 12 (end of DB study)	26.0	14.7	51.7	15.2
End of treatment	44.8	50.0	41.4	42.4

[Key efficacy endpoints for patients in the OLE etrasimod 2-mg group (mITT evaluable cohort)]

**Results:** 118 patients (84% of DB completers) entered the OLE; 112 patients (safety population) received etrasimod 2 mg at any point in the OLE, of whom 105 patients (evaluable cohort) received etrasimod 2 mg throughout the OLE and 92 patients (82% of OLE enrollers) completed the OLE. At EOT, 70% of patients had a clinical response, an increase from 40% at week 12 (Table). Clinical response at EOT was seen in 87% (33/38) and 81% (13/16), respectively, of week-12 responders who received OLE etrasimod 2 mg or were in the 2-mg TT group; clinical remission at EOT was seen in 60% (12/20) and 64% (9/14), respectively, of week-12 remitters who received OLE etrasimod 2 mg or were in the 2-mg TT group. Median lymphocyte

reduction from the DB baseline was 44.6% at week 12 with etrasimod 2 mg and 42.9% at EOT in the 2-mg TT group. Of patients who received etrasimod 2 mg at any point during the OLE, 60% (67/112) experienced  $\geq 1$  TEAE (most of mild or moderate severity) and 9% (10/112) discontinued study drug due to a TEAE (worsening UC, atrial fibrillation, or headache). Of the 14 serious TEAEs reported in 7 patients, only 1 was considered treatment-related (worsening UC). The impact on heart rate and atrioventricular (AV) conduction was minimal, with no study discontinuations related to bradycardia or AV block.

**Conclusion:** Etasimod 2 mg demonstrated sustained clinical response, clinical remission, and endoscopic improvement at the end of the OLE compared with the end of induction therapy. Etasimod demonstrated a favourable long-term safety profile, with most AEs of mild to moderate severity; no new safety findings were reported.

## P0404 NONCLINICAL SAFETY ASSESSMENT OF LC51-0255, AN ORAL SPHINGOSINE-1-PHOSPHATE 1 RECEPTOR (S1P1) MODULATOR WITH A FAVORABLE PROFILE

Kim K.C.<sup>1</sup>, Kim J.<sup>1</sup>, Hong P.S.<sup>2</sup>, Seo D.O.<sup>1</sup>

<sup>1</sup>LG Chem, Ltd, Regulatory Toxicology Team, Drug Discovery Center, Life Sciences R&D, Seoul, Korea (Republic of), <sup>2</sup>LG Chem, Ltd, Drug Discovery Center, Life Sciences R&D, Seoul, Korea (Republic of)

**Contact E-Mail Address:** kichankim@lgchem.com

**Introduction:** LC51-0255 is a highly selective and potent S1P1 modulator under the clinical development for the treatment of Ulcerative Colitis (UC). The objective of this study was to evaluate the safety of LC51-0255 in non-clinical toxicity studies with rats and monkeys.

**Aims & Methods:** GLP toxicity studies were conducted in Sprague-Dawley rats and Cynomolgus monkeys. LC51-0255 was orally administered in 0.5% methylcellulose for up to 26 weeks in rats and 39 weeks in monkeys.

**Results:** LC51-0255 was evaluated for 4-, 13- and 26-week repeated oral dosing toxicity in Sprague-Dawley rats. The no-observed-adverse-effect-level (NOAEL) of LC51-0255 was 3 mg/kg/day in the toxicity studies in rats. Due to immunosuppressive nature of pharmacological effects of LC51-0255, low leukocyte and lymphocyte counts were observed, and changes in organ weight and histopathology from lymphoid tissues were mainly observed from 10 mg/kg/day groups. But those changes showed a tendency of recovery at the end of each recovery period of the studies. Although there were no functional abnormalities, toxicity target organs from the rat studies were considered to be liver and lung, based on the changes in organ weight and histopathology.

In toxicokinetic analysis in rats, the values of  $C_{max}$  and  $AUC_{0-24}$  of LC51-0255 increased in a dose proportional manner throughout the studies, and no clear sex-related differences were noted. Estimated human safety margins based on  $AUC_{0-24}$  were over 20-fold and over 30-fold for male and female rats, respectively.

To evaluate the systemic toxicity of orally administered LC51-0255 on Cynomolgus monkeys, 4-, 13- and 39-week toxicity studies were examined. The NOAEL of LC51-0255 was 3 mg/kg/day throughout the toxicity studies in monkeys. Similar to the rat toxicity studies, low leukocyte and lymphocyte counts were observed due to immunosuppressive effects of LC51-0255. In the spleen, organ weight loss and atrophy were observed. But those changes showed a tendency of recovery at the end of each recovery period of the studies.

Clinical signs including diarrhea and soft stool were mainly observed from 10 mg/kg/day groups. But those signs were considered to be related to the physicality of the test article formulation and toxicologically insignificant. Although there were no functional abnormalities, toxicity target organs from monkey toxicity studies were considered to be liver and lung, based on the changes in organ weight and histopathology.

In toxicokinetic analysis in monkeys, the values of  $C_{max}$  and  $AUC_{0-24}$  of LC51-0255 increased in dose proportional manner on the Day 1 of dosing throughout the studies. But accumulation ratio of LC51-0255 showed a tendency to decrease with increasing dose. From 3 mg/kg/day, the mean values of  $C_{max}$  and  $AUC_{0-24}$  showed similar values throughout the dosing period. Estimated human safety margins based on  $AUC_{0-24}$  were over 20-fold and over 30-fold for male and female monkeys, respectively.

**Conclusion:** LC51-0255 is a potent S1P1 modulator with high selectivity at S1P1 receptor versus the other S1P receptors

Nonclinical safety of LC51-0255 was assessed for genotoxicity, safety pharmacology, general toxicity and reproductive/developmental toxicity studies, and there were no specific safety concerns. Most of findings are related to its pharmacological activity as a S1P1 modulator.

These safety assessments support the continuing development of LC51-0255 for Ulcerative Colitis and other potential autoimmune disorders.

**Disclosure:** Nothing to disclose

## P0405 LONG-TERM BUDESONIDE TREATMENT AND RISK OF OSTEOPOROTIC FRACTURES IN PATIENTS WITH MICROSCOPIC COLITIS

**Contact E-Mail Address:** olebonde@rm.dk

**Introduction:** Budesonide is a well-established treatment of microscopic colitis (MC). Due to a substantial first-pass metabolism of oral budesonide the systemic bioavailability is low compared to other oral corticosteroids. This may lead to a decreased risk of adverse effects normally related to long-term use of corticosteroids. Due to a high risk of relapse long-term treatment of MC is often necessary. However, adverse effects related to long-term use of budesonide are of concern.

**Aims & Methods:** The aim was to determine whether use of oral budesonide is associated with risk of osteoporotic fractures in patients with MC. Based on data from the Danish nationwide health registries, we conducted a case-control study nested within patients with a histologically verified diagnosis of MC from 2004 to 2012. Cases were individuals with a first-occurrence of a fracture likely caused by osteoporosis i.e., fracture of hip (ICD-10: S72), wrist (S525) or spine (S220 & 320). Controls were patients with MC without fractures matched according to age, gender and type of MC. Cases were matched to controls by risk set sampling in a ratio of 1:3. We estimated odds ratios (ORs) for the association between ever use of budesonide and any osteoporotic related fractures, and for hip-, wrist and spinal fractures independently. Further, we investigated dose-response associations and associations for subgroups at suspected high or low risk of fractures. Potential confounding was adjusted for by risk set sampling and regression analyses

**Results:** Among 10,652 patients with a diagnosis of MC we identified 485 cases with a first occurrence of an osteoporotic fracture as defined above. The majority were women (86%) and the median age was 78 years. After adjustment for confounding, a modestly increased adjusted OR was observed for the overall association between use of budesonide and osteoporotic fractures (OR 1.39, CI: 1.09-1.76). Stratification by type of fracture revealed the highest risk of spinal fractures (2.15, CI: 1.09-4.25), followed

hip-, and wrist fractures (OR 1.34 (CI: 0.94-1.93) and OR 1.26 (CI: 0.87-1.83), respectively). No dose-response association was evident (OR for doubling of cumulative dose 1.03 (CI: 0.91-1.16). When addressing differences across subgroups, we generally found moderately increased ORs (1.28-1.97).

	Cases Exposed/ unexposed	Controls Exposed/ unexposed	Crude odds ratio 95% CI	Adjusted* odds ratio 95% CI
No use	120 / 365	460 / 976	1.00 (Ref)	1.00 (Ref)
Spinal fracture	54 / 14	128 / 74	2.29 (1.19 - 4.42)	2.15 (1.09 - 4.25)
Wrist fracture	141 / 51	386 / 181	1.29 (0.90 - 1.86)	1.26 (0.87 - 1.83)
Hip fracture	170 / 55	462 / 205	1.37 (0.97 - 1.93)	1.34 (0.94 - 1.93)

[The association between budesonide use and types of osteoporotic fractures.]

Cases: MC-patients with an osteoporotic fracture; Controls: MC-patients without fractures; matched according to age, gender and type of MC.

\*Adjusted for all comorbid conditions and co-prescribed medication.

CI = 95% confidence interval; DDD = Defined daily dose

**Conclusion:** A moderate increased risk risk of osteoporotic fractures related to use of oral budesonide among individuals with MC was found. However, no dose-response association could be demonstrated. Based on present study we suggest using bone densitometry to periodically assess bone mineral density in MC patients on long-term oral budesonide to maintain clinical remission.

## P0406 SAFETY AND IMMUNE MODULATORY PROPERTIES OF LC51-0255, AN ORAL, SELECTIVE SPHINGOSINE 1-PHOSPHATE 1 (S1P1) RECEPTOR MODULATOR, IN HEALTHY VOLUNTEERS

Hwang I.<sup>1</sup>, Lee S.W.<sup>2</sup>, Na H.<sup>3</sup>, Jeon S.<sup>3</sup>, Kim K.C.<sup>3</sup>, Yu K.S.<sup>1</sup>

**Contact E-Mail Address:** kichankim@lgchem.com

**Introduction:** LC51-0255 is a potent, selective, and orally available sphingosine-1-phosphate 1 (S1P1) receptor agonist which exerts anti-inflammatory effect. Once it is bound to S1P1 receptor, it is internalized from the cell membrane and is introduced to receptor degradation pathway, leading to the capture of immune cells in the secondary lymph node. We herein present the phase 1 clinical study results of LC51-0255 as a potential treatment of auto-immune diseases such as ulcerative colitis (UC).

**Aims & Methods:** A dose blocked-randomized, double-blind, placebo-controlled, single and multiple dosing, dose-escalation phase 1 clinical study was conducted to investigate the safety, tolerability, pharmacokinetic/pharmacodynamic (PK/PD) characteristics and food effect on the bioavailability of LC51-0255 after oral administration in healthy male volunteers. Eligible subjects were healthy male, 19 - 45 years of age with BMI 18.0 - 27.0 kg/m<sup>2</sup>. In the single ascending dose (SAD) study, 50 subjects (n=10/dose group) were randomly assigned, in 4:1 ratio, to receive either LC51-0255 (0.25 - 4 mg) or placebo, and the food effect was evaluated in LC51-0255 2 mg dose group. In the multiple-ascending dose (MAD) study, 40 subjects (n=10/dose group) were randomized (4:1) to receive either LC51-0255 (0.25 - 1.5 mg) or placebo once daily for 21 days. Safety and tolerability assessment included adverse events (AE), electrocardiogram (ECG), laboratory tests, and Holter monitoring. Blood samples were collected to evaluate the PK and PD of LC51-0255.

**Results:** There was no serious adverse event in SAD study. Decreased heart rate (bradycardia) was the most common AE, and one case of asymptomatic 2nd degree atrioventricular block occurred after single administration of LC51-0255 4 mg, both of which are well-known AEs in the same class of S1P agonists. These AEs were well tolerated and resolved within study period without any intervention. No clinically significant QT prolongation was reported in ECG and Holter monitoring. In present, MAD study is ongoing. Systemic exposure of LC51-0255 increased dose-dependently after a single dose, in dose range of 0.25 to 4 mg, with the mean area under the plasma concentration time curves (AUC) ranging from 127.72 to 2498.99 µg·h/L. There was no apparent effect of food on the systemic exposure of LC51-0255. The peak plasma concentration of LC51-0255 was observed at 3 - 4 hours after oral administration and the mean elimination half-life was 70 -130 hours, making it suitable for once daily administration. The fraction excreted into urine was less than 0.1% across all dose levels, indicating that the renal excretion is not the major route of elimination. The absolute lymphocyte count (ALC), a PD biomarker, decreased dose-dependently with the mean maximum change from baseline of ALC ranging from 34 to 77%. These results showed that the pharmacodynamics of LC51-0255 was consistent with expected pharmacology. All dose levels reached its maximum pharmacodynamic effect at 6 hours post administration except for 4 mg (10 hours). Reduced ALC levels were recovered to normal range during the study period.

**Conclusion:** Overall, LC51-0255 was well tolerated at all doses tested in this study. Systemic exposure increased dose-dependently and PK profile was favorable for once daily administration. ALC displayed a dose-dependent reduction, showing the potential of LC51-0255 as an effective treatment for UC. These findings support further evaluation of LC51-0255 in phase 2 clinical studies to determine the safe and efficacious dose in UC patients.

**Contact E-Mail Address:** edouard.louis@ulg.ac.be

**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) are chronic, debilitating inflammatory bowel diseases (IBD). Medications used in the treatment of IBD include aminosaliclates, glucocorticoids, immunomodulators, biologics, and small molecules, with each class having distinct characteristics a patient may consider. Research into patient preferences in IBD indicates that values regarding medical treatment may vary depending on the clinical disease phenotype.<sup>1-4</sup> The development of a comprehensive descriptive system addressing all the meaningful aspects related to the management of IBD conditions is of utmost importance to enable a rigorous analysis of patients' preferences.

**Aims & Methods:** We present a descriptive system that includes the most relevant attributes for IBD treatment decision making, focusing on the patient perspective.

A three-step approach was used to develop the descriptive system. First, a literature review was performed and an initial list of attributes was developed and classified within domains and categories. Second, a focus group meeting was conducted with eight patient representatives and nine gastroenterologists. Using feedback elicited from the focus group meeting, the research team constructed an initial draft of the descriptive system,

including a subset of domains and attributes. Third, all participants of the focus group meeting participated in two-rounds of structured online interviews. The structured interviews were used to refine the wording used for naming and defining each attribute and the levels of those attributes in the initial descriptive system.

**Results:** We identified 32 eligible publications and a list of 127 attributes grouped into 7 domains (effectiveness, side-effects, health related quality of life [HRQoL], well-being, available evidence, administration/convenience, and other) was developed. This list was discussed in the focus group meeting and a draft of the descriptive system containing 16 relevant attributes was constructed.

The same attributes were defined for UC and CD while taking into consideration that the relative weights for each disease may differ. During the first round of interviews, patients ranked all attributes included in the descriptive system and based on the second round of interviews, the final descriptive system containing a total of 3 domains, 10 attributes, and their corresponding levels was developed (Table).

Domain	Attribute name/Descriptor
Efficacy	Abdominal pain (8 levels)
	Other disease-related pain (8 levels)
	Bowel urgency (4 levels)
	Fatigue (4 levels)
Complications/ Risk	Risk of cancer and serious infections within the next 10 years (3 levels)
	Risk of mild to moderate complications (4 levels)
	Aesthetic complications related to treatment (3 levels)
Health related quality of life	Emotional status (3 levels)
	Sexual life (3 levels)
	Social life and relationships (3 levels)

[Table. Final list of attributes]

**Conclusion:** This qualitative research shows which attributes within the domains of efficacy, complications/risk, and HRQoL patients value most when making treatment decisions. We developed a descriptive system that outlines the IBD treatments by means of the 10 most relevant attributes, which should be considered by physicians and nurses when discussing treatment options with a patient. These attributes will be weighted in a future study based on patient preferences.

**Introduction:** There is an increasing body of evidence supporting earlier use of anti-tumor necrosis factor (anti-TNF) agents to improve outcomes and change the natural course of Crohn's disease (CD). The objective of this study was to perform a meta-analysis to assess the impact of early anti-TNF use in the treatment of CD.

**Aims & Methods:** The PubMed and Embase databases were searched for English language papers and conference abstracts published through 31 December 2017. Studies were selected for inclusion if patients initiated anti-TNFs within 2 years of a CD diagnosis or if anti-TNFs were used before or with immunosuppressants (top-down) in clinical trials and retrospective observational studies based on PRISMA guidelines. Random-effects meta-analyses were conducted to compare clinical remission (including steroid-free remission), disease relapse and endoscopic healing rates with early anti-TNF treatment (< 2 years of disease duration or top-down treatment strategy) to late/conventional treatment (defined as biologic use after >2 years of disease duration or conventional step-up treatment strategy in recently diagnosed patients).

**Results:** A total of 3,061 records were identified, of which 39 references met the selection criteria for systematic review. The meta-analysis included 14 studies that reported comparative remission, relapse and endoscopic healing rates for early vs late/conventional anti-TNF treatment. Early vs. late/conventional anti-TNF use was more likely to result in clinical remission or steroid-free remission, with an odds-ratio (OR) of 2.11 (95% CI: 1.66-2.68, n=2,113, P< 0.001). The positive results were observed in both adult (OR 1.97 at week 26 [95% CI: 1.53-2.53, n=803, P< 0.001]) and pediatric subgroups (OR 3.07 at week 52 [95% CI: 1.59-5.94, n=217, P< 0.001]). Conversely, early treatment with anti-TNFs was associated with reduced risk of relapse compared to late/conventional treatment, with an OR of 0.31 (95% CI: 0.14-0.68, n=596, P=0.003). A subgroup analysis for adults was not feasible, however in the pediatric patient subgroup, the OR for relapse with early treatment was 0.18 (95% CI: 0.07-0.43, n=105, P< 0.001). Early anti-TNF treatment was also more likely to result in endoscopic heal-

ing compared to late/conventional treatment (OR 2.06 [95% CI: 1.35-3.15, n=454, P< 0.001]). A subgroup analysis for pediatrics was not feasible, but in the adult patient subgroup, the OR for endoscopic healing with early treatment was 2.21 (95% CI: 1.34-3.64, n=424, P=0.002).

	Early anti-TNF Treatment <sup>a</sup>			Late/conventional Treatment <sup>a</sup>			Odds Ratio (95% CI)	P value
	Total (n)	Events (n)	Event rate	Total (n)	Events (n)	Event rate		
Clinical Remission <sup>b</sup>	524	341	65.1%	1589	610	38.4%	2.11 (1.66, 2.68)	<0.001
Disease Relapse <sup>c</sup>	123	32	26.0%	473	227	48.0%	0.31 (0.14, 0.68)	0.003
Endoscopic Healing <sup>d</sup>	200	108	54.0%	254	92	36.2%	2.06 (1.35, 3.15)	<0.001

<sup>a</sup> Early treatment is defined as anti-TNF use <2 years of disease duration or top-down treatment strategy; late/conventional treatment is defined as anti-TNF use after >2 years of disease duration or conventional step-up treatment strategy <sup>b</sup> Definition of clinical remission: 3 studies used CDAI<150; 1 study used CDAI<150 plus no bowel resection and no steroid use; 2 studies used PCDAI≤10; 1 study used corticosteroid free remission <sup>c</sup> Definition of disease relapse: 1 study used increase in CDAI≥70 and an absolute CDAI>220; 3 studies used PCDAI>10 <sup>d</sup> Definition of endoscopic healing: 2 studies used SES-CD=0; 1 study used CDEIS<4 and absence of deep ulcers; 1 study used absence of any mucosal ulcers (including aphthous ulcers); 1 study used absence of mucosal ulceration; 1 study used disappearance of ulcerations, multiple erosions, bleeding and friability (grade 0 or 1) CDAI: Crohn's Disease Activity Index; PCDAI: Pediatric Crohn's Disease Activity Index; SES-CD: Simple Endoscopic Score for Crohn's Disease; CDEIS: Crohn's Disease Endoscopic Index of Severity

*Table. Results of meta-analysis on clinical remission, relapse and endoscopic healing with early anti-TNF treatment versus late or conventional treatment in Crohn's disease*

**Conclusion:** Early use of anti-TNF in CD patients is associated with improved outcomes in clinical remission, disease relapse, and endoscopic healing compared to late/conventional treatment.

## P0410 ST-0529 IN MODERATE TO SEVERE ACTIVE ULCERATIVE COLITIS: LESSONS LEARNED AND PERSPECTIVES

Gardzinski P., Dzyngel B., Hall J.  
Sublimity Therapeutics, Solana Beach, United States

**Contact E-Mail Address:** peter.gardzinski@sublimitytherapeutics.com

**Introduction:** There is an unmet need for safe and effective treatment options for patients with moderate to severe ulcerative colitis (UC) who have intolerance to, experience an inadequate response to, or relapse of the current recommended treatments. Many patients experience infusion or injection site reactions with biologic therapies, and immunomodulators increase malignancy risk, highlighting the need for new safe oral alternatives. Although cyclosporine (CsA) has similar safety and efficacy to infliximab for acute severe UC management, its use is limited due to its serious systemic side effects (SSE). Sublimity has developed ST-0529, an oral formulation of CsA with a diffusion-controlled mechanism of release that delivers CsA directly to diseased tissue of the ileum and colon, thereby reducing systemic absorption, and potentially minimising the risk of SSE and the need for extensive drug monitoring.

**Aims & Methods:** Two phase 1 and one phase 2 studies have been completed with ST-0529.[1] Phase 1 results showed that ST-0529 (dose range 37.5-150 mg) achieves similar or higher colonic tissue concentrations of CsA and significantly lowers systemic CsA levels compared to continuous IV CsA in healthy subjects.[2],[3] Phase 2a pilot results confirmed safety of ST-0529 75 mg once-daily in patients with mild or moderate UC after 4 weeks of treatment and showed a numerical increase in rates of remission and response with ST-0529 compared to placebo, although not statistically significant. Post-hoc analysis found that compared to placebo, patients with moderate disease (35% vs 17%,  $p=0.0499$ ) and moderate disease taking concomitant 5-aminosalicylate and/or steroids without immunosuppressives (47.8% vs 17.9%,  $p=0.026$ ) did significantly better on ST-0529.[4] To further investigate ST-0529 in UC, a phase 2b, multicentre, randomised, double-blind, placebo-controlled, parallel-group study will evaluate efficacy, safety and tolerability of ST-0529 in achieving clinical remission in subjects with moderate to severe UC. This study will also characterise the pharmacokinetic (PK) and pharmacodynamic (PD) profile of ST-0529 as well as its impact on quality of life in subjects with UC. Key inclusion criteria will include a diagnosis of histologically confirmed moderate to severe UC for  $\geq 3$  months defined as 3-Component Mayo Score (Mayo) of 5-9. Approximately 280 subjects are planned to be enrolled (40 are targeted for participation in a PK sub-study), randomised 1:1:1:1 (dosage regimen in table 1). Randomisation will be stratified according to disease severity as assessed by Mayo, prior treatment with anti-TNF therapy and corticosteroid use. The primary efficacy outcome will be clinical remission at week 12, defined as stool frequency subscore  $\leq 1$  associated with a decrease  $\geq 1$ -point, rectal bleeding subscore 0, and an endoscopic subscore  $\leq 1$  using Mayo. Rectal bleeding and stool frequency subscores will be calculated from data collected in subject diaries and endoscopic subscore provided by a central reader.

#### Results:

	ST-0529 Dosage 1 (n=70)	ST-0529 Dosage 2 (n=70)	ST-0529 Dosage 3 (n=70)	Placebo (n=70)
Dosage regimen	18.75 mg twice-daily, oral (capsule)	37.5 mg twice-daily, oral (capsule)	75 mg twice-daily, oral (capsule)	To match ST-0529 dose twice-daily, oral (capsule)
Treatment duration	12 weeks			
PK sub-study	Whole blood samples being collected at Week 2 at 0 (pre-dose), and at 2, 4, 6, and 8 hours post-dose (n=40)			

[Table 1: Phase 2b trial overview - Test product (ST-0529) and comparator (placebo)]

**Conclusion:** Orally administered ST-0529 represents a novel approach to attaining therapeutically relevant tissue concentrations of CsA in the colon and may offer an alternative for inadequate clinical response to traditional therapies. The results from this trial will help identify the appropriate dose(s) of ST-0529 for use in phase 3 clinical studies.

**Contact E-Mail Address:** maitane.ortiz@takeda.com

**Introduction:** Mesenchymal stem cells (MSCs) are the focus of intensive efforts directed towards developing cell-based therapies in immunologic disorders.<sup>1,2</sup> MSCs have been shown to activate the endogenous immune regulatory system of the recipient to induce a therapeutic effect.<sup>1,2</sup> Darvadstrocel (DVS) is an expanded, allogeneic, adipose-derived MSC (ASC) therapy approved in Europe<sup>5,6</sup> and Israel for the management of treatment-refractory complex perianal fistula (CPAF) in patients with inactive or mildly active Crohn's disease (CD)<sup>3,4</sup>. DVS has been shown to have long-term success rates comparable with existing medical and surgical therapies for CPAF.<sup>3,4</sup>

The mechanism of action of DVS is only partially understood.<sup>3,4</sup> It has been suggested that MSCs can modulate phenotype and function of monocytes via prostaglandin E2 (PGE2) and interleukin 6 (IL-6) during their differentiation to macrophages (Mphs) and dendritic cells.<sup>7,8,9</sup>

**Aims & Methods:** To characterise the modulatory effect of DVS on human myeloid cells *in vitro*.

Freshly isolated human monocytes from peripheral blood were differentiated *in vitro* towards M0 Mphs, M1 pro-inflammatory Mphs, M2 anti-inflammatory Mphs or mature dendritic cells (mDCs) in the presence or absence of DVS in non-contact conditions. The phenotype and function of the differentiated Mphs and dendritic cells were determined by flow cytometry, and their secretome (sets of secreted proteins) was assessed by Olink technology (a proteomic analysis system based on the Proximity Extension Assay). The role of the soluble factors PGE2 and IL-6 was investigated using neutralisation assays.

**Results:** The co-culture of monocytes in the presence of DVS during their differentiation to Mphs or mDCs resulted in polarisation towards an anti-inflammatory and phagocytic phenotype. This was characterised by an increased expression of phagocytic receptors and modulation of surface chemokine receptors, a reduced expression of co-stimulatory and activation molecules, and a decrease in the amount of cell debris present. Additionally, the morphology of M1 and M2 Mphs was modulated when differentiated in the presence of DVS. DVS promoted an elevation of secreted factors with anti-inflammatory, reparative and antimicrobial functions. DVS appeared, therefore, to be able to modulate monocyte cells towards an anti-inflammatory and reparative phenotype through secretion of soluble factors. Chemical inhibition of PGE2 with indomethacin resulted in complete neutralisation of the modulatory effect of DVS on mDC phenotype, whereas inhibition of IL-6 resulted in only a minor reduction of DVS-mediated modulation. The data indicate that PGE2 and IL-6 are the main soluble factors responsible for this modulatory effect.

**Conclusion:** The results demonstrate a mechanism of the DVS-mediated induction of anti-inflammatory and reparative phenotypes that potentially modulates monocyte/Mph/mDC differentiation. The modulatory effects of DVS on human myeloid cells are mediated by PGE2, and to a lesser extent, IL-6 examined on mDCs.

**Contact E-Mail Address:** sdanese@hotmail.com

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). The safety of tofacitinib for the treatment of moderate to severe UC was evaluated in a randomised, placebo-controlled Phase (P) 2 induction study (NCT00787202),<sup>1</sup> 2 induction P3 studies (NCT01465763; NCT01458951), 1 maintenance P3 study (NCT01458574),<sup>2</sup> and an ongoing, open-label, long-term extension (OLE) study (NCT01470612).<sup>3</sup> A safety signal for pulmonary embolism (PE) was seen in the tofacitinib 10 mg twice daily (BID) arm of an FDA post-marketing requirement study in rheumatoid arthritis designed to evaluate the long-term risk of major cardiovascular events and malignancy. Patients (pts) eligible for this ongoing, open-label, safety-endpoint-driven study had to be ≥50 years of age, have ≥1 cardiovascular risk factor and be on a stable dose of methotrexate. UC is a known risk factor for deep vein thrombosis (DVT) and PE, with reported incidence rates ranging from 0.07 to 0.30 and 0.04 to 0.20, respectively.<sup>4,5</sup> Here, we report the incidence of DVT and PE in the tofacitinib UC clinical programme, as of Sep 2018.

**Aims & Methods:** Pts who received placebo, tofacitinib 5 or 10 mg BID were analysed in three cohorts: Induction (P2/P3 induction studies, N=1220), Maintenance (P3 maintenance study, N=592) and Overall (pts receiving tofacitinib 5 or 10 mg BID in P2, P3 or ongoing OLE studies, N=1157). DVT and PE events were identified using preferred terms in the Standardised Medical Dictionary for Regulatory Activities query 'embolic and thrombotic events, venous' and incidence rates (unique pts with events per 100 pt-years [PY] of exposure) were evaluated. For Overall Cohort analysis, pts were categorised based on the average daily dose of tofacitinib: predominant dose (PD) tofacitinib 5 mg BID (average total daily dose < 15 mg) and PD tofacitinib 10 mg BID (average total daily dose ≥15 mg).

	Induction Cohort (8 weeks) <sup>a</sup>		Maintenance Cohort (52 weeks) <sup>a</sup>			Overall Cohort (≤6.1 years) <sup>a,b</sup>		
	Placebo (N=282; 44.8 PY)	Tofacitinib 10 mg BID (N=938; 156.2 PY)	Placebo (N=198; 100.4 PY)	Tofacitinib 5 mg BID (N=198; 146.2 PY)	Tofacitinib 10 mg BID (N=196; 154.3 PY)	PD Tofacitinib 5 mg BID (N=197; 595.5 PY)	PD Tofacitinib 10 mg BID (N=960; 1801.1 PY)	Tofacitinib All (N=1157; 2403.6 PY)
DVT, n (%), IR [95% CI]	1 (0.4), 1.99 [0.05, 11.07]	0 (0.0), 0.00 [0.00, 2.22]	1 (0.5), 0.97 [0.02, 5.39]	0 (0.0), 0.00 [0.00, 2.48]	0 (0.0), 0.00 [0.00, 2.35]	0 (0.0), 0.00 [0.00, 0.61]	1 (0.1), 0.05 [0.00, 0.30]	1 (0.1), 0.04 [0.00, 0.23]
PE, n (%), IR [95% CI]	1 (0.4), 1.98 [0.05, 11.04]	0 (0.0), 0.00 [0.00, 2.22]	1 (0.5), 0.98 [0.02, 5.44]	0 (0.0), 0.00 [0.00, 2.48]	0 (0.0), 0.00 [0.00, 2.35]	0 (0.0), 0.00 [0.00, 0.61]	4 (0.4), <sup>d</sup> 0.21 [0.06, 0.55]	4 (0.3), 0.16 [0.04, 0.41]

For Overall Cohort analysis, pts were categorised based on the average daily dose of tofacitinib (placebo exposure was not included): PD tofacitinib 5 mg BID (average total daily dose <15 mg) and PD tofacitinib 10 mg BID (average total daily dose ≥15 mg)

<sup>a</sup>Excluding events occurring after 28 days from the last dose of the corresponding cohort; <sup>b</sup>Data are as of Sep 2018 (OLE study database not locked); <sup>c</sup>DVT event occurred in 1 pt (58 years of age at DVT event) 1149 days following the first dose of tofacitinib; <sup>d</sup>PE events occurred in 1 pt (25 years of age at PE event) with prior DVT and PE, 216 days following the first dose of tofacitinib; 1 pt (57 years of age at PE event) with prior phlebotrombosis and stroke, 236 days following the first dose of tofacitinib; 1 pt (70 years of age at PE event) with cholangiocarcinoma and metastases to the peritoneum, 383 days following the first dose of tofacitinib; and 1 pt (21 years of age at PE event) who was receiving oral contraceptives for dysfunctional uterine bleeding, 569 days following the first dose of tofacitinib  
BID, twice daily; CI, confidence interval; DVT, deep vein thrombosis; IR, incidence rate; N, number of patients; n, unique number of patients with a particular adverse event; OLE, open-label, long-term extension; PD, predominant dose; PE, pulmonary embolism; pts, patients; PY, patient-years

[Table. Incidence rates (unique pts with event per 100 PY of exposure) of DVT and PE among pts in the Induction, Maintenance and Overall Cohorts]

**Results:** The Overall Cohort comprised 1157 pts who received ≥1 dose of tofacitinib 5 or 10 mg BID, with 2404 PY of tofacitinib exposure and up to a maximum of 6.1 years of treatment. Results for DVT and PE are shown in

the Table. In the Induction and Maintenance Cohorts, 2 pts had DVT and 2 had PE; all had received placebo in the study. In the Overall Cohort, there was 1 pt with DVT and 4 pts with PE; all 5 pts had received PD of tofacitinib 10 mg BID and all events occurred during the OLE study. Pts with PE had the following notable medical history: 1 with prior DVT and PE, 1 with phlebotrombosis and stroke, 1 was receiving oral contraceptives for dysfunctional uterine bleeding, and 1 had cholangiocarcinoma and metastases to the peritoneum, and PE was the cause of death. The pt with DVT was diagnosed following a long-haul flight and management of an infected leg wound sustained in a recent motorbike accident.

**Conclusion:** In this post-hoc analysis of pts from the OCTAVE programme, during tofacitinib exposure, 4 pts had PE and 1 pt had DVT. All of the events in pts taking tofacitinib occurred during the OLE study in pts treated with PD of tofacitinib 10 mg BID (83% of pts in the Overall Cohort received a PD of tofacitinib 10 mg BID) and with risk factors for thrombotic events. This post-hoc analysis is limited by small sample size and limited drug exposure, and further study is needed.

**Contact E-Mail Address:** brian.feagan@robertsinc.com

**Introduction:** Ozanimod is an oral immunomodulator that selectively targets S1P<sub>1</sub> and S1P<sub>5</sub>. TOUCHSTONE, a randomised, double-blind, placebo-controlled phase 2 trial that evaluated patients with moderately to severely active ulcerative colitis (UC) showed significantly higher rates of clinical remission, clinical response, and endoscopic mucosal healing (Mayo endoscopic subscale score of 0/1) at Weeks 8 and 32 in patients assigned to ozanimod 1 mg compared to those who received placebo (Sandborn NEJM 2016). The objective of this analysis was to assess clinical remission at Week 32 across subgroups of interest.

**Aims & Methods:** Patients were randomised 1:1:1 and received ozanimod 1 mg, ozanimod 0.5 mg, or placebo. Mayo score, based on stool frequency, rectal bleeding, mucosal appearance at endoscopy, and physician rating of disease activity, was calculated at baseline, end of induction (Week 8), and end of maintenance (Week 32). Clinical remission was defined as total Mayo score ≤2, with no subscore >1. A post hoc sub-group analysis evaluated clinical remission rates at Week 32 according to baseline Mayo score, years since UC diagnosis, and body mass index (BMI).

**Results:** A total of 197 patients were randomised and received ozanimod 1 mg (n=67), 0.5 mg (n=65), or placebo (n=65), with 103 (52.3%) entering a maintenance period based on response criteria (ozanimod 1 mg, n=42; 0.5 mg, n=36; placebo, n=25), and 91 (88.3%) completing the study. Differences in the proportion of patients in clinical remission with ozanimod 1 mg versus placebo by subgroup illustrate that the treatment effect favoured ozanimod 1 mg in every subgroup analysed (Table).

The 95% confidence intervals for the treatment difference between ozanimod 1 mg and placebo exclude 0 for the overall population and subgroups of baseline Mayo score >8, years since UC diagnosis >6, and BMI <25 kg/m<sup>2</sup>.

	Treatment Difference in Week 32 Remission Rate (Ozanimod 1mg vs placebo)	95% Confidence Limits	
		Lower	Upper
Clinical Remission at Week 32			
Overall	16.23%	4.67%	27.80%*
Baseline Mayo score (≤8)	14.35%	-4.20%	32.89%
Baseline Mayo score (>8)	18.18%	5.02%	31.34%*
Years of UC diagnosis at baseline (≤6)	12.90%	-0.07%	25.87%
Years of UC diagnosis at baseline (>6)	23.48%	1.10%	45.87%*
BMI at baseline (≥25 kg/m²)	15.44%	-2.10%	32.98%
BMI at baseline (<25 kg/m²)	16.82%	1.41%	32.23%*

BMI: body mass index; ITT: intent-to-treat; NRI: non-responder imputation; UC: ulcerative colitis. \*P<0.05.

[Clinical Remission at Week 32 by Subgroup of Interest (ITT, NRI)]

**Conclusion:** In the TOUCHSTONE trial, ozanimod therapy was consistently more efficacious than placebo for induction of clinical remission across a wide range of patient subtypes including those with relatively long disease duration and high disease activity.

**Contact E-Mail Address:** g.dhaens@amc.uva.nl

**Introduction:** Upadacitinib (UPA), an oral selective Janus kinase 1 inhibitor, demonstrated clinical and endoscopic efficacy and a favourable safety profile as induction and maintenance treatment in patients with moderate to severe Crohn's disease (CD).<sup>1,2</sup>

**Aims & Methods:** To report the 1-year efficacy and safety results of UPA long-term treatment in the ongoing CELEST open-label extension (OLE) study.

Patients who completed the 52-week CELEST study<sup>2</sup>, either receiving double-blind or open-label rescue treatment during CELEST, were enrolled to receive the once daily (QD) UPA modified release formulation for up to 8 years; patients on double-blind therapy received 15 mg QD and those on open-label rescue therapy received 30 mg QD. Clinical remission 2.8/1.0, enhanced clinical response, CD activity index (CDAI) remission, CDAI response 70, endoscopic remission, endoscopic response 50%, Inflammatory Bowel Disease Questionnaire (IBDQ) remission, and change from baseline (BL) in C-reactive protein and faecal calprotectin, as defined in the table, were analysed at Week 0 to Month 12 (Table).

Missing data were imputed via last observation carried forward; observed-case analysis was done for the endoscopic endpoints. Adverse events (AEs) were collected throughout the study up to 30 days after the last UPA dose.

**Results:** Of 107 patients enrolled, 76 received 15 mg QD and 31 received 30 mg QD, with median (range) age of 40 (19, 76) years and disease duration 10.4 (1.4, 47.4) years. At Week 0, the mean (SD) UPA exposure was 303.0 (108.8) days. Overall, the number of patients with clinical remission, clinical response, endoscopic remission, endoscopic response, and reporting IBDQ remission was maintained from Week 0 to Month 12 (Table).

Incidences of AEs were 75.0% and 83.9% for UPA 15 and 30 mg QD groups, respectively. AEs leading to discontinuation of study drug were 6.6% in the UPA 15 mg and 19.4% in the UPA 30 mg QD groups. Serious AEs occurred in patients receiving UPA 15 mg QD (10.5%) and UPA 30 mg QD (12.9%).

The most frequently reported serious AE (4.7%) and AE leading to study drug discontinuation (4.7%) was CD. One case of serious infection was reported in each of the UPA treatment groups. Herpes zoster was reported in patients receiving UPA 15 mg QD (1.3%, n=1) and UPA 30 mg QD (6.5%, n=2). One case of malignancy (basal cell carcinoma) occurred in the UPA 15 mg QD group and one case of latent tuberculosis in the UPA 30 mg group.

No cases of opportunistic infection, thromboembolic event, or death were reported.

**Conclusion:** The 1-year efficacy of UPA observed after induction and maintenance was sustained in patients with CD. No new safety signals were identified.

<sup>a</sup>Last observation carried forward analysis; <sup>b</sup>Observed cases analysis; <sup>c</sup>Baseline (BL) of the CELEST study

For the LOCF analysis, any missing data was mainly due to (1) discontinuation, (2) missing visit (3) loss of data due to technical reason, e.g., ePro malfunction. During the study, subjects who met the criteria for inadequate response were allowed to dose escalate from 15 mg QD to 30 mg QD. In the 15 mg QD group, these subjects (N=15) were removed from the 15 mg QD analysis after dose escalation visit.

UPA=upadacitinib; QD=once daily; CDAI=Crohn's disease activity index; CR=CDAI response; IBDQ= Inflammatory Bowel Disease Questionnaire; hs-CRP=high sensitivity C-reactive protein; FCP=faecal calprotectin

Clinical remission 2.8/1.0: very soft/liquid stool frequency (SF)  $\leq 2.8$  and abdominal pain (AP) score  $\leq 1.0$ , both not worse than BL in patients with SF $\geq 4$  or AP score  $\geq 2.0$  at BL of CELEST study  
Enhanced clinical response:  $\geq 60\%$  reduction from BL in SF or  $\geq 35\%$  reduction from BL in AP and both not worse than BL of CELEST study  
CDAI remission: CDAI  $< 150$   
Endoscopic remission: Simplified Endoscopic Score for CD (SES-CD)  $\leq 4$  and at least 2-point reduction from BL of CELEST study and no subscore  $\geq 1$   
Endoscopic response 50%: SES-CD reduction  $> 50\%$  from BL of CELEST study or endoscopic remission  
IBDQ remission: IBDQ  $\geq 170$

*[Clinical and endoscopic endpoints at Week 0 and Month 12 in the CELEST OLE study]*

**Introduction:** The loss of response to biologic therapies in Inflammatory Bowel Disease (IBD) is common. Treatment intensification may be helpful in regaining response in up to 1/3 of patients. To date, there have been no studies comparing the need for escalation between different biological therapies.

**Aims & Methods:** To compare the need and predictors of therapy escalation in Crohn's Disease (CD) and Ulcerative Colitis (UC). This was a retrospective cohort single center study including patients under maintenance therapy with Infliximab (IFX), Adalimumab (ADA), Golimumab (GLB) or Vedolizumab (VDZ). Patients with at least 2 years of follow-up were included. Non-responders and patients with treatment interruption prior to the need of escalation were excluded.

**Results:** 344 patients were included: 258 with CD and 86 with UC; 51.7% were male with mean age of 43.6 $\pm$ 13 years. IFX: 229 (180 CD, 49 UC), ADA: 74 (62 CD, 12 UC), GLB: 14 (all UC) and VDZ: 27 (16 CD, 11 UC). In general, the need for treatment escalation was superior in UC (Log Rank test, p=0.001). In UC, therapeutic escalation in GLB patients was less frequent than IFX patients (p=0.035). For CD we could not find a difference in the need of escalation between drugs. In multivariate analysis age, gender, localization and behavior of the disease and combo therapy weren't predictors of the need of drug escalation during the two years of follow-up, independently of the biologic therapy used.

**Conclusion:** Therapeutic intensification is more frequent and occurs earlier in patients with UC, regardless of the treatment used.

**Disclosure:** Nothing to disclose

## P0416 USTEKINUMAB MAINTAINED CLINICALLY MEANINGFUL IMPROVEMENT IN HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH MODERATE TO SEVERE CROHN'S DISEASE: RESULTS FROM THE IM-UNITI LONG-TERM EXTENSION

**Introduction:** The IM-UNITI study evaluated the safety and efficacy of subcutaneous (SC) ustekinumab (UST) maintenance therapy in patients with moderately to severely active Crohn's disease (CD) who completed induc-

tion treatment with UST. Previously, we reported the effects of UST on health-related quality of life (HRQoL) through Wk44. Here, we evaluated HRQoL through Wk140 in patients who entered the long-term extension of the IM-UNITI study.

**Aims & Methods:** Patients who completed the safety and efficacy evaluation at Wk44 of the maintenance study were eligible to continue their regimen in the extension study (placebo [PBO], UST 90 mg q12w, or UST 90 mg q8w). All patients who were treated in the extension study were included in this analysis of Inflammatory Bowel Disease Questionnaire (IBDQ) and SF-36 data according to the treatment they received during the extension study. The IBDQ is a 32-item questionnaire with 4 dimensions: bowel symptoms, systemic symptoms, emotional function, and social function. The total score ranges from 32 to 224, higher scores indicate better quality of life, and a change  $\geq 16$  points was defined as clinically meaningful. For SF-36, a change  $\geq 5$  points was defined as clinically meaningful.

**Results:** For patients who entered the extension, mean total IBDQ scores and SF-36 scores at maintenance baseline were comparable across treatment groups (Table). Patients who received UST maintained the improvement in IBDQ and SF-36 that was achieved by maintenance baseline through Wk140, and those who received PBO generally worsened. Through Wk140, 26.5% of patients receiving PBO, 61.5% of patients receiving UST 90 mg q12w, and 59.3% of patients receiving UST 90 mg q8w had  $\geq 16$ -point improvements from induction baseline in IBDQ score. In addition, 10.9%, 51.6%, and 54.2%, respectively, had  $\geq 5$ -point improvements in SF-36 physical component summary scores, and 8.7%, 43.8%, and 43.7%, respectively, had  $\geq 5$ -point improvements in SF-36 mental component summary scores during the same period.

**Conclusion:** In patients who entered the long-term extension of the IM-UNITI study, those who received SC UST maintenance generally maintained improvements in IBDQ and SF-36 scores that were achieved through IV induction, and those who received PBO gradually lost these improvements.

Outcome	Placebo SC	Ustekinumab 90 mg SC q12w	Ustekinumab 90 mg SC q8w
Patients who entered the long-term extension, n	151	213	354
IBDQ maintenance baseline score, mean (standard deviation)	165.0 (32.04)	148.0 (36.15)	151.8 (36.61)
IBDQ change from baseline to Week 140, mean (standard deviation)	0.8 (37.12)	19.2 (40.65)	17.6 (40.36)
SF-36 physical component maintenance baseline score, mean (standard deviation)	45.85 (7.200)	43.65 (8.189)	43.77 (8.291)
SF-36 physical component change from baseline to Week 140, mean (standard deviation)	1.19 (8.091)	3.52 (8.378)	3.90 (8.132)
SF-36 mental component maintenance baseline score, mean (standard deviation)	46.29 (10.765)	42.51 (11.466)	43.82 (11.253)
SF-36 mental component change from baseline to Week 140, mean (standard deviation)	-0.30 (11.126)	3.76 (10.712)	1.95 (11.784)

\*Patients who had prohibited CD-related surgery or discontinued study agent due to lack of efficacy or due to an adverse event of worsening CD before week 140 had their induction baseline value carried forward or were considered not to have achieved the  $\geq 16$ - or  $\geq 5$ -point improvement. Patients who had insufficient data at week 140 had their last value carried forward.

[Table: Inflammatory Bowel Disease Questionnaire (IBDQ) and SF-36 scores through Week 140 in patients who entered the long-term extension study\*]

**Introduction:** In the real-world settings, few studies have focused on the short-term effectiveness of adalimumab (ADA) therapy in patients with ulcerative colitis (UC). In particular, determination of demographic features of patients with UC who rapidly respond to ADA are relevant clinical issues, but are currently unknown. We report results from our Adalimumab Multi-centre Cohort Study on Effectiveness in Patients with Ulcerative Colitis (ADVENTURE).

**Aims & Methods:** In the ADVENTURE study, our major interests were to investigate the short-term effectiveness of ADA therapy in patients with UC and understand the relevant prognostic factors. This was a retrospective, multi-centre, cohort study involving seven institutes in Japan, compiling data from patients with UC who had received at least one induction dose of 160 mg of ADA between June 2013 and May 2017. Patients had to have a Litchiger clinical activity index (CAI) score of  $\geq 5$  at the initial ADA administration. The CAI scores were analysed at baseline, at 2 and 12 weeks after the initial ADA administration. Remission was defined as CAI score  $\leq 4$ , while response was defined as a decrease of  $\geq 50\%$  relative to baseline. Rapid responder was defined as a patient who achieved response at 2 weeks. The related prognostic factors in rapid responders were determined using univariate and multivariate logistic regression analyses. Receiver operating characteristic (ROC) curves were also constructed, and the area under the ROC curve (AUC) was calculated to determine the cut-off value for the prognostic factors of rapid response. Additionally, we looked at the rate of remission at 12 weeks in rapid responders, stratified by the identified prognostic factors.

**Results:** A total of 91 patients were included in this study (median age, 37.9 years; 37 female), and median duration of UC was 3.3 years. At baseline, the median CAI score was 9, and the median platelet count was  $300 \times 10^9/L$ . Prior to initiation of ADA therapy, 32 patients had previously been exposed to infliximab (IFX). Of the 91 patients, 37.4% and 45.1% achieved response at 2 weeks and remission at 12 weeks. Among these 34 rapid responders, 82.4% (28 of 34) achieved remission at 12 weeks. Multivariate logistic regression analysis identified a higher platelet count as an independent prognostic factor for a higher rate of rapid response. Likewise, ROC curve showed that a platelet count cut-off value  $\geq 312 \times 10^9/L$  (AUC = 0.725; 95% confidence interval, 0.614-0.836) was associated with a rapid response (73.7% specificity, 70.6% sensitivity). In the univariate analysis, the rate of rapid response with platelet count  $\geq 312 \times 10^9/L$  (61.5%) was significantly higher than with platelet count  $< 312 \times 10^9/L$  (19.2%) ( $P < 0.001$ ).

Further, patients with platelet count  $\geq 312 \times 10^9/L$  showed significantly more rapid responses in both IFX-naïve (61.5% vs. 27.3%,  $P = 0.016$ ) and IFX-exposed patients (61.5% vs. 5.3%,  $P = 0.001$ ), while the proportion of rapid responders in IFX-exposed patients with platelet count  $< 312 \times 10^9/L$  was only 5.3%. Similarly, 5.3% of the IFX-exposed patients with platelet count  $< 312 \times 10^9/L$  achieved remission at 12 weeks.

**Conclusion:** Approximately 40% of patients with UC showed a rapid response to ADA therapy after 2 weeks. Up to an 80% of the rapid responders also achieved remission at 12 weeks. The rate of rapid response was significantly higher in patients with platelet count  $\geq 312 \times 10^9/L$ . However, in this study we found that both rapid response and remission at 12 weeks were difficult to attain, especially in the IFX-exposed patients with a platelet count of  $< 312 \times 10^9/L$ .

## P0418 ASSESSING THE LEVEL OF UNMET NEED AMONGST ULCERATIVE COLITIS PATIENTS IN THE UNITED STATES AND EUROPE

Kershaw J.<sup>1</sup>, Lucas J.<sup>1</sup>, Naessens D.<sup>2</sup>

<sup>1</sup>Adelphi Group, Macclesfield, United Kingdom, <sup>2</sup>Janssen-Cilag, Beerse, Belgium

**Contact E-Mail Address:** dnaessens@its.jnj.com

**Introduction:** To assess the level of unmet need within Ulcerative Colitis (UC) patients currently prescribed biologic treatment and patients prescribed conventional treatments in Europe and the USA.

**Aims & Methods:** This is a real-world survey of treating Gastroenterologists and their consulting UC patients conducted in 2017 after the introduction of vedolizumab to the UC market. Patients were included from France, Germany, Italy, Spain, the United Kingdom and the United States of America. Physicians completed patient record forms for the next seven eligible adult patients diagnosed with UC. Patient record forms contained details on patient demographics, clinical factors, satisfaction with control of condition and details on current treatment received. Only patients with a diagnosis of moderate-to-severe disease severity were included in the analysis. Patients currently receiving biologic treatment with a duration over 3 months allowing time for response to treatment were compared to patients receiving conventional treatments.

**Results:** A total of n=1714 patients from the EU and n=619 from the US were included in the analysis. In the EU n=522 / US n=182 of UC patients were currently receiving biologic treatment and EU n= 1049 / US n=389 were currently receiving conventional treatment. Physicians reported in the EU 34% / US 42% of biologic patients were not currently in remission, EU 44% / US 57% for conventional patients. 36% of biologic patients in the EU and 51% in the US had experienced in the last 12 months or were currently experiencing a flare, 36% EU and 28% US for conventional patients. In the EU 71% / US 75% of biologic patients currently experienced symptoms, suffering a mean EU 3.2 / US 3.3 symptoms. For conventional patients EU 77% / US 85%. Patients with symptoms suffered a mean of EU 3.8 / US 3.3 symptoms.

**Conclusion:** A high proportion of UC patients receiving conventional treatments were not classed as currently being in remission by their physician, were currently experiencing symptoms and had currently or had suffered from a flare in the last 12 months. This was similar for patients who were currently receiving biologic treatment despite the introduction of vedolizumab to the market.

**Contact E-Mail Address:** fraser.cummings@uhs.nhs.uk

**Introduction:** Biosimilar infliximab products have become part of routine clinical care for patients with IBD. As part of the regulatory process, the European Medicines Agency compare a biosimilar product with the originator molecule but do not compare biosimilar products with each other. The introduction of multiple biosimilar products into clinical practice means that patients maybe asked to transition from one biosimilar product to another. Whilst Remicade™, CT-P13 and SB2 have been compared in a laboratory setting<sup>1</sup>, there is a paucity of clinical outcome data, as well as data on the patient experience of this process. The aim of this study is to assess the outcome of transitioning a cohort of IBD patients from CT-P13 to SB2 in a real world setting.

**Aims & Methods:** IBD patients treated with CT-P13 6 or 8 weekly at a dose of 5mg/kg at Southampton General Hospital were approached to participate in the study. After giving informed consent, at their next routine infliximab infusion they were transitioned to SB2. Demographics, disease history, disease activity scores (mHBI or partial Mayo), IBD Control PROM<sup>2</sup>, adverse events and FBC, UE, CRP, and LFTs were collected at baseline and week 16/18 (depending on the infusion regime). A historical cohort of CT-P13 patients was used to assess drug persistence. SAS was used to conduct the analysis. Data is presented as mean +/- standard deviation. t-Test was performed to compare outcomes at week 0 and week 16/18.

**Results:** 133/144 patients approached (105 CD, 28 UC) participated in the study with a mean duration of disease of 9.64 +/- 8.96 yrs and had been treated with infliximab for 2.96 +/- 2.72 years. 89/133 were on immunomodulators. The mean mHBI and partial Mayo scores at week 0 vs week 16/18 were 3.13 +/- 3.31 vs 3.15 +/- 3.17 (p=0.32) and 1.53 +/- 1.75 vs 0.91 +/- 1.64 (p=0.15) respectively. The overall disease control component of the IBD control PROM at week 0 and week 16/18 for CD and UC were 74.99 +/- 23.4 vs 78.09 +/- 19.27 (p=0.66) and 76.22 +/- 23.80 vs 81.57 +/- 21.21 (p=0.49) respectively. The treatment specific components of the IBD-Control PROM (Q1b, 3f, 4a, 4b and 4c) showed no significant differences between Week 0 and Week 16/18. 7 patients stopped treatment due to therapeutic failure, 6 due to adverse drug reactions, 2 withdrew consent, 2 were lost to follow up and 1 for other reasons. There was no significant difference in drug persistence between a historical CT-P13 treated patient cohort and the SB2 treated patients in this study.

**Conclusion:** The advent of multiple biosimilar infliximab molecules means patients maybe asked to consider transitioning from one biosimilar to another biosimilar. There are considerably challenges to demonstrate the safety of interchangeability of multiple switches between different biosimilar products. This study has set out examine the outcomes of transitioning from one biosimilar to another biosimilar in a real world cohort of patients. This data suggests that there does not appear to be a detrimental effect on patient outcomes as assessed by disease activity, the treatment specific domains of the IBD-control PROM and drug persistence for at least 4 months. Further longer term data is required in multiple large cohorts of patients to confirm this finding as well as examine the outcomes of multiple switches between biosimilar products.

## P0420 OPTIMIZATION OF DOSES OF THIOPURINIC DRUGS (AZATHIOPRINE AND MERCAPTOPYRINE) IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER TREATMENT COMBINED WITH ANTI-TNF ALPHA (INFLIXIMAB/ADALIMUMAB)

Lucas Ramos J.<sup>1</sup>, Suárez Ferrer C.<sup>2</sup>, Martín-Arranz M.D.<sup>3</sup>, Poza Cordon J.<sup>3</sup>, Martín-Arranz E.<sup>3</sup>, Andaluz Garcia I.<sup>1</sup>, Yebra Carmona J.<sup>1</sup>, Mora Sanz P.<sup>1</sup>  
<sup>1</sup>Hospital La Paz, Madrid, Spain, <sup>2</sup>Hospital Puerta de Hierro Dept. de Gastroenterología, Madrid, Spain, <sup>3</sup>Hospital La Paz, Gastroenterology, Madrid, Spain

**Contact E-Mail Address:** jlucasr77@gmail.com

**Introduction:** The combination of Anti-TNF drugs with thiopurinic drugs in the treatment of IBD, has shown greater clinical efficacy<sup>1</sup>, serum drug levels in therapeutic range in a higher proportion of patients, and less antibody formation, than monotherapy with Anti-TNF<sup>2,3</sup>. However, the dose of the thiopurinic drug in combined treatments has not been clearly established. Some authors consider that this dose could be lower than that used in monotherapy<sup>4</sup>(2.5 mg/kg/day).

**Aims & Methods:** A retrospective study was performed, selecting all patients with established diagnosis of IBD in follow-up at the IBD Unit of the Hospital La Paz, from 2006 to 2018, who were on combined maintenance treatment with azathioprine and Anti-TNF. 91 patients were recruited for treatment with infliximab and 52 for treatment with adalimumab. Two groups of patients were established for both infliximab and adalimumab, one with the standard dose (2-2.5 mg/kg) and one with a lower dose (less than 2 mg/kg). The main objectives are to evaluate the clinical and pharmacokinetic response: through the measurement of the levels of the biological drug and the formation of anti-drug antibodies(ADA), as well as the loss of clinical response (defined as the need to intensify or change the treatment). As secondary variables, PCR and fecal calprotectin are determined.

**Results:** In the adalimumab group, there are no statistically significant differences in remission rates, response without remission, or failure depending on the dose of thiopurines (adequate or low). If we join response and remission in the same group (efficacy versus failure), the low dose group and the standard dose group also showed no statistically significant differences. There are no differences between PCR and calprotectin levels among patients with optimal doses of thiopurines and low doses. The last determinations of mean adalimumab levels were not significantly different between groups. No ADA formation was detected.

In the infliximab group, there is no statistically significant difference in remission, response or failure rates depending on the dose of thiopurines (adequate or low). If we compare efficacy vs failure, there are no statistically significant differences depending on the dose of thiopurines. There are no differences between the levels of PCR and fecal calprotectin, nor in the formation of ADA; nor in the last two determinations of mean infliximab levels among patients with optimal doses of thiopurines vs lower doses. If we consider pharmacokinetic failure (infliximab levels < 1000 ug/ml and/or ADA), there were also no statistically significant differences(p=0.063).

**Conclusion:** Consistent with the findings of other studies, there are no differences in the pharmacokinetic characteristics or in the responses of patients with the biologic treatment combined with thiopurine a standard dose with respect to the group with low dose (< 2 mg/kg). The use of a lower dose of Azathioprine can provide a better tolerance of the drug, a better safety profile, and lower economic cost.

## P0421 META-ANALYSIS: DEEP REMISSION IN IBD WITH ANTI-TNF AGENTS

Alipour O.<sup>1</sup>, Gulati A.<sup>1</sup>, Shao L.<sup>1</sup>, Zhang B.<sup>2</sup>

<sup>1</sup>University of Southern California, Gastroenterology and Liver Diseases, Los Angeles, United States, <sup>2</sup>University of California, Department of Medicine, Division of Gastroenterology, San Francisco, United States

**Contact E-Mail Address:** omeedalipour@gmail.com

**Introduction:** Clinical remission and mucosal healing have been therapeutic targets in the treatment of inflammatory bowel disease (IBD). However emerging paradigms suggest deep remission (DR) as an impactful and achievable goal of therapy. Although there is no consensus on the definition of deep remission, many authors consider clinical remission with mucosal healing with or without additional criteria as deep remission. Achieving deep remission may positively impact the long-term trajectory of disease. This meta-analysis aims to determine the rate of deep remission with anti-TNF agents, the oldest and most utilized biologics therapy.

**Aims & Methods:** Using the search terms ("inflammatory bowel diseases" OR "IBD" OR "crohn\*" OR "ulcerative colitis" OR "UC" OR "colitis") AND ("mucosal healing" OR "deep remission" OR "complete remission" OR "full remission" OR "endoscopic remission"), 7,514 articles and abstracts were identified between Pubmed and EMBASE on October 1, 2018. Inclusion criteria were adult IBD patients treated with anti-TNF medications, with report of achieving deep remission defined as at least clinical remission and mucosal healing or endoscopic remission. Exclusion criteria were studies focusing on pediatric patients, reporting < 10 patients, and non-

[P0420Table 1. Results of the study according to the doses of thiopurines]

English publications. Publications were independently reviewed for inclusion by two authors. A third author reviewed studies not agreed upon. Statistical analysis was performed using OpenMetaAnalyst.

**Results:** 14 peer-reviewed manuscripts, two of which were randomized control trials, with 1248 total cases were included. Most patients were treated with infliximab (IFX) or adalimumab (ADA). Length of follow-up ranged from 10 to 138 weeks. Overall, 37.7% (509/1248, CI 0.267-0.488) of patients achieved deep remission with anti-TNF medications. Rates of DR ranged from 7% to 63%. There was significant heterogeneity ( $I^2=94.82\%$ ,  $P<0.001$ ). In sub-analysis, 37.1% of patients with CD and 50.3% with UC achieved deep remission. 40.1% of patients on ADA and 41.1% on IFX achieved deep remission. Two studies (Magro 2016, Kaymak 2018) with histologic remission as a criteria reported only 10.1% (13/129) rate of deep remission combined.

#### [Studies Reporting Rates of Deep Remission with Anti-TNF Agents]

**Conclusion:** This study systematically reviewed the effect of Anti-TNF agents on achieving deep remission. Anti-TNF agents achieved deep remission in IBD in 37.7% of patients, with rates similar between adalimumab and infliximab. Unfortunately, a lack of available trials precludes the comparison of IFX and ADA in UC and CD. A limitation is the heterogeneity amongst studies, including reported findings, variable definitions of deep remission, length of follow up, and concomitant medications such as immunomodulators. Future studies comparing anti-TNF agents to newer biologics with other mechanisms of action may elucidate the best treatment approach for achieving deep remission.

## P0422 A LARGE POOLED SAFETY ANALYSIS OF 3 POST-MARKETING STUDIES CONDUCTED IN INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH BIOSIMILAR INFlixIMAB (CT-P13)

Lee S.<sup>1</sup>, Baek K.<sup>1</sup>, Lee Y.<sup>1</sup>, Lee S.<sup>1</sup>, Kim H.<sup>2</sup>, Lee S.G.<sup>1</sup>, Park J.E.<sup>1</sup>

<sup>1</sup>Celltrion, Incheon, Korea (Republic of), <sup>2</sup>Celltrion Healthcare, Incheon, Korea (Republic of)

**Contact E-Mail Address:** sangjoon.lee@celltrion.com

**Introduction:** CT-P13 (biosimilar infliximab) has well established its place in the treatment of rheumatoid diseases and Inflammatory Bowel Disease (IBD) in the European Union (EU) since gaining marketing authorisation in 2013. However, real-world safety data of patients with Crohn's Disease (CD) and Ulcerative Colitis (UC) receiving infliximab biosimilar in the EU are limited. This analysis presents a pooled analysis of available UC and CD safety data from 3 open-label post-marketing studies.

**Aims & Methods:** The primary objective of the analysis was to evaluate adverse events of special interest (AESIs) in patients with IBD in a real-world setting. Safety data from the Pfizer CONNECT-IBD study (13 EU countries), the Celltrion CT-P13 4.3 registry (5 EU countries) and Celltrion CT-P13 KO-

REA PMS were collected up to the data cut-off date of 27 December 2017. Descriptive analyses are presented for the safety population ( $\geq 1$  dose of CT-P13). Overall, 2813 patients were included in the safety analysis of which 2,215 patients (78.7%) were from the EU.

**Results:** A total of 999 UC and 1814 CD patients were included in the safety population. Mean age was 41.6 and 35.8 years and the mean treatment duration of CT-P13 was 264.6 and 266.4 days in UC and CD patients, respectively. EU patients constituted 76.0% (759 patients) of the UC and 80.3% (1456 patients) of the CD population. Thus, the results of this analysis can be considered representative of real-world CT-P13 (biosimilar infliximab) safety data from the EU. Overall, 27.43% and 27.78% of UC and CD patients, respectively, experienced at least 1 treatment-emergent adverse event (TEAE) and 10.01% and 10.92% of UC and CD patients, respectively, experienced at least 1 treatment-emergent serious adverse event (TESAE). A total of 8.81% and 5.68% patients discontinued treatment due to TEAEs in UC and CD patients respectively. Three deaths (attributed to sudden heart death, sepsis and unknown cause, 1 each) were reported among the UC patients and 1 death attributed to rupture of aneurysm of the abdominal aorta was reported among the CD patients.

Incidences of AESIs are included in Table 1 and are aligned with the known safety profile of the reference product as described in the literature and Summary of Product Characteristics (SmPC)

(<sup>1, 2, 3, 4, 5</sup>). More specifically, active TB was reported in 2 patients (0.20%) and 4 patients (0.22%) in the UC and CD population, respectively. Of the 6 patients, 1 patient was from Portugal and the remaining 5 patients were from Korea. Incidences of active TB and serious infections including TB were within the range of the reference values from observational studies of the reference product (incidence of active TB: 0.7% and 1.18%; incidence of serious infection: 8.16% and 7.3%) (<sup>1, 2, 3</sup>).

AESI	UC (N = 999)	CD (N = 1814)
Serious Infection including TB	24 (2.40%)	40 (2.21%)
Active TB	2 (0.20%)	4 (0.22%)
Serum sickness	1 (0.10%)	0
Haematologic reactions	4 (0.40%)	23 (1.27%)
Systemic lupus erythematosus/ lupus-like syndrome	1 (0.10%)	3 (0.17%)
Non-haematologic malignancy	5 (0.50%)	7 (0.39%)
Hepatobiliary event	4 (0.40%)	7 (0.39%)
Intestinal or perianal abscess	NA	31 (1.71%)

[Table 1. Incidence of AESIs]

**Conclusion:** Incidence of AESIs, including active TB and serious infection, among IBD patients treated with CT-P13 in the 3 post-marketing studies were low and consistent with the known safety profile of infliximab. The pooled safety analysis suggests a favourable benefit-risk balance and safety profile for IBD patients treated with CT-P13 in EU.

**Contact E-Mail Address:** doronsh90@gmail.com

**Introduction:** Psychological stress in Crohn's disease (CD) triggered symptomatic activity independently of calprotectin levels (Targownik 2015). Patients with active CD had significantly more stress than those in remission (Sarid 2018). We examine whether cognitive behavioral intervention (CBI) can reduce psychological stress as well as disease symptoms in CD.

**Aims & Methods:** Unselected adults (≥18 years) with active CD attending routine follow-up at a university hospital were randomized to enter a stress reduction CBI program combining cognitive behavioral and mindfulness techniques, or act as controls. CBI was taught by trained social workers in 8 on-line sessions, delivered one-to-one for 1 hour weekly over 8 weeks. Home practice twice daily with feedback to an application was required. Disease activity was measured by Harvey-Bradshaw Index (HBI) and psychological stress by the Brief Symptom Inventory (BSI), at entry and at 3 months follow-up. The BSI assesses 53 symptoms in categories of Somatization, Obsessive-Compulsive, Interpersonal Sensitivity, Depression, Anxiety, Hostility, Phobic Anxiety, Paranoid Ideation and Psychoticism. Combining the category scores yields the Global Severity Index (GSI). BSI range is 0-4; a higher score indicates more stress.

**Results:** The cohort comprised 41 patients: mean age 35 years, BMI 22.7, disease duration 5.5 years, 63.4% female, 78% with higher education, 88% non-smokers. Median HBI was 8.0 (range 5-16). Twenty patients were taught CBI and 21 were controls. There were no differences in age, gender, education, smoking habit and disease severity between the groups. In CBI patients there was a large reduction of HBI at 3 months, and significant decreases in all category scores except anxiety and paranoid ideation. In controls the drop of HBI was minor, and category scores were unchanged or increased. The GSI score decreased significantly in CBI, but there was no significant change in controls. See Table (Wilcoxon signed-ranks test, entry vs. 3 months. \*p<.05, \*\*p<.01).

	CBI		Controls	
	Entry	3 months	Entry	3 Months
HBI	8.0	4.0**	8.0	7.0*
Somatization	1.2	0.8*	1.1	1.3
Obsessive -Compulsive	1.1	0.8*	1.8	2.1
Interpersonal sensitivity	1.0	0.4*	1.5	1.5
Depression	1.1	0.5*	1.5	1.5
Anxiety	1.1	0.8	1.7	1.7
Hostility	0.6	0.4*	0.8	0.8
Phobic anxiety	0.4	0.2*	0.8	0.8
Paranoid ideation	1.0	0.6	1.0	1.4
Psychoticism	0.9	0.2**	0.6	1.0
GSI	1.0	0.6*	1.2	1.4

[Table 1: Median HBI and BSI values in patients taught CBI versus controls]

**Conclusion:** Patients taught CBI demonstrated significant less psychological stress and diminished disease activity, whereas control subjects exhibited no improvement in stress measures and little change of disease activity. These findings may imply a role for psychological stress impacting disease activity in CD patients.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** mathurinf@hotmail.fr

**Introduction:** Endoscopic balloon dilation (EBD) is widely used to manage Crohn's disease (CD) ileal stricture. However, data of EBD on inflammatory bowel diseases (IBD) colorectal strictures are scarce.

**Aims & Methods:** We performed a retrospective study in 9 tertiary centers, including all consecutive IBD patients who underwent EBD for native or anastomotic colorectal stricture between 1999 and 2018. Outcomes were rate of technical success defined by a passable stricture at the end of the EBD, clinical success defined by a passable and asymptomatic stricture and colonic resection at the end of follow-up. Factors associated with EBD success were also investigated by logistic regression.

**Results:** Fifty-seven patients (25 women, median age: 36 years, InterQuartile Range, 31-48) were included. All patients had CD and 42 (74%) had symptomatic stricture. Regarding the 60 strictures, 52 (87%) were native and the most frequent location was left colon (27%). 39 (65%) measured less than 5 cm, 57 (95%) were non-passable by the scope and 35 (58%) ulcerated.

Among the 161 EBD performed (median number of dilatations per strictures: 1, IQR 1-3), technical success was observed in 123 (76%) EBD. One perforation occurred (0.6% per EBD and 2% per patient). After a median follow-up of 4.3 years [IQR 2.0-8.4], 24 patients (42%) underwent colonic resection, 9 (16%) had symptomatic strictures non-passable by the scope, 11 (19%) had asymptomatic non-passable strictures and 13 (23%) had asymptomatic strictures passable by the scope.

One colon lymphoma and one colorectal cancer were diagnosed (3.5% of patients), respectively on endoscopic biopsies and at the time of surgery. None factor was associated with technical, clinical success, or surgery including therapeutic modification.

**Conclusion:** EBD of CD-associated colorectal strictures is feasible, efficient and safe as more than 50% of patients avoid surgery.

## P0425 BARRIERS AND FACILITATORS IN CONDUCTING THERAPEUTIC TRIALS IN INFLAMMATORY BOWEL DISEASE: A MONOCENTRIC ITALIAN SURVEY

Giubilei L., Larussa T., Suraci E., Imeneo M., Marasco R., Abenavoli L., Luzzo F.  
 University of Catanzaro Magna Graecia, Health Sciences, Catanzaro, Italy

**Contact E-Mail Address:** lidiagiubilei83@gmail.com

**Introduction:** Anti-TNF agents and other currently available biologic drugs represent a valid therapeutic option for inflammatory bowel diseases (IBD). However, these treatments are not effective in all patients, and moreover the initial response diminishes over time. So, clinical therapeutic trials are a fundamental tool for identifying new categories of drugs useful for

ensuring clinical benefit in patients with IBD. However, a number of difficulties, still not clearly investigated, may affect the recruitment of patients in large clinical trials.

**Aims & Methods:** The aim of this survey was to assess patients' perceptions regarding their willingness to take part in clinical therapeutic trials in a local resident group of IBD patients from Southern Italy. Consecutive patients with Crohn's disease (CD) and ulcerative colitis (UC) were recruited to complete a self-administered, locally validated, questionnaire dealing with their knowledge about clinical trials and attitude towards participation. Patients also completed the Short Inflammatory Bowel Disease Questionnaire (S-IBDQ) to investigate their quality of life (QoL). Demographic and clinical data were recorded.

**Results:** Of the 132 patients who completed the survey, 38 (29%) had CD and 94 (71%) UC; 57% were male, the mean age was 47.8 (range 16-82) years and 75 (57%) had a long-standing disease (> 10 years). Sixty (45%) patients displayed active disease, 30 (23%) were currently on biologic therapy while 21 (16%) underwent surgery. More than half (65%) showed a poor QoL according to S-IBDQ. Sixty-six per cent were married or cohabiting, 20% had a family history of IBD, and 78% had a high school diploma.

Although few (16%) patients have previously participated in clinical research, 67% claimed their willingness to take part in a clinical therapeutic trial for IBD. Overall, 43% feared taking placebo, 88% would refuse if the drug had never been tested on humans, 24% were poor inclined to frequent visits, 76% were more prone to participate when the medical staff was always the same. Monetary remuneration and gastroenterologist conditioning were a motivation for participation in 34 (26%) and 27 (20%) patients, respectively.

Using multivariate analysis, the chance of taking placebo was the only significant risk factor for denying participation in a clinical trial [adjusted odd ratio (OR) 12.46, 95% confidence interval (CI) 7.81-50.73,  $p=0.000$ ] while monetary remuneration (OR:5.46, 95% CI:1.21-18.67,  $p=0.03$ ) and having the same medical staff (OR:8.46, 95% CI:2.08-20.13,  $p=0.02$ ) were predictive factors of willingness to participate. Age, gender, type and duration of disease, current biologic therapy, prior participation, poor QoL, marital status, level of education, and previous surgery did not affect the decision to take part.

**Conclusion:** In a native local resident series of IBD patients more than half of the patients were willing to participate in a clinical therapeutic trial. Placebo represented a barrier to enrollment while the presence of an established medical staff and monetary compensation could be facilitative. Clinicians should pay attention to understanding the critical issues affecting enrollment in clinical IBD therapeutic trials, in order to improve their quality and optimize their management.

**Introduction:** Several studies have reported positive outcomes for efficacy measures in inflammatory bowel disease patients treated with CT-P13, an infliximab biosimilar. Still, data from follow-up periods longer than 1 year are scarce. Here, we assessed the long term data of effectiveness, loss of response, safety and immunogenicity of switching from infliximab to CT-P13 in patients with inflammatory bowel disease.

**Aims & Methods:** This was a prospective single-center observational study in patients with moderate to severe Crohn's disease (CD) and ulcerative colitis (UC) switched from infliximab original to infliximab biosimilar (CT-P13) since March 2015 and followed up to 24 months. Montreal classification status and previous/concomitant therapies were recorded (Table1). The efficacy endpoint was the change in the Harvey-Bradshaw for CD and partial Mayo score for UC. Clinical Remission was considered HBs < 4 and

partial Mayo score was ≤ 2. Changes in C-reactive protein, infliximab-drug levels, and antidrug antibodies were collected during followed up. All adverse events (AEs) were monitored.

**Results:**

Characteristics		n(%)	CI (95%)
Sex	Men // Women	51(51) // 49(49)	40.7; 61.3 // 38.7; 59.3

[Table 1. Baseline demographics/clinical characteristics]

100 patients were included (64 CD, 36 UC). Most of them (72%) remained on CTP-13 and 28% of patients discontinued the therapy due to loss of response, adverse events or remission/mucosa healing. Remission at 18 and 24 months occurred in 69.9% and 68.5% of patients, respectively. Global remission in patients with Crohn's disease was: 79.7%, 67.7%, 67.7% and 65.6% to basal remission, 12 months, 18 months and 24 months, respectively. Global remission in patients with Ulcerative Colitis was: 75.0%, 74.2%, 74.2% and 74.2% to basal remission, 12 months, 18 months and 24 months, respectively. 22% of patients received a dose increase, with remission being reached in 60% of them. HB score, partial Mayo score, C-reactive protein and infliximab-drug levels did not show significant changes. AEs were reported in 14% of patients.

**Conclusion:** Most of the patients switching from infliximab original maintained CT-P13 at 2 years of follow-up with a good profile of effectiveness and safety.

## P0427 PATIENTS' PERCEPTIONS AND UNMET NEEDS IN INFLAMMATORY BOWEL DISEASES: A MONOCENTRIC ITALIAN SURVEY

Giubilei L., Larussa T., Flauti D., Suraci E., Imeneo M., Marasco R., Abenavoli L., Luzzza F.  
 University of Catanzaro Magna Graecia, Health Sciences, Catanzaro, Italy

**Contact E-Mail Address:** lidiagiubilei83@gmail.com

**Introduction:** Inflammatory bowel diseases (IBD) significantly impact the patient's quality of life (QoL) and clinicians should be aware of patients' perspectives and needs in the everyday life.

**Aims & Methods:** The aim of this survey was to assess patients' perceptions regarding their QoL, quality of care, and satisfaction in a local resident series of IBD patients from Southern Italy. Consecutive patients with

Crohn's disease (CD) and ulcerative colitis (UC) were recruited. The survey consisted of the following self-administered questionnaires: the Short Inflammatory Bowel Disease Questionnaire (S-IBDQ), the Hospital Anxiety and Depression Scale (HADS), the Brief Illness Perception Questionnaire (B-IPQ) and a questionnaire dealing with impact of IBD on patients' life locally validated. Demographic and clinical characteristics were recorded. Multivariate logistic regression analysis (MVA) was performed to assess association between variables.

**Results:** Of the 120 IBD patients who completed the survey, 34 (28%) had CD and 86 (72%) had UC, 73 (60%) were male, the median age was 44 years (range 18-80), the mean body mass index (BMI) was  $23.7 \pm 3.2$ , and the mean disease duration was  $14 \pm 11$  years. Seventy-four (62%) per cent were married or cohabiting, 25 (20%) had a family history of IBD, and 90 (75%) had a high school diploma. Overall, 77 (64%) had poor QoL as assessed by S-IBDQ, 61 (51%) had HADS positive for anxiety/depression, the mean illness perception score was significantly high, and 46 (38%) claimed a poor sleep quality. Of 51 and 31 patients who experienced biologic agents and surgery, 63% and 74% were satisfied, respectively. Participation in therapeutic clinical would be accepted from 92% patients. Only 44 (37%) patients considered themselves satisfied with the relationship with the family doctor, while 97 (81%) trusted their gastroenterologist. Independent risk factors (adjusted odd ratio, 95% confidence interval) for low S-IBDQ were a poor sleep quality (5.88, CI 1.8-20.2), a positive HADS (6.31, CI 1.93-20.6) and a high illness perception (1.13, CI 1.05-1.2). At MVA, age, gender, BMI, type and duration of disease, biologic therapy, surgery, marital status, and level of education did not affect S-IBDQ score.

**Conclusion:** In a local resident setting of IBD patients from Southern Italy, more than half reported a low QoL. This was significantly associated with anxiety/depression, high illness perception and poor sleep quality. Biologics and surgery are well accepted from IBD patients and their willingness in participating to clinical trials claimed. Relationship with family doctors should be improved.

## P0428 SAFETY AND TOLERABILITY OF BIOLOGIC AGENTS IN INFLAMMATORY BOWEL DISEASE: A RETROSPECTIVE STUDY IN A TERTIARY REFERRAL CENTER

Neve V.<sup>1</sup>, Carparelli S.<sup>2</sup>, Losurdo G.<sup>2</sup>, Ierardi E.<sup>2</sup>, Barone M.<sup>2</sup>, Principi M.<sup>3</sup>, Di Leo A.<sup>2</sup>

<sup>1</sup>University of Bari, Bari, Italy, <sup>2</sup>University of Bari, Section of Gastroenterology, DETO, Bari, Italy, <sup>3</sup>Policlinico di Bari, Bari, Italy

**Contact E-Mail Address:** carparelli.sonia@gmail.com

**Introduction:** Inflammatory bowel diseases (IBD), which include Crohn's Disease (CD) and Ulcerative Colitis (UC), are chronic conditions with a relapsing-relapsing course. The main therapeutic goal in IBD patients is to induce and maintain long-term remission. Besides conventional therapy, biologic agents are widely and increasingly used. Such drugs, however, may arise safety issues due to increased risk of infections, severe infusion reactions and cancer. Therefore, we aimed to evaluate safety and tolerability of biologic drugs.

**Aims & Methods:** We retrospectively reviewed patients followed at our tertiary referral center from 1999 and 2018 and treated with biologics in order to assess the prevalence of adverse events (AE), their characteristics and predictors. We used t-test or chi-squared test for univariate analysis. We draw Kaplan-Meier curves and used Cox regression for multivariate analysis and to calculate Hazard Ratio (HR) and 95% confidence intervals (CI).

**Results:** Three hundred sixty patients were recruited (61.7% CD). They underwent 538 biologic courses overall. Male/female ratio was 209/151 and mean age was  $37.2 \pm 14.5$ . Eighty patients (14.9%) experienced an AE, mostly infusion reactions (77.5%). Additionally, we recorded 4 severe infections and one case of melanoma. AEs were significantly more frequent in UC patients compared to CD patients (19% versus 12.3%,  $p=0.03$ ). UC patients with AE had more severe partial Mayo ( $3.6 \pm 3.1$  versus  $2.3 \pm 3.0$ ,  $p<0.001$ ) and full Mayo score ( $4.9 \pm 4.1$  versus  $3.3 \pm 4.1$ ,  $p<0.001$ ) and extra-intestinal manifestations were less common (21.2% versus 33%,  $p=0.04$ ). Finally, AEs were more commonly related to infliximab (67.5% versus 41% for other biologic agents,  $p<0.001$ ).

However, at multivariate analysis, none of the following factors was independently associated to AE: UC (HR=1.6, 95% CI 0.8-3.3  $p=0.17$ ), partial Mayo (HR=1.3, 95% CI 0.9-1.7  $p=0.14$ ), full Mayo (HR=0.9 95% CI 0.7-1.2,

$p=0.66$ ), extraintestinal manifestations (HR=0.7 95% CI 0.4-1.2,  $p=0.14$ ) or type of biologic drug ( $p=0.45$ ). More details are listed in table 1.

**Conclusion:** On the basis of our data, the most common AEs of biologic therapies were hypersensitivity reactions. Although there are not single predictors of AE, probably many factors are likely to influence each other and to contribute to AE onset. Further studies are needed to assess long term safety.

**Introduction:** Ustekinumab (UST) is a fully human monoclonal antibody against IL-12/23 approved in Brazil for the treatment of moderate-to-severe Crohn's disease (CD) in November 2017. UST has demonstrated its efficacy in induction and maintenance therapy for patients with CD. Real world data regarding the efficacy and safety of UST in this population is lacking in our country. We hereby report our experience with UST in patients with moderate to severe CD.

**Aims & Methods:** A retrospective chart review and a prospective study were performed including patients from eleven IBD referral centers with moderately to severely active CD starting on UST (IV infusions followed by scheduled subcutaneous [SC] injections) between November 2017 and March 2019. We accessed clinical response and remission (based on Harvey-Bradshaw index [HBI]), fecal calprotectin (FC) and C-reactive protein (CRP) levels. Clinical response and clinical remission were defined by HBI decrease  $\geq 3$  and HBI  $\leq 3$ , respectively. Clinical remission was accessed in weeks 0, 8, 16, 24, 32, 40, 48 and 56. CRP levels were evaluated in weeks 0, 8, 16, 24, 32, 40 and 48. FC levels were evaluated in weeks 0, 8, 16 and 40.

**Results:** One-hundred and fifty-one patients were treated with UST during the study period. The mean age was 38.2 years, disease duration was 10.8 years, 57.6% had previous surgeries, 45.0% had perianal disease, 49.3% had anaemia, 55.7% were female, 15.9% were smokers. The majority of patients were treated with 90mg every 8 weeks (97.4%) during mainte-

nance. The majority of patients was previously exposed to biological therapy (87.6%). Of these, 16 patients were naïve, 38 were previously exposed to one biologic, 63 exposed to two biologics and 9 exposed to three biologics. Previous biological therapies included infliximab (n=93), adalimumab (n=88), vedolizumab (n=11) and certolizumab pegol (n=8). Mean HBI at baseline was 10.1 and 73.5% of patients had HBI higher than 3 at baseline. At baseline mean CRP was 22.7 mg/L and mean FC was 1243.3 mg/kg. At week 8, 80.2% of patients achieved clinical response and 44.9% achieved clinical remission. Clinical remission was observed in 57.4% (week 16), in 60.7% (week 24), in 69.8% (week 32), in 75.0% (week 40), in 63.8% (week 48) and in 72.0% (week 56) of patients. CRP decreased to 15.1mg/L at week 8, followed by a significant decrease until week 48 (8.1 mg/L). Sixty-three percent of the patients showed a decrease in the FC levels from baseline until week 40. However, the mean FC at week 40 was 1201.0mg/Kg, exhibiting a decrease of 42.3mg/Kg from baseline. Adverse events occurred in 28.6% of patients. Twelve patients stopped UST, three due to pregnancy, five due to a lack of response and four due to others. No new safety signals were observed.

**Conclusion:** UST therapy was successful for inducing and maintenance of clinical remission and improving laboratory biomarkers of disease activity in patients with moderate-to-severe CD and who were refractory to anti-TNF therapy. Both UST induction and maintenance regimens until week 56 were overall well tolerated. These results support a favorable safety and efficacy profile.

<sup>1</sup>Caisse Nationale Assurance Maladie, Dept. des Etudes en Santé Publique, St-Denis, France, <sup>2</sup>CHU Bicetre, Dept. de Hepato-Gastroenterologie, Le Kremlin Bicetre, France, <sup>3</sup>Hôtel Dieu, AP-HP, Biostatistique et Épidémiologie, Paris, France

**Contact E-Mail Address:** franck.carbonnel@aphp.fr

**Introduction:** CT-P13, a biosimilar of the reference product infliximab, has been approved for the treatment of ulcerative colitis on the basis of the results of trials conducted in patients with spondyloarthritis and rheumatoid arthritis.

**Aims & Methods:** The objective was to compare the effectiveness and safety of CT-P13 and the reference product in infliximab-naïve patients with ulcerative colitis.

A comparative real-life equivalence cohort study was conducted using the French nationwide health administrative database. Infliximab-naïve patients with ulcerative colitis over 15 years of age who started infliximab with no other indications for infliximab were included. The primary outcome was a composite endpoint (death, ulcerative colitis-related surgery, all-cause hospitalization and reimbursement for other biologics). Equivalence was defined as a 95% confidence interval (CI) of the hazard ratio (HR) of CT-P13 versus the reference product, in a multivariable marginal Cox model situated within prespecified margins of [0.80 to 1.25].

**Results:** 3,112 patients were included between January 1, 2015 and June 30, 2017: 1,434 received the reference product, 1,678 received CT-P13. Overall, 710 patients in the reference product group and 743 patients in the CT-P13 group met the composite endpoint. In multivariable analysis of the primary outcome, CT-P13 was equivalent to the reference product (HR 1.04; 95%CI: 0.94-1.15). The number of serious infections was lower in the CT-P13 group (HR 0.65; 95%CI: 0.48-0.88). There was no difference in the incidence of solid or hematologic malignancy (HR 0.81; 95%CI: 0.41-1.60).

**Conclusion:** The effectiveness of CT-P13 is equivalent and the risk of serious infections could be lower than that of the reference product for infliximab-naïve patients with ulcerative colitis.

**Disclosure:** Dr. Meyer, Mr. Drouin, Dr. Weill and Prof. Coste declared no conflict of interest. Dr. Rudant reports personal fees from CNAM during the conduct of the study. Prof. Franck Carbonnel received board or lecture fees from Enterome, MSD, BMS, Janssen, Pfizer, Abbvie, Mayoly Spindler, Takeda, Pileje.

**Introduction:** There are few studies on the usefulness of granulocyte and monocyte adsorptive apheresis (GMA) in elderly patients with inflammatory bowel disease (IBD). We report the result of the "Post-marketing surveillance study on the safety and response of GMA treatment in patients with Crohn's disease or ulcerative colitis with at least one special situation who received Adacolumn (PARTICULAR)".

**Aims & Methods:** The aim of this study is to investigate the safety and effectiveness of GMA in elderly patients with IBD who participated in the PARTICULAR study. This retrospective, multicentre cohort study included patients with ulcerative colitis (UC) or Crohn's disease (CD) who had at least one special situation feature and who had received GMA therapy in medical institutions of Japan between November 2013 and March 2017. Patients with at least one special situation, including elderly patients, patients with anaemia and patients on multiple immunosuppressants (IMs) were enrolled. Patients ≤64 years were excluded from this study. GMA was performed using Adacolumn (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 sessions. All adverse events (AEs) were recorded during the observation time interval. The safety of GMA was assessed in all patients. The effectiveness of GMA was assessed in patients with UC with a partial Mayo (pMayo) score of ≥3. Remission was defined as a pMayo score of ≤2, while response was defined as a decrease in the pMayo score by ≥2 points and by ≥30% decrease relative to that at baseline plus all 3 sub-scores ≤1. Patients receiving concomitant treatment with infliximab, adalimumab or calcineurin inhibitors were excluded from the effectiveness assessment.

**Results:** A total of 125 patients (118 UC, 7 CD) from 93 institutions were included. The median age was 72.0 years. Fifty-one patients did not have any special situation, and 74 had one or more special situations. The incidence rate of AEs was 11.2% in all patients. The incidence rate of AEs was significantly lower in patients without any special situation (3.9%) than in those with one or more special situations (16%). The incidence rate of AEs with the special situation subgroups were: 21.9% (7/32) in anaemic patients, 22.7% (5/22) in patients on multiple IMs, 25.0% (4/16) in patients with diabetes mellitus, 25.0% (4/16) in patients with ischaemic heart disease/arrhythmia, 20.0% (2/10) in hypertensive patients, 16.7% (1/6) in patients with dyslipidemia, 25.0% (1/4) in patients with liver dysfunction and 33.3% (1/3) patients with renal dysfunction. A univariate analysis found the occurrence of AEs significantly higher in patients with anaemia, on multiple IMs, diabetes mellitus and ischaemic heart disease/arrhythmia than in patients without any special situation. Anaemia and multiple IMs were also identified as independent predictors for a higher incidence of AEs. The effectiveness of GMA was assessed in 92 patients with UC, showing response and remission rates of 72.8% and 48.9%, respectively. The response and remission rates were slightly higher in patients without any special situation (81.0%, 52.4%) than in those with one or more special situations (66.0%, 46.0%).

**Conclusion:** A rather low incidence rate of AEs (3.9%) was identified in elderly IBD patients treated with GMA, and not displaying any special situation, while the incidence of AEs was significantly higher in patients with one or more special situation (16%), which could be attributed to anaemia or multiple IMs. Remission and response was achieved by GMA in approximately 50% and 70% of the elderly UC patients, respectively.

**Disclosure:** Hiroki Tanaka has received lecture fees from JIMRO Co. Ltd., AbbVie GK, EA Pharma Co. Ltd., Mochida Pharmaceutical Co. Ltd., Kyorin Pharmaceutical Co. Ltd. and Mitsubishi Tanabe Pharma Corporation. Taro

Osada has received research grant from JIMRO Co. Ltd. Reiko Kunisaki has received research grant from JIMRO Co. Ltd. Eiji Hosoi is employee of JIMRO Co. Ltd. All other authors have nothing to disclose.

## P0432 SAFETY OF GRANULOCYTE AND MONOCYTE ADSORPTIVE APHERESIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDERGOING CONCOMITANT TREATMENT WITH IMMUNOSUPPRESSANT MEDICATIONS: A MULTICENTRE COHORT STUDY

Miyakawa M.<sup>1</sup>, Tanaka H.<sup>1</sup>, Shibuya T.<sup>2</sup>, Osada T.<sup>3</sup>, Hosoi E.<sup>4</sup>  
<sup>1</sup>Sapporo Kosei General Hospital, IBD Center, Sapporo, Japan, <sup>2</sup>Juntendo University School of Medicine, Department of Gastroenterology, Bunkyo, Japan, <sup>3</sup>Juntendo University Urayasu Hospital, Department of Gastroenterology, Chiba, Japan, <sup>4</sup>JIMRO Co., Ltd., Tokyo, Japan

**Contact E-Mail Address:** a030086m1982@yahoo.co.jp

**Introduction:** Few studies have assessed the safety of granulocyte and monocyte adsorptive apheresis (GMA) in patients with inflammatory bowel disease (IBD) undergoing concomitant treatment with multiple immunosuppressant medications. To address this research gap, we investigated adverse events (AEs) associated with GMA in patients with IBD treated with multiple immunosuppressants who participated in the "Post-marketing surveillance study on the safety and response of GMA treatment in patients with Crohn's disease or ulcerative colitis with at least one special situation who received Adacolumn (PARTICULAR)".

**Aims & Methods:** The aim of this study is to investigate the safety of GMA in patients with IBD treated with multiple immunosuppressants who participated in the PARTICULAR study. This retrospective, multicentre cohort study included patients with ulcerative colitis (UC) or Crohn's disease (CD) who had at least one special situation feature and who had received GMA therapy in medical institutions of Japan between November 2013 and March 2017. Patients with at least one special situation, including elderly patients, patients with anaemia and patients on multiple immunosuppressants were enrolled. GMA was performed using Adacolumn (JIMRO, Takasaki, Japan). Each patients received up to a maximum of 11 sessions. All adverse events (AEs) were recorded during the observation time interval. In addition, feasibility problems (FPs) including difficulty in achieving blood access, technical problems related to the system operation during the operation of the GMA column were recorded. Any AE for which the causality of GMA could not be ruled out was classified as adverse device effect (ADE). The safety of GMA was assessed in all patients. The incidence of AEs was investigated relative to the number and type of immunosuppressants using univariate and multivariate logistic regression analyses.

**Results:** A total of 437 patients (368 UC, 69 CD; 45.5% female) from 93 institutions were included. Of these, 140, 169, 101 and 27 patients received none, 1, 2 and  $\geq 3$  immunosuppressants, respectively. Concomitant prednisolone, immunomodulators, anti-tumor necrosis factor agents and calcineurin inhibitors were administered in 189, 151, 89 and 24 patients, respectively. Among all patients, AEs, ADEs and FPs were observed in 50 (11.4%), 11 (2.5%) and 71 (16.2%) patients, respectively. AEs in  $\geq 1\%$  of patients included headache in 10 patients (2.3%), nausea/vomiting in 9 (2.1%) and fever in 6 (1.4%). The rates of AE in patients receiving none, 1, 2 and  $\geq 3$  immunosuppressant medications were 7.9%, 11.8%, 11.9% and 25.9%, respectively. In multivariate logistic regression analysis, anaemia and concomitant immunosuppressants were independently associated with the incidence of AEs. Particularly, a higher number of concomitant immunosuppressants showed an increasing trend with odds ratios related to AEs. In contrast, concomitant prednisolone were associated with a reduced risk of AEs. Nausea/vomiting and headache were the most common AEs in patients on multiple immunosuppressant medications (5.6% and 3.2%, respectively).

**Conclusion:** Concomitant treatment with immunosuppressants was independently associated with the incidence of AEs such as nausea/vomiting and headache in patients with IBD receiving GMA. As the number of concomitant immunosuppressants increased, the incidence of AEs also increased. However, our data also suggest that GMA is safe in patients with IBD receiving prednisolone.

**Introduction:** There are few treatment options that can be applied repeatedly as remission induction therapy for patients with inflammatory bowel disease (IBD). Granulocyte and monocyte adsorptive apheresis (GMA) is a treatment option for patients with IBD, which can be applied repeatedly as remission induction therapy. Nonetheless, currently, there is no report on the safety and efficacy of repeated treatment with GMA in patients with IBD. We report the result of the "Post-marketing surveillance study on the safety and response of GMA treatment in patients with Crohn's disease or ulcerative colitis with at least one special situation who received Adacolumn (PARTICULAR)".

**Aims & Methods:** The aim of this study was to assess the safety and effectiveness of retreatment with GMA in patients with IBD who participated in the PARTICULAR study. Our retrospective, multicentre cohort study included patients with ulcerative colitis (UC) or Crohn's disease (CD) who had at least one special situation feature and who had received GMA therapy at 93 medical institutions of Japan between November 2013 and March 2017. Patients with at least one special situation, including elderly patients, patients with anaemia and patients on multiple immunosuppressants were enrolled. Patients who received GMA for the first time were excluded. GMA was performed using Adacolumn (JIMRO, Takasaki, Japan). Each patients received up to a maximum of 11 sessions. All adverse events (AEs) were recorded during the observation time interval. In addition, feasibility problems (FPs) during the operation of the GMA column were recorded. The safety of GMA was assessed in all patients. The effectiveness of GMA was assessed in patients with UC with a partial Mayo (pMayo) score of  $\geq 3$ . Remission was defined as a pMayo score of  $\leq 2$ , while response was defined as a decrease in the pMayo score by  $\geq 2$  points and by  $\geq 30\%$  decrease relative to that at baseline plus all 3 sub-scores  $\leq 1$ .

**Results:** A total of 131 patients who received GMA retreatment (109 UC, 22 CD; 51.9% female) with a median age 41.0 years were included. Among all patients, 81 did not have any special situation, while 50 had at least one special situation, including 17 elderly, 18 with anemia and 24 on multiple immunosuppressants. AEs and FPs were observed in 9.9% and 8%, respectively. The FPs rate (3.7%) in the GMA retreated patients without any special situation was significantly lower than the rate (16.0%) in patients with at least one special situation ( $P=0.021$ ). The rates of AEs and FPs in the elderly, patients with anaemia and those on multiple immunosuppressants were 17.6% and 23.5%, 22.2% and 16.7% and 12.5% and 8.3%, respectively. The effectiveness of GMA retreatment was assessed in 78 patients with UC. Remission and response rates were 41.0% and 55.1%, respectively. There were no significant differences in the rates of remission (43.4% vs. 36.0%) and response (56.6% vs. 52.0%) between patients without any special situation and those with at least one special situation. Remission and response rates in 11 elderly, 8 with anemia and 8 on multiple immunosuppressants were 36.4% and 63.6%, 37.5% and 50.0% and 25.0% and 37.5%, respectively.

**Conclusion:** Relatively low rates of AEs and FPs and favourable response and remission rates were observed in patients who received GMA retreatment. The rate of FPs in patients who received GMA retreatment without any special situation was significantly lower than those with special situation. Although the rate of FPs in the elderly was relatively high, approximately 60% of the elderly patients achieved response by receiving GMA retreatment.

## P0434 REAL LIFE EFFECTIVENESS OF VEDOLIZUMAB IN PATIENTS WITH IBD: A SINGLE CENTER EXPERIENCE

Bossa F., Biscaglia G., Terracciano F., Martino G., Fontana R., Nardella M., Andriulli A.

Fondazione Casa Sollievo della Sofferenza, Gastroenterology, San Giovanni Rotondo, Italy

**Contact E-Mail Address:** f.bossa@operapadrepio.it

**Introduction:** Vedolizumab is a fully humanized monoclonal antibody that selective binds the  $\alpha 4\beta 7$  integrin, recently approved for the treatment of patients with Inflammatory Bowel Diseases (IBD). It acts blocking the migration of circulating T-lymphocytes into inflamed gastro-intestinal tissue. **Aims & Methods:** Here we present a real-life experience with patients affected with IBD treated with Vedolizumab.

All consecutive patients observed at a single Center (Gastroenterology Department of "Casa Sollievo della Sofferenza" Hospital) treated with Vedolizumab from September 2016 were included. Demographic and clinical data (age at disease diagnosis, disease location and duration, behavior, and previous therapies) were collected. We also collect clinical activity before and during therapy with Vedolizumab and concomitant medications. The clinical response to induction (valued by means of Harvey Bradshaw index and partial Mayo score for Crohn's disease and Ulcerative Colitis patients respectively) was assessed after 3 months of therapy. Persistence of therapy with Vedolizumab was also evaluated.

**Results:** A total of 68 patients (30 Crohn's Disease (CD) and 38 Ulcerative Colitis (UC)) were included. Thirty-eight patients were male (55.8%), and the mean disease duration was  $10.2 \pm 7.3$  years and  $11.8 \pm 6.8$  years for CD and UC respectively. The majority of patients had moderate activity when started Vedolizumab (90% and 86.8% of those with CD and UC, respectively). Fifty-two patients (76.5%) had been treated with Anti TNF alpha before Vedolizumab. Clinical response after three months of therapy was achieved in 22 CD patients (73%) and 33 UC patients (87%). Fifteen patients (11 CD and 4 UC) definitively discontinued Vedolizumab (9 for primary non response, 1 for intolerance, and five for loss of response after a mean of  $25 \pm 2.9$  months of therapy - range 21-30). Fifty-two patients (76.4%) are ongoing in treatment with a mean persistence of therapy of  $12.2 \pm 7.3$  months (range 1 - 33). No significant differences for clinical response rate were found between patients naïve vs previous treated with anti TNF alpha (87% vs 83%,  $p=1.0$ ), short ( $\leq 2$  years) vs long disease duration (75% vs 83%,  $p=0.6$ ), older ( $\geq 65$  years) vs younger patients (70% vs 85%,  $p=0.1$ ), and disease behavior for Crohn's disease (66.6% of patients with B1 responded to Vedolizumab vs 80% both for B2 and B3,  $p=0.3$ ).

**Conclusion:** Vedolizumab was effective in patients with IBD (both CD and UC), irrespective of previous anti TNF alpha therapy, age of patients, disease duration and disease behavior in Crohn's disease.

**Introduction:** Patients with psoriasis and rheumatologic diseases are eventually treated with biological agents using treatment schedules with more spaced administrations than those approved in data sheet. These schedules are cheaper, and they even might reduce the risk of adverse events. However, they are scarcely used in inflammatory bowel disease (IBD).

**Aims & Methods:**

**Aim:** To describe the clinical outcomes of IBD patients treated with anti-TNF agents by means of a spacing schedule (administration interval greater than 8 weeks for infliximab or 2 weeks for adalimumab).

**Methods:** Using the local databases from two referral centers, all the patients with IBD who were in clinical remission at the time they were moved to a spaced schedule with infliximab or adalimumab, were identified. Patients with ostomy or ileoanal pouch, indication of anti-TNF therapy for perianal disease, or adverse events as the main cause for spaced schedule, were excluded. The spaced schedule was considered successful if, at the end of the follow-up, the patient remained in clinical remission with the same spaced schedule or without biological therapy and if no return to the conventional schedule, dose-escalation, change to another biological agent, a course of systemic corticosteroids or surgery were required.

**Results:** 85 patients were included (58 Crohn's disease, 27 ulcerative colitis/IBD unclassified). 60 were treated with infliximab (49 every 10 weeks and 11 every 12 weeks) and 25 with adalimumab every 3 weeks. Before the spaced schedule, 38% of patients had previous courses of anti-TNF, and 7% required dose-escalation. The spaced schedule was initiated after the median of 25 months of anti-TNF treatment (IQR 14-49). Baseline C-reactive protein (CRP) was available in all patients (95% with CRP < 5mg/L). Baseline faecal calprotectin was available in 31% of patients (100% < 250  $\mu$ g/g). Morphological assessment of disease activity (colonoscopy, MRI enterography) within 6 months before the spaced schedule was available in 48% of patients (3% and 17% with endoscopic and RMI activity, respectively). 64% were on combination therapy with an immunosuppressant at the beginning of the anti-TNF. The median time on spaced schedule was 15 months (IQR 12-25). 37% of patients returned to a conventional schedule and 9% required dose-escalation. In 16 patients (19%) the anti-TNF was stopped because of sustained remission (9/22). 12 patients had available trough infliximab levels before the spaced schedule (median: 2.8  $\mu$ g/mL [IQR, 1.12-4.30]) and 21 patients after two spaced doses (median: 1.6  $\mu$ g/mL [IQR, 0.5-3.5]). 10 patients had available trough infliximab levels before and after the spaced schedule; with a significant decrease in drugs levels ( $p=0.007$ ). At the end of follow-up, 50 out of 85 patients (59%) met the success criteria of the spaced schedule. A longer time (> 5 years) from IBD diagnosis to the introduction of anti-TNF treatment (RR 2.1 [IC 95% 1.1 - 4.3];  $p=0.034$ ) and a baseline CRP >2mg/L prior to spacing (RR 3.2 [IC 95% 1.4 - 7.5];  $p=0.008$ ), were the only independent predictive factors of the failure of the spacing strategy.

**Conclusion:** Anti-TNF administration at longer intervals than those provided in the data sheet of the drug can be a convenient and cheaper alternative, particularly effective in patients in whom anti-TNF treatment was early initiated (within 5 years from disease diagnosis) and once deep remission has been achieved.

**Introduction:** Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are associated with high healthcare expenditures related to medications, hospitalisations, and surgeries. Our aim was to analyse disease outcomes and treatment algorithms in newly diagnosed IBD patients in Québec over the past 2 decades, comparing periods before and after routine public reimbursement of biologics.

**Aims & Methods:** Overall, 34644 newly diagnosed IBD patients (CD: 20644 or 59.5%; M:F CD: 3:4, UC: 1:1; CD < 40 years old: 46% vs. UC < 40 years old: 35%) were identified from the population-based health insurance database of Québec from 1996 to 2015. The primary and secondary outcomes included time to and probability of first hospitalisation and first major surgery, and medication exposures. Prescription data were collected from the public prescription database (RAMQ).

**Results:** Probability of major surgery increased after 2010 in CD (at 5 years after diagnosis: before and after 2010: 8% (SD: 0.2%) vs. 15% (0.6%);  $p < 0.0001$ ) and UC patients (6% (0.2%) vs. 10% (0.6%);  $p < 0.0001$ ). Hospitalisation rates remained unchanged, but were higher in CD compared with UC ( $p < 0.0001$ ). IBD patients on biologics had overall lower probability of hospitalisations compared with other drug types (overall 5 years probability for all IBD patients using 5-ASA: 37% (0.6%); biologics: 31% (1.8%),  $p < 0.0001$ ). Biologics were more commonly prescribed in CD after 2010 (4% (0.2%) vs. 16% (0.6%),  $p < 0.0001$ ), especially in patients less than 40 years old at diagnosis. Thiopurine exposure increased in IBD patients after 2010 (CD: 21% (0.4%) vs. 24% (0.6%)  $p < 0.0001$ ; UC: 13% (0.4%) vs. 16% (0.7%),  $p < 0.0001$ ), while methotrexate use remained overall low (overall 5 years probability in CD: 4% (0.1%); UC: 1% (0.1%);  $p < 0.0001$ ). Corticosteroid exposure was unchanged before and after 2010 (CD: 31% (0.4%) vs. 30% (0.7%)  $p=0.46$ ; UC: 31% (0.5%) vs. 34% (0.9%);  $p=0.03$ ). 5-ASA use was higher in UC (40% (0.4%),  $p < 0.001$ ), while in CD it became lower after 2010 (33% (0.4%) vs. 21% (0.6%),  $p < 0.0001$ ).

**Conclusion:** The probability of first hospitalizations remained unchanged whilst the probability of first major surgery was increased despite the higher and earlier use of biologics therapies in IBD in this large population-based inception cohort from Québec. Overall, there was a slight increase in the use of thiopurines and methotrexate, while the use of corticosteroids was unchanged.

## P0437 ANALYSIS OF UC COLECTOMY RATES IN PRE- AND POST- BIOLOGIC ERA IN LOTHIAN, SCOTLAND

Jenkinson P.<sup>1</sup>, Jones G.R.<sup>1</sup>, Plevris N.<sup>1</sup>, Lyons M.<sup>2</sup>, Kirkwood K.<sup>3</sup>, Arnott I.D.<sup>1</sup>, Lees C.W.<sup>1</sup>

<sup>1</sup>NHS Lothian, Gastroenterology, Edinburgh, United Kingdom, <sup>2</sup>University of Edinburgh, Edinburgh, United Kingdom, <sup>3</sup>NHS Lothian, Pathology, Edinburgh, United Kingdom

**Contact E-Mail Address:** philipjenkinson@nhs.net

**Introduction:** The use of biologic therapy for UC in the UK has lagged significantly behind that of Crohn's disease because of restricted guidance from NICE (NICE Clinical Guideline 166, June 2013). Following approvals of anti-TNF and vedolizumab for UC in early 2015 there has been a significant increase in prescribing. The aim of this study was to describe trends in colectomy rates for UC over time spanning the pre- and post-biologic era.

**Aims & Methods:** All patients (adult and paediatric) with a diagnosis of UC who received maintenance biologic treatment and/or underwent a colectomy in Lothian between 1st January 2005 and 31st December 2018 were identified by interrogating multiple clinical and administrative databases.

Patient phenotype, prescribing and surgical data including complications were extracted by manual review of the EHR. Operations were classified by extent of resection and by time interval from diagnosis to colectomy (early within 6 months vs established after 6 months from diagnosis). Linear regression and segmental regression assuming poisson variance were used to identify temporal changes (statistical joinpoints) in the trend of biologic prescription and colectomy rates. Biologic prescription and colectomy rates were described per 100 UC patients, with yearly prevalence data obtained from the Lothian IBD Registry (Jones et al, ECCO 2019).

**Results:** A total of 175 patients were treated with maintenance biologic therapy during the study (Table 1). Rates of initiation of maintenance biologic therapy increased from 0.05 per 100 UC patients in 2005 to 1.26 in 2018 ( $p < 0.001$ ). For the whole study period the biologic prescription annual percentage change (APC) was 30.4% (14.5-48.6% 95% CI). Rates of prescription of infliximab as rescue therapy remained at a steady state throughout the study.

A total of 448 colectomies for UC were performed during the study period (Table 1). Colectomy rates per 100 UC patients fell throughout the study period; from 1.47 colectomies per 100 UC patients in 2005 to 0.44 in 2018 ( $p < 0.001$ ). There was a significant inflection point in the rate of change with a statistical joinpoint identified in 2014. The colectomy rate APC was -4.1% per year from 2005 to 2014 and -18.9% from 2014 to 2018 ( $p=0.019$ ). There was no increase in complications in patients treated with biologics pre-operatively.

Year	UC Prevalence	Colectomies	1st Biologic prescriptions	Year	Population	Colectomies	1st Biologic prescriptions
2005	2152	32	1	2012	3164	30	2
2006	2289	35	0	2013	3279	34	5
2007	2445	33	0	2014	3415	40	13
2008	2548	32	1	2015	3566	26	32
2009	2727	36	2	2016	3678	26	28
2010	2881	46	1	2017	3798	24	39
2011	3003	37	2	2018	3876	17	49

[Table 1 UC colectomy and first maintenance biologic prescription numbers per year]

**Conclusion:** The increase in biologic prescribing for UC has been paralleled by a significant reduction in colectomy rates without increased post-operative complications. This is the first population based study that shows a reduction in colectomy rates in parallel with increased use of biologics for UC.

**Introduction:** The Rutgeerts' score (RS) grades the severity of signs of endoscopic Crohn's disease (CD) recurrence in the postoperative patient after ileocolonic resection. Although the International Organization for the

Study of Inflammatory Bowel Disease (IOBD) agreed that a RS< i2 reflects endoscopic remission, the risk of late post-operative disease recurrence in these patients remains unclear.

**Aims & Methods:** We performed a multicenter, retrospective cohort study to evaluate the risk of late post-operative CD recurrence in patients who are in endoscopic remission after ileocaecal resection. All CD patients that underwent an ileocolonic resection with curative intent between 2006-2016 were screened for eligibility in three large-volume IBD centres. Only those who had no signs of endoscopic recurrence (defined as RS< i2) at baseline assessment between month 3 and 18 after surgery were included. Post-operative recurrence during follow-up was defined as a composite endpoint of at least one of the following: clinical recurrence (i.e. new or worsening IBD-related abdominal pain and/or diarrhea), IBD related hospitalization, development of bowel damage (i.e. new intra-abdominal fistulae, abscesses and/or strictures), the need for endoscopic balloon dilatation of the anastomosis, and the need for redo-surgery. Time to disease recurrence was estimated by Kaplan-Meier analysis, and cox regression analysis was used to identify potential risk factors for recurrence.

**Results:** A total number of 86 patients (n=55 female; n=27 active smokers) were included. Median (IQR) time between CD diagnosis and ileocolonic resection was 6.1 (0.9-19.4) years. Seventeen (19.8%) patients had undergone previous surgery, while the majority (n=55, 64%) had received treatment with immunomodulators and/or biologicals before ileocolonic resection. Median (IQR) time between surgery and baseline endoscopy was 7 (5.7-9.5) months and forty (46.5%) patients received therapy with immunomodulators and/or biologicals in this period. Median (IQR) follow-up time after baseline endoscopy was 3.5 (1.6-5.3) years. Based on the composite endpoint, late post-operative CD recurrence was seen in 35 (40.7%) patients (Table 1). Recurrence status was comparable between patients with RS of i0 (20/55) or i1 (15/31) at baseline endoscopy (p=0.28), and independent whether or not patients had received medical therapy between surgery and baseline endoscopy (16/40 with therapy vs. 19/46 without therapy; p=0.9). Median (IQR) time to disease recurrence was 14.2 (6.3-26.1) months. No risk factor for late post-operative CD recurrence could be identified after bivariate cox regression analysis.

**Conclusion:** This is the first study looking at the risk of late post-operative CD recurrence after ileocaecal resection with curative intent. It was seen in up to 40% of patients despite initial endoscopic remission, and continuous follow-up of this population remains therefore warranted.

Outcome parameter	Yes	No
Clinical recurrence, % (n)	36 (31)	64 (55)
IBD-related hospitalization, % (n)	15.1 (13)	84.9 (73)
Need for endoscopic balloon dilatation, % (n)	4.7 (4)	95.3 (82)
New intra-abdominal bowel damage, % (n)	16.3 (14)	83.7 (72)
Need for IBD-related surgery, % (n)	3.5 (3)	96.5 (83)
Composite endpoint, % (n)	40.7 (35)	59.3 (51)

**Contact E-Mail Address:** ymstmstktbssr@ac.auone-net.jp

**Introduction:** Studies on the natural history of Crohn's disease (CD) show that up to 50% of CD patients require their first intestinal resection within 10 years of diagnosis. In recent years, immunomodulators (IM) and anti-tumour necrosis factor (TNF) agents have become available and used to treat CD worldwide, but currently, there is inadequate information regarding the need when the first intestinal resection should be undertaken.

**Aims & Methods:** The aim of this study was to investigate the time when the first intestinal resection becomes necessary after the diagnosis of CD and understand the relevant prognostic factors including concomitant administration of IM or anti-TNF agents. We retrospectively compiled and reviewed the data on patients with CD who had been treated at our hospital between January 2010 and December 2012. Patients who were diagnosed with CD prior to 1989 and had undergone intestinal resection before the diagnosis of CD were excluded. All patients were followed until the initial intestinal resection was done or until March 2019. Patients who were lost to follow-up were censored. Patients were divided into two groups according to the year of CD diagnosis (Group A, 1990-2001; Group B, 2002-2012). Between groups A and B, patients' demographic variables were compared using univariate analysis. Further, the cumulative rates of the initial intestinal resection following the diagnosis of CD in the two groups were evaluated using the Kaplan-Meier method together with the log-rank test.

**Results:** A total of 291 patients, median age, 21.7 years; 93 female were available for evaluation. At the diagnosis of CD, 157 patients had ileocolitis, 84 had ileitis and 50 had colitis. Two-hundred and two patients were diagnosed with non-stricturing, non-penetrating disease, 75 with stricturing disease and 14 with penetrating disease. Perianal disease was diagnosed in 159 patients. During the observation period, concomitant prednisolone, IM (azathioprine or 6-mercaptopurine) and anti-TNF agents (infliximab or adalimumab) were administered to 72, 162 and 177 patients, respectively. Among the 291 patients, 125 were assigned to Group A and 166 to Group B. The proportion of the patients diagnosed with non-stricturing, non-penetrating disease, stricturing disease and penetrating disease were 60%, 33% and 7% in Group A and 77%, 20% and 3% in Group B, respectively indicating that the number of patients with non-stricturing, non-penetrating disease in Group B significantly increased compared to Group A, while patients with stricturing and penetrating disease decreased compared with Group A (P = 0.008). Patients who had received concomitant treatment with prednisolone were significantly lower in Group B than in Group A (19% vs. 34%, P = 0.007), while patients on concomitant IM or anti-TNF agents were significantly higher in Group B than in Group A (IM: 66% vs. 42%, P < 0.001; anti-TNF agents: 78% vs. 44%, P < 0.001). Further, the cumulative rates of 1, 5, 10 and 15 years intestinal resection were 16%, 29%, 47% and 57% in Group A and 8%, 15%, 21% and 24% in Group B, respectively showing that the cumulative rates of intestinal resection in Group B were significantly lower than in Group A (P < 0.001).

**Conclusion:** This study showed a significant reduction in the rates of initial intestinal resection in patients with CD diagnosed during 2002-2012 than those diagnosed during 1990-2001. It is assumed that a decrease in patients with stricturing and penetrating disease and an increase in IM and anti-TNF agents use may have contributed to the decrease in the intestinal resection rate beyond 2001.

**Contact E-Mail Address:** angela.variola@sacrocuore.it

**Introduction:** Total mesorectal excision (TME) is the gold standard resectional strategy for rectal cancer. In benign diseases so called close rectal dissection (CRD), has been traditionally advocated to minimize damage to pelvic neural plexuses and complications reducing dead space, compared to TME. In daily practice laparoscopic CRD has never spread because affects a worse visualization, a chopsticks conflict and a more difficult hemostasis. Transanal approach bottom to up to the pelvis (taCRD) could allow a better visualization and an easily and safer hemostatic control.

**Aims & Methods:** Aim of the study was to evaluate safety and feasibility of TaCRD proctectomy in our inflammatory bowel diseases (IBD) cohort. From January 2016 to December 2018 prospective colorectal disease database maintained at IRCCS Sacred Heart - Don Calabria Hospital of Negrar was required to identify patients underwent taCRD proctectomy for IBD). Transanal platform of choice was Gel Point Path™. We analyzed all clinical and operative data.

**Results:** Nineteen patients (median age 43,6 ± 11,4, male/female 13/6, median BMI 22,3 ± 3), 16 with ulcerative colitis (UC) and 3 with Crohn's disease (CD). TaCRD proctectomy was always performed when dysplasia or cancer are not suspected. In 9 cases an ileal pouch-anal anastomosis (ta-IPAA) (47,3%) was done. Operative time was 85 min (±21) in 89,1 % of patients. Dissection was properly carried on with radiofrequency plus hook in 69,4 % of cases. The main intraoperative problem was smoke evacuation in 15,7 % of cases; No bleeding was experienced neither chopstick conflict that led to conversion to abdominal approach. During postoperative course we experienced 2 complication (10,4 %); one bleeding that has been no need of blood transfusion (Clavien-Dindo I) and one collection, successfully treated with antibiotics (Clavien Dindo II). In our series taIPAA creation did not affect further complications.

**Conclusion:** Our experience confirmed that TaCRD is feasible and safe with proper indication. It allows a less rate of complication even when performed as the road to pouch creation. A next step will be the evaluation of functional results compared with laparoscopic TME and TaTME.

**Introduction:** Transabdominal bowel ultrasound (BUS) is being increasingly adopted for diagnosing and monitoring of patients with Crohn's disease (CD), due to its wide availability and readiness. Specifically, BUS has been reported to accurately evaluate CD extension, activity and to detect presence of CD-related complications. Moreover, ultrasound elastography has been recently demonstrated able to quantify bowel wall fibrosis. No study has so far assessed feasibility and usefulness of laparoscopic bowel ultrasound during CD-related surgery.

**Aims & Methods:** The aim of the study is to assess the feasibility and usefulness of laparoscopic bowel ultrasound during CD-related surgery. Consecutive CD patients undergoing their first laparoscopic surgery were enrolled. Intraoperative laparoscopic ultrasound was performed in the first stage of surgical intervention by a dedicated surgeon expert in CD-related surgery. A dedicated 5-10 Mhz US laparoscopic transducer with a flexible tip and a depth of 4-10 centimeters was used for all examinations.

**Results:** Between March 2016 and March 2017 10 CD patients were enrolled. Intraoperative US was feasible in all patients (i.e. intraoperative US study of CD-affected tract), and no procedure-related complication was reported. Mean US execution time was 25 minutes (range 15-40 minutes). Median follow-up following surgery was 29 months (range 24-36). In all patients,

intraoperative US was helpful for CD surgical management (Table).

During post-operative follow-up, 1 patient experienced a grade I complication according to Clavien-Dindo while 1 patient experienced a grade IIIa complication. No patient underwent a second bowel resection at the end of follow-up

Pts (n)	Intraoperative laparoscopic ultrasound-related advantage
2	Suggesting not to perform bowel resection
1	Helping to rule out CD diagnosis
2	Clarification of intestinal and mesenteric morphology
3	Identification of the exact location of CD-related complications (fistula and abscesses)
1	Identification and characterization of concomitant lesions
4	Clarification of imaging discrepancies
8	Exact definition of bowel resection margin

[Table 1]

**Conclusion:** Results of the present study demonstrate that laparoscopic intraoperative ultrasound is feasible and safe in patients with Crohn's disease. Our preliminary data seem to suggest that this technique may be helpful for CD surgical management, even if these results should be confirmed in a prospective study.

## P0443 COLECTOMY RATES AND POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH ULCERATIVE COLITIS REGISTERED IN A TERTIARY CENTER

Costache R.E.<sup>1</sup>, Anda L.<sup>1</sup>, Saizu I.A.<sup>1</sup>, Stanciulea O.<sup>2</sup>, Dumitrascu T.<sup>2</sup>, Iacob R.<sup>1</sup>, Popescu I.<sup>2</sup>, Gheorghe L.S.<sup>1</sup>, Gheorghe C.<sup>1</sup>

<sup>1</sup>Fundeni Clinical Institute, Gastroenterology, Bucharest, Romania, <sup>2</sup>Fundeni Clinical Institute, Surgery, Bucharest, Romania

**Contact E-Mail Address:** roxanaelenacostache@gmail.com

**Introduction:** According to disease duration, surgical intervention rate in patients with UC varies from 4.9% to 15.6%.<sup>1</sup> The standard procedure is proctocolectomy with ileal pouch, its curative goal being limited by the postoperative complications, which occurs in 30% of the cases.<sup>2</sup>

**Aims & Methods:** The purpose of our study was to assess the colectomy rates and the main postoperative complications in patients with UC admitted in a Tertiary Gastroenterology Center - Fundeni Clinical Institute, Bucharest, Romania - during January 2012 - March 2019. Among 592 of patients with UC admitted in our clinic during the mentioned period, 111 patients (18%) with severe disease, we retrospectively analysed the data from 28 patients (4.7%) who underwent surgical intervention. We extracted the data using our hospital information system. The mean age at diagnosis was 38 years. Disease extension, surgical indication, intervention type, postoperative and long-term complications with their specific treatment were analysed.

**Results:** The main indications for the surgery intervention were severe, medically unresponsive flare (69.2%), the presence of dysplasia/adenocarcinoma (11.54%), toxic megacolon (7.69%), stenosis (7.69%) and abscess (3.85%). The most common intervention was the restorative procedure (53.85%), followed by proctocolectomy with a permanent ileostomy (19.23%), hemicolectomy (15.38%) and total colectomy with ileorectal anastomosis (11.54%). The progression of disease extension was observed in 30.77% of the patients, being strongly correlated to the medical intractability ( $p < 0.001$ ). Postoperatively, the most frequent complications were the local and systemic infections (50.00%), haemorrhage (18.75%), early stomal complications (12.50%), anastomotic leak (6.25%), eventration (6.25%) and fistulas (6.25%). 52.63% of the interventions were performed laparoscopically; the laparotomic procedures and also the urgent surgeries (23.08%) were associated with more frequent infectious complications ( $p < 0.001$ ). Pouch-related complications (pouchitis, stenosis, pouch failure and irritable pouch syndrome) were the most common long-term complications - 41.67%, with a response rate to the medical treatment of 50.00%.

**Conclusion:** The data regarding the colectomy rate registered in our clinic is similar to those mentioned in the literature. The timing and surgical approach have an essential role in the postoperative evolution.

**Introduction:** Transthyretin amyloid (ATTR) amyloidosis is a rare systemic disorder characterized by amyloid deposits formed by misfolded monomers of transthyretin (TTR). Gastrointestinal (GI) manifestations are common in ATTR amyloidosis, however their pathogenesis is not fully elucidated.

**Aims & Methods:** In the current study, we aimed to evaluate the diagnostic role of fecal calprotectin (FC) in ATTR patients with GI manifestations and to evaluate the role of intestinal inflammation in the pathogenesis of the disease. We recruited 21 consecutive ATTR amyloidosis patients and 42 sex and age-matched healthy controls. Presence of GI symptoms and severity of peripheral neuropathy had been evaluated. Colonoscopy and FC assessment were performed in all subjects.

**Results:** Mean levels of FC in ATTR amyloidosis patients 184 µg/g (30-430) were significantly higher than those of controls 40 µg/g (30-70),  $p < 0.001$ . ROC curve analysis indicated a FC cut-off level of 71 µg/g differentiates ATTR amyloidosis with GI manifestations from healthy subjects with 91% sensitivity, 100% specificity, 100% positive predictive value, 95% negative predictive value and 97% overall accuracy. FC values were significantly associated with the presence of neutrophilic granulocytes infiltration in the colonic mucosa ( $p=0.002$ ), with the presence of amyloid deposits in rectal mucosa ( $p=0.007$ ) and the presence of diarrhea ( $p=0.046$ ).

**Conclusion:** FC levels are elevated in patients with ATTR amyloidosis with GI manifestations, which suggests an inflammatory component in the pathogenesis of the disease. The presence of elevated FC concentrations could help gastroenterologists to include ATTR amyloidosis in their diagnostic work-up

**Contact E-Mail Address:** alessandromannucci11@gmail.com

**Introduction:** Microbiota alterations seem to play an associated role in colorectal cancer (CRC) pathogenesis. Bacteroides, Fusobacterium, Salmonella, Escherichia and Campylobacter have been widely studied, demonstrating their promoting role on inflammatory environment, production of molecules affecting DNA stability and alteration of proliferative responses. Few projects are ongoing on microbiota alterations in patients affected by Lynch Syndrome (LS).

**Aims & Methods:** Our aim was the characterization of oral and fecal microbiota in LS patients compared with healthy normal controls. We analyzed oral and fecal microbiota of 17 LS patients: 12 patients were MSH2 mutation carriers, 3 MLH1 mutation carriers, 2 MSH6 mutation carriers. 11 underwent on emicolectomy and one proctocolectomy for CRC, besides one gastric cancer, one endometrial cancer and one duodenal cancer. Total DNA was purified from fecal samples and oral washes. The V3-V4 region of the 16S rRNA gene was amplified. Purified DNA was quantified and libraries were diluted and mixed for pooling with unique molecular tags. Sequences with high quality score and length >250bp were used for the taxonomic analysis with QIIME software.

**Results:** Oral wash microbiota of Lynch patients and 41 matched normal healthy controls were analyzed. Alpha diversity was statistically different between the two groups, with a lower observed otus/chao1 index in Lynch patients compared to controls. The unweighted beta diversity was able to distinguish the two populations. At the genus level, taxonomic analysis of oral wash samples showed a statistically significant increase of *Veillonella* (17% vs 11%) and a decrease of *Neisseria* (10% vs 17%) and *Prevotella* (3% vs 5%) in Lynch patients compared to control subjects. Fecal microbiota of Lynch patients and 21 matched normal healthy controls were analyzed. No statistically significant differences were observed neither in alpha diversity and nor in beta diversity between the two groups. Taxonomic analysis of fecal samples identified a statistically significant increase of Bifidobacteriaceae in Lynch patients compared to controls (2% vs 0%) and a slight increase of Enterobacteriaceae in Lynch samples (1% vs 0%).

**Conclusion:** An increase of *Veillonella* and a decrease of *Neisseria* was observed in oral wash samples of Lynch patients. In fecal samples of Lynch patients we observed an increase of Bifidobacteriaceae. These associations were described in sporadic colorectal cancer and Crohn's disease (CD) too. Further study on larger groups of patients are needed to confirm or revoke these results.

### P0446 SERUM METABOLITE PROFILES IN ACUTE RADIATION ENTERITIS: AN ANIMAL MODEL STUDY

Zhang Q., Zhan Q., An F., Nie H.  
Wuxi People's Hospital Affiliated to Nanjing Medical University,  
Gastroenterology, Wuxi, China

**Contact E-Mail Address:** zhang517068@126.com

**Introduction:** Acute radiation enteritis (ARE), a complication with radiotherapy for pelvic and abdominal tumors, seriously undermines the life quality, even shortens the life span of survivors. Untargeted metabolomics analysis may help find the diagnostic biomarkers, metabolic mechanism and intervention strategies for ARE.

**Aims & Methods:** ARE rat model was established through single abdominal irradiation with a gamma-ray dose of 10 Gy. The fecal condition of each rat was recorded. H&E staining was employed to evaluate the change in intestinal structure at four days after radiation. Serum from 15 ARE models and 10 controls were collected for untargeted metabolomics detection by ultra-high-performance liquid chromatography/quadrupole-time-of-flight-mass spectrometry (UHPLC-Q-TOF/MS). Variable importance for the projection (VIP) was calculated in Orthogonal partial least squares discrimination analysis (OPLS-DA) which worked together with heat map to categorize samples and screen metabolites. Significantly differentially expressed metabolites (VIP > 1 and P < 0.05) between ARE group and control group were identified. At last, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis was employed to explore the metabolomic pathways affected by abdominal irradiation.

**Results:** At two days after radiation, ARE rats showed obvious diarrhea, while the control rats continued to defecate normally. H&E staining revealed a dramatic destruction in the intestinal villi of irradiated animals, which confirmed the occurrence of ARE. Based on the metabolomics data, 6044 positive peaks and 4241 negative peaks were extracted from each sample. In OPLS-DA, the explanation rate for Y variable (R<sup>2</sup>Y) and prediction ability (Q<sup>2</sup>) (0.998 and 0.788 in positive ion mode, 0.997 and 0.866 in negative ion mode) confirmed the stability and reliability of the model. The heat map for cluster analysis showed satisfactory discriminatory power between ARE rats and controls. Further analysis identified 66 significantly differentially expressed metabolites, ten of which changed by more than three folds and might be biomarkers for ARE. KEGG pathway enrichment analysis indicated that the differentially expressed metabolites were involved in multiple different pathways, including central metabolism in cancer, mineral absorption, protein digestion and absorption, aminoacyl-tRNA biosynthesis, ABC transporters, pyrimidine metabolism.

**Conclusion:** Ten metabolites, with more than three folds change in expression, may serve as useful biomarkers for ARE. The pathways through which abdominal irradiation disrupts metabolic activity of intestinal cells may provide a clue for elucidating ARE pathophysiology.

**Disclosure:** The authors declare no conflict of interest

## P0447 LOSS OF THE MICROBIALLY REGULATED HEXOKINASE 2 IN INTESTINAL EPITHELIAL CELLS PROTECTS FROM ACUTE COLITIS

**Introduction:** Hexokinases (HK) are a group of five isoenzymes, which catalyze the first step of glycolysis and thereby limit its pace. HK activity is tightly linked to immune responses<sup>1</sup> and HK2 also functions as a pattern recognition receptor sensing a bacterial cell wall component and thereby mediates a pro-inflammatory response<sup>2</sup>.

**Aims & Methods:** Our goal was to examine the function of HK2 for host-microbiota-interactions and intestinal inflammation. To that end, we generated mice lacking *Hk2* specifically in intestinal epithelial cells (*Hk2*-ΔIEC) and tested their susceptibility to acute inflammation using the dextran sodium sulfate (DSS) colitis model. In parallel we stimulated epithelial cell lines and gnotobiotic mice with bacterial strains and metabolites to identify bacterial agents that may modulate *Hk2* expression and thereby intestinal inflammation.

**Results:** Under unchallenged conditions *Hk2*-ΔIEC mice did not exhibit a major metabolic or inflammatory phenotype, whereas loss of HK2 in the intestinal epithelium was protective during acute inflammation. We found that the normal microbiota strongly regulates HK2 expression and activity. Additionally, we identified individual bacteria and metabolites that repress *Hk2* expression in intestinal epithelial cells and gnotobiotic mice. We currently test whether supplementation with these bacterial factors protects from intestinal inflammation.

**Conclusion:** Our data identified the microbiome as a central regulator of HK2 and glycolysis and thereby as a potential therapeutic target for acute inflammatory conditions.

**Introduction:** Colorectal cancer (CRC) development is a multistep process, from normal epithelial cells via inflammation to aberrant crypt foci (ACF) and progressive adenoma stages, to carcinomas and then metastatic disease [1, 2]. In order to reduce the incidence and consequences of CRC, effective prevention and treatment strategies need to be identified. Due to the long precancerous stage of identifiable disease, dietary intervention may exert favorable effect on polyp formation and/or inhibition of adenomas transformation to CRC. Recent findings indicate that long-term consumption of a diet rich in vegetables may prevent the development of CRC [3].

For the prevention of CRC by dietary measures, vegetables such as carrots are highly interesting due to their content of the bioactive polyacetylenic falcariol (FaOH) and falcariindiol (FaDOH) [4]. FaOH and FaDOH have shown many interesting bioactivities including anti-inflammatory and cytotoxic activity [4-6] as well as antineoplastic effect in animal models [7, 8]. In this study, we demonstrate that FaOH and FaDOH prevent the development of early neoplastic lesions in the colorectal intestine in a dose-response relationship corresponding to the logarithmic of the concentration of the contents of FaOH and FaDOH in the diet. Furthermore, the results presented also demonstrate that FaOH and FaDOH have an effect on inflammatory markers and they seem to act as selective COX-2 inhibitors, which appears to be their main mechanism of action in relation to colon cancer prophylactics.

**Aims & Methods:** The gene expression of seven inflammatory markers COX-1, COX-2, NFκβ1, IL1β, IL6, PPARγ and TNFα in tissue from biopsies was analyzed by means of Real-time quantitative PCR (RT-qPCR). The biopsies include neoplastic tissue from the control group, receiving standard rat diet (SRD) without the supplement of FaOH and FaDOH and size matched neoplastic tissue from the test group receiving SRD supplemented with 7 μg FaOH g<sup>-1</sup> feed and 7 μg. Prior to the RT-qPCR, RNA from the tissue was extracted using QIAzol and EconoSpin column purification where after it was converted into complementary DNA.

**Results:** The expression level of seven different inflammatory and cancer biomarkers COX-1, COX-2, TNFα, IL-6, NF-κβ, IL-1β, and PPARγ2, were examined in both neoplastic and healthy tissue from biopsies obtained from rats receiving either SRD or SRD supplemented with FaOH and FaDOH.

Upregulation of most biomarkers, except COX-1, TNFα, and IL-1β, was observed in neoplastic tissue compared to normal tissue. Contrary, a significant downregulation in expression levels were detected in five of the seven biomarkers when comparing biopsies of neoplastic tissue from rats receiving a SRD with biopsies of neoplastic tissue from rats receiving the FaOH and FaDOH as a food supplement. A significant downregulation in the expression of TNFα, IL-6, NF-κβ, PPARγ2 and COX-2 was detected. The qRT-PCR analyses showed no significant difference in the expression level in healthy tissue for all biomarkers when the rats received FaOH and FaDOH as a food supplement compared to rats receiving SRD.

**Conclusion:** Collectively, the results of the present study shows that FaOH and FaDOH in combination has a chemopreventive effect on CRC in a cancer primed rat model and that this effect is due to their inhibitory effect on key biomarkers in the NF-κB signaling pathway and in particular the downstream target COX-2. The present study therefore opens up for precise dietary advices to prevent this disease and to develop new selectively COX-2 inhibitors with no or only minor side effects.

**Introduction:** Immunotherapy has significantly improved the traditionally poor prognosis of several malignant diseases including metastatic melanoma and Non Small Cell Lung Cancer (NSCLC), while their efficacy in a number of other tumor types is vigorously studied. Immune check point inhibition can lead to activation of autoreactive T-cells resulting in a new spectrum of side effects called immune-related adverse events (IRAEs). Gastrointestinal manifestations are common complications of immunotherapy, being often the cause of treatment discontinuation.

**Aims & Methods:** We retrospectively assessed 9 patients (5 males, mean age: 65.4 years) admitted to the Gastroenterology Department, because of gastrointestinal symptoms while being on therapy with immune checkpoint inhibitors for NSCLC (7 patients) and metastatic melanoma (2 patients). Two patients were treated with ipilimumab, 6 with nivolumab, and one with a combination treatment.

**Results:** Diarrhoea was the most common symptom, followed by abdominal pain, fever and nausea. The mean time of symptom occurrence was 17 weeks after initiation of immunotherapy (8-27 weeks). The colonoscopy findings in 6 patients were consistent with colitis with continuous inflammation pattern (mucosal erythema, ulcerations, loss of subepithelial vascular pattern and friable mucosa), while 3 patients had normal endoscopic findings. Cryptitis, and crypt abscesses were common pathological findings. Granulomas were not detected. Hospitalization was required for three patients as they met the Truelove-Witts criteria for acute severe colitis. CRP levels were elevated in 8 cases (mean 7.3 mg/dl, 3.9 - 10.6) and returned to normal after the treatment. The albumin levels were decreased in 7 patients (mean 3.3 g/dl, 2.6 - 3.9). Seven patients were treated with corticosteroids and one patient received salvage therapy with infliximab after failure of steroid treatment. Time to symptom resolution was noted to be variable (ranging from 1 day to 4 weeks).

**Conclusion:** Given the constantly expanding use of immune checkpoint inhibitors, it is important for the gastroenterologists to be familiar with the gastrointestinal IRAEs. Steroids comprise the first line of treatment, but salvage therapy with infliximab may be necessary in case of a steroid treatment failure. The role of alternative biologics, mainly vedolizumab is being studied. Long-term management of immune related colitis and the effect of infliximab on the malignant disease have to be further evaluated.

## P0450 LOSS OF PTPN2 IN EITHER DENDRITIC CELLS OR T CELLS RESULTS IN REDUCED TUMOR BURDEN IN THE ORTHOTOPIC COLON TUMOUR MOUSE MODEL

Katkeviciute E., Hering L., Montalban-Arques A., Busenhardt P., Atrott K., Scharl M., Spalinger M.

University Hospital Zurich, USZ, Department of Gastroenterology and Hepatology, Zürich, Switzerland

**Contact E-Mail Address:** egle.katkeviciute@usz.ch

**Introduction:** In the recent years, protein tyrosine phosphatase non-receptor type 2 (PTPN2) has emerged as a potential cancer immunotherapy target. Our previous data demonstrate that loss of PTPN2 in dendritic cells (DC) or in T cells results in reduced tumour burden in the azoxymethane (AOM)-dextran sodium sulphate (DSS) induced model of colitis-associated colorectal carcinoma (CRC). However the role of PTPN2 in inflammation independent CRC pathogenesis has not yet been determined. Here, we show that tissue-specific deletion of PTPN2 in DCs or T cells results in reduced tumour load in the orthotopic cecum injection mouse model of CRC.

**Aims & Methods:** Tumours were induced in mice specifically lacking PTPN2 in either DCs (PTPN2<sup>fl/fl</sup>-CD11cCre) or T cells (PTPN2<sup>fl/fl</sup>-CD4Cre) and their WT littermate controls by injecting MC38 tumour cells into the mouse caecum. Immune cells in spleen, mesenteric lymph nodes (mLN), tumour (T) and tumour-adjacent normal tissue (non-T) were analysed using flow cytometry and immunohistochemistry.

**Results:** Although tumour burden varied between individuals, PTPN2<sup>fl/fl</sup>-CD11cCre and PTPN2<sup>fl/fl</sup>-CD4Cre mice had clearly less and smaller tumours compared to their littermate controls. In turn, PTPN2-deficient mice exhibited significantly increased levels of CD44<sup>+</sup> effector/memory CD4<sup>+</sup> and CD8<sup>+</sup> T cells in spleen and mLN, indicating enhanced T cell activation. Additionally, we observed increased granzyme B expression in the spleen from PTPN2<sup>fl/fl</sup>-CD4Cre mice compared to their littermate controls, suggesting increased cytotoxic/anti-tumour activity of PTPN2-deficient CD8<sup>+</sup> T cells. Furthermore, expression of regulatory T cells was decreased in PTPN2-deficient mice, showing lower effector/memory T cells suppression in PTPN2<sup>fl/fl</sup>-CD11cCre and PTPN2<sup>fl/fl</sup>-CD4Cre mice compared to their littermate controls. Finally, PTPN2-deficient mice presented increased levels of the checkpoint marker PD-1 on T cells in the spleen, further displaying highly increased immune response.

**Conclusion:** Our results demonstrate an important *in vivo* role for PTPN2 in the pathogenesis of inflammation independent CRC. Loss of PTPN2 in either DCs or T cells exerts anti-tumour effects and ultimately results in lower colon tumour burden. This effect is likely mediated via promoting anti-cancer immune responses by modulating T cell activation, cytotoxicity and immune checkpoint molecules expression.

**Introduction:** Data from clinical research suggest that certain probiotic bacterial strains have the potential to modulate colonic inflammation in patients with inflammatory bowel diseases. Nonetheless, this data differs considerably among studies due to the probiotic bacterial strains used and the poor knowledge of their mechanisms of action.

**Aims & Methods:** The aim of our study was to better characterize the mechanisms of the anti-inflammatory activity of *Escherichia coli* Nissle 1917 (EcN), a probiotic used for the treatment of multiple intestinal disorders. Lipids were extracted from pathogenic *Escherichia coli* (E. coli) strains UTI, Nu14, SP15, CFT, NC101, from an asymptomatic E. coli ABU, from a commensal E. coli M1/5 and from the probiotic EcN. Lipid extracts were analyzed by liquid chromatography coupled to high resolution mass spectrometry for identification and by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) for quantification. To assess the passage of 3-hydroxyoctadecaenoic acid (C18-3OH) across the intestinal barrier, we used caco2 cells

differentiated in transwell and colon biopsies in Ussing chambers. Time-resolved fluorescence resonance energy transfer (TR-FRET)-based competitive binding assay was performed to assess the C18-3OH agonist properties for the peroxisome proliferator activated receptor gamma (PPAR $\gamma$ ). Mice received an oral administration of C18-3OH and were injected with a PPAR $\gamma$  antagonist (GW9662, IP). Concentration of C18-3OH and mRNA expression of genes dependent on the PPAR $\gamma$  activation (*Fiaf* and *Lfabp*) were quantified in mouse colons. In order to test the impact of the C18-3OH on colitis, mice have been submitted to DSS-induced colitis model and to oral administration of C18-3OH. Intensity of colitis was determined by the quantification macroscopic and microscopic scores, paracellular permeability, pro-inflammatory and pro-resolving lipids and mRNA expression of protein implicated in barrier functions (Zo1, Occludin, Muc2, ...), chemokines (Cxcl1, Cxcl2,...) and cytokines (IL6, IL1 $\beta$ , ...).

**Results:** In EcN, we identified and quantified free long chain fatty acids (LCFA) from 8 to 18 carbons hydroxylated on the 3<sup>rd</sup> carbon. The concentration of C18-3OH was increased in EcN compared to other *E. coli* strains. This bacterial lipid was not able to cross caco2 cells in transwell or tissue in Ussing chambers but penetrated the cells. The C18-3OH bonded the receptor-binding site of PPAR $\gamma$ . Oral administration of C18-3OH increased its concentration in the colon and increased *Fiaf* and *Lfabp* mRNA expression; treatment with a PPAR $\gamma$  antagonist inhibited these effects. C18-3OH treatment to mice with DSS-induced colitis significantly decreased paracellular permeability, colon thickness, macroscopic and microscopic scores and pro-inflammatory lipid concentration compared to DSS-treated mice. In addition, the C18-3OH decreased *Reg3 $\gamma$* , *Zo1*, *Cxcl1* and *Cxcl2* mRNA expression.

**Conclusion:** The bacterial lipids C18-3OH is a agonist of PPAR $\gamma$ . It could therefore represent a new mechanism of probiotics anti-inflammatory activities.

**Contact E-Mail Address:** paulagarciamacara@gmail.com

**Introduction:** Immune checkpoint inhibitors (ICIs), such as anti-CTLA-4 and anti-PD-1 antibodies, are effective against several malignancies. They are associated with gastrointestinal and liver immune-related adverse events (GI-IrAEs and LI-IrAEs), which may be severe and lead to ICI discontinuation.

**Aims & Methods:** The aim of this study is to evaluate real-world data about the efficacy and gastrointestinal and liver toxicity of ICIs in several cancers among patients who have progressed on one or more prior lines of chemotherapy.

**Methods:** All patients with advanced cancers who received at least 1 molecular-targeted therapy after the failure of chemotherapy between May 2015 and September 2018 at our center were retrospectively assessed. Information about efficacy and toxicity was collected and analyzed. The grade of IrAEs was defined based on the Common Terminology Criteria for Adverse Event (CTCAE) version 4.0.

**Results:** 132 patients who had received ICIs were included, 32% female, with mean age 66.3 (SD 10.4) years. Primary tumors were as follows: 86 (65.6%) non-small cell lung cancer; 30 (22.9%) melanoma; 12 (9.16%) kidney cancer; and 3 (2.29%) others tumors. ICIs therapy included atezolizumab (N=13), nivolumab (N=82), pembrolizumab (N=28), durvalumab (N=2), ipilimumab (N=1) and combined programmed cell death protein 1/cytotoxic T-lymphocyte-associated protein 4 antibodies (N=6). 19.6% of evaluable patients achieved a response. 51 (38.6%) patients developed any IrAEs. GI-IrAEs were observed in 17 (12.9%) patients: 9 grade 1, 6 grade 2 and 2 grade 3. 8 out 17 (47%) needed steroids and 1 patient needed surgery due to colonic perforation. 4 of 6 patients with combined treatment suffered from GI-IrAEs. No more treatment-related discontinuations or deaths occurred because of GI-IrAEs. LI-IrAEs were observed in 4 patients (3.03%), which all consisted of mild grade hepatitis (grade 1 and 2). 50% patients needed steroids and 1 patient stopped treatment. Any patient with combined treatment suffered from LI-IrAEs. IrAEs were no related with age or sex. IrAEs development did not predict response.

**Conclusion:** GI-IrAEs are among the most commonly encounter IrAEs, mainly with combination treatment. LI-IrAEs are rare. Both are potentially life-threatening events. Their management in a multidisciplinary approach will help to reduce morbidity and therapy interruptions.

<sup>2</sup>Saiseikai Fukuoka General Hospital, Infection Control Team, Fukuoka, Japan

**Contact E-Mail Address:** mdyoshimura@gmail.com

**Introduction:** *Clostridioides difficile* infection (CDI) in adults is an important nosocomial intestinal infectious disease, which can be life-threatening. An efficient diagnosis of CDI is needed both for patient safety and for hospital cost saving. The stool toxin enzyme immunoassay (EIA) is a major method of laboratory rapid testing, however, its sensitivity is inadequate. On the other hand, the sensitivity of toxigenic culture (TC) or nucleic acid amplification test (NAAT) is excellent, however, it costs much and may overdiagnose CDI. The glutamate dehydrogenase (GDH) EIA is also reported as high sensitivity, but the significance compared with TC is not clear.

**Aims & Methods:** We performed a single-center prospective study to examine the effectiveness of EIAs detecting toxin A/B and GDH (C.DIFF QUIK CHEK, Alere), compared with selective anaerobic culture (cycloserin-cefoxitin mannitol agar; CCMA-EX, Nissui) as the reference method (TC). During the period from August 2012 to December 2013, the hospitalized patients with unexplained and newly onset watery diarrhea (defined as more than 3 stools/day) were included in the study. All the stool specimen was simultaneously tested by EIA and TC. For the positive selective culture plate, all the colonies in a single plate were picked up and suspended at once in saline, then applied to the toxin A/B EIAs. In this study, CDI was defined as positive with TC (both selective culture and toxin EIA).

**Results:** A consecutive 447 stool specimens were tested. Toxin A/B EIAs were positive for 62 samples (13.9%), and all of them were also positive with GDH and TC. Among the 385 specimens that were negative with toxin A/B EIAs, 35 samples (9.1%) were positive with GDH and also with TC. Twenty (57.1%) out of those 35 culture positive specimens were positive with toxin tests. There was no specimen that was positive in selective culture while the GDH test was negative. Accordingly, the prevalence of CDI was 18.3% in this study. The sensitivity of the rapid test only for toxin A/B was 75.6%, while the combination of GDH test resulted in the positive predictive value of 84.5% and the negative predictive value of 100%. This study also proved the GDH EIA to be equivalent to TC.

**Conclusion:** Our study indicated that the two-step combination of TC for the GDH negative stool samples is not needed. The combination rapid test for *Clostridioides difficile* GDH and toxins is useful that could save unnecessary TC costs. In accordance with the study, we have established the algorithms for CDI test (Figure 1). Patients positive with GDH while negative for toxin EIAs could be placed on preemptive contact precautions and could also be treated empirically until the results of TC are revealed. During the period from January 2014 to December 2018, 1442 stool specimens were tested, and 216 cases (15.0%) were diagnosed as CDI, without any nosocomial outbreak incident.

**Introduction:** Bacterial infections are important cause of acute infectious diarrhea. Conventional stool culture and microscopic examination are time consuming and often lack sensitivity and specificity. Recently, there has been substantial development of multiplex molecular assays for the detection and identification of pathogens responsible for causing diarrhea.

**Aims & Methods:** In this study, we evaluated the efficacy of multiplex stool polymerase chain reaction (PCR) test in patients with acute infectious diarrhea. A total of 250 admitted patients with acute infectious diarrhea were recruited in Kangdong Sacred Heart Hospital from January 2016 to December 2018. Multiplex PCR detected 7 enteropathogenic bacteria including Salmonella, Campylobacter, Shigella, Escherichia coli O157:H7, Aeromonas, Vibrio, Clostridium difficile. We reviewed clinical and laboratory findings by stool multiplex PCR test and compared with those by stool culture.

**Results:** Mean age was 49.7±20.5 years and hospital stay was 7±10.5 days. Multiplex stool PCR test detected much more enteropathogens compared with stool culture (61.2% vs. 5.2%). Of culture-positive specimens, 4% of those were the same pathogens detected in multiplex PCR test. Stool multiplex PCR detected 88 Campylobacter, 46 E. Coli H7, 16 Clostridium, 11 Salmonella, 5 Aeromonas, 4 Shigella and 4 Vibrio. Campylobacter was the most common pathogen in stool PCR (88/250, 35.2%) and culture (4/10, 40%). Stool PCR-positive patients presented more fever >38°C [72/153 (47.1%) vs. 33/97 (34%), P=0.04] and higher C-reactive protein (CRP) at admission [100.9±79mg/L vs. 65.1±83mg/L, P=0.001] compared with PCR-negative patients.

**Conclusion:** Multiplex stool PCR test showed superior sensitivity to conventional culture for detection of pathogens in acute infectious diarrhea. Stool PCR result may be useful to predict clinical severity of infectious diarrhea.

**Introduction:** Clostridium difficile infection (CDI), is the leading cause of antibiotic-associated diarrhea (AAD), a disease which increased in incidence and severity over the last years. Antibiotics exposure is considered the most significant risk factor for CDI among elderly and hospitalized patients. Probiotics have been proposed for the prevention and treatment of a variety of gastrointestinal conditions, but guidelines do not recommend probiotic use for prevention of CDI (1). The aim of this study is to evaluate the efficacy of probiotics in preventing CDI.

**Aims & Methods:** We performed an unblinded, randomized, prospective study (October 2018– March 2019), in which 140 patients admitted in our department, who fulfilled the inclusion criteria and received antibiotics, regardless the indications, were included. Four arms of study were created: three probiotics and one group placebo. The patients received probiotics in less than 24 hours from the first antibiotic dose, during the treatment and 7 days after, according to their dose indication. Strains such as Lactobacillus, Clostridium Butiricum, Bacillus Mesentericus, Bifidobacterium and Streptococcus faecalis were used. Primary and secondary outcomes were frequency of AAD and CDI and adverse events.

**Results:** Out of 140 patients, 54 female and 86 male, mean age 63±12 years, mean hospitalization days 7.5±6.1. 35.5%(50/140) were on placebo and 64%(90/140) received probiotics. 16.4% received prophylaxis antibiotics. Among those with infection, the most frequent was urinary infection 28.2%. Other risk factors for CDI accounted were: use of proton pump inhibitors 18.5%(26/140) patients, 46.4%(65/140) patients with age >65 years, liver cirrhosis 47.1%(66/140) patients.

13.5%(19/140) of patients developed antibiotic-associated diarrhea, 30%(15/50) patients from the placebo group and 4.4%(4/90) patients on probiotics (p< 0.0001). Out of 140 patients, 4.2%(6/140) were confirmed with CDI, 10%(5/50) patients from placebo group and only 1.1% (1/90) patient on probiotics (p=0.013). Patients exposed to antibiotics, without taking probiotics had a higher risk of CDI: OR=9.8 CI 95% (1.12-87) p=0.039. None of the patients reported adverse events.

**Conclusion:** The rate of antibiotic-associated diarrhea and CDI was significantly lower in the probiotics group, but further studies are required in order to determine the optimal strain.

**Introduction:** Colonoscopy for colonic diverticular bleeding (CDB) within 24 hours after hematochezia is useful to make a diagnose and perform therapeutic intervention, but it has problems due to the necessity of pre-treatment and a low CDB identification rate. Intravenous contrast material-enhanced computed tomography (CT) before colonoscopy contributes to improvement of the rate of identifying stigmata of recent hemorrhage (SRH) compared with that by colonoscopy alone, but the timing of CT to improve the colonoscopic hemostatic rate has remained unclear.

**Aims & Methods:** We assessed the usefulness of performing contrast-enhanced CT early after the first hematochezia (within 6 hours) for CDB patients retrospectively. A diverticulum with active hemorrhage, blood clots, and an exposed hemorrhagic vessel was defined as the diverticulum responsible for CDB. The subjects were 146 CDB patients who visited our hospital between January 2012 and January 2018 and were examined by contrast-enhanced CT within 6 hours and after 6 hours were designated as an early CT group (69 patients (47 %)) and elective CT group (77 patients (53%)), respectively. The treatment effectiveness of contrast-enhanced CT early after the onset of CDB was investigated.

**Results:** Ninety-nine patients (67.8%) were male and the mean age was 72 years old (37-96 years old). There was no difference in the characteristics between the early and elective CT groups. The extravasation-positive rate significantly improved in the early CT group compared with that in the elective CT group (49 vs. 27%, respectively; P=0.006). In addition, the colonoscopic hemostatic rate significantly improved in the early CT group compared with that in the elective CT group (32 vs. 13%, respectively; P=0.006). No adverse event after contrast-enhanced CT, such as contrast-induced nephropathy, occurred.

**Conclusion:** Early contrast-enhanced CT after the onset of CDB significantly improved the responsible diverticulum identification rate and colonoscopic hemostatic rate in the early CT group. By performing contrast-enhanced CT in the early phase, extravasation positivity served as an index to apply hemostasis to the responsible diverticulum, suggesting that the responsible diverticulum was safely and accurately identified by contrast-enhanced CT performed early after hematochezia, which significantly contributed to colonoscopic control of hemorrhage.

**Introduction:** Delayed post-procedural bleeding (DPPB) is a common adverse event after endoscopic resection (ER) for colorectal tumors and occasionally requires additional interventions. Recently, O blood group of ABO blood group system has been reported as a risk factor for various bleeding events, but the relationship with DPPB has yet to be investigated. This study aimed to evaluate if the O blood group would be relevant to DPPB.

**Aims & Methods:** This was a case-control study comparing cases who did and did not developed DPPB who underwent colorectal ER at four university hospitals between January 2014 and December 2017. We enrolled the consecutive patients who underwent colorectal ER using any of the following ER techniques (EMR, ESD, cold snare/forceps polypectomy, and hot snare/forceps polypectomy) during the study period. We excluded the patients whose ABO blood group was unidentified or who underwent procedures without interrupting antithrombotic agents. We reviewed medical records and the endoscopy database which included the following information: 1) ABO blood group, 2) age, 3) sex, 4) daily use of anti-platelets/coagulants, 5) size of resected tumors, 6) the number of resected tumors, 7) procedure. The control group consisted of all the patients who completed the treatment without DPPB. DPPB was defined as the occurrence of hematochezia or melena requiring blood transfusion or hemostatic intervention with colonoscopy, surgery, or radiology up to 28 days after endoscopic resection. Univariate and multivariate logistic regression analysis were performed to determine the risk factor for colorectal DPPB using the independent variables including ABO blood group.

**Results:** Among 10,253 consecutive patients who underwent colorectal ER, 1,628 patients (15.9%) were excluded according to the criteria for unidentified blood group (n=1,604) and/or continued antithrombotic agents (n=25). A total of 8,625 patients who met the eligibility criteria were enrolled in the analysis. Of the 8,625 patients, 6,111 (70.9%) were male; the age was 66.3 years  $\pm$  11.4 (mean  $\pm$  SD); the median number of tumors resected per patient was 2 (IQR, 1-3); the number of cases with a large lesion ( $\geq$  20 mm) was 1,158 (13.4%). In total, 237 (2.75%) patients developed DPPB (the case group); 8,625 patients did not (the control group). In univariate analysis, O blood group was significantly related to increased risk of DPPB (odds ratio [OR], 1.57; 95% confidence interval [CI], 1.21-2.04;  $P=0.00079$ ) equivalent to other known risk factors: younger age ( $< 60$  years) (OR, 1.71; 95% CI, 1.31-2.24;  $P=0.00097$ ), sex (male) (OR, 1.83; 95% CI, 1.32-2.55;  $P=0.00034$ ), the number of tumors (OR, 1.44; 95% CI, 1.10-1.89;  $P=0.0088$ ), tumor-size  $> 2$  cm (OR, 1.90; 95% CI, 1.39-2.59;  $P=0.00057$ ). In multivariate logistic regression analysis, O blood group remained as an independent risk factor for DPPB (adjusted OR, 1.57; 95% CI, 1.20-2.04;  $P=0.0009$ ) (Table 1).

		Coefficient ( $\beta$ )	Standard error	Wald	Adjusted OR	95% CI	P-value
Age	$< 60$ years	0.626	0.143	4.39	1.87	1.41 - 2.47	0.00011
Sex	Male	0.565	0.171	3.31	1.76	1.26 - 2.46	0.00092
Use of antithrombotic agents	Yes	0.402	0.163	2.47	1.49	1.09 - 2.06	0.013
Blood group	O	0.448	0.135	3.32	1.57	1.20 - 2.04	0.00091
Number of polyps	$\geq 2$	0.448	0.147	3.05	1.57	1.17 - 2.09	0.0023
Tumor-size	$\geq 20$ mm	0.577	0.193	2.99	1.78	1.22 - 2.60	0.0028
Procedure	ESD	0.490	0.302	1.63	1.63	0.90 - 2.95	0.104

[Table 1 : Multivariate analysis of risk factors for DPPB based on ABO blood group and other known factors]

**Conclusion:** The patients with O blood group were associated with an increased risk of DPPB. The pre-operative screening of ABO blood group may improve the preoperative risk assessment.

**Disclosure:** Nothing to disclose

## P0458 EFFECTIVENESS OF TRANSCATHETER ARTERIAL EMBOLIZATION FOR COLONIC DIVERTICULAR BLEEDING

Machida T., Fukami Y., Ishii R., Hara H., Sugiyama Y., Yonemoto Y., Ikemiyagi H., Yoshino K., Sakita S.

**Contact E-Mail Address:** tomoyo.machida@gmail.com

**Introduction:** Colonic diverticular bleeding is the most common cause of acute severe lower gastrointestinal bleeding. Recently, it has been increasing with the aging of the population and the widespread use of anti-thrombotic drugs. Although it stops spontaneously in many cases, a small number of patients experience re-bleeding or shock. Persistent or acute massive bleeding with hemodynamic disorders sometimes requires an in-

terventional treatment. Persistent bleeding or acute massive of presenting with hemodynamic disorders requires an interventional treatment. In our institution, we perform transcatheter arterial embolization (TAE) for cases in which bleeding points are not able to be detected and cannot be treated successfully by endoscopic procedures.

**Aims & Methods:** The aim of this study is to evaluate the effectiveness of TAE for colonic diverticular bleeding.

The subjects are 21 patients who were diagnosed as colonic diverticular bleeding and were performed endovascular treatment in our institution from January 2006 to December 2018. We retrospectively evaluated patient characteristics and clinical outcomes, including success rates of hemostasis, transfusion requirement, early rebleeding, and complications.

**Results:** In all 21 patients, endoscopic hemostasis was difficult and early rebleeding developed. The median time of endoscopic procedures before TAE was 2 times. The hemostasis by arterial embolization was successful in 15 patients (71.4%), while the bleeding points could not be identified in 6 patients. In 11 cases (52.3%), an extravasation image was observed by angiography, and in all cases, hemostasis was succeeded by TAE.

In 4 cases no extravasation was found by angiography, but TAE was performed because an approximate bleeding point could be identified by CT and endoscopic findings. After TAE, no recurrence of bleeding were observed. In 2 patients (9.5%) intestinal ischemia was observed as adverse event and operation was performed.

**Conclusion:** TAE is effective treatment for colonic diverticular bleeding in which endoscopic hemostasis is not successful, or in massive bleeding.

**Disclosure:** Nothing to disclose

## P0459 UTILITY OF SHOCK INDEX FOR RISK STRATIFICATION IN ACUTE LOWER GASTROINTESTINAL BLEEDING

Garcia-Iglesias P.<sup>1,2</sup>, Martinez-Bauer E.<sup>2,3</sup>, Da Costa J.<sup>1</sup>, Lira Aguilar A.<sup>3</sup>, Llibre G.<sup>1</sup>, Vives J.<sup>1</sup>, Machlab S.<sup>3</sup>, Soria A.<sup>1</sup>, Brunet E.<sup>1</sup>, Hernandez L.<sup>1</sup>, Junquera F.<sup>3</sup>, Puig-Divi V.<sup>3</sup>, Campo R.<sup>3</sup>, Brullet E.<sup>3</sup>, Melcarne L.<sup>1</sup>, Gallach M.<sup>1</sup>, Calvet X.<sup>1,2,4</sup>

**Contact E-Mail Address:** pgarcia171@gmail.com

**Introduction:** Although the incidence of acute lower gastrointestinal bleeding (LGB) is increasing, the predictors of outcomes are not as well studied and defined as for acute upper gastrointestinal bleeding. Several risk scores have been developed over the past years in order to early stratify patients according to the risk of complications. The shock index (SI) score (heart rate divided by systolic blood pressure) is a simple tool that can provide an assessment of hemodynamic status.

**Aims & Methods:** The aim of this study was compare the utility of Shock Index (SI) for predicting outcomes: a) Transfusion, b) Treatment (endoscopic, vascular embolization or surgery), c) Clinical intervention (transfusion and treatment), d) Rebleeding, e) Readmission and f) Mortality in patients with LGB between scores used for risk prediction in upper gastrointestinal bleeding (Glasgow-Blatchford Score (GBS) and Pre-endoscopic Rockall) and in LGB (Oakland, Strate, Velayos and Newman scores).

International Classification of Diseases, 9 Revision, Clinical Modification codes for admission diagnosis were used to identify retrospectively a cohort of patients with acute LGB from January 2013 to December 2017 hospitalized to a tertiary care, university-affiliated hospital. Data were extracted from the electronic clinical records of the Hospital. Area under the receiver operating characteristic (AUROC) curve were calculated for SI and the different risk scores for each outcomes. AUROCs were compared with the DeLong method by using STATA 14.1 software (StataCorp.2015).

**Results:** A total of 406 consecutive patients admitted with LGB were identified. Median age was 76.6 years (range 23-97), 277 (68.1%) of patients were older than 70 years, 219 (53.8%) were men. Six (1.5%) died, 36 (8.8%) rebleeding, 20 (4.95) needed readmission, 110 (27%) needed transfusion, 52 (12.5%) needed treatment (48 endoscopic, 4 vascular embolization, 0 surgery). The most common source bleeding was diverticular 115 (28.3%). SI was not useful to predict any outcome (AUROC  $< 0.6$ ). The SI was similar to the acute LGB scores for prediction rebleeding or readmission. The GBS and Oakland score was the best for predicting transfusion, need clinical intervention. All the risk scores were more accurate for determining need transfusion than need treatment or clinical intervention.

SCORE	TRANSFU-SION	TREATMENT	CLINICAL INTERVEN-TION	REBLEEDING	READMIS-SION	DEATH
SHOCK INDEX	0.58 (0.51-0.64)	0.49 (0.40-0.57)	0.55 (0.49-0.61)	0.58 (0.48-0.69)	0.57 (0.45-0.69)	0.58 (0.38-0.77)
GLASGOW-BLATCHFORD	0.89 (0.85-0.92)	0.65 (0.56-0.73)	0.82 (0.78-0.87)	0.72 (0.63-0.81)	0.70 (0.58-0.82)	0.76 (0.49-1.00)
PRE ENDOSC ROCKALL	0.70 (0.65-0.76)	0.56 (0.49-0.64)	0.68 (0.62-0.73)	0.68 (0.60-0.76)	0.63 (0.51-0.75)	0.82 (0.58-1.00)
OAKLAND	0.89 (0.85-0.93)	0.63 (0.55-0.72)	0.82 (0.77-0.86)	0.74 (0.65-0.83)	0.71 (0.59-0.83)	0.78 (0.63-0.93)
STRATE	0.67 (0.62-0.73)	0.60 (0.52-0.67)	0.65 (0.60-0.71)	0.67 (0.59-0.76)	0.70 (0.59-0.81)	0.56 (0.31-0.80)
VELAYOS	0.78 (0.74-0.82)	0.65 (0.57-0.73)	0.74 (0.70-0.79)	0.68 (0.60-0.76)	0.68 (0.57-0.79)	0.80 (0.67-0.92)
NEWMAN	0.78 (0.73-0.82)	0.64 (0.56-0.71)	0.75 (0.70-0.79)	0.68 (0.60-0.75)	0.67 (0.55-0.79)	0.78 (0.63-0.92)

[Table 1: AUROC and IC 95 % for shock index and risk scores]

**Conclusion:** SI was not useful to predict any outcome. Both Oakland Score and GBS were superior for predicting transfusion or clinical intervention. The GBS may be and useful tool for risk stratification in LGB. It can be used for as common score for predicting need of clinical intervention in upper and lower gastrointestinal bleeding. More precise prognostic scales are needed in LGB.

Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain

**Contact E-Mail Address:** ebrunet@tauli.cat

**Introduction:** "Weekend effect" refers to worse outcomes among patients presenting to the hospital on weekends. Many different processes are required in the management of patients with acute lower gastrointestinal bleeding (LGB). The availability of some of these procedures may be reduced on weekend. The weekend effect closely reflect the organizational level and performances of healthcare services under "off-hour" conditions, it can identify the possible deficiencies in functioning and the need for improvements. At present, it is not known whether there is a weekend effect in LGB.

**Aims & Methods:** The primary aim of this study is to investigate whether adverse outcomes for patients admitted with LGB differ depending on weekend versus weekday admission. The secondary aim was to determine whether any such differences are mediated by the timing of colonoscopy. International Classification of Diseases, 9th Revision, Clinical Modification codes for admission diagnosis were used to identify retrospectively a cohort of patients with acute LGB from January 2013 to December 2017 hospitalized to in a tertiary care, university-affiliated hospital. Data were extracted from the electronic clinical records of the Hospital. Time of admission was recorded defining weekend as midnight Friday to midnight Sunday. Hospital admissions on holidays no weekend were excluded. We used definition for adverse outcomes as the composite outcome: a) Transfusion, b) Treatment (endoscopic, vascular embolization or surgery), c) Clinical intervention (transfusion and treatment), d) Re-bleeding and f) Mortality in patients with LGB.

Our center has endoscopy available 24 hours a day, 7 days a week.

For discrete variables we tested for significant differences between groups with X2 tests If 25 %or more of cells had expected values less than 5; the

Fisher exact test was used.. For continuous variables we used t-test (two-tailed). P values < 0.05 were considered statistically significant. Statistical analysis was performed using STATA 14.1 software (StataCorp.2015).

**Results:** A total of 452 consecutive patients admitted with LGB were identified. Of these 348 (73.9%) were admitted during the weekday and 104 (23.1%) during the weekend. Compared to patients admitted on a weekday, weekend admissions had similar adverse outcomes, need transfusion similar, treatment or need clinical intervention and had similar re-bleeding and mortality in patients with LGB.

Results are resumed in Table 1.

	WEEKEND 104 (23%)	WEEKDAY 348 (73.9%)	P value
Age(years) (mean± sd)	72.1 (±14.6)	73.4 (± 13.8)	0.39
Gender (Female) (%)	47 (45.2)	167 (48)	0.62
Heart rate (mean ± sd) / Systolic blood pressure (mean±sd)	84.52(±17.2)/ 133 (±24.9)	82.6 (±18) / 133.1(±25.7)	0.41 / 0.93
Antiplatelet /Anticoagulant	21(20.2) / 39(37.5)	74 (21.3) / 127(36.5)	0.84 / 0.82
Hemoglobin (gr/dl) mean (±sd)	120 (±26.5)	118 (±29.7)	0.59
Length of hospital stay (days) (mean ±sd)	8.38 (±7.7)	7.8 (±6.9)	0.6
Time to colonoscopy (days) (mean ±sd)	4.6 (±3.2)	4.5 (±2.6)	0.5
Adverse outcome (%)	33(31.7)	123(35.4)	0.49
Transfusion (%)	25 (24.0)	102 (29.3)	0.29
Treatment (%)	9 (8.7)	52 (14.9)	0.10
Clinical Intervention (%)	30 (28.8)	124 (35.6)	0.2
Rebleeding (%)	11 (10.6)	30 (8.6)	0.54
Severe Bleeding (%)	29 (27.9)	109 (31.3)	0.50
Death (%)	3 (0.9)	3 (2.9)	0.14

[Table 1: Characteristics and results of patients admitted for LGB on weekend and weekday]

**Conclusion:** The outcomes for patients admitted with acute lower gastrointestinal bleeding (LGB) no differ depending on weekend versus weekday admission. The timing of colonoscopy no differ on weekday versus weekend. This study was limited by being a single institution study, which could lead to a sampling bias. Our findings should be reevaluated in other healthcare systems under the same socioeconomic conditions.

**Introduction:** The use of multiple antithrombotic medications, including anticoagulants and antiplatelet agents have been on the rise. When prescribed in dual or triple combinations, these regimens are considered complex antithrombotic therapies (CAT). CAT is frequent in patients with acute lower gastrointestinal bleeding (LGB). However, there is little data on the clinical course of patients undergoing CAT.

**Aims & Methods:** The aim of this study was to analyze the relationship of CAT (dual treatment: antiplatelet - anticoagulant or antiplatelet - antiplatelet) and the adverse outcomes on patients with LGB.

International Classification of Diseases, 9th Revision, Clinical Modification codes for admission diagnosis were used to identify retrospectively

a cohort of patients with acute LGB from January 2013 to December 2017 hospitalized to in a tertiary care, university-affiliated hospital. Data were extracted from the electronic clinical records of the Hospital. The primary outcome studied was severe LGIB as defined

(1) continued bleeding in the first 24 hours of admission (transfusion  $\geq 2$  units of packed red blood cells and/or a decrease in hematocrit  $\geq 20\%$ ) and/or

(2) recurrent bleeding after 24 hours of clinical stability (rectal bleeding accompanied by a further decrease in hematocrit  $\geq 20\%$  and/or additional blood transfusions and/or readmission for LGIB). Secondary outcomes included:

- Re-bleeding,
- Transfusion requirements,
- Treatment (endoscopy, interventional radiology or surgery),
- Readmission and
- Death.

Re-bleeding was defined as

(1) clinically significant recurrent bleeding requiring repeat endoscopic or radiographic procedures (after initial colonoscopy) or

(2) additional blood transfusion requirements or

(3) a further decrease in hematocrit of 20% or more after a 24-hour period of stability after initial presentation.

For discrete variables we tested for significant differences between groups with X2 tests. If 25 % or more of cells had expected values less than 5; the Fisher exact test was used. P values  $< 0.05$  were considered statistically significant. Differences in outcomes were expressed in odds ratio (OR) with 95% confidence intervals (95%CI). Statistical analysis was performed using STATA 14.1 software (StataCorp.2015)

**Results:** A total of 471 consecutive patients admitted with LGB were identified 417 (88.5 %) in not CAT group versus 54 (11.5%) in CAT group. Mean age was 76.8 years in CAT group versus 72.6 in not CAT group, 203 (48.7%) were men in not CAT group and 42 (77.8 %) in patients using CAT. The most common source bleeding was diverticular 114 (27.3%) in not CAT group and ischemic colitis 13 (24.1%) in CAT group. Outcomes of patients admitted for lgb (with CAT treatment versus without CAT treatment) are shown in Table 1.

	WITH CAT 54 (11.5%)	WITHOUT CAT 417 (88.5%)	OR (95%CI)
SEVERE LGB	24 (44.4)	115 (27.8)	2.1 (1.18 - 3.75)
TRANSFUSION	23 (42.6)	105 (25.2)	2.21 (1.23 - 3.95)
REBLEEDING	8 (14.3)	34 (8.2)	1.96 (0.86 - 4.49)
TREATMENT	10 (18.5)	50 (12)	1.67 (0.79 - 3.52)
READMISSION	8 (14.3)	12 (2.9)	5.87 (2.28 - 15.1)
DEATH	0 (0)	6 (1.4)	2.1 (1.18 - 3.75)

[Table 1: Outcomes of patients admitted for LGB (with CAT treatment versus without CAT treatment)]

**Conclusion:** Patients in CAT have a higher frequency of severe LGB; transfusion and readmission compared to patients without CAT. No difference was found between them for re-bleeding, need for treatment and death.

## P0462 EPIDEMIOLOGY AND TIME TRENDS OF LOWER GASTROINTESTINAL BLEEDING - A POPULATION BASED COHORT STUDY OVER MORE THAN 30 YEARS

Vora P.<sup>1,2</sup>, Pietilä A.<sup>3</sup>, Brobert G.<sup>4</sup>, Salomaa V.<sup>3</sup>

<sup>1</sup>Bayer AG, Epidemiology, Berlin, Germany, <sup>2</sup>Ludwig-Maximilians-University, IBE, Munich, Germany, <sup>3</sup>National Institute for Health and Welfare (THL), Department of Public Health Solutions, Helsinki, Finland, <sup>4</sup>Bayer AB, Epidemiology, Solna, Sweden

**Contact E-Mail Address:** pareen.vora@bayer.com

**Introduction:** Gastrointestinal bleedings (GIBs) are acute events which are potentially severe but not always life threatening and often can be safely treated. There have been numerous studies reporting on the rates of GIBs associated with use of drugs mostly focusing on upper GIBs and data regarding lower GIBs (LGIBs) in the general population is limited

**Aims & Methods:** The aim of this study was to evaluate the incidence rates of IGIBs and the trends overtime in the general population of Finland. Data from participants of prospectively conducted population-based FINRISK health examination surveys was utilized for this study. FINRISK enrolled persons aged 25-74 years, recruited by random sampling from the population register, stratified by 10-year age group, sex and study area. The total number of participants in each survey was approximately 6000-8000. The participation rate in 1972 survey was  $>90\%$  with a gradually declining trend to 57% in men and 67% in women in 2012. The follow-up took place using record linkage to the country-wide electronic health registers which included hospital discharge register and causes of death register. With the help of these national registers, the coverage of the follow-up was 100% for persons living in Finland. The follow-up period was from the enrollment up to the onset of an IGIB leading to hospitalization, death due to any cause, or end of the follow-up period which was December 31<sup>st</sup>, 2016. Participants with a history of GIBs before the baseline were excluded from the analyses. Incidence rates, recurrence rates (events recorded were  $>30$  days apart), cause-specific mortality rates and 28-day case-fatality rates for IGIBs were calculated with 95% confidence intervals (CIs). The time-trends in event rates were calculated using a log-linear poisson regression model adjusting for baseline age, gender, region, and the year of enrollment. Age standardization was conducted using weights from the European standard population

**Results:** A total of 71,068 participants were included in the study and they experienced 1750 incident IGIBs. The median age of participants experiencing IGIBs was 49.9 years and among the ones without GIBs it was 45.4 years. The age standardized incidence rates for IGIBs in males and females were 1.58 and 1.29 per 1000 py, respectively. Among men, there was a slight increase in the early 1990's but after that a constant decline ending at the level of about one-third of those in the late 1980's (ref. period). Among women, there was a steady decline over the years ending up to less than 15% of the rates in the late 1980's by the end of the study period in 2012-16. Among incident IGIBs, the recurrence rates of IGIBs in males and females were 11.4 and 11.1 per 1000 py, respectively. There was a substantial random variation in the proportion of recurrent IGIBs but in general an increasing trend was observed. Cause-specific mortality rates for IGIBs were the lowest in the study with 24 deaths. Cause-specific mortality rates in males and females were 0.01 and 0.03 per 1000 py, respectively. The 28 day case-fatality rates in males and females were 0.7% and 1.7%, respectively. Trends overtime of cause-specific mortality rates and case-fatality rates due to IGIBs could not be calculated due to the low number of cases

**Conclusion:** Overall, the age-standardized incidence rates of IGIBs are higher in males than in females. The rates of IGIBs have significantly decreased since the late 1980's. The mortality rates due to IGIBs were in general low but tended to be higher in females compared to males

## P0463 PROSPECTIVE EVALUATION OF GASTROINTESTINAL BLEEDING IN PATIENTS UNDER DIRECT ORAL ANTICOAGULANT THERAPY: A REAL-WORLD STUDY

Alcalá L.<sup>1</sup>, Jimenez Hernandez C.<sup>1</sup>, Cerdá M.<sup>2</sup>, Santamaría A.<sup>2</sup>, Alonso-Cotner C.<sup>1,3</sup>

<sup>1</sup>Hospital Universitari Vall d'Hebron & Facultat de Medicina, Universitat Autònoma de Barcelona, Gastroenterology, Barcelona, Spain, <sup>2</sup>Hospital Universitari Vall d'Hebron & Facultat de Medicina, Universitat Autònoma de Barcelona, Hematology, Hemostasis Unit, Barcelona, Spain, <sup>3</sup>CIBER de Enfermedades Hepáticas y Digestivas (CIBERehd), Gastroenterology, Barcelona, Spain

**Contact E-Mail Address:** lgalcala1986@gmail.com

**Introduction:** Gastrointestinal bleeding (GIB) is a common adverse event associated to anticoagulant therapy. Pivotal clinical trials have shown that compared to warfarin, direct oral anticoagulants (DOACs) have a similar efficacy to prevent thromboembolic complications, but with higher rates of GIB. However, real-world studies are needed to assess the risk and severity of GIB in patients under direct oral anticoagulant therapy.

**Aims & Methods:** We aimed to analyse the severity of GIB with DOACs, compared to vitamin K antagonists (VKAs) in patients admitted to the emergency department with GIB who were under anticoagulant therapy. Patients under anticoagulant therapy admitted to the emergency department with GIB were prospectively recruited from July 2016 to January 2018. Inclusion criteria were patients with non-valvular atrial fibrillation (NVAF) or thromboembolic disease treated with DOACs, and patients with AF of any cause, mechanical heart valve or thromboembolic disease treated with VKAs. Patients under heparin therapy were excluded. Clinical presentation, the need for blood transfusion, length of hospital stay, and results of endoscopic and radiologic studies were recorded. Severity of the bleeding episode was defined through the International Society of Hemostasis and Thrombosis (ISTH) scale. Patients were followed up until discharge or death.

**Results:** Throughout the study, a total of 208 events of GIB were documented in 178 patients: 119 events under AVKs, and 89 events under DOACs (Apixaban=36, Rivaroxaban=29, Dabigatran=19, Edoxaban=5). Female sex was more prevalent in both groups (54% in the VKA group and 59% in the DOAC group). Mean age in both groups was similar (VKAs: 78.6±0.9 years, DOACs: 80.2±0.7 years,  $p = ns$ ). CHADS<sub>2</sub>/VASC score and previous history of GIB were similar in both groups, although a higher prevalence of chronic kidney disease in the AVK group was observed ( $p = 0.009$ ) while a higher prevalence of chronic cerebrovascular disease was seen in the DOAC group ( $p = 0.024$ ). Concomitant anti-platelet therapy was 16% in the VKA group, and 24.7% in the DOAC group ( $p = ns$ ). Clinical presentation was lower GIB in 52.9% of the VKA group patients and 53.9% in the DOAC group ( $p = ns$ ). According to ISTH, major bleeding was the most frequent in both groups (VKAs: 77.3%, DOACs: 82%;  $p = ns$ ). Mean hemoglobin on admission was 10±0.5 g/dL in the VKA group, and 10.1±1 g/dL in the DOAC group ( $p = ns$ ). Decrease of hemoglobin compared to last known value was 2.7±0.2 g/dL in the VKA group, and 3±0.2 g/dL in the DOAC group ( $p = ns$ ). The mean number of packed red blood cells transfused was similar in both groups (2.26 ± 0.23 in VKA group, and 2.30 ± 0.28 in DOAC group ( $p = ns$ ). No differences were observed in the length of hospital stay between groups.

**Conclusion:** Gastrointestinal bleeding severity is similar in patients taking DOACs when compared to patients under VKAs therapy. Future studies with a higher number of patients are needed to confirm our data.

## P0464 SILENCING OF MBD2 AND EZH2 INHIBIT THE PROLIFERATION OF COLORECTAL CARCINOMA CELLS BY RESCUING THE TRANSCRIPTION OF SFRP

Xie Y.<sup>1</sup>, Wang F.<sup>2</sup>, Zhang J.<sup>2</sup>, Qi J.<sup>3</sup>

<sup>1</sup>Zhongnan Hospital of Wuhan University, Gastroenterology, Wuhan, China,

<sup>2</sup>Zhongnan Hospital of Wuhan University, Wuhan, China, <sup>3</sup>Zhongnan Hospital of Wuhan University, GI Department, Wuhan, China

**Contact E-Mail Address:** qiqidelizi@163.com

**Introduction:** The secreted frizzled related proteins (SFRPs) is an extracellular inhibitors of wnt pathway signaling and was found to be underexpressed in the early stage of colorectal tumorigenesis due to hypermethylation of the promoter. MBD2 and EZH2 are core members of MBD and PCG protein families respectively, which have been known as crucial proteins of epigenetic regulation.

**Aims & Methods:** The aim of this study is to figure out the potential role of MBD2 and EZH2 proteins in colorectal cancer (CRC) and its effects on the transcription of SFRP. The mRNA expression of SFRPs in CRC and adjacent noncancerous tissues are analyzed by bioinformatics. Real-time quantitative polymerase chain reaction (qRT-PCR) and western blot were used to detect the expression of MBD2, EZH2 and SFRPs in CRC cell lines and human normal intestinal mucosa cell NCM460. We knockdown of MBD2 and EZH2 using small interfering RNA (siRNA) to clear its role in the regulation of SFRPs gene expression. The function of MBD2 and EZH2 in cell proliferation, cycle, apoptosis and invasion was examined in CRC cell lines.

**Results:** The mRNA expression level of SFRPs was significantly decreased in CRC tissues and cell lines compared to adjacent tissues and NCM460 ( $P < 0.05$ ). However, the mRNA level of EZH2 and MBD2 were highly expressed in CRC cell lines ( $P < 0.05$ ). In SW480 cell, interference with MBD2 could reactivate the expression of SFRP1 ( $P < 0.05$ ), but interference with EZH2 could not reactivate it ( $P > 0.05$ ); Interference with EZH2 could reactivate the expression of SFRP2, SFRP4 and SFRP5 ( $P < 0.05$ ), but interference with MBD2 could not activate it. In HCT116 cell, interference with MBD2

could reactivate the expression of SFRP1 ( $P < 0.05$ ), but interference with EZH2 could not reactivate it ( $P > 0.05$ ). However, in SW480 and HCT116 cells, interfering with MBD2 and EZH2 at the same time was more effective than interfering one of them alone in restoring the expression of SFRP1, SFRP2, SFRP4 and SFRP5 genes ( $P < 0.05$ ). We found that compared with interfering with MBD2 or EZH2 alone, interfering with MBD2 and EZH2 together could significantly inhibit the proliferation, migration and invasion of CRC cells. Flow cytometry analysis showed that simultaneous interference with MBD2 and EZH2 in SW480 cell was more effective than interfering with MBD2 or EZH2 alone in blocking cell cycle and causing more cells to stagnate in S phase ( $P < 0.05$ ); however, in HCT116, compared with interfering with MBD2 or EZH2 alone, more cells stagnated in G0/G1 phase when interfering with MBD2 and EZH2 at the same time ( $P < 0.05$ ). In addition, compared with interfering with MBD2 or EZH2 alone, interfering with MBD2 and EZH2 in SW480 and HCT116 cells together could remarkably increase apoptosis ( $P < 0.05$ ).

**Conclusion:** Compared with silencing MBD2 or EZH2 alone, silencing MBD2 and EZH2 can inhibit the proliferation of CRC cells by restoring the expression of SFRP more effectively. MBD2 and EZH2 may be potential therapeutic targets for colorectal tumors, however, the regulatory mechanism of SFRP remains to be further studied in the future.

**Introduction:** Colorectal cancer (CRC) is the conclusive result of a multi-step phenomenon that, in most cases, goes through the adenoma-carcinoma sequence pathway. Some substances of plant origin have been reported to exert an effect in reducing intestinal neoplasm development, especially in animal models. In detail, silymarin, a phytoestrogen compound derived from milk thistle (*Silybum marianum*) may decrease intestinal carcinogenesis through both anti-oxidant and estrogen receptor-beta agonist properties. Previous studies have shown that silymarin is able to hamper intestinal carcinoma (IC) development in Apc<sup>Min/+</sup> mice and familial adenomatous polyposis patients with ileal pouch-anal anastomosis. *Boswellia serrata* is a plant with anti-inflammatory properties. Interestingly, boswellic acids, especially Acetyl-11-Keto-beta-Boswellic Acid (AKBA), a component of the gum resin of *Boswellia serrata*, has been recognized as a promising agent for the prevention of intestinal tumorigenesis in a mouse model of inherited carcinogenesis, i. e. APC multiple intestinal neoplasia (min) animals.

**Aims & Methods:** Our aim was to assess whether an enriched nutritional formulation with anti-carcinogenic properties may prevent inherited intestinal cancer (IC) in animal model.

Eighty male mice were used (40 wild type for diet safety test and 40 adenomatous polyposis coli multiple intestinal neoplasia ApcMin/+). Forty ApcMin/+ mice were divided into two groups: 20 standard and 20 enriched diet. At the 100th day, colonoscopy was performed, then animals were sacrificed after 10 days. In each group, four subgroups received intraperitoneal bromodeoxyuridine (BrdU) injection. We evaluated: lesion number/size, histological inflammation/dysplasia/neoplasia, pro-inflammatory cytokine mRNA expression, BrdU/TUNEL.

**Results:** No mice died during the safety test. Compared to standard, enriched diet reduced solid lesion total number (203 versus 416) and mean number±SD/animal (12.6±5.0 versus 26.0±8.8;  $p < 0.001$ ). In enriched diet group a reduction in polyp size was observed ( $p < 0.001$ ). Histological inflammation and pro-inflammatory cytokine expression were similar. Low grade dysplasia (LGD;  $p < 0.001$ ) and intestinal carcinoma (IC;  $p < 0.001$ ) areas were decreased in enriched diet. IC was observed in 100% in standard and 85% in enriched formulation assuming animals. Enriched diet showed higher epithelial proliferation/migration and increased apoptosis in normal mucosa and LGD areas ( $p < 0.001$ ).

**Conclusion:** Our results are promising for a chemo-preventive synergic effect of enriched formulation in inherited IC.

## P0466 MICRORNA 375 REGULATES PROLIFERATION OF COLORECTAL CANCER CELLS BY SUPPRESSING THE MTDH EXPRESSION

Han S.H., Mo J.-S., Chae S.

School of Medicine, Wonkwang University, Department of Pathology, Iksan, Korea (Republic of)

**Contact E-Mail Address:** chaesc@wku.ac.kr

**Introduction:** MicorRNAs play important roles in the pathogenesis of human diseases by down-regulation of target genes in various cells or tissues. We have previously identified MicoRNA 375 (MIR375) as a colorectal cancer associated microRNA. It is significantly down-regulated in human colorectal cancer tissues. The putative MIR375 target genes were also identified by comparing the mRNA microarray analysis data of MIR375-overexpressing cells with the candidate MIR375 target genes predicted by public bioinformatic tools.

**Aims & Methods:** The purpose of this study is to determine the correlation between the MIR375 and its novel target gene, metadherin (MTDH), in human colorectal cancer cells and tissues. A luciferase reporter system was used to confirm the effect of MIR375 on MTDH expression. Protein or mRNA expression of the target gene and associated molecules were by western blot or qRT-PCR, respectively. Cell proliferation assays were employed using an EZ-Cytox cell viability assay kit. And flow cytometry was used to compare cell cycle progression.

**Results:** MTDH is a direct target gene of MIR375. MTDH mRNA and protein expression levels were directly down-regulated by MIR375 mimic transfection. We observed that MIR375 down-regulated the several MTDH-mediated pathways which include PIK3CA, NFkB and BRAF-MAPK-CTNNB1 in colorectal cancer cells. Our results showed that the cell proliferation and angiogenesis in colorectal cancer cells were regulated by MIR375.

**Conclusion:** Our results indicate that MTDH is a direct target of MIR375 in human colorectal cancer cell lines, and suggest that the down-regulation of MIR375 modulates MTDH signaling pathways in human colorectal cells and tissues. Thus, MIR375 may have a therapeutic value in relation to human colorectal cancer.

**Introduction:** Human endogenous retroviruses (HERVs) are human DNA sequences that are homologous to exogenous retroviruses. Accumulating evidence has highlighted the close correlation between colorectal cancer (CRC) and HERVs [1]. In a previous study, we identified and designated a new H family HERV (HERV-H) gene, HERV-HX, which is actively expressed in CRC tumor tissues as compared to adjacent normal tissues [2]. However, the functional and clinical significance of HERV-HX remains unexplored.

**Aims & Methods:** This study aimed to elucidate the biological function, molecular mechanism and clinical significance of HERV-HX in CRC. HERV-HX expression was assessed by TaqMan probe RT-qPCR and in situ hybridization. siRNA specifically targeting HERV-HX and expression vector carrying the ORF of HERV-HX were used for the loss- and gain-of-function assays in different CRC cells. The biological functions of HERV-HX were determined by cell viability assay, colony formation, wound-healing migration and matrigel invasion assays, cell cycle and apoptosis flow cytometry,

Ki-67 and TUNEL staining. Effects of HERV-HX on tumorigenicity and metastasis *in vivo* were assessed using subcutaneous xenograft and tail vein injection models respectively. Protein levels were assessed by western blot and immunostaining. Protein localization was investigated by immunofluorescence staining and western blot. Molecular mechanism was investigated by RNA sequencing and pathway luciferase reporter assays.

**Results:** HERV-HX was specifically upregulated in cell lines of colon cancer but not other cancer types, and was significantly upregulated in CRC tumors as compared to adjacent normal tissues ( $P < 0.0001$ ). HERV-HX expression was not associated with age, gender, lesion location, but was positively associated with TNM staging ( $\rho = 0.721$ ,  $P = 0.0004$ ). HERV-HX expression was significantly higher in samples with vs without lymph node or distant metastasis ( $P < 0.0001$ ), while no significant difference was found between TNM stage I and II or between III and IV cases.

Knockdown of HERV-HX in HT29 and LoVo cells significantly suppressed cell viability and colony formation, induced apoptosis and cell cycle arrest, and inhibited migration/invasion ability. Conversely, overexpression of HERV-HX in SW480 and HCT116 cells produced opposite effects. HERV-HX expression significantly promoted tumorigenicity and also increased metastases to the lung and/or liver *in vivo* (overall metastatic rates: 53% in HERV-HX group vs 28% in control group).

In concordance with the growth- and migration-promoting effects of HERV-HX, protein levels of cell cycle markers (p21, p27, cyclin D1 and CDK4), apoptosis markers (cleaved forms of caspase-8, caspase-9, caspase-3 and PARP), the proliferation marker PCNA and epithelial-mesenchymal transition markers (E-cadherin, N-cadherin,  $\beta$ -catenin, Vimentin, Slug and Snail) were significantly altered following knockdown or overexpression of HERV-HX. HERV-HX significantly activated Wnt/ $\beta$ -catenin signaling as indicated by the increased TOP/FOP luciferase activity. Importantly, examination in cells, subcutaneous xenografts and liver/lung metastatic nodules showed that HERV-HX increased the total level and nuclear translocation of  $\beta$ -catenin by inhibiting its phosphorylation.

**Conclusion:** Upregulation of HERV-HX plays a pivotal role in tumor progression and metastasis of CRC. HERV-HX inhibits phosphorylation-mediated degradation of  $\beta$ -catenin, causes its cellular accumulation and nuclear translocation, and subsequently activates Wnt/ $\beta$ -catenin signaling to promote colorectal tumorigenesis.

**Introduction:** Colon cancer is one of the principal types where a functional link between inflammation, tumor microenvironment and progression had been noted; colitis-associated cancer is also related to striking changes in the lymphatic vasculature and dysfunction in the intestinal lymphatic network is a well-established feature of human inflammatory bowel disease. The ECM protein EMILIN1 is expressed, among several other tissues, in the normal colonic mucosa; it controls elastogenesis, blood pressure homeostasis and is a key structural element in the maintenance of the integrity of lymphatic vessels. It is an adhesive ligand of  $\alpha$ 4/ $\alpha$ 9 $\beta$ 1 integrins via its gC1q domain and this interaction down-regulates cell proliferation. The aim of this project is to analyze the possible role of EMILIN1 in inflammatory colon cancer.

**Aims & Methods:** The impact of intestinal inflammation and carcinogenesis was analysed in *Emilin1*<sup>-/-</sup> (KO) and E933A EMILIN1 transgenic mice (E933A TG), in which a mutant EMILIN1, unable to be engaged by  $\alpha$ 4 $\beta$ 1,

is deposited. Chronic colitis was induced treating mice with 2% DSS in the drinking water; colon tumours were induced with a single injection of AOM followed by three 1-week exposures to 2% DSS. Colitis and tumour growth were analysed over time by endoscopy; clinical scoring of colitis was performed applying the MEICS and DAI indexes.

**Results:** KO and E933A-TG presented higher colitis scores and more severe mucosal injury, fibrosis and inflammatory infiltrates than WT. RNAseq analysis confirmed the up-regulation of several inflammatory response genes and the down-regulation of cell-cell adhesion molecules in E933A-TG. KO and E933A-TG mice had also higher tumour incidence, bigger adenomas and less survival. Whole-mount analyses on colon specimens demonstrated that both KO and E933A-TG lymphatic vessels are irregular, dilated and characterized by dysmorphic structures and wide lacunae. This abnormal network architecture leads to enhanced lymphatic dysregulation, decreased lymph flow and impaired inflammatory cell drainage, providing a possible explanation for the reduced inflammatory resolution observed in KO and TG models.

**Conclusion:** Overall these data demonstrate that EMILIN1 by virtue of its multifaceted functions is centrally located in the context of the development and progression of inflammatory colon cancer. The integrity of EMILIN1 is necessary to control proliferation and to guarantee the regeneration of competent and well functioning lymphatic vasculature.

**Introduction:** Stem cells of the colon epithelium are dysregulated in chronic inflammatory diseases such as ulcerative colitis and colorectal cancer, both pathologies with high incidence in the population. In order to better understand the pathophysiology of those diseases, we used the organoid model to study stem cell functions and demonstrated the critical roles of protease-activated receptors (PAR<sub>1</sub>, PAR<sub>2</sub>, PAR<sub>3</sub>) in stem cell regulation.

**Aims & Methods:** Colon crypts were isolated from WT or PAR KO male and female mice. Crypts were cultured in 3D conditions as organoids (colonooids) for one week. From day 2 to day 6 of culture, PARs were activated by specific agonist peptides. Number and size of colonoids were measured to analyze survival and proliferation of colon stem cells. Expression of PARs and key signaling molecules were studied by qRT-PCR and immunolabeling.

**Results:** The PAR activation by specific agonist peptides differently influenced stem cell proliferation. While PAR<sub>1</sub> promoted stem cell proliferation, PAR<sub>2</sub> was found to slow down this process. Interestingly, PAR<sub>2</sub> was highly expressed in colon primitive cells from male mice compared to females. Its brake on cell proliferation was specific of male sex since, in females, stem cell proliferation was increased by both PAR<sub>1</sub> and PAR<sub>2</sub> activation. This sexual dimorphism was linked to the PAR<sub>2</sub>-dependent expression of genes implicated in stem cell proliferative pathways. The Glycogen Synthase Kinase 3beta (GSK3beta) plays a critical role in stem cell behavior and has been implicated in colon inflammation and cancer. Using PAR<sub>2</sub> or PAR<sub>3</sub> KO mice, we found its activation under the control of PAR<sub>2</sub> and PAR<sub>3</sub> and critical for male stem cell survival. Finally, better recovery of passaged male colonoids (further improved by PAR<sub>2</sub> activation) and of primitive sorted male cells as colonoids suggested that male stem cells have higher resistance capacities compared to females.

**Conclusion:** Our results demonstrate that PAR<sub>1</sub>, PAR<sub>2</sub> and PAR<sub>3</sub> play specific roles in colon stem cell regulation that could be targeted in anti-inflammatory and anticancer therapies. Work is ongoing to determine the fine impact of PARs on stem cell differentiation and the implication of specific proteases in colon stem cell regulation.

**Contact E-Mail Address:** claudia.a.mourato@gmail.com

**Introduction:** Colorectal cancer (CRC) is the main tumour-related cause of death worldwide, being the third most common cancer, with rectal adenocarcinoma accounting for almost one-third of all CRC [1]. Treatment of advanced rectal cancer consists mainly in pre-operative chemoradiotherapy (CRT), a strategy that not always induces tumour response and that decreases the quality of life of patients [2]. In addition, there is no available method to determine whether a patient will benefit from CRT, with all patients receiving the same therapy regardless of its outcomes. Therefore, the possibility to predict disease progression and response of patients to CRT would allow its selective use, thus avoiding toxicity and associated morbidity in non-responders. In this sense, microRNAs (miRNAs) with a role in the pathogenesis of CRC, may function as regulators of tumour response to therapy and are being increasingly evaluated as potential diagnostic, prognostic and predictive biomarkers of response to therapy [3].

**Aims & Methods:** The aim of this work was to identify miRNAs as potential biomarkers of disease progression and pre-CRT predictors of pathological response in rectal cancer. Using a targeted approach, the expression profile of single miRNAs (miR-16-5p, miR-145-5p, miR-335-5p, miR-135b-5p and miR-21-5p) was analysed in 94 patients with locally advanced rectal cancer. 14 were identified as pathological complete responders (pCR) and 80 as pathological incomplete responders (pIR). Total RNA was isolated from normal (adjacent non-tumour) and tumour rectal samples tissues collected before and after long course CRT by biopsy and colectomy, respectively. The miRNA expression profile was analysed by Real Time-PCR using TaqMan® Advanced miRNA assays. miR-484 was used for normalization.

**Results:** In pIR patients, miR-21-5p demonstrated higher expression ( $p \leq 0.05$ ) in pre-CRT tumour tissue when compared with pre-CRT normal tissue and the same expression profile was observed in post-CRT samples ( $p \leq 0.01$ ). In addition, a similar expression profile was observed in miR-135b-5p analysis, with higher levels of miR-135b-5p in pre- and post-CRT ( $p \leq 0.001$ ) tumour samples when compared with normal samples. On the contrary, the expression profile of both miR-21-5p and miR-135b-5p showed the opposite tendency in pCR patients, with similar or lower miRNAs levels in pre-CRT tumour samples comparing with normal tissue. This suggests that a lower tumour expression of these miRNAs prior to pharmacological intervention could be indicative of a better response to treatment, which is also in line with the well-described oncogenic role of miR-21 and miR-135. On the other hand, no significant differences were observed in the expression profiles of miR-16-5p, miR-145-5p and miR-335-5p between pIR and pCR patients.

**Conclusion:** This work highlights that miRNAs are differentially expressed between pre- and post-CRT normal and rectal cancer tumour samples. Among the evaluated miRNAs, miR-21-5p and miR-135b-5p appear to be the most promising predictors of pre-treatment pathological complete response and may provide new insights for consolidating discovery of biomarkers of response to treatment.

**Introduction:** There is ongoing debate about factors that drive pathogenesis of different types of colonic polyps. Several studies have reported an enrichment for stomach-specific genes in sessile serrated lesions in the right colon.

**Aims & Methods:** Aim of the present study was to assess if a gene-panel derived from analysis of upper gastrointestinal cancers can discriminate different phenotypes of colonic polyps. RNA was extracted from 64 colonic samples collected as part of the S:CORT study. This comprised 15 sessile serrated lesions (SSL), 15 tubulo-villous adenomata from the proximal (right) colon (p-TVA), 14 from the distal (left) colon (d-TVA), 10 tubulo-sessile adenomata (TSA), and 5 biopsies each from normal colonic mucosa adjacent to tubulo-villous and to tubulo-serrated adenomata. RNA-Sequencing was performed for transcriptome analysis. Data were log<sub>2</sub>-transformed, and 66 genes have been selected that have been identified in a previous study applying an unsupervised stratification to distinguish phenotypes of oesophago-gastric adenocarcinomas.

**Results:** Stratification of the colonic samples according to expression of the 66 genes was done by using the mclust algorithm on R. This revealed a distribution into 4 separate groups. The "normal" samples from non-polypoid mucosa clustered in group 3 (100.0%), without any of the polyp samples being represented in this group. SSL clustered in group 4 (86.7%), whereas both p-TVA and d-TVA clustered in groups 1 (64.3%, 46.7%, resp.) and 2 (35.7%, 53.3%, resp.). TSA were mainly represented in group 1 (80.0%), together with a subgroup of d-TVA and p-TVA. The phenotype distribution was confirmed in the principle component analysis with the first principle component being dominated by gastric genes (TFF2, MUC5AC, CTSE, CA2) and the second principle component by intestinal genes (CDX2, PHGR1) as well as genes involved in epithelial cell-cell interaction such as CLDN15 and A1CF. Phenotypic discrimination was further assessed by Fisher's exact test revealing highly significant association of the distribution given by the 66 genes and histopathology results ( $P < 0.00001$ ).

**Conclusion:** A gene panel derived from upper GI adenocarcinoma can successfully stratify phenotypes of colonic polyps. This indicates common denominators that are involved in gastrointestinal carcinogenesis, most likely luminal pathogens. SSL, TSA and TVA in the colon can be discriminated by their transcriptome profile. TSA cluster with TVA, not with SSL. There does not seem to be a difference between classic tubulovillous adenomata of proximal and distal location, but they cluster with a subgroup of tubulosessile adenomata. Prospective validation of the key markers for immuno-histochemistry is ongoing.

**Contact E-Mail Address:** alexandra.kalmar@gmail.com

**Introduction:** Long non-coding RNAs (lncRNAs) contribute to pathomechanism of various cancers including colorectal cancer (CRC). Altered LINC00152 expression in CRC was reported, but its exact localization and detailed role in CRC formation and progression are not well studied.

**Aims & Methods:** We aimed to evaluate the effects of LINC00152 silencing on whole transcriptome in colon carcinoma cells and to analyze the DNA methylation alterations caused by LINC00152 knockdown. Tissue localization of LINC00152 was investigated by using *in situ* hybridization (ISH). LINC00152 were silenced in SW480 colon carcinoma cells using Stealth siRNAs. Flow cytometric cell cycle analysis was performed using propidium-iodide DNA staining. The effect of LINC00152 silencing to genome-wide gene expression was studied on Human Transcriptome Array 2.0 microarrays. The expression of selected proteins was determined using western blot. DNA methylation alterations after LINC00152 knockdown were evaluated using Reduced Representation Bisulfite Sequencing (RRBS) method.

**Results:** Using ISH, elevated LINC00152 expression was found in both epithelial and stromal cells of CRC tissue samples. Silencing of LINC00152 significantly suppressed cell growth compared to negative control cells and caused approximately two-fold increase in apoptosis ( $p < 0.05$ ). Whole transcriptome analysis of LINC00152 silenced cells revealed significant underexpression of genes with oncogenic and/or metastasis promoting function (e.g. STC1, YES1, HES1, KLK6, PORCN) and upregulation of tumor suppressor genes (e.g. DKK1, PERP) (FDR  $p < 0.05$ , abs. value of  $\log_{2}FC > 1$ ). Knockdown of LINC00152 significantly reduced the cyclin D1 expression without attenuation of phospho-S6 protein ( $p < 0.05$ ). The decreased expression of PORCN and YES1 in LINC00152 silenced cells was also confirmed at protein levels. DNA methylation alterations after LINC00152 silencing could be genome-wide detected by RRBS including hypomethylation in SFRP4 and ALDH1A3 gene promoters.

**Conclusion:** Our results indicate that LINC00152 lncRNA can contribute to CRC pathogenesis by promoting cell proliferation through upregulation of several oncogenes/metastatic genes in WNT, PI3K/Akt, Notch and TP53 pathways and of cyclin D1 cell cycle progression gene, furthermore, by affecting the promoter methylation status of certain CRC associated genes.

## P0474 FAECAL IMMUNOCHEMICAL TESTING IN PATIENTS WITH RECTAL BLEEDING: A WASTE OF TIME?

D'Souza N.<sup>1</sup>, Benton S.<sup>2</sup>, Abulafi M.<sup>1</sup>

<sup>1</sup>Croydon University Hospital, Colorectal Surgery, Croydon, United Kingdom,

<sup>2</sup>Southern Bowel Cancer Screening Hub, Guildford, United Kingdom

**Contact E-Mail Address:** nigel151@gmail.com

**Introduction:** The faecal immunochemical test (FIT) can be used to rule out bowel cancer. Patients with rectal bleeding (RB) have been recommended not to be tested with FIT due to concerns of a high false positive rate. This study aimed to investigate the positivity rate and diagnostic accuracy for colorectal cancer of FIT in patients with rectal bleeding.

**Aims & Methods:** Patients referred from primary care in England with symptoms of suspected bowel cancer according to NICE NG12 guidelines were recruited in a prospective, ethics-approved, multicentre, diagnostic test of accuracy study, and were tested with FIT prior to colonoscopy. FIT samples were processed on the HMJACK-arc analyser. Patients were then split into groups, based on the presence or absence of RB symptoms. Faecal haemoglobin (FHB) levels and colonoscopy findings in each group were analysed. Cutoffs of FHB were set at the limit of detection, calibrated at 2ug blood per gram of faeces (ug/g), and the limit of quantification, calibrated at 10ug/g. Statistical analysis was performed on Stata using the Kruskal-Wallis or Chi-Square tests to compare continuous and categorical outcomes.

**Results:** The results of 5332 patients were analysed, of whom 1730 presented with RB with or without other associated bowel symptoms.

Patients with RB had a higher mean faecal haemoglobin than patients without RB (264.6 (std. dev. 1135) vs 62.8 (std. dev. 493),  $p < 0.01$ ), although the median value in both groups was undetectable FHB ( $< 2\text{ug/g}$ ).

FHB was undetectable ( $< 2\text{ug/g}$ ) in 57% (983/1730) of patients with RB vs 65% (2365/3602) in patients without RB ( $p < 0.01$ ). Faecal haemoglobin was less than 10ug/g in 75% (1289/1730) of patients with RB vs 85% (3065/3602) of patients without RB ( $p < 0.01$ ).

Colorectal cancer was diagnosed in 67 patients without RB, and 65 patients with RB. At a cut-off of 2ug/g, there were 2 missed cancers in patients without RB (3%) vs 2 missed cancers in patients with RB (5%,  $p = 0.63$ ). The sensitivity of FIT at a cut-off of 2ug/g for CRC was 95% in patients with RB vs 97% in patients without RB.

At a cut-off of 10 ug/g, there were 9 missed cancers in patients without RB (13%) vs 5 missed cancers in patients with RB (8%,  $p = 0.29$ ). The sensitivity

of FIT at a cut-off of 10µg/g for CRC was 92% in patients with RB vs 87% in patients without RB.

**Conclusion:** FIT can be used to triage patients with RB for investigation. The mean FHB level was significantly higher in patients with RB. However, a substantial number of patients with RB had less than 2 or 10 µg/g of FHB when tested with FIT, with similar sensitivity to patients without RB. This suggests that FIT could be used to rule out cancer in patients with RB and still reduce the negative colonoscopy rate.

**Contact E-Mail Address:** ldelapena.hv@gencat.cat

**Introduction:** The faecal immunochemical test (FIT) has a specificity of 94% for colorectal cancer (CRC) screening resulting in false positive (FP) results. The use of proton pump inhibitors (PPI) prior to FIT could decrease the accuracy of the test which would lead to a reduction in the efficacy of CRC screening.

**Aims & Methods:** We included participants with a positive FIT result who underwent total colonoscopy between 2013 and 2014. A FP result was defined as having a positive FIT ( $\geq 20$  µg haemoglobin per gram of faeces) and follow-up colonoscopy without intermediate/high-risk lesions or cancer. Screening data was anonymously linked to pharmaceutical dispensing during the study period obtained through the public data analysis program for health research and innovation (PADRIS). PPI consumption for each FIT was measured according to whether the individual had collected prescriptions with the ATC code: A02BC for the 3 months prior to the FIT. Logistic regression models, adjusted for sex and age, were carried out to analyse whether PPI consumption increased the risk of FP.

**Results:** We included 4253 positive FIT (4204 participants) with diagnostic colonoscopy. The proportion of FP was 53.49% (45.8% in men; 54.2% in women). In 1019 (23.96%) FIT, the person had received PPI 3 months prior to testing (21.0% men; 27.8% women). PPI consumption increased the probability of obtaining a FP by 13% (95% CI 9.5-16.3%) from 50.4% to 63.3% (adjusted OR: 1.65; 95% CI: 1.42 to 1.92).

**Conclusion:** Concurrent use of PPIs at the time of FIT increases the likelihood of a false positive result. The recommendation to avoid their use before colonoscopy could reduce up to 1 out of 8 FP.

**Disclosure:** Nothing to disclose

## P0476 THE NICE FIT STUDY INTERIM RESULTS: PROSPECTIVE, MULTICENTRE, DIAGNOSTIC ACCURACY STUDY OF THE FAECAL IMMUNOCHEMICAL TEST FOR COLORECTAL DISEASE IN 5332 SYMPTOMATIC PATIENTS

D'Souza N.<sup>1</sup>, Benton S.<sup>2</sup>, Abulafi M.<sup>1</sup>

<sup>1</sup>Croydon University Hospital, Colorectal Surgery, Croydon, United Kingdom,

<sup>2</sup>NHS, Bowel Cancer Screening Programme, Guildford, United Kingdom

**Contact E-Mail Address:** nigel151@gmail.com

**Introduction:** The faecal immunochemical test (FIT) detects the amount of blood in stool (faecal haemoglobin or FHB) to the nearest microgram of blood per gram of faeces (µg/g). A recent meta-analysis[1] reported that FIT could be used to rule out colorectal cancer (CRC) if less than 10µg blood was present per gram of faeces. We designed a powered, prospective, diagnostic cohort study to investigate whether this non-invasive, accurate and cheap test could be used rule out serious bowel disease such as CRC, but also high risk adenoma (HRA) and inflammatory bowel disease (IBD) instead of a colonoscopy.

**Aims & Methods:** Investigate the diagnostic accuracy of the FIT at cut-offs of 2 or 10µg/g for CRC, as well as HRA and IBD.

The study was approved by the UK Health Research Authority to recruit patients prospectively from multiple centers in England. Symptomatic patients meeting NICE referral criteria and awaiting colonoscopy were recruited via telephone and post at over 40 hospitals, and invited to perform a FIT. The HM-JACKarc analyser was used to process all FIT samples. Colonoscopy findings of serious bowel disease ie colorectal cancer (CRC), high risk adenoma (HRA) and inflammatory bowel disease (IBD), were compared to faecal haemoglobin (FHB) levels at cut-offs of 2 or 10 micrograms of blood per gram of faeces (µg/g). 2µg/g has recently been suggested as the limit of detection of faecal haemoglobin[2]. All clinical data underwent a three-level process of quality assurance, including final checks by colorectal surgeons who were all accredited endoscopists. Statistical analysis included Chi-squared test for proportions.

**Results:** The trial has recruited over 11 000 patients, and quality assured the data of 5332 patients. The prevalence of CRC was 2.5% (132/5332), HRA was 4.3% (230/5332) and IBD was 6.1% (326/5332). At cut-off of 2 or 10µg/g, the sensitivity of FIT for CRC was 96.2% and 89.4% respectively. Significantly more cases of CRC (14 vs 5,  $p=0.03$ ), HRA (107 vs 54,  $p<0.01$ ) and IBD (181 vs 131,  $p<0.01$ ) were missed at a cut-off of 10µg/g than 2 µg/g. Less patients would be triaged to colonoscopy at a cut-off of 10µg/g (81.7%) than 2µg/g (62.8%).

**Conclusion:** The diagnostic accuracy of FIT suggests it could be used to triage symptomatic patients for further investigation. Although a cut-off of 10µg/g permits a greater reduction in referral for colonoscopy, significantly more CRC, HRA and IBD is missed.

## P0477 DIGITAL CHROMOENDOSCOPY SYSTEMS (I-SCAN AND OPTICAL ENHANCEMENT) FOR COLORECTAL POLYP PREDICTION: THEIR ROLE IN THE NICE CLASSIFICATION

Robles-Medrandá C., Soria-Alcivar M., Oleas R., Olmos J.L., Baquerizo-Burgos J., Puga-Tejada M., Ospina J., Alcivar-Vasquez J., Alvarado-Escobar H., Del Valle R., Pitanga-Lukashok H., Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Gastroenterology and Endoscopy Division, Guayaquil, Ecuador

**Contact E-Mail Address:** robertoleas@gmail.com

**Introduction:** The validity of the narrow-band imaging international colorectal endoscopic (NICE) classification, using other digital chromoendoscopy systems remains unknown.

**Aims & Methods:** Aim: to validate the NICE classification using digital chromoendoscopy systems (I-scan and Optical Enhancement) for endoscopic colonic polyps prediction.

**Methods:** consecutive adult patients referred to a tertiary-center for endoscopic polypectomy, or biopsy were prospectively enrolled from April 2017 to May 2018. Lesion size, location and macroscopic features (color, vessels and surface pattern) were recorded. Real-time, endoscopic classification of polyps via NICE classification using digital chromoendoscopy systems was performed. All lesions were photographically recorded and then biopsied or resected for histology analysis (criterion standard). Accuracy, sensitivity, specificity, positive and negative predictive values for each component of the classification and for the overall prediction was calculated. A 30 randomly-selected image set was collected for inter and intra-observer agreement analysis.

**Results:** A total of 95 patients were enrolled, 52.6% were female. The mean age was 60.30 (±14.04) years. The reasons for colonoscopy were diagnostic (49.5% of cases), surveillance (27.4%), and screening (23.3%). The median Boston bowel preparation scale was 8 (range: 6-9). A total of 139 polyps were found during colonoscopy. 31/139 (22.3%) were located in the left

colon, 27/139 (19.4%) in the right colon, 26/139 (18.7%) in the transverse colon, 25/139 (18.0%) in the sigmoid colon, 19/139 (13.7%) in the rectum, and 11/139 (7.9%) in the cecum. 52/139 of the polyps (37.4%) were  $\geq 10$ mm, 44/139 (31.7%) were  $\leq 5$ mm, and 43/139 (30.9%) were 6-9mm. According to the Paris classification: 111/139 (79.9%) were sessile polyps (Is), 19/139 (13.7%) were pedunculated (Ip), 6/139 (4.3%) were subpedunculated, 2/139 (1.4%) were flat elevated lesions of the mucosa, and 1/139 (0.7%) was flat mucosal change. According to the NICE classification, the color was classified as clear (73/139 [52.5%]), intermediate (60/139 [43.2%]), and dark (6/139 [4.3%]); the surface was subdivided into uniform pattern (78/139 [56.1%]), tubular pattern (57/139 [41.0%]), and amorphous pattern (4/139 [2.9%]); vessels were distributed as no vessels (51/139 [36.7%]), regular vessels (69/139 [49.6%]), and irregular vessels (19/139 [13.7%]). NICE types were type 1 (63/139 [45.3%]), type 2 (68/139 [48.9%]), and type 3 (8/139 [5.8%]). Using I-scan and Optical Enhancement, NICE classification reached a sensitivity specificity, positive and negative predictive value of 89%, 70%, 36% and 97%, respectively. Every NICE classification parameter reached an excellent inter and intra-observer agreement ( $>0.80$  K value) (table 1).

Macroscopic features	Overall accuracy [% (95% CI)]				Interobserver agreement (K)		Intraobserver agreement (K)	
	Sensitivity	Specificity	PPV	NPV	M.S.A.	M.S.A.	H.A.E.	J.O.
Color	68 (45 - 86)	96 (78 - 100)	94 (70 - 100)	76 (56 - 89)	0.81	0.93	0.95	0.95
Vessels	55 (32 - 77)	83 (59 - 96)	79 (49 - 95)	62 (41 - 81)	0.92	0.93	0.94	0.94
Surface	86 (65 - 97)	96 (81 - 100)	95 (75 - 100)	90 (73 - 98)	0.85	0.94	0.95	0.94
NICE type	89 (52 - 100)	70 (55 - 83)	36 (17 - 59)	97 (85 - 100)	0.85	0.94	0.89	0.94

[Table 1. Overall accuracy, inter and intraobserver agreement analysis of the NICE classification using digital chromoendoscopy systems.]

**Conclusion:** Digital chromoendoscopy systems (I-scan and Optical enhancement) are useful also with NICE classification for prediction of polyps histology during colonoscopy.

## P0478 COMPARATIVE STUDY OF GREEK PATIENTS WITH CANCER OF THE LEFT AND RIGHT COLON BASED ON CLINICAL PRESENTATION, COMORBIDITY, HISTOPATHOLOGY AND MOLECULAR BIOMARKERS

Kalantzis L.<sup>1</sup>, Gakiopoulou X.<sup>2</sup>, Nonni A.<sup>2</sup>, Ziras N.<sup>3</sup>, Gkoumas K.<sup>1</sup>, Paulaki A.<sup>2</sup>

<sup>1</sup>Hellenic Red Cross Hospital, Gastroenterology, Athens, Greece, <sup>2</sup>University of Athens, Pathology, Athens, Greece, <sup>3</sup>Metaxa Anticancer Hospital, Oncology, Piraeus, Greece

**Contact E-Mail Address:** johnkalantzis@hotmail.com

**Introduction:** The differences in histopathology and molecular biology between right and left colon cancer were first reported in the literature by Bufill in 1990. Since then a large number of studies have confirmed their differences in epidemiology, clinical presentation, comorbidity and biological behavior, which may be related to the difference in prognosis and overall survival between the two groups.

**Aims & Methods:** Investigating statistically significant differences between Greek patients with right and left colon cancer based on clinical presentation, comorbidity, histopathology and molecular biomarkers. 144 patients diagnosed with colon cancer of any stage who received chemotherapy regimens in a Greek Oncology Hospital were included in the study. Data analysis was performed with the SPSS statistical package.

**Results:** 144 patients (86 males and 58 females) participated in the study. 100 (69.4%) patients had a primary lesion in the left and 44 (30.6%) in the right colon. The average age of diagnosis was 65.4 years and that of the BMI was 28.3 without statistically significant differences between the two groups. Statistically significant differences resulted from the clinical presentation of the disease, wherein patients with right colon cancer localization were more likely to display anemia (OR=3.09, p=0.008), while patients

with left colon cancer localization were more likely to develop bloody stools (OR=3.37, p=0.003) and feeling of incomplete evacuation (OR=2.78, p=0.05). In the case of comorbidity, patients with right primary lesion were more likely to receive metformin (OR=3.31, p=0.016), while marginal significance (p=0.056) was found in coronary artery disease, where patients with right sided neoplasia suffered from the disease to a greater percentage (20.5% vs. 9% left). Statistically significant differences were also observed in the histological characteristics between the two groups. On one hand the percentage of mucinous differentiation was higher in the right-sided group (15.9% vs 4.0% left-sided group, p=0.035, OR=4.49), while on the other hand the percentage of high grade differentiation was higher in the group of patients with left-sided colon cancer (78% vs 56.1% right-sided group, p=0.010, OR=2.78). Furthermore, the percentage of infiltrated lymph nodes was higher in the group of patients with right colon cancer compared with the left-sided group (N<sub>0</sub> left 33.3% vs 24.3% right, N<sub>1-3</sub> right 62.2% vs 38.1% left, p=0.039) as it was also the average of removed lymph nodes (right 18.1 vs 14.6 left). The study of three genes (KRAS, NRAS and BRAF) revealed statistically significant difference only regarding the KRAS gene, wherein the neoplasms of the left colon had a higher percentage of wild type KRAS gene (65.2%), in comparison with the right colon cancer group (47.2%) (p=0.062, marginal significance).

**Conclusion:** The differences in clinical presentation and symptoms of right and left colon cancer were confirmed. The highest rate of metformin and coronary artery disease in patients with right colon neoplasia may reflect correlation with the metabolic syndrome in this group and requires further study. The location of colon cancer seems to play a significant role in the behavior of the disease. Left and right colon cancer present different pathogenic mechanisms, probably related to the differences in histology and molecular pathways between them.

## P0479 CLINICOPATHOLOGICAL STUDY OF LATERALLY SPREADING TUMORS OF THE COLORECTUM

Iwabuchi M., Sugimura M., Mano Y., Ukai K.  
NHO Sendai Medical Center, Gastroenterology, Sendai, Japan

**Contact E-Mail Address:** s7856@snh.go.jp

**Introduction:** Laterally spreading tumors (LSTs) of the colorectum are classified into the following four subtypes according to their morphology; granular homogeneous type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

**Aims & Methods:** The aims of this study was to clarify the clinicopathological features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 7229 endoscopically resected specimens during January 2007 and December 2018 at our institution. A total of 548 LSTs were detected. We examined the clinical features (mean age, male to female ratio, size, location, Incidence of concomitant carcinoma) according to their subtypes.

**Results:** Of these 548 lesions, a total of 204 (37.2%) were LST-GH, 61 (11.1%) LST-GM, 246 (44.9%) LST-NGF, and 37 (6.8%) LST-NGPD. Mean age of patients with each subtype was 68.4 years old for LST-GH, 67.2 for LST-GM, 66.9 for LST-NGF, and 66.2 for LST-NGPD. Male to female ratio (M/F) was 1.4 for LST-GH, 1.9 for LST-GM, 1.8 for LST-NGF, and 1.7 for LST-NGPD. Mean size of LST-GH (22.4mm) and LST-GM (26.8mm) were significantly larger than that of LST-NGF (17.0mm) and LST-NGPD (15.6mm). All subtypes were located predominantly in the proximal colon.

Incidences of concomitant carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 17.6% (36 out of 204), 37.7% (23 out of 61), 16.7% (41 out of 246), and 51.4% (19 out of 37), respectively. Incidences of concomitant submucosal carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0.5% (1 out of 204), 13.1% (8 out of 61), 2.4% (6 out of 246), and 18.9% (7 out of 37), respectively.

**Conclusion:** Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

**Contact E-Mail Address:** kruchmargo@yandex.ru

**Introduction:** The aim of the work was to study the diagnostic efficiency of using the electric and viscoelastic parameters of red blood cells (RBC) in combination with the fatty acid profile (FA) of their membranes and serum (BS) for early diagnosis and evaluation of tumor progression in patients with colorectal cancer (CRC).

**Aims & Methods:** The CRC patients (62.7±8.6 years old) included 65 patients with early stages (TNM staging I, II) and 64 with late stages (TNM staging III, IV) and different tumor locations. The healthy controls (n=35, 61.7±7.5 years old) were selected by routine clinical examination. Electric, viscoelastic parameters of RBC were studied by dielectrophoresis, RBC membrane and BS FA composition were measured using GC/MS system triple quad Agilent 7000B (USA).

Using the methods of statistical and inductive analysis, a population of logical-mathematical models was formed, from which the best model for each diagnostic task was chosen on the basis of the vector quality characteristic.

**Results:** In the patients with CRC RBC tended to have much lower findings of the range of deformation, dipole moment, polarizability at 10<sup>6</sup> Hz, capacity of membranes and much higher levels of summarized findings of viscosity, rigidity, indices of destruction, aggregation and conductivity as compared to the ones in healthy subjects under study (p< 0.0001-0.02). The diagnostic panel containing proportion of deformed cells, the amplitude of RBC deformation at a frequency of 10<sup>6</sup> Hz, the summarized rigidity, electric conductivity - achieved high diagnostic accuracy (0.97) with AUC of 0.95, a sensitivity of 0.97 and a specificity of 0.93 for differentiating early stage patients from healthy controls.

A total of 21 differentially expressed FA in RBC membrane and BS were identified. Each FA class demonstrated specific changing trends in CRC progression (down-regulation in saturated FA, monounsaturated FA and up-regulation in polyunsaturated FA during cancer progression) (p<0.0001-0.001). The combination of the above RBC electrical and viscoelastic parameters and the list of FA, including C18:1:c9, C20:2n-6, C20:3n-6, C20:4n-6, C22:4n-6, C22:5n-3, C22:6n-3 - showed the best predictive power when comparing the early stages CRC patients and late ones (AUC 0.80, diagnostic accuracy 0.77, sensitivity 0.76, specificity 0.78).

Metastasis was associated with significant changes in the electric characteristics of erythrocytes: increase of conductivity (r=0.486, p<0.0001), decrease of electric membrane capacity (r=-0.548, p<0.0001), dipole moment (r=-0.527, p<0.0001) at the background of increase of PUFA, especially C22:5n-3 (r=0.355, p<0.0001) and C22:6n-3 (r= 0.252, p<0.0001). The significant role of PUFA in carcinogenesis is probably related to the effect of their high concentrations on the immune environment (it can incorporate into the membrane phospholipids to alter their fluidity to inhibit the T-cell proliferation).

**Conclusion:** Created diagnostic panels, including electric, viscoelastic parameters and fatty acids of RBC membranes and BS, should be considered promising for early diagnosis, detection of progression of CRC.

**Disclosure:** Nothing to disclose

## P0481 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

Sugimura M., Iwabuchi M., Mano Y., Ukai K.  
NHO Sendai Medical Center, Gastroenterology, Sendai, Japan

**Contact E-Mail Address:** sugimura.mikako.fp@mail.hosp.go.jp

**Introduction:** Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.

**Aims & Methods:** The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 7229 endoscopically resected specimens performed during January 2007 and December 2018 in our hospital. A total of 668 serrated lesions (9.2%) resected were classified into three categories: HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluate the morphologic characteristics by using immunochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

**Results:** Of these 668 lesions, a total of 348 (52.1%) were HP, 178 (26.6%) SSA/P, and 142 (21.3%) TSA. Male to female ratio (M/F) was 2.28 for HP, 0.94 for SSA/P, and 2.02 for TSA. Mean size of SSA/Ps (12.1mm) and TSAs (13.5mm) were significantly larger than that of HP (8.0mm) (p<0.005, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 84% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 348), 3.4% (6 out of 178), and 3.5% (5 out of 142), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetrical pattern, whereas most of those cells in TSA distributed in the so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were significantly different between serrated lesions, SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs.

**Conclusion:** Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

**Disclosure:** Nothing to disclose

## P0482 COLONOSCOPIC WITHDRAWAL TIMES AND ADENOMA DETECTION RATE DURING SURVEILLANCE COLONOSCOPY AFTER SURGERY FOR COLORECTAL CANCER

Huh C.W.<sup>1</sup>, Jung D.H.<sup>2</sup>  
<sup>1</sup>Incheon St. Mary's Hospital, The Catholic University of Korea, Department of Internal Medicine, Incheon, Korea (Republic of), <sup>2</sup>Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea (Republic of)

**Contact E-Mail Address:** leah10042@gmail.com

**Introduction:** Withdrawal time (WT) and adenoma detection rate (ADR) are widely used quality indicators for colonoscopy. Although current guideline suggests a minimum withdrawal time of 6 minutes during screening colonoscopy, little is known about appropriate withdrawal time during surveillance colonoscopy after colorectal cancer (CRC) surgery.

**Aims & Methods:** We investigated the association between WT and ADR during surveillance colonoscopy after CRC surgery.

We performed a retrospective analysis of data from 1,341 subjects who underwent 1<sup>st</sup> surveillance colonoscopy after curative colectomy between January 2013 and April 2018. The colonoscopies were performed by 8 board-certified colonoscopists. We recorded the numbers, sizes, and histologic features of the neoplastic lesions detected during colonoscopy, as well as the duration of insertion and of withdrawal of the colonoscope during the

procedure. Colonoscopists were classified as fast or slow based in their mean WT for colonoscopy without polypectomy. The primary outcome was the ADR for each colonoscopist.

**Results:** The mean WT during colonoscopy without polypectomy was  $8.1 \pm 5.6$  minutes. Using 8 minutes as cutoff, we classified 5 colonoscopists as fast (mean WT,  $6.8 \pm 3.2$  minutes) and 3 colonoscopists as slow (mean WT,  $10.3 \pm 4.5$  minutes). Each colonoscopist's mean WT correlated with their ADR ( $r_s=0.874$ ,  $P=0.005$ ). As compared with colonoscopists with mean withdrawal times of less than 8 minutes, those with mean withdrawal times of 8 minutes or more had higher ADR ( $49.1\%$  vs.  $32.2\%$ ,  $P<0.001$ ).

**Conclusion:** In this study, we found that a minimum of 8 minutes of WT was necessary during surveillance colonoscopy after surgery for CRC. Because patients who underwent CRC surgery possess high risk for meta-chronous CRC and adenoma, ample amount of time for observation on colorectal mucosa is necessary.

**Disclosure:** Nothing to disclose

## P0483 ADENOMA DETECTION RATE IN COLORECTAL CANCER SCREENING PROGRAMS: MASTER SHOW ME THE WAY TO BECOME A HIGH DETECTOR!

Rosa-Rizzotto E.<sup>1</sup>, Saia M.<sup>2</sup>, Caroli D.<sup>3</sup>, Zorzi M.<sup>4</sup>, Monica F.<sup>5</sup>, Narne E.<sup>4</sup>, De Lazzari F.<sup>6</sup>, and Veneto Endoscopists Group for Colorectal Cancer Screening

<sup>1</sup>St. Anthony Hospital Gastroenterology Unit, Internal Medicine, Padova, Italy, <sup>2</sup>Veneto Region, Padova, Italy, <sup>3</sup>St. Anthony Hospital, Gastroenterology, Padova, Italy, <sup>4</sup>Azienda Zero, Padova, Italy, <sup>5</sup>ASUITS Cattinara Hospital, Gastroenterology, Trieste, Italy, <sup>6</sup>St. Anthony Hospital Gastroenterology Unit, Padova, Italy

**Contact E-Mail Address:** erik.rosarizzotto@gmail.com

**Introduction:** Although the adenoma detection rate (ADR) cut-off for colonoscopies after positive fecal immunochemical tests (FIT) continues to be a debated issue, the ADR is one of the most accepted benchmarks for colonoscopy quality. There is some evidence that the quality of colonoscopy screening can be improved by educational interventions.

**Aims & Methods:** This study aimed to analyze the effect of endoscopist-related characteristics on colonoscopy quality indicators and to evaluate the factors affecting ADR patterns registered in the colorectal (CRC) screening program in the Veneto Region between 2015-2017. The following data about endoscopists in screening programs between 2015-2017 were collected: age, sex, years as physician, specialization, annual colonoscopy volume. During 2010-2014, younger endoscopists (< 40 yr) underwent four meetings with a senior endoscopist (Christopher Williams), to improve general endoscopic ability and, in particular, the sensibility to detect adenomatous lesions. ADR was calculated for each operator. Data were analyzed with SPSS program.

**Results:** During the three year period, 191 endoscopists performed a total of 42,706 first colonoscopies after FIT positivity. One hundred forty with at least 20 colonoscopies after FIT positivity/yr, (mean age  $48.2\text{yr} \pm 10.8\text{yr}$  ( $M \pm SD$ ), Male 53.9%) were selected. Three hundred eight-two ADRs were collected during the observation period. Overall ADR was  $43.7 \pm 9.5\%$ . Ninety-six of the endoscopists were specialized in gastroenterology, 35 in general surgery, and 8 in other specialities. ADR was  $44.1 \pm 9.7\%$  for the gastroenterologists,  $42.7 \pm 9.6\%$  for the surgeons ( $p=ns$ ) and  $39.5 \pm 7\%$  for those with other specialities ( $p=0.033$ ). ADR was significantly higher for the younger endoscopists (30-39yr 47.5%; 40-49yr 44.6%; >50yr 41.4%, with  $p<0.001$ ). The ADRs over the three year period were similar ( $44.2\%$  vs  $42.9\%$  vs  $43.3\%$ ,  $p=ns$ ). No significant association between ADR and number of screening colonoscopies performed we found. When the ADR in 2017 of 81 endoscopists was analyzed depending on the cumulative number of total colonoscopies/yr, it was found that the those with > 300 colonoscopies/yr had higher ADRs ( $35.5 \pm 21.4\%$  vs  $43.5 \pm 11.5\%$ ,  $p=0.04$ ) in colonoscopies after FIT positivity/yr.

**Conclusion:** Study findings demonstrated that junior endoscopists and those specialized in gastroenterology were more effective in identifying adenomas during screening colonoscopy procedures. High annual colonoscopy volumes and working exclusively as endoscopists but not years of experience or being older were associated with higher ADRs. Educational interventions seemed to be effective in improving sensitivity and performance.

**Contact E-Mail Address:** rachelgingoldbelfer@gmail.com

**Introduction:** Polyp detection rate (PDR) is an accepted quality measure of colonoscopy in the average-risk population screening scenario (1).

**Aims & Methods:** **Aim:** We aimed to evaluate whether endoscopist's PDR calculated in symptomatic/ non screened situation is associated with long term post colonoscopy cancer (PCC) after initial normal colonoscopy (2).

**Methods:** A cohort of 16,645 symptomatic patients aged >50 years who underwent first-time colonoscopy in 2003-2010 was analyzed to calculate PDR of each endoscopist [divided into quartiles: Q1 (21.2-26.7), Q2 (27.8-29.6), Q3 (31.4-32.1), Q4 (38.3-42.0)]. Thereafter, 9,497 patients with normal colonoscopy were followed for PCC through National Cancer Registry or death up to Dec 2017. Cox proportional analysis was calculated for PCC and advanced stage disease (stage III,IV).

**Results:** During a median follow-up time of 7.58 years (interquartile range 6.0-8.3), PCC was documented in 38 patients and advanced cancer in 19 patients. The rate of total PCC and advanced cancer among patients that underwent the procedure by endoscopists with lower quartile ( $Q_1$  vs. other quartiles ( $Q_{2-3-4}$ ) was 10.0 vs. 4.4 cases/1,000 years and 5.6 vs. 2.0 cases/1,000 years,  $p=0.012$  &  $0.023$  respectively. After adjusting for multiple covariates the risk of total PCC and advanced stage CRC among subjects that underwent the procedure by endoscopist with lower quartile PDR was HR 1.97 (95%CI: 1.03-3.78) & 2.47 (1.00-6.14) respectively.

**Conclusion:** Symptomatic patients who undergo colonoscopy by an endoscopist with lower quartile PDR are at significantly increased risk of total and advanced stage PCC. PDR is a significant predictor of PCC also in the non-average risk population.

## P0485 SHOULD SESSILE SERRATED POLYPS HAVE SEPARATE SURVEILLANCE

O'Riordan F.<sup>1</sup>, McNamara D.<sup>1,2</sup>, Ryan B.<sup>1,2</sup>, Breslin N.<sup>1,2</sup>, O'Connor A.<sup>1,2</sup>

<sup>1</sup>Tallaght Hospital/Trinity College Dublin, Gastroenterology, Dublin, Ireland, <sup>2</sup>Trinity Academic Gastroenterology Group, Clinical Medicine, Dublin, Ireland

**Contact E-Mail Address:** fionaoriordan85@gmail.com

**Introduction:** The serrated pathway accounts for up to 30% of colorectal cancer (CRC). Sessile serrated polyps (SSPs) have the highest malignant potential of serrated lesions. SSPs occur sporadically or as part of the serrated polyposis syndrome (SPS). More recently, increased CRC risk has also been associated with an oligo-SPS phenotype and large,  $\geq 10\text{mm}$  lesions.

**Aims & Methods:** Our aim was to describe and evaluate SSP characteristics in an Irish cohort. Following ethical approval, patients with  $\geq 1$  SSP confirmed on histology between 2016-2018 were identified. Patients were stratified into four known risk groups: SPS defined by WHO criteria (SPS),  $\geq 2$  SSPs with  $\geq 10\text{mm}$  (Oligo-SPS), SSP  $\geq 10\text{mm}$  (Large-SSP), and all other SSP's (Low-risk SSP).

**Results:** 195 SSPs in 145 patients were identified; 4/145 (2.8%) SPS, 10/145 (7%) Oligo-SPS, 25/145 (17%) Large-SSP and 106/145 (73%) Low-risk SSP. Mean SSP size was 6.5mm. The most common SSP location was the ascending colon 54/195 (28%), while a significant proportion were sigmoid lesions 45/195 (23.1%). Overall, SSP subjects had a high synchronous polyp burden;  $\geq 2$  SSPs 47/145 (37%),  $\geq 1$  advanced adenoma 17/145 (12%),  $\geq 1$  non-serrated adenoma 59/145 (41%). This did not differ significantly between

groups; advanced adenomas; SPS 0%, Oligo-SPS 10%, Large-SSP 16%, Low-risk SSP 11% and  $\geq 1$  non-serrated adenoma; SPS 25%, Oligo-SPS 40%, large-SSP 44%, low-risk SSP 41%. SPS was recognised by endoscopists in 2/4 (50%) cases.

**Conclusion:** SSP patients, irrespective of risk, have a high synchronous polyp burden, including advanced adenomas. The sigmoid, excluded by two WHO SPS categories was the location for 1/4 of SSPs. Further studies to evaluate the need for SSP targeted surveillance and to consider broadening the WHO criteria are warranted.

**Contact E-Mail Address:** clarebarry72@hotmail.co.uk

**Introduction:** Ten percent of cancers diagnosed within the English Bowel Cancer Screening Programme are polyp cancers. The management of polyp cancers usually involves a choice between surgery and surveillance. This choice is contentious and can be described as 'preference sensitive': a situation where one treatment option does not have superiority in terms of evidence. The best choice therefore depends on how individual patients value the risks and benefits of treatments. Difficulties in decision making for both clinicians and patients can arise because of the unexpected nature of a diagnosis of polyp cancer. This research focuses on the experiences of clinicians and patients of treatment decision making following a diagnosis of colorectal polyp cancer. To date, and to the author's knowledge, there are no previous studies which investigate how patients make the decision between surgery or surveillance, even though each option could have a significant impact on the individual patient's quality of life.

**Aims & Methods:** This study was carried out across four NHS Trusts within the North East of England. A qualitative approach was taken, using Interpretative Phenomenological Analysis (IPA) as the approach to explore the experience and perspectives of both clinicians and patients following an unexpected diagnosis of polyp cancer. In depth semi-structured interviews with ten clinicians who were involved in the care of patients diagnosed with polyp cancer, and five patients who had experience of making a treatment decision were carried out. The focus of the interviews was around the experiences of making the decision between surgery and surveillance. The phenomenological and interpretive nature of IPA allowed the researcher to use her experiences as a nurse consultant within the analysis to identify important themes and issues expressed by the participants.

**Results:** Analysis of the interview transcripts showed that clinicians and patients were supportive of a shared approach to treatment decision making. Several themes were identified which currently prevent this from taking place. Themes which were common to both groups include: complexity of the risk information; lack of patient information resources; system (patient pathway) factors and time. Additional clinician related themes included lack of clinical data to support discussion, and influences from the multi-disciplinary team. Patient related themes included the influence of family and significant others. Many of the themes were directly related to the unexpected nature of the diagnosis of polyp cancer.

**Conclusion:** This research study has evidenced several factors which are preventing patients being fully involved in important treatment decisions following a diagnosis of polyp cancer. Recommendations for improvements in practice resulting from this study include: improving awareness of preference sensitive decisions amongst the population; improvements in patient pathways and improved access to information and resources relating to polyp cancer management for patients.

**Contact E-Mail Address:** enomo430@gmail.com

**Introduction:** As colonic stent has been covered by Japanese medical insurance, emergency operation and colonic stent have become a mainstream of treatment for the colorectal cancer obstruction instead of transanal decompression tube. But "Bridge to Surgery" by colonic stent is not recommended in the European guidelines 2014.

**Aims & Methods:** We evaluated retrospectively the treatment outcomes and long-term outcome of patients with obstructive colorectal cancer in Japan. This is a retrospective multi-center observational study under the Japan Colonic Stent Safe Procedure Research Group. The subjects were patients with histologically proven stage II/III left-sided colon or upper rectal cancer with obstruction, who underwent subsequent surgery with curative resection between 2010 and 2014. The patient age ranged from 20 to 80 years. The definition of the obstruction was defined as the necessary of continual decompression or the difficulty of oral intake. There were 302 patients from 27 institutions. Patients were divided into three groups; group E (emergency surgery, n=103), group S (stent placement, n=114), and group T (transanal decompression tube placement, n=85).

**Results:** There were no significant differences in age, gender, site of primary tumor between the E group and the S group. The ratio of rectal cancer was significantly higher in the group T than the group E, and the ratio of Stage IIb was significantly higher in the group S and in the group T than the group E. The 3-year Recurrence Free Survival (RFS) rate was 64.8 % in S group, 68.9 % in E group, 53.0 % in T group, respectively. There was no difference between S group and E group, and T group was significantly lower than E group (p=0.0170). Subgroup analysis showed that the 3-year RFS of patients with colon cancer did not differ among the three groups, while the 3-year RFS in patients with upper rectal cancer was lowest in the in the T-group (P< 0.05). Technical success rate was not different between group S: 99.1% and group T: 94.1%, but clinical success rate was higher in group S: 98.2% compared with group T: 85.9%. Complications of perforation and migration tended to be high in group T: 7.1% compared with group S: 1.8%. Complications after curative surgery are lower in S group and T group than in Group E. Temporary or permanent stoma rate was significantly lower in group S than in group E.

**Conclusion:** There was no difference in 3-year relapse-free survival rate between emergency surgery and colon stent, and the transanal ileus tube was poor. This is possibly due to tumor locations and stages, as well as complications related procedure such as perforation and migration. Safe colonic stenting has good treatment outcomes and might have not poor prognosis compared with other procedure for the patients of obstructive colorectal cancer.

**Disclosure:** Nothing to disclose

## P0488 INITIAL TREATMENT OF LEFT SIDED MALIGNANT COLONIC OBSTRUCTION WITH SELF-EXPANDING METAL STENTS IN ELDERLY PATIENTS. A COMMUNITY HOSPITAL EXPERIENCE

García-Cano L.<sup>1</sup>, Taberna-Arana L.<sup>2</sup>, Godoy-López M.A.<sup>3</sup>

<sup>1</sup>Hospital Virgen de La Luz, Department of Digestive Diseases, Cuenca, Spain,

<sup>2</sup>Health District, Family Practice, Cuenca, Spain, <sup>3</sup>Hospital Virgen de La Luz, Radiology, Cuenca, Spain

**Contact E-Mail Address:** jegarca59@gmail.com

**Introduction:** The European Society of Gastrointestinal Endoscopy (ESGE) guideline<sup>1</sup> suggests that, if available, self-expandable metal stent (SEMS) insertion should be considered in elderly (age > 70 years) or frail patients with malignant colorectal obstruction (MCRO). After initial obstruction relief SEMS can serve either as a definitive palliation or as a “bridge to elective surgery” (BTS). We aimed to evaluate the outcomes of this procedure in a Community Hospital.

**Aims & Methods:** Retrospective analysis. MCRO was diagnosed using a combination of clinical symptoms, radiographic exams and colonoscopy. SEMS insertion was attempted from eight cm above the anal verge to the splenic flexure. Two methods were employed. For tumors located between eight to 20 cm, an ultrathin gastroscope with an outer diameter of 6 mm was employed to pass the stricture. A metal Savary guidewire (GW) was placed beyond the stenosis through the working channel. The ultrathin gastroscope was withdrawn leaving the GW in place. Afterwards an Ultraflex Precision stent (Boston Scientific, Natick, Massachusetts) was inserted over the wire (OTW) and deployed monitored with the ultrathin gastroscope placed side by side. No fluoroscopy was employed. For tumors beyond 20 cm, an endoscope with therapeutic channel was used to reach the stricture, which was subsequently negotiated, under fluoroscopic control, with a 0.035 in hydrophilic tip GW, loaded into an ERCP catheter. Once the GW traversed the stricture, a Wallflex colonic stent (Boston Scientific) was inserted through the scope (TTS) and deployed both under fluoroscopic and endoscopic guidance. All procedures were performed by an experienced endoscopist.

**Results:** In the last five years stenting was attempted in 31 patients (18 M and 13 F, mean age 81.46 years [SD 6.15] range 72-91). There were 20 OTW and 11 TTS procedures respectively. Tumor location was: rectum five cases, recto-sigmoid junction four, sigmoid colon 14, descending colon seven and splenic flexure in one case. Technical success was 29/31 (93.5%). There were two failures for inability to traverse the stricture (one in each group, OTW and TTS). MCRO symptoms did not improve in the tumor located in the splenic flexure. Therefore, clinical success was 28/31 (90 %). One patient died two days after the procedure for a not technique-related cause. Out of the 27 remaining patients SEMS served as a BTS in 10 (37%) and 17 (63%) had the stent as a definitive palliation. Two patients presented mild tenesmus, and one had stent migration.

**Conclusion:** Colorectal stenting using either the OTW or TTS technique appears to be safe and effective in this elderly population for the initial treatment of MCRO.

**Introduction:** Sulforaphane (SFN), a phytochemical compound, which belongs to isothiocyanates family found in abundance in broccoli sprouts, potentially induces a variety of antioxidant enzymes via NF-E2-related factor 2-Kelch-like ECH-associated protein 1-mediated pathway, thereby protects cells from injury induced by various kinds of oxidative stresses. We have previously shown that SFN protects gastric mucosa from oxidative injury induced by *H. pylori* infection. SFN also down-regulates histone deacetylase (HDAC) activity, thereby induces apoptosis and inhibits proliferation of tumor cells in variety of tissues. On the other hand, colon cancer has been increasing in Japan. Since numerous epidemiological studies have shown that colon cancer is inversely associated with intake of anti-oxidant vegetables, we examined if daily intake of SFN prevents colon tumorigenesis in mice, and in human subjects.

**Aims & Methods:**

1. Effects of SFN on Colonic tumorigenesis in Mice Treated with Chemical Carcinogen: Effects of SFN on colonic tumorigenesis were examined in the ICR male mice, pretreated with a chemical carcinogen, azoxymethane (AOM) (15 mg/kg). The mice treated with AOM for 3 or 6 times were fed for 8 or 24 weeks with or without sulforaphane glucosinolates (SGS: 2,200 ppm/kg/day), which is a precursor of SFN. Effects of SGS treatment on formation of the microscopic aberrant crypt foci (ACF), and the macroscopic tumors in colonic mucosa were evaluated.

2. Effects of SFN on formation of Colonic ACF in patients with colonic adenoma: Effects of intake of raw broccoli sprouts (BS), 50 g/day, which contains 220 mg SGS every other day, for 6 months on changes in the number of ACF in rectal mucosa was examined by colonoscopy in patients with colonic adenoma. This study was conducted by members of Tsukuba Cancer Clinical Trial Group.

3. Effects of SFN on intestinal microbiota in human subjects: Effects of dietary intake of raw BS, 20 g/day, which contains 88 mg SGS every other day, for 2 weeks on intestinal microbiota in healthy volunteers was assessed by measuring composition of stool bacteria, using a method of terminal restriction fragment length polymorphism flora analysis. In human studies, alfalfa sprouts, which contains no SFN was used as a placebo control. The human studies 1 and 2 were approved by the ethical committee of each hospital, and were registered with the University Hospital Medical Information Network in Japan (Study 1: UMIN-000012022; Study2: UMIN-000032565).

**Results:**

1. Daily administration of SGS suppressed formation of microscopic ACF and macroscopic colonic tumors in the AOM-pretreated mice in vivo.

2. Intake of BS for 6 months tended to decrease the number of colonic ACF in patients with colonic adenoma.

3. Intake of BS for 2 weeks increased percentages of *Bifidobacterium* and *Clostridium XlVa*, which has been shown to enhance protection of colonic mucosa by increasing butyrate production in colonic lumen.

**Conclusion:**

1. Daily intake of SFN affords chemoprotection against colonic tumors in the mice treated with a chemical carcinogen.

2. The present study further suggests that, in addition to previously reported mechanisms, changes in the intestinal microbiota by SFN intake may also play a role in chemoprevention against colon cancer.

**Disclosure:** The Human studies 1 and 2 were financially supported in part by a research grant from Murakami Noen. Co. Ltd. Akinori Yanaka is an endowed chair of Hitachi Medical Education and Research Center in Tsukuba University Hospital, funded by Hitachi Co. Ltd.

## P0493 ROLE OF LOW GRADE DYSPLASIA SMALL POLYPS DURING SCREENING COLONOSCOPIES SURVEILLANCE: A PROSPECTIVE COHORT STUDY

Caroli D.<sup>1</sup>, Rosa-Rizzotto E.<sup>2</sup>, Saia M.<sup>3</sup>, Lo Mele M.<sup>4</sup>, Zorzi M.<sup>5</sup>, Narne E.<sup>5</sup>, De Lazzari F.<sup>6</sup>

**Contact E-Mail Address:** d.caroli@libero.it

**Introduction:** The role diminutive polyps and small polyps play in the development of advanced neoplasia (AN) or cancer during follow-up (FU) continues to be debated. Recent studies have shown that the risk of AN development during FU is higher in patients with > 5 small polyps but similar in patients with 1-2 or 3-4 small polyps<sup>2,3</sup>.

**Aims & Methods:** the current study aimed to evaluate if current European FU guidelines<sup>1</sup> at first screening colonoscopy according to the number of low-grade dysplasia tubular adenoma < 1 cm ("micropolyps", MP) are too strict. A longitudinal cohort study was carried out on a representative sample (50%) of patients who underwent a screening colonoscopy (clean colon) in 2010 showing at least 1 polyp. Patients with AN or cancers were excluded. Polyps > 1 cm or villous or high grade dysplasia/carcinoma in situ were considered AN. These patients made a FU colonoscopy according to UE screening CCR guidelines. Patients were split up according to European guidelines in Low risk (1-2 MP), Intermediate risk (3-4 MP) and High risk (>5 MP). Data were analyzed by SPSS program.

**Results:** Of 640 patients included in the sample 172 (27%) were included in the surveillance program (mean age 62.2±5.7 yr, 50-70), 120 male (69.8%). During first colonoscopy (2010) 370 MP were detected (M±SD 2.1±1.5, range 1-13 polyps for each patient). During FU (median 5.5 years), 315 colonoscopies were performed (mean 1.8; range 1-5) and an AN was detected in 23 patients (13.4%): 20/23 tubulovillous microadenoma, 1/23 high grade dysplasia, 2/23 tubular adenoma > 1 cm. The detection of AN among patients in treatment with ASA was non significantly lower than the others. AN detection was lower among Low risk patients (13/108; 10.7%) as compared to Intermediate risk (7/33; 17.5%) and High risk (3/8; 27.3%) (P=ns). According to Kaplan-Meier analysis, the cumulative risk of AN among High risk was significantly increased (p=0.035). No interval cancers were found during the follow-up.

**Conclusion:** These findings suggest that EU guidelines for surveillance colonoscopies for > 3 small LGD polyps are excessively strict. We propose extending the time for a repeat colonoscopy FU for these patients to 5 yrs

**Contact E-Mail Address:** k.j.c.haasnoot-2@umcutrecht.nl

**Introduction:** Recently, two simplified prediction models have been published to determine which patients should undergo adjuvant surgery after endoscopic resection of T1 colorectal cancer (CRC). In the Scottish screen-detected T1 CRC based algorithm (Scottish model), the model identified low-risk cases based on completeness of resection (resection margin >0.1 mm) and absence of lymphovascular invasion (LVI).<sup>1</sup> The model of the French group identified low-risk cases based on a resection margin of ≥1 mm (French model).<sup>2</sup> Both models showed promising results but were never externally validated.

**Aims & Methods:** In this study, we investigated two proposed algorithms and the Dutch guideline for prediction of adverse outcome in T1 CRC after endoscopic resection. Adverse outcome was defined as lymph node metastasis (LNM) at baseline or any recurrence at follow-up. Cases were derived from a multicenter retrospective observational cohort of patients with an endoscopic resection of a T1 CRC diagnosed from 2014-2017 in 8 hospitals in the Netherlands. Recorded features included: screen-detection, polyp morphology and histological parameters (LAI, differentiation grade, and resection margins). Risk classification by the Dutch guideline algorithm (Dutch model) included absence of LAI, good/moderate differentiation and a resection margin of >1 mm as low-risk factors. The endpoints of the study were the percentage of low-risk cases identified, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy for each model.

**Results:** In 754 endoscopically treated T1 CRCs (median follow-up 20 months, IQR 13-28), 250 patients (33.1%) had secondary surgery. A total of 55 (7.3%) patients had an adverse outcome. LNM was present in 40 (5.3%) and recurrence in 17 (2.3%) patients (2 patients with LNM also developed recurrence). The Dutch, Scottish and French models identified 256 (35%), 394 (68%), and 347 (70%) patients as low-risk respectively. Sensitivity, specificity and accuracy were 92.5%, 36.6%, and 40.6% for the Dutch model, 77.1%, 71.1%, and 71.5% for the Scottish model and 67.7%, 72.4%, and 72.1% for the French model (see table 1 for PPV, NPV and corresponding 95% CIs). This corresponded with 4 (0.5%), 8 (1.4%), and 11 (2.2%) missed cases with an adverse outcome in the total cohort for the Dutch, Scottish and French model respectively. Within the predicted high-risk groups according to the Dutch, Scottish and French model, 49 (10%), 27 (15%), and 23 (15%) patients truly had an adverse outcome respectively. The models did not perform differently when stratified for polyp morphology or screen-detection.

**Conclusion:** For endoscopically treated T1 CRCs the analyzed models could adequately identify cases at low risk for adverse outcome in a large cohort (screen- and non-screen detected). These results show that a stringent model, such as the Dutch model, has the highest sensitivity, but leads to 59% of patients being referred for surgery without any benefit. Less stringent models such as the Scottish and French models may result in an absolute reduction of unnecessary surgery referrals of up to 33%, but at the cost of an increase in missed adverse outcomes. Considering these results there is room for improvement of the current Dutch model, provided that a cautious approach is taken.

	Dutch model	Scottish model	French model
Sensitivity, (95% CI)	92.5% (81.8%-97.9%)	77.1% (59.9%-89.6%)	67.7% (49.5%-82.6%)
Specificity, (95% CI)	36.6% (33.0%-40.3%)	71.1% (67.1%-74.9%)	72.4% (68.1%-76.4%)
Positive predictive value, (95% CI)	10.1% (9.25%-11.0%)	14.7% (12.1%-17.7%)	15.2% (12.0%-19.1%)
Negative predictive value, (95% CI)	98.4% (96.1%-99.4%)	98.0% (96.3%-98.9%)	96.8% (94.9%-98.0%)
Accuracy, (95% CI)	40.6% (37.0%-44.2%)	71.5% (67.6%-75.1%)	72.1% (67.9%-76.0%)

## P0495 ABSENCE OF NEO1 PREDICTS A POOR PROGNOSIS AND PROMOTES TUMOR PROGRESSION IN COLORECTAL CANCER

Zhang M., Zhou Z., Zhou Y., Li H., Liu L., Liu J., Zhao Q.  
Zhongnan Hospital of Wuhan University, Gastroenterology, Wuhan, China

**Contact E-Mail Address:** zhangmeng81@whu.edu.cn

**Introduction:** Colorectal cancer (CRC) is one of the most common malignancies worldwide, and its morbidity is increasing sharply in the young population. CRC progression and prognosis are associated with oncogene activation and tumor suppressor gene inactivation. Recently, many bioinformatics methods provided the platform to screen biomarkers with prognostic and treatment implications of CRC. As a homologue of the Deleted in Colorectal Cancer (DCC) gene, NEO1 has been reported to be downregulated in CRC and other several cancer types, but the specific role of NEO1 in CRC needs further exploration. The present study aimed to validate NEO1 expression in CRC and explore the role and potential mechanism of NEO1.

**Aims & Methods:** Firstly, several bioinformatics methods were utilized to examine NEO1 expression in CRC. Quantitative real-time PCR was further performed to validate NEO1 expression in CRC tissues. Next, ROC curve analysis and Survival analysis were used to test the relationship between NEO1 and prognosis of CRC. Subsequently, the effects of NEO1 were evaluated through colony formation, cell proliferation, migration and invasion assays by transfection NEO1 plasmids or siRNAs. Finally, we took advantage of Gene Ontology (GO) analysis and Gene Set Enrichment Analysis (GSEA) to explore potential function and mechanism of NEO1 in CRC.

**Results:** In our study, results showed that NEO1 was downregulated in online CRC datasets, GSE41258 dataset and CRC tissues. Its low expression was associated with shortened survival of CRC patients. Moreover, overexpression of NEO1 promoted CRC cell proliferation, migration and invasion while silencing NEO1 inhibited CRC cell proliferation, migration and invasion. Finally, GO analysis revealed that NEO1 was associated with iron transport and response to wounding. GSEA indicated that NEO1 lower expressed samples were enriched in DNA repair.

**Conclusion:** In conclusion, a tumor suppressor gene NEO1 was identified and demonstrated to be associated with the progression and prognosis of CRC, which might be a potential therapeutic target and prognostic biomarker for CRC patients.

**Introduction:** Endoscopic submucosal dissection (ESD) offers a minimally invasive *en-bloc* resection technique for rectal lesions with superficial submucosal invasion (T1 CRCs). However, as ESD dissects through the submucosa, it is often impossible to obtain a radical deep resection margin when deeper invasion in the submucosa (Sm2-3) is present. There is accumulating evidence that deep submucosal invasion is not an independent predictor of lymph node metastasis. Therefore, there is need for endoscopic techniques for resection of deep submucosal invasive T1 CRCs. Instead of dissecting through the submucosa, dissection between the circular and the longitudinal layers of the m. propria (intermuscular dissection), could provide the necessary radical deep margin, but without compromising the mesorectal fat plane allowing future completion surgery.

**Aims & Methods:** In this prospective cohort, 15 rectal tumors with optical features of deeper invasion in the submucosa were treated with an intermuscular dissection (EID). Brief description of the technique: Standard submucosal dissection was performed until non-lifting developed. The intermuscular space was then lifted, followed by careful selective circumferential myotomy of the circular muscle layer, until the longitudinal muscle fibres were visualized. Then the intermuscular space was dissected. The EID area was not routinely clipped. Prophylactic antibiotics were administered intravenously. Patient-, polyp, procedural, and histological characteristics were recorded. Primary endpoints were feasibility of performing EID, ability to obtain an R0 resection, and complication rate. Technical success was defined as achieving an *en bloc* resection. R0 resection was defined as free deep and lateral resection margins confirmed by histology.

**Results:** Between December 2018 and April 2019, 15 patients (73% male, mean age 67 yrs, SD ± 11 yrs) with a lesion with suspicion of deeper submucosal invasion in the rectum were treated with EID (mean size 28 mm (range 16 to 50 mm)). The Paris classification was 0-Ia in 66%, and 0-IIa in 33%. Surface morphology was non-granular in 80%, and a depression was present in 79%. Optical diagnosis with NBI showed a Hiroshima C1 pattern in 1 (7%), C2 in 2 (13%) and C3 in 12 (80%) cases. Technical success was achieved in 13/15 (87%) of cases. In the 2 failed cases, it was impossible to discriminate and lift the intermuscular space. An R0 resection was achieved in 11/13 (85%) technically successful cases. In 2 cases, a small area of fat was visualized which was closed with 2 hemoclips. Two cases had a positive deep resection margin. All these lesions were carcinomas microscopically. The depth of submucosal invasion was Sm1 in 1 (7%), Sm2 in 3 (23%), Sm3 in 8 (61%), and T2 in 1 (7%) cases. Lymphovascular invasion was observed in 7/13 (54%) cases, high-grade (Bd2-3) tumor budding in 4/12 (25%), and poor differentiation in 1/13 (7%). One patient developed fever postoperatively without need for intervention. No other complications were observed. In total 6/13 (46%) cases had no histological risk factor other than deep invasion. A wait and see follow-up strategy was applied in 7/13 (54%) technically successful cases. No residual carcinoma was detected at the scar in the surgical specimen, and lymph node metastasis was detected in 1 case.

**Conclusion:** Endoscopic intermuscular dissection (EID) seems a promising and safe new technique to remove deep submucosal invasive T1 carcinomas in the rectum, with a technical success rate of 87% and an R0-resection rate of 85%.

**Contact E-Mail Address:** henrik.thorlacius@med.lu.se

**Introduction:** Depth of submucosal invasion is commonly used to predict risk for lymph node metastasis in T1 colorectal cancers although published data are conflicting on the risk of metastasis in relation to level of submucosal growth.

**Aims & Methods:** The aim of this study was to identify risk factors for lymph node metastasis in T1 colorectal cancers. Data on all patients with T1 colorectal cancer undergoing surgical resection between 2009-2017 were collected from the Swedish Colorectal Cancer Registry. Potential risk factors for lymph node metastasis, including age, gender, tumour location, submucosal invasion (Sm1-3), grade of differentiation, lymphovascular invasion, perineural invasion, tumour deposits and mucinous subtype were recorded. Patients lacking one of these factors were not included.

**Results:** 991 patients (51% male) were included with median age of 72 years. 110 patients (11%) had lymph node metastasis in the surgical specimens. The overall incidence of lymph node metastasis was 8% (26/314) in Sm1, 12% (28/231) in Sm2 and 13% (56/446) in Sm3. In the absence of lymphovascular infiltration, the rate of lymph node metastasis was 6% in Sm1, 9% in Sm2 and 13% in Sm3.

Notably, the incidence of lymph node metastasis markedly increased to 40% (37/92) in cases with lymphovascular infiltration regardless of Sm classification. Presence of tumor deposits (14 cases) and perineural invasion (15 cases) also increased the rate of metastasis but the numbers of these cases were too few for solid conclusions. Grade of differentiation and mucinous subtype had only a minor impact on the incidence of lymph node metastasis (16%).

**Conclusion:** This is the largest study in the literature examining risk factors for lymph node metastasis in T1 colorectal cancers. Our results show that depth of submucosal invasion has limited influence and that lymphovascular infiltration is the most important risk predictor for lymph node metastasis in T1 colorectal cancers.

## P0498 PERINEAL FLAP RECONSTRUCTION FOLLOWING PELVIC EXENTERATION

Gould L., Pring E., Fletcher J., Hadjikyriacou E., Antoniou A., Constantinides J., Jenkins J.T.  
St Mark's Hospital, London, United Kingdom

**Contact E-Mail Address:** laura.e.gould@gmail.com

**Introduction:** Perineal wound complications following pelvic exenteration (PE) are a significant cause of morbidity. We assessed our long-term experience of using perineal flap reconstruction for patients undergoing PE at a tertiary referral unit.

**Aims & Methods:** Retrospective review of all PE procedures from 2009-2018 was performed. Demographics, neoadjuvant/adjuvant or historical chemoradiotherapy, perineal wound closure, flap type, inpatient stay and post-operative complications were recorded.

**Results:** 209 PEs were performed, 120 (57%) patients had reconstruction with a perineal flap. 87% of these were for locally advanced or recurrent rectal cancer. 88% had prior pelvic radiotherapy. 75% of defects were closed using an inferior (IGAP) or superior (SGAP) gluteal artery perforator flap. Other flaps used were gracilis, vertical rectus abdominis and anterolateral thigh. 58% suffered wound complications, 14% were classified as a major complication (return to theatre within 90 days or readmission with a wound complication). Superficial dehiscence requiring vacuum dressing was the commonest complication (34%). Perineal wound complications increased median length of stay from 22 to 34 days ( $p=0.001$ ). No significant association between BMI, neoadjuvant treatment, complexity of resection, post-operative nutrition and wound complications was observed. IGAP flap was associated with fewest complications OR 0.40 (0.18-0.87).

**Conclusion:** Perineal wound complications cause significant morbidity increasing inpatient stay, IGAP flaps have fewer post-operative complications in our series. Strategies to optimise perineal wound care are needed.  
**Disclosure:** Nothing to disclose

## P0499 TAILORING LYNCH SYNDROME SURVEILLANCE

Marques de Sá L., Castro R., Pita I., Dinis-Ribeiro M., Brandão C.  
Portuguese Institute of Oncology, Gastroenterology, Porto, Portugal

**Contact E-Mail Address:** inesmarquesdesa@gmail.com

**Introduction:** Lynch syndrome (LS) is associated with increased risk of colorectal cancer (CRC) as well as extracolonic cancer. Identification and follow-up of individuals with LS is extremely important because they can benefit from surveillance programmes by reducing cancer-risk. There is an increased awareness that cancer risk varies with specific mismatch repair mutation. However, gene-specific surveillance as well as family-specific surveillance have not been systematically studied.

**Aims & Methods:** Our aim was to assess the surveillance programme and tailoring strategies in a tertiary centre. We conducted a retrospective cohort of all patients ( $n=241$ ) under surveillance programme in our centre since their admission or treatment of the index cancer (median time of 4 years). The main outcomes were cancer-related death and risk for new lesions.

**Results:** Forty-eight percent had MSH2 mutation, 32% MLH1, 15% MSH6 and 5% PMS2. 95% had family history of CRC, 37% of endometrial cancer, 32% of gastric cancer and 12% of urinary tract cancer. From the 68 (28%) patients with CRC at admission, 4% developed metachronous cancer and 3% died of CRC. Left-colectomy was related to higher risk of metachronous lesions than right-colectomy ( $RR=12$ ,  $p<0.006$ ). From the 173 patients without CRC on admission, 26% developed low-risk lesions, 23% high-risk lesions and 5% CRC. From the 237 patients without gastric cancer on admission, 3% developed dysplasia or adenocarcinoma. From the 108 patients without endometrial cancer on admission, 7% developed endometrial cancer and 53% underwent prophylactic hysterectomy (10% with atypia and 5% with cancer on the surgical specimen). The risk of endometrial cancer was higher when family history was present ( $RR=2.38$ ,  $p<0.007$ ). From the 237 patients without urinary tract cancer on admission, 7 developed this cancer (4 were asymptomatic and diagnosed by imaging). The risk of urinary tract cancer was higher with MSH2 mutation ( $RR=8$ ,  $p<0.001$ ) or when family history was present ( $RR=11$ ,  $p<0.004$ ). 3% of patients on follow-up died of extracolonic cancer (median time of 7 years).  
**Conclusion:** This cohort demonstrates the effectiveness of SL surveillance programme and suggests the possibility of tailoring strategies by gene and family history.

**Disclosure:** Nothing to disclose

## P0500 PREVALENCE OF OPIOID THERAPY IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS REVIEWED AT A TERTIARY CENTRE

Mari A.<sup>1,2</sup>, Pesce M.<sup>3</sup>, Patel K.<sup>4</sup>, Legidis F.<sup>3</sup>, Emmanuel A.<sup>5</sup>, Zarate-Lopez N.<sup>6</sup>  
<sup>1</sup>University College London Hospital, GI Physiology Unit, Qalansawa, Israel, <sup>2</sup>Nazareth Hospital EMMS, Gastroenterology, Nazareth, Israel, <sup>3</sup>University College London Hospital, London, United Kingdom, <sup>4</sup>University College Hospital, London, United Kingdom, <sup>5</sup>National Hospital for Neurology and Neurosurgery, Neuro-Gastroenterology, London, United Kingdom, <sup>6</sup>Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** amir.mari@hotmail.com

**Introduction:** The appropriateness of chronic opioid use in patients with non-cancer pain is increasingly challenged due to limited evidence of its efficacy and the risk of problematic use and dependence. The side effects of opioids on gut function suggest this therapy should be particularly avoided in patients with functional gastrointestinal (GI) disorders. Data on the prevalence of opioid use in patients with functional GI disorders is unknown. We aimed to evaluate the prevalence of opioid use in functional GI patients referred to a tertiary Neurogastroenterology clinic and to determine the risk factors for their initiation.

**Aims & Methods:** 100 consecutive outpatients (85 females, 37±15 years) with functional GI disorders referred for a specialist opinion at our tertiary referral centre were retrospectively reviewed. Two independent research-

ers (AM and FL) carried out a detailed chart evaluation of the presence and type of comorbidities and concomitant pharmacotherapy. Patients were also specifically asked about opioid use, the duration of therapy and the clinical indication for starting the opioids.

**Results:** Twenty-one patients (20F, 38±12 years) were taking chronic opioid therapy. The main reason for opioid initiation was chronic musculoskeletal pain (12 patients, 57%), chronic abdominal pain (5 patients, 24%) and chronic pelvic pain (1, 5%). The mean duration of the opioid treatment was 2.7±1 years. The risk factors associated with opioids use are depicted in table 1. In terms of management, patients under opioid were offered naloxegol (20%), psychology-based interventions (29%), and referral to pain specialists to rationalize opioid use (38%). The majority of the patients in the opioid group (80%) were referred for tertiary opinion from other areas of the UK, as compared to the 60% of patients without chronic opioid use.

**Conclusion:** Female patients with chronic functional GI disorders with associated extra-intestinal functional pain syndromes and psychological comorbidity are prescribed opioid therapy more frequently. These patients are at increased risk of developing eating difficulties requiring advanced nutritional support, which is known to be more complicated in opioid users. Access to multidisciplinary coordinated therapy including pain management and psychological therapy is required early in these patients to avoid these adverse outcomes.

**Disclosure:** Nothing to disclose

## P0501 CLUSTER ANALYSIS OF CHRONIC SYMPTOM PROFILES CHARACTERIZES SUBGROUPS OF FUNCTIONAL GASTROINTESTINAL DISORDERS THAT DIFFER IN THEIR SENSORY RESPONSE TO SUGAR BREATH TESTING

Wilder-Smith C.H.<sup>1</sup>, Mohr Drewes A.<sup>2</sup>, Materna A.<sup>1</sup>, Olesen S.S.<sup>2</sup>

<sup>1</sup>Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland, <sup>2</sup>Aalborg University Hospital, Dept. of Gastroenterology and Hepatology, Aalborg, Denmark

**Contact E-Mail Address:** info@ggp.ch

**Introduction:** Patients with gastrointestinal (GI) symptoms but devoid of recognizable pathology are classified into various functional gastrointestinal disorders (FGID) according to their GI symptoms. Sugar breath tests are used in patients with FGID to elucidate possible mechanisms, such as malabsorption and hypersensitivity. Due to the heterogenous nature of FGIDs, underlying mechanisms and the reactions during breath tests are likely to be divergent.

Furthermore, the presence of prominent extra-GI symptoms may indicate a different pathogenesis than when GI symptoms related to intestinal fermentation preponderate.

**Aims & Methods:** The aim of this large study was to examine the symptom and gas responses during sugar breath tests in patients with FGID grouped according to their long-term GI and extra-GI symptoms by cluster analysis. Successive male and female patients over 18 years of age referred to our GI practice in the past 10 years for investigation of FGID and without evidence of organic disease were included in this study. Patients completed a standardized questionnaire rating their long-term GI and extra-GI symptoms. These data were subjected to latent class analysis to identify unobserved clustering in the patient population. Patients also performed standardised fructose and lactose breath tests (35g and 50g, respectively), and GI and extra-GI symptoms as well as H<sub>2</sub> and CH<sub>4</sub> breath concentrations were documented hourly for 5h during the breath test. The areas-under-the-curve (AUC) of aggregate GI and central nervous system (CNS) symptoms and of the breath gas concentrations were compared between the patient clusters.

**Results:** In total 2083 FGID patients (mean age 39.7 years, 70% females) were enrolled in the study and subjected to cluster analysis. The optimal number of clusters defined was 6, with good face validity. GI fermentation-type symptoms were present across all 6 clusters and exclusively characterized Cluster 1 (35% of patients). The further clusters were distinguished by additional reflux-like (cluster 2: 19%), allergy-like (cluster 3: 6%), central nervous system (cluster 4: 17%), musculoskeletal (cluster 5: 10%), and generalized extra-GI (cluster 6: 14%) symptoms. Complete fructose and lactose breath tests were available in 1422 patients. The areas-under-the-curve (AUCs) of hydrogen and methane breath concentrations were not significantly different across all the 6 clusters following fructose and lactose (all p>0.05).

However, the AUCs of both GI and CNS aggregate symptoms scores differed significantly across the 6 clusters during fructose and lactose breath tests (all p<0.001). Maximum aggregate symptom scores were consistently greater in the clusters with most extra-GI symptoms.

**Conclusion:** The chronic symptom clusters of patients with FGID, distinguished mainly by extra-GI symptoms, did not differ in their breath gas concentrations following fructose or lactose ingestion. The distinct symptom patterns are consequently not explained by differences in the gaseous markers of malabsorption. The clusters were, however, distinguished by differences in the GI and CNS symptoms provoked following both sugars. Clearly, patients with a greater number of chronic extra-GI symptoms also show significantly more GI and CNS symptoms after fructose or lactose ingestion than those with mainly chronic GI symptoms. These results suggest malabsorption does not explain the different phenotypical presentations of FGID. We hypothesize that hypersensitivity to the sugars or their metabolites underlies the differing symptoms, especially the multiorgan, extra-GI symptoms, in FGID.

**Disclosure:** Nothing to disclose

## P0502 SYMPTOMS ASSOCIATED WITH MAST CELL ACTIVATION SYNDROME ARE COMMON IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

Wilder-Smith C.H.<sup>1</sup>, Mohr Drewes A.<sup>2</sup>, Materna A.<sup>1</sup>, Olesen S.S.<sup>2</sup>

<sup>1</sup>Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland, <sup>2</sup>Aalborg University Hospital, Dept. of Gastroenterology and Hepatology, Aalborg, Denmark

**Contact E-Mail Address:** info@ggp.ch

**Introduction:** Patients with functional gastrointestinal disorders (FGID) often have a wide range of gastrointestinal (GI) and extra-GI symptoms. Extra-GI symptoms are not included in the diagnostic criteria for FGID and are often attributed to separate functional or somatization syndromes. The mast cell activation syndrome (MCAS) encompasses a variety of disorders with either increased numbers or activation of mast cells leading to a wide range of both GI and extra-GI symptoms. Idiopathic MCAS is currently defined by typical symptoms and the response to medications targeting mast cell activation, as there are no specific biochemical markers. The apparent overlap in symptoms associated with MCAS and FGID, the increases in mast cell numbers and/or activation in FGID, and the abnormalities in histamine pathways shown in irritable bowel syndrome (IBS) suggest a potential functional association.

**Aims & Methods:** The aim of this large single-centre study was to investigate the overlap in GI and extra-GI symptoms most frequently associated with MCAS with the symptoms seen in patients with FGID.

Successive male and female patients over 18 years of age referred to our GI practice for investigation of FGID and without evidence of organic disease were included. Patients completed a standardized, extensive GI and extra-GI symptom questionnaire and FGID was classified as IBS and functional dyspepsia (FD) according to the Rome III criteria. The prevalence of at least 7 of the symptoms most commonly used to define MCAS (abdominal pain, bloating, diarrhoea, nausea, gastro-oesophageal reflux, excessive tiredness, problems concentrating, headache, anxiety/depression states, skin rash, urticaria/pruritus, chronic sinusitis/rhinitis, irregular heartbeat, joint pain, myalgias) was determined for the overall patient cohort and for the Rome III subgroups.

**Results:** We included 2083 patients with FGID in the study (mean age 39.7 years, 70% females). IBS was diagnosed in 672 (32%), FD in 1839 (88%) and overlapping IBS and FD in 625 (30%) of patients. More than 7 of the defining symptoms of MCAS were reported in 748 (36%) of all 2083 patients, and in 281 (42%) of IBS patients, in 702 (38%) of FD patients and in 266 (43%) of patients with overlapping IBS and FD. Of the 748 patients with more than 7 symptoms of MCAS, 281 (38%) had IBS, 702 (94%) had FD and 266 (36%) had overlapping IBS and FD.

**Conclusion:** Symptoms associated with mast cell activation syndrome are common in patients with functional gastrointestinal disorders. Conversely, functional gastrointestinal disorders are common in patients with symptoms of MCAS. Mast cells and associated biogenic amines, such as histamine and serotonin, have been shown to be involved in the pathogenesis of both syndromes. The significance of the relationship between MCAS and FGID needs to be investigated further, as a better understanding of this overlap may open new treatment possibilities in FGID.

**Disclosure:** Nothing to disclose

## P0503 HISTOMORPHOLOGICAL AND MOLECULAR CHARACTERIZATION OF PARKINSON'S DISEASE PATIENTS WITH CHRONIC CONSTIPATION: A PILOT STUDY

**Contact E-Mail Address:** lorenzobertani@gmail.com

**Introduction:** Parkinson's disease (PD) patients can report gastrointestinal symptoms even years before the onset of neurological symptoms. It has been suggested that the digestive pathways could be used by a pathogen to access the target neuronal populations inducing PD.

**Aims & Methods:** The aim of this pilot study was to evaluate constipated PD patients for: 1) possible changes of inflammatory markers in blood and stool; 2) alterations of colonic mucosal factors involved in the maintenance of the intestinal barrier; 3) possible correlations of these parameters with the severity of motor and non-motor symptoms and impairment of quality of life.

Ten constipated PD patients and 10 constipated, sex and age matched, patients (Rome IV) were enrolled. All patients were requested to fill gastroenterological (Bristol Stool Chart, PAC-SYM, PAC-QoL, ODS score) and neurological (UPDRS, PDQ-39, MMT, HAM-D-17, SCOPA-AUT, NMSS) questionnaires. Blood (CBC, TSH, CRP, TNF, IL-1 $\beta$ , LBP) and stool (Hp antigen, fecal calprotectin, IL-1 $\beta$ , TNF) tests were carried out. All subjects underwent a colonoscopy with biopsies (sigma and descending colon). Colonic samples were processed for morphological evaluations (haematoxylin/eosin, sirius red/fast green, toluidine blue, confocal immunofluorescence) to evaluate respectively: eosinophilic density (inflammatory index) and collagen deposition (marker of remodelling due to chronic inflammation) in the lamina propria; acid mucin (changes in mucus producing cells) and claudin-1 (component of tight junctions) in intestinal epithelial barrier.

**Results:** The onset of constipation anticipated that of PD onset in 7/10 patients. Faecal IL-1 $\beta$  levels were higher in PD patients as compared to controls (18.2 $\pm$ 9.7 pg/g vs 9.3 $\pm$ 3.7 pg/g;  $p < 0.05$ ). Faecal TNF and serum LBP levels were higher in PD, without reaching statistical significance (66.2 $\pm$ 47.5 vs 56.3 $\pm$ 34.6 pg/g and 33.6 $\pm$ 14.8 vs 23.9 $\pm$ 5.6 ng/ml, respectively). Eosinophilic density was higher in controls than PD patients (56 $\pm$ 16 vs 13 $\pm$ 4 / mm<sup>2</sup>;  $p < 0.05$ ). Collagen levels and acid mucin were higher in PD patients (18.6 $\pm$ 2.5 vs 13.1 $\pm$ 1.3 PPP;  $p < 0.05$ , and 14.7 $\pm$ 1.6 vs 10.3 $\pm$ 1.5 PPP;  $p < 0.05$ ). Claudin-1 expression decreased along the epithelial surfaces in PD patients. A lack of correlation was found between these findings and the severity of digestive and neurological symptoms.

**Conclusion:** PD constipated patients display higher levels of intestinal inflammation and tissue remodeling, as well as a higher degree of enteric barrier impairment than constipated patients without PD. These findings confirm an intestinal involvement in PD, and open the way for future pathophysiological studies.

**Disclosure:** Nothing to disclose

## P0504 ALLERGIES AND EXTRA-DIGESTIVE MANIFESTATIONS IN FUNCTIONAL GASTROINTESTINAL DISORDERS

Stanghellini V.<sup>1</sup>, Cogliandro R.<sup>1</sup>, Morselli Labate A.M.<sup>2</sup>, Del Vecchio S.<sup>1</sup>, Birtolo C.<sup>2</sup>, Bellacosa L.<sup>1</sup>, Cremon C.<sup>1</sup>, Barbara G.<sup>1</sup>

<sup>1</sup>University of Bologna Policlinico S.Orsola-Malpighi Internal Med. & Gastroenterology - Department of, Department of Digestive System, Bologna, Italy, <sup>2</sup>University of Bologna, Bologna, Italy

**Contact E-Mail Address:** v.stanghellini@unibo.it

**Introduction:** Extra-digestive manifestations are frequently reported by patients with functional gastrointestinal disorders (FGIDs). Gut neuroinflammation and gut-brain axis are putative shared mechanisms. Gut barrier damages associated with mast cells and/or eosinophils infiltration are common features of FGIDs, suggestive of a possible pathogenetic role of allergic reactions. An association between allergies and extra-digestive disorders in FGIDs has never been elucidated.

**Aims & Methods:** Aim. To evaluate prevalence of food and non-food allergies in FGID patients with and without extra-digestive manifestations.

**Materials and Methods.** In a single center setting, we prospectively investigated clinical features and allergies in outpatients referred for digestive symptoms. Each patient answered validated questionnaires on digestive and extra-digestive symptoms and underwent both serum and cutaneous allergological tests: IgE and skin prick testing to food and inhalant allergens; patch testing (SIDAPA 40 aptens). FGIDs were diagnosed according the Rome III criteria. Extra-digestive syndromes included general (tiredness, foggy mind, joint or muscle pain), neurologic (restless leg syndrome, migraine/headaches, dizziness, epilepsy, sensory symptoms), psychological (anxiety/panic disorders, depression, sleeping disorders, eating disorders), rheumatologic and immunologic (psoriasis, Raynaud's, fibromyalgia, Sjogren, multiple sclerosis), urogenital (cystitis, vaginitis, prostatitis, vestibulitis, dyspareunia, dysmenorrhea, infertility), cutaneous (acne, alopecia) and other manifestations (tachyarrhythmias, presyncope, discopathies, endometriosis, multiple chemical sensitivity). The study was approved by the S. Orsola University Hospital Ethic Committee.

**Results:** Between 2011 and 2014, 80 patients with organic diseases (F=51.3%, age 48.7 $\pm$ 16.7 yrs, m $\pm$ SD) and 970 FGID patients were enrolled (F=75.1%; 42.8 $\pm$ 14.6 yrs). 827 FGID patients (85.3%; F=78.1%; 43.2 $\pm$ 14.5 yrs) complained of  $\geq 1$  extra-digestive disorders (ExtraD-FGIDs) vs 53 organic patients (71.6%; F=78.1%; 49.2 $\pm$ 17.1 yrs;  $p=0.004$ ). 718 FGID patients (74.0%; F=76.7%; 41.8 $\pm$ 14.3 yrs) vs 42 patients with organic diseases (52.5%; F=52.4%; 43.7 $\pm$ 14.9 yrs;  $p=0.001$ ) had  $\geq 1$  positive allergic tests. 622 patients (75.2%) with and 96 (67.1%) without extraD-FGIDs had  $\geq 1$  positive allergic tests ( $p=0.049$ ). The difference was driven by a higher prevalence of chemical allergies (40.1% vs 28.5%;  $p=0.014$ ), while no significant difference was found for food or inhalant allergies. Specifically, a significant higher frequency of chemical allergies was detected in patients with than in those without urogenital (47.2% vs 33.2%,  $p=0.001$ ), cutaneous (58.1% vs 37.7%,  $p=0.025$ ), neurological (43.9% vs 36.1%,  $p=0.019$ ), and psychological manifestations (41.4% vs 33.6%,  $p=0.013$ ).

**Conclusion:** Extra-digestive disorders are frequent in allergic patients with FGIDs. Non-food and specifically chemical allergies are significantly associated to urogenital, cutaneous, neurological and psychological disorders in patients with FGIDs.

**Disclosure:** Nothing to disclose

## P0505 ARE DIGESTIVE SYMPTOMS FREQUENT IN PATIENTS WITH CHRONIC ADRENAL INSUFFICIENCY?

Qu  n  h  r   L.<sup>1,2</sup>, Coron E.<sup>1,2</sup>, Dru   D.<sup>3</sup>, Blin J.<sup>3</sup>, Masson D.<sup>2</sup>, Bach K.<sup>2</sup>

**Introduction:** Acute adrenal insufficiency is frequently associated with digestive symptoms such as vomiting, diarrhea and abdominal pain. However their prevalence in patients having a chronic adrenal insufficiency (CAI) is unknown. The hypothalamic-pituitary-adrenal axis plays also a role in the pathophysiology of irritable bowel syndrome (IBS).

**Aims & Methods:** The aim of this study was to characterize and to quantify digestive symptoms in CAI patients using Rome IV questionnaire.

An online questionnaire was published on the website of a CAI patients association from June to October 2017. Information about demographics, adrenal insufficiency (age at diagnosis, etiology, type of medication) and quality of life was collected. Patients also answered to a French version of the Rome IV questionnaire and the Bristol scale.

**Results:** We analyzed responses from 165 patients (Addison's disease (AD) (n=74), congenital adrenal hyperplasia (CAH) (n=56), impairment of the hypothalamic-pituitary-adrenal axis (IHA) (n=35). Abdominal pain at least once a week during the 3 last months was reported by 38%, 31% and 54% of patients with AD, CAH and IHA respectively. Symptoms were consistent with the IBS criteria in 24%, 31% and 31% of patients with AD, CAH and IHA respectively.

Patients described their quality of life as bad in 34%, 21% and 54% of patients with AD, CAH and IHA respectively.

**Conclusion:** Our study is the first to our knowledge to consider digestive symptoms in CAI beside acute adrenal insufficiency. Digestive symptoms are frequent and invalidating in CAI patients and are close to those of IBS patients in 50% of CAI patients.

**Introduction:** Visceral hypersensitivity, i.e. the increased response towards colonic stimuli, contributes to abdominal pain complaints observed in irritable bowel syndrome (IBS). In this study, we aimed to identify targets for stress-induced visceral hypersensitivity. To this end, we analyzed the transcriptome through RNA sequencing (RNAseq) of descending colon samples obtained from our rat model after which we confirmed our findings in a separate cohort of rats, as well as in patient biopsies.

**Aims & Methods:** In this study, we aimed to identify genes involved in the development of post-stress visceral hypersensitivity in rats. In the discovery cohort, adult maternally-separated (MS) rats and non-handled (NH) rats were exposed to acute water avoidance (WA)-stress for one hour or left undisturbed (4 groups, n=3). Rats were sacrificed 4 hours after WA after which RNA was isolated for subsequent sequencing at GenomeScan (Leiden, The Netherlands; NextSeq 500, 10M reads). Statistical significance of differentially expressed genes was defined as genes with a Benjamini-Hochberg adjusted p-value of less than 0.05.

Subsequent validation of the gene of interest was done using quantitative real-time polymerase chain reaction (qRT-PCR) on distal colon samples obtained from an independent rat cohort. In this experiment, NH and MS animals were sacrificed 21 days after WA (n=8-9)[1].

Qualitative PCR analyses of the same gene of interest was performed in human biopsies obtained from colon descendens of normosensitive healthy volunteers and hypersensitive IBS patients (n=10 per group)[2]. Additionally, immunohistochemical staining on paraffin-embedded tissues was performed to investigate whether possible changes in gene expression manifested at protein level; uPA positive cells were counted manually and quantified as positive cells per mm<sup>2</sup>.

**Results:** RNAseq analysis of the four groups did not reveal differentially expressed genes. However, comparing MS without WA vs. MS after WA, revealed 1 differentially expressed gene: Plau (effect size =1.256 log2 fold change; p<sub>adj</sub>=0.0011), which encodes for the protein urokinase-type Plasminogen Activator (uPA). qPCR analysis on the independent rat cohort confirmed an increased expression of Plau in colonic tissue after maternal separation plus WA (NH after WA vs. MS after WA; Mann-Whitney test; p<0.005). Further investigation of the ortholog PLAUI in human colon descendens revealed no statistically significant differential expression (Mann-Whitney test; p=0.0575). Nonetheless, subsequent immunohistochemistry revealed a non-significant increase in the number of uPA-positive cells in hypersensitive IBS colon (t-test; p=0.49).

**Conclusion:** In this exploratory analysis we observed elevated expression of Plau associated with stress-induced visceral hypersensitivity in rat. Enhanced expression of this gene transcript was confirmed in an independent rat cohort that underwent MS and WA stress. However, we could not confirm these findings in hypersensitive IBS patients on neither mRNA nor protein expression. Based on literature, uPA may activate protease activated receptor-1 (PAR-1)[3]. PAR-1 antagonism was found to successfully reduce activity of sensory neurons in vitro upon exposure to supernatants of colonic IBS biopsies[4, 5]. To address the translational relevance of these findings, additional research should be performed on uPA protein levels and activity in human colon.

**Introduction:** The decrease in enzymes activity of the membrane digestion (EAMD) in the small intestine providing digestion of carbohydrates can cause clinical symptoms of irritable bowel syndrome (IBS).

**Aims & Methods:** To estimate EAMD, namely glucoamylase (GA), maltase (M), sucrose (S) and lactase (L), in patients with IBS and the effect of their activity in long-term therapy with rebamipide. 102 patients with IBS, aged from 18 to 50 (41 men and 61 women) were examined. According to Rome IV criteria (2016), 68 patients had IBS with predominance of diarrhea, 20 patients had IBS with predominant constipation and 14 patients showed mixed type of IBS. In all patients there was a more or less pronounced association of intestinal symptoms when consuming product containing milk (48.6%), potato starch (47.3%) and sugar (27.0%). The activity of GA, M, S and L were determined by Dahlquist-Trinder method in duodenal biopsies obtained during esophagogastroduodenoscopy. The control group consisted of 20 healthy people aged 23-47. They showed following enzyme activity: L - 42 ±13 ng glucose/mg tissue x min, GA - 509 ±176, M - 1735 ±446, S - 136 ±35 ng glucose/mg tissue x min. These figures were taken as the norm.

**Results:** 10.8% of the study group showed normal EAMD (11 out of 102 patients), 32.3% had decreased activity of all studied enzymes and 58.8% had selective reduction of EAMD. Thirteen patients with reduced EAMD were recommended the FODMAP diet and ingest rebamipide 3 times a day x 200 mg for 3 months. Before the treatment the activity of GA of these patients averaged 83 ±78, M-417 ±221, S - 32 ±17, L-11 ±17 ng glucose/mg tissue x min. After the treatment 11 patients reported a decreased or no flatulence, abdominal pain, stool disorder; 2 people reported no change. The activity of GA increased to an average of 149 ±82 (by 78%, p = 0.016), M to 864 ±472 (by 131%, p = 0.0019), S - 63 ±35 (by 95%, p = 0.0041) and L - 10 ±8 ng glucose/mg tissue x min. (the activity did not change significantly).

**Conclusion:** In 89.2% of patients with IBS, there was a decrease of EAMD responsible hydrolysis of carbohydrates. The 3-month treatment with rebamipide helped reduce clinical symptoms and increase EAMD.

**Disclosure:** Nothing to disclose

## P0508 EFFICACY AND SAFETY OF SACCHAROMYCES BOULARDII CNCM I-745 IN THE TREATMENT OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN PATIENTS SUFFERING IRRITABLE BOWEL SYNDROME WITH DIARRHEA

Bustos Fernandez L.<sup>1</sup>, Man F.<sup>2</sup>, Dorribo C.<sup>1</sup>, Lasa J.S.<sup>1</sup>

<sup>1</sup>CMBF, Buenos Aires, Argentina, <sup>2</sup>Gastro, Buenos Aires, Argentina

**Contact E-Mail Address:** luisbustosfernandez@gmail.com

**Introduction:** Irritable bowel syndrome (IBS) is a very common chronic gastrointestinal condition with abdominal pain, altered bowel habits and stool consistency. IBS-D is a sub-type with predominant diarrhea. Altered intestinal microbiota and the presence of small intestinal bacterial overgrowth (SIBO) have been documented in IBS. *Saccharomyces boulardii* CNCM I-745 (*S. boulardii*) is a probiotic yeast with proven efficacy in antibiotic-associated diarrhea and acute gastroenteritis. However, there is scarce evidence regarding the impact of *S. boulardii* on IBS-D patients.

**Aims & Methods:** **Aim:** To assess the efficacy and safety of *S. boulardii* on SIBO-positive IBS-D patients.

**Materials and methods:** It was a randomized open label phase IV study on adult patients from two referral centers in Buenos Aires, Argentina with a diagnosis of IBS-D (Rome III criteria), with no systemic or severe diges-

tive signs nor intake of drugs known to alter microbiota. Patients were randomized to receive either *S. boulardii* 250 mg *b.i.d.* plus dietary advice (Sb group) OR dietary advice only (Control group) for 15 days. SIBO was assessed by lactulose hydrogen breath test (LHBT). LHBT was done at inclusion (D0) and end of study (D15). Other criteria included IBS Symptom Severity Scale IBS-SSS (values 0 to 500), Bristol Stool Scale, Quality of Life (measured with the IBS-QoL questionnaire) and safety.

**Results:** Fifty-four patients were included and treated, 6 were prematurely discontinued from the study and 48 (27 Sb, 21 Control) were included in the efficacy analysis. Mean age was 44-years old, BMI 25. At D15 the mean change from baseline of LHBT area under the curve (AUC) was greater in the Sb group (Table 1 part A). More patients in the Sb group had decreased LHBT AUC : 74% vs 57% ( $p=0.217$ ). A post-hoc ANCOVA adjusted on baseline AUC level showed that the inter-group difference of approximately 1800 ppm was statistically significant (Table 1 part B & Fig2) and also that AUC at D0 had a strong impact on change under treatment. IBS-SSS decreased from 306 and 300 in the Sb and Control groups respectively to 180 and 203 at D15.

A trend to a higher proportion of patients with normal stool consistency was observed in Sb group (70.4% vs 47.6%,  $p=0.07$ ). In each group, 5 patients reported at least an adverse event (AE). One AE was serious (papillophlebitis, Control) and another one (sinusitis, Sb) led to study discontinuation, both unrelated to the treatment.

**Conclusion:** This pilot study suggests that Sb in addition to dietary advice seems to positively affect SIBO in patients with IBS-D, although the difference between groups was statistically significant only in a post-hoc parametric analysis, without any safety issue. A confirmatory study is needed.

**Disclosure:** Dr. Luis Bustos Fernandez is member of the Latin American Board of Biocodex

## P0509 IMPACT OF SACCHAROMYCES BOULARDII CNCM I-745 ON MICROBIOTA & MYCOBIOTA FOR THE TREATMENT OF BACTERIAL OVERGROWTH IN IBS-D PATIENTS

Lasa J.S.<sup>1</sup>, Man F.<sup>2</sup>, Dorribo C.<sup>1</sup>, Bustos Fernandez L.<sup>1</sup>

<sup>1</sup>CMBF, Buenos Aires, Argentina, <sup>2</sup>Gastro, Buenos Aires, Argentina

**Contact E-Mail Address:** luisbustosfernandez@gmail.com

**Introduction:** Intestinal microbiota dysbiosis is thought to be associated with diarrhea-predominant Irritable Bowel Syndrome (IBS-D); therapeutic alternatives that could modify microbiota (e.g. diet, antibiotics and probiotics) have been proposed for the treatment of IBS-D. Probiotics such as *S. boulardii* CNCM I-745 (Sb) may be efficacious in IBS associated to dysbiosis or bacterial overgrowth.

**Aims & Methods:** To compare the efficacy and safety of Sb plus dietary advice versus dietary advice only on small intestinal bacterial overgrowth (SIBO) in IBS-D patients and to describe their impact on intestinal microbiota composition and clinical improvement.

Adult patients from 2 referral centers in Buenos Aires with IBS-D (Rome III criteria) and SIBO were randomized (1:1) to receive either Sb plus dietary advice (Sb group) or dietary advice only (Control group) for 15 days. At the beginning and at the end of treatment, patients were asked to collect a fecal sample and underwent a lactulose breath test. Severity of symptoms was assessed with the IBS-SSS score and stool consistency was evaluated with the Bristol Stool Scale. Bacterial and fungal composition of fecal samples were analyzed based on 16S rDNA and ITS2 sequencing respectively. Additional qPCR analysis was performed to quantify the abundance of *F. prausnitzii*, *M. smithii*, *B. thetaotomicron* and *P. aeruginosa*.

**Results:** Fifty-four patients were included and 48 (27 Sb, 21 control) were evaluated for efficacy. Sb treatment led to a significant decrease of hydrogen excretion (difference between groups: -1800, IC95[-3595 ; -53],  $p=0.04$ ). Microbiological analyses showed an adequate alpha and beta diversity, which enforced the good quality of samples.

With regards to bacterial composition, *c*.Coriobacteriia (-67%), *c*.Delta-proteobacteria (-77.6%) and *g*.Hungatella (-74.9%) were decreased. Interestingly, *F. prausnitzii* was more abundant in patients with marked clinical improvement with Sb: stool consistency normalization (+120%), negative SIBO with improved IBS-related symptoms (+400%), such as reduction of abdominal pain (+76.5%).

Mycobiota analyses showed significant modifications in Saccharomyces and phylogenetic related lineage (*g*.Saccharomyces (+27%), *g*.Debaryomyces (-88%)) and *g*.Filobasidium (>1000%) and upper related taxa. In addition *g*.Penicillium and upper related lineage were 100 times more

abundant in SIBO negative samples after Sb treatment. Five patients in each group reported at least one adverse event (AE). One patient reported 1 serious AE (papillophlebitis) unrelated to the treatment.

**Conclusion:** Sb CNCM I-745 reduced the bacterial overgrowth and improved digestive symptoms in IBS-D patients. These effects were associated with intestinal microbiota modifications. The increased abundance of *F. prausnitzii* observed in *S. boulardii* patients with symptom resolution merits further research.

**Disclosure:** Dr. Luis Bustos Fernandez is member of the Latin America Board of Biocodex

## P0510 HOW ADDING PROBIOTICS TO FODMAP DIET EFFECTS SYMPTOMS OF IRRITABLE BOWEL SYNDROME: RANDOMIZED DOUBLE BLIND PLACEBO-CONTROLLED STUDY

Bengi G.<sup>1</sup>, Turan B.<sup>2</sup>, Soytürk M.<sup>2</sup>, Cehreli R.<sup>2</sup>

**Contact E-Mail Address:** drgokselbengi@hotmail.com

**Introduction:** In the treatment of Irritable Bowel Syndrome (IBS), physician-patient relationship, diet and lifestyle changes should be considered in addition to medical treatment. Recent studies have shown that FODMAP (fermentable oligo- di- monosaccharides and polyols) restricted diet and probiotics may affect IBS symptoms.

**Aims & Methods:** The aim of this study was to evaluate the combined effect of FODMAP-restricted diet and probiotic supplementary food products on IBS symptoms. In this study, out of all patients diagnosed with IBS according to Rome IV criteria, 51 of them are randomly placed in FODMAP + probiotics group and the other 51 are randomly placed in FODMAP + placebo group. Before starting the study, all patients are asked to fill in questionnaires for Visual Pain Score, Bristol Stool Chart and IBSSS. Patients forwarded to a dietician to receive nutrition advice on low FODMAP diet. Low FODMAP diet applied as 9 gr/day. Patients, who are in low FODMAP diet + probiotics group, received food supplement containing 2 grams of probiotics once a day while the other group were receiving a placebo once a day in addition to their diet. Patients are assessed and scored via same tools in 1 month. A data analysis was made using abovementioned scales and scores about patients in FODMAP + probiotics group and FODMAP + placebo group before and after this program.

**Results:** In both groups, placebo and probiotic fractures were significantly improved in VAS and IBSS scores. The change in VAS score was 2.56 ( $p=0.002$ ) in the probiotic group and 2.77 ( $p=0.019$ ) in the placebo group. When the IBS score was evaluated, the score of 307.46 in the probiotic group was 176.64; in the placebo group, it decreased from 310.26 to 183.87.

**Conclusion:** A low FODMAP diet is a treatment option that has a positive effect on IBS symptoms. In our study, the low FODMAP diet showed significant efficacy in correcting symptoms, but no additional contribution of probiotic was found.

**Disclosure:** Nothing to disclose

## P0511 LOW FODMAP DIET IN THE LONG TERM: EFFICACY, ACCEPTABILITY AND INDIVIDUAL PERCEPTION OF TRIGGER FOODS: A PILOT STUDY

Bellini M.<sup>1</sup>, Bertani L.<sup>1</sup>, Pancetti A.<sup>1</sup>, Tonarelli S.<sup>1</sup>, Gambaccini D.<sup>2</sup>, Costa F.<sup>2</sup>, de Bortoli N.<sup>1</sup>, Morganti R.<sup>3</sup>, Mosca M.<sup>4</sup>, Marchi S.<sup>5</sup>, Rossi A.<sup>4</sup>

**Contact E-Mail Address:** lorenzobertani@gmail.com

**Introduction:** The low-FODMAP diet (LFD) in IBS patients is efficacious in the short term, however, its acceptability and long-term effects still need to be clarified. Moreover, it is not clear if what patients report during the clinical history about the "trigger" FODMAP foods is reliable.

**Aims & Methods:** The aim of this ongoing study was to evaluate: 1) the efficacy and acceptability of a long-term FODMAP diet; 2) the patients' reli-

ability in detecting the real FODMAP foods able to provoke their symptoms. Sixty-three IBS patients (Rome IV), consecutively recruited, started (T0) a LFD for 8 weeks (T1), and then followed a 8-12 week reintroduction period (T2). After that a personalized adapted LFD (aLFD) was issued to each patient. To assess long-term effects, patients were evaluated again at least 6 months after T2 (T3). The following scales were used: IBS-SSS for assessing the severity of IBS symptoms, Likert scales to evaluate the degree of symptom relief and the degree of satisfaction with the diet, and the FODMAP Adherence Report Scale (FARS) to evaluate dietary adherence. Patients' opinions about FODMAP trigger foods at T0 were compared with data obtained at the end of the reintroduction period. Dietary acceptability and food-related quality of life were evaluated using a 20-item questionnaire adapted from the nutrition-related QOL questionnaire.

**Results:** At T3 (11.2±4.2 months) IBS-SSS improved compared to T0 (218.9±105.8 vs 324.1±90.2;  $p < 0.002$ ). Patients' satisfaction with aLFD was 7.5±2.4 on a 10-point Likert scale and degree of relief was 1.8±1.3 on a 7-point Likert scale). Regarding dietary acceptability patients reported that they needed more time for cooking ( $P < 0.0001$ ), it had higher costs ( $p = 0.00001$ ) and they had problems eating out ( $P < 0.0001$ ) during the LFD, but not during the aLFD. Adherence to the LFD was constantly high (T1: 24.2 ± 0.9; T2: 24.2 ± 0.8; T3: 24.0 ± 1.5 ns). Regarding patients' perception of trigger foods, a moderate concordance was found only for lactose (k: 0.54), a fair one for fructans, fructose and galactans (k: 0.38, 0.27 and 0.28, respectively) and a poor one for polyols (k: 0.12).

**Conclusion:** IBS patients are satisfied with LFD because it improves symptoms. A LFD is well accepted and effective also in the long term. The patients' perception regarding "trigger" foods reported during their clinical history is not reliable.

**Disclosure:** Nothing to disclose

## P0512 FECAL TRANSPLANTATION ADMINISTERED VIA COLONOSCOPY IN IRRITABLE BOWEL SYNDROME: RESULTS OF A RANDOMIZED PLACEBO-CONTROLLED STUDY

**Contact E-Mail Address:** perttu.lahtinen@phsotey.fi

**Introduction:** Irritable bowel syndrome (IBS) is a common functional gut disorder with unknown etiology. Aberrant microbiota composition has been associated with IBS and is considered to play a role in the symptom development. Fecal microbiota transplantation (FMT) has been shown to be highly successful in treating patients with recurrent *Clostridium difficile* infection. We performed a randomized, double blind, placebo-controlled trial to evaluate the effect of a single FMT administered in colonoscopy on the symptom relief of IBS patients.

**Aims & Methods:** We recruited 56 adult IBS patients with any level of symptom severity and including all the IBS subtypes. The participants were randomized 1:1 to receive either frozen and thawed FMT from a tested general donor or a placebo made from patients own fresh stool. The participants were asked to fill questionnaires at baseline and 4, 8, 12, 26 and 52 weeks after the FMT. Changes in symptom severity were recorded with IBS Symptom Severity Score (IBS-SSS) scored 0-500. Additionally, quality of life was recorded with questionnaires IBS-QoL and 15-D, anxiety with Beck Anxiety Inventory (BAI) and depression with Beck Depression Inventory (BDI).

**Results:** The primary endpoint of the study was a sustained reduction of IBS symptoms defined by a drop of IBS-SSS score of 50 points. This was achieved only at 12 weeks after the FMT in the treated group when compared to the baseline (unpaired t-test  $p = 0.03$ , 95%, CI 3.79 to 126.71). There was no statistical difference between the placebo and treated group at any time point. There were no other significant changes in the mental health status or quality of life measures between the treatment or placebo group or compared to the baseline.

**Conclusion:** In this randomized placebo-controlled trial we did not find significant differences between FMT and placebo. The IBS symptom severity of the treatment group decreased significantly 12 weeks after FMT as compared to the baseline, but the change was transient. Adverse events

were mild and indifferent between the two groups. The transient relief of IBS symptoms in the FMT treatment group indicate that microbiota is a potential therapeutic target in IBS. Larger placebo-controlled studies are needed with more homogenous study population and with different treatment protocols. Currently, FMT cannot be recommended in treatment of IBS outside of study protocols.

**Disclosure:** Nothing to disclose

## P0513 COMPLIANCE TO PROBIOTIC THERAPY IN IRRITABLE BOWEL SYNDROME IN CLINICAL PRACTICE: A REAL-LIFE STUDY

Laterza L., Napoli M., Petito V., Scaldaferrì F., Gaetani E., Gasbarrini A.  
 Fondazione Policlinico Universitario A. Gemelli IRCCS, Internal Medicine and Gastroenterology Unit, Rome, Italy

**Contact E-Mail Address:** marco.napoli.md@gmail.com

**Introduction:** Probiotics have been evaluated in multiple clinical trials on irritable bowel syndrome (IBS) showing efficacy on different IBS-related symptoms. Among them, the multistrain probiotic VSL#3 (manufactured by Nutrilinea Srl and distributed by Ferring SPA) has been the object in clinical trials evaluating its administration for 4 to 8 weeks. However, whereas in clinical trials patients are closely monitored for compliance, in real-life setting long term compliance could be low. Furthermore, in many countries probiotics are fully paid by patients and the cost of therapy could further limit the compliance to probiotic therapy.

**Aims & Methods:** This is a single-center, observational, prospective study to evaluate the compliance to prescription of probiotic therapy in real life and to identify factors able to influence adherence to therapy. Patients diagnosed with IBS according to Rome IV criteria and receiving a clinical prescription of VSL#3 for their IBS symptoms were evaluated for eligibility. Patients providing informed consent received a diary at the start of therapy to evaluate safety and effect of treatment for two months. After two months a final visit (at clinic or by telephone) was made to assess compliance and eventual reasons for discontinuation.

**Results:** Fifty patients (mean age 41±SD 14.4 years, 26% males) have been enrolled and 49 completed the planned follow up. IBS subtypes are distributed as following: 44% diarrhea, 42% constipation and mixed in the remaining cases. Eighty-six percent of patients received a 4-week prescription of one sachet per day. Sixty percent of patients resulted adherent in the FAS population. Among the 20 patients with reduced compliance, 5 assumed less than 50%, 12 assumed 50% and 2 assumed more than 50 but less than 80% of prescribed doses. Principal reasons of not adherence among the 20 patients are the price of the product (40%), mild adverse events (AEs) (30%) and poor appreciation of flavour (15%). Furthermore, one patient (5%) forgot to take the treatment, one (5%) stopped the treatment for inefficacy and, for the patient who was lost at follow up (5%), the reason was not available. About AEs, 20% of patients experienced at least one (only one patient two AEs). All AEs were mild and they were: bloating (6/10 patients), constipation (2/10 patients) and flatulence (3/10 patients). The AEs were considered related to treatment in 9/10 cases and they were a reason for discontinuation in 6/10 cases. All AEs completely resolved without sequelae. No serious adverse events have been reported. Sixty-two percent of patients who assumed the therapy reported overall satisfactory benefit on their IBS symptoms with the prescribed therapy.

**Conclusion:** According to our results, despite a good safety profile, 60% of patients assumed all the prescribed probiotic therapy in real life setting with reported overall satisfactory benefit. The main reasons for lack of compliance were price of the product, mild AEs (mainly bloating) and low palatability.

**Contact E-Mail Address:** veronicagamelas@gmail.com

**Introduction:** Perianal fistula significantly decrease quality of life and are traditionally treated by fistulotomy or fistulectomy. Efficacy and safety of fistula seton placement followed by superficial fistulotomy have been discussed in the past years.

**Aims & Methods:** The aim of our study is to evaluate the efficacy and safety of this procedure on the treatment of perianal fistula.

This is a retrospective observational study of patients with cryptogenic perianal fistula aged 18 to 90 years old, who were followed in a central hospital proctology consultation between January 2006 and December 2017. Clinical records of patients informatically coded as having anal fistula were analysed. Parks Classification was used to characterize anal fistula. We identified 263 patients, of whom 167 were excluded: 111 for incomplete information, 19 for submucosal fistula, 16 for coding error, 7 for complex fistula, 7 for HIV infection, 4 for inflammatory bowel disease, 2 for still having seton in situ at the time of data collection and 1 for age over 90.

Fistula were characterised by proctologic examination and imaging (ano-rectal ultrasound and/or MRI). The treatment consisted of defining fistula anatomy by passing a probe through the fistula tract (cannulation). This was followed by seton placement which remained in situ for a variable time until fistula tract was exteriorized. Superficial fistulotomy was then performed with an electric cautery, under local anesthesia.

**Results:** Ninety six patients with perianal fistula were included (66.67% males, mean age 56±15 [23-86] years old). Nineteen (19.89%) patients had previous history of anal fistula and 14 (14.58%) previous anorectal surgery. Of the 96 patients, fistula cannulation was not possible in 2 (2.08%), for a partially closed fistula tract. Of the 94 patients submitted to fistula cannulation, fistulotomy was possible in 74 (78.72%). Among the others, fistulotomy was not possible due to: loss of follow up - 16 patients (17.02%), loss of seton - 3 patients (3.19%) and therapeutic failure due to nonprogression of seton - 1 patient (1, 06%) - (ITT 80.2%, PP 98.7%).

We evaluated 74 patients submitted to cannulation and fistulotomy for perianal fistula treatment. The mean follow-up time was 59±45 [6,144] months. Of these patients, 47 (63.51%) had intersphincteric fistula (time with seton 15±31 weeks), 26 (35.14%) transsphincteric fistula (time with seton 32±47 weeks), 1 (1.35%) suprasphincteric fistula (time with seton 11 weeks).

Adverse events were reported in 4 (5.4%) patients: 2 (2.7%) had transient pain after the procedure and 2 (2.7%) reported incontinence.

Two patients (2.7%) had recurrence after fistulotomy, in less than 8 weeks.

**Conclusion:** Placement of seton followed by fistulotomy is a safe and effective method for perianal fistula treatment.

**Disclosure:** Nothing to disclose

## P0515 "ANAL TAPE" A GENUINE EXTERNAL DEVICE FOR FECAL INCONTINENCE

Livovsky D.M., Koslowsky B., Lysy J., Shaare Zedek Medical Center, Digestive Diseases Institute, Jerusalem, Israel

**Contact E-Mail Address:** lysyj@szmc.org.il

**Introduction:** Fecal incontinence (FI) is a common underreported, debilitating condition with devastating negative impact in quality of life. Its prevalence ranges from 7-18%. Management includes: Conservative / behavioral treatment, anal or vaginal plugs, and invasive methods. We developed an "anal tape" with an adjusting applicator to adapt the device to the skin surrounding the anus. We used an available elastic band with a special adhesive that is approved for use in the skin.

**Aims & Methods:** The aim of this study was to determine the safety and efficacy of the "anal tape" device in patients with fecal incontinence. This is a four week prospective, self-controlled open label study of patients

with mild to moderate FI. The primary outcome was improvement in any of the 4 domains in the "Fecal Incontinence quality of life scale (FIQOLS)" using a 5 point Likert scale (higher score meaning better quality of life). Secondary outcomes included improvement in severity and frequency of FI events according to the Wexner score and stool diaries, and safety. The first two weeks, served as the control period since no treatment was provided. During the third and fourth week, the tape was applied and served as the study period. Questionnaires were completed on days 0, 14 and 28 of the study. At day 28 patients were asked to rate their general satisfaction and willingness to use the anal tape in the future using a visual analog scale.

**Results:** Twenty patients were included, all females. The median age was 64 (Range 27-82). Four patients developed FI after an obstetric anal sphincter injury (OASIS) and one had FI secondary to peripheral neuropathy; In 15 the FI was considered idiopathic, but seven of them had a remote history of OASIS. Significant improvement was observed in all domains of the FIQOLS from baseline to day 28 (Lifestyle: 2.8(0.69) to 3.3(0.68) p< 0.001; Coping/Behaviour 1.9(0.64) to 2.5(0.73) p=0.0002; Depression/Self-Perception 3.1(0.75) to 3.5 (0.74) p=0.006; Embarrassment 2.13(0.67) to 2.65 (0.76) p=0.002) but not between baseline and day 14 (Lifestyle: 2.8(0.7) to 2.9 (0.7) p=0.6; Coping/Behaviour 1.9(0.64) to 2.1(0.67) p=0.06; Depression/Self-Perception 3.1(0.75) to 3.2 (0.71) p=0.09; Embarrassment 2.13(0.67) to 2.26 (0.89) p=0.4). Quality of life Improved significantly between day 14 and day 28 in all domains except Depression/Self-Perception (p=0.08, in all other comparisons p value was < 0.04). The mean Wexner score in days 0, 14 and 28 was 12.5(3.6), 11.9(3.5) and 10.3(4.8) (day0 vs. day14 p=0.13, day0 vs day28 p=0.054, day14 vs. day 28 p=0.18). Fifteen complete stool diaries were available for analysis.

Absolute number of FI events between the control period and the treatment period decreased by a mean of 52.3% in 11/15 patients, 2 patients reported no change and 2 patients had a small (non-statistically significant) increased in the number of FI events. Five patients (25% intention to treat) had 50% or more improvement in FI events. Out of 17 patients that completed the VAS scales, the median overall satisfaction with the device was 80 (IQR 30-85) mm and the willingness to use the anal tape in the future was 90 (IQR50-90) mm. Other than mild difficulty to remove the anal tape, no adverse events were reported.

**Conclusion:** The use of the anal tape was safe and effective. The primary outcome of significant improvement in quality of life was achieved

**Disclosure:** Nothing to disclose

## P0516 CONSERVATIVE MANAGEMENT OF CHRONIC ANAL FISSURE: IS THE BOTOX A GOOD RESCUE THERAPY?

Meixedo Arieira C.V.<sup>1,2,3</sup>, Dias de Castro F.<sup>1,2,3</sup>, Rosa B.J.F.<sup>1,2,3</sup>, Berkeley Cotter J.<sup>1,2,3</sup>

<sup>1</sup>Hospital da Senhora da Oliveira, Gastroenterology, Guimarães, Portugal,

<sup>2</sup>Life and Health Sciences Research Institute (ICVS), School of Medicine,

University of Minho, Braga/Guimarães, Portugal, <sup>3</sup>ICVS/3B's PT Government Associate Laboratory, Braga/Guimarães, Portugal

**Contact E-Mail Address:** catia\_arieira@hotmail.com

**Introduction:** Chronic anal fissure (CAF) is one of the commonest proctological diseases that presents with severe perianal pain and bleeding. Because of the disability associated with anal surgery, medical alternatives have been sought. Most recently, pharmacologic methods that relax the anal smooth muscle have been used to obtain fissure healing.

**Aims & Methods:**

**Aim:** To investigate the effectiveness and the factors associated to CAF healing with conservative management.

**Methods:** Retrospective study. Included consecutive patients referred for CAF to coloproctology consultation between March 2015 and June 2018. All the patients had a minimum follow up of 3 months.

**Results:** Included 75 patients, 55 (73.3%) female with mean age of 47.0±16.1 years. Nine patients (12.0%) had previous history of anal surgery and 6 (8%) suffered from IBD. The CAF was anterior in 19 patients (25.3%), posterior in 49 (65.3%) and 7 patients presented anterior and posterior CAF. All the patients were appropriately started on conservative dietary therapy and laxatives. Associated with this therapy all the patients performed topical medications (1 or 2 cycles): nitroglycerin in 85.6% of the patients and in 68% diltiazem. 43 patients (55.1%) were submitted sequentially to the 2 topical treatments. CAF healing was achieved with topical treatment in 33 (44%) patients.

The remaining patients who did not achieved CAF healing with topical therapy (56%) underwent botulinum toxin injection (Botox®). Fissure healing was observed in 54.7% (n=23) and partial healing in 3 patients (7.1%) with Botox®.

Two patients were re-injected with Botox®, one achieving complete fissure healing. Sixteen (21.3%) were referred to anal surgery. Nevertheless, we observed that patients with higher age more frequently had fissure healing with medical therapy (49.4vs40.7 years; p=0.034).

**Conclusion:** We observed that more than three quarters of the patients presented fissure healing with conservative management (topical+botox injection). Older patients may respond better to conservative management. This highlights the benefit of early conservative and medical management of CAF, before attempting anal surgery.

**Disclosure:** Nothing to disclose

## P0517 EVOLUTION IN THE MANAGEMENT OF PRESACRAL TUMOURS

Gould L., Fletcher J., Pring E., Corr A., Burling D., Tozer P., Warusavitarne J., Antoniou A., Jenkins J.T.  
St Mark's Hospital, London, United Kingdom

**Contact E-Mail Address:** laura.e.gould@gmail.com

**Introduction:** Presacral tumours represent a small group of pathologies encountered by colorectal surgeons where specialist input is likely to be required. They represent a disparate number of pathological phenomena which are classified together through a shared anatomical association. These rare tumours can be either benign or malignant and arise de novo or from embryological remnants in the pelvis. With the increased use of radiological investigations there has been an increase in the identification of these lesions many of which are incidental. Understanding how the management of such tumours has evolved would be informative to the colorectal community.

**Aims & Methods:** Retrospective database assessment of presacral tumours treated in a tertiary referral hospital from 1980s-2019. Patient demographics and related radiological and clinico-pathological data were assessed in relation to short and long term outcomes. From 2008, presacral tumours have been assessed through a formal MDT process.

**Results:** 132 presacral tumours were identified: 72% Female: 98 congenital benign; 10 congenital malignant; 8 benign neurogenic; 4 malignant neurogenic; 2 malignant osseous; 6 miscellaneous malignant; 4 miscellaneous benign. 102 [77%] underwent surgical excision; 30 [23%] deferred surgery or in surveillance. The total number cases seen has increased each decade from 13 in 1980s, 19 in 1990s, 23 in 2000s to 77 patients in 2010s. Surgical intervention occurred in nearly all early cases with 90% of patients in 2000s undergoing resection. There has been a shift towards surveillance in the 2010s with 64% operated and 36% in surveillance. Stoma formation was required in 10%. Increasing proportions of patients were asymptomatic and noted incidentally on imaging.

**Conclusion:** Presacral tumours are increasingly noted incidentally on imaging and significant proportions may be managed with radiological surveillance. A formal specialist MDT process is required and referral to a specialist centre is recommended.

**Disclosure:** Nothing to disclose

## P0518 HOW TO ESTABLISH A DEDICATED LOW ANTERIOR RESECTION SYNDROME (LARS) CLINIC

Metry M.<sup>1</sup>, Miah M.<sup>1</sup>, Kaur G.<sup>2</sup>  
<sup>1</sup>Scunthorpe General Hospital, Scunthorpe, United Kingdom, <sup>2</sup>Scunthorpe General Hospital, Surgery, Scunthorpe, United Kingdom

**Contact E-Mail Address:** mario.metry@nhs.net

**Introduction:** Sphincter saving resection with TME with/without preoperative radiotherapy are considered standard treatment for rectal cancer. This can result in bowel dysfunction of variable severity in these patients, including faecal urgency and frequency, incontinence, and difficult or incomplete evacuation. An internationally validated patient-reported outcome measure, Low Anterior Resection Syndrome (LARS) score, enables these symptoms to be measured. The Pre-Operative LARS score (POLARS) is a validated online tool developed by the Pelican Group, Basingstoke, which may be used to predict bowel dysfunction severity prior to anterior

resection to help patients understand their risk of bowel dysfunction and also to highlight those patients who may require additional postoperative support.

**Aims & Methods:** We aimed to assess the risk factors for and the predicted incidence of LARS in our anterior resection patient population to validate the need for a LARS clinic in our Lower GI physiology department.

All patients who had undergone curative surgery for rectal cancer in our district general hospital Jan 2016 - Dec 2018 were included in the study. Only those who had undergone restorative anterior resection were included- the rest, including non-resection procedures (TEMS/ EMR etc) or AP resections with permanent colostomy, were excluded. Demographics, tumour height from the anal verge, preoperative treatment and details of the surgery were documented and the POLARS for each patient was calculated.

**Results:** There were 53 male and 31 female patients in the study; the age ranged from 36 to 98 years, with 80.92% in the 51-80 year age group, 58.33% in the 61-80 year group. The incidence of Major LARS was predicted as 8.33%, minor LARS was 78.57% and no LARS was only 13.1%. Interestingly, the mean age in the Major LARS group was 53 as compared to 77 years in the no LARS group. The mean distance of the tumour from the anal verge was 10.14 cm in the Major LARS group as compared to 22.82 cm in the no LARS group. No patient in the no LARS group had preoperative radiotherapy as compared to 71.43 % in the major LARS group. There was only 1 female in the no LARS group whereas in the major LARS group 71.43 % patients were female.

**Conclusion:** Bowel dysfunction is well known following sphincter-preserving resection. We used the POLARS to help target the patients needing intensive support post treatment to prevent QOL issues. We found the risk of major LARS strongly correlated with female sex and younger age group patients as well as a shorter distance of the tumour from the anal verge; it was significantly higher in the group that had neoadjuvant therapy. We found our predicted incidence of minor/major LARS was 86.9% of our anterior resection population on POLARS. Therefore, we set up a LARS clinic in the lower GI physiology department, specifically for these patients following oncologic/surgical treatment of pelvic cancer- we have already received excellent feedback from the patients.

**Disclosure:** Nothing to disclose

## P0519 FECAL INCONTINENCE EVALUATION AND ITS CONSEQUENCES ON QUALITY OF LIFE - STUDY IN A SECONDARY ATTENTION CLINIC

Grabin Grainero G.<sup>1</sup>, Bonadio C.B.<sup>2</sup>, Brisotti J.L.<sup>2</sup>, Araújo M.N.F.<sup>2</sup>  
<sup>1</sup>FACISB, Medicine, Barretos, Brazil, <sup>2</sup>FACISB, Barretos, Brazil

**Contact E-Mail Address:** grabingui@gmail.com

**Introduction:** Anal incontinence (AI) is a involuntary loss of stool or gas and affects the individual quality of life in regards to physical, psychological and social spheres. It is known that quality of life is usually under the influence of the grade of anal incontinence, but social facts can also affect the real quality of life, for example, older patients may be less disturbed by the symptoms.

**Aims & Methods:** To evaluate the relation between the prevalence of anal incontinence and its grades of gravity in a population from a secondary care clinic and the real impact of symptoms in quality of life of those individuals, using quantitative and qualitative scores (of symptoms and of quality of life).

This is a transversal analytic study with the application of questionnaires in patients from secondary care clinic. A personal and medical health survey were applied as well as two questionnaires, already validated in medical literature (Jorge-Wexner Anal Incontinence Scale and Fecal Incontinence Quality of Life - FIQL) were also applied in patients with FI symptoms (FI solid, liquid and gas; soiling, non-sensitive loss, urgency evacuation. FIQL scale already underwent both translation and cultural adaptation processes and consists of four different domains: lifestyle, behavior, depression and embarrassment. Jorge-Wexner scale is the most utilized to evaluate grades of AI. The patients were divided in 2 groups: mild AI (score 1-9) and moderate/serious AI (score 10-20) and according to age 18-59 and older than 60.

**Results:** The reproducibility was tested through application of 1200 personal and medical questionnaires, being the population predominantly female (64.1%), with median age: 54 (iq 40-65). 162 patients (16%) presented AI symptoms. Among these patients, 153 that answered Jorge-

Wexner scale, 116 (75.8%) demonstrated mild AI. 9 patients did not have symptoms that were nominated in the scale (soiling, non-sensitive loss and urgency evacuation). The media of aspects assessed at FIQL scale was, respectively, in mild and moderate/serious AI: lifestyle 3.36 (sd 0.95) vs 2.4 (sd 1.04), behavior 3.35 (sd 0.89) vs 2.09 (sd 0.88), depression 3.64 (sd 0.82) vs 2.38 (1.0) and embarrassment 3.25 (sd 0.94) vs 2.15 (0.96); all comparisons were statistically significant ( $p < 0.05$ ). Moreover, the patients were divided in two range of ages: patients from 18 until 59 years old and more than 60 years old. Comparing FIQL scale between those groups, there was no statistical difference regarding all aspects of the questionnaire: (lifestyle  $p=0.74$ ); behavior  $p=0.61$ ; depression  $p=0.99$  and embarrassment  $p=0.39$ ).

**Conclusion:** In the studied population, there was a direct association between the severity of AI, as stated by Jorge-Wexner scale and the quality of life, according to the classification of mild AI and moderate/serious AI. On the other side, there is no correlation between worse quality of life in patients younger than 60 years of age, despite the gravity of AI.

**Disclosure:** Nothing to disclose

## P0520 ASSESSING THE RISK FOR GASTROESOPHAGEAL REFLUX DISEASE AND ITS COMPLICATIONS IN PATIENTS WITH CONSTIPATION

Asfari M.M.<sup>1</sup>, Sarmini M.T.<sup>2</sup>, Ellison S.B.<sup>1</sup>, Jackson C.S.<sup>3</sup>, Vega K.I.<sup>1</sup>

<sup>1</sup>Augusta University-Medical College of Georgia, Division of Gastroenterology and Hepatology, Augusta, United States, <sup>2</sup>Cleveland Clinic, Cleveland, United States, <sup>3</sup>Loma Linda VA Healthcare System, Loma Linda, United States

**Contact E-Mail Address:** kvega@augusta.edu

**Introduction:** Constipation is a common gastrointestinal disorder which can result in infrequent hard stools that are difficult and/or painful to pass. Constipation is also frequently associated with straining which is known to promote gastroesophageal reflux disease (GERD). Data on the presence of GERD in patients reporting constipation is limited. The aim of this study was to investigate if constipation increases the risk for GERD and its main complications including Barrett's esophagus (BE), esophageal stricture (ES) as well as esophageal cancer (EC) using a large patient database.

**Aims & Methods:** Using data from the National Inpatient Sample (NIS) database between 2004 and 2014, we identified patients who were diagnosed with constipation using appropriate ICD 9 coding. The control group were patients who did not have a diagnosis of constipation. Demographic information, tobacco use, hernia presence and GERD diagnosis along with its complications (esophageal stricture, Barrett's esophagus as well as esophageal cancer), by ICD 9 coding, was then compared between the 2 groups to determine if any association existed using univariate and multivariate logistic regression.

**Results:** The total population studied in the NIS database comprised of 53,237,367 patients, of which 1,751,039 (3.2%) were diagnosed with constipation. Constipated patients were older (61 years old vs 49), more likely to be female (59.8% vs 57.8%) and African American (15.7% vs 14.6%) compared to the control group ( $P < 0.01$  for all). Furthermore, patients with constipation were more obese (10.3% vs 9%), had increased tobacco use (11.8% vs 11%) and diaphragmatic hernias present (3% vs 1.6%) compared to those without constipation ( $P < 0.01$  for all). Of note, constipated patients had less alcohol abuse (3.1% vs 3.8%) and bariatric surgery (0.1% vs 0.4%) compared to the control group ( $P < 0.01$  for both). History of para-esophageal surgical repair was similar in both groups (0.1%). Using multivariate logistic regression, constipated patients had statistically significant higher rates of GERD (OR 1.57, 95% CI 1.56-1.58), BE (OR 1.24, 95% CI 1.21-1.27), ES (OR 1.21, 95% CI 1.18-1.24) and EC (OR 1.68, 95% CI 1.61-1.74) ( $P < 0.001$  for all) compared to patients without constipation.

**Conclusion:** Constipation is associated with a significant increase in risk for GERD and complications of GERD. The most significant association is for esophageal cancer. Screening for and treating GERD along with its complications, if present, is essential for the optimal management of patients with constipation.

**Introduction:** In the recent years medical malpractice claims have contributed significantly to the rising cost of medical practice in all specialties in the United States by increasing the malpractice insurance premiums and costs associated with the practice of defensive medicine. Being a procedure oriented specialty, the trends in gastroenterology diagnoses and endoscopy related malpractice claims need to be studied to educate the gastroenterologists and allied health care professionals towards risk management and cost containment in this field.

**Aims & Methods:** Retrospective analysis of Medical professional liability (MPL) claims data for the years 2006-2015 obtained from the MPL association [formerly the Physician Insurers Association of America (PIAA) Data Sharing Project (DSP)] was done. Among the gastroenterology claims the presenting medical condition, operative procedure, outcomes of the claims and the costs associated with the closed claims were compared between 2006-2010 and 2011-2015 time periods to analyze the trend over the years.

**Results:** From 2006-2015, there were 90,743 MPL closed claims and 24,106 paid claims in all medical and surgical specialties. Out of all the claims, 2.07 % (1879) of closed claims and 1.5% (367) of all paid claims were against gastroenterologists. In the claims against gastroenterologists, 71.0% of were dropped, withdrawn, or dismissed. Out of the claims that went to trial, 88.4% of claims that received a verdict were favorable toward the gastroenterologists. Within the GI, MPL claims involving diagnostic procedures of large intestine were the most common accounting for 26% of all closed claims leading to a payment of \$18,392,668 in total and \$301,519 as average indemnity. Average indemnity was highest for diagnostic procedures of gallbladder and biliary tract including ERCP procedures (\$484,364). This was followed by procedures involving small intestine (\$336,078), large intestine (\$301,519) and esophagus (\$267,577). In the time frame 2006-2015, the average indemnity increased by 8.2% from \$341,563 in 2006-2010 to \$369,508 in 2011-2015. Amount spent on legal defense also increased by 8.7% (\$44,625 vs. \$48,506) in gastroenterology related claims for the respective time periods.

**Conclusion:** Gastroenterology specialty has an increasing trend in spending on average indemnity and defense. Diagnostic procedures of the biliary tract including ERCP have the highest average indemnity among the endoscopic procedures. Adequate endoscopic training, meticulous focus on procedural indication and well informed consent might help to reduce the costs associated with claims. Further studies are needed to investigate the variables associated with this trend in gastroenterology.

**Introduction:** Constipation increases the risk of colorectal cancer [1-4]. Low frequency of defecation increases the risk of cardiovascular mortal-

ity by 21-39% [5]. Constipation increases the risk of obesity [6]. However, the most initial risk factors for constipation and colorectal cancer remain poorly understood.

**Aims & Methods:** Aim of this study was the description of the Colorectal Bradyarrhythmia Syndrome (CBS) as an early risk factor of constipation and colorectal cancer.

Using the method of "Chronoenterography" - weekly monitoring of enteral circadian rhythm [7, 8] surveyed 3 groups of volunteers. The first group was 356 medical students (20-22 years, 71% of women). The second - was 100 gastroenterologists (30-64 years, 41% of women). The third - 2501 doctors (24-75 years, 66% of women). 4 rhythms of defecation were revealed: normal (daily) - regular colorectal rhythm (RCR) - 7 times a week, CBS-I - 5-6 times/wk., CBS-II - 3-4 times/wk., CBS-III - 1-2 times/wk., (constipation). The presence of physiologically optimal morning (06:00-12:00) acrophase of the circadian rhythm of defecation was determined. 3 levels of quality of life (QOL) were estimated: high - 80-100% of optimal; medium - 60-80%; low - 40-60%. The level of mood and laxative were revealed.

**Results:** RCR was detected in 53% of medical students, CBS - in 47%. Morning phase of defecation was almost 3 times more common for students with RCR than with CBS. CSC-I, CSC-II and CSC-III were detected in 33%, 11% and 3% of students, respectively. The high level of QOL in students with RCR was (in 36%) 1.5 times more often than with CBS (in 24%). The low level of QOL in students with CBS was (21%) 1.7 times more often than in students with RCR (12%).

Low mood level was found in 34% with CBS-I, but in 55% of students with CBS-III.

Laxatives took 13%, 30% and 64% of students with CBS-I, CBS-II and CBS-III, respectively.

RCR was detected in 57% of gastroenterologists, and CBS - in 43%. Morning phase of bowel habits was almost 7 times more likely for gastroenterologist with RCR than for persons with CBS. High QOL level was found for 63% gastroenterologist with RCR but only for 49% with CBS.

Regular colorectal rhythm was detected in 56% of doctors, and CBS - in 44%. Morning phase of defecation was 4 times more common for doctors with RCR than with CBS. CBS -I, CBS -II, CBS -III (constipation) was detected in 27%, 13% and 4% of doctors respectively. Doctors with RCR had predominantly the high level of QOL (80-100% of optimum), but doctors with CBS - had predominantly average level of QOL (60-80% of the optimum). CBS was associated with a significant decrease in the level of mood in 30-55% of medical students. CBS is characterized by a progressive increasing in using laxatives (from 13% in CBS-I to 64% in CBS-III).

**Conclusion:** CBS occurs in all age groups, starting from the age of 20. CBS-I was 7-10 times more common than CBS-III (constipation). CBS-I is the earliest predictor of constipation. The QOL of persons with CBS was lower than of persons with RCR. CBS is manifested by 3 main features: slowing the rhythm of defecation, the absence of the morning phase of defecation and the decreasing QOL level. Screening of the CBS is necessary for the earliest (at 20 years) detection of this syndrome as a functional predictor of constipation. CBS can be used for the functional primary prevention of colorectal cancer and to identify new risk groups for endoscopic screening of this type of cancer.

**Introduction:** Drivers of health care utilization in the irritable bowel syndrome (IBS) and inflammatory bowel disease (IBD) are unclear but symptoms and psychological distress may be important.

**Aims & Methods:** This study aimed to explore the links between health care utilisation, type of bowel symptoms and severity of bowel symptoms in patients with IBS and IBD referred by GPs to a tertiary hospital. We randomly selected 282 patients without evidence for structural causes for GI symptoms who had an outpatient appointment between 15 and 18 months ago. Symptoms were assessed with the validated SAGIS-instrument and patients categorised based upon the symptom pattern as (IBS-M (IBS with diarrhea and constipation symptoms), IBS-C (constipation) and IBS-D (diarrhea), and non-IBS symptoms). In addition, we selected 149 patients with IBD. Electronic medical records were reviewed and episodes of care, hospital admissions, gastroenterology and other specialists outpatient department (OPD) consultations, diagnostic procedures (MRI, CT, ultrasound) and the number of therapeutic day procedures for a period of 12 month before and 12 month after the index consultation determined. Costs for outpatients' consultations and other procedures were quantitated based upon published data costs for the respective jurisdiction. Group differences were analysed using one-way analysis of variance and correlations were measured using Pearson correlation coefficients.

**Results:** Out of 282 patients, 61 reported a mix of IBS diarrhea and constipation (21.6% 95%CI 17.2-26.8), 106 (37.5% 95%CI 32.1-43.4) IBS diarrhea, 17 (6.0%, 95% CI 3.8-9.4) IBS constipation only and 98 (34.8% 95%CI 29.4-40.5) with other non-IBS symptoms. In total 149 patients had IBD but 83 IBD patients did not report clinically relevant GI symptoms (total SAGIS score < 10). As shown in Table 1 patients with active IBD had higher health care utilisation, in particular gastroenterology outpatient consultations and imaging compared with patients with IBD in remission but were *not* different to those with IBS.

Patient Group	Hospital admissions	OPD GI	OPD other	MRI	CT	Ultrasound	Procedures
IBD-remission (n=83)	1.16 (1.87)	4.35 (1.80)*	2.28 (4.32)	0.49 (0.83)*	0.63 (0.91)	0.32 (0.63)	1.80 (2.78)
IBD-active (n=66)	1.88 (2.61)	5.30 (2.92)	2.09 (4.55)	1.27 (2.01)	0.80 (1.43)	0.50 (0.93)	2.24 (1.61)
IBS-M (n=61)	2.48 (4.40)	4.15 (2.48)	4.41 (7.76)	1.38 (2.49)	0.82 (1.71)	0.39 (0.86)	2.12 (1.53)
IBS-D (n=106)	1.68 (3.32)	4.10 (2.46)	3.51 (5.41)	0.70 (1.07)	0.64 (0.92)	0.41 (0.76)	2.03 (3.09)
IBS-C (n=17)	1.23 (1.75)	3.65 (2.85)	4.82 (6.44)	0.29 (0.49)	0.71 (0.95)	0.43 (0.53)	2.43 (1.40)
Other (n=98)	0.84 (1.68)	4.03 (3.47)	2.42 (5.79)	0.71 (1.17)	0.71 (1.02)	0.38 (0.79)	1.76 (1.51)

\*IBD remission versus active P< 0.05

[Table 1. Total health care utilisation among patient groups, all cell entries are mean (SD)]

Gastroenterology outpatient costs were significantly higher in patients with active IBD (\$2,121) compared with IBD in remission (\$1,739) (P=0.02) and similar to patients with IBS-M (\$1,659), IBS-D (\$1,642), IBS-C (\$1,459) and IBS-other (\$1,612). Compared with non-IBS patients with symptoms, patients with IBS-D (P=0.03), IBS-C (P=0.03) and IBS-M (P=0.02) had higher other OPD costs. Other procedure costs were similar in patients with IBS and active IBD but higher than in non-IBS patients.

SAGIS intensity scores were correlated with the number of hospital admissions  $r=0.23$ ,  $P<0.001$ , length of stay  $r=0.12$ ,  $P=0.01$ , other outpatient consultations  $r=0.18$ ,  $P<0.001$ , CT scans  $r=0.115$ ,  $P=0.02$ , other OPD costs  $r=0.18$ ,  $P<0.001$ , anxiety  $r=0.31$ ,  $P<0.001$  and depression  $r=0.28$ ,  $P<0.001$ . **Conclusion:** Health care utilisation in patients with IBS is not different to patients with active inflammatory bowel disease and exceeds health care utilisation of patients with inactive inflammatory bowel disease. The intensity of gastrointestinal symptoms is significantly associated with health care utilisation and health care costs.

**Disclosure:** This study was sponsored by Allergan Pty Ltd.

## P0524 THE ROLE OF AN 'ADVANCED ENDOSCOPY MULTIDISCIPLINARY TEAM MEETING' FOR OPTIMAL MANAGEMENT OF PATIENTS REFERRED FOR COMPLEX ENDOSCOPIC PROCEDURES: ONE YEAR EXPERIENCE FROM A TERTIARY REFERRAL CENTRE

**Introduction:** Optimisation of patient care through multidisciplinary team (MDT) meetings is now established as the standard of care in cancer pathways. Cases presented at MDTs are discussed by a panel of multidisciplinary experts in order to provide optimal management, tailored to the needs of individual patients, also considering co-morbidities and available expertise. Within the subspecialty of endoscopy, management of pathological findings may vary significantly and could be approached through an array of different techniques/procedures. Similar to cancer pathways, an advanced endoscopy MDT platform, may help to achieve consensus on decision-making and management of complex cases, clinical outcomes and patient satisfaction.

**Aims & Methods:** Over the last year, in our tertiary referral institution, we developed and adopted an 'advanced endoscopy MDT' to evaluate and manage complex cases referred to us for advanced endoscopic intervention. An hourly bi-weekly meeting was established with the presence of at least two expert interventional endoscopists, a radiologist, a histopathologist, a dedicated gastrointestinal (GI) surgeon and a nurse endoscopist. Depending on the cases discussed, additional experts were also in attendance (e.g. hepato-pancreatico-biliary surgeons and neuroendocrine tumor specialists). Patients from our institution and other centres referred with lesions of the upper, lower and mid GI tract were presented and thoroughly discussed. Endoscopic images, radiological scans and histopathology reports were assessed in order to decide treatment options and surveillance intervals. We retrospectively reviewed all patients that were presented at our MDT over the last 12 months. Demographic, clinical, endoscopic findings and outcome data were analysed.

**Results:** Over 12 months, 25 meetings were conducted; 312 cases were discussed for a total of 217 patients. Fifty-two patients (24%) were tertiary referrals from other centres. The main reasons for MDT referral were for consideration of double-balloon enteroscopy (DBE) (56 patients; 26%) and for appropriate endoscopic or surgical management of mucosal/submucosal GI lesions. Through MDT discussion, 15 patients (7%) were referred for surgical management; 30 patients were treated with endoscopic submucosal dissection (ESD) and 41 patients with endoscopic mucosal resection (EMR) (14% and 19% respectively). One ESD procedure was abandoned due to high suspicion of deep invasion and was referred for surgery. From the remaining 29 cases, R0 margins were reported for 28/29 patients. Five patients referred for DBE did not require endoscopic input and 17 cases were reviewed twice as additional radiological investigations or small bowel capsule endoscopy were deemed necessary.

All patients were informed about the MDT's outcome and 16 (7%) were offered an additional clinic appointment to discuss management options; all patients were reviewed in clinic after any endoscopic intervention. No ma-

jor adverse event including perforation, severe delayed GI bleed or sepsis occurred after any endoscopic procedure discussed at the MDT.

**Conclusion:** Based on our preliminary one-year experience of an 'Advanced Endoscopy MDT' is a useful platform for the safe, effective and efficient management of complex advanced endoscopic procedures. In our experience, it also appears to improve the quality of the service, clinical outcomes and facilitates optimal management. Studies are warranted to further assess the role of the MDT in endoscopy and patient satisfaction aspects.

**Introduction:** Overdiagnosis is the diagnosis of a disease that would not have developed to cause symptoms or death in the patient's lifetime. While largely disregarded 10 years ago, overdiagnosis is now increasingly recognized as a major harm of cancer screening.

**Aims & Methods:** We used data from a randomized trial comparing screening with guaiac-based fecal occult blood testing (FOBT) every other year with no screening in Nottingham, UK, and estimated colorectal cancer overdiagnosis in FOBT screening [1,2]. 152,850 individuals aged 45-74 were randomized to screening (three to six screening rounds), or no screening. Attendance to at least one screening round was 59.9%, and 38.2% attended all screening rounds. Since screening might prevent cancer also through adenoma removal, estimation of overdiagnosis requires knowledge about the natural history of adenomas to colorectal cancer - which cannot be observed. We used the following microsimulation models to inform the natural growth of adenomas to colorectal cancer: 1. the Microsimulation Screening Analysis, MISCAN; 2. the Colorectal Cancer Simulated Population model for Incidence and Natural history, CRC-SPIN; 3. the Simulation Model of Colorectal Cancer, SimCRC; and 4. a model derived by the German Cancer Research Center.

We calculated annual transition rates for the progression from adenoma to cancer using the published median dwell time in the different models. For model 4, annual transition rates from non-advanced adenoma to advanced adenoma differed depending on age and sex, and we used the lowest (German, low) and the highest (German, high) reported rate in two independent analyses.

We estimated overdiagnosed cancers as the difference between the number of cancers expected in the screening group (i.e. the total of observed cancers and cancers prevented by adenoma removal) and the number of cancers observed in the control group. The amount of overdiagnosis (percentage) is presented as the number of overdiagnosed cancers divided by cancers observed in the control group.

**Results:** The observed colorectal cancer incidence was 3.0% in the screening group and 3.1% in the control group after a median of 19.5 years of follow-up (hazard ratio 0.97; 95%CI 0.91-1.03). In the screening and control group, respectively, 2,139 (2.8%) and 1,484 (2.0%) individuals had at least one adenoma resected. The number of cancers prevented due to adenoma removal ranged from 45 to 296 in the screening group and from 37 to 179 in the control group. The expected number of cancers in the screening group was between 2,324 and 2,575, which is 30 fewer to 221 more cancers than observed in the control group. Overall, the amount of overdiagnosed cancers is between -1.3% to 9.4%.

**Conclusion:** This is the first study to report overdiagnosis in colorectal cancer screening with FOBT. Our results indicate that the amount of overdiagnosis of colorectal cancer in FOBT screening is less than 10%, but the estimates are highly dependent on adenoma transition rates.

**Introduction:** This study aimed to analyze the healthcare resource utilization (HCRU) and medication use of pediatric Crohn's Disease (CD) patients in the United States (US) insured population from 2007 to 2017.

**Aims & Methods:** Trends in HCRU (emergency department (ED) visits, inpatient visits, any outpatient visits, and bowel surgery) and medication use were calculated for the 11-year period covering January 1, 2007 to December 31, 2017. Pediatric (0-17 years) patients with ≥1 CD diagnosis code (ICD-9: 555.x; ICD-10:K50.x) within the calendar year were included in this retrospective analysis of medical and pharmacy claims data from the IBM MarketScan Commercial, Medicaid, and Medicare-Supplemental Claims database. Patients with an Ulcerative Colitis diagnosis were excluded from this study.

**Results:** The rate of biologic use among pediatric CD patients increased from 15.6% in 2007 to 52.9% in 2017. During this time, rates of corticosteroids (35.8% to 29.6%), immunomodulators (37.9% to 18.5%), opioids (26.0% to 25.0%), and 5-ASAs (49.9% to 24.8%) decreased. Rates of bowel surgery remained stable in the pediatric CD population between 2007 and 2017. However, gastroenterologist visits and ED visits increased, while inpatient visits decreased (Table 1). The mean number of outpatient visits increased from 16.64 in 2007 to 21.63 in 2017.

	2007 N=2,506	2012 N=5,737	2017 N=4,507
Surgery; n (%)	63 (2.5%)	218 (3.8%)	134 (3.0%)
Gastroenterologist Visit; n (%)	1,309 (52.2%)	2,572 (44.8%)	2,709 (60.1%)
Emergency Department Visit; n (%)	791 (31.6%)	2,083 (36.3%)	1,762 (39.1%)
Inpatient Hospital Visit; n (%)	479 (19.1%)	1,092 (19.0%)	688 (15.3%)
Outpatient Visit; n (%)	2,503 (99.9%)	5,733 (99.9%)	4,506 (100.0%)
Number of Outpatient Visits; mean (SD)	16.64 (19.32)	19.06 (23.35)	21.63 (29.73)

[Table 1. Healthcare Resource Utilization among Pediatric Crohn's Disease Patients]

**Conclusion:** This study provides real-world evidence on the medication use and HCRU of pediatric patients with CD in the US. From 2007-2017, there was an increase in HCRU and over half of pediatric CD patients were prescribed a biologic. Real-world data are needed to capture changes in HCRU patterns due to the evolving CD treatment landscape.

**Disclosure:** Nothing to disclose

### P0527 TRENDS IN MEDICATION USE AND HEALTHCARE RESOURCE UTILIZATION OF PEDIATRIC ULCERATIVE COLITIS PATIENTS IN THE UNITED STATES, 2007-2017

**Introduction:** This study aimed to analyze the healthcare resource utilization (HCRU) and medication use of pediatric Ulcerative Colitis (UC) patients in the United States (US) insured population from 2007 to 2017.

**Aims & Methods:** Trends in HCRU (emergency department (ED) visits, inpatient visits, any outpatient visits, and bowel surgery) and medication use were calculated for the 11-year period covering January 1, 2007 to December 31, 2017. Pediatric (0-17 years) patients with ≥1 UC diagnostic code (ICD-9: 556.x; ICD-10:K51.x) within the calendar year were included in this retrospective analysis of medical and pharmacy claims data from the IBM MarketScan Commercial, Medicaid, and Medicare-Supplemental Claims database. Patients with a Crohn's Disease diagnosis were excluded from this study.

**Results:** The rate of biologic use among pediatric UC patients increased from 3.2% in 2007 to 22.4% in 2017. Corticosteroids use increased from 28.6% to 34.8%, while rates of immunomodulators (20.6% to 15.6%), opioids (24.8% to 22.5%), and 5-ASAs (62.7% to 60.0%) decreased. Rates of bowel surgery remained stable in the pediatric UC population between 2007 and 2017. However, gastroenterologist visits and ED visits increased, while inpatient visits decreased (Table 1). The mean number of outpatient visits increased from 15.92 in 2007 to 20.89 in 2017.

	2007 N=1,327	2012 N=2,767	2017 N=2,296
Surgery; n (%)	24 (1.8%)	55 (2.0%)	43 (1.9%)
Gastroenterologist Visit; n (%)	655 (49.4%)	1,304 (47.1%)	1,357 (59.1%)
Emergency Department Visit; n (%)	422 (31.8%)	904 (32.7%)	905 (39.4%)
Inpatient Hospital Visit; n (%)	257 (19.4%)	488 (17.6%)	414 (18.0%)
Outpatient Visit; n (%)	1,327 (100%)	2,765 (99.9%)	2,295 (100%)
Number of Outpatient Visits; mean (SD)	15.92 (25.62)	17.80 (24.99)	20.89 (31.27)

[Table 1. Healthcare Resource Utilization among Pediatric Ulcerative Colitis Patients]

**Conclusion:** This study provides real-world evidence on the medication use and HCRU of pediatric patients with UC in the US. From 2007-2017, there was an overall increase in the use of biologics and corticosteroids, as well as HCRU. Real-world data are needed to capture changes in HCRU patterns and cost due to the evolving UC treatment landscape.

**Contact E-Mail Address:** kofinova@abv.bg

**Introduction:** Paediatric inflammatory bowel diseases (PIBD), comprising Crohn's disease (CD), ulcerative colitis (UC) and inflammatory bowel disease unclassified (IBDU) are immune-mediated disorders characterized by dysregulated immune responses leading to tissue damaging inflam-

mation. The treatment regimens for patients with IBD often involve immunosuppressive therapy and increase susceptibility to infections, many of which can be prevented by vaccinations. The aim of our study was to analyze the immunization status of children diagnosed with IBD and identify factors affecting the immunization coverage.

**Aims & Methods:** We retrospectively reviewed the medical records of paediatric IBD patients treated in the Department of Gastroenterology and Hepatology at the University Paediatric Hospital "Prof. Ivan Mitev", Sofia and the Department of Paediatrics at the University Hospital "Saint George", Plovdiv for the period September 2013–September 2018. The immunization status of the enrolled patients was assessed as per the national immunization programme.

**Results:** A total of 90 children (39 girls and 51 boys) were included in the final analysis. The median age of the study participants was 15 years (range 2–17 years), 52.2% (47/90) were with UC, 45.5% (41/90) with CD and 2.3% (2/90) with IBDU.

The overall immunization coverage with traditional vaccines (hepatitis B, tuberculosis, poliomyelitis, diphtheria, tetanus and pertussis, 1<sup>st</sup> dose measles, mumps and rubella) was very good. 28.8% (26/90) of the study participants had incomplete immunization course against measles, mumps and rubella. 95.5% (86/90) of them were non-immunized against *Haemophilus influenzae type b* disease and pneumococcal disease (Both vaccines were included in the Bulgarian childhood immunization schedule in 2010 and the vaccination rates are still low).

Despite having a full course of hepatitis B vaccination in the infancy, 25.5% (23/90) of our patients had undetectable antibodies against hepatitis B. Only three girls had a human papillomavirus (HPV) vaccination. Child's age was the main factor affecting the immunization coverage.

**Conclusion:** The assessment of the immunization status at IBD diagnosis is a critical step in the treatment planning process. It is important to administer all necessary vaccinations as soon as possible before the initiation of an immunosuppressive therapy.

**Contact E-Mail Address:** lucia.cococcioni@gmail.com

**Introduction:** A relationship between small bowel motility and inflammatory activity in Crohn's Disease is now well described in adults against endoscopic and histopathological measures of activity. This retrospective study explores this relationship between terminal ileal (TI) motility in children against an endoscopic endpoint.

**Aims & Methods:** A review of Great Ormond Street Hospital paediatric imaging database was performed to identify subjects with good quality MRE studies and an endoscopic review  $\pm 3$  months to determine an endoscopic score for disease activity (SES-CD score). 38 subjects were identified (median age 11, range 5 to 18) with dynamic 'cine' imaging through the terminal ileum.

The dynamic imaging was processed, blind to any clinical data, with a previously validated motility assessment algorithm (GIQuant®, Motilent, London, UK). A consultant radiologist delineated the TI on each subject within 5 cm of the ileocecal valve and the motility score derived.

The TI was used as a reproducible reference to enable comparison between subjects. The TI motility score was correlated against the SES-CD and the population split into 'active' and in-active groups based on SES-CD <2 = remission

**Results:** The median TI motility was 0.2 (range 0.05 to 0.6) and the median SES-CD score was 9.5 (range 0 to 32). The correlation between the two measures was  $R = -0.45$ ,  $P = 0.005$ . The median SES-CD active motility was 0.17 (range 0.05 - 0.47) and inactive was 0.37 (range 0.2 - 0.6) and mean difference was 0.16,  $P = 0.006$ .

**Conclusion:** Increased endoscopic activity correlated negatively with TI motility, consistent with observations in adults. The motility score was quick to calculate and represents a potential novel biomarker of disease activity in the paediatric population that now needs prospective validation.

**Introduction:** The cellular and molecular carcinogenesis of the esophageal squamous cell carcinoma (ESCC) involves alterations in cell growth, death and metabolism. Advances in basic tumor biology and prognosis biomarkers may contribute to the clinical management and the development of new therapeutic strategies to these tumors. Autophagy is a self-catabolic physiological mechanism involved in the degradation of aged or malfunctioning organelles and proteins. Molecularly, autophagy is mediated by the Atg family of proteins, which mediates the formation of a double-membrane structure called autophagosome. Key markers in this process are Beclin-1 (Atg6), which forms a protein complex to initiate the formation of autophagosome, and MAP1LC3 (Atg8), that mediates the closure of autophagosome.<sup>9,10</sup> Autophagosome englobes cellular components marked to degradation by adaptor proteins such as Sequestosome 1 (SQSTM1 or p62). The autophagosome fuses with lysosomes to form the autolysosome where cell components are degraded. The products of degradation are then released through lysosomal permeases back to the cytoplasmic environment. The role of autophagy depends on the step of carcinogenesis and the tumour type. In different cancers, its promotion and progression involves the reactivation of autophagy, allowing the tumor cells to adapt to the metabolic stress associated with tumor growth. Disturbs in autophagy have been associated with carcinogenesis.

**Aims & Methods:** We compared the levels of three autophagy markers, SQSTM1, MAP1LC3B and BECN1 in ESCC and non-neoplastic biopsy samples. Then we evaluated the influence of autophagy gene expression in the survival and staging of ESCC in TCGA database. We also used a Nuclear Morphometric Analysis (NMA) to correlated nuclear morphometry with autophagy.

**Results:** The three markers were significantly increased in ESCC samples in comparison to control. We proposed an Autophagic Index (AutoIndex), by adding the individual levels of the three proteins and found this a stronger indication of the autophagic status. AutoIndex displayed an even higher difference, between ESCC and control, than single autophagy markers. ESCC samples showed a reduction in nuclear area, which correlated negatively with the increase of autophagy. Using the TCGA database we discovered that high levels of MAP1LC3 A/B, SQSTM1, Atg4A and Atg12 expression were associated with a poor prognosis and advanced staging, suggesting that autophagy contributes to ESCC aggressiveness.

**Conclusion:** We found that an increase of autophagy may be involved in the progression of normal esophageal epithelia to ESCC. The combination of autophagy markers (AutoIndex), instead of its single values, has a great potential to be used as a prognostic tool in the strategy to diagnose and treat the ESCC.

**Introduction:** Gastroparesis is a disorder characterized by delayed gastric emptying of solid food in the absence of a mechanical obstruction of the stomach, resulting in the cardinal symptoms of early satiety, postprandial fullness, nausea, vomiting, belching and bloating. To ascertain the genetic risk factors for gastroparesis we conducted the first to date whole genome sequencing (WGS) study of gastroparesis cohort.

**Aims & Methods:** We investigated the frequency and effect of rare loss-of-function (LOF) variants in patients with idiopathic and diabetic gastroparesis enrolled in a clinical study, VLY686-2301. The dataset consisted of 119 WGS samples.

**Results:** Among rare LOF variants, we report an increased frequency of a frameshift mutation within Motilin Receptor (MLNR) gene, variant rs562138828. Motilin is a 22 amino acid peptide hormone expressed throughout the gastrointestinal (GI) tract. The protein encoded by this gene is a motilin receptor which is a member of the G-protein coupled receptor 1 family. We have shown an increased frequency of a frameshift mutation with MAF 0.01 as compared 0.0009 AF in GNOMAD (p-value = 0.01) with Odds Ratio of 21.9. We detect 4/119 gastroparesis patients carry the variant of interest that results in p.Leu202ArgfsTer105.

Noteworthy is the fact that the 4 cases were equally split among idiopathic and diabetic, so this possible GP risk factor appears to be agnostic as to condition. The finding may be of direct relevance to treatment as individuals with the identified mutation may respond differently to gastroparesis treatments especially those targeting MLNR.

Among other rare LOF, we identified a case of CHD7 discussed in literature in gastro-related context and a case of CFTR duodenal stenosis pathogenic variant. The CFTR variant has been seen in pancreatitis and is likely causative of Cystic Fibrosis Gut which is characterized by increased mucous viscosity and development of intestinal inflammation, dysbiosis and dysmotility.

**Conclusion:** Whole genome sequencing of gastroparesis patient samples showed enrichment for rare variants in the MTLR in cases compared with controls. The identified LOF variants within the region can serve as risk factor for disease as well as inform treatments, especially given the knowledge of direct response to treatment.

**Introduction:** Colorectal cancer (CRC) is a complex disease caused by the interaction of environmental and genetic factors. Due to the insidious symptoms of colorectal cancer, about 50% of patients with colorectal cancer have reached the advanced stage at the time of diagnosis, hence, missed the optimal time for surgical treatment and had a poor prognosis. Therefore, we need to explore new biomarkers for colorectal cancer and find a convenient and effective screening method to achieve the purpose of early diagnosis and treatment. Tumor microenvironment has become one of the hotspots of research.

More and more studies have confirmed that the development of tumor is closely related to the extracellular matrix (ECM). Some researches have shown that DPT is involved in the occurrence and development of many types of tumors, but there are no studies on the expression and regulatory mechanism of DPT in colorectal cancer.

**Aims & Methods:** In this study, we aimed to investigate the expression of DPT in colorectal cancer and its effect on the growth, proliferation, migration and invasion of human colorectal cancer cell lines. 126 pairs of colorectal cancer tissues and corresponding adjacent normal tissues were selected from the West China Hospital of Sichuan University. The expression level of DPT gene in tissue samples was detected by real-time quantitative PCR, and the correlation between the expression level of DPT and the clinical pathological characteristics and prognosis of patients was further analyzed. In addition, colorectal cancer cell lines with stable overexpression of DPT gene were constructed and verified by real-time fluorescence quantitative PCR. After that, CCK-8 and Transwell cell migration and invasion experiments were used to detect the influence of overexpression of DPT gene on the growth, proliferation, migration and invasion ability of human colorectal cancer cells.

**Results:** qRT-PCR showed that the expression of DPT mRNA in colorectal cancer tissues was significantly lower than that in adjacent normal tissues. Patients with low DPT expression level were more likely to have low grade differentiation (P=0.040), poor TNM stage (P=0.004) and lymph node metastasis (P=0.025) than those patients with high DPT expression level. Kaplan-meier survival analysis found that the cumulative survival rate of colorectal cancer patients with higher DPT expression level was significantly better than those with lower DPT expression level (P=0.0224). Further Cox multivariate analysis showed that the expression level of DPT was an independent risk factor for the prognosis of patients with colorectal cancer (P=0.035). By comparing the expression levels of DPT mRNA in such human colorectal cancer cell lines: RKO, HCT15, HCT116 and LS174T, we selected HCT15 and HCT116 to construct DPT overexpression and blank control cell lines. CCK-8 assay showed that overexpression DPT could significantly inhibit the proliferation of HCT15 and HCT116 cells. Further Transwell migration and invasion assay showed that overexpression DPT could significantly inhibit the migration and invasion ability of HCT15 and HCT116 cells.

**Conclusion:** The abnormal expression of DPT is related to the occurrence of colorectal cancer. DPT can be used as a potential molecular biomarker to predict the prognosis of colorectal cancer patients.

**Contact E-Mail Address:** costanza.caccia@gmail.com

**Introduction:** Autoimmune atrophic gastritis (AAG) is an organ-specific disease characterised by a wide clinical spectrum. AAG affects individuals of any age, causing atrophy of the corpus-fundus mucosa of the stomach, with vitamin B12 and iron malabsorption. The aim of this study was to investigate AAG-related histopathological lesions and their evolution during a prolonged follow-up.

**Aims & Methods:** Between January 2007 and July 2018 we enrolled and followed-up all patients diagnosed with AAG at our Gastroenterology outpatient clinic. For each patient we collected and analysed data from gastric biopsy specimens and AAG-specific laboratory investigations (anti-parietal cell antibody, gastrin, and serum chromogranin A level).

**Results:** 1059 gastric biopsy samples from 307 patients with AAG (mean age 59±15 years, F:M 2.3:1 ratio) were analysed. Typical histopathological features were present in 282/307 patients. Of these, 15% were classified as early stage, 19% as florid stage, and 67% as end stage. Only 4% had a complicated disease at diagnosis (8 patients presented dysplasia and 4 NETs). Intestinal and pseudopyloric metaplasia are increasingly evident in end stages (in early stage 20/41 have intestinal metaplasia and 14/20 have pseudopyloric metaplasia, whereas in end stage 138/175 have intestinal and 150/175 pseudopyloric metaplasia); enterochromaffin-like cells hyper-

plasia is more commonly linear in early stage (21/41) and micronodular in end stage (14/175). A progressive increase in gastrin level through stages (326±435 vs 832±761;  $p < 0.05$ ) was noticed, whereas chromogranin A level is similar in all stages (196±249 vs 178±180;  $p = ns$ ). Anti-parietal cell antibodies were detected in 80% of patients. Data indicated that 34% of early stage disease evolves unfavourably within 5 years. Dysplasia showed a prevalence of 8% in 5 years and 11% in 10 years, whilst NET G1 5% and 7% in 5 and 10 years, respectively. Among patients with no histopathological features of AAG, 17/25 demonstrated autoantibodies against parietal cells and have been defined as potential AAG. At 24 months follow-up, 50% developed overt AAG, of which 2 patients lately evolved in end stage and 1 progressed in NET after 11 years.

**Conclusion:** We herein showed that in AAG natural history, histological lesions progress from early to end stage within 10 years in most patients. Irrespective of the stage, patients must undergo a surveillance endoscopic program. The presence of antibodies directed against parietal cells could be an indicator of pre-atrophic autoimmune gastritis.

**Disclosure:** Nothing to disclose

## P0538 DO WE STILL NEED OF BIOPSY FOR DIAGNOSIS OF GASTROINTESTINAL MALIGNANCY? UTILITY OF CRUSH CYTOLOGY IN FAST DIAGNOSIS OF GI MALIGNANCY

Desai P.N.<sup>1</sup>, Kabrawala M.V.<sup>2</sup>, Patel C.<sup>1</sup>, Mehta R.<sup>2</sup>, Nandwani S.<sup>2</sup>, Kalra P.<sup>2</sup>, Prajapati R.<sup>2</sup>, Patel N.<sup>2</sup>, Arora P.<sup>3</sup>

<sup>1</sup>Surat Institute of Digestive Sciences, Endoscopy, Surat, India, <sup>2</sup>Surat Institute of Digestive Sciences, Gastroenterology, Surat, India, <sup>3</sup>Surat Institute of Digestive Sciences, Pathology, Surat, India

**Contact E-Mail Address:** drp\_desai@hotmail.com

### Introduction:

- Gastrointestinal malignancies are commonly encountered in medical practice, and endoscopic examination and biopsy are extremely important first diagnostic modalities.
- Crush cytology of gastrointestinal malignancy is a simple, cheap, and readily available technique that increases diagnostic yield and expedites diagnostic workup of such cases.
- Compared with biopsy, crush preparations require a minute amount of tissues and provide rapid diagnosis. Hence, the study was designed to access the diagnostic performance of crush cytology.

**Aims & Methods:** To see the efficacy of crush cytology (smears prepared from biopsy material) in obtaining rapid diagnosis of GI cancers

### Method:

- All cases of gastrointestinal malignancy of the esophagus, stomach, and colo-rectum, which underwent endoscopic examination from August 2018 to March 2019, in SIDS Hospital and Research Centre, Gujarat, India, were included in the study.
- The diagnosis on crush cytology stained with H-E stain and histopathological diagnosis based on paraffin-embedded H&E sections was compared. Diagnostic accuracy, sensitivity,

### Results:

- A total of 197 cases of gastrointestinal malignancy were evaluated with endoscopy and crush cytology during this period.
- There were 187 cases of histologically confirmed carcinomas
- Rest 10 cases of polyps ( $n = 7$ ), ulcers ( $n = 2$ ) and stenosis ( $n = 1$ ).
- Crush smear cytology positively diagnosed 161 cases of carcinomas
- Male/female ratio - 2.6:1 and
- Mean age - 60.3 years.
- Incidence of carcinomas was highest in the seventh decade of life, with 36.6% cases.
- The most common site of carcinoma was Colorectal (57.8%) followed by esophagus (24.1%), stomach (13.9%), and ampulla of Vater with 4.3% cases each.
- The most common histological types of gastric and colorectal malignancy were well-differentiated adenocarcinoma (83.8% & 69.2%) and poorly-differentiated adenocarcinoma (2.7% & 30.8%), respectively.
- Squamous cell carcinoma (52.9%) was the most common malignancy of the esophagus. Crush smears were unable to provide definite diagnosis in 26 cases because of the morphological characteristics- well-differentiation (61.5%), low cellularity (23.1%) and carcinoma in-situ (15.4%).
- The sensitivity of crush cytology was 79.5%, with a specificity of 100%, positive predictive value 90.3%, and negative predictive value of 19.8%.
- The diagnostic accuracy of crush cytology was 82.5%.

**Conclusion:** Crush cytology is a cost-effective diagnostic tool with high diagnostic accuracy, specificity, and sensitivity, and it provides early diagnosis, which is helpful in planning further management of gastrointestinal carcinoma cases.

**Disclosure:** Nothing to disclose

## P0539 CD24 FOR EARLY DETECTION AND SURVEILLANCE OF CANCER USING A UNIVERSAL SIMPLE BLOOD TEST

Aviv Medical Center, Gastro, Tel Aviv, Israel

**Contact E-Mail Address:** shiranshapira@gmail.com

**Introduction:** In 2018, the global cancer burden has risen to 18.1 million new cases with 9.6 million deaths. The ultimate cancer therapy is prevention or at least early detection. There are many attempts to develop a blood test for early detection, but none is in clinical use. CD24, a mucin-like cell surface protein, is overexpressed in numerous human cancers. We have shown that a simple non-invasive blood test evaluating CD24 levels had good sensitivity and specificity for detecting colorectal adenomas and cancer in patients undergoing screening colonoscopy at an urban medical center.

**Aims & Methods:** To develop a universal improved simple blood test that could reliably identify individuals with common cancer types through assessment of the levels of CD24 on PBLs.

Blood samples were obtained from consecutive patients and healthy volunteers.  $1 \times 10^6$  leukocytes were stained using anti-CD11b-PerCp-Cy5.5 and anti-CD24-FITC and analyzed by flow cytometry. Percentage of positive cells was determined by subtracting the percentage of CD24 and CD11b-positive cells (dual stain) from CD24-positive cells (single stain). Healthy subjects underwent a thorough evaluation at the ICPC. All cancers were verified histologically.

**Results:** The suggested screening assay distinguished normal from patient subjects especially with breast, pancreas, lung and colorectal cancers as well as early stage of adenoma (table 1). Interestingly, the levels of CD24 drop back to near normal level following successful surgery/chemotherapy. Furthermore, CD24 score, in normal individuals with family history of cancer, was higher than those without family history (11.7±7.1 and 19.3±8.9%, respectively).

	Healthy	Healthy with F.H	Healthy without F.H	All cancers	Bladder	Pancreas	CRC	Colon Adenoma	Stomach
CD24 score	17 ± 8	20 ± 8	14 ± 7	38.3 ± 11	39 ± 13	35 ± 8	39 ± 7	33 ± 11	40 ± 8.5
Sensitivity				94%	100%	89%	100%	87%	100%
Specificity	84%	74%	95%						
NPV Vs.H				94%		98%		98%	
F.H No F.H				93%	100%	98%	100%	96%	100%
				96%		99%		97%	

[Table 1]

### Conclusion:

- CD24 expression in PBLs may serve as a universal blood test for the early detection of numerous cancers.
- The first ever blood test to detect adenomas.
- CD24 may serve as a novel predictive marker in cancer therapy.
- The test can identify family members that are at an increased risk for cancer.
- Obviously, the test has to be validated in a prospective multi-center study.

**Disclosure:** Nothing to disclose

## P0540 MOUSE ORGANOID CULTURES ARE THE NOVEL MODEL TO STUDY THE ESOPHAGEAL ION TRANSPORT MECHANISMS

Korsos M.M., Venglovecz V.

University of Szeged, Department of Pharmacology and Pharmacotherapy, Szeged, Hungary

**Contact E-Mail Address:** margaretakorsos@gmail.com

**Introduction:** Esophageal epithelial cells (EECs) protect the lower layers during esophageal reflux. One of the major components of the epithelial defensive mechanisms is the ion transport processes, however their role under physiological and pathophysiological conditions is not completely clear. One of the reason for this is the lack of good experimental models on which the functional changes of EECs can be investigated. Therefore, our aim in this study was to generate esophageal organoid cultures (EOC) from epithelial tissue of mice and to characterize the presence of ion transporters on these EOCs.

**Aims & Methods:** EECs were isolated from three different mice strains (CD1, C75/Bl6 and FVB/N). The esophagus was removed and digested with dispase (2 U/ml) for 30 min. After the digestion the epithelia was peeled from the submucosa and incubated with trypsin in order to obtain individual cells. Cells were then suspended in Matrigel for 10-14 days and media was changed in every second days. Changes in intracellular pH (pH<sub>i</sub>) was measured using microfluorometry and the pH-sensitive dye, BCECF-AM. For determining the resting pH<sub>i</sub>, the high K<sup>+</sup>/nigericin technique was used.

**Results:** EOCs were successfully generated from all three mouse strains. In each cases, organoids have a three-dimensional, approximately spherical structure, growing in the extracellular matrix. Their maximum size was about 200 µm at the end of the second week, although differences in morphology and size have been observed between the mice strains. Using EOCs, generated from CD1 mice, we have determined the resting pH<sub>i</sub> and the buffering capacity of the cells. Microfluorometric measurement showed the presence of functionally active Na<sup>+</sup>/H<sup>+</sup> exchanger (NHE) and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> (CBE) transporters on the EOCs.

**Conclusion:** We have successfully set up the culturing of mice esophageal organoids and our preliminary results showed that EOCs express both alkalizing (NHE) and acidifying (CBE) transporters. We strongly believe that EOCs are a suitable, *in vitro* experimental model to study esophageal epithelial function and can also be used to investigate the pathomechanism of reflux-induced esophageal diseases. This study was supported by the National Research, Development and Innovation Office (FK123982) and the National Research, Development and Innovation Office, by the Ministry of Human Capacities (EFOP 3.6.2-16-2017-00006).

**Introduction:** Cancer stem cells (CSCs), a small cell subpopulation having intrinsic chemo resistance mechanisms and expressing CD44 cell surface glycoprotein, have been characterised in gastric adenocarcinoma. The link between the Hippo/YAP/TEAD pathway, key regulator of organ size and tissue homeostasis, and CSC properties has recently been suggested in gastric adenocarcinoma. Recent studies have defined Leukaemia Inhibitory Factor Receptor (LIFR) and its ligand Leukaemia inhibitory Factor (LIF) as being upstream regulators of the Hippo pathway and LIF/LIFR signalling as having an anti-metastatic role in breast cancer cells.

**Aims & Methods:** Consequently, this study aimed to determine the effect of LIF supplementation on the YAP/TEAD pathway and its impact on CSC phenotype and properties in gastric adenocarcinoma. AGS and MKN45 gastric cancer cell lines as well as patients' derived gastric adenocarcinoma cells were used. The expression of Hippo/YAP/TEAD pathway related genes and

of CSC markers was assessed by RTqPCR, western blot and immunofluorescence analysis. YAP/TEAD transcriptional activity was evaluated by TEAD-luciferase reporter assay and proliferation assays as well as tumorsphere assays were carried out *in vitro* to evaluate CSC functional properties.

**Results:** Results demonstrate that LIF supplementation represses the YAP/TEAD pathway through a decreased YAP translocation to the nucleus and decreased expression of YAP/TEAD target genes. In addition, LIF decreases proliferation, tumorsphere initiation capacity and expression of gastric CSC markers in gastric adenocarcinoma cells.

**Conclusion:** Our results indicate that LIF represses the YAP/TEAD pathway and presents anti-tumorigenic effects on gastric adenocarcinoma cells. Whether the effect of LIF on CSC properties passes through the YAP/TEAD pathway repression needs to be further investigated. This could *in fine* lead to the development of targeted strategies against CSCs to help decrease the number of relapse cases and bad prognosis in gastric cancer.

**Contact E-Mail Address:** celine.deraison@inserm.fr

**Introduction:** In the gastrointestinal tract, proteolytic activity is tightly regulated to prevent inappropriate and potentially harmful proteolysis. In IBD this regulation is broken and our recent work has demonstrated that elastolytic activity is significantly increased in colonic epithelium from IBD patients. We have shown that (i) the expression of the only elastase released by epithelial cells ELA2 is up-regulated; and (ii) the selective elastase inhibitor ELAFIN is severely down regulated in colonic epithelium from IBD patients. We showed that oral treatments with ELAFIN-expressing *L. Lactis bacteria* restored proteolytic balance in the inflamed gut and was protective against acute and chronic colitis.

ELAFIN is a low-molecular weight molecule (10-kDa), which specifically inhibits elastases. At N-terminal terminus, a cationic helix showed antimicrobial activities and could interact with phospholipids. Moreover ELAFIN is also able to inhibit NFκB and AP-1 activation but this domain is not localized on protein. Therefore, several mechanisms of action are thus possible to explain ELAFIN's protective property, either from the extracellular or the intracellular compartment.

**Aims & Methods:** If ELAFIN-recombinant *L. lactis* has to be considered as a possible treatment for IBD in human, there is an absolute need to define the mechanisms by which ELAFIN delivery protects against intestinal inflammation.

Because ELAFIN has demonstrated several biological properties, we generated and expressed in LAB ELAFIN's mutants allowing investigation the biological properties of ELAFIN individually. To decipher the mechanisms by which ELAFIN is protective against intestinal inflammatory insult, different forms of ELAFIN-recombinant LAB were co-culture with thapsigargin (10mg/ml) and ELAFIN (10<sup>7</sup> CFU/well). After 6H, cells were additionally exposed to gentamicin (100 mg/ml) to limit bacterial development. The barrier function was measured using FITC-dextran passage through the epithelial layer. The elastolytic activity and CXCL8 release were quantified from the culture media. Expression of inflammatory mediators was quantified by qPCR.

**Results:** Addition of thapsigargin for 24H on Caco2 cells induced ER-stress and disruption of elastolytic balance. ELAFIN expression was decreased with up-regulation of ELA2, leading to increase of elastolytic activity in medium, disclosed in IBD patients. Concomitantly, barrier function was reduced, and expression of CXCL8, CXCL10 and hBD2 was increased. Co-culture with ELAFIN expressing-LAB normalized all these parameters confirming anti-inflammatory properties of ELAFIN.

Neutralization of  $\alpha$ -helix (mutant K44D/K50G) did not modify ELAFIN's properties. However, disruption of protease inhibitory function (mutant A62G/M63G) was not able to modify permeability and inflammatory phenotype induced by exposure of intestinal epithelial cells to thapsigargin, showing that anti-inflammatory activity of ELAFIN was based on the control of elastase activity released by epithelial cells.

Surprisingly, ELAFIN immunostaining revealed the exogenous protein in the epithelial cells, in the nucleus. The ELAFIN's transport was dependent to its elastase inhibitory function. We showed that epithelial cells expressed LRP1 (LDL-related receptor 1) which is known to internalize complexes of proteases and protease inhibitors.

**Conclusion:** This suggests that ELAFIN could act as anti-inflammatory molecule based on multifactorial mechanisms from outside to inside the epithelial cells.

#### **P0544** PROPHYLACTIC TRANSCATHETER ANGIOGRAPHIC EMBOLIZATION REDUCES THE RISK OF REBLEEDING IN PATIENTS WITH FORREST IIA ULCER: A RETROSPECTIVE STUDY

Lan L., Tong H., Wu H., Tang C.

West China Hospital, Sichuan University, Department of Gastroenterology, Chengdu, China

**Contact E-Mail Address:** lthust@outlook.com

**Introduction:** About 20% of Forrest Ila ulcers rebleed even after endoscopic hemostasis. Prophylactic transcatheter angiographic embolization (p-TAE) might be a feasible way to reduce rebleeding, but its efficacy is controversial.

**Aims & Methods:** This study aimed to evaluate the clinical efficacy of p-TAE to prevent rebleeding and to assess the risk factors for rebleeding in the patients with Forrest Ila ulcers after endoscopic hemostasis. The patients with Forrest Ila ulcer underwent endoscopic hemostasis in West China Hospital during May 2009 and May 2018 were retrospectively reviewed. The patients were assigned to endoscopy (E) group and endoscopy plus p-TAE (E+p-TAE) group according to whether they received p-TAE after endoscopic hemostasis. Demography, data of laboratory tests, medication intake history, amount of fluid and red cell suspension infusion, time duration between admission and initial endoscopic hemostasis, morphological characteristics of ulcers and non-bleeding visible vessels, Glasgow-Blatchford score, modalities and sessions of endoscopy hemostasis, rebleeding rate after endoscopic hemostasis, rate of salvage hemostasis and intensive care unit transfer, hospital stay and mortality were collected for comparison of baseline characteristics, clinical efficacy and risk analysis of rebleeding.

**Results:** Most of the baseline data in the two groups except for the protruded blood vessel and fluid infusion pre-procedure were comparable. The rebleeding occurrence of E+p-TAE group (n = 27) were significantly lower than that of E group (n = 86), 3.7% vs 25.6%,  $P = .014$ . Survival analysis also showed lower rebleeding risk of E+p-TAE group,  $P = .016$ . Protruded vessel in Forrest Ila ulcer (OR: 5.316, 95% CI: 1.538 - 18.374,  $P = .008$ ) and no p-TAE intervention (OR: 20.932, 95% CI: 2.067 - 211.984,  $P = .010$ ) were identified as independent risk factors for rebleeding of Forrest Ila ulcers. The rebleeding occurrence of protruded vessel within the first week after initial endoscopic hemostasis was significantly decreased by E+p-TAE intervention (E vs E+p-TAE, 18.6% vs 0%,  $P = .011$ ).

**Conclusion:** No p-TAE after endoscopic hemostasis and protruded visible vessels were the independent risk factors for rebleeding of the patients with Forrest Ila ulcer. p-TAE following endoscopic hemostasis may effectively prevent rebleeding for those patients partly through compensation for the inadequate endoscopic hemostasis due to the technical heterogeneity of endoscopists.

**Contact E-Mail Address:** everyday.enjoy29@gmail.com

**Introduction:** The first choice of treatment of gastric cancer is surgery, and adjuvant chemotherapy is performed in advanced stage. External beam radiotherapy (RT) alone is an effective and well tolerated modality in the local palliation of gastric cancer, with palliation lasting the majority of patients' lives. Endoscopic hemostasis techniques for gastric cancer, the rebleeding hemostatic response rate is high. Treatment for the inoperable progressive stomach cancer includes hemostasis RT. Effectiveness of RT is well known. Tey et al. reported the review of palliative RT for gastric cancer of 7 researches. However, their analyses were all retrospective study, there were no prospective study of hemostasis RT in our best knowledge. From those results, we conducted prospective study.

**Aims & Methods:** A total of 28 patients with gastric cancer with bleeding was enrolled. The initial dose was 20 Gy / 5 fractions for all stomach. The salvage dose was 15 Gy / 5 fractions for partial stomach. When hemoglobin level stabilized by blood test within 2 weeks after irradiation, we judged a hemostatic effect was achieved. When re-bleeding was found, the patients selected whether to take re-irradiation or not.

**Results:** The response ratio of initial RT was 85% (22 / 26 patients). Six patients underwent re-irradiation, and all of them responded (100%). The median OS of all patients was 52 days. The median OS of non re-irradiation (one-time) group and re-irradiation group were 54 days and 36 days without statistically significant. The adverse events were not occurred 3 or more in all patients.

**Conclusion:** The salvage RT followed by initial RT is effective to reduce adverse event. The OS was same between one-time irradiation and re-irradiation group. No grade 3 or more AEs was occurred. This RT is completed only 5 days and re-irradiation option is favorable to the patients. The range of effective hemostatic time was wide and no predictive factors was found in our prospective study. It might be necessary to determinate ideal dose and fraction number of initial irradiation, preferably less than 20 Gy.

**Introduction:** Nonvariceal upper gastrointestinal (GI) bleeding have an associated morbidity and mortality. Through-the-scope (TTS) hemostatic clips limitations are difficult of clip application during active bleeding, use in ulcers with a fibrotic base, or difficult-to-access because anatomic locations or large size. The over-the-scope clip (OTSC) is an atraumatic, large-size clipping device, with a high-pressure closure for larger a deeper ulcers.

**Aims & Methods:** Aim: to evaluate the efficacy and safety of OTSC as first-line therapy in patients with high-risk (HR) bleeding ulcers compared to combined therapy (TTS clip and adrenaline injection).

**Methods:** A retrospective analysis of a prospectively collected data in consecutive patients who presented with HR ulcer GI-bleeding between May-2014 and September 2018. High risk upper GI bleeding were considered as those ulcers located in a major arterial territory, if the lesion had an endoscopically visible large-caliber artery (>2 mm), if there was a fibrotic ulcer with high-risk endoscopic stigmata (Forrest classification types I and II). The primary endpoint was the incidence of rebleeding or perforation with-

in 30 days of index endoscopy. Patients were excluded if they had bleeding caused by varices, received OTSC for fistula or tissue defect closure or if the bleeding did not meet the criteria for HR ulcer bleeding. Baseline characteristics were confirmed through the corresponding hypothesis test. Analysis was performed on R v3.4.3.

**Results:** 95 patients were included, 46 received an OTSC as primary therapy for HR bleeding ulcers and 49 matched cases received TTS hemostatic clips in combination with epinephrine injection (combined therapy). The mean age was  $60.9 \pm 19.1$ , 32.6% female. Most lesions were gastric ulcers (71.6%). The median number of OTSC used was 1 (1 - 3), whereas for combined therapy was 2 (1 - 8) TTS clips. Table 1 summarizes baseline characteristics. Six cases of rebleeding (6.3%) were observed: two in the OTSC group and four in the combined therapy group ( $p=0.444$ ). Two cases of the OTSC group (4.3%) had rebleeding after 48 hours of the procedure; meanwhile, one case of rebleeding was observed in the combined therapy group at the same period and was treated with APC ( $p=0.520$ ). Three cases in the combined therapy group had rebleeding in less than 48 hours after the procedure ( $p=0.088$ ), two treated with an OTSC and one with APC. The median procedure time was 11 (10-15) mins for OTSC and 20 (15-40) for combined therapy ( $p<.001$ ) (table 1).

	OTSC (n=46)	Combined therapy (n=49)	p-value	
Age, mean $\pm$ SD	60.9 $\pm$ 19.1	62 $\pm$ 17.4	59.8 $\pm$ 20.6	<0.001
Female, n (%)	31/95 (32.6%)	16/46 (34.8%)	15/49 (30.6%)	0.664
No anticoagulation therapy, n (%)	72/95 (75.7%)	34/46 (73.9%)	36/49 (76.5%)	0.140
NSAID therapy, n (%)	6/95 (6.3%)	3/46 (6.5%)	3/49 (6.1%)	0.886
Previous transfusion, n (%)	15/95 (15.8%)	9/46 (19.5%)	6/49 (12.2%)	0.294
Lesion detected, gastric ulcer/duodenal ulcer	68/27	32/14	36/13	0.583
Forrest classification of Upper GI Bleeding, IA-B / IIA-C	15/80	11/35	4/45	0.009

[Table 1. Baseline characteristics of included patients.]

**Conclusion:** The OTSC as first line single therapy is as safety and effective as combined therapy for the management of HR bleeding peptic ulcers; improving the procedure time statistically significant. The OTSC could become in the future as a first line-therapy for HR bleeding peptic ulcers.

**Disclosure:** Nothing to disclose

## P0547 THE INCIDENCE OF MAJOR BLEEDING EVENT AND PERFORATION AFTER ENDOSCOPIC BALLOON DILATION: A RETROSPECTIVE MULTICENTER STUDY

**Contact E-Mail Address:** y.kishida@scchr.jp

**Introduction:** Endoscopic balloon dilation (EBD) has been established as an effective treatment for gastrointestinal stricture. However, bleeding and perforation are main complications associated with EBD, and EBD is classified as a high-risk endoscopic procedure in the guidelines concerning the endoscopy in patients on antithrombotics from *European Society of Gastrointestinal Endoscopy*. Although the incidence of these complications has been previously reported based on small studies, there are still few data to judge EBD as a high-risk procedure.

**Aims & Methods:** The aim of this study was to investigate the incidence of bleeding and perforation after EBD and evaluate whether antithrombotic agents increases bleeding events through a large-scale study. This study

was a retrospective multicenter study conducted in six hospitals across Japan. From April 2010 to March 2015, the patients who underwent EBD for upper gastrointestinal stricture were enrolled. Medical records and endoscopic findings were reviewed, and the primary endpoints were the incidence of major bleeding event and perforation after EBD.

**Results:** 878 patients with upper gastrointestinal stricture were analyzed. The causes of stricture were as follows: surgery 417, endoscopic resection 280, chemo-radiotherapy 130, tumor 18, and benign disease 33. A total of 4884 procedures of EBD were performed in 878 patients and the mean number of EBD session per patient was 5.6 times. The incidence of major bleeding events which required urgent endoscopic hemostasis and hospitalization was 0.18% per total EBD session (9/4884). Endoscopic hemostasis was successfully achieved in all the bleeding events and 3 patients required blood transfusion. 670 EBD sessions were performed under antithrombotic therapy. The major bleeding rate in the antithrombotic-users was higher than that in the non-users (0.75% vs 0.09%,  $P=0.004$ ). On the other hand, there was no significant difference between the continued-use group and the cessation group (1.01% vs 0.71%,  $P=0.657$ , respectively). The incidence of perforation was 0.43% (21/4884). As for the management of perforation, 17 patients could recover by conservative treatment including endoscopic closure, and 4 patients received urgent surgery.

**Conclusion:** This retrospective study with a large sample size demonstrated that EBD could safely be performed even under continued use of anti-thrombotic agents.

**Disclosure:** Nothing to disclose

**Introduction:** During the past decade, potential risk and prognostic factors for upper gastrointestinal bleeding (UGIB) have been evolved in developed countries in particular with an increased use of direct oral anticoagulants in thromboembolic diseases and a better management of UGIB by gastroenterologists with the use of new effective endoscopic haemostatic devices. As few studies investigated prognostic factors associated with UGIB in this context, we conducted such a study to better understand the role of new determinants of UGIB on its outcomes.

**Aims & Methods:** From November 2017 to October 2018, we carried out a prospective study in 46 public hospitals. We enrolled patients with symptoms of UGIB and subsequently confirmed UGIB by endoscopy (those who were admitted to the emergency medicine departments (EDs) with UGIB symptoms and those who were hospitalised for other reasons than UGIB). They were followed up at least for six weeks. Patients' characteristics, endoscopic and follow-up data were collected and analysed. Univariable and

multivariable analyses using logistic regression models were performed to identify predictors of rebleeding and those of in-hospital and six-week mortality.

**Results:** Of the 2498 enrolled patients, 74.6% were diagnosed with UGIB after admission to EDs and 25.4% during hospitalisation. Median age of patients was 68.5 years  $\pm$  16.3, 67.1% were men and 20.9% had a cirrhosis. Median Charlson score was 2 (IQR: 1-4), median Blatchford score was 11 (IQR: 7-13), and median Rockall score was 5 (IQR: 3-6). Among included patients, 19% had an oral anticoagulant medication: 43.8% of them with direct oral anticoagulants. Endoscopy was performed within 24 hours in 84.2% of patients and with general anaesthesia in 31%. An endoscopic assistant was present in most cases (91.5%).

Main causes of bleeding were: 1) peptic ulcers and gastroduodenal erosions (44.9%), 2) lesions related to portal hypertension (18.8%) and 3) oesophagitis (11.5%). Active bleeding was observed in 24.5% of patients, mainly associated with peptic ulcers and portal hypertensive lesions, and was endoscopically treated in 86.7% and 79.6% of the cases, respectively. During hospitalisation, 10.5% of patients experienced rebleeding and 8.6% of them died. In-hospital mortality rate was lower among patients from EDs than those who were hospitalised (5.8% vs 16.8%,  $p < 0.0001$ ). Predictors associated with rebleeding were in-hospital bleeding (OR=1.36; 95%CI: 1.03-1.79), Blatchford score  $\geq 11$  (OR=1.45; 95%CI: 1.08-1.94) and active bleeding (OR=1.94; 95%CI: 1.48-2.55).

The six-week mortality rate was 12.0%. It was significantly lower in the EDs group than the in-hospital group (9.1% vs 22.2%;  $p < 0.0001$ ). Predictors associated with six week mortality were initial transfusion (OR=1.53; 95%CI: 1.04-2.27), Charlson score  $\geq 4$  (OR=1.80; 95%CI: 1.31-2.48), Rockall score  $\geq 5$  (OR=1.97; 95%CI: 1.39-2.80), in-hospital bleeding (OR=2.44; 95%CI: 1.75-3.40), and rebleeding (OR=2.59; 95%CI: 1.85-3.64).

**Conclusion:** This study showed an improved management of UGIB compared to previous studies. Despite this improvement, mortality rate remained high at six-week follow-up in particular for patients who experienced UGIB while they were hospitalised for other reasons than UGIB. This can be explained by the severity of underlying disease for which patients were initially hospitalised. Strong predictors of mortality were in-hospital bleeding and rebleeding without major role of the anticoagulation therapy. This study confirmed that previously known predictors were still valid in the recent advancement in the management of UGIB patients.

**Introduction:** Anti-platelets drugs are one of the most important drugs in this aging society, widely utilizing for cardiovascular and cerebrovascular diseases. Over the past decades, it has been common to discontinue antiplatelet drugs prior to gastrointestinal endoscopy, with emphasis on the prevention of bleeding. In recent years, non-interruption of anti-platelets peri-operatively is recommended in guidelines for endoscopic submucosal dissection (ESD) as a treatment for early gastric cancer (EGC). Although there have been several reports(1,2), the art of balancing between ischemia and bleeding during ESD remains unclear.

**Aims & Methods:** In this study, we investigated the association between the aggressive continuation of anti-platelets in recent years and both cardiac ischemic and bleeding events after ESD in the real world clinical settings. We conducted a retrospective cohort study comprising 1383 consecutive patients, who were hospitalized for ESD at the Department of Gastroenterology in our hospital between January 2007 and July 2018. Among them, patients regularly taking anti-platelet drugs before hospitalizations ( $n = 255$ ) were extracted and divided into two groups: anti-platelets discontinued group ( $n = 164$ ) and continued group ( $n = 91$ ). Primary outcomes were 30-days cardiac ischemic and gastrointestinal bleeding events. We defined 3rd look endoscopy and blood transfusion as the bleeding events, and urgent electrocardiogram (ECG) and coronary angiography (CAG) as the ischemic events, respectively. We performed bivariate analysis, multivariate

analyses, and propensity score matching for 19 baseline characteristics, which are known as ischemic or bleeding risks reported before.

**Results:** ESDs are increasingly being performed without interrupting anti-platelet drugs in our hospital; 13% in 2007, 64% in 2017. Bleeding event rate (3rd look endoscopy and blood transfusion) was significantly higher in the continued group than in the discontinued group (38.5% v.s 23.8%  $p = 0.015$  and 12.1% v.s 2.4%  $p = 0.004$ ).

However, there are no significant differences about ischemic event rate (urgent ECG and CAG) between two groups. Patients in the anti-platelets continued group were observed to have older age, higher prevalence of hypertension, dyslipidemia, diabetes, ischemic heart disease, heart failure, and cerebral infarction, lower serum albumin level, and lower hemoglobin level.

Comparison of propensity score matched groups ( $n=91$ , each) also revealed that continuation of anti-platelets during ESD was associated with higher bleeding risk (38.5% v.s. 24.2%  $p = 0.055$  and 12.1% v.s. 3.3%  $p = 0.048$ ), but it was not associated with lower ischemic events.

	anti-platelets discontinued group (n=91)	anti-platelets continued group (n=91)	p-value
3rd look(%)	22(24.2%)	35(38.5%)	0.055
blood transfusion(%)	3(3.3%)	11(12.1%)	0.048
urgent ECG(%)	6(6.6%)	7(7%)	NS
urgent CAG(%)	1(1.1%)	0(0%)	NS

*[Bleeding and ischemic events: comparison of propensity score matched groups]*

**Conclusion:** This study reveals that continued use of anti-platelets during ESD does not decrease cardiac ischemic events, but may increase gastrointestinal bleeding events. Gastroenterologists and cardiologists need to discuss more carefully in judging the continuity of antiplatelet drugs in the ESD perioperative period, and continued use of anti-platelets may have to be limited to the patients with higher risk of ischemia in the future.

## P0550 EFFICACY OF GLASGOW BLATCHFORD SCORE TO PREDICT THE DIFFICULTY OF ENDOSCOPIC HEMOSTASIS FOR ACTIVE DUODENAL ULCER HEMORRHAGE

Yonemoto Y., Fukami Y., Isii R., Hara H., Mochida T., Machida T., Sugiyama Y., Watanabe A., Kaneshiro M., Ikemiyagi H., Yoshino K., Sakita S.

**Introduction:** Endoscopic procedure is performed for active duodenal ulcer hemorrhage. But if endoscopic hemostasis fails, transarterial embolization (TAE) or operation is considered. The risk factors for difficulty of endoscopic hemostasis are poorly documented, whereas Glasgow Blatchford Score (GBS) has been attracting attention for predicting intervention for upper gastrointestinal hemorrhage and some studies have described the usefulness.

**Aims & Methods:** We performed a retrospective analysis involving patients with hemorrhage of benign duodenal ulcer who had been admitted to our hospital and had endoscopic therapy from April 2005 to December 2017. We compared each GBS in the groups in which only endoscopic procedure were performed (endoscopy group) and interventional radiology was additionally performed (TAE group), having made statistical analysis for items of GBS.

**Results:** A total of 154 patients were included in this study. 141 patients (91.6%) of them were success in only endoscopic procedure, 12 patients (7.8%) were underwent TAE additionally, and 1 patient (0.6%) was underwent operation. The mean GBS ( $\pm$ SD) in endoscopy group was  $11.1 \pm 3.6$ , and the mean GBS in TAE group was  $13.8 \pm 2.1$ . The GBS in TAE group was statistically higher than in endoscopic group ( $p=0.0087$ ), and the area under the receiver operating characteristic curve (AUROC) was 0.74 (95% confidence interval 0.63 to 0.86). A threshold GBS of 12 or more was best at predicting TAE, with sensitivity of 54.0%, specificity of 91.7%. Making an analysis of each item of GBS, haemoglobin was statistically lower ( $p=0.0076$ ) in TAE

group. The other items (blood urea, systolic blood pressure, pulse, melena, syncope, hepatic disease, and cardiac failure) were no significant difference between two groups.

**Conclusion:** The GBS is useful to predict need for TAE for active duodenal ulcer hemorrhage. This study may suggest that GBS $\geq$ 12 is high risk of endoscopic hemostasis fails and TAE performed.

## P0551 RISKS OF HOSPITALIZATION FOR UPPER GASTROINTESTINAL BLEEDING IN SELECTIVE SEROTONIN REUPTAKE INHIBITORS USERS AFTER *HELICOBACTER PYLORI* ERADICATION: A TERRITORY-WIDE COHORT STUDY

Leung W.K.<sup>1</sup>, Guo C.-G.<sup>2</sup>, Chen L.<sup>1</sup>, Cheung K.S.<sup>1</sup>

**Introduction:** Selective serotonin reuptake inhibitors (SSRIs) are currently recommended as the first line treatment for depression. Though many studies have evaluated the risk of upper gastrointestinal bleeding (UGIB) associated with SSRI use, the potential confounding effects of *H. pylori* (HP) and other medications have not been addressed.

**Aims & Methods:** This was a propensity score matched cohort study to determine the risk of UGIB in HP infected patients who used SSRI after HP eradication therapy. HP-infected patients who had received a course of clarithromycin-containing triple therapy between 2003 and 2012 were identified from the territory-wide electronic health database. We excluded patients who failed HP eradication therapy and those who had used SSRI before the study start date. The follow-up period commenced from 60 days after the HP therapy until the occurrence of UGIB, death or the end of the study. The primary outcome was hospitalization for UGIB. To address for potential immortal time bias, time-dependent Cox regression model was used to compute the hazards ratios (HR) and 95% confidence intervals (CI) of UGIB risk, in which follow-up time was split into 1-month intervals. Covariates included baseline characteristics, medical conditions and concurrent medications. As SSRIs and other medication uses could change over time, drug usage was defined as at least one day use in each interval. To adjust for the baseline difference between SSRI users and non-users, propensity score (PS) matching analysis with a ratio of 1:2 was performed, in which concurrent medications uses in the first 1-month interval were used to calculate the propensity scores. Multivariate time-dependent Cox regression model was performed as sensitivity analysis.

**Results:** 61,264 patients who had received HP eradication therapy were analyzed, including 3,358 SSRI users and 57,906 non-users. The median follow-up duration was 7.7 (interquartile range, 5.3-10.4) years. The overall crude incidence rate of hospitalization for UGIB was 3.98 (95% CI 3.80-4.16) per 1000 person-year. In the time-dependent Cox model with 1:2 PS matching, SSRI was associated with higher risk of hospitalization for UGIB than non-users (HR1.95, 95% CI 1.41-2.70). This result was consistent in multivariate analysis (HR 1.81, 95% CI 1.34-2.45). After stratifying by age, the increased risk of SSRI was only significant among older patients (> 50 years old). Apart from SSRIs, other independent risk factors of UGIB includes older age, male sex, history of UGIB or ulcer, presence of comorbid illnesses (hypertension, diabetes, cirrhosis and renal disease) and concomitant use of aspirin, other antiplatelet drugs, non-steroidal anti-inflammatory drugs (NSAIDs), anticoagulants and corticosteroids (Table). In contrast, gastroprotective agents was associated with lower risk of UGIB (HR 0.54, 95% CI 0.47-0.63).

Variables	HR (95% CI)
Age	1.06 (1.05-1.06)
Male sex	1.31 (1.19-1.44)
History of UGIB or ulcer	3.21 (2.91-3.55)
Gastroprotective agents	0.54 (0.47-0.63)
Aspirin	1.95 (1.67-2.28)
Other antiplatelets	2.04 (1.63-2.54)
NSAIDs	1.80 (1.46-2.22)
Anticoagulants	2.36 (1.76-3.16)

[Hazard ratios for UGIB]

**Conclusion:** SSRI users have a higher risk of hospitalization for non-variceal UGIB than non-users even after treatment for *Helicobacter pylori*, particularly among older patients, those with history of UGIB, comorbid illnesses and concurrent use of other medications that increased the bleeding risk.

**Disclosure:** Nothing to disclose

## P0552 HEMORRHAGIC COMPLICATIONS IN PATIENT RECEIVING ANTI-PLATELET AND/OR ANTICOAGULANT WITH OR WITHOUT PROTON-PUMP INHIBITORS

Yaophruekchai S.<sup>1</sup>, Maneerattanaporn M.<sup>1</sup>, Leelakusolvong S.<sup>2</sup>

**Contact E-Mail Address:** monthira.man@mahidol.ac.th

**Introduction:** Antiplatelet and anticoagulant are widely used in various indications. Bleeding complications usually raise physicians' concern; especially gastrointestinal bleeding (GIB). Proton-pump inhibitors (PPI) have been co-prescribed with the aforementioned drugs. However, there were evidence indicated that PPI might increase the risk of bleeding complications when they were co-administered with clopidogrel or warfarin, as it synergist metabolisms of these drugs.

**Aims & Methods:** To study bleeding events in patient receiving antiplatelet and/or anticoagulant, both GIB and extra-gastrointestinal bleeding (EGIB) compared between PPI status (with/without PPI).

**Methods:** This is a nested case-control study. We recruited subjected who developed bleeding as defined by new onset of anemia or any visible bleeding after taking antiplatelet/anticoagulant. Data were retrospectively collected from medical records of Siriraj Hospital from January 2013 to July 2014. Demographic data, co-morbidities, bleeding outcomes were recorded. Events of both GIB and EGIB between 2 groups (with/without PPI) were compared. Descriptive data were presented in mean $\pm$ SD and comparative data were analyzed using chi-square. Multivariate analysis was also conducted when appropriate.

**Results:** 1146 cases (mean age 71.89  $\pm$  13.3 years) met the inclusion criteria. PPI was prescribed in only 495 cases. Most of the patients (99.7%) had multiple comorbid diseases. Hypertension (83.7%), Diabetic Mellitus (51.6%) and Chronic Kidney Disease (42.84%) were the 3 most common. 392 patients were receiving anticoagulant. Minor bleeding (the patient who developed new onset of anemia but no visualized bleeding) were found in 681 cases (59.42%) while major bleeding (anemia with visualized bleeding) 465 cases (40.6%). In major bleeders, 553 cases (48.25%) had UGIB, 202 cases (17.6%) had LGIB and 100 cases (8.72%) developed EGIB (56 patients had internal organ bleeding, 24 patients had skin and soft tissue bleeding and 20 patients had intracranial hemorrhage). In patients with GIB, PPI group had less UGIB [43.23% vs 52.38% OR = 0.692 (95%CI 0.547-0.876) P = 0.002 in antiplatelet and/or anticoagulant takers, and 44.17% vs 57.97% OR = 0.573 (95%CI 0.422-0.788) P < 0.001 in aspirin monotherapy taker]. However, there were no differences of overall bleeding between PPI/non-PPI group. Amongst EGIB; sites of bleeding between PPI/non-PPI groups were comparable. Patients who took warfarin containing regimen had a greater proportion of bleeding compared to aspirin monotherapy group; 34 patients (70.83%) with warfarin containing regimen tended to have more bleeding than 6 patients (12.5%) with aspirin alone in PPI group. These findings were similar to non-PPI group. Interestingly, aspirin combined with warfarin had more EGI bleeding in PPI group compared to non-PPI group, 31.25% vs 11.53%; OR 3.484 (95%CI 1.233-9.929), P = 0.019. The medians of overall INR level were 3.13 (1.33-4.40) and 3.07(1.88-4.40) in EGIB and GIB respectively with P = 0.309.

**Conclusion:** As in general knowledge, our study demonstrated that PPI helped in alleviating UGIB in patients who took aspirin monotherapy regardless of PPI status. Interestingly, EGIB was high in our study, most of the cases were contributed from warfarin containing regimen although all group were in therapeutic level. Warfarin combine with aspirin significantly increased EGIB in PPI group in particular, this interaction need to be explored.

## P0553 OPTIMAL ENDOSCOPY TIMING IN PATIENTS WITH ACUTE VARICEAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

Huh C.W.<sup>1</sup>, Jung D.H.<sup>2</sup>

<sup>1</sup>Incheon St. Mary's Hospital, The Catholic University of Korea, Department of Internal Medicine, Incheon, Korea (Republic of), <sup>2</sup>Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea (Republic of)

**Contact E-Mail Address:** huhcw@catholic.ac.kr

**Introduction:** Although current guidelines recommend performing endoscopy within 12 hours for acute variceal bleeding (AVB), the optimal timing of endoscopy for AVB remains controversial.

**Aims & Methods:** To perform a systematic review and meta-analysis of all eligible studies to assess the effect of endoscopy timing on mortality and re-bleeding in AVB.

PubMed, Cochran Library, and EMBASE through January 2019 were searched for relevant publications. Overall mortality rate, re-bleeding rate, and other clinical outcomes (successful hemostasis, need for salvage therapy, length of hospital stay, and number of blood transfusions) were determined. Methodological quality of included publications was evaluated using the Risk of Bias Assessment tool for Non-randomized Studies. Mantel-Haenszel random effect model of RevMan software (Cochrane) was used to analyze binary endpoints and inverse variance method was used to analyze continuous outcomes.

**Results:** This meta-analysis included five studies with 854 and 453 participants undergoing urgent endoscopy ( $\leq 12$  hours) and non-urgent endoscopy ( $> 12$  hours), respectively. There was no significant difference in overall mortality rate between urgent and non-urgent groups (OR: 0.72, 95% CI: 0.36 - 1.45,  $P = 0.36$ ). Re-bleeding rate was similar between urgent and non-urgent groups (OR: 1.21, 95% CI: 0.76 - 1.93,  $P = 0.41$ ). Other outcomes were also similar between the two groups.

**Conclusion:** This study demonstrated that endoscopy timing did not affect mortality or re-bleeding rate of patients with AVB. Therefore, an appropriate timing of endoscopy would be more important than an urgent endoscopy depending on each patient's condition.

**Contact E-Mail Address:** aymanahmedsakr@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) and acute myocardial injury (AMI) are potentially life-threatening conditions that must be managed urgently (1). UGIB can be complicated by hypovolemia, hypotension, and diminished oxygen-carrying capacity, which cause myocardial ischemia and necrosis (2). liver cirrhosis is known to cause bleeding tendency, but sometimes may cause ischemic manifestations. Both UGIB and liver cirrhosis have a higher mortality when developing AMI than either of them alone (1).

**Aims & Methods:** To assess the relationship between UGIB in both portal hypertensive cirrhotic and non-cirrhotic groups and the development of AMI. A single-center prospective study done on 263 patients presented with UGIB, divided in to 4 groups; GI (no=118) cirrhotic patients with UGIB, GII: non-cirrhotic patients with UGIB (n=85), GIII: cirrhotic patients (30) with no history of UGIB and GIV: the healthy control group (30).

**Results:** Age is higher in GI than GII ( $P=0.0001$ ). Smoking, diabetes, history of previous MI and ICU admission were common associations in patients with UGIB and MI. Cardiac troponin I (cTn-I) level was not statistically significant different between the groups ( $p=0.16$ ), but cTn-I was positive for MI in 18/118 (15.3%) in GI and in 20/85 (23.5%) in GII ( $P=0.001$ ). ECG ischemic signs were statistically significant different ( $P=0.01$ ). OVs and PU were the most common causes of bleeding in GI&II (63.6%&90.6%), respectively ( $p=0.0001$ ). Mortality rate was 11/118 (9.3%) in GI and 4/85 (4.7%) in GII ( $P=0.0001$ ). Length of hospital stay (LOS) was higher in GI than GII ( $>5$  days

(83.1% vs 31.8%). There was a positive correlation between Glasgow Blatchford score (GBS) and cTn-I elevation ( $R=0.19$ ,  $P=0.003$ ). There was a high statistical significant difference between GI & II regarding GBS at cut off level (15 days) ( $p=0.0001$ ). In cTn-I positive cases, ROC curve for Troponin elevation was AUC 0.97, sensitivity and specificity were 97.4 & 100%, respectively. Odds ratio of smoking, viral hepatitis and LOS in cTn-I positive patients were 12.61, 14.49 & 2.76 times troponin negative patients, respectively ( $P=0.0001$ ).

**Conclusion:** UGIB in cirrhotic patients may predispose to AMI especially in older ages, men, comorbid diseases than non-cirrhotic. Patients with cirrhosis when developing UGIB have increased LOS, more complications and higher mortality than non-cirrhotics. Also, bleeding severity is positively correlated with developing AMI in all groups. cTn-I level is not different statistically between the groups.

## P0555 PATIENTS PRESENTING WITH AN ACUTE UPPER GI BLEED CAN BE SAFELY DISCHARGED TO RETURN FOR OUTPATIENT ENDOSCOPY WHEN THEIR GLASGOW-BLATCHFORD SCORE IS $\leq 2$

Richards B.<sup>1</sup>, MacDonald S.<sup>2</sup>, Creed E.<sup>2</sup>, Penman D.<sup>2</sup>, Priestley S.<sup>2</sup>, McClements D.<sup>2</sup>

<sup>1</sup>St Helens & Knowsley NHS Trust, Gastroenterology, Lancashire, United Kingdom, <sup>2</sup>St Helens & Knowsley NHS Trust, Liverpool, United Kingdom

**Contact E-Mail Address:** beth.richards@doctors.org.uk

**Introduction:** Upper Gastrointestinal (GI) Bleeding is one of the most common presentations to hospitals worldwide with an estimated incidence of between 40-150/100,000 annually.<sup>1</sup> In the UK this translates to approximately 1 presentation every 6 minutes and results in a significant financial burden for the National Health Service (NHS).<sup>2,3</sup>

Current guidelines in the UK and Europe suggest the use of the Glasgow Blatchford Score (GBS) to predict high and low risk patients.<sup>1,4,5</sup> The outpatient management of patients who score as low risk is widely accepted as a way of reducing pressure on inpatient services and potentially offsetting some of the aforementioned financial burden. In the UK, the guidelines suggest this strategy only for those who score 0, in Europe this is extended to 0-1.<sup>1,4</sup> Recently, a number of research papers have hypothesised that this could safely be extended further.<sup>3,6</sup>

At St Helens and Knowsley NHS Trust, UK, the score threshold has already been extended to those with a GBS of 2 or less with the introduction of an Ambulatory GI Bleed Pathway in 2016. The aim of this audit was to evaluate the safety of this pathway, which may subsequently influence future guidelines by revealing ambulatory care is safe for those with a higher GBS.

**Aims & Methods:** Data was collected retrospectively from May 2016-December 2018. Scanned medical notes were accessed and data collected under a number of headings: basic demographics, documented GBS, presenting date, date of endoscopy and findings at endoscopy. The 3 main end-points assessed were:

1. The need for endoscopic intervention.
2. Re-bleed rates within 30 days.
3. Thirty day mortality rate.

**Results:** A total of 224 patients were referred via the ambulatory GI bleed pathway with the majority presenting with fresh haematemesis, 'coffee-ground' vomit or malaena. Patients were excluded from analysis for a number of reasons including those who were inappropriately referred. Of the remaining 196 patients, 54.59% (107) were male and 45.41% (89) were female. The average age of presentation was 39 years of age (range 18-79). The mean GBS was 0.57 (mode 0).

The average number of days from presentation to endoscopy was 2.35 (range 0-19). We found 24 patients did not attend their appointment. 3 did not tolerate the procedure. 57 patients had an entirely normal endoscopy. Of the remaining 112, a number of diagnoses were seen at endoscopy. Of most significance, only 3 patients required endoscopic therapy, GBS scores for these patients were 0, 0 and 2. Just 2 suffered a re-bleed (GBS 0 and 0) within 30 days and 30-day mortality was 0%.

**Conclusion:** Although more than half of patients had a diagnosis at endoscopy (57.14%), only a very small number of patients required intervention (1.5%), even fewer (1%) suffered a re-bleed and no patients died within 30 days of being referred onto the ambulatory GI bleed pathway. Therefore, we conclude that ambulating patients presenting with Acute Upper GI Bleed who have a GBS of 2 or less is safe and that following more robust, multi-centre studies, perhaps this could be adopted into future guidance.

## P0556 ENDOSCOPIC TREATMENT ON GASTROESOPHAGEAL VARIX AFTER OXALIPLATIN-BASED CHEMOTHERAPY

Huang X.<sup>1</sup>, Ni L.<sup>2</sup>, Fan X.<sup>3</sup>, Chen S.<sup>1</sup>

<sup>1</sup>Zhongshan Hospital, Fudan University, Endoscopy Center and Endoscopy Research Institute, Shanghai, China, <sup>2</sup>Zhongshan Hospital, Fudan University, Department of Gastroenterology, Shanghai, China, <sup>3</sup>Hackensack University Medical Center, Hackensack, United States

**Contact E-Mail Address:** huangxiaoquan1010@aliyun.com

**Introduction:** Oxaliplatin has been used as the first choice for colorectal cancer, which might induce sinusoidal endothelial injury and portal hypertension. However, gastroesophageal varix formation after oxaliplatin-based chemotherapy may sometimes be overlooked when these patients presented with melena or hematemesis.

**Aims & Methods:** The aim of this study was to investigate the characteristics of oxaliplatin-induced portal hypertension and the efficacy of endoscopic prophylaxis of re-bleeding. Between 2010 and 2017, patients with gastroesophageal varix after oxaliplatin-based chemotherapy were included. We excluded patients with hepatitis, alcoholic, and other known etiology of cirrhosis. In the same time period, cirrhotic patients with hepatitis B related variceal bleeding and received first endoscopic treatment for prophylaxis of rebleeding were included as controls.

**Results:** A total of 31 patients with colorectal cancer and portal hypertension were identified, with an average of 6 cycles of oxaliplatin-based chemotherapy. Among them, 28 (90.32%) patients had an episode of variceal bleeding. The mean period retrospect to the start time of chemotherapy and the diagnosis of gastroesophageal varix was  $61.9 \pm 6.63$  months. Liver biopsy confirmed no evidence of liver fibrosis while the obstruction of hepatic vessels. Two of them had liver arterio-portal fistula and eight patients had portal-systemic shunt. Endoscopic ligation and cyanoacrylate injection were performed in 22 patients with a history of variceal bleeding episode. The other 6 patients had endoscopy evaluation for unsuitable for endoscopic treatment. Four patients received drugs (Carvedilol) and two received interventional procedures (transjugular intrahepatic portosystemic shunt (TIPS) and partial splenic embolization (PSE)). The comparison between oxaliplatin-based portal hypertension patients and cirrhotic patients with hepatitis B were showed in Table 1. Prothrombin time (PT), INR, alanine transaminase (ALT) and aspartate aminotransferase (AST) and MELD scores were much lower in chemotherapy patients ( $p < 0.001$ ). Kaplan-Meier analysis revealed that the 3-year re-bleeding rate for patients received oxaliplatin-based chemotherapy was higher than cirrhotic patients with hepatitis B ( $p = 0.0018$ ). Multivariate cox regression

analysis included age, MELD score, portal vein thrombosis, PT, AST, AST and platelet count indicated that oxaliplatin-based chemotherapy were the independent factors for re-bleeding (95% CI 1.228-6.282,  $p = 0.014$ ).

	oxaliplatin-induced portal hypertension	cirrhosis with hepatitis B	p value
age at first diagnosis of varix	61.82±1.96	50.45±1.00	<0.001
sex(male)	10(45.5%)	84(75%)	p=0.007
hemoglobin (Hb)	88.24±5.25	89.98±2.13	0.748
platelets	81.48±9.6	62.80±2.62	0.077
prothrombin time	13.28±0.20	14.35±0.14	<0.001
INR	1.15±0.016	1.25±0.012	<0.001
ALT	17.22±1.29	34.00±3.30	<0.001
AST	23.84±1.86	40.03±3.07	<0.001
total bilirubin	14.31±1.68	16.08±0.77	0.361
albumin	36.21±0.93	34.08±0.51	0.088
creatinine	67.39±3.92	72.70±2.09	0.241
Child Pugh score	6.55±0.23	6.38±0.11	0.543
MELD score	7.95±0.27	9.10±0.032	<0.001
portal vein thrombosis (%)	5(22.7%)	25(22.3%)	0.580

[Baseline clinical and biochemical characteristics]

**Conclusion:** Oxaliplatin-induced portal hypertension may lead to portal hypertension with mild liver injury. Endoscopic treatment can be used for preventing variceal bleeding, however, the rebleeding rate was much higher than other cirrhotic portal hypertension.

**Disclosure:** Nothing to disclose

**Introduction:** The 2015 UK National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report 'Time to Get Control' highlighted the need to improve the quality of care of patients with acute upper GI bleeding (AUGIB)<sup>1</sup>. The British Society of Gastroenterology Endoscopy Quality Improvement Project created an evidence based care bundle for AUGIB targeting ward based management of patients within the first 24 hours (The UK AUGIB bundle). The impact of implementation of the UK AUGIB bundle has not been assessed in clinical practice.

**Aims & Methods:** An audit of the impact of the UK AUGIB bundle was undertaken in 15 Scottish hospitals. Data were collected relating to demographics and management of patients with AUGIB within the first 24 hours of presentation, for a six-week period pre- and post-implementation of the UK AUGIB bundle. A period of bundle promotion was undertaken in all centres between data collection cycles. Outcomes measures included documentation of bundle implementation, risk scores and transfusion strategy. Caldicott approval was obtained in each site.

**Results:** A total of 459 patients were included in the pre-bundle audit period, and 434 patients in the post-bundle audit period. Following implementation, the AUGIB bundle was utilised in 41.2% of patients. The table demonstrates patient demographics and the impact of bundle implementation, highlighting improvements in recording of the Glasgow-Blatchford score and a re-bleeding plan, and improvements in transfusion strategies.

Variable	Pre-bundle period	Post-bundle period	p-value	Bundle not used	Bundle used	p value
<b>DEMOGRAPHIC VARIABLES</b>						
Number of patients	459 (51.4%)	434 (48.6%)	N/A	205 (53.4%)	179 (46.6%)	N/A
Age (years)	64.7 (63.0-66.4)	64.4 (62.7-66.0)	0.772	65.8 (63.4-68.1)	62.2 (59.5-64.8)	0.043
Male/ Female	264 (57.8%)/ 193 (42.2%)	266 (61.4%)/ 167 (38.6%)	0.530	123 (60.0%)/ 82 (40.0%)	113 (63.1%)/ 66 (36.9%)	0.395
Glasgow Blatchford score	6.3 (0-19)	7.4 (0-20)	0.011	7.0 (0-18)	8.0 (0-20)	0.141
Varices	27 (7.3%)	51 (13.3%)	0.007	24 (13%)	24 (14%)	0.733
<b>BUNDLE VARIABLES</b>						
Glasgow Blatchford Score recorded	163 (38.4%)	225 (57.3%)	<0.001	86 (42.2%)	122 (74.0%)	<0.001
Target haemoglobin stated	53 (35.3%)	78 (44.8%)	0.083	34 (36.6%)	35 (53.0%)	0.039
Transfusion threshold appropriate	58 (13.3%)	83 (19.6%)	0.012	40 (19.6%)	36 (20.2%)	0.880
Rebleeding plan documented	121 (33.2%)	196 (50.7%)	<0.001	83 (44.9%)	95 (56.55%)	0.028

[Patient demographic and bundle variables.]

No significant differences were observed in use of PPI in high risk bleeders, use of terlipressin/antibiotics in variceal haemorrhage or resumption plan for antithrombotics, with high pre-bundle performance in these domains. **Conclusion:** Implementation of the UK AUGIB bundle in Scottish hospitals resulted in significant improvements in quality standards including documentation of risk scoring, target haemoglobin, transfusion thresholds and re-bleed plan.

**Introduction:** Identifying errors in the ward environment, healthcare organisation or interaction between multiprofessional team members is crucial. Such identification may prevent serious mistakes that can occur in high pressure gastroenterology emergencies. Unannounced multiprofessional in situ simulation can be an effective means of identifying latent patient safety threats before they occur. We set up a standardised in situ simulation programme centred around speciality specific emergency scenarios; not only to improve skills, team working and communication but also to identify and address latent errors. The in situ faculty consisted of a consultant gastroenterologist; skills tutor; education fellow and director of medical education.

**Aims & Methods:** We identified key learning objectives for several different emergency scenarios including: massive upper gastrointestinal haemorrhage; septic shock; post-procedure complications and cardiac arrest. Using a wireless high fidelity simulation manikin we ran 18 unannounced sessions between February 2017 and April 2019. There was a minimum of three faculty in attendance in each of the sessions and an overall total of 79 participants representing the spectrum of different professions including: doctors; nurses; health care assistants and students from nursing,

medical, and physician associate backgrounds. Following completion of the scenario a structured debrief was conducted. Latent errors affecting patient safety at an individual, team or organisational level were identified and discussed. Following the scenarios, actions were put in place designed to address the identified errors in a timely fashion.

**Results:** During the 18 unannounced sessions between February 2017 and April 2019 we identified the following latent errors:

- unavailability of Sengstaken-Blakemore tubes, Bair Huggers, electrocardiogram machines and a step for CPR on the ward
- lack of awareness as to how to activate the major haemorrhage protocol
- not checking allergy status before administering antibiotics
- junior doctors without working pagers
- deficiencies in resuscitation skills amongst non-training grade doctors
- members of the multiprofessional team forgetting each others' names and parts of the ALS algorithm
- not knowing where the oral glucose gel is kept on the ward

Since the identification of these errors, corrective measures have included: laminated ALS algorithms attached to the resuscitation trolleys and dedicated major haemorrhage protocol training at junior doctor induction. Equipment availability has been addressed by ward management. Dedicated training days for the non-training grade doctors has also been undertaken.

**Conclusion:** In situ simulation is highly effective in identifying latent errors that could have potentially deleterious consequences on patient safety. This allows corrective measures to be undertaken in advance of real-life emergencies.

**Disclosure:** Nothing to disclose

## P0559 AN ENDOSCOPIC MAPPING DEVICE FOR GASTROINTESTINAL SLOW WAVE PROPAGATION PATTERNS

**Introduction:** Gastric slow waves regulate peristalsis, and gastric dysrhythmias have been implicated in functional motility disorders. To accurately define slow wave patterns, it is currently necessary to collect recordings during open surgery, which is invasive and limit their application. We therefore developed a novel gastric slow wave mapping device for use during endoscopic procedures. We aimed to assess feasibility of the new device for acquisition of gastrointestinal slow wave.

**Aims & Methods:** The device consists of a spreading catheter constructed of a flexible core coated with Pebax. Acquisition of gastric electrical signals was performed on healthy fasted weaner pigs under general anesthesia. Once deployed with endoscopic guidewire, catheter arrays is revealed with 12 electrode at 5mm intervals. A multi-channel recorder (Acknowledge 4.4, MP150; Biopac Systems, Santa Barbara, CA) was used to record gastric myoelectrical

activity throughout the study. We compared gastric electrical signals from gastric mucosal according to various lesions.

**Results:** Gastric slow wave activity was successfully recorded simultaneously via both the novel endoscopic probe and the serosal measurement. Recordings from the device and a reference array in pigs were identical in frequency, and activation patterns and velocities were consistent. Device and reference amplitudes were comparable.

**Conclusion:** In conclusion, the novel endoscopic device achieves high-quality mucosal slow wave recordings. It might be applied for endoscopic diagnostic studies to document slow wave patterns in patients with gastric motility disorders.

**Contact E-Mail Address:** kipcaksevgi@gmail.com

**Introduction:** Achalasia is a rare disorder with an incidence of approximately 1.6 cases per 100,000. The etiology of the disease especially changes at the epithelial permeability is not known.

**Aims & Methods:** The aim of this study was to investigate the electrophysiological and permeability characteristics of esophageal epithelium in patients with a diagnosis of achalasia before and after balloon dilatation compared with healthy controls and gastroesophageal reflux phenotypes. 27 patients (F: 17, M: 10, mean age 46 ± 15) diagnosed with upper gastrointestinal endoscopy with distal esophageal biopsies, timed barium swallow radiology, high resolution esophageal manometry (HRM) (according to Chicago 3.0v; 4 Type 1; 20 Type 2; 3 Type 3). 23 healthy volunteers and 60 erosive gastroesophageal reflux patients (ERD A / B: 48, ERD C / D: 12) were also included. Upper gastrointestinal endoscopy, HRM, 24h pH-MII studies were performed in both healthy volunteers and ERD patients. Esophageal electrophysiology and permeability measurements were performed before the treatment of 27 achalasia patients. 14 patients were also evaluated 2-3 months after the balloon dilatation. 3-4 esophageal biopsies were put into the mini-Ussing chambers to measure the transepithelial resistance (TEER), potential difference and tissue permeability via fluorescein diffusion within 2 hours.

**Results:** TEER and permeability of esophageal epithelium of Achalasia patients were not significantly different compared to the healthy volunteer group. However, when compared to the ERD group, the tissue resistance of achalasia patients were significantly higher and the permeability of the esophageal epithelium was significantly lower. Both tissue resistance and permeability of the esophageal epithelium after treatment were significantly higher, epithelial permeability was significantly lower in Achalasia patients compared to healthy volunteer and ERD groups. When pre- and post-treatment were compared, an increase in tissue resistance and decrease in epithelial permeability were determined after treatment, but no significant difference was found (Table).

	TEER (ohm) (mean±sd)	Permeability (pmol) (mean±sd)
Healthy volunteer	166,8 ± 47,2 §§§	36,9±13,8 §§
Achalasia (pre-treatment)	188,3± 55,7	33,6±15
Achalasia (post- treatment)	216± 80	22,2±9,1
ERD A/B	133,2 ± 34,4 * §§	49,6±28,4 ** §
ERD C/D	112,1 ± 38,6 * §	60,1±40,5*** §§§

\*p<0,001 vs Achalasia (pre- treatment), \*\* p<0,005 vs Achalasia (pre- treatment), \*\*\* p<0,05 vs Achalasia (pre- treatment), §p<0,001 vs Achalasia (post- treatment), §§p<0,005 vs Achalasia (post- treatment), §§§p<0,05 vs Achalasia (post- treatment)

### [TEER and Permeability Results]

**Conclusion:** Patients with achalasia have less gastric reflux however the mechanical trauma and long-term stasis of food inside the esophagus might have a noxious effect on the epithelium. Different than the expectations, pre-treatment findings of esophageal epithelial resistance and tissue permeability were similar with HC. GERD is not uncommon in Achalasia patients following treatments. In spite of that, no significant change was determined when the patients' esophageal epithelial resistance and permeability were compared before and after treatment with balloon dilatation. Based on these results, we assume that, an adaptive cytoprotective mechanism might develop in the esophageal epithelium of achalasia patients.

**Introduction:** The role of acid suppression with proton pump inhibitors (PPI) in relation to duodenal alterations and symptoms in functional dyspepsia (FD) patients is unknown. We studied duodenal permeability, eosinophil infiltration and symptoms in healthy volunteers (HV) and FD patients before and during PPI treatment.

**Aims & Methods:** Duodenal biopsies and blood samples were collected in healthy volunteers (HV) and FD patients before and after treatment with pantoprazole 40mg OD for 4 weeks. Transepithelial electrical resistance (TEER) and paracellular passage of a fluorescein-labeled dextran (4kDa) were measured in Ussing chambers and eosinophils counted on H&E-stained sections per high-power field (HPF; 0.24mm<sup>2</sup>). After each endoscopy, a naso-duodenal tube was positioned in the second part of the duodenum with aspiration of fasting and fed (Fortimel, 300kCal) fluids with measurement of pH. Plasma high-sensitivity C-reactive protein (hs-CRP), the Patient Assessment of Gastrointestinal Disorders Symptom Severity Index (PAGI-SYM) and Perceived Stress Scale (PSS) were measured at both visits. Non-parametric and correlation analyses were performed within- and between-groups.

**Results:** In total, 24 HV (15 female, median (IQR) age 26 (24-32) years) and 15 FD (13 female, 27.5 (22-34) years) were included. TEER was similar within- and between-groups. Dextran passage was higher in FD vs. HV off-PPI (p< 0.01) and significantly decreased in FD patients on-PPI. Duodenal eosinophil counts were higher in FD vs. HV both off- (p< 0.0001) and on-PPI (p=0.03) despite a significant reduction in eosinophilia in FD patients on-PPI. Duodenal fasting (p=0.02) and fed pH (p=0.03) were higher in FD vs. HV off-PPI with a trend for higher fed pH (p=0.08) in FD vs. HV on-PPI and an increase in both HV and FD on-PPI. Plasma hs-CRP was higher in FD vs. HV off-PPI (p=0.06) with a trend for decreased hs-CRP in FD on-PPI. PAGI-SYM decreased in FD on-PPI and was higher in FD vs. HV off- and on-PPI (both p< 0.0001). PSS was similar in FD on-PPI with higher scores in FD vs. HV both off- (p=0.04) and on-PPI (p< 0.01). Correlations were found between hs-CRP and passage (r=0.65, p=0.01) in FD off-PPI. Fed pH correlated positively with passage (r=0.58, p=0.03) in FD on-PPI. PAGI-SYM correlated with duodenal eosinophil counts (r=0.57, p=0.02) in FD off-PPI but not on-PPI. No correlations were found for HV.

Variable	HV (n= 24)			FD (n= 15)		
	Off-PPI	On-PPI	p-value	Off-PPI	On-PPI	p-value
TEER (Ω*cm2)	25.3 (19.7-31.5)	23.1 (19.8-26.4)	0.56	22.1 (19.2-27)	26.6 (20.7-28.5)	0.27
Paracellular passage (pmol)	19 (10.1-23.2)	22.7 (12.9-33.1)	0.07	25.6 (20.2-31)	15.5 (11.4 -29.3)	0.02
Eosinophils (per HPF)	3 (2-4)	1 (3-4)	0.72	12 (9-18)	4 (3-6)	<0.001
Fasting pH	5.9 (3.9-6.7)	7.2 (6.7-7.3)	<0.001	7 (5-7.4)	7.2 (6.6-7.5)	0.02
Fed pH	6.3 (5.2-6.5)	6.6 (6.4-6.8)	<0.01	6.4 (6-6.9)	6.8 (6.7-7.0)	0.03
hs-CRP (mg/L)	0.9 (0.3-1.5)	0.7 (0.2-1.6)	0.57	2 (0.6-5.5)	0.9 (0.2-1.6)	0.06
PAGI-SYM	0 (0-0.3)	0 (0-0.4)	0.75	2.8 (2-3)	1.5 (1-2.3)	<0.01
PSS	5 (2.5-9.5)	5 (1-6)	0.12	13.5 (8.8-18.3)	12.5 (1.8-18)	0.40

[Table 1]

**Conclusion:** In FD, elevated duodenal permeability, eosinophilia and symptoms but not stress are reduced by PPI and may be associated with systemic inflammation, which is associated with increased paracellular

passage in FD off-PPI. Increased duodenal pH on-PPI is associated with increased passage and hence is unlikely to explain the restored permeability in FD patients observed during PPI, suggesting the involvement of other factors such as duodenal eosinophils, which may drive dyspeptic symptoms.

**Disclosure:** Nothing to disclose

## P0562 CARBON MONOXIDE (CO) RELEASED FROM ITS PHARMACOLOGICAL DONOR PREVENTS ESOPHAGEAL MUCOSA AGAINST EXPERIMENTAL REFLUX ESOPHAGITIS. POSSIBLE INVOLVEMENT OF ANNEXIN 1, PROSTAGLANDIN E2, ENDOGENOUS HYDROGEN SULFIDE PRODUCING ENZYMES AND SELECTED VASOACTIVE MECHANISMS

**Contact E-Mail Address:** m.magierowski@uj.edu.pl

**Introduction:** Carbon monoxide (CO), similarly to hydrogen sulfide (H<sub>2</sub>S) is a gaseous mediator. CO is produced from heme via activity of heme oxygenase-1 (HO-1) and HO-2. CO and H<sub>2</sub>S exert anti-inflammatory and anti-oxidant effects. However, possible preventive effect of CO released from its pharmacological donor, tricarbonyldichlororuthenium (II) dimer (CORM-2) against acute reflux esophagitis (RE)-induced esophageal damage has not been explained.

**Aims & Methods:** The RE was induced in Wistar rats within 4 h by ligating pylorus and transitional region between the forestomach and glandular portion. Before induction of RE animals were pretreated with CORM-2 (0.5 - 10 mg/kg i.g.), HO-1 inducing hemin (5 mg/kg i.g.) or HO-1 inhibiting zinc protoporphyrin IX (ZnPP, 10 mg/kg i.p.). CORM-2 was applied alone or in combination with indomethacin (5 mg/kg i.g.) to inhibit PG biosynthesis, L-NNA (15 mg/kg i.g.) to inhibit NO-synthase activity, capsazepine (5 mg/kg i.g.) to block TRPV1 activity or capsaicin (125 mg/kg s.c.) to suppress the activity of sensory nerves. RuCl<sub>3</sub> (2.5 mg/kg i.g.) which is not a CO releaser, was administered as a negative control for CORM-2. The esophageal blood flow (EBF) was determined by laser flowmetry, esophageal lesions index (LI) and mucus production was assessed by macro- and microscopically by planimetry and histology (H&E, alcian blue/PAS staining), the mucosal expression of mRNA and/or protein for HO-1, HO-2, Annexin-1, Nrf-2, hypoxia inducible factor 1α (HIF-1α), IL-1β and TNF-α, COX-1 and COX-2, TRPV1 and endogenous H<sub>2</sub>S producing enzymes CTH, CBS and MPST were analyzed by real-time PCR, Western blot and/or immunohistochemistry. 8-hydroxyguanosine (8-OHG) as DNA oxidation marker and PGE<sub>2</sub> concentration in esophageal mucosa were determined by ELISA.

**Results:** CORM-2 reduced LI, maintained mucus production and increased EBF with selected ED50 dose being 2.5 mg/kg i.g. Similar effects were observed for hemin but not for RuCl<sub>3</sub> or ZnPP. Capsazepine and capsaicin denervation but not L-NNA or indomethacin reduced esophagoprotective effects of CORM-2. CO donor increased HO-1/Nrf-2 or TRPV1 but did not affect CTH, CBS or MPST expression. CORM-2 downregulated COX-2, TNF-α, IL-1β and iNOS esophageal expression, decreased 8-OHG concentration and maintained Annexin-1 and HIF-1α expression and PGE<sub>2</sub> concentration increased by RE.

**Conclusion:** We conclude that CO released from CORM-2 prevents esophageal mucosa against the damage induced by RE via its hyperemic, anti-inflammatory and anti-oxidative properties. These effects involved in CORM-2-mediated esophagoprotection are partly mediated by the ability of CO to maintain protective PGE<sub>2</sub> level and by the activity of Nrf2, Annexin-1 and HIF-1α but the possible role of H<sub>2</sub>S biosynthesis enzymes remains unclear. [Funding source: National Science Centre, Poland (UMO-2016/23/D/NZ4/01913)].

## P0563 ENDOGENOUS GLUCAGON-LIKE PEPTIDE 2 PLAYS AN IMPORTANT PHYSIOLOGICAL ROLE IN THE ADAPTIVE RESPONSE AFTER SMALL INTESTINAL INJURY

Billeschou A.<sup>1</sup>, Hunt J.<sup>1,2</sup>, Agerlin Windeløv J.<sup>1,2</sup>, Juul Holst J.<sup>1,2</sup>, Kissow H.<sup>1,2</sup>  
<sup>1</sup>University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark, <sup>2</sup>Copenhagen University, NNF Center of Basic Metabolic Research, Copenhagen, Denmark

**Contact E-Mail Address:** anna.billeschou@sund.ku.dk

**Introduction:** Acute small intestinal injury such as chemotherapy-induced gastrointestinal mucositis often leads to extensive loss of mucosa, which can lead to malabsorption, abdominal pain and increased infection risks<sup>1,2</sup>. Intestinal adaptation is an important response and a natural compensatory mechanism to the acute injury and is critical for recovery. Glucagon-like peptide 2 (GLP-2) is secreted from enteroendocrine L-cells in response to food intake. GLP-2 has been demonstrated to enhance mucosal repair following intestinal damage<sup>4</sup>, however, whether the endogenous secretion of GLP-2 is physiologically essential for mucosal repair and protection remains unresolved.

**Aims & Methods:** This study aims to investigate whether deficiency of GLP-2 receptor (GLP-2R) activity increases intestinal susceptibility and reduces the adaptive response to injury, using a model of chemotherapy-induced mucositis.

Female GLP-2R knock out (KO) mice and their wild type (WT) littermates received an intraperitoneal injection of chemotherapy (5-fluorouracil 400 mg/kg) inducing acute mucositis followed by regeneration. Additionally, GLP-2R KO and WT control received a saline injection. Bodyweight was monitored daily and recorded.

Mice were sacrificed 3 or 6 days after induction of injury; the small intestines were harvested, cleaned and the weight was recorded. Tissue from duodenum, jejunum, and ileum was analysed for myeloperoxidase (MPO) activity.

**Results:** The body weight of GLP-2R KO mice and their WT littermates showed the same decrease in the acute phase of injury and the same increase in the adaptive phase. No difference in small intestinal weight between the KO and WT was found in the acute phase of injury. Six days after injury GLP-2R KO mice showed a significant decrease in small intestinal weight compared to the WT mice (P < 0.0001).

Only WT mice were able to show the additional adaptive regrowth normally seen after chemotherapy-induced injury in mice; with a small intestinal weight significantly higher than healthy WT controls (P < 0.0001). In the acute state of injury, a significant increase in the inflammatory marker MPO was detected for the GLP-2R KO mice compared to their WT littermates in the middle part of the small intestines (P < 0.05).

Whereas no significant difference was found in the proximal and distal part of the small intestine. During the adaptive phase of injury, the MPO activity was back to baseline for both the GLP-2R KO and WT mice compared to the healthy controls.

**Conclusion:** This study shows that in the acute phase of injury GLP-2R activation might be less important for intestinal protection. However GLP-2R activation seems to play an important physiological role in the adaptive response after intestinal injury.

**Introduction:** Per-oral endoscopic myotomy (POEM) has established its place in the management of achalasia. Gastroesophageal reflux is an important concern after POEM. However, there is limited data on the risk factors for GER after POEM.

**Aims & Methods:** In this study, we aim to analyse the variables affecting the occurrence of GER after POEM.

All patients who underwent POEM (December 2017 to January 2018) at a single tertiary centre were offered GER evaluation using 24-hour pH impedance, esophagogastroduodenoscopy (EGD) and symptoms. Multivariate analysis was performed to identify the variables affecting the incidence of GER after POEM.

**Results:** A total of 260 patients with achalasia underwent POEM during the study period. 167 (64.2%) patients (mean age 41±14.42 years, 47.6% females, mean body mass index 22.2±3.89 kg/m<sup>2</sup>) underwent comprehensive evaluation of GER. Majority (70.6%) of the patients were treatment naïve. High De-Meester score (>14.7) and reflux esophagitis was identified in 47.9% and 41.9% of patients, respectively. Symptomatic GER was found in 29.3% patients. On univariate analysis only sigmoid oesophagus was found to be associated with GER (OR 0.20; CI 0.04-0.99; p=0.04). On multivariable analysis type of achalasia, technique of POEM (anterior vs posterior), objective variables including pre or post POEM esophageal manometry and patient characteristics (age, sex, BMI, type of achalasia) were not associated with GER.

	Odds Ratio	95% Confidence interval	p value	Adjusted odds ratio	95% confidence interval	p value

## P0566 DOES ETIOLOGY, PRIOR THERAPIES AND OPERATIVE TIME AFFECT OUTCOME OF G-POEM IN REFRACTORY GASTROPAARESIS - A SYSTEMATIC REVIEW AND META-ANALYSIS

Chandan S.<sup>1</sup>, Mohan B.<sup>2</sup>, Choudhry Chandan O.<sup>3</sup>, Hewlett A.<sup>1</sup>, Bhat I.<sup>1</sup>, Jha L.<sup>1</sup>

<sup>1</sup>University of Nebraska Medical Center, Gastroenterology and Hepatology, Omaha, United States, <sup>2</sup>University of Arizona/Banner University Medical Center, Internal Medicine, Tucson, United States, <sup>3</sup>University of Nebraska Medical Center, Pediatric Gastroenterology, Hepatology & Nutrition, Omaha, United States

**Contact E-Mail Address:** babupmohan@gmail.com

**Introduction:** Gastric per-oral endoscopic myotomy (G-POEM) was first introduced in 2013 for the management of refractory gastroparesis. Most of the studies included small sample size with short term follow up. Literature on the efficacy of G-POEM when considering the etiology of gastroparesis, prior therapies and total operative time is limited.

**Aims & Methods:** We performed a systematic review and meta-analysis to evaluate the clinical efficacy of G-POEM in patients with refractory gastroparesis. We also evaluated if variation in total operative time, prior therapies (botulinum toxin, gastric electrical stimulation) and etiology affected clinical success. We conducted a search of several databases to locate items pertaining to peroral endoscopic pyloromyotomy or gastric peroral endoscopic myotomy (G-POEM) in patients with refractory gastroparesis (Jan 2013 to Feb 2019). Random-effects model was used. Heterogeneity between study-specific estimates was calculated using Cochran Q test and I<sup>2</sup> statistics. Publication bias was ascertained by funnel plot and Egger test. The outcome assessed was the pooled rate of clinical success with G-POEM as determined by total Gastroparesis Cardinal Symptom Index (t-GCSI) ≤2 at follow up and improvement in the 4-hr Gastric Emptying Study (GES). Sub-group analysis was performed based on the total operative time. Meta-regression analysis was used to evaluate the effect of prior treatments on clinical success.

**Results:** Our initial search yielded 67 results. After excluding duplicates and non-english literature, 62 full length articles were screened and 16 studies with 442 patients were included in the final analysis. Follow up t-GCSI and 4-hr GES data was available for 373 and 258 patients respectively. The pooled rate of clinical success based on t-GCSI was 75.9% (95% CI 69.7-81.2, I<sup>2</sup>=37.8) and based on improvement in 4-hr GES was 84% (95% CI 71.9-91.5, I<sup>2</sup>=66.2). Sub-group analysis was done to evaluate the clinical success of G-POEM as influenced by the total procedure time. Based on t-GCSI scores, for a procedure time of < 50 min (8 studies, 214 patients) the pooled rate of clinical success was 74.6% (95% CI 65.6-81.8, I<sup>2</sup>=3.3) whereas for >50 min (8 studies, 159 patients) it was 78.4% (95% CI 68.4-85.9, I<sup>2</sup>=57.9). There was no statistical difference between the two (p=0.53). Similarly, based on 4-hr GES for a procedure time of < 50 min (6 studies, 126 patients) the pooled rate of clinical success was 76.5% (95% CI 56.2-89.2, I<sup>2</sup>=73.5) whereas for >50 min (8 studies, 132 patients) it was 88.7% (95% CI 75-95.4, I<sup>2</sup>=36.4). There was no statistical difference (p=0.20) between the two. The pooled rate of total adverse events was 13.4% (95% CI 6.8-24.8, I<sup>2</sup>=63.7) and follow up time ranged from 2 months (shortest) to 18 months (longest). Length of hospital stay ranged from 1 to 6 days. On meta-regression analysis, prior treatment with botulinum toxin injection (2-sided p-value =0.03) and gastric electrical stimulation (2-side p-value=0.03) seemed to significantly influence 4-hr GES success rate. Etiology (diabetes, idiopathic, post-surgical) and/ or prior treatments did not affect the outcome of G-POEM based on t-GCSI score.

**Conclusion:** G-POEM is an effective and safe treatment modality for refractory gastroparesis. Our study shows that there is no difference in the successful outcomes based on the etiology of gastroparesis or total operative time. However, prior treatment with botulinum toxin and gastric electrical stimulation had a statistically significant influence on the success rate based on 4-hr gastric emptying.

## P0567 PREDICTORS OF REFLUX ESOPHAGITIS AFTER PER-ORAL ENDOSCOPIC MYOTOMY (POEM)

Masuda T., Yano F., Omura N., Tsuboi K., Hoshino M., Yamamoto S., Akimoto S., Kashiwagi H., Yanaga K.

**Contact E-Mail Address:** masudatahiro730@gmail.com

**Introduction:** Per-oral endoscopic myotomy (POEM) is known as an effective therapeutic option for patients with achalasia and also for spastic esophageal disorders including Jackhammer esophagus and diffuse esophageal spasm. Gastroesophageal reflux disease (GERD) is common in patients who undergo POEM, with a reported prevalence of up to 40%, due to the lack of fundoplication. Subset of such patients clinically require an additional laparoscopic fundoplication due to a poor response to acid neutralization therapy. However, potential risks of GERD after POEM remains unstudied.

**Aims & Methods:** The aim of this study is to propose predictors of post-POEM GERD. All patients who were diagnosed with achalasia and spastic esophageal disorders at our tertiary referral esophageal center are entered into a prospectively maintained institutional database. After Institutional Review Board approval, we queried this database to identify patients who underwent POEM procedure between January 2016 and March 2019 (n=42). Of these, patients with a history of prior endoscopic/laparoscopic myotomy (n=8) or whose post-operative upper endoscopic evaluation were unavailable (n=8) were excluded. Endoscopic surveillance was conducted at 3 months, 1 year, and then yearly after POEM procedure. The patients were divided into two groups based on post-POEM endoscopic findings using the Los Angeles classification, ie, non-GERD group (grade N or M) and GERD group (grade A or more). Pre-operative evaluations based on timed barium esophagogram (TBE), high-resolution esophageal manometry (HRM), and Eckardt score were compared between the groups.

**Results:** Twenty-six patients met the study criteria. Their median age was 47 years, 16 patients were men, and the median BMI was 21.4 kg/m<sup>2</sup>. The median follow up period was 13 months. Eleven of 26 patients (42%) had an evidence of GERD based on post-POEM endoscopy. Age, sex, and BMI were comparable between the patients with and without GERD. Duration of disease was longer in patients with post-POEM GERD than those without GERD, although it did not reach statistical significance (120 vs. 36 months, p=0.069). Pre-operative Eckardt score was similar between the groups. According to Japan Esophageal Society classification of esophagogram in patients diagnosed with achalasia, there were no differences in morphology type (straight esophageal type: sigmoid type: advanced sigmoid type, 11:3:0 in non-GERD group and 8:2:1 in GERD group; p=0.793) and maximal esophageal transverse diameter (41.0 mm in non-GERD group vs. 44.0 mm in GERD group, p=0.536) between the groups. Manometric diagnosis based on Chicago classification v3.0 was similar between the patients in non-GERD group and those in GERD group (achalasia type I: type II: type III: Jackhammer esophagus, 3:8:3:1 in non-GERD vs. 4:5:2:0 in GERD, p=0.922). No patient had a manometric hiatal hernia. The resting lower esophageal sphincter (LES) pressure and intraabdominal LES length were similar among the groups; however, the patients in the GERD group had significantly shorter overall LES length (OL) than those in the non-GERD group (2.9 vs. 3.5 cm, p=0.003). ROC curve analysis for OL revealed the cut-off value of 3.0 cm (AUC 0.885 [95%CI: 0.722-1.000], p=0.006) with the sensitivity of 100% and specificity of 71%. Prevalence of GERD was 100% in patients with OL < 3 cm and 13% in patients with OL ≥ 3 cm (p=0.001).

**Conclusion:** Longer duration of disease may be a risk factor of esophagitis after POEM. Longer OL (≥ 3 cm) appears to prevent reflux esophagitis after POEM. Further study is warranted.

**Disclosure:** Nothing to disclose

## P0568 EFFECT OF CLEARANCE RATE OF THE ESOPHAGUS FOR SYMPTOMS AND SURGICAL RESULTS IN PATIENTS WITH ESOPHAGEAL ACHALASIA

**Introduction:** Esophageal achalasia is one of the primary esophageal motility disorders, and dysphagia and vomiting due to difficult passage at the lower part of the esophagus are main symptoms in patients with esophageal achalasia. Timed barium esophagogram (TBE) is a useful method to evaluate the clearance at the lower part of the esophagus in patients with esophageal achalasia, which we usually performed before and after surgery. Meanwhile, laparoscopic Heller-Dor operation (LHD) is a gold standard treatment of esophageal achalasia and is prevalent all over the world.

**Aims & Methods:** The aim of this study is to analyze the effect of clearance rate of the lower part of the esophagus for symptoms and surgical results in patients with esophageal achalasia. Between May 2002 and March 2019, 588 patients who underwent LHD at our institution were extracted from the database. Out of these, 433 patients met our inclusion criteria; such as the patients who underwent LHD as an initial operation with complete evaluation of preoperative esophageal clearance by TBE. These patients were divided into three groups based on the clearance rate of the lower part of the esophagus (Group A: clearance rate <10%, Group B: 10%≤clearance rate <50%, and Group C: 50%≤clearance rate). Patients' background, pre- and post-operative symptom scores, surgical results and post-operative course were compared. Before and after surgery, a standardized questionnaire was used to assess the degree of frequency and severity of symptoms (dysphagia, vomiting, chest pain and heartburn). For each symptom, frequency and severity were separately assessed on a five-point scale (range: 0-4), and a symptom score was calculated by multiplying these points (range: 0-16). Moreover, satisfaction with operation was evaluated using the standardized questionnaire. Statistical analysis was performed by using Krasukal-Wallis test or chi-square test, and p-value less than 0.05 was defined as statistically different.

**Results:** Their mean age was 44.6 years and 217 of them were male (50.1%). One hundred and eighty-six patients (43.0%) were in Group A, 163 (37.6%) in Group B, and 84 (19.4%) in Group C. The maximum width of the esophagus in Group C was smaller than that in other groups (p=0.0181). As to the pre-operative symptom score, dysphagia was significantly lower in Group C (p=0.0442), whereas chest pain was significantly higher in Group C (p=0.0489). Surgical outcomes including the incidence of mucosal injury were not different among three groups. Moreover, the patient satisfaction with LHD was excellent regardless of preoperative esophageal clearance.

**Conclusion:** Pre-operative clearance rate of the lower part of the esophagus correlated with pre-operative dysphagia and chest pain, but did not affect the surgical outcomes of LHD, post-operative course or post-operative symptoms in patients with esophageal achalasia.

**Introduction:** Peroral endoscopic myotomy (POEM) is nowadays considered as a standard method for treatment of esophageal achalasia, however, the

high risk of post-POEM reflux tempers the POEM enthusiasm. The aim of our case series was to assess the long-term clinical outcome of POEM and a thorough analysis of post-POEM reflux.

**Aims & Methods:** A retrospective analysis of prospectively collected data of consecutive patients undergoing POEM at our tertiary center (December 2012- March 2019). All patients were scheduled for follow up at 3 and 12 months after the procedure and every year thereafter. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM; endoscopy was then repeated between 24-36 months. Main outcomes were treatment success defined as Eckardt score < 3, recurrence rate and parameters of post-POEM gastroesophageal reflux evaluated by 24h pH monitoring, presence of reflux esophagitis, reflux symptoms and use of proton pump inhibitors (PPIs).

**Results:** A total of 292 patients with achalasia underwent 306 POEM procedures. Follow-up visits at 3, 12, 24, 36 and 48 months were completed in 250, 179, 131, 69 and 28 patients. At 3, 12, 24, 36 and 48M, treatment success was achieved in 98% (CI 96-100), 95% (92-98), 90% (85-95), 82% (73- 91) and 79% (67-91) of patients. A total of 25 patients experienced treatment failure (n=6) or recurrence (n=19). At 3 months, reflux esophagitis was observed in 107/251 (42.6%, LA C/D in 12 patients). Abnormal acid exposure was detected in 93/215 (44.3%) patients. At 24-36 months, endoscopy was performed in 84 patients and reflux esophagitis was present in 27 patients (32.1%). PPIs were administered to 37.2% and 42.7% of patients at 3 and 24 months, respectively.

**Conclusion:** POEM is a highly effective endoscopic treatment for achalasia with still favorable treatment success of almost 80% at 4 years after the procedure. Higher rate of post-POEM reflux esophagitis seems to decrease over time.

**Contact E-Mail Address:** catia\_arieira@hotmail.com

**Introduction:** Esophageal junction outflow obstruction (EGJO) is a new diagnosis recently introduced in Chicago Classification V3.0. It is a pathological entity of unclear clinical significance and represents a heterogeneous range of conditions. It may be classified as structural (SO) when there is a mechanical cause for the obstruction such as the presence of hiatal hernia, esophageal rings and post-surgery or as functional (FO) when a potential obstructive cause is not identified.

**Aims & Methods:** Aim: to evaluate the prevalence of EGJO and to compare the clinical, manometric and phmonitoring characteristics of the patients according to the cause: SO versus FO.

**Methods:** Retrospective and single center study. All patients presented a High Resolution Manometry (HRM) with 36 channels of solid state. All the HRM between 01/2012 and 01/2019 were reviewed and were included patients with EGJO diagnosis and then classified in SO and FO.

**Results:** From 2357 HRM reviewed, 79 (3.4%) patients met criteria of EGJO according to Chicago Classification v3.0, 57.0% females with mean age of 59.8 (±13.8) years. Of them, 42 (53.2%) patients presented simultaneous esophageal pH monitoring.

Forty patients (50.6%) were categorized as SO and 39 (49.4%) as FO. Fourteen patients presented previous history of Nissen fundoplication, 3 presented bariatric surgery, 3 distal esophageal ring and 26 hiatal hernia. Patients with SO presented more frequently typical symptoms (52.5% vs 20.5%; p=0.003) and atypical symptoms (22.5% vs 5.1%; p=0.026) of GERD when compared to FO.

Patients with FO presented higher intrabolus pressure (18.4 vs 15.5; p=0.039) when compared to SO and in multiple swallowing, FO presented higher distal contractile integral (DCI) (2818.3 vs 1670.9; p=0.003) comparing to SO.

No other differences were observed between the groups regarding other HRM parameters and pH monitoring.

**Conclusion:** The frequency of EGJO in our population was low and it represents a heterogeneous group of patients. The differences between SO and FO are scarce, however we found higher intrabolus pressure and DCI on multiple swallows in patients with FO.

**Disclosure:** Nothing to disclose

**Introduction:** Some patients feel dysphagia as a stuck sensation in their throat, while the real obstruction site is in their lower oesophagus. Chest pain is also often reported by achalasia patients, but the mechanism of chest pain is still unknown. High-resolution manometry (HRM) enable us to categorize achalasia into three distinct subtypes by the status of the oesophageal body (Chicago classification :CC).

**Aims & Methods:** The aim of this study was to clarify the symptoms of oesophageal achalasia patients using HRM. Seventy one newly diagnosed achalasia patients were enrolled. Symptoms, HRM and radiographic findings were retrospectively reviewed. A structured self-reported questionnaire focused on dysphagia and chest pain were obtained from all the patients. The questionnaire consists of the main site of symptom (dysphagia and chest pain), timing, duration, food or behavior that cause symptoms, accompanying symptoms, and the preferable way to relieve symptoms. HRM was performed with ManoScan and assessed by CC v3.0. Oesophagograms were taken with 100ml of barium. Characteristics of the symptoms and the differences in symptom details among the manometric subtypes were investigated.

**Results:** Of total 71 patients, 69 patients(97%) reported dysphagia and 39 patients(54%) reported chest pain. According to HRM findings, patients were classified into types I/II/III 25/37/9 patients (35/52/12%) by CC. The pressurization of oesophageal body after swallows was different among the subtypes (I/II/III 13.4/27.7/70.3mmHg, p< 0.05). Oesophagogram also showed the difference in the diameter of the oesophagus (I/II/III 5.4/4.8/3.1cm, P< 0.05). Regarding dysphagia, Type II patients mostly felt dysphagia in the throat (54%), while type I and III patients mostly felt it in the epigastrium (52%, 55%). Type II patients often had dysphagia immediately after swallowing (41%), but that was only the case in 8.7% of type I and 33% of type III patients (p< 0.05). Drinking water was preferred to relieve dysphagia in type I and II patients (78% and 70%), but less so in type III (33%). About chest pain, patients with chest pain had higher pressurization in the oesophageal body than patients without pain (34.8 vs. 21.5mmHg, p< 0.05). Type I patients rarely felt pain in the interdigestive period (14%), but more often while sleeping (43%) and in early morning (43%). Type III patients reported more pain in the interdigestive period (67%), but none while sleeping. The most reported answer for the duration was 5-10minutes for type I (36%), within 1 minute for type II (26%), and 1-5minutes for type III (67%). Type III patients reported more often than type I and II patients that solid food caused pain (I/II/III 0/10/33%, p=0.09).

**Conclusion:** Detailed symptoms of achalasia, such as its site and timing, varied by subtypes. The status of the oesophageal body might induce those differences in symptoms.

**Disclosure:** Nothing to disclose

## P0573 COMPARISON OF PERORAL ENDOSCOPIC MYOTOMY BETWEEN DE-NOVO ACHALASIA AND PRIOR TREATMENT FAILURE ACHALASIA

Yoo I.K.<sup>1</sup>, Yeniova A.O.<sup>2</sup>, Cho J.Y.<sup>1</sup>

<sup>1</sup>CHA Bundang Medical Center, CHA University, Division of Gastroenterology, Department of Internal Medicine, Seongnam, Korea (Republic of), <sup>2</sup>Tokat Gaziosmanpaşa University Faculty of Medicine, Department of Internal Medicine Division of Gastroenterology, Tokat, Turkey

**Contact E-Mail Address:** ozgur.yeniova@gop.edu.tr

**Introduction:** Peroral endoscopic myotomy (POEM) has been recognized as an effective treatment for patients with achalasia (1). Prior treatment may affect the outcome of subsequent treatment (2). We aimed to compare the safety and efficacy of POEM in treatment-naïve patients (TN) vs. those with prior treatment failure (PTF).

**Aims & Methods:** We retrospectively analyzed the data of achalasia patients who underwent POEM from November 2011 to January 2018. A comparative analysis was performed between TN and PTF cases. Technical and clinical success, adverse events, operative time for POEM, hospital stay and length of myotomy were compared between the two groups.

**Results:** Overall, 209 patients with achalasia underwent POEM during the studied period, including 113 patients (54%) in the TN group and 96 patients (45%) in the PTF group. The baseline characteristics of the TN and PTF groups were not significantly different except for duration of disease. The PTF group had longer disease duration than the TN group. (7.92 ± 9.28 vs 4.45 ± 5.67 years respectively p=0.005). Both groups were technically successful. All of the POEM cases' procedures were completed successfully. Operative time was longer in the PTF group than that in the de novo group, but the difference was not statistically significant. The occurrence rates of gas-related events and severe complications were similar in both groups. The operation time, hospital stay, length of myotomy were not significantly different between the two groups.

Changes in the Eckardt score before and after POEM (5.11 ± 0.23 vs. 4.99 ± 0.253; P=0.042 vs. P=0.001) were comparable in the TN and PTF cases. IRP and LES pressure decreased after POEM. The decreases in the IRP and LES pressure values were significantly different between TN group and the PTF group (Table 1). After 6 months, more patient suffered from reflux symptoms in the PTF group but DeMeester score and endoscopic evaluation were not significantly different between the two groups.

	Treatment naïve group(n=113)	PTF group (n=96)	P-value
Technical success, n (%)	113 (100%)	96 (100%)	not applicable
Length of myotomy, cm (Esophagus)	7.22 ± 2.27	7.11 ± 1.97	0.630
Length of myotomy, cm (Stomach)	1.81 ± 0.59	1.82 ± 0.54	0.979
Operation time, minute	74.08 ± 31.93	76.52 ± 32.27	0.539
Duration of nil per oss, day	5.23 ± 1.51	5.28 ± 1.46	0.884
Hospital stay, day	7.23 ± 1.51	7.28 ± 1.46	0.884
Adverse event, n (%)	52 (46.0)	66 (68.7)	0.214
Clinical success (Eckardt score ≤3)	107 (94.6%)	91 (94.7%)	0.978
Difference of Lower esophageal sphincter pressure	22.88 ± 18.17	8.83 ± 18.10	0.001
Difference of Integrated Relaxation Pressure	18.02 ± 21.92	7.32 ± 14.21	0.004
Reflux symptoms after 6 months (Yes : No), n	41 : 71	47 : 46	0.045

[Table 1]

**Conclusion:** Our results were comparable to other studies that compared TN and PTF in terms of the mean values of adverse effects, operation time and technical and clinical success of POEM (3,4). POEM is safe and equally effective for de-novo patients and for those in whom prior treatment failed. POEM should be considered as the treatment of choice in patients with history of failed prior treatment.

**Contact E-Mail Address:** rhustak@gmail.com

**Introduction:** G-POEM is an emerging method for treatment of severe gastroparesis (GP). Safe and reliable mucosal closure is necessary to avoid major adverse events.

**Aims & Methods:** The aim of this prospective (ongoing) study was to compare the effectivity of two closure methods: endoscopic clips (Resolution<sup>TM</sup> or Instinct<sup>TM</sup>) and endoscopic suturing (ES, Apollo OverStitch<sup>TM</sup>) in patients undergoing G-POEM for refractory GP.

A single center, prospective study (NCT:03679104). All patients, who underwent G-POEM in our centre and agreed to participate were enrolled. The closure method was assigned at the discretion of an endoscopist (one endoscopist performed all procedures) prior to the procedure. The main outcome was the proportion of subjects with successful closure. Unsuccessful closure was defined as a need for a rescue method, or a need for an additional intervention (e.g. in case of leak). Secondary outcomes were easiness of closure [measured by means of a questionnaire on a VAS (visual analogue scale, 0=impossible, 10=very easy, scored by endoscopist as well as an endoscopy nurse)] and closure time.

**Results:** A total of 15 patients [M:F:7:8; mean age 50.5 (29-74)] have been included so far; 8 patients received ES closure and 7 patients received a closure with endoclips [mean 6, range (5-19)]. All patients with ES had successful closure but 2 pts (29%) with clips needed a rescue method (n=1, KING closure with an endoloop) and an additional clipping because of leak on POD1 (n=1). The remaining patients (n=5, 71%) had a successful closure with clips. Closure with clips tended to be quicker [mean closure time and range 10.4 (8-13) vs 14.8 (9-20) min, p=0.189]. Endoscopist assessed closure with ES easier compared to clips [mean VAS, SD: 7.6 ±1.3 (ES) vs. 5.4 ±1.7 (clips) p=0.02], nurses assessed easiness of both closure methods as comparable (VAS 6.6 ±2.6 (ES) vs 7 ±1.2 (clips) p= 0.536).

**Conclusion:** Endoscopic suturing system may be more reliable than clipping for mucosal closure in patients undergoing G-POEM, even though is technically more demanding. Besides clips, centers performing G-POEM should have an alternative (rescue) closure method. (Supported from Czech Ministry of Health 17-28797A). Clin Trial: NCT03679104

**Introduction:** Achalasia is a benign esophageal motor disorder that results from a progressive degeneration of ganglion cells in the myenteric plexus of the esophageal wall. It leads to failure of relaxation of the lower esophageal sphincter associated to the loss of the peristalsis in the distal esophagus. The etiology of the primary or idiopathic achalasia is unknown. In Chagas disease, the esophageal infection with the protozoan parasite Try-

panosoma cruzimay result in the loss of the intramural ganglion cells. The peroral endoscopic myotomy (POEM) is an effective and safe treatment for achalasia. However, there is no study comparing outcomes of POEM according to the etiology of the achalasia.

**Aims & Methods:** We evaluated our prospectively collected database of POEM procedures performed at a single institution from November 2016 to August 2017. Demographic data, clinical success, Eckardt score, lower esophageal sphincter (LES) pressure, body mass index (BMI), erosive esophagitis, adverse events, pneumoperitoneum requiring needle decompression, operative time, and length of hospital stay were assessed. Clinical success was defined as an Eckardt score  $\leq 3$  at 1 year. Student T-test and Logistic regression analyses were performed.

**Results:** Fifty-one patients (52.9% F, mean age  $50 \pm 13.8$ ) underwent POEM as a treatment for achalasia in this period, 20 patients with chagasic and 31 with idiopathic etiology. All procedures were posterior full-thickness POEMs. The overall clinical success rate was 92.2%. There was no statistical difference between groups regarding clinical success (90% in the chagasic group vs 93.6% in the idiopathic group,  $p = 0.640$ ). Both groups presented significant reduction in Eckardt score compared to baseline (1.00 vs 7.50 in the chagasic group,  $p < 0.001$ ; and 0.00 vs 8.00 in the idiopathic group,  $p < 0.001$ ), LES pressure (10.32 vs 21.76 in the chagasic group,  $p < 0.001$ ; 10.70 vs 25.21 in the idiopathic group,  $p < 0.001$ ), and increase in BMI (27.11 vs 25.41 in the chagasic group,  $p < 0.001$ ; 25.99 vs 22.17 in the idiopathic group,  $p < 0.001$ ) at 1 year follow-up. There was no statistical difference between groups regarding Eckardt score ( $p = 0.439$ ), LES pressure ( $p = 0.507$ ), and BMI ( $p = 0.254$ ) at 12 months. There were no significant differences between groups concerning the rates of erosive esophagitis (35% vs 44%,  $p = 0.432$ ), adverse events (30% vs 12%,  $p = 0.311$ ), pneumoperitoneum requiring needle decompression (35% vs 35%,  $p = 0.81$ ), operative time (101.3 min vs 99.1 min,  $p = 0.840$ ), and length of hospital stay (3.75 days vs 3.58 days,  $p = 0.622$ ).

**Conclusion:** POEM is an effective and safe treatment in patients with achalasia. There is no difference in outcomes comparing chagasic and idiopathic achalasia.

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic immune/antigen-mediated disorder, characterized by symptoms of esophageal dysfunction and esophageal eosinophilic-infiltration. EoE has been often associated with esophageal motility abnormalities, ranging from hypo- to hyper- contractile motility disorders.

**Aims & Methods:** The aim of this study is to evaluate the incidence and clinical characteristics of esophageal motility disorders in EoE.

97 consecutive patients (mean age 39, range 18-75yo, 20 F) with a diagnosis of EoE assessed in our unit between 2012 to 2018, were included. The diagnosis was posed according to international criteria. Among 97 patients, in 47 (48%) high resolution manometry (HRM) was not performed, so they were excluded from the study. Patients undergone HRM, were studied using the standardised international protocol and manometric diagnoses were made according to Chicago Classification 3.0. For the statistical analysis Fisher exact test was used.

**Results:** Among 50 patients included (mean age 41, range 20-75 yo, 42M), 26 (52%) showed normal manometric pattern. Between EoE patients with pathological pattern, 16 (67%) had hypocontractile disorders, and 8 (33%) had hypercontractile abnormalities. In particular, EoE patients with hypocontractile patterns had frequent failed peristalses (N=4), ineffective esophageal motility (N=6), fragmented peristalsis (N=4), absent peristalsis (N=2). Among EoE patients with hypercontractile patterns, we found achalasia type III (N=2), achalasia type II (N=2), achalasia type I (N=1), EGJ outflow obstruction (N=1), Jackhammer esophagus (N=1), and 1 distal esophageal spasm (N=1).

We then analysed both patients with normal and pathological manometric pattern in terms of age, sex and response to PPI.

**Patients with normal motility** n=26 (52%) showed:

Age (mean and median) 43,4yo; 40,5yo

Age at diagnosis (mean and median) 36,1yo; 33yo

Sex 22M (84,6%)

PPI response (9 of 17) 52,9%

**Patients with motility disorders** n=24 (48%) showed:

Age (mean and median) 37,9yo; 33,7yo

Age at diagnosis (mean and median) 29,2yo; 25yo

Sex 20M (83,3%)

PPI response (7 of 18) 38,9%

Among the group with abnormal motility, the same characterization was done.

**Patients with hypercontractile disorders** n=8 (33%)

Age (mean and median) 41,9yo; 36,2yo

Age at diagnosis (mean and median) 27,2yo; 29,5yo

Sex 6M (75%)

PPI response (2 of 9) 22%

**Patients with hypocontractile disorders** n=16 (67%)

Age (mean and median) 36yo; 32yo

Age at diagnosis (mean and median) 30,4yo; 24yo

Sex 14M (87,5%)

PPI response (5 of 9) 55%

There was no difference in terms of prevalence of motility abnormalities ( $p = 0.49$ ) nor a predominance of hypo/hyper contractile pattern ( $p = 0.14$ ), between PPI responsive/non-responsive patients. Similarly, no difference in terms of motility abnormalities ( $p = 1$ ), nor a predominance of hypo/hyper contractile ( $p = 0.60$ ) were found between females and males. Considering the mean age of the group (39yo), there was a different prevalence of motility abnormalities between younger and older patients, with greater frequency of pathological pattern in young patients ( $p = 0.045$ ). However, there was no difference in terms of frequency of hypo- or hypercontractile disorders between young and old EoE patients ( $p = 0.49$ ).

**Conclusion:** This series shows that esophageal motility abnormalities are present in about half of EoE patients, especially in young subjects who showed a higher prevalence of hypocontractile disorders. A correlation with patient's gender or response to PPI therapy was not observed.

**Introduction:** Eosinophilic oesophagitis (EoE) is a common cause of oesophageal disease in Europe and the USA. Limited data have been reported on its epidemiology in the Russian Federation. The aim of this study was to evaluate the prevalence of EoE in the Russian Federation among adult patients undergoing esophagogastroduodenoscopy (EGDS) due to upper gastrointestinal (UGI) symptoms.

**Aims & Methods:** This study was conducted in 11 endoscopy departments in the Russian Federation (4 in Moscow, 1 in Yaroslavl, 1 in Ivanovo, 1 in Kazan, 2 in Saint Petersburg, 1 in Ekaterinburg, 1 in Kemerovo) between October 2017 and March 2018. We enrolled 49240 patients aged 18 to 80 years old who underwent an EGDS due to UGI symptoms (heartburn, dysphagia, food impaction, acid regurgitation, chest pain, epigastric pain, nausea, vomiting). Patients with endoscopic findings of EoE (oedema, rings, exudates, furrows, and strictures) were underwent oesophageal biopsy (at least 6 biopsies were obtained from the proximal and distal oesophagus to quantify the maximum eosinophil count per high-power field (eos/hpf; hpf=0.24 mm). Patients were diagnosed with EoE if the number of eosinophils was  $\geq 15$ .

**Results:** EGDS revealed endoscopic features of EoE in 137 patients. Oesophageal biopsy confirmed eosinophilic oesophagitis in 62 cases. EoE patients had a mean age of 38.2 years (range 20-67) years, 83.3% of patients were under 45 years of age, 79.1% patients were male. Individuals with EoE suffered predominantly from dysphagia (62.5%), heartburn (54.1%), food impaction (37.5%), and nausea (29.1%). 79.1% of EoE patients had a past history of gastroesophageal reflux disease, 25% suffered from allergic rhinitis, 33.3% had atopic dermatitis, 8.3% asthma. 1 patient had a family history of EoE (his sibling and mother also suffered from dysphagia due to EoE).

**Conclusion:** The prevalence of EoE among adult patients undergoing upper endoscopy in the Russian Federation is 1 case for 794 UGI endoscopies (0.13%). The characteristic findings of EoE patients included male gender, age under 45 years and history of atopic diseases.

**Introduction:** Eosinophilic esophagitis (EoE) is an allergic disorder characterized by a Th2 mediated immune response, esophageal dysfunction and esophageal eosinophilic infiltration. While several genetic, and environmental factors have been implicated in EoE, recent evidence supports a role for the gut microbiome. Abnormalities in the gut microbiome are associated with suppressed Th2 response and predisposition to atopic disease such as asthma and eczema.

**Aims & Methods:** In this study we evaluated the gut microbiome represented in the stool from patients with EoE matched to healthy controls. All human studies were approved by the institutional IRB. Stool bacterial DNA was extracted using MoBio fecal DNA extraction kit, followed by 16S rRNA amplification using primers flanking the V4 hypervariable region (515F, 806R) and sequenced on Illumina MiSeq. Paired sequence reads were processed via the *hybrid-denovo* bioinformatics pipeline. A linear regression model (t-test) was used for testing the association with alpha-diversity after rarefaction to 20,000 reads/sample. Taxa-level association analyses were performed at multiple taxonomic levels. Permutation-based false discovery rate (FDR) control was used to correct for multiple testing on each taxonomic level, and FDR-adjusted p-values or q-values  $\leq 0.1$  were considered significant. All statistical analyses were performed in R 3.4.2.

**Results:** Patients with EoE had a median age of 48 (34-64), body mass index (BMI) was 29.51 (22.40-36.49), 4 were male and all were Caucasian. Only one patient had asthma and one had atopic dermatitis. Six patients were on a regular diet. No patients were on PPIs. The healthy control patients had a median age 51 (33-61), BMI 24.75 (19.73-41.39), 3 were male and all were Caucasian.

We compared the 16S rRNA-based microbial community composition in stool samples from the patients with EoE (n=12) and healthy control subjects (n=12). At the phylum level, we observed a marked decrease in Firmicutes and increase in Bacteroidetes in patients with EoE. The gut microbial communities from patients with EoE were characterized by a lower alpha diversity (species richness,  $p = 0.09$ ; Shannon index,  $p = 0.01$ ; linear regression). The beta-diversity was also significantly different between patients with EoE and healthy controls ( $p = 0.03$ , PERMANOVA based on weighted UniFrac;  $p = 0.04$ , omnibus test combining multiple beta diversity measures). There were significant differences in relative abundance at

multiple taxonomic levels when comparing the two communities, which included significant decreases in *Clostridia* and *Clostridiales* in patients with EoE ( $q \leq 0.1$ , permutation test with t-statistic).

**Conclusion:** This finding is particularly important as previous studies show that members of *Clostridia* group are protective against the development of food allergies in a rodent model. *Clostridia*-containing microbiota is also associated with the expansion of intestinal regulatory T cells, and induction of IL-22 production by ROR $\gamma$ <sup>t</sup> ILCs promoting an immune environment conducive for tolerance to dietary antigens. While our study is limited by the small sample size, the strengths of the study are a lack of confounders that have been associated with altered stool microbiome such as proton pump inhibitors, and other atopic illnesses in most patients. Our findings suggest defined microbial consortia containing *Clostridia* may be a potential therapeutic option in EoE.

**Introduction:** Majority of food bolus obstruction (FBO) is caused by a benign esophageal stricture for which endoscopic dilation is an effective treatment. However, it is unknown whether same-session endoscopic dilation (SSED) after removal of food bolus (FB) is clinically safe.

**Aims & Methods:** To evaluate the safety of performing SSED immediately after FB removal. **Methods:** A randomized controlled study was conducted between 2017-2019 on patients who had FBO due to oesophageal stricture were randomized into 2 groups: (i) SSED group - who had SSED using wire-guided Savary Gillard dilators vs (ii) non SSED group - deferred dilation to another date. Primary outcome measures were technical success, procedural-related complication(s) and mortality.

**Results:** 456 patients had endoscopic removal of food bolus, of which 236 were excluded due to absence of an oesophageal stenosis (n=93), concurrent anticoagulation or antiplatelet (n=136), dilators were not available (n=7). 220 patients were randomized to group SSED (n=110) and non SSED group (n=110). Technical success of dilation and immediate clinical response were achieved in all patients. The median maximal dilation diameter was 14mm (range 11-18mm). Apart from chest pain occurred in 9 (8%) patients immediately after dilation that resolved with simple analgesia, there was no perforation, major bleeding requiring blood transfusion or death. Recurrent of FBO occurred in 41 (18.6%) at a mean time of 31  $\pm$  19 days, and was significantly higher in the non-SSED than SSED group (39 vs. 2;  $P < 0.01$ ).

**Conclusion:** Same-session esophageal stricture dilation after FB removal is safe and significantly reduced the risk of recurrence, preventing repeat admission. Thus, our data support the use of routine use of SSED for patients who present with FBO.

**Introduction:** A 6-week treatment with a novel budesonide orodispersible tablet twice daily (BOT 1mg BID), with a unique mode of delivery and esophageal targeting, was highly effective and safe in the EOS-1 study for induction of clinico-histological remission in adult patients with active eosinophilic esophagitis (EoE) according to standard criteria (1). Here we present in a post-hoc analysis the efficacy of BOT 1mg BID using new, most stringent criteria, e.g., as previously suggested by Greuter et al. (2).

**Aims & Methods:** To assess the efficacy of BOT 1mg BID using most stringent endpoints for the induction of complete normalization of esophageal biopsies, absence of endoscopic abnormalities and absence of clinical symptoms in adult patients with active EoE.

Adults with active EoE (n=88) randomly received 6-weeks double-blind treatment with either BOT 1mg BID (n=59) or placebo BID (n=29).

**A priori defined endpoints were:** Clinico-histological remission: < 16 eos/mm<sup>2</sup> hpf AND ≤2 points on daily numerical rating scales (0-10 points) each for dysphagia and odynophagia on each of the last 7 days

**Histological remission:** peak < 16 eos/mm<sup>2</sup> hpf

**Clinical remission:** ≤2 points on numerical rating scales (0-10 points) each for dysphagia and odynophagia on each of the last 7 days.

**Post-hoc stringently defined endpoints were:**

**Deep clinical remission (2):** '0' points on daily numerical rating scales (0-10 points) each for dysphagia and odynophagia on each of the last 7 days.

**Deep endoscopic remission (2):** modified EREFS subscores: fixed rings = 'Grade 0: none' or 'Grade 1: mild', exudates = 'Grade 0: none', furrows = 'Grade 0: absent', and edema = 'Grade 0: absent'.

**Histological remission (2):** peak < 15 eos/hpf

**Deep histological remission:** '0' eos/mm<sup>2</sup> hpf in all biopsies.

**Deep disease remission (2):** Being in deep clinical AND deep endoscopic AND histologic remission.

**Results:** BOT 1mg BID was highly statistically superior to placebo in achieving all stringently defined clinical, endoscopic, and histological endpoints (see Table).

	Number (%) of patients at week 6 (LOCF)		
	BOT 1mg BID (n=59)	Placebo BID (n=29)	p-value (2-sided)
A priori defined endpoints: Clinico-histological remission	34 (58%)	0 (0%)	< .0001
Histological remission	55 (93%)	0 (0%)	< .0001
Clinical remission	35 (59%)		< .0001
Post-hoc defined most stringent endpoints: Deep clinical remission (2)	15 (25%)	0 (0%)	= .0018
Deep endoscopic remission (2)	34 (58%)	0 (0%)	< .0001
Histological remission (2)	56 (95%)	0 (0%)	< .0001
Deep histological remission	53 (90%)	0 (0%)	< .0001
Deep disease remission (2)	12 (20%)	0 (0%)	= .0072

[Table: Standard & stringent efficacy endpoints]

**Conclusion:** A 6-week treatment with BOT 1mg BID was highly effective for inducing deep histological, endoscopic and clinical remission as well as deep disease remission in adult EoE patients according to most stringent criteria.

**Introduction:** Eosinophilic oesophagitis (EoE) is a chronic inflammatory disease characterised by a dense eosinophilic infiltration of the oesophagus and symptoms of oesophageal dysfunction. EoE is recognized as a particular form of non-IgE-mediated food allergy commonly associated with other IgE-mediated atopies. The novelty of the disease has contributed to a considerable diagnostic delay in many cases and to variable management of patients in clinical practice, who frequently underwent serum and skin allergy testing to find triggering antigens. Recent evidence discourages this practice due to its low yield.

**Aims & Methods:** To investigate delay in EoE diagnosis, number of previous useless endoscopies performed in these patients and unneeded allergy testing (laboratory, skin prick and atopy patch testing) once a EoE diagnosis is established, we searched within the EoE CONNECT database, a prospectively-maintained registry that resulted from the UEG Link Award program.

Patients' data was extracted on 25<sup>th</sup> March 2019. For statistical comparisons, all variables were assessed depending on the date in which the different EoE clinical guidelines were published (2007, 2011, 2013 & 2017). Statistical analyses (Mann-Whitney test and Kruskal-Wallis test followed by Dunn post-hoc test) were performed using GraphPad software.

**Results:** Data from 608 EoE patients recruited at 9 hospitals in Spain and 1 more in Italy were retrieved from the EoE CONNECT registry. From those, dates for both symptoms onset and definitive EoE diagnosis were available for 434 patients. The diagnostic delay resulted in a mean ± standard deviation (SD) of 1778 ± 2411 days (approximately 4 years and 10 months). A significant decrease in diagnostic delay along time was noted, when patients were classified in five groups according to the publication dates of the different EoE guidelines (p< 0.001). Thus, for patients diagnosed up to 2007 the diagnostic delay was 4661 ± 3123 days, while it was only 164 ± 142 days for patients diagnosed after the release of 2017 guidelines. Group comparisons displayed significant differences between most of the periods analysed.

Twenty-eight patients had information on dates of upper endoscopies performed prior to EoE diagnosis. Overall, 37 exams were performed before the one that provided an EoE diagnosis. The number of superfluous endoscopies were higher for patients diagnosed up to 2011 (n=13; 1.6 ± 1.0) compared to those diagnosed after 2011 (n=15, 1.1 ± 0.3) (p< 0.05).

An assessment of allergy tests performed after a diagnosis of EoE as a part of the diagnostic or therapeutic management was performed in 173 patients who had at least one laboratory, skin prick or atopy patch test after the date of diagnosis. The overall number of allergy tests was 348, with a mean  $\pm$  SD of  $2.0 \pm 1.2$  per patient. Three groups of patients were considered for statistical analysis: diagnosis in 2011 or before ( $n=50$ ,  $2.8 \pm 1.5$ ), 2012-2013 ( $n=35$ ,  $1.8 \pm 1.1$ ), and after 2014 ( $n=88$ ,  $1.6 \pm 0.7$ ). Significant reductions in the performance of allergy tests were noted among periods ( $p < 0.001$ ) and for two group comparisons, when diagnosis  $\leq 2011$  vs 2012-2013 and diagnosis  $\leq 2011$  vs  $\geq 2014$  were compared (both  $p < 0.001$ ).

**Conclusion:** Our data demonstrate an increased awareness on EoE over time, with significant reductions in diagnostic delay and number of superfluous endoscopic exams as new clinical practice guidelines were released. The performance of allergy testing for the diagnostic and therapeutic management of EoE reduced significantly. A significant effect towards a proper management of EoE was found for the 2011 guidelines.

**Disclosure:** Nothing to disclose

## P0582 ACHALASIA IS A COMMON FINDING IN PATIENTS WITH EOE UNDERGOING HIGH-RESOLUTION MANOMETRY

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic immune/antigen-mediated disorder, characterized by symptoms of esophageal dysfunction (dysphagia and/or food impaction) and, histologically, by eosinophilic-infiltration. EoE has been associated with various esophageal motility disorders, ranging from hypo- to hyper- contractile motility abnormalities, and more recently achalasia.

**Aims & Methods:** The aim of this study was to assess the incidence of achalasia in patients with EoE, and to evaluate the disease course of EoE after achalasia treatment.

97 consecutive patients (mean age 39, range 18-75 yo, 20 F), with a diagnosis of EoE assessed in our Unit between 2012 to 2018, were included. The diagnosis was posed according to international criteria (presence of typical symptoms of esophageal dysfunction; at least 15 eosinophils per high-power field at mid/proximal oesophagus), excluding other causes of eosinophilia. Among 97 patients, in 47 (48%) conventional manometry (CM) or high resolution manometry (HRM) were not performed and were excluded from the study. Patients who accepted to undergo HRM, were studied by using the standardised international protocol and manometric diagnoses were carried out according to Chicago Classification 3.0.

**Results:** Among the 50 EoE patients (mean age 41, range 20-75 yo, 8 F), 26 (52%) showed normal manometric pattern. Between patients with abnormal manometric pattern, 16 (67%) had hypocontractile disorders, 8 (33%) hypercontractile abnormalities and 5 (21%) had a diagnosis of achalasia. Among them 1 type I achalasia, 2 type II achalasia and 3 type III achalasia were present. 3 was male; 3 received EoE diagnosis in adolescent age, 2 after fifties, with a significant diagnostic delay. 3 had history of allergic disease. The main symptom was dysphagia (4 patients), but also globus, odynophagia and regurgitation were present in some of them. 3 of them showed EREFS score=3, 1 showed value of 4 and 1 value of 5. At the esophagogram 4 of them had narrowed EGJ and 2 of them with dilation of the esophagus, 1 showed delayed esophageal emptying. From a therapeutic point of view, only 2 patients responded to PPI. There was a response to topic steroid therapy in 2 cases, no response in 2 cases, no administration in 1. Considering therapy of achalasia, in 2 cases no treatment was required, in 1 case endoscopic dilation was performed, in 1 case surgery was accomplished and in 1 case endoscopic and then surgical therapy was necessary. Basing on this data, patients was characterized as follows: 2 PPI-responder, 1 refractory EoE, 2 steroid responder EoE

**Conclusion:** This retrospective study of consecutive patients showed that achalasia, is not uncommon in patients with EoE, affecting about 10% of patients of this cohort. No specific subtype of achalasia is associated with

EoE. The high frequency of this association seems to hypothesize a causal link between these two pathologies, whereas all this variability in manometric pattern, epidemiological characteristic and response to therapy, suggests that the relationship is not univocal and that there may be different mechanisms that act independently to determine such association.

**Contact E-Mail Address:** matteoghisa@yahoo.it

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic disease characterized by significant impairing of quality of life (QoL). The EoE-QoL-A (EQA) is a 5-scale, 30-item, self-reported, validated questionnaire for the assessment of QoL in these patients. Data on the usefulness of this questionnaire in clinical practice are lacking.

**Aims & Methods:** The aim of the study is to apply the EQA in a consecutive population of EoE Italian patients, in order to evaluate whether the EQA changes on the basis of histological disease activity and therapeutic response to drug administration.

Thirty patients (7 Female, mean age 33-yo, range 18-75-yo) with a definite diagnosis of EoE, referred to our Unit, were included. The diagnosis was done according to the latest international criteria. Patients were enrolled at outpatient level, at first admission or follow-up, between January 2018 to February 2019. Patients, were evaluated clinically and histologically before (baseline) and after medical therapy (proton pump inhibitors or topical steroid for 8 weeks). At both time points, EoE patients completed the EQA. Histological activity was described as dichotomous parameter: 0 for less than 15 eos/hpf and 1 for more than 15 eos/hpf. Pearson correlation coefficient and paired t test were used for the analysis.

**Results:** At baseline, all patients were histologically active, with a mean value of EQA of  $45.07 \pm SD 32.69$ . After 8 weeks of medical treatment, EQA mean value was  $37.63 \pm SD 28.37$ . A strong significant decrease of EQA score was therefore observed ( $p=0.021$ ). After 8 weeks of medical treatment, 21 patients (70%) achieved histological response. However, no difference in terms of EQA values between histological responders and non-responders, was shown ( $p=0.296$ ). Moreover, no significant EQA changes occurred in non-responder patients, before and after treatment ( $p=0.878$ ). In contrast, EQA significantly improved in histologically responder patients, before and after treatment ( $p=0.013$ ).

**Conclusion:** EQA is a valid, reliable disease-specific tool for the measurement of QoL in adult EoE Italian population. It can facilitate the assessment of therapeutic response and histological remission. Our data confirmed that therapy significantly improves QoL in EoE, mainly when histological remission is achieved. Developing multiple national-language versions of EQA is an important step in the standardization of research protocols and ambulatory management of this disease.

## P0584 USEFULNESS OF REAL-TIME MEASURE OF GASTRIC PH AND STANDARD CLINICAL PARAMETERS TO PREDICT PERSISTENT ACID REFLUX IN A PATIENT TREATED WITH PROTON-PUMP INHIBITORS FOR GASTROESOPHAGEAL REFLUX DISEASE

**Introduction:** Gastroesophageal reflux disease (GERD) is the second commonest GI outpatient diagnosis in the US and has a prevalence reaching up to 30% in many western countries. Proton-pump inhibitors (PPIs) are the mainstay of GERD treatment, however, up to one-third of patients have a poor symptomatic response. PH-impedance is the gold standard to assess whether this is due to persistent acid reflux, however, this test is inconvenient for patients and requires two hospital visits with significant indirect costs. PPIs suppress the acid production in the stomach, hence, gastric acidity might provide important information on pharmacological response to PPIs. EndoFaster is a novel endoscopic adjunct device that uses the gastric juice suctioned during endoscopy to provide a real-time measure of the gastric pH.

**Aims & Methods:** We aimed to assess whether clinical parameters, including real-time gastric pH measure with EndoFaster device, could be useful in predicting persistent acid reflux during PPI therapy and stratify patients for further testing. We prospectively recruited patients with GERD on PPIs that underwent gastroscopy as either initial investigation or surveillance for Barrett's esophagus. All patients filled out a dedicated symptom questionnaire (RDQ) and received their clinically indicated endoscopy with gastric pH analysis by EndoFaster, immediately followed by ambulatory 24-hour pH-impedance. We used a modified cut-off of 1.3% for pathological esophageal acid exposure time (AET). Multiple linear regression models were used to analyze the correlation between AET and predictive variables. The accuracy of gastric pH in predicting persistent acid reflux was calculated.

**Results:** We recruited 122 patients, of which 91 (74.6%) were included in the final analysis [46 male (50.5%), median age 53 years (IQR: 41-65)]. Forty-one patients (45.1%) had persistent acid reflux (AET $\geq$ 1.3%) and were classified as PPI non-responders, and 50 had AET < 1.3% (PPI responders). Median AETs were 2.4 (IQR 1.2-4.9) and 0.1 (IQR 0.0-0.2), respectively ( $P<.001$ ).

There was no difference in age, gender, BMI, PPI-regimen, presence of hiatus hernia and BE, and severity of symptoms between groups. Gastric pH was significantly lower in non-responders as compared to responders [6.2 ( $\pm$ 1.6) vs. 5.3 ( $\pm$ 2.2),  $P=.037$ ] with a mean difference in pH of 0.9 (95%CI 0.06 - 1.73).

Single-point gastric pH significantly correlated with AET ( $P=.042$ ;  $R^2=11.0\%$ ). A pH cut-off of 5.05 had the best diagnostic accuracy in predicting persistent acid reflux on PPIs with a sensitivity and specificity of 39.5% and 85.4%, respectively.

**Conclusion:** Symptoms and clinical characteristics are not useful to predict persistent acid reflux in GERD patients on PPIs. One-point gastric pH is significantly lower in PPI non-responders as compared to responders, and correlates with 24-hour esophageal AET. Endofaster, in association with systematic symptoms assessment, could be used to triage patients for pH-impedance test and should be evaluated in larger trials.

## P0587 GASTROESOPHAGEAL REFLUX DISEASE AND PAROXYSMAL NON-VALVULAR ATRIAL FIBRILLATION - A CASE-CONTROL STUDY

Barboi O.B.<sup>1</sup>, Floria M.<sup>2</sup>, Ciortescu I.<sup>1</sup>, Drug V.L.<sup>3</sup>

<sup>1</sup>Saint Spiridon Hospital Iasi, Gastroenterology, Iasi, Romania, <sup>2</sup>Saint Spiridon Hospital Iasi, Internal Medicine, Iasi, Romania, <sup>3</sup>University of Medicine and Pharmacy "Grigore T Popa", Gastroenterology, Iasi, Romania

**Contact E-Mail Address:** oany\_leo@yahoo.com

**Introduction:** There is still a controversy regarding the relationship between gastroesophageal reflux disease (GERD) and paroxysmal non-valvular atrial fibrillation (AF). Having the same predisposing factors as well as the adjacent anatomical positioning and nerve innervations between esophagus and atria can explain this relationship. The aim of this study was to evaluate the association between GERD and AF.

**Aims & Methods:** A prospective case-control study was conducted at a tertiary care centre from North-East of Romania over a period of 13 months (July 1, 2014 - July 31 2015). We included 135 patients divided in four groups: patients with GERD and paroxysmal non-valvular AF (GERD+AF group), patients with GERD and sinus rhythm (GERD+non-AF group), patients with AF and non-GERD (AF+non-GERD group) and patients without GERD and AF (non-GERD+non-AF group). All patients underwent upper endoscopy, echocardiography, 24-hour electrocardiographic Holter monitoring and lab tests.

**Results:** The 135 patients were divided as follow: 36 GERD+AF patients, 25 GERD+non-AF patients, 39 AF+non-GERD patients and 35 non-GERD+non-AF patients. All groups were homogenous regarding sex distribution and age. Esophagitis increased the relative risk of the association of AF and GERD by 2.5 times ( $p< 0.005$ ). Heart rate variability in terms of time-domain parameter (SDNN) was lower in GERD+AF group patients than the other three groups (69.60 vs 109.33 vs 123.56 vs 12.1,  $p< 0.005$ ). Regarding cardiac ultrasound parameters, median value of left atrial area in the group with GERD and AF patients was statistically higher comparatively with GERD+non-AF group (25.79 $\pm$ 5.13 cm<sup>2</sup> vs 23.88 $\pm$ 5.10 cm<sup>2</sup>,  $p< 0.005$ ). Hypertriglyceridemia was statistically significantly higher in GERD+AF group than in the other groups ( $p=0.005$ ).

**Conclusion:** These results suggest the association of GERD and AF, which is sustained by both the theory of inflammation and of the autonomic nervous system imbalance.

**Disclosure:** Nothing to disclose

## P0588 THE ROLE OF ESOPHAGEAL HIGH-RESOLUTION MANOMETRY IN APPROACH OF GASTROESOPHAGEAL REFLUX DISEASE

Santos A.L.<sup>1,2,3</sup>, Peixoto A.<sup>2,3,4</sup>, Silva J.<sup>2,3,5</sup>, Ramalho R.<sup>2,3,6</sup>, Macedo G.<sup>2,3,6</sup>

<sup>1</sup>Centro Hospitalar de São João, Gastroenterology, Porto, Portugal, <sup>2</sup>WGO Oporto Training Center, Porto, Portugal, <sup>3</sup>Porto Medical School, University of Porto, Porto, Portugal, <sup>4</sup>Centro Hospitalar De São João, Department of Gastroenterology, Porto, Portugal, <sup>5</sup>Joel Ferreira da Silva, Gastroenterology, Sao Felix da Marinha, Portugal, <sup>6</sup>Centro Hospitalar de São João, Porto, Portugal

**Contact E-Mail Address:** anaasantos89@gmail.com

**Introduction:** Recent studies have demonstrated the important role of high-resolution manometry (HRM) in assessment of patients with gastroesophageal reflux disease (GERD) and it is now formally recommended by The Lyon Consensus.

**Aims & Methods:** We intended to relate the findings in HRM with those of 24h pHmetry in patients with GERD.

Retrospective study, with inclusion of patients who were referred to perform 24h pHmetry and submitted to HRM, in a tertiary referral center, between March 2018 and July 2019. Chicago Classification v3.0 and The Lyon Consensus were used for the interpretation of data from the procedures.

**Results:** A total of 49 patients were included, 53% females, with a mean age of 50 $\pm$ 14 years.

In pHmetry assessment, 38% of patients had findings compatible with GERD and 9% with reflux hypersensitivity. Among the referenced patients, 71% presented changes in HRM: 38% esophagogastric junction obstruction (EGJ), 15% hypotonicity of the LES and 5% ineffective esophageal motility (IEM). The presence of IEM was associated with an abnormal pHmetry ( $p=0.040$ ) as well as with the positive symptom association probability (SAP). The median acid exposure times (AET) was 0.7% (IQR 0.2-5.5%)

and the median DeMeester score (DmS) was 3.8 (IQR 1.2-10). HRM was performed after a median time of 5 years (IQR 2-8) after the symptoms' onset. The most prevalent symptom was the heartburn (67%) but regurgitation and chronic cough were those more often associated with reflux in the pHmetry ( $p=0.002$  and  $p=0.014$ , respectively). In 75% of cases there was a previous therapeutic trial with proton pump inhibitor, mostly without clinical improvement (57%); this fact was related with a LES hypotonicity in HRM ( $p=0.018$ ). In 71% of patients, the HRM's findings had an impact in the subsequent patients' therapeutical strategy.

**Conclusion:** The routine performance of a manometric study in patients submitted to a pHmetry allows the identification of motor findings in approximately three-quarters of patients, facilitating the subsequent therapeutic approach.

**Disclosure:** Nothing to disclose

## P0589 CLINICAL APPLICATION OF THE GASTROESOPHAGEAL REFLUX DISEASE QUESTIONNAIRE IN PATIENTS WITH SUSPECTED LARYNGOPHARYNGEAL REFLUX SYMPTOMS

Kim Y.D.<sup>1</sup>, Shin C.M.<sup>1</sup>, Jeong W.J.<sup>2</sup>, Kim N.<sup>1</sup>, Park Y.S.<sup>1</sup>, Lee D.H.<sup>1</sup>

<sup>1</sup>Seoul National University Bundang Hospital, Internal Medicine, Seongnam-si, Korea (Republic of), <sup>2</sup>Seoul National University Bundang Hospital, Otorhinolaryngology, Seongnam-si, Korea (Republic of)

**Contact E-Mail Address:** nskyyd@naver.com

**Introduction:** Gastroesophageal reflux disease (GERD) is one of the most common esophageal diseases in Gastroenterology. Laryngopharyngeal reflux (LPR) is different clinical symptoms that occur simultaneously with GERD.

**Aims & Methods:** To evaluate the usefulness of Gastroesophageal Reflux Disease Questionnaire (GerdQ) in patients with suspected laryngopharyngeal reflux (LPR) symptoms (globus, cough, hoarseness and throat pain). A total of 111 patients with suspected LPR symptoms were incorporated from either

otorhinolaryngology or gastroenterology clinic. Patient's laryngoscopic findings were graded by reflux finding score (RFS,  $n = 98$ ), and  $RFS \geq 7$  was considered as positive LPR. Patient's LPR symptoms were evaluated using reflux symptom index (RSI). Erosive esophagitis by endoscopy ( $n = 111$ ) or abnormal results on 24-hr multichannel intraluminal impedance-pH (MII-pH) testing ( $n = 111$ ) were used as diagnostic references for gastroesophageal reflux disease (GERD). Esophageal motor function

was evaluated using high resolution esophageal manometry (HREM,  $n = 111$ ); distal contractile integral (DCI)  $< 450 \text{ mmHg} \cdot \text{cm} \cdot \text{s}$  or fragmented peristalsis (defect  $> 5 \text{ cm}$ ) or absent peristalsis was considered as esophageal hypomotility.

**Results:** Ninety-one of 98 (92.9 %) subjects were diagnosed as LPR but only 17 of 111 (15.3 %) had GERD. For GerdQ, the cutoff value of 9 showed the highest area under curve (AUC) by receiver operating curve (ROC) analysis (AUC = 0.616); the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 52.9 %, 70.2 %, 24.3 % and 89.2 %, respectively. For RSI, the cutoff value of 13 showed the highest diagnostic yield (AUC = 0.654); the sensitivity, specificity, PPV and NPV were 75.3 %, 40.0 %, 95.9 % and 8.0 %, respectively. In patients with GERD ( $n = 17$ ), both distal and proximal baseline impedance levels (3 cm and 15 cm above esophagogastric junction, respectively) were decreased ( $p < 0.05$ ) and proximal extent of reflux were increased ( $p < 0.001$ ). However, there was no difference in esophageal body motor function between patients with or without GERD ( $p > 0.05$ ).

**Conclusion:** GERD is infrequent among patients with suspected LPR symptoms. In this population, the sensitivity of GerdQ is low thus GerdQ has a limited role in GERD diagnosis.

**Disclosure:** Nothing to disclose

## P0590 MNBI IS A BETTER MARKER OF OESOPHAGEAL DISEASE SEVERITY COMPARED TO USING TOTAL ACID REFLUX

Abdul-Razakq H., Raeburn A., Patel K., Emmanuel A., Zarate N., Sweis R. University College London Hospital, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rami.sweis@nhs.net

**Introduction:** The Lyon Consensus 2018 describes mean nocturnal baseline impedance (MNBI) as a possible measure of oesophageal mucosa permeability, with lower values associated with damage; however MNBI has not yet entered routine clinical practice. This study aims to determine the relationship of MNBI across three common presentations of reflux; Barrett's oesophagus, NERD and functional heartburn (FH).

**Aims & Methods:** Standard pH-Impedance measurements as well as symptom index (SI) were acquired for all patients. The impedance channel at 3cm was used to calculate MNBI by averaging 3 nocturnal 10 minute intervals 1hr apart. Consecutive tracings between 2014 and 2016 for 3 reflux subgroups were analysed; 22 Barrett's Oesophagus (13 on proton pump inhibitors; PPI), 26 NERD and 26 FH. Results are presented as median (IQR; interquartile ratio). Comparisons were made using Kruskal-Wallis test and Mann-Whitney U test as appropriate. Correlations were performed using Spearman's correlation coefficient.

**Results:** There was no significant difference in total reflux (TR) between patients with Barrett's (median TR 11.2%(2.5%,18.7%) and NERD (8.1%(5.5%,12.9%) ( $p=0.497$ ). The difference with FH (TR 22%(12%,34%) is defined by the entry criteria ( $p < 0.0001$ ). SI was significantly lower in Barrett's (SI 4%(0%,25.6%) than NERD (30%(0%,45.2%) ( $p=0.48$ ), but not FH (0%(0%,7.9%) ( $p=0.129$ ).

There was no statistically significant difference in MNBI between Barrett's while on or off PPIs ( $p=0.556$ ). There was also no difference in MNBI between 9 patients with persistent Barrett's who had attempts at ablation therapy compared to the 13 who had not ( $p=0.96$ ). Using the Kruskal-Wallis test, there was a significant difference observed in MNBI between all 3 categories of reflux ( $p < 0.0001$ ). Specifically, there was a difference in patients with Barrett's (median MNBI 429.5Ω(293Ω,950Ω) compared to NERD (1160Ω(964.5Ω,2764Ω) ( $p=0.003$ ) and FH (3355Ω(2866.5Ω,3809.25Ω) ( $p < 0.0001$ ). There was also a significant difference in patients with NERD compared to FH ( $p < 0.0001$ ).

There was a moderately inverse correlation between Barrett's segment length (median 6cm(3cm,10cm) and MNBI ( $r = -0.436$ ;  $p=0.038$ ).

**Conclusion:** In keeping with the published literature, this study shows that severity of reflux disease, as measured by ambulatory pH-impedance monitoring, was not dissimilar between Barrett's oesophagus and NERD, while symptom burden was greater in NERD. On the other hand, MNBI can differentiate between the disease states despite the reduced symptom burden. Also, it correlates with the degree of mucosal damage associated with Barrett's regardless of PPI use or previous therapy. MNBI may be a better marker of reflux disease severity than standard pH measurements.

**Disclosure:** Nothing to disclose

## P0591 A RE-ASSESSMENT OF UPPER ABDOMINAL SYMPTOMS BASED ON 24-HOUR PH TESTING

Holzswanger E.<sup>1</sup>, Gladney D.<sup>2</sup>, Liu D.<sup>1</sup>, Marya N.<sup>3</sup>, Cave D.<sup>4</sup>

<sup>1</sup>UMass Memorial Medical Center, Internal Medicine, Worcester, United States, <sup>2</sup>UMass Memorial Medical Center, Gastroenterology, Worcester, United States, <sup>3</sup>UCLA Medical Center, Medicine-Gastroenterology, Los Angeles, United States, <sup>4</sup>University of Massachusetts Medical School, Medicine-Gastroenterology, Wayland, United States

**Contact E-Mail Address:** drdcave@gmail.com

**Introduction:** Differentiating functional dyspepsia (FD) from gastroesophageal reflux disease (GERD) by symptoms continues to remain a challenge. It has been thought that symptoms including upper abdominal pain, nausea, bloating correlates more with a diagnosis of functional dyspepsia whereas burning chest pain after eating and worse with lying down is thought to be more related to GERD. We analyzed the relationship of symptoms to 24 pH measurements to help better differentiate between FD and GERD based on symptoms.

**Aims & Methods:** We performed a prospective study at one center involving 124 patients who have been experiencing various types of upper GI symptoms from 2015-2018. A survey was given to each patient to record

whether they had what was thought to be symptoms of GERD (burning, upward abdominal pain, ascending chest pain, awakened by symptoms) vs. symptoms of FD (intermittent, non-radiating upper abdominal pain, nausea, vomiting, bloating). Each patient then had a Bravo 24-hour pH study and De Meester scores were recorded to serve as the gold standard. Univariate analyses, including chi square and Fisher exact test, and multivariate logistic regression was done.

**Results:** There was a total of 124 patients, 80 women and 44 men, with a mean age of 52.97 years were recruited. There were 113 Caucasians, 7 Hispanics, 3 Asian Americans, and 1 African American. Mean BMI was 30.73. Mean De Meester score was 31.71. Most symptoms were found to be not clinically significant for evaluation of GERD vs. FD, apart from radiating upward pain as a negative predictor of true GERD ( $p=0.006$ ) and intermittent nature of pain as a positive predictor of true GERD ( $p=0.001$ ). From here, an equation was formulated incorporating this data: (Ascending pain  $\times -1.51$ ) + (Intermittent pain  $\times 1.89$ ) and a ROC curve was developed (graph 1) with ROC area of 0.76 with sensitivities and specificities listed in table 1.

Cutpoints on ROC curve	Sensitivity (%)	Specificity (%)	Correctly Classified (%)	Positive Likelihood Ratio	Negative Likelihood Ratio
$\geq -1.51$	100	0	18.26	1	
$\geq 0$	85.71	32.98	42.61	1.2789	0.4322
$\geq 38$	76.19	61.7	64.35	1.9894	0.3859
$\geq 1.89$	57.14	91.49	85.22	6.7143	0.4684
$> 1.89$	0	100	81.74		1

[Table 1: Sensitivities and specificities of GERDYS equation]

**Conclusion:** This study revealed that most "classic" symptoms of GERD and FD cannot truly differentiate between the two. Using our GERDYS equation as above can help support one diagnosis vs. the other with the understanding that overlap of these conditions occurs. This also demonstrates the necessity of performing pH studies on any patient presenting with symptoms that could be concerning for either or concurrent disease processes. The importance of differentiating the two lies in the differing treatment of each disorder. Ultimately, this study acts as a stepping stone in better differentiating GERD from FD and in the future will help promote a decrease in the inappropriate use of proton pump inhibitors in the community and improve patient care as well as reduce costs.

**Introduction:** The novel metrics from pH-impedance monitoring, postreflux swallow-induced peristaltic wave (PSPW) index and the mean nocturnal baseline impedance (MNBI) appear particularly useful for the diagnosis of gastroesophageal reflux disease (GERD). The threshold values for PSPW index and MNBI are 61% and 2292  $\Omega$  respectively.

**Aims & Methods:** We aimed to evaluate the power of PSPW index and MNBI to predict PPI response in patients with extra-esophageal syndrome. We enrolled 44 consecutive patients (M/F 19/25, mean age 48.8 $\pm$ 14.3 yrs, BMI 24.7 $\pm$ 5.6). The predominant symptoms were hoarseness (76.1%), globus (73.9%) chronic cough (63%), sore throat (60.9%), throat discomfort (43.3%) and heartburn (38.6%). They underwent EGD according to Los Angeles classification. Off-medication pH-impedance was performed.

**Results:** According with the pH-impedance results GERD was confirmed in 17 out of 44 pts (group GERD) and 27 subjects resulted negative for reflux (group No-GERD). Upper endoscopy showed erosive esophagitis in 7 out of 44 pts (15.9%). Acid refluxes were significantly higher in group

GERD (26.8 $\pm$ 19) than in group No-GERD (10.4 $\pm$ 8.3) ( $p=0.0003$ ). Weakly acid refluxes didn't differ between the two group (group GERD 14.4 $\pm$ 12.8 vs. group No-GERD 9.6 $\pm$ 6,  $p=0.099$ ). PSPW index and MNBI had shown a significantly lower value in group GERD (MNBI 1660.6 $\pm$ 489  $\Omega$ ; PSPW index 36 $\pm$ 16.8%) than in group No-GERD (3222 $\pm$ 671.2  $\Omega$ ; PSPW index 73.4 $\pm$ 11.8%) ( $p < 0.0001$ ).

PPI response was higher in group GERD than in group No-GERD for both heartburn (10/17 group GERD vs 1/27 group No-GERD) and extra-esophageal symptoms (11/17 group GERD vs 1/27 group No-GERD) ( $p < 0.0001$ ).

Patients with a positive response to PPI, regardless of group which they belonged, had lower MNBI and PSPW index values (MNBI  $p=0.003$ ; PSPW index  $p=0.003$ ).

**Conclusion:** The evaluation of PSPW index and MNBI showed statistically significant differences between GERD and No-GERD patients and between PPI responders and PPI non-responders. MNBI and PSPW index are the best parameters to identify patients with GERD and the response to PPI therapy, underlying the importance of evaluation in clinical setting of patients with GERD.

**Introduction:** Early detection of adenocarcinoma in the esophagus is essential for curative treatment. Targeted and random biopsies are the standard in diagnostic gastroscopy. This approach is time consuming and results are depending on endoscopists experience.

**Aims & Methods:** The aim of the study was to investigate the diagnostic value of impedancespectroscopy in Barrett's esophagus. We developed a pencil probe with eight golden electrodes for impedance measurement from 100 Hz to 1MHz. Immediately after endoscopic resection of esophageal neoplasia in Barrett's esophagus, the specimen was pinned on cork. Subsequently the tissue was measured in 10 different electrode combinations and after that ink- marked for further pathological assessment.

**Results:** From February 2017 to February 2018, 47 patients (45♂, 2♀) with 87 measurements were included. The mean age of patients was 66y (min 48y to max 91y). Measurement from 58kHz to 119kHz showed significant ( $p < 0.005$ ) difference in impedance to distinguish between Barrett's mucosa and high-grade intraepithelial neoplasia / adenocarcinoma. A cut-off value of  $> 291 \Omega$  (at a frequency of 58kHz) showed a sensitivity of 81% by ROC-analysis. However, the specificity remains low at 41%.

**Conclusion:** Impedancespectroscopy has the potential as a screening tool for Barrett's neoplasia. Further development for an in-vivo model are necessary to proof this novel diagnostic tool.

**Introduction:** Barrett's esophagus (BE) is defined as the replacement of squamous epithelium in the distal esophagus with metaplastic intestinal columnar epithelium and develops because of chronic inflammation resulting from gastroesophageal reflux disease. BE is associated with an increased risk of developing esophageal adenocarcinoma (EAC). Experimental, clinical and immunohistochemical studies show that one of the

factors in the pathogenesis of esophageal injury, BE and EAC is duodenal reflux and the associated synergistic damage to the esophagus by bile acid (BA) and gastric acid reflux. Oxidative stress secondary to bile acids (BAs) exposure has been associated with metaplastic degeneration of normal esophageal mucosa into BE cells and eventually EAC.

At the current time, a diagnosis of Barrett's esophagus can only be made using endoscopy and detecting a change in the lining of the esophagus. The definitive diagnosis of Barrett's esophagus requires biopsy confirmation of the change in the lining of the esophagus.

The Prague classification system is universally accepted standardized endoscopic grading system for BE and uses the "C" value as the "circumferential extent" and the "M" value as "maximal extent" of BE above the gastroesophageal junction in centimeters for endoscopic standardization of BE lengths.

**Aims & Methods:** We studied the content of selected BAs in saliva samples in a cohort of 15 patients with endoscopically and histologically proven BE (Prague Classification C: 1-10, M: 2-13) and a control group consisting of 10 subjects without known medical history or treatment for GERD or BE at least in the last 5 years. Concentration of major salivary BAs (glycocholic acid, glycodeoxycholic acid, and glycochenodeoxycholic acid) in saliva were analyzed using high-performance liquid chromatography-mass spectrometry (HPLC-MS) detection.

Saliva samples were collected from healthy individuals and patients with BE during the day, but all subjects were asked not to eat, drink nor brush their teeth at least 3 hours before sampling. Afterwards were samples stored at -80 °C.

Before the measurement saliva samples were let to thaw at room temperature. After that 900 µl of MeOH was added to 300 µl of saliva sample for protein precipitation. This mixture was vortexed, sonicated and centrifuged and 1 mL of the supernatant was transferred to a new vial. Supernatant was dried under stream of nitrogen. Dried sample was re-dissolved in 300 µl of 80% MeOH, vortexed, sonicated and the supernatant was analyzed by HPLC-MS. The analysis was completed under 4 minutes.

**Results:** We compared the concentrations of selected BAs in both groups of patients, and we found significantly increased concentrations of glycochenodeoxycholic acid ( $p < 0.01$ ) in the group of patients with BE. Significantly better statistical differentiation of samples was observed by using principal component analysis, especially in patients with high C and M values of BE length by Prague classification.

**Conclusion:** Analysis of selected bile acids in saliva by HPLC-MS appears to be a potential new non-invasive diagnostic method for detection of Barrett's esophagus and for estimation of its severity. HPLC-MS is a highly sensitive method to measure low amounts of bile acids in human saliva. The analysis is fast, but the sample preparation is more complicated. Further refinement of this new diagnostic method is needed.

**Contact E-Mail Address:** maria.mangano@asst-ovestmi.it

**Introduction:** Barrett's esophagus (BE) is defined as the presence of columnar metaplasia in the lining of the distal esophagus instead of squamous epithelium. This condition represents a factor that predispose to esophageal adenocarcinoma, neoplasia significantly incremented in the last decade. BE, a known precursor, has a high prevalence but only few patients with this condition progress to malignancy. Surveillance and screening programs are controversial and lack proven efficacy.

**Aims & Methods:** The aim of this retrospective analysis was to establish the prevalence of BE and related complications (dysplasia and adenocarcinoma appearance) by reviews the database of consecutive patients presenting in our Endoscopy Unit from January 1997 to March 2019 for upper endoscopy.

We retrospectively assessed 148.000 the endoscopic reports of 63.994 outpatients seen in our Endoscopy Unit from January 1997 to March 2019, evaluating the prevalence of BE and analyzed the demographic (sex, age) and endoscopic findings (BE extension). Collaterally we evaluate in BE

population the presence of hiatal hernia and Hp infection. In 1428 cases the endoscopist described the presence at the distal esophagus of columnar epithelium (suspected BE) and in this group the pathologist confirmed in 690 the presence of BE (defined histologically as replacement of the normal squamous epithelium of the distal esophagus by columnar epithelium containing intestinal metaplasia). The presence of short Barrett (< 1cm) it was not considered in the analysis, because the risk of progression to high grade dysplasia or esophageal adenocarcinoma seem very low in this subset of patients.

**Results:** The Database analysis shows that the prevalence of Barrett's esophagus in our endoscopic population in the last twenty years was 1,07%. The mean age of patients with Barrett's esophagus at the diagnosis was 57 year (range 17-96 yr) and the male sex was prevalent (435 vs 256). The extension of columnar epithelium, measured in accord to Prague Classification (M Prague score) (Pearson's correlation coefficient for the relationship  $r = -0,0007$ ) and the presence of hiatal hernia ( $r = 0,013$ ) weren't independently associated with Barrett's esophagus. The prevalence of Hp infection in patients with BE was 14,2%.

In all cases with progression to malignancy, the extension of metaplastic epithelium was >3 cm (long BE).

**Conclusion:** In our population the overall prevalence of BE was 1,07 % with predominance of male sex, middle age and gastroesophageal reflux symptoms as suggested by the high prevalence of hiatal hernia. Our data confirmed also that the appearance of dysplasia or adenocarcinoma is related to BE extension, regarding only the cases of long Barrett. This suggest that in the next years the surveillance programs, also in terms of cost-effectiveness, will be to differentiate and ask in this direction.

**Introduction:** Barrett's esophagus (BE) is a premalignant condition of esophageal epithelium caused by gastroesophageal reflux disease (GERD). Thus, several in vivo animal and in vitro models of GERD and BE were developed. However, clinical relevance of each of them implemented separately was considered to be questionable.

**Aims & Methods:** Therefore, we aimed to select appropriate translational molecular expression markers comparing particular genes expression profile observed in clinical biopsies derived from BE patients, animal surgical model and in vitro model of GERD involving human derived esophageal cell lines, optimizing this in vitro model to reflect as much as possible these molecular alterations observed clinically.

Gene Expression Omnibus 2R (GEO2R) tool and GSE34619, GSE1420, GSE13083 database were used to select up/downregulated genes in human BE: KRT1, KRT4, KRT5, KRT7, KRT8, KRT14, KRT15, KRT18, KRT19, KRT20, MUC2, MUC5ac, MUC6, MUC3, TFF1, TFF2, TFF3, VILL1. 2. Male Wistar rats underwent microsurgical procedure to generate duodeno-esophageal anastomosis leading to the development of metaplasia after 12 weeks in 70% of animals.

Esophageal biopsies were collected to assess mRNA expression for abovementioned genes using TaqMan probes and real-time PCR only in samples with confirmed microscopically metaplasia development. We also determined whether Barrett's esophagus (BE) - specific mRNAs are regulated in squamous esophageal epithelial (HET-1A) and esophageal keratinocytes (EPC2-hTERT) human cell lines after exposure to hydrochloric acid and bile mixture (BA). EPC2-hTERT and HET-1A cells were exposed for 30 minutes to the medium adjusted to a pH of 7.0 or 5.0 using HCl together with BA or separately mixture at increasing concentrations

(0-600  $\mu$ M). Concentration range was determined by cell viability MTT assay (50% inhibitory concentration (IC<sub>50</sub>) = 1250  $\mu$ M for pH 7.0; IC<sub>50</sub> = 65  $\mu$ M for pH 5.0). The BA mixture consisted of 25% deoxycholic acid, 45% glycocholic acid and 30% taurochenodeoxycholic acid. The treatment was implemented one time or repeated daily during one week. After the treatment period, the cells were harvested and RNA was isolated and mRNA expression for abovementioned genes was determined by real-time PCR using TaqMan probes.

**Results:** Changes in mRNA level were observed only for KRT genes in EPC2-hTERT cell line (up regulation of KRT7, KTR18 and KRT19; down-regulation of KRT4, KRT5, KRT14 and KRT15) in acidic medium with the BA concentrations close to IC<sub>50</sub>. In HET-1A cell line BA treatment slightly up-regulated MUC2, KRT8, KRT19 and down-regulated KRT15. Alterations in gene expressions in both investigated cell lines are consistent with gene expression profiles in human BE.

We conclude that in contrast with single treatment, one-week treatment with BA and HCl mixture in concentrations close to IC<sub>50</sub> is able to induce BE specific factors in EPC2-hTERT cell line. In animal model of BE, KRT-4, KRT-8, KRT-15, KRT-18, KRT-20, MUC-2, MUC-6, MUC-13, TFF-2, VILL-1 mRNA expressions were modulated in the manner observed in human BE.

**Conclusion:** We conclude that one week of daily treatment of EPC-2 or HET-1A cells with 100  $\mu$ M of BA in pH= 5.0 reflects the most efficiently molecular profile of human BE. Moreover, we conclude that animal model of GERD (12 weeks) modulates expression profile reflecting in about 80% these alterations observed in human BE. We assume that combination of these two experimental BE models is relevant to be implemented in further pharmacological studies testing possible novel therapeutic targets of this disorder.

## P0597 ALCOHOL AND SMOKING INFLUENCE IONTRANSPORTER MECHANISMS OF GUINEA PIG ESOPHAGEAL EPITHELIAL CELLS, CP-D DYSPLASTIC BARRETT'S CELL LINE AND OE-33 ADENOCARCINOMA CELL LINE

Becskeházi E., Gál E., Székács I., Rábóczki B., Venglovecz V.  
University of Szeged, Department of Pharmacology and Pharmacotherapy, Szeged, Hungary

**Introduction:** Several clinical studies indicate that alcohol and smoking predispose the consumers to esophageal inflammatory and malignant diseases, but the cellular mechanism is not completely clear. Iontransporters play an important protective role in the esophageal epithelial cells (EECs), however the effect of ethanol (EtOH) and smoking on them is not known. Our aim in this study was to examine the effect of EtOH and smoking on the esophageal epithelial iontransport mechanisms.

**Aims & Methods:** EECs were isolated from guinea pig after an enzymatic digestion. Changes in pH<sub>i</sub> were measured using a fluorescent dye, BCECF-AM. For the determination of the starting pH the high-K<sup>+</sup>/nigericin method was used. Total buffering capacity of EECs was measured by the NH<sub>4</sub> pulse technique. The effect of EtOH (0.1, 1 and 10% vol) and cigarette smoke extract (CSE) (1, 10, 100  $\mu$ g/ml) on Na<sup>+</sup>/H<sup>+</sup> exchanger (NHE) activity was estimated by the NH<sub>4</sub>Cl pulse technique. CP-D and OE-33 cells were treated with various concentrations of EtOH and CSE for 6 and 24 hours. Total mRNA was isolated and transcribed to cDNA. mRNA expression of NHE1 was detected using qPCR.

**Results:** We have improved an EEC isolation technique which allows the functional characterization of these cells. The resting pH of the EEC preparation was 7.59±0.011. EtOH dose-dependently decreased the pH<sub>i</sub> of both guinea pig EECs and OE33 cells and also the activity of NHE. 1-hour incubation with CSE increased the NHE activity in EECs, but decreased it in CP-D cells. 6-hour incubation of OE33 cells with CSE and EtOH increased, whereas 24-hour incubation with these agents decreased the mRNA expression of NHE. Interestingly, combination of EtOH and CSE induced the most robust effect in the expression of NHE. In CP-D cells, alteration of NHE1 expression was not significant.

**Conclusion:** We optimized an EEC isolation technique by which the ion-transporter activity of EECs can be investigated. Our results have shown that alcohol induces acidosis and significantly impairs NHE function thus decreases the defensive mechanisms. As a result of CSE incubation, NHE

activity rises, which can be a compensatory reaction for this toxic agent. In order to estimate the importance of these results in the pathology of inflammatory esophageal diseases further investigations are needed.

**Contact E-Mail Address:** mpbrzozo@cyf-kr.edu.pl

**Introduction:** Barrett's esophagus may develop after an irritation in the lining of the esophagus caused by chronic gastrointestinal reflux into the esophagus. The long exposure to mixed reflux of the gastroduodenal contents can predispose to chronic esophagitis and premalignant Barrett's esophagus. Histamine H<sub>2</sub>-receptor antagonists and proton pump inhibitors (PPI) are effective against esophageal reflux but efficacy of L-tryptophan, an essential amino acid considered as melatonin precursor from pineal gland in experimental rat model of Barrett's esophagus has not been fully clarified.

**Aims & Methods:** We determined whether the treatment with L-tryptophan which is considered as the precursor of melatonin, can reduce the mucosal damage induced by chronic reflux esophagitis progressing into Barrett's esophagus in rat model which resembles human Barrett's esophagus. Eighty rats prepared with esophagogastrroduodenal anastomosis (EGDA) with or without pinealectomy (removal of pineal gland) resulting in chronic esophagitis were randomly divided into 4 groups treated i.g. daily either with: 1) vehicle 2) L-tryptophan (200 mg/kg-d i.g.) or melatonin (20 mg/kg-d i.g.) applied alone or combined with luzindole, the antagonist of Mel1 receptor, 3) PPI pantoprazole (10 mg/kg-d) or H<sub>2</sub>-receptor antagonist, ranitidine (30 mg/kg-d). At 4 months, the macroscopic and microscopic lesion score, the esophageal blood flow (EBF) was determined by H<sub>2</sub>-gas clearance method, and plasma levels (ELISA) of TNF- $\alpha$  and IL-1 $\beta$  and , and mucosal expression of COX-2, EGF and EGFR mRNA was evaluated by RT-PCR.

**Results:** Macroscopic and microscopic chronic esophagitis was developed in all EGDA animals followed by a decrease in the EBF and the significant rise in the plasma TNF- $\alpha$  and IL-1 $\beta$  levels. Extensive esophageal ulcerations with development of columnar epithelium and formation of mucus glands in squamous epithelium, intestinal metaplasia distant to anastomosis were observed. Pinealectomy, which blunted the plasma melatonin levels, aggravated the damage score and significantly decreased EBF compared with vehicle-control animals. Treatment with L-tryptophan or melatonin significantly reduced the LI by 45% and 39%, respectively, while causing a significant rise in the EBF.

These beneficial effects of melatonin and L-tryptophan were significantly abrogated by co-treatment with luzindole. The expression of COX-2, EGF and EGFR mRNAs were absent in the esophageal mucosa of sham-control animals but strongly upregulated in metaplastic Barrett's epithelium and this effect was significantly decreased by treatment with L-tryptophan, melatonin, or standard antisecretory agents pantoprazole or ranitidine. Concurrent treatment with the COX-2 inhibitor celecoxib significantly reduced the L-tryptophan and melatonin-induced damage to esophageal mucosa in EGDA rats.

**Conclusion:** The development of chronic reflux esophagitis in experimental rat model of esophageal injury resembling Barrett's esophagus in humans is associated with severe morphology changes, an impairment of EBF due to excessive release of TNF- $\alpha$ , IL-1 $\beta$  and PGE<sub>2</sub>, overexpression of COX-2, EGF and its receptor, 2) treatment with L-tryptophan or melatonin acting on Mel2 receptors exert beneficial effect in Barrett's esophagus via the suppression of the release of TNF- $\alpha$  and IL-1 $\beta$  and attenuation of mRNA ex-

pression of COX-2, EGF, and its receptor in esophageal mucosa, and 3) acid suppressive drugs such as pantoprazole, could be useful as the therapeutic option in the treatment of Barrett's esophagus.

**Disclosure:** Nothing to disclose

**Introduction:** Improved diagnostic tools to dissect the risk factors that drive the transition from normal epithelium to Barrett's Esophagus (BE) and Esophageal Adenocarcinoma (EAC) represent a clear need for new therapeutic alternatives. Gut microbiota exerts a crucial role in health, as well as in several gastrointestinal diseases and in various types of cancers.

**Aims & Methods:** The aim of our study was to characterize esophageal microbiota composition and the microbiota-related functional predictions in patients with BE and EAC. A total of 26 patients was enrolled on the base of specific including and excluding criteria: 10 without any endoscopic sign of pathological mucosa at the gastroscopy, as control group (1:1 ratio according to PPI use); 10 with a new diagnosis of BE (1:1 ratio according to PPI use); and 6 with a new diagnosis of distal esophageal/esophagogastric junction cancer, confirmed histologically. Genomic DNA was extracted from distal esophagus biopsies obtained during gastroscopy and V3-V4 regions of the 16S rRNA gene were sequenced by MiSeq Illumina platform. In patients with BE, biopsies were obtained from both the esophageal metaplastic lesion (BEM) and the normal esophageal mucosa (BEU).

**Results:** BE and EAC patients showed a higher level of biodiversity. BEU samples showed significant higher values of  $\alpha$ -diversity when compared with control patients, while BEM shared similar values with EAC, being lower than BEU and higher than control patients. A substantial divergence on the first axis was registered for unweighted Unifrac with control patients significantly separated from BEU and EAC. A lower level of Firmicutes and a significantly higher percentage of Bacteroidetes in BEU and EAC compared with control subjects was assessed. BEU and BEM exhibited a significantly higher presence of Fusobacteria compared with controls. Streptococcus relative abundance showed a progressive significant reduction in the disease spectrum from controls to EAC. Veillonella exhibited a gradual abundance increase in this spectrum. Porphyromonas and Prevotella resulted consistently higher in BEU, and in both BEU and EAC, respectively, compared with controls. Actinobacillus was significantly higher in both BEU and BEM compared with controls and EAC. Fusobacterium and Leptotrichia levels were consistently increased in BEU and in both BEU and BEM, respectively, when compared with controls. Patients with EAC showed significantly upregulated microbial genes related to energy metabolism, metabolism of cofactors and vitamins, cellular processes and signaling, while immunologic system disease and apoptosis pathways were consistently down-regulated compared with controls. Microbiota associated to BEM was characterized by a high potential for replication and repair, genetic information processing, metabolism of cofactors and vitamins, energy metabolism, amino acids, nucleotides, lipids and gly-

can metabolisms compared with controls. When compared EAC and BEM samples, EAC-associated microbiota showed a significantly increased amino acid and energy metabolism with a decreased apoptosis pathway compared with BEM group.

**Conclusion:** Overall, these data describe a specific microbial signature for both BE and EAC with a consequent functional impact on esophageal mucosa metabolism and open new horizons towards the identification of potential risk factors and innovative diagnostic/therapeutic tools.

**Introduction:** Early diagnosis of squamous cell carcinoma (SCC) in digestive tract including oral, pharynx to esophagus is difficult under current imaging tool. Microvascular change, like intrapapillary capillary loop (IPCL) observed by magnifying endoscope with narrow band imaging (NBI), is the most important key to differentiate benign and early malignant lesion of these area. However, the operation of the scope is sometimes difficult and limited by anatomy, especially in oral cavity. The judgment of IPCL morphology is also subjective and needs learning curve. Optical coherence tomography (OCT) is a new optical imaging system with characteristics of non-contrast, non-contact, high resolution and 3D imaging. In our published study, the morphology of IPCL presented by the OCT angiography is similar to endoscopic imaging and can be a diagnostic marker for early SCC. In addition to the IPCL, OCT angiography can further image deeper submucosal vessels and quantify these microvascular changes. The aim of this pilot study is to quantify the microvascular change to diagnose the early SCC in mice model.

**Aims & Methods:** 12 weeks 4NQO induction was done to produce tongue SCC in mice model. The OCT imaging was performed every month after induction to observe different stage of carcinogenesis, including hyperplasia, dysplasia, carcinoma in situ to early SCC. The mice was sacrificed after OCT imaging and the induced lesion was sent for histology. The histological results were classified into three stages: normal (control mice), hyperplasia to low-grade dysplasia and high-grade dysplasia to early SCC. Three microvascular parameters of OCT angiography including density, diameter and tortuosity were analyzed and were compared between different stages

**Results:** Total seventeen lesions were analyzed. Among them, three lesions were normal, nine lesions were hyperplasia to low-grade dysplasia and five lesions were high-grade dysplasia to early SCC. It is easy to identify the tumor area on en-face microvascular mapping because change of microvascular pattern. After quantification, significant increased microvascular density ( $p < 0.05$ ) and diameter ( $p < 0.01$ ) is seen in high-grade dysplasia to early SCC than other stages. But the change of tortuosity is not significant between high grade-dysplasia to early SCC than hyperplasia to low-grade dysplasia.

**Conclusion:** Like morphology of IPCL, the change of microvascular density, diameter and tortuosity can be a marker to diagnose early SCC. This is a first study to mapping this microvascular change en-face and quantify it in diagnosing SCC. These "quantified and objective markers" may be an automatic tool for diagnosing SCC in the future.

**Introduction:** Endoscopic submucosal dissection (ESD) is a widely recognised treatment for superficial esophageal squamous cell carcinoma (SCC). However, reports from European centres on this endoscopic technique remain scarce and most of the available data still originates from Japanese series.

**Aims & Methods:** The aim of our study is to present the results and evaluate the efficacy and safety of ESD treatment for superficial oesophageal SCC in one European academic tertiary center.

We performed a single-center systematic prospectively collected registry, including all the patients with superficial oesophageal SCC treated by ESD from March 2016 to November 2018. Our main outcomes were: R0 resection (defined as vertical and lateral margins clear from carcinoma or dysplasia), curative resection (an en-bloc R0 resection with histology no more advanced than pT1a m2 SCC, with no lymphovascular invasion and no poor differentiation, as defined by the European Society of Gastrointestinal Endoscopy), procedure-associated complications and locally or distant recurrence rate.

**Results:** We included twenty ESD independent procedures performed on nineteen patients (mean age 65 [41-83] year old, 55% men). Most of the lesions were located in the medium and distal esophagus (45%, respectively), with only 2 lesions (10%) located in the proximal region. The mean lesion size was 39 [15-100] mm and the mean procedure duration was 115 [30-180] min. 65% occupied more than 50% of esophageal circumference. En-bloc resection was achieved in 20 cases (100%) and R0 resection in 18 cases (90%), with 2 patients presenting focal positive horizontal margins. A 6 months follow-up available in both cases showed no endoscopic or pathologic signs of SCC suggesting a coagulation artefact on the specimen. Curative resection was accomplished in 9 cases (45%). The resection was non curative in 11 cases for the following reasons: 3 en-bloc R0 G1 pT1a m3 SCC, 6 deep submucosal (sm2) SCC with free vertical margins, and 2 due to positive lymphovascular infiltration.

One patient benefited from complementary radio-chemotherapy and one was submitted to complementary oesophagectomy (pToNo). Other patients were followed endoscopically knowing their age or comorbidities, after multidisciplinary discussion.

The endoscopic follow-up (median 15 [1-29] months) was available for 13 of the 17 patients without adjuvant oncological therapy and disclosed that 12 (92.3%) patients had no signs of recurrence.

The only case with lymphatic recurrence appeared in a patient with non curative ESD and past history of lymph node metastatic pharyngeal SCC. In 80% of the cases, there were no complications needing any intervention.

Despite steroid administration in 65% of cases for secondary strictures prevention (locally injected triamcinolone for >50% circumference resection or oral steroid for circumferential resections), 3 patients developed symptomatic strictures requiring endoscopic treatment.

One patient presented delayed post-ESD local hemorrhage, treated successfully by endoscopic hemostasis.

**Conclusion:** Our preliminary data confirm the safety and technical quality of esophageal ESD for SCC in a tertiary European center. The complexity to predict the oncological stage opens the room for staging ESD with the major limit being the risk of secondary stricture. Further work must be done by multicentric studies to better stratify the place of adjuvant oncologic treatment.

## P0602 MULTIPLE PRIMARY TUMORS IN PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA

van de Ven S.<sup>1</sup>, Falger J.M.<sup>1</sup>, Verhoeven R.H.A.<sup>2</sup>, Bruno M.J.<sup>1</sup>, Koch A.D.<sup>1</sup>

<sup>1</sup>Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands, <sup>2</sup>Netherlands Comprehensive Cancer Organization, Department of Research & Development, Utrecht, Netherlands

**Contact E-Mail Address:** s.vandeven@erasmusmc.nl

**Introduction:** Patients with primary esophageal squamous cell carcinoma (P-ESCC) may develop multiple primary tumors (MPTs) in the upper aerodigestive tract (UADT). [1] The MPT prevalence in these patients is reported to be high, up to 21.9%. [1-3] Most studies, however, are performed in Asia, where the ESCC prevalence is higher than in Western countries. [4]

**Aims & Methods:** The aim of this study was to evaluate the prevalence of MPTs in the UADT in patients with P-ESCC in a Western population. We performed a nationwide, retrospective cohort study in collaboration with the Netherlands Comprehensive Cancer Registry (IKNL). All adult patients, diagnosed between 2000 and 2016 with ESCC as index tumor were included in this study.

Follow-up data were available until January 2018. No screening programs for MPTs were in place within this timeframe. Our primary endpoint was the prevalence of MPTs in the UADT in patients with P-ESCC. Secondary endpoints were; (1) MPT localization, (2) MPT histology, (3) the proportion of patients with synchronous (within 6 months before and after diagnosis of P-ESCC) or metachronous (> 6 months after diagnosis of P-ESCC) MPTs, and (4) risk factors associated with MPT development. We performed univariate and multivariate analysis to analyze these risk factors.

**Results:** A total of 9,058 patients were diagnosed with P-ESCC between 2000 and 2016 (male: 57.3%). The median age was 67 years (IQR 60-75). Initial ESCC tumor stage was high (stage III/IV) in the majority of patients (59.9%). Most patients were treated with radiotherapy (n=2,163; 23.9%) or chemoradiotherapy (n=1,812; 20.0%). In 850 (9.4%) patients, ESCC was treated by primary surgery or endoscopic resection, and 1,288 (14.2%) patients received neoadjuvant therapy before surgery.

A total of 545 MPTs were registered in 476 (5.3%) patients. Most MPTs were located in the head and neck region (47.9%), followed by the lungs (40.8%) and stomach (6.6%). Squamous cell carcinoma (61.8%) was the most common histology, followed by adenocarcinoma (14.5%). Of all MPTs, 329 (60.4%) were diagnosed synchronously and 216 (39.6%) metachronously.

Of all patients who were alive 6 months after P-ESCC diagnosis (n=5,938), 191 patients (3.2%) developed a metachronous MPT. The median time between diagnosis of P-ESCC and the metachronous MPT was 3.0 years (IQR 1.8-5.9). Of patients with metachronous MPT, MPT stage was high (stage III/IV) in 57.4%. These patients had a significantly worse 2-year survival than low stage MPT (stage I/II) (15.1% vs. 51.9%,  $p < 0.01$ ).

The following factors were significantly correlated with MPT development: male sex (OR: 1.519;  $p < 0.01$ ), age  $\leq 70$  years (OR: 2.129;  $p < 0.01$ ), and lower tumor stage (stage I/II vs. III/IV) (OR: 2.053;  $p < 0.01$ ). There was no significant difference in P-ESCC tumor stage between patients with synchronous and metachronous MPTs.

**Conclusion:** Based on this nation-wide registry study a minimum of one out of twenty patients with P-ESCC develops an MPT. The majority of the registered MPTs were detected synchronously, screening from diagnosis of P-ESCC should therefore be recommended. Since patients with metachronous MPTs had more often high-stage MPTs and a worse survival compared to low-stage metachronous MPTs, we should screen for metachronous MPTs to detect MPTs at an earlier, and lower tumor stage.

## P0603 THE ACCURACY OF THE PREOPERATIVE DIAGNOSIS OF LYMPH NODE METASTASIS USING COMPUTED TOMOGRAPHY FOR T1B ESOPHAGEAL CANCER PATIENTS RECEIVING ESOPHAGECTOMY AFTER ENDOSCOPIC TREATMENT

Kawada K.<sup>1,2</sup>, Nakajima Y.<sup>1,2</sup>, Tokairin Y.<sup>1,2</sup>, Hoshino A.<sup>1,2</sup>, Okada T.<sup>1,2</sup>, Matsui T.<sup>1,2</sup>, Yamaguchi K.<sup>1,2</sup>, Kinugasa Y.<sup>2</sup>

<sup>2</sup>Tokyo Medical and Dental University, Gastrointestinal Surgery, Tokyo, Japan

**Contact E-Mail Address:** kawada.srg1@tmd.ac.jp

**Introduction:** The standard treatment for T1b esophageal squamous cell carcinoma (tumor invasion to submucosa) is esophagectomy with lymphadenectomy in Japan. However, some cases are given endoscopic treatment as the initial therapy. Based on the histopathological findings, the patients in whom the tumor has invaded to the submucosa are then recommended to undergo additional therapy. The accurate clinical evaluation of the lymph nodes is therefore crucial for selecting the optimum treatment strategy for individual esophageal cancer patients.

**Aims & Methods:** To investigate the accuracy of the preoperative diagnosis of lymph node metastasis for T1b esophageal cancer patients given esophagectomy after endoscopic treatment. Between January 2002 and December 2016, 139 cases of T1b esophageal cancer were treated with endoscopic treatment as the initial treatment. Thirty-six patients (25.9%) received esophagectomy with lymphadenectomy. The concordance between the clinical and pathological nodes was then evaluated. The preoperative diagnosis was based on computed tomography (CT) findings.

**Results:** The patient background characteristics were as follows: male/female, 30/6; median age, 64 years old (range 41-78); primary tumor site at cervical/upper/middle/lower/Barrett's esophagus, 2/5/15/10/4; cNo/cN1, 32/4. Lymph node metastasis was observed in 13 patients and 19 lymph nodes (36.1%). The number of lymph node metastases was one in eight cases, two in one case, three in three cases and five in one case. The lymph node-positive sites were cervical/thoracic/abdominal in 11/5/3 cases. Lymph node metastasis was most frequently observed in the right para-thoracic area. The sensitivity and specificity of clinical nodes for a diagnosis of pathological nodes were 30.8% and 100%, respectively, and the positive and negative predictive values were 100% and 71.9%, respectively. In 12 (63.1%) of the 19 sites, the size of the lymph nodes with metastasis was estimated to be < 3 mm on CT.

**Conclusion:** The diagnosis of clinical nodes has low sensitivity and a low negative predictive value for the prediction of the pathological node category in the preoperative diagnosis of lymph node metastasis for patients with T1b esophageal cancer treated endoscopically. We therefore need to carefully consider indications of endoscopic treatment for T1b esophageal cancer. Clinical staging techniques should be improved.

## P0604 THE EFFICACY OF PHOTODYNAMIC THERAPY WITH A NEW PHOTOSENSITIZER (TALAPORFIN SODIUM) AS A SALVAGE TREATMENT FOR ESOPHAGEAL CANCER WITH A FOCUS ON THE EFFECT OF VASCULAR SHUTDOWN

Tanaka M.<sup>1</sup>, Suzuki T.<sup>1</sup>, Nishie H.<sup>1</sup>, Kataoka K.<sup>2</sup>

<sup>1</sup>Nagoya City University Graduate School of Medical Sciences, Departments of Gastroenterology and Metabolism, Nagoya, Japan, <sup>2</sup>Nagoya City University Gastroenterology and Metabolism, Nagoya, Japan

**Contact E-Mail Address:** mtanaka@med.nagoya-cu.ac.jp

**Introduction:** Esophageal cancer is one of the most common cancers worldwide. Chemoradiotherapy (CRT) is one of the curative treatments for esophageal cancer in patients with unresectable tumors or those who refuse surgery. However, local failure after CRT is a problem. An alternate treatment in such patients is photodynamic therapy (PDT).

PDT consists of the intravenous administration of a photosensitizer, followed by activation with a specific wavelength light. Activation of the photosensitizer causes the conversion of molecular oxygen into various reactive oxygen species that directly induce the death of the tumor cells or shut down the tumor-associated vasculature. However, the mechanism of the vascular shut down is not clear.

Talaporfin sodium, a second-generation photosensitizer, is rapidly cleared from the skin and requires a shorter sun-shade period. Furthermore, the depth of effect is expected to extend to deeper layers.

In this study, we evaluated the efficacy of PDT with Talaporfin for esophageal cancer focusing on the vascular shutdown effect.

**Aims & Methods:** Patients with histologically proven local failure limited within the muscularis propria after radiotherapy (RT) of 50 Gy or more for esophageal cancer were eligible.

The PDT procedure commenced with intravenous administration of a 40 mg/m<sup>2</sup>-dose of talaporfin sodium, followed by laser irradiation at a 664-nm wavelength 4 to 6 hours after administration.

The local efficacy was classified based on endoscopic evaluation as local complete response (L-CR). The L-CR rate per patients was the primary endpoint of this study. The secondary endpoints were confirmed local progression-free survival (L-PFS), and overall survival (OS).

Xenograft tumor mouse models were established with colon cancer cell lines (HCT116). After talaporfin intravenous injection, tumors were illuminated with the diode laser system (664nm). Tumor blood flow was measured by a laser speckle blood flow analyzing system; OMEGA ZONE2. Temporal changes of the flow were compared with the positive control; Combretastatin A-4 phosphate (CA4P).

**Results:** Sixteen patients with a total of 19 lesions received additional laser irradiation. The median total laser exposure dose was 298 (range: 100-800) J. Thirteen patients with a total of 16 lesions achieved L-CR after PDT (L-CR rate: 84.2%). The L-CR rate of T1 failure lesions was 92.8% (13/14), whereas the L-CR rate of T2 failure lesions was 60.0% (3/5).

PDT with Talaporfin decreased the blood flow in tumors but not in the neighboring healthy tissue.

**Conclusion:** The possibility of esophageal perforation after PDT should be considered for longer than 1 month post-therapy. PDT with Talaporfin decreased the tumor blood flow significantly in vivo. The vascular shutdown effect of PDT with Talaporfin was suggested as an important part of its antitumor effects. PDT using talaporfin sodium and a diode laser is a curative salvage treatment for local failure after CRT for patients with esophageal cancer.

## P0605 RISK FACTORS FOR STRICTURE AFTER ESOPHAGEAL ESD: CAN WE PREVENT STRICTURE WITH STEROID INJECTION AND PGA SHIELDING?

Sakaguchi Y., Tsuji Y., Koike K.

University of Tokyo, Department of Gastroenterology, Graduate School of Medicine, Tokyo, Japan

**Contact E-Mail Address:** sakaguchi-ty@umin.ac.jp

**Introduction:** Endoscopic submucosal dissection (ESD) is currently the standard method of treatment for superficial esophageal carcinoma in many countries. However, resection of more than 3/4 the circumference of the esophagus has been reported to be a risk factor for postoperative stricture after ESD. A previous pilot study has shown that combining triamcinolone injection and shielding with polyglycolic acid (PGA) sheets is effective in preventing postoperative stricture (Am J Gastro 2016). This analysis was performed to obtain more definitive evidence on the efficacy of this method, and determine factors which may induce stricture even after this method.

**Aims & Methods:** We have performed a retrospective analysis of patients who have undergone esophageal ESD from Jan 2002 to Dec 2018 at the University of Tokyo Hospital. 136 consecutive patients who underwent esophageal ESD for superficial esophageal squamous cell carcinoma covering over 1/2 the circumference of the esophagus were extracted. Of these, after ethics committee approval in 2013, patients have undergone either "PGA shielding" or "steroid injection + PGA shielding" following ESD. After exclusion of patients who did not undergo 12 week post-ESD follow-up, patients who underwent salvage surgery, and patients with regular oral steroid use, 111 patients (age 69.8±9.0 years) were analyzed. Multivariate logistic regression analysis was performed to evaluate risk factors associated with stricture, which was defined as the state where dilation was required for an upper gastrointestinal endoscope to pass.

**Results:** 82.9% (92/111) of these high-risk patients required resection of over 3/4 the circumference of the esophagus. By multivariate logistic regression analysis, location (p=0.037), resection circumference (p< 0.001), and method of prevention (p=0.020) were the only factors significantly associated with stricture. Further analyses demonstrated that stricture rates in the cervical esophagus (75.0%, p=0.040), and after total circumferential resection (83.3%, p< 0.001) were especially high.

Comparison on the efficacy of “steroid injection + PGA shielding” vs “PGA shielding” vs “control” was performed. In the relatively low-risk subgroup excluding cervical esophageal cancer and complete circumferential resection, the postoperative stricture rate was 18.9% vs 41.4% vs 51.7% respectively ( $p=0.014$ ). The rate of patients requiring long-term dilation treatment was 16.2% vs 31.0% vs 28.0% respectively ( $p=0.320$ ), indicating that “steroid injection + PGA shielding” is the most effective method in both preventing and alleviating stricture. However “steroid injection and PGA shielding” showed only limited effects in extremely high-risk cases with either cervical esophageal cancer or complete circumferential resection.

**Conclusion:** Combining steroid injection and PGA shielding is effective for preventing and alleviating postoperative stricture after esophageal ESD. There is a need for even more effective methods for cervical esophageal cancer and complete circumferential resection.

**Contact E-Mail Address:** yasuaki1975@hotmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) is accepted as the standard treatment for early-stage esophageal neoplasia. However, esophageal perforation may occur, leading to mediastinitis and pneumothorax, which sometimes require emergency surgery. In addition, failure of en bloc resection causes local recurrence. Until now, few studies have reported on predictors of failure of en bloc resection or perforation during ESD.

**Aims & Methods:** The aim of the present study is the risk factors of failure of en bloc resection or perforation in ESD for esophageal neoplasia. This was a retrospective observational study conducted at a single institution. Between May 2004 and March 2016, 543 consecutive patients with 927 esophageal lesions were treated with ESD. Patients with metachronous esophageal neoplasia or missing data were excluded. The primary outcome was determining the predictors of failure of en bloc resection or perforation in patients who underwent esophageal ESD. Perforation was defined as a visible hole in the esophageal wall, exposing the mediastinal cavity.

**Results:** A total of 543 patients with 736 lesions were evaluated. Failure of en bloc resection occurred in 6 patients (1.1%) with 6 lesions, and perforation occurred in 11 patients (2.0%) with 11 lesions (1.5%). Lesion diameter [odds ratio (OR), 1.05; 95% confidence interval (CI): 1.02-1.07;  $p < 0.001$ ], wider tumor circumference (OR, 9.80, 95% CI: 1.61-59.5;  $p=0.01$ ), and previous chemoradiotherapy for esophageal cancer (OR, 3.87; 95% CI: 1.19-12.53;  $p=0.02$ ) were associated with failure of en bloc resection or perforation according to crude logistic regression analysis. Multivariate logistic regression analysis showed that lesion diameter (OR, 1.04; 95% CI: 1.02-1.06;  $p < 0.001$ ) and previous chemoradiotherapy (OR, 5.24; 95% CI: 1.52-18.06;  $p = 0.009$ ) were independent predictive factors.

**Conclusion:** Larger lesions and previous chemoradiotherapy for esophageal cancer increased the risk of failure of en bloc resection or perforation in patients who underwent esophageal ESD.

**Disclosure:** Nothing to disclose

### P0608 ADENOCARCINOMA OF THE ESOPHAGOGASTRIC JUNCTION IN JAPAN: A 10-YEAR PROSPECTIVE MULTICENTER EPIDEMIOLOGICAL STUDY IN KURASHIKI, JAPAN

**Contact E-Mail Address:** km5453@kchnet.or.jp

**Introduction:** Gastroesophageal reflux disease-related diseases, such as Barrett's esophagus and adenocarcinoma of the esophagogastric junction (AEGJ), are believed to occur less frequently in Japan than in Western countries. The number of cases of these conditions reported in Japan has been gradually increasing in recent years; however, there is limited information on the epidemiology of AEGJ. Based on previously reported data (Matsueda K, et al. *Dis Esophagus* 2017; 30: 1-6), we decided to extend the observational period in order to conduct a long-term follow-up study.

**Aims & Methods:** The aim of this study was to investigate the clinicoepidemiological characteristics of AEGJ in Japan. We divided the investigation period into the following three parts: first period (2.5 years; January 1, 2008-June 30, 2010), second period (4 years; July 1, 2010-June 30, 2014), and third period (3.5 years; July 1, 2014-December 31, 2017). During the first period, 88,199 consecutive cases (48,548 males and 39,651 females; mean age, 62 years) involving upper gastrointestinal endoscopy performed at 12 hospitals in Kurashiki, Japan were recruited. The cases were prospectively followed up for 7.5 to 10 years (mean, 8.7 years). Over a 10-year period from January 2008 to December 2017, we reviewed all endoscopy reports and associated medical records. AEGJ was defined as an adenocarcinoma of the distal esophagus (Siewert classification type I) and a true carcinoma of the cardia (Siewert type II). A new-onset patient was defined as a patient who had newly developed AEGJ, esophageal squamous cell carcinoma (SCC), and/or gastric cancer (GC) during the follow-up period. The new-onset rates of AEGJ, SCC, and GC, including Siewert type III, were calculated.

**Results:** During the 10-year study period, 158 patients with AEGJ were identified (131 males and 27 females; mean age, 68 years), and of these patients, 16 had Siewert type I AEGJ and 142 had Siewert type II. The incidence rate of AEGJ was 0.018%/year during the 10-years period and did not increase over the years. However, the proportion of patients with Siewert type I AEGJ significantly increased during the follow-up period (Table 1).

	First period (n=47)	Second period (n=55)	Third period (n=56)	P value
type I/type I+II	1/47 (2%)	5/55 (9%)	10/56 (18%)	< 0.05

[Table 1 The proportion of patients with Siewert type I AEGJ]

With regard to female patients, the number of cases increased from 5 (1.3 cases/year) in the second period to 13 (3.7 cases/year) in the third period. The new-onset rate of AEGJ was very low compared with that of SCC or GC, but it gradually increased from 1.1/100,000 person-years (SCC, 3.4/100,000; GC, 42.3/100,000) in the second period to 3.2/100,000 person-years (SCC, 8.8/100,000; GC, 37.7/100,000) in the third period.

**Conclusion:** The incidence of AEGJ is still lower in Japan than in Western countries; however, the proportion of patients with Siewert type I AEGJ and the new-onset rate of AEGJ are gradually increasing.

**Contact E-Mail Address:** kami\_hi\_koki@yahoo.co.jp

**Introduction:** Linked color imaging (LCI) installed in the FUJIFILM's LASE-REO endoscope system can highlight minor differences of color through image processing to expand the saturation and hue differences in the region of red color.

This study investigated the usefulness of LCI in SESCC.

**Aims & Methods:** We examined the visibility of lesions using LCI compared with that using white-light imaging (WLI) in 46 consecutive patients (29 men and 17 women; average age: 68.1 ± 9.6 years; 40 heavy drinkers and 36 smokers) with SESCC who underwent esophagogastroduodenoscopy using LCI in our department from April 2018 to November 18, 2018. The clinicopathological characteristics of the 46 cases were studied.

The average tumor diameter was 21.4±17.6 mm (5-60 mm), and the tumor stage was 0-IIc in 40 cases and 0-IIa in 6; the tumor depth was limited to the epithelium or was invading the lamina propria (EP/LPM) in 30 cases, invading the muscularis mucosa or the upper third of the submucosal layer (MM/SM1) in 12, and invading the middle third of the submucosal layer (SM2) in 4.

Changes in the visibility of the lesions were evaluated by 8 endoscopy specialists using the evaluation scale (+2: improved; +1: slightly improved; 0: equal; -1: slightly decreased; -2: decreased), and the overall score was defined as 8 or more in case of improved visibility, 7 to -7 in case of equal visibility, and -8 or less in case of decreased visibility.

Furthermore, in each lesion, the color difference between the cancerous and noncancerous areas observed by LCI was compared to that by WLI. In addition, tumor diameter, macroscopic type, depth, smoking and drinking history, and multiple lugol-voiding lesions (multiple LVLs; 10 small LVLs of the surrounding mucous membrane) were examined.

**Results:** The rate of change in the visibility of lesions by LCI was 41% (19/46) for improved visibility, 59% (27/46) for equal visibility, and 0% (0/46) for decreased visibility. The colors were significantly different between the cancerous and non-cancerous areas. The improved visibility was significantly different between LCI and WLI ( $p < 0.01$ ; two sample t-tests), but no significant differences were observed for equal visibility.

The improved visibility of the lesions by LCI had no correlations with the tumor diameter, macroscopic type, color tone, depth, or smoking and drinking history, but was significantly correlated with the presence of multiple LVLs ( $p < 0.05$ ;  $\chi^2$  test). The kappa value of the interobserver agreement was 0.45, which means that the observations were roughly consistent.

**Conclusion:** LCI for SESCC does not reduce the visibility of the lesion compared with WLI, and in particular, improves the visibility of the lesions with multiple LVLs.

**Introduction:** Esophageal squamous cell carcinoma (ESCC) is often accompanied by head and neck second primary tumors (HNSPTs).[1] The prognosis and survival of patients with an additional HNSPT is worse compared to patients with only ESCC (5-year survival rate of 9.2% vs. 21.0%). [2] Therefore, early detection of HNSPTs may improve the overall outcome of patients with ESCC.

**Aims & Methods:** The aim of this study was to investigate the yield of endoscopic screening for HNSPTs in patients with primary ESCC. Secondary aims were to investigate whether screening should be performed synchronously or metachronously, and to investigate whether there is enough evidence to justify endoscopic screening in the Western world. We conducted a systematic literature search until February 2019 to retrieve studies from all available databases. Studies were included if ESCC patients were endoscopically screened for HNSPT. The primary outcome was the pooled prevalence of HNSPTs.

**Results:** Twelve studies, all performed in Japan, were included in this systematic review with a total of 6483 patients (Table 1). The pooled prevalence of HNSPTs was 6.7% (95% CI: 4.9-8.4). The overall heterogeneity was high across the studies ( $I^2 = 89.0\%$ ,  $p < 0.001$ ). The proportion of synchronous (48.2%) and metachronous (51.8%) HNSPTs was comparable. Most HNSPTs were low-stage (85.3%) and located in the hypopharynx (60.3%).

**Conclusion:** Based on our results, HNSPT screening could be considered in patients with primary ESCC. The majority of HNSPTs were classified as low-stage, which can be treated curatively and have an excellent prognosis. All studies were performed in Japan, it is therefore not clear if this consideration applies to the Western world.

**Introduction:** Low-dose aspirin (LDA) use is increasing dramatically around the world. Particularly in Japan, the number of LDA users is expected to increase rapidly due to the country's aging population. Therefore, it is an urgent issue for us to understand the features of gastric mucosal injury in patients taking LDA.

**Aims & Methods:** The aim of this study is to explore the generation difference in prevalence of gastric mucosal injury in LDA users. This is a case-controlled study conducted at our department. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and February 2019. Of the 4,983 subjects analyzed, we focused on the subjects who did not take potassium-competitive acid blockers, proton pump inhibitors or histamine 2 receptor antagonists. We analyzed data for subjects diagnosed endoscopically with gastric erosions and ulcers. These mucosal injuries are based on the definition of ulcer classification which was defined by Murakami and Suzuki in 1971. We compared the prevalence of gastric mucosal injuries between patients taking LDA (LDA users) and taking NO LDA (nonusers) by age. Statistical analyses were performed by Mann-Whitney U test.

**Results:** This study included 147 subjects taking LDA (101 men, 26 women; mean age 72.5 years) and 3,362 subjects taking NO LDA (1,874 men, 1,488 women; mean age 63.1 years). In LDA users, the prevalence of gastric mucosal injury was 23.1% (3/13) (ages 39 and under), 25.0% (3/12) (ages 40-49), 40.0% (2/5) (ages 50-59), 31.8% (7/22) (ages 60-69), 23.2% (10/38) (ages 70-79), 26.3% (10/38) (80 and over). In nonusers, the prevalence of gastric mucosal injury was 17.3% (125/722) (ages 39 and under), 19.30% (96/497) (ages 40-49), 21.9% (102/465) (ages 50-59), 21.4% (183/857) (ages 60-69), 20.5% (191/232) (ages 70-79), 20.5% (79/386) (80 and over) (p=0.0039). The prevalence of gastric mucosal injury was highest in the age group 50-59 in both LDA users and nonusers.

**Conclusion:** We have demonstrated that the prevalence of gastric mucosal injury in LDA users was statistically significantly higher than in nonusers. In all age groups, the prevalence in LDA users was higher than in nonusers.

**Introduction:** Five-year cumulative incidence of metachronous gastric cancer (MGC) occurring after curative gastric endoscopic submucosal dissection (ESD) of several studies was reported in 10-16%<sup>1</sup>. However, most subjects of previous studies were patients undergoing ESD of differentiated-type (D-type) early gastric cancer (EGC), and little is known about long-term follow-up data of MGC occurring after gastric ESD of undifferentiated-type (UD-type) EGC.

**Aims & Methods:** The aim of this study was to evaluate incidence and treatment outcomes of MGC after curative gastric ESD of UD-type EGC. This study included patients who underwent curative ESD of initial solitary UD-type EGC from JCOG1009/1010, which is a multicenter single-arm confirmatory trial in Japan and showed excellent long-term outcomes in patients undergoing curative ESD of UD-type EGC<sup>2</sup>. Curative ESD of UD-type EGC was defined as histologically proven mucosal poorly differentiated adenocarcinoma or signet ring cell carcinoma of major histological type without ulceration nor lymphovascular invasion ≤ 20mm with free lateral and deep margin. Undifferentiated dominant-type (e.g., poorly to moderately differentiated adenocarcinoma) was also included as UD-type EGC. Surveillance endoscopy was performed biannually for the first three years and then annually. This study assessed the time to MGC occurrence after ESD, lesion characteristics, and treatment outcomes of MGC. MGC was defined as a gastric cancer that was located in a different position to the initial EGC occurring more than one year after the index ESD. Time to MGC occurrence was estimated by cumulative incidence function, regarding deaths and total gastrectomy as competing risks.

**Results:** A total of 198 patients undergoing curative ESD of UD-type EGC were analyzed in this study. Male/female was 96/102, and the median age was 60 (range: 23-80). Gastric atrophy (none/mild/severe) was classified 64/64/70, respectively. Eighty-five patients had *Helicobacter pylori* (*H. pylori*) infection, 59 did not have *H. pylori* infection, and 26 had successful *H. pylori* eradication at index gastric ESD (missing in 28 patients). Four patients post ESD of UD-type EGC developed MGC during a median follow up period of 5.8 years (range: 0.2-7.2). Five-year cumulative incidence function of MGC was 1.0% (95% CI: 0.2%-3.3%). The tumor location (Upper/Middle/Lower) were 1/1/2, respectively. The macroscopic type was 0-IIc in all four lesions. All MGCs were treated with ESD. Two MGCs were histologically D-type EGC, and the remaining two were UD-type EGC. The median tumor size of MGCs was 1.0 (range: 0.7-1.7) cm, and the depth of invasion (M/SM1/SM2) was 2/1/1, respectively. Three out of the four patients achieved curative resection.

**Conclusion:** MGC could occur less commonly after curative ESD of UD-type EGC compared with that of D-type EGC, and three out of four MGC were resected curatively with ESD.

**Contact E-Mail Address:** s-tanabe@kitasato-u.ac.jp

**Introduction:** Along with the development of endoscopic submucosal dissection (ESD) for early gastric cancer (EGC), increasing numbers of patients have metachronous multiple lesions developing during follow-up after ESD. We often encounter patients in whom treatment is difficult to perform owing to the presence of metachronous multiple lesions developing near scars remaining after ESD.

**Aims & Methods:** We compared the incidence of metachronous multiple lesions developing near scars after ESD with that of lesions developing at other sites to examine the clinicopathological characteristics of metachronous multiple lesions developing near scars after ESD and the incidence of complications at the time of ESD.

**Subjects & Methods:** Among 2182 patients (2762 lesions) who underwent ESD for EGC in our hospital from September 2002 through August 2018, we studied 15 patients (20 lesions) with metachronous multiple lesions that developed near scars (group A) and 161 patients (304 lesions) with metachronous multiple lesions that developed in other regions (group B). The median follow-up period was 61 months (range, 13 to 186 months).

**Results:** Group A comprised 9 men and 6 women with a median age of 76 years, and group B comprised 129 men and 32 women with a median age of 73 years. In group A, 9 patients had elevated-type lesions, and 11 patients had flat, depressed-type lesions. The median lesion diameter was 10 mm. Differentiated-type lesions were found in 19 patients, and predominantly differentiated-type lesions in 1 patient.

The curability was eCuraA in 15 patients, eCuraC-1 in 2 patients, and eCuraC-2 in 3 patients. In group B, 123 patients had elevated-type lesions, and 181 patients had flat depressed-type lesions. The median lesion diameter was 13 mm. Differentiated-type lesions were found in 281 patients, differentiated-predominant mixed type lesions in 18 patients, undifferentiated-type lesions in 1 patient, and undifferentiated-predominant mixed type lesions in 4 patients.

The curability was evaluated to be eCuraA in 247 patients, eCuraB in 19 patients, eCuraC-1 in 17 patients, and eCuraC-2 in 21 patients. In group A, the site of gastric cancer was the upper part of the stomach in 1 patient, the middle part of the stomach in 13 patients, and the lower part of the stomach in 6 patients. In group B, the site of gastric cancer was the upper part of the stomach in 41 patients, the middle part of the stomach in 132 patients, the lower part of the stomach in 118 patients, and other parts of the stomach in 13 patients.

Three or more metachronous multiple lesions were found in 10 patients (67%) in group A and 50 patients (31%) in group B; this difference was significant ( $p < 0.01$ ). The ESD procedure time was significantly longer in group A (110 minutes; range, 65 to 211) than in group B (78 minutes; range, 24 to 332;  $p < 0.01$ ).

Complications comprised perforation in 3 patients (16.6%) and subsequent bleeding in 4 patients (22.2%) in group A and perforation in 12 patients (3.8%) and subsequent bleeding in 21 patients (5.0%) in group B. These differences were significant (both  $p < 0.01$ ).

**Conclusion:** Patients in whom many metachronous multiple lesions develop during follow-up observation after ESD for EGC may have a higher risk of metachronous multiple lesions developing near scars. ESD for metachronous multiple lesions developing near scars requires a long

procedure time and is associated with a high incidence of complications. Treatment should therefore be carefully performed, taking into account that such lesions are technically difficult to treat.

### P0615 THE EFFECT OF ANTICOAGULANT THERAPY ON POST ENDOSCOPIC SUBMUCOSAL DISSECTION BLEEDING FOR GASTRIC CANCER: A PROPENSITY SCORE MATCHING ANALYSIS

Toya Y.<sup>1</sup>, Endo M.<sup>1,2</sup>, Oizumi T.<sup>1</sup>, Akasaka R.<sup>1</sup>, Yanai S.<sup>1</sup>, Kawasaki K.<sup>1</sup>, Nakamura S.<sup>1</sup>, Eizuka M.<sup>3</sup>, Fujita Y.<sup>3</sup>, Uesugi N.<sup>3</sup>, Sugai T.<sup>3</sup>, Matsumoto T.<sup>1</sup>  
<sup>1</sup>Iwate Medical University, Division of Gastroenterology, Department of Internal Medicine, Morioka, Japan, <sup>2</sup>Kaiunbashi Endoscopy Clinic, Morioka, Japan, <sup>3</sup>Iwate Medical University, Division of Molecular Diagnostic Pathology, Department of Pathology, Morioka, Japan

**Contact E-Mail Address:** ytoya@iwate-med.ac.jp

**Introduction:** Endoscopic submucosal dissection (ESD) has been accepted as a standard treatment for early gastric cancer (EGC). In the guideline published by the Japan Gastroenterological Endoscopy Society, it has been suggested that an anti-platelet medication should be continued throughout the peri-treatment period. However, the optimal management of anticoagulant therapy for gastric ESD remains controversial. Moreover, little is known about the effect of anticoagulant therapy on post-ESD bleeding.

**Aims & Methods:** In order to investigate the effect of anticoagulants for post-ESD bleeding for EGC, we retrospectively analyzed 2355 EGCs treated by ESD, including 137 lesions in patients under anticoagulants. Anticoagulant therapy included warfarin and direct oral anti-coagulants (DOACs), such as dabigatran, rivaroxaban, edoxaban and apixaban. Using propensity score matching analysis, clinicopathological findings were evaluated between lesions in patients with anticoagulant therapy and those in patients without. We used a one-to-one propensity score matching selected by age, gender, comorbidities (such as diabetes mellitus, renal failure and liver cirrhosis), tumor location, macroscopic appearance, histology, depth of tumor, ulcerative findings, procedure time, resected specimen size and perforation as parameters. Factors associated with post-ESD bleeding were analyzed with multivariable analyses with a logistic regression method.

**Results:** After propensity score matching, post-ESD bleeding was significantly more frequent in lesions in patients with than without anticoagulant therapy (11.7% vs 1.5%, respectively;  $P = 0.001$ ). Univariate analyses revealed that anticoagulant therapy, heparin bridge therapy, undifferentiated type, deep submucosal invasion and resected specimen size were associated with post-ESD bleeding. Multivariate analysis revealed anticoagulant therapy (OR 23.1, 95% CI 3.61-147.52) and resected specimen size (OR 1.03, 95% CI 1.00-1.06) to be independent factors associated with post-ESD bleeding.

**Conclusion:** Anticoagulant therapy and resected specimen size were risk factors associated with post-ESD bleeding for EGC. Strategies for the prevention of post-ESD bleeding should be seriously considered for patients under anticoagulant medication.

**Disclosure:** Nothing to disclose

**Introduction:** Risk factors for gastric cancer during continuous infection with *Helicobacter pylori* (*H. pylori*) have been well documented and *H. pylori* eradication is expected to suppress the occurrence of gastric cancer. However gastric cancer still remains one of the leading cancers in the world with a high mortality worldwide. In addition, the risk of developing a metachronous lesion following endoscopic resection of an early gastric cancer has been reported to between 1% and 4% per year. The gastric

mucosal atrophy has been known as the risk factor range development of metachronous gastric cancer, however no reports of bile reflux has been reported.

**Aims & Methods:** A retrospective study was conducted to clarify the risk factors associated with the development of metachronous gastric cancer (MGC) in patients whose early gastric cancers were treated by endoscopic submucosal dissection (ESD).

Three hundred thirty-eight patients who underwent ESD for the treatment of early gastric cancer between January 2013 and March 2018 at our hospital were enrolled in this study. The mean age was 78 years, 251 patients were male, and 87 were female. MGC was defined as secondary gastric cancer discovered after one year of endoscopic therapy of early primary gastric cancer (PGC).

The factors considered were age, gender, BMI, current cigarette smoking, current alcohol drinking, the status of *H.pylori* infection, and gastric mucosal atrophy, bile reflux into the stomach, presence of xanthoma diagnosed by endoscopy.

**Results:** MGC was found in 33 patients out of 338 patients (9.8%). Among them, 12 cases with MGC developed within 2 years, and 21 cases from 2 years to 5 years. Of the 33 cases of recurrence of gastric cancer, 22 cases (66.7%) were after *H.pylori* eradication. The ratio of presence of bile reflux into the stomach was significantly higher in MGC than in PGC (54.5% [18 of 33] vs 36.7% [109 of 305],  $P=0.039$ ). The ratio of presence of xanthoma was higher in MGC than in PGC (51.5% [17 of 33] vs 32.9% [100 of 305],  $P=0.036$ ).

Higher prevalence of current alcohol drinking (48.5% [16 of 33] vs 31.1% [95 of 305],  $P=0.052$ ), and gastric mucosal severe atrophy (87.9% [29 of 33] vs 75.0% [229 of 305],  $P=0.055$ ) was tended to find in MGC than in PGC. No significant differences were found in age, gender, BMI, the status of *H.pylori* infection, current cigarette smoking between two groups.

**Conclusion:** In the present study, the presence of bile reflux into the stomach was shown to be a candidate factor which was associated with MGC. We should perform long follow-up endoscopy carefully even after *H.pylori* eradication, with special attentions in patients with xanthoma or biliary reflux.

## P0617 METFORMIN USE AND RISK OF GASTRIC ADENOCARCINOMA IN A SWEDISH POPULATION-BASED COHORT STUDY

Zheng J.<sup>1</sup>, Xie S.-H.<sup>1</sup>, Santoni G.<sup>1</sup>, Lagergren J.<sup>1,2</sup>

<sup>1</sup>Karolinska Institutet, Molecular Medicine and Surgery, Stockholm, Sweden,

<sup>2</sup>King's College London, School of Cancer and Pharmaceutical Sciences, London, United Kingdom

**Contact E-Mail Address:** jiao.jiao.zheng@ki.se

**Introduction:** Whether the use of metformin decreases the risk of gastric non-cardia and cardia adenocarcinoma is unclear.

**Aims & Methods:** This was a Swedish nationwide and population-based cohort study in 2005-2015. Firstly, associations between metformin use and gastric non-cardia and cardia adenocarcinomas were examined within a cohort of diabetes patients using anti-diabetes medication ('diabetes cohort'). Secondly, the same associations were analysed in another cohort including metformin users and 10 times as many non-users of metformin ('matched cohort'). The non-users were frequency-matched with metformin users for sex and age. Multivariable Cox proportional hazard regression analyses provided hazard ratios (HR) and 95% confidence intervals (CI). The HRs were adjusted for sex, age, calendar year, comorbidity, *Helicobacter pylori* eradication treatment, use of non-steroidal anti-inflammatory drugs or aspirin, and use of statins.

**Results:** The diabetes cohort consisted of 544,130 individuals, including 407,149 (74.8%) metformin users and 136,981 (25.2%) non-users of metformin. During the follow-up, 892 (0.1%) individuals developed gastric adenocarcinoma. Compared to non-users, metformin users had no decreased risk of gastric non-cardia adenocarcinoma (adjusted HR 0.93, 95% CI 0.78-1.12) or cardia adenocarcinoma (adjusted HR 1.49, 95% CI 1.09-2.02). The matched cohort included 4,525,543 individuals, of whom 411,413 (9.1%) were metformin users and 4,114,130 (90.9%) were non-users. During the follow-up, 6,395 (0.1%) individuals developed gastric adenocarcinoma. Compared to non-users, metformin users had no decreased risk of gastric non-cardia adenocarcinoma (adjusted HR 1.30, 95% CI 1.18-1.42) or cardia adenocarcinoma (adjusted HR 1.58, 95% CI 1.38-1.81).

**Conclusion:** Metformin use may not prevent gastric non-cardia or cardia adenocarcinoma.

**Disclosure:** Nothing to disclose

## P0618 EFFECTS OF HELICOBACTER PYLORI ON BIOLOGICAL CHARACTERISTICS IN EARLY GASTRIC CANCER

Ni Z., Ye F., Zhang S.

The First Affiliated Hospital, Zhejiang Chinese Medical University, Hangzhou, China

**Contact E-Mail Address:** zhangshuotcm@126.com

**Introduction:** Early gastric cancer (EGC) is an early stage of gastric cancer, a curable malignant disease with a high cure rate. Finding the clinicopathological features of early gastric cancer is an important part of its early detection and timely diagnosis and reducing the mortality rate of gastric cancer.

**Aims & Methods:** To elucidate the differences between the biological characteristics of tumor cells in early gastric cancer and *Helicobacter pylori* (HP). Of the 111 patients with early gastric cancer were enrolled in this study, of whom were divided into 4 groups: 23 HP- GC patients, 47 HP+ GC patients without a history of HP eradication (U-HP+ group), 12 HP+ GC patients with a history of HP eradication (E-HP+ group), 36 HP- GC patients without a history of HP infection (U-HP- group) and 28 HP- GC patients with a history of HP infection (I-HP- group) were enrolled in this study. We compared biological characteristics of tumor between the four groups.

**Results:** Compare with the U-HP- group, the I-HP- group was more frequently in upper one third of stomach ( $P = 0.01$ ). There was no significant difference in the expression of Ki67 ( $P > 0.05$ ). The expression of HER2 in U-HP+ group was higher ( $P = 0.049$ ) than the E-HP+ group. In addition, there was a significant increase ( $P = 0.002$ ) in the expression of HER2 of the HP+ group than that of the HP- group. In the HP+ group, there was a positively correlation in HP and the expression of HER2 ( $P=0.014$ ).

**Conclusion:** HP- EGC patients without a history of HP infection more frequently occurred in the upper part of the stomach. The proliferative capacity of the cancer in different HP eradication and eradication were similar, while the neoplasm invasion in HP+ EGC were increase, especially in HP+ GC with a history of HP eradication.

**Disclosure:** Nothing to disclose

**Introduction:** Epstein-Barr Virus (EBV)-associated gastric cancer (EBVGC) accounts for approximately 10% of gastric cancers. EBVGC is classified into one of the four molecular subtypes proposed by The Cancer Genome Atlas Research Network (Nature, 2014), and there have been reports which imply the relatively low risk of lymph node metastasis (LNM) in EBVGC with submucosal invasion (pT1b-EBVGC). However, a large cohort study is still lacking.

**Aims & Methods:** The present study aims to investigate the risk of LNM in pT1b-EBVGC through a multicenter study. This is a retrospective multicenter study. 5 institutes, which have pathologists specializing in the diagnosis of EBVGC, participated in this study. We reviewed medical records and extracted all pT1b-EBVGC cases diagnosed between 2001 and 2016. Lesion characteristics, patients background factors and clinical outcomes were obtained. The diagnostic criteria for EBVGC were as follows: 1) gastric adenocarcinoma with lymphoid stroma; and 2) a positive result of in-situ hybridization for EBV encoded small RNA (EBER-ISH). For surgery cases, LNM was investigated based on the histopathological evaluation of resect-

ed LNs. For endoscopic resection (ER) cases, no LNM was defined as the case where computed tomography scan did not identify any LNM during follow-up  $\geq 3$  years.

**Results:** A total of 190 pT1b-EBVGC cases were enrolled. The number of ER and surgery cases were 30 and 160, respectively. Additional surgery was performed in 25 of 30 ER cases. LNM was identified in 9 cases (4.7%), which were all surgery cases. Table 1 shows the association between LNM and various factors.

	LNM - (181)	LNM + (9)	P value
Age	64.7 $\pm$ 10.1	69.8 $\pm$ 9.9	0.141
Sex (M/F)	149/32	8/1	1.000
Lesion size (mm)	29.5 $\pm$ 17.0	36.7 $\pm$ 22.3	0.230
Macroscopic appearance (depressed/protruded/others)	122/53/6	5/4/0	0.296
Location (U/M/L)	75/87/19	4/3/2	0.367
Depth ( $\geq$ SM500/ $<$ SM500)	159/22	9/0	0.602
Ly (0/1)	160/21	3/6	$<$ 0.001
V (0/1)	153/28	7/2	0.635

[The association between LNM and clinical factors]

Lymphatic invasion (Ly) is the only significant risk factor for LNM ( $p < 0.001$ ); neither lesion size nor submucosal invasion depth ( $\geq 500\mu\text{m}/< 500\mu\text{m}$ ) were significantly correlated to LNM. The present study revealed that the risk for LNM in pT1b-EBVGC without Ly was 1.8% (3/163, 95%CI; 0.6-5.3%). Moreover, as for pT1b-EBVGC without Ly and  $\leq 20\text{mm}$ , the rate of LNM was 0% (0/62, 95%CI; 0-4.7%).

**Conclusion:** The present study demonstrated the relatively low risk for LNM in pT1b-EBVGC, considering that the LNM risk of all pT1b-GC is approximately 20%. This result implies that pT1b-EBVGC is a good candidate for ER or local resection.

### P0621 HISTOLOGIC VALIDATION OF ARGON PLASMA COAGULATION VERSUS MONOPOLAR COAGULATION FOR GASTRIC ADENOMA WITH LOW GRADE DYSPLASIA: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

Huh C.W.<sup>1</sup>, Jung D.H.<sup>2</sup>, Kim B.-W.<sup>1</sup>

<sup>1</sup>Incheon St. Mary's Hospital, The Catholic University of Korea, Department of Internal Medicine, Incheon, Korea (Republic of), <sup>2</sup>Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea (Republic of)

**Contact E-Mail Address:** huhcw@catholic.ac.kr

**Introduction:** Endoscopic electrocoagulation such as argon plasma coagulation (APC) or monopolar coagulation (MC) is a safe alternative treatment for gastric adenoma with low grade dysplasia (LGD). However, there was no study regarding the histologic validation of endoscopic electrocoagulation for gastric LGD.

**Aims & Methods:** The aim of this study was to validate the histologic complete eradication of endoscopic electrocoagulation for gastric LGD. This was a prospective randomized controlled study involving patients who diagnosed gastric LGD and underwent endoscopic submucosal dissection (ESD) after endoscopic electrocoagulation from March 2014 to December 2018. Patients were randomly assigned to either APC or MC group. The main outcome was the complete histologic eradication rate.

**Results:** In 68 patients, 34 patients were treated with ESD after APC and 34 patients were treated with ESD after MC. The overall histologic complete eradication rate was 33.8% (23/68). The complete eradication rate was significantly higher in the APC group than those in the MC group (55.9% vs. 11.8%,  $P < 0.001$ ). In multivariate analysis, APC was the only significant predictor of histologic complete eradication. (OR 7.66; 95% CI 2.139-27.448). There were no adverse events related to the procedure in both groups.

**Conclusion:** Although APC is a more effective treatment option than MC in treating gastric LGD, both methods revealed disappointing results in histologic complete eradication. Therefore, endoscopic resection must be performed for curative treatment of gastric LGD.

**Contact E-Mail Address:** nohmiya@med.nagoya-u.ac.jp

**Introduction:** Needle-based confocal laser endomicroscopy (nCLE) allows for real-time optical biopsies during endoscopic ultrasound-guided fine needle aspiration (EUS-FNA).

**Aims & Methods:** Little is known about the nCLE imaging of gastrointestinal subepithelial lesions (GI-SELs); therefore, we determined its feasibility. We performed nCLE during EUS-FNA in 23 consecutive patients with GI-SELs between November 2015 and May 2018. We retrospectively compared nCLE findings with pathologic findings of EUS-FNA or surgical specimens.

**Results:** The median number (range) of needle passes per EUS-FNA procedure was 2 (1-3). The adequate sample acquisition rate was 67.0% per needle pass and 95.7% per patient. EUS-FNA was diagnostic in 78.3% (18/23), suspicious in 4.3% (1/23), and nondiagnostic in 17.4% (4/23). The concordance rate of nCLE findings with final pathology was 95.7% (22/23), which was not significantly different from diagnostic and suspicious EUS-FNA ( $P = .2482$ ). nCLE could differentiate GI stromal tumors from leiomyoma, in that GISTs were characterized by contrast-enhanced densely populated spindle cell tumors with unenhanced rod-shaped nuclei in 100% of 12 patients, whereas leiomyomas were characterized by narrower spindle cell tumors with fewer and smaller unenhanced nuclei in 100% of 3 patients. A desmoid tumor appeared as spindle cell tumors both with unenhanced nuclei in some parts and with fewer and smaller nuclei in other parts. In rectal metastasis from lung adenocarcinoma, some pleomorphic dark nests were observed. There were no adverse events associated with nCLE and EUS-FNA.

**Conclusion:** nCLE can be safe and useful for the on-site detection of abnormalities of GI-SELs.

**Disclosure:** Nothing to disclose

### P0624 THE ROLE OF INSULIN-LIKE GROWTH FACTOR AXIS IN THE PROGRESSION AND SURVIVAL IN GASTRIC CANCER

<sup>1</sup>National Taiwan University Hospital, Taiwan Helicobacter Consortium, Dept. of Internal Medicine, Taipei, Taiwan, <sup>2</sup>National Taiwan University Hospital, GI, Taipei, Taiwan, <sup>3</sup>Fu Jen Catholic University, School of Medicine, New Taipei City, Taiwan, <sup>4</sup>National Taiwan University Hospital, Dept. of Internal Medicine, Taipei, Taiwan

**Contact E-Mail Address:** dtmedo46@pchome.com.tw

**Introduction:** Overexpression of insulin-like growth factors and its binding proteins has been reported to be associated with the progression and survival of several cancers. However, their roles in the progression of gastric cancer remain poorly understood.

**Aims & Methods:** We aimed to assess the impact of circulating levels of levels of insulin-like growth factors (IGF1, IGF2) and their binding proteins (IGFBP1, IGFBP2, IGFBP3) and the expression of IGFBP2 in gastric cancer issues on the progression and survival of gastric cancer. A total of 481 gastric cancer patients were enrolled in this prospective hospital-based cohort study. Another 114 subjects without gastric cancer were recruited as control group. Plasma levels of IGF1, IGF2, IGFBP1, IGFBP2, and IGFBP3 were determined by commercially available enzyme-linked immunosorbent assay or radioimmunoassay kits. Expression of IGFBP2 was assessed by immunohistochemical stains. Their impacts on gastric cancer survival were analyzed by log-rank test and Cox proportional hazards regression models.

**Results:** Plasma levels of IGFBP2 was significantly higher in patients with gastric cancer as compared to healthy controls ( $p < 0.001$ ). Plasma levels of IGFBP2 was also significantly higher in patients with more advanced AJCC stages ( $p < 0.001$ ). However, the plasma levels of IGF1, IGF2, IGFBP1,

and IGFBP3 were not significantly differed in gastric cancer patients and controls. Patients with the highest tertile of IGFBP-2 levels were associated with a worse overall survival compared to those with the lowest IGFBP2 tertile levels (Hazard Ratio =1.51, 95% CI=1.19-1.92, p=0.001) after adjustment for age, gender, location, histology type, depth of invasion, and nodal metastasis. Higher expression of IGFBP2 in gastric cancer tissues was also associated with a worse overall survival than those with lower expression of IGFBP2, after adjustment of the above variables. In contrast, the plasma levels of IGF1, IGF2, IGFBP1, and IGFBP3 were not correlated with the overall survival in gastric cancer patients.

**Conclusion:** IGFBP2 plasma level, but not IGF1, IGF2, IGFBP1, or IGFBP3 levels, was higher in patients with gastric cancer and correlated with stage and survival. Higher expression of IGFBP2 in gastric cancer tissues also correlated with a worse overall survival. The finding lends support that IGFBP2 is a potential therapeutic target for gastric cancer.

**Disclosure:** Nothing to disclose

## P0625 OMENTAL FAT TISSUE PROMOTES PERITONEAL DISSEMINATION OF GASTRIC CANCER

Natsume M., Shimura T., Iwasaki H., Okuda Y., Kataoka H.  
Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan

**Contact E-Mail Address:** makoto04130510@gmail.com

**Introduction:** Gastric cancer (GC) has a clear predilection for peritoneal metastasis that cause poor prognosis. However, the exact mechanism why peritoneal metastasis frequently occurs in GC remains unknown. Omentum is the major cite for peritoneal metastasis, which is consisted of a huge fat tissue. We hypothesize that omental adipocytes trigger GC cell toward malignant activity inducing peritoneal metastasis.

**Aims & Methods:** We used 2 gastric cancer cell lines that were derived from primary GC tumor without metastasis. Omental adipocyte (OmAd) was used to assess interaction with GC cells. Endothelial cells (EC) were also used for *in vitro* angiogenesis assay including EC recruitment assay and tube formation assay. Cytokine protein array and PCR array were used for comprehensive analysis to identify responsible factors, and western blot analysis and qPCR were used to determine expression level of each gene and protein.

**Results:** Conditioned media (CM) derived from OmAd (OmAd-CM) significantly promoted proliferation and migration of GC cells compared to control media. OmAd-CM also reinforced the ability of GC cells inducing EC recruitment and tube formation. The cytokine array identified that GRO was abundantly contained in OmAd-CM and CXCL2 is the most expressed among GRO family. Silencing CXCL2 from OmAd (siCXCL2-OmAd) inhibited OmAd-induced cell growth and migration in both GC cell lines, as well as angiogenesis. In addition, OmAd-CM induced HIF1 $\alpha$  and VEGF-A production of GC cells through AKT phosphorylation.

**Conclusion:** Omental adipocytes triggers GC cells on aggressive phenotype through CXCL2 secretion, which induces angiogenesis followed by cell growth and peritoneal metastasis.

**Disclosure:** Nothing to disclose

## P0626 HOXA11 GENE IDENTIFIED BY DNA METHYLATION PROFILING AS PROGNOSTIC MOLECULAR MARKER IN HUMAN GASTRIC ADENOCARCINOMA

Ignatavicius P.<sup>1</sup>, Dauksa A.<sup>1</sup>, Zilinskas J.<sup>1</sup>, Kazokaite M.<sup>2</sup>, Barauskas G.<sup>1</sup>

<sup>1</sup>Lithuanian University of Health Sciences, Surgery, Kaunas, Lithuania,

<sup>2</sup>Lithuanian University of Health Sciences, Kaunas, Lithuania

**Contact E-Mail Address:** ignatavicius@gmail.com

**Introduction:** Gastric cancer is one of the most often diagnosed cancers worldwide with over 1,000,000 new cases annually. One of the most important epigenetic mechanism in the carcinogenesis is DNA methylation with 2 main processes of hypermethylation of tumor suppressor genes and hypomethylation of oncogenes.

Multiple studies have shown the importance of these changes as possible biomarkers for the early diagnosis, treatment effectiveness and disease progression in various cancers.

**Aims & Methods:** The aim of this study was to assess the DNA methylation status of selected genes in gastric cancer tissues samples and evaluate the prognostic importance of these genes. Patients (99) diagnosed with gas-

tric adenocarcinoma were included in the study. All patients underwent total or distal gastrectomy. Gastric cancer tissues and adjacent healthy gastric mucosa was taken from the surgical specimen. Genomic DNA was extracted from 25 to 40 mg of frozen tissues using "AllPrep DNA/RNA Kit" according to manufacturer's recommendation.

We selected a group of genes (*RAD51B*, *GFRA3*, *AKR7A3*, *HOXA11*, *TUSC3*, *FLI1*, *SEZ6L*, *GLDC*, *NDRG*) which are involved in cellular pathways such as signal transduction, apoptosis, cell to cell communication, cell cycles and cytokine signaling, are down-regulated in cancers and may be considered as potential tumor suppressor genes or oncogenes. Specific primers for methylated and unmethylated DNA sequence were designed using "MethPrimer". Methylation-specific polymerase chain reaction was performed in 25 ml of total volume. The presence of a Polymerase chain reaction product signal of the correct molecular weight indicates the presence of either unmethylated or methylated alleles.

**Results:** Only methylation of the *HOXA11* gene (Candidate tumor suppressor) promoter was significantly more frequent in gastric cancer tumor tissue (P = 0.006) than in adjacent healthy gastric mucosa. Limited significance (P = 0.054) was observed in *SEZ6L* gene (Tumor suppressor) promoter region comparing methylation frequency between gastric cancer tissue (50.5%) and healthy gastric mucosa (29.3%). The probability to survive longer was observed only with unmethylated *HOXA11* promoter in cancer tissues 71.2 months (95% CI 57-85.3) comparing to methylated cases with survival of 44.3 months (95% CI 34.8-53.9). Moreover, survival time was significantly shorter (28.5 months (95% CI 20.8-36.2) vs. 61.2 months (95% CI 50.9-71.4)) in gastric cancer patients, when methylation was observed in adjacent healthy gastric mucosa comparing to patients with methylation in one tissue alone (healthy gastric mucosa or gastric cancer tissue). Multivariate Cox analysis revealed the *HOXA11* methylation as significantly associated with gastric cancer patients' survival (HR=2.4, 95% CI 1.19-4.86).

**Conclusion:** DNA methylation of *HOXA11* gene promoter is more frequent in gastric cancer tumor tissue (68.7%) than in healthy gastric mucosa (39.4%) and is associated with shorter postoperative survival in patients diagnosed with gastric adenocarcinoma. Our results suggest that *HOXA11* gene might be a prognostic molecular marker in patients with gastric adenocarcinoma.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** asgarcia@unizar.es

**Introduction:** Repair of DNA damage is a complex and crucial process involving multiple enzymes and pathways (base excision repair, mismatch repair, nucleotide excision repair, and double strand break repair). Defi-

ciencies in this system likely lead to genomic instability affecting cancer development and prognosis. Some specific polymorphisms in DNA repair genes have been reported to play a key role in the prognosis of gastric cancer (GC). However, results are inconsistent among studies.

**Aims & Methods:** Since allele frequencies differ notably among ethnicities, we aimed to assess the prognostic value (overall survival) of DNA repair gene polymorphisms on GC in a Caucasian population in Spain. Six hundred and three unrelated patients diagnosed with primary GC from January 2003 to December 2010 in a network of 16 general Spanish hospitals were included in the study. Genomic DNA from GC patients was typed for a panel of 120 single nucleotide polymorphisms (SNPs) located in 52 key DNA repair pathway genes by using the Illumina platform. Overall Survival (OS) among different genotype groups was estimated using the Kaplan-Meier method and compared using the log rank test. Moreover, Cox proportional hazards models were performed to evaluate the prognostic value of DNA repair gene polymorphisms on patient's survival. *Helicobacter pylori* infection and CagA/VacA antibody status were determined in serum by western blot.

**Results:** The median follow-up time for all GC patients in our study was 12.5 months (range: 0.3-124). Four hundred and eighty five GC patients (80.4%) had died at the end of the follow-up period (December 2017) with a median OS of 10.07 months (CI 95%: 6.65-9.42). For censored patients, the median OS was 45.07 months (CI 95%: 36.21-53.38). Of the environmental and clinicopathologic features evaluated in this study, Cox regression analysis identified tumor stages TNM III (HR:4.32, 95% CI:2.84-6.59) and IV (HR:9.27, 95%:6.2-13.85) as prognosis factors associated with significantly reduced OS in GC patients, whereas surgical treatment (HR:0.45, 95% CI:0.36-1.57), and chemotherapy (HR:0.52, 95%:0.39-0.68) were related to a better prognosis of the disease. Concerning gene polymorphisms, only the rs1799796A>G gene variant was associated with overall survival in GC patients after correction for multiple testing. This SNP is located in the *XRCC3* gene which encodes a member of the Rad51-related protein family that participates in the double-strand break repair pathway. We found that GC patients carrying the *XRCC3* rs1799796G variant showed a significantly higher OS than non-carriers (375 days vs.184 days; HR:0.7, 95% CI:0.57-0.86). Further stratification of GC patients by age, gender, smoking habit, *Helicobacter pylori* status, tumor location, histological type, TNM stage, treatment and Charlson index, showed no effect of gene variants on patient's survival.

**Conclusion:** Our data show that the specific *XRCC3* rs1799796G gene variant is relevant in determining the individual prognosis of gastric cancer in Caucasians.

**Disclosure:** Nothing to disclose

**Introduction:** Autoimmune Chronic Atrophic Gastritis (ACAG) is epidemiologically and biologically linked to the development of gastric carcinoids type I (GCs) and gastric adenocarcinoma.

ACAG is often associated to other autoimmune disorders. The aim of the study was to evaluate the incidence of GCs development and to discover potential diagnostic markers related to GCs in patients (pts) with ACAG.

**Aims & Methods:** 141 pts with ACAG enrolled between years 2006-2017 and were evaluated by endoscopy for the presence of GCs. Pepsinogen I (PG1), Pepsinogen II (PG2) and Gastrin 17 (G17) serum levels were quantified using an enzyme-linked immune-sorbent assay kit. Serum levels of PGs and G17 were used to discriminate among pts with ACAG and pts affected by GCs in univariate and in multivariate analysis. A panel of genetic polymor-

phisms of PG2 gene and miRNA, that are known to modulate PG2 expression (rs9471643 C/G; rs6458238 A/G; rs811742 A/G; rs121224 C/G; rs1002765 A/G; TATA-BOX length), was tested by real time PCR.

**Results:** Out of the 141 ACAG pts (26 M, 115 F; mean age 54.5), 21 (15 %) (4M, 17F) presented GCs. A secondary autoimmune disorder was displayed by 98 pts (69.5%) and autoimmune thyroiditis was the most frequent (61.9%). A statistically significant difference in PG1/PG2 and G17 levels was found between ACAG pts with or without GCs ( $r=-0.3768$  95% CI-0.5499 to -0.1726  $p=0.0005$ ).

Although it is known that PG2 levels correlate with *Helicobacter Pylori* (HP) infection in our series of ACAG and GCs and ACAG pts there wasn't a statistical significant difference nor in number of HP positive (+) pts nor in IgG anti HP load (HP+ GCs pts 17.6%, HP+ ACAG pts 30.2%; GCs pts IgG anti HP mean 19.42 SD:  $\pm 27.71$ , ACAG pts IgG anti HP mean 33.43 SD:  $\pm 41.43$   $p=ns$ ). Among the 6 genetic polymorphisms, we found that rs811742 A/G, rs121224 C/G were associated to a difference in serum PG2 levels and GCs ( $p=0.0016$  and  $p=0.0051$ ). No significant differences were found between pts with thyroiditis and GCs and pts without thyroiditis and with GCs (6.3 % and 8.5 %  $p=0.07$ ).

**Conclusion:** GCs are often diagnosed incidentally during endoscopy. We found a higher association between GCs type I and ACAG than data present in literature and of interest we found a statistically significant difference in PG1/PG2 and G17 levels between ACAG pts with or without GCs. The identification of a different level of PGs ratio and G17 in GCs-positive ACAG could be proposed as a potential indicative marker for a further endoscopic targeted evaluation for GCs in ACAG pts.

**Disclosure:** Nothing to disclose

## P0629 EXPRESSION OF AKT, MTOR, VEGFR2, GSK3 $\beta$ IN GASTRIC CANCER, PRECANCEROUS LESIONS AND CONDITIONS

Denisova A.<sup>1</sup>, Salmina A.<sup>2</sup>, Cherdantsev D.<sup>3</sup>, Zhegalov P.<sup>1</sup>

**Contact E-Mail Address:** a.b.denisova@mail.ru

**Introduction:** Gastric cancer (GC) is one of the leading causes of cancer deaths worldwide[1]. Unfortunately GC is often found when it is not curable [2]. GC development is a consecutive process which is called "Correa cascade", that describes development of GC from *H.pylori* chronic gastritis through atrophic changes, metaplasia, dysplasia to gastric cancer [3,4,5]. Prevention of GC development and diagnostic of early GC is a very important direction in modern gastroenterology, endoscopy and anticancer programs. More and more attention is paid to the molecular processes of GC development, especially to grow factor receptor pathway. Research in this field could help to understand more about this process and to improve diagnostic systems and targeted therapy.

**Aims & Methods:** Biopsy from 99 patients 22-93 years old admitted to Krasnoyarsk Regional Hospital were collected during gastroscopy. After histological assessment patients were divided in 4 groups: 1st group - chronic nonatrophic pangastritis (n=27), 2nd - chronic atrophic pangastritis with intestinal metaplasia (n=31), 3rd - chronic atrophic pangastritis with dysplasia (n=11), 4th - GC (n=30) with signet ring cell carcinoma (n=15) and adenocarcinoma (n=15). Undirected immunohistochemical analysis with fluorescent marking was done in order to reveal the expression of AKT, mTOR, VEGFR2, GSK3 $\beta$  molecules, TUNEL method was used to assess apoptosis level.

**Results:** Expression of AKT was significantly increased in patients with precancerous lesions and decrease in GC group ( $p_{1-3} = 0.0007$ ,  $p_{2-3} = 0.006$ ,  $p_{3-4} = 0.031$ ). mTOR expression was decreased in GC group ( $p_{1-4} = 0.021$ ,  $p_{3-4} = 0.05$ ). Changes in VEGFR2, GSK3 $\beta$  expression was not statistically significant, but the tendency with maximal value in group with dysplasia and moderate decreasing in GC group was observed. There was no difference in expression in two types of cancer inside the GC group. The highest apoptosis level was observed in gastritis with metaplastic changes and lowest in GC group ( $p_{1-4} = 0.004$ ,  $p_{2-4} = 0.021$ ,  $p_{3-4} = 0.00002$ ). These changes in molecules expression could mark the stages of tumor growth such as angiogenesis, decreasing of apoptosis and proliferation.

**Conclusion:** Changes in AKT/mTOR/VEGFR/GSK3 $\beta$  pathway is an early event in gastric mucosa transformation, could happen even on stage of precancerous conditions, lesions and mark the stages of each step of Correa cascade. AKT is responsible for cell growth and proliferation and high

level of mTOR expression could explain metabolic changes, low apoptosis level and cell survival which are inherent characteristics of malignant tumor. Further research is needed to understand more about molecular processes in GC development.

**Contact E-Mail Address:** asgarcia@unizar.es

**Introduction:** The innate immune response constitutes the first line of defense against infection by microbes such as *Helicobacter pylori* (*H. pylori*). This system senses, recognizes, and responds to bacterial components by activating a complex signaling cascade of pattern-recognition receptors (PRRs), which include the Toll-like receptors (TLRs). Several polymorphic variants in *TLR* genes have been shown to affect responsiveness to *H. pylori* infection leading to an aberrant activation of the NF- $\kappa$ B pathway and up-regulation of pro-inflammatory molecule expression.

**Aims & Methods:** Given the relevance of *H. pylori* infection and chronic inflammation in gastric carcinogenesis, we aimed to assess the role of specific *TLR* gene polymorphisms on gastric cancer (GC) risk and phenotype in a Caucasian population in Spain. Genomic DNA from 673 unrelated Spanish patients with primary GC and 673 sex- and aged- ( $\pm$  5 years) matched cancer-free healthy controls was typed for 26 single nucleotide polymorphisms (SNPs) in the *TRL1* (rs10004195, rs4833095, rs4833103, rs5743551), *TLR2* (rs5743708, rs121917864, rs1898830, rs3804099, rs3804100), *TLR4* (rs4986790, rs4986791, rs11536889, rs10759932, rs16906079, rs2149356), *TLR5* (rs5744168, rs5744174, rs2072493), *TLR6* (rs5743810), *TLR8* (rs1980499, rs3764880), *TLR9* (rs5743836, rs352140, rs187084), and *TLR10* (rs11466657, rs4129009) genes by using the Massarray (Sequenon) platform. Analysis of genotyping data was performed by the bioinformatic tool SNPAssoc (R). *H. pylori* infection and CagA/VacA antibody status were determined in serum by western blot in patients and controls.

**Results:** Logistic regression analysis identified *H. pylori* infection with CagA strains (OR: 2.13; 95% CI: 1.68-2.69), smoking habit (OR: 1.82; 95% CI: 1.29-2.55) and positive family history of GC (OR: 2.83; 95% CI: 1.89-4.23) as independent risk factors for GC. Concerning gene polymorphisms, the most remarkable association was observed in the *TLR2* gene with the G allele of rs1898830 being associated with a higher risk of GC (log-additive model OR: 1.21; 95% CI: 1.06-1.42). Moreover, the *TLR1* rs10004195T>A polymorphism, previously reported to be related with *H. pylori* seroprevalence, was significantly associated with susceptibility to *H. pylori* infection in our control population (recessive model OR: 0.70; 95% CI: 0.51-0.97). No significant differences in carriage, genotype, and allele frequencies of the *TLR* gene polymorphisms were found when GC patients were categorized according to gender, age, smoking habit, *H. pylori* infection, CagA/VacA antibody status, family history of GC, tumor location, and histological subtype.

**Conclusion:** Our data show that the *TLR2* rs1898830A>G gene polymorphism is involved in defining the genetic basis of the risk to GC, and support the relevance of *TLR1* rs10004195 gene variant on *H. pylori*-infection susceptibility.

## P0631 PLASMA LONG NONCODING RNAS PANDAR, FOXD2-AS1, AND SMARCC2 AS POTENTIAL NOVEL DIAGNOSTIC BIOMARKERS FOR GASTRIC CANCER

Shi Y.<sup>1</sup>, Ding S.<sup>2</sup>

<sup>1</sup>Peking University Third Hospital, Research Center of Clinical Epidemiology, Beijing, China, <sup>2</sup>Gastroenterology, Beijing, China

**Contact E-Mail Address:** 0729xst@163.com

**Introduction:** Gastric cancer is still a common cancer worldwide. Investigation of potential plasma biomarkers for gastric cancer diagnosis is essential for prevention strategies and early intervention for gastric cancer-control planning.

**Aims & Methods:**

**Objectives:** This study was aimed to explore the lncRNAs PANDAR, FOXD2-AS1, and SMARCC2 as potential novel diagnostic biomarkers for gastric cancer.

**Method:** 109 gastric cancer patients and 106 healthy controls were involved in this study. Plasma lncRNAs PANDAR, FOXD2-AS1, and SMARCC2 were detected by real-time PCR. Student's t-test, Mann-Whitney U test, and Chi-square test were used to verify the differences of clinical variables between two groups. Receiver operating characteristic curve (ROC) was used to evaluate the diagnostic value of every biomarker. Multivariable analysis of risk factors for gastric cancer was performed using logistic regression analysis.

**Results:** There were significant differences in age, gender, CEA, CA153 between gastric cancer and healthy controls ( $P < 0.05$ ). Comparing with healthy subjects, the levels of plasma lncRNAs PANDAR, FOXD2-AS1, and SMARCC2 were all significantly higher in gastric cancer patients ( $P < 0.05$ ). These lncRNAs were significantly associated with clinicopathological parameters of gastric cancer, like pathological differentiation, TNM stage, and/or lymph nodes metastasis, and/or invasion depth ( $P < 0.05$ ). The AUC for lncRNA PANDAR was 0.767, for FOXD2-AS1 was 0.700, for SMARCC2 was 0.748, and the AUC of the combinative diagnostic value of these three lncRNAs was 0.839. Adjusted by other variables, these lncRNAs expression were significantly associated with gastric cancer.

**Conclusion:** Plasma lncRNAs PANDAR, FOXD2-AS1, and SMARCC2 might be appropriate diagnostic biomarkers for gastric cancer.

**Contact E-Mail Address:** yolanda.pazos.randulfe@sergas.es

**Introduction:** Obestatin is a 23-aminoacid peptide derived from pre-proghrelin, was isolated from the stomach in 2005 and binds to the GPR39 receptor. Our group has described the expression of the obestatin/GPR39 system in healthy human stomach, as well as in gastric adenocarcinoma, where we have shown a role in both the pathogenicity and the prognosis of this tumor. The obestatin/GPR39 system regulates proliferation, epithelial-mesenchymal transition, migration capacity, invasion and metastasis in the AGS cell line, which derives from a moderately differentiated adenocarcinoma. The GPR39 expression levels found in human gastric adenocarcinomas provide the basis for including GPR39 as a prognostic marker for these tumors.

**Aims & Methods:** The objective of this study is to evaluate the involvement of this system in the proliferation of cell lines of human pancreatic cancer with different degrees of differentiation: the AGS cell line, a moderately differentiated adenocarcinoma; the KATO III cell line, a poorly differentiated adenocarcinoma; and the NCI-N87 cell line, a liver metastasis of a well-differentiated adenocarcinoma.

The analysis of the obestatin/GPR39 system expression in the tumor cell lines (AGS, KATO-III and NCI-N87) was performed by using immunocytochemical techniques. In addition, cell proliferation assays were performed after obestatin treatment (100 nM) by BrdU incorporation (AGS and NCI-N87) and manual counting (AGS and KATO-III). 10% FBS was used as positive control.

**Results:** All the studied cell lines strongly expressed the obestatin/GPR39 system. No immunostaining was shown in negative controls incubated without primary antibody. Obestatin (100 nM) exerted a mitogenic effect in the AGS line (46,2 8,66% over control;  $p < 0,01$ ), the NCI-87 cells (60,82 2,83% over control;  $p < 0,001$ ) and in the KATO-III cell line (44,00 3,10% over control;  $p < 0,01$ ).

**Conclusion:** This study offers two main findings:

1. The obestatin/GPR39 system is intensely expressed in tumor cell lines of the human stomach;
2. The exogenous obestatin treatment increased the proliferation of these cell lines, with no differences between the different cell lines. The obtained results showed that the obestatin/GPR39 system is involved in the proliferative processes in gastric cancer.

**Disclosure:** Nothing to disclose

## P0633 WITHDRAWN

**Contact E-Mail Address:** dc.dalilacosta@gmail.com

**Introduction:** Sporadic duodenal neuroendocrine tumors (NETs) are relatively rare tumors of the gastrointestinal tract, but their incidence shows gradual increase in recent histopathological series. Gastrin-producing cells (G-Cells) NETs is the most frequent, though little is known about the features involved in its pathogenesis.

**Aims & Methods:** Considering the role of atrophic gastritis and Helicobacter pylori (Hp) infection in antral G-cells hyperplastic changes, we aimed to investigate the relationship between these factors and the development of sporadic bulb NETs. A prospective, case-control study was performed with 77 patients: 13 bulb NETs patients and 64 controls, randomly selected (28 chronic atrophic gastritis, CAG; 21 chronic superficial gastritis; and 15 normal subjects). All participants underwent upper gastrointestinal endoscopy with biopsies (antrum, corpus and bulb). Gastritis pattern was assessed. Bulb samples were evaluated for D- and G-cells quantification and G-cells hyperplastic changes. Hp infection was determined in both locations. Baseline biodemographic variables were also analysed.

**Results:** All NETs were G-cells tumors, small in size (median 7 mm), restricted up to submucosa, resected by mucosectomy, with no evidence of dissemination at diagnosis or during follow-up. At multivariate analysis, gastric Hp infection (OR=8,2;  $p=0,022$ ), duodenal Hp infection (OR=16;  $p=0,027$ ) and bulbar G-cells linear/micronodular hyperplasia (OR=79;  $p<0,001$ ) were independent predictors of G-cells NETs development. Additionally, bulbar G-cells linear/micronodular hyperplasia had a significant association with chronic use of proton pump inhibitors ( $p=0.018$ ). Both, NETs and G-cells hyperplasia, were not associated with body CAG.

**Conclusion:** Data reinforced that sporadic G-cells NETs may originate from a proliferative phase sequence. Our data suggests that Hp and related inflammation, seems the most important factor in our population. Its involvement as cause or epiphenomena in bulb G-cells hyperplasia and tumor should be further studied.

## P0635 PREVALENCE OF HELICOBACTER PYLORI INFECTION IN NONDIABETIC NAFLD AND IT ASSOCIATION IN SEVERITY OF FIBROSIS

Siricharoonwong W., Boonsirichan R.

Faculty of Medicine, Vajira Hospital, Internal Medicine, Bangkok, Thailand

**Contact E-Mail Address:** kwangwarisara@gmail.com

**Introduction:** Nonalcoholic fatty liver disease (NAFLD) is one of the most common causes of cirrhosis worldwide. A considerable amount of patients without DM still has NASH and advanced fibrosis. Helicobacter pylori (H. pylori) infection contribute to the increase in levels of pro-inflammatory cytokines which have different metabolic effects and associated with insulin resistance (IR). Therefore, H. Pylori may possibly have an effect on fibrosis progression in NAFLD in nondiabetic patients.

**Aims & Methods:** Investigate the prevalence of H. pylori infection in nondiabetic NAFLD patient and its association in advance fibrosis.

Nondiabetic patients who were diagnosed NAFLD by abdominal ultrasonography and/or controlled attenuation parameter (CAP) from FibroScan® were recruited for H. pylori infection testing by a 14C-urea breath test. All participants were evaluated liver fibrosis with transient elastography. They were collected standard biochemical test (eg. FPG, LDL, liver function test) and interleukin-6 to evaluate the inflammatory response. To minimized the confounding effect, we excluded patients who had BMI > 28 kg/m2 or

received steatogenic drugs. The outcome was the prevalence of *H. pylori* infection in NAFLD patients. We also investigated factors which independently associated with advanced fibrosis.

**Results:** A total of 117 NAFLD patients were enrolled. We found overall *H. pylori* infection in 54 patients (46%). In patients with advanced fibrosis (defined as fibrosis stage > 3 from transient elastography), the prevalence of advanced hepatic fibrosis in NAFLD patients with *H. pylori* infection is higher (22/54, 40.7%) than in non-infected group (18/63, 28.6%). Obesity was the variable most associated with advanced fibrosis (OR 3.18 [1.25-8.09], p-value 0.02) in univariate analysis. *H. pylori* infection had a marginal effect to advanced fibrosis (OR 1.72 [0.8-3.71], p-value 0.17) but no statistically significant in multivariate analysis. Other metabolic variables and interleukin-6 were not significantly associated with advanced fibrosis.

**Conclusion:** Prevalence of *H. pylori* infection in nondiabetic NAFLD patient similar to the general Thai population. Our results could not demonstrate the risk of *H. pylori* infection to advanced fibrosis. However, NAFLD patients with *H. pylori* infection tend to have a higher prevalence of advanced hepatic fibrosis.

**Contact E-Mail Address:** camille.tiffon@u-bordeaux.fr

**Introduction:** Gastric cancer is the third leading cause of cancer-related death worldwide and *Helicobacter pylori* is recognised as its main risk factor. We have reported that *H. pylori* infection leads, through an epithelial mesenchymal transition (EMT), to the emergence of CD44+ cells with cancer stem cell (CSC) properties. The Hippo tumour suppressor pathway and its oncogenic targets YAP/TAZ control cancer initiation and progression in many cancers.

Their regulation in the context of *H. pylori*-mediated gastric carcinogenesis has not been described. We hypothesized that TAZ could be involved in the EMT process and CSC-like cells generation observed during *H. pylori* infection.

**Aims & Methods:** The aim of this project was to investigate the role of TAZ during the EMT and the emergence of CSC induced by chronic infection with *H. pylori* and during gastric carcinogenesis.

The consequences of TAZ inhibition were studied on *H. pylori*-induced EMT and CSC signature and properties in gastric epithelial cell lines *in vitro*. The consequences of TAZ inhibition by a siRNA strategy were studied in MKN45 and NCI-N87 gastric epithelial cell lines infected or not with the carcinogenic *H. pylori* strains 7.13 and P12 as well as *cagA* and *cagPAI* isogenic mutants. The expression of Hippo/TAZ/TEAD pathway related genes and of EMT/CSC markers was assessed by RTqPCR, western blot and immunofluorescence. TAZ/TEAD transcriptional activity was evaluated by TEAD-luciferase reporter assay. EMT and CSC functional properties were evaluated by invasion and tumorsphere assays *in vitro*.

**Results:** We showed that *H. pylori* infection transiently stimulates TAZ nuclear translocation and co-transcriptional activity in a CagA-dependent manner. TAZ inhibition reduced EMT markers expression, which correlated with a decrease of invasive properties induced upon *H. pylori* infection. Moreover, TAZ inhibition reduced spheroid formation which involves the CSC sub-population.

**Conclusion:** The Hippo/TAZ pathway is activated upon *H. pylori* infection in gastric epithelial cells and TAZ activation participates to the regulation of *H. pylori*-induced EMT and CSC invasive and tumorigenic properties.

**Disclosure:** Nothing to disclose

## P0637 HIGH CONCORDANCE RATES OF PREMALIGNANT GASTRIC LESIONS ASSESSED BY OLGA AND OLGIM IN MONOZYGOTIC AND DIZYGOTIC TWINS

**Contact E-Mail Address:** aukstaitis.mindaugas@gmail.com

**Introduction:** The development and progression of chronic *H. pylori* gastritis toward pre-neoplastic gastric lesions is a multifactorial process, which depends on interactions between environmental factors, *H. pylori* infection, gastric microbiota and host genetic factors. To date, there are no studies that would evaluate the role of shared genetic influences on susceptibility and phenotype of chronic *H. pylori* gastritis and premalignant gastric alterations in twins.

**Aims & Methods:** To compare histological alterations of gastric mucosa according to Sydney classification, OLGA and OLGIM staging systems in monozygotic and dizygotic twins. This prospective study included 58 individuals with 13 pairs of monozygotic and 16 pairs (11 same-sex pairs and 5 mixed-sex pairs) of dizygotic twins aged >18 years. Endoscopy for both twins was performed simultaneously on the same day. At endoscopy 5 biopsy specimens were collected: 2 from the greater and lesser curvatures of antrum, 1 from incisura angularis, 2 from the anterior and posterior walls of the corpus. *H. pylori* gastritis was assessed by histology and graded by OLGA and OLGIM staging systems.

**Results:** Mean age of monozygotic and dizygotic twins was 41.23 y and 38.43 y, respectively. Total prevalence of *H. pylori* was 53.4%. Among monozygotic twins, six pairs were both positive, three pairs were both negative and four pairs were discordant for the presence of *H. pylori*.

Among dizygotic twins, four pairs were both positive, five pairs were both negative and seven pairs were discordant for presence of *H. pylori*. Concordance rate for chronic *H. pylori* gastritis in monozygotic twins was 69.2 % (9/13 pairs) and in dizygotic twins 62.5% (10/16 pairs), p>0.05. Concordance for antrum atrophy in monozygotic twins was 76.9 % and 75 % in dizygotic twins (p>0.05). Concordance for corpus atrophy in monozygotic twins was 92.3% and in dizygotic twins 87.5% (p>0.05). Concordance for antrum IM in monozygotic twins was 84.6% and in dizygotic 75 % (p>0.05). Concordance for corpus IM in monozygotic twins was 84.6 % and in dizygotic 93.7 % (p>0.05). There was no statistical difference in concordance rates for OLGA and OLGIM stages both for monozygotic and dizygotic twins.

**Conclusion:** Histological gastric mucosa alterations related to *H. pylori* gastritis and premalignant lesions in monozygotic and dizygotic twins show high rates of concordance.

**Disclosure:** Nothing to disclose

**Introduction:** The stomach-colonizing Gram-negative bacterium *Helicobacter pylori* establishes a life-long infection in humans, infecting more than half of the world population. *H. pylori* is the main etiological factor of several gastroduodenal diseases, including chronic gastritis, peptic ulcers, gastric mucosa-associated lymphoid tissue lymphoma, gastric adenocarcinoma, and more recently it has been associated with some extra-gastric diseases.

Gram-negative bacterial membrane vesicles are nanosized vesicles ranging from 20 nm to 300 nm that are secreted by virtually all bacteria. They constitute a successful strategy used by bacteria to manipulate host cell functions important for their survival, colonization, and persistence in the host with implications in bacteria-mediated pathogenesis.

**Aims & Methods:** The effect of bacterial membrane vesicles on host gene expression is poorly understood. Thus, the aim of this study was to investigate the impact of *H. pylori*-derived membrane vesicles uptake by gastric epithelial cells in the modulation of gene expression. Total RNA was isolated from the human gastric epithelial cell line MKN74 either unchallenged (N=3) or challenged (N=6) for 24 hours with membrane vesicles isolated from the *H. pylori* 26695 strain. A targeted RNA sequencing analysis covering 20,000 human genes was performed using the Ion Ampliseq Transcriptome kit. Differential expression analysis between unchallenged and challenged MKN74 cells was performed using the DESeq R package. Overrepresentation of gene ontology terms was determined using topGO.

**Results:** Our results show that ~1% (224/20,000) of the interrogated genes were differentially expressed between unchallenged and membrane vesicle-challenged MKN74 cells (adjusted P-value < 0.05), of which 99 genes were downregulated and 125 genes were upregulated. Enrichment analysis of the top forty differentially expressed genes (20 up- and 20 down-regulated) were clustered to gene ontology terms such as cytoskeleton and extracellular region for cellular components; growth factor and cytokines activity, protein binding, signalling receptor and protein kinase binding for molecular functions, and; regulation of phosphorylation, regulation of apoptotic process, signal transduction, and cell cycle regarding biological processes.

**Conclusion:** In summary, our findings show that *H. pylori*-derived membrane vesicles are able to modify gene expression of the gastric epithelial cell line MKN74, suggesting a role for these vesicles in the bacteria-mediated pathogenesis.

**Introduction:** Colonization of the gastric mucosa with *Helicobacter pylori* (*Hp*) leads to the cascade of pathologic events including local inflammation, gastric ulceration and adenocarcinoma formation. Paracrine loops between tissue cells and *Hp* have recently been implicated in the formation of gastric cancerous loci, however, the specific mechanisms underlying existence of these loops remain unknown. Here, we determined the phenotypic properties of gastric fibroblasts recently considered as the target for *Hp* (cagA+vacA+) infection and their influence on normal epithelial RGM-1 cells.

**Aims & Methods:** RGM-1 cells were cultured in the media conditioned with *Hp*-activated gastric fibroblasts. Their morphology and phenotypical changes associated with epithelial-mesenchymal transition (EMT) were assessed by Nomarski contrast microscopy, fluorescent microscopy and Western Blot analysis. Motility pattern of RGM-1 cells in infected and non-infected fibroblast supernatant was examined by time-lapse videomicroscopy, and by transwell migration assay. The content of TGFβ in *Hp* activated fibroblasts conditioned media was determined by ELISA.

**Results:** The supernatant from *Hp*-activated gastric fibroblasts caused the EMT-like phenotypic diversification of RGM-1 cells. In particular, the formation of fibroblastoid cell sub-populations was observed along with disappearance of their collective migration. These cells were characterized by efficient movement, increased transmigration potential, thick actin stress fibers development and decreased proliferation activity. Concomitantly, we observed the downregulation of E-cadherin protein, upregulation of N-cadherin protein and the increased TGFβ level in the secretome of *Hp*-activated gastric fibroblasts. The fibroblast-CAF like transition was

manifested by increased level of α-SMA protein and its incorporation into stress fibers. The actin fibers dispersion characteristic for *Hp* (cagA+ vacA+) infection correlated with Snail mRNA upregulation.

**Conclusion:** Gastric fibroblasts which are one of the main targets for *Hp* infection contribute to the paracrine interactions between *Hp*, gastric fibroblasts and epithelial cells. TGFβ secreted by *Hp*-activated gastric fibroblasts prompting their differentiation towards CAF-like phenotype promotes the EMT-related phenotypic shifts in normal gastric epithelial cell populations. This mechanism may serve as the prerequisite for gastric cancer development.

**Introduction:** TLR4 is involved in the development of *H. pylori* induced gastropathies, but also in gastric carcinogenesis.

**Aims & Methods:** The aim of the study was to assess the clinical, endoscopic, and socioeconomic aspects, but also TLR4 rs4986791 gene polymorphism in children with *H. pylori* gastritis.

**Methods:** We performed a prospective study on 147 children admitted in a Pediatric Tertiary Gastroenterology Department from Romania, divided into 2 groups according to the presence, or absence of *H. pylori* infection: group 1 - 50 children with *H. pylori* associated gastritis and group 2 - 97 children with gastritis without *H. pylori* infection.

**Results:** We observed that poor socioeconomic status was a significant risk factor for *H. pylori* infection (p=0.002, OR=4.03, 95% CI: [1.71; 9.50]). We found that the most frequent symptoms in patients with gastritis were epigastric pain, abdominal pain, heartburn, but without significant differences between the two groups.

We identified significant correlations between the histopathological exam and rapid urease test (p< 0.001). The variant genotype of TLR4 rs4986791 gene polymorphism was a protective factor against *H. pylori* infection, but without statistical significance.

**Conclusion:** Socioeconomic status is a risk factor for *H. pylori* infection. The rapid urease test is a useful diagnostic tool for *H. pylori* infection. The variant genotype of the TLR4 rs4986791 gene polymorphisms might be a protective factor against *H. pylori* infection in children, but further studies are necessary in order to clearly identify its role.

**Introduction:** *Helicobacter pylori* (*H. pylori*) is classified as a Class 1 carcinogen. Eradication of *H. pylori* is therefore imperative to prevent the natural progression of disease and help restore the gastric mucosa from peptic pathologies. Apart from non-invasive testing using breath testing and stool sampling, the use of the rapid-urease test (RUT) during oesogastroduodenoscopy (OGD) is widely practiced. Whilst previously pansensitive, there is mounting evidence showing increased resistance of *H. pylori* to standard antibiotic regimens, which has resulted in reduced eradication rates.

**Aims & Methods:** To compare *H. pylori* detection through real-time polymerase chain reaction (RT-PCR) to the RUT done during OGD and determine the antibiotic sensitivity for quinolones and clarithromycin.

**Method:** Patients above 18 years of age, scheduled for an elective OGD were considered for recruitment. Exclusion criteria included: previous *H. pylori* treatment and antibiotic usage within the preceding three months. Two biopsies from the antrum and two from the corpus were collected. All four biopsies were combined and digested with tissue-lysing buffer and Proteinase K. Automated DNA extraction was performed followed by RT-PCR for *H. pylori* DNA detection. Positive samples were tested for clarithromycin and fluoroquinolones resistance using amplification and reverse hybridization techniques. Data regarding the result of RUT performed during the OGD was also noted.

**Results:** 200 patients (range 20-92 years) were recruited (females = 53.1%) Real-Time PCR detected *H. pylori* in 21% of patients compared to the 29.5% detection rate by the RUT. A positive RUT and a positive RT-PCR result was observed in 17.0% of patients while 12.5% of patients had a positive RUT result but a negative RT-PCR result. Furthermore, 4.0% of patients had a negative RUT but a positive RT-PCR result. Additionally, detection of *H. pylori* was also performed using reverse hybridization techniques with determination of its antibiotic susceptibilities. *H. pylori* was detected in 19.5% of total patients using this secondary molecular technique.

Fluoroquinolone resistance was present in 21.4% of patients and 26.2% of patients exhibited clarithromycin resistance, while dual resistance to both clarithromycin and fluoroquinolones was detected in another 4.8% of patients.

**Conclusion:** This data demonstrates similar *H. pylori* detection rates using RT-PCR and/or reverse hybridisation techniques but lower rates than the RUT. Moreover, our data also demonstrates a high resistance rate to both clarithromycin and fluoroquinolones. Such modern techniques should be considered to replace the RUT, to avoid unnecessary antibiotic prescription due to false-positive results. This would therefore ensure the prescription of adequate antibiotic regimens when *H. pylori* infection is in fact present.

**Introduction:** In gastric mucosal atrophy *H. pylori* density may be decreasing leading to false-negative histology results. Therefore, Maastricht V guidelines (Malfertheiner et al., 2016) accept the use of serological tests for non-invasive *H. pylori* diagnosis.

**Aims & Methods:** To evaluate the presence/absence of *H. pylori* by molecular methods in subjects with discrepant histology and serology result. Individuals with discrepant serology/histology result (group 1 - positive-serology, but negative-histology, group 2 - negative-serology, but positive-histology) were selected from a GISTAR pilot-study database. Subjects having received *H. pylori* eradication therapy in life-time or reporting use of proton pump inhibitors, antibacterial medications, bismuth containing drug use one month prior upper endoscopy were excluded.

Antibodies to *H. pylori* were assessed in plasma by enzyme-linked immunosorbent assay (ELISA). *H. pylori* deoxyribonucleic acid (DNA) detection in frozen biopsy sample was performed using a real-time polymerase chain reaction (PCR) as a gold standard. Immunohistochemistry (IHC) was performed in subjects with positive-histology and negative-serology. Presence of inflammation was evaluated according to mucosal neutrophil infiltration, subjects with stage II or III in any of biopsies was considered as a group with inflammation, meanwhile 0 or I in all biopsies - as group without inflammation.

**Results:** The final patient sample for analysis contained data from 97 individuals: serology-positive/histology-negative cases: 81, serology-negative/histology-positive: 16. Among the first group there were approximately one fifth (21.0%) falsely positives by serology, while in the second group there were 6.3% false positives by histology. In the PCR positive group six of 15 (or 40%) gastric mucosa showed no inflammation in all biopsies but the majority (14 subjects) had ICH positive results.

The overall analysis of *H. pylori* tests' discrepant cases are shown in the Table.

Serology/histology result	PCR result	Number of cases n/total (%)	Inflammation present in any of biopsies n/total (%)	Inflammation absent in all biopsies n/total (%)
Serology positive, histology negative cases	PCR positive	17/81 (21.0)	1/17 (5.9)	16/17 (94.1)
	PCR negative	64/81 (79.0)	1/64 (1.6)	63/64 (98.4)
Serology negative, histology positive cases	PCR positive	15/16 (93.8)	9/15 (60.0)	6/15 (40.0)
	PCR negative	1/16 (6.3)	0/1	1/1 (100)

[Table. Analysis for total patient sample in *H. pylori* tests' discrepant cases.]

**Conclusion:** Among this high *H. pylori* prevalence middle-aged population, the majority of discrepant cases between serology and histology were rather due to false positive-serology than false-negative histology. This could be explained by possible loss of bacterium due to atrophic changes in mucosa.

**Disclosure:** Nothing to disclose

## P0645 CLINICAL ASPECTS AND THE ROLE OF ADIPOKINES IN GALLSTONE DISEASE IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

**Introduction:** Close relationship between non-alcoholic fatty liver disease (NAFLD) and gallstone disease (GD) has been proved. Being aware of the specific features of the diseases the issue remains burning due to constant increase of patient number because of elevating the metabolic risk factors among the population, including obesity, overweight, diabetes mellitus type 2, dyslipidemia, etc.

**Aims & Methods:**

**Objective:** Update the comorbidity information about NAFLD and GD, evaluation of clinical and laboratory data, including insulin, leptin and adiponectin in patients with NAFLD in combination with GD.

**Materials and methods:** According to the design, the open comparative study with 215 patients with NAFLD was conducted. The following comparison groups were formed: group 1 (n = 94) - patients with NAFLD without GD, group 2 (n = 63) - patients with NAFLD and GD and group 3 (n = 58) - patients with NAFLD, GD and previous cholecystectomy.

**Results:** A high prevalence of coronary heart disease was detected in the group of patients with GD and cholecystectomy ( $X^2=6.198$ ,  $p\leq 0.05$ ); positive, statistically significant correlation

relationships of cholelithiasis, cholecystectomy with ischemic heart disease ( $r_s = 0.172$ ,  $p\leq 0.05$  and  $r_s=0.241$ ,  $p\leq 0.05$ , respectively). There was a statistically significant decrease in total bilirubin and total protein in patients in group 3 ( $H=7.376$ ,  $p\leq 0.03$  and  $H=6.345$ ,  $p\leq 0.04$ ). Insulin and leptin resistance were registered in patients with NAFLD and GD: insulin level 14.5 (7.12-35.78) mKED/ml, HOMA-IR (5.23(2.35-11.45)), leptin (14.53(9.56-28.67) ng/ml), its soluble receptors (8.03(3.98-9.45) ng/ml). There was a statistically significant increase in adiponectin ( $U=1106$ ,  $p\leq 0.05$ ) for patients with NAFLD and GD. The level of leptin was statistically significantly higher and positively interrelated with cholecystectomy ( $H=5.812$ ,  $p\leq 0.05$ ,  $r_s=0.313$ ,  $p\leq 0.05$ ).

**Conclusion:** Patients with NAFLD, GD and previous cholecystectomy have a high incidence of coronary heart disease; the phenomenon of insulin and leptin resistance, a high level of adiponectin were determined in patients with NAFLD and gallstone disease; hyperleptinemia was registered in patients with NAFLD and GD after cholecystectomy.

**Contact E-Mail Address:** mdyoshimura@gmail.com

**Introduction:** *Helicobacter pylori* (Hp) infection is the principal pathogenic cause of gastric cancer (GC), and eradication of Hp has been expected to decrease the incidence of GC. The recent rapid decline of Hp infection rate and global standardization of eradication therapy may affect the efficiency of GC diagnosis for screening endoscopy. We previously reported the increasing numbers of GC cases without Hp infection<sup>1</sup>, however, the GC detection rate in accordance with Hp infection status on screening endoscopy is not elucidated.

**Aims & Methods:** We performed a single-center retrospective study to examine the GC incidence rate in accordance with Hp infection status for examinees of screening endoscopy from April 2014 to March 2018. All examinees were screened for GC using ultrathin endoscopes mostly inserted transnasally, and Hp infection status was also diagnosed by Kyoto classification of endoscopic gastritis into three groups as Hp-infected, Hp-past infected (mostly post Hp eradication), and Hp-uninfected. Clinical and pathological characteristics of GC cases and GC detection rate of each group were investigated.

**Results:** During the study period, 28894 examinees (11622 females, 40.0%) were screened. Among them, 14402 (49.8%) were under the age of 50, and 476 (16.5%) were over the age of 70. Those who were examined annually for more than 2 years were 84.9% (24532 examinees). All the examinees were diagnosed into three groups as Hp-infected (2843, 9.8%), Hp-past infected (8239, 28.5%), and Hp-uninfected (17812, 61.6%), based upon Kyoto classification of endoscopic gastritis. Forty-eight GC cases (0.17%) were detected consisting of 16 cases of Hp-infected, 14 of Hp past-infected, and 18 of Hp-uninfected. All GC cases were treated endoscopically or surgically, and 46 cases were early cancers. Accordingly, GC detection rate in accordance with Hp infection status was 0.56% for Hp-infected, 0.17% for past-Hp infected, and 0.10% for Hp-uninfected. Both the past-Hp infected and the Hp-uninfected groups showed significantly lower detection rates of GC ( $p < 0.001$ , chi-square tests) than the Hp-infected group.

**Conclusion:** Our study elucidated that Hp eradication could decrease the incidence of GC drastically. However, unignorable numbers of early GC cases were also detected among the Hp-past infected and Hp-uninfected examinees, indicating that the screening intervals should be optimized in accordance with the Hp infection status. Our study has limitations because of the single-center study and of a large proportion of repeated examinees.

**Contact E-Mail Address:** n\_c\_par7@yahoo.co.jp

**Introduction:** Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is considered to be closely related to *Helicobacter pylori* (*H. pylori*) infection. Although eradication of *H. pylori* is the mainstay of treatment for patients with gastric MALT lymphoma, 20% of them cannot be cured by eradication therapy. And treatment for patients with *H. pylori*-negative or eradication therapy-resistant gastric lymphoma has not yet been established.

**Aims & Methods:** The aim of this study is to assess the efficacy of low-dose radiation therapy on *H. pylori*-negative or eradication therapy-resistant MALT lymphoma. We enrolled patients with gastric MALT lymphoma from January 1994 through April 2018. The diagnosis was made based on morphological and immunophenotypic analysis of biopsies obtained from gastric lesions on esophagogastroduodenoscopy (EGD) in accordance with the current WHO classification. Patients with localized (stages I and II) gastric MALT lymphoma according to the Lugano classification were eligible for enrollment. Patients were also examined to confirm *H. pylori* infection status. Those with *H. pylori* infection received eradication therapy. And patients who were not cured by eradication therapy were categorized into eradication therapy-resistant cases. Patients with *H. pylori*-negative or eradication therapy-resistant MALT lymphoma received low-dose radiation therapy. A total dose of 30 Gy was administered and the fraction size was 1.5 Gy for 20 days. Response assessment was carried out every 3-6 months by EGD, various imaging techniques, and clinical examination. Patients with no endoscopic abnormality and no atypical lymphocytes detected by biopsy at endoscopic follow-up were considered to have achieved complete remission (CR). Patients with atypical lymphocytes detected by biopsy were diagnosed as having partial remission (PR).

**Results:** A total of 112 patients with gastric MALT lymphoma were enrolled. The median follow-up period was 76.4 months. 67 of them had *H. pylori* infection. 54 of those *H. pylori*-positive patients were successfully cured

by eradication therapy. 40 patients with *H. pylori*-negative or eradication therapy-resistant MALT lymphoma received radiation therapy. Of the 40, 32 patients had *H. pylori*-negative gastric MALT lymphoma and 8 patients were eradication therapy-resistant. 36 of them achieved CR (90.0%). 29 survived event-free. Two patients with CR were diagnosed with other diseases; one was diagnosed with primary gastric cancer while the other with follicular lymphoma. Distant recurrence was detected in five patients with CR during follow-up. 2 of them died. One of the two died from primary lung cancer while the other died from metastases to the cervical lymph nodes and bone marrow from primary MALT lymphoma. One of the patients with distant recurrence in the rectum was diagnosed with primary gastric cancer. 4 patients only achieved partial remission. One of them died because of the transformation of the disease to diffuse large B-cell lymphoma while the remaining 3 sustained survival.

**Conclusion:** Low-dose radiation therapy may be effective in treating *H. pylori*-negative or eradication therapy-resistant MALT lymphoma. However, careful systemic follow-up for distant involvement and second malignancy in the field of radiation is warranted. To monitor lymphoma and detect transformation at its earliest stages is crucial because transformation to diffuse large B-cell lymphoma is one of the leading causes of death in patients with gastric MALT lymphoma.

## P0648 CLOSE ASSOCIATION OF ENDOSCOPIC SCORES FOR GASTRIC CANCER RISK ACCORDING TO "KYOTO CLASSIFICATION OF GASTRITIS" WITH SERUM RISK CLASSIFICATION KNOWN AS "ABC METHOD"

Hirai R.<sup>1</sup>, Shimodate Y.<sup>1</sup>, Ishikawa S.<sup>1</sup>, Minami M.<sup>1</sup>, Kanatani T.<sup>1</sup>, Hirai M.<sup>2</sup>, Doi A.<sup>1</sup>, Nishimura N.<sup>1</sup>, Mouri H.<sup>1</sup>, Matsueda K.<sup>1</sup>, Yamamoto H.<sup>1</sup>, Mizuno M.<sup>1</sup>  
<sup>1</sup>Kurashiki Central Hospital, Gastroenterology And Hepatology, Kurashiki, Japan, <sup>2</sup>Okayama University, Gastroenterology and Hepatology, Okayama, Japan

**Contact E-Mail Address:** me20070@s.okayama-u.ac.jp

**Introduction:** In Japan, endoscopic examination has been approved for a population-based gastric cancer screening program since 2016. Kyoto classification of gastritis provides the information of *Helicobacter pylori* infection, a major cause of gastric cancer, i.e., non-gastritis, no history of *H. pylori* infection; active gastritis, current infection with *H. pylori*; and inactive gastritis, past infection. "ABC method", a blood test examining serum *H. pylori* antibody and pepsinogen, has been also accepted as non-invasive and alternative method to assess *H. pylori* infection status and gastric cancer risk.

**Aims & Methods:** In this study, we aimed to clarify whether endoscopic evaluation of gastritis according to "Kyoto classification" helps to judge the risk of gastric cancer in the setting of population-based gastric cancer screening program. A prospective case registration study was conducted (UMIN000028629). Data were collected from 1784 participants who underwent both of endoscopic screening for gastric cancer at Kurashiki Central Hospital Health Managing Center from September 2017 to June 2018. We compared the endoscopic score for gastric cancer risk according to "Kyoto classification of gastritis" with the results of "ABC method", and evaluated the association between them by using Spearman's correlation coefficient.

**Results:** Endoscopically, non-gastritis was diagnosed in 1315 (73.7%) participants, active or inactive gastritis was diagnosed in 446 (25%), and judgement was difficult in 23 (1.3%). In the ABC method, 1312 (73.5%) were classified into group A, and 472 into group B-D. The average endoscopic scores of each ABC group were as follows: group A, 0.11 ± 0.6; group B, 2.5 ± 2.1; group C, 4.7 ± 1.6; and group D, 4.4 ± 2.1. The endoscopic score based on the Kyoto classification correlated well with the risk classification of ABC method (correlation coefficient, 0.80).

ABC method	Group A	Group B	Group C	Group D
<i>H. pylori</i> antibody (≥3U/mL)	-	+	+	-
Pepsinogen (PG I≤70 and PG I/II≤3)	-	-	+	+
Gastric cancer risk	Minimal	Low	High	High
N (%)	1312 (73.5%)	335 (18.8)	121(6.8%)	16 (0.9%)
Endoscopic score	0.11± 0.56	2.5± 2.1	4.7± 1.6	4.4± 2.1

[Gastric cancer risk according to the ABC method and the endoscopic scores based on Kyoto classification of each group.]

**Conclusion:** Endoscopic scores for gastric cancer risk according to "Kyoto classification of gastritis" were highly correlated with the known risk classification as "ABC method". Our findings suggest that endoscopic evaluation of gastritis according to "Kyoto classification of gastritis" is useful to judge the risk of gastric cancer in the setting of population-based gastric cancer screening program.

## P0651 THE ROLE OF HEPATOMA-DERIVED GROWTH FACTOR (HDGF) IN RECRUITMENT OF MESENCHYMAL STEM CELLS AND GASTRIC

Kuo C.-H.<sup>1,2</sup>, Liu C.-J.<sup>3</sup>, Wang Y.-K.<sup>2,3</sup>, Wu D.-C.<sup>2,3</sup>

<sup>1</sup>Kaohsiung Municipal Hsiao-Kang Hospital, Division of Gastroenterology, Department of Internal Medicine, Kaohsiung, Taiwan, <sup>2</sup>Kaohsiung Medical University, Department of Medicine, College of Medicine, Kaohsiung, Taiwan, <sup>3</sup>Kaohsiung Medical University Hospital, Division of Gastroenterology, Department of Internal Medicine, Kaohsiung, Taiwan

**Contact E-Mail Address:** kjh88kmu@gmail.com

**Introduction:** Gastric carcinoma is one of the most prevalent cancers worldwide and is the secondary leading cause of cancer-related mortality because of the poor prognosis of patients. Hepatoma-derived growth factor (HDGF) is shown to contribute to cell proliferation, anti-apoptosis and VEGF expression, lymph node metastasis and poor prognosis in human gastric carcinoma. Carcinoma-associated fibroblasts (CAFs) possess abilities to promote primary tumor growth and progression by stimulating processes of neoangiogenesis, tumor cell proliferation, survival, migration, invasion and therapy resistance. Mesenchymal stem cells (MSCs) are reported to promote tumor malignance through differentiation of MSCs toward CAFs.

**Aims & Methods:** HDGF is induced by co-culture experiments with *Helicobacter Pylori* strain ATCC 49503 and AGS cells. CAF markers are detected using reverse transcription and real-time PCR assays. The effect of HBMMSCs on invasive motility of gastric cancer cells is measured using transwell migration assay.

**Results:** In the present study, *H. pylori* infection promotes HDGF expression in human gastric cancer cells. Human bone marrow mesenchymal stem cells (HBMMSCs) treated with HDGF assume properties of CAF-like myofibroblastic phenotypes through measuring myofibroblast markers [α-smooth muscle actin (α-SMA), procollagen α1, tropomyosin I, desmin, fibroblast activation protein (FAP)], and fibroblast markers [prolyl-4-hydroxylase A1 (PHA1) and fibroblast specific protein-1 (FSP-1)/S100A4]. HDGF-recruited HBMMSCs enhances cell proliferation and invasive motility of human gastric cancer cells. Hepatoma-derived growth factor neutralizing antibody (HDGF-NAb) and serum significantly inhibit HDGF-induced recruitment and differentiation of HBMMSCs.

**Conclusion:** These findings suggest that HDGF might play an important factor in gastric cancer progress through stimulation of HBMMSCs differentiation to CAF-like myofibroblasts cells.

### P0652 A MODEL TO STUDY ISCHEMIA-REPERFUSION INJURY IN HUMAN INTESTINAL ORGANIDS

Kip A.M., Olde Damink S.W.M., Lenaerts K.  
Maastricht University Medical Centre, Department of Surgery, Maastricht, Netherlands

**Contact E-Mail Address:** m.kip@maastrichtuniversity.nl

**Introduction:** Intestinal ischemia-reperfusion (IR) is a phenomenon related to a variety of pathophysiological conditions (e.g. acute mesenteric ischemia, major surgery, shock). IR leads to damage of the intestinal epithelium, which functions as a physical and immunological barrier and is therefore crucial in maintaining intestinal homeostasis. In

order to investigate potential therapeutic targets to protect the epithelium during intestinal IR and promote a regenerative response, we aim to validate a model to study IR in human intestinal organoids. Intestinal organoids have been shown to closely resemble self-renewal kinetics, 3D architecture, and cell-type composition of the intestinal epithelium *in vivo*.

**Aims & Methods:** A well-established human experimental model to study IR was used for temporal expression profiling of the *in vivo* intestinal response to IR. The top perturbed pathway was further validated using qPCR. Intestinal epithelial organoids were cultured from crypts isolated from surgical specimens of normal human small intestine. To simulate IR, organoids were subjected to 12 hours of hypoxia (1% O<sub>2</sub>) followed by 30 and 120 minutes of reoxygenation. Activation of the UPR response was assessed by qPCR for CHOP, GADD34, BiP and XBP1 splicing, and, in addition, signs of endoplasmic reticulum (ER) stress were evaluated using electron microscopy (EM).

**Results:** The unfolded protein response (UPR) was the top perturbed pathway during reperfusion of the ischemically injured human small intestine *in vivo*.

Subjecting small intestinal organoids to 12 hours of hypoxia followed by 30 minutes of reoxygenation significantly increased expression of UPR-related genes CHOP and GADD34 and splicing of XBP1 mRNA compared to organoids not subjected to hypoxia. In addition, EM showed dilated ER after reoxygenation which is indicative of ER stress.

**Conclusion:** In line with findings in the *in vivo* human IR model, revealing the response to unfolded protein as a highly regulated process during reperfusion, hypoxia-reoxygenation in intestinal organoids induces significant activation of the UPR. Intestinal organoids can be used to improve insight in the pathophysiology of epithelial IR injury and regeneration, which could lead to new therapeutic targets.

**Introduction:** Small intestinal bacterial overgrowth (SIBO) is a disorder whose diagnosis can be made directly by quantitative cultures (jejunal suction fluid) or indirectly by respiratory tests. Different treatment are proposed in this indication, but not available in all countries.

**Aims & Methods:** The purpose of this study is to evaluate in patients with Rome III irritable bowel syndrome (IBS) and a SIBO, the effectiveness of antibiotic treatment COLIGENTA (COLIMYCINE / GENTAMYCINE) on digestive symptoms and SIBO diagnosed by lactulose breath test.

In 99 consecutive patients with Rome III IBS (16 IBS-Constipation, 45 of type IBS-Diarrhea, 12 Mixed IBS, and 26-non-specific IBS), a SIBO was diagnosed by lactulose breath test. After a 72 hours no-residue diet, the test consisted of a hydrogen breath test with samples every 10 minutes during 3 hours after ingestion of 10 g of LACTULOSE. The test was positive when the H<sub>2</sub> production was greater than 20 ppm within the first 90 minutes after ingestion of lactulose. Treatment with COLIGENTA (3 capsules

daily for 10 days, each capsule containing 135 mg COLIMYCINE, 100 mg of GENTAMYCINE, AP-HP) was established. Four weeks after the treatment, a new lactulose breath test was performed.

**Results:** Four weeks after treatment, an overall improvement in symptoms was observed in 92 patients (93%). There was also a significant decrease in expired H<sub>2</sub> (P < 0.001) for all times. And a normalization of breath tests was registered in 42 patients (43%).

Age, gender, BMI, IBS subtypes, duration of illness were not associated with breath test normalization after antibiotic therapy. Only a lower concentration of hydrogen expired at times 70 and between time 140 to 180 min was predictive of a positive response to treatment (P=0.001).

During treatment, an increase in diarrhea was observed in 13 patients and increased abdominal pain in 10 patients.

**Conclusion:** In IBS patients, this study shows that COLIGENTA can be used for the treatment of SIBO. The reported clinical improvement (93%) was not systematically associated with standardization of respiratory tests (42%). These results prompt to perform a double-blind study with a period longer evaluation.

### P0654 SPY GLASS'S APPLICATION IN ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY FOR THE MANAGEMENT OF ACUTE APPENDICITIS

Liu B.-R., Ling-Jian K.  
The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China

**Contact E-Mail Address:** bingrongliu@qq.com

**Introduction:** To evaluate the feasibility of Spy Glass applied in endoscopic retrograde appendicitis therapy (ERAT) for the management of acute appendicitis.

**Aims & Methods:** An electronic colonoscope (CFHQ290I, Olympus) with a cone-shape transparent cap was inserted into ileocecum to observe appendix orifice. After Inserting Spy Glass through the electronic colonoscopic tunnel, the guide wire lead Spy Glass to the appendix cavity for observation. The appendiceal cavity was observed and treated accordingly (removal of fecal stones, flushing, biopsy if necessary). This was done without X-ray or ultrasound guidance during the whole procedure.

**Results:** Spy Glass could enter into appendix cavity and completed ERAT successfully.

**Conclusion:** By using Spy glass ERAT can be successfully performed without guidance of X-ray or ultrasound, avoiding the hazard of radiation.

**Disclosure:** Nothing to disclose

### P0656 PREDICTIVE FACTORS AND CLINICAL IMPACT OF "DEEP REMISSION" IN CELIAC DISEASE

Peixoto A.<sup>1</sup>, Silva M.<sup>1</sup>, Santos A.L.<sup>1</sup>, Costa-Moreira P.<sup>2</sup>, Ferreira da Silva J.<sup>1</sup>, Dias E.<sup>2</sup>, Macedo G.<sup>1</sup>

<sup>1</sup>Centro Hospitalar De São João, Department of Gastroenterology, Porto, Portugal, <sup>2</sup>Centro Hospitalar de São João, Department of Gastroenterology, Porto, Portugal

**Contact E-Mail Address:** armandoafp5@gmail.com

**Introduction:** Despite the usefulness of serology in the follow-up of patients with celiac disease, the ultimate indicator of adherence to the gluten-free diet is the demonstration of mucosal healing, although this may not occur even in compliant patients.

However, the need for duodenal reassessment biopsies is a controversial subject among "experts".

**Aims & Methods:** The aim of this study was to evaluate patients who underwent histological reevaluation after starting a gluten-free diet, in order to identify those with histological improvement, including complete mucosal healing and associated factors.

Starting from a dedicated consultation celiac disease consultation, patients with apparent clinical remission with normalization of antibody titres after at least twelve months of diet, were evaluated and who agreed to a proposed histological reassessment through upper endoscopy with bi-

opsies were included. The data needed to perform this investigation were obtained from the electronic clinical records, later aggregated into a SPSS database, which was subsequently subjected to treatment and statistical analysis.

**Results:** A total of 69 patients were included, 79.7% (n = 55) of the female sex, with a mean age of 22.5 years, in 36.2% of the cases diagnosed at pediatric age. In 68% of cases, the diagnosis was made in the context of "classic" clinical presentations, 17% in the context of "non-classical" presentations and 15% in latent phase. In most patients (79.2%) the diagnosis was initially suspected by serology. At endoscopy 11.8% of the patients did not present macroscopic features suggestive of celiac disease, and a histological grade of Marsh 3a-c was observed in 72.5% of all cases. A minority of patients (7%) had concomitant diagnosis of other autoimmune diseases.

Four of the patients developed complications of the disease, including refractory disease (n = 1), ulcerative jejunitis (n = 1), and osteoporosis (n = 2). Eight patients (11.6%) underwent reassessment endoscopy within 24 months of starting the diet, and the remainder after 24 months. The histological findings were normalized in 37.7% (n = 26), which was associated with the presence of lower Marsh score values at diagnosis (p = 0.014) and the presence of other autoimmune conditions (p = 0.046).

A histological improvement over baseline was observed in 55 patients (79.7%), of two or more grades in 37 cases, which was related to the initial transferrin saturation (p = 0.027), and with higher values of the Marsh score at diagnosis (p = 0.005).

**Conclusion:** Even under a gluten-free diet, normalization of the histological findings of celiac disease is difficult to obtain and appears to be independent of most clinical and serological findings at diagnosis. Patients with less severe histologic levels at diagnosis reach remission more easily, but only represent the minority of the population.

**Disclosure:** Nothing to disclose

## P0657 HISTOLOGICAL, IMMUNOHISTOCHEMICAL AND RNA GENE EXPRESSION RESPONSES IN COELIAC DISEASE PATIENTS CHALLENGED WITH GLUTEN

Taavola J.<sup>1,2</sup>, Viiri K.<sup>2</sup>, Popp A.<sup>2,3</sup>, Oittinen M.<sup>2</sup>, Dotsenko V.<sup>2</sup>, Peräaho M.<sup>1</sup>, Staff S.<sup>4,5</sup>, Sarin J.<sup>5,6</sup>, Leon F.<sup>7</sup>, Mäki M.<sup>2</sup>, Isola J.<sup>5,6</sup>  
<sup>1</sup>Central Finland Central Hospital, Jyväskylä, Finland, <sup>2</sup>Tampere Centre for Child Health Research, Tampere, Finland, <sup>3</sup>University of Medicine and Pharmacy "Carol Davila" and National Institute for Mother and Child Health "Alessandrescu-Rusescu", Bucharest, Romania, <sup>4</sup>Department of Gynaecology and Obstetrics, Tampere University Hospital, Tampere, Finland, <sup>5</sup>Laboratory of Cancer Biology, Faculty of Medicine and Health Technology, Tampere, Finland, <sup>6</sup>Jilab Inc, Tampere, Finland, <sup>7</sup>Celimmune LLC, Bethesda, Maryland, United States

**Contact E-Mail Address:** juha.taavola@tuni.fi

**Introduction:** There is an unmet need for novel treatments, such as drugs or vaccines, adjunctive to or replacing a burdensome life-long gluten-free diet for coeliac disease. Hence, several phase 1 and 2 clinical trials are in progress to investigate whether novel treatment attenuates or prevents gluten-induced mucosal injury in coeliac disease. The gold standard for successful treatment is a healed small intestinal mucosa, and therefore, the outcome measures in proof-of-concept studies should be based on evaluation of small intestine biopsies.

**Aims & Methods:** We evaluated quantitative morphometric (both architectural and inflammatory), immunohistochemical and mRNA gene expression in coeliac disease patients challenged with gluten using PAXgene fixed paraffin-embedded specimens.

Fifteen coeliac disease patients were challenged with 4 grams of gluten per day for 10 weeks and twenty-eight non-coeliac patients served as disease controls.

**Results:** Digitally measured duodenal biopsies showed significant gluten-induced morphological (villus height: crypt depth ratio) and inflammatory changes (intraepithelial CD3+ T-lymphocyte and lamina propria CD138+ plasma cell densities). Stainings for  $\gamma\delta$  T cells and IgA deposits, where previously frozen samples have been needed, were successful in PAXgene fixed paraffin-embedded samples. Molecular morphology, using the mRNA expression ratio of villous epithelium-specific gene APOA4 to crypt proliferation gene Ki67, showed a similar significant distinction between paired baseline and post-gluten challenge biopsies as quantitative histomorphometry.

**Conclusion:** Rigorous histologic and molecular markers suitable for gluten challenge studies can be obtained from a single paraffin-embedded biopsy specimen. In addition, molecular morphometry seems to be a promising new tool to be further developed.

**Disclosure:** Nothing to disclose

## P0658 COELIAC DISEASE - OLDER PATIENTS HAVE THE MOST EXTENSIVE SMALL BOWEL INVOLVEMENT ON CAPSULE ENDOSCOPY

Chetcuti Zammit S.<sup>1</sup>, Sanders D.S.<sup>2</sup>, Sidhu R.<sup>3</sup>

<sup>1</sup>Royal Hallamshire Hospital, Gastroenterology, Sheffield, United Kingdom,

<sup>2</sup>Royal Hallamshire Hospital - NHS Trust, Royal Hallamshire Hospital; Sheffield/GB, NHS Trust, Sheffield, United Kingdom, <sup>3</sup>Sheffield Teaching Hospitals, Sheffield, United Kingdom

**Contact E-Mail Address:** stf\_che@yahoo.com

**Introduction:** The relationship between symptomatology, serology and findings on small bowel capsule endoscopy (SBCE) in patients with coeliac disease (CD) remains unclear. Clarifying such associations will help determine if symptoms and serology can predict severity and extent of disease on SBCE.

**Aims & Methods:** Patients with newly diagnosed CD (villous atrophy on duodenal histology and positive CD serology) were recruited. Patients underwent a SBCE at the time of diagnosis. Information on SBCE was recorded. Signs and symptoms at presentation, serological markers, histological classification of disease in the duodenum were noted.

**Results:** Sixty patients with newly diagnosed CD (mean age 44.9 years SD $\pm$ 17.4, 17 - 76) were included in this study. Older patients (p=0.025) and patients presenting with iron deficiency anaemia had more extensive small bowel (SB) involvement (p=0.026). Patients presenting with weight loss were more likely to have SB involvement beyond the duodenum (p=0.027). Patients presenting with iron deficiency anaemia (p=0.038) and weight loss (p=0.009) were significantly older at diagnosis. Serum albumin was lower in those patients diagnosed later on in life (p=0.007).

There was no significant association between anti-tissue transglutaminase antibody (p=0.396) and extent of affected SB mucosa.

Patients with more severe Marsh classification of disease on histology from the duodenal bulb had more extensive SB involvement (p=0.017).

**Conclusion:** This is the largest study on newly diagnosed CD and SBCE. Older patients are likely to have more extensive disease on SBCE at diagnosis. Symptoms and serology had no impact on the findings on SBCE apart from weight loss and iron deficiency anaemia.

**Disclosure:** Nothing to disclose

## P0659 CAPSULE ENDOSCOPY IN ESTABLISHED COELIAC DISEASE: CLINICAL SYMPTOMS, EXTENT OF DISEASE AND SMALL BOWEL TRANSIT

Chetcuti Zammit S.<sup>1</sup>, Kurien M.<sup>1</sup>, Sanders D.S.<sup>2</sup>, Sidhu R.<sup>3</sup>

<sup>1</sup>Royal Hallamshire Hospital, Gastroenterology, Sheffield, United Kingdom,

<sup>2</sup>Royal Hallamshire Hospital - NHS Trust, Sheffield, United Kingdom,

<sup>3</sup>Sheffield Teaching Hospitals, Sheffield, United Kingdom

**Contact E-Mail Address:** stf\_che@yahoo.com

**Introduction:** Patients with established coeliac disease (CD) can present with recurrent symptoms requiring further investigations including small bowel capsule endoscopy (SBCE). There is paucity of data on the relationship between the extent, severity of disease and small bowel transit (SBT) on capsule endoscopy in relation to histology, clinical and serological parameters.

**Aims & Methods:** Hundred patients with CD and 200 controls were recruited. All of these patients underwent a SBCE because of symptoms, abnormal serology or a suspicion of complications. Extent of disease SBCE and SBT were studied in relation to symptomatology, serology and severity of histology from the duodenum.

**Results:** In patients with CD, 30 (30.0%) had a normal SBCE, 56 patients (56.0%) had proximal small bowel (SB) involvement, 7 patients (7.0%) had proximal and mid SB involvement and 7 patients (7.0%) had diffuse disease. SBT was shortest in controls (275.0; range 60.0 - 981.0 minutes), followed by those with established CD but a normal SBCE (260.0; range 104.0 - 467.0 minutes) and those with established CD and macroscopic evidence of CD on SBCE (286.0; range 60.0 - 981.0 minutes) (p=0.0001). Age at time of SBCE (p=0.006), serum albumin (p=0.004) and haemoglobin (p=0.0001), Marsh score of histology from the duodenal bulb (D1)

( $p=0.0001$ ) and the second part of the duodenum ( $p=0.0001$ ), the presence of RCD features on histology correlated significantly with the percentage of affected mucosa on SBCE on univariate analysis. On multiple regression analysis, serum albumin level ( $p=0.036$ ) and Marsh score of histology taken from the duodenal bulb (D1) ( $p=0.019$ ), serum vitamin B12 ( $p=0.001$ ) and folic acid levels ( $p=0.008$ ) were statistically significant.

**Conclusion:** Patients with CD have a persistently prolonged SB transit even if there is no evidence of disease on SBCE. This is the first study showing correlation between extent of disease and severity of duodenal histology according to the Marsh classification.

**Disclosure:** Nothing to disclose

## P0660 NON-RESPONSIVE AND REFRACTORY COELIAC DISEASE: THE LARGEST UK EXPERIENCE FROM THE NHS ENGLAND RARE DISEASES COLLABORATIVE NETWORK

Baggus E.<sup>1</sup>, Rej A.<sup>1</sup>, Schieppati A.<sup>1,2</sup>, Zammit S.<sup>1</sup>, Marks L.J.<sup>1</sup>, Trott N.<sup>1</sup>, Hadjivassiliou M.<sup>1</sup>, Sanders D.S.<sup>1</sup>

<sup>1</sup>University of Sheffield, Academic Unit of Gastroenterology, Sheffield, United Kingdom, <sup>2</sup>University of Pavia, Coeliac Centre, Pavia, Italy

**Contact E-Mail Address:** emrbaggus1@sheffield.ac.uk

**Introduction:** Non-responsive coeliac disease (NRCD) is defined by persisting symptoms or laboratory abnormalities in patients with coeliac disease (CD), and affects up to 30% of CD patients on a gluten-free diet (GFD). Causes of NRCD are heterogeneous, with refractory CD (RCD) being associated with poor prognosis.

**Aims & Methods:** The aims of this study were to identify the aetiologies for persisting symptoms in patients with NRCD referred to a national UK centre for CD, and to assess and compare mortality in each group. Data on all CD patients, including those with persisting symptoms and tertiary referrals, was collected prospectively from 1998-2018. Patients were systematically investigated to establish the aetiology of their continued symptoms. They were also referred to a specialist coeliac dietitian to identify any lapses in GFD adherence or gluten cross-contamination. A repeat duodenal biopsy was performed and compared to previous biopsies where possible to check for histological remission. Colonoscopy, lactose hydrogen breath test, glucose hydrogen breath test, SeHCAT scan, CLO testing, faecal elastase, faecal calprotectin, stool culture, immunohistochemistry and  $\gamma$ -TCR clonality were performed where appropriate to establish a final diagnosis. Data on follow-up and outcomes was then collected for each group and survival analyses performed.

**Results:** A total of 2,356 patients with suspected CD were seen in this time period (121 were tertiary referrals). Of these, 157 were excluded from analysis due to unconfirmed diagnosis. Of the remaining 2,199 patients with confirmed CD, 2,123 had both villous atrophy and positive IgA-EMA/TTG, and 76 had seronegative CD. Of the 2,199 patients with confirmed CD (67% female, mean age at diagnosis  $42.8 \pm 18.5$ ), 292 (13.3%) had persisting symptoms. The leading causes for persisting symptoms in patients without evidence of RCD (73% female, mean age at diagnosis  $35.7 \pm 19.2$ ) were: gluten contamination (24%), functional/irritable bowel syndrome (20%), pancreatic exocrine insufficiency (7%), reflux dysmotility (5%), and microscopic colitis (5%). Of a total of 74 patients who were identified with RCD (26% of all NRCD), 56 were diagnosed with RCD I (71% female, mean age at CD diagnosis  $41.8 \pm 19.0$ ) and 18 RCD II (33% female, mean age at CD diagnosis  $55.4 \pm 13.3$ ). Eighteen patients (6% of all NRCD) had developed further complications consisting of enteropathy associated T-cell lymphoma (EATL) (4), B cell lymphoma (4), ulcerative jejunitis (3), small bowel adenocarcinoma (3), oesophageal adenocarcinoma (2), cutaneous T cell lymphoma (1), and neuroendocrine carcinoma of small bowel (1). Higher age at diagnosis of CD was a predictor for having RCD in patients with persisting symptoms ( $p < 0.001$ ). Patients diagnosed with RCD II were significantly older at CD diagnosis ( $p=0.003$ ), had a shorter delay between CD and RCD diagnosis ( $p=0.002$ ) and were more likely to be male ( $p=0.006$ ) compared to those diagnosed with RCD I. After a median follow up of 40.5 months (IQR 21.8-73.3), mortality was 7% in the RCD I group, compared to 39% in the RCD II group ( $p=0.019$ ), with a five-year survival of 68% in patients with RCD II.

**Conclusion:** This is the largest UK study of NRCD and RCD. The contemporary mortality data in RCD II remains poor. Management of this group is challenging, and more evidence is required. Patients with suspected RCD should be referred to the National Centre for consideration of novel therapies such as IL-15 and Stem Cell Transplant.

## P0661 ASSESSING GLUTEN FREE DIET ADHERENCE USING CDAT AND BIAGI QUESTIONNAIRES IN PATIENTS WITH COELIAC DISEASE

Baggus E., Rej A., Lau M., Zammit S., Mooney P., Marks L.J., Rees M., White W., Hadjivassiliou M., Sanders D.S.

University of Sheffield, Academic Unit of Gastroenterology, Sheffield, United Kingdom

**Contact E-Mail Address:** emrbaggus1@sheffield.ac.uk

**Introduction:** The gold standard currently for assessing adherence in individuals with coeliac disease (CD) is via duodenal biopsies, which is invasive and costly. There is currently no reliable non-invasive surrogate marker to detect gluten ingestion and persisting villous atrophy in CD patients.

**Aims & Methods:** In view of this, our aim was to assess the utility of the CDAT and Biagi questionnaires for non-invasive assessment of gluten free adherence. Patients with an established diagnosis of coeliac disease, referred for further evaluation of dietary adherence and disease remission were assessed between January 2016 to December 2018. Patients were prospectively recruited, and completed CDAT and Biagi questionnaires at their endoscopy appointment, with at least 4 duodenal biopsies taken from D2 in addition to at least one biopsy from the duodenal bulb. The presence (Marsh 3a or above) or absence (Marsh 0-II) of villous atrophy was used to determine the sensitivities of the questionnaires in detecting persisting villous atrophy.

**Results:** A total of 151 patients were recruited, 101 females (66.9%), median age 55.0 years, median duration of GFD of 72.0 months. The sensitivities of CDAT, Biagi, and combined CDAT & Biagi were 52.0% (95% CI 37.6-66.1), 22.4% (12.2-37.0), 61.2% (46.2-74.8) respectively, compared to 30.6% (18.7-45.6) and 34.3% (26.7-42.7) for IgA-TTG and EMA. Specificity of CDAT, Biagi and combined CDAT & Biagi were 69.8% (60.9-77.5), 93.1% (85.6-97.0), and 69.3% (60.5-77.2) respectively, compared to 91.6% (83.6-96.0) and 92.5% (84.8-96.7) for IgA-TTG and EMA.

**Conclusion:** The sensitivity of the CDAT questionnaire was not superior to IgA-TTG for predicting villous atrophy in patients with coeliac disease. However, the use of a combination of both Biagi and CDAT had a greater sensitivity than IgA-TTG and IgA-EMA ( $p < 0.05$ ), but lower specificity ( $p < 0.05$ ). Duodenal biopsy remains the gold standard, although these scores remain useful tools in the assessment of dietary adherence.

**Disclosure:** Nothing to disclose

**Introduction:** Several studies have shown that a substantial proportion of adult CD patients on a gluten-free diet (GFD) exhibit persistent villous atrophy (VA) on follow-up duodenal biopsy, suggesting that the most frequent cause was poor adherence to the GFD.

**Aims & Methods:** To evaluate VA persistence after 2 years on a GFD in adult CD patients with strict control of diet adherence.

Symptomatic adult CD patients were prospectively included at diagnosis and started on a GFD. CD diagnosis was done according to established guidelines. A 2-year follow-up was carried out with clinical visits and di-

etary surveillance at 6 weeks and after every 6 months. Dietary adherence was assessed using the validated CD adherence test questionnaire (Leffler 2009). In each visit clinical status, serum anti-tTG2 and faecal gluten immunogenic peptides (f-GIP) were checked. For f-GIP, two faecal samples in different days of the week prior each visit were obtained and stored at -80°C until processing. The concentration of GIP in stools was analysed by ELISA using the iVYLISA GIP stool (Biomedal S.L., Seville, Spain), considering positive values >80 ng GIP per g faeces. Duodenal follow-up biopsy was performed at 2 years. Biopsies were blindly evaluated by two expert pathologists, in case of disagreement, a consensus was achieved. Mucosal recovery was defined as the absence of VA. A sample size of 90 patients was calculated to estimate a persistent VA rate of 40%, loss of follow-up of 15%, with an accuracy of 10%. We examined age, gender, educational attainment, marital status, employment situation, clinical and serological remission, and positive f-GIP to determine predictors of persistent VA.

**Results:** 95 patients were included, three were excluded for not presenting VA and one for age < 16 years. Fifteen of 91 (16%) did not ended the follow-up. Therefore, 76 patients finalized the study (36.5±1.6 years, 73% women). Follow-up duodenal biopsy showed persistent VA in 40 patients (53%, 95% CI, 41-63%) (Marsh 3a, 75% and Marsh 3b-c, 25%). Of the 40 patients, 72.5% were asymptomatic and 75% had negative serology. There were no differences in the f-GIP+ rate among patients with persistent VA and those with recovery, which in general indicated weak gluten transgressions. On multivariate analysis only older age was an independent predictive risk factor of persistent VA (32% for 16-30 yrs; 60% for >30 yrs; p=0.016).

**Conclusion:** Persistent VA rate after 2 years on a GFD was high in adult patients with CD, despite a strict control of diet adherence and that there were no differences in f-GIP values between persistent VA and recovery. There was an effect of increasing age on the frequency of persistent VA that was not related to dietary noncompliance and social differences.

**Introduction:** Seronegative villous atrophy (SNVA) on duodenal histology can be secondary to coeliac disease (CD) or other causes such as medications or infections. The introduction of small bowel capsule endoscopy (CE) has enabled us to study this condition further and to establish whether these patients develop complications.

**Aims & Methods:** The CEs of patients (128) with SNVA on duodenal histology were retrospectively analysed for features of CD (fissuring, scalloping, mosaic pattern, nodularity, villous atrophy, ulcers). Extent of affected SB mucosa was determined. 3 categories of patients were identified: group 1: no identifiable cause for SNVA, group 2: histological response to gluten free diet (GFD), group 3: alternative cause for SNVA.

**Results:** Overall, 49 (38%) patients had a positive CE. Patients with more severe histological pattern on duodenal biopsies were more likely to have a positive CE (partial villous atrophy (PVA) 21, 26%, subtotal villous atrophy (SVA) 12, 60% total villous atrophy (TVA) 13, 59%, p=0.001). More extensive SB disease corresponded to a more severe histological pattern (PVA 1%, SVA 15%, TVA 17%, p=0.001).

Patients with alternative causes for SNVA had the least extensive SB involvement (group 1: 9.13 (+/-25.2), group 2: 9.77 (+/-23.5), group 3: 0.025(+/-0.13)% p=0.038). Most patients had proximal SB disease (40, 82%).

These patients were followed up for a median of 5 years (1 - 18 years).

**Group 1:** 43% (55) had no identifiable cause for SNVA. 40% (22) of these patients had a positive CE. 71% (39) had spontaneous resolution of SNVA without any intervention. The other patients received a trial of GFD to which none responded. Further treatment included steroids +/- immunosuppressants in 10 patients. CE at diagnosis was positive in 8 (20.5%) of those with spontaneous resolution of SNVA, 14 (87.5%) patients with persistent SNVA (p=0.0001).

**Group 2:** 27% (35) patients had a histological response to a GFD. 5 of these patients (14%) were IgA deficient. 49% (17) patients had a positive CE. 7 patients eventually developed complications. All of them had a positive CE at the time of diagnosis (p=0.022). They also had more extensive SB disease than those patients who did not develop complications (50% vs 1% p=0.002). 3 patients developed refractory coeliac disease (RCD) 1, 2 developed RCD 2. 2 patients developed RCD 2 and ulcerative jejunoileitis.

**Group 3:** 37 patients (29%) had alternative causes for SNVA. 10 (27%) patients had positive CEs (2, 60% - NSAIDs, 2, 15% - H pylori positive, 4, 67% - Giardia, 1, 33%) - angiotensin receptor blocker, 1 - Crohn's disease, p=0.125).

**Conclusion:** CE can be useful in patients with an unknown cause for SNVA as more extensive disease on CE at diagnosis can predict those with persistent SNVA. In SNVA-CD, more extensive disease on CE at diagnosis can be a predictor of development of complications. These patients need to be monitored more closely.

**Disclosure:** Nothing to disclose

## P0664 IS THERE A CORRELATION BETWEEN DUODENAL HISTOLOGY AND DISEASE SEVERITY ON CAPSULE ENDOSCOPY IN PATIENTS WITH VILLOUS ATROPHY?

<sup>2</sup>Royal Hallamshire Hospital - NHS Trust, Sheffield, United Kingdom,

<sup>3</sup>Sheffield Teaching Hospitals, Gastroenterology, Sheffield, United Kingdom

**Contact E-Mail Address:** stf\_che@yahoo.com

**Introduction:** There is a lack of uniformity of reporting on features of coeliac disease (CD) on small bowel capsule endoscopy (SBCE). This makes determining extent of disease and comparison of severity of disease between SBCEs challenging even for experts in the field.

**Aims & Methods:** The de-identified SBCEs of 300 patients with CD (78; 26%), antibody negative villous atrophy (18, 6%) and control patients (204; 68%) with normal duodenal histology were reviewed by 2 expert SBCE reviewers. All patients had duodenal histology taken 2 weeks from undertaking SBCE. The degree of agreement between identifying CD features (fissuring, villous atrophy, scalloping, mosaicism, nodularity, ulcers) and determining extent of disease was then assessed. Multiple regression analysis was carried out to determine the correlation of CD features with extent of abnormal small bowel (SB). Ranks were then used to optimise the odds ratio obtained for each factor using an inbuilt function in SPSS. This resulted in the formulation of a score for each factor in each SB tertile.

**Results:** The overall kappa co-efficient for all CD features for reviewers 1 and 2 was 0.67. The intraclass correlation co-efficient for percentage extent of affected SB mucosa was 0.97 (p=0.0001). Percentage of extent of affected SB mucosa correlated with overall severity of disease as classified by each reviewer (p=0.0001) and with histology from the second part of the duodenum (p=0.0001). The multivariate regression analysis resulted in statistically significant odds ratios of CD features correlating with extent of affected SB mucosa for both reviewers 1 and 2. These were then utilized to generate a score for features of CD in the SB. The overall scores for each patient correlated with extent of affected SB mucosa for reviewer 1 (Pearson correlation co-efficient 0.662, p=0.001) and 2 (Pearson correlation co-efficient 0.838, p=0.001). The median overall scores of patients increased significantly according to the independent classification by reviewers: mild (34, 0-254), moderate (50, 27-133), severe (96, 69-128) (p=0.0001).

**Conclusion:** The good correlation of CD scores between expert reviewers confirms the validity of CD features on SBCE. An objective score of CD features in the SB might be useful in the follow up of patients with CD and serology negative villous atrophy.

**Introduction:** Fructose intolerance (FI), i.e. symptoms following ingestion of fructose, is common in patients with Functional Gastrointestinal Disorders (FGID). Malabsorption of fructose resulting in intestinal distension and fermentation is generally assumed to be the underlying mechanism. Malabsorption can be indirectly characterized by measurement of intestinal gases exhaled in breath (e.g. hydrogen, methane), or by quantifying the systemically absorbed fructose and its metabolites. We have previously shown that FI is not characterised by changes in expression of the main intestinal fructose transport proteins, GLUT5 and GLUT2 (1). Consequently, the cause of malabsorption in FI remains unclear.

**Aims & Methods:** We aimed to investigate malabsorption as a cause for symptoms in FGID patients following ingestion of fructose. Plasma concentrations of fructose and fructose metabolites, short-chain fatty acids (SCFA), and the gaseous fermentation products hydrogen and methane were used as measures of fructose absorption. Thirty-one male or female patients with FGID (Rome III) ingested either 35g fructose or water in a randomised, blinded, crossover study in Switzerland (2). Plasma fructose and its metabolites (glucose, alanine, lactate, glycerate) and SCFAs (acetate, propionate, butyrate, isobutyrate, valerate, isovalerate, and caproic acid) were quantified via liquid chromatography tandem mass spectrometry from blood samples drawn at 0, 0.5, 1 and 2 hours post-dosing. Breath hydrogen and methane concentrations were measured and GI symptoms recorded at the same times. The aggregate GI symptom score, the sum of 8 GI symptoms graded by intensity as 0=none, 1=mild, 2=intense, was used to classify patients regarding FI (defined as increase of >2, maximum score of 16). Analyses were performed using areas-under-the-curve of the variables for the first 2 hours post-dosing ( $AUC_{0-2h}$ ).

**Results:**  $AUC_{0-2h}$  of fructose and metabolite plasma concentrations were similar in the 15 patients with and the 15 patients without FI ( $p>0.05$ ), and did not correlate significantly with  $AUC_{0-2h}$  of aggregate GI symptom scores ( $r=-0.007$ ). However, the  $AUC_{0-2h}$  of symptoms correlated positively with  $AUC_{0-2h}$  of hydrogen ( $r=0.73$ ) and methane ( $r=0.62$ ) concentrations. Patients with FI produced significantly more hydrogen and methane than fructose-tolerant patients (both  $p=0.04$ ). The  $AUC_{0-2h}$  of the concentration of the SCFA valerate correlated positively with breath hydrogen ( $r=0.34$ ) and methane ( $r=0.45$ ), but negatively with plasma fructose ( $r=-0.41$ ) concentrations.

AUC of parameters	FI n=15	Non-FI n=15	p-values
Fructose ( $\mu M \cdot h$ )	573 $\pm$ 134	547 $\pm$ 91	0.53
Hydrogen (ppm·h)	58.5 $\pm$ 49.2	26.6 $\pm$ 22.5	0.03
Methane (ppm·h)	20.1 $\pm$ 10.6	12.9 $\pm$ 6.9	0.04
Aggregate GI symptoms (score·h)	8.57 $\pm$ 4.88	0.45 $\pm$ 0.54	<0.0001

[Study parameters in fructose-intolerant (FI) and non-FI subjects (means $\pm$ SD, independent t-test)]

**Conclusion:** In patients with FGID, fructose intolerance is not correlated with decreased post-ingestion plasma fructose and its metabolites as indicators of malabsorption, consistent with our findings on intestinal transporter expression (1). Instead, FI appears to be associated with changes in the intestinal microbiome metabolism of fructose, arising from altered composition or activity of the intestinal microbiome in these patients.

## P0666 VALIDITY AND GENERALIZABILITY OF THE NEWLY DEVELOPED ADULT CARBOHYDRATE PERCEPTION QUESTIONNAIRE (aCPQ)

Hammer J.<sup>1,2</sup>, Engeßer K.M.<sup>1</sup>, Riedl G.<sup>1</sup>, Vogelsang H.<sup>1</sup>, Hammer H.F.<sup>3</sup>

<sup>1</sup>Medizinische Universität Wien, Vienna, Austria, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Division of Gastroenterology and Hepatology, Dept. of Internal Medicine, Graz, Austria

**Contact E-Mail Address:** heinz.hammer@medunigraz.at

**Introduction:** Breath tests are extremely popular in clinical practice to determine carbohydrate malabsorption. Guidelines recommend assessment of symptoms which are more relevant for clinical management (1) to diagnose carbohydrate intolerance. We have recently developed a test-specific perception questionnaire for the assessment of carbohydrate induced gastrointestinal symptoms, the adult Carbohydrate Perception Questionnaire (aCPQ).

**Aims & Methods:** Our aim was to validate the aCPQ for the assessment of carbohydrate related perception by internal-, cross- and external validation.

The aCPQ is a VAS-based questionnaire for the assessment of the presence and the severity of five complaints before and during the breath test: pain, nausea, meteorism, flatulence, diarrhoea. Criteria of internal validity were determined after the implementation of the questionnaire during lactose and fructose breath tests in 342 subjects ('Vienna-original' group). Correlation between the questionnaire and a medical interview (n=338) was determined, interviews were performed by a physician who was blinded as to the results of the questionnaire. Cross validation was performed in a follow-up patient group in the same institution ('Vienna-cross' group, n=182), external validity was assessed in a group from another university center ('Graz-external' group, n=156). NS=not significant

**Results:** The scale has good face validity as it is simple, easy to understand and brief. The content validity ratio according to Lawshe equals 1. Intraclass correlation coefficients for test-retest reliability (n=159; 30 minutes interval) demonstrate good repeatability ( $p<0.001$ ), Cohen's d as a measure of effect size is small (i.e. < 0.40; 0.19 or smaller for the five symptoms). Cronbach's alpha is 0.85, indicating good internal consistency. Convergent validity and discriminant validity is supported according to the multitrait-multimethod-matrix method. Moreover, the results given by the questionnaire highly correlate with the result of the medical interview ( $p<0.001$ ; Fisher exact test). Responsiveness to change has been verified during breath tests with medium to large effect sizes ( $p<0.05$ ). 146 patients were diagnosed with malabsorption, 179 patients with intolerance, among them 97 patients having both malabsorption and intolerance. The 'Vienna-cross' group included significantly more fructose tests (54%;  $p=0.02$ ) and was significantly younger ( $43\pm 1.3$  years;  $p=0.05$ ) than the 'Vienna-original' group. The percentage of patients who was diagnosed with intolerance AND malabsorption, only intolerance or only malabsorption was comparable in both 'Vienna' groups before and after correcting for age, gender and carbohydrate tested (NS). The 'Graz-external' group was significantly younger ( $40\pm 1.5$  years;  $p<0.001$ ) than the 'Vienna-original' group. The percentage of patients who was diagnosed with intolerance AND malabsorption, only intolerance or only malabsorption was comparable in 'Graz-external' and 'Vienna-original' before and after correcting for age, gender and carbohydrate tested (NS).

**Conclusion:** The adult Carbohydrate Perception Questionnaire (aCPQ) is a simple, test-specific questionnaire. It is a valid instrument with excellent psychometric properties and generalizability for the assessment of gastrointestinal symptoms after carbohydrate ingestion. The aCPQ should replace non-validated symptom assessment during carbohydrate breath tests, e.g. by interview, use of non-validated questionnaires or generic, non-test-specific instruments and allows a uniform diagnosis of carbohydrate intolerance.

**Introduction:** The morphological damages of intestinal villi's/ Crypt architecture by the intraepithelial lymphocytic infiltration (IEL) in non-coeliac gluten sensitivity (NCGS) have been much less quantified compared to coeliac disease (CD).

### Aims & Methods:

**Aim:** Morphological changes including IEL infiltration in intestinal villi's and Crypt architecture were measured in gluten induced enteropathies aiming to differentiate between NCGS, CD and controls.

**Method:** The study was designed at the International Meeting on Digestive Pathology, Bucharest 2017. Investigators from 22 centres, 9 countries of 4 continents, recruited CD patients with Marsh 0-II histology (n=261),

NCGS (n=175), and 262 controls and used one agreed protocol to analyse the small bowel mucosa in well-oriented duodenal biopsies. Demographic and serological data were also collected.

**Results:** Participant countries consisted of Australia (20), Finland (20), India (25), Iran (37), Italy (239), Romania (10), Turkey (30), UK (166) and USA (151). The villus height was significantly shorter in NCGS compared to control ( $p < 0.001$ ), the difference was significant even when the analysis limited to Marsh 0. Conversely, the villus height of NCGS was significantly longer than that in CD [600 (IQR: 400-705) vs 427 (IQR: 348-569),  $p < 0.001$ ], the result was unchanged when analysis was limited to Marsh I-II [500 (IQR:410-629) vs 423 (IQR:349-574),  $p=0.009$ ]. The median Crypt depth was significantly increased in NCGS group compared to controls [296 (IQR: 205-300) vs 222 (IQR: 158-294),  $p < 0.001$ ] and it was similar to CD group [269 (IQR: 182-322),  $p=0.822$ ]. Interestingly NCGS with Marsh 0, still had significantly increased crypts depth compared to controls ( $p < 0.001$ ). The crypt depth value was similar in Marsh I-II for both NCGS and CD groups [273 (IQR: 180-296) vs 269 (IQR: 180-324),  $p=0.822$ ]. In addition, the ratio of villus height to crypt depth was significantly lower in NCGS compared to controls ( $p < 0.001$ ), the difference was significant even when the analysis was limited to Marsh 0 ( $p < 0.001$ ). In contrast, the ratio of villus height /Crypt Depth in NCGS was significantly higher than that in CD ( $p=0.009$ ), the result was still significant when analysis was limited to Marsh I-II ( $p=0.046$ ). The median IEL density was significantly higher 23/100EC in NCGS group compared to 14 in controls ( $p < 0.001$ ) and lower than that in CD group 40/100EC ( $p < 0.001$ ). When comparison was restricted to Marsh 0, NCGS still had significantly higher IEL density than controls ( $p < 0.001$ ). Comparing IEL densities in Marsh I/II NCGS to Marsh I/II CD groups showed similar values ( $p=0.055$ ). When the analyses were restricted to Marsh 0, the IEL density cut off scored 79% sensitivity and 55% specificity at 14/100EC for NCGS with 0.71 (95% CI: 0.64- 0.77,  $p < 0.001$ ) area under curve. Similar analysis limited to Marsh I-II showed a cut-off of 25/100EC to diagnose CD and NCGS (together) from controls, with 95% sensitivity, 86% specificity and 0.94 (95% CI: 0.93-0.96,  $p < 0.001$ ) area under the curve.

**Conclusion:** Morphometric assessment of intestinal mucosa of NCGS patients showed a range of subtle abnormalities even when the histology is reported as Marsh 0 or normal. Comparing Marsh 0 of NCGS with controls, revealed the former have significantly higher IEL density, increased crypt depth, shorter villous height and decreased villous/crypt ratio. This global morphometric assessment brings novel insight into the Marsh 0 histology spectrum that can improve the NCGS diagnostic yield as an additional biomarker.

**Introduction:** Most of the cases of chronic diarrhoea after excluding organic disorders are labelled as functional diarrhoea or irritable bowel syndrome (IBS). Bile acid malabsorption (BAM) is a frequently underinvestigated cause of chronic diarrhoea in adult population. In Europe the diagnosis is commonly established by the Selenium homocholic acid taurine test scan (SeHCAT). BAM is defined as mild (10-15% retention), moderate (5-10%), or severe ( $< 5\%$ ).

**Aims & Methods:** We aimed to evaluate and identify risk factors associated to MAB type 2.

**Methods:** We retrospectively reviewed all patients who had SeHCAT scan performed between June 2014 and October 2018 in a University tertiary referral Hospital. We excluded all patients who had known risk factors for BAM. The diagnosis of BAM was established when SeHCAT retention was inferior to 15%. We collected the following variables: demographic characteristics, IBS-D Rome III criteria, duration of diarrhoea (months), stool culture, parasitic investigation on stool specimens, *H. pylori* infection, drugs use, and HLA-DQ2/DQ8 haplotype. Univariate and multivariate

statistical analysis was performed with binary logistic regression model with analysis of successive steps forward to identify potential predictors of having a positive SeHCAT test. Variables with  $p < 0.1$  in the univariate analysis were selected for the multivariate analysis.

**Results:** 298 patients referred for chronic diarrhoea underwent SeHCAT testing (109M/189F). In the whole group, the median age was 46 yo (95% C.I 44.0-50.1), the median body mass index (BMI) was 24.8 kg/m<sup>2</sup> (95% C.I 25.4-26.8). Out of all, 75.2% met IBS-D Rome III criteria, the median duration of diarrhoea was 36 months (95% C.I 42.5-54.8), 41.9% (70/167) exhibited a history of *H. pylori* infection, and 17.5% (17/131) showed parasitic stool infestation. The percentage of positive HLA-DQ2 and DQ8 haplotypes was 52.7% (109/207) and 17.4% (36/207), respectively. SeHCAT test was positive for BAM in 47.9% (143/298): 25.2% mild, 40.6% moderate, and 34.3% severe. Patients with positive SeHCAT test exhibited higher BMI and longer periods of diarrhoea (Table 1).

	Postive SeHCAT	Negative SeHCAT	P
Gender (M:F)	68:78	41:111	<0.010
Age(yo) (median;95% IC)	43.0 (41.3-46.1)	40.0 (39.0-44.1)	0.036
BMI (Kg/m2:median;95%IC)	26.8 (26.4-28.4)	23.9 (24.0-25.7)	<0.010
Duration of diarrhoea (months; median; 95% C.I)	36.0 (44.7-65.5)	24.0 (35.9-49.2)	0.073
IBS-D Rome III criteria (%)	105/146	119/152	0.228
Blastocystis Hominis (n)	8/124	20/122	0.016
Giardia Lamblia (n)	2/124	1/122	1.000
Dientamoeba fragilis (n)	8/124	2/122	0.085
Endolimax nana (n)	1/124	6/122	0.065
Helicobacter pylori (n)	28/74	42/93	0.349
ISRS (n)	21/145	13/152	0.144
IBPs (n)	21/145	15/151	0.286
HLA-DQ2 Haplotype (n)	49/98	60/108	0.463
HLA-DQ8 Haplotype (n)	21/98	15/108	0.199

#### [Demographic Characteristics]

The following variables were selected for multivariate analysis: sex, age, BMI, duration of diarrhea, previous finding of parasites in stool specimens and consumption of proton pump inhibitors. Female sex, absence of parasites in stools, and high BMI were identified as predictive factors for positive SeHCAT. The R-square of Cox and Snell, and of Nagelkerke of our model were of 11.4% and 15.2%, respectively.

**Conclusion:** Although we identified female sex, a high BMI and the absence of parasites in stools as independent indicators of idiopathic BAM, these factors have a low capacity to predict a positive SeHCAT test. Additional studies are needed to identify better prognostic factors indicative of idiopathic bile acid malabsorption.

**Disclosure:** Nothing to disclose

## P0669 WITHDRAWN

## P0670 PANORAMIC VERSUS AXIAL SMALL BOWEL CAPSULE ENDOSCOPY IN OVERT OBSCURE GASTROINTESTINAL BLEEDING

Chetcuti Zammit S.<sup>1</sup>, McAlindon M.<sup>1</sup>, Sidhu R.<sup>2</sup>

<sup>1</sup>Royal Hallamshire Hospital, Gastroenterology, Sheffield, United Kingdom,

<sup>2</sup>Sheffield Teaching Hospitals, Sheffield, United Kingdom

**Contact E-Mail Address:** stf\_che@yahoo.com

**Introduction:** Literature comparing axial small bowel capsule endoscopy (SBCE) (Pillcam, Given Imaging) and panoramic SBCE (Capsocam, Capvision) in obscure gastrointestinal bleeding (OGIB) is limited and contradictory (1,2).

**Aims & Methods:** Consecutive patients who presented with overt OGIB at a tertiary centre over a 5 year period underwent either Capsocam SBCE or Pillcam SB3 SBCE. All had negative gastroscopies and colonoscopies / CT colonographies. SBCEs were reviewed by 2 experts. Findings in the 2 groups were compared.

**Results:** 94 patients (39.4% Capsocam; 60.6% Pillcam; 57.4% males; mean age 64.3±18.0 years) were included. Both groups were age ( $p=0.174$ ) and gender ( $p=0.137$ ) matched. Severity of anaemia ( $p=0.053$ ) and duration of anaemia ( $p=0.264$ ) were similar in both groups.

There was no difference between groups in incomplete SBCEs ( $p=0.151$ ). Diagnostic yield (DY) was comparable in both groups but Pillcam had a higher DY than Capsocam in the stomach (table 1).

Capsocam identified blood (2, 5.4%), erosions (1, 2.7%) and ulcers (1, 2.7%) in the stomach. Pillcam showed blood (4, 5.4%), erosions (11, 19.3%), ulcers (2, 3.5%), varices (1, 1.8%) and GAVE (1, 1.8%) in the stomach.

Patients who underwent Capsocam examination had the following findings in the SB: 1 (2.7%) ulcer, 7 (18.9%) angioectasia, 8 (21.6%) blood, 2 (5.4%) erosions, 1 (2.7%) tumour, 1 (2.7%) diverticulum. Patients who underwent Pillcam had these findings in the SB - 10 (17.5%) ulcers, 11 (19.2%) angioectasia, 7 (12.3%) blood, 19 (33.3%) erosions, 1 (1.75%) tumour, 2 (3.51%) diverticulum, 2 (3.51%) phlebotactasia, 4 (7.02%) polyps, 1 (1.75%) haemangioma, 1 (1.75%) intussusception.

	Capsocam n(%)	Pillcam n(%)	Significance (p)
Gastric DY	3 (8.1)	15 (26.3)	0.033
Small bowel (SB) DY	17 (45.9)	25 (43.9)	0.842
Colon DY	2 (5.4)	3 (5.3)	0.976

[Table 1: DY of panoramic and axial SBCE for patients with overt OGIB;]

**Conclusion:** SB DY was comparable between Capsocam and Pillcam groups in patients with overt OGIB but Pillcam offered a better gastric DY than Capsocam. This might be of relevance as a considerable number of lesions are missed in the upper GI tract in patients undergoing gastroscopy.

**Introduction:** Capsule endoscopy has been widely accepted as a tool to investigate chronic occult blood loss from the gastrointestinal tract as a cause of anaemia.

**Aims & Methods:** The aim of the study is to investigate the long term yield of capsule endoscopy (CE) for patients with occult gastrointestinal bleeding (OGIB) over 10 years in a tertiary referral hospital.

A retrospective analysis of a prospectively collected database on patients with OGIB who underwent CE to investigate persistent anemia in a tertiary referral center during 2007-2017 was performed. Medical records were reviewed. CE findings were classified as significant, suspicious/equivocal and negative. Sites of pathology were categorized into proximal, mid, distal or diffuse.

**Results:** A total of 644 [mean age 33.5 (range 18-88); n=432 (67%) female] had CE over this period. 174 patients (27%) with overt gastrointestinal bleeding were excluded from the study. A total of 470 patients (73%) who were suspected to have occult gastrointestinal bleeding were included into the study. Median time interval of CE after onset of anaemia was 296 days (range 1-745 days). Mean follow-up was 668.5days (range 81-1348 days). Capsules reached caecum in 459 cases (97.7%) and capsule retention was

found in 4 cases (0.9%). Small bowel pathology identified in proximal, mid, distal and throughout (diffuse) small bowel based on small bowel transit time (SBTT) were 58.6%, 9.9%, 24.1%, 9.9% and 7.3% respectively. Diagnostic yield of CE for significant pathology versus equivocal/negative finding were 34.5% and 65.5%, respectively. Significant small bowel pathology was identified in 162 cases, of which 102 (63%) were angiodysplasia, 38 (23.5%) were inflammation or ulcers, 12 (7.4%) were polyps, 9 (5.6%) were tumor, 1 (0.5%) was blue rubber bleb syndrome. Small bowel ulcers were significantly associated with NSAID use (46%,  $p=0.023$ ). A total of 191 patients underwent a single balloon enteroscopy (172 antero-grade 19 retrograde approach) with an overall diagnostic yield 109 (57.1%). 308 patients with negative CE were subsequently diagnosed with poor dietary intake of iron ( $n=167$ ), heavy menstruation ( $n=54$ ) hematologic disorders ( $n=26$ ), colon cancer ( $n=2$ ), colonic Dieulafoy's ( $n=1$ ), hemorrhoid ( $n=1$ ) and hemosuccus pancreaticus ( $n=1$ ). A total of 56 (18.2%) had no identifiable cause detected. Survival for positive CE vs equivocal/negative CE were 63.7% vs. 99.4% ( $p<0.01$ ).

**Conclusion:** Our study demonstrated that the yield of CE in persistent anemia was 34.5% and prognosis of patients with equivocal or negative CE was excellent.

<sup>1</sup>Università degli Studi di Roma Tor Vergata, Medicina dei Sistemi, Rome, Italy, <sup>2</sup>ASST Ospedale Maggiore di Crema, Scienze Mediche, Unità di Gastroenterologia ed Endoscopia Digestiva, Crema, Italy, <sup>3</sup>University of Rome Tor Vergata, GI Unit, Systems Medicine, Roma, Italy

**Contact E-Mail Address:** samantaromeo87@gmail.com

**Introduction:** Gastrointestinal (GI) bleeding from the small bowel is rare (5-10% of all the GI bleedings)(1). Since 2001, videocapsule endoscopy (VCE) allowed the visualization of bleeding source in most (75%) of the previous obscure GI bleedings (OGIB)(1)

**Aims & Methods:** In a prospective study, we aimed to assess the diagnostic yield of VCE in a cohort of consecutive patients (pts) with OGIB. Secondary endpoints was to assess the usefulness of VCE in the diagnostic work-up and management of pts with OGIB. From March 2016 to Feb. 2018, all pts with indication to perform VCE were considered. Inclusion criteria: 1) diagnosis of OGIB/iron-deficient anemia (IDA); 2) age>18<85 yrs; 3) non-diagnostic bidirectional endoscopy; 4) Follow up ≥5mos; 5) Informed consent. Exclusion criteria: 1) swallowing disorders; 2) VCE contraindications; 3) Concomitant relevant GI diseases. 4) Pregnancy. All VCE images (PillCam, Covidien plc, Dublin, Ireland) were examined by 2 independent investigators. Data were expressed as mean [range].

**Results:** During the study period, 50 out of the 84 pts (59.5%) referred for VCE, fulfilled the inclusion criteria (18 males [36%]; age 68 [27-83] yrs; haemoglobin 8 g/dL [4.5-12.9]). Indication for VCE: ongoing overt OGIB in 11 (22%), previous overt OGIB in 14 (28%), occult-obscure bleeding (with IDA) in 25 (50%) pts. The time interval between OGIB (or diagnosis of IDA) and VCE was 30 [3-240] days. No VCE retentions occurred. Incomplete examinations were reported in 3 (6%) pts. All VCE were discharged in ≤7 days. Ongoing treatment: single antiplatelet therapy (aspirin, ADP receptor antagonist) in 15 (30%), dual antiplatelet therapy in 7 (14%), oral anticoagulant therapy in 7 (14%), nonsteroidal anti-inflammatory drugs in 13 (26%), SSRI-drugs in 3 (6%) pts. Lesions compatible with obscure GI bleeding (positive findings) were observed in 46 (92%) pts, including (%): small bowel (SB) angiodysplastic lesions in 24 (46%), SB erosions in 20 (40%), red signs of recent bleeding in 10 (20%), blood or clots in 8 (16%), venous ectasia in 8 (16%), mucosal or submucosal polyp/tumor mass in 5 (10%), ulcers in 1 (2%) pt. Additional findings included (%): erosive gastroduodenitis in 17 (34%), gastric/duodenal angiodysplastic lesions in 4

(8%), ulcers in 2 (4%) pts. VCE was negative in 4 (8%) pts: 1 (2%) pt with erosive gastroduodenitis (false negative), 2 (4%) pts with rectal bleeding due to rectal solitary ulcer and to hemorrhoids (true negative), respectively. In 1 (2%) pt VCE was not diagnostic. Clinically significant lesions were observed more frequently in pts with occult OGIB (24/25 [96%] pts), followed by pts with ongoing overt OGIB (10/11 [91%]) and previous overt OGIB (12/14 [85.5%]).

After VCE treatments were: medical in 30 (60%) pts; endoscopic in 7 (14%), surgical in 3 (6%), clinical observation with supportive treatments in 9 (18%) pts. After VCE, 49/50 (98%) pts were followed up for ≥5 mos (17.8 [5-28]). Bleeding resolution in these 49 pts was: complete in 31 (63.2%), partial in 9 (18.4%), absent in 9 (18.4%). Death occurred in 3 pts for non-related OGIB conditions.

**Conclusion:** In a prospective study, VCE use provided a high diagnostic yield in patients with OGIB, suggesting its use VCE as the first-line investigation in suspected mid-GIB. In this setting, VCE should be performed by dedicated gastroenterologists, in order to optimize the timing and the selection of patients.

<sup>4</sup>Medical Center K+31, Moscow, Russian Federation, <sup>5</sup>Moscow Hospital №17, Moscow, Russian Federation

**Contact E-Mail Address:** katerina-t-91@mail.ru

**Introduction:** Patients having gastrointestinal bleeding (GIB) of unknown source usually presented with general clinical symptoms of blood loss and often this can only be reflected in a decrease level of hemoglobin.

**Aims & Methods:** The aim of the study is to analyze, evaluate and compare clinical features and identified sources of bleeding in patients with intestinal sources of bleeding.

From 14.02.2007 to 10.03.2019 there were 229 patients (m-117, f-112, mean age 52.3±18.3 years, range 17-89) who admitted to our clinics with GIB of unknown source. Obscure overt bleeding had 142 (62.0%) pts, obscure occult bleeding - 87 (38.0%) pts, that associated with severe anemia in 86 (37.5%) pts, moderate anemia - in 87 (37.9%) pts and mild anemia - in 56 (24.4%) pts. Bleeding was associated with other complaints (incl. combination of complaints in 40 pts) in 98 (42.7%) pts: abdominal pain in 50 (51.0%) pts, diarrhea in 26 (26.5%) pts, nausea/vomiting in 22 (22.4%) pts. Video capsule enteroscopy (VCE) was used for the small bowel examination in 179 (78.2%) pts. and balloon-assisted enteroscopy (BAE) - in 146 (63.7%) pts. BAE was performed after VCE in 96 (53.6%) pts.

**Results:** The source of GIB was found in 191 (83.4%) pts: in small bowel (SB) - in 170 (89.0%) pts; in the upper/lower GI tract - in 21 (11.0%) pts. No pathology was found in 38 (16.6%) pts. The sources of SB bleeding included vessel malformations in 65 (35.7%) pts, tumors - in 54 (29.7%) pts, erosive/ulcerative enteropathy - in 42 (23.1%) pts, diverticula - in 9 (5.3%) pts (incl. Meckel's diverticulum in 6 pts). Clinical features of the pts with SB sources of bleeding are presented in the table 1.

**Conclusion:** The main indication for small bowel examination is GIB of unknown source, which can have a little bit different clinical manifestations depending on the source of bleeding. All the sources of SBB tend to be recurrent, and pts mostly have severe/moderate anemia. Vessel malformations are more frequent sources of SBB in pts elder than 50 years old ( $p=0.008$ ), more often presented with overt bleeding ( $p=0.007$ ). Pts with tumors tend to have a long period of detection, more than 1 year; they usually have complaints of abdominal pain. Pts with enteropathy tend to have a shorter period of detection, less than 1 year, usually associated with diarrhea. All pts with SB diverticula have overt GIB, apparent with severe anemia, without any other complaints.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) and vitamin D deficiency (VDD) is highly prevalent in morbidly obese patients and can advance to non-alcoholic steatohepatitis (NASH), fibrosis, liver cirrhosis and liver cancer. Moreover, metabolic surgery might carry an increased risk for liver decompensation and mortality in cirrhotic patients. We examined the prevalence of liver fibrosis and response to metabolic surgery.
