**Aims & Methods:** In a randomized controlled trial, baseline intraoperative needle liver biopsy was performed in 46 patients with VDD who underwent one-anastomosis gastric bypass (OAGB). Patients were followed for 12 months for non-invasive Fibroscan™ (FS) measures (M and XL probe) for the non-invasive detection of the presence of histologically advanced fibrosis and response to metabolic surgery as well as metabolic signatures and laboratory improvements. Univariate and multivariable analysis were used to test the predictive relevance of data assessed.

**Results:** 78% of subjects were female, mean age was 42 (SD 12) years with a BMI of 44 (4) kg/m<sup>2</sup>, a waist circumference of 128 (11) cm, and a HOMA index of 6.96 (5.81). 26% suffered from diabetes, 50% from hypertension, and 26% from hyperlipidemia. 72% demonstrated NASH, 11% simple steatosis, and 17% normal liver morphology. 30% showed significant fibrosis (F≥2), 9% advanced fibrosis (F3) and 4% cirrhosis (F4).

(I) Metabolic surgery significantly improved BMI, waist circumference, HOMA Index, liver tests, and liver stiffness. Importantly, patients with F<2 responded better. (adjusted for baseline value, age, sex, and diabetes mellitus). Of note, the groups (F<2 vs. F≥3) did not differ at baseline.

(II) FS correlated significantly (r=0.516; p<0.001) with histological fibrosis readings and showed an AUC of 0.738 (p=0.009) to predict F≥2 and an even better AUC 0.815 (p=0.015) for F≥3.

(III) Importantly, we observed a high variance in FS measurements (SD at baseline: 3.1 kPa, 1 months: 3.1 kPa, 3 months: 4 kPa, 6 months: 2.1 kPa, 12 months: 2.4 kPa,) before weight loss.

#### Conclusion:

(I) Metabolic surgery significantly improves liver stiffness, metabolic signatures and γ-GT. Patients with fibrosis stage < 2 responded significantly better.

(II) Fibroscan™ is a useful tool to detect patients with F≥2, demonstrating highly variable measures before weight loss (until 3 months). Hence, suggesting critical evaluation during measurement and application of novel standards such as multiple region measurements to decrease sampling error and increase accuracy in morbidly obese patients.

Fibroscan™ is an important tool to preoperatively select patients for optimal outcome and potential risk of metabolic surgery.

**Introduction:** There are several studies considering obesity as the risk factor for various lower gastrointestinal symptoms. But the evidence regarding the relationship between visceral abdominal tissue (VAT) and the incidence of irritable bowel syndrome (IBS) are sparse. Moreover, the exact measurement method for VAT is still debatable. Lee. GC et.al reported VAT measurement by CT scan which is an invasive and expensive method and not appropriate in everyday usage. We aimed to measure VAT by Body composition measurements were obtained using the dual-energy X-ray absorptiometry (DXA) (Hologic Horizon W, Waltham, MA, USA) and multifrequency bioelectrical impedance analysis (BIA) (Seca mBA 515, Hamburg, Germany) and correlate the values with the presence of IBS symptoms.

**Aims & Methods:** The primary outcome of this study was to investigate the association between VAT and the risk of IBS. The secondary outcome is to compare two different methods for VAT measurement. Totally we enrolled 94 obese patients (76.5% F; mean age M=47.99; SD=11.8 years). In this case-control study we compare the VAT, Fatty mass (FM), Free Fatty Mass (FFM), Waist circumference (WC) between subjects with obesity and IBS (IBS group N=29; 30.9%) and controls (obese patients without IBS, non-IBS group N=65; 69.1%), who underwent obesity programme at tertiary care centre from January 2018. to January 2019. IBS was diagnosed by using Rome IV criteria questionnaire. The association between IBS and abdominal obesity was evaluated by measuring VAT, FFM, FM and waist

circumference (WC) Body composition measurements were obtained using the dual-energy X-ray absorptiometry (DXA) (Hologic Horizon W, Waltham, MA, USA) and multifrequency bioelectrical impedance analysis (BIA) (Seca mBA 515, Hamburg, Germany).

**Results:** The prevalence of IBS in this sample was 30.8%, (OR 0.44; 95% (CI): 0.2645 to 0.7525,  $P = 0.0025$ ) among all enrolled subjects.

VAT(L) measured by bioimpedance is significant predictor for IBS in obese patients  $t = 2.51$ ,  $df = 63.51$ ,  $p < .05$  ( $p = 0.01468$ ); Cohen's  $d = 0.51$  (moderately high) IBS ( $M = 4.27$ ;  $SD = 2.35$ ), non-IBS ( $M = 6.09$ ;  $SD = 3.94$ ).

Moreover, there is significant correlation between VAT measurement with bioimpedance and DEXA. FFM, FM and WC as well are not important predictors for IBS in obese patients. Younger obese patients are more prone to have IBS symptoms than older patients (OR 0.93; 95%(CI): 0.88 to 0.97;  $P = 0.007$ ).

**Conclusion:** Visceral adiposity measured by simple and non-invasive method is associated with an increased risk of IBS. Bioimpedance and DEXA are reliable methods for VAT measurement. However, neither FFM, FM, BMI and WC are associated with an increased risk of IBS.

**References:** Lee CG. Visceral abdominal obesity is associated with an increased risk of irritable bowel syndrome. *Am J Gastroenterol*. 2015;110(2):310-9.

**Introduction:** Obesity is a worldwide epidemic that continues to be pervasive and associated with significant comorbidities that can result in poor quality of life along with reduced life expectancy. Despite progress in the understanding of the complex mechanisms in obesity, bariatric surgery remains the only current treatment of obesity that demonstrates long-term effectiveness. Endoscopic sleeve gastroplasty (ESG) is a novel minimally invasive technique that was first presented in 2008 and improved upon in 2013. Data is limited in terms of the efficacy and safety of ESG, and evidence has not been synthesized in comparison to other options of bariatric surgery like laparoscopic sleeve gastrectomy (LSG).

**Aims & Methods:** In this study, we aim to assess and compare the outcomes of ESG with LSG by meta-analysis. We conducted a comprehensive search of several databases and conference proceedings (earliest inception to March 2019). Pooled rates of total weight loss (TWL%), excess weight loss (EWL%), and body mass index (BMI) with ESG were calculated at 1 month, 6 months, and 12 months. The outcomes at 12 months with ESG were compared to the outcomes at 12 months with LSG.

**Results:** A total of 3713 patients were included in the analysis from 13 studies. Outcomes of ESG were analyzed from a total of 7 studies (1569 patients) and outcomes of LSG were analyzed from 6 studies (2144 patients). Baseline population characteristics were comparable between the ESG and LSG groups. The mean and/ or median age ranged from 30 years to 48 years, with predominantly female population (75%). Mean range of BMI (kg/m<sup>2</sup>) was 33.3 to 38.9 in ESG cohort and 37.4 to 48 in LSG cohort. The pooled rates of TWL at 1m, 6m, and 12m were 8.5 (95% CI 7.7-9.3,  $I^2 = 87.9$ ), 15.4 (95% CI 13.8-16.9,  $I^2 = 94.7$ ), and 17.5 (95% CI 15.3-19.7,  $I^2 = 94.6$ ) respectively. The pooled rates of EWL at 1m, 6m, and 12m were 30.1 (95% CI 22.1-38.2,  $I^2 = 96.6$ ), 57.8 (95% CI 48.6-66.9,  $I^2 = 93.5$ ), and 64.1 (95% CI 51.9-76.4,  $I^2 = 92.7$ ) respectively. The pooled rates of BMI at 1m, 6m, and 12m were 32.6 (95% CI 30.4-34.8,  $I^2 = 97.5$ ), 30.9 (95% CI 29.1-32.6,  $I^2 = 96.7$ ), and 31.3 (28.2-34.3,  $I^2 = 98$ ) respectively. At 12 months, the pooled rates of TWL, EWL, and BMI with LSG was 46.3 (30.9-61.7,  $I^2 = 99$ ), 69.9 (95% CI 59.4-80.5,  $I^2 = 99$ ), and 27.9 (95% 25.2-30.6,  $I^2 = 98.9$ ) respectively. LSG demonstrated

statistically superior TWL when compared to ESG with a statistical p-value of 0.02. EWL and BMI change with LSG and ESG were comparable with a statistical p-value of 0.5 and 0.13 respectively.

**Conclusion:** ESG, as a minimally invasive treatment modality, demonstrates successful clinical outcomes in patients with obesity, in terms of TWL% EWL%, and BMI. Outcomes at 12 months are similar to LSG, except for TWL that was statistically superior with LSG when compared to ESG. This study was limited by heterogeneity and indirect comparison. Well-conducted large scale studies with adequate follow-up time are needed to establish the role of ESG in the treatment of obese patients.

**Introduction:** Perinatal period is characterized by phases of development with high sensitivity to the environmental factors. Among the risk factors, malnutrition or maternal obesity are now recognized to program children's metabolism and promote the occurrence of obesity or type 2 diabetes during postnatal life. This study aims to identify the effects of maternal perigestational exposure to an obesogenic diet in offsprings. This exposure might increase the occurrence of obesity, associated with metabolic disorders, inflammation and disturbances of digestive function in male offsprings.

**Aims & Methods:** 8 female Wistar rats were fed a HFD, and 8 control female rats a standard diet (controls), supplemented or not with inulin.

Female rats were exposed to these experimental conditions during a 4-months pre-gestational period as well as during the gestation and lactation periods.

After weaning, 50 male pups were studied at young adulthood (D60), without any treatment during the experiment. Different segments of the digestive tract were studied for histological analysis, metabolic assays, inflammation and intestinal permeability.

**Results:** Rats from mothers fed a HFD have a higher weight than control pups at weaning time ( $p < 0.001$ ), and the inulin appears to limit this weight gain (HFD vs HFDi  $p < 0.05$ ), phenomenon still present at d60 (C vs HFD  $p < 0.01$ ; HFD vs HFDi  $p < 0.01$ ). Lipid and glycemic assays did not show significant differences. FITC assays didn't show any perturbation of the paracellular intestinal permeability. LPS and pro inflammatory cytokines assays (IL6, IL1 $\beta$ , TNF $\alpha$ ) didn't reveal any tissue inflammation.

**Conclusion:** Our results indicate that pups from mothers fed an obesogenic diet are overweight at both weaning and young adulthood. Interestingly, inulin limits weight gain in these animals.

The obesogenic diet of the mother promotes the occurrence of obesity in male offsprings and an inulin-based dietary supplement could help limiting these deleterious effects. This hypothesis remains to be confirmed after analysis of the intestinal barrier tight junction proteins expression, other inflammatory markers and morphological alterations of the digestive system.

**Introduction:** Obesity is major disease in our society. Intra-gastric balloon is the endoscopic gold standard on short time weight loss. Endoscopic plication can offer us better middle long term results than balloon for its durability.

**Aims & Methods:** This is a multi-center, prospective pilot study intended to evaluate the safety and efficacy of the Gastric Endoscopic Sleeve Plication procedure (mid & distal body plications) (GESP).

Study was Ethics approved at institutions. Written consent obtained. Indications have been obesity grade II. Use of the Incisionless Operating Platform (IOP)<sup>TM</sup> (USGI Medical, San Clemente, CA, USA) with a defined new pattern of disposition of the transmural plications with the g-cath<sup>TM</sup> EZ suture anchors in the greater curvature shortening and tubulizing the stomach to potentially delay gastric emptying and reduce gastric volume / accommodation for an enhanced physiological effect.

Follow up data will be obtained prospectively every 2 weeks initially for the first 2 months and then monthly for the next 10 months on as part of our long term follow-up program that also emphasized changes in unhealthy eating/lifestyle habits.

Gastric emptying studies previously to the intervention, 2 months after and 6 months after intervention are scheduled. Satiety test are also scheduled during the follow up, basal, 2 months and 6 months after the intervention. Liver test with analytics and fibroscan are also done in those patients basal, 2 months and 6 months.

**Results:** 39 operations in 39 patients were successfully performed (M: 17 F: 22). Mean BMI 36.9 (Range 31.2 - 40.3). Mean number of anchors placed was 18.3. All patients were discharged ≤ 24 hours. No serious adverse events (SAE). % Mean Total body weight loss at 5 months for the 34 patients was 13.93 ± 4.14 Kg.

**Conclusion:** The GESP procedure seems to be a safe intervention without significant adverse effects to date. Initial results in weight loss are encouraging. However, long term follow-up and further study remains necessary to assess its value in treating the etiology of obesity.

## P0679 TRANSLATABLE MODEL OF METABOLIC SYNDROME AND LIVER DISEASE IN SMALL ANIMALS USING PRECLINICAL ULTRASOUND

Babenko L.<sup>1</sup>, Bubnov R.<sup>1,2</sup>, Lazarenko L.M.<sup>1</sup>, Spivak M.Y.<sup>1</sup>

<sup>1</sup>Zabolotny Institute of Microbiology and Virology of NAS of Ukraine, Department of Problems of Interferon and Immunomodulators, Kyiv, Ukraine, <sup>2</sup>Clinical Hospital Pheophania, Diagnostic and Interventional Ultrasound, Kyiv, Ukraine

**Contact E-Mail Address:** babenkolidiia@gmail.com

**Introduction:** Diagnostic ultrasound (US) using general US imaging devices can be effectively used for preclinical studies in small animals providing dynamic life-time control [1], furthermore, can enhance drug delivery and therapeutic effects with visual treatment monitoring (theranostic).

**Aims & Methods:** The aim was to develop model of metabolic syndrome in small animals using general US machines for longitudinal in vivo observation and screening large numbers of cases for facilitating further translation. The modeling of metabolic syndrome performed in compliance with the ethical standards and includes conducting an experiment on laboratory animals (mice, rats, murine) with the introduction of high calorie diet

or industrial fat-enriched diet; and further US monitoring using 5-20 MHz probes of diagnostic US machines in grey scale, Doppler, sonoelastography, M-mode detecting tissue movement, US-guided interventions, injection US contrast agents:

1) for precise diagnosis transabdominal US detecting signs of metabolic syndrome via detailed **imaging of internal organs:** liver size, echogenicity, stiffness, kidneys size, structure, Doppler measuring resistance index (RI) on segmental renal arteries, spleen size, muscle thickness at midfemoral level, assessment of visceral vessels, systemic hemodynamics, etc.;

2) for screening all involved animals we measured the visceral fat thickness (threshold considered as 1.5 mm in mice) on sagittal probe position and collected records of panoramic abdominal scans (in sagittal and transverse probe positions) and measured the largest longitudinal liver size (via sub-costal approach). Weight, body size, laboratory indices (cholesterol, uric acid, glucose, etc.), microbiome, genetic markers were also determined. After sacrificing we evaluated studied organs.

**Results:** The model was successfully applied to study effects of new drugs: probiotic strains on high calorie-induced obesity model in BALB/c during 21 days [2] and prebiotic effect on high-calorie diet-induced obesity in rats [3]. US detected development metabolic syndrome, endogenous intoxication syndrome, visceral obesity and liver and kidney dysfunction in mouse and rats. Ultrasound data showed visceral obesity, injury of the liver and organs in all experimental animals. We revealed nephropathy signs (thinning, increasing echogenicity of kidney parenchyma, detecting increasing RI in renal arteries (over 0.7) was feasible in rats. Studies using the models demonstrated efficacy of studied strains, substances improving parameters during experiment. All observed changes were confirmed post mortem.

**Conclusion:** The method of modeling is reliable, allows to monitor metabolic syndrome signs with high translation potential reflecting development disease in humans.

**Contact E-Mail Address:** dragasevicsanja@gmail.com

**Introduction:** Metabolic syndrome (MeS) and inflammatory bowel disease (IBD) share common pathophysiological features including chronic inflammation in visceral adipose tissue, but the interplay still remains unrevealed. Great interest has been recently devoted to the association of FTO gene and obesity, although the biological function is still unclear. FTO is a member of a superfamily of Fe (II)- and 2-oxoglutarate-dependent dioxygenases and presents a nucleic acid demethylase. The proposed FTO pathophysiological mechanism includes alterations of methylation-demethylation states of genes expression in metabolically active tissues.

**Aims & Methods:** Newly diagnosed 94 Crohn's disease (CD) and 98 ulcerative colitis (UC) patients and 91 non-IBD controls with parameters of MeS were analyzed for FTO rs9939609 variant using PCR-ARMS (Polymerase Chain Reaction - Amplification Refractory Mutation System) method.

**Results:** We analyzed distribution of genetic variant FTO rs9939609, previously associated with obesity, in our study population. The genotype distribution was in Hardy-Weinberg equilibrium in each and total analyzed group. Results showed that FTO AA genotype was more frequent in CD

than UC and control group, 29.8%, 23.5% and 14.3%, respectively. It has been demonstrated that AA genotype was significant predictor of CD occurrence ( $p = 0.01$ ), adjusted for age and gender in the logistic regression model. Compared to TT and TA carriers, carriers of AA genotype had 2.6 higher odds for CD development (OR = 2.6 95% CI [1.2 - 5.4])

**Conclusion:** The nutrigenetic approach in IBD could improve understanding of obesity-associated complex diseases and contribute to better risk stratification, considering that genetic markers are not influenced by confounding factors such as education, physical activity, social-economic status and diet. Association of FTO variant with CD could direct further nutrigenomic studies in IBD research.

**Contact E-Mail Address:** edoardo.savarino@unipd.it

**Introduction:** Inflammatory bowel disease (IBD) is characterized by severe inflammation of the small bowel and/or the colon leading to recurrent diarrhea and abdominal pain. Butyrate represents one of the final product of saccharolytic fermentation of complex and nondigestible polysaccharides by anaerobic bacteria and has shown anti-inflammatory and regenerative properties, providing symptomatic relief when orally supplemented in patients suffering from a various range of colonic diseases(1). Limited data are available on butyrate effectiveness in patients with IBD due to the difficulties of proving an adequate concentration of butyrate in the colon.

**Aims & Methods:** We investigate the effect of a microencapsulated form of sodium Butyrate (MSB, Butyrose<sup>®</sup>, SILA, Noale, Italy) on the faecal microbiota of patients with IBD. In this prospective-randomized-placebo-controlled study, 49 IBD patients, 19 CD and 30 UC with mild-to-moderate clinical activity were enrolled. Eighteen volunteers were recruited to provide a healthy microbiota model of the local people. Patients with extensive surgery were excluded. After stratification by clinical assessment, colonoscopy, and fecal calprotectin (FC) levels, the patients were randomized to oral administration of MSB (1800 mg/die) or placebo for 2 months, in addition to conventional therapy. Clinical activity was defined according to HBI in case of Crohn's Disease (CD) and Mayo score in case of ulcerative colitis (UC). Before (T0) and after (T1) butyrate treatment, stool samples were collected for faecal microbiota assessment analysis by 16S ribosomal RNA Illumina MiSeq sequencing. Patients completed the quality of life questionnaire in IBD (IBDQ) on T=0 and T=1

**Results:** We confirmed the evidence of a significant difference ( $p < 0.001$ ) between the microbiota of healthy controls and IBD patients. MSB induced similar changes in the microbiota of IBD patients by increasing the bacteria able to produce shortchain fatty acids (SCFA). However, an increased abundance of butyrogenic colonic bacteria (including genera *Butyrivibrio* and *Subdoligranulum*) were observed in CD patients, whereas in UC patients we observed a major increase of *Lachnospiraceae* (sPLSDA analysis). Clinically, when only patients with calprotectin levels above 250ug/g for CD and 150ug/g(2) for UC were considered, a 30% decrease of calprotectin levels were observed in 67% of CD patients treated with MSB versus 33.3% in those treated with placebo. Subjective improvement in QoL based on IBDQ was significantly observed either in the treatment ( $p=0.0046$ ) and in placebo ( $p=0.039$ ) group. However, a greater effect was observed among the UC patients.

**Conclusion:** Microencapsulated sodium butyrate supplementation showed an increase of butyrogenic and SCFA bacteria stimulating growth with a mimicking prebiotic effect increasing the production of endogenous and physiological SCFAs with a marked improvement of QoL and reduction of the level of inflammatory markers.

**Introduction:** Perinatal period is characterized by phases of development with high sensitivity to environmental factors. Among the risk factors, pesticide exposure are now recognized to program children's metabolism and promote the occurrence of obesity or type 2 diabetes. This study purposes the peri-gestational exposure of mothers (animal model: rat) to a low dose of pesticide (chlorpyrifos, CPF). This exposition might increase the occurrence of obesity, associated with metabolic disorders and disturbances of digestive function in male offsprings.

**Aims & Methods:** 8 female Wistar rats were exposed to CPF, and 8 female rats to its vehicle (controls), supplemented or not with inulin. Female rats were exposed to these experimental conditions during a pre-gestational period of 4 months as well as during the gestation and lactation periods. After weaning, 56 male pups were studied at young adulthood (D60), without any treatment during the experiment. Different segments of the digestive tract were studied for histological analysis, metabolic assays, inflammation and intestinal permeability.

**Results:** Rats from mothers exposed to CPF have lower birth weights than control pups ( $p < 0.05$ ), but this difference appears to decrease at young adult age (J60). Lipid and glycemic assays did not show significant differences. We noticed a decrease of IGF1 ( $p < 0.01$ ) and leptin plasma levels but not significantly in animals from CPF-exposed mothers. FITC assays didn't show any perturbation of the intestinal permeability. LPS and pro inflammatory cytokines assays (IL6, IL1 $\beta$ , TNF $\alpha$ ) didn't show any tissue inflammation.

**Conclusion:** Preliminary results reveal that pups from mothers in contact with a pesticide during the peri-gestational period have developmental disabilities characterized by a lower birth weight, but also a decrease in plasma levels of factors involved in growth and metabolism (IGF1 and leptin).

We suggest that the pesticide slows down fetal and postnatal development. This hypothesis remains to be confirmed after analysis of tight junction proteins of the intestinal barrier, other inflammatory markers and morphological alterations of the digestive system.

**Introduction:** Crohn's disease (CD) is characterized by chronic intestinal inflammation and dysbiosis in the gut. Riboflavin (vitamin B<sub>2</sub>) has anti-inflammatory, anti-oxidant and microbiome-modulatory properties. Here, we analyzed the therapeutic potential of riboflavin in CD and its effect on markers of inflammation, oxidative stress and the gut microbiome.

**Aims & Methods:** In this prospective clinical intervention study, 70 CD patients were included and divided into one group with low and one group with high disease activity at baseline (defined by faecal calprotectin (FC)

cut-off value: 200 µg/g). Patients received 100 mg riboflavin (DSM, Nutritional Products Ltd.) daily for 3 weeks. Clinical disease activity (Harvey-Bradshaw Index: HBI), serum biomarkers of inflammation and redox status (plasma free thiols), and gut microbiome taxonomical composition and functionality (fluorescent *in-situ* hybridization, FISH, and metagenomic shotgun sequencing, MGS), were analyzed before and after riboflavin intervention.

**Results:** Riboflavin supplementation significantly decreased serum levels of inflammatory markers. In patients with low disease activity IL-2 decreased, while in patients with high disease activity C-reactive protein (CRP) and tumor necrosis factor-α (TNF-α) were reduced, and free thiols significantly increased after supplementation. Moreover, HBI was significantly decreased by riboflavin supplementation. Riboflavin supplementation led to decreased *Enterobacteriaceae* in patients with low FC levels as determined by FISH, however, MGS analysis showed no effects on diversity, taxonomy or metabolic pathways of the gut microbiome.

**Conclusion:** Three weeks of riboflavin supplementation suppresses systemic inflammation and attenuates systemic oxidative stress in CD, concomitant with relief of clinical symptoms. FISH analysis showed decreased *Enterobacteriaceae* in quiescent CD, though this was not observed in MGS analysis. Our data demonstrates that riboflavin supplementation has beneficial effects in CD.

**Introduction:** Zinc (Zn) is an essential micronutrient involved in processes of transcription and synthesis of nucleic acids and proteins. Zn deficiency may lead to modulation of the immune system, resulting in the decrease of cytokine levels, interleukins and IFN-γ. Patients with inflammatory bowel disease (IBD) may have micronutrient deficiency more common than assumed. In previous studies Zn deficiency in IBD patients was in correlation with reduced food intake, enteric loss of nutrients and malabsorption.

**Aims & Methods:** We aimed to assess Zn levels in IBD patients as well as healthy individuals, and to examine is there a correlation of Zn levels with disease activity.

Complete medical records of all patients with histologically diagnosed IBD were evaluated. As a control group we analyzed medical records of age and sex matched healthy volunteers, who had done their annual health check up. A case-control study was performed among 45 newly diagnosed IBD patients and the same number age, sex matched healthy controls. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained in addition to inflammatory markers (CRP, erythrocyte sedimentation rate-ESR). Serum levels of Zn were measured spectrophotometrically. Mayo score, UCEIS and CDAI respectively were calculated for each patient.

**Results:** Serum levels of Zn were significantly lower ( $P < 0.05$ ) in IBD patients than controls. Moreover serum levels of Zn negatively correlated with younger age at the time of diagnosis, CRP, sedimentation levels and TIBC, whereas we found positive correlation of Zn and Iron levels. Additionally Zn levels negatively correlated with CDAI, UCEIS and Mayo score ( $P < 0.05$ )

**Conclusion:** Our results suggest that Zn deficiency may be potential noninvasive indicator of disease activity in IBD patients as well as the necessity of additional supplementation in these patients, which could potentially affect the disease course.

**Disclosure:** Nothing to disclose

## P0685 DOES GASTRIC LEPTIN PLAY A KEY ROLE IN CONTROLLING FOOD INTAKE?

Ohta H.<sup>1,2</sup>

**Introduction:** Patients with obesity maintain high levels of leptin (anorexigenic hormone) generate from amount of fat cells, which is called leptin resistance [1]. Recent research in mice suggested that gastric leptin secreted from chief cells into the stomach could control satiety during eating [2].

This study investigated whether the gastric leptin levels in human changed due to eating as mice and there were the differences between in normal body weight subjects and in obese subjects.

**Aims & Methods:** Twelve patients with obesity and 5 volunteers of normal weight were enrolled in this study from February 2015 to October 2018. Visceral and subcutaneous fat volumes were evaluated by a CT scan before starting the bariatric therapy and at 6 months. The leptin levels in the serum were measured by radioimmunoassay before a meal and at 15 and/or 30 minutes after beginning the meal.

The co-relations between the leptin level, the volume of adipose tissue and the stimulation of gastric leptin secretion during eating were evaluated statistically.

**Results:**

1) The co-relation coefficients between the sera leptin levels at hunger and subcutaneous fat volume was 0.83 and it is less co-related to visceral (0.21) or total (0.40) fat volume individually.

2) The leptin levels were not co-related to data of insulin, liver function and cholesterol.

3) The leptin levels were highly correlated with body weight loss by bariatric therapy.

4) Increases in leptin levels were observed in the normal subjects and in the patients with obesity only after eating more amount of food than threshold level.

5) Dietary stimulation of gastric leptin secretion was available to regulate appetite in a short term only for people without hyperleptinemia.

**Conclusion:** The leptin level was associated with the volume of adipose tissue in the long term but it was not clear whether gastric leptin regulated appetite shortly after eating.

## P0686 INTESTINAL LUMEN OMEGA-3 POLYUNSATURATED FATTY ACID LEVELS AFTER ORAL SUPPLEMENTATION

Nana G.R.<sup>1</sup>, Watson H.<sup>1</sup>, Volpato M.<sup>1</sup>, Race A.D.<sup>2</sup>, Loadman P.M.<sup>2</sup>, Toogood G.J.<sup>3</sup>, Hull M.A.<sup>1</sup>

<sup>1</sup>University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom, <sup>2</sup>University of Bradford, Institute of Cancer Therapeutics, Bradford, United Kingdom, <sup>3</sup>St James's University Hospital, Department of Hepatobiliary Surgery and Transplantation, Leeds, United Kingdom

**Contact E-Mail Address:** gaelromy@gmail.com

**Introduction:** The omega-3 polyunsaturated fatty acids (O3PUFAs), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) display anti-colorectal cancer (CRC) activity. Oral administration of mixed O3PUFAs in healthy volunteers is associated with changes in the intestinal microbiome in favour of short-chain fatty acid (SCFA) producing bacteria<sup>1</sup>.

However, it remains unclear whether this anti-CRC activity is mediated through direct exposure of O3PUFAs in the gut lumen and/or via systemic bioavailability. We tested whether EPA and DHA levels increase in the distal small bowel after oral supplementation with mixed O3PUFAs.

**Aims & Methods:** Patients with a temporary ileostomy following anterior resection for colorectal cancer were studied. Ileostomy fluid (IF) and red blood cell (rbc) membrane EPA and DHA levels were measured by liquid chromatography-tandem mass spectrometry before (V1), a few hours after the first dose (V2), and a few hours after the final dose (V3), following 28 days of daily oral supplementation with 4g mixed EPA/DHA triglycerides

(1:1) as capsules with food. The primary end-point was the change in relative amount (% total fatty acid) and absolute concentration of EPA and DHA in IF and rbc.

**Results:** Eleven patients (8 male:3 female) with a median age of 63 years (range 42-81) completed the study. The ileostomy was present for a median 9 months (range 2-18) prior to enrolment. Individual compliance with capsules (pill counting) was 100% (range 50-107) over 28 days (range 1-33). Overall, the median relative amount of EPA (V2 0.53%; V3 0.36%) and DHA (V2 0.67%; V3 0.51%) in IF rose post-treatment compared to baseline values (V1: 0.19% and 0.23% for EPA and DHA, respectively). The median absolute concentration ( $\mu\text{g/ml}$ ) in IF also increased for EPA (V2 1.53; V3 1.13) and DHA (V2 2.62; V3 1.33) from baseline values (V1: 1.06 and 0.79 for EPA and DHA, respectively). Only four patients (36%) displayed a statistically significant increase (Mann Whitney U test,  $p=0.006$ ) of O3PUFAs in IF after the first dose of capsules. At V2, this group displayed a higher relative amount of EPA (range 6.1 - 22.3%) and DHA (range 7.2 - 23.6%) in IF, compared with the other seven patients (range 0.1 - 1.07% and 0.3 - 1.21% for EPA and DHA, respectively).

However, there was no significant inter-individual variation in levels of O3PUFAs in IF when measured at an equivalent amount of time (V2 median 2 hrs, V3 median 2 hrs) after the final dose of capsules (V3). There was no significant difference in the time interval between oral dosing and IF/rbc sample collection, or frequency of stoma bag changes in the previous 24 hours for V2 and V3. As expected, the relative amount of O3PUFAs in rbc increased after 28 days daily dosing compared to baseline values (EPA: V1 1.19%, V2 1.08%, V3 2.76% and DHA: V1 4.61%, V2 4.50%, V3 6.88%), in keeping with previous studies.

**Conclusion:** Intestinal lumen O3PUFA exposure is variable after oral consumption. Reduction in luminal O3PUFA concentrations after 28 days dosing suggests intestinal adaptation in individuals who displayed high O3PUFA levels after the first dose of oral O3PUFA supplementation. Knowledge of EPA and DHA concentrations in ileostomy fluid can be used to study changes in the microbiome and metabolome (SCFA) associated with O3PUFA treatment.

### P0687 SELECTIVE MICROBIOTA TRANSPLANTATION IS EFFECTIVE FOR CONTROLLING TOURETTE'S SYNDROME

Ding X., Li Q., Xiang L., Li P., Zhang T., Zhang F.

Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China

**Contact E-Mail Address:** xding@njmu.edu.cn

**Introduction:** Emerging scientific data support the significant role of microbiota in the modulation of the central nervous system. The reconstitution of gut microbiota might be a potential option to treat Tourette's syndrome (TS).

**Aims & Methods:** This study aimed to evaluate the role of selective microbiota transplantation on TS. Patients aged 7 to 60 years old with TS and a Yale Global Tic Severity Scale (YGTSS) -total tic score  $\geq 25$  were enrolled in this open-label clinical trial. Participants received 200ml selective microbiota suspension (mixed species of cultured bacteria) daily through the nasojejunal transendoscopic enteral tubing (TET) tube for 3 days. Clinical evaluations before, 1, 4 and 8 weeks after SMT were assessed with the YGTSS, the Adult Tic Questionnaire (ATQ)/the Parent Tic Questionnaire (PTQ), the Gilles de la Tourette Syndrome Quality-of-Life Scale (GTS-QoL) and the Clinical Global Impression (CGI)-Severity. 16S rRNA stool analysis was performed to assess associated microbial changes. The urinary metabolic profiles of those patients were generated using nuclear magnetic resonance (NMR) spectroscopy. Safety was assessed in all patients after treatment.

**Results:** Eleven males aged  $19.2 \pm 7.4$  years old finished the study and were analyzed. SMT led to a significantly decrease on the YGTSS-total tic score from baseline to week 4 ( $46.2 \pm 11.9$  to  $35.7 \pm 17.9$ ,  $p < 0.05$ ). 45.5% (5/11),

45.5% (5/11) and 36.4% (4/11) of patients achieved improvement ( $\geq 30\%$  reduction in YGTSS -total tic score) at week 1, week 4 and week 8 after mini-FMT, respectively. The significant improvement in quality of life was demonstrated by a decreased GTS-QoL score from  $42.1 \pm 19.5$  to  $25.5 \pm 19.6$  at week 8 after treatment ( $p = 0.024$ ).

Patients with gastrointestinal symptoms ( $n = 5$ , such as diarrhea, constipation or flatulence) seemed show better response to SMT than others, although there was no significant difference [80% (4/5) vs. 16.7% (1/6),  $p = 0.080$ ].

Microbiota analysis showed that SMT altered the composition greatly. SMT induced significant alterations in urinary metabolic profiles. No severe adverse events related to SMT occurred during treatment and follow-up.

**Conclusion:** SMT improves quality of life and symptoms of TS by altering microbiota and metabolic mechanism.

**Disclosure:** Nothing to disclose

### P0688 CLINICAL, ENDOSCOPIC AND HISTOLOGICAL CHARACTERISTICS OF ARMENIAN CHILDREN WITH RECURRENT ABDOMINAL PAIN AND DYSPESIA

Shahinyan T.<sup>1,2</sup>, Amaryan G.<sup>1,2</sup>, Braegger C.<sup>3</sup>

<sup>1</sup>Arakir Medical Centre-Institute Child and Adolescent Health, Yerevan, Armenia, <sup>2</sup>Yerevan State Medical University after Mkhitar Heratsi, Yerevan, Armenia, <sup>3</sup>University Children's Hospital Zürich, Division of Gastroenterology and Nutrition, Zürich, Switzerland

**Contact E-Mail Address:** shahinyan\_tatevik@yahoo.com

**Introduction:** Recurrent abdominal pain and dyspepsia are among the most common complaints in paediatric patients. They are often related to gastroduodenal disease (GDD), functional dyspepsia (FD) and other gastrointestinal disorders.

Aim of the study was to analyze clinical, endoscopic and histological characteristics of Armenian children with recurrent abdominal pain and dyspeptic symptoms.

**Aims & Methods:** 150 patients aged 2-18 years (70 males and 80 females, mean age  $9.2 \pm 3.9$  years) with recurrent abdominal pain and dyspepsia were involved in the study. All patients underwent EGDS with biopsies: 2 from the antrum (1 for rapid urease test and histology, 1 for Hp culture), 1 from the duodenal bulb and 1 from the distal esophagus. Histology was assessed according to the updated Sydney system. Gastric and duodenal biopsy specimens were stained by Giemsa modification for Hp infection. 1 antral biopsy was cultured in Hp selective media.

**Results:** The patients were divided into 2 groups: 1<sup>st</sup> group GDD- 70 (46.7%) (presence of erosions or ulcer in the stomach and/or duodenum, proven Hp infection by 2 invasive tests) and 2<sup>nd</sup> group FD -80 (53.3%) (no lesions in the stomach and duodenum, proven or excluded Hp infection by 2 invasive tests).

The most common complaints in both groups were recurrent epigastric pain, nausea and vomiting. Night time pain was more prevalent in patients with GDD in comparison to FD group (6.25% vs 17.1%) [Fisher 0.04,  $\chi^2=4.41$  ( $< 0.05$ )]. Heartburn was almost equally observed in both groups (10 patients, 14.3% vs 8 patients, 10%). By endoscopy in the 1<sup>st</sup> group 4 patients had nodular gastritis (5.7%), 55 aphtous erosions in the stomach and/or duodenum (78.6%) and 11 had PUD (15.7%). 74 (58.7%) FD patients were Hp positive.

By histological examination in the 1<sup>st</sup> group normal stomach mucosa was seen in 2 patients (2.8%), chronic active gastritis in 8 (11.4%), chronic non-active gastritis in 60 (85.7%), normal duodenal mucosa in 25 (35.7%), chronic active duodenitis in 4 (5.7%), chronic non-active duodenitis in 38 (54.2%) and acute duodenitis in 3 (4.3%) patients. In the 2<sup>nd</sup> group distribution of histological changes was: normal gastric mucosa in 28 (35%), chronic active gastritis in 2 (2.5%) and chronic non-active gastritis in 50 (62.5%) patients, normal duodenal mucosa in 52 (65%), chronic active duodenitis in 4 (5%), acute duodenitis in 1 (1.25%), chronic non-active duodenitis in 23 (28.75%). In 36 (24%) patients esophagitis was diagnosed: 9 by endoscopy (2 proven by histology) and 27 only by histological investigation: 20 (28.6%) in the GDD group and 16 (20%) in FD group.

A certain number of serious histologic lesions (22 patients, 14%) was noticed in patients with GDD and FD, respectively: gastric metaplasia in 0 (0%) and 2 (2.5%), gastric dysplasia in 1 (0.7%) and 2 (2.5%), gastric atrophy in 4 (2.8%) and 1 (1.25%), gastric metaplasia in duodenum in 8 (11.4%) and 3 (3.75%), duodenal glandular dysplasia in 1 (0.7%) and 0 (0%).

## Conclusion:

- Functional dyspepsia was diagnosed in 53.3%, and GDD in 46.7% of children with recurrent abdominal pain and dyspepsia.
- Heartburn and nausea were equally observed in both groups of patients: 14.3% with GDD and 10% with FD.
- A certain number (22 patients, 14%) of serious histologic lesions was noticed in both groups: 3.5% with GDD and 6.25% children with FD.
- EGDS with biopsies might be recommended in patients with FD to exclude serious histological changes even in case of macroscopically normal mucosa.

**Disclosure:** Nothing to disclose

## P0689 MALNUTRITION IN PAEDIATRIC PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

Rodríguez Manchón S., Domínguez Ortega G., San Mauro Martín I., Velasco Rodríguez-Belvis M., Viada Bris J.F., Cañedo Villarroya E., Pedron Giner C., Babelo Ruano I., Martínez Ibeas M.Á., Muñoz Codoceo R.A. *Hospital Infantil Universitario Niño Jesús, Section of Gastroenterology and Nutrition. Department of Paediatrics., Madrid, Spain*

**Contact E-Mail Address:** silviarodman@gmail.com

**Introduction:** Patients with Eosinophilic Esophagitis (EoE) may be at nutritional risk due to their own disease, to low dietary intake because of symptoms or to elimination diets. The aim of our study was to screen the presence of malnutrition in paediatric patients with EoE.

**Aims & Methods:** We conducted a prospective observational study from November 2018 to February 2019 in a Paediatric tertiary referral centre. We included patients with EoE younger than 18 years. Patients with a previous diagnosis of other chronic disease were excluded. Demographic and anthropometric data, as well as medical history were recorded. The anthropometric assessment was made measuring weight (W), height (H) and obtaining Z-scores according to the WHO definitions for malnutrition in children  $\leq 5$  years and according to local growth charts (Hernandez et al 1988<sup>1</sup>) in those  $> 5$  years. Acute malnutrition was considered severe when  $W/H < -3$  SD and mild when  $W/H < -2$  SD; chronic malnutrition was considered severe if  $H/age < -3$  SD, mild if  $H/age < -2$  and acute superimposed on chronic if  $H/age < -2$  SD and  $W/H < -2$ . Children  $\leq 5$  years were considered overweight if  $W/H > 2$  SD and obese if  $W/H > 3$  SD. Children  $> 5$  years were considered overweight if  $W/H > 1$  SD and obese if  $W/H > 2$  SD. SPSS 20 was used for statistical analysis.

**Results:** We included 33 patients with a median age of 15 years (range 10.7-17), 24 (72.7%) were male. 16 (48.5%) had asthma and 22 (66.7%) Ig E-mediated food allergies. Most patients (81.2%) were on an elimination diet: 15 because of their IgE-mediated food allergy, 4 as a dietary treatment for their EoE and 7 secondary to both indications. The median diet duration was 4 years (1.6-9.8) and the median of group foods excluded per patient was 2 (1-4). In 16 (48.5%) patients, 2 or more group foods were excluded. The food groups most commonly excluded were: milk (12), nuts (14), fruits (8), egg (7), fish and shellfish (6), gluten (5) and legumes (4). 22 (41.5%) patients received medical treatment for their EoE: 11 swallowed topical steroids (STS) and 11 proton pump inhibitors (PPI). Almost half of the patients (15, 45.5%), had active EoE in their last endoscopy and 8 (15.1%) referred symptoms in the moment of the assessment.

Malnutrition was found in 9 (27, 2%) patients: acute mild malnutrition in 1 (3%), chronic mild malnutrition in 1 (3%), obesity in 4 (12, 1%) and isolated growth retardation in 3 (9.1%). Of those with malnutrition, 8 (88, 9%) patients were on an elimination diet ( $p=0.4$ ), with a median of 3 (1-6) food groups excluded per patient and a median of diet duration of 4.8 years (3.3-10.8). A third of those patients received previous nutritional supplements with elemental formulas. No statistical differences were found between the presence of malnutrition and the number of food groups excluded ( $p=0.4$ ), nor in relation to diet duration ( $p=0.2$ ). Nevertheless, we found a trend towards statistical difference between the duration of the disease since diagnosis and the presence of malnutrition ( $p=0.08$ ). No statistical differences were found in relation to existence of Ig-E related food allergies nor in relation to medical treatment: 2 of the patients with isolated growth retardation received treatment with PPI and 1 with STS; 3 of the obese patients received medical treatment (2 PPI and 1 STS).

**Conclusion:** Up to 27% of patients with EoE presented malnutrition. Most of them were on exclusion diets of prolonged duration and had multiple food groups excluded. Patients with a longer duration of their EoE tend to present malnutrition in a higher frequency.

## P0690 GENETIC STRUCTURE OF HELICOBACTER PYLORI IN RELATIVES: RESULTS FROM A FAMILY STUDY

Eugeniy S., E.M. Spivak, O.M. Manyakina, R.M. Levit, M.Yu. Kirillov, L.V. Ogneva, I.S. Akkuratova  
*Yaroslavl State Medical University, Paediatric, Yaroslavl, Russian Federation*

**Contact E-Mail Address:** spivak58@mail.ru

**Introduction:** Ways of transmission of Hp-infection cause the possibility of the existence of its family tanks and transmission to close relatives of the infected person. The risk of developing Hp-associated diseases of the upper digestive tract largely depends on the genetic structure of Hp. It is known that the most pronounced inflammation in the gastric mucosa is observed during colonization by its highly pathogenic strains of Hp. Chronic gastritis associated with low pathogenic strains of Hp is more often characterized by a superficial process of initial manifestation without signs of atrophy of the gastric mucosa. These facts are important to consider when deciding on the appointment of therapy for Hp-infected family members of the patient.

**Aims & Methods:** To determine the genetic structure of HP in close relatives of patients with HP-associated chronic gastritis.

**Patients and methods.** Among 120 children aged 8-15 years with verified chronic HP-associated gastritis, 16 patients with severe widespread inflammation in the gastric mucosa were selected. All patients underwent gastroscopy with the morphological study of materials of gastrobiopsy. In them using the polymerase chain reaction has identified 16 factors of pathogenicity of Hp: genes of the CagA, CagC, CagE, CagF, CagH, CagM, CagT, VacAs1, VacAs2, IceA, BabA, hpaA, OipA, AlpB and genes encoding the urease subunit B (UreB) and I (UreI). Next, we conducted serologic screening with the definition of class G antibodies to HP antigens among close relatives (parents and sibs of DM). The two and a large excess of antibody titers above the reference values, all of them conducted a similar survey ( $n = 38$ ).

**Results:** All children and their relatives were diagnosed with moderate or severe chronic inflammation in the gastric mucosa. Morphological signs of its atrophy were revealed in 75 % of children and 90 % of their parents and sibs. Every fourth adult patient was diagnosed with intestinal metaplasia. Highly pathogenic HP strains were found in 81.3 % of children and 90 % of their close relatives. Statistical analysis showed that the genetic structure of HP in most families (12 out of 16) is almost identical. The highest reproducibility in families is characteristic for such factors of HP pathogenicity as, BabA, hpaA, VacA, Cag E, CagM, CagH, AlpB и UreB.

**Conclusion:** The identity of the genetic structure of HP in children and their close relatives with chronic gastritis is established. Highly pathogenic strains of HP cause a pronounced inflammatory process in the gastric mucosa. In endoscopic verification of this process, serological screening among close relatives of the patient is recommended. In patients with high titers of antibodies to HP antigens, an in-depth examination with an assessment of their genetic structure of HP is necessary.

**Disclosure:** Nothing to disclose

## P0691 THE INFLUENCE OF THE GENETIC STRUCTURE OF HELICOBACTER PYLORI ON THE CLINICAL AND MORPHOLOGICAL MANIFESTATIONS OF CHRONIC GASTRITIS IN ADOLESCENTS

Eugeniy S., E.M. Spivak, O.M. Manyakina, R.M. Levit, M.Yu. Kirillov, L.V. Ogneva, I.S. Akkuratova  
*Yaroslavl State Medical University, Paediatric, Yaroslavl, Russian Federation*

**Contact E-Mail Address:** spivak58@mail.ru

**Introduction:** The genetic structure of *Helicobacter pylori* (Hp) is one of the most important factors determining the severity of chronic inflammation in the gastric mucosa. This makes it important to study the genome of Hp in diseases of the upper digestive tract.

**Aims & Methods:** To establish the features of clinical manifestations and pathomorphology of gastric mucosa in Hp-associated chronic gastritis in adolescents, depending on the genetic characteristics of Hp.

**Patients and methods:** 133 adolescents aged 15-18 years with Hp-associated chronic gastritis were examined. In material of gastrobiopsy, using the polymerase chain reaction has identified 16 factors of pathogenicity of Hp: genes of the CagA, CagC, CagE, CagF, CagH, CagM, CagT, VacAs1, VacAs2, IceA, BabA, hpaA, OipA, AlpB and genes encoding the urease subunit B (UreB) and I (UreI).

**Results:** In Hp-associated chronic gastritis in adolescents in 60,9 % of cases there is a colonization of the gastric mucosa with highly pathogenic strains of Hp. Almost all these patients (98,5 %) there is a combination of several genes of the island of pathogenicity, including 60,2 % of cases simultaneously 10 and more. Most often identified factors, promote adhesion of Hp on the epithelial cells and the formation of biological films: hpaA - 76,7 %, OipA - 62,8 %, AlpB - 79,1 %. There were allocated 2 group of patients: the main group - teenagers, which identified highly pathogenic Hp strains (n = 81) and comparison group - patients associated with low pathogenic Hp strains (n = 52). Analysis of clinical syndromes of Hp-associated chronic gastritis in adolescents have not found the dependence of the symptoms of the disease from the structure of the genome of Hp. At the same time, the presence of highly pathogenic strains of Hp according to the morphological study is associated with high rates of contamination, increased inflammation, the appearance of signs of atrophy of the gastric mucosa.

**Conclusion:** The genetic structure of Hp does not affect the clinical manifestations of chronic gastritis in adolescents, but determines the severity of the inflammatory process and atrophy in the gastric mucosa.

**Disclosure:** Nothing to disclose

## P0692 THE EFFECTIVENESS OF THERAPY OF HELICOBACTER PYLORI IN CHRONIC GASTRITIS IN ADOLESCENTS, DEPENDING ON THE GENETIC STRUCTURE OF HELICOBACTER PYLORI

Eugeny S., O.M. Manyakina, E.M. Spivak E.M., R.M. Levit, I.S. Akkuratova  
Yaroslavl State Medical University, Paediatric, Yaroslavl, Russian Federation

**Contact E-Mail Address:** spivak58@mail.ru

**Introduction:** Features of the genetic structure of the *Helicobacter pylori* (Hp) can have a significant impact on the nature of changes in the gastric mucosa of the upper digestive tract and on the development, course, prognosis of gastroduodenal pathology, as well as the effectiveness of therapy.

**Aims & Methods:** To establish the dynamics of pathomorphological changes in the gastric mucosa in adolescents with chronic gastritis associated with high and low pathogenic strains of Hp, after a course of anti-*Helicobacter pylori* therapy.

**Patients and methods.** 40 adolescents aged 15-17 years with chronic Hp-associated gastritis were examined. The polymerase chain reaction in material of gastrobiopsy determined the Hp virulence factors: CagA, VacAs1, IceA, BabA and the gene encoding the urease subunit I (I Ure). All patients were examined twice: before and after 6 months a course of anti-*Helicobacter* therapy.

**Results:** There were allocated 2 group of patients: the main group - teenagers, which identified highly pathogenic Hp strains (n = 27) and comparison group - patients associated with low pathogenic Hp strains (n = 13). In repeated morphological study found that after a course of anti-*Helicobacter* therapy expressed colonization of gastric mucosa Hp in the main group was found in 33,3 % of cases in the comparison group of only 7,7 %,  $p < 0,05$ . In the main group, moderate and severe inflammation of the gastric mucosa of 92,6 % versus 31,8 %,  $p < 0,005$ . More than half of the patients of the main group in the morphological study retained signs of atrophy of gastric mucosa; significantly, more often revealed areas of hyperplasia and microerosis.

**Conclusion:** Colonization of the gastric mucosa with highly pathogenic Hp strains is a factor preventing eradication of infection in chronic Hp-associated gastritis in adolescents. The majority of these patients 6 months after a course of anti-*Helicobacter* therapy remains moderate or severe degree of inflammation in the gastric mucosa.

**Disclosure:** Nothing to disclose

### P0693 EATING BEHAVIOR CORRECTION IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE DEPENDING ON POLYMORPHISMS OF THE PPARG2 AND ADRB2 GENES

Nikiforova Y., Fadienienko G.

Government Institution L.T. Malaya Therapy National Institute of the National Academy of Medical S, Department of the Study of Diseases of the Digestive System and their Comorbidity with the Noncommunicable Diseases, Kharkov, Ukraine

**Contact E-Mail Address:** dr.jana@mail.ru

**Introduction:** According to the World Health Organization, the health of the population is 68-74% dependent on lifestyle and 18-20% on genetics. At the present stage in the treatment of patients with non-alcoholic fatty liver disease (NAFLD) not enough attention is paid to the study of the individual characteristics of eating behavior (EB) and nutrigenetics. At the same time, EB violations are a modifiable risk factor, the correction of which can positively modulate nutrigenetic features - a possible metabolic response to the use of certain nutrients. Personalized approach is a priority in improving the effectiveness of treatment of patients with NAFLD. The study of nutrigenetics and its application in practice in the correction of nutrition is an important step towards personalized medicine.

**Aims & Methods:** Fifty patients (26 men and 24 women) with NAFLD were examined. The control group consisted of 30 practically healthy patients reciprocating by sex and age. All patients studied the characteristics of EB (DEBQ questionnaire), anthropometric indicators, lipid and carbohydrate metabolism, the degree of liver steatosis, the area of visceral adipose tissue (CT scan), nutrigenetic features (definition of 5 polymorphisms: Pro12Ala of the PPARG2 gene (rs1801282), Gln27Glu of the ADRB2 gene (rs1042714), Arg16Gly of the ADRB2 gene (rs1042713), Trp64Arg of the ADRB3 gene (rs4994) and Thr54Ala of the FABP2 gene (rs1799883)), associated with the risk of metabolic disorders. Patients were prescribed individual nutritional correction for 12 months, taking into account the identified polymorphisms associated with EB violation, namely: carriers of the Pro12Ala genotype of the polymorphism of the PPARG2 gene were prescribed a therapeutic diet with moderate fat intake of 1.1-1.2 g / kg / day and carbohydrate restriction of 2.5-3 g / kg / day, Pro12Pro genotype carriers - diet with restriction of fats up to 1.0 g / kg / day and moderate consumption of carbohydrates up to 3.5-4 g / kg / day.

**Results:** After 12 months after individual correction, significant positive dynamics of the main anthropometric and laboratory-instrumental indicators were observed: a decrease in body mass index and waist circumference by a factor of 1.2 ( $p < 0.05$ ), a decrease in the level of total cholesterol and low-density lipoproteins of 1.5 and 1.3 times, respectively ( $p < 0.001$ ), the level of triglycerides, 2.1 times ( $p < 0.001$ ) and the increase in high-density lipoproteins by 1.4 times ( $p < 0.001$ ), a decrease in HOMA-IR in 2.2 times ( $p < 0.001$ ), liver samples (reduction of alanine aminotransferase 2.4 times and aspartate aminotransferase 2.5 times ( $p < 0.05$ )), CT scan - signs of steatosis (35% increase in liver x-ray density ( $p < 0.001$ )) and indicators of visceral obesity (a decrease of 2.1 times the area of visceral adipose tissue ( $p < 0.001$ )). In addition, during the control questionnaire, normalization of EB was observed in 86% of patients and a decrease in the degree of eating disorders in 14% of patients compared with baseline indicators ( $p < 0.001$ ).

**Conclusion:** Thus, the appointment of individual correction of EB taking into account nutritional features for at least 12 months contributes to a significant improvement in metabolic parameters associated with the risk of development and progression of NAFLD, the formation and stabilization of proper eating habits, which improves the effectiveness of treatment of patients with NAFLD.

### P0694 A NEW METHOD OF TREATMENT FOR DECOMPENSATED LIVER CIRRHOSIS: ENDOSCOPIC ULTRASOUND-GUIDED TRANSGASTRIC, TRANSHEPATIC INTRAPORTAL AUTOLOGOUS BONE MARROW TRANSPLANTATION

Wang E., Zheng S.

The Third Xiang-Ya Hospital, Central South University, Department of Gastroenteropathy, Changsha, China

**Contact E-Mail Address:** wfen-judy@csu.edu.cn

**Introduction:** Stem cell therapy recently has been explored extensively as a promising treatment for decompensated liver cirrhosis. However, the genomic instability of cultured stem cells and the low efficiency in obtaining them hindered the progress of stem cell transplantation. Moreover, it is pivotal to optimizing transplantation routes by which the stem cells can be delivered effectively. Here we report the novel Endoscopic ultrasound (EUS)-guided transgastric and transhepatic intraportal autologous bone marrow transplantation to achieve therapeutic goals in patients with decompensated liver cirrhosis.

**Aims & Methods:** To investigate the effects of EUS-guided intraportal autologous bone marrow transplantation in decompensated liver cirrhosis, five patients with decompensated liver cirrhosis were recruited. All patients were successfully performed autologous bone marrow transplantation through EUS-guided portal vein (PV) access using the transgastric and transhepatic approach. Regular revisiting was conducted every 1 month and now in 6 months follow-up.

**Results:** Clinical symptoms of patients underwent portal vein transfusion of autologous bone marrow were improved obviously, while no side effects and complications were observed within 6 months follow-up. Specifically, albumin levels, ascites degree, and Child-Pugh score were significantly ameliorated in 1 month, and all follow-up data indicated the continuing improvement irrespective of postoperative time.

Characteristic	Baseline	1st month	P value (1st month vs Baseline)	6th month	P value (6th month vs Baseline)
Albumin, g/L	27.58±4.91	35.76±5.87	0.044	38.68±8.98	0.041
Tbil, umol/L	22.08±10.99	24.48±11.92	0.749	22.58±13.40	0.951
PT, sec	16.02±1.73	14.48±1.11	0.132	14.36±1.60	0.153
No ascites	0% (0/5)	20% (1/5)	-	60% (3/5)	-
Mild ascites	40% (2/5)	40% (2/5)	-	20% (1/5)	-
Moderate and large ascites	60% (3/5)	40% (2/5)	-	20% (1/5)	-
Child-pugh class A	20% (1/5)	40% (2/5)	-	80% (4/5)	-
Child-Pugh class B	60% (3/5)	60% (3/5)	-	20% (1/5)	-
Child-Pugh class C	20% (1/5)	0% (0/5)	-	0% (0/5)	-

[Characteristics of patients]

**Conclusion:** EUS-guided intraportal transplantation of autologous bone marrow improves both clinical symptoms and liver function for patients with decompensated liver cirrhosis. It may thus provide a safe, effective, non-radioactive, and minimally invasive treatment.

**Disclosure:** Nothing to disclose

### P0695 GENETICALLY MODIFIED HSCS STIMULATES LIVER REGENERATION AND COULD BE A NEW PERSPECTIVE APPROACH FOR DEVELOPMENT LIVER DISEASE TREATMENT

Zaikina E.L., Shafigullina A., Titova A., Garanina E., Mavlikeev M., Pevnev G., Gumerova A., Titova M., Rizvanov A., Kiyasov A.

Kazan Federal University, Institute of Fundamental Medicine and Biology, Kazan, Russian Federation

**Contact E-Mail Address:** elwish@mail.ru

**Introduction:** Mortality from chronic liver disease is rising exponentially. Nowadays a lot of effort is made to find new approaches to stimulate liver regeneration and to develop new methods for liver diseases treatment. Cell and gene therapy methods, which are based on using regional stem

cells seems to be perspective. Currently a particular interest is paid to hepatic stellate cells (HSCs). Besides, it's known that HSC is the only source of hepatocyte growth factor (HGF) and fibroblast growth factor 4 (FGF4) in the liver - growth factors, which play a key role in hepatocytes differentiation during embryogenesis and liver regeneration. It is assumed that using genetically modified HSCs (gmHSCs) that express these growth factors could enhance their therapeutic potential.

**Aims & Methods:** The aim of our work was to study gmHSCs properties *in vitro* and their influence on liver regeneration after transplantation into the rats after partial hepatectomy (PH). HSCs were isolated from Wistar rat's liver, genetic modification was carried out by adenovirus Ad5-optHGF-optFGF4-RFP, which contained HGF, FGF4 and reporter gene of Red Fluorescent Protein (RFP). At first, we have studied gmHSCs phenotype *in vitro*, then we have injected gmHSCs into the rats' portal vein during PH operation (experimental group-EG). Control group (CG) of animals received HSCs, transduced by Ad5-RFP vector, which contains only RFP. The animals were sacrificed on 1, 2, 3, 5, 7, 10, 14 and 21 days after HSC transplantation. Paraffin slices were stained immunohistochemically with antibodies to RFP (reporter),  $\alpha$ -FP (hepatoblasts) and  $\alpha$ -SMA (myofibroblasts).

**Results:** The results demonstrated that *in vitro* gmHSCs expressed hepatoblast marker  $\alpha$ -FP earlier than native HSCs and the gene expression level (by RT-PCR) was also significantly higher in gmHSCs group than in native one. This means positive influence of HGF and FGF4 on gmHSCs differentiation in hepatocyte direction *in vitro*. *In vivo* transplanted HSCs saved their viability and migrated to liver parenchyma. A large number of RFP+hepatocyte-like cells were detected even on the 1<sup>st</sup> day after transplantation (4,94 $\pm$ 2,37 %) in the EG, then their number increased to 8,57 $\pm$ 5,15 % by the 2<sup>nd</sup> day. After that, RFP+ cells quantity gradually decreased to 4,82 $\pm$ 3,64 % by the 14<sup>th</sup> day. In the CG dynamics was the same, but the average number of cells was less.  $\alpha$ -FP+ hepatocytes were also detected in both groups, but in the EG  $\alpha$ -FP+ cells amount was significantly higher than in the CG. In all the groups  $\alpha$ -SMA+ myofibroblasts, responsible for liver fibrosis, were not detected.

**Conclusion:** gmHSCs transplantation had more intensive repopulating effect on hepatocytes during the transplantation. It proves the positive effect of the inserted HGF and FGF4 genes on the liver regeneration process. Thus, gmHSCs transplantation stimulates liver regeneration and contributes to hepatocytes repopulation without risk of liver fibrosis.

## P0696 THE EFFECT OF MESENCHYMAL STEM CELLS DERIVED MICROVESICLES TRANSPLANTATION ON LIVER REGENERATION AFTER PARTIAL HEPATECTOMY IN RATS

Shafigullina A., Gomzikova M., Titova A., Mavlikeev M., Barkov A., Kundakchyan G., Usmonova G., Bilyalov A., Gumerova A., Rizvanov A., Kiyasov A.

Kazan (Volga Region) Federal University, Kazan, Russian Federation

**Contact E-Mail Address:** sh.aygul@gmail.com

**Introduction:** There are numerous studies of stimulation of liver regeneration by transplantation of mesenchymal stem cells. Their effect is explained by direct intercellular interactions and paracrine communications. One of the alternative ways to influence on liver regeneration is injection of microvesicles. Microvesicles are extracellular vesicles that contain growth factors and cytokines and play a major role in intercellular paracrine communications. It is said, that in compare to cells microvesicles transplantation is not accompanied by risk of metaplasia and mutations, because they do not contain any genetic information.

**Aims & Methods:** To study the effect of transplantation of mesenchymal stem cells microvesicles derived from adipose fat tissue on liver regeneration after partial hepatectomy in rats.

Mesenchymal stem cells, isolated from visceral rat fatty tissue (adMSC), were treated by Cytochalasin B to derive microvesicles. These microvesicles were transplanted into portal vein of rats after partial hepatectomy. Control group of rats after partial hepatectomy received injection of PBS. On 2, 5, 7 and 14 days after operation rats were sacrificed. Functional parameters of liver were analyzed by biochemical tests, morphological changes were studied by immunohistochemical staining of liver slices with antibodies to desmin (HSC marker), Ki-67 (proliferation marker),  $\alpha$ -SMA (myofibroblasts marker), CK-19 (cholangiocytes marker).

**Results:** According to immunohistochemistry results injection of microvesicles: 1) inhibits activation of HSC - there were 20% less desmin+ cells; 2) there were no transformation of HSC into  $\alpha$ -SMA+ myofibroblasts and no risk of liver fibrosis; 3) inhibition of cellular proliferation. So, Ki-67+ hepatocytes number (area of portal tract and central vein) decreased in compare to control group. Number of Ki-67+ nonparenchymal cells in portal tract area was 2 times less, than in control. 4) there were no differences in CK-19 expression in experimental and control groups. As far as the cellular proliferation and thus liver regeneration was inhibited, we've seen higher numbers of ALT levels in experimental group. Decreased regeneration could be also visualized by lower triglycerides and cholesterol levels, there were less, than normal values. Blood urea nitrogen normalized in control group on the 4<sup>th</sup> day, but in experimental - by the 7<sup>th</sup> day already.

**Conclusion:** Injection of adMSC microvesicles inhibits general cellular response to partial hepatectomy. Inhibition of hepatocytes activation and proliferation slows down liver regeneration, that is proved by biochemical tests. Inhibition of HSC activation means also lesser risk of their transformation into myofibroblasts and fibrosis development. Thus microvesicles transplantation is not for stimulation of liver regeneration. Probably these inhibitory effects could be applied for treatment of liver fibrosis, that needs to be studied.

**Introduction:** Regenerative medicine of liver and pancreas has a paramount importance. Common precursors for liver, biliary tree and pancreas exist at early stage of development in the definitive ventral endoderm forming the foregut (1).

**Aims & Methods:** Therefore, the aims of the present study were:

- to evaluate whether adult human duodenal submucosal glands (SGs) contain cells expressing stem cell traits,
- to establish a protocol for isolating these cells based on their anatomical and phenotypic traits,
- to characterize self-renewal properties of duodenal SG cells and their potency to generate functional liver and  $\beta$ -pancreatic cells.

Human duodenum (N=15) were obtained from deceased adult organs and analyzed by immunohistochemistry and immunofluorescence (2). The entire duodenum was processed through a chemical dissolution of the mucosa layer that preserved the sub-mucosa, which was successively digested mechanically and enzymatically (2). Isolated cells were immune-selected for the markers of pluripotent stem cells Tra-1-60+ SG cells and successively cultured in self-renewal or differentiation media (2). Parallel experiments were conducted *in vivo* through injection of Tra-1-60+ cells in the spleen of immunocompromised mice, or in streptozotocin-induced diabetic mice, or in Krt19CreTdTomatoLSL C57BL/6J mice (1, 2).

**Results:** In human duodenum, SGs contain cells expressing stem cell markers and with a phenotype which differs from intestinal crypts. Uniquely, duodenal SGs contained Ck7+ and Tra-1-60+ cells which are not present in intestinal crypts. Lineage tracing study in mice demonstrates homeostatic

self-renewal of SGs, which is not supported by duodenal crypt cells. In vitro, SG cultures were composed of cells expressing Ck7, Sox9, EpCAM, Lgr5, and pluripotency markers (Sox2, Tra-1-60, Tra-1-81). SG cells have self-renewal properties, form organoids, and differentiate towards hepatic and pancreatic lineages with distinctive functional properties. In vivo, transplanted cells engraft into livers of severe combined immunodeficient (SCID) mice and differentiate to mature liver cells; in experimentally induced diabetes, insulin-positive cells appear within duodenal SGs.

**Conclusion:** Actual candidate cell sources for regenerative medicine of liver and pancreas are mature cells (hepatocytes and islets) with poor success in literature or reprogrammed cells with the related limits of cell manipulation and tumorigenic risk. Duodenal SGs could represent an easily available cell source for regenerative medicine of ventral endoderm organs with no need of reprogramming.

**Contact E-Mail Address:** rui.magalhaes.med@gmail.com

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease worldwide. Transient elastography (TE, Fibroscan) with controlled attenuation parameter (CAP) has already been proven as an accurate measure for hepatic fibrosis and steatosis. However, its role in stratifying cardiovascular (CV) risk is unknown.

**Aims & Methods:** Cohort, retrospective, single center study, including consecutive NAFLD patients that underwent Fibroscan. Patients were followed at least a year.

Co-variables were chosen bearing in mind clinical relevance and literature evidence.

The correlation towards the outcome variable (Cardiovascular event) was assessed with univariate and multivariate analysis, using SPSS - p value < 0.05 was considered statistically significant

**Results:** We assessed 96 patients with NAFLD, of whom 64 (66.7%) were female, with a mean age of 51.6 years old, all Caucasian. From our cohort, 55.2 % of the patients met criteria for metabolic syndrome.

Several variables had statistical significance towards cardiovascular events incidence on the univariate analysis. (Cardiac failure; Hypertension; dyslipidemia, diabetes mellitus, metabolic syndrome, body mass index, CAP higher 290 db/m, Framingham score and some therapeutics, hypocoagulation agents, antiplatelet agents, statins, antihypertension agents.)

We report 14 (14.4%) cardiovascular events during follow up, the CAP mean in this subgroup was 318.4 db/m.

For CAP values superior to 290 db/m (decibels per meter), the odd of incidence of cardiovascular events were 4.2 times higher, for each unit of cap increase (Odds ratio crude 4.250; p value 0.05). Adjusting the regression multivariate model with previous significant variables, the association trend to statistically non-significance.

Framingham score was not correlated statistically with CAP values.

**Conclusion:** We were able to establish a correlation between CAP and incidence of cardiovascular disease events. Meaning that, a CAP increase is associated with increase of incidence on CV events, mainly in high cap values, over 290 db/m. However, this correlation is diluted adjusting to another CV risk predictor covariables. Fibroscan is easy to apply, safe and a cost-effective method to evaluate NAFLD. CAP values are related to CV events, nevertheless, further studies are needed to identify properly the subpopulation that would most benefit from this feature.

**Contact E-Mail Address:** danaivanc@gmail.com

**Introduction:** The inverse association between NAFLD and diet rich in fruit and vegetables has been demonstrated, but the specific compounds that may be responsible for this association need to be elucidated.

**Aims & Methods:** The aim of this study was to test the association between phenolic acids (PA) consumption, liver steatosis, liver fibrosis, and insulin resistance (IR). This was a cross-sectional study among general population, included in a metabolic screening program. Liver steatosis was evaluated by ultrasonography to determine NAFLD and quantified by the HepatoRenal Index (HRI); fibrosis was assessed by FibroTest; IR by the sample upper quartile of HOMA score. Nutritional intake was measured by food frequency questionnaire (FFQ). Phenolic acids food content was calculated according to Phenol Explorer.

**Results:** A total of 789 subjects were included (52.6% men, age 58.83±6.58 years). Higher (above the upper median) phenolic acids intake was inversely associated with the presence of NAFLD, higher HRI and IR (OR=0.69, 95%CI 0.49-0.98, P=0.036; OR=0.64, 95%CI 0.45-0.91, P=0.013; OR=0.61, 95%CI 0.42-0.87, P=0.007, respectively), adjusting for age, gender, BMI, dietary and lifestyle factors. Considering specific classes of PA, higher hydroxybenzoic acids intake was independently associated with lower odds of NAFLD, higher HRI and fibrosis (OR=0.72, 95%CI 0.51-0.99, P=0.049; OR=0.63, 95%CI 0.45-0.89, P=0.008; OR=0.28, 95%CI 0.12-0.64, P=0.003, respectively). Higher hydroxycinnamic acids consumption was independently associated with lower odds of IR (OR=0.63, 95%CI 0.44-0.90, P=0.012).

**Conclusion:** Phenolic acids may represent food compounds that are protective against insulin resistance and NAFLD-related liver damage.

**Disclosure:** Nothing to disclose

**Introduction:** This study aimed to investigate the risk of metabolic syndrome in subjects with normal ALT level for the general population.

**Aims & Methods:** A cross-sectional study was conducted using nationally representative samples from the Korean National Health and Nutrition Examination Survey 2007-2015. A total of 43,402 adults (men: 17,535 and women: 25,867) with ALT ≤40 U/L and no history of hepatitis B, hepatitis C, liver cirrhosis, and liver cancer were analyzed. The risk of metabolic syndrome were evaluated according to ALT level (men: < 15 U/L, 15-30 U/L, and 30-40 U/L / women: < 10 U/L, 10-20 U/L, 20-40 U/L). Metabolic syndrome was defined by updated National Cholesterol Education Program Adult Treatment Panel III standards.

**Results:** The prevalence of metabolic syndrome is significantly increased as ALT increases regardless of sex. The proportion of metabolic syndrome in men is 12.6%, 25.2%, and 39.7% in ALT < 15 U/L, 15-30 U/L, and 30-40 U/L, respectively (p< 0.001) and that of metabolic syndrome in women is 7.2%, 23.3%, and 44.7% in ALT < 10 U/L, 10-20 U/L, and 20-40 U/L, respectively (p< 0.001). There is an ALT-dependent relationship in the risk of metabolic syndrome within normal ALT level adjusting age, alcohol intake, and body mass index.

The adjusted odds ratios (ORs) of metabolic syndrome in men are 1.55 (95% confidence interval [CI]: 1.38-1.74), and 2.48 (95% CI: 2.16-2.85) in ALT 15-30 U/L, and 30-40 U/L, respectively ( $p < 0.001$ ). And, the adjusted ORs of metabolic syndrome in women are 1.58 (95% CI: 1.35-1.86), and 2.67 (95% CI: 2.26-3.15) in ALT 10-20 U/L, and 20-40 U/L, respectively ( $p < 0.001$ ).

**Conclusion:** The risk of metabolic syndrome is increased as ALT increases within normal ALT level. Even if the ALT level is within normal range, it may be a useful marker to evaluate metabolic syndrome.

**Disclosure:** Nothing to disclose

## P0702 VITAMIN E AND C INTAKE IS INVERSELY ASSOCIATED WITH LIVER DAMAGE IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Ivanovsky-Wajcman D.<sup>1</sup>, Fliss-Isakov N.<sup>2</sup>, Salomone F.<sup>3</sup>, Webb M.<sup>2,4</sup>, Shibolet O.<sup>2,4</sup>, Kariv R.<sup>2,4</sup>, Zelber-Sagi S.<sup>1,2</sup>

**Contact E-Mail Address:** danaivanc@gmail.com

**Introduction:** Evidence is limited regarding to the association between dietary intake of antioxidants and non-alcoholic fatty liver disease (NAFLD) and steatohepatitis (NASH).

**Aims & Methods:** The aim was to test the association between dietary vitamins E and C intake and NAFLD, NASH and fibrosis markers. This was a cross-sectional study of general population. NAFLD was evaluated by ultrasonography and presumed steatosis, NASH and fibrosis by FibroMax. The level of steatosis was defined using SteatoTest, significant NASH defined  $\geq 2$  and borderline-significant fibrosis  $\geq F1-F2$ . Nutritional intake was measured by food frequency questionnaire (FFQ).

**Results:** Overall, 789 subjects were included (52.6% men, age 58.83 $\pm$ 6.58 years), 714 had reliable FibroMax. Adjusting for BMI, dietary and lifestyle factors, the upper tertile of vitamin E intake/1000 Kcal was associated with lower odds of NASH (OR= 0.64, 0.43-0.94,  $P = 0.024$ ). There was an inverse association between reaching the recommended vitamin E intake and NASH (OR= 0.48, 0.30-0.77,  $P = 0.002$ ). The upper tertile of vitamin C intake/1000 Kcal was associated with lower odds of NAFLD and NASH (OR = 0.68, 0.47-0.99,  $P = 0.045$ ; OR= 0.57, 0.38-0.84,  $P = 0.004$ , respectively). Both vitamins were related with the level of steatosis according to SteatoTest.

**Conclusion:** Vitamin E and C intake may be protective from NAFLD related liver damage.

**Disclosure:** Nothing to disclose

## P0703 PREVALENCE AND RISK FACTORS OF NONALCOHOLIC FATTY LIVER DISEASE IN A RURAL COMMUNITY OF SOUTH ASIA

**Contact E-Mail Address:** drmasud47@yahoo.com

**Introduction:** The prevalence and risk factors of nonalcoholic fatty liver disease (NAFLD) varies in different populations. Although nonalcoholic fatty liver disease (NAFLD) has been reported high from the Western and affluent Asian countries, there is paucity of such data from less developed countries, particularly rural areas where most of the people live in Asia. Hence, we undertook a study on the epidemiology of NAFLD among the general population in a rural community of Bangladesh.

**Aims & Methods:** All the adult persons ( $\geq 18$  years) of a defined area of three villages (Charcharia and Churian, Dhaka District, Kharrah, Munshi-

ganj District) identified by manual census were interviewed by a door-to-door survey using a structured questionnaire by trained field research assistants in this cross sectional study. Clinical examination and anthropometric measurements were done by the investigators. Biochemical tests on blood were done after overnight fasting and ultrasonography were done by experienced radiologist on every subject. BMI was categorized by WHO standards and metabolic syndrome (MetS) was defined by Adult Treatment Panel III.

**Results:** Of the total 1682, 1353 subjects responded (response rate 80.44%). In the final analysis 1305 subjects (mean age 41.28  $\pm$  15.10, female 908, 69.6%) were included after exclusion of forty eight subjects for any amount alcohol consumption, HBsAg or Anti-HCV positivity. On ultrasonography, NAFLD was present among 242 (mean age 46.10  $\pm$  12.30, male 93, female 149) subjects with an overall prevalence of 18.5 % (male 23.40% vs female 16.4%,  $p = 0.003$ ). Among subjects with underweight, normal weight, overweight and obesity, NAFLD was present in 0/161(0%), 57/643 (8.9 %), 119/383 (31.1%) and 66/118(55.9%) respectively ( $p < 0.001$ ). NAFLD was more common among subjects aged 40 years or more [153/667, 24.4% vs 89/678, 13.1%; odds ratio (OR) 2.13, 95% confidence interval (CI):1.60-2.85]; DM (82/168,48.8% vs 160/1137, 14.1%; OR=5.82; 95% CI:4.12-8.23,  $p < 0.001$ ), abdominal obesity (134/365,36.7 % vs 108/940, 11.5 %; OR=4.45, 95% CI:3.34-5.99,  $p < 0.001$ ) and MetS (163/373, 43.7% vs 79/932, 8.5 %; OR=8.38, 95% CI: 6.16-11.41). Table 1 compares the significant key parameters of MetS among subjects with and without NAFLD.

Additionally, elevated ALT ( $> 40$ U/L) was present among 53/242(22.0%) subjects with NAFLD. On binary logistic regression analysis, male sex, fasting hyperglycemia or pre-existing DM, higher SBP, abdominal obesity, BMI $> 25$  kg/m<sup>2</sup>, presence of MetS and higher serum triglyceride were found to be risk factors for NAFLD.

Characteristics	Subjects with NAFLD (mean $\pm$ SD)	Subjects without NAFLD (mean $\pm$ SD)	P value
SBP	126.84 $\pm$ 19.76	113.82 $\pm$ 17.65	$< 0.001$
DBP	82.19 $\pm$ 11.46	75.54 $\pm$ 10.56	$< 0.001$
Fasting blood glucose (mmol/L)	6.40 $\pm$ 3.13	4.90 $\pm$ 1.41	$< 0.001$
S. Total cholesterol (mg/dl)	210 $\pm$ 82.12	188.08 $\pm$ 56.22	$< 0.001$
S.LDL-C (mg/dl)	187.85 $\pm$ 41.24	122.22 $\pm$ 51.84	0.115
S.HDL-C (mg/dl)	37.62 $\pm$ 9.51	38.84 $\pm$ 10.91	0.109
Fasting S. triglyceride (mg/dl)	226.84 $\pm$ 140.12	142.48 $\pm$ 93.01	$< 0.001$
BMI (kg/m <sup>2</sup> )	27.93 $\pm$ 4.04	22.87 $\pm$ 4.06	$< 0.001$

[Comparisons of metabolic syndrome parameters between subjects with and without NAFLD]

**Conclusion:** NAFLD imposes a great burden of liver disease in the rural community of Bangladesh. Male sex, DM, higher SBP, abdominal obesity, BMI $> 25$ , presence of MetS and higher serum triglyceride are found to be risk factors for NAFLD.

**Contact E-Mail Address:** amalou\_kh@yahoo.fr

**Introduction:** Epidemiologic data suggest that colonic adenomas have an increased tendency to occur in patients who are obese, or have a positive family history of colon cancer, or diabetes mellitus. Recent data suggest that impaired glucose tolerance, dyslipidemia, and metabolic syndrome are associated with a higher risk for colonic adenomas. Patients with non-alcoholic fatty liver disease (NAFLD) often share several of the aforementioned risk factors for colonic adenomas. However, data are lacking about the relationship between NAFLD and colonic adenomas.

**Aims & Methods:** The aim of this study was to systematically evaluate whether NAFLD is an independent risk factor for colonic adenomas.

A prospective study. Setting University central hospital of army with case recruitment from the community and clinics. Patients Subjects aged 30-70 years were recruited for colonoscopic screening from two study cohorts: (1) community subjects; and (2) consecutive patients with biopsy proven NAFLD. In the community cohort, hepatic fat was measured by fibroscan. Main outcome measures Prevalence of colorectal adenomas. Advanced colorectal neoplasm was defined as cancer or adenomas with villous architecture or high grade dysplasia.

**Results:** NAFLD patients (n=203) had a higher prevalence of colorectal adenomas (34.7% vs 21.5%; p=0.043) and advanced neoplasms (18.6% vs 5.5%; p=0.002) than healthy controls (N=201). Thirteen of 29 (45%) NAFLD patients with advanced neoplasms had isolated lesions in the right sided colon. Among patients with biopsy proven NAFLD, patients with non-alcoholic steatohepatitis (N=49) had a higher prevalence of adenomas (51.0% vs 25.6%; p=0.005) and advanced neoplasms (34.7% vs 14.0%; p=0.011) than those with simple steatosis (N=86). After adjusting for demographic and metabolic factors, non-alcoholic steatohepatitis remained associated with adenomas (adjusted OR 4.89, 95% CI 2.04 to 11.70) and advanced neoplasms (OR 5.34, 95% CI 1.92 to 14.84). In contrast, the prevalence of adenomas and advanced neoplasms was similar between patients with simple steatosis and control subjects.

**Conclusion:** Non-alcoholic steatohepatitis is associated with a high prevalence of colorectal adenomas. The adenomas are found more commonly in the right sided colon. Colorectal cancer screening is strongly indicated in this high risk group.

**Introduction:** Treatment of non-alcoholic fatty liver disease (NAFLD) is essentially based on life style modification: diet and physical activity and managing risk factors. Weight loss of at least 3-5% has proven to improve steatosis and 7-10% to improve fibrosis.

**Aims & Methods:** To assess weight loss after 3 and 6 months of life style modification

Prospective study conducted over one year (December 2017 to December 2018) including all patients followed for NAFLD. All patients have been educated about diet and physical activity, and have been informed about complications and risks of the metabolic syndrome.

**Results:** We included 58 patients: 46 women and 12 men (sex-ratio =0.2) with an average age of 49.4 years [14-81 years]. Type 2 diabetes was found in 22 patients (37.9%), high blood pressure in 20 patients (34.5%) and dyslipidemia in 24 patients (41.4%). The average body mass index was 32.6 Kg/m<sup>2</sup> [20-55 kg/m<sup>2</sup>]. Seventeen patients (29.1%) were overweight and 35 (60.6%) patients were obese. The average waist circumference was 104.24 cm [67-138cm]. Android obesity was objective in 46 patients (79.3%) and hepatic cytolysis was found in 9 patients (15.5%).

The average weight loss at 3 months was 1.26% [0.8-10%] and at 6 months was 2.33% [0.9-13.6%].

After 6 months of follow-up: 38 patients (65.5%) lost weight, 13 patients (22.4%) gained weight and 7 patients (12.1%) maintained a stable weight. Only 8 patients had a weight loss ≥5%.

Normalization of hepatic cytolysis was noted in 66.6% of patients who lost weight and had initial cytolysis.

Ischemic heart disease, gonalgia and advanced age were factors of non-adherence in patients who had not lost weight.

**Conclusion:** Life style modification allowed weight loss in 65.5% of patients and normalization of hepatic cytolysis in 65.5% of cases. Non-adherence to the treatment was related to the impossibility to perform regular physical activity.

**Disclosure:** Nothing to disclose

## P0706 OCTREOTIDE AMELIORATES ENDOPLASMIC RETICULUM DYSFUNCTION IN A NONALCOHOLIC STEATOHEPATITIS MICE MODEL

**Introduction:** Nonalcoholic fatty liver diseases (NAFLD), from simple steatosis to progressive nonalcoholic steatohepatitis (NASH), fibrosis and cirrhosis, are most common chronic liver diseases in the world. Somatostatin (SST), a kind of neuroendocrine hormone, can suppress the release of gastrointestinal peptide, including cytokines. Octreotide, longer half-time somatostatin analog, is used as a replacement of somatostatin due to similar effects.

**Aims & Methods:** We aim to explore the relationship between endoplasmic reticulum and nonalcoholic steatohepatitis and octreotide effects. A total of 30 male C57BL/6J mice were assigned to normal chow (NC), high fat and high cholesterol diet (HFHC), HFHC + octreotide (HFHC+O) groups. After 16-week feeding, mice received i.p. injection of either octreotide (60µg/Kg/12h) or saline for 4 weeks. Body weight, food intake, liver weight, serum and hepatic lipid levels, serum insulin, glucose tolerance test were measured, and serum and hepatic inflammatory cytokines were analyzed with ELISA. Hepatic histology was investigated with H&E staining, Oil red O staining, Sirius red staining and immunohistochemical (IHC) staining. Expression of endoplasmic reticulum function related molecules were measured with RT-PCR and western blot, respectively.

**Results:** In contrast to NC group, Mice with HFHC showed significant increased liver weight, ALT and AST levels, serum cholesterol and inflammatory cytokines, hepatic triglyceride and cholesterol levels, accompanied by aggregated fat deposition in hepatocytes and infiltrated inflammatory cells around hepatocytes, which were attenuated by octreotide treatment. Compared with NC mice, HFHC mice demonstrated increased F4/80 and α-SMA expression in IHC staining, and elevated expression of inositol requiring enzyme 1 (IRE-1α), activating transcription factor 6 (ATF 6) and spliced X-box binding protein 1 (sXBP-1) with RT-PCR and western blot, while octreotide treatment reversed these changes.

**Conclusion:** Octreotide can attenuate hepatic inflammation and lipid metabolism in a NASH mice model, probably by improving endoplasmic reticulum dysfunction. The further underlying mechanisms are under investigation.

**Disclosure:** Nothing to disclose

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is a multifactorial disease. Among others, the interaction of gut microbiome with the host has been proposed as potential mechanism of NAFLD pathogenesis and progression. However, data about the composition of duodenal microbiome of these patients is scarce.

**Aims & Methods:** We aimed to characterize the duodenal microbiome (DM) of NAFLD patients and compare it to that of healthy controls. Patients with histological, biochemical or radiological diagnosis of NAFLD underwent upper gastrointestinal endoscopy and duodenal juice (2cc) was aspirated

from the 3<sup>rd</sup>-4<sup>th</sup> part of duodenum in sterile traps. Patients without liver disease, undergoing gastroscopy due to gastroesophageal reflux disease, comprised the control group. DNA was isolated using the MagAttract PowerSoil DNA Kit. Microbiota was analyzed by 16S rRNA metagenomic sequencing in MiSeq platform (Illumina). Operational Taxonomic Units (OTU) clustering and taxonomic analysis were performed with CLC Microbial Genomics Module v. 2.5. A Negative Binomial GLM model was used to obtain maximum likelihood estimates for an OTU's fold change between the two groups, and the Wald test was used to determine significance.

**Results:** 19 subjects with NAFLD (7 females; age 57.1±11.2 yrs) and 12 controls (7 females; age 45±17.6 yrs) had their DM fully mapped. Principal Coordinate Analysis (PCoA) of the UniFrac distance generated from taxon abundance (beta-diversity) revealed important differences in the DM profile of subjects with NAFLD when compared to controls, resulting in two distinct clusters on PCoA plots. Intriguingly, the  $\alpha$ -diversity indexes of subjects with NAFLD were similar when compared to controls (Total number,  $P=0.2520$ ; Simpson's index,  $P=0.8320$ ). The DM of control subjects was characterized by high relative abundance (RA) of the Firmicutes phylum (68%), followed by Bacteroidetes, Actinobacteria and Fusobacteria (14%, 7%, and 5% respectively). Comparatively to controls, the DM of subjects with NAFLD was also characterized by high RA of the Firmicutes phylum (63%,  $P=0.346$ ), but the RA of the Actinobacteria phylum was increased in these subjects (Fold change (FC)=1.60,  $P=0.02$ ). Interestingly, the relative abundance of the TM7 phylum was also increased in subjects with NAFLD when compared to controls (FC=1.91,  $P=0.02$ ). At order level, the RA of specific taxon from Actinobacteria and TM7 phyla were also increased in subjects with NAFLD when compared to controls, including the Bifidobacteriales order (FC=6.96,  $P=0.03$ ) and CW40 order (FC=4.86,  $P=0.02$ ) respectively. Additionally, the Bacillales order from Firmicutes phylum and the Enterobacteriales order from Proteobacteria, were also increased in NAFLD subjects when compared to controls.

**Conclusion:** The duodenal microbiome of NAFLD patients is different at phylum and order level compared to that of controls. A deeper assessment of the small bowel microbiome in this population may lead to clues to the development of NAFLD.

**Disclosure:** Nothing to disclose

## P0708 NON-INVASIVE SCREENING OF ESOPHAGEAL VARICES: A MULTICENTER STUDY EVALUATING THE BAVENO CRITERIA AND PROPOSING AN ALTERNATIVE APPROACH

Protopapas A.<sup>1</sup>, Mylopoulou T.<sup>2</sup>, Papadopoulos V.<sup>2</sup>, Vogiatzi K.<sup>2</sup>, Goulis I.<sup>1</sup>, Mimidis K.<sup>2</sup>

<sup>1</sup>Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Thessaloniki, Greece, <sup>2</sup>Democritus University of Thrace, First Department of Internal Medicine, Alexandroupolis, Greece

**Contact E-Mail Address:** adoprot@hotmail.com

**Introduction:** Variceal bleeding is a common complication of patients with cirrhosis that can mark the transition from compensated advanced liver disease (cALD) to decompensated cirrhosis. Therefore, endoscopic screening for high-risk varices (HRVs) was initially proposed for all cirrhotics. In an effort to avoid unnecessary endoscopies, the Baveno VI workshop proposed criteria that would identify cirrhotics with low risk of having HRVs. According to these criteria, in patients with cALD, platelet count > 150000/ $\mu$ l and liver stiffness measurement (LSM) < 20 kPa, screening endoscopy could be avoided.

**Aims & Methods:** Aim of this study is to validate the Baveno VI criteria and explore other possible parameters that can be used for the non-invasive screening of esophageal varices. Patients with advanced liver disease (defined as LSM > 12 kPa) were prospectively enrolled. Patients with splenic vein thrombosis, use of beta-blockers and esophageal varices were excluded. The study participants were evaluated according to the Baveno criteria, undergoing LSM, laboratory tests and esophagogastroduodenoscopy (EGD) which was conducted within six months of liver stiffness and laboratory measurements.

**Results:** One-hundred and seven consecutive patients were enrolled in the study and underwent LSM and screening endoscopy. Fifty-one patients (47.7%) had portal gastropathy or normal endoscopic findings (F0), 34 patients (31.8%) exhibited small varices without red spots (F1), and 22 patients (20.5%) had HRVs (F2/F3). Thirteen patients met the Baveno VI criteria, none of which had HRVs. The Baveno VI criteria achieved 100% sensitivity and negative predictive value (NPV) while decreasing the number

of endoscopies by 12.1%. Additional parameters were examined, among which the quotient PLT / LogkPa exhibited the larger area under the curve. By setting a cut-off of  $\leq 122000 \mu\text{l}^{-1} \cdot \text{kPa}^{-1}$ , this method maintained 100% sensitivity and NPV, managing at the same time to increase the percentage of endoscopies avoided to 20.6%. An additional cut-off of  $\leq 92000 \mu\text{l}^{-1} \cdot \text{kPa}^{-1}$  was examined due to its capability to further increase this percentage to 44.9%. However, this happened at the expense of an increased percentage of missed HRVs (6.3%).

**Conclusion:** The Baveno VI criteria are validated in our study population. The new criteria developed in this study succeed in further decreasing the number of screening EGDs and appear as a legitimate alternative to the Baveno VI criteria. More studies are required, in order to verify their effectiveness.

## P0709 CHRONIC RENAL DISEASE AFTER THE FIRST EPISODE OF ACUTE KIDNEY INJURY IN CIRRHOTIC PATIENTS - A REALITY WE SHOULD KEEP IN MIND

Xavier S.<sup>1,2,3</sup>, Monteiro S.<sup>1,2,3</sup>, Magalhães J.<sup>1,2,3</sup>, Marinho C.<sup>1,2,3</sup>, Cotter J.<sup>1,2,3</sup>

<sup>1</sup>Hospital da Senhora da Oliveira, Guimarães, Gastroenterology, Guimarães, Portugal, <sup>2</sup>University of Minho, School of Medicine, Braga, Portugal,

<sup>3</sup>University of Minho, ICVS/3Bs PT Government Associate Laboratory, Braga/ Guimarães, Portugal

**Contact E-Mail Address:** smaxavier@gmail.com

**Introduction:** Acute kidney injury (AKI) is frequently identified in cirrhotic patients and associates with bad prognosis. Recent studies suggest that after the first event, a non-neglectable percentage of patients evolves to chronic kidney disease (CKD).

**Aims & Methods:** We aimed to assess risk factors for progression to CKD and its' impact on patients' prognosis.

Unicentric, retrospective study, including patients with cirrhosis admitted for acute decompensation with AKI. Excluded patients with previous CKD (glomerular filtration rate (GFR) < 60mL/min/1.73m<sup>2</sup> for >3 months), patients who died before 3 months of follow-up and patients without adequate electronic records. Assessed GFR 3 months after the initial event and several outcomes.

**Results:** Included 87 patients. Three months after the initial event, 34.5% of patients had CKD. Patients who developed CKD were more frequently under proton pump inhibitors (66.7% vs 36.8%,  $p=0.008$ ), had higher basal creatinine levels (1.1±1.1mg/dL vs 0.8±0.3mg/dL,  $p<0.001$ ) and reached higher maximum creatinine levels in the first AKI episode (1.8±1.1mg/dL vs 1.4±0.7,  $p=0.004$ ). On multivariate logistic regression, only basal creatinine level significantly associated with progression to CKD ( $p=0.006$ , OR 28.7, IC 95% 2.6-315.8).

Regarding outcomes, patients who developed CKD showed higher rates of new AKI episodes (90.0% vs 38.6%,  $p<0.001$ ) and had higher mortality rates at 6 months, 1 and 2 years (40.0% vs 10.5%,  $p=0.001$ ; 53.3% vs 15.8%,  $p<0.001$  and 56.7% vs 29.8%,  $p=0.015$ , respectively).

**Conclusion:** After the first AKI episode over one third of patients evolve to CKD and these patients have not only higher rates of new episodes of AKI but also higher mortality rates at 6 months, 1 and 2 years. Basal creatinine level was the only independent predictor of progression to CKD.

**Disclosure:** Nothing to disclose

## P0710 ESTIMATION OF GLOMERULAR FILTRATION RATE (GFR) IN CIRRHOTICS: EVALUATION OF EQUATIONS CURRENTLY USED IN CLINICAL PRACTICE AND VALIDATION OF ROYAL FREE HOSPITAL CIRRHOSIS GFR (GFR-RFH)

Protopapas A.<sup>1</sup>, Papagiouvanni I.<sup>1</sup>, Fragkou N.<sup>1</sup>, Agorastou P.<sup>1</sup>, Tzoumari T.<sup>1</sup>, Vettas C.<sup>1</sup>, Alevroudis E.<sup>2</sup>, Notopoulos A.<sup>2</sup>, Goulis I.<sup>1</sup>

<sup>1</sup>Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Thessaloniki, Greece, <sup>2</sup>Hippokration General Hospital, Nuclear Medicine Laboratory, Thessaloniki, Greece

**Contact E-Mail Address:** adoprot@hotmail.com

**Introduction:** Many studies have stressed that the equations used currently for the estimation of GFR may overestimate renal function in cirrhotics. The GFR-RFH equation was developed in order to accurately estimate GFR in this population.

**Aims & Methods:** Aim of this study was to evaluate the use of widely available equations (CKD-EPI, MDRD-4, MDRD-6) and the GFR-RFH equation to correctly estimate the measured GFR of patients with cirrhosis. We retrospectively analyzed data from cirrhotic patients that were evaluated for liver transplantation. These patients were submitted to somatometric tests, laboratory tests and measurement of GFR with the use of <sup>51</sup>Cr-EDTA (GFR-M). The CKD-EPI, MDRD-4, MDRD-6 and GFR-RFH equations were calculated, while bias, precision and accuracy were estimated for each one of them and then compared with paired t-tests. Bias was defined as the mean difference between the GFR-M and the result of each equation; precision was defined as the standard deviation of the differences and accuracy was defined as the square root of the mean squared error (mean of the squared differences). Higher values are associated with higher bias and smaller precision/accuracy.

**Results:** One-hundred and thirty four cirrhotic patients were included (95 male, 39 female). Twenty-one patients were Child-Pugh A, 66 Child-Pugh B and 47 Child-Pugh C. The patients displayed mean GFR-M: 72.36 ± 23.52, CKD-EPI: 78.28 ± 23.53, MDRD-4: 75.5 ± 25.7, MDRD-6: 71.45 ± 25 and RFH-GFR: 54.3 ± 17.96. Bias was estimated for CKD-EPI, MDRD-4, MDRD-6 and GFR-RFH at -5.91, -3.13, 0.92 and 18.24 respectively. Statistically significant differences were observed between all equations separately (p < 0.001 for all comparisons). Precision was estimated at 18.47, 20.81, 18.86 and 16.6, respectively. Only the comparison between MDRD-4 and GFR-RFH yielded a statistically significant result (p = 0.037). Finally, accuracy was estimated at 19.32, 20.97, 18.81 and 24.61, respectively. CKD-EPI and MDRD-6 exhibited statistically better accuracy than GFR-RFH (p = 0.006 and 0.001).

**Conclusion:** GFR-RFH fails to provide a better estimation of renal function in cirrhotics in our sample, in comparison to the equations used in clinical practice. Among equations that are widely used in a clinical setting, MDRD-6 seems to achieve the best overall result (smaller bias, equal precision, better accuracy) in patients with cirrhosis.

## P0711 SOLUBLE CD163 IS ASSOCIATED WITH PORTAL HYPERTENSION AND PREDICTS SURVIVAL IN PATIENTS WITH HEPATITIS C AND ALCOHOL-INDUCED LIVER CIRRHOSIS

Gelman S.<sup>1</sup>, Salteniene V.<sup>2</sup>, Pranculis A.<sup>3</sup>, Kupcinskas L.<sup>4</sup>, Kupcinskas J.<sup>4</sup>

<sup>1</sup>Lithuanian University of Health Sciences, Department of Gastroenterology, Kaunas, Lithuania, <sup>2</sup>Lithuanian University of Health Sciences Institute for Digestive Research, Kaunas, Lithuania, <sup>3</sup>Lithuanian University of Health Sciences, Department of Radiology, Kaunas, Lithuania, <sup>4</sup>Lithuanian University of Health Sciences Institute for Digestive Research, Department of Gastroenterology, Kaunas, Lithuania

**Contact E-Mail Address:** j.kupcinskas@yahoo.com

**Introduction:** Clinically significant (CSPH) and severe portal hypertension (SPH) increase the risk for decompensation and life-threatening complications in liver cirrhosis. The search for non-invasive markers capable of predicting portal hypertension and patient survival is ongoing. Soluble CD163, a marker of Kupffer cell activation, has been associated with viral hepatitis, cirrhosis and portal hypertension. Additional data would aid in creating new non-invasive diagnostic and even treatment approaches in this field.

**Aims & Methods:** In this study we aimed to evaluate plasma levels of soluble CD163 in patients with liver cirrhosis, CSPH, SPH and biomarker potential to predict CSPH and SPH as well as patient survival. We prospectively investigated 100 patients with hepatitis C virus and alcohol-induced liver

cirrhosis with characterized hepatic venous pressure gradient (HVPG) and 30 healthy controls. Plasma levels of CD163 were determined by enzyme-linked immunosorbent assay. Patients were observed for follow-up period of 24 months. Associations of CD163 with Child-Pugh score, HVPG, CSPH (HVPG ≥ 10 mmHg), SPH (HVPG ≥ 12) and patient survival were assessed.

**Results:** Plasma CD163 levels were significantly higher in cirrhotic patients than in healthy controls (p < 0.0001) and increased with disease severity (Child-Pugh class A 1.3; Child-Pugh class B 1.5; Child-Pugh class C 1.8 mcg/ml; p = 0.004). There was a moderate correlation between CD163 and HVPG (r = 0.377; p < 0.0001). Higher levels of CD163 predicted CSPH and SPH independently from Child-Pugh class. AUC for the diagnosis of CSPH was 0.731 (p < 0.0001) and for the diagnosis of SPH 0.7 (p = 0.001). A total of 15 patients died during the follow-up period. Plasma levels of CD163 higher than 1.55 mcg/ml were associated with increased mortality (24 month survival: 76% vs. 98%, p < 0.0001). When stratifying patients according to this cut-off value, the OR for death in 24 months was 15.5 (p = 0.01).

**Conclusion:** Higher plasma levels of CD163 predicted CSPH, SPH and mortality in patients with hepatitis C and alcohol-induced liver cirrhosis. Biomarker could be used as a surrogate marker for long-term survival in this patient population.

**Disclosure:** Nothing to disclose

## P0712 ENDOGENOUS MOTION OF THE LIVER CORRELATES WITH THE SEVERITY OF PORTAL HYPERTENSION

Gelman S.<sup>1</sup>, Sakalauskas A.<sup>2</sup>, Jurkonis R.<sup>2</sup>, Lukosevicius A.<sup>2</sup>, Kupcinskas L.<sup>3</sup>, Kupcinskas J.<sup>3</sup>

<sup>1</sup>Lithuanian University of Health Sciences, Department of Gastroenterology, Kaunas, Lithuania, <sup>2</sup>Kaunas University of Technology, Biomedical Engineering Institute, Kaunas, Lithuania, <sup>3</sup>Lithuanian University of Health Sciences Institute for Digestive Research, Department of Gastroenterology, Kaunas, Lithuania

**Contact E-Mail Address:** j.kupcinskas@yahoo.com

**Introduction:** Portal hypertension (PH) causes life threatening complications in patients with liver cirrhosis, therefore timely diagnosis of clinically significant (CSPH) is of utmost importance. Hepatic venous pressure gradient (HVPG) measurement remains the gold standard to assess the severity of portal hypertension, however the procedure is invasive and is only performed in specialized centers. Non-invasive assessment using elastography techniques has been successfully introduced, however these techniques have certain limitations. The search for non-invasive, accurate and applicable methods for the evaluation of portal hypertension is ongoing.

**Aims & Methods:** In this study we aimed to evaluate the performance of the radiofrequency ultrasound signal analysis algorithm based on endogenous motion of the liver in predicting CSPH. The study included 36 patients with hepatitis C virus or alcohol-induced liver cirrhosis with characterized HVPG measurements. All patients underwent ultrasound examination using a research dedicated ultrasound scanner Ultrasonix SonixTouch. Raw B scans forming radiofrequency signals (record duration - 7.62 s) were acquired and stored for off-line analysis. The signal analysis algorithm was developed for the assessment of liver motion induced by cardiovascular activity. The statistical analysis of endogenous displacement and strain parameters was performed.

**Results:** Three parameters showed statistically significant weak to moderate correlation with HVPG measurement -  $d_{\text{retro}}$  (maximal amplitude of the displacements backward,  $\mu\text{m}$ ; r = 0.39; p = 0.02);  $\sigma_{\text{ROI}[0...10\text{Hz}, 2 \times 2 \text{ cm}]}$  (standard deviation of strain [0...10 Hz, 2 × 2 cm]  $\mu\text{m}/\text{cm}$ ; r = -0.41; p = 0.01);  $\mu_{\text{ROI}[0...10\text{Hz}, 1 \times 1 \text{ cm}]}$  (average strain [0...10 Hz, 1 × 1 cm]  $\mu\text{m}/\text{cm}$ ; r = -0.34; p = 0.04). The median values of parameters were significantly higher in patients with CSPH (p = 0.005, p < 0.05 and p < 0.01 respectively). AUC for the diagnosis of CSPH for  $d_{\text{retro}}$  was 0.84 (p < 0.0001); with a cut-off value of 0.72  $\mu\text{m}$  providing 100% sensitivity and 73% specificity. AUC for the diagnosis of CSPH for  $\sigma_{\text{ROI}[0...10\text{Hz}, 2 \times 2 \text{ cm}]}$  was 0.71 (p = 0.036); with a cut-off value of 0.48  $\mu\text{m}/\text{cm}$  providing 76% sensitivity and 72% specificity. AUC for the diagnosis of CSPH for  $\mu_{\text{ROI}[0...10\text{Hz}, 1 \times 1 \text{ cm}]}$  was 0.78 (p = 0.0024); with a cut-off value of 0.57  $\mu\text{m}/\text{cm}$  providing 76% sensitivity and 81% specificity.

**Conclusion:** The new algorithm estimating endogenous strain of the liver provides reliable parameters which can predict the presence of CSPH.

## P0713 NON-INVASIVE SCREENING OF ESOPHAGEAL VARICES - IS IT TIME TO EXPAND THE BAVENO VI CRITERIA?

Alexandrino G.<sup>1</sup>, Dias Domingues T.<sup>2</sup>, Figueiredo L.M.<sup>1</sup>, Rafael M.A.<sup>1</sup>, Costa M.N.<sup>3</sup>, Carvalho R.<sup>4</sup>, Folgado Alberto S.<sup>4</sup>, Martins A.<sup>4</sup>  
<sup>1</sup>Hospital Professor Doutor Fernando Fonseca, Gastroenterology, Amadora, Portugal, <sup>2</sup>Centro de Estatística e Aplicações da Universidade de Lisboa (CEAUL), Lisbon, Portugal, <sup>3</sup>Hospital Professor Doutor Fernando Fonseca, Gastroenterology, Lisboa, Portugal, <sup>4</sup>Hospital Professor Doutor Fernando Fonseca, Amadora, Portugal

**Contact E-Mail Address:** goncaloalexandrino@gmail.com

**Introduction:** The role of non-invasive methods for detecting liver fibrosis has been investigated in the identification of esophageal varices. The Baveno VI consensus states that in patients with compensated cirrhosis, liver stiffness by transient elastography (TE) < 20 kPa and platelets >150.000, screening endoscopy may be dispensed, given the very low probability of having high-risk varices with indication for prophylaxis or treatment (small varices with red wale marks and medium-large varices).

**Aims & Methods:** We aimed to apply the Baveno VI criteria in a cohort of cirrhotic patients and see how they performed in real life clinical practice. Retrospective study of all patients evaluated between January 2017 and December 2018 with a liver stiffness by TE compatible with cirrhosis and platelet count and upper endoscopy performed up to 6 months after TE. Patients with history of esophageal varices or decompensated cirrhosis were excluded.

**Results:** If the Baveno VI recommendations had been applied to this cohort, endoscopy would have been avoided in 47 (41.2%) patients, none of them with high-risk varices: specificity 100%, sensitivity 2.1%, positive predictive value 100%, and negative predictive value 47% for absence of varices requiring treatment (Table 1). Additionally, both platelet count (AUROC=0.894; p-value=0.0) and TE (AUROC=0.780; p-value=0.001) were individually effective in predicting absence of high-risk varices. However, considering all patients eligible for endoscopy, 53 (79.1%) did not have varices with therapeutic indication.

	Patients who would avoid endoscopy (n=47)	Patients eligible for endoscopy (n=67)
No high-risk varices	47 (100.0%)	53 (79.1%)
High-risk varices	0 (0.0%)	14 (20.9%)

[Table 1]

**Conclusion:** The Baveno VI criteria effectively identified a group of cirrhotic patients without varices requiring treatment in whom screening endoscopy could have been safely avoided. All patients with high-risk varices would be screened. The major drawback of the Baveno VI criteria seems to be the high number of futile screening endoscopies. With the greater availability of non-invasive methods of liver fibrosis, in the future we will probably be able to safely avoid endoscopy in a greater number of patients. Studies are needed to confirm this findings and explore cutoffs or other variables to safely dispense endoscopy in a larger number of patients.

## P0714 LONG-TERM EFFECT ON HEPATIC RESIDUAL FUNCTION AFTER SIMULTANEOUSLY COMBINED BALLOON-OCCCLUDED RETROGRADE TRANSVENOUS OBLITERATION WITH PARTIAL SPLENIC EMBOLIZATION FOR GASTRIC VARICES

Waguri N., Osaki A., Yakubo S., Watanabe Y., Sato M.  
 Niigata City General Hospital, Gastroenterology & Hepatology, Niigata, Japan

**Contact E-Mail Address:** waguri@hosp.niigata.niigata.jp

**Introduction:** Balloon-occluded retrograde transvenous obliteration (B-RTO) has been widely adopted for the management of gastric fundal varices (GV). There are only several reports that B-RTO leads to the improvement of the hepatic residual function in the mid- and long-term. We have performed partial splenic embolization (PSE) simultaneously combined with B-RTO for the purpose of reduction of portal venous blood pressure.

We retrospectively investigated the long-term effect on hepatic residual function and the prognosis of the patients who had underwent B-RTO.

**Aims & Methods:** We have performed B-RTO in 60 patients with GV since 2005 at a single institute. Concomitant PSE underwent in 46 of those patients. We examined the parameters of hepatic functional reserve such as encephalopathy, ascites, total bilirubin, albumin, prothrombin time, and Child-Pugh score in the follow-up period 3, 6, 12, 24, and 36 months after B-RTO. We analyzed the survival curve using Kaplan-Meier method, and investigated the preoperative factor which affected a prognosis independently with multivariate analyses. The study was approved by the Ethics Committee of Niigata City General Hospital. The study protocol conformed to the ethical guidelines of the Declaration of Helsinki.

**Results:** GV were well-embolized in 57 patients (95.0%), and GV disappeared in all patients successfully treated by B-RTO. The serum albumin levels were significantly elevated from 3.3 to 4.0 g/dL (p= 0.0076) and Child-Pugh scores decreased significantly from 7.0 to 5.7 (p= 0.4333) after B-RTO in three years. The median survival was of all cases was 2207 days, and the survival rate was 86.3 % at 1 year, 80.5 % at 3 years, 63.5 % at 5 years. Multivariate analyses revealed that "with the cancer" and "pre-operative Child-Pugh B-C grade" were the predictors of poor prognosis.

**Conclusion:** B-RTO for GV has the long-term favorable effect on hepatic functional improvement. The addition of the PSE inhibits exacerbation of EV after B-RTO without increasing invasiveness.

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** Platelet (PLT) indices have been proposed as potential markers in numerous pathologies for several years. Their role was also highlighted in the assessment of liver fibrosis and exacerbation of liver failure.

**Aims & Methods:** The aim of our study was to verify PLT indices in the evaluation of liver fibrosis in the course of alcoholic liver cirrhosis (ALC) and non-alcoholic fatty liver disease (NAFLD) and to compare them with serological: indirect and direct markers of liver fibrosis. Another goal was to assess the relationship between PLT indices and clinical progression of liver failure in ALC (MELD score). Three hundred and two persons were enrolled to the study: 142 patients with ALC, 92 with NAFLD and 68 healthy volunteers in control group. Hematological indices were measured in each participant: mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT). Indirect markers of liver fibrosis were also assessed: AAR [aspartate aminotransferase (AST) to alanine aminotransferase (ALT) ratio], APRI (AST to PLT Ratio Index), FIB-4 (Fibrosis-4) and GPR (γ-glutamyl-transferase to PLT ratio). Among direct indices of liver fibrosis, procollagen I carboxyterminal propeptide (PICP), procollagen III aminoterminal propeptide (PIIINP), platelet-derived growth factor AB (PDGF-AB), transforming growth factor-α (TGF-α) and laminin were obtained. The assessment of clinical progression of liver failure in ALC patients was done with MELD score. NAFLD fibrosis score and BARD score were calculated in NAFLD patients. Achieved results were compared to controls and between ALC and NAFLD groups. Then a correlation between evaluated indices was performed. Diagnostic value of each assessed parameter together with proposed cut-off in research group were measured with AUC (area under the curve).

**Results:** PDW value in ALC group was significantly higher in comparison to controls (p< 0.0001), level of PCT was significantly lower (p< 0.0001) and MPV value did not differ significantly. PLT indices correlated positively with indirect indices of liver fibrosis: MPV with: APRI, FIB-4 and GPR (p< 0.001), PDW with: APRI and FIB-4 (p< 0.0001). There were also negative relationships between PCT and both: APRI and FIB-4 (p< 0.0001). Strong positive correlations were noted between PCT and direct markers of liver fibrosis: PDGF-AB (p< 0.001) and TGF-α (p< 0.05). MELD score correlated with PLT indices; positively with: MPV and PDW (p< 0.001) and negatively with PCT (p< 0.05). MPV and PDW values in NAFLD group were significantly higher (p< 0.0001 and p< 0.01, respectively) and PCT - lower (p<

0.01). PDW correlated positively with indirect markers of liver fibrosis (APRI and FIB-4;  $p < 0.05$ ) and PCT - negatively (APRI -  $p < 0.01$ , FIB-4 -  $p < 0.0001$ ). There was a strong negative relationship between PCT and NAFLD fibrosis score ( $p < 0.0001$ ) and a weaker one between PCT and laminin ( $p < 0.05$ ). MPV and PDW were significantly higher in ALC group compared to NAFLD patients ( $p < 0.0001$  and  $p < 0.001$ , respectively); PCT level was significantly lower in ALC group ( $p < 0.0001$ ). AUC values and proposed cut-offs for MPV, PDW and PCT in ALC patients were: 0.458 ( $>11.1$  fl), 0.764 ( $>59.3$  %) and 0.839 ( $<0.17$  %), respectively. AUC values and proposed cut-offs for MPV, PDW and PCT in NAFLD patients were: 0.808 ( $<7.9$  fl), 0.643 ( $>52.8$  %) and 0.622 ( $<0.23$  %), respectively.

**Conclusion:** Hematological indices are closely related to serological markers of liver fibrosis. They reflect clinical progression of ALC. PCT in ALC and MPV in NAFLD were found to have the greatest clinical accuracy.

## P0716 RED BLOOD CELL DISTRIBUTION WIDTH AND ITS DERIVATIVES AS PREDICTORS OF FIBROSIS AND CLINICAL OUTCOME IN ALCOHOLIC LIVER CIRRHOSIS AND NON-ALCOHOLIC FATTY LIVER DISEASE PATIENTS

Michalak A.<sup>1</sup>, Guz M.<sup>2</sup>, Kozicka J.<sup>1</sup>, Cybulski M.<sup>2</sup>, Kasztelan-Szczerbinska B.<sup>1</sup>, Chichoz-Lach H.<sup>1</sup>

<sup>1</sup>Medical University of Lublin, Department of Gastroenterology with Endoscopy Unit, Lublin, Poland, <sup>2</sup>Medical University of Lublin, Department of Biochemistry and Molecular Biology, Lublin, Poland

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** Higher values of red blood cell distribution width (RDW) and RDW to platelet ratio (RPR) have been proposed as predictors of poor survival in cirrhotic patients, recently. RDW to lymphocyte ratio (RLR) has been only proved to correlate positively with advanced liver fibrosis in primary biliary cholangitis patients and clinical manifestation of hepatitis E in the field of hepatology, so far.

**Aims & Methods:** The aim of our survey was to assess the utility of RDW, RPR and RLR in the evaluation of liver fibrosis in alcoholic liver cirrhosis (ALC) and non-alcoholic fatty liver disease (NAFLD) patients. We also aimed to assess a relationship between above-mentioned parameters and clinical progression of ALC. 302 persons were included to the study: 142 patients with ALC, 92 with NAFLD and 68 volunteers in control group. Hematological indices (RDW, RPR and RLR) were obtained from each participant. Indirect markers of liver fibrosis were also measured: AAR [aspartate aminotransferase (AST) to alanine aminotransferase (ALT) ratio], APRI (AST to PLT Ratio Index), FIB-4 (Fibrosis-4) and GPR ( $\gamma$ -glutamyl-transferase to PLT ratio). Among direct indices of liver fibrosis, procollagen I carboxyterminal propeptide (PICP), procollagen III aminoterminal propeptide (PIIINP), platelet-derived growth factor AB (PDGF-AB), transforming growth factor- $\alpha$  (TGF- $\alpha$ ) and laminin were obtained. The assessment of clinical progression of liver failure in ALC patients was done with MELD score. NAFLD fibrosis score and BARD score were calculated in NAFLD patients. Achieved results were compared to controls and between ALC and NAFLD groups. Then a correlation between evaluated indices was performed. Diagnostic value of each assessed haematological parameter together with proposed cut-off in research group were measured with AUC (area under the curve).

**Results:** RDW, RPR and RLR values were significantly higher in ALC patients compared to controls ( $p < 0.0001$ ). There were strong positive correlations between RPR and indirect markers of liver fibrosis - FIB-4 and RPR ( $p < 0.0001$ ). RDW and RPR correlated also negatively with PDGF-AB ( $p < 0.01$  and  $p < 0.0001$ , respectively). Positive relationship was observed between RPR and MELD score ( $p < 0.01$ ). RDW, RPR and RLR values were significantly higher in NAFLD patients compared to controls ( $p < 0.05$ ,  $p < 0.0001$ ,  $p < 0.0001$ , respectively). RDW correlated positively with FIB-4 ( $p < 0.05$ ) and RPR - with APRI ( $p < 0.0001$ ). There was also a strong rela-

tionship between RPR and NAFLD fibrosis score ( $p < 0.0001$ ). RDW, RPR and RLR values were significantly higher in ALC patients compared to NAFLD group ( $p < 0.0001$ ). AUC values and proposed cut-offs for RDW, RPR and RLR in ALC patients were: 0.912 ( $>14.2$  %), 0.965 ( $>0.075$ ) and 0.914 ( $>8.684$ ), respectively. AUC values and proposed cut-offs for RDW, RPR and RLR in NAFLD patients were: 0.606 ( $>12.8$ %), 0.724 ( $>0.047$  %) and 0.691 ( $>6.25$  %), respectively.

**Conclusion:** RDW and its derivatives seem to be powerful diagnostic markers of liver fibrosis especially in ALC patients. They might also reflect a decompensation of liver function in this group.

## P0717 EFFICACY AND SAFETY OF ANTICOAGULANT TREATMENT IN PORTAL VEIN THROMBOSIS ASSOCIATED WITH CIRRHOSIS: RESULTS OF A COHORT OF 43 PATIENTS

Ouldgougam R.<sup>1</sup>, Zemmouchi S.<sup>1</sup>, Chikhi Y.<sup>1</sup>, Lounes F.<sup>1</sup>, Faraoune S.<sup>2</sup>, Cheraitia S.<sup>1</sup>, Kouihal W.<sup>1</sup>, Benmaouche F.<sup>1</sup>, Lahcene M.<sup>1</sup>

<sup>1</sup>Bologhine Hospital, Internal Medicine and Gastroenterology, Algiers, Algeria, <sup>2</sup>CHU BAB EL Oued, Medical Imaging, Algiers, Algeria

**Contact E-Mail Address:** rogougam@yahoo.fr

**Introduction:** An increase risk of portal vein thrombosis (PVT) in cirrhotic patients is more reported, without the true impact of PVT being properly assessed. PVT in cirrhotic patients can lead to complications in both liver function and portal hypertension.

**Aims & Methods:** The aim of the study was to evaluate efficacy and safety of anticoagulants in patients with cirrhosis and portal vein thrombosis without hepatocellular carcinoma. It was a prospective, single-center study including 43 patients with portal vein thrombosis recruited among 580 cirrhotic patients between January 2009 and June 2017. Existence, extension and cruoric aspect of the thrombotic obstruction were established in all cases by Doppler ultrasound and angio-CT scan. Anticoagulant treatment was initiated in case of symptomatic portal vein thrombosis or identification of a pro-thrombotic disease. 28 patients (65.1%) received anticoagulants (group G1) and 15 patients did not (group G2). The end-points were: patency of the splanchnic venous system and evaluation of liver function based on the Child score: improvement was defined as a decrease of at least 2 points; deterioration by an increase of at least 2 points, liver function was unchanged if stability or decrease of less than 2 points.

**Results:** The mean age was 47.4 years [37-81] and sex ratio 0.6. Diagnosis of cirrhosis was already known in 22 patients and clinical manifestations of portal vein thrombosis revealed in 21 (48.8%) patients. Thrombosis was revealed by: ultrasound in 14 (32.5%) patients, complications of portal hypertension in 19 (44.2%) patients, acute abdominal pains in 7 patients and signs of intestinal ischemia in 3 patients. Seventeen patients presented at least one pro-thrombotic factor. Mean follow-up was 30.2 [21-62] months. Complete permeability of the venous portal system was achieved in 57.1% of treated patients (n=16) at the end of the study. Further, in G1 compared to G2, improvement of Child score and absence of hepatic insufficiency worsening were respectively recorded in 46.4% vs 0% and 21.4% vs 53.3% of cases, with  $p < 0.01$ . Moreover, no significant side effect of anticoagulants was observed.

**Conclusion:** Anticoagulation therapy for portal vein thrombosis in cirrhotic patients is a safe and effective treatment. It improves the hepatic function and the prognosis of patients.

## P0718 AN INSUFFICIENT PORTOSYSTEMIC PRESSURE GRADIENT REDUCTION AFTER TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT IS ASSOCIATED WITH INCREASED RISK OF VARICEAL REBLEEDING

Wang X.<sup>1</sup>, Zhu Y.<sup>1</sup>, Yang J.<sup>1</sup>, Yan Y.<sup>2</sup>, Luo X.<sup>1</sup>, Yang L.<sup>1</sup>

<sup>1</sup>Sichuan University West China Hospital, Department of Gastroenterology and Hepatology, Chengdu, China, <sup>2</sup>West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

**Contact E-Mail Address:** yuling.yan@scu.edu.cn

**Introduction:** Transjugular intrahepatic portosystemic shunt (TIPS) markedly reduces portosystemic pressure gradient (PPG). A hepatic venous pressure gradient (HVPG) < 12 mm Hg is the most consistent threshold that is protective from having recurrent complications. However, PPG after TIPS may be incoordinate to predict variceal rebleeding due to the inescapable impact of artificial portosystemic shunt. This study aimed to evaluate the incidence, clinical outcomes and predicting factor of insufficient PPG reduction after TIPS.

**Aims & Methods:** The present study retrospectively analyzed the data of 192 patients in whom a TIPS was indicated by the prophylaxis of variceal rebleeding and control of acute bleeding between June 2015 and April 2018. and. The PPG was measured before and after TIPS placement. The patients with PPG ≥ 12 mm Hg were divided into group A, and the rest into group B. The primary endpoint was recurrent rate of variceal hemorrhage, and other clinical outcomes were also evaluated during the follow-up.

**Results:** Forty-seven patients (24.5%) had an insufficient reduction of PPG (≥ 12 mm Hg) after TIPS implantation. PPG significantly decreased from 26.5±4.4 mm Hg to 15.5±3.4 mm Hg ( $P < 0.001$ ) in group A and from 21.0±5.2 mm Hg to 7.6±2.5 mm Hg ( $P < 0.001$ ) in group B. The median follow-up period was 422 days (range, 45-1082 days). During the follow-up period, 8 patients (17.0%) in group A and 10 patients (6.9%) in group B had recurrent variceal bleeding ( $P = 0.039$ ). But there was no significant difference of variceal rebleeding rates among patients in different PPG grades ( $P = 0.785$ ). The 1-year and 2-year probability of remaining free of variceal bleeding rates were 83.6% and 73.6%, respectively. Mortality was higher in group A than group B (14.9% vs 4.1%,  $P = 0.011$ ), while the overt hepatic encephalopathy rate (27.7% vs 32.4%,  $P = 0.541$ ) between two groups showed no significant difference.

	Overall (n=192)	Group A (n=47)	Group B (n=145)	P value
PPG before TIPS, mm Hg	22.3±5.6	26.5±4.4	21.0±5.2	<0.001
PPG after TIPS, mm Hg	9.5±4.4	15.5±3.4	7.6±2.5	<0.001
12-15 mm Hg, n (%)		28 (60)		
16-19 mm Hg, n (%)		11 (23)		
≥20 mm Hg, n (%)		8 (17)		
Reduction in index pressure gradient, mm Hg (%)	12.8±5.5	11.0±5.0	13.4±5.5	0.039
Variceal rebleeding, n (%)	23 (12)	8 (17)	10 (7)	0.039
Overt hepatic encephalopathy, n (%)	60 (31)	13 (28)	47 (32)	0.541
Mortality, n (%)	13 (7)	7 (15)	6 (4)	0.011

[Comparison of clinical outcomes between two groups]

**Conclusion:** PPG declines to < 12 mm Hg after TIPS creation is necessary to protects patients from variceal rebleeding. Stent-graft with adequate diameter should be chosen carefully to achieve sufficient reduction of PPG, otherwise endoscopic and (or) pharmacological therapy should be combined.

## P0719 LIVER STIFFNESS MEASURED BY SHEAR WAVE ELASTOGRAPHY FOR PREDICTING ESOPHAGEAL VARICES IN PATIENTS WITH HEPATITIS B VIRUS RELATED CIRRHOSIS

Yan Y., Xing X., Yang L., Yang J.

West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

**Contact E-Mail Address:** yuling.yan@scu.edu.cn

**Introduction:** Variceal bleeding is one of the most fatal complication in patients with liver cirrhosis. A screening esophagogastroduodenoscopy (EGD) is recommended in all patients with cirrhosis to detect those patients at risk of variceal bleeding. However, this technique is invasive, uncomfortable and costly. Therefore, to find reliable noninvasive methods for predicting varices is crucial for clinic.

Real-time shear wave elastography (SWE), which is a new method for measuring liver stiffness, has been developed. It has been confirmed that SWE has a higher technical success rate and a better diagnostic value for evaluating clinically significant portal hypertension than transient elastography [1]. However, there was also no coincident cut-off value for predicting varices, and only several studies about SWE evaluating the varices risk in compensated liver cirrhosis, and with all etiology cirrhosis patients [2, 3]. Different etiology of cirrhosis would affect the LS values, especially, alcohol and cholestasis. Therefore, to evaluate LS values of different etiology's cirrhosis respectively is valuable. Hepatitis B virus (HBV) related cirrhosis was the biggest part of cirrhosis patients in China. To our knowledge, no published study has examined the efficacy of SWE for predicting esophageal varices in HBV related liver cirrhosis. The purpose of this retrospective study was to investigate the diagnostic performance of SWE for predicting the presence of esophageal varices and high-risk varices in patients with HBV related cirrhosis.

**Aims & Methods:** To investigate liver stiffness of shear wave elastography (SWE) for predicting the presence of esophageal varices and high-risk varices in patients with hepatitis B virus (HBV) related cirrhosis. Clinical data from 135 patients with HBV virus related cirrhosis who underwent SWE and endoscopy were collected consecutively. Liver stiffness (LS) was measured by SWE. The time interval between SWE and endoscopy examination no more than 3 months. Comparisons of the accuracy of prediction between groups were made by areas under the receiver operating characteristic curves (AUROCs), and regression analyses were performed for the multiple variables related to the presence of esophageal varices and high-risk varices.

**Results:** The optimal cutoff values for predicting the presence of esophageal varices and high-risk varices were 12.95 and 13.05 kPa, respectively. AUROC of LS (0.883) was higher than platelet count (PLT) (0.805), APRI (0.809), FIB-4 (0.814), portal vein diameter (PVD) (0.739) and spleen vein diameter (SVD) (0.738) for predicting the presence of esophageal varices. AUROC of LS (0.901) was also higher than platelet count (0.755), APRI (0.767), FIB-4(0.767), PVD (0.742) and SVD (0.742) for predicting high risk varices. LS, albumin (ALB) and SVD were independent factors for predicting the presence of esophageal varices and high-risk varices. AUROCs of patients without ascites for predicting presence of esophageal varices and high-risk varices were 0.863 and 0.879. LS combined ALB and SVD with AUROCs 0.934 and 0.966 for predicting the presence of esophageal varices and high-risk varices, respectively.

**Conclusion:** LS of SWE, or LS combines albumin and SVD improves the diagnostic accuracy are reliable factors for predicting presence of esophageal varices and high-risk varices in patients with HBV-related cirrhosis. In addition, SWE is a reliable noninvasive tool for predicting esophageal varices with ascites.

## P0720 INFECTION AS A PREDICTOR OF MORTALITY IN PATIENTS WITH DECOMPENSATED LIVER CIRRHOSIS: EXPLORING THE RELATIONSHIP TO SEVERITY OF LIVER FAILURE

Bozin T.<sup>1</sup>, Madir A.<sup>1</sup>, Miletic M.<sup>1</sup>, Trkulja V.<sup>2</sup>, Grgurevic I.<sup>1,3</sup>

<sup>1</sup>University Hospital Dubrava, Department of Gastroenterology, Hepatology and Clinical Nutrition, Zagreb, Croatia, <sup>2</sup>University of Zagreb School of Medicine, Department of Pharmacology, Zagreb, Croatia, <sup>3</sup>University of Zagreb School of Medicine, Zagreb, Croatia

**Contact E-Mail Address:** tbozin@gmail.com

**Introduction:** To evaluate predictive value of infection on 30-day and overall medium-term mortality in patients with decompensated liver cirrhosis and to explore its relationship with severity of liver failure.

**Aims & Methods:** We retrospectively reviewed medical records of patients with decompensated liver cirrhosis hospitalized at a single center between 1<sup>st</sup> March 2014 and 31<sup>st</sup> December 2017. The primary outcome was 30-day mortality after the 1<sup>st</sup> hospitalization. Secondary outcome was overall medium-term mortality: patients were tracked (direct contact, medical records) until death, liver transplantation, loss of contact or 31<sup>st</sup> December 2018 (censoring). Presence of infection was documented and classified as Healthcare associated (HCA) or community acquired (CA). Patients were evaluated for the Child-Pugh, MELD and CLiF OF score.

**Results:** Of the 155 included patients (77% males, median age 62 years), 90 had an infection (HCA n=42, CA n=48), mostly urinary tract infection, 53% G+ strains, with multidrug resistant bacteria in 23.8% of HCA and 4.2% CA infections. Thirty-day mortality was 10.8% in patients without infection, 22.9% in patients with CA and 31.0% in patients with HCA infection. With adjustment for Child-Pugh score, age, platelet count and hemoglobin levels, infection (HCA&CA combined) was independently associated with higher 30-day mortality (OR 2.73, 95%CI 1.07-6.94). The association disappeared after adjustment for the CLiF OF or the MELD score (higher scores associated with higher 30-day mortality).

However, infection was also independently associated with higher CLiF OF (b=0.99, 95%CI 0.50-1.48) and higher MELD (b=3.81, 1.92-5.70) scores. Mediation analysis revealed an indirect association between infection and 30-day mortality that was mediated through its association with higher CLiF OF/MELD scores.

Infection "added" to risk of 30-day mortality at each level of liver failure: adjusted estimated probabilities of 30-day mortality in models with infection\*Child-Pugh class (or CLiF OR or MELD score) interactions, were (i) 7.1% with Child-Pugh class B, 13.3% with Child-Pugh class C, 9.3-10.6% with CLiF OF scores 6, 8 and 10, respectively, and 9.3%-10.7% with MELD scores increasing from 10 to 30 if no infection, and (ii) 12.2% and 32.1% (Child-Pugh B and C), 4.9%-44.4% (CLiF OF 6-10) and 5.0% - 40.3% (MELD scores 10-30) in patients with infection.

As for the overall medium-term mortality, HCA infection, but not CA infection, was independently associated with 2.0 to 2.8-times higher risk of death irrespective of whether CLiF OF or MELD scores were accounted for (HR=2.77, 1.67-4.62 if accounting for neither, HR=2.07, 1.21-3.59 if accounting for CLiF OF and HR=2.13, 1.24-3.65 if accounting for MELD).

**Conclusion:** In patients with decompensated liver cirrhosis, infection is associated with higher 30-day mortality. It is also associated with worse liver function scores hence the association with mortality appears to be both direct and indirect via the level of liver failure.

**Disclosure:** Nothing to disclose

## P0721 LIRER SCORE - A NEW PROGNOSTIC TOOL IN HEPATIC CIRRHOSIS DECOMPENSATION

Freitas M.<sup>1,2,3</sup>, Xavier S.<sup>1,2,3</sup>, Magalhães R.<sup>1,2,3</sup>, Magalhães J.<sup>1,2,3</sup>, Marinho C.<sup>1,2,3</sup>, Cotter J.<sup>1,2,3</sup>

<sup>1</sup>Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal, <sup>2</sup>Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal, <sup>3</sup>ICVS/3B's, PT Government Associate Laboratory, Braga/Guimarães, Portugal

**Contact E-Mail Address:** smaxavier@gmail.com

**Introduction:** The liver-renal-risk (LIRER) score was developed to predict adverse outcomes in cirrhotic patients with Model for End-stage Liver Disease (MELD) < 18, helping the allocation to liver transplantation in this population.

**Aims & Methods:** Aim: To assess the prognostic performance of LIRER compared to other prognostic scores in patients with hepatic cirrhosis decompensation, stratifying them in MELD < 18 e MELD ≥ 18.

**Methods:** Retrospective, unicentric study that included patients admitted for initial decompensation of cirrhosis between January 2010 and February 2017. The LIRER, Child-Pugh (CP), MELD and MELD-Na scores were calculated at admission.

**Results:** 146 patients were included, 65.1% with MELD < 18. In the performed analysis, LIRER was a predictor of in-hospital mortality (p=0.02), at 30 days (p=0.04), 1 year (p=0.001), 2 years (p< 0.001) and overall mortality (p=0.007). The ROC curve analysis showed that LIRER (0.699, 0.719, 0.689) was superior to CP (0.614; 0.642; 0.614), MELD (0.625; 0.639; 0.572) and MELD-Na (0.668; 0.670; 0.580) to predict 1 year, 2 years and overall mortality, respectively. Stratifying patients in MELD < 18 and MELD ≥ 18, LIRER was found to be an independent predictor of 1 year, 2 years and overall mortality only in patients with MELD < 18 (0.674; 0.702; 0.723). The LIRER score was superior to the other scores to predict 30-day hospital readmission (AUC 0.748), and the only significant in both groups (MELD < 18: 0.728; MELD ≥ 18: 0.736), with patients with LIRER > 15.9 having a significantly higher probability to be readmitted at 30 days (sensitivity 69.6%, specificity 77.0%).

**Conclusion:** The LIRER score is a better predictor of overall, at 1 and 2 years mortality than CP, MELD and MELD-Na scores, in the decompensation of cirrhosis in patients with MELD < 18. LIRER is therefore an important tool to predict medium-long-term outcomes in this population. Besides, it allows predicting the 30-day readmission probability in overall patients.

## P0722 SURGICAL RISK ASSESSMENT IN CIRRHOSIS

Frias Gomes C., Morão B., Neto C., Barjas E., Ferreira A., Cravo M. Hospital Beatriz Ângelo, Loures, Portugal

**Contact E-Mail Address:** catarinagomes27@gmail.com

**Introduction:** Patients with cirrhosis are living longer, with more advanced disease because of improved medical management. As a result, they are at an increase risk for other diseases and may require emergent or elective surgical procedures other than liver transplantation. Nevertheless, the adequate selection of these patients to surgery is still challenging due to previous reports of high mortality rate and postoperative complications.

**Aims & Methods:** Our goal was to review the clinical performance of cirrhotic patients who underwent surgery in our hospital and to identify risk factors for mortality. A retrospective analysis of patients with cirrhosis who underwent abdominal or non-abdominal (orthopedics, vascular, ENT) surgery between 2016 and 2018 was performed. Primary outcomes were mortality, hospitalization length and need to hospital readmission.

**Results:** A total of 49 patients were included (91.8% male, mean age 61.1 ± 10.1 years, CHILD A 69.4% (34/49), CHILD B 30.6% (15/49), CHILD C 0). ASA classification was the following: 32.7% ASA II, 49% ASA III and 18.4% ASA IV. The majority of the patients was submitted to an abdominal surgery (63.3%) and 40.8% (29/49) underwent an urgent procedure. Mortality rate was 10.2%. Median time of hospitalization was 3 [1-70] days, with 10% of patients needing readmission. MELD Na (OR 1.33 IC 95% [1.02-1.49], p=0.03), ASA > III (OR 1.18 IC 95% [1.02-1.36], p=0.0049) and urgent surgery (OR 1.33 IC 95% [1.03 - 1.72], p=0.004) were associated with a higher postoperative mortality. Hospital readmission was higher in patients with MELD Na > 13 (3/6 vs 2/38, p=0.04). Urgent procedures (1 vs 13 days, p < 0.001), ASA > III (1 vs 5 days, p=0.004), albumin < 3.5 (1 vs 6 days, p=0.01) and MELD Na > 13 (2 vs 7 days, p=0.03) were associated with longer hospital stay.

**Conclusion:** In this cohort of CHILD A and B cirrhotic patients, the postoperative mortality rate was 10.2%. MELD Na, ASA > III and urgent procedure were independent associated with a higher mortality risk.

**Contact E-Mail Address:** marwahassan.777@yahoo.com

**Introduction:** Hepatitis C virus (HCV) infection poses a great health problem to the world today, affecting hundreds of millions of people, and millions more are infected every year. Because HCV typically takes years, if not decades, to progress, the burden it places on healthcare systems will inevitably increase in the coming years despite the currently available therapy. Chronic HCV infection is one of the main causes of hepatic fibrosis, which if untreated for years, will cause distortion of hepatic architecture and progression to liver cirrhosis with its serious complications e.g. hepatocellular carcinoma (HCC). The mechanisms of HCV-induced liver fibrosis and hepatocarcinogenesis are not yet well-recognized. E-cadherin is a cell surface glycoprotein that retains the stability of intercellular adhesion and cellular polarity, maintaining the epithelial barrier integrity. Its down-regulation, as a result of up-regulation of its transcriptional repressors including twist, snail (snail1), and slug (snail2), may induce epithelial-mesenchymal transition (EMT), a mechanism that is involved in HCC development and progression. The identification of molecular factors that promote EMT in HCV infection may provide valuable targets to prevent or to treat its fatal complications.

**Aims & Methods:** This study was designed to determine the role of E-cadherin and the transcription factors snail, slug, and twist2, which are the major regulators of EMT, in assessing chronic HCV activity and its associated fibrosis and carcinogenesis. Selected patients were subjected to thorough clinical examination and were assessed by:

- (a) laboratory investigations
- (b) abdominal U/S and triphasic CT.

Fifty-nine liver biopsies were examined by histopathology and by immunohistochemistry for E-cadherin, snail, slug, and twist2 expression. Grading of hepatitis activity (A) and staging of fibrosis (F) were evaluated using the METAVIR scoring system.

**Results:** E-cadherin expression showed a significant progressive decline with increased stage of fibrosis and with hepatic carcinogenesis ( $p < 0.001$ ). In contrast, snail and slug were positively associated with fibrosis staging and with HCC ( $p < 0.001$ ). However, twist2 wasn't affected by the degree of hepatitis activity, the stage of fibrosis, or by the development of HCC.

	E-cadherin	Snail and Slug	Twist2
Low activity (A1 and A2) (n=24)	50.41±3.23	17.62±3.07	53.83±5.17
High activity (A3) (n=22)	51.13±4.24	20.13±4.74	63.63±6.13
Low fibrosis (F1 and F2) (n=36)	59.16±2.01	13.08±2.03	61.77±5.21
High fibrosis (F3 and F4) (n=10)	20.50±4.24 <sup>b</sup>	39.50±9.95**	46.80±9.61
Hepatocellular Carcinoma (n=13)	10.61±2.4 <sup>a, b</sup>	65.76±4.59*, **	59.61±3.82

Results are expressed as mean±SEM.

<sup>a</sup>Significant decrease than low and high hepatitis activity and than high fibrosis ( $p < 0.001$ ).

<sup>b</sup>Significant decrease than low fibrosis ( $p < 0.001$ ).

\*Significant increase than low and high hepatitis activity and than high fibrosis ( $p < 0.001$ ).

\*\*Significant increase than low fibrosis ( $p < 0.001$ ).

[Table: E-cadherin, snail and slug, and twist2 expression patterns in hepatitis activity grades, liver fibrosis stages, and hepatocellular carcinoma]

**Conclusion:** E-cadherin and its transcriptional regulators; snail and slug are potential indicators for assessing the stage of HCV-induced liver fibrosis and carcinogenesis but not for assessing the degree of hepatitis activity. Therefore, the snail family could be a promising target for designing effective preventive and therapeutic strategies for chronic HCV infection serious co-morbidities.

## P0724 CAN SPLEEN STIFFNESS MEASUREMENT REPLACE THE UPPER ENDOSCOPY TO PREDICT OESOPHAGEAL VARICES IN CHRONIC LIVER DISEASE B?

Mnif L.<sup>1</sup>, Hachicha S.<sup>1</sup>, Hela G.<sup>2</sup>, Boudabous M.<sup>1</sup>, Chtourou L.<sup>1</sup>, Amouri A.<sup>1</sup>, Tahri N.<sup>1</sup>

<sup>1</sup>Hedi Chaker Hospital, Gastroenterology, Sfax, Tunisia, <sup>2</sup>Medecine University of Sfax, Gastroenterology, Sfax, Tunisia

**Contact E-Mail Address:** safa.hachicha@yahoo.fr

**Introduction:** The upper endoscopy is the gold standard method to search oesophageal varices, signes of portal hypertension. But, it is an invasive and non-risk-free examination. Few studies have investigated other non-invasive tools that can replace the upper endoscopy in predicting portal hypertension.

**Aims & Methods:** A total of 84 patients with viral Chronic B liver disease (28 liver cirrhosis, 56 chronic hepatitis) were prospectively randomised; all patients underwent TE for measurement of LSM/SSM and upper endoscopic examination for the diagnosis of OV.

**Results:** 53 men and 31 women were included, with a mean age of 49.04 ± 12.80 years. 42.86% of patients had no OV (Vo); 14.27% had OV grade I (V1) and 28.57% had large oesophageal varices (OV grade II and III). Patients were divided into two groups, those with non varices and those with OV (42.86%). Spleen stiffness showed higher values in liver cirrhosis as compared with chronic hepatitis B patients (58.79KPa versus 26.93KPa;  $p < 0.001$ ) and in patients with OV as compared to those without OV (52.09KPa versus 26.64KPa;  $p < 0.001$ ). The median value of SSM for patients with V1 was 29.92 KPa (12.90 - 75KPa) , 61.27KPa (13.90 - 75KPa) for patient with V2 (OV grade II) and 65.85 KPa (35.50-75KPa) for patients with V3 (OV grade III). A significant difference of SSM was observed between V1,V2 ,V3 subgroups ( $p=0.005$ ). But, there was no significant difference between Vo and V1. For a SSM higher than 33.1KPa, we managed to predict the presence of OV with an area under ROC (AUROC) at 0.795, a sensibility (ss) at 72.2% , a specificity (sp) at 77.1% and a negative predictive value (NPV) at 63%. For a SSM higher than 43KPa, we manage to predict the presence of large oesophageal varices with an AUROC at 0.906, a ss at 83.3%, a sp at 83.3% and NPV at 81%. The SSM was more interesting in predicting the presence of large OV than the presence of OV (AUROC 0.906 versus 0.795). To increase the performance of SSM, we calculate the arithmetic sum of SSM and LSM and we found that SSM+LSM was better than SSM to predict the presence of OV and large OV with AUROC at 0.824 and 0.937 respectively.

**Conclusion:** The SSM seems to be an interesting non invasive tool to predict the presence of large OV requiring primary prophylaxis of varicose haemorrhage in order to reduce the number of screening endoscopy. The Association LSM+SSM may be considered as the first line non-invasive tool to predict the presence of OV in patients with viral chronic B liver disease.

**Contact E-Mail Address:** pargabriella@gmail.com

**Introduction:** In chronic HCV hepatitis immune cells have increased expression TIM-3 checkpoint inhibitor receptor that downregulates T cell activation, resulting T cell exhaustion. In contrast to immune dysfunction of adaptive immune response high levels of TIM-3 expression on NK cells was associated with an activated phenotype towards cytotoxicity. Elimination of hepatitis C virus with direct-acting antiviral (DAA) treatment may modify host immune response via changing TIM-3 immune checkpoint molecule expression.

**Aims & Methods:** In this prospective study we aimed to analyse changes in TIM-3 receptor expression by peripheral blood mononuclear cells in chronic HCV hepatitis patients during DAA treatment. Phenotype distribution and expression of TIM-3 by peripheral blood CD3+, CD4+, CD8+ T cells, regulatory T cells, NK, NK dim, NK bright, NKT cells and monocytes were determined by multicolor flow cytometry in 14 patients with chronic hepatitis C pretreatment and after 12 weeks of dasabuvir, ombitasvir, paritaprevir/ritonavir combination treatment. Blood samples were collected baseline (BL), at the end of treatment (EOT) and at 12 weeks after EOT (SVR12). All patients achieved sustained virological response (SVR12).

**Results:** While the percentage of NK bright cells significantly decreased during DAA therapy (BL: 3.1%, SVR12: 1.7%), the percentage of peripheral blood CD3+ T lymphocytes was significantly higher at SVR12 compared to baseline values (BL: 47 % vs SVR12: 56.3%). TIM-3 expression by NKT (BL: 4.9% vs SVR12: 3.5%) and by NK bright cells (BL: 64% vs SVR12: 50.4%) decreased significantly after treatment.

**Conclusion:** Sustained virological response was associated with increased percentage of peripheral cytotoxic T cells and also with decreased inhibitory TIM-3 checkpoint inhibitor expression by NKT and NK bright cells. Our data suggest that DAA therapy via decreasing the expression of TIM-3 immune checkpoint molecules on NK cell subpopulations may induce the modulation of NK cell cytotoxicity against T cells and contribute to the recovery of exhausted adaptive immune responses.

**Contact E-Mail Address:** nelzouki\_1999@yahoo.com

**Introduction:** Hepatitis D virus (HDV) is a hepatotropic virus that is dependent on the hepatitis B virus (HBV) and supplies the viral envelope containing the surface antigen of hepatitis B. An estimated 15-20 million people are co-infected with HBV and HDV worldwide; with areas of high endemicity in the Middle East, and the Mediterranean region. Viral genetic diversity is related to the geographical origin of the isolates, and there are at least eight genotypes that are referred to as HDV-1 through HDV-8. Data on molecular characterization of HDV in Libya are lacking.

**Aims & Methods:** This study aims to assess the HDV genotypic of patients infected with HDV in Libya. was genotyped by nested PCR-RFLP and sequencing from serum samples of 10 patients with HDV infection whom found to be positive in a cohort of 400 patients with hepatitis B infection. The genotypes were correlated with the clinical characteristics presented by patients with HBV/HDV infection.

All HDV strains belonged to genotype 1, with a wide distribution within the HDV-1 group. They all share the African amino acid marker, a serine at position 202 of the large hepatitis D virus protein.

**Results:** All HDV strains belonged to genotype 1, with a wide distribution within the HDV-1 group. They all share the African amino acid marker, a serine at position 202 of the large hepatitis D virus protein.

**Conclusion:** HDV genotype-1 is the only genotype found, with a high diversity within this group. Further studies are needed in order to better characterize and manage the HBV/HDV-infected patients according to the genetic variability of the viral strains.

**Introduction:** In June 2017, a hepatitis C (HCV) clinic was established in the local substance misuse service (SMS) as an outreach clinic from the local hospital. The clinic initially operated once a month, but due to demand, fortnightly clinics were commenced in March 2018. The objective of the clinic was to provide HCV care (including work-up and treatment) to clients who, because of their substance misuse, might not attend hospital clinics.

**Aims & Methods:** The aim of this study was to assess whether the outreach clinic improved attendance and engagement among these patients compared to hospital-based clinics. The outreach clinic database was used to identify individuals who were offered an appointment between June 2017 and December 2018. The hospital electronic booking system was then used to review historic appointments made for these patients in secondary care. Attendance and engagement with the hospital and outreach clinics were compared.

**Results:** 51 individuals were referred to the SMS clinic between June 2017 and December 2018. 31 of these (61%) had, at some point (dating as far back as the early 2000s), been referred to secondary care for assessment of their HCV. Among those referred, 12 (39%) never attended an appointment, 18 (58%) attended at least once but were subsequently lost to follow-up and 1 (3%) was initiated on HCV treatment but was subsequently transferred to the SMS clinic once established on treatment. In comparison, of the 51 referred to the SMS clinic, 17 (33%) never attended an appointment, 12 (24%) attended at least once but were then lost to follow-up while 22 (43%) remained engaged with the outreach clinic.

**Conclusion:** This study demonstrates that, compared to a hospital setting, an outreach clinic in the community substantially improves attendance and engagement among HCV patients with substance misuse. Contributory factors may include reduction in barriers with SMS oriented care, and ease of access as these patients regularly attend the SMS centre.

**Introduction:** HBV infection is one of the most common infectious diseases worldwide. Chronic infection may be complicated by cirrhosis and/or liver cancer. Despite the introduction of a vaccine several decades ago, this disease is still widely prevalent. The prevalence of HBV infection varies according to geographic location, with relatively low rates in Western Europe (< 1%). Overall trends in incidence in this region have improved, however, increasing immigration from countries with higher prevalence has impacted the problem.

**Aims & Methods:** This epidemiological study was carried out to determine trends in incidence of chronic HBV infection in Malta, a country which has recently recorded the highest rate of immigration in the European Union. HBV infection was defined as the presence of positive hepatitis B surface antigen (HBsAg) and/or positive total antibody to hepatitis B core protein (anti-HBc). Patients infected with hepatitis B between 2008 and 2017 were identified through the Virology laboratory and Molecular Diagnostics (Infectious Diseases) which caters for all patients within the Maltese National

Health Service. Demographic and clinical data were recorded, including age, gender, ethnic and racial group, viral hepatitis markers, radiology as well as histology results. Statistics on the Maltese population were obtained from the Eurostat database.

**Results:** Four hundred and forty-one patients were noted to suffer from HBV infection. With an average population of 425,000 during the period studied, the calculated prevalence of known chronic HBV infection was 0.1%. The proportion of non-migrants suffering from HBV infection was 0.06% (n=245) of the average non-migrant population in Malta (n=398,604). The equivalent statistic for migrants was 0.6% (n=164) of the average migrant population (n=27,162). A third of HBV-infected patients were aged 34 years or less, 74% of these being migrants (see Table). The proportion of infected migrants was lower in older age groups where correspondingly lower rates of migrants prevail. The most prevalent race was Caucasian (78%, n=321) and the main ethnic group was non-Hispanic (97.5%, n=399). Cirrhosis was present in 20% of patients, while 6% (n=26) had hepatocellular carcinoma. None of the patients studied had documented Hepatitis C or HIV co-infection, while one (5%) had previous exposure to Hepatitis A.

**Conclusion:** The prevalence demonstrated in our population is similar to that found in other countries in Western Europe. The risk of HBV infection was found to be 10-fold in the migrant population, hence emphasizing migrant status as a risk factor for infection. Rates of infection in individuals aged 34 years or less were much higher in the migrant population, most of which were presumably not protected by vaccination. Identification of specific patient characteristics allows for appropriate planning of public health initiatives, hence contributing to the success of eradication programs. The results obtained in the course of this investigation suggest the need for screening and treatment of migrants, while ensuring that all children are vaccinated.

Age	% of Total	Proportion of Migrants
< 34	33%(n=146)	74%
35-44	16.6%(n=73)	66%
45-54	13.9%(n=61)	25%
55-64	19.4%(n=86)	2%
65-74	6.2%(n=24)	1%
>75	2.1%(n=12)	0%
Unknown	11.1%(n=49)	Unknown

[Percentage of hepatitis B virus infected patients stratified by age group]

**Contact E-Mail Address:** luisa\_mmfigueiredo@hotmail.com

**Introduction:** Noninvasive methods for estimation of liver fibrosis may help to avoid liver biopsy in many contexts. In chronic hepatitis C (CHC), guidelines recommend transient hepatic elastography (TE) prior to initiation of treatment. The validation of biochemical scores (BQS), such as APRI and FIB-4, may contribute to the simplification of treatment.

**Aims & Methods:** The aim of this study was to compare the diagnostic accuracy of TE in comparison to BQS in staging of fibrosis in CHC. Cross-sectional study of patients with CHC followed at a Hepatology Unit, from February/2015 to February/2019, with baseline TE, determined with FibroScan: F0-F1 < 7; 7EF<sub>2</sub> < 9.5; 9.5EF<sub>3</sub> < 12.5; F4≥12.5. APRI and FIB4 scores were calculated at the TE date and the respective cut-offs were calculated (Youden index) to define F0-F1, F2-F3 and F4, as well as sensitivity, speci-

ficity, positive predictive value (PPV) and negative (NPV) and diagnostic accuracy expressed using the area under the receiver operating curve (AU-ROC).

**Results:** 405 patients, 68% men; mean age 53.17 ±9.10 (15-81). TE fibrosis stage: F0-F1 48%, F2 18.6%; F3 10.1%, F4 23.3%. The diagnostic accuracy, sensitivity and specificity of the BQS, as well as cut off, PPV and NPV are shown in Table 1.

**Conclusion:** In the present real-life cohort, APRI and FIB-4 had diagnostic accuracy between 83.4 and 84.6% for cirrhosis, using TE as a reference, mainly because of its high NPV of 93% for APRI (cut off < 0.883), and for FIB-4 (cut off < 1.902). The BQS were less accurate than TE in the detection of intermediate stages of fibrosis.

	Score	AUROC	Sensitivity	Specificity	Cut off	PPV	NPV
F0-F1	APRI	0.806	0.771	0.743	0.558	0.764	0.750
	FIB-4	0.789	0.686	0.773	1.539	0.766	0.694
F2-F3	APRI	0.582	0.759	0.489	0.506	0.374	0.834
	FIB-4	0.550	0.724	0.444	1.185	0.344	0.800
Cirrhosis	APRI	0.834	0.808	0.809	0.883	0.562	0.933
	FIB-4	0.846	0.798	0.813	1.902	0.563	0.930

[Table 1]

## P0730 WITHDRAWN

## P0731 IMPROVEMENT OF SEROLOGICAL MARKERS OF FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS TREATED WITH DIRECT ACTION ANTIVIRALS

Fernandez Alvarez P., Barranco Castro D., Guerra Veloz M.F., Cordero Ruiz P., Bellido Muñoz F., Caunedo Alvarez A., Carmona Soria I. Hospital Universitario Virgen Macarena, Gastroenterology and Endoscopy Unit, Sevilla, Spain

**Contact E-Mail Address:** paulafer7@gmail.com

**Introduction:** The new direct-acting antiviral (DAA) achieve rates of sustained virological response (SVR) in patients with chronic hepatitis C that exceed 95%. Achieving SVR has been shown to prevent progression to liver disease final stages.

**Aims & Methods:** The aim of this study is to evaluate changes in liver fibrosis by non-invasive serological methods after achieving SVR with new therapies in patients with chronic hepatitis C.

A unicenter retrospective observational study of patients with chronic hepatitis C treated with DAA between 2014 and 2016 was carry out. Basal fibrosis assesment was performed by transitional elastography (TE). Advanced fibrosis was defined as > 9.5 KpA. Serological markers of fibrosis (FIB-4 / APRI) were determined before treatment and 24 weeks post-treatment.

**Results:** We found that among the sample 419 of 438 patients achieved SVR. Two hundred and seventy-eight patients (66.3%) were men with a median age of 55 years (48-64). One hundred and fifty-three patients (36.5%) were hypertensive and seventy-five (17.9%) were diabetic. Fifty-three percent of the patients presented genotype 1b and 10.7% showed genotype 3.

According to ET 285 patients (68%) had advanced fibrosis. The median fibrosis stage before treatment was 11.7 KpA (8.35; 19.3) by ET 2.23 (1.3;

4,22) and 0,86 (0,49; 1,82) according to FIB-4 and APRI, respectively. This measurements 24 weeks after treatment were 1,35 (0,93; 2,16) and 0,30 (0,21; 0,47) by FIB-4 and APRI, respectively ( $p < 0,001$ ).

Serological markers	Basal	Week 24	p-value
<b>Advanced ET: &gt;9,5 KpA</b>			
FIB-4	2,87 (1,75; 5,31)	1,57 (1,1; 2,76)	<0,001
APRI	1,21 (0,64; 2,39)	0,34 (0,24; 0,61)	<0,001
<b>No advanced TE: &lt; 9,5 KpA</b>			
FIB-4	1,4 (0,94; 2,01)	0,99 (0,73; 1,28)	<0,001
APRI	0,58 (0,36; 0,88)	0,22 (0,18; 0,30)	<0,001

[Table 1]

**Conclusion:** Patients with hepatitis C virus infection who achieved a SVR after received DAA showed a significant regression of the validated serological markers of fibrosis. This findings accomplish in patients with and without advanced fibrosis.

It is probably that these changes allow us to select patients who do not benefit themselves from a long-term follow-up. Nevertheless, to consolidate this, prospective studies with a larger patients number and follow-up time are needed.

**Introduction:** Hepatitis C Virus (HCV) infection is one of the leading causes of cirrhosis worldwide and is associated with an increased risk of cardiovascular events (stroke, acute coronary syndrome) [1]. Furthermore, these patients can develop cirrhotic cardiomyopathy (CCM) defined by a blunted adaptative response of the myocardium to stress. [2] Direct-acting antivirals (DAAs) are a new class of drugs with very high efficacy for the treatment of HCV. We aimed to assess the impact of HCV eradication on the cardiac profile of cirrhotic patients.

**Aims & Methods:** This is an initial report from an ongoing prospective observational study. 17 consecutive patients with HCV cirrhosis were included before undergoing treatment with DAAs for a period of 3/ 6 months. Exclusion criteria were pre-existent cardiovascular disease, obesity and chronic alcohol intake (above 80mg/day in the last 5 years). Routine blood tests, standard 12-lead electrocardiogram, N-terminal pro-brain natriuretic peptide levels and contrast enhanced echocardiography examination with tissue Doppler imaging were performed in all patients at baseline and after 1 year of follow-up. CCM was diagnosed by echocardiography showing systolic dysfunction (SS, left ventricle ejection fraction < 55%) and/or diastolic dysfunction (DD, at least 2 out of 3 of the following: age-corrected E/A < 1, IVRT > 80ms and DT > 200 ms) [3]. The main outcome was change in cardiac function after viral clearance assessed by echocardiography.

**Results:** 17 patients were enrolled between July 2017-March 2018, of whom 4 were lost to follow-up, 2 did not receive treatment and 1 was excluded due to presence of atrial fibrillation. 2 patients had decompensated cirrhosis based on Child-Pugh score. CCM was diagnosed in 8 out of 10 patients based on the presence of isolated DD in 6 and mixed systolic and diastolic dysfunction in 2.

There was a significant statistical improvement in thrombocyte count, albumin, INR and total bilirubin following treatment, but not for the Child or MELD score. There was a significant decrease in the lateral mitral annular systolic velocity (9.24 vs 8.52 cm/sec,  $p=0.05$ , Wilcoxon test), an increase in late velocity flow (A and VA waves) and a significant increase in mean arterial pressure (92 vs 106 mmHg,  $p=0.018$ ). NT-proBNP, corrected QT and incidence of SD/DD did not significantly differ before and after viral eradication.

There were 2 new cases of CCM based on DD and 1 case with normalisation of diastolic function. One patient developed exertional dyspnea during treatment with sofosbuvir/ledipasvir and the follow-up echocardiography showed a marked difference in pulmonary artery pressure before and after treatment (26 vs 53mmHg), with the exclusion of pulmonary or left cardiac diseases. Right heart catheterization ruled out severe arterial pulmonary hypertension.

**Conclusion:** Eradication of HCV may influence cardiac function in patients with cirrhosis. Alterations in cardiac parameters in our cohort potentially due to viral clearance indicate that further study is warranted.

**Contact E-Mail Address:** m.gamal.work@gmail.com

**Introduction:** Hepatitis C virus (HCV) infection is one of the main causes of chronic liver diseases worldwide. HCV infection has been associated with numerous extra-hepatic manifestations. Also, up to 50 percent of patients with advanced cirrhosis have features of cardiac dysfunction. Treatment for chronic HCV infection is evolving from interferon-based therapy to direct-acting antiviral agents. Previous interferon-based anti-HCV therapies were mostly not tolerated by patients with advanced heart failure and had limited elimination efficacy. Those new highly anti-HCV-specific drugs lack the complex unspecific side effects upon cardiac. However, new regimens comprised of DAAs that target different steps in the HCV life cycle are in development and some have received breakthrough therapy status by the U.S. Food and Drug Administration. Also, recent retrospective studies, case reports and post marketing reports suggest that those drugs may cause a toxic cardiomyopathy.

**Aims & Methods:** The aim of the study is to assess the effect of treatment of naive Egyptians chronic hepatitis C patients on cardiac functions using direct acting antivirals. This study is a prospective cohort study that was conducted on 90 treatment-naïve adult patients with chronic hepatitis C infection. Patients were divided into 2 groups :

**Group 1:** 45 non cirrhotic patients received treatment with Sofosbuvir + Daclatasvir for 12 months.

**Group 2:** 45 cirrhotic patients received treatment with Sofosbuvir + Daclatasvir + ribavirin for 12 months.

All patient achieved sustained virological response at week 12 (SVR12)

All patients were assessed at week 0 ( start of treatment) and week 12 ( SVR 12) with laboratory studies including level of NT- Pro BNP, ultrasonography, Echocardiography.

**Results:** Assessment of LV systolic functions using EF % revealed no significant difference between the studied groups regarding EF before and after treatment ( P value 0.266 ,0.169 respectively) Change in EF was significantly higher in non-cirrhotic group (P value 0.024) . EF significantly increased in non-cirrhotic group after treatment( P value 0.003 ). Assessment of diastolic function using E/A ratio revealed no significant difference between the studied groups regarding E/A ratio before and after treatment(P value 0.752, 0.881 respectively ) . E/A ratio was non-significantly changed in both groups(P value 0.202, 0.108 respectively ) . Assessment of mean pulmonary artery pressure (MPAP) revealed No significant difference between the studied groups regarding MPAP before and after treatment ( P value 0.466, 0.923 respectively ) . MPAP was non-significantly changed in both groups(P value 0.693, 0.479 respectively) . Regarding serum level of NT-Pro BNP , it was significantly increased in both groups after treatment ( P value

<0.001 in both groups) with no significant difference between the studied groups before and after treatment (*P* value 0.058, 0.099 respectively). Also, there was no significant changes in ECG findings in both groups and there was also no significant difference between the studied groups.

**Conclusion:** Treatment of chronic HCV infection using DAAs (Sofosbuvir, Daclatasvir, Ribavirin) has no clinically significant effect on cardiac functions. However, some sort of sub-clinical myocardial affection can occur for further analytical studies.

**Contact E-Mail Address:** c.j.isfordink-2@umcutrecht.nl

**Introduction:** Hepatitis C virus (HCV) infection prevalence in the Netherlands is estimated at 0.16%<sup>1</sup>. As of November 2014, direct-acting antiviral (DAA) therapy is reimbursed in the Netherlands for everyone with health insurance. Unfortunately, up to 30% of the diagnosed population has been lost to follow-up (LTFU) before receiving proper treatment<sup>2,3</sup>. Around 320 patients in the Netherlands die annually as a result of HCV infection<sup>4</sup>. The Hepatitis C Elimination in The Netherlands (CELINE) project is a nationwide retrieval project that aims to retrieve and re-evaluate HCV patients who are LTFU, and link them to care. The ultimate goal is to eliminate HCV in the Netherlands, in line with the WHO goals<sup>5</sup>.

**Aims & Methods:** This multicentre cohort study aims to include patients from all 47 Dutch hepatitis treatment centres. Patients are identified based on laboratory records (HCV antibodies, immunoblot, RNA and genotype). Subsequently, patient records are reviewed to identify current HCV-positive but untreated patients. The Municipal Personal Records Database is used to obtain current addresses, which accords with privacy legislations. Patients are contacted for an assessment of current HCV status, liver disease severity and if needed DAA treatment. The primary endpoint of the study is the number of LTFU patients who have been successfully linked to care. Secondary endpoints are number of patients already cured, the total number of LTFU patients, reasons for being LTFU, transmission route and liver fibrosis severity of the LTFU population.

**Results:** CELINE started mid-2018 and is scheduled to finish mid-2021. So far, four hepatitis treatment centres have finished the identification phase and initiated the retrieval phase. Of 3054 potential ever chronically infected patients, 61% (n=1852) have already been cured and 10% (n=298) were LTFU and eligible for retrieval (alive and current address information available).

Currently, 74 patients have been invited for outpatient clinic evaluation. Of these 74 patients, 24% (n=18) were already (being) treated, 7% (n=5) had too severe comorbidity or were deceased, 19% (n=14) refused to be re-evaluated and in 41% (n=30) contact is not yet established.

So far, seven patients (9%) have successfully been linked to care. The reasons for being LTFU were: no indication or options for therapy (n=4), LTFU during therapy (n=2) and no consequence given to HCV test (n=1). Probable transmission routes were intravenous drug use (n=4) and blood transfusion (n=3). For other patient characteristics see Table 1.

**Conclusion:** These interim results show the first step in reaching HCV elimination in the Netherlands. As the retrieval phase is ongoing in four hospitals and soon to start in several other hospitals, we expect to increase the number of patients linked to care in the short term.

Results are in line with those of the CELINE pilot project (REACH), which retrieved 16% of LTFU patients (n=47)<sup>3</sup>. CELINE can be used to serve as a blueprint for retrieval projects in other countries.

Patient characteristic (n=7)	
Age at last contact in years (median, IQR)	50 (43-58)
Male gender (n, %)	7 (100)
Years since last contact (median, range)	13 (4-20)
Treatment experienced (n, %)	4 (57)
RNA-positive at re-evaluation (n, %)	3 (43)
LSM RNA-positive patients $\geq 9.5$ kPa (n, %)	1 (33)
Treatment initiated (n, %)	3 (100)
IQR: interquartile range, n: number, LTFU: lost to follow-up, LSM: Liver Stiffness Measurement

**Introduction:** Chronic HCV infection is a leading risk factor for HCC worldwide. Some recent studies have shown an unexpected high rate and aggressive pattern of tumor recurrence following successful therapy of HCV with DAAs. It has been suggested that disruption of immune surveillance may facilitate the emergence of metastatic clones.

**Aims & Methods:** To assess recurrence of HCC after successful therapy in a cohort of Egyptian patients with chronic hepatitis C genotype 4 treated with Direct-Acting Antiviral agents (DAAs). **Methods:** This retrospective cohort study included 100 patients with HCV-induced cirrhosis who were treated with DAA therapy between December 2015 and December 2016. Patients were categorized into 2 groups: Group (I): included 50 patients with liver cirrhosis without any evidence of HCC. Group (II): included 50 patients with successfully treated HCC on top of HCV-induced liver cirrhosis.

According to the guidelines of National committee for control of viral hepatitis (NCCVH) released in November 2015, these patients were included in the study only four weeks after successful intervention for HCC aiming at cure, with no evidence of activity by dynamic imaging. All patients were

treated with Sofosbuvir, Daclatasvir with or without Ribavirin. Abdominal ultrasound (U/S) and abdominal (CT) were performed for groups I and II patients respectively at 12 weeks intervals during treatment and follow up period. Triphasic (CT) was ordered in group I patients if suspicious focal lesion was detected by U/S or raising in AFP values was observed.

**Results:** Most patients in both groups were males (74% in group I and 78% in group II) with a mean age of  $56.38 \pm 8.18$   $57.9 \pm 6.2$  years in groups I and II respectively. Treatment modality prior to DAA therapy was radiofrequency ablation (RFA) in 30 patients (60%), percutaneous ethanol injection (PEI) in 15 patients (30%) and liver resection in 5 patients (10%). Forty-one patients (82%) had undetectable HCV RNA at the end of treatment. Two patients in group I developed HCC during follow up period. Eleven patients (22%) in group II showed active nodules of HCC on repeated follow up. Of these patients with HCC activity, five patients (45.5%) developed local recurrence of a previous focal lesions, while six patients (54.5%) developed de-novo focal lesions. Two patients (18.2%) had vascular invasion and one patient (9.1%) had bone metastasis.

**Conclusion:** Treatment with a Sofosbuvir-based regimen was associated with a high recurrence of HCC in a cohort of Egyptian patients with HCC associated with chronic hepatitis C genotype 4. Patients with HCC should be properly evaluated prior to antiviral therapy with DAAs and followed up carefully during and after therapy.

### P0736 HCV MICROELIMINATION: INTERVENTIONAL STUDY IN DIAGNOSED PATIENTS WITHOUT ACCESS TO THE SYSTEM (TWO PHASE STUDY)

del Pino Bellido P., Guerra Veloz M.F., Cordero Ruiz P., Bellido Muñoz F., Caunedo Alvarez A., Carmona Soria I.  
Hospital Universitario Virgen Macarena, Gastroenterology, Seville, Spain

**Contact E-Mail Address:** pilardelpino4@gmail.com

**Introduction:** According to national data, 117,453 patients with chronic Hepatitis C (CHC) have been treated in Spain until September 2018. However, there is an important group of patients that have not got access to the system. The introduction of the one-step diagnostic process tries to improve referral in patients with detectable viral load, but, in our system, this is only applied to new diagnoses, so those previous positive serologies that have not fulfilled the diagnostic process may be excluded.

**Aims & Methods:** The aim of this study is to confirm CHC infection in patients with positive HCV-antibodies who have never been referred to a gastroenterologist / hepatologist and to recover patients with CHC infection who have not completed treatment due to not attendance to medical visits/ loss of follow-up.

This was a retrospective (first phase) and interventional (second phase) single center study in which we included all positive HCV antibodies between January 2013 and May 2018 in Virgen Macarena's health area (Seville-Spain), prior to the implementation of the one-step diagnosis of HCV infection.

In the first phase, we identified subjects who had never been referred and those who, after being referred, had lost follow-up. In a second phase, after contacting with primary care to establish a direct circuit for simplified referral, a specific Hepatitis C consultation was created. Later, patients were contacted by letter or phone call and blood tests, viral load and transient elastography (Fibroscan) were performed. Patients with confirmed viral load were summoned to a second visit where they were offered treatment.

**Results:** 1329 patients with positive HCV antibodies were included. 55,75% of them had a previous positive serology.

PHASE I (Table 1)

PHASE I	Retrospective
Global referral rate	1040/1329 = 78.3 %
Non-referral rate	289/ 1329 = 21.7%
HCV-antibodies diagnostic rate	914/1040 = 87.8%
Active infection rate	658/914 = 72%
Unnecessary referral rate	256/1040 = 24.6%
Treatment rate	451/658 = 68.5%

[Table 1. Phase I.]

Loss / non-attendance rate 231/1040 = 22.2%

PHASE II (PRELIMINARY DATA)

Lost / non-attendance clinical visits = 231:

We were able to contact 51.7% of them. The additional 17.1% did not answer phone calls/ did not have a valid telephone number, and 3% refused to attend consultations.

At the moment, viral load determination was requested in 87 patients. Active infection was confirmed in 82.8% of them. 57.1% of these patients were ex-ADVP; 14% were active drug users and 10% had a significant alcohol consumption, 37.9% presented advanced fibrosis (fibroscan > 9.5Kpa) and 4.6% had space-occupying lesions in ultrasound.

Never referred:

Of those patients, we were able to contact 40.6%. Until now, viral load determination was requested in 81 patients, 50% confirmed active infection, 22.9% spontaneous resolution, 27.1% SVR of previous treatments. 63% of patients knew they had HCV. 55.1% of these patients were ex-ADVP; 11% were active drug users, 30% presented advanced fibrosis.

**Conclusion:**

- One-step diagnosis of CHC infection avoids unnecessary referral of patients. However, there is an important group of patients who might get lost in the system.
- Simplified referral system with primary care allows high rates of diagnosis and treatment.
- A high percentage of patients who were lost in the system have advanced liver fibrosis and need long-term follow-up.

**Contact E-Mail Address:** anaasantos89@gmail.com

**Introduction:** Patients with HBeAg-negative chronic infection by hepatitis B virus (HBV) (previously inactive carriers) are expected to have a stable clinical course.

**Aims & Methods:** The aim of this study was to compare the clinical evolution of these patients regarding to HBsAg levels. Retrospective and unicentric study with assessment of patients with HBeAg-negative chronic HBV infection (EASL criteria), in a reference centre. Demographic characterization and assessment prognostic determinant factors.

**Results:** A total of 89 patients were included, 51% of female gender, with mean age of  $53 \pm 16$  years. Most of patients (83%) had mild or no fibrosis. The initial HBsAg quantification median was 949 IU/mL (IQR 129-4208) and patients with HBsAg >1000 IU/mL (48%) presented lower age (mean  $49 \pm 15$  years;  $p=0.032$ ). During a median follow-up of 8 years (IQR 4-9), HBsAg negativation was achieved in three cases, as well as a paired decrease in HBsAg levels [median 0.30 log10 IU/mL (IQR 0.02-0.62);  $p<0.001$ ]. A decrease HBsAg >1 log10 IU/mL was more frequent if initial HBsAg < 1000 IU/mL ( $p=0.029$ ). Five patients needed to start antiviral therapy, after a median time of 6 years (IQR 3-8), one due to intrahepatic cholangiocarcinoma; however, an association with HBsAg >1000 IU/mL wasn't verified (7 vs 4%). The median initial HBV-DNA was 409 IU/mL (IQR 49-1290) and the higher median viremia in follow-up was 1070 IU/mL (IQR 158-3489). Initial HBsAg >1000 IU/mL was associated to higher viremia in follow-up ( $p<0.001$ ), including HBV-DNA >2000 IU/mL ( $p<0.001$ ) e HBV-DNA >20.000 IU/mL ( $p=0.023$ ).

**Conclusion:** Patients with HBsAg >1000 IU/mL were associated to a lower age and higher viremia, which can be related with a shorter period of HBV infection. Generally, the prognosis was benign with significant HBsAg reduction during a long term follow-up; a decrease >1 log10 IU/mL was less frequent if HBsAg >1000 IU/mL. However, one hepatobiliary neoplasm was diagnosed and 4 patients presented progression to chronic hepatitis, which highlights the needed of surveillance.

**Disclosure:** Nothing to disclose

## P0738 SCHEDULED SUSPENSION OF ANTIVIRAL THERAPY IN SELECTED CASES OF CHRONIC B HEPATITIS: HIGH SUSTAINED RESPONSE AND HBSAG LEVELS REDUCTION

Santos A.L.<sup>1,2,3</sup>, Cardoso H.<sup>2,3,4</sup>, Macedo G.<sup>1,2,3</sup>

<sup>1</sup>Centro Hospitalar de São João, Gastroenterology, Porto, Portugal, <sup>2</sup>WGO Oporto Training Center, Porto, Portugal, <sup>3</sup>Porto Medical School, University of Porto, Porto, Portugal, <sup>4</sup>Centro Hospitalar de São João, Gastroenterology, Baguim do Monte, Portugal

**Contact E-Mail Address:** anaasantos89@gmail.com

**Introduction:** EASL guidelines consider antiviral therapy suspension in selected cases of chronic B hepatitis, under rigorous monitoring. In this study, we intend to evaluate the clinical course of chronic B hepatitis patients after scheduled suspension of therapy.

**Aims & Methods:** Retrospective, monocentric and longitudinal study, from a prospectively registered cohort. Adults patients with diagnosis of chronic B hepatitis, without advanced fibrosis, with at least 4 years of undetectable viremia were included. After informed consent antiviral therapy was suspended. The cases that didn't presented criteria for retreatment (EASL guidelines) were considered as sustained response. Demographic characterization of population, evaluation of sustained response and HBsAg levels.

**Results:** A total of 26 patients were included (62% of woman, with mean age of 59±13 years). Antiviral drugs were tenofovir in 58% of cases, entecavir in 35% and lamivudine in 8%.

The mean time of HBV undetectably until antivirals suspension was 8.8±2.5 years.

A sustained response was observed in 54% of patients, during a mean follow-up of 24±9 months, after treatment suspension. It wasn't possible to identify predictive response factors. Most retreatments (67%) were due to increasing viremia and ALT; two patients developed jaundice, with complete reversion. The most used therapy was tenofovir (67%) and viral suppression was observed with a mean time of 6±3 months. Although HBsAg levels were previously stable, a significant reduction in HBsAg after treatment suspension was observed [0.6log10IU/mL (0.19-1.5)], independently of sustained response (p< 0.001).

**Conclusion:** In this study, a high rate of sustained response was observed, which may be related to a long duration of viral suppression; however, two cases of jaundice were observed, highlighting the relevance of a rigorous surveillance. A significant decrease in HBsAg levels suggests that there may be a benefit, in therapeutic suspension, even in patients without sustained response; these facts should be assessed with a longer follow-up period.

## P0739 LONG-TERM IMPACT OF DIRECT-ACTING ANTIVIRALS IN PATIENTS WITH HEPATITIS C AND ADVANCED FIBROSIS

Barranco Castro D., Fernández Álvarez P., Guerra Veloz M.F., Cordero Ruiz P., Bellido Muñoz F., del Pino Bellido P., Lorenzo González L., Caunedo Álvarez Á., Carmona Soria M.I.  
Hospital Universitario Virgen Macarena, UGC Aparato Digestivo, Seville, Spain

**Contact E-Mail Address:** daniel@barranco.ws

**Introduction:** The introduction of direct-acting antivirals (DAAs) have revolutionized the treatment of Hepatitis C (HCV), achieving cure rates above 95% (SVR). However, the long-term impact of treatment on clinical complications and mortality in patients with advanced fibrosis is not currently known.

**Aims & Methods:** The aim of our study is to describe long-term decompensations in patients with advanced fibrosis treated with DAAs.

This is a retrospective observational study of patients with chronic HCV and advanced fibrosis (Fibroscore>9.5Kpa and/or APRI>1) treated with DAAs from 2014 to 2016 in the Virgen Macarena Hospital and followed up to December 2018. We collected demographic variables, pre-treatment decompensations, response to treatment, post-treatment decompensations (ascites, encephalopathy, variceal upper gastrointestinal bleeding, development of hepatocellular carcinoma HCC) and mortality (hepatic or non-hepatic cause).

**Results:** A total of 298 patients were included, 67.8% (202) men, with a mean age of 57 (± 12) years, and a median follow-up of 37 months (range) (30; 43). 41.9% (125) had high blood pressure, 23.5% (70) were diabetic,

and 15.1% (45) had pre-treatment alcohol consumption. The predominant genotype was 1b in 51.3% followed by genotype 3 in 13.8%. 96% (286) reached SVR. Table 1 shows the pre and post-treatment decompensation.

Pre-treatment % (n)	Post-treatment % (n)
Ascites 8.7% (26)	Ascites 2.3% (7)
Variceal gastrointestinal bleeding 3.7% (11)	Variceal gastrointestinal bleeding 2.7% (8)
Spontaneous bacterial peritonitis (no cases)	Spontaneous bacterial peritonitis 0.3% (1)
Hepatic encephalopathy 2.7% (8)	Hepatic encephalopathy 1.7% (5)

[Table 1. Pre and post-treatment decompensation.]

During follow-up, 3.4% (10) of the patients developed HCC. The median time to development of HCC was 12.5 months (6.7; 21), and all cases occurred in patients with fibroscore >12.5kPa (F4). Additionally, 3 cases occurred in patients who did not reach SVR, and 4 cases had a previous diagnosis of HCC with a good response to local treatment (radiofrequency). The post-treatment mortality was 6.4% during the follow-up: 5.4% (16) of hepatic cause and 1% (3) of non-hepatic cause.

**Conclusion:** SVR after treatment with DAAs decreases the risks of decompensation in patients with chronic HCV and advanced fibrosis, although they do not eliminate them. This fact, along with the presence of associated comorbidities, implies a greater mortality risk and so means that long-term follow-up is necessary.

## P0740 HEPATITIS C SCREENING IN HOSPITALIZED SUBJECTS. A PROSPECTIVE STUDY IN THE VENETIAN AREA (NORTH-EAST OF ITALY)

Caroli A.<sup>1</sup>, Franceschet I.<sup>1</sup>, Forti A.<sup>2</sup>, Girardi L.<sup>1</sup>, Pozzan C.<sup>1</sup>, Cappuccio R.<sup>1</sup>, Checchin D.<sup>1</sup>, Lamboglia F.<sup>1</sup>, Scarpato C.<sup>3</sup>

<sup>1</sup>Ospedale dell'Angelo, AULSS 3 Serenissima, UOC Gastroenterologia ed Epatologia, Venezia-Mestre, Italy, <sup>2</sup>Ospedale dell'Angelo, AULSS 3 Serenissima, UOC Laboratorio Analisi, Venezia-Mestre, Italy, <sup>3</sup>Ospedale dell'Angelo, AULSS 3 Serenissima, UOC Microbiologia, Venezia-Mestre, Italy

**Contact E-Mail Address:** alessandro.caroli@aulss3.veneto.it

**Introduction:** The World Health Organization (WHO) recommends the implementation of strategies for the identification of HCV affected subjects for a "test-and-treat" approach in order to achieve HCV elimination in the next years. The best strategy to bring out the hidden chronic HCV infection remains uncertain. Current guidelines recommend screening in high risk populations. Hospitalized patients may represent an ideal population for HCV screening and for referral to treatment, but few data are available in this specific setting of subjects.

**Aims & Methods:**

**Aim:** of this study was to determine the prevalence of HCV infection in hospitalized subjects in the Venetian area, North-east of Italy, in order to plan an extensive treatment strategy.

**Methods:** All patients consecutively admitted to the surgical departments of the "dell'Angelo" Hospital, Venezia-Mestre, from 01/01/2017 to 31/12/2017, were tested for anti-HCV antibodies (CMA Abbott laboratories). In case of borderline values, a confirmatory RIBA test (INNOLIA HCV) was carried out. Positive patients were tested for HCV-RNA (RT-PCR Abbott laboratories) and HCV-genotype.

**Results:** Overall, 6981 patients were tested at admission (2821 males, 4160 females). 142 subjects resulted anti-HCV positive, with a prevalence of 2.0%. The prevalence was significantly higher in men (2.5%) than in women (1.7%) and increased with age (from 0.6% in 15-30 years patients to 2.7 % in 51-60 and over 70 years patients). The highest prevalence was observed in Vascular Surgery (3.6%), Traumatology (3.4%) and Neurosurgery (2.6%), the lowest in Gynecology (1.0%) and Urology (1.6%). HCV-RNA was detectable in about two-thirds of patients and the most represented genotype was genotype 1 (80%). The large majority of subjects (76%) was unaware of its status and is now recruiting for the treatment.

**Conclusion:** Our data show a significant prevalence of HCV infection in hospitalized subjects, two to three times higher than that expected in the general population of the Veneto region. Screening for HCV infection in

this specific setting of subjects may thus represent an useful and simple strategy to identify hidden HCV-infection and to facility HCV treatment, in order to achieve HCV elimination.

### **P0741 THE RETREATMENT EFFICACY OF ALL-ORAL DIRECT ANTIVIRAL THERAPY FOR PATIENTS WITH HEPATITIS C VIRUS INFECTION**

Mawatari S., Kasai A., Taniyama O., Ijuin S., Sakae H., Tabu K., Oda K., Kumagai K., Ido A.

*Kagoshima University Graduate School of Medical and Dental Sciences, Digestive and Lifestyle Diseases, Kagoshima, Japan*

**Contact E-Mail Address:** mawatari@m2.kufm.kagoshima-u.ac.jp

**Introduction:** Direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) shows high sustained virologic response (SVR) rates. However, patients who have failed DAA therapy acquire resistance-associated substitutions (RASs). Glecaprevir + Pibrentasvir (GLE/PIB) therapy is approved for DAA failure patients in Japan. We therefore evaluated the efficacy of DAA retreatment and the factors associated with retreatment failure.

**Aims & Methods:** A total of 60 patients with HCV infection who had failed all-oral DAA therapy in the past were introduced to DAA retreatment. We evaluated the factors associated with retreatment failure. NS5A Q24, L28, R30, L31, P32, A92 and Y93 RASs at baseline and virologic failure were investigated by direct sequencing.

**Results:** The patient age ranged from 54 to 87 years (mean, 71), 17 patients (28%) were male, 25 (42%) patients had cirrhosis, and 12 patients (20%) had a history of hepatocellular carcinoma therapy.

Fifty-five patients had received Dacatasvir + Asunaprevir, three had received Sofosbuvir + Ledipasvir (SOF/LDV), and one each had received Omnitaspvir + Paritaprevir and Sofosbuvir + Ribavirin (SOF/RBV).

Thirty-three patients were retreated with SOF/LDV, 2 were retreated with Elbasvir + Grazoprevir (EBR/GZR), and 25 were retreated with GLE/PIB. The SVR rates were 81.8% with SOF/LDV retreatment, 0% with EBR/GZR retreatment, and 87.0% with GLE/PIB retreatment.

Eleven patients did not achieve an SVR. Six and two patients failed SOF/LDV and EBR/GZR retreatment, respectively, and seven of these patients had coexisting NS5A Q24, L28, and/or R30 RASs, L31 RAS and Y93 RAS, while the other had P32L and A92K RASs at baseline. However, no marked change in the RASs between baseline and virologic failure were noted. Four patients who had initially failed DCV/ASV and SOF/LDV achieved an SVR on retreatment with GLE/PIB.

However, one patient re-treated with EBR/GZR did not achieve an SVR. Of the three patients who failed GLE/PIB retreatment, two had Q24, L28, R30 and A92 RASs, and the other had P32 deletion RAS at baseline. In those who failed GLE/PIB retreatment, the R30Q or A92T RASs at baseline changed to R30E or A92K at virologic failure. Interestingly, 10 of 11 retreatment failure patients had an interleukin 28b single nucleotide polymorphism (IL28b SNP) minor allele.

The SVR rate of patients with an IL28b SNP minor allele was significantly lower than in those with a major allele (58.3% and 95.2%, respectively;  $p=0.004$ ). Furthermore, the SVR rate of patients with  $\geq 2$  NS5A RASs was lower than those with  $\leq 1$  RAS (73.2% and 100%, respectively;  $p=0.014$ ). In addition, all patients who had an NS5A Y93 RAS achieved an SVR with GLE/PIB retreatment, even if they had coexisting NS5A RASs, such as Q24, L28, R30 or L31.

**Conclusion:** DAA retreatment with GLE/PIB resulted in a high SVR rate for patients with the NS5A Y93 RAS. However, viral factors, such as Q24, L28, R30 and A92 RASs, and host factors, such as the IL28b SNP, may influence the therapeutic effect of DAA retreatment.

**Disclosure:** Nothing to disclose

### **P0742 THE GLOBE SCORE IN ASSESSING PROGNOSIS OF PRIMARY BILIARY CHOLANGITIS WITH CONCOMITANT SJOGREN'S SYNDROME**

Ayari M., Ayadi S., Belhadjmabrouk E., Zaimi Y., Said Y., Mouelhi L., Debbeche R.

*Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia*

**Contact E-Mail Address:** ayari.myriam@hotmail.fr

**Introduction:** Sjögren's syndrome (SS) is a systemic autoimmune chronic epithelitis that mainly affects the salivary and lacrimal glands. The coexistence of SS and primary biliary cholangitis (PBC) is not an uncommon condition, but remains poorly studied in the literature. In fact the influence of SS on the clinical outcomes of PBC patients remains unclear.

**Aims & Methods:** The aim of the study was to determine the prevalence and the prognostic value of SS during PBC. A retrospective study was conducted including all patients followed for PBC at our department between 2000 and 2018. SS was systematically sought. The diagnosis was done when at least 4 of the following criteria was met: dry eye for  $>3$  months, dry mouth for  $>3$  months, positive Schirmer test, abnormal salivary gland scintigraphy findings, diagnostic minor salivary gland biopsy, and positive anti-Ro (SS-A) or anti-La (SS-B) antibodies.

In subgroup analysis, PBC patients were classified into 2 groups: with concomitant SS or without SS. The response to UDCA therapy was evaluated according to Paris-2 criteria at 1 year of the treatment. The Globe score, a prognostic tool predicting survival without transplantation, was calculated for the 2 groups.

**Results:** Overall, 53 patients were included with mean age of 55 years (range 19-78 years). There was naturally a female predominance with a sex ratio F/M = 5.6. The median follow-up was 6 years. SS was diagnosed in 14 patients. The prevalence of SS in PBC patients was 26%. There were no significant differences in age, sex, and levels of albumin, international normalized ratio, creatinine, alanine aminotransferase, alkaline phosphatase, gamma-glutamyl transferase, total bilirubin or platelet count between the 2 groups. In the PBC-SS subgroup, the mean age was 50 years. The circumstances of discovery of PBC were: cholestasis with pruritus (61%), jaundice (30%), asthenia assessment (6%) and exploration of celiac lymph nodes (3%).

At one year of UDCA therapy, a biochemical remission according to Paris II criteria was noted in 38% of PBC-SS patients and 36% in PBC-only patients ( $p>0.05$ ). The mean value of the Globe score in PBC-SS patients was 1.4 versus 1.6 in PBC patients without SS ( $p>0.05$ ). The presence of SS was not significantly correlated with a poor therapeutic response, nor the prognosis of PBC.

**Conclusion:** To our knowledge, this is the first study to investigate the prognostic value of SS in patients with PBC using the globe score. Although their association does not appear to affect the course of PBC, screening should be systematic to improve the quality of life of the patients. Further validation of these findings in prospective studies with a larger population of patients is needed.

**Disclosure:** Nothing to disclose

### **P0743 ADD-ON STATINS IMPROVE RESPONSE TO URSODEOXYCHOLIC ACID IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS**

Higuera-de la Tijera E., Díaz-Castro M.A.<sup>1</sup>, Servin-Caamaño A.<sup>2</sup>

<sup>1</sup>Hospital General de México, Gastroenterology and Hepatology, Mexico City, Mexico, <sup>2</sup>Hospital General de México, Internal Medicine, Mexico City, Mexico

**Contact E-Mail Address:** fatimahiguera@yahoo.com.mx

**Introduction:** Ursodeoxycholic acid (UDCA) is the standard therapy for primary biliary cholangitis (PBC); however, the proportion of non-responders to UDCA is as high as 40-50%. Non-response to UDCA is related to progression of the disease and bad prognosis.

**Aims & Methods:** To identify risk factors related to treatment failure with UDCA in patients with PBC.

A case-control study nested in a cohort, which included patients with PBC in whom the response to treatment with UDCA was evaluated according to Barcelona criteria. We compared characteristics between responders and non-responders to UDCA, and to evaluate risk factors related to treatment failure we performed univariate and multivariate logistic regression analyses. A  $P<0.01$  value was considered significant. Patients with self-reported non-adherence to UDCA were excluded ( $n=15$ ).

**Results:** 119 patients with PBC, 98.3% women, the mean age was 49.9±11.4 years-old. All received UDCA (dose= 13-15 mg/kg/day), all reported adherence to therapy; nevertheless, according to Barcelona criteria, 49 (41.2%) were classified as non-responders. In the univariate analysis, albumin (mg/dL) and platelets count (cell/10<sup>9</sup>/L) (U/L) were lower in non-responders than in responders: 3.5(range=2.0-4.8) vs. 4.0(range=2.6-4.8), P< 0.0001; 118 (range=52-518) vs. 200 (78-436), P< 0.0001, respectively. Bilirubin (mg/dL) and alkaline phosphatase (U/L) were higher in non-responders: 1.9 (range=1.0-6.4) vs. 1.6 (range=1.0-3.0), P< 0.0001; and 666 (range=143-1445) vs. 480 (range=170-1556), P=0.01, respectively. Non-responders had a higher proportion of advanced fibrosis/cirrhosis (83.7% vs. 25.7%; P< 0.0001; OR=14.8, 95%CI=5.8-37.4); obesity (81.6% vs.31.4%; P< 0.0001; OR=9.7, 95%CI=4.0-23.4); overlap with autoimmune hepatitis (AIH) (42.9% vs. 7.1%; P< 0.0001; OR=9.8, 95%CI=3.3-28.5); and longer course of the disease: 5-10 years (44.9% vs. 38.6%; P=0.004; OR=4.3, 95%CI=1.6-11.5), and >10 years (40.8% vs. 8.6%; P< 0.0001; OR=17.6, 95%CI=5.2-59.6). The add-on of statins enhanced the response to UDCA (60% vs. 16.3%; P< 0.0001; OR=0.1, 95%CI=0.05-0.3). Fibrates did not have any effect (47.1 vs. 46.9%; P=0.98; OR=1.0, 95%CI=0.5-2.1). Age, AST, ALT, GGT, cholesterol and INR were not different between groups. The results obtained in the multivariate analysis are shown in Table 1.

Variable	OR (95% CI)	P
Bilirubin (> 2.0mg/dL)	4.4 (1.1 - 17.0)	0.03
Fibrosis F3 or F4	7.1 (1.9 - 26.6)	0.004
Obesity	4.9 (1.4 - 17.9)	0.015
AIH overlap	20.8 (3.1 - 137.6)	0.002
Add-on statin *	0.08 (0.02 - 0.4) *	0.002
Time of evolution (5-10 years)	1.2 (0.3 - 5.4)	0.78
Time of evolution (>10 years)	6.1 (1.0 - 38.3)	0.05

AIH autoimmune hepatitis; CI confidence interval; F3 advanced fibrosis; F4 cirrhosis; OR odds ratio; PBC primary biliary cholangitis; UDCA ursodeoxycholic acid. \* = protective factor. Multivariate analysis: Binary logistic regression.

*[Multivariate analysis contrasting factors related to treatment failure to UDCA in patients with PBC according with Barcelona criteria]*

**Conclusion:** Statins improved the response to UDCA. The overlap with AIH, the presence of advanced fibrosis/cirrhosis, bilirubin >2.0mg/dL, and obesity are factors related to treatment failure with UDCA according to Barcelona criteria.

**Disclosure:** Nothing to disclose

**Introduction:** Mutations in the ABCB4 gene initially described as responsible for Progressive Familial Intrahepatic Cholestasis Type 3 (PFIC3), presenting in childhood, are increasingly associated to a wide and heterogeneous spectrum of cholestatic liver diseases in adults, such as Intrahepatic Cholestasis of Pregnancy (ICP), Low Phospholipid Associated Cholelithiasis syndrome (LPAC), Hormone-induced Cholestasis, Drug-induced liver injury and sporadic cases of cryptogenic biliary cirrhosis.

**Aims & Methods:** Characterization of the phenotypic and genetic features of patients with ABCB4 mutations diagnosed between 2015 and 2019 in a Hepatology outpatient clinic. Data from 14 patients was retrospectively collected and analysed.

**Results:** Fourteen patients from seven families were included (11 female, mean age of 41.3 years, 17-69 years). Nine patients presented with recurrent elevated serum liver tests, of which three had a gamma-glutamyl transferase (GGT) 10 times the upper limit of normal, five had a previous diagnosis of ICP and six with cholelithiasis and cholecystectomy at a young age (mean age of 27 years), two patients with intra-hepatic stones, and one case of drug-induced liver injury. ABCB4 gene screening identified six different mutations. Two patients with mutation in a homozygous state, c.504C>T(p.N168N) and 12 with heterozygous mutations. Two patients are compound heterozygotes with missense mutations, c.959C>T (p.S320F) and c.1529A>G (p.N510S). Heterozygous missense variants were found in

seven patients, c.959C>T (p.S320F) in five cases, c.3082A>G (p.Met1028Val) in one case and c1529A>G (p.Asn510Ser) in another case. Three patients have nonsense mutations detected, C.874A>T (p.Lys292) in two cases and nonsense deletion c.1181delT (p.L394fs\*18) in another case. Liver biopsy was performed in three patients and revealed mild macrovesicular steatosis in two of these and portal fibrosis, ductopenia and mild necroinflammatory activity was found in one of the patients with heterozygous compound mutation.

**Conclusion:** Although, phenotype-genotype relationships have not been clear defined, an early diagnosis of genetic variants, namely heterozygous compound states, may have an important role in management decisions and patient outcomes. To our knowledge, we describe a not previously reported deletion (c.1181delT) in ABCB4 gene. The c.504T>C polymorphism, although a silent mutation at the protein level has been previously described as associated with predisposition to ICP.

**Introduction:** Primary sclerosing cholangitis [PSC] is a chronic inflammatory disease of biliary epithelium leading to strictures of intra- and extrahepatic bile ducts causing cholestasis and biliary cirrhosis (1). PSC is associated with markedly increased risk of cholangiocarcinoma [CCA] (2), SIR ranging from 161 to 973 (2-3), with the lifetime risk around 10% (4-5). CCA is the most common reason for death among patients with PSC (6,7). Most of the CCA's are diagnosed within first year after diagnosis of PSC warranting diagnosis of PSC in much earlier state. For the moment, no good screening tests are available for PSC, except elevated P-ALP. Bile proteomic analysis has previously been demonstrated to discriminate benign conditions from CCA in patients with PSC (8,9).

**Aims & Methods:** **Aims:** To evaluate the proteomic profiles in serum and bile samples in controls and PSC patients to find new noninvasive markers for screening and diagnosing PSC.

**Patients and methods:** In total, 79 patients with confirmed PSC referred for ERC for diagnosis and surveillance of the disease were included (48 females). During ERC bile sample was aspirated using balloon catheter and then stored in -80°C. Brush cytology (BC) was collected both from extra- and intrahepatic bile ducts for Papanicolaou staining for grading dysplasia. Cholangiographic findings are scored according to modified Amsterdam score (Helsinki score). Serum samples are collected at the time of ERC. 18 serum and 6 bile samples from healthy controls were included. Label-free quantitative proteomics from serum and bile from the same individuals was performed UDMSE mode in Synapt G2-Si, nUPLC-TRIZAC C18 tile as previously described.

**Results:** Quantitative serum proteomics from 79 patients with PSC, but not dysplasia or CCA were compared to 18 serum from healthy controls. 112 significantly (Mann-Whitney) differentially expressed proteins were found with a maximal fold change of 2.8. The Ingenuity network analyses showed enriched expression on Protein synthesis, Cell morphology and Tissue development functions. Concomitantly the bile proteomics from same set of patients expressed 64 differentially expressed proteins, but here the fold changes were much higher, up to 128. The Ingenuity network analyses showed enriched expression on Cell morphology, Free radical scavenging and Infections diseases.

**Conclusion:** We show in a large set of clinical serum and bile specimens that PSC alters significantly the proteomic profiles and further analyses could identify putative novel biomarkers for screening and detection of PSC in its early, asymptomatic phase.

## P0746 ISOLATED ELEVATION OF ANTIMITOCHONDRIAL ANTIBODIES (AMA): PERSONALIZED FOLLOW-UP ACCORDING TO THE RISK OF PROGRESSION

Jardim Carvao J.L.<sup>1</sup>, Magno Pereira V.<sup>1</sup>, Abreu N.<sup>1</sup>, Abreu I.<sup>2</sup>, Sousa Andrade C.<sup>1</sup>, Jasmins L.<sup>1</sup>

<sup>1</sup>Hospital Central do Funchal, Gastroenterology, Funchal, Portugal, <sup>2</sup>Hospital Central do Funchal, Clinical Pathology, Funchal, Portugal

**Contact E-Mail Address:** joanacarvao@hotmail.com

**Introduction:** The presence of AMA in patients with elevation of alkaline phosphatase (ALP) allows the diagnosis of primary biliary cholangitis (PBC). Without cholestasis however is insufficient for the diagnosis. The European Association for the Study of the Liver (EASL) recommends annual follow-up for these patients in order to detect liver disease, with a low evidence level.

**Aims & Methods:** Characterize the population with isolated AMA elevation and further identification of group risks for the progression of CBP. Observational study of a prospectively maintained database of AMA positive patients between January 2010 and December 2018. A positive AMA was considered by indirect immunofluorescence reactivity testing ( $\geq 1:40$ ). Exclusion criteria: previous diagnosis of PBC, cirrhosis, any upper limit of normal (ULN) of the reference level for ALP (120 U/L). Baseline levels were defined with simultaneous collection of AMA. When applicable, liver blood tests were collected annually. Statistical analysis was performed with SPSS (v.23). Significance level was set at  $< 0.05$ .

**Results:** 49 patients were included in this study of which 93.9% were female and the median age was 51 years (40.5 - 62.5). 36.7% had a diagnosis of systemic autoimmune disease. Baseline median values of ALP, gamma-glutamyl transferase (GGT) and total bilirubin (TBil) were 76 U/L (59 - 86.5), 29.7 U/L (18.7 - 58.3) and 0.5 mg/dl (0.4 - 0.7), respectively. Only 28.6% of patients were submitted to annual biochemical follow-up. 5 patients fulfilled PBC EASL criteria in the follow-up. These patients had higher baseline cholestasis levels than those who did not develop PBC (median ALP U/L 88 vs. 70,  $p=0.007$ ; GGT U/L 118 vs. 27  $p=0.002$ ; TBil mg/dl 1.3 vs. 0.45,  $p=0.002$ , respectively). ALP, GGT and TBil had an area under the curve (AUC) for predicting PBC of 0.854, 0.958 and 0.933, respectively ( $p < 0.05$ ). An ALP value of  $> 86.5$  U/L had a 75% sensibility and 80% specificity in predicting the development of PBC.

**Conclusion:** Patients with higher baseline cholestasis levels, in the normal range (86-120 U/L) may have a higher risk for developing PBC. The further categorization of a risk group suggests a personalized rather than a generalized follow-up.

## P0747 MANAGEMENT OF PRIMARY BILIARY CHOLANGITIS: EXPERIENCES FROM A DISTRICT GENERAL HOSPITAL

Leow K., Agbna M., Yusuf A., Alfred S., Neal D., Jeevagan A., Mayhead P. Eastbourne District General Hospital, Gastroenterology, Eastbourne, United Kingdom

**Contact E-Mail Address:** khai.leow@doctors.org.uk

**Introduction:**

- Primary biliary cholangitis (PBC) is an uncommon but important cause of chronic liver disease which undiagnosed will often lead to cirrhosis and its associated complications.
- Lifelong Ursodeoxycholic acid (UDCA) therapy at a dose of 13-15 mg/kg/day remains the mainstay of treatment, with biochemical response indices at one year invaluable in predicting long term outcomes (1).
- HCC surveillance should be undertaken in patients with overt cirrhosis identified on baseline ultrasonography as part of risk stratification for PBC (1).

**Aims & Methods:** Aims:

- To assess if the optimum dose of UDCA is utilized in our PBC cohort.
- To assess if HCC surveillance is being carried out in PBC patients with cirrhosis.

**Methods:**

- 318 Anti-mitochondrial antibody (AMA) positive patients over a 10 year period (January 2008 - December 2017) were identified via a laboratory search.
- Those with a clinical diagnosis of PBC, defined by AMA positivity accompanied by unexplained cholestatic liver enzymes were included in this study.

**Results:**

- The sample size ( $n=74$ ) consisted of 68 female patients (91.9%), with a median age of 65 years at diagnosis in this cohort.
- 16 subjects (21.6%) were on the recommended UDCA dosage of 13-15mg/kg/day with 4 patients (25%) having their biochemical response assessed after 12 months of therapy.
- Overt cirrhosis was diagnosed in 20 patients (27%) via ultrasonography, from which 15 (75%) were assimilated into the HCC screening programme.
- Among the non-cirrhotic cohort, 42 subjects (77.8%) remained on surveillance.

**Conclusion:**

- This audit emphasises the importance of raising awareness regarding the correct dosing of UDCA in the treatment of PBC in order to maximise therapeutic response.
- Disease staging should be driven by the use of transient elastography over ultrasonography in light of its diagnostic accuracy, which will minimize the need for unnecessary surveillance in patients without advanced disease.

**Introduction:** De novo neoplasms (DNN) after liver transplantation (LT) have been reported as one of the major causes of mortality in liver recipients, being the most common cause of death after the second decade after LT. Current post-LT surveillance strategies are based largely on data collected on general population, but should be customized in the light of risk factors specific to LT recipients. The influence of donor-recipient sex and age matching on long-term survival after liver transplant is controversial, and data on the possible effect on DNN risk are lacking

**Aims & Methods:** A cohort study was conducted using data collected in 9 Italian centres between 1985 and 2014. Patients were excluded if:  $\leq 18$  years old, follow-up shorter than 90 days after LT, cancer diagnosis done within 90 days after LT. Person-years (PYs) at risk for DNN were computed from 90 days post-LT to the date of death, date of cancer diagnosis or end of follow-up, whichever came first.

A competing risk approach was applied to estimate 5-year cumulative cancer incidence by time since LT. Hazard ratios for DNN and the corresponding 95% confidence intervals (CIs) were obtained using Cox models adjusted for recipient gender, age at transplant, calendar year at transplant, and aetiology of liver disease

**Results:** A total of 1927 patients (75.5% males, median age at LT 53 years-old) were transplanted during the study period (85% after year 2000) receiving an organ from a deceased donor in 95.5% of cases. Distribution of LT recipients according to recipient/donor gender and donor age is shown in Table 1. Cumulative cancer incidence at 5 years after LT for all recipients was 5.4%, with no differences when the results were stratified by donor gender (male 5.8 vs females 4.6%,  $p=0.45$ ). Considering both donor gender and age, among male patients receiving a graft from a male donor, the 5-year cumulative incidence was higher when donor was  $\geq 60$  years-old ( $p=0.03$ ) (Figure 1). In the multivariate analysis, donor age or gender were not associated with DNN risk. However, considering their joint effect, at elevated donor age ( $\geq 60$  years), the risk of DNN increased for patients receiving an organ from male donors (HR=2.00, 95% CI: 1.02-2.50). Conversely, among patients receiving an organ from female donors, the risk did not vary according to donor age. When the associations were examined in strata of recipient gender, a similar pattern of risk emerged among male only (HR=2.26; 95% CI: 1.05-4.87 for those receiving an organ from male donors  $\geq 60$  years vs  $< 35$  years)

**Conclusion:** In our cohort the risk of DNN occurrence was increased in male patients receiving a liver graft from older male donors, irrespectively from patients' age at transplant. Gender and age differences in liver donor could influence DNN risk due to both patients' and donors' biologic and lifestyle factors. These results, if confirmed in other studies with different cohorts' characteristics, could be useful to further guide post-LT DNN screening-personalization and risk stratification

## P0750 ANGIOTENSIN II RECEPTOR BLOCKERS MIGHT BE PROTECTIVE AGAINST NON-ALCOHOLIC FATTY LIVER DISEASE AFTER LIVER TRANSPLANTATION

Eshraghian A.<sup>1</sup>, Nikeghbalian S.<sup>2</sup>, Malek-Hosseini S.A.<sup>2</sup>

<sup>1</sup>Avicenna Center for Medicine and Organ Transplant, Gastroenterology and Hepatology, Shiraz, Iran (Islamic Republic of), <sup>2</sup>Avicenna Center for Medicine and Organ Transplant, Shiraz, Iran (Islamic Republic of)

**Contact E-Mail Address:** eshraghiana@yahoo.com

**Introduction:** Renin-angiotensin system (RAS) has been proposed to be involved in pathogenesis of non-alcoholic fatty liver disease (NAFLD). Some evidences suggest that angiotensin II receptor blockers (ARBs) are effective for treatment of NAFLD. This study aimed to investigate association of treatment with angiotensin II receptor blockers (ARBs) after liver transplantation and occurrence of NAFLD in liver transplant recipients.

**Aims & Methods:** Study population were recruited from Shiraz Liver Transplant Registry (SLTR). All liver transplant recipients between March 2014 and March 2017 who were treated with ARBs for hypertension were included. These patients were matched to a group of liver transplant recipients on age, sex, diabetes and hypertension not treating with ARBs. NAFLD was defined as presence of hepatic steatosis diagnosed by ultrasound and exclusion of secondary causes of hepatic steatosis. Data were analyzed using Student's t-test and by Chi-square test. Independent variables associated with NAFLD were analyzed by logistic regression method.

**Results:** Totally, 81 patients were included. 26 patients treated with ARBs were compared to 55 patients not treated with these medications. No adverse effects were reported with ARBs treatment.

Univariate	Multivariate analysis					
	NAFLD (+)	NAFLD (-)	P-Value	OR	95 % CI	P-value
Age (years)	51.7 $\pm$ 8.27	53.8 $\pm$ 11.28	0.330			
PTDM (yes/no)	32/14	17/13	0.251	1.68	0.58-4.90	0.336
Weight (kg)	81.18 $\pm$ 15.39	75.78 $\pm$ 15.42	0.127	1.017	0.98-1.05	0.335
ARBs	20 %	50 %	0.005	3.62	0.096-0.793	0.017
Hyperlipidemia (yes/no)	31/18	18/14	0.528			
NODAT (yes/no)	18/29	9/19	0.591			
Triglyceride (mg/dL)	236.7 $\pm$ 150.2	178.7 $\pm$ 89.05	0.05	1.003	0.998-1.008	0.188

[Clinical characteristics of patients with and without NAFLD after liver transplantation]

Age, sex, hypertension and diabetes were not statistically different between two groups ( $P>0.05$ ). NAFLD was diagnosed in 10 patients (38.4 %) among those who were treated with ARBs versus in 39 patients (70.9 %) among those who were not treated with ARBs (OR: 3.9; 95 % CI: 0.96-0.684;  $P$ -value= 0.005).

In univariate analysis, higher serum triglyceride level was associated with NAFLD after liver transplantation ( $P=0.05$ ). In regression analysis patients treating with ARBs were less likely to develop NAFLD after liver transplantation (OR: 3.62; 95 % CI: 0.096-0.793;  $P$ -value= 0.017).

**Conclusion:** NAFLD is less likely to be diagnosed in liver transplant recipients treating with ARBs after liver transplantation. ARBs can be considered for treatment of hypertension after liver transplantation especially in those who are at risk for development of hepatic steatosis.

**Introduction:** Chronic kidney disease (CKD) is a frequent complication after liver transplantation that leads to increased mortality and decreased quality of life. CKD has a multifactorial etiology, and is in part related to calcineurin inhibitor exposure (e.g. tacrolimus). The immunosuppression protocol at Sahlgrenska University Hospital was revised in 2010 to comprise basiliximab induction with reduced and delayed tacrolimus exposure; the effects of this revised protocol on kidney function has not been studied.

**Aims & Methods:** We aimed to retrospectively evaluate the effect of reduced and delayed (R&D treatment) tacrolimus exposure on kidney function after liver transplantation in a real-life setting. 624 liver transplant recipients received immunosuppression with either conventional dose tacrolimus (target trough level M0-2: 10-15  $\mu$ g/L, 5-10  $\mu$ g/L thereafter) + corticosteroids (conventional treatment, n=201) or basiliximab induction with reduced-dose (target trough level M0-3: 5-8  $\mu$ g/L, 3-5  $\mu$ g/L thereafter) tacrolimus delayed until post-operative day 3 and mycophenolate mofetil (MMF) (R&D treatment, n=342). The primary end-point was measured glomerular filtration rate (mGFR, Chrome-EDTA or iothexol) 12 months after transplantation. Secondary endpoints included 3-month mGFR, graft and patient survival. A subgroup analysis was performed by baseline mGFR ( $< 60$  ml/min/1.73m<sup>2</sup>). Statistical analyses were performed using the Student's t-test, linear regression and Kaplan-Meier survival analysis.

**Results:** Baseline characteristics were comparable between the conventional and R&D treatment groups. Through univariate linear regression age, sex, malignancy or alcohol as primary indication, baseline mGFR, intraoperative blood loss, ischemia time, bilirubin at waitlist, creatinine at waitlist, INR at waitlist, hemodialysis on transplantation day and waiting list time were relevant confounders that were adjusted for. Mean mGFR at 12 months after transplantation was significantly higher in the R&D treatment group after adjusting for relevant confounders (adjusted mean 69.7 vs 58.6 ml/min/1.73m<sup>2</sup>;  $P<0.001$ ). Mean mGFR 3 months after transplantation was also significantly higher in the R&D treatment group (adjusted mean 64.2 vs 56.4;  $P=0.003$ ).

Five-year graft survival was higher in the R&D treatment group (85% vs 75%,  $P=0.013$ ) and five-year patient survival rates were comparable between the groups (88% vs 84%,  $P=0.125$ ). A subgroup analysis in patients with baseline mGFR  $< 60$  ml/min showed significantly higher 12-month mGFR in the R&D treatment group (unadjusted mean 53.9 vs 45.5 ml/min;  $P=0.046$ ) and higher 3-month mGFR (unadjusted mean 48.7 vs 41.5;  $P=0.034$ ).

**Conclusion:** In a real-life setting, induction with basiliximab and reduced and delayed tacrolimus exposure and MMF is associated with less peri-operative kidney damage and similar survival compared to conventional tacrolimus exposure in liver transplantation recipients.

**Introduction:** *de novo* metabolic syndrome (MS) is an emerging complication after liver transplantation (LT), resulting in an increased cardiovascular morbidity and mortality. This prospective study aimed to assess the incidence of MS post-LT and its possible associated risk factors.

**Aims & Methods:** LT patients between April 2013 and October 2016 were prospectively included. Patients with pre-LT MS were excluded. General and metabolic variables were collected at LT and at 6 months, 1 and 2-years post-LT as well as donor variables. Post-LT MS was evaluated according to the modified NCEP-ATP III criteria.

**Results:** 42 liver transplanted patients were included. The most common indications to LT were HCV (38%) and alcoholic liver disease (ALD) (36%). Six-month, 1- and 2-year incidence of *de novo* MS was 43%, 57% and 71% respectively. The incidence of post-LT MS at 6 months, 1 and 2 years post-LT was significantly higher in patients transplanted for ALD compared to patients transplanted for other causes (80%, 86.7% and 93.3% vs. 22.2%, 40.7% and 59.3% respectively;  $p < 0.001$ ).

Considering the individual metabolic variables, patients transplanted for ALD presented a significantly higher incidence of obesity (33.3%, 46.7% and 53.3% vs. 0.3%, 14.8% and 18.5%;  $p = 0.012$ ), hypertension (66.7%, 73.3% and 73.3% vs. 18.5%, 25.9% and 33.3%;  $p = 0.006$ ) and hypercholesterolemia (40%, 60% and 66.7% vs. 18.5%, 29.6% and 33.3%;  $p = 0.034$ ) compared to non-ALD liver transplanted patients, whereas no differences were found in the incidence of diabetes or hypertriglyceridemia.

No differences were found in terms of anthropometric and metabolic variables pre-LT between these two groups. At multivariate analysis ALD remained a risk factor significantly associated with *de novo* MS (HR 2.35, 95%CI 1.06-5.19;  $p = 0.035$ ).

**Conclusion:** *de novo* MS is a frequent complication post-LT showing a progressive increase overtime. A strict metabolic follow-up is mandatory starting early after LT, particularly for patients transplanted for ALD.

**Contact E-Mail Address:** ewa.sobczak@wsht.nhs.uk

**Introduction:** The approach to patients with suspected choledocholithiasis requires careful consideration. Missed common bile duct stones (CBDS)

pose a risk of recurrent symptoms, pancreatitis, and cholangitis. However, the morbidity and cost from indiscriminant and/or invasive biliary evaluation should also be minimized. Utilizing resources for CBDS identification in efficient way is of utmost importance. MRCP is the recommended investigation for patients with intermediate likelihood of common bile duct stones (CBDS) following first line investigations -ultrasound scan (USS) and liver function tests (LFTs). In accordance with American Society of Gastrointestinal Endoscopy (ASGE) and British Society of Gastroenterology (BSG) Guidelines MRCP prior to scheduled endoscopic or surgical duct clearance is not mandated in strong likelihood of CBDS.

**Aims & Methods:** The clinical audit was set up to evaluate current practice of CBDS stone diagnosis prior to endoscopic biliary duct clearance procedures against recommendations of the ASGE and BSG Guidelines in the UK's general district hospital. Data was collected retrospectively. All MRCPs requests during the period of 01/07/2017 - 01/07/2018 in UK's district general hospital were reviewed. Cases of MRCP requests for suspected CBDS were identified.

Electronic records were reviewed for clinical indications and rational to suspect CBDS. Identified patients were stratified into low, intermediate and high risk of CBDS as per ASGE guidelines. Cases with incomplete data, paediatric patients, MRCP requested after bile ducts draining procedure were excluded.

**Results:** In 28.9% of performed MRCPs there was no justification for requesting MRCP for suspected CBDS. The most common reasons for unjustifiable MRCP requests were: strong likelihood of CBDS (hence should have gone directly to bile ducts clearance procedure), low likelihood of CBDS and/or suboptimal clinical details for MRCP, failure to perform first line investigations prior to requesting MRCPs.

**Conclusion:** MRCPs to diagnose CBDS are frequently made without rational, and hence do not result in change in management. Results of the single centre audit are likely to represent situation on a larger scale. This may be partly because there is no agreed pan-European guidelines for the management of moderate and high risk of CBDS and/or agreed set threshold for determining likelihood of CBDS.

Establishment of pan-European registry or international snapshot audit on diagnostic strategies and further management in moderate and high likelihood of CBDS will enable to identify degree of variability in practices across different sites as well as gives opportunity to derive trends in clinical outcome depending on different approaches in diagnosis and management. Large scale pan-European audit will aid in developing pan-European guidelines on the role of MRCP in management of CBDS.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is common among severely obese patients. Two-dimensional shear wave elastography (2D-SWE) has been validated as a noninvasive diagnostic tool for liver stiffness measurement. However, the technical feasibility and accuracy of this method in severely obese patients are still under debate.

**Aims & Methods:** We aimed to assess the diagnostic accuracy of 2D-SWE in bariatric surgery candidates in comparison with the gold standard liver biopsy.

**Methods:** 90 severely obese candidates for bariatric surgery were included. Liver stiffness was measured using 2D-SWE fourteen days before liver biopsy. Liver biopsy was taken on the day of surgery. The area under the receiver operating curve (AUROC) was calculated for the staging of liver fibrosis.

**Results:** 2D-SWE was performed in 97.3% of patients successfully. Histologic stages of fibrosis (F0-F4), were detected in 34.2%, 36%, 6.3%, 3.6%, and 0.9% of patients, respectively. The AUROC for 2D-SWE was 0.77 for

F1, 0.72 for F2, 0.77 for F3, and 0.70 for F4. In univariate analysis, 2D-SWE values were correlated with BMI, waist circumference, NAFLD activity score (NAS) and steatosis, whereas these components did not affect liver stiffness in multivariate analysis.

**Conclusion:** Two-dimensional shear wave elastography of the liver can be feasible and has good accuracy in severely obese candidates for bariatric surgery. Therefore, 2D-SWE may be a good option for assessing liver fibrosis, especially in the early stages of fibrosis to lessen complications of surgery in this population. However, this method should be applied on a larger scale for late stage of fibrosis.

**Introduction:** Choline is a quaternary ammonium base serving as an essential nutrient in all mammalian cell membranes, including hepatocytes. Its metabolism is cell- and tissue-specific [1,2]. Choline plays a role in hepatic mitochondrial impairment, oxidative stress and DNA methylation levels of genes involved in lipid metabolism [3].

### Aims & Methods:

**Aim:** The aim of this study was to compare findings between patients with liver cirrhosis and subjects with a normal liver on a [<sup>11</sup>C]choline PET/CT.

**Methods:** This prospective pilot study was conducted between the years 2012-2016. The cohort included 14 patients with prostate cancer (reference group) and 11 patients with cirrhosis attending a tertiary medical center. Demographic, clinical and laboratory data were obtained from the medical files. All participants underwent a dynamic [<sup>11</sup>C]choline PET/CT (Discovery ST, GE Medical Systems, Milwaukee WI). We compared the maximal standard uptake values (SUVmax) and the area under the curve (AUC) at 1110 seconds in both groups.

**Results:** The mean age of the cirrhosis group (63.4% men) was 68.4±10.7 and the control group, 69.7±7.3 years. The mean SUVmax was significantly higher in the cirrhosis group than in the controls (right lobe, 10.06±12 vs. 6.3±1.6, *p*=0.011; left lobe, 8.6±11.6 vs. 5.4±0.9, *P*=0.024; spleen 17.99±27.8 vs. 13.4±2.6, *P*=0.027; kidney, 35.9±59.5 vs. 19.3±4.8, *P*=0.025). The corresponding AUC values at 1110 seconds was significantly distinguished between the groups (right lobe, 13538±20020 vs. 8427.3±1557.9, *p*=0.026; left lobe 12304±18871 vs. 6878.9±1294.3, *p*=0.024; spleen, 12875±17930 vs. 8263.9±1279.2, *p*=0.023; kidney, 24623±36025 vs. 13667±3873.9, *P*=0.032). No correlations were found between the clinical characteristics and the imaging-derived parameters in the patients with cirrhosis.

**Conclusion:** Our findings suggest a role for [<sup>11</sup>C]choline PET/CT as a non-invasive biomarker of cirrhosis. Further larger-scale studies are needed to confirm these observations

**Introduction:** Chronic liver diseases are a major health problem. The detection of initial stages of liver fibrosis allows an adequate handling of these patients. This could change the natural evolution, delaying decompensation in advanced stages.

Recently, the comparability between non-invasive methods and liver biopsy for assessment of fibrosis has been demonstrated.

**Aims & Methods:** The aim of this study was to correlate the values of fibrosis determined by non-invasive methods, serological markers (APRI and FIB-4) and ultrasound shear wave elastography (SWE) in patients with chronic liver disease. A unicenter retrospective study was carried out. All liver disease patients who underwent SWE (ITACHI US) for any indication in the University Hospital Virgen Macarena between June 2017 and November 2018 were selected.

Serological fibrosis markers were calculated for all etiologies with close analytics (< 3 months) to the performance of the test. To classify the stage of fibrosis we used the accepted cut points of advanced fibrosis: APRI> 1 and FIB-4> 2.67.

**Results:** Two hundred thirty nine cases were included. Thirty patient presented advanced fibrosis according to serological markers. The area under the curve for advanced fibrosis by SWE was 0.803 (CI 95%). The best cut-off point to determine advanced fibrosis was ≥ 7.55 with a sensitivity of 83.3% and a specificity of 66.8%. A negative predictive value (NPV) of 96.5% was obtained.

Table 1 shows the diagnostic capacity of advanced fibrosis according to SW and serological markers by etiology.

	Advanced fibrosis (APRI/FIB4)			Advanced fibrosis (SWE)		
	Yes	No		Yes	No	
	N (%)	N (%)	p-value	N (%)	N (%)	p-value
Viral	11 (36.7)	116 (55.%)	0.028	43 (45.7%)	84 (57.9%)	<0.001
Enolism	7 (23.3%)	21 (10.1%)	0.028	23 (24.5%)	5 (3.4%)	< 0.001
NASH	7 (23.3%)	57 (27.4%)	0.028	18 (19.1%)	47 (32.4%)	< 0.001
Autoimmune	5 (16.7%)	14 (6.7%)	0.028	10 (10.6%)	9 (6.2%)	< 0.001

[Table 1]

**Conclusion:** SWE had an adequate diagnostic ability for determining advanced fibrosis in patients with chronic liver disease compared with serological markers.

A cut-off point SWE lower than 7.55 predicts with high probability the absence of advanced fibrosis.

Prospective studies are needed to support our results and compare them with other types of elastography-based imaging techniques or transient elastography.

*"Victor Babeş" University of Medicine and Pharmacy, Gastroenterology and Hepatology, Timisoara, Romania*

**Contact E-Mail Address:** ruxi2323@yahoo.com

**Introduction:** Nonalcoholic Fatty Liver Disease (NAFLD) has recently been recognized as the most prevalent liver disease worldwide, fibrosis stage being the strongest predictor for disease-specific mortality. Non-invasive assessment of liver fibrosis has been increasingly used instead of liver biopsy. ElastPQ is a point Shear Wave Elastography (pSWE) technique that has good accuracy for staging liver fibrosis (1).

**Aims & Methods:** The aim of this study was to assess the value of ElastPQ as a screening tool for liver fibrosis in NAFLD patients. The study group included 420 consecutive patients with NAFLD evaluated in daily outpatient practice over a period of 18 months. The diagnosis of NAFLD was made by the presence of hepatic steatosis on ultrasound ("bright liver" with posterior attenuation and increased hepato-renal index), after excluding significant alcohol consumption. Liver fibrosis was assessed by means of pSWE (ElastPQ; Affinity 70, Phillips). Valid liver stiffness values were defined as the median of 10 liver "non-zero" measurements in a homogeneous area of liver parenchyma. Reliable liver stiffness measurements were defined as the median value of 10 measurements with an IQR/M < 30%. To discriminate between ElastPQ fibrosis stages we used the following cut-off values:  $F \geq 2$ : 6.9 kPa;  $F \geq 3$ : 8.4 kPa and for  $F=4$ : 12.4 kPa (2).

**Results:** NAFLD consisted of 42.4% (420/990) of cases evaluated by liver elastography in daily outpatient practice. We enrolled 414 consecutive patients with NAFLD with reliable liver stiffness measurements, mean age  $48.6 \pm 12.6$  years, 70% male, 30% female. After applying the cut-off values proposed, we found out that 86.4% (358/414) of patients were below the cut-off value of significant < F2 fibrosis, while advanced fibrosis  $F \geq 3$  was found in 6% (25/414) of patients.

**Conclusion:** NAFLD was the most frequent indication for performing ElastPQ in daily outpatient practice. ElastPQ is a good and reliable point of care tool for fibrosis screening that could rule out significant fibrosis in the majority of patients and help identify patients with advanced fibrosis related to NAFLD and prioritize them for referral and treatment of their liver disease.

**Contact E-Mail Address:** moga.tudor@yahoo.com

**Introduction:** The aim of this paper was to evaluate the inter- and intra-server reproducibility of the new time-harmonic elastography diagnostic system (THED) (1) and the impact of ultrasound (US) experience in acquiring reliable measurements, since no official recommendations are available for this system.

**Aims & Methods:** Elastographic measurements (EM) were obtained in 27 consecutive subjects using THED. Three examiners with different levels of experience in US and US-based elastography, performed 10 valid EM on each subject.

We defined their experience as follows: E1- no experience in elastography and less than 50 ultrasound (US) examinations, E2: more than one year elastographic experience and more than 500 US examinations and E3: more than 1000 US examinations, without any experience in elastography. We used the intraclass correlation coefficient (ICC), inter-rater agreement (Kappa coefficient) and concordance correlation coefficient to assess the inter- and intraobserver reproducibility

**Results:** We did not find significant differences between the means of EM obtained by the examiners overall and across study group [1.66 (E1) vs 1.66 (E2) vs 1.65 (E3),  $p=0.76$ ]. The overall agreement between examiners was excellent: 0.94 (95% CI: 0.89-0.97). There was at least a good agreement between examiners (E1 vs. E3:  $k=0.80$ , 95% CI: 0.67-0.94; E1 vs. E2:  $k=0.81$ , 95% CI: 0.69-0.94), and good to excellent in E2 vs. E3:  $k=0.89$ , 95% CI: 0.82-0.96. The intraobserver reproducibility for each of the examiners was excellent, however the ICCs were higher in more experienced examiners in US: E1- 0.92, (95% CI: 0.82-0.96) vs. E3-0.94 (95% CI: 0.87-0.97) vs. E2-0.97 (95% CI: 0.95-0.99). The concordance correlation coefficients were similar: E1 vs. E3-0.84, E1 vs. E2-0.89 and E3 vs. E2-0.89.

**Conclusion:** The good ICCs and Kappa coefficients for the mean values show that THED is a reproducible method. Ultrasound experience did not significantly influence the results.

**Introduction:** In chronic liver disease fibrosis is the key prognostic factor. Liver biopsy, the reference standard for hepatic fibrosis assessment, is an invasive procedure with a small but significant risk of life-threatening complications. Many non-invasive tests have been evaluated as alternatives. Liver surface nodularity (LSN) is the highest-accuracy ultrasonographic sign to detect advanced liver fibrosis (F3-F4) [1-3].

Pocket-size Ultrasound Devices – with their small size, low cost and ease of use – have been assessed in several clinical settings, but never in CLD.

**Aims & Methods:** Our cross-sectional study evaluated PUD feasibility, reproducibility and accuracy in identifying LSN.

Between September 2017 and January 2019 we enrolled all consecutive consenting adults referred for liver parenchymal biopsy..

LSN was evaluated by 2 independent operators using PUD (Vscan® Dual Probe GE Healthcare, UK), and by an operator using standard GIUS. Transient elastography (TE) and liver biopsy were performed on all patients. PUD reproducibility was evaluated by K coefficient. PUD, GIUS and TE results were compared with histology (METAVIR). The estimated pre-test probability of severe fibrosis was 35%. Sensitivity, specificity, positive/negative likelihood ratios, and post-test probability were calculated.

**Results:** For 72 patients (31 M, age  $47 \pm 28$  years, NAFLD/NASH 35%, AIH 25%, PBC/PS 14%, HBV/HCV 12%, other 14%) PUD reproducibility ( $k=0.82$ , 95% CI 0.68–0.96) and concordance between PUD and GIUS ( $k=0.78$ , 95% CI 0.64–0.94) were excellent. In diagnosing  $F \geq 3$  PUD achieved: 87% sensitivity, 91% specificity, LR+ 9.7, LR- 0.14, PPV 84%, NPV 93% against GIUS (95% sensitivity, 93% specificity, LR+ 13.5, LR- 0.05, PPV 88%, NPV 97%) and TE (67% sensitivity, 96% specificity, LR+ 16, LR- 0.35, PPV 89%, NPV 86%).

**Conclusion:** PUD proved feasible, with excellent reproducibility. PUD performed very well in diagnosing advanced compensated CLD, and comparably to GIUS and TE. PUD is deployable as first-line screening to select patients for more invasive techniques, thus shortening clinical decision times.

**Introduction:** To date no study has ever explored the potential role of a new 2-dimensional Shear Wave Elastography (2D-SWE) technique that has been recently implemented on Esaote MyLab Nine devices. The aim of our study was to evaluate the agreement between 2D-SWE with Esaote MyLab Nine (QELaXto) and 2D-SWE with Aixplorer Supersonic Imagine (SSI) as the reference standard.

**Aims & Methods:** Data was collected prospectively from November 2018 to February 2019 on patients who were scheduled to undergo liver elastography as requested by our Hepatology Unit. Exclusion criteria were HCC/malignant liver nodules, severe extra-hepatic comorbidities and liver stiffness (LS) >50kPa. LS was sampled from the same intercostal space with both QELaXto and SSI when possible. Values were tested with correlation coefficient analysis and Bland-Altman analysis (B&A); agreement between the two elastography techniques was assessed with Spearman correlation.

**Results:** The study included 130 patients (42[32%] HCV and 26[20%] NAFLD; 96% Child-Pugh A). Failure of LS measurements occurred in only one patient for both elastography techniques (BMI >40) and another patient was excluded from the analysis because of LS>50 kPa. Correlation coefficient was very good at 0.951; B&A analysis showed a mean of 1.4 kPa, with limits of agreement at -1.5 and 4.3 kPa. Spearman's rho correlation of SSI versus QELaXto was 0.885. The relationship became less strong in the higher range of LS (≥14 kPa), corresponding to patients with liver cirrhosis.

**Conclusion:** There is an overall excellent degree of concordance of QELaXto as compared to the "reference standard" SSI, with the first method showing lower LS results as compared to the latter. Further studies are warranted in order to validate this new technique in comparison or in combination with other non-invasive methodologies and liver biopsy.

**Introduction:** The prevalence of cardiomyopathy in cirrhotics remains unknown because of its latent nature, characterized by blunted contractile responsiveness to stress, altered diastolic relaxation, and electrophysiological abnormalities.

**Aims & Methods:** Our aim was to detect early myocardial dysfunction using new echocardiography technologies in cirrhotic patients and correlating them to liver stiffness (LS) and severity of liver disease.

Consecutive patients with liver cirrhosis without structural heart disease, portal vein thrombosis, hepatocellular carcinoma outside Milan criteria, transjugular intrahepatic portosystemic shunt (TIPS) and with optimal acoustic echocardiography window in order to assess the myocardial strain were included. Conventional and speckle-tracking echocardiography (Vendor GE, EchoPAC PC software) were performed by a single investigator (EACVI TTE certified). Subclinical myocardial dysfunction of left ventricle was defined as average global longitudinal strain (GLS) < -18 % (Lang RM, et al. J Am Soc Echocardiogr 2015;28:1-39).

LS was assessed by transient elastography (TE, Fibroscan®, Echosens) and shear wave elastography (SWE) from Hitachi (Arietta V70). Reliable results were defined as median value of 10 valid measurements with an IQR/Med < 30 % and expressed in kPa. The presence of ascites, esophageal varices, splenomegaly and/or thrombocytopenia were considered as sign of portal hypertension.

**Results:** We evaluated 60 patients, but 10 did not fulfilled the inclusion criteria (1 portal vein thrombosis, 2 coronary artery disease, 1 cor pulmonale, 4 patients with valvular dysfunction and 2 with suboptimal acoustic echocardiography window). The final analysis included 50 patients, with mean age of 58.3 ± 10.5 years (66% males).

Compensated cirrhosis (Child-Pugh A) was present in 60% of patients, 24% were classified as Child-Pugh B and 16% as Child-Pugh C.

LS could be evaluated in 76 % of cases by TE and in all patients by Hitachi SWE.

Slightly reduced left ventricular ejection fraction (EF) was observed in 4% of patients. Subclinical systolic dysfunction as assessed by GLS was present in 16 % of cases. The presence of systolic dysfunction seems to correlate with LS assessed by Hitachi SWE (Table).

Parameter	GLS < -18% or reduced EF (n=10)	GLS ≥ -18% and normal EF (n=40)	p value
LS by TE (kPa)	43.1±26.2	33.2±20.5	0.16
LS by SWE (Hitachi)(kPa)	10.8±3.8	14.2±5.7	0.002
MELD	9.9±3.8	11.3±4.5	0.36
Child-Pugh: compensated (A), decompensated (B+C)	A:7(70%), B+C:3(30%)	A:24(60%), B+C:16(40%)	A: 0.82, B+C: 0.82
Portal vein velocity (cm/s)	17.1±3.9	15.3±3.2	0.15
Signs of portal hypertension	6 (60%)	31 (77.5%)	0.46
Etiology: alcoholic (A), other etiologies (B)	A:5 (50%), B:5 (50%)	A:27(67.5%), B:13(32.5%)	A:0.50, B:0.50
Age (years)	61.5±12.2	57.2±10.1	0.29
Gender: male (A), female (B)	A:5(50%), B:5(50%)	A:28(56%), B:12(44%)	A: 0.98, B: 0.98
CO-Cardiac output (ml/min)	5.9±1.3	5.6±1.7	0.55

[Table Correlation between myocardial dysfunction and liver stiffness and severity of liver disease]

**Conclusion:** Clinical or subclinical left ventricular dysfunction was identified in 20% of cirrhotic patients and this seems to correlate with LS assessed by Hitachi SWE, but not with the severity of liver cirrhosis.

**Disclosure:** Nothing to disclose

## **P0762 THE POTENTIAL OF RIGHT HEPATIC VEIN DIAMETER AS SENSITIVE MARKER FOR LIVER REMODELING IN PATIENTS WITH VIRUS C RELATED CIRRHOSIS WHO HAVE ACHIEVED SUSTAINED VIROLOGIC RESPONSE AFTER THE ADMINISTRATION OF DIRECT-ACTING ANTIVIRALS TREATMENT**

**Introduction:** Cirrhosis is a major cause of morbidity and mortality worldwide.

The rapid progress of medicine has transformed the representation of the hepatitis C virus infection, in no more than three decades, from an unknown disease to a safe and simple to treat one, with virologic cure in most patients.

Advances in understanding of HCV molecular biology have created the opportunity to develop designed drugs that target specific steps in the infection and replication of HCV. This breakthrough has led to the development of direct-acting antivirals (DAAs) and, from this, to the rapid approval of HCV treatment and the possibility for disease elimination.

For a long period of time, cirrhosis was considered an irreversible end stage of liver disease, mostly due to lack of treatment possibilities. Today, this irreversibility is no longer a "dogma". There are some research studies showing the potential for liver remodeling, at least at microscopic level, with regression of fibrosis after the removal of causative agents in both patient and experimental fibrosis models.

The main question is what happens next with liver, remaining in a frozen status with some degree of microscopical changes or improvements are visible at the macro level, detectable by sectional imaging tools such as CT. Our hypothesis is based on improvements in the features of cirrhosis seen on CT scan that can suggest the reversibility of liver fibrosis/cirrhosis after the achievement of sustained virologic response (SVR) in HCV related cirrhotic patients.

**Aims & Methods:** The purpose of this study is to evaluate the capability of CT examination to identify changes in hepatic morphology, able to demonstrate the liver remodeling after obtained SVR in patients with HCV related cirrhosis.

CT examinations of 45 patients with HCV related cirrhosis were performed before and after the administration of a direct-acting antivirals (DAAs) treatment. The liver changes were assessed by measuring volume, caudate right hepatic ratio, hepatic vessel diameters, periportal widening space and right posterior notch. There have been measured the portal vein trunk, splenic and superior mesenteric veins and the volume of the spleen as part of portal hypertension assessment.

**Results:** The significant variations were detected in the right hepatic vein showing a statistically significant widening after the treatment ( $Mdn=8.12$ ), compared to the diameters recorded before treatment ( $Mdn=6.35$ ),  $z=-3.894$ ,  $p<0.001$ ,  $r=-0.20$ . The liver volume of the patients prior to the treatment was significantly higher ( $Mdn=1786.77$ ) than the estimated volume subsequent to the treatment ( $Mdn=1716.44$ ),  $z=-1.970$ ,  $p=0.049$ ,  $r=-0.20$ . The volume of the spleen before ( $Mdn=564.79$ ) the treatment was significantly higher than the volume determined after the treatment ( $Mdn=474.44$ ),  $z=-2.500$ ,  $p=0.012$ ,  $r=-0.269$ . The other parameters showed no improvement.

**Conclusion:** The sectional imaging techniques such as CT can be used to demonstrate the improvement of hepatic status after treatment. The most sensitive parameters are the right hepatic vein diameter and the splenic volume reduction, followed by liver volume reduction.

**Disclosure:** Nothing to disclose

## **P0763 HEPATIC PORTAL VENOUS GAS: ITS CLINICAL FEATURES AND OPTIMAL MANAGERMENTS**

**Contact E-Mail Address:** tatsuya.osuga@ajk.takatsuki-hp.or.jp

**Introduction:** Hepatic portal venous gas (HPVG) is generally recognized to indicate poor prognoses in patients with serious intestinal damage. Although surgical removal of the damaged portion is only considered an effective therapy, some of the patients can recover with non-surgical conservative treatments.

**Aims & Methods:** To establish diagnostic algorithm for determining an optimal treatment, we reviewed our experienced cases of HPVG and attempted to clarify their clinical features. Thirty-five cases of HPVG [34 patients (19 women and 15 men); ages 34-99 yr (median, 85 yr)] diagnosed at Takatsuki General Hospital from April 2012 to February 2019, were included in the present retrospective study. Their most common complaint was abdominal pain (28 cases). Necessity for surgical treatment had been determined mainly by computed tomography (CT) findings, namely, abdominal free-air, lack of contrast enhancement of the intestinal wall, and intestinal emphysema. The patients' data including clinical backgrounds, physical examination findings, blood test results, CT images, and treatment outcomes were analyzed separately of surgical patients and non-surgical patients. Fisher's exact test and Mann-Whitney U-test were used for statistical analysis, and  $p<0.05$  was considered to be significant.

**Results:** 1) Eight cases were surgically treated. Seven (87.5%) of them survived and one (12.5%) died. Intestinal necrosis was confirmed in all cases during surgery, and the necrotic portions were removed. Final diagnoses were non-occlusive mesenteric ischemia ( $n=4$ ), clostridium difficile enteritis ( $n=1$ ), strangulation ileus ( $n=1$ ), superior mesenteric artery thrombosis ( $n=1$ ) and gastric perforation ( $n=1$ ; a fatal case).

2) Twenty-seven cases were treated conservatively (non-surgical patients). Thirteen of them had needed surgical operations to be cured but operations were abandoned because of their poor general conditions, such as extremely low performance status (ECOG PS 4;  $n=9$ ). However, three (23%) of these 13 patients survived. The remaining 14 of 27 patients were diagnosed as being able to be sufficiently cured by conservative treatments. Of these 14 patients, only one patient (7%) died.

3) To identify potential prognostic factors in the non-surgical patients, comparative analyses were performed between the fatal ( $n=11$ ) and the surviving ( $n=16$ ) cases. Ascites (82% vs 31%), signs of peritoneal irritation (80% vs 6%), and shock (55% vs 0%) were significantly frequent in the fatal cases. Compared with the surviving cases, base excess was lower (median -5.5 vs 1.8 mEq/L) in the fatal cases. Percentage of patients fulfilling SIRS criteria (80% vs 37.5%) and plasma levels of CRP (median 10.22 vs 2.09 mg/dL) and lactic acid (median 39 vs 26 mg/dL) tended to be higher in the fatal cases, but the differences were not significant.

**Conclusion:** HPVG has a high mortality rate, that of our hospital was 34%. If intestinal necrosis is suspected, surgical removal of the necrotic portion should be considered. In non-surgical patients, ascites, signs of peritoneal irritation, shock, and low base excess were closely associated with poor prognoses. Conversely, absence or fewness of these findings may predict recovery from the life-threatening condition with conservative treatments.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** zahra.bouhoun@gmail.com

**Introduction:** The Budd-Chiari syndrome (BCS) is an uncommon illness of the liver whose incidence is estimated at 0.9 /million/ year and results from the obstruction of the hepatic venous drainage whatever is the site of the obstacle, from the hepatic venules until the final part of the lower vena cava. The goal of our work was to trace the epidemiologic profile of this syndrome.

**Aims & Methods:** It is a descriptive retrospective study including all the patients presenting a BCS over a 14-year period (from January 2001 to December 2015). We studied the epidemiologic, clinical, biological, radiological, etiologic and evolutionary data of the patients.

**Results:** During the 14-year period, we collected 1323 portal hypertension cases (PHT), of which 3.9% (N=52) patient presented a Budd-Chiari syndrome. The median age of the patients was 35 years [15-75 years], with a slight female prevalence (52% of the cases). The ascites was the most revealing symptom in 48% of the cases. Radiological exploration had shown a primitive origin of the SBC on thrombosis of the hepatic veins known in 71%, thrombosis of the retro-hepatic lower vena cava in 10% and the association of both in 15% of the cases. The thrombosis of the portal vein was associated with 15% of the cases. The secondary origin of the BCS was found in two cases (4%): the first case was secondary to a compression by a hepatic mass and the second by a cyst hydatid.

The fibroscope has materialised Esophageal varices in 59.6% of the cases. The etiology of the Budd-Chiari was related to a deficit in antithrombin III in 9.6% of the cases, and a deficit out of protein S and C in 11.5% of the cases, a myélofibrose in 0.5% of the cases and two cases (4%) for each following etiology: a agenesis of the IVC, a secondary compression, a cœliaque disease and a disease of Behcet. The anticoagulants were managed in 90% of the cases. The evolution was marked by the development of a carcinoma hépatocellulaire in 4% of the cases, the hemorrhagic decompensation in 10%, the refractory ascites in 19% and hepatic encephalopathy in 12%. Intrahospital mortality was of 11.5%.

**Conclusion:** In our series the Budd-Chiari accounted for 3.9% of the PHT, it interested primarily the young subject of the female sex. The hepatic thrombosis of the veins known accounted for 71% of the patient with an assessment of thrombophilia disturbed in 21% of the cases and intrahospital mortality rather important of 11.5% of the cases

**Disclosure:** Nothing to disclose

## P0766 EFFICIENCY GAINS ASSOCIATED WITH A NEW CHRONIC HEPATITIS C TREATMENT PARADIGM IN PORTUGAL

Peixe P.<sup>1</sup>, Aragao F.<sup>2</sup>, Calinas F.<sup>3</sup>, Martins A.<sup>4</sup>, Marques N.<sup>5</sup>, Pedroto I.<sup>6</sup>, Serejo F.<sup>7</sup>, Valente C.<sup>8</sup>

<sup>1</sup>Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal, <sup>2</sup>Maple Health Group, New York, United States, <sup>3</sup>Centro Hospitalar de Lisboa Central EPE, Lisbon, Portugal, <sup>4</sup>Hospital Prof. Doutor Fernando da Fonseca, Amadora, Portugal, <sup>5</sup>Hospital Garcia de Orta, EPE, Serviço de Infecçiology, Almada, Portugal, <sup>6</sup>Centro Hospitalar Universitário do Porto, Oporto, Portugal, <sup>7</sup>Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal, <sup>8</sup>Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Contact E-Mail Address:** paulapeixe@gmail.com

**Introduction:** The current paradigm (CP) of chronic hepatitis C (CHC) treatment in Portugal is characterized by a lengthy process between diagnosis and treatment. The number of patients lost to follow-up (LTFU) within that period is a barrier to hepatitis C virus (HCV) elimination by 2030.

**Aims & Methods:** The objective of this analysis was to quantify the efficiency gains that could be obtained by changing to a new paradigm (NP) that minimizes time between diagnosis and treatment considering the population to be treated in the next 5 years in Portugal. A Microsoft Excel® model was developed to simulate patients' pathway from diagnosis to end of

treatment, quantifying time elapsed, LTFU, disease progression and costs (excluding HCV treatment costs) from the societal perspective. Four groups of patients were considered: people who inject drugs (PWID), incarcerated (INC), men who have sex with men (MSM) and general population (GP). Model inputs, specific to each subgroup, were obtained from the literature complemented by an expert panel. All patients were assumed to be treated for 12 weeks. The CP was compared to two scenarios: a simplification of complementary diagnosis tests at the specialist level (NP1) and NP1+a streamlined path to the specialist after a positive rapid HCV test.

**Results:** A total of 3,500 patients were estimated to be treated per year in the next 5 years. The majority were PWID (58.5%) followed by 23.5% from GP, 11.0% from MSM and 7.0% being incarcerated individuals. The CP comprised of 17 steps, 15 of which require the patient to physically attend a health care facility. LTFU in the CP was highest among PWID (40%) followed by INC (33%). The simplification of the CP would reduce the number of patient visits to 9 (NP1) or 6 (NP2). Out of 1,104 patients who would be LTFU per year under the CP, 7% would be retained in the NP1 and 71% in the NP2. Summary results comparing CP to NP1 and NP2 in terms of health outcomes and cost reductions, are detailed in Table.

Endpoint	Current Paradigm [CP]	New Paradigm 1 [NP1]	New Paradigm 2 [NP2]
Total process time from diagnosis to end of treatment	67 weeks	58 weeks	45 weeks
Proportion LTFU	32%	29%	7%
Patient time used (3,500 patients per year, 5 years)	23 years	15 years (-34%)	11 years (-55%)
Cirrhosis cases over 5 years	94	86 (-9%)	32 (-66%)
Total costs over 5 years	20.4 million €	15.8 million € (-23%)	14.6 million € (-29%)

[Results of simplifying the process from diagnosis to treatment]

**Conclusion:** Simplification of the current CHC treatment paradigm results in efficiency gains in terms of LTFU, reduction of advanced liver disease cases, reduction in medical costs and productivity gains.

**Disclosure:** This analysis received financial support from Gilead Sciences, Portugal.

## P0767 ESTIMATING PROPORTION OF CIRRHOSIS AND HEPATOCELLULAR CARCINOMA ATTRIBUTABLE TO HEPATITIS B AND C IN CLINICAL CENTRES IN SOFIA (BULGARIA) AND LISBON (PORTUGAL) - RESULTS FROM A EUROPEAN PILOT

Simões C.<sup>1</sup>, Simonova M.<sup>2</sup>, Mardh O.<sup>3</sup>, Duffell E.<sup>3</sup>, Quinten C.<sup>3</sup>, Pavlova S.<sup>2</sup>, Hadzhiolova T.<sup>2</sup>, Katzarov K.<sup>2</sup>, Cortez-Pinto H.<sup>1</sup>

<sup>1</sup>Hospital de Santa Maria, CHULN, Serviço de Gastreenterologia e Hepatologia, Lisbon, Portugal, <sup>2</sup>Military Medical Academy, Clinic of Gastroenterology, Sofia, Bulgaria, <sup>3</sup>European Centre for Disease Prevention and Control, Solna, Sweden

**Contact E-Mail Address:** carolinabaptistasimoes@gmail.com

**Introduction:** WHO set target to reduce mortality attributable to hepatitis B (HBV) and hepatitis C (HCV) by 65% by 2030. While national mortality data from cirrhosis (CIR) and hepatocellular carcinoma (HCC) exist, proportion of cases due to HBV and/or HCV are unknown. A study protocol was developed to calculate the attributable fraction of HBV, HCV and other risk factors for CIR and HCC in a standardised way and piloted in Sofia (Bulgaria) and Lisbon (Portugal).

**Aims & Methods:** All patients presenting with CIR and/or HCC at the national reference centre in Sofia during 2016-2017 and the first 100 sequential patients with CIR and 100 with HCC presenting at national reference centre in Lisbon during 2015-2016 were included. Cases with CIR and HCC were identified based on ICD-10 codes in Sofia and on clinical criteria in Lisbon. Patients diagnosed with both CIR and HCC were classified as HCC. HBsAg and anti-HCV positivity were considered markers for chronic HBV and HCV, respectively. When markers for both HBV and HCV were present, HCV-RNA existence defined the case as being attributable to HCV. When viral markers were absent, excessive alcohol consumption (>30 grs/day) or non-alcoholic-fatty liver disease (NAFLD) were considered main risk factors for CIR or HCC.

**Results:** Data for 518 CIR, 84 HCC cases were collected in Sofia and 100 CIR and 100 HCC in Lisbon. 70% of CIR and 80% of HCC cases in Sofia and 78% of CIR and 82% of HCC in Lisbon were males. 38% of CIR, 68%

of HCC in Sofia and 53% of CIR and 71% of CIR in Lisbon were  $\geq 60$  years. In both sites, distribution of CIR and HCC cases did not differ by gender (p Sofia = 0.07, p Lisbon = 0.48) but patients with HCC were significantly older (p Sofia = 0.00, p Lisbon = 0.03). In Sofia the main risk factors for CIR were: alcohol 46%, HBV 18%, HCV 16% and NAFLD 4% and for HCC: HBV 37%, HCV 25%, alcohol 8%, NAFLD 8%. In Lisbon main risk factors for CIR were: alcohol 56%, HCV 25%, HBV 6%, NAFLD 6% and for HCC: alcohol 46%, HCV 37%, HBV 9%, NAFLD 3%. Considerable overlap between risk factors was observed.

**Conclusion:** Viral hepatitis B and C were important risk factors for liver morbidity in both centres. The pilot demonstrated the feasibility of collecting data on viral hepatitis prevalence that can be used to estimate mortality attributable to HBV and HCV for monitoring elimination. Further consideration should be given to representativeness of samples collected from reference centres, assessment of cases with overlapping risk factors, data collection simplification.

**Disclosure:** Nothing to disclose

## P0768 A RETROSPECTIVE ANALYSIS OF NAFLD REFERRALS TO A PORTUGUESE TERTIARY HOSPITAL

Alves da Silva J.L.<sup>1</sup>, Falcão D.<sup>1</sup>, Guedes T.<sup>1</sup>, Garrido M.<sup>1</sup>, Maia L.<sup>2</sup>, Raquel da Silva Moreira T.<sup>3</sup>, Ferreira J.M.<sup>1</sup>, Pedroto I.<sup>4</sup>

<sup>1</sup>Centro Hospitalar Universitário do Porto, Gastroenterology, Porto, Portugal,

<sup>2</sup>Centro Hospitalar do Porto, Gastroenterology, Porto, Portugal, <sup>3</sup>Hospital Geral St.º António, Gastroenterologia, Porto, Portugal, <sup>4</sup>Centro Hospitalar Universitário do Porto, Porto, Portugal

**Contact E-Mail Address:** joana.ines.silva@gmail.com

**Introduction:** Nonalcoholic Fatty Liver Disease (NAFLD) is a common cause for increased values in liver blood tests and abdominal ultrasound findings, in the primary care (PC) setting. Advanced fibrosis is a significant predictor of long-term complications and mortality. Accordingly, a major focus of clinical care for patients with NAFLD should be the determination of those at highest risk for the complications of advanced liver disease, pointing out the PC critical role for identification, risk stratification and adequate referral.

**Aims & Methods:** The purpose of this paper is to assess the referral letters for Hepatology appointments of NAFLD patients in a tertiary hospital. In Portugal, referral letters are in the form of an electronic free text paper. Retrospective assessment of referral letters (RL) for first Hepatology appointments between January 2016 and December 2018.

**Results:** A total of 975 patients were referred to Hepatology appointments, with 121 NAFLD diagnosed (12.4%), a growing number in the three years of this study.

Within NAFLD patients, 52.9% are men, with an average age of 56. The main reasons for NAFLD patients referrals were: *altered liver blood tests and steatosis on abdominal ultrasound* (31.4%); *altered liver blood test* (23.9%); *steatosis in abdominal ultrasound* (12.4%). Only 5 RL (4%) made reference to the calculation of the NAFLD Fibrosis Score (NFS) and none mentioned the Fibrosis-4 (FIB4). Immunologic and virologic studies were mentioned on 12.4% RL.

Upon first observation in the Hepatology appointment, 63.3% of patients had a NFS predicting absence of significant fibrosis, 26.5% an undetermined NFS and 10.2% with an NFS predicting advanced fibrosis. Liver biopsy was performed in 27 patients, with findings of fibrosis score F3-F4 in 12 of them (10% of the population).

Currently, 61.4% maintain follow-up in Hepatology appointments and 33% were discharged to the PC setting. From the ones discharged, 24.2% had a normalization of the blood tests after risk factor management. The average number of appointments was 2.69 and 4% were discharged on the first appointment.

**Conclusion:** In a population of NAFLD patients referred to Hepatology appointments in a tertiary hospital, most had a NFS predicting low risk fibrosis. Only a small percentage of RL mentioned this, which may translate an overuse of speciality appointments.

As the growing prevalence of NAFLD, an effective hospital response for clinical management of NAFLD implies a communication within the medical community for the development of significant transformations. Using stratification methods such as NFS was shown cost-effective and as such it should be increasingly used in the PC setting. Creating referral protocols is an efficient way of promoting the use of such tools.

**Disclosure:** Nothing to disclose

## P0769 FIBROBLAST GROWTH FACTOR 19 STIMULATION BY THE FARNESOID X RECEPTOR AGONIST EYP001 IN HUMAN ILEAL EXPLANTS

Sadiq F.<sup>1,2</sup>, Radreau-Pierini P.<sup>3</sup>, Darteil R.<sup>3</sup>, Scalfaro P.<sup>3</sup>, Meldrum E.<sup>3</sup>, Vonderscher J.<sup>3</sup>, Walters J.R.E.<sup>1</sup>

<sup>1</sup>Imperial College London, Division of Digestive Diseases, London, United Kingdom, <sup>2</sup>Shifa Tameer-e-Millat University, Islamabad, Pakistan, <sup>3</sup>ENYO Pharma SA, Lyon, France

**Contact E-Mail Address:** julian.walters@imperial.ac.uk

**Introduction:** The farnesoid X receptor (FXR) is expressed in the liver and intestine at high levels. Among its actions, it is important in regulating multiple steps in the enterohepatic circulation of bile acids which are important for cholestatic diseases and in bile acid diarrhoea. It has previously been demonstrated that transcription of fibroblast growth factor 19 (FGF19) is one of the most potently stimulated effects regulated by FXR. Ileal FGF19 is important for the regulation of hepatic bile acid synthesis. EYP001 is a selective, synthetic, non-bile acid FXR agonist, which is being developed for several liver and intestinal diseases. EYP001 has been shown to be safe and well-tolerated and to stimulate serum FGF19 levels, together with inhibition of markers of hepatic bile acid synthesis and bile acid levels.

**Aims & Methods:** The aim of this study was to determine the FXR-dependent effects of EYP001 in human ileum. Normal human ileal mucosal biopsies were obtained at routine ileo-colonoscopy. Incubations were performed for 6h with EYP001 or with negative or positive (chenodeoxycholic acid, CDCA) controls. RNA was extracted and transcript expression measured by QRT-PCR. FGF19 protein was measured in the culture fluid by ELISA.

**Results:** FGF19 transcripts were potently stimulated by EYP001 (50  $\mu\text{mol/L}$ ) with a median 1400-fold increase (p=0.012, n=8). This was 1.2x more potent than CDCA (50  $\mu\text{mol/L}$ ). EYP001 at 10  $\mu\text{mol/L}$  was about 25% as active; 100  $\mu\text{mol/L}$  was not more potent. Expression of other FXR-responsive genes SHP, OST $\alpha$  and FABP6 was increased about 4-fold by EYP001, much less than the 1000-fold changes found with FGF19. ASBT was not significantly affected. FGF19 protein was also stimulated significantly by EYP001.

**Conclusion:** These studies have shown that EYP001 is a potent FXR agonist in human ileal mucosal explant culture, stimulating FGF19 transcript levels and protein production. These findings justify further studies of EYP001 in human diseases where a response to FXR agonists is predicted such as in bile acid diarrhoea.

**Disclosure:** PRR, RD, PS, EM, JV are employed by Enyo. FS and JW have received grant funding from Enyo

## P0770 THE INFLUENCES OF EST AND ANTIBIOTIC TREATMENT ON THE BILIARY MICROBIOTA OF CHOLEDOCHOLITHIASIS PATIENTS

Shen H.<sup>1</sup>, Ye F.<sup>2</sup>, Zhang X.<sup>1</sup>

<sup>1</sup>Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Gastroenterology Internal Medicine, Hangzhou, China, <sup>2</sup>Institute of Biomedicine of East China, Disease Prevention and Control, Nanjing, China

**Contact E-Mail Address:** sakshen@126.com

**Introduction:** The number of samples involved in previous studies of the bile duct microbiota in cholelithiasis patients is relatively small, thus a comprehensive understanding of the biliary microbiota is still lacking. In addition, the influences of endoscopic sphincterotomy (EST) and pre-operative use of antibiotics on the biliary bacterial community still remain unclear.

**Aims & Methods:** Bile samples (obtained by ERCP from the common bile duct) and clinical data of 121 patients were collected. The samples were divided into 4 groups (NN: with no antibiotic use and no history of EST, n = 31; NE: with no antibiotic use but with a EST history, n = 20; AN: with antibiotic use but no EST history, n = 55; AE: with antibiotic use and EST history, n = 15). Based on 16S rDNA sequencing method, the putative impacts of EST and antibiotics on the biliary microbiota were investigated.

**Results:** The NN samples had a distinguished bacterial profile from those of the NE group, with 20 genera having differential relative abundances among the two groups, which thus might be related with relapse of the common bile duct stones.

Moreover, the history of EST could affect the beta-diversity rather than alpha-diversity of the biliary microbiota of patients without antibiotic treatment. The predicted KEGG pathways were also altered in NN and NE

samples, of which the majority were related with metabolic pathways. Antibiotic treatment had diverse effects on the composition of the biliary microbiota, which were characterized by different or fluctuant variance patterns of some specific genera. Regardless of the antibiotic type and treatment course, a panel of bacterial taxa, including *Escherichia/Shigella*, *Fusobacterium*, *Neisseria*, *Haemophilus*, *Aeromonas* and *Porphyromonas*, were always observed to have differential relative abundances in the samples receiving antibiotics relative to those without preoperative treatment. Notably, after antibiotic treatment, the alpha-diversity indexes were significantly increased in treated samples than the rest ones, which was different from the results obtained from the gut microbiota. Meanwhile, the potential interactions among biliary bacteria as well as the predicted profiles of KEGG orthologies were also affected by the introduction of antibiotics.

**Conclusion:** The compositions of the biliary bacterial community could be impacted by both routine EST operation and the use of antibiotics, which suggested the possibility of optimizing the therapy methods. And further in-depth exploration of the pathogenic mechanism of the biliary bacterial flora in choledocholithiasis should benefit the treatment of patients.

**Contact E-Mail Address:** yucelustundag@yahoo.com.tr

**Introduction:** Cholestasis can present with jaundice and intense pruritus, the pathophysiology of which is unclear. Data from the relevant studies indicated that hepatic mast cells have potential roles in progression of cholestasis and cholestasis induced itch such as elevated total blood histamine concentration in bile duct ligation (BDL) models of cholestasis, activation of mast cells by bile acids, increased skin mast cell accumulation in jaundiced animals and decreased biliary hyperplasia in cholestatic rodents after mast cell stabilizer; cromolyn sodium administration. In this study, we aimed to compare the effects of cromolyn sodium and other various therapeutic agents on serum biochemistry, serum histamine, total bile acids, autotaxin levels, liver histopathology and mast cell distribution in the liver, skin and peritoneum in experimental cholestasis induced by BDL in rats. We also aimed to investigate its efficacy on cholestatic pruritus and to compare the effectiveness with a group of therapeutic agents used in this area.

**Aims & Methods:** Sixty-nine male rats of Sprague Dawley, weighing between 193-296 grams, were randomly divided into 8 groups. We weighed the rats preoperatively and applied the determined treatment every day consecutively for 10 days after the surgery. The BDL was not performed during the laparotomy and no medical treatment was given to the sham group (n=9). The control group (n=12) underwent BDL and intraperitoneal (ip) saline was given as the treatment. BDL was applied to the other 6 groups. Group 1 (n=9) received ip cromolyn sodium, group 2 (n=8) received ip chlorpheniramine maleate, group 3 (n=8) received oral sertraline, group 4 (n=8) received ip ondansetron, group 5 (n=7) received oral ursodeoxycholic acid and lastly group 6 (n=8) received ip naloxone. On the fifth and tenth days of the experiment, subjects were observed for 5 minutes in terms of itching behavior. After 10 days, the rats were weighed and blood samples were taken under general anesthesia. Lastly, tissue (skin-subcutaneous, peritoneal membrane, liver) samples were taken for histopathological studies with sacrifice.

**Results:** Other than groups 2 to 6, the significant decreases in all parameters including serum histamine and autotaxin levels, plasma total bile acids, total and direct bilirubin concentrations, alkaline phosphatase and gamma-glutamyl transpeptidase measures were observed only in group

1 compared to the control group ( $p<0.05$ ). When liver specimens were evaluated histopathologically; portal inflammation, lobular inflammation, bile duct proliferation, necrosis and fibrosis were significantly improved in group 1 and 3 ( $p<0.05$ ). We identified increased mast cell accumulation in the liver, the skin and the peritoneum in the control group. Only in group 1, liver and peritoneal mast cells were significantly decreased compared to the control group ( $p=0.003$ ,  $p=0.004$ , respectively), whereas the decrease in skin mast cells was not significant ( $p=0.09$ ). On the fifth and tenth days of the experiment, the mean duration of the rat's itching was significantly lower in all groups compared to the control group ( $p<0.05$ ). Duration of the itching was observed to increase in the control group from day 5 to 10 and the itching period was detected to decrease in Group 1, 2, 4 and 5.

**Conclusion:** Our study has shown that cromolyn sodium has promising anti-pruritic efficacy and has provided biochemical and histopathological recovery in the relevant parameters of cholestasis in the animal model.

### P0772 UTILITY OF SEHCAT SCAN IN EVALUATION OF CHRONIC DIARRHEA

Nigam G., Bhandare A.P., Trimarco L., Sharma R.K.

Pennine Acute NHS Trust, Gastroenterology, Manchester, United Kingdom

**Contact E-Mail Address:** gaurav.nigam@nhs.net

**Introduction:** SeHCAT scan, is an essential diagnostic modality for bile acid malabsorption (BAM). The British Society of Gastroenterology (BSG) recommends use of this test for identifying BAM in diarrhoea-predominant irritable bowel syndrome (IBS-D) and people with Crohn's disease (CD) without ileal resection.<sup>1</sup> However, its use for evaluation of chronic diarrhoea and its cost-effectiveness to the National Health Service (NHS) is subject to further evidence. We aim to demonstrate the utility of this investigation in patients with chronic diarrhoea classifying them into different associated gastrointestinal (GI) conditions.

**Aims & Methods:** We retrospectively analysed SeHCAT scans done over a period of 1 year. This data was further classified based on their association with diarrhoea predominant irritable bowel syndrome (IBS-D), Crohn's disease (CD), ulcerative colitis (UC), post-cholecystectomy, celiac disease and chronic pancreatitis (CP). The patients with CD were further sub-categorised and analysed.

**Results:** Total patients included were 122 with 72.1% (n=88) females, average age 49.6 years (range 81 -17). BAM was present in 50% (n=61) of those evaluated. Positive cases were classified as mild (21.3%, n=13), moderate (23%, n=14) and severe (55.7%, n=34). On analysis of prevalence of BAM based on associated GI conditions it was found 70.3% of 37 patients with CD had the condition. Similarly the prevalence of BAM noted in other groups were 42.3% of 26 IBS-D, 55.5% of 27 Post-cholecystectomy, 33.33% of 6 UC, 60% of 5 CP. We had only one patient with celiac disease and was found to have BAM. There were 16 patients who did not have a GI diagnosis but were evaluated for chronic diarrhoea with a SeHCAT scan. Three of these were diagnosed to have BAM. Of the 37 CD patients 18 had CD without ileal disease, 72.2% (n=13) having BAM. Nine had ileal involvement (Montreal L1 or L3) and 66.7% (n=9) with BAM. Seven of the CD patient had previous ileal resection and 71.4%(n=5) were positive for BAM. Similarly 3 CD patients had other colonic surgery and BAM was noted in 66.7% (n=2).

**Conclusion:** We noted that SeHCAT scan is a useful test for evaluation of chronic diarrhoea in conditions with high pre-test probability. If done earlier in suspected cases it saves the cost of undergoing more investigations for chronic diarrhoea. Our analysis also indicated that in inflammatory bowel disease (IBD), especially CD, regardless of the location phenotype and surgical history, BAM was noted with equal prevalence. Further studies with larger dataset are needed to identify the utility and cost-effectiveness of SeHCAT scan in diagnostic algorithm for chronic diarrhoea.

## P0773 THE IMPORTANCE OF 24 BILE ACIDS IN LIVER BILE OF BENIGN AND MALIGNANT BILIARY STENOSIS

Rejchrt S.<sup>1</sup>, Hroch M.<sup>2</sup>, Repak R.<sup>1</sup>, Fejfar T.<sup>1</sup>, Douda T.<sup>1</sup>, Peterova E.<sup>1,2</sup>, Bures J.<sup>1</sup>

<sup>1</sup>Charles University Faculty of Medicine and University Hospital, 2nd Department of Internal Medicine - Gastroenterology, Hradec Kralove, Czech Republic, <sup>2</sup>Charles University Faculty of Medicine, Department of Medical Biochemistry, Hradec Kralove, Czech Republic

**Contact E-Mail Address:** rejchrt@lfhk.cuni.cz

**Introduction:** Differential diagnosis of benign and malignant biliary stenosis might be difficult. Histology of bioptic specimens is often indeterminate. Laboratory markers (serum bilirubin > 75 µmol/L, CA 19-9 > 400 U/ml) and the length of stenosis (> 15 mm) can be helpful but not specific enough (ref. 1). Only one study of altered bile composition has been published so far. Bile salts, phospholipids and cholesterol were significantly lower in 14 patients who developed non-anastomotic biliary strictures after liver transplantation (ref. 2).

**Aims & Methods:** The aim of our prospective study was to investigate 24 different bile acids in liver bile of patients with benign and malignant biliary stenosis and controls without stenosis.

A total of 73 patients entered the study: 7 subjects with benign biliary stenosis (6 men, 1 woman; 68±13 years old), 21 with malignant biliary stenosis (15 men, 6 women; 72±14 years old) and 45 patients without biliary stenosis (22 men, 23 women; 70±13 years old), out of those 25 subjects with and 20 without choledocholithiasis. Serum total bilirubin and C-reactive protein were investigated before ERCP. Samples of hepatic bile were collected from the common hepatic duct endoscopically (prior to contrast media use) and immediately frozen at -80 °C until the analysis. Twenty-four different bile acids were investigated by high-performance liquid chromatography / mass spectrometry: lithocholic, ursodeoxycholic, hyodeoxycholic, chenodeoxycholic (CDCA), deoxycholic, *alpha*- and *beta*-muricholic, hyocholic, obeticholic, glycolithocholic (GLCA), glyoursodeoxycholic (GUDCA), glychohyodeoxycholic, glychenodeoxycholic (GCDCA), glycodeoxycholic (GDCA), glycocholic (GCA), glyohyocholic, tauroolithocholic (TLCA), taoursodeoxycholic (TUDCA), taurohyodeoxycholic, taurochenodeoxycholic, taurodeoxycholic (TDCA), taumuricholic (TMCA), trihydroxycholestanic (THCA), taurocholic (TCA) and cholic (CA) acid.

**Results:** Serum total bilirubin was significantly higher in patients with malignant biliary stenosis compared with non-stenotic controls ( $p = 0.005$ ). Significant relationship ( $r > 0.7$ ) was found between several pairs of bile acids (GLCA-GDCA; GLCA-TLCA; GCDCA-GDCA; GCDCA-GCA; CDCA-CA; GUDCA-TUDCA; GDCA-TDCA; TCDCA-TCA; TMCA-THCA). Significantly lower bile acids concentrations in malignant biliary stenosis compared with controls without stenosis were found for GLCA (median 12.4, IQR 0 - 44.7 vs 32.1, 4.1 - 260.1 µmol/L;  $p = 0.032$ ), GUDCA (median 123.7, IQR 2.6 - 319.9 vs 259.2, 38.0 - 1247.0 µmol/L;  $p = 0.032$ ), GCDCA (median 4995.0, IQR 2404.9 - 9474.5 vs 2642.0, 308.7 - 5746.8 µmol/L;  $p = 0.006$ ), GDCA (median 381.0, IQR 8.9 - 1497.8 vs 1110.5, 135.9 - 4421.3 µmol/L;  $p = 0.031$ ), GHCA (median 8.0, IQR 2.7 - 14.6 vs 16.4, 10.3 - 33.8 µmol/L;  $p = 0.005$ ), TUDCA (median 19.2, IQR 0 - 58.8 vs 58.9, 9.5 - 152.8 µmol/L;  $p = 0.044$ ) and TDCA (median 118.3, IQR 7.1 - 321.6 vs 377.5, 79.8 - 930.7 µmol/L;  $p = 0.036$ ). Significant difference between benign and malignant stenosis was found for CA (median 97.8, IQR 5.8 - 465.9 vs 0, 0 - 20.4 µmol/L;  $p = 0.022$ ). Other results did not reach statistical significance.

**Conclusion:** Analysis of bile acids might be helpful in the differential diagnosis of malignant and benign biliary stenosis. However, more patients must be enrolled in the study in order to be able to evaluate the real diagnostic yield of bile acids monitoring.

The study was supported by the Research Project MH CZ - DRO (UHHK, 00179906).

**Introduction:** Biliary excretion from the liver to the intestinal tract, an excretion route in addition to the renal clearance via glomerular filtration, is an important biomedical phenomenon related to health and diseases such as jaundice, gallstone formation, and excretion of therapeutic drugs. We hypothesized that an emerging fluorescence imaging system in the wavelength range of over-thousand-nanometre (OTN) near-infrared (NIR), which allows deep bioimaging with high spatial resolution due to its less scattering by biological tissues [1-4], may be available to monitor the dynamic change of the biliary excretion.

**Aims & Methods:** The aim of the present study was to investigate the possibility of real-time monitoring of the biliary excretion using the *in vivo* deep OTN-NIR fluorescence imaging system in a non-clinical experimental (mouse) model. An OTN-NIR fluorescence dye IR-1061 (Sigma-Aldrich) was loaded into micelle nanoparticles (MNPs) composed of an amphiphilic polymer N-(carbonyl-methoxypolyethyleneglycol 2000)-1,2-distearoyl-sn-glycero-3-phosphoethanol-amine (DSPE-PEG<sub>2k</sub>) by a simple 'one-pot' procedure as described previously [5] with minor modifications.

The particle size of the prepared OTN-NIR fluorescence MNPs (OTN-MNPs) was 9 nm. The OTN-MNPs emit OTN-NIR fluorescence peaked at 1100 nm under 980-nm excitation.

After intravenous injection of the OTN-MNPs into 6-week-old mice under anesthesia, OTN-NIR fluorescence images of mice were observed by a portable NIR fluorescence *in vivo* imaging system SAI-1000 (Shimadzu). All animal care and experiments were carried out according to the guidelines on care and use of laboratory animals as stated by Tokyo University of Science.

**Results:** Following intravenous injection of the OTN-MNPs into mice, whole-body blood vessels were visualized using the proposed system. The OTN-MNPs were trapped by the reticuloendothelial system and mostly distributed to the liver within 60 min post-injection. The mice were fed a high-fat diet to enhance bile secretion, and after 90-180 min, OTN-NIR fluorophores are excreted from the liver with bile to the duodenum. We successfully imaged time-dependent dynamic change of distribution of the fluorophores encapsulated by the MNPs in the hepatobiliary route of live mice.

**Conclusion:** The OTN-MNP is useful for *in vivo* real-time imaging of hepatobiliary excretion with the OTN-NIR fluorescence imaging technique. This technique is useful for screening hepatobiliary excretion of administered substances and for monitoring of the bile excretion from the liver through the intestinal tract.

**Introduction:** Enteroendocrine L cells express the bile acid receptor Takeda-G-protein-receptor-5 (TGR5). Activation of TGR5 triggers the release of glucagon-like peptide 1 (GLP-1) and glucagon-like peptide 2 (GLP-2). Treatment with GLP-2 analogues, and to a lesser extent GLP-1, results in intestinotrophic effects and ameliorates intestinal injury in rodents.

**Aims & Methods:** In this study, we aim to investigate the contributions of the TGR5 receptor to glucagon-like peptide secretion and the impact on the intestinal architecture and healing response.

Female mice (n=8) were treated with the orally bioavailable TGR5 agonist RO5527239 (30 mg/kg) or vehicle twice daily for ten days and the intestinal parameters explored; including intestinal weight, morphometry and gut hormone analysis. In a subsequent study, GLP-2r KO mice (n=12) and their wild type littermates were either treated with RO5527239 (30 mg/kg) or vehicle twice daily for ten days and small intestinal weight was recorded. Finally, female mice (n= 8) received a single injection of the chemotherapy 5-fluorouracil (5-FU) (400 mg/kg) or saline and were treated with RO5527239 (30 mg/kg) or vehicle twice daily until sacrifice 72 h after 5-FU. Body weight and intestinal parameters were explored.

**Results:** Agonist treatment resulted in a significant increase in relative small intestinal weight ( $p < 0.0001$ ). Morphological changes were primarily located proximally leading to an increase in mucosa cross-sectional area and villus height in the duodenum ( $p < 0.01$ ). The large intestine was structurally unaffected but the concentration of intact GLP-1 and GLP-2 was increased in colonic tissue ( $p < 0.01$ ).

Agonist treatment resulted in an increase in relative small intestinal weight ( $p < 0.01$ ) in the wild type mice, which was not present in the GLP-2r KO mice. Agonist treatment of 5-FU treated mice resulted in an increase in villus height ( $p < 0.05$ ), crypt depth and a decrease in histological severity score.

**Conclusion:** This study shows that activation of the TGR5 resulted in small intestinal growth and the increased secretion of GLP-1 and GLP-2 from the colon. Additionally, TGR5 activation produced a growth response in the small intestine in a GLP-2 dependent manner and ameliorated 5-FU mucositis in mice. Taken together, this work suggests TGR5 as a potential target for alleviating intestinal injury through the stimulation of GLP-2 secretion.

**Introduction:** To prevent stent migration, transpapillary stent placement has been recommended for the endoscopic treatment of malignant hilar biliary stricture. However, placement above the papilla is currently favored because it is believed to prevent reflux of duodenal contents and prolong stent patency.

**Aims & Methods:** The aim of the current study was to compare the efficacies and safety aspects of transpapillary and suprapapillary stent placement. In addition, success rates of stent revision were evaluated with respect to stent location.

The medical records of 73 hilar cholangiocarcinoma patients that underwent endoscopic metal stent insertion between January 2005 and December 2015, were retrospectively reviewed. Patients were allocated by stent location to a suprapapillary group (S group; N=44) or a transpapillary group (T group; N=29). Clinical outcomes, durations of stent patencies, adverse events related to stent placement, and revision success rates in the two study groups were compared.

**Results:** Suprapapillary stent placement was performed in 44 patients and transpapillary placement was performed in 29. Patency periods were similar in the two groups (group S, 140 days; group T, 157 days;  $P = 0.476$ ). Rates of stent obstruction in the S and T groups were 38.4% and 21.9%, respectively ( $P = 0.470$ ). An adverse event related to stent insertion occurred in 15 (20.5%) of the 73 study subjects with no significant intergroup difference. The success rate of endoscopic revision was significantly higher in the T group ( $P = 0.01$ ), and the time required for revision tended to be shorter in the T group.

**Conclusion:** The effectiveness and safeties of suprapapillary and transpapillary stent insertion were found to be similar, but the success rate of endoscopic revision was significantly higher for transpapillary stent inser-

tion. Therefore, we recommend transpapillary stent placement be considered for patients with hilar cholangiocarcinoma and biliary obstruction.

## P0777 A POSITIVE LYMPH NODE RATIO-BASED NOMOGRAM STAGING SYSTEM TO PREDICT CANCER-SPECIFIC SURVIVAL FOR PATIENTS WITH RESECTED GALLBLADDER CANCER

Yan Y., Mao K., He C., Zhang J., Wang J., Xiao Z.

Sun Yat-Sen University, Hepatobiliary Surgery of Sun Yat-Sen Memorial Hospital, Guangzhou, China

**Contact E-Mail Address:** yanyc@mail2.sysu.edu.cn

**Introduction:** Gallbladder cancer (GBC) is one of the most aggressive malignant tumors with a poor long-term prognosis worldwide, and there is no effective and convenient method for predicting cancer-specific survival (CSS). Positive lymph node ratio (pLNR), but not the location or number of invaded nodes, independently predicts the surgical outcomes of patients who have undergone curative resection. We aim to analyze the significance of pLNR in GBC patients and develop a novel staging system based on a formulated nomogram for CSS.

**Aims & Methods:** A total of 1,356 patients with resected GBC were divided into a training set (n=904) in an earlier period and a validation set (n=452) thereafter. We used a univariate Cox regression analysis to screen for risk clinicopathological factors for CSS in the SEER discovery set. We further performed stepwise multivariate Cox regression analysis to screen for important independent factors for CSS. A competing risk model based on risk factors was evaluated by Cox multivariate analysis to ensure that they were related to CSS. A novel nomogram based on the pLNR for predicting CSS at 1 and 3 years was formulated with the other identified independent important factors. The SEER internal testing set was used to evaluate the predictive reliability and accuracy of the nomogram. The concordance index and calibration plots were used to evaluate model discrimination. The predictive accuracy and clinical value of the nomograms were measured by decision curve analysis (DCA). The CSS nomogram was further validated in an internal validation set.

**Results:** The 1-, 2- and 3-year CSS rates were 54.94%, 29.65%, and 15.12%, respectively, in the entire SEER cohort. The optimal cutoff value for pLNR determined by the maximum Youden index of the ROC curve was 0.08. According to the survival analysis, patients in the  $pLNR \leq 8\%$  group had a poorer CSS than those in the  $pLNR > 8\%$  group in the discovery set. pLNR was associated with histologic type, histologic grade, tumor size, tumor extension, N classification, M classification, TNM staging system, and distant organ metastasis (including bone, brain, liver and lung) by statistical significance. The pLNR was an independent prognostic factor for CSS based on Cox regression analyses. A prognostic nomogram that combined T classification, pLNR, M classification, histologic grade, liver metastasis and tumor size was formulated with a c-index of 0.763 (95% CI, 0.728-0.798), while the c-indexes for the staging system of AJCC 8th, the AJCC 7th, and the AJCC 6th for CSS prediction were 0.718, 0.718, and 0.717, respectively. The calibration curves showed perfect agreement. The DCA showed that the nomogram provided substantial clinical value. The nomogram (the AUCs of time-dependent ROC curve analysis for one, three, and five years were 0.693, 0.716, and 0.726, respectively) showed high prognostic accuracy.

**Conclusion:** Based on the clinical risk factors identified in a large population-based cohort, especially the pLNR, a robust prognostic predictor of CSS for resected GBC patients, we established the first practical formulated nomogram staging system that includes the T classification, pLNR, N classification, tumor size, histologic grade and liver metastasis. Moreover, the internal cohort validation results demonstrated that these nomograms performed very well and showed excellent discrimination compared with the AJCC 7th and 8th edition staging systems. Our nomograms were demonstrated to be clinically useful in a DCA, and they should therefore help clinicians generate better risk stratifications and formulate individual treatments.

## P0778 SUFFICIENT TISSUE ACQUISITION RATE OF PERORAL CHOLANGIOSCOPY-GUIDED FORCEPS BIOPSY

Onoyama T., Takeda Y., Yamashita T., Hamamoto W., Sakamoto Y., Koda H., Kurumi H., Matsumoto K., Isomoto H.  
Tottori University, Division of Medicine and Clinical Science, Department of Multidisciplinary Internal Medicine, Faculty of Medicine, Yonago, Japan

**Contact E-Mail Address:** golf4to@yahoo.co.jp

**Introduction:** Peroral cholangioscopy (POCS)-guided forceps biopsy (FB) is a commonly used method for diagnosing indeterminate biliary lesions and for the preoperative identification of the exact perihilar and distal margins of biliary tract cancer (BTC). However, POCS-FB may result in the acquisition of an insufficient amount of specimen at times. Therefore, we evaluated the sufficient tissue acquisition rate (TAR) and the factor affecting the sufficient TAR of POCS-FB for the biliary tract.

**Aims & Methods:** Patients who underwent POCS-FB for biliary disease between September 2016 and October 2018 at our hospital were enrolled retrospectively. We evaluated the sufficient TAR of POCS-FB for biliary lesion and that for non-stenotic bile duct. Sufficient tissue was defined as a specimen that allowed the evaluation of the histological finding of the biliary epithelium. A specimen that contained only interstitial tissue was deemed insufficient. Moreover, the factors affecting sufficient TAR of POCS-FB were evaluated. Subgroup analyses of age, sex, malignant biliary disease, the location of the biliary lesion, length of biliary stricture, macroscopic types of BTC, presence of acute cholangitis, level of serum total bilirubin, level of CEA, level of CA19-9, procedure time, EST, biopsy site, and previous biliary stenting before POCS were assessed to determine the sufficient TAR of POCS-FB. We carried out univariate analyses to assess the sufficient TAR, and factors with  $P < 0.1$  were included in the multivariate logistic regression analyses. The pathological diagnostic ability for BTC and the adverse event of the POCS-FB were also evaluated.

**Results:** We enrolled 47 patients with biliary disease and performed POCS-FB for biliary lesion and POCS-FB for non-stenotic bile duct in 40 and 36 patients, respectively. The malignant group included 12 patients with perihilar cholangiocarcinoma (CCA), 14 patients with distal CCA, one with intrahepatic CCA and one with cystic ductal carcinoma. The benign group included 9 patients with benign biliary strictures, 3 patients with immunoglobulin G subclass 4-associated sclerosing cholangitis, 3 patients with primary sclerosing cholangitis, 2 patients with drug-induced cholangitis, one with intraductal papillary neoplasm of the bile duct, and one with a peribiliary cyst. The sufficient TAR of POCS-FB for biliary lesions and that for non-stenotic bile duct were 86.4%, and 68.9%, respectively.

In the multivariate logistic regression analyses, age  $< 65$  years old (odds ratio 0.170, 95% Confidence interval [CI] 0.044-0.649,  $P = 0.004$ ) and previous biliary stenting before POCS (odds ratio 0.199, 95% CI 0.053-0.756,  $P = 0.017$ ) were the significant factors affecting the sufficient TAR of POCS-FB for biliary lesion. For non-stenotic bile duct, the biliary lesion in the distal bile duct (odds ratio 0.322, 95% CI 0.139-0.744,  $P = 0.008$ ), procedure time in 75 minutes or less (odds ratio 3.012, 95% CI 1.092-8.312,  $P = 0.033$ ), and EST (odds ratio 7.041, 95% CI 2.117-23.421,  $P = 0.002$ ) were the significant factors affecting the sufficient TAR of POCS-FB. Sensitivity, specificity, and accuracy of POCS-FB for BTC were 76.2%, 94.7%, and 85.0%, respectively. The adverse event rate of POCS-FB was 17.0%, including acute pancreatitis (8.5%), infection (cholangitis, 6.4%), and hemorrhage (2.1%).

**Conclusion:** The previous biliary stenting was a factor affecting low TAR of POCS-FB for biliary lesion. In the POCS-FB for non-stenotic bile duct, the presence of the lesion in the distal bile duct, the POCS-FB without EST, and the long procedure time of POCS were factors affecting low TAR.

**Disclosure:** Nothing to disclose

## P0779 EFFECTS OF SARCOPENIA AND BACKGROUND FACTORS ON ELDERLY BILIARY CANCER PATIENTS RECEIVING CHEMOTHERAPY

Meguro K.<sup>1</sup>, Hosono K.<sup>2</sup>, Watanabe S.<sup>1</sup>, Nakajima A.<sup>3</sup>  
<sup>1</sup>Yokohama Sakae Kyosai Hospital, Gastroenterology, Yokohama, Japan,  
<sup>2</sup>Yokohama City University Hospital, Department of Gastroenterology and Hepatology, Yokohama, Japan, <sup>3</sup>Yokohama City University Hosp. Dept. of Gastroenterology, Dept. of Gastroenterology, Yokohama, Japan

**Contact E-Mail Address:** meguo180@yahoo.co.jp

**Introduction:** Recently, as the number of elderly biliary tract cancer patients has increased, the opportunities for administering chemotherapy to these patients has also increased. On the other hand, sarcopenia is an important prognostic factors in various types of carcinoma, and it is possible that it may influence the treatment effectiveness. However, clinical trials of chemotherapy for biliary tract cancer often target patients up to the age of 75 years, but too few studies have been done on chemotherapy for the elderly with sarcopenia.

**Aims & Methods:** The aim of this study was to investigate the effects of sarcopenia and other background factors on treatment and prognosis in elderly biliary cancer patients who received chemotherapy. A retrospective analysis was performed on 46 patients aged 65 years or older who underwent chemotherapy for unresectable biliary tract cancer at two related institutions between November 2012 and April 2018. Sarcopenia was assessed by measurement of the psoas muscle index (PMI). PMI at the third lumbar spine level was calculated from prechemotherapeutic computed tomography images. Treatment-related factors included age, sex, medical history (hypertension, diabetes, dyslipidemia, cholelithiasis), Eastern Cooperative Oncology Group performance status (ECOG PS), tumor site, metastatic site, postoperative recurrence, chemotherapy regimen, body mass index, body fat composition, laboratory data (white blood cell, albumin, hepatobiliary enzymes, lactate dehydrogenase, C-reactive protein (CRP), serum tumor markers (CA19-9, CEA)). We also used the modified Glasgow Prognostic Score (mGPS), Platelet-Lymphocyte Ratio (PLR), and the CRP/Albumin Ratio (CAR) as an indicator of nutritional status. The associations between these clinical factors and overall survival (OS) and time to treatment failure (TTF) were determined using univariate and multivariate analysis. Furthermore, stratification was performed based on the presence or absence of sarcopenia, and the influence of sarcopenia on OS and TTF was similarly examined.

**Results:** The mean age of the patients was 75.9±5.5 years at the start of chemotherapy.

The univariate analysis showed that the significant factors affecting OS included sarcopenia, PS, lung metastasis, liver metastasis, CA 19-9, PLR, and CAR ( $p < 0.05$ ).

Next, a multivariate analysis using Cox proportional hazards regression showed that independent significant results were obtained for sarcopenia (HR 5.55 : 95%CI 1.96~15.94 :  $P = 0.0013$ ) and CAR (HR 3.04 : 95%CI 1.23~7.50 :  $P = 0.016$ ). Similarly, in TTF, the significant factors included sarcopenia, PS, CA 19-9, PLR, and CAR in univariate analysis, and independent significant results were obtained for sarcopenia (HR 2.85 : 95%CI 1.20~6.80 :  $P = 0.018$ ) in multivariate analysis. Finally, as a result of stratification according to the presence or absence of sarcopenia, significant differences from univariate analysis were seen in PS, lung metastasis, CRP, CA19-9, mGPS and CAR in OS, and PS, CRP, CA 19-9, mGPS and CAR in TTF.

**Conclusion:** In chemotherapy of elderly biliary tract cancer patients, the presence or absence of sarcopenia and the nutritional status are related to the treatment effect, and should be considered as potential markers to predict the outcome of chemotherapy. We suggest that maintenance of muscle mass and improvement of nutritional status may affect the effect of chemotherapy.

## P0780 DEVELOPMENT OF A BILIARY MULTI-HOLE SELF-EXPANDABLE METALLIC STENT FOR BILE TRACT DISEASES

Kobayashi M.

Yokkaichi Municipal Hospital, Gastroenterology, Yokkaichi, Japan

**Contact E-Mail Address:** makoto-kobayashi@outlook.com

**Introduction:** Uncovered stents used for malignant obstructions in the biliary tree, especially in the hilar area, are prone to obstruction by tumor ingrowths. In comparison, however, covered stents may block bile duct branches and are at risk of migration. We have developed a Multi-Hole Self-Expandable Metallic Stent (MHSEMS), with a hole in each cell, to prevent the obstruction of bile duct branches. In addition, the holes may prevent migration due to small ingrowths by reducing the tension of the membrane.

**Aims & Methods:** A MHSEMS has a hole in each stent cell on its covering membrane. When the stent is positioned in a junction connected by side branches, bile flows inside the stent through the holes in its covering membrane. Tumors may grow through these holes but may become suppressed due to the size of the ingrowth. As a result of low membrane tension caused by the holes, the placed stent becomes fixed to surrounding tissues and is prevented from migrating. Presently, the MHSEMS is available with two types of hole sizes: small and large.

In addition, a lasso attached to the distal end of the MHSEMS is helpful for stent removal. Even if an obstruction by a tumor ingrowth does occur, the silicone cover will protect the surrounding tissue and enhance any ablation effect, such as during endobiliary radiofrequency ablation (RFA), allowing the patient to be a candidate for such treatment. Using MHSEMS, we treated six patients with malignant biliary obstruction and one case with uncontrolled post-endoscopic sphincterotomy bleeding.

**Results:** We had a 100% success rate for stent deployment. Stent patency was also 100% successful. In addition, jaundice improved in all patients with a malignant stricture, while complications such as pancreatitis, bleeding and cholangitis did not occur. The mean patency duration was found to be 274 days. None of the six cases showed any stent migration. For post-endoscopic sphincterotomy bleeding, complete hemostasis was achieved and the stent was successfully removed after 2 weeks.

**Conclusion:** MHSEMS may be considered a hybrid-type stent, with characteristics that fall between those of UCSEMS and CSEMS. Thus, MHSEMS may be regarded as a promising new treatment option for benign and malignant bile duct strictures.

**Disclosure:** Makoto Kobayashi has a patent on the Multi-Hole Self-Expandable Metallic Stent (MHSEMS) with royalties paid by M.I.Tech Co., Ltd.

## P0781 PERORAL SINGLE OPERATOR CHOLANGIOSCOPY FOR INDETERMINATE BILIARY STRICTURES IN CLINICAL PRACTICE OF A TERTIARY REFERRAL CENTER: INSUFFICIENT DIAGNOSTIC ACCURACY AND A LIMITED CLINICAL IMPACT

de Vries B.<sup>1</sup>, van der Heide F.<sup>1</sup>, ter Steege R.<sup>2</sup>, Koornstra J.J.<sup>3</sup>,

**Introduction:** Peroral single operator cholangioscopy (pSOC) is considered to be a valuable diagnostic modality for indeterminate biliary strictures. 1. Nevertheless, the chosen measures of diagnostic accuracy for pSOC vary and the impact on patient management is scarcely reported. The aim of this study was to estimate diagnostic accuracy of pSOC visual assessment and targeted biopsies for indeterminate biliary strictures. Additional aims were to compare diagnostic accuracy pSOC with sequentially taken brush cytology and to assess the clinical impact of pSOC outcome on patient management.

**Aims & Methods:** A retrospective single center open label cohort study was performed for patients of 18 years and older who underwent pSOC for indeterminate biliary strictures between November 2007 and May 2017 with the Spyglass® or Spyglass DS® system. Indeterminate biliary strictures were defined as strictures of the intra- or extrahepatic bile duct without a mass detectable on abdominal imaging, in which conventional workup

was non-diagnostic and a clear explanation from the clinical context was lacking (e.g. no recent trauma or biliary surgery)<sup>2,3</sup>. Endoscopy and pathology reports were reviewed for results of brush cytology and pSOC visual impression and targeted biopsies. Diagnostic accuracy of pSOC was defined as sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) and compared to same parameters of brush cytology. Clinical impact was assessed by review of medical records and was classified in three categories; change, confirmation or no influence in patient management.

**Results:** A total of 76 patients were included, with primary sclerosing cholangitis being present in 40%. In 87% of patients prior ERCP was performed, combined with brush cytology in 59%. In 55% of patients a biliary stent was in situ and removed prior to pSOC procedure. A malignant stricture was diagnosed in 22 patients (30%), including 17 cholangiocarcinoma. The sensitivity, specificity, PPV and NPV for pSOC visual impression was 64%, 61%, 42% and 83%. For pSOC targeted biopsies, the sensitivity, specificity, PPV and NPV was 15%, 63%, 75% and 67%. In contrast, sequential brush cytology yielded a sensitivity, specificity, PPV and NPV of 47%, 92%, 73% and 81%. The clinical impact of pSOC outcome on patient management was limited, as it had no influence on management in 33% of patients and only resulted in change of management in 13% of patients.

**Conclusion:** In a population with a high prevalence of primary sclerosing cholangitis and prior biliary stents in situ, the diagnostic accuracy of pSOC for indeterminate biliary strictures was found to be inferior to brush cytology and had low impact on patient management.

## P0782 ROLE OF PERORAL CHOLANGIOSCOPY FOR DIAGNOSIS AND STAGING OF BILIARY TUMORS

Morais R.<sup>1</sup>, Santos S.<sup>2</sup>, Gaspar R.<sup>1</sup>, Rodrigues-Pinto E.<sup>1</sup>, Vilas-Boas F.<sup>1</sup>, Pereira P.<sup>1</sup>, Macedo G.<sup>1</sup>

**Introduction:** In the approach to biliary strictures it is important to establish a histopathological diagnosis. On the other hand, in the preoperative evaluation of malignant biliary lesions, intraductal extension may condition therapeutic approach. Peroral cholangioscopy (POC) has shown to be a useful diagnostic procedure in the evaluation of biliary strictures, however its role on preoperative staging has not been established.

**Aims & Methods:** The aim of our study was to evaluate POC role in the diagnosis and preoperative intraductal staging of extrahepatic biliary cancer. Retrospective cohort study that included all patients who underwent POC with SpyGlass™ Direct Visualization System (Boston Scientific) for diagnosis of biliary strictures or preoperative evaluation of extrahepatic biliary tumors, between January 2015 and January 2019, in a single tertiary center. The primary endpoint was to assess the accuracy, sensitivity and specificity of SpyGlass visual findings and SpyGlass-guided biopsy findings in the diagnosis of patients with biliary strictures. A final diagnosis of malignancy was made based on positive histopathology of SpyGlass-guided biopsy/other tissue sampling procedures or evidence of disease progression consistent with malignancy during at least a 6 months follow-up. The secondary endpoint was to evaluate the ability of POC to detect mucosal cancerous extension preoperatively in possibly resectable peri-hilar cholangiocarcinoma (CCA) and the changes on surgical approach based on findings. In all malignant cases, we compared previous imagiologic anatomic classification with that accessed with POC. Anatomic classification was based on Bismuth-Corlette Classification (BCC).

**Results:** Forty-three patients were included, 63% male with a median age of 62 years (IQR 53-72). Thirty-eight (88.3%) underwent POC due to indeterminate biliary strictures, 3 (7%) due to bile duct filling defect and 2 (4.7%) for intraductal staging of perihilar CCA. In the follow-up, a final

diagnosis of malignancy was established in 56%. Visual impression accuracy with *SpyGlass* was 95% (100% sensitivity and 90% specificity). *SpyBite* biopsies accuracy was 81% (67% sensitivity and 100% specificity). In the 19 patients with a final perihilar CCA diagnosis, intraductal evaluation with *SpyGlass* altered anatomic classification (BBC) defined by previous imagiologic findings in 8 (42.1%) patients (BCC 3a to 4, n=3; BCC 2 to 4, n=3; BCC 2 to 3a, n=2). In 2 cases, a resectable BCC type 2 was a type 3a based on *SpyGlass* examination, which modified the surgical approach from a bile duct resection (BDR) to a BDR with right hepatic lobectomy. In 3 cases, a previous BCC type 2 lesion was reclassified as BCC type 4 on *SpyGlass* approach and in two of these cases the lesions were considered irresectable.

The remaining 3 patients were previous classified as a BCC type 3a based on imagiologic findings and were actually a BCC type 4 on *SpyGlass* examination. One patient previously considered candidate for surgical resection was deemed irresectable.

Although, TNM data was missing in another, was considered irresectable and was referred for palliative biliary stent. The remaining case was irresectable, so there was no change on therapeutic approach after POC.

**Conclusion:** POC was useful in the diagnostic evaluation of biliary stenosis. Its use in potentially resectable cases of CCA was important to establish best therapeutic approach. In the future, preoperative staging of perihilar CCA with POC combined with imagiologic evaluation of vascular extension of the lesions may optimize surgery results.

**Introduction:** Digital single-operator cholangioscopy (DSOC) (*SpyGlass* DS™, Boston Scientific, MA, USA) allows for high-definition imaging of the biliary tree. The superior visualization has led to the development of two different sets of criteria to evaluate and classify indeterminate biliary strictures: the Monaco criteria and the criteria in Carlos Robles-Medrand's publication (CRM). Our objective was to assess the interrater agreement (IA) of DSOC interpretation for indeterminate biliary strictures using the two newly published criteria.

**Aims & Methods:** 40 de-identified DSOC video clips were sent to 15 interventional endoscopists with experience in cholangioscopy. They were asked to score the videos based on the presence of Monaco Classification criteria: stricture, lesion, mucosal changes, papillary projections, ulceration, white linear bands or rings, and vessels. Next they scored the videos using CRM criteria: villous pattern, polypoid pattern, inflammatory pattern, flat pattern, ulcerate pattern and honeycomb pattern. The endoscopists then diagnosed the clips as neoplastic or non-neoplastic based on the criteria. Intraclass correlation (ICC) analysis was done to evaluate interrater agreement for both criteria sets and final diagnosis.

**Results:** Clips of 26 malignant lesions and 14 benign lesions were scored. The IA using both the Monaco criteria and CRM criteria ranged from poor to excellent (range 0.1 to 0.76) and (range 0.1 to 0.62) respectively. Within the Monaco criteria, IA was excellent for lesion (0.75) and fingerlike papillary projections (0.74); good for tortuous vessels (0.7), mucosal features (0.62), uniform papillary projections (0.53), and ulceration (0.58); and fair for white linear bands (0.4). Within the CRM criteria, the IA was good for villous pattern (0.62), flat pattern (0.62), and honeycomb pattern; fair for ulcerated pattern (0.56), polypoid pattern (0.52) and inflammatory pattern (0.54). The diagnostic IA using Monaco criteria was good (0.65), while the diagnostic IA using CRM was fair (0.58). The overall diagnostic accuracy using the Monaco classification was 61% and CRM criteria was 57%.

**Conclusion:** The IOA and accuracy rate of DSOC using visual criteria from both Monaco Criteria and CRM are similar. However, some criteria from both sets suffer from poor IA, thus affecting the overall diagnostic accuracy. More formal training and refinements in visual criteria with additional validation are needed to improve diagnostic accuracy.

**Introduction:** Endoscopic papillectomy is widely used for the curative treatment of ampulla of Vater tumors replacing surgical resection. However, there are scarce data on the treatment outcome in tumors with high-grade adenoma or early adenocarcinoma. The aim of this study was to evaluate the outcome after endoscopic papillectomy of ampullary tumor with high-grade adenoma or early adenocarcinoma.

**Aims & Methods:** From January 2005 to December 2018, all the patients underwent endoscopic papillectomy as an initial curative treatment for ampullary high-grade adenoma or early adenocarcinoma at Seoul National University Hospital were retrospectively reviewed. The patients who were confirmed with high-grade adenoma or early adenocarcinoma were recommended to undergo subsequent surgical resection. Patients who refused to undergo surgery were followed up at 1 month with endoscopy. If residual tumor was identified at follow up endoscopy, it was considered as incomplete resection, and progression free survival of patients without incomplete resection was evaluated.

**Results:** A total of 230 endoscopic papillectomy were performed during study period. Among them, 80 were high-grade adenoma or adenocarcinoma (46 high-grade adenoma and 34 adenocarcinoma). One patient with adenocarcinoma was died after the procedure related complication (massive hemorrhage). Within 1 month after the procedure, 13 patients received subsequent surgical resection and presence of residual tumor on surgical specimen was 9 of 13 (69.2%). 21 patients had residual tumor on follow up endoscopy (incomplete resection rate of 35%) and 6 patients were lost to follow up. Total recurrence was 13 cases during the follow up period. Median progression free survival of patients without incomplete resection (n = 39) were 963 days (95% confidence interval, 525 - N/A).

**Conclusion:** Incomplete resection rate and probability of remaining tumor in surgical specimen were remarkably high after the endoscopic papillectomy of ampullary high-grade adenoma or early adenocarcinoma. In addition, tumors recurred frequently in long-term follow-up even after the complete resection. Endoscopic papillectomy should be cautiously applied in ampullary tumor with high-grade adenoma or early adenocarcinoma.

**Introduction:** Mitochondrial dysfunction has crucial role in the development of acute pancreatitis (AP), however the accurate molecular mechanism is not known yet.

**Aims & Methods:** In this study we investigated a possible molecular target - the genetic and pharmacological inhibition of mitochondrial transition pore (mPTP, which has a regulator unit; the Cyclophilin D (Cyp D)) in the aspect of AP. Pancreatic ducts (PD) and acinar cells were isolated by enzymatic digestion from Bl/6 wild type or Cyp D knock out (Cyp D KO) mice. In vitro measurements were performed by confocal and microfluorometry. AP was induced by cerulein (10x50µg/kg) or taurocholic acid (2ml/kg, 4%). As a non immunosuppressant pharmacological inhibitor of Cyp D: NIM811 were used (in vitro -2µM, in vivo - 5mg/kg or 10 mg/kg NIM811).

**Results:** Genetic and pharmacologic inhibition (NIM811, cyclosporinA) of Cyp D significantly reduced the loss of Δψ (in PD and acinar cells) and protected PDs HCO<sub>3</sub><sup>-</sup> secretion during the administration of 500µM chenodeoxycholic acid (CDC) or 100 mM ethanol (EtOH) and 200µM palmitoleic acid (PA) treatment (p< 0.05). Immunofluorescence measurements revealed a significant difference in the amount of the mitochondrial protein TOM20 levels between the CDC and the EtOH+PA treated WT and mPTP inhibited (Cyp D KO or CYA/NIM811) groups (PD and acini). We detected significantly reduced apoptosis, necrosis levels in Cyp D KO and NIM811 treated groups compared to WT controls (PD and acinar cells).

Significantly reduced oedema, necrosis, leukocyte infiltration, serum amylase and in vivo ductal fluid secretion levels were detected in samples from Cyp D KO animals or NIM811 treated animals (p< 0.05) compared to WT controls in vivo.

**Conclusion:** Our data highlights a potential new pharmacological target; the NIM811 which reduced the severity of AP in mice. Our results also revealed that protecting mitochondrial homeostasis have a central role in the function of pancreatic ductal epithelial cells presumably by providing ATP for fluid and ion secretion. These data suggests that NIM811 could open up new perspectives in the treatment of AP.

### P0786 NOCICEPTIN RECEPTORS AS A NOVEL TARGET FOR THE TREATMENT IN ACUTE PANCREATITIS

Tarasiuk A., Fichna J.

Medical University of Lodz, Department of Biochemistry, Lodz, Poland

**Contact E-Mail Address:** jakub.fichna@umed.lodz.pl

**Introduction:** The pathophysiology of experimental acute pancreatitis (AP) consists of the activation of pancreatic enzymes within acinar cells, the release of the activated enzymes in the interstitium, the autodigestion of the pancreas, and the release of activated pancreatic enzymes and other factors into the circulation that result in the development of multiple organ dysfunction. Current treatment options are limited, and predominantly aimed at supportive therapy. Better understanding of the underlying pathophysiology of AP may lead to more targeted therapeutic options, potentially leading to improved survival. In general, the effects mediated by the nociceptin receptors (NOP) on gastrointestinal functions resemble those of classic analgesic opioid agonists and nociceptin, the endogenous NOP agonist, has been reported to play an important role in the regulation of pancreatic exocrine secretion.

**Aims & Methods:** The primary aim was to examine the potential role of NOP in AP.

The AP mouse model was induced by the intraperitoneal (i.p.) administration of the L-arginine solution followed by second i.p. injection after 1h (dose 400mg/100g body weight (BW)). After 12h from the first L-arginine i.p. injection, mice were divided into 3 experimental groups: AP mice treated with a potent and selective NOP agonist (SCH 21510, i.p. injection every 12h; 1 mg/kg BW), AP mice treated with a potent and selective NOP antagonist ((±)-J 113397, i.p. injection every 12h; 12 mg/kg BW), and non-treated AP mice (injected with equivalent volume of 0.9% NaCl every 12h). Control mice were injected with equivalent volume of 0.9% NaCl. Mice were kept under observation, allowed free access to feed and water, and sacrificed at 72h. Pancreatic and lung tissues were collected for histology in 10% buffered formalin or snap frozen in liquid nitrogen for myeloperoxidase (MPO) analysis.

**Results:** Treatment of mice with SCH 21510 did not influence histopathological changes or the MPO activity in pancreas and lungs while (±)-J 113397 reduced pancreatic injury and MPO activity, as well as inhibited pancreatitis-associated lung injury.

**Conclusion:** The results of the present study showed that the modulation of NOP through selective NOP antagonist ((±)-J 113397 significantly decreased AP symptoms and for that reason the receptor may be considered as a novel treatment target in AP.

**Introduction:** The exocrine and endocrine pancreas work in close interaction with each other in which the CFTR Cl<sup>-</sup> channel plays an essential role by regulating ductal secretory processes and, as shown by some studies, β-cell insulin secretion. The role of the channel under certain pathological conditions is not completely known, therefore our aim in this study was to investigate the exocrine and endocrine functions in diabetes- or pancreatitis-induced wild-type (WT) and CFTR knock out (KO) mice.

**Aims & Methods:** Intra-interlobular pancreatic ductal fragments were isolated from WT and CFTR KO mice by enzymatic digestion. Pancreatic ductal fluid and HCO<sub>3</sub><sup>-</sup> secretion was measured by in vivo fluid secretion measurements and fluorescence microscopy. Islet functions during i.p. glucose tolerance test were investigated by serum insulin and glucagon measurements. Pancreas tissue sections were prepared and immunohistologically stained against insulin, glucagon and CFTR to observe islet and ductal morphology. Pancreatitis was induced by i.p. injection of cerulein and disease severity was assessed by evaluation of histological sections and serum amylase measurements. Diabetes was induced by i.p. administration of streptozotocin and disease development was confirmed by glucose tolerance test.

**Results:** Pancreatic ductal fluid and HCO<sub>3</sub><sup>-</sup> secretion significantly increased in diabetic and decreased in pancreatitis induced mice. Serum levels of insulin decreased in diabetic animals, whereas the serum levels of glucagon were elevated. The absence of CFTR decreased ductal fluid and HCO<sub>3</sub><sup>-</sup> secretion and resulted in lower serum insulin and higher glucagon levels. Immunohistological staining of insulin and glucagon in pancreas tissue sections revealed a morphological change in CFTR KO islets with higher content of α-cells that localized towards the center. Diabetic animals did not show difference in CFTR expression compared to the control group, whereas mice with pancreatitis showed less staining of intercalated and intralobular ducts.

**Conclusion:** Our results suggest that CFTR Cl<sup>-</sup> channel plays a key role in ductal HCO<sub>3</sub><sup>-</sup> secretion and has a direct or indirect role in islet function and structure.

**Contact E-Mail Address:** tel.balint@gmail.com

**Introduction:** Numerous case-reports and observational studies suggest that several medications, such as azathioprine (AZA) and 5-aminosalicylic acid (5-ASA), can induce acute pancreatitis. The important role of pancreatic ducts in the pathomechanism of acute pancreatitis has been highlighted recently. Pancreatic ductal functions are essential for the homeostasis and integrity of the pancreas. Toxic factors, such as alcohol or bile acids, can impair the ductal HCO<sub>3</sub><sup>-</sup> secretion which can ultimately lead to pancreatic injury. Our knowledge about pancreatic ductal functions in drug induced pancreatitis is, however, limited. Since medications can also act as toxic factors, we wanted to investigate what effects do AZA and 5-ASA have on pancreatic ductal functions and HCO<sub>3</sub><sup>-</sup> secretion.

**Aims & Methods:** For investigation of *in vivo* effect of drugs C57BL6 mice were fed daily with 15 and 150 mg/kg AZA, as well as 50 and 500 mg/kg 5-ASA by gastric feeding needle for one and four weeks. Control mice received 10 ml/kg 0.9% NaCl solution. Mice were euthanized and pancreatic ductal segments were isolated with microdissection technique. Changes in intracellular pH was estimated using a fluorescent dye, BCECF-AM. Cells were incubated with 2 µM BCECF-AM in standard Hepes solution for 30 min at room temperature. To determine HCO<sub>3</sub><sup>-</sup> secretion rates and activity of basolateral transporters (NHE and NBC), we used the ammonium pulse method. Pancreatic ducts from non-treated animals were also isolated and HCO<sub>3</sub><sup>-</sup> secretion was assessed under normal conditions and under acute perfusion with solutions containing different concentrations of AZA and 5-ASA.

**Results:** In the presence of either 1 or 10 µg/ml AZA or 5-ASA the regeneration from alkalosis was significantly lower compared to control ducts, which means that either AZA or 5-ASA in 1 and 10 µg/ml concentrations can inhibit HCO<sub>3</sub><sup>-</sup> secretion across the apical membrane of the ductal cells. We found similar results in case of regeneration from acidosis with the exception of 1 µg/ml AZA. Administration of 10 µg/ml AZA or 5-ASA and 1 µg/ml 5-ASA significantly decreased the regeneration of acidosis in pancreatic ducts, which suggests that 10 µg/ml AZA or 5-ASA and 1 µg/ml 5-ASA can inhibit HCO<sub>3</sub><sup>-</sup> influx across the basolateral membrane. However, 1 µg/ml AZA caused no significant changes in regeneration from acidosis in isolated pancreatic ducts. Per os treatment of mice both with AZA and 5-ASA for one week caused no changes in HCO<sub>3</sub><sup>-</sup> secretion in either concentration. Treatment with AZA caused significantly lower basolateral transporter activity compared to control animals in a dose dependent manner, while treatment with 5-ASA showed no effect. After four weeks of treatment both drugs impaired the ductal HCO<sub>3</sub><sup>-</sup> secretion rates. No correlation to 5-ASA doses was to be observed, while treatment with 150 mg/kg AZA proved to be lethal after 12-14 days. Basolateral transporter activity was only impaired after treatment with 15 mg/kg AZA.

**Conclusion:** Both azathioprine and 5-aminosalicylic acid can impair ductal HCO<sub>3</sub><sup>-</sup> secretion under acute exposure. Per os treatment for a longer time-period with both drugs can also reduce the ductal functions. This effect might explain the relatively high number of acute pancreatitis cases in patients treated with these medications. In order to understand the exact molecular mechanisms further investigations are highly needed.

**Introduction:** Our research group previously showed that ethanol (EtOH) increases the severity of acute alcohol-induced pancreatitis by disrupting level and function of the cystic fibrosis transmembrane conductance regulator (CFTR). It is well known that Ivacaftor (VX-770) and Lumacaftor (VX-809) can correct the impaired CFTR function and expression in cystic fibrosis (CF) patients.

**Aims & Methods:** The main aim of the study is to test the effect of these compounds on the CFTR expression during EtOH exposure.

Intact guinea pig pancreatic ducts (PDs) and Capan-1 cells were treated with different concentration of EtOH (30, 50 and 100 mM) alone and in combination with VX-770 (10 µM) and/or VX-809 (10 µM) for 12 hours. CFTR expression was evaluated by immunofluorescent staining and our images were captured by confocal microscopy.

**Results:** Exposure of Capan-1 cells and guinea pig PDs to EtOH dose-dependently decreased the plasma membrane expression of CFTR. 10 µM VX-770 and VX-809 alone had no significant effect on the channel's expression, however, both of the compounds dose-dependently prevented the EtOH-induced CFTR damage that could be observed even after 2 hours of treatments. Co-administration of VX-770 and VX-809 also prevented the EtOH-induced (30 and 50 mM) decrease in CFTR expression, however was not able to prevent the effect of 100 mM EtOH. In addition, combination of the two drugs did not potentiate each other's effect.

**Conclusion:** Our findings suggest that VX-809 and VX-770 can restore the CFTR expression defect caused by alcohol. These data suggest that correcting CFTR function or expression could have therapeutic benefits in pancreatitis.

**Introduction:** AR42J are immortalized pancreatic adenocarcinoma cells that share similarities with pancreatic acinar cells. AR42J are often used as a cell-culture model of cerulein (CN)-induced acute pancreatitis (AP). Nevertheless, it is controversial how to treat AR42J for reliable induction of AP. Also, gene knockout or overexpression often remains challenging. In this study, we provide evidence for optimized CN-induced AP in AR42J and high transfection efficacy using glyoxalase-I (Glo-I) as target of interest.

**Aims & Methods:** Effect of dexamethasone (dexa) and CN on cell morphology and amylase secretion was analyzed via ELISA of supernatant. Effect of CN on IL-6 and TNF-alpha and NF-KB-p65 was measured via qRT-PCR, ELISA and Westernblot (WB). Transfection efficacy was measured by WB, qRT-PCR and immune fluorescence of pEGFP-N1-Glo-I-Vector and Glo-I-siRNA

**Results:** Treatment of AR42J with 100nm dexamethasone is mandatory for differentiation to an acinar cell like phenotype and amylase production. CN resulted in secretion of amylase but does not influence amylase pro-

duction. High levels of amylase secretion were detected between 3 and 24 hours of incubation. Treatment with LPS alone or in combination with CN did not influence amylase secretion. CN led neither to increased secretion nor production of TNF- $\alpha$ . No CN-induced elevation of IL-6 was observed. CN-induced stimulation of NF- $\kappa$ B was found to be highest on protein level after 6h of incubation. Only cells up to a passage of 35 should be used for experiments. DNA-amount of 2.5 $\mu$ g was sufficient to induce Glo-I overexpression on protein and mRNA levels with highest effect after 12 to 24 hours. Knockdown was achieved by using 30pM of Glo-I-siRNA leading to effective reduction of protein levels after 72 hours. AR42J cell passages of 35 or more should not be used for CN-induced AP.

**Conclusion:** CN-induced AP in AR42J cells is a reliable *in-vitro* model of AP but specific conditions are mandatory to obtain reproducible data.

### P0791 GLYOXALASE-I IS UPREGULATED IN ACUTE CERULEIN-INDUCED PANCREATITIS: A NEW MECHANISM IN PANCREATIC INFLAMMATION?

Hollenbach M., Sonnenberg S., Sommerer I., Lorenz J., Mössner J., Hoffmeister A.

University of Leipzig, Department of Internal Medicine, Neurology and Dermatology; Division of Gastroenterology and Rheumatology, Leipzig, Germany

**Contact E-Mail Address:** marcus.hollenbach@web.de

**Introduction:** Inflammation caused by oxidative stress (ROS) is an essential mechanism for initiation and deterioration of acute pancreatitis (AP). An important source for ROS comprises the reactive compound methylglyoxal (MGO) itself and the MGO-derived formation of advanced glycation end-products (AGEs). AGEs bind to RAGE and activate NF- $\kappa$ B leading to production of proinflammatory cytokines. MGO is detoxified by glyoxalase-I (Glo-I). The importance of Glo-I has been shown in different models of inflammation and carcinogenesis. Nevertheless, the role of Glo-I and MGO in AP has not been evaluated so far. This study analyzed Glo-I in cerulein (CN)-induced AP and determined the effects of Glo-I knockdown, -overexpression and pharmacological modulation.

**Aims & Methods:** AP was induced in C57BL/6 mice by 10 i.p. injections of 50  $\mu$ g/kg b.w. CN. Glo-I was analyzed in explanted pancreata by Western-blot (WB), qRT-PCR and immunohistochemistry. AR42J cells were differentiated by dexamethasone and an AP was induced *in-vitro* by 100nM CN. Cells were co-treated with ethyl pyruvate (EP) and BrBzGSHCp2, two Glo-I modulators. Knockdown and overexpression of Glo-I was achieved by transient transfection with Glo-I siRNA and pEGFP-N1-Glo-I-Vector. Amylase secretion, TNF- $\alpha$  production (ELISA), Expression of Glo-I, RAGE and NF- $\kappa$ B (WB) were measured.

**Results:** Glo-I was significantly upregulated on protein and mRNA levels in CN treated mice. In AR42J cells, treatment with EP and BrBzGSHCp2 resulted in significant reduction of CN-induced amylase secretion. CN-induced NF- $\kappa$ B expression was attenuated by BrBzGSHCp2 but not EP. Overexpression of Glo-I resulted in significant reduction of CN-induced amylase levels. Glo-I knockdown was accompanied by consecutive increase of amylase-secretion. Interestingly, Glo-I knockdown but not overexpression reduced NF- $\kappa$ B expression via decrease of RAGE.

**Conclusion:** Glo-I is overexpressed in a model of CN-induced AP. Pharmacologic modulation and overexpression of Glo-I reduced amylase secretion in AP *in vitro*. Targeting Glo-I in AP could be an innovative therapeutic approach for future *in vivo* studies.

**Introduction:** Severe hypertriglyceridemia is an important, well-known cause of acute pancreatitis (AP). Existing data on clinical characteristics of hypertriglyceridemia-induced acute pancreatitis (HTG-AP) are very limited. **Aims & Methods:** The aim of this project was examine prevalence, patient characteristics and clinical outcomes of HTG-AP patients compared to other etiologies from a large, international cohort study.

Acute Pancreatitis Patient Registry to Examine Novel Therapies In Clinical Experience (APPRENTICE) is a global, multicenter, cohort study. AP patients were prospectively enrolled in 22 international centers. Data were collected via standardized questionnaires and registered in REDCap (Research Electronic Data Capture). Revised Atlanta Classification definitions were used to determine severity. Primary HTG-AP was confirmed when common etiologies were excluded and serum triglycerides were >500mg/dl. Pearson's chi-squared test and t-test were used to compare categorical and continuous variables, respectively. Multivariable logistic regression model was used with severe/moderate condition as the outcome.

**Results:** 1478 patients were prospectively enrolled, of whom 69 diagnosed with HTG-AP (prevalence=4.6%). Compared to the other etiologies, HTG-AP patients were younger (40.4 vs 50 years;  $p < 0.0001$ ) had higher BMI (30.4 vs 27.5kg/m<sup>2</sup>;  $p = 0.0002$ ) and more frequent alcohol use (70.6% vs 48.9%;  $p < 0.0001$ ), were more likely diabetics (59.4% vs 15.3%;  $p < 0.0001$ ), and had more frequently recurrent AP (RAP) (40.6% vs 24%;  $p = 0.002$ ). Median TG level for HTG-AP patients was 1675 mg/dl and 133 mg/dl for the others. In terms of clinical outcomes, ICU admission was more frequent in HTG-AP patients (26.1% vs 16.4%;  $p = 0.036$ ), but no significant difference was found in terms of rate of moderate/severe AP, length of hospital stay, or mortality. At the multivariable logistic regression, male sex and increasing BMI were associated with risk of moderate/severe AP while HTG-AP was not. Within the HTG-AP population, no differences were found in terms of patient and hospitalization features based on magnitude of HTG levels.

**Conclusion:** HTG-AP accounts for 4.6% of AP cases, affects younger, overweight and diabetic patients, and those who use alcohol, require ICU and have RAP more often compared to other etiologies. This suggests that HTG-AP has a higher cost compared to other etiologies. However, no difference was found in terms of severity, length of stay or mortality. Also, basal HTG levels do not seem to affect the clinical outcome of these patients.

**Introduction:** Gallstones are considered the most common cause of acute pancreatitis. Despite that most of the stones are expelled spontaneously through the papilla due to their small size; about 20% to 30% of patients with acute biliary pancreatitis (ABP) will have persistent CBD stones. Therefore, the identification of retained common bile duct stone after an acute episode of biliary pancreatitis is of paramount importance since stone extraction is mandatory.

**Aims & Methods:** We aimed to generate a simple non-invasive scoring model to predict the presence of CBD stones in patients with biliary pancreatitis. We performed a retrospective study at Galilee Medical Cen-

ter including patients with an established diagnosis of pancreatitis with suspected CBD stone. One hundred and fifty-four patients were included, among them thirty-three patients (21.5%) were diagnosed with CBD stone by endoscopic ultrasound (US).

**Results:** In univariate analysis, age (OR 1.048,  $P=0.0004$ ), aspartate transaminase (OR 1.002,  $P=0.0015$ ), alkaline phosphatase (OR 1.005,  $P=0.0005$ ), gamma-glutamyl transferase (GGT) (OR 1.003,  $P=0.0002$ ) and CBD width by US (OR 1.187,  $P=0.0445$ ) were significantly associated with CBD stone. In multivariate regression analysis, three parameters were identified to significantly predict CBD stone; age (OR 1.062,  $P=0.0005$ ), GGT level (OR 1.003,  $P=0.0003$ ) and dilated CBD (OR 3.685,  $P=0.027$ ), with area under the curve of 0.8433. We developed a diagnostic score that included the 3 parameters that were significant on multivariate analysis, with assignment of weights for each variable according to the co-efficient estimate. A score that ranges from 51.28 to 73.7 has a very high specificity (90% - 100%) for CBD stones, while a low score that ranges from 9.16 to 41.04 has a high sensitivity (82% - 100%). By performing internal validation, the NPV of the low score group was 93%.

**Conclusion:** We recommend incorporating this score as an aid for stratifying into patients with acute biliary pancreatitis with low or high probability for the presence of CBD stone.

**Introduction:** Recent guidelines advocate the step-up approach for the management of infected pancreatic necrosis (IPN). Nearly half of patients will require secondary necrosectomy after drainage. A previous study (1) identified 4 risk factors of catheter drainage failure: male gender, multiple organ failure, percentage of necrosis and heterogeneous collection, leading to propose a nomogram with an area under receiver operating characteristic (ROC) curve of 0.76. Our primary objective was to validate this novel nomogram. Our secondary goals were to explore others potential predictors of failure of catheter drainage.

**Aims & Methods:** We retrospectively studied 72 consecutive patients admitted in 3 university hospitals for suspected IPN requiring interventions by catheter drainage first between 2012 and 2016. All computed tomography (CT) examinations performed prior to the first drainage procedure were reviewed by a single blinded radiologist. Drainage success or failure rates were assessed. Success was defined by survival without any additional necrosectomy, while failure was defined by death and/or additional necrosectomy after the drainage procedure because of lack of improvement. ROC curve of predictors of drainage failure according to Hollemans nomogram and area under the curve (AUC) were also calculated.

**Results:** Catheter drainage alone achieved success in 44.4% of patients. Nomogram predicted catheter drainage failure with an area under the ROC curve of 0.71. Scores  $\leq 8$  (low) or 40 (maximum) resulted in 100% success or failure rates of primary catheter drainage, respectively. In multivariate analysis, catheter drainage failure was independently associated with body mass index (BMI) (OR: 1.14; 95% CI: 1.01-1.29;  $P: 0.02$ ), heterogeneous collection (OR: 18.84; 95% CI: 2.02-175.86;  $P: 0.01$ ) and respiratory failure 24 hours prior catheter drainage (OR: 16.76; 95% CI: 1.94-144.4;  $P: 0.01$ ).

**Conclusion:** More than half of patients required necrosectomy because of failure of radiological catheter drainage. However, Hollemans nomogram can be useful to predict catheter drainage failure, especially for extreme values. Heterogeneous collection on CT and respiratory failure 24h prior to drainage were strongly associated with catheter drainage failure. Early identification of patients at risk of drainage failure alone might help improving their management and reducing antibiotics duration.

**Introduction:** Recent guidelines ruled out prophylactic antibiotics to prevent IPN and advocate the step-up approach for the management of IPN. Emerging drug resistant bacteria is a rising problem among SAP and ICU patients. However, there is no recommendation regarding antimicrobial therapy management for IPN (molecules and duration). In real life, many patients will have culture levied under broad spectrum antimicrobial therapy. Our primary objective was to determine the impact of prior antibiotherapy on samples cultures collected during interventions for a suspected infected pancreatic necrosis (IPN) among patients admitted for severe acute pancreatitis (SAP) and to determine if prior antibiotic therapy negatively affects the results of the culture. Description of microbiological species and their patterns of resistance were our secondary goals.

**Aims & Methods:** We retrospectively studied 62 consecutive patients admitted in ICU for suspected IPN requiring interventions. We collected data about microbiological samples, as well as antimicrobial therapy type and duration before and after intervention for suspected IPN. We classified species according to the definitions proposed by Magiorakos et al.

**Results:** IPN was confirmed for 48 patients, with 137 samples collected during interventions. 57% of positive cultures were levied under efficient antibiotherapy, previous antibiotherapy did not influence cultures results ( $p=0.84$ ). 1/3 of samples were polymicrobial. Half of the patients developed multi and extensively drug resistant bacteria. Prolonged antibiotics did not sterilized collections or necrotic tissues for extensively drug resistant bacteria that were founded into necrotic collection even after several weeks of adapted antibiotics.

**Conclusion:** Previous antibiotherapy did not influence microbiological culture results and prolonged adapted broad-spectrum antibiotics did not allow sterilizing necrotic tissue or fluid collections. Our results showed a 50% prevalence of drug resistant bacteria. Negative cultures among patients under antibiotics should question the diagnosis of IPN and antibiotics discontinuation. Strategies to reduce antimicrobial therapy use and exposure in the course of SAP are needed. Futures prospective studies should determine the optimal antimicrobial therapy duration.

**Contact E-Mail Address:** vancsas@yahoo.com

**Introduction:** Acute pancreatitis (AP) is a life-threatening condition with an average mortality of 2-5%, which can rise up to 30% in severe cases. Tremendous efforts were made to identify factors that can predict diseases course. A potential predictor may be pre-existing fatty liver disease (FLD).

**Aims & Methods:** The aim of this study was to perform a meta-analysis on the prognostic role of FLD in AP.

We performed a systematic search in seven medical databases for cohort studies reporting on adult AP cases with and without FLD of any origin proven by cross-sectional imaging and/or histology. The primary outcome was in-hospital mortality, secondary outcomes included AP severity,

length of hospital stay (LOH), necrotizing AP and systemic inflammatory response syndrome (SIRS). We calculated risk ratio (RR) for categorical variables (i.e., mortality, AP severity, and necrosis) and weighted mean difference (WMD) for LOH with 95% confidence intervals (CIs) with the random effect model. Heterogeneity was tested with  $I^2$ -statistics.

**Results:** Twelve studies containing data on 6233 patients were eligible for meta-analysis. Patients with FLD were more likely to die (RR=3.24, CI: 1.65-6.34,  $p=0.001$ ;  $I^2=41.6\%$ ), to develop severe (RR=2.27, CI: 1.9-2.7,  $p<0.001$ ;  $I^2=0.0\%$ ), and necrotizing AP (RR=2.37, CI: 1.92-2.92,  $p<0.001$ ;  $I^2=30.4\%$ ) compared to those not having pre-existing FLD. The presence of systemic complications affecting at least one organ (RR=2.03, CI: 1.54-2.67,  $p<0.001$ ;  $I^2=68.1\%$ ) and SIRS (RR=1.94, CI: 1.64-2.29,  $p<0.001$ ;  $I^2=34.4\%$ ) was significantly higher in the FLD group. There was a tendency for longer LOH with FLD (WMD=2.08 days, CI: 1.09-3.07,  $p<0.001$ ;  $I^2=0.0\%$ ).

**Conclusion:** Our results showed that fatty liver disease is a risk factor of mortality, severe disease course, necrosis, systemic complications and longer length of hospitalization in AP; therefore, we suggest the incorporation of FLD into the prognostic tools in AP.

**Contact E-Mail Address:** joselarnoi@outlook.es

**Introduction:** IPN is associated with a high morbimortality. Current treatment of IPN is based on minimally invasive methods, mainly endoscopic or percutaneous drainage and necrosectomy. We designed a step-up protocol for the treatment of IPN based on local administration of antibiotics with drainage previous endoscopic necrosectomy (Pancreatology 2016;16:719-25).

**Aims & Methods:** Aim of our study was to analyse the proportion of patients requiring necrosectomy in our step-up protocol for IPN. Methods: Retrospective, observational and descriptive study of patients with acute pancreatitis (AP) admitted to our department between January 2015 and December 2018. Cases with pancreatic necrosis (PN) and IPN (defined as positive culture of the necrosis) were evaluated. The number of patients who responded to each of the three steps of our protocol were analysed: Step 1, systemic antibiotics; step 2, endoscopic transmural drainage + local administration of antibiotics; step 3, endoscopic necrosectomy. Transmural drainage was performed by endoscopic ultrasound, by using plastics and/or metal stents. During the same procedure, a nasocystic catheter was placed deep in the necrotic cavity through metal stents or in parallel to plastic stents. Endoscopic necrosectomy was performed when previous steps failed. Data are shown as percentage.

**Results:** 1158 patients with AP were included. 110 patients (8.4%) suffered from necrotising pancreatitis, and 48 of them (42.6% of necrotising pancreatitis) had IPN and were treated with systemic antibiotics. Nineteen patients (39.6% of IPN) responded to systemic antibiotics. Six patients with IPN on systemic antibiotics died within the first 4 weeks of disease before a second therapeutic step could be applied. Three patients underwent urgent surgical necrosectomy within the first 4 weeks of disease with a 100% mortality. The remaining 20 patients underwent endoscopic transmural drainage and local antibiotic administration through nasocystic catheter. Nine of them (47.4%) did well and 9 needed endoscopic necrosectomy (45% of all IPN). Two patients died before necrosectomy could be performed. Overall mortality of the total cohort of AP was 2.53%.

**Conclusion:** Addition of local infusion of antibiotics through a nasocystic catheter to endoscopic transmural drainage avoids the need of necrosectomy in half of patients with IPN, who did not respond to systemic antibiotics. These data justify a randomized controlled trial to evaluate this approach.

**Disclosure:** Nothing to disclose

**Introduction:** Both alcohol consumption and smoking have been reported to be harmful to the pancreas and these addictions often go together.

**Aims & Methods:** Our aim is to epidemiologically characterize smoking and alcohol consumption habits and evaluate their independent and joint clinical effects in acute pancreatitis (AP).

A total of 1435 adult patient with the diagnosis of AP from 28 healthcare centers were enrolled between 2012 and 2017 by the Hungarian Pancreatic Study Group. Four groups of patients were retrospectively formed: non-smoker-non-drinker (NS-ND), smoker-non-drinker (S-ND), non-smoker-drinker (NS-D) and smoker-drinker (S-D).

**Results:** 693 (48.7%) of the patients were ND-NS, 119 (8.4%) S-ND, 334 (23.5%) NS-D and 278 (19.5%) were S-D. The average age of onset of AP was significantly lower in the S-ND, NS-D and S-D groups as compared to the NS-ND group (51.7±15.1, 54.9±16.0 and 46.3±11.9 years respectively vs. 61.1±17.6,  $p<0.001$ ). The male/female ratio was 0.6 in the ND-NS group, 0.9 in the S-ND, 3.2 in the NS-D and 6.0 in the S-D groups. Drinking alone had no effect on the BMI (NS-ND: 28.3±5.9, NS-D: 28.2±5.1), but smoking in addition to drinking was associated with lower BMI (S-ND: 27.5±6.5 and S-D: 25.7±5.3,  $p<0.001$ ).

There are fewer mild cases and more moderately severe cases in the NS-D and S-D groups as compared to the NS-ND group of patients. To reason this change, we can observe an increase in the rate of local complications (ND-NS: 34.4%, NS-D: 37.5%, S-D: 44.1%) including fluid collection (28.3%, 31.3%, 35.5%), pseudocyst (9.0%, 9.2%, 13.3%) and necrosis (8.8%, 11.0%, 11.5%).

Drinking and smoking together also elevate the risk for recurrent AP (RAP). 18.9% of the patients had RAP in the NS-ND, while 23.5% in the NS-D and 31.9% in the S-D groups.

Concerning on admission serum blood parameters, smoking together with drinking has a significant synergic moderating effect on amylase and lipase levels. The amylase in the S-D group was significantly lower than in the NS-ND group (710 vs. 1309,  $p<0.05$ ). Smoking and alcohol consumption together are associated with higher levels of C-reactive protein (CRP) but has no effect on white blood cell count.

**Conclusion:** Drinking and smoking together result in the onset of pancreatitis 15 years earlier, in addition, it elevates the risk of recurrent disease. Drinking and smoking synergize with each other and increase the rate of local complications and moderately severe cases.

**Contact E-Mail Address:** xqr322@alumni.ku.dk

**Introduction:** Although endoscopy is a cornerstone in the treatment of walled-off pancreatic necrosis (WON), long term outcomes are unclear.

**Aims & Methods:** We performed a retrospective cohort study of patients with WON who have been treated with transgastric drainage and necrosectomy (ETDN) in a tertiary referral center. Primary outcomes were development of exocrine- or endocrine insufficiency, use of analgesics, number of WON- and non-WON related re-admissions, and need for endoscopic intervention during follow-up due to main pancreatic duct (MPD) abnormalities. From Jan. 2010 to Dec. 2018, 215 patients with WON underwent ETDN in our center. We excluded patients who underwent ETDN more than 90 days from the onset of acute pancreatitis (n=35), patients with known chronic pancreatitis (n=4), patients who died during admission (n=29) and during follow-up (n=18), and patient with missing data (n=7). We registered patient characteristics including the development of exocrine (need for pancreatic enzyme replacement therapy) and endocrine insufficiency (need for peroral antidiabetics or insulin), number of WON-related re-admissions, use of analgesics, and need for endoscopic therapy on MPD during follow-up.

**Results:** We included 122 patients (68 males, median age 57 years). Gallstones were the main etiology (52%). Median time from onset to index intervention was 33 days (range 11-88). ETDN was performed primarily due to infection (81%). Median computer tomography severity index (CTSI) and modified CTSI scores were 7 and 9, respectively. Median follow-up time was 52 months (range 11-112 months).

During follow-up, 21 (17%) patients developed exocrine insufficiency and 33 (27%) developed endocrine insufficiency, ten patients (8%) needed potent opioids and ten patients needed mild opioids. The median number on WON-related readmissions was 0 (range 0-16) and 18 (15%) patients needed endoscopic therapy on MPD during follow-up.

Presence of diabetes at index endoscopy (OR 7.57; 95% CI, 2.54-22.55;  $p < 0.001$ ) and endoscopic therapy on MPD during follow-up (OR 7.67; 95% CI, 2.55-23.09;  $p < 0.001$ ) both predicted development of exocrine insufficiency in univariate regression analyses. In multivariate analysis, only endoscopic therapy on MPD predicted development of exocrine insufficiency (OR 7.98; 95% CI, 2.37-26.83;  $p < 0.001$ ). CTSI (OR 1.55; 95% CI, 1.23-1.97;  $p < 0.001$ ) and modified CTSI (OR 1.71; 95% CI, 1.25-2.34;  $p < 0.001$ ) predicted development of endocrine insufficiency both in univariate and multivariate analysis.

**Conclusion:** This study reports long-term data on patients with WON treated with ETDN. The proportion with endocrine and exocrine insufficiency was relatively small as was the proportion with opioid requiring pain. WON-related readmissions were rare.

This suggests that the treatment has beneficial long-term outcomes. The risk of developing exocrine and endocrine insufficiency is correlated to main pancreatic duct abnormalities and imaging severity index, respectively.

## P0801 PROGNOSIS OF ACUTE PANCREATITIS ASSOCIATED WITH HIGH SERUM TRIGLYCERIDES MANAGED IN A TERTIARY CENTER OF GASTROENTEROLOGY

Bunduc S.<sup>1,2</sup>, Covasa L.<sup>1</sup>, Iacob R.A.<sup>1,2</sup>, Gheorghe C.<sup>1,2</sup>

<sup>1</sup>I. C. Fundeni, Gastroenterology and Hepatology, Bucharest, Romania, <sup>2</sup>Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

**Contact E-Mail Address:** stfnbndc@gmail.com

**Introduction:** After alcohol and gallstones, hypertriglyceridemia (HTG) is the third most common cause of acute pancreatitis (AP). Data in the literature regarding correlation between level of serum triglycerides (TG) and disease severity is at variance.

**Aims & Methods:** The objective in our study was to analyze the prognosis of AP in patients who associated high level of serum TG. Data was collected in a retrospective manner and included all cases of AP admitted in our clinic between 1<sup>st</sup> of January 2014 and 31<sup>st</sup> of December 2018. Revised Atlanta Classification was used to define severity. Levels of TG were measured at admission and 48 hours afterwards - the first value obtained during day 3 to 7 of hospitalization was considered. They were recorded according to the definition of the National Cholesterol Education Program/Adult Treatment Panel III (NCEP/ATPIII) as high - 200-499 mg/dL and very high - > 499 mg/dL respectively.

**Results:** There were 123 cases of AP admitted in our center during the 5-year study period. We found no correlation between abnormal TG levels and severity, mortality rate, admission duration and local complications rate, defined as mentioned. High TG at admission and persistent high TG during hospitalization were significantly associated with occurrence of systemic complications, at a similar rate (27.8%,  $p = 0.03$  and 27.3%,  $p = 0.04$  respectively). Acute kidney injury was more prevalent in those with high TG at admission (16.7%,  $p = 0.02$ ), while sepsis occurred more often in those with persistently high TG (13.6%,  $p = 0.01$ ). Only persistently high TG levels correlated with necessity (27%,  $p = 0.05$ ) and a longer duration ( $p = 0.03$ ) of Intensive Care Unit (ICU) admission. Presence of very high TG level at admission correlated with length of ICU stay. No correlations were found between persistence of very high TG during hospitalization (8, 6.5%), and other registered variables.

**Conclusion:** In our study HTG was significantly associated with an increased incidence of systemic complications in AP. Nevertheless need for ICU admission and length of stay were only correlated with persistent HTG longer than 48 hours after admission. Mortality and severity of AP were not impacted by presence of HTG in our group.

## P0802 LEFT VENTRICULAR ASSIST DEVICE (LVAD) USE IS ASSOCIATED WITH ACUTE PANCREATITIS: A MULTICENTER RETROSPECTIVE COHORT

Corral J.E.<sup>1</sup>, Yarlagadda B.<sup>2</sup>, Vemireddy L.P.<sup>2</sup>, Kroner P.T.<sup>3</sup>, Goswami R.M.<sup>2</sup>, Raimondo M.<sup>2</sup>, Bi Y.<sup>2</sup>

<sup>1</sup>Mayo Clinic, Florida, Gastroenterology and Hepatology, Jacksonville, United States, <sup>2</sup>Mayo Clinic, Florida, Jacksonville, United States, <sup>3</sup>Mayo Clinic, Gastroenterology, Jacksonville, United States

**Contact E-Mail Address:** corral.juan@mayo.edu

**Introduction:** Case series suggest that left ventricular assist devices (LVAD) increase the risk of acute pancreatitis. Hemolysis and ischemia have been proposed as putative mechanisms. Cardiac transplant recipients also have perioperative ischemia and medications that can potentially cause pancreatic inflammation.

**Aims & Methods:** We aim to compare the incidence of acute pancreatitis in patients receiving advanced heart failure therapies. Our secondary goal is to identify potential risk factors associated with acute pancreatitis in the same population.

A retrospective cohort of patients with advanced heart failure (NYHA class III and IV) was followed from 2012 to 2018 in three referral hospitals. Three groups were compared: LVAD recipients (final destination), transplant recipients (with LVAD as a bridge for transplant, or direct transplant recipients) and controls that refused or did not qualified for advanced therapies. Patients were enrolled the day they had an AICD placed (or the day they presented to our heart failure clinic).

Demographics, body mass index (BMI), tobacco and alcohol use, baseline ejection fraction, history of gallstone disease and development of hemo-

lysis were recorded. Log-rank test and adjusted hazard ratios compared pancreatitis incidence between groups. Kaplan Meier curves were elaborated.

**Results:** 1,344 patients were included in the cohort: 407 with LVAD as final destination, 589 with transplant (233 with LVAD bridge and 356 transplanted directly) and 348 controls. 987 (73.4%) patients were male, mean age was  $60.9 \pm 14.3$  years, average BMI was  $28.4 \pm 5.9 \text{ Kg/m}^2$ . 701 (55.3%) patients had previous alcohol use, and 263 (21.5%) had history of gallstones. Mean follow-up was  $85.7 \pm 61.2$  months. 423 (31.5%) patients died during cohort follow-up.

A total of 39 cases of acute pancreatitis were reported. Annual incidence was 6.7 cases per 1000 LVAD patients, 2.3 per 1000 transplant recipients, 4.1 per 1000 patients on bridge therapy (after receiving a heart transplant) and 3.2 per 1000 controls (log-rank test for equality  $p=0.03$ ). Combined, the annual incidence of acute pancreatitis was 5.6 cases per 1000 LVAD users and 2.7 cases in 1000 nonusers ( $p=0.009$ ).

Unadjusted hazard ratio for acute pancreatitis in LVAD was 2.4 (95%CI 1.2-4.6) and 2.0 (95%CI 0.7-5.5) after adjusting for gender, age, BMI, ejection fraction, alcohol use, smoking, history of gallstones disease and hemolysis. History of gallstone disease had the highest effect on developing acute pancreatitis (adjusted hazard ratio 4.0, 95%CI 1.6-9.9).

Among the patients who developed pancreatitis, 4 (10.5%) had history of significant alcohol use and 19 (48.7%) moderate use; 17 (46.9%) had history of smoking, 21 (55.3%) had history of gallstone disease and 14 (36.8%) hemolysis.

Prevalence of gallstone disease was similar in patients with or without LVAD (21.0% vs. 22.0%  $p=0.6$ ). History of hemolysis was significantly higher in patients with LVAD (6.0% vs. 35.0%,  $p<0.001$ ).

Abdominal imaging showed a spectrum of disease including a normal pancreas (17.9%), edematous pancreatitis (44.7%), small fluid collections (17.9%) and hemorrhagic/necrotic pancreatitis (5.3%).

**Conclusion:** Patients with LVAD have twice the risk of developing acute pancreatitis compared to heart transplant recipients and heart failure controls. The effect of LVAD seems to dissipate once patients undergo cardiac transplantation and gallstone disease likely plays an important effect in pathogenesis. Studies that elucidate the mechanisms behind pancreatic injury in advanced heart failure and interventions to prevent them are strongly suggested.

**Introduction:** Hypertriglyceridaemia (HTG) is the third most common cause of acute pancreatitis (AP) and opposite to the other etiologies, most often moderate or severe AP develop. Unfortunately, only small amount of data are available concerning its dose-dependency.

**Aims & Methods:** Our aim was to investigate the dose-dependent effects of serum triglyceride levels on AP. Data of 716 patients were retrospectively analyzed from the prospectively collected, international, multicenter AP registry operated by the Hungarian Pancreatic Study Group (HPSG). AP patients over 18-year-old, who underwent triglyceride measurement within the first three days were included from 31 centers and 12 countries. Six groups were created based on the highest triglyceride level of the initiating three days ( $<1.7 \text{ mmol/l}$ ,  $1.7\text{--}2.19 \text{ mmol/l}$ ,  $2.2\text{--}5.59 \text{ mmol/l}$ ,  $5.6\text{--}11.19 \text{ mmol/l}$ ,  $11.2\text{--}22.39 \text{ mmol/l}$ ,  $>22.4 \text{ mmol/l}$ ). HTG was indicated above  $1.7 \text{ mmol/l}$ .

**Results:** The total data quality was 81%. 30.6% ( $n=219$ ) of the patients presented with HTG. The ratio of male gender in the whole cohort was 59% ( $n=421$ ) and was significantly elevated in the HTG group, compared to

patients with normal triglyceride level ( $p<0.001$ ). BMI and diabetes in the personal history correlated with the hypertriglyceride level ( $p=0.001$ ,  $p<0.001$ ). Triglyceride dose-dependently and above  $22.4 \text{ mmol/l}$  significantly ( $p=0.003$ ) elevated the risk for severe pancreatitis. HTG above  $11.2 \text{ mmol/l}$  was significantly related to a higher risk for local complications ( $p<0.001$ ), local fluid collection ( $p=0.004$ ), pancreas necrosis ( $p=0.02$ ) and HTG above  $5.6 \text{ mmol/l}$  was significantly related to a higher incidence of diabetes as complication ( $p=0.008$ ). Risk for systemic organ failure was significantly elevated above  $22.4 \text{ mmol/l}$  triglyceride ( $p=0.002$ ).

**Conclusion:** Serum triglyceride has a dose-dependent effect on the risk for local and systemic complications and severity of AP.

**Disclosure:** Nothing to disclose

**Introduction:** Chymotrypsinogen C (CTRC) plays a significant role in regulating trypsinogen activation. Early activation of trypsinogen inside the pancreas is a key molecular mechanism in the pathogenesis of pancreatitis that results in self-digestion and local inflammation of the organ. Loss-of-function mutations in the CTRC gene encoding Chymotrypsinogen C impair either the catalytic activity or the expression of the enzyme. Impaired expression of CTRC might be caused by variants in the 5' upstream region, however, this region of the gene was not investigated yet.

**Aims & Methods:** Our aim was to sequence the 5' upstream region of the CTRC gene in patients and controls in order to identify variants that may predispose to chronic pancreatitis. We selected 117 patients with non-alcoholic (NACP), 147 patients with alcoholic chronic pancreatitis (ACP) and 263 controls recruited by the Hungarian Pancreatic Study Group (HPSG - www.pancreas.hu). Mutations within the ~1.4 kb CTRC 5' upstream region were analyzed by Sanger sequencing.

**Results:** We found 2 common polymorphisms (c.-913A>G and c.-811G>A) and 4 further variants (c.-993G>T, c.-314AAAT[5], c.-92C>T and c.-59C>T) in the ~1.4 kb long 5' upstream region of the CTRC gene. However, we found that the variant c.-913A>G slightly accumulated in patients compared to controls, genotype and allelic distribution of the identified variants were generally comparable between each group of patients and controls.

**Conclusion:** Based on our preliminary results, the identified mutations in the 1.4 kb long 5' upstream region of the CTRC gene are not associated with chronic pancreatitis.

**Introduction:** Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and cystic fibrosis conductancia regulator- CFTR) is diminished in CP. Earlier we demonstrated that cigarette smoking significantly diminishes fluid and HCO<sub>3</sub><sup>-</sup> secretion, and CFTR activity in guinea pig pancreas, however, the underlying mechanisms are unknown. The aim of this study was to understand the pathomechanism of smoke-induced pancreatic ductal cell damage.

**Aims & Methods:** CFTR function was measured in non-smoker and smoker patients with, or without chronic pancreatitis based on Cl<sup>-</sup> concentrations in sweat. The effect of smoking on CFTR expression was analysed by RT-qPCR, immunofluorescence staining. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water. Intracellular pH, Ca<sup>2+</sup> concentration and ATP levels were evaluated by fluorescence microscopy. Mitochondrial membrane potential was measured by using confocal microscopy.

**Results:** Cl<sup>-</sup> concentrations increased in sweat samples from patients from CP and further elevation was detected in a smoker group. Smoking significantly decreased the membrane expression of CFTR in human tissue samples. CSE incubation decrease CFTR mRNA and protein expression on Capan 1 cells. Smoking CSE incubation also decreases HCO<sub>3</sub><sup>-</sup> secretion in guinea pig pancreatic ducts via inhibition of the Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger, Na<sup>+</sup>/H<sup>+</sup> exchanger and Na<sup>+</sup>/HCO<sub>3</sub><sup>-</sup> cotransporter. CSE pretreatment decreased the amplitude of carbachol-induced Ca<sup>2+</sup> signal in pancreatic ducts, suggesting that cigarette smoking alters Ca<sup>2+</sup> signaling pathways in some way. CSE incubation was reduced mitochondrial membrane potential in guinea pig pancreatic ducts.

**Conclusion:** The inhibition of CFTR and other ion transporters by CSE could play a crucial role in the development of ductal insufficiency and chronic pancreatitis. This study was supported by OTKA, MTA, SZTA and ÚNKP.

**Contact E-Mail Address:** lia.oliver@goodgut.eu

**Introduction:** Pancreatic exocrine insufficiency (PEI) is an inflammatory condition of the pancreas in which the fibrosis development and loss of pancreatic parenchyma lead to an alteration of the endocrine and exocrine function. Genetic predisposition is one of the main common causes of PEI development, although malformations, autoimmunity, alcohol and nicotine are other predisposing factors, especially the interaction among several of them. The possible involvement of certain microbial groups in scenarios where the disease and inflammation have control needs to be elucidated.

**Aims & Methods:** The objective of this work was to explore the state of the intestinal microbiota in search of some indicative bacteria that allow us to differentiate healthy individuals from an PEI population.

Two cohorts were included in this study at Hospital Dr. Josep Trueta (Girona, Spain): 11 patients with PEI and 6 low risk, healthy (i.e., non-smokers and non-drinkers) subjects. Patients with PEI had fecal elastase values <

15 µg/g or between 15 and 200 µg/g and values below 29% of C<sup>13</sup>-triglycerides in the breath test. Patients brought a sample of feces from which 17 bacterial markers representing the main physiological and ecological phyla were analyzed. Two different indexes were defined according to the different functional groups of microorganisms based on the enzymatic activities of amylase, lipase and protease. In addition, 1 index indicative of eubiosis was also defined. The indexes were calculated by adding the relative abundance of the bacterial markers. The relative abundance was calculated according to the total bacterial load (Eubacteria). Therefore, the lower the value of the index the greater the abundance of the markers that constitutes it.

**Results:** When analyzed separately, the different bacterial markers did not present significant differences between the patients with PEI and the healthy subjects. However, significant differences were observed when comparing PEI and healthy subjects when the all bacterial indexes were combined. The 2 indexes based on enzymatic activity were significantly higher in healthy controls than in PEI patients (*p*-value=0.044, *p*-value=0.032, respectively). In contrast, the eubiosis index was significantly higher in PEI patients than in healthy controls (*p*-value=0.039).

**Conclusion:** Patients suffering from PEI have lower (log)-ratios indexes defined according to amylase, proteolytic, and lipase bacterial activities and an increase in the eubiosis. Since no clinical/physiological implications were derived from these enzymatic activity differences, the results suggest a possible involvement of the bacteria present in the digestive tract to compensate the lack of enzymatic activity characteristic of PEI.

**Introduction:** The calcium sensing receptor (CASR) plays an essential role in maintaining mineral ion homeostasis and is also expressed in human pancreatic acinar and ductal cells. Over the past years, the possible involvement of common CASR variants in chronic pancreatitis (CP) has emerged, however, their role in the pathogenesis of CP remains controversial due to the lack of large case-control studies.

**Aims & Methods:** Our aim was to analyze the clinically frequent CASR variants in an ethnically homogenous group of Hungarian CP patients and healthy controls. 257 CP patients (cases) and 183 controls with no pancreatic disease from the Hungarian National Pancreas Registry were enrolled. As the most common CASR variants are located in exon 7, we PCR amplified and sequenced this exon with its flanking intronic regions.

**Results:** We identified three common exon 7 variants in our cohort: c.2956G>T (p.A986S), c.2968A>G (p.R990G) and c.3031C>G (p.Q1011E). No significant differences were found in allele frequencies of these variants in cases compared to the control group: p.A986S (19.26% vs 18.58%, OR=1.05, *p*=0.8), p.R990G (7.8% vs 6.3%, OR=1.26, *p*=0.4) and p.Q1011E (3.7% vs 4.1%, OR=0.9, *p*=0.8). However, genotype distribution analysis revealed, that the p.A986S variant in homozygous state was overrepresented

in patients relative to controls (3.5% vs 1.1%, OR=3.3, p=0.13). Although this difference was not statistically significant, there is a clear trend which warrants extension of the studies to a larger cohort in the future.

**Conclusion:** The homozygous c.2956G>T (p.A986S) variant is overrepresented in the Hungarian cohort of chronic pancreatitis patients relative to the control group. Our results strengthen the previous findings in a French cohort (Masson E, 2015) and support the possible pathogenic role of the homozygous p.A986S variant in chronic pancreatitis.

## P0809 ASSOCIATION BETWEEN ENDOSCOPIC ULTRASONOGRAPHY FINDINGS AND PATHOLOGY/BLOOD BIOCHEMICAL FINDINGS IN CHRONIC PANCREATITIS

**Introduction:** Endoscopic ultrasonography (EUS) diagnostic categories for changes indicating early chronic pancreatitis were formulated as the Rosemont classification. Japan was the first in the world to introduce diagnostic criteria for "early-stage chronic pancreatitis," centered on EUS imaging diagnostics, in the Japanese Clinical Diagnostic Criteria for Chronic Pancreatitis 2009. However, EUS findings and diagnostic factors for chronic pancreatitis are often inconsistent. This study aimed to investigate the usefulness of EUS by conducting a statistical analysis of EUS findings in patients with chronic pancreatitis diagnosed on the basis of EUS findings and the volume of alcohol consumption, presence of diabetes, history of acute pancreatitis, and blood biochemical findings, and by comparing EUS and pathological findings.

**Aims & Methods:** Between February 2014 to December 2017, 54 patients with repeat episodes of upper abdominal pain or abnormalities in pancreatic blood enzymes who had been diagnosed with early-stage chronic pancreatitis or chronic pancreatitis on the basis of EUS testing at our hospital were categorized into confirmed, probable, and early-stage chronic pancreatitis cases in accordance with the Japanese Clinical Diagnostic Criteria for Chronic Pancreatitis 2009. Statistical analysis was conducted for each group on the association with the volume of alcohol consumption, presence of diabetes, history of acute pancreatitis, blood biochemical findings, and Rosemont classification.

**Results:** The 54 study participants were comprised of 37 men and 17 women, with a mean age of 58.0 years. Of the cases, 24, 5, and 25 were confirmed, probable, and early-stage chronic pancreatitis, respectively. The mean alcohol consumption (pure alcohol by grams per day) tended to be higher in the confirmed cases (89 g/day) than in the probable (27.5 g/day) or early-stage chronic pancreatitis cases (30.1 g/day; p=0.08). No significant differences were observed among the groups for the presence of diabetes, history of acute pancreatitis and blood biochemical findings. When the EUS and pathological findings were compared, the imaging results were consistent with the EUS fibrosis findings and irregular pancreatic duct images.

**Conclusion:** Our study showed no association between the clinical diagnosis of chronic pancreatitis based on EUS findings and the presence of diabetes, history of acute pancreatitis, or blood biochemical findings. One previous report suggested a tendency of anomalous EUS findings to increase in patients aged ≥60 years. Thus, at present, whether EUS findings of chronic pancreatitis, considered to be representative of histological fibrosis, are changes due to aging is difficult to determine, which makes careful diagnosis vital to avoid overdiagnosis of the condition.

**Introduction:** Paraduodenal pancreatitis (PP) is a focal form of chronic pancreatitis that affects the groove area between duodenum and the head of the pancreas. Consensus regarding surgical or non-surgical management as the best treatment option still is lacking.

**Aims & Methods:** We retrospectively evaluated all patients managed for PP at The Pancreas Institute of the University of Verona Hospital. The outcomes of surgical vs. medical treatment with regards to pain control, quality of life (QoL) and pancreatic insufficiency were evaluated through specific questionnaires.

**Results:** The final study population consisted of 75 patients: 62.6% underwent surgery and 37.4% were managed without surgery. All surgical procedures consisted of pancreaticoduodenectomy. The median follow-up from the diagnosis of PP was 60 (12 - 240) months. Patients who underwent surgery experienced a similar incidence of steatorrhea (44.7 vs. 52.6%; p= 0.4) but a significant higher incidence of diabetes (59.6 vs. 10.7%; p< 0.01) when compared to those managed without surgery. There was no difference in terms of reported chronic pain (Graded chronic pain scale, median 0 vs. 1; p= 0.1) and QoL (Pancreatitis QoL Instrument, median 82 vs. 79; p=0.2). However, surgical patients reported a worse level of self-care activities associated with glycemic control (Diabetes self-management questionnaire, median 20 vs. 28, p=0.02).

**Conclusion:** In patients affected by PP, surgery and medical therapy seem to obtain similar results in terms of QoL and pain control. However, surgery is associated with an increased prevalence of postoperative diabetes with consequent relevant issues in the self-care management.

**Introduction:** Chronic pancreatitis (CP) is associated with high morbidity and mortality. Chronic inflammatory changes leading to systemic atherosclerosis can cause ischemic heart disease (IHD). Studies observing this relationship are limited, particularly describing associated epidemiological relationships, mortality rates, and the role of statin therapy. This study aims to analyze variables that pose a risk of IHD development in patients with chronic pancreatitis, and report the role of statin use.

**Aims & Methods:** A population-based study was conducted using a cloud-based, HIPAA-enabled web platform called Explorys (IBM, New York) to collect aggregated de-identified electronic health records. At the time of

the study, Explorys had access to over 62 million unique records. Data was obtained using ICD-9 code criteria for chronic pancreatitis, ischemic heart disease, and HMG-CoA reductase inhibitors (statins). Patient characteristics and all-cause mortality rates were compared with patients of IHD after a diagnosis of CP as a first time event using relative risk (RR) with 95% confidence interval (CI) in a random-effect model.

**Results:** Chronic pancreatitis was found in 81,820 patients, of which 14,500 (17.7%) had subsequent development of IHD. The RR of IHD was significantly higher in patients with prior CP vs. the control population in our registry [RR 7.50 (95% CI: 7.37-7.63),  $P < 0.0001$ ]. Family history of cardiac disease, tobacco use, obesity, and aspirin use were higher in the CP with IHD population. Patients that were elderly ( $> 65$ ), male, and African-American were at higher risk of IHD with prior CP. Also, there was a higher rate of all-cause mortality in patients with CP and IHD vs. patients with CP alone. The younger population (18 - 65) and African-Americans with CP on statins had a beneficial effect in the prevention of IHD. Statins did not affect all-cause mortality in patients with CP and IHD vs. patients on statins with CP with subsequent IHD ( $P=0.3338$ ).

Characteristic	Chronic Pancreatitis [n=81,820]	Chronic Pancreatitis with subsequent IHD [n=14,500]	Relative Risk [95% CI]	P
Age, n [%]				
18-65	53,640 [66]	6,870 [47]	0.47 [0.46, 0.49]	$< 0.0001$
$> 65$	27,740 [34]	7,590 [52]	2.14 [2.08, 2.20]	$< 0.0001$
Male, n [%]	42,390 [52]	8,290 [57]	1.24 [1.21, 1.28]	$< 0.0001$
Ethnicity, n [%]				
Caucasian	58,240 [71]	10,340 [71]	1.01 [0.97, 1.04]	0.7039
African-American	16,670 [20]	3,500 [24]	1.24 [1.20, 1.29]	$< 0.0001$
Hispanic	4,390 [5]	740 [5]	0.95 [0.89, 1.01]	0.1246
Cormorbidities, n [%]				
FH of Cardiac Disease	11,620 [14]	2,410 [17]	1.20 [1.16, 1.25]	$< 0.0001$
History of tobacco use	31,770 [39]	6,450 [44]	1.26 [1.23, 1.30]	$< 0.0001$
BMI $> 30$	47,300 [58]	11,210 [77]	2.48 [2.40, 2.58]	$< 0.0001$
Aspirin use, n [%]	32,600 [40]	10,710 [74]	4.26 [4.12, 4.42]	$< 0.0001$
All-cause Mortality, n [%]	10,670 [13]	3,160 [22]	1.86 [1.80, 1.92]	$< 0.0001$

[Baseline characteristics]

**Conclusion:** Patients at higher risk of IHD post CP diagnosis include being elderly, male, and African-American. Mortality is significantly increased in patients with CP and IHD vs. CP alone. Statins had a beneficial effect in decreasing the rates of IHD in patients that were less than 65 and African-Americans.

## P0813 QUALITY OF LIFE ASSESSMENT IN PATIENTS WITH PANCREATIC DISORDERS AND EXOCRINE INSUFFICIENCY RECEIVING ENZYME REPLACEMENT THERAPY

Kovacheva-Slavova M., Genov J., Golemanov B., Vladimirov B.  
University Hospital Tsaritsa Ioanna-ISUL, Gastroenterology, Sofia, Bulgaria

**Contact E-Mail Address:** kovacheva\_mila@abv.bg

**Introduction:** With disease progression and complications appearance patients with pancreatic disorders complain of impaired overall quality of life (QoL). Nowadays the QoL assessment is adopted as part of the monitoring strategy of the treatment and the patients' outcome.

**Aims & Methods:** The aim of this study was to investigate QoL in patients with pancreatic disorders, receiving pancreatic enzyme replacement therapy due to pancreatic exocrine insufficiency. Study enrolled 142 patients (88 males, mean age 52years); 82 patients had chronic pancreatitis (CP), 30-acute pancreatitis (AP), 30- pancreatic cancer/pancreatic resection (PC/PR). QoL was evaluated by the European Organization for Research and Treatment of Cancer QoL questionnaire (QLQ-C30), containing 30 questions. The QLQ-C30 is composed of both multi-item scales and single-item

measures. These include five functional scales, three symptom scales, a global health status / QoL scale, and six single items. Each of the multi-item scales includes a different set of items - no item occurs in more than one scale. Severity of CP was assessed by M-ANNHEIM classification. We evaluated nutritional status (prealbumin and retinol binding protein (RBP) by immunonephelometry, fat-soluble vitamins A, D, E by HPLC and LC-MS/MS. Statistical analysis was performed via SPSSv22.

**Results:** Patients with pancreatic cancer had shown worst QoL, including all functional scales, symptomatic scales (fatigue, nausea, pain), dyspnoea, loss of appetite and diarrhoea. Mean levels of scale scores of physical functioning ( $p=0.013$ ), role functioning ( $p=0.06$ ) and dyspnoea ( $p=0.032$ ) were significantly lowest in patients with PC/PR. We demonstrated significant worsening of mean levels of scale scores according to global health status and almost all functional scales and symptomatic scales/items (except of cognitive functioning, dyspnoea, insomnia, constipation, and diarrhoea) with progression of CP with significant lowest QoL in patients with advanced CP. Patients with AP without walled-off necrosis had significant overall better QoL scale scores compared to those with walled-off necrosis. In all groups of patients (CP, AP, PC/PR) we observed a tendency to better QoL assessment with nutritional status normalization. Significant differences were found mainly in the protein markers prealbumin and RBP in patients with CP and PC/PR.

**Conclusion:** An effort should be point at multidisciplinary approach for up-to-date strategy for patients with pancreatic disorders, focusing not only on the improvement of symptoms and nutritional status, but also on social well-being. Questionnaires on quality of life are useful clinical tools that would identify patients at risk who to be provided with therapeutic education and physical rehabilitation, behavioral support and medication.

**Introduction:** Multiple case reports and case series describe the successful management of pancreatic duct stones with mechanical lithotripsy (ML), electrohydraulic lithotripsy (EHL), and extracorporeal shock wave lithotripsy (ESWL). Combining ESWL with ERCP may increase the rate of complete main pancreatic duct (MPD) clearance. However, no randomized studies have compared the efficacy of ESWL with other lithotripsy modalities for MPD clearance.

**Aims & Methods:** To evaluate the adequate methods of pancreatic stone treatments and compare the abilities of lithotripters to fragment pancreatic stones, we retrospectively evaluated 161 cases from June 2012 to December 2018 that were performed by 8 well-trained pancreaticobiliary physicians. For the preparation management of ESWL, endoscopic pancreatic sphincterotomy (EPST) was routinely performed with ERCP. Cases complicated by abdominal complaints (exacerbation of pancreatitis, pseudocysts, and fistula), endoscopic nasal pancreatic drainage (ENPD) or endoscopic pancreatic stent (EPS) placement were initially possible. Pancreatic stones treated with endoscopic monotherapy were excluded in this study. ESWL was continued until the stone disintegration was observed. If sufficient effect was not achieved, endoscopic electrohydraulic lithotripsy (EHL) or endoscopic lithotomy using basket or grasping forceps was additionally performed. For ESWL, we used a third-generation electromagnetic shock wave lithotripter (Lithoskop, Siemens, Erlangen, Germany; group 1) from 2008 to 2016 and Modulith SLX-F2 (Storz Medical AG, Tagerwilen, Switzerland; group 2) from 2017 to 2018. ESWL disintegration and additional endoscopic lithotomy rates were evaluated and compared between the two lithotripters.

**Results:** In this study, 161 patients (169 stones; Lithoskop, 129 cases and Modulith, 40 cases) were evaluated. The ENPD/EPS placement success rates were 43.9% and 45.7% in groups 1 and 2, respectively, showing no significant difference between the ESWL preparations. No significant dif-

ferences were also found between the stone characteristics (stone size, computed tomography value, and number and location of stones). For the 144 stones in the MPD head, the success rates of the initial ESWL procedure were 68.1% in group 1 and 78.6% in group 2, showing no significant difference between the two lithotripters. The overall success rate with additional endoscopic lithotomy was decreased to 66.7% in group 1 and increased to 92.9% in group 2, showing a higher stone lithotomy rate using Modulith SLX-F2 and additional endoscopic treatments ( $p < 0.05$ ). For the 25 stones in the MPD body, the success rate after the initial ESWL procedure was 53.9% in group 1 and 83.3% in group 2, respectively, showing no significant difference between the two lithotripters. The overall success rate with additional endoscopic lithotomy was increased to 61.5% in group 1 and 91.7% in group 2, showing no significant difference between the two treatment methods ( $p = 0.07$ ). MPD head stricture was significantly associated with factors of unsuccessful additional stone lithotripsy and was the only factor of unsuccessful stone lithotripsy.

**Conclusion:** No significant differences were found in the disintegration rates between the two lithotripters. However, pancreatic stone disintegration rate attained more than 90% by using a Modulith SLX-F2 lithotripter with additional endoscopic lithotomy.

### P0815 UTILITY OF A 21-GAUGE MENGHINI TYPE BIOPSY NEEDLE FOR AN ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE BIOPSY FOR THE HISTOPATHOLOGICAL DIAGNOSIS OF AUTOIMMUNE PANCREATITIS

Tsutsumi K.<sup>1</sup>, Ueki T.<sup>1</sup>, Kawahara S.<sup>1</sup>, Oda T.<sup>1</sup>, Noma Y.<sup>2</sup>

<sup>1</sup>Fukuyama City Hospital, Department of Internal Medicine, Fukuyama, Japan,

<sup>2</sup>National Hospital Organization Fukuyama Medical Center, Department of Gastroenterological Medicine, Fukuyama, Japan

**Contact E-Mail Address:** tsutsumi@cc.okayama-u.ac.jp

**Introduction:** The pancreatic histology is a cardinal factor influencing a diagnosis of autoimmune pancreatitis (AIP), but the International Consensus Diagnostic Criteria (ICDC) state that it should be assessed only using surgical or core biopsy specimens. We evaluated the utility of pancreatic tissue collection using a 21-gauge Menghini type biopsy needle with an endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) for the diagnosis of AIP.

**Aims & Methods:** From January 2015 to December 2018, 14 patients at our institution who had been diagnosed with definitive type 1 AIP (n=13) or not-definitive type 1 AIP (n=1) based on pancreatic imaging, serum IgG4 levels, and other organ involvement according to the ICDC underwent an EUS-FNB using a 21-gauge biopsy needle (EUS Sonopsy CY®; HAKKO, Nagano, Japan) originally made for a liver biopsy. No patients had type 2 AIP. After the enlarged lesion in the pancreas had been punctured, the needle was pushed forward quickly with aspiration under 10 mL of negative pressure, and then the handle of the needle was turned until the tip of the needle was confirmed to be rotated in the lesion. To reduce the contamination of blood, this procedure was repeated only three times. The male-to-female ratio of patients was 11:3, and the median age was 71 (range: 50-79) years old. Diffuse enlargement and segmental or focal enlargement of the pancreas was present in 10 (71%) and 4 (29%) patients, respectively.

**Results:** Adequate specimens were obtained in all patients, with a median of 4.5 (range: 2-6) punctures. Regarding the histopathological findings based on the ICDC, lymphoplasmacytic infiltration, IgG4-positive plasma-cyte infiltration (>10/high-power field), storiform fibrosis, and obliterative phlebitis were detected in 9 (63%), 9 (63%), 4 (29%), and 0 patients, respectively. Consequently, 9 patients (63%) were histopathologically diagnosed with AIP (level 1 and level 2 criteria of lymphoplasmacytic sclerosing pancreatitis met by 4 [29%] and 5 [36%] patients, respectively). This histological finding contributed to a diagnosis of definitive type 1 AIP in a patient who had had not definitive type 1 AIP. Two patients (14%) who had undergone endoscopic pancreatography on the same day had procedure-related pancreatitis.

**Conclusion:** The 21-gauge Menghini type biopsy needle may be useful for the histopathological diagnosis of AIP because of its high recovery rate of pancreatic tissue with relatively little blood contamination.

**Disclosure:** Nothing to disclose

### P0816 IMMUNOGLOBULIN G SUBTYPES-1 AND 2 (IGG1 AND IGG2) CAN DIFFERENTIATE BETWEEN AUTOIMMUNE PANCREATITIS WITH ASSOCIATED CHOLANGIOPATHY AND PRIMARY SCLEROSING CHOLANGITIS

**Contact E-Mail Address:** mvujas@gmail.com

**Introduction:** Autoimmune pancreatitis (AIP) type 1 is part of a larger systemic disease defined by fibrosclerotic processes and elevated IgG4 and hence called IgG4-related disease (IgG4-RD). Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive destruction of the bile ducts and eventually development of biliary cirrhosis. IgG4 associated cholangiopathy (IAC) may be present at the time of AIP type 1 diagnosis or occurs later in the disease course. IgG4 is considered reliable but not ideal marker for diagnosis of AIP type 1 with reported sensitivity between 71 to 81%. It is essential to differentiate sclerosing cholangitis with AIP from primary sclerosing cholangitis (PSC) as the treatment and prognosis of the two diseases are totally different.

**Aims & Methods:** Based on circumstantial evidence on other IgG subclasses found elevated in autoimmune rheumatologic diseases the aim of this study was to test all IgG subclasses to assess their usefulness to differentiate AIP with IAC from PSC as the other chronic and autoimmune disease of the bile ducts. We performed retrospective analysis of patients with AIP at our outpatient clinic. Patients from the PSC registry were taken as a control group. Blood samples for the measurement of all IgG subclasses were analyzed at the time of diagnosis before the patients received corticosteroid/immunosuppressive therapy.

**Results:** From our patient registries, we included 142 patients where all IgG subclasses were measured, 69 with AIP type 1 and 73 with PSC. Patients with AIP and IAC had higher values in IgG2 when compared to AIP alone or PSC with a high specificity (97%) and high positive predicted value (PPV=91%). In patients with normal or low IgG2 or IgG4, a high IgG1 indicated PSC.

**Conclusion:** IgG1 and IgG2 can distinguish patients with AIP-related cholangitis (IAC) from those with PSC. High serum IgG2 in those who are IgG/IgG4 positive and elevated IgG1 in those who have low or normal IgG2 and IgG4 indicating PSC in this context can be considered an additional aid in establishing the one condition and/or excluding the other.

### P0817 LUNG INVOLVEMENT IN PATIENTS WITH AUTOIMMUNE PANCREATITIS

Vujasinovic M.<sup>1</sup>, Panic N.<sup>1</sup>, Valente R.<sup>1</sup>, Haas S.L.<sup>2</sup>, Löhr J.-M.<sup>3</sup>

<sup>1</sup>Karolinska University Hospital, Department of Digestive Diseases, Stockholm, Sweden, <sup>2</sup>Karolinska University Hospital, Stockholm, Sweden, <sup>3</sup>Karolinska Institutet, Department of Clinical Science, Intervention, and Technology (CLINTEC), Stockholm, Sweden

**Contact E-Mail Address:** mvujas@gmail.com

**Introduction:** Immunoglobulin G4-related disease (IgG4-RD) is a systemic immune-mediated disease characterized pathologically by the infiltration of IgG4-bearing plasma cells into involved organs. Autoimmune pancreatitis (AIP) is a form of chronic pancreatitis with a heavy lymphocytic infiltration and two distinct histopathological subtypes: lymphoplasmacytic sclerosing pancreatitis (AIP type 1) and idiopathic duct-centric pancreatitis (AIP type 2). Pulmonary involvement (including lung, pleura and mediastinum) has been reported in 12% of patients with systemic IgG4-RD presentations. Most of the epidemiological data is coming from Japan and there is a lack of information from Europe, especially from Scandinavian countries. We are presenting first results on lung involvement in patients with AIP in European population.

**Aims & Methods:** We performed a single-center retrospective study on a prospectively collected cohort of patients diagnosed with AIP at the outpatient clinic of the Department for Digestive Diseases at Karolinska University Hospital in Stockholm, Sweden from 2004 to 2018. Demographic and clinical data were collected from the medical charts.

**Results:** Eighty-seven patients with AIP were included in the study; 56.3% male and 43.7% female, average age of 50.3±19.2 years. Patients were followed for 51.7±40.6 months after the diagnosis of AIP. Majority were never smokers (60.7%). Lung involvement was diagnosed in 17 (19.5%) patients: 13 patients with asthma, 5 patients with nodular lesions, 2 patients with granulomatosis with polyangiitis and 2 patients with mediastinal lymphadenopathy (in 4 patients combination of mentioned clinical conditions were presented).

**Conclusion:** Lung involvement was diagnosed in 17 (19.5%) patients in AIP. Compare with other studies, our patients were younger, presentation of OOI was more often and the proportion of female was higher. There was no connection with environmental factors such as occupation of patients.

**Disclosure:** Nothing to disclose

## P0818 IL1R1 GENE POLYMORPHISMS IN IGG4-RELATED DISEASE PATIENTS ARE ASSOCIATED WITH IGG4-RELATED PERIAORTITIS/PERIARTERITIS

Ashihara N., Ota M.  
Shinshu University School of Medicine, Second Department of Internal Medicine, Asahi, Japan

**Contact E-Mail Address:** kenta55226@gmail.com

**Introduction:** Immunoglobulin G4-related disease (IgG4-RD) is a systemic condition characterized by high serum immunoglobulin G4 (IgG4) concentration and IgG4-bearing plasma cell infiltration in affected organs. Recently, IgG4-RD has been recognized to affect the cardiovascular system as the IgG4-related periaortitis/periarteritis, which includes the inflammatory aneurysms, lymphoplasmacytic aortitis, and aortic dissection. IgG4-related periaortitis/periarteritis show adventitia and/or tunica media thickness by IgG4-positive plasma cells. Nearly half of the inflammatory abdominal aortic aneurysms leading to surgical treatment might be classified into IgG4-related. Therefore, it is important to predict the onset of vascular lesions at the time of diagnosis of IgG4-RD. However, the factors of onset of IgG4-related periaortitis/periarteritis are unclear.

**Aims & Methods:** In this study, we performed GWAS screening analysis for 124 cases of IgG4-related disease. And the association analysis was performed between the groups with vasculitis (41) and without vasculitis (83). The vasculitis was detected by imaging findings using contrast-enhanced CT.

**Results:** Some SNPs in candidate genes (*CAMK2A*, *VPS13B*, *IL1R1*) showed a statistically significant correlation to the onset of vasculitis. Among them, we focused in investigation of *IL1R1* gene involved in various immune responses. We performed fine mapping of additional 8 SNPs (rs3917225, rs2287049, rs3917273, rs2160227, rs951192, rs3917318, rs7582198) with TaqMan assays. 3 minor alleles of rs951192, rs3917318 and rs7582198 showed significant correlation ( $p < 0.0009$ ,  $OR > 4$ ) with the vasculitis group as the additive model.

**Conclusion:** These results suggest that *IL1R1* gene polymorphisms are related with the onset of IgG4-related periaortitis/periarteritis.

**Introduction:** Previously we reported pancreatic atrophy after the beginning of steroid therapy was associated with diabetes control worsening and incidence of new onset of diabetes in patients with autoimmune pancreatitis (AIP). However, the predictor for pancreatic atrophy and the exacerbation of diabetes after steroid therapy remains unknown.

**Aims & Methods:** To evaluate the role of equilibrium computed tomographic (CT) imaging for the prediction of pancreatic atrophy after steroid therapy. Forty-six steroid treated AIP patients, who underwent CE-CT examinations before and after steroid therapy, were included in this study during December 2005 to December 2017. CT attenuation (Hounsfield units [HU]) values in noncontrast (NC) and equilibrium phase (EP) images were measured by placing three regions of interest (ROIs) from the pancreas swelling at the diagnosis of AIP. The incidence of the pancreatic atrophy and diabetes exacerbation after steroid therapy was estimated by the following three parameters in CE-CT before steroid therapy:

- 1) HU values in NC images;
- 2) HU values in EP images; and
- 3) subtracted HU values between NC and EP images.

Pancreatic atrophy after steroid therapy was defined to be present when the width of the pancreatic body was less than 10 mm. Pancreatic volume of whole pancreas was measured in CE-CT before and after steroid therapy, and volume reduction rate was also calculated.

**Results:** Pancreatic atrophy was observed in 14 patients and not in 32 patients after the steroid therapy. The volume of the whole pancreas after steroid therapy correlated with the diameter of the pancreatic body ( $r=0.59$ ,  $P<0.0001$ ). Volume reduction rate of whole pancreas was also correlated with pancreatic body diameter ( $r=-0.49$ ,  $P=0.001$ ). Pancreatic atrophy was associated with the thickness of pancreatic body on HU values in EP and subtracted images ( $114.5\pm 12.8$  vs  $99.5\pm 11.1$ ;  $P=0.0002$ ,  $70.9\pm 14.72$  vs  $57.2\pm 13.1$ ;  $P=0.003$ ) before steroid therapy, but not with HU values in NC images ( $P=0.42$ ). HU values in EP and subtracted images were correlated with exacerbation of diabetes ( $P=0.0085$ ,  $P=0.04$ ). In addition, pancreatic body diameter, pancreas volume, and volume reduction rate after steroid therapy were associated with the exacerbation of diabetes ( $P=0.0003$ ,  $P=0.002$ ,  $P=0.0006$ ).

**Conclusion:** Equilibrium contrast and subtracted CT imaging at the diagnosis of AIP would be a potential predictor for pancreatic atrophy and the exacerbation of diabetes after steroid therapy.

**Introduction:** Autoimmune pancreatitis (AIP) is an immunemediated fibro-inflammatory disease of the pancreas. It frequently shows an incomplete response to glucocorticoids and immunosuppressants. Bcell depletion is

an effective treatment for type 1 AIP. Rituximab (RTX) seems to be an appealing alternative to conventional therapies for nonresponder or relapsing patients.

**Aims & Methods:** The aim of this study was to assess the efficacy of RTX in type 1 AIP in a prospective panel study. 15 patients with relapsing type 1 AIP after conventional steroid therapy and not responding or intolerant to Azathioprine, were treated with 4 doses of RTX (1000 mg each) from February 2013 to December 2017. Diagnosis of type 1 AIP was achieved with ICDC criteria. 14 of them had extrapancreatic involvement. Disease response was measured by IgG4-Related Disease Responder Index (IgG4RDI) and by serum IgG4 levels.

**Results:** Disease remission was achieved by 14 of the subjects (93%). The baseline IgG4RDI declines from a mean of 13.4 (range 721) to 1.5 (range 110) 6 months after the treatment ( $p < 0.001$ ). Serum IgG4 levels decreased from 492 mg/dl (range 1181260) to 92.5 mg/dl (range 37180) ( $p < 0.001$ ). The 36% of patients relapsed (5/15) after 28 months of followup (range 1539). The follow up was significantly lower in patients in complete remission (10, range 320) compared with those who relapsed (36, range 1746) ( $p = 0.005$ ). Two mild adverse infuse reactions associate with the use of RTX were reported (13%).

**Conclusion:** RTX seems to be effective in type 1 AIP. Overall, RTX treatment was well tolerated with minimal side effects. We need more trials to evaluate the long term safety profile.

**Disclosure:** Nothing to disclose

**Introduction:** Autoimmune pancreatitis (AIP) is an inflammation of the pancreas which was first described in 1961 but received its current name in 1995. Since it was detected there have been several different diagnostic criteria for AIP, the most recent being the International Consensus Diagnostic Criteria (ICDC) for AIP which were proposed in 2011. The first-line treatment for AIP typically consists of a steroid treatment; a response to steroid treatment also forms part of the diagnostic criteria for AIP. Pancreatic atrophy has been observed in several patients with AIP and it has been discussed whether the development of atrophy is aggravated by the treatment with steroids. Another disease which has been associated with AIP is diabetes mellitus (DM), the prevalence ranging from 12%-83.3%. Although AIP can be seen as a type of chronic pancreatitis (CP) and patients with AIP also can develop signs of CP, there have only been very few studies that have compared the course of the two diseases with each other.

**Aims & Methods:** Aim of our study was to compare these two groups with each other in regard to the rate at which these patients developed pancreatic atrophy and DM. For this study we collected the data of 105 patients who had come to the Gastrocentrum of the Karolinska University Hospital for AIP and CP and who in the course of time had developed an atrophy of the pancreas. Two patients were excluded because they lacked follow-up. The imaging which best coincided with the patients time of diagnosis was determined as month zero and all follow-up imaging evaluated to determine when the patient developed an atrophy, classified as first or second degree. Furthermore we determined if and when the patient had developed DM and looked at the measures of fecal elastase 1 (FE-1) as parameter for the exocrine function.

**Results:** The study showed that patients with AIP developed pancreatic atrophy significantly faster than patients with CP. Furthermore, the patients with AIP who had received steroid treatment had a significantly quicker development of atrophy 2nd degree compared to patients with AIP who did not receive steroid treatment. We also found that the time to development of DM was significantly shorter in the group of patients with AIP when compared with CP. Furthermore, at the time of diagnosis, patients with AIP had significantly lower values of fecal elastase-1 than patients with CP.

**Conclusion:** Patients with AIP develop pancreatic atrophy and DM significantly quicker than patients with CP of other etiology. Steroid treatment may aggravate the development of pancreatic atrophy in patients with AIP.

**Disclosure:** Nothing to disclose

## P0822 SURVIVAL OF RESECTABLE PANCREATIC CANCER: THE IMPACT OF POST-OPERATIVE CHEMOTHERAPY

<sup>1</sup>Allegheny Health Network, Gastroenterology, Pittsburgh, United States, <sup>2</sup>Allegheny Health Network, Radiation Oncology, Pittsburgh, United States, <sup>3</sup>Allegheny Health Network, Surgery, Pittsburgh, United States, <sup>4</sup>Allegheny Health Network, Heme/Onc, Pittsburgh, United States, <sup>5</sup>Allegheny Health Network, Radiology, Pittsburgh, United States

**Contact E-Mail Address:** aslam.syed@ahn.org

**Introduction:** Surgical resection with chemotherapy remains the preferred treatment for pancreatic ductal adenocarcinoma (PDA). Data remains limited regarding survival rates for resectable PDA with adjuvant chemotherapy treatment when managed by a multidisciplinary team. The objective of this study is to assess survival rates and outcomes of adjuvant chemotherapy for resectable PDA following presentation at a multidisciplinary pancreas conference (MDPC).

**Aims & Methods:** All patients presented at a tertiary care center from April 2013 to August 2016 with PDA were discussed at the MDPC and were followed prospectively until November 2018. Patients were included in the study if the MDPC determined they had resectable PDA. Resectable PDA was defined as no involvement or abutment of regional vascular structures and no extra-pancreatic disease as determined by radiologic imaging. Patients underwent attempted upfront surgery and were followed until the end of the study timepoint.

**Results:** A total of 278 patients were presented at the MDPC during the study period. The MDPC determined that 91 patients met criteria for resectable disease and 70 were fit for surgery. A total of 64 patients underwent successful surgery, as 6 patients had metastatic disease upon laparotomy (91.4% resection rate). Of the 64 patients that underwent surgery, 37 (58%) started adjuvant chemotherapy with only 16 (25%) completing treatment. Patients who completed their adjuvant chemotherapy had a significantly prolonged survival time versus those who did not complete all cycles (36.9 months vs. 18.8 months,  $P = 0.014$ ) (Figure 1). Reasons for patients who did not receive adjuvant chemotherapy included debilitation and post-operative complications (Table 1). Patients receiving any adjuvant chemotherapy had a median overall survival of 34.8 months versus a median overall survival of 17.1 months for those that did not ( $P = 0.43$ ). Each additional cycle of chemotherapy conferred a relative survival advantage of 13.7% ( $P = 0.016$ ).

Reasons for Not Starting Chemotherapy	Number of Occurrences
Post-Op Complications	7
Debilitation/Not Tolerating	5
ICU Admission	3
Metastatic Disease	3
Loss of follow-up	2
Prolonged Recovery	1
Surgically Curative	1
Unknown	5
Reasons for Not Completing Chemotherapy	Number of Occurrences
Side effects	8
Metastatic Disease	4
Debilitation	3
Not Tolerable	1
Unknown	5

[Failed Chemotherapy]

**Conclusion:** Our data suggest that successful completion of adjuvant chemotherapy has better survival outcomes, specifically for those who completed 4-6 cycles versus those that completed 1-3 cycles. Each successive

cycle following resection provides a significant survival advantage of nearly 14%. Given that only 25% of patients in this study completed adjuvant chemotherapy due to debilitation, operative complications, family issues, etc., consideration should be given for optimizing fitness or providing pre-operative neoadjuvant therapy in resectable PDA. Further studies are warranted.

**Contact E-Mail Address:** fnat98@yahoo.co.jp

**Introduction:** Although application of MR diffusion-weighted imaging (DWI) for pancreatic cancer diagnosis has spread in recent years, its sensitivity and specificity for pancreatic tumors has not been elucidated. Furthermore, results of its use in combination with magnetic resonance cholangiopancreatography (MRCP) remain unclear.

**Aims & Methods:** We attempted to clarify sensitivity and specificity, as well as positive and negative predictive values of DWI for pancreatic tumors. In addition, each of those 4 factors were examined with MRCP, and combined use of DWI and MRCP. Of 671 cases that underwent DWI and MRCP examinations from June 2017 to March 2019 at our hospital, 203 also evaluated by a pathological examination or contrast-enhanced endoscopic ultrasound sonography were retrospectively reviewed. Those included a case with a solid pancreatic mass in which both endoscopic ultrasound fine-needle aspiration biopsy (EUS-FNA) and surgery were rejected. Therefore, 202 patients were eligible for this study. Cases positive for a pancreatic tumor were defined based on pathological diagnosis following surgical excision, or EUS-FNA or pancreatic fluid cytology findings. On the other hand, those negative for a pancreatic tumor were defined when no solid tumor was detected by contrast-enhanced EUS, or cases with a solid mass detected by contrast-enhanced EUS ultimately denied based on EUS-FNA or pancreatic juice cytology findings. DWI was performed with a b-value of 800 and cases with high signal were defined as DWI-positive. MRCP-positive was determined when localized main pancreatic duct stenosis accompanied by caudal pancreatic duct dilation were detected by MRCP.

**Results:** Among the 202 cases, 15 had pancreatic tumors (invasive ductal carcinoma, 11; PanIN-3, 1; intraductal papillary mucinous neoplasia high grade (IPMN HGD), 3; neuroendocrine tumor (NET) G1, 1). DWI showed a sensitivity of 93.3%, specificity of 94.1%, positive predictive value of 56.0%, and negative predictive value of 99.4%, while those values for MRCP alone were 86.7%, 98.9%, 86.7%, and 98.9%, respectively, and for the combination of DWI and MRCP were 100%, 94.1%, 57.7%, and 100%, respectively. Of the 15 cases with a pancreatic tumor, all but 1 (PanIN-3) were revealed by DWI, including a 5-mm NETG1 tumor. The PanIN-3 case not seen in DWI findings was visualized by MRCP as localized main pancreatic duct stenosis with dilation of the caudal main pancreatic duct.

**Conclusion:** For pancreatic tumor diagnosis, DWI was found to be more sensitive than MRCP, while those in combination resulted in increased sensitivity. DWI was able to reveal lesions at the edge of the pancreas not shown by MRCP. Based on our findings, we consider that the combination of DWI and MRCP is a rational protocol. However, the positive predictive value of DWI is low and false positive findings are often noted, thus additional imaging methods such as EUS and contrast-enhanced CT are necessary for qualitative diagnosis.

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) has a suboptimal response to systemic treatments with an impact on survival due to its power to evade host immune surveillance (1). The binding of Programmed-cell Death 1 (PD-1) to its ligand Programmed-cell Death Ligand 1 (PD-L1) gives rise to a major immune tolerance mechanism (2). Thus, PD-L1 hyper-expression induced by tumor cells generates T cell apoptosis, escaping the tumor from immune surveillance. In addition, evaluation of MMR-D status is equally important, considering FDA approval of PD-1 inhibitor, pembrolizumab, for the treatment of unresectable or metastatic, microsatellite instability-high (MSI-H) or MMR-D PDAC that have progressed following prior treatment (3).

**Aims & Methods:** Considering that PDAC PD-L1 expression quantification is limited to surgical resection due to the current IHC test requirement for a histologic rather than a cytologic evaluation, (4) the objectives of the project include the assessment of tumor PD-L1/MMR-D expression in patients with PDAC using Endoscopic Ultrasound-Fine Needle Biopsy (EUS-FNB) samples.

**Results:** At this moment, in this prospective, non-randomized, single-arm, interventional study we

enrolled 20 patients with suspicion of pancreatic masses who performed EUS-FNB for

confirmation of diagnosis. All patients have had a confirmed diagnosis of PDAC and

subsequently IHC was made for PD-L1/MMR-D testing. Through EUS-FNB, PD-L1/MMR-D

status was determined in all cases. PD-L1 positive rate measured by immunohistochemistry was 20% while MMR-D mutation was absent in all cases. In addition, PD-L1 status was positive in 2 patients with a PDAC T4 stage.

**Conclusion:** EUS-FNB can successfully determine primary pancreas malignancy PD-L1/MMR-D status. PD-L1 expression levels represent a poor prognosis factor in PDAC patients

## P0825 PANCREATIC CANCER IN LIVER TRANSPLANT RECIPIENTS

**Macinga P.**, Gogova D., Chmelova K., Bajér L., Frankova S., Sperl J., Spicak J., Hucl T.

*Institute for Clinical and Experimental Medicine, Department of Gastroenterology and Hepatology, Prague, Czech Republic*

**Contact E-Mail Address:** peter.macinga@ikem.cz

**Introduction:** The chronic use of immunosuppressive agents in liver transplant recipients increases the long-term risk of malignancy (including gastrointestinal cancers), compared with that of general population.

**Aims & Methods:** The purpose of our study was to investigate incidence and characteristic of pancreatic cancer in liver transplant recipients. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between years 1996 and 2017. All patients were treated by combination of calcineurin inhibitors and mycophenolate mofetil with or without concomitant corticosteroids.

**Results:** In examined period, one thousand, three hundred fifty-two adult patients underwent liver transplantation in our center; the median follow-up was 60 (1-276) months. Adenocarcinoma of the pancreas was diagnosed in five patients (0.4%, SIR 1.76), four men and one woman. Average age of patients diagnosed with pancreatic cancer was 61 (56-67) years, the mean period between liver transplantation and occurrence of malignancy was 54 (26-136) months. Indications for liver transplantation were alcoholic liver cirrhosis (2x), overlap syndrome of primary sclerosing cholangitis and autoimmune hepatitis, liver cirrhosis due to chronic HCV infection and secondary sclerosing cholangitis. Four of five patients were non-smokers; the only smoker had tumor duplicity (lung cancer). Two patients were diabetics; one of them was diagnosed with new-onset DM six months prior to finding of cancer. One patient had chronic pancreatitis. One patient was diagnosed with stage IB cancer, all the others with stage IIB. Three patients underwent surgical treatment. Median overall survival was 3 (1-30) months, in resected group it was 12 (1-30) months.

**Conclusion:** In our study, liver transplant recipients had higher incidence of pancreatic cancer compared to that of general population. They were diagnosed in younger age and with earlier stage of the disease. Despite that, the prognosis was unfavorable.

**Disclosure:** Nothing to disclose

## P0826 SIGNIFICANCE OF IN VITRO PHOTODYNAMIC CYTODIAGNOSIS USING 5-AMINOLEVULINIC ACID IN SOLID PANCREATIC TUMORS EXTRACTED BY ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION

Hirao M.<sup>1</sup>, Housui A.<sup>1</sup>, Ashida M.<sup>1</sup>, Wakahara Y.<sup>1</sup>, Tanimoto T.<sup>1</sup>, Onishi K.<sup>1</sup>, Kusumoto Y.<sup>2</sup>, Yamaguchi T.<sup>1</sup>, Yamada T.<sup>3</sup>, Hiramatsu N.<sup>1</sup>

<sup>1</sup>Osaka Rosai Hospital, Gastroenterology, Osaka, Japan, <sup>2</sup>Osaka Rosai hospital, gastroenterology, Sakai, Japan, <sup>3</sup>Osaka Rosai Hospital, Gastroenterology & Hepatology, Sakai, Japan

**Contact E-Mail Address:** snowmotty1@yahoo.co.jp

**Introduction:** Recently photodynamic diagnosis using 5-aminolevulinic acid (5-ALA) has been gaining attention in diagnosing neoplastic diseases in the field of urology.

In the present study, *in vitro* method of photodynamic cytodagnosis (PDCD) using the reagent 5-ALA in the cytodagnosis of solid pancreatic tumors was attempted to develop and the accuracy of PDCD for malignancy was assessed.

**Aims & Methods:** EUS-FNA was performed for patients with solid pancreatic tumors at Osaka Rosai Hospital from September 2015 to March 2018. Samples were diagnosed independently by conventional cytology and PDCD. The definitive diagnosis of benign or malignant diseases was evaluated with the histopathological examinations on surgical specimens. In patients who did not undergo surgery, the final diagnosis was evaluated with the clinical, radiological, and serological evaluation during follow-up over 6 month as well as the histopathological examinations on cell blocks. ALA is the natural precursor in the heme biosynthetic pathway that induces the intracellular accumulation of endogenous protoporphyrin IX (PPIX) when provided exogenously in large excess. It is metabolized into PPIX in the mitochondria and is characterized by excessive intracellular accumulation in cancer cells. Because PPIX is overproduced in cancer cells, when stimulated by blue light, ALA-induced PPIX can be applied as a red fluorescence detection marker for photodynamic diagnosis (PDD).

**Results:** A total of 53 patients with solid pancreatic tumors (35 males and 18 females, average age: 70.2 years old [range, 38-89 years old]) were enrolled. The definitive diagnosis were 7 benign lesions (2 with chronic pancreatitis and 5 with autoimmune pancreatitis) and 46 malignant lesions (41 with pancreatic ductal carcinoma, 4 with pancreatic acinar cell carcinoma, and 1 with neuroendocrine tumor). With regard for malignant patients with class 4 and 5 disease, the diagnoses of conventional cytology had a sensitivity of 93.5% (43/46), a specificity of 85.7% (6/7), a positive predictive value of 97.7% (43/44). By *in vitro* PDCD method, the reddish fluorescence was detected in the cell samples, which was judged as cancer cells. PDCD showed a sensitivity of 91.3% (42/46) and specificity of 100%

(7/7), while conventional cytology showed a sensitivity of 93.5% (43/46) and specificity of 85.7% (6/7). Two patients are successfully diagnosed as malignancy by only PDCD method, while four patients were false-negative, two of which had pancreas cancer with formy gland pattern. In formy gland cells, PPIX is poorly produced since there are no mitochondria in these cells.

**Conclusion:** *In vitro* PDCD performed using the 5-ALA method can effectively and safely identify a diagnosis of pancreatic cancer without requiring an expert pathologist. The sensitivity of this technique could be increased in the diagnosis of pancreatic malignancy by combining it with the conventional method.

**Introduction:** Pancreatic cancer (PaC) is the third leading cause of all cancer related deaths with a high mortality rate and poor prognosis. Identifying risk factors and symptoms help improve the clinical management and outcomes of PaC. Depression often occurs in patients diagnosed with cancer, and is prevalent in up to 50-78% of patients with PaC. This study aims to evaluate demographical trends and mortality rates in patients diagnosed with PaC with preceding and subsequent depressive disorder. Additionally, the role of mental health professionals and its effect on survival is observed.

**Aims & Methods:** A longitudinal population-based study, using an IBM platform called Explorys was used to collect de-identified data. Over 60 million patients, spanning nationally in over 40 healthcare systems' electronic medical records are in this cloud-based, HIPAA-enabled platform. Data was obtained using SNOMED and ICD-9 code criteria with search terms "malignant tumor of the pancreas" and "depressive disorder." A temporal relationship was established to delineate relationship of depression diagnosis with PaC. Demographical data, mortality rates, depressive disorder symptoms and the role of mental health professionals (psychiatrist, psychologist, and behavioral professional) was observed and reported.

	Depression and PaC [N = 11,730]	Control [N = 5,290,190]	Odds Ratio [95% CI]	P

### [Depression Preceding Pancreatic Cancer]

**Results:** A total of 58,140 patients were found to have diagnosis of PaC, of which 11,730 (20.2%) had prior diagnosis of depression, and 11,690 (20.1%) had subsequent diagnosis of depression. Incidence was higher in females, Caucasians, African-Americans, and younger patients (18 - 65). All-cause mortality was higher in patients with depressive disorder and PaC vs. PaC

patients without depression ( $P < 0.001$ ). Patients with PaC and depressive disorder that were referred to a mental health professional had a lower rate of all-cause mortality when compared to patients without a referral ( $P = 0.009$ ). Additionally, 83.1% of patients had a diagnosis of PaC within 6 months of their depressive disorder diagnosis. Over 90% had diagnosis of PaC within 3 years. Preceding symptoms of anxiety, sleep disorder, agitation, and weight loss were strongly associated with higher rates of PaC.

**Conclusion:** Identifying and treating symptoms of PaC potentially helps improve outcomes and survival. This study shows that depressive disorder is under diagnosed in PaC and leads to higher mortality. Identifying clinical signs and symptoms of depression may help diagnose PaC earlier, and treatment improves survival. High vigilance is encouraged within the first 3 years of depressive disorder diagnosis for those at risk of pancreatic cancer. Referral to mental health care professionals improves survival in patients with PaC, therefore referrals or screenings should be considered as part of a multidisciplinary team management in pancreas cancer.

**Introduction:** Despite the high rate of recurrence after resection of pancreatic ductal adenocarcinoma (PDAC), Dutch and European guidelines for standardized follow-up are lacking. This has led to different surveillance strategies in daily clinical practice. In this context, data on the exact incidence, symptomatology, treatment and survival following PDAC recurrence in the Netherlands are lacking.

**Aims & Methods:** A multicenter retrospective observational cohort study was performed in 17 Dutch pancreatic cancer centers. Data from the first 10 centers were used for preliminary analyses. All patients registered in the prospective Dutch Pancreatic Clinical Audit who underwent PDAC resection (2014-2016) were included. Additional data on follow-up and treatment of PDAC recurrence were collected. Mean survival was evaluated using Kaplan-Meier curves. Multivariable Cox regression was performed to compare survival rates between patients who underwent treatment for recurrence and patients who received best supportive care. Survival analyses were stratified for symptomatic and asymptomatic patients.

**Results:** 401 resected patients with a median follow-up of 15 months (IQR 9-25 months) were analyzed. A total of 305 patients (76%) developed PDAC recurrence at a median follow-up of 9 months (IQR 6-15 months). Median overall survival in these patients was 13 months (IQR 9-21 months). In total, 91 patients (30%) underwent treatment for PDAC recurrence. Treatment was independently associated with longer survival, in both symptomatic patients (HR0.16 (95%CI 0.09-0.30);  $P < 0.001$ ) and asymptomatic patients (HR0.16 (95%CI 0.04-0.63);  $P = 0.01$ ). Of 57 patients with asymptomatic recurrence, 25 patients (44%) received palliative treatment, as compared with 63 (29%) of 214 symptomatic patients ( $P = 0.04$ ).

**Conclusion:** Treatment of both asymptomatic and symptomatic PDAC recurrence seems independently associated with improved survival. As these results are subjected to confounding by indication, lead-time bias and guarantee-time bias, prospective studies are needed to determine the true value of standardized follow-up and treatment of PDAC recurrence, accounting for psychosocial and economic aspects.

## P0829 REDUCTION OF ROCK2 GENE EXPRESSION CORRELATES WITH LIVER METASTASIS AS AN INDEX OF METASTASIS FOR INVASIVE DUCTAL CARCINOMA OF THE PANCREAS

Hamada Y.<sup>1</sup>, Kato D.<sup>2</sup>, Ishiguro M.<sup>1</sup>

**Contact E-Mail Address:** yoshihiro42@me.com

**Introduction:** Although resections for invasive ductal carcinoma of the pancreas (IDCP) are expected to leave no residual carcinoma (R0), the 5-year survival rate is only 37.4% [1]. The cause of the poor prognosis after surgical resection of IDCP is recurrent carcinoma. Recurrent sites after pancreatic resection of IDCP are usually found in the liver and local site. Notably, survival of patients with liver metastasis (LM) is significantly shorter than that of patients with local site recurrences [2]. Effective diagnosis and treatment of LM are primary steps to improve IDCP prognoses. We found that the median numbers of invaded veins and percentage of invaded veins/total number of veins in the IDCP area were significantly higher in the LM group (UEGW 2016, [3]). However, there remains the need to identify gene mutations related to liver metastasis for possible gene therapies. Various studies have shown that RNA microarray analysis improves the diagnosis and risk stratification of many cancers, but few studies have investigated the potential for liver metastasis of IDCP. In this study, we analyzed potential gene mutations involved in liver metastasis of IDCP by RNA microarray. Furthermore, immunohistochemistry was performed using diagnosed sections.

**Aims & Methods:** Of 402 patients who were diagnosed with IDCP, 21 (5.2%) had tumors with pT5. The follow-up period of the 21 patients was 6 months to 25 years. All patients underwent an R0 resection. Handling of the surgical specimens and assessment of vascular permeation by the carcinoma were performed as described previously [4]. Clinicopathological factors were assessed according to the Classification of Pancreatic Carcinoma (4th English edition) by the Japan Pancreas Society. Messenger RNA was obtained from formalin fixed, paraffin-embedded pancreatic sections. RNA harvested from resected pancreatic cancers was hybridized to RNA microarrays. Immunohistochemical staining was also performed. The antibody clone and dilution were ROCK2 (Gene Tex, USA) and 1:500, respectively.

**Results:** The small tumour group (n=21) included 12 males and nine females aged 51-80 years. Five patients died because of liver metastasis (LM group, n=5), and 12 patients survived without recurrence. The other patients died of non-pancreatic disease. We searched for gene mutation groups correlated to liver metastasis of IDCP, such as the vascular smooth muscle contract group, pathway in cancer group, Wnt signal group, and focal adhesion group. Significant reduction of ROCK2 gene expression was a common occurrence in the four groups ( $p = 0.013$ ). Moreover, reduction of ROCK2 expression in diagnosed sections was found in all cases of LM, but not in non-LM patients ( $p = 0.009$ ).

**Conclusion:** IDCP patients with reduction of ROCK2 gene expression have the potential for liver metastasis regardless of R0 resection of IDCP.

**Introduction:** Pancreatoduodenectomy (PD) is associated with significant incidence of morbidity, including postoperative pancreatic and biliary fistula (POPF and POBF), delayed gastric emptying (DGE), and other major and minor postoperative complications. These affecting the need and modality of nutritional support and prolongs hospital stay.<sup>1,2</sup> The reluctance to initiate early oral feeding arises from the fear of an increased risk for postoperative complications.<sup>3,4</sup>

**Aims & Methods:** Aim of this study was to evaluate the influence of early per oral food intake on development of postoperative complication after PD. This prospective observational study included 72 patients underwent PD due to pancreatic cancer. Patients were divided into 2 groups regarding time of initiation of solid per oral food intake (group 1 from 3-5 and group 2 >5 postoperative day). The groups were compared in relation to the occurrence of POPF, POBF, DGE and the Clavien-Dindo (CD) grade.

**Results:** The group 1 included 24(33%), and the group 2 48(67%) patients. There were no difference in age (p=1), gender (p=0.99), ASA score (p=1) and intraoperative blood loss (p=0.74) between groups. Duration of surgery was shorter in the group 2 (p=0.02), where 39(81%) patients underwent pylorus preserving PD versus 9(37%) patients with standard Whipple procedure in group 1 (p=0.001). POPF (grade A to C) occurred in 15(20%) patients, and clinical relevant POPF (grade B and C) occurred in 7(9.7%) patients. POBF occurred in 6(8%) patients and DGE was present in 16(22%) patients, respectively. POPF (grade A to C) developed in 5(21%) patients in group 1 and 10(21%) patients in group 2, (p=1). POPF (grade B and C) developed in 3(12.5%) patients in group 1 and 4(8.3%) patients in group 2, (p=0.62). POBF occurred in 0 patients in group 1 and 6(12%) patients in group 2, (p=0.17). One (4%) patient in group 1 experienced DGE and 15(31%) patients in group 2, (p=0.001). CD grade ≥3 had 4(17%) patients in group 1 and 21(44%) patients in group 2, (p=0.001). The presence of CD grade ≥3 was associated with delayed initiation of per oral food intake (p=0.009). Significant correlation between CD grade and time of initiation of per oral food intake was found (p<0.001).

**Conclusion:** Early initiation of oral feeding in patients underwent PD had no impact on POPF and POBF occurrence. Delayed initiation of per oral food intake was associated with the presence of DGE and CD grade ≥3.

	Total n=72	Group 1 (n=24)	Group 2 (n=48)	P
POPF n(%)	15 (20)	5 (21)	10 (21)	1.000
POBF n(%)	6 (8)	0	6 (12)	0.169
DGE n(%)	16 (22)	1 (4)	15 (31)	<0.001
CD grade n(%)				
0	27 (38)	16 (66)	11 (23)	<0.001
1	14 (19)	3 (13)	11 (23)	0.002
2	6 (8)	1 (4)	5 (10)	0.017
≥3	25 (35)	4 (17)	21 (44)	<0.001

**Contact E-Mail Address:** gianegeniotontini@libero.it

**Introduction:** Recent pilot studies assessed the feasibility of the Thulium and Erbium laser system (TELS) for endoscopic haemostasis, ablation and resection. Herein, we investigated for the first time ever, the safety and efficacy of endoscopic treatment with TELS in patients with gastrointestinal bleeding due to vascular lesions.

**Aims & Methods:** Consecutive patients treated with TELS for chronic gastrointestinal bleeding with moderate/severe anaemia due to vascular lesions were enrolled in two Italian centres between March 2016 and October 2018.

Technical success and safety as established by the ASGE Lexicon, were defined as primary endpoints.

As secondary endpoints, we assessed the biological success comparing the lowest haemoglobin values ±1 month prior to and after treatment, along with the need of packed red blood cells (PRB) transfusions ±6 month prior to and after treatment. For gastric antral vascular ectasia (GAVE), a new scoring system was proposed to evaluate pre/post-treatment endoscopic severity by assessing both mucosal involvement (< 30%=+1, 30-50%=+2, >50%=+3), and presence of bleeding (traces of blood=+3, active=+5). For each procedure, image/video documentations and TELS technical parameters (i.e., lasing time, power output, energy employed) were digitally recorded. Student paired t-test was performed.

**Results:** Twenty-six patients (20 men; range 48-91 years) underwent 32 endoscopic TELS sessions for the treatment of angioectasias (14/26), GAVE (9/26), and RP (3/26). All procedures resulted in a complication-free technical success, thereby reaching the primary study endpoints. Haemoglobin values showed a significant rise along with a decreased need of PRB transfusions. The median value of GAVE endoscopic severity remarkably improved within a six-month follow-up.

TELS endoscopic treatments (for each vascular lesion type)	32 (13 for GAVE; 14 for Angioectasia; 5 for RP)
Complication-free (any degree of adverse event) technical success	32/32
Δ Lowest Hb ± 1month (30/32 procedures*)	+1.58 g/dl (95%CI = 0.93-2.23, p-value <0.001)
Δ PRB ± 6months (30/32 procedures*)	-1.8 units (95%CI = -2.8--0.8; p-value <0.001)
GAVE endoscopic severity (9/14 procedures*)	5 to 2

[Results - Ongoing follow-up data\*]

**Conclusion:** This multicentre study conducted in real-life setting suggests that TELS is a safe and effective tool for the endoscopic treatment of patients with gastrointestinal bleeding caused by various types of superficial vascular lesions.

**Disclosure:** Nothing to disclose

## P0832 PERCUTANEOUS TRANSESOPHAGEAL GASTROTUBING (PTEG) -THREE WAYS OF PROCEDURE

Murakami M.<sup>1,2</sup>, Nishino K.<sup>1</sup>, Okamoto T.<sup>1</sup>, Murakami S.<sup>1</sup>, Mori K.<sup>1</sup>, Murakami B.<sup>1</sup>, Azuma M.<sup>2</sup>, Tanabe S.<sup>3</sup>, Kida M.<sup>4</sup>, Koizumi W.<sup>2</sup>

**Contact E-Mail Address:** masato@murakami-kinen.or.jp

**Introduction:** Percutaneous transesophageal gastrotubing (PTEG) was established as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated. PTEG will be an ideal method for tube feeding and decompression. There are three ways of procedure, and a similar effect is expected.

**Aims & Methods:** The aim of this study is to evaluate the clinical usefulness of PTEG for the patients who need tube feeding or decompression from gastrointestinal tract. A rupture-free balloon (RFB) catheter is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. Conventional procedure supported by fluoroscopy was classified in group A, Group B was supported by endoscopy. Double Balloons equipped Over tube type RFB were used instead of primary RFB under endoscopic support was classified in group C that the puncture needle is punctured into the over tube trough the balloon. We perform PTEG in a total of 185 patients (115men and 70women, mean age 71.3 years) in whom PEG was not feasible. PTEG was performed for nutrition in 104 patients and for decompression in 81.

**Results:** The number of patients was 30 in group A, 117 in group B, and 38 in group C respectively. Satisfactory results were achieved in all 185 patients. Median follow-up was 327.0 days in those who received nutrition and 66.0 days in patients who received decompression. Nine of the 30 patients who were started in the fluoroscopically assisted (Group A) needed endoscopic assistance to complete the procedure. Two of the 117 patients in the endoscopic assistance (Group B) required fluoroscopy because of the tube insertion into the jejunum. All patients could free from nasal tube prior insertion. Six of 104 patients for nutrition were able to free from tube feeding due to PTEG tube feeding support. Oral ingestion could be achieved in 44.0% and home care could achieved in 66.0% of decompression group patients. Major complications were bleeding in two patients required blood transfusion and one patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in thirteen patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. Complication rate of each group was 16.7%, 11.1%, 15.7%, respectively. No patient required surgical treatment or died after PTEG.

**Conclusion:** PTEG is safe and useful for long-term nutrition and/or decompression for the patient who is contraindicated to PEG. PTEG is a suitable procedure of the patients having an eating disorder and/or the malignant disease as tubal feeding and palliative care. Same result is achieved in any way of procedure.

**Disclosure:** Nothing to disclose

## P0833 FEASIBILITY AND EFFECTIVENESS OF IRREVERSIBLE ELECTROPORATION APPLIED BY ENDOSCOPIC CATHETERS ON GASTROINTESTINAL TRACT: AN EXPERIMENTAL ANIMAL STUDY

Han Jo J., Choi H.S., Lee K.W., Kim S.H., Kim S.H., Jang S.H., Choi S.J., Kim S.H., Lee J.M., Kim E.S., Keum B., Jeon Y.T., Lee H.S., Chun H.J., Kim C.D.

Korea University College of Medicine, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** roadstar82@naver.com

**Introduction:** Irreversible Electroporation (IRE) is an ablation technique that induces apoptosis by applying an electric field. IRE has several advantages over other ablation techniques. Recently, ablation therapy studies have been performed on Barrett's esophagus and gastrointestinal tumors,

and they are becoming popular as next ablation therapy in various cancers. The purpose of this study was to investigate the possibility of applying IRE therapy to gastrointestinal tract using newly designed endoscopic ablative catheters.

**Aims & Methods:** After a pig was anesthetized, the esophagogastroduodenoscope was approached into the stomach of the pig. We inserted the IRE catheters into the channel of the endoscope. Then the DC generator was connected to the IRE catheter and applied electrical stimulation to the target of duodenum, stomach, and esophagus. The conditions of electrical stimulation are as follows; amplitude ranged from 500V to 2000V, pulse number ranged from 20 to 60, pulse duration was 100us, pulse length was 100ms. Pigs were sacrificed after 24 hours later and ablated tissues were analyzed by H & E staining and TUNEL assay.

**Results:** Result from H & E staining, there was no damage at 500 V in all the organs. On the contrary, erosion and necrosis occurred in mucosa at 1000V, and inflammation occurred in submucosa at 1500V in both stomach and duodenum. At 2000V, extensive hemorrhage and inflammation occurred in the submucosa. However, submucosal inflammation was also developed in pulse number 80. In the esophagus, epithelial separation occurred at 1000V and epithelial erosion occurred at 1500V. It was the 2000V that inflammation of submucosa occurred. Secondly, TUNEL assay was used to confirm apoptosis, and as the voltage and pulse became larger, the area in which apoptosis was induced was wider.

**Conclusion:** Tissue apoptosis was successfully induced by using the IRE catheter. Our newly designed IRE catheters showed feasibility and effectiveness on GI tract.

## P0834 LONG TERM SURVIVAL OF EARLY GASTRIC CANCER WITH SUBMUCOSAL INVASION AFTER ESD

Takagi Y.<sup>1</sup>, Yamamoto K.<sup>1</sup>, Michida T.<sup>2</sup>, Sato Y.<sup>1</sup>, Tokuda Y.<sup>1</sup>, Hiyama S.<sup>1</sup>, Tatsumi N.<sup>1</sup>, Ito T.<sup>1</sup>

<sup>1</sup>Japan Community Healthcare Organization Osaka Hospital, Department of Gastroenterology, Osaka, Japan, <sup>2</sup>Saitama Medical College, Gastroenterology and Hepatology, Kawagoe, Japan

**Contact E-Mail Address:** risv4k2b@yahoo.co.jp

**Introduction:** Clinical outcome of early gastric cancer (EGC) with submucosal (SM) invasion after endoscopic submucosal dissection (ESD) is not fully elucidated. Additional surgery may decrease the mortality by lymph node metastasis, but can be an overtreatment for some patients with SM invasion gastric cancer. We investigated the clinical outcome for SM invasion gastric cancer after ESD.

**Aims & Methods:** We investigated the clinical outcomes for EGC with SM invasion after ESD and validity of Japanese guideline

**Methods:** ESD was performed for 1196 patients (1637 lesions) of EGC at our hospital between July 2006 and December 2018. 148 patients (153 lesions) were histopathologically diagnosed as tubular adenocarcinoma with SM invasion. Based on the Japanese guideline, we recommended the patients to undergo radical surgery or be followed up without additional treatment after ESD. Concretely, the patients whose histopathological findings revealed SM invasion depth were shallower than 500µm, lymphatic and venous invasion were negative, horizontal and vertical margin, ulcerative findings were negative, and tumor size were 3cm or smaller, pathological findings were undifferentiated type were followed up without additional treatment. Other patients were recommended to undergo radical surgery. Patients were divided into radical surgery group (n=78) and no additional treatment group (n=70). We retrospectively analyzed the disease-specific survival (DSS) and disease-free survival (DFS) in both groups, and risk factors of lymph node metastasis in surgical specimen or recurrence after ESD.

**Results:** 3 year and 5 year DSS are 98 % and 98 % in radical surgery group, and 98 % and 98 % in no additional treatment group. 3 year and 5 year DFS were 97 % and 97% in radical surgery group, and 96 % and 93 % in no additional treatment group, respectively. There are no statistically significant differences between the radical surgery group and no additional treatment group in DSS and DFS. In radical surgery group, six patients had lymph node metastasis in surgical specimen. Two patients who had not have lymph node metastasis recurred afterwards. On the other hand, three patients who were recommended to undergo radical surgery but didn't do it had a local recurrence in no additional treatment group. The rate of lymph node metastasis in surgical specimen or recurrence were 13.4%

(11/82) in the subgroup of histopathologic findings with deep submucosal invasion (SM deeper than 500µm), 40% (6/15) with venous invasion, 20.6% (7/34) with lymphatic invasion, 21.2% (7/33) with ulcerative findings, 15% (6/40) with large tumor size (>30mm), 10% (2/20) with vertical margin positive or unclear and 14.3% (2/14) with undifferentiated histological type, respectively. Multivariate analysis revealed that venous invasion and ulcerative finding were independent risk factors of lymph node metastasis in surgical specimen or recurrence (odds ratio: 3.9, 3.7 95% confidence interval 1.13 to 14.4, 1.10-14.4; p=0.03, p=0.03, respectively).

**Conclusion:** This study demonstrates that the patients of gastric cancer with SM invasion after ESD revealed long term survival. Venous invasion, and ulcerative finding seemed to be significant risk factors of lymph node metastasis in surgical specimen or recurrence.

### P0835 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC HETEROTOPIC PANCREAS WITH RECURRENT PANCREATITIS

Noh J.H., Kim D.H., Yoon J.Y.

University of Ulsan College of Medicine, Asan Medical Center, Gastroenterology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** mdjh1432@gmail.com

**Introduction:** Gastric heterotopic pancreas (GHP) is generally asymptomatic and rarely has complications such as pancreatitis, pseudocysts, gastric outlet obstruction, upper gastrointestinal bleeding, obstructive jaundice, or intussusception. We investigated clinical outcomes to determine the feasibility and effectiveness of ESD for GHP with recurrent pancreatitis.

**Aims & Methods:** Subjects who underwent ESD for GHP with recurrent pancreatitis at Asan Medical Center between 2003 and 2017 were eligible. The clinical features of patients and tumors, image finding, histopathologic characteristics, adverse events, results of ESD, and long-term outcome were investigated. We diagnosed with acute gastric heterotopic pancreatitis when the patient with GHP has recurrent severe abdominal pain and meets more than one of the following criteria. (1) increased size of GHP on endoscopic ultrasonography (EUS) or CT during the pain; (2) increase of serum pancreatic enzyme with normal pancreas on image; (3) no more abdominal pain after ESD.

**Results:** A total of 5 patients had undergone ESD for acute gastric heterotopic pancreatitis after conservative management. The median age was 32 years (interquartile range [IQR]: 28-37 years), and 2 was male. All lesions were located on greater curvature of antrum and 3 out of the lesions had a typical central indentation. On EUS, all lesions involved muscularis mucosa, submucosa and muscularis propria. The median tumor size was 20 mm (IQR: 18-35 mm), and the median procedure time was 26 minutes (IQR: 17-27 minutes). There were no procedure-related complications such as delayed bleeding or stricture. The 4 patients had increased in size of GHP on EUS or CT during the pain, one of them accompanied by elevation of serum pancreatic enzymes and had a complication of pseudocyst formation. In 1 patient, there was no increase in size of GHP but continued severe abdominal pain and had elevation of amylase. He resolved the recurrent abdominal pain after ESD. All patients had no recurrent abdominal pain during the follow-up period after ESD (mean follow-up period: 24.8±12.3 months).

**Conclusion:** ESD appears to be a feasible and effective alternative option to surgery for the treatment of GHP with recurrent pancreatitis, based on the favorable clinical outcomes.

**Disclosure:** Nothing to disclose

### P0836 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC LESIONS USING A NOVEL DIATHERMY KNIFE WITH SUCTION FUNCTION FOR BLEEDING CONTROL ASSISTANCE

**Introduction:** The Endosaber (Sumitomo Bakelite, Tokyo, Japan) is a newly developed, inexpensive multi-functional, needle-type knife with four tiny channels at the tip of the sheath capable of both suctioning and injecting. The equipped feature distinct from conventional endoscopic devices is the suction function, which enables clear visibility of the bleeding point during hemostasis. The tip of the sheath can come directly in contact with the bleeder, and with suction, clear the field at the same time. The aim of this study was to evaluate the clinical outcomes and safety of ESD using Endosaber for gastric lesions.

**Aims & Methods:** We included patients who underwent ESD for gastric lesions between June 2018 and August 2018 in this retrospective study. Lesions treated with ESD using a novel diathermy knife with suction capability, Endosaber (ESD-E) and conventional ESD (ESD-C) were compared. The endpoints were the treatment outcomes of ESD (en bloc resection rate, total procedure time, the procedure speed of specimen, the rate and procedures of using hemostatic therapies, the adverse events and the cost-effectiveness).

**Results:** Thirty-six gastric lesions in 33 consecutive patients (25 male, 8 female) were analyzed. ESD-E group consisted of 12 gastric lesions and ESD-C group consisted of 24 gastric lesions. The mean age was 68.2±10.6 years. There were no significant differences between the two groups with age, gender, location of lesions, morphology, and operator level. There were no significant differences in the average size of lesions between the two groups (17.2±10.7mm in ESD-E vs. 12.8±10.1 mm in ESD-C (p=0.24)).

Treatment outcomes of ESD showed an en bloc resection rate of 100% in both groups in gastric ESD; complete resection rate of 100% in ESD-E group vs. 97.0% in ESD-C group (p=1). With respect to adverse events, there was one micro-perforation observed in ESD-C group. There were no significant differences in the average time of ESD between the two groups (34.8±19.9 min in ESD-E vs. 37.8±22.5 min in ESD-C (p=0.70)). In the procedure speed of ESD specimens there were no significant differences between the two groups (30.0 mm<sup>2</sup>/min in ESD-E group vs. 19.3 mm<sup>2</sup>/min in ESD-C group (p< 0.20)). However multivariate regression analysis with operator level that was variables potentially affecting clinical outcomes identified using Endosaber as significantly correlated with gastric ESD. In rate of using hemostatic therapies there were no significant differences between the two groups (44.4% in ESD-E group vs. 47.1% in ESD-C group (p=1)). Fewer hemostatic procedures using the hemostatic forceps were performed in ESD-E group than in ESD-C, although the difference was not significant (0.9±1.7 in ESD-E group vs. 1.9±2.6 in the ESD-C group (p=0.3)). Then the cost of devices in ESD was significantly different between the two groups (338.6±155.9 EUR in ESD-E group vs. 414.5±0 EUR in ESD-C group (p< 0.05)).

**Conclusion:** ESD using Endosaber was safe and comparable to conventional ESD in gastric ESD. Using Endosaber appears to be faster than ESD-C significantly. Moreover, using Endosaber significantly lowered the ESD cost compared to conventional ESD. Further prospective studies are needed, but the sufficient utilization of the suction function might reduce the use of hemostatic forceps.

**Contact E-Mail Address:** myxn@ig.com.br

**Introduction:** Endoscopic resection has become a therapeutic option for the treatment of gastrointestinal(GI) tumors with or without superficial submucosal invasion. Endoscopic Submucosal Dissection(ESD) is a technique developed for en bloc resection of GI tumors that has been consolidated as safe, effective and with few complications, allowing adequate tumoral staging and improving rates of curative resections.

**Aims & Methods:** To describe the experience of a tertiary center for endoscopic treatment of esophageal, gastric and colorectal tumors by the ESD. A retrospective study evaluate patients with esophageal, gastric and colorectal tumors submitted to ESD from 2008 to 2018. Indication criteria for ESD were based on Guidelines of the Japanese Society and European Society. All resection products were sent for histopathological analysis.

**Results:** Ninety-two patients underwent ESD: 10 esophageal, 40 gastric and 42 colonic. In relation to esophageal tumors, mean age was 58(45-71)years, 90% male, being 9 squamous cell carcinomas(SCC) and 1 adenocarcinoma(ACA). Average size of tumors: 30.5 (20-40)mm and mean procedure time: 114(60-160)min. Complication rate: 20%, with 2 cases of perforation successfully treated endoscopically. Resection en bloc was possible in 9 patients. Histopathological analysis: 7 SCC intramucosal (m1=3;m2=1;m3=2)and 3 submucosal tumors (Sm1=1;Sm2 = 2). Nine cases had free deep resection margin; 2 had lateral margin invasion and 1 case the margins evaluation was not possible (peacemeal resection). Cure rate: 40%. About gastric tumors, mean age was 58(53-88)years, 57.5% male, with 25 ACA and 15 adenomas. Mean size: 30.4(15-60)mm and mean procedure time: 124(60-240)min. Complication rate: 8.5%, with 1 perforation and 2 late bleeding(1 of them elderly, with liver disease and blood dyscrasia that evolved to death). Resection en bloc was possible in 33 patients. Histopathological study showed: 15 cases pre-diagnosed as adenomas, 8 were ACA. Twenty five pre-diagnosed as ACA, 22 confirmed ACA and 3 showed adenomas with high-grade dysplasia(HGD). Among the ACA, 20 were intramucosal(m1=5;m2= 6;m3 = 9)and 10 with submucosal invasion(Sm1=8;Sm2=2). All cases had free deep resection margins, 2 with lateral focal involvement and 3 with vascular invasion. In 1 case, there was recurrence 3 months after ESD and the patient underwent gastrectomy. Cure rate: 90%. Regarding colorectal tumors, the mean age was 61(34-85)years, 57.1% female. Twenty six(62%) classified as granular laterally-spreading tumor(LST-G) and 16(38%) as non-granular LST(LST-NG), according to Kyoto Classification. The mean lesion size was 29.7(20-100)mm, with 20 located in the rectum, 3 sigmoid, 6 ascending, 6 transverse, 6 descending and 4 in the cecum. Mean duration of the procedure: 150 min(60-420 min). Histological diagnosis evidenced 28 adenomas: 19 with HGD, 8 with low grade dysplasia(LGD), 3 serrated with LGD. Twelve ACA: 11 mucosal invasion(m1=4;m2=4;m3=3)and one with submucosal invasion(Sm2). Among the LST-G (26), 7 had histological diagnosis of ACA, 12 adenomas with HGD and 7 with LGD. In relation to the LST-NG(16), 5 had diagnosis of ACA, 5 adenomas with HGD and 6 adenomas with LGD. Deep margins were all free of lesion, and in 3 cases(7.1%) lateral margin was compromised. There were 6 complications(14,3%): 2 minor bleedings without hemodynamic instability and 4 perforations, treated with conservative measures(clinical support and placement of endoscopic clips), all with good evolution. Cure rate: 98%.

**Conclusion:** ESD was safe, effective method, curative in gastric and colorectal tumors with few complications.

**Disclosure:** Nothing to disclose

## P0838 DIAGNOSTIC ACCURACY OF ENDOFASTER COMPARED TO HISTOLOGY FOR CHRONIC ATROPHIC GASTRITIS IN HYPO-ACHLORHYDRIC PATIENTS USING NARROW BAND IMAGING TARGETED BIOPSIES: A REAL-TIME PROSPECTIVE STUDY

**Introduction:** NISO Biomed EndoFaster is a medical device which automatically analyzes gastric juice in real time through its aspiration during upper gastrointestinal endoscopy. The operating principle of the device is based on determining the pH of gastric juice allowing the detection of hypo-achlorhydric conditions.

**Aims & Methods:** The aim of this study was to compare the diagnostic accuracy of EndoFaster with histological examination as gold standard for chronic atrophic gastritis through narrow band imaging (NBI) targeted biopsies.

Prospective study on consecutive adult patients undergoing to gastroscopy for the suspect of chronic atrophic gastritis (anemia, dyspepsia), in a single unit of Digestive Endoscopy (University Hospital Sant'Andrea, Rome) in the period between April and November 2018 were included. Patients in therapy with proton pump inhibitor in the previous 4 weeks, gastric surgery and/or known gastric neoplasia were excluded. At the beginning of the endoscopic examination, a sample of gastric juice (2 ml) was aspirated and analyzed by EndoFaster in real time (15 seconds). Endoscopists were blinded for the report of the device. Evaluation of gastric mucosa in high resolution white light (HR-WL) was firstly performed, then with narrow band imaging (HR-NBI) allowing to perform targeted biopsies where the suspicion of intestinal metaplasia was present. In case of normal gastric mucosa with NBI, biopsies were performed randomly using the Sydney System protocol.

**Results:** Overall, 124 patients were included (64% F; 56 (18-80) years). Chronic atrophic gastritis was present in 42% of patients. Endofaster showed an accuracy for atrophic gastritis of 87.1% and a sensitivity, specificity, PPV and NPV of 77.4%, 94.4%, 91.1% and 84.9%, respectively. The pH value measured by Endofaster showed a positive correlation with the grade of atrophy ( $r = 0.67$ , 95% CI 0.73 to 0.81,  $p < 0.0001$ ). NBI showed an accuracy of 90% and a sensitivity, specificity, PPV and NPV of 90%, 89.7%, 83.7% and 93.8%, respectively, for the diagnosis of intestinal metaplasia. Endofaster allowed to diagnose atrophic gastritis in 3.0% of patients negative to NBI (atrophic gastritis without intestinal metaplasia).

**Conclusion:** Endofaster seems a promising tool to diagnose chronic atrophic gastritis. The evaluation of hypo-achlorhydria during gastroscopy can also address biptic sampling in chronic atrophic gastritis patients without metaplasia.

**Disclosure:** Nothing to disclose

## P0839 FINAL RESULTS OF A PROSPECTIVE STUDY COMPARING CONFOCAL LASER ENDOMICROSCOPY WITH STANDARD BIOPSIES IN THE ASSESSMENT OF PERSISTENT OR RECURRENT INTESTINAL METAPLASIA/NEOPLASIA AFTER ENDOSCOPIC TREATMENT OF BARRETT'S ESOPHAGUS RELATED NEOPLASIA

**Introduction:** Patients after endoscopic treatment of Barrett's esophagus (BE) related neoplasia (BORN) should undergo regular endoscopic surveillance with biopsies to detect persistent or recurrent intestinal metaplasia (IM) or neoplasia (N). Probe-based confocal laser endomicroscopy (pCLE) offers detailed examination of cellular structures and may examine larger

areas compared to standard biopsy. The role of pCLE in the surveillance of patients after endoscopic treatment of BORN has not been systematically assessed.

**Aims & Methods:** The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN.

This is a single center, prospective, controlled and pathologist-blinded study in patients undergoing surveillance endoscopy after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (in few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (minimally 4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present).

Intestinal metaplasia (IM) on pCLE was defined by the presence of regular capillaries in upper and deeper parts of the mucosal layer along with identification of dark ("non-refractile") mucin in goblet cells in columnar-lined mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, and irregular leaking capillaries in the mucosa.

**Results:** We examined 52 patients, from these 22 patients (42%) had the initial diagnosis of low-grade intraepithelial neoplasia (LGIN), 10 patients (19%) had high-grade intraepithelial neoplasia (HGIN) and 20 patients (39%) had an early adenocarcinoma (EAC). Eight patients (15%) underwent endoscopic resection (ER) only, 25 patients (48%) underwent ER or ESD of all visible lesions followed by radiofrequency ablation (RFA), and 19 patients (37%) had RFA as a single treatment modality.

Persistent/recurrent IM was detected only at the level of neo-Z-line in 12 patients (23%, 12/52 pts) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 4 patients (8%, 4/52), another 2 patients had IM present in biopsies but not in pCLE (4%, 2/52).

pCLE (but not biopsies) diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, no other recurrences of BORN occurred.

Sensitivity and specificity of pCLE in detection of persistent/recurrent IM was 87.5% (95% CI 61.7 - 98.5) and 90.5% (95% CI 77.4 - 97.3), respectively, with a positive predictive value of 77.8% (95% CI 57.5 - 90.1) and a negative predictive value of 95.0% (95% CI 83.8 - 98.6). Agreement of pCLE and histopathological findings was 90%.

**Conclusion:** pCLE is comparable to standard biopsies in detection of persistent/recurrent IM after endoscopic treatment of BORN.

Supported by a grant from Ministry of Health of the Czech Republic, No. 16-27648A.

**Introduction:** In recent years, Near-Infrared Hyperspectral Imaging (NIR-HSI) has been attracting attention. HSI data includes spectral information in each pixel that is handled as images of any wavelength band<sup>1</sup>. The spectral signature of each pixel in the images enables the HSI to identify various pathological conditions. The HSI system can cover NIR spectral ranges (700-2,500 nm) which can penetrate biological tissues more efficiently than visible light because the tissues scatter and absorb less light at longer wavelengths<sup>2</sup>. On the other hand, to analyze big data of NIR-HSI, machine learning is useful for recognizing and extracting the feature of NIR-HSI<sup>3</sup>. Therefore, NIR-HSI with machine learning provides great advantages for supplying diagnostic support information to detect tumor beneath a normal mucosa such as gastrointestinal stromal tumor (GIST).

**Aims & Methods:** The aim of this study was to establish the method of diagnosis of GIST covered by normal mucosa by using NIR-HSI machine learning. The subjects were surgically resected gastric GIST specimens at our hospital from April 2016 to March 2018. Before fixation, NIR-HSI images of specimens were captured from the mucosal surface side with an NIR hyperspectral camera, Compovision (Sumitomo Electric Industries, Ltd., CV-N800HS). On the obtained NIR-HSI images, the area of GIST regions was defined by a pathologist to prepare training data for GIST and normal regions. The GIST specimens for analysis were selected using the following criteria: (i) GIST was covered with normal mucosa, (ii) normal mucosa existed around GIST in surgical resected specimen, (iii) GIST with a certain size capable of spectral extraction. For each selected specimen, the spectra were extracted from the pixels which were labelled as normal and GIST regions to prepare training data. The number of extracted spectra from the normal and GIST regions was the same to prevent the occurrence of bias in the training data. Then, one of the machine learning systems, support vector machine (SVM), was employed to predict normal and GIST regions from spectral data of each pixel in the NIR-HSI and the prediction accuracy was analyzed by leave-one-out cross-validation.

**Results:** Images of 14 specimens were captured with Compovision and four specimens that met the criteria mentioned above were selected to use for the analysis. For each specimen, the number of extracted spectra from the normal and GIST regions as training data was 1700 to 3000 pixels, respectively. At wavelength between 1000 and 1600 nm, average accuracy, sensitivity and specificity were 86.9% (95% CI, 81.5-92.2%), 91.7% (95% CI, 81.6-101.8%) and 80.2% (95% CI, 70.5-89.9%), respectively.

**Conclusion:** GIST diagnostic system with NIR-HSI and machine learning could identify GIST regions covered by normal mucosa with high accuracy. Applying this system to a flexible scope that can be inserted into the forceps channel can enable us to use it in clinical setting.

**Introduction:** Caustic and foreign body ingestion represent a significant part of endoscopic urgencies. They can lead to critical conditions and severe complications that may need a multidisciplinary approach. A correct use and interpretation of diagnostic findings at admission is mandatory for risk stratification and subsequent clinical decision.

**Aims & Methods:** Aim of this retrospective single center study was to evaluate predicting factors of clinical outcome of inpatients with esophageal non-hemorrhagic urgencies, especially Foreign body ingestion (FBI) and caustic ingestion (CAI). All consecutive cases of esophageal non-hemorrhagic urgencies admitted as inpatients in the tertiary Referral University Hospital São João in Porto were collected, in a period between 2000 and 2019. Type of urgencies and clinical history were evaluated together with clinical records regarding preliminary exams (blood tests, EGDS, TC), length of hospitalization, complications and outcome.

**Results:** Sixty-seven patients were included (M/F: 1.79, mean age 54.3±13.3 years): 44 cases of FBI (most frequently animal bones), 22 cases of CAI (most commonly Sodium Hypochlorite) and 1 case of other substances ingestion (polyurethane). The Charlson Comorbidity score index had a mean value of 3, with no significant difference between FBI and CAI groups. Twenty-seven patients (40%) were affected by psychiatric disease, in particular alcoholism and depression. Psychiatric disease was strongly associ-

ated with CAI and intentional ingestion ( $p < 0.0001$ ). Among all patients, 66 had a mean length of hospitalization (LoH) of 15 days (CAI Vs FBI, 24.9 Vs 11.3 days,  $p = 0.05$ ) while only 1 patient died after 5 days from caustic ingestion. Blood tests at first day showed a mean value of C-reactive protein (CRP) of 68.9 mg/L in FBI group and 27.2mg/L in CAI group with a significant difference ( $p=0.036$ ) and significantly associated with LoH in the FBI group ( $p>0.001$ ), but not in CAI group. WBC had a mean value of  $10.3 \times 10^9/L$  in FBI and  $11.3 \times 10^9/L$  with no significant differences between FBI and CAI ( $p = 0.28$ ) and no significant association with LoH ( $p = 0.37$ ). EGDS was performed in the majority of cases within the first 24h. In the CAI group, esophageal involvement was complete in the 65% of the cases. Zargar classification showed a significant association with LoH in CAI group ( $p = 0.042$ ). In the FBI group, lacerations were recognized in 41.5% of the cases, while perforation was present in 29.3%, with no significant association with outcome.

Among the findings of CT scan, edema of the esophageal wall was the most common finding in CAI group ( $p = 0.02$ ) and perforation in FBI group ( $p = 0.006$ ). In the CAI group, CT scan Severity Index was significantly associated with LoH ( $p = 0.01$ ), while the presence of perforation was the most significant factor in the FBI group ( $p = 0.06$ ).

**Conclusion:** EGDS with Zargar Classification is useful for risk stratification in patients with caustic ingestion. CT scan Severity Index for caustics and the presence of perforation for foreign body ingestion are associated with severity of the condition.

CRP at admission is an excellent and inexpensive predictor of clinical outcome in foreign ingestion cases. However, in caustic ingestion patients, it may underestimate the severity of the clinical picture.

	EGDS - Zargar classification	EGDS - presence of perforation	CT scan - caustic ingestion severity index	CT scan - presence of perforation	C-reactive protein at admission	White blood count at admission
Caustic Ingestion group- Length of hospitalization	$p = 0.042$	$p = 0.38$	$p = 0.01$	$p = 0.38$	$p = 0.36$	$p = 0.2$
Foreign object group- Length of hospitalization	na	$p = 0.37$	na	$p = 0.006$	$p = 0.0001$	$p = 0.8$

[Table 1: risk factors and clinical outcome]

**Introduction:** Intestinal graft-versus-host disease (GvHD) is a frequent complication after hematopoietic progenitor cell transplantation (HSCT) and biopsies are recommended for diagnosis. However, the best biopsy sites have yet not been clearly established and final histology results are often delayed as specific staining is required.

**Aims & Methods:** **Aim:** We aimed to assess the diagnostic yield of endoscopy for prediction of GvHD of the upper gastrointestinal tract. In addition, we aimed to determine the best sites for obtaining biopsies for diagnosis of GvHD.

**Material and methods:** A large scaled retrospective cohort study was conducted. Patients diagnosed with acute GvHD in the upper gastrointestinal tract were included. Details included symptoms at time of referral for endoscopy, type of procedure performed, macroscopic findings on endos-

copy, and histologic findings of biopsies obtained. Biopsies were graded with the Lerner score. Sensitivity, specificity, positive predictive value (PPV), and negative predictive values (NPV) were calculated.

**Results:** : A total of 101 patients (mean age 50.24, 44%female) underwent upper endoscopy and were diagnosed with intestinal GvHD. Mean Lerner score was 2.0, 1.5, 1.5, and 1.8 for the esophagus, antrum, corpus and duodenum, respectively.

Sensitivity, specificity, PPV and NPV for endoscopic prediction of GvHD were inconclusive and not significantly ( $P>0.05$ ) different between the esophagus (Sensitivity=54%, Specificity=62%, PPV=45%, NPV=70%), antrum (Sensitivity=53%, Specificity=66%, PPV=42%, NPV=75%), corpus (Sensitivity=50%, Specificity=54%, PPV=40%, NPV=64%) and duodenum (Sensitivity=58%, Specificity=83%, PPV=83%, NPV=58%).

**Conclusion:** The diagnostic yield of endoscopy for prediction of acute GvHD in the upper gastrointestinal tract is considerable low and cannot replace histopathological evaluation. No specific biopsy side showed superior prediction of GvHD. Therefore, we recommend a stepwise biopsy-protocol for patients undergoing upper endoscopy for diagnosis of GvHD.

**Introduction:** Endoscopic resection (ER) is a standard treatment for superficial esophageal squamous cell carcinoma (SESICC). Metachronous development of SESICC due to field cancerization is a major issue to be solved even with a high en bloc resection rate of endoscopic submucosal dissection (ESD). Furthermore, ER for lesions on the post ER scar is difficult in technique, and new therapeutic options are necessary to develop.

The Cryoballoon Ablation system (CBAS), (HOYA Pentax Medical), is a new endoscopic ablation therapy. Operation using CBAS is simple and fast, and high efficacy and safety for patients with dysplastic Barrett's esophagus or SESICC are reported. While CBAS might be a good candidate for additional treatment after ER or salvage treatment for lesions on post ER scar.

**Aims & Methods:** The study objective was to evaluate the technical feasibility and tissue damage of combination treatment of ER and CBAS in porcine models.

In this study, feasibility of combination therapy were evaluated in three pigs (pigA,B,C). All ER procedure were performed by EMR using Cap method(EMR-C). The detail of combination therapy for each pigs were as follows;

a) Simultaneous EMR-C and CBAS( CBAS was performed for post EMR-C mucosal defect ; ER+CBAS) for pig A, EMR-C+CBAS were performed at two sites on the first day, and at other two sites on the 28 days later.,

b) CBAS for post EMR-C scar for pig B, EMR-C was performed at two sites on the first day, and CBAS was performed for two sites of EMR-C scars and two sites of normal mucosa at 28 days after EMR-C. c) EMR-C for post CBAS scar for pig C, CBAS was performed in two sites on the first day, and 28 days later EMR-C was performed at two sites on post CBAS scar and two normal sites.

All pigs were euthanized at 32 days after initial procedure and evaluated tissue damage. EMR-C specimens were evaluated pathologically. The outcome parameters, the occurrence of any bleeding or perforation, weight loss were evaluated in all pigs.

**Results:** All endoscopic procedures were as schedule. In pig B, CBAS was performed for EMR-C scars without any technical difficulty. In Pig C, only a mild scar was observed with endoscopy at the site after CBAS at 28 days. And, lifting with submucosal injection was smooth and resection was technically easy in EMR-C for CBAS scars. All pigs did not experience anorexia, rapid weight loss, bleeding and perforation during the observation period and was euthanized at 32 days after initial endoscopic procedure. Pathological evaluation of EMR-C specimens showed only mild fibrosis in the lamina propria mucosae after CBAS compared to EMR-C specimens in normal areas. Tissue damage of treatment against pig A B were as shown

in table1. There was no significant difference between CBAS alone and combination with ER. While the tissue damage of CBAS or EMR-C+CBAS spread throughout the entire esophageal wall at 4 days after treatment, only mild fibrosis was observed in the lamina propria mucosa at 28 days after treatment.

Animal number	treatment	Ablation duration (seconds)	Time to euthanasia from treatment (days)	Maximum depth of ablation damage (wall layers)
pigA	EMR+CBAS	8	4	adventitia
pigA	EMR+CBAS	8	4	muscularis propria
pigB	CBAS for EMR sca	8	4	muscularis propria
pigB	CBAS for EMR sca	8	4	submucosa
pigB	CBAS	8	4	adventitia
pigB	CBAS	8	4	submucosa

[Histological damage of treatment against pig A, B]

**Conclusion:** Combination treatment of endoscopic resection and CBAS can be technically feasible, and there was no significant difference of tissue damage comparing with CBAS alone.

**Introduction:** Histologic assessment of atrophy or intestinal metaplasia, or serum pepsinogen are reportedly useful for risk stratification of gastric cancer. However histologic assessment requires biopsy, and pepsinogen levels are affected by *Helicobacter pylori* eradication therapy. Endoscopic atrophy gradually proceed from the distal part of the stomach to proximal, and the degree of endoscopic atrophy using Kimura-Takemoto classification is reported useful even after eradication, but Kimura-Takemoto classification is unfamiliar outside Japan.

**Aims & Methods:** In this study, we constructed convolutional neural network (CNN), and evaluated its ability to classify the degree of the endoscopic atrophy. We performed standard esophagogastroduodenoscopy (EGD) and captured esophagogastroduodenal mucosal images. Clinical diagnosis of the degree of endoscopic atrophy using Kimura-Takemoto classification as reference standard was established by board certified endoscopists of Japanese gastroenterological endoscopy society. Endoscopic images were classified into four categories according to the location of the stomach, "antrum", "body (antegrade view)", "body (retroflex view)", and "cardia or fundus". A deep CNN was pre-trained and fine-tuned on a dataset of 11497 images (4373 with atrophy and 7124 without atrophy; 4294 are body (downward view), 4003 body (retroflex view), and 3200 "antrum") obtained from 2016 to 2018. Images of cardia or fundus were excluded from the training data set. A separate test data set (3124 images from 92 patients (34 no atrophy, 14 mild (C1, C2), 26 moderate (C3, O1) and 18 severe atrophy (O2, O3)) obtained from January to February 2019 was evaluated by the CNN.

**Results:** The trained CNN output a continuous number between 0 and 1 as the probability index for the presence or the absence of atrophy, and location of the stomach per image. If the number of images diagnosed as atrophy are equal or larger than no atrophy in each location classified by the CNN, the location was judged as atrophic. Either the body (antegrade view) or the body (retroflex view) is judged as atrophic, it is classified as moderate to severe atrophy. On the other hand, both of the body (antegrade view) and the body (retroflex view) are judged as non-atrophic, it is classified as none to mild atrophy. Among 48 none to mild atrophy diagnosed by endoscopists, the CNN "correctly" diagnosed as none to mild in 41 cases (85%). And among moderate to severe atrophy diagnosed by endoscopists, the CNN "correctly" diagnosed in 33 case (75%). Time needed to diagnose 3124 images was 84 seconds.

**Conclusion:** The degree of endoscopic atrophy could be diagnosed based on endoscopic images using CNN in a considerably short time. It was suggested that the CNN can be introduced to risk stratification of gastric cancer based on endoscopic images.

**Disclosure:** Nothing to disclose

**Introduction:** The clinical success of per-oral endoscopic myotomy (POEM) has led to the development of a new field of 'submucosal endoscopy'. This study aimed to evaluate the safety, efficacy, and limitations of per-oral endoscopic tumor resection (POET) in the management of submucosal tumors (SMTs) in the esophagus and the gastric cardia.

**Aims & Methods:** POET was performed in 47 patients from January 2011-December 2017. Indication for POET was SMT < 30mm in size in minor axis. Patient and tumor characteristics (age, gender, tumor location, size, and histology), operative and clinical results of POET (procedure time, procedure completion rate, en bloc resection rate, length of hospitalization, adverse events, recurrences) were collected prospectively and analyzed retrospectively.

**Results:** POET was successfully completed in 43 patients (91.5%) without any major adverse events (Clavian-Dindo IIIb-IV). Four patients required conversion to an open surgical procedure due to suboptimal visualization during POET. Two patients had a piecemeal resection of their SMTs. Median follow-up was 44 months (10-96 months), during which time there were no incidences of recurrence. Tumors in which the minor axis was >30mm or if the product of the major and minor axes, termed tumor mass index (TMI) was greater than 1000, had a high likelihood of being converted to surgical resection.

**Conclusion:** POET is a safe and effective treatment for SMTs. However, in patients where the minor axis is greater than 30mm or the TMI >1000, surgical excision should be considered. Furthermore, application of POET for SMTs with malignant potential should be carefully considered to ensure optical oncologic outcomes.

**Introduction:** Chronic mesenteric ischemia (CMI) is a grave and debilitating condition. Variability of symptoms and abundant collateral circulation, makes diagnosing CMI challenging, especially in single vessel disease. Functional tests such as tonometry and visible light spectroscopy are used to detect mucosal ischemia, but both have their limitations(1).

An easy-to-use and accurate functional test to diagnose CMI is highly desired. Protoporphyrin IX-triplet state lifetime technique (PpIX-TSLT) is a novel method used to measure oxygen in mitochondria(2). After administration of aminolevulinic acid (ALA) mitochondrial PpIX increases. Green light is used to excite PpIX, causing light emission by delayed fluorescence. After collision with oxygen molecules PpIX returns to its ground state, halting light emission. The duration of light emission is measured. When few mitochondrial oxygen is present, collisions are less likely to occur resulting in a longer duration of light emission. *In vivo* measurements of mitochondrial oxygen have been performed in skin and liver, but this technique has never been applied to perform *in vivo* endoscopic mucosal oxygen measurements(3,4).

**Aims & Methods:** Aim of the current study was to verify the feasibility of measuring mucosal mitochondrial oxygen during upper endoscopy. Mitochondrial oxygen measurements were performed in six healthy volunteers during 10 upper endoscopies, 4 hours after oral administration of ALA. The ALA dose administered was 0, 1, 5 or 20mg/kg. Measurements were conducted at 3 mucosal spots in the antrum, duodenal bulb and descending duodenum. Measurements were performed with the catheter close to the mucosa and while applying pressure in order to induce local ischemia by compromising capillary circulation. Measurements are reported as 1 divided by duration of light emission in microseconds, whereby high values represent high oxygen content.

**Results:** Measurements proved easy to perform and were successful in all volunteers. ALA dose of 5 mg/kg showed adequate signal-to-noise ratio values of >20 in duodenal bulb and descending duodenum, without occurrence of side effects. Median and interquartile ranges (IQR) of the measurements without application of pressure were 0.092 (0.061-0.132) in antrum, 0.041 (0.032-0.049) in duodenal bulb and 0.016 (0.011-0.026) in descending duodenum. Values decreased significantly ( $p < 0.001$ ) at all locations when pressure was applied. Median (IQR) during pressure in the antrum was 0.052 (0.032-0.069), in the duodenal bulb 0.013 (0.010-0.022) and in the descending duodenum, 0.009 (0.008-0.011).

**Conclusion:** Endoscopic measurement of mucosal mitochondrial oxygen is technically feasible and demonstrated to be oxygen dependent, with an optimal ALA dose of 5mg/kg. *In vivo* endoscopic mucosal mitochondrial oxygen measurements are a possible novel functional test for the diagnosis of CMI.

**Introduction:** Endoscopic submucosal dissection (ESD) has been developed as an option for treatment of esophageal, gastric and colorectal lesions. Recently, in Japan, endoscopic submucosal dissection (ESD) for the duodenal tumors has come to be treated. Meta-analysis for superficial non-ampullary duodenal epithelial tumors (SNADETs) reported that ESD might achieve higher en bloc and complete resections at the expense of a greater perforation rate compared to endoscopic mucosal resection. However, the high incidence rate of complications involving bleeding, perforations, and postoperative leakages require mainly high invasive surgery. Some studies

were reported that prophylactic defect closure using Over-The-Scope Clips (OTSCs) was useful for preventing postoperative complications. Therefore, ESD for the duodenal tumors is increasing gradually.

In such a situation, we have recently detected the lesions near ampulla of Vater. Those lesions make it the most technically difficult to perform endoscopic submucosal dissection and also perform combined laparoscopic and endoscopic surgery due to the location. In this study, we investigated the clinical outcomes for SNADETs located within 10 mm from the ampulla of Vater which were defined as para-ampullary tumors (PA) compared to non-ampullary tumors (NA).

**Aims & Methods:** We enrolled the patients with duodenal tumors that received ESD in June 2016 to October 2018. 3 patients as PA and 35 patients as NA were included in this study. All SNADETs were performed ESD using the pocket-creation method. The post-ESD mucosal defect was closed using OTSC or conventional clip. We examined the clinical outcomes of PA compared to NA.

**Results:** Clinical characteristics were male / female (PA/NA 3:0/23:12), mean age (PA/NA 64.3/61.7 years), mean tumor diameter (PA/NA 30.0/16.9 mm), tumor morphology (PA/NA 1:11a:11b:11c 1:1:0:1/3:22:0:10). All of the SNADETs were completely removed by ESD with all the scissors forceps. We performed prophylactic defect closure using OTSCs and clip by clipping. Endoscopic retrograde biliary drainage was also placed in all PA, because the ampulla of Vater was included in the resected area. The mean procedure time and closure time were 97 and 45 minutes in PA and 70 and 22 minutes in NA respectively. The complete defect closure was achieved in 100% in PA and 97.1% in NA respectively. R0 resection rate and en bloc resection rate were 100 and 100% in PA and 94.3 and 100% in NA, respectively. There was no complication in PA and there were 2 cases in NA. 1 case was delayed bleeding and other was postoperative perforation. Perforation occurred in only one patient who did not have successful closure of the defect. Delayed bleeding was detected in one patient who occurred the bleeding from the mucosal surface sutured in OTSC. Lesions consisted of 1 adenocarcinoma and 2 adenomas in PA and 30 adenocarcinomas, 1 adenoma and others in NA. Although the tumor size was significantly larger in the PA group (30 vs 16mm, respectively  $p = 0.02$ ) and the treatment time and the closure time were longer due to ERBD placement, (97+45min vs 62+22min, respectively), complete closure was possible and there was no significant difference in the treatment results.

**Conclusion:** ESD with prophylactic defect closure using OTSC and conventional clip for para-ampullary tumors was as efficient and safe as that for non-ampullary tumors regardless of technical difficulties.

**Introduction:** Methods for preventing complications following endoscopic submucosal dissection (ESD) have recently been investigated; however, currently, there is no available method to efficiently prevent scar contraction after ESD. We have reported that usage of high-adhesion gelatin porous films reduce inflammation and tissue contraction during gastric ulcer healing following ESD in a swine model.

However, the sheet had a complication that the lesion to stick was limited and the operability was poor. We changed the dosage form from sheet type to spray type.

Sprayable wound dressing comprises multi-functional hydrophobized microparticles (hMPs) that possess the abilities for tissue adhesiveness in wet environments, acceleration of blood coagulation, enhancement of epithelialization, and enhancement of angiogenesis.

**Aims & Methods:** In the present study, we aimed to determine the effects of hMPs on the healing of gastric ulcers following ESD in miniature swine model. The gastric ulcers were generated by performing ESD. Following

ESD (Day 0), the artificial ulcers were either sprayed with hMPs (hMPs group, n = 4) or left unsprayed (control group, n = 4). Macroscopic and microscopic examinations were performed on Day 14 following ESD.

**Results:** Infiltration of inflammatory cells in the submucosal layers were significantly reduced ( $p = 0.034$ ). Expressions of alpha-SMA-positive cells and Type I collagen were significantly suppressed ( $p = 0.002$  and  $p = 0.019$ , respectively), indicating that hMPs suppressed fibrosis after ESD. The numbers of VEGF-positive cells and microvessels were not significantly different between the groups, whereas the number of cells positive for vWF were significantly increased ( $p = 0.016$ ). Furthermore, there was a significant reduction in the atrophy and fibrosis score ( $p = 0.024$ ), which reflects the degree of atrophy or fibrosis of the muscularis propria.

**Conclusion:** The use of hMPs reduced the degree of inflammation, fibrosis, and tissue contraction during the gastric ulcer healing process following ESD. hMPs can be easily delivered using clinically-available air pump devices and can be tightly localized. Therefore, hMPs would contribute to reduce the burden on operators and patients by reducing operation times and ensuring an accurate procedure. Specifically, hMPs may offer successful treatment of wounds without stricture after ESD procedures and also provide a novel therapeutic modality for wound treatment after ESD.

**Introduction:** According to a recent meta-analysis the rate of missed gastric cancer during upper endoscopy is approximately 10% (1). While risk factors for missed upper gastrointestinal cancer have been identified in retrospective studies, the effect of missed upper gastrointestinal cancer on long-term survival is not clearly documented.

**Aims & Methods:** We aimed to identify risk factors associated with missed upper gastrointestinal cancer and to compare survival between missed and non-missed upper gastrointestinal cancer. This is a single centre, retrospective cohort study. All upper endoscopies performed at our department between January 2007 and December 2015 were included in the study. The endoscopy database was cross-referenced with the Slovenian Cancer Registry Database. Missed cancers were defined as those diagnosed within 36 months since the last upper endoscopy. We excluded patients with a history of previous upper gastrointestinal cancer and those who were in surveillance program due to high risk conditions for the cancer development (Barrett's oesophagus, intestinal metaplasia with OLIGIM stage  $\geq 3$ ). The association of demographic and endoscopic characteristics was analysed with multivariable logistic regression, categorical data were compared using the chi-squared test. Survival analysis was performed with the Kaplan-Meier method.

**Results:** During the study period 29,617 upper endoscopies were performed and 663 upper gastrointestinal cancers were diagnosed; 164 (24.7%) patients were excluded because of previous upper gastrointestinal cancer, further 10 (1.5%) were excluded because their cancer was diagnosed during surveillance for precancerous conditions. In the final cohort of 489 upper gastrointestinal cancers, 37 were missed (7.6 %; esophagus: 3.8%; gastric: 8.0%; duodenum: 23%) (Table 1).

	Diagnosed cancer (n=443)	Missed cancer (n=37)	P value
Age, mean (SD)	69 (12)	69 (12)	0.92
Female, n (%)	138 (31.2)	12 (32.4)	0.87
Alarm symptoms at index endoscopy	379 (85.5)	20 (54.1)	<0.0001
Stage at diagnosis, n (%)			0.714
limited to organ	74 (16.7)	5 (13.5)	
locally advanced	199 (44.9)	16 (43.2)	
metastatic	126 (28.4)	10 (27.0)	
incomplete data	44 (9.9)	6 (16.2)	
Treatment with curative intent	210 (47.4)	13 (35.1)	0.278

[Characteristics of missed and non-missed upper gastrointestinal cancers in the study cohort.]

**Conclusion:** Median survival of patients with missed upper gastrointestinal cancer during upper endoscopy was shorter compared to non-missed upper gastrointestinal cancer.

**References:** Pimenta-Melo AR, Monteiro-Soares M, Libânio D, Dinis-Ribeiro M. Missing rate for gastric cancer during upper gastrointestinal endoscopy: a systematic review and meta-analysis. *Eur J Gastroenterol Hepatol.* 2016 Sep;28(9):1041-9.

**Introduction:** Superficial duodenal epithelial tumors (SDETs) are rare, and there is no report of detailed endoscopic diagnosis of many SDET cases.

**Aims & Methods:** We investigated the relationship between endoscopic findings and final histopathological diagnosis of a large number of SDETs. Four hundred fifty-six SDETs in 434 patients who underwent endoscopic resection was retrospectively reviewed in this study, including 195 prospectively registered SDETs in 186 patients who underwent magnified endoscopic examination with image-enhanced endoscopy (IEE-ME). We investigated the location, size, macroscopic type, and color of SDETs and confirmed IEE-ME findings including surface structures (closed- or open-loop structure) and presence of white opaque substance (WOS) in these SDETs. We performed histopathological diagnosis based on the Vienna classification (VCL) and divided the lesions into category 3 (C3) and beyond category 4.1 (C4/5).

**Results:** The proportion of VCL C4/5 cases decreased from 30% for lesions of lesions in the duodenal bulb to 12.4% for lesions in the horizontal portion ( $P=0.0087$ ) and increased with lesion size ( $P < 0.0001$ ). Based on IEE-ME findings, lesions with closed-loop structure and negative WOS were significantly more frequently diagnosed as VCL C4/5 ( $P=0.0222$ , and 0.0038, respectively). In multivariate analysis, tumor size (odds ratio (OR), 20.39; 95% confidence interval (CI), 2.23-186.40;  $P < 0.0093$ ) and negative WOS (OR, 5.81; 95% CI, 1.24-27.18;  $P < 0.0268$ ) were significant predictors of VCL C4/5 of SDETs.

Factor	Odds ratio	95% CI	P value
Size (per cm)	20.39	2.17-198.68	0.0093
WOS (negative)	5.81	1.23-28.35	0.0268

[Multivariate analysis of predictors of duodenal cancer]

**Conclusion:** We found that negative WOS by IEE-ME and lesion size were independent predictors of VCL C4/5 in SDETs. These factors may help us select more appropriate therapeutic strategies for SDETs.

**Disclosure:** Nothing to disclose

## P0852 OUTCOMES OF A NOVEL BARIATRIC STENT IN THE MANAGEMENT OF SLEEVE GASTRECTOMY LEAKS: A MULTICENTER STUDY

**Introduction:** The management of laparoscopic sleeve gastrectomy (LSG) leaks remains a challenge. This can be treated with placement of self-expandable metal stents, which are most effective in the acute and early settings. However, migration is a frequent adverse event (AE). Novel fully covered stents with a larger proximal flare to limit migration designed specifically to treat post-sleeve leaks were recently introduced.

**Aims & Methods:** The aim of this study is to evaluate the safety and efficacy of a novel stent specifically designed for post-sleeve leaks treatment.

This is a multicenter retrospective study, including patients with acute and early post-LSG leaks, treated with a large bariatric stent. The outcomes include technical success, clinical success, and safety profile. A multivariable regression was performed to assess predictors of success.

**Results:** Thirty-seven patients were included (10 acute and 27 early leaks), with 30 stents in the post pyloric (POST) and 7 in the pre-pyloric (PRE) position. Technical success was 100%. Mean stent dwell time was 29.08 days. Clinical success was achieved in 78.37%. Leak duration, leak size and stent dwell time did not correlate with clinical success. During follow-up, 8 patients had stent migration (21.62%) and all were in a POST position. AE post stent removal were also evaluated (PRE:57.14% vs POST:33.3%,  $p=0.45$ ). There was no difference between PRE and POST position in the severe AE analysis.

**Conclusion:** This novel large-caliber fully-covered stent specifically designed for sleeve leaks appears to be effective at treating acute and early leaks.

However, the large flanges and long stent length do not appear to reduce migration rate, and may be associated with higher overall adverse event rates. Additionally, avoiding placement in the post-pyloric position may help mitigate migration risk.

**Introduction:** Recently, synchronous multiple early gastric cancers are being increasingly reported due to the aging society and development of endoscopic techniques.

**Aims & Methods:** We usually perform reexamination of esophagogastroduodenoscopy (re-EGD) for the patients who have a gastric adenoma or adenocarcinoma before ESD, and sometimes detect the another lesion. We evaluated the clinicopathological findings of those lesions.

Between January 2014 and December 2018, we performed re-EGD for 1299 patients in our hospital. The lesions which were detected anew in re-EGD were extracted, then we investigated their clinicopathological characteristics retrospectively.

**Results:** 76 patients with 83 lesions were detected in re-EGD. The location is cardia/ gastric body/ angle/ pylorus: 7/ 30/ 36/ 20, and les/ ant/ gre/ pos: 29/ 15/ 19/ 20. The average diameter was 9.1mm(2-40mm). The pathological diagnosis were 18 adenoma, 46 differentiated adenocarcinoma, and 1 undifferentiated adenocarcinoma. The invasion depth was all intramucosal cancer. Their H.pylori infection status was 29 were positive, 46 were after eradication, and 1 was negative. The degree of atrophy was 1 was mild(C-1, 2), 19 were moderate (C-3, 0-1), and 56 were severe(0-2, 3). On the other hand, with respect to the 83 lesions which were detected from the beginning, the average diameter was 14.8mm, and pathological diagnosis were 5 adenoma, 76 differentiated adenocarcinoma, and 2 undifferentiated adenocarcinoma. The lesions which were detected in re-EGD were significantly smaller than those were detected from the beginning ( $p<0.01$ ), and ratio of adenocarcinoma is lower than those ( $p<0.01$ ). With respect to the location, 64/83 (77%) of the lesion were located in the same area of the lesions which were detected previously.

**Conclusion:** The patients with a gastric cancer often have the another lesion synchronously. The lesions which were detected newly tend to be smaller than the lesions which were already detected, and located in same area of those frequently.

**Introduction:** Buried bumper syndrome (BBS) is an uncommon complication of percutaneous endoscopic gastrostomy (PEG) placement; its incidence is 1%. Several techniques for endoscopic management of BBS have been described, given the absence of a dedicated device to date.

**Aims & Methods:** This was a retrospective, international multicentre, cohort study involving 15 Endoscopy Units across Europe between December 2016 and February 2019. Patients with BBS treated endoscopically with a novel, sphincterotome-like, dedicated device were included. A total of 55 cases were retrospectively analysed. The primary endpoint was success rate of buried bumper endoscopic removal with the dedicated device. A median follow-up of 96 days was performed in 38 patients and complications rate were registered.

**Results:** The study group included 42 men (76%) and 13 women (24%) with a median age of 66 years (range 17-94). Diagnosis of BBS was suspected through clinical assessment and confirmed through endoscopic

examination. Radiological examinations were performed in only 7 cases (12.7%). Patients underwent PEG placement 859.5 days (range 49-4380) before the removal of the buried bumper, due to cerebrovascular disease (16 patients, 29%), cerebral palsy (9 patients, 16.4%), head and neck cancer (9 patients, 16.4%), Parkinson's disease (4 patients, 7.3%), neurological diseases and psychomotor retardation (4 patients, 7.3%), amyotrophic lateral sclerosis (4 patients, 7.3%), multiple sclerosis (2 patients, 3.6%), cancer (2 patients, 3.6%), cerebral tumor (1 patient, 1.8%), head injury (1 patient, 1.8%), oesophageal cancer (1 patient, 1.8%), poly-trauma (1 patient, 1.8%), miscellaneous (1 patient, 1.8%). Nine patients had a clinical history of previous BBSs (16%), treated with a different therapeutic approach. The buried bumper was located in the gastric body in 46 patients (83.6%) and in the gastric antrum in 9 patients (16.3%). The use of additional devices was applied in 40 procedures (72.7%). In this regard, a wire was used in 14 patients (25.4%), a snare in 14 patients (25.4%), a forceps in 8 patients (14.5%), a knife in 2 patients (3.6%) and a balloon in two patients (3.6%). The median time for the endoscopic removal of the buried bumper, recorded in 42 patients, was 22 minutes (range 5-60). The buried bumper was successfully removed in 53 cases (96.4%). Peri-procedural endoscopic complications occurred in 7 procedures (12.7%). Significant bleeding, in particular, occurred in 4 patients (7.3%), a small perforation in 2 patients (3.6%) and in one patient (1.8%) a slight laceration of the gastro-oesophageal junction occurred during the PEG extraction. Two patients (3.4%) developed a post-procedure sepsis that was successfully treated with antibiotics. In 44 patients (80%) a new PEG was placed during the same procedure of removal of the buried bumper, through the same site of the gastric wall in 35 patients (80%), while a new gastrostomy was required in 9 patients (20%). In 5 patients (9.1%) a second PEG was placed after a median time of 4.5 days (range 2-14), all the times through a new site of the gastric wall. A median follow up of 96 days (range 1-593) was performed in 38 patients (69.1%), during which no significant complications occurred and one patient died of unrelated condition (encephalitis).

**Conclusion:** To the best of our knowledge this is the first international multicentre study regarding the endoscopic management of BBS with a dedicated device. Based on our preliminary data it appears to be user-friendly, safe, quick and effective for minimally invasive, endoscopic management of BBS.

**Disclosure:** Dr Despott and Dr Murino receive research/ education support from Aquilant Medical, Fujifilm, Olympus, Pentax Medical, Boston scientific and GI supply. All others authors have no conflicts of interest to disclosure.

## P0855 EYE TRACKING FOR ASSESSMENT OF PROFICIENCY IN ENDOSCOPIC SUBMUCOSAL DISSECTION

Maehata T.<sup>1</sup>, Mizutani M.<sup>1</sup>, Tsutsumi K.<sup>1</sup>, Sasaki M.<sup>1</sup>, Kiguchi Y.<sup>1</sup>, Akimoto T.<sup>1</sup>, Takatori Y.<sup>1</sup>, Nakayama A.<sup>1</sup>, Ochiai Y.<sup>1</sup>, Kato M.<sup>1</sup>, Yahagi N.<sup>2</sup>

**Introduction:** Endoscopic submucosal dissection (ESD) has recently become widely accepted as the ideal minimally invasive curative treatment for early stage gastrointestinal cancer. However, the safety and success of ESD depends on doctors' skill levels. There are no established training systems to overcome this difficulty, with the level of proficiency still being dependent on the skill of the individual doctor.

**Aims & Methods:** The aim of this study was to use an eye tracking device to measure endoscopic skill, assess the differences between experienced and novice endoscopists, isolate commonalities between experienced endoscopists, and identify elements required for ESD. Three endoscopists who were experienced in ESD (Group E) and three who were novices (Group N) each performed ESD on an ex vivo porcine stomach model while wearing eye-tracking glasses. Eye tracking is technically to measure the point of gaze or measurement of eyes activity. We measured the area of distribution of gaze and compared between two groups.

**Results:** The area of distribution of gaze was significantly smaller for Group E than for Group N ( $P=0.021$ ). We divided into three phases; prediction, incision and dissection phase. In terms of prediction and dissection phase, there was significantly smaller for Group E than for Group N.

**Conclusion:** The experienced endoscopists in this study were able to predict their next step in advance and their movements were consistent. This showed that not only endoscopic skills but also the knowledge required

to predict the next movement is important in ESD. The development of a training system based on this analysis could make ESD a safer and more efficient procedure.

**Introduction:** Endoscopic hand suturing (EHS) is one of closure techniques for mucosal defects after endoscopic submucosal dissection (ESD) using a curved needle with absorbable suture and a trough-the-scope needle holder<sup>1</sup>. However, it is unclear whether EHS can keep post-ESD mucosal defects closed and promote healing. Furthermore, the histologic healing process of the sutured defects is also unknown.

**Aims & Methods:** To evaluate how EHS contributes to the mucosal healing, we investigated histological analyses of the sutured defect after ESD in in vivo porcine models.

We conducted this study using two live pigs. Under general anesthesia, the first pig underwent gastric ESD to create two 2 cm-mucosal defects (one on the anterior wall (AW) and another on the posterior wall (PW), respectively). The defect on PW was closed by EHS (a sutured group), and that on AW was left open as a control group. On postoperative week (POW) 1 and 2, the previously-created sites were observed endoscopically, and subsequently the same procedure as mentioned above was conducted to create new lesions (one for ESD plus EHS, another for ESD only), respectively. In the second pig, the control groups were set on PW and the sutured groups were set on AW. On POW 3, the pigs were killed for histology after endoscopic observation. In each session, the size of the mucosal defects was endoscopically estimated and recorded.

When the mucosal defects were replaced with scar tissue or remained closed by EHS without dehiscence, they were recorded as zero. For histological assessment, the width of absent epithelium in hematoxylin and eosin stain and the width of absent muscularis mucosae in alpha-smooth muscle actin ( $\alpha$ SMA) stain were measured in each treated sites. In addition, fibroblast, which contributes to the healing process of ulcers, was defined as the area of positive  $\alpha$ SMA in submucosa of the treated areas. It was measured in 3 fields ( $\times 400$  magnification) for each slice using software ImageJ with the IHC profiler plugin. The endoscopically-estimated size of the mucosal defects and the histologically-measured widths and the area were compared between the two groups. Furthermore, histological morphology of the mucosal layer in the sutured group was assessed.

**Results:** The endoscopic average size of the mucosal defects (mm) ( $n = 6$  on POW 1, 4 on POW 2, 2 on POW 3) were  $15 \pm 2.6$ ,  $6.3 \pm 2.8$ ,  $2.0 \pm 2.0$  in the control group and 0, 0, 0 in the sutured group ( $p = 0.001$ , 0.004, 0.21), respectively. The histologic average width of absent epithelium (mm) ( $n = 2$  on POW 1, 2 on POW 2, 2 on POW 3) were  $10.7 \pm 2.2$ ,  $4.2 \pm 3.5$ ,  $1.1 \pm 1.1$  in the control group and  $0.88 \pm 0.30$ , 0, 0 in the sutured group ( $p = 0.023$ , 0.18, 0.21), respectively. The histologic average width of absent muscularis mucosae (mm) ( $n = 2$  on POW 1, 2 on POW 2, 2 on POW 3) were  $13.2 \pm 2.6$ ,  $8.2 \pm 2.9$ ,  $7.5 \pm 1.0$  in the control group and  $2.8 \pm 0.7$ , 0, 0 in the sutured group ( $p = 0.030$ , 0.054, 0.009), respectively.

The area of fibroblast ( $\mu\text{m}^2$ ) ( $n = 2$  on POW 1, 2 on POW 2, 2 on POW 3) were 7079, 16963, 19656 in the control group and 9728, 6577, 4908 in the sutured group ( $p = 0.21$ , 0.0001, 0.0003), respectively. In the histological assessment of the sutured sites on POW 2 and 3, the muscularis mucosae fused to each other, and the connected epithelium covered on it in line without inversion.

**Conclusion:** EHS may contribute to faster healing of the post-ESD mucosal defects without dehiscence in the porcine models. Histologically, layer-to-layer healing seems to be obtained in the sutured mucosa by EHS as with a natural healing process of the mucosal defect after ESD.

**Introduction:** Upper gastrointestinal (UGI) anastomotic leaks have a high risk of morbidity and mortality. A variety of endoscopic techniques are currently available; however, no definite consensus exists on the most appropriate therapeutic approach. Knowledge of current practices is important for the design of prospective studies.

**Aims & Methods:** To explore the current practices on the management of UGI anastomotic leaks. A survey questionnaire consisting of 35 opinion-probing questions and 4 short clinical cases was distributed among international expert therapeutic endoscopists regarding management of UGI anastomotic leaks.

**Results:** A total of 44% of 163 surveys were returned. Majority (69%) were gastroenterologists and 56% had >10 years of experience. A third of respondents treat between 10-19 patients annually. Stent placement is the technique most frequently used (average ranking [AR]: 6.3), followed by endoscopic internal drainage (EID) (AR: 4.7), OTSC (AR: 4.6) and endoscopic vacuum therapy (EVT) (AR: 4.1). Regarding stents, 56% use FC-SEMS as their usual first option. The vast majority (80%) utilize techniques to minimize migration (suture: 33%); 4 weeks was the most common (49%) reported stent dwell time. The majority of respondents perform epithelial ablation prior to OTSC placement (62%) and suturing (61%). Regarding EVT, 75% change the sponge every 3-5 days and 56% perform balloon dilation and intracavitary EVT in patients with large cavities but small leak defects. Regarding endoscopic septotomy, 56% consider a minimal interval of 4 weeks from surgery and 90% consider the need to perform further septotomy sessions, with a median of 11 days between treatments. Regarding EID, 82% prefer to place two plastic stents and 62% shorter stents (Table 1). Persistent inflammation with clinical sepsis was the definition most commonly (55%) reported for endoscopic failure. Regarding clinical cases,

EVT and stent placement, with or without percutaneous/surgical drainage, were the therapeutic options most often chosen by respondents in patients with previous oncologic surgery; EVT and EID were the therapeutic options most often chosen in patients with previous bariatric surgery.

**Conclusion:** There is a wide variation in the management of patients with UGI anastomotic leaks, even among experts. Future prospective studies are needed to move from an expert- to an evidence- and personalised-based care.

## P0858 HYBRID ARGON-PLASMA-COAGULATION VERSUS RADIOFREQUENCY ABLATION IN BARRETT'S ESOPHAGUS AFTER ENDOSCOPIC RESECTION OF NEOPLASTIC LESIONS: A RANDOMIZED TRIAL AT A TERTIARY CENTER

Knabe M., Wetzka J., Kronsbein H., Richl J., May A.  
Sana Clinic Offenbach, Medizinische Klinik II/IV / Gastro.,  
Pneumol., Hämatol.-Onkol., Offenbach, Germany

**Contact E-Mail Address:** mate.knabe@googlemail.com

**Introduction:** Neoplastic Barrett esophagus (BE) is usually treated by a combination of endoscopic resection for (visible) neoplasia followed by ablation of the remaining Barrett's mucosa with the aim to eradicate the entire BE. Different ablation techniques have been established in clinical routine for this therapy approach. Radiofrequency ablation (RFA) and argon-plasma -coagulation (APC) are most frequently used. There is some evidence that prior injection to APC (Hybrid-APC) lowers stricture rates in these patients. There is only very rare data comparing APC and RFA in a randomised trial setting and no study comparing H-APC with RFA so far.

**Aims & Methods:** The Aim of this study is to compare the two major ablation techniques in a large group of patients. The study was planned as a non-inferior trial. All patients who have been treated for neoplastic lesions in Barrett's esophagus and were planned for subsequent ablation were randomized to RFA or H-APC. Time of deviation, complications and post-interventional pain (1-10 on scale, duration) were measured. All patients are planned for follow-up gastroscopy after 3,6,12 and 24 months with chromoendoscopy and biopsies at the Z-line.

**Results:** 64 patients (60 males, 4 females, mean age 64.9 years) have been included to the study with N=28 randomized to RFA and N=38 to H-APC group. N=28 patients have completed ablation and short-term follow-up (3 or 6 months). 114 ablative interventions have been performed so far. In mean 1,8 ablations (min 1 max 5) were needed for successful Barrett's

[P0857 Table. Ideal patient characteristics for each endoscopic technique]

Monday, October 21, 2019

eradication. There was no significant difference in Barrett's length between the two groups. The mean length of BE before ablation was 3.7cm (H-APC) and 4.9cm (RFA).

Barrett's eradication rate after 6 months follow-up was 90% in the RFA group and 78 % in the hybrid- APC group. Except of non-healers (10.1 %) all Barrett remnants were localized at the neo-Zline. However, the post interventional pain was significantly higher in the RFA group: mean 3.7 /10 and duration of 7.3 days, whereas patients in H-APC group complained about pain for 3.3 days in mean and severity of 1.9/10.

**Conclusion:** Both the ablation techniques have good results in eradication rate with slightly better outcome for the RFA group. The pain severity and duration therefore were significantly higher in the RFA group. Combination of H-APC in the tubular esophagus and RFA at the Z-Line might lead to a better outcome for Barrett's eradication and patients discomfort.

## Po859 ENDOSCOPIC FULL THICKNESS RESECTION FOR TREATMENT OF GASTRIC SUBEPITHELIAL TUMORS

Chiu P.W.Y., Yip H.C., Chan S., Teoh A., Wong S., Ng E.  
Chinese University of Hong Kong, Department of Surgery, Hong Kong, Hong Kong, China (SAR)

**Contact E-Mail Address:** philipchiu@surgery.cuhk.edu.hk

**Introduction:** Submucosal tunnel endoscopic resections (STER) had been increasingly performed for treatment of gastric subepithelial tumors. One of the limitations for STER is the risk of incomplete tumor resection due to close dissection and bridging of tumor capsule. Endoscopic full thickness resection (EFTR) allowed complete resection of the tumor with margins to prevent recurrence. This study aimed to review the techniques and outcomes of EFTR for treatment of gastric subepithelial tumors.

**Aims & Methods:** Patients who received endoscopic resection for gastric subepithelial tumors were recruited. The gastric subepithelial tumors were considered eligible for endoscopic resection with size < 40mm. All patients received preoperative assessments including EUS and CT scan to define the extend of tumors and the proportion of extra and intraluminal components. All the procedures were performed under general anesthesia with CO2 insufflation. EFTR started after injection with mucosal incision up to 50% of tumor circumference, followed by submucosal dissection to identify tumor margin. Further dissection was performed using ESD devices. After adequate exposure of lateral margins, incision into muscularis propria was performed to achieve full thickness resection. Luminal defects were closed by either clips, clip-loop crown method or Overstitch suturing.

**Results:** From 2012 to 2019, 18 patients received EFTR for gastric subepithelial tumors. The mean age was 60.6 years, and 6 were male. The GIST were located at greater curvature (4), cardia (6), lesser curve (4) and antrum (2). The mean size was 21.9mm (10 - 50 mm). Half of the EFTR were performed in operation theatre while half were done at endoscopy. The mean hospital stay was 4.2 days, and mean operative time was 92 minutes (34-180 mins). There was one conversion to laparoscopic resection. Closure of luminal defect were performed with clips (7), Overstitch endoscopic suturing (7) and clip and loop crown closure (3). Most patients resumed full diet on day 3, and all the pathologies confirmed GIST tumors with clear resection margins.

**Conclusion:** Endoscopic Full Thickness Resection is technically feasible and safe procedure for treatment of gastric GIST. Future research should focus on refining the techniques of EFTR and closure of the defect.

**Disclosure:** Nothing to disclose

## Po860 ENDOSCOPIC STENT PLACEMENT FOR TREATMENT OF SLEEVE GASTRECTOMY LEAK: A SINGLE INSTITUTION EXPERIENCE WITH FULLY-COVERED STENTS

**Introduction:** Laparoscopic sleeve gastrectomy (LSG) is one of the most commonly performed bariatric procedures for treatment of morbid obesity. Despite its popularity, it is not without risks, the most serious of which is the staple line leak. Staple line leaks are difficult to manage and require significant resources in the form of surgical, radiological and endoscopic interventions, resulting in long hospital and intensive care stays and significant morbidity.

**Aims & Methods:** The objective of this report is to describe our single-institution experience in managing SG staple-line leaks with fully-covered self-expanding metal stents (SEMS) across the leak sites.

Data for all patients who underwent endoscopic stent placement for an SG leak between 12/2016 and 02/2019 at a single academic institution were retrospectively reviewed. Patient medical history, perioperative information, stent placement details, outcomes, and subsequent interventions were recorded.

**Results:** Twenty-six patients with SG staple-line leaks treated with fully-covered endoscopic stents were identified. Leaks were detected at a median of 11.5 days post-procedure (range, 1-31 d). Stents remained in place for an average of 44.8 ±10.8 days. Complete migration occurred in three (12%) and partial migration (1 - 4 cm) in five (20%) of the stent placements. One patient was lost to follow-up, and 22 of the remaining 25 patients (88%) healed after stent placement. Two patients (8%) ultimately required operative revision with partial gastrectomy and Roux-en-Y oesophagojejunostomy for management of persistent leakage.

**Conclusion:** Endoscopic management using fully-covered SEMS for staple-line leaks after SG is effective in the majority of patients. However, migration is the limiting factor for optimal management. Algorithms are needed for the management of chronic staple-line leaks, which are less likely to heal after stent placement. Our data indicate that earlier use of SEMS seems to reduce the time until closure and the length of the total hospital stay.

**Introduction:** Acute non-variceal upper gastrointestinal bleeding (NVUGIB) is a common medical problem that results in high morbidity and mortality. Endoscopic hemostasis has been widely accepted as first-line management for patients with NVUGIB. Hemostatic nanopowder is a novel therapy used to treat patients with upper gastrointestinal bleeding. Hemostasis is achieved by adhering of the powder to the bleeding site, which leads to a mechanical barrier. The powder has been shown to enhance clot formation and shortens coagulation time. It is delivered through a catheter and sprayed onto the bleeding site under direct endoscopic guidance, without direct tissue contact. The reported success rate of hemostatic nanopowder in patients with NVUGIB ranges between 75 to 100%, with the re-

bleeding rate of 10-49%. This systematic review and meta-analysis aimed to assess the effectiveness of hemostatic powder in achieving initial hemostasis, either as primary monotherapy, or as a part of salvage therapy in treating patients with NVUGIB.

**Aims & Methods:** We performed a comprehensive literature search of PubMed, EMBASE, Web of Science, and Cochrane Library through November 2018. Studies with more than ten patients were selected according to predefined criteria and analyzed to generate pooled data. Weighted pooled rate (WPR) for initial hemostasis, rebleeding rate for primary monotherapy or salvage therapy, and post-procedure complications were calculated for overall studies. Heterogeneity was quantified using the I-squared measure. Meta-analysis with Fixed effects model was performed to calculate data for initial hemostasis, rebleeding rate, and complications. **Results:** Out of 1379 studies obtained from the initial database search, 16 studies with a total of 688 patients met the inclusion criteria and were included in the meta-analysis. Most of the patients were treated for peptic ulcer bleeding (62.5%). Hemostatic powder was used in 473 (68.8%) patients as primary monotherapy and in 215 (31.2%) patients as a salvage therapy. The weight pooled rate (WPR) for initial hemostasis as primary monotherapy was 93% (95% CI: 0.93-0.90) and 95% (95% CI: 0.91-0.97) as a salvage therapy. The rate of rebleeding after initial hemostasis in monotherapy was 19% (95% CI: 0.16-0.23) and salvage therapy was 31% (95% CI: 0.25-0.13) respectively. The WPR for post-procedure complications was 4% (95% CI: 0.02-0.07).

**Conclusion:** Hemostatic nanopowder appears to be a safe and effective therapeutic option for the management of acute non-variceal upper gastrointestinal bleeding. This study represents the first meta-analysis that demonstrates the success of the hemostatic nanopowder in those patients. Further trials should clarify the ideal setting for the use of hemostatic powder.

## P0862 FOURTH-GENERATION ENDOCYTOSCOPY FOR IN-VIVO DIAGNOSIS OF SUPERFICIAL SQUAMOUS CELL CARCINOMA: DIAGNOSTIC ACCURACY OF NON-EXPERTS

Shimamura Y, Rodriguez de Santiago E., Abad M.R.A., Fujiyoshi Y., Quarta Colosso B.M., Ueno A., Tanabe M., Sumi K., Tomida H., Iwaya Y., Ikeda H., Onimaru M., Inoue H.  
Showa University Koto Toyosu Hospital, Digestive Disease Center, Tokyo, Japan

**Contact E-Mail Address:** yutoshimamura1219@gmail.com

**Introduction:** Fourth-generation endocytoscopy (EC; GIF-H290EC; GIF-Y0074 [prototype], Olympus., Tokyo, Japan) was newly developed to provide high-definition images with ultrahigh magnification (x520 fold) allowing in-vivo histologic assessment of gastrointestinal lesions by visualizing the cellular nuclei and cytoplasm.

**Aims & Methods:** This study aimed to evaluate the diagnostic accuracy of EC in the diagnosis of superficial esophageal squamous cell cancer between non-expert endoscopists. A single-center, retrospective study of prospectively collected data of all squamous esophageal EC examinations was conducted. The double staining method using crystal violet and methylene blue was applied to all lesions. Two endoscopists with expertise in EC collected images of 57 esophageal lesions, whose histology was established between June 2015 and April 2018. The image quality was assessed by these experts and poor quality images were discarded. Two non-experts endoscopists with no experience in EC and blinded to white-light and narrow-band imaging findings as well as histopathologic diagnosis, independently reviewed and diagnosed all endocytoscopic images after

one hour lecture of EC. EC diagnosis was made based on the new simplified criteria that we modified from a previously reported classification (Inoue H, et al. *Gastrointest Endosc Clin N Am.* 2004). The classification is based on the density and size of the nucleus, the shape of the cells, and the frontline of cellular border: EC 1a: normal; EC 1b: inflammation; EC 2: intraepithelial neoplasia (IN); and EC 3: squamous cell carcinoma (SCC). The diagnostic performance of fourth-generation EC was assessed while using the gold standard histopathology as a reference and the interobserver agreement by using the K value.

**Results:** EC images of 47 lesions (82.4%) were selected for image review. The histopathology of the 47 lesions were as follows: normal 2; inflammation 14; intraepithelial neoplasia 4; and SCC 27. The sensitivity, specificity, and overall accuracy of EC for esophageal cancer diagnosis (EC1+2 vs EC3) were 82.1% (95%CI:64.4-92.1), 78.9% (95%CI:56.7-91.5), and 80.9% (95%CI:67.5-89.6) by endoscopist A; and 100.0% (95%CI:87.9-100.0), 68.4% (95%CI:46.0-84.6), and 87.2% (95%CI:74.8-94.0) by endoscopist B. The inter-observer agreement, *Kappa* statistic= 0.68 (95%CI:0.47-0.89), was good.

**Conclusion:** Fourth generation endocytoscopy using a new simplified classification yielded optimal diagnostic accuracy for the diagnosis of superficial SCC in endoscopists without previous expertise in EC. EC aids in the diagnosis of early esophageal cancer and can be applied in clinical settings after minimal training.

**Introduction:** Ergonomics is the study of physical and cognitive demand of a task in accordance with an individual's capacity, to minimize injury and maximize efficiency. Studies have suggested a high prevalence of musculoskeletal injuries among endoscopists and ancillary staff. Survey-based studies estimate a 37% to 89% prevalence of musculoskeletal pain among gastroenterologists.

There is paucity of data especially of endoscopists from eastern populations.

**Aims & Methods:** Assess the frequency and severity of musculoskeletal injury among endoscopy staff who are involved in endoscopic procedures To assess the effect of musculoskeletal injury on quality of work in endoscopy

A questionnaire was developed based upon the recommendation of the present guidelines. The data will be collected by the self-administered questionnaire, focusing on eleven components, covering demographics, musculoskeletal injury and working hours and duration.

**Results:** A total of 47 participants, 30 (63.8%) male, 39 (83%) had right hand dominance and 8 (12.8%) had left hand dominance. There were endoscopists, trainees and ancillary staff, 13 (27.7%), 9 (19.1%) and 29 (53.2%) respectively. Assessing level of activity, 18 (38.3%) had no regular exercise, 11 (23.4%) exercised less than 150 minutes per day, 13 (27%) more than 150 minutes.

23 (48.9%) of the participants had been doing endoscopies for upto 5 years, 24 (51%) had been involved in endoscopy for more than 5 years.

37 (78.7%) reported experiencing pain or numbness, of these 16 (42.6%) had neck pain, 13 (34%) lower back pain, 9 (25%) shoulder pain, 7 (19.1%) hand pain, 6 (14.9%) thumb pain, 4 (10.6%) elbow pain and 3 (8.5%) reported carpal tunnel syndrome. 10 (27%) of those having pain attributed it to endoscopy 21 (56%) were not certain, 6 (16%) said that symptoms were not caused by endoscopy.

16 (44.4%), said pain was evident during endoscopy in 12 (34.3%) were quite bothered by their symptoms. The duration of symptoms was more than 6 months in 14 (37%), in 28 (77%) symptoms were static. 11 (29.7%) had to take time off from work, 23.4% of total group. 17 (45.9%) took medications for resolution of pain.

The responders were asked if they use some modifications to prevent these injury and 11 (23.4) endoscopic monitor at eye level, 3 (7%) cardiac monitor at bedside, 5 (10.6) stopped to move patients 7 (14.9%) sit while performing colonoscopy, 12 (25%) use height adjustable beds.

**Conclusion:** There is high prevalence of musculoskeletal injury in personnel involved in endoscopy, much of which has been attributed to endoscopic practice by responders in this study. Strategies to improve the ergonomics are vital.

Raising awareness and enhancing ergonomics in endoscopy may prevent endoscopic-related injury.

Neck pain	16 (42.6%)
back pain	13 (34%)
Shoulder pain	9 (25%)
hand pain	7 (19.1%)
Thumb pain	6 (10.6%)
Elbow pain	4 (8.5%)
Carpal tunnel	3 (8.5%)

[Musculoskeletal injury frequency]

## P0864 ENDOSCOPIC MANAGEMENT OF PLUMMER-VINSON SYNDROME

**Ben Mohamed A.**, Medhioub M., Mahmoudi M., Khsiba A., Hamzaoui L., Azzouz M.M.

Faculty of Medicine of Tunis, Tunis, Tunisia

**Contact E-Mail Address:** asmabenmed2014@gmail.com

**Introduction:** Plummer Vinson Syndrome (PVS) also called Kelly Patterson is a rare clinical condition. It is characterized by dysphagia associated with iron deficiency anemia and upper esophageal webs in the post-cricoid region. Endoscopic esophageal dilatation is sometimes necessary. The purpose of our study was to evaluate the clinical, morphological, therapeutic features of this syndrome.

**Aims & Methods:** Twenty patients with PVS, diagnosed from January 2007 to December 2016, were collected. Treatment was based on endoscopic dilation associated with iron supplementation. The dilation was performed as an outpatient by Savary-Gilliard esophageal bougies with an increasing caliber from 7 to 14 mm. A new dilatation session was performed in case of recurrence of dysphagia and / or esophageal stricture.

**Results:** There were 20 patients (18 women (90%) and 2 men (10%)). The average age was 52 years (35-73). All patients suffered from dysphagia and anemic syndrome with an average duration of 22 months. All patients had iron deficiency anemia with an average hemoglobin level of 9.7g / dL (5.9-11) and a mean ferritin level of 11 µg / L (4-20). Twenty-three dilatation sessions were performed, on average 1.25 sessions per patient (1 to 3 sessions). One patient had 2 webs, the rest of our patients had a single web. The associated diseases were celiac disease in one case (5%), Biermer anemia in 4 cases (20%) and chronic gastritis Helicobacter Pylori negative in 3 patients (15%). No post-dilation complications occurred. The evolution was favorable marked by a disappearance of the dysphagia and a correction of the anemia in all the cases. No case of malignancy was observed during the patient follow-up with a mean follow-up of 30 months (8-60).

**Conclusion:** Plummer Vinson syndrome is a rare condition that affects the quality of life of patients. Its treatment is based on endoscopic dilatation and iron supplementation. Due to the progressive risk of malignancy regular monitoring is required.

**Disclosure:** Nothing to disclose

## P0865 VALIDATION OF A SCORING SYSTEM FOR THE QUALITY OF VIEW AT UPPER GI ENDOSCOPY

**King D.**<sup>1</sup>, Harvey P.<sup>1</sup>, Rees J.<sup>2</sup>, Cheung D.<sup>1</sup>, Khan F.<sup>3</sup>, Cole A.<sup>3</sup>, Trudgill N.<sup>1</sup>

<sup>1</sup>Sandwell and West Birmingham NHS Trust / University of Birmingham, Gastroenterology, West Bromwich, United Kingdom, <sup>2</sup>Sandwell and West Birmingham NHS Trust / University of Birmingham, Gastroenterology, Birmingham, United Kingdom, <sup>3</sup>Derby Digestive Diseases Centre, Royal Derby Hospital, Gastroenterology, Derby, United Kingdom

**Contact E-Mail Address:** dominic.king@nhs.net

**Introduction:** Despite Oesophagogastroduodenoscopy (OGD) being the gold standard for visualising the upper gastrointestinal (GI) tract, there are few criteria for a successful procedure compared to e.g. colonoscopy. Post OGD upper GI cancer - failing to diagnose upper GI cancer at endoscopy up to 3 years before diagnosis - occurs in 10% of upper GI cancers. Our aim was to validate an OGD visualisation score through evaluating its reproducibility.

**Aims & Methods:** Subjects undergoing diagnostic OGD were prospectively recruited. The OGD was recorded, and video footage anonymised. Eight experienced endoscopists rated 16 pre-selected video recordings providing two scores for six areas (upper and lower oesophagus, upper and lower stomach, first and second part of duodenum). The first score is an adapted luminal contents score.<sup>1,2</sup> The second view score is based on bowel preparation quality scales. Each area was scored between 1 and 4 with 1 being excellent and 4 being poor; the best score a video could receive was 6 and the poorest was 24 (example contents and view scores - Table 1). The Intra-Class Correlation (ICC) estimate (two-way random effects model for absolute agreement of raters) was used to measure the correlation of the average ratings for both the median scores and the poorest scores for each scoring system.<sup>3</sup>

**Results:** 16 patients were included in the validation study (50% male, median age 55 (40.5-67.5) years. The median contents score was 11 (range 6-21). The highest contents score recorded by area was: 1 - 5%; 2 - 38%; 3 - 41%; 4 - 16%. The highest view score recorded by area was: 1 - 13%; 2 - 26%; 3 - 45%; 4 - 16%. The median view score was 10 (range 6-19). Both the contents and the view scores demonstrated respectable correlation between mean observer scores.<sup>3</sup> The contents ICC for the median score was moderate, at 0.74 (95% CI 0.48-0.89) and for the highest score, good, at 0.90 (0.81-0.96). The view score also demonstrated good ICC values for the median rating at 0.90 (0.59-0.92) and for the highest score, at 0.85 (0.70-0.93).

**Conclusion:** The quality of OGD visualisation scoring showed good correlation between observers and appears to be a valid tool for the assessment of OGD quality. Having validated this scoring system, a cohort study will examine the association between visualisation scores and patient and endoscopist specific factors and allow assessment of interventions to improve OGD quality.

Contents Score Description	Grade	View Score Description	Grade
No foam, mucus, bubbles, debris, food or blood	1	Full distension, allowing clear view of all 4 quadrants on withdrawal	1
Minimal foam, mucus, bubbles, food or blood that does not obscure view	2	Full distension not completely achieved resulting in some limitation of view	2
Moderate foam, mucus, bubbles, debris, food or blood obscuring view to some extent	3	Reduced distension resulting in limited mucosal views	3
Abundant foam, mucus, bubbles, debris, food or blood significantly obscuring view	4	A collapsed oesophagus that does not distend, making the mucosa very difficult to assess or impassable stricture preventing full examination or failed intubation	4

[Table 1: example scores]

## Po866 AN AUDIT OF POST OGD UPPER GASTROINTESTINAL CANCERS (POUGIC): 41% ARE POTENTIALLY PREVENTABLE

Flais A.<sup>1</sup>, Maruf S.<sup>1</sup>, Dhanji A.<sup>1</sup>, Mahmood M.<sup>1</sup>, Dhanji M.<sup>1</sup>, King D.<sup>2</sup>, Trudgill N.<sup>2</sup>

<sup>1</sup>Sandwell and West Birmingham NHS Trust, Gastroenterology, West Bromwich, United Kingdom, <sup>2</sup>Sandwell and West Birmingham NHS Trust / University of Birmingham, Gastroenterology, West Bromwich, United Kingdom

**Contact E-Mail Address:** dominic.king@nhs.uk

**Introduction:** Upper gastrointestinal (GI) cancer has a poor prognosis, with most diagnosed at a late stage and only 1 in 5 surviving beyond 5 years. Failure to diagnose a cancer during an oesophagogastrroduodenoscopy (OGD) may postpone effective treatment. This study examined post OGD upper GI Cancers within two hospitals to estimate how many were potentially preventable.

**Aims & Methods:** Between 2016-18 all cases of upper GI cancer were identified through coding records. Electronic case files were reviewed for evidence of an OGD between 6 months and 3 years before the cancer diagnosis. An OGD that failed to diagnose upper GI cancer within this time frame was considered a post OGD upper GI cancer (POUGIC). An algorithm was developed to categorise POUGIC cases based on previous work on post colonoscopy colorectal cancer, the presence or absence of a pre-malignant or cancer associated lesion and whether the OGD procedure was adequate or not (Table 1).

**Results:** 324 upper GI cancer cases were identified during the study period. 66% were male and median age was 72 (IQR 64-80) years. 17 (5%) were considered POUGIC cases - 47% male and median age 71 (64-78) years. 24% were Barrett's surveillance OGDs. Sedation was used in 38% of cancer cases (35% of POUGIC) and 81% of cancer cases were recorded as being well tolerated (71% of POUGIC).

Applying the POUGIC algorithm to the 17 cases identified, adequate OGDs and sampling or follow up were found in: type 1a - 11.8%; 2a - 11.8%; 3a - 35%. For those cases with inadequate OGDs or sampling or follow up: type 1b - 11.8% (pre-malignant lesion - inadequate sampling or follow up); 2b - 17.6% (cancer associated lesion - inadequate sampling or follow up); 3b - 11.8% (possible missed lesion prior exam inadequate). In total 41% of cases were type "b" cases and potentially preventable, examples of which included Barrett's surveillance period being longer than current guidance (Type 1b), inadequate follow up of an oesophageal ulcer (Type 2b) and alternative and inferior investigations arranged when endoscopies were abandoned due to poor patient tolerance of the procedure (Type 3b).

Type 1	Premalignant lesion (Barrett's oesophagus, adenoma, hyperplastic polyp, gastric Intestinal Metaplasia or atrophy) in the same segment as cancer.
a	biopsy and surveillance adequate
b	biopsy and surveillance inadequate
Type 2	Lesion associated cancer same segment as cancer (oesophageal ulcer or stricture, grade C or D reflux oesophagitis, gastric ulcer)
a	Cancer associated lesion noted and biopsy sampling and follow up adequate
b	Cancer associated lesion noted but biopsy sampling and follow up inadequate
Type 3	No pre-malignant lesion/lesion associated cancer same segment as cancer
a	Possible missed lesion, prior exam adequate
b	Possible missed lesion, prior exam inadequate

[Table 1. POUGIC Algorithm]

**Conclusion:** 5% of upper GI cancer cases identified in this audit were POUGIC, which is lower than previously reported. The POUGIC algorithm used in this audit allows for the categorisation of cases into those which are potentially avoidable and unavoidable - 41 % were potentially avoidable. A focus on quality improvement of Type "b" cases is important to diagnose upper GI cancer earlier and improve outcomes in upper GI cancer.

## Po867 ADVANTAGES OF CAP-ASSISTED DEVICE IN THE ENDOSCOPIC MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE ESOPHAGUS: A MULTICENTER RANDOMIZED, CONTROLLED TRIAL

Ooi M.<sup>1,2</sup>, Wong S.<sup>1,2</sup>, Duong T.<sup>1</sup>, Appleyard M.<sup>3</sup>, Rayner C.<sup>1</sup>, Grimpén F.<sup>3</sup>, Nguyen N.<sup>1</sup>

<sup>1</sup>Royal Adelaide Hospital, Adelaide, Australia, <sup>2</sup>Queen Elizabeth Hospital, Woodville South, Australia, <sup>3</sup>Royal Brisbane and Women's Hospital, Herston, Australia

**Contact E-Mail Address:** quocnam.nguyen@sa.gov.au

**Introduction:** Food bolus (FB) is a common presentation to emergency department. Endoscopic removal of FB can be challenging. Data on the use of a cap in FB is limited. This study compares the safety and advantages of cap-assisted device in removal of FB compared to conventional devices.

**Aims & Methods:** A randomized, prospective multicenter trial at 3 high-volume tertiary-care referral endoscopic centers in Australia was performed. Consecutive patients who underwent an endoscopy for acute food bolus were randomized into this multicenter study. Patients were randomized to use either (i) transparent cap-assisted device or (ii) conventional device/s. Food bolus retrieval time, rate of en-bloc removal, total procedure time, procedure adverse events, type, size and location of FB were studied.

**Results:** A total of 342 patients were enrolled into the study. The cap-assisted group had a shorter food bolus retrieval time (FBRT) (4.6+3.1min vs. 22.3+11.3mins,  $P < 0.01$ ) procedure time (22.9+6.1min vs. 47.7+17.1min,  $P < 0.01$ ), a higher success rate of FB removal (99.4% vs 93.6%,  $P = 0.01$ ) a higher rate of en-bloc removal (93.0% vs. 28.1%,  $P < 0.01$ ), a lower rate of major adverse events (9/171 vs. 13/171,  $P < 0.01$ ) and a larger measured mean FB size (FB length: 17.6+2.9mm vs. 8.3+9.2mm,  $P < 0.01$  and FB width: 52.3+20.7mm vs. 26.6+27.5mm,  $P < 0.01$ ) compared to conventional group. The type and location of FB were comparable between the two groups, with no significant differences ( $p > 0.05$ ).

**Conclusion:** The use of a transparent cap was found to be safe and effective in removal of oesophageal FB. This technique was associated with a shorter procedure time, a higher rate of en bloc removal of FB, a lower rate of adverse events and a larger mean FB size retrieved compared to conventional technique.

## Po868 MUCOSAL TRANSPLANTATION FOR THE MANAGEMENT OF STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

Saif U., Zhou Y., Liu B.-R.

The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China

**Contact E-Mail Address:** karypton@hotmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) of high grade dysplasia and early esophageal cancer has gained acceptance in the last decade as an effective therapeutic option. Although the short term results of ESD are promising, a high risk of procedure related complications, including post-procedural stricture remains unresolved.

**Aims & Methods:** The aim of this study were to assess the effectiveness and safety of mucosal transplantation into esophagus from the stomach in preventing stricture formation after ESD in early esophageal cancer. Six patients who underwent circumferential ESD for early esophageal cancer were enrolled. After the patients underwent ESD, the mucosal patches taken from the posterior wall of the middle part of the gastric body by the ESD were placed to the ulcer site of esophagus. The guide wire was then inserted into the gastric cavity via flexible endoscopic channel to fix the patches with the stent at the ulcer site. The stent was removed after the performance with media of 7.83 days (range 7-9). All of the patients were followed up with endoscope.

**Results:** The graft survival rate was 83.3% with strictures occurred at a mean of 33.67 days (range 20-56) after the procedure. The median number of endoscopic balloon dilatation sessions was 5.67 (range 4-7).

**Conclusion:** Gastro-esophageal mucosal transplantation for stricture prevention after circumferential submucosal dissection for early esophageal cancer and or high grade dysplasia seems feasible with excellent outcome. This study opens new perspective in this field.

**Disclosure:** Nothing to disclose

## P0869 SAFETY PROFILE OF PERORAL ENDOSCOPIC MYOTOMY (POEM)

Drazilova D.<sup>1</sup>, Vackova Z.<sup>1</sup>, Hucl T.<sup>2</sup>, Štirand P.<sup>1</sup>, Kieslichova E.<sup>3</sup>, Janousek R.<sup>4</sup>, Ryska O.<sup>5</sup>, Spicak J.<sup>1</sup>, Martinek J.<sup>1</sup>

<sup>1</sup>Institute for Clinical and Experimental Medicine, Hepatogastroenterology, Prague, Czech Republic, <sup>2</sup>Institute for Clinical and Experimental Medicine, Gastroenterology and Hepatology, Prague, Czech Republic, <sup>3</sup>Institute for Clinical and Experimental Medicine, Anesthesiology and Intensive Care, Prague, Czech Republic, <sup>4</sup>Institute for Clinical and Experimental Medicine, Radiodiagnostic and Interventional Radiology, Prague, Czech Republic, <sup>5</sup>Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Surgery, Lancaster, United Kingdom

**Contact E-Mail Address:** drazilovad@gmail.com

**Introduction:** Peroral endoscopic myotomy (POEM) is endoscopic method of esophageal myotomy with high clinical efficacy and safety and represents a desirable therapeutic alternative to laparoscopy as a less invasive approach. Nevertheless, POEM remains an invasive intervention carrying risk of potential complications.

**Aims & Methods:** The aim of our analysis was to assess the perioperative and early postoperative adverse events (AEs) in patients undergoing POEM.

We retrospectively evaluated the prospectively collected data from all consecutive patients who underwent POEM at our institution between December 2012 and May 2018 and searched for periprocedural complications.

**Results:** A total of 231 patients have undergone 243 POEM procedures (12x re-POEM) from which 50 procedures (20.6%) passed uneventfully while in 193 procedures (79.4%), some AE occurred. Perioperative AEs included subcutaneous emphysema (79/243; 32.5%; no treatment needed), capnoperitoneum requiring puncture (14; 5.8%), allergic reaction to antibiotics (2; 0.8%), anaesthesia-related complications (14; 5.8%). Postoperative AEs included pain requiring analgesics (158; 65%), fever (20; 8.2%) and pneumonia (3; 1.2%). One patient (0.4%) lost taste and smell irreversibly. A total of 10 serious adverse events occurred in 8 patients (3.3%): post-POEM leak from mucosal incision requiring endoscopic clipping in 5, pneumothorax in 2 (1 required drainage), pleural effusion requiring drainage in 1 and scrotum emphysema in 1 case. One patient died during the procedure due to cardiac arrest (the autopsy revealed unrecognized pulmonary hypertension and severe ischemic heart disease). The mean length of stay was 2.5 ( $\pm 0.5$ ) days, prolonged ( $\geq 4$  days) hospitalization was required in 25 (10.8%) patients.

ASA score was available in 170 patients: I- 44/170 (25.9%), II- 90 (52.9%) and III- 36 (21.2%). In patients with ASA I, II, III no adverse events occurred in 18.2%, 17.8% and 16.7% respectively. Serious complications were diagnosed in patients with ASA I, II, III in 2.3%, 4.4% and 5.6% respectively. The correlation between severe complications and ASA score was not statistically significant ( $p=0.754$ ).

**Conclusion:** POEM-related adverse events are rather common; however, most of them are mild. Although being quite rare, severe complications, and even fatal, may still occur. ASA score does not seem to be a significant predictor of major complications.

**Disclosure:** Nothing to disclose

## P0870 FITTING THE QUALITY INDICATORS IN FECAL IMMUNOHISTOCHEMICAL TEST (FIT) POSITIVE COLONOSCOPY

<sup>1</sup>Singapore General Hospital, Gastroenterology, Singapore, Singapore, <sup>2</sup>HM Sanchinarro University Hospital, Bariatric Endoscopy Unit, Madrid, Spain, <sup>3</sup>Toronto General Hospital, Gastroenterology and Hepatology, Toronto, Canada, <sup>4</sup>Singapore General Hospital, Health Services Research Unit (HSRU), Singapore, Singapore

**Contact E-Mail Address:** kimwei.lim2@mohh.com.sg

**Introduction:** Adenoma detection rate (ADR) is an important quality measure to assess the colonoscopy examination and high ADR is shown to protect against CRC. The ADR varies widely amongst endoscopist. Recently, adenoma per colonoscopy (APC) has been proposed as an additional quality measure to overcome the limitations with ADR. It was suggested that high ADR with low APC rate may reflect less thorough "remove one adenoma and done" type colonic evaluation.

We hypothesized that this may not be true and ADR consistently correlates with APC during colonoscopy. We studied the relationship of ADR and APC in FIT positive patients where adenoma prevalence is higher and compared their efficacy based on correlation with advanced adenoma detection rate (AADR).

**Aims & Methods:** We retrospectively studied the FIT positive database from November 2016 to October 2018 at Singapore General Hospital. Four gastroenterologist and 13 surgeons performed the colonoscopy. We excluded endoscopist who performed less than 10 cases from analysis. We defined advanced adenoma as adenoma  $\geq 10$ mm in size or with villous histology or high-grade dysplasia. We included them in the ADR and APC calculation. We used descriptive and Student-t test statistics for comparison. We used Pearson's correlation and Fisher r-to-z transformation to compare the relationship between ADR and APC, ADR and AADR, and APC and AADR. We performed multivariate analysis to identify factors that predicted high ADR. Our institutional review board approved this audit.

**Results:** We analyzed 476 FIT positive patients who underwent colonoscopy: 118 evaluated by gastroenterologist and 358 by surgeons. The mean  $\pm$  SD age was  $64 \pm 8$  years and majority were females (53%). Each endoscopist performed  $28 \pm 14$  colonoscopies. The mean Boston bowel preparation score was  $6.3 \pm 1.6$ . The caecal intubation rate was 100% and the mean withdrawal time was  $11.6 \pm 1.7$  minutes. The overall ADR, APC and AADR was 51%, 1.06 and 16%, respectively. We found the ADR, APC and AADR was significantly higher for gastroenterologist than surgeons (45% vs. 70%, 0.8 vs. 1.8, 14 vs 22,  $p=0.0001$ ). We found the overall ADR correlated strongly with APC ( $R=0.89$ ,  $p=0.0001$ ) and moderately with AADR ( $R=0.71$ ,  $p=0.001$ ). Similarly, the APC correlated significantly to AADR ( $R=0.61$ ,  $p=0.009$ ). We did not observe any difference in the correlation coefficient between ADR-AADR and APC-AADR (0.71 vs. 0.61,  $p=0.63$ ). Age and withdrawal significantly predicted high ADR ( $p < 0.001$ ) in multivariate analysis. The cancer detection rate in this entire cohort was 5%.

**Conclusion:** ADR was significantly higher in FIT positive patients and correlated significantly with APC and AADR. In quality assessment of colonoscopy, ADR should be used as the indicator than APC. We did not observe "remove one adenoma and done" behavior.

**Disclosure:** Nothing to disclose

## P0871 UNDERWATER ENDOSCOPIC RESECTION FOR COLONIC LESIONS IN DIFFICULT AND CHALLENGING SITUATIONS

**Contact E-Mail Address:** hugoikuo@hotmail.com

**Introduction:** Classical endoscopic mucosa resection (EMR) creates a submucosal cushion of fluid to avoid muscle layer damage at the time of snare resection. Sometimes the submucosal injection may narrow the working space in the colon, or increase the tension of the lesion and sometimes make it harder to snare (specially nongranular lesions). Underwater endoscopic resection (UEMR), first described by Dr. Binmoeller,<sup>1</sup> avoids the need for submucosal injection, and it may be helpful in challenging situations such as non-lifting lesions, or difficult locations.

**Aims & Methods:** The aims of the study were to assess the safety, utility and technical success rate of the underwater technique for the treatment of challenging colonic lesions.

Clinical, endoscopic and histological data were collected from cases of UEMR performed in 4 centers between January 2016 and July 2018. Inclusion criteria was lesions with no-lifting sign (in previous endoscopic injection).

tion) that were poor candidates for classic EMR, difficult location (ileocec valve, diverticulum or appendix) or lesions with a previous failed attempt for EMR in an expert center. SMSA polyp score was not applied because previous attempt of EMR is not addressed by this scoring system.

**Results:** 60 UEMR in challenging situations were performed, of which 57 completed follow-up (mean 186 days) to date. The mean age of the patients was 66.14, being 68% men.

There were 37 (61.67%) non-lifting lesions (including recurrent/residual lesions in ICV and appendix, and non-treated lesions), 17 (28.3%) appendicular or ileocecal valve lesions not previously treated, 1 (1.6%) intradiverticular lesion, 2 (3.3%) lesions in complex sigma and 3 (5%) residual lesion including ileocecal valve.

The mean size (diameter) of the lesions was 19 mm, and the mean size (largest diameter) of the resection specimen was 15.3 mm (95% CI 13.68 - 16.99 mm) being the largest specimen of 30 mm in diameter, with En bloc resection in 34 cases (56.67%), and piecemeal resection in 2-3 fragments in 19 cases (31.67%). The histology showed pT1 in 4 cases (one low risk pT1a), HGD and intramucosal cancer in 8 cases, and no advanced histology (LGD, SSP/A without displasia) in the others. There was one postprocedural bleeding requiring endoscopic treatment and no major complications (no perforations). The success (complete macroscopic resection) of the technique was 98% with 3 recurrences, that were successfully re-treated endoscopically and 4 patients underwent surgery, 3 cases due to high risk features at histology (pT1b) and 1 case of deep intraappendicular lesion.

**Conclusion:** Underwater endoscopic resection in the colon is a safe and useful technique for challenging colorectal lesions such as non-lifting lesions, appendiceal, ileocecal valve, diverticular, and difficult sigmoid locations.

Residual/Recurrent lesion non-lifting	27 (45%) -includes AO & ICV
Non-lifting untreated lesion	10 (16,67%)
AO untreated lesion	12 (20%)
ICV untreated lesion	5 (8,3%)
Intradiverticular untreated lesion	1 (1,6%)
Failed EMR attempt at sigmoid lesion	2 (3,3%)
Incomplete resection (re-schedule)	3 (5%) -one case ICV

#### [Location of the lesions]

**Contact E-Mail Address:** hugoikuo@hotmail.com

**Introduction:** Endoscopic full-thickness resection (EFTR) using a modified over-the-scope clip (FTRD kit) in the colorectum is a technique that allows *en-bloc* full-thickness resection of lesions for selected cases (e.g. non-lifting lesions suspicious of flat malignant polyps), especially for lesions < 20mm.

**Aims & Methods:** To study the safety and feasibility of the endoscopic full-thickness resection (EFTR) in colorectal lesions using an over-the-scope clip.

The clinical, endoscopic and histological data were collected prospectively in all cases of EFTR performed in 10 centers of Spain using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany) during the period from June 2015 to July 2018.

**Results:** 71 EFTR were scheduled.

In 3 patients EFTR was not possible due to impossibility to pass the sigmoid with the kit. In the other 68 patients the technical success was 85.2% with *en-bloc* resection in 83.8%.

The mean age of the patients was 67 years (range 40-86), being men 64.79%.

Indications were: non-lifting sign recurrent lesions (46.47%), non-lifting sign untreated lesions (23.94%), incomplete resection of non-lifting sign lesions (11.26%), appendicular lesions (2.8%), suspected T1 lesion (7%), EFTR of suspicious scar (4.2%), subepithelial lesions (4.2%).

The mean diameter of the resected specimen was 21.53mm (95% CI 19.87-23.2).

Final histology: LGD adenoma (40%), HGD adenoma (23%), intramucosal adenocarcinoma (4.47%), SSP (5.87%), T1sm1 (2.9%), advanced adenocarcinoma >sm2 (13%), scar tissue (6%) and others (2.8%).

In one case the OTSC was not deployed, with intraprocedural perforation. There were 2 cases of delayed perforation and 1 case of delayed bleeding. 10 patients underwent surgery: 3 perforation, 1 intraappendicular lesion, and 6 for advanced adenocarcinoma.

During the follow-up, 3 recurrences / residual tissues were treated endoscopically (benign histology).

**Conclusion:** EFTR using a modified OTSC (FTRD system) for selected cases (such as failure of other endoscopic treatments in lesions < 20-25mm) is a safe and feasible technique.

Evaluation of the insertion with a long cap (e.g. "PROVE" cap) and traction of the lesion prior to EFTR is highly recommended. Special care must be taken to avoid performing the resection if the OTSC is not deployed.

**Contact E-Mail Address:** hugoikuo@hotmail.com

**Introduction:** Endoscopic full-thickness resection (EFTR) using a modified over-the-scope clip (FTRD kit) in the colorectum is feasible for selected cases (e.g. suspicious of flat malignant polyps), allowing *en-bloc* resection of lesions up to 20-25mm. But in some cases there is a risk of technical failure due to poor traction, rupture of the snare or losing of the resection plane, and part of the lesion or the whole of it might get trapped inside the over-the-scope clip (OTSC).

**Aims & Methods:** Our aim was to study the outcomes of the patients with the lesion trapped in the OTSC due to technical failure. Clinical, endoscopic and histological data were collected prospectively in all cases of EFTR performed in 10 centers of Spain using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany) during the period from June 2015 to July 2018.

Cases of technical failure with part or the entire lesion trapped inside the OTSC were analyzed.

**Results:** 68 cases of EFTR were evaluated.

In 10 cases, the lesion was trapped in the OTSC and could not be resected properly.

The mean age of the patients was 71 years, being men 80%.

Indications were: non-lifting sign recurrent lesions (6 cases), non-lifting sign untreated lesions (1), incomplete resection with non-lifting sign (2), appendicular lesions (1).

Location were appendix (1 case), stump (1), right colon (1), transverse colon (2), left colon (2), sigma (2), rectosigmoid junction (1).

The mean diameter of the lesion was 19mm.

In 8 cases there was a partial resection of the lesion (mean diameter of the lesion 18mm), and in 2 cases only biopsies were taken.

Final histology: LGD (4 cases), HGD (2), intramucosal adenocarcinoma (1), SSP (2), advanced adenocarcinoma >sm2 (2).

In the follow-up, three lesions underwent surgery (appendicular lesion and advanced adenocarcinoma), 3 residual lesions were treated endoscopically and in 4 cases the scar showed no residual tissue.

**Conclusion:** In some cases of intended EFTR, residual tissue trapped inside the OTSC might be easily treated endoscopically and sometimes might be treated by the OTSC itself, if the residual lesion is small.

**Disclosure:** Nothing to disclose

## P0874 LONG-TERM EFFICACY AND SAFETY OF COLD SNARE POLYPECTOMY VERSUS CONVENTIONAL ENDOSCOPIC MUCOSAL RESECTION FOR 5-9 MM COLORECTAL POLYPS

**Introduction:** Cold snare polypectomy (CSP) is becoming a common method for removal small or diminutive polyps without submucosal injections or electrocautery. The aim of this study was to assess long-term efficacy and safety of cold snare polypectomy versus conventional endoscopic mucosal resection for 5-9 mm colorectal polyps with well-matched patient groups.

**Aims & Methods:** In this retrospective analysis, 328 colorectal polyps from 187 patients were removed with CSP or endoscopic mucosal resection (EMR) in Seoul St. Mary's Hospital between March 2014 and June 2014. Resected polyps were divided into CSP group and EMR group. A 1:2 propensity case-matches analysis was used with covariates of baseline characteristics, including sex, age, polyp size, follow-up duration, and procedure-performed endoscopists. Finally, 5-9 mm sized polyps were included in this study. The recurrence rate and complication rate were compared between the matched two groups.

**Results:** Two groups were well balanced by propensity score matching, and 151 polyps were matched. Fifty eight polyps from 35 patients were treated by CSP and 93 polyps from 71 patients treated by EMR. In CSP group and EMR group, mean age (years, mean  $\pm$  SD) was 64.8 $\pm$ 7.6 and 64.1 $\pm$ 9.5 (p=0.638), polyp size 5.9 $\pm$ 0.8 cm and 6.0 $\pm$ 0.9 cm (p=0.397), and follow-up duration 33.1 $\pm$ 9.2 months and 32.2 $\pm$ 10.0 months (p=0.584), respectively. While 6 of 58 polyps (10.3%) in CSP group recurred during follow-up period, 1 of 93 polyps (1.1%) recurred in EMR group (p=0.008). Serious adverse events such as delayed bleeding and perforation did not occur in either group.

**Conclusion:** CSP group had significantly higher recurrence rate than EMR group after resection of 5-9 mm colorectal polyps. Both methods were safe without serious adverse events. Further prospective study including a large number of patients is required.

**Disclosure:** Nothing to disclose

## P0875 TIP-IN ENDOSCOPIC MUCOSAL RESECTION FOR LARGE COLORECTAL SESSILE POLYPS

Sato Y., Ozawa S.-I., Yasuda H., Kato M., Kiyokawa H., Yamashita M., Matsuo Y., Yamamoto H., Itoh F.

St. Marianna University School of Medicine, Dept. of Gastroenterology and Hepatology, Kanagawa, Japan

**Contact E-Mail Address:** y2satou@marianna-u.ac.jp

**Introduction:** Tip-in endoscopic mucosal resection (EMR) is a modified EMR technique using which en bloc resection of large colorectal sessile polyps can be performed; however, its usefulness for colorectal sessile polyps of >20 mm has not been reported. This study examined treatment outcomes of tip-in and conventional EMR for large colorectal sessile polyps of  $\geq$ 20 mm.

**Aims & Methods:** This was a retrospective case-control study conducted at a single tertiary center in Japan. Subjects included those with large colorectal sessile polyps of  $\geq$ 20 mm, excluding pedunculated-type polyps, who underwent endoscopic resection between January 2010 and January 2019. For tip-in EMR, 15-mm snare master or 20-mm spiral snare (Olympus Co., LTD, Tokyo, Japan) was used. After a sufficient local injection, the snare tip was projected by 2 mm and a mucosal incision was created on the oral side of the lesion. After this, while fixing the snare tip to the submucosal layer, the snare was expanded while gradually pulling the scope. Once the lateral margin of the lesion was completely secured, the snare was closed while de-airing, and resection was then performed. The primary outcome was endoscopic treatment outcomes when using tip-in and conventional EMR, and the secondary outcome was the local recurrence rate after endoscopic treatment.

**Results:** During the study period, 126 patients 126 lesions (72 men and 54 women, mean age: 69.9±12 years, mean tumor size: 23.6±4.1mm) were resected using tip-in or conventional EMR. Forty-three colorectal lesions were treated using tip-in EMR and 83 using conventional EMR. Tip-in EMR had a significantly higher en bloc resection rate (90.7% vs. 50.7%,  $P = 0.008$ ), and significantly shorter treatment duration ( $6.64 \pm 0.64$  min vs.  $10.47 \pm 0.81$  min,  $P = 0.005$ ) than conventional EMR. Perforation rates with tip-in and conventional EMR were 4.6% and 3.6%, respectively, indicating no significant difference ( $P = 0.556$ ). All cases with perforation were successfully sutured using hemoclips, and additional surgical intervention was not required. Local recurrence was examined in 80 cases who were followed up for >6 months after endoscopic resection. The mean follow-up period was  $25.7 \pm 15.5$  months. Recurrence rate was 0% and 7.0% in tip-in and conventional EMR cases, respectively, without significance difference ( $P = 0.495$ ).

**Conclusion:** Tip-in EMR showed high en-block resection rate and no residual tumor was found. This technique is a potential endoscopic treatment alternative for large colorectal sessile polyps of  $\geq 20$  mm.

**Introduction:** The development of the procedure questionnaire, by the European Colonoscopy Quality Investigation (ECQI) Group, has been previously described in posters presented at United European Gastroenterology Week, 2015 and 2016.

**Aims & Methods:** To assess the factors associated with sedation use in diagnostic and screening patients  $\geq 50$  years of age using questionnaire responses from across Europe. Data collection is an ongoing process: we analysed data collected between 2/6/16 and 30/4/18 (n=6445).

All screening and diagnostic colonoscopies in patients aged  $\geq 50$  years were identified in our dataset (n=3365). Stepwise multivariable logistic regression analysis was conducted to determine the main factors associated with sedation use. Analysis was performed on the following variables: age in 10-year categories; body mass index (BMI) categories; gender; inpatient status; reason for procedure; time of day colonoscopy performed; previous total colonoscopy in last 5 years; Boston Bowel Preparation Score (BBPS)  $\geq 6$ ; retraction time categories; chromoendoscopy used; high-definition equipment used; assistive technology used; intended endpoint; and intended endpoint reached.

**Results:** There were 1394 procedures where the results of all selected variables were known provided by 59 practitioners from 38 institutions: 71.0% of procedures used sedation. In order, the most associated variables were:

1. Use of high-definition equipment (76.3% vs. 55.5%,  $p < 0.0001$ ).
2. Use of assistive technology (59.0% vs. 72.8%,  $p < 0.0001$ ).
3. Female gender (78.8% vs. 62.2% male,  $p < 0.0001$ ).

4. Longer retraction time (83.9% > 10 minutes vs. 65.1% 6 - 10 minutes and 66.7% < 6 minutes,  $p < 0.0001$ ).

5. Use of chromoendoscopy (76.3% vs. 69.5%,  $p = 0.0051$ ).

6. Younger patient age (78.0% 50 - 59 years vs. 67.6% 60 - 69, 68.1% 70 - 79, 69.4%  $\geq 80$ ,  $p < 0.0001$ ).

7. Inpatient status (84.0% vs. 68.7% outpatient,  $p < 0.0001$ ).

**Conclusion:** The use of sedation appears to be more associated with factors related to the equipment/techniques used during colonoscopy than patient characteristics.

**Contact E-Mail Address:** yasshifive@yahoo.co.jp

**Introduction:** Underwater endoscopic mucosal resection (UEMR) is simple and effective technique, and recently widespread for the treatment of colorectal polyps. Although UEMR has lots of benefits compared to conventional EMR, UEMR has some problems to be solved. Especially, in underwater condition, diagnosis of the extent of the superficial colorectal lesions is sometimes difficult compared to that in conventional air fulfilled condition because chromoendoscopy is not available. Image enhanced endoscopy (IEE) such as blue laser imaging (BLI) or narrow band imaging was reportedly useful to diagnosis the lesion extent, but these IEE are not good at poor bowel preparation. On the other hand, linked color imaging (LCI) which enhances color contrast seemed theoretically useful to diagnose the lesion extent even in underwater. Thus, we evaluated which observation mode (white light imaging [WLI], BLI, or LCI) was the most effective to diagnose the lesion extent of superficial colorectal polyps in underwater condition.

**Aims & Methods:** Between April 2018 and December 2018, consecutive superficial colorectal polyps observed by three mode (WLI, BLI, and LCI) in underwater condition before UEMR were prospectively registered into database of our endoscopy unit, and the images were retrospectively analyzed. Observation in underwater and UEMR was conducted by using a LASEREO system (FUJIFILM, Tokyo, Japan) with an EC-L600ZP endoscope. Color values of the lesion and surrounding non-neoplastic mucosa were calculated using Photoshop (CIE L\*a\*b\* color space). Then, color difference between the lesion and surrounding non-neoplastic mucosa ( $\Delta E$ ) was examined in each mode. The extent of the lesion was confirmed histologically after UEMR. The visibility score of images in each mode was also evaluated by four evaluators (2 experts and 2 non-experts, who were blinded to background and histology). The visibility score was categorized from 4 (excellent visibility) to 1 (poor visibility).

**Results:** In total, 73 colorectal polyps (50 adenomatous polyps [Ad] and 23 sessile serrated adenoma/polyps [SSA/P]) observed by each mode were analyzed. Median lesion size (range) was 7 (5-25) mm. Among them, 61 polyps (44 Ad and 17 SSA/P) were observed in transparent underwater condition, and 12 polyps (6 Ad and 6 SSA/P) were observed in cloudy underwater condition due to poor bowel preparation. In transparent condition, color difference between the lesion and surrounding non-neoplastic mucosa ( $\Delta E$ ) of 61 lesions with BLI (8.2) and LCI (7.4) was significantly higher than with WLI (5.2) ( $P < .002$ ). The mean visibility score of BLI (3.5) and LCI (3.4) was significantly higher than that of WLI (3.4) ( $P < .001$ ). There was no significant difference between BLI and LCI regarding color

difference and visibility score. The color difference and visibility score of 44 Ad was similar to 61 polyps as mentioned above. But, the color difference of 17 SSA/P with BLI was significantly higher than that of WLI, and there was no significant difference between LCI and WLI. In crowded underwater condition, the mean visibility score of WLI (2.5) and LCI (2.8) was significantly higher than that of BLI (2.1) ( $P=0.02$ ,  $P<.001$ , respectively). The mean visibility score of LCI was tend to be higher than that of WLI ( $P=0.08$ ). Accurate measurement of color difference was impossible in crowded condition.

**Conclusion:** BLI and LCI was useful to evaluate the extent of colorectal polyps in transparent underwater condition. BLI seemed to be suitable to evaluate the extent of SSA/P. In crowded underwater condition, LCI was better to evaluate the colorectal polyps.

## P0878 REVIEW OF EFFECTIVENESS OF PATIENT INFORMATION LEAFLET (PIL) IN PATIENTS UNDERGOING GASTROINTESTINAL ENDOSCOPY

Ho S.<sup>1</sup>, Koo S.<sup>1</sup>, Butt F.<sup>2</sup>

<sup>1</sup>South Tyneside and Sunderland NHS Foundation Trust, Gastroenterology, South Shields, United Kingdom, <sup>2</sup>South Tyneside NHS Foundation Trust, Gastroenterology, South Shields, United Kingdom

**Contact E-Mail Address:** sophie.koo@gmail.com

**Introduction:** In the United Kingdom, endoscopy services are overburdened and waiting times are long due to limited resources. To improve this, there is a national drive for increasing Straight to Test (STT) patients. An effective Patient Information Leaflet (PIL) is paramount to facilitate this. PILs are an effective patient education tool to support patients in making informed choices for their health care. Multiple factors influence the effectiveness with readability being the most important factor that directly affects patient's ability to access the information provided. (1) Effective provision of information can improve patient satisfaction, greater compliance to treatment and follow up, thereby improving patient care. Research shows patients retain only 20% of verbal discussion with health care providers, but this improves to 50% with additional written or visual information. (2)

As per our endoscopy unit policy, all patients are provided with a paper PIL pre-procedure (updated every 3 years).

**Aims & Methods: Primary aims:**

1. To assess patient use and effectiveness of PIL
2. To assess effectiveness of PIL in STT patients at South Tyneside District Hospital.

**Secondary aims:**

1. To assess preferred formats of PIL

**Methods:** All consecutive patients attending the endoscopy day ward over a 10 week period were asked to fill in a questionnaire and return it prior to discharge.

**Results:** 206 patients returned the PIL (M=97, F=105, Prefer not to say=4). Patients underwent gastroscopy (n=79), colonoscopy (n=70), flexible sigmoidoscopy (n=12), capsule endoscopy (n=14). Majority of patients (52.7%) were aged 55-74 years.

Only 76.2% of patients read the PIL in full with women more likely than men. There is interest in electronic format and audio-visual aids despite a majority (88.1%) of patients still preferring printed PIL. 1 in 5 of patients who did not read the PIL thought an electronic PIL would be useful.

1 in 6 patients did not find the PIL useful. Issues reported were that the PIL was too long/difficult to understand/too complicated (n=8). Others felt the PIL had incorrect information or caused anxiety (n=5). Patients who did not find the PIL useful were >45 years.

Patients who had a prior discussion with their clinician or had an endoscopy pre-assessment found the PILs very or extremely useful (n=151, 85.6%). STT patients account for 10% of all patients (these patients neither had a discussion with a clinician nor a pre-assessment). Only 62% of these patients read the PIL in full and 23.5% of them did not find the PIL useful, suggesting poor understanding of the procedure.

**Conclusion:** Almost a quarter of patients did not read the PIL and 18% of patients found the PIL somewhat useful or not useful. This implies poor understanding of the procedure which may have legal consequences.

Although our numbers are low, our results still show a significant proportion of STT patient did not find the PIL useful. In view of increasing use of STT pathway, there is a need to reinforce the use of pre-assessment clinics and to introduce newer innovations such as audio-visual aids. Use of audio-visual aids in an ophthalmology pre-operative setting has shown to meet patient information needs, improve patient satisfaction and reduce patient anxiety.(3)

Our results show a demand for electronic platforms to access patient information and healthcare providers need to adapt to this.

We aim to re-audit patient satisfaction after introduction of audio-visual aids.

## P0879 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL LESIONS: OUTCOMES FROM A UNITED STATES EXPERIENCE

Gupta N.R.<sup>1</sup>, Rodriguez Ruiz G.<sup>2</sup>, Donboli K.<sup>1</sup>, Siddiqui U.D.<sup>1</sup>,

Chapman C.G.<sup>1</sup>, Waxman I.<sup>1</sup>

<sup>1</sup>University of Chicago, Center for Endoscopic Research and Therapeutics, Chicago, United States, <sup>2</sup>Hospital Central Norte Petroleos Mexicanos, Mexico City, Mexico

**Contact E-Mail Address:** nina.gupta@uchospitals.edu

**Introduction:** Endoscopic submucosal dissection (ESD) is an endoscopic resection technique used for removal of large non-pedunculated colorectal polyps and early (T1) colorectal cancers. This innovative modality provides an alternative to surgical resection. It allows for en bloc resection regardless of lesions size, which facilitates specimen orientation and accurate pathologic staging. The technique is also often curative as previously demonstrated by experiences showing a high R0 resection rate with low recurrence rate. While ESD is a well established technique in Asia for management of early gastrointestinal (GI) neoplasia, adoption in the western world has been limited.

**Aims & Methods:** We aim to describe outcomes from a colorectal ESD program at a United States (US) academic tertiary medical center and compare this to published non-Asian and Asian experiences.

Retrospective review was performed of colonic lesions referred to the University of Chicago Medical Center for ESD from 2012 to 2019. Data collected included lesion characteristics, procedural outcomes, histology findings, and patient follow up.

**Results:** The study included 73 patients with a median age of 63 years (range 30-83) of which 34 were male (46.6%) and 39 were female (53.4%). The rectum was the most common location (n=47, 64.4%). Mean lesion size was 30.1 mm (SD± 18.0 mm) and most frequent Paris classification was IIa (n=21, 28.8%).

Complete ESD was achieved in 72 cases (98.6%) with 61 patients (83.6%) confirmed to have an R0 resection on histology. ESD was performed en bloc in 50 cases (68.5%). The en bloc resection rate improved from 54.1% to 83.3% from the first half of the cases to second half ( $p=0.007$ ). Adenocarcinoma was present in 14 of the resected lesions (19.2%). The mean procedure time was 116.3 min (SD± 54.4). Complications occurred in 9 cases (12.3%) with 4 cases of delayed bleeding (5.5%), 4 cases of perforation (5.5%) and 1 case of perforation with delayed bleeding (1.4%).

Most complications (n=6, 66.7%) were successfully treated endoscopically. Surgery was needed in three cases of perforation. Follow up procedures were performed in 32 patients (43.8%) while the remaining 41 patients (56.2%) followed up elsewhere or are not due yet. Mean follow up interval was 7.4 months (SD± 4.1).

Follow up endoscopy showed inflamed or regenerative mucosa in almost all cases (n=31, 96.9%) with only 1 case of recurrent adenoma (3.1%). Table 1 compares these US outcomes to a recent meta-analysis<sup>1</sup> of pooled ESD outcomes in non-Asian and Asian countries.

	United States Center	Non-Asian Countries	Asian Countries
En Bloc Resection	68.5%	81.2%	93.0%
Ro Resection	83.6%	71.3%	85.6%
Recurrence	3.1%	5.2%	1.1%
Delayed Bleeding	6.8%	4.2%	2.4%
Perforation	6.8%	8.6%	4.5%
Need for Surgery Post ESD Complication	4.1%	3.1%	0.8%

[Colorectal ESD Outcomes at a United States Single Center Compared to Pooled Outcomes from Non-Asian and Asian Countries]

**Conclusion:** This study shows successful outcomes of colorectal ESD at a US tertiary center. While the en bloc resection rate was lower than in other published cohorts, there was a learning curve with significant improvement over time. Additionally, both the Ro resection rate and lesion recurrence rate were more favorable than in other Western experiences, and approach the rates seen in Asian countries. Complications were slightly higher in this study, but most were managed endoscopically. Overall, colorectal ESD is an important endoscopic advancement and effective non-surgical treatment for early neoplasia. ESD training in the United States should be increased to optimize utilization and achieve outcomes comparable to Asia.

## P0880 FEASIBILITY OF THE ENDOSCOPIC CLASSIFICATION OF FIBROSIS IN ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR COLORECTAL NEOPLASMS

Tamegai Y.<sup>1</sup>, Takeda S.<sup>2</sup>, Takarabe S.<sup>3</sup>

<sup>1</sup>Cancer Institute Hospital, Dept. of Endoscopy, Tokyo, Japan, <sup>2</sup>Matsudo City Medical Center, Department of Gastroenterology, Matsudo City, Chiba, Japan, <sup>3</sup>Ichikawa General Hospital, Tokyo Dental College, Department of Gastroenterology, Ichikawa City, Chiba, Japan

**Contact E-Mail Address:** yoshiro.tamegai@jfc.or.jp

**Introduction:** The possibility of complete curative en bloc resection is sometimes related to the presence and degree of fibrosis in the submucosal layer (SM), rather than tumor size and location. In this study, we analyzed the clinical outcomes of ESD for colorectal neoplasms accompanied by fibrosis. The aim of this study was thus to establish a safe and curative ESD procedure for colorectal neoplasms showing fibrosis in the SM layer.

**Aims & Methods:** ESD was performed for 1,659 epithelial neoplasms in 1,620 patients (male 906, female 714, average 66.7 years old) from January 2003 to October 2018, and was completed for 1,643 lesions. Of these cases, 359 showed SM fibrosis. These cases were divided into three groups: absence of fibrosis (A), fibrosis due to benign causes (B), and fibrosis due to cancer invasion (C). Furthermore, cases were classified as mild (grade 1), moderate (grade 2), or severe (grade 3). Clinical outcomes and pathological findings of the above-mentioned ESD cases were analyzed according to these endoscopic classifications to facilitate the safe achievement of ESD. In addition, histological validation of endoscopic diagnosis was examined for the 240 of the 359 cases with fibrosis, to clarify for differential diagnosis between Type B and C.

**Results:** Of the 359 cases with fibrosis, 226 cases involved benign causes (Type B), and 133 cases were considered related to cancer invasion (Type C). As the results of the validation study (n=240) for differential diagnosis between Types B and C as follows; sensitivity: 88.7%, specificity: 90.5%, accuracy: 89.2%, PPV: 96.3%, NPV: 74.0%. En bloc resection rates (n=359) were as follows: A, 97.7%; B-1: 97.1%; B-2: 88.8%; B-3: 63.3%; Type C-1: 100%; C-2: 91.4%; C-3: 61.5%. The en bloc resection rates for Types B-3 and C-3 were significantly lower ( $P < 0.05$ ) than that for Type A. Similarly, Ro rates for Type B (82.8%) and C (82.9%) were significantly lower than that for Type A (93.5%). There were 12 cases (0.7%) of perforation, 5 of which (Type B) required emergency surgery. From these results, tumors accompanied by mild to moderate fibrosis become the standard indication for ESD. The tumors accompanied by severe fibrosis should be indicated as relative indications for ESD and required high quality of ESD technique to avoid perforation.

**Conclusion:** Accurate diagnosis of fibrosis based on the perioperative endoscopic findings appears feasible and contributes to completing the ESD procedure safely and curatively.

**Disclosure:** Nothing to disclose

## P0881 ONLY LINKED COLOR IMAGING INCREASES COLOR CONTRAST BETWEEN COLON POLYPS AND SURROUNDING MUCOSA

Weigt J.<sup>1</sup>, Arciniegas Sanmartin I.D.<sup>2</sup>, Obst W.<sup>3</sup>, Canbay A.E.<sup>1</sup>

<sup>1</sup>Otto-von-Guericke University Magdeburg, Gastroenterology, Hepatology & Infectious Diseases, Magdeburg, Germany, <sup>2</sup>Hospital Santa Casa de Misericordia de Porto Alegre, Gastroenterologia, Porto Alegre, Brazil, <sup>3</sup>Otto-von-Guericke University Hospital Magdeburg, Gastroenterology, Hepatology & Infectious Diseases, Magdeburg, Germany

**Contact E-Mail Address:** jochen.weigt@med.ovgu.de

**Introduction:** HD-white light endoscopy (WLE) is the gold standard in the detection of colon adenoma. Virtual chromoendoscopy cannot improve adenoma detection. Recently linked color imaging (LCI) was developed which is combining special light and a post processing in one imaging modality. First study results show a better visibility and a higher adenoma detection rate using LCI.

**Aims & Methods:** Evaluation of color difference between colon adenoma and surrounding mucosa as a potential explanation of higher detection rate.

**Results:** Prospective acquisition of images from adenoma in the three light modes WLE, Blue Light Imaging (BLI) and LCI.

Transformation of the images into  $L^*a^*b^*$  color space. Measurement of color at areas of  $31 \times 31$  pixels, two inside the polyp and 2 in the surrounding mucosa each. Calculation of the color difference according to the Delta E (Lab) Method.

We used paired t-test for statistical analysis.

**Results:** In total 90 polyps were evaluated. Delta-E in WLE was lowest ( $12.34 \pm 6.73$ ). The highest Delta-E value was calculated for LCI ( $16.83 \pm 10.85$ ). The Delta-E using BLI was  $14.38 \pm 11.42$ . The difference between LIC vs BLI and BLI vs. WLE was not significant. The difference between WLE and LCI was highly significant ( $p=0.002$ )

**Conclusion:** Only linked color imaging leads to a significant increase of the color contrast of colon adenoma. This is a useful explanation for the reported increased adenoma detection rate using LCI.

<sup>2</sup>Center for Bionics, Korea Institute of Science and Technology, Seoul, Korea (Republic of)

**Contact E-Mail Address:** roadstar82@naver.com

**Introduction:** Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempts are needed to straighten the shaft of the scope. A prototype Fiber Brag Grating(FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination. The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscope image using FBG sensor.

**Aims & Methods:** In the first part of the study, the FBG sensor was inserted into the working channel of a general colonoscope in the first 100 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement of the scope in all three dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. The fluoroscopy was used in all investigations for comparison.

**Results:** In the first part of the study, the results showed that the shape sensor was reliable at a maximum bending curvature of 80mm-1. The average tip position error was  $1.22 \pm 0.82$  mm, which corresponds to  $0.82 \pm 0.7\%$  of the total length of the sensor. Colonoscopy movement and loops were detected correctly through the monitor. The prototype FBG in the second part of the study showed a high correlation and little discrepancy with the comparative findings on fluoroscopy. During the colonoscopy, we could confirm the shape of the loop made in the body.

**Conclusion:** Image of colonoscopy reconstructed by FBG sensor can be successfully applied to display colonoscopy configuration. This flexible, thin and almost weightless shape sensor would be a novel technique for identification of colonoscopy shape.

### P0883 EFFECTIVENESS OF SUCTION VALVE BUTTON REMOVAL FOR POLYP FRAGMENTATION AND PATHOLOGICAL DIAGNOSIS IN EXTRACTING RESECTED COLON POLYPS ON THE BASIS OF PROPENSITY SCORE MATCHING ANALYSIS

Kishida Y., Hotta K., Imai K., Ito S., Yabuuchi Y., Yoshida M., Kawata N., Kakushima N., Takizawa K., Ishiwatari H., Matsubayashi H., Ono H. *Shizuoka Cancer Center, Division of Endoscopy, Shizuoka, Japan*

**Contact E-Mail Address:** y.kishida@schr.jp

**Introduction:** When colorectal polyps were endoscopically resected, they were usually extracted by suctioning and sent for pathological examination. However, the fragmentation of polyp during extraction is one of the limitations for appropriate pathological diagnosis. Suction valve button is one of the intruding parts in construction of endoscope which may have implicit fragmentation risk.

**Aims & Methods:** In this study, we retrospectively evaluated the effect of removing the suction valve button during extracting polyp for fragmentation and pathological cut-end diagnosis.

We reviewed the reports of endoscopically removed polyps between September 2018 and February 2019. Cases included in this study were clinically diagnosed as neoplasm using magnifying endoscopy, collectively resected by cold snare polypectomy (CSP) or EMR, and extracted by suctioning. Endoscopic and pathological findings listed as following were collected; patient age, sex, colonoscope (HQ-290ZL: device channel 3.7 mm, PCF-290ZL: device channel 3.2 mm, Olympus), lesion location, lesion size, resection method (CSP or EMR), removal of suction valve button during polyp extraction, and for the outcomes, polyp fragmentation rate, pathological histology, and pathological cut-end among neoplastic lesions ("negative" or "positive/imponderable"). Polyp extraction with suction valve button was the conventional method of pressing the button and retrieving the polyp into a polyp trap affixed to the suction connector of the colonoscope. For the polyp extraction without suction valve button, we removed the button from the colonoscope before suctioning the polyp and sealed the suction valve cylinder by finger to apply suction.

Fragmentation was defined as the macroscopic presence of multiple pieces of extracted polyp in the trap, all of which was double-checked by doctor and nurse, and all of the pieces were put into the formalin bottle for fixation. We used one-to-one propensity score matching method to adjust for the difference between the groups of with and without suction valve button.

**Results:** We selected 322 pairs of cases for analysis on the basis of propensity score matching. After matching, the difference of the variables between each group were closely balanced. The fragmentation rate was significantly different between the extraction with and without suction valve button (36.7% vs. 22.4%,  $P < .001$ ). For histological diagnosis in each group, the rate of normal colon mucosa was 8.4% and 9.9%, whereas that of neoplastic lesion was 90.0% and 88.6%, which were not significantly different. Among the neoplastic lesions, the rate of cut-end negative was higher in button-removed group (82.8% vs 90.8%,  $P = .010$ ). On the other hand, when we concern pathological histology of normal colon mucosa as cut-end "imponderable", the cut-end negative rate was 76.7% vs 81.8% ( $P = .113$ ). In the multivariate analysis, suction valve button removal was the only independently associated factor for fragmentation (Odd ratio [OR] 0.496,  $P < .001$ ) and for negative cut-end in neoplastic lesions (OR 0.505,  $P = .009$ ). Additionally, the rate of pathological diagnosis as normal colon mucosa was independently associated with the resection method (CSP 10.4%, EMR 2.1%, OR 0.342,  $P = .003$ ), but not with button removal (OR 1.23,  $P = .453$ ).

**Conclusion:** Suction valve button removal during extracting polyps was an effective way to improve the rates of fragmentation and pathological cut-end diagnosis of neoplastic lesions.

### P0884 FLEXIBLE SIGMOIDOSCOPY FOR EVALUATION OF ANASTOMOTIC INTEGRITY PRIOR TO THE REVERSAL OF A LOOP ILEOSTOMY

Oh S.Y.

*Ajou University School of Medicine, Department of Surgery, Suwon, Korea (Republic of)*

**Contact E-Mail Address:** kgsosy@gmail.com

**Introduction:** Preoperative evaluation for anastomotic status has been routinely done with contrast enema (CE) before ileostomy closure. However, there are few data supporting the routine practice of examining CE prior to ileostomy closure. Actually, CE gives limited information to surgeon compared to endoscopic evaluation and even can cause colon perforation and contrast peritonitis.

**Aims & Methods:** The aim of this study is to evaluate the feasibility and usefulness of preoperative flexible sigmoidoscopic examination instead of contrast enema (CE) prior to ileostomy closure in rectal cancer patients who underwent anterior resection with a loop ileostomy.

We reviewed prospectively collected data of patients with rectal cancer who underwent anterior resection with a loop ileostomy from October 2008 to November 2016. We compared postoperative outcomes between patients who underwent flexible sigmoidoscopy (FS) and underwent CE study.

**Results:** Ninety-eight patients underwent CE examination, and 49 patients underwent FS prior to the reversal of a loop ileostomy. There was no significant difference in gender, body mass index, anastomotic type and anastomotic level between two groups except for age and time to ileostomy closure. Two patients in CE group developed anorectal suppuration after the reversal of an ileostomy. They showed intact anastomotic site on preoperative examination. Patients in FS group developed no anorectal suppuration after the reversal of an ileostomy.

**Conclusion:** Preoperative findings on CE could not predict postoperative anorectal problem. FS can evaluate the status of anastomotic site without increasing the postoperative anorectal problem. We suggest that CE can be replaced by FS in assessment of anastomotic integrity prior to the reversal of a loop ileostomy.

**Contact E-Mail Address:** nevarezja78@gmail.com

**Introduction:** Many technological advances have been made to optimize the detection of colorectal cancer lesions. Research has shown that the electromagnetic properties of healthy and cancerous tissues differ in many biological tissues.

**Aims & Methods:** We aim at analyzing electromagnetic properties of healthy and pathological colon tissue and their differences with biopsies gathered from colonoscopy procedures. The dielectric constant and the conductivity of healthy and pathological colorectal samples of 70 patients were analyzed using the open-ended coaxial technique and were later correlated with their pathology results. Since these properties depend on multiple factors like tissue's temperature, system calibration and the patient itself, polyps were analyzed by computing the difference between the healthy and the pathological samples within each patient. Measurements were performed on adenocarcinomas (CRC), adenomas without dysplasia, adenomas with low-grade dysplasia, adenomas with high-grade dysplasia, hyperplastic and hamartomatous polyps.

**Results:** The differences obtained in dielectric constant between CRC and healthy pairs are higher than in the rest of pathologies. Within the frequency region where larger differences appear, the median of this difference is 4.8 units. Differences in conductivity are lower, having a median of 2 units. By selecting a threshold in the difference of dielectric constant that maximizes the diagnostic capability of CRC, the system showed a sensitivity of 75% and a specificity of 89% for detecting this disease (table 1). **Conclusion:** Results have shown that measurements of electromagnetic properties of tissue could aid in the detection of colorectal pathologies. The variability of the results is quite large, and hence the system should be improved prior to a potential implementation.

## P0886 CONECCT CLASSIFICATION: A NEW CLASSIFICATION TO BEST CHOOSE THE TREATMENT IN CASE OF LARGE SUPERFICIAL COLORECTAL LESION

Brule C.<sup>1</sup>, Jacques J.<sup>2</sup>, Albouys J.<sup>1</sup>, Bordillon P.<sup>1</sup>, Fabritius M.<sup>3</sup>, Legros R.<sup>4</sup>, Rivory J.<sup>5</sup>, Sautereau D.<sup>6</sup>, Ponchon T.<sup>7</sup>, Pioche M.<sup>8</sup>

<sup>1</sup>University Hospital of Limoges, Limoges, France, <sup>2</sup>CHU Limoges, Hepato-Gastro-Enterology, Limoges, France, <sup>3</sup>HEH, Lyon, France, <sup>4</sup>CHU Limoges, Limoges, France, <sup>5</sup>Hopital Edouard Herriot, Lyon, France, <sup>6</sup>CHU Limoges Gastroentérologie, Limoges, France, <sup>7</sup>Edouard Herriot University Hospital, Digestive Diseases, Lyon, France, <sup>8</sup>Hospices Civils de Lyon, Gastroenterology and Endoscopy, Lyon, France

**Contact E-Mail Address:** brule.clementine@gmail.com

**Introduction:** Several classifications has been developed to predict the risk of submucosal invasion in case of superficial colorectal lesion. We developed the CONECCT (Colorectal NEoplasia Classification to Choose the Treatment) classification that merged all existing classification (Paris, SANO, KUDO, WASP, LST, NICE) in one table to simplify endoscopic characterization. The originality of this classification is the combination of macroscopic features with mucosal pattern and vascular pattern abnormalities without using magnification.

We performed a prospective study to evaluate the performance of the CONECCT classification to differentiate adenoma (CONECCT IIA) and high risk adenoma or superficial carcinoma (CONECCT IIC: SANO IIIA or Macronodule bigger than 1 cm or ulceration or non-granular type).

**Aims & Methods:** Bicenter prospective study of all characterization data recorded before ESD for large superficial colorectal lesions in two European expert's centers. Sensibility (Se) Specificity (Spe) Positive predictive value (PPV) Negative predictive value (NPV) of presence of macronodule bigger than 1 cm, SANO IIIA, Paris O-IIC (presence of ulceration) and CONECCT IIC were calculated.

Lesions were evaluated thanks to last generations endoscope: FUJIFILM series 760 or OLYMPUS series 190 without magnification or dual focus just before the ESD procedure.

**Results:** 515 colorectal ESDs were performed between 01/2016 and 04/2019 at 2 European expert's centers.

Results of ESD: En bloc Resection = 95,7%, R0 resection = 81%, Curative resection = 80%

466 lesions with a mean size of 57 mm that had all characterization data (Paris, SANO, KUDO, WASP, LST, NICE, CONECCT) were included. 64% of lesions were LST-G, 21% LST-NG and 15% protruded lesions. 80% of lesions were CONECCT IIC, 42% SANO IIIA, 14% had an ulceration (Paris O-IIC) and 51% had a macronodule.

Histological analysis: LGD : 147 (32%) ; HGD (Vienne 4.2 and 4.3) : 174 (37%) ; IM carcinoma: 101 (22%) ; Sm < 1000 : 22 (5%), sm > 1000:17 (4%) T2: 4 (1%)

Sensibility and specificity:

• LST with macro-nodule bigger than 1 cm:

- Submucosal cancer: Sen=74% / Spe=51% / PPV=13.6% / NPV=95,1%

• Paris IIC

- Submucosal cancer: Sen=24.4% / Spe=86.8% / PPV=15.4% / NPV=92%

• Sano IIIA

- Submucosal cancer: Sen=69.8% / Spe=60.4% / PPV=15.4% / NPV=95.1%

• CONECCT IIC

- Submucosal cancer: Sen=100% / Spe=21.1% / PPV=11.6% / NPV=100%

No difference was observed using FUJIFILM or OLYMPUS Scope (p=0,95): FUJIFILM:

• Sano IIIA

- Submucosal cancer: Sen=66.7% / Spe=59,2% / PPV=13,5% / NPV=94,9%

• CONECCT IIC

- Submucosal cancer: Sen=100% / Spe=23.6% / PPV=10.4% / NPV=100% OLYMPUS:

Sano IIIA

- Submucosal cancer: Sen=78.9% / Spe=57.1% / PPV=14.6% / NPV=96.7% CONECCT IIC

- Submucosal cancer: Sen=100% / Spe=20% / PPV=10.4% / NPV=100%

**Conclusion:** The CONECCT classification allows to predict with a 100% sensibility and a 100% NPV the risk of submucosal invasion with high definition scope without magnification.

PPV is always very small (around 15%) indicated that we are not able to clearly identify the submucosal cancer. However NPV of CONECCT classification is perfect (100%) indicated that we are able to exclude submucosal carcinoma using the CONECCT classification (CONECCT IIA). CONECCT IIA lesions never presented submucosal adenocarcinoma and are best target for a piece-meal resection, however en-bloc resection by ESD should be the treatment of choice for CONECCT IIC lesions.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** philippe.willems@umontreal.ca

**Introduction:** Polypectomy plays a key role in colorectal cancer (CRC) prevention. In recent years new polypectomy techniques, like cold snare resection, have been introduced. Ablative techniques, such as hot forceps resection and argon plasma coagulation (APC), have been associated with more complications and seemed to be losing popularity. We conducted an international survey to better understand changes in polypectomy practice patterns during recent years, uptake of cold snare polypectomy and adherence to guideline recommendations.

**Aims & Methods:** Colonoscopy practitioners were contacted through Gastroenterology, Colorectal Surgery and Endoscopy societies around the world and asked to participate in a Google Form online survey. The primary aim was to evaluate the uptake of cold snare polypectomy in the last 5 years and to evaluate the current predominant polypectomy approaches for colorectal polyps between 1-20mm. Secondary aims were to evaluate perceived benefits and concerns related to each specific polypectomy techniques and to evaluate adherence to recent guideline recommendations.

**Results:** The survey was distributed by 9 societies and completed by 808 colonoscopy practitioners around the world. Survey participants reported an 87.5 % (95% CI 85.2%-89.8%) increase in use of cold snare during the last 5 years, with 55.3% (95% CI 51.9%- 58.7%) of survey participants reporting more than a 50% increase in its use. Cold snare was reported to be the predominant polypectomy technique for 4-5 mm polyps (67.0% (95% CI 63.7%-70.2%) and also for 6-10mm polyps (55.2% (95% CI 51.7%-58.6%). For polyps 1-3 mm, cold forceps remains the predominant utilized polypectomy technique (78.4% (95% CI 75.6%-81.3%), while hot snare polypectomy remains the predominant utilized polypectomy technique for polyps 10-20 mm (92.5% (95% CI 90.7%-94.3%)) (table 1). 54.8 % (95% CI 51.4%-58.3%) of survey participants reported having no concerns for using cold snare, which was more than for other techniques: cold forceps (29.7%), hot snare (27.0%), APC (13.1%) and hot forceps (9.5%). Cold forceps most reported concern was incomplete resection (60.6% (95% CI 57.3%-64.0%)). Hot snare most reported concerns were delayed bleeding (54.8%; 95% CI 51.4%-58.3%) and perforation (48.1%; 95% CI 44.7%-51.6%). 66.6% (95% CI 63.3%- 69.8%) of survey participants reported never using APC and 61.5% (95% CI 58.2%-64.9%) never using hot forceps for standard polypectomy.

**Conclusion:** This survey found a substantial increase in utilizing cold snare polypectomy during recent years. Cold snare polypectomy has meanwhile become the predominant polypectomy approach for 4-10mm colorectal polyps among endoscopists. For smaller (1-3mm) polyps cold forceps and for larger (10-20 mm) polyps hot snare polypectomy currently remains the

predominant polypectomy approach. Ablative techniques (hot forceps and APC) are not used anymore by the majority of endoscopist for standard 1-20 mm polypectomy. Current clinical practice patterns are well aligned with recently issued guideline recommendations.

**Disclosure:** Nothing to disclose

Polyp size	APC	Cold Forceps	Hot Forceps	Cold Snare	Hot Snare
1 - 3 mm	3 (0.4%)	626 (78.4%)	25 (3.1%)	140 (17.5%)	4 (0.5%)
4 - 5 mm	3 (0.4%)	188 (23.4%)	28 (3.5%)	537 (67.0%)	46 (5.7%)
6 - 10 mm	2 (0.2%)	22 (2.7%)	15 (1.9%)	442 (55.2%)	320 (40.0%)
11 - 20 mm	10 (1.2%)	3 (0.4%)	10 (1.2%)	37 (4.6%)	742 (92.5%)

**Contact E-Mail Address:** s.j.de.jongh@umcg.nl

**Introduction:** White-light colonoscopy is the gold standard for colorectal polyp detection and colorectal cancer (CRC) prevention. However, there is still a polyp detection miss-rate of up to 22%.<sup>1</sup> Fluorescence molecular endoscopy (FME) using EMI-137, a c-Met targeted fluorescent peptide, has the potential to guide the endoscopist and improve polyp detection rates.<sup>2</sup> The aim of this study was to determine the optimal dose-to-imaging interval for FME and to further evaluate the safety and tolerability of EMI-137 in a population at high-risk for CRC.

**Aims & Methods:** FME was performed in 15 patients with a colorectal adenoma containing at least low-grade dysplasia. EMI-137 was administered intravenously (0.13 mg/kg) to three patients at either 1, 2 or 3 hours prior to colonoscopy. The two cohorts with the most optimal target-to-background ratio (TBR), or the 1- and 2-hour cohort in case of similar TBRs, were expanded to six patients. Fluorescence was visualized and quantified *in vivo* using multi-diameter single-fiber reflectance, single-fiber fluorescence (MDSFR/SFF) spectroscopy. Fluorescence was correlated to standard histology and c-Met expression on 4mm tissue sections *ex vivo*. EMI-137 localization was assessed using fluorescence microscopy and confirmed by *in vitro* c-Met binding experiments.

**Results:** FME using EMI-137 appeared to be safe and well tolerated. The dose-to-imaging interval for the 1-, 2- and 3-hour cohort was 0:54 - 1:28 hour (n=6), 1:50 - 2:33 hours (n=6) and 2:41 - 3:20 hours (n=3). *In vivo* visualization and quantification of fluorescence showed significantly increased fluorescence in dysplastic versus normal tissue for the 1-, 2- and 3-hour cohorts (median intrinsic fluorescence  $Q_{m,ax}^I = 3.46 \cdot 10^{-4}$  vs.  $2.15 \cdot 10^{-4} \text{ mm}^{-1}$ ,  $P < 0.0001$ ;  $3.28 \cdot 10^{-4}$  vs.  $2.04 \cdot 10^{-4} \text{ mm}^{-1}$ ,  $P < 0.0001$  and  $3.22 \cdot 10^{-4}$  vs.  $1.94 \cdot 10^{-4} \text{ mm}^{-1}$ ,  $P < 0.0001$  respectively). *Ex vivo*, an overall median TBR of 1.62 was observed based on histological delineation of 41 tissue sections, with significant c-Met membrane overexpression in dysplasia. Fluorescence microscopy showed increased fluorescence in the proximity of the dysplastic crypts compared to normal tissue. A dose-dependent specific binding of EMI-137 was observed *in vitro*.

**Conclusion:** We demonstrate that FME using EMI-137 appeared to be safe and feasible within a one-to-three hour timeframe. No significant differences have been observed between the time-cohorts, although a dose-to-imaging interval of one hour was considered preferable from a clinical perspective. Future pivotal studies will study the use of EMI-137 for improved detection of colorectal polyps in screening colonoscopies of patients at average risk of developing colorectal cancer.

## P0889 USE OF THE BOSTON BOWEL PREPARATION SCALE IN THE REAL WORD: WHAT AFFECTS IT?

Saraiva S.<sup>1</sup>, Lemos Garcia J.<sup>1</sup>, Rosa I.<sup>2</sup>, Dias Pereira A.<sup>2</sup>

<sup>1</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, Gastroenterology, Lisboa, Portugal, <sup>2</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Gastroenterology, Lisboa, Portugal

**Contact E-Mail Address:** joanalemosgarcia@gmail.com

**Introduction:** The adequacy of bowel cleansing is one of the quality measures for lower intestinal endoscopy, affecting both the security and the diagnostic accuracy of the procedure. The aim of this study was to evaluate the quality of bowel preparation in a series of consecutive exams and to determine its predictive factors.

**Aims & Methods:** Retrospective study assessing patients that underwent colonoscopy in a tertiary hospital between 01/2016 and 06/2018. For the morning procedures, the preparation was given on the day before colonoscopy and for the afternoon procedures, a split-dose bowel cleansing regimen was adopted. The Boston Bowel Preparation Scale (BBPS) was used to evaluate the quality of the bowel preparation - total BBPS score  $\geq 6$  was considered as adequate.

**Results:** A total of 4872 colonoscopies in 3839 patients [men - 51.4%, mean age -  $61.2 \pm 13.9$  years] were performed, by 11 endoscopists. The main indications were: surveillance for neoplastic polyps/colorectal cancer (CRC) (52.0%); family history of CRC (21.9%). In this last case, patients were educated regarding bowel preparation by the Family Risk Clinic nurses. Cecal intubation rate was 96.2%. Inadequate bowel preparation (BBPS < 6) was observed in 32.3% of the colonoscopies, with BBPS being  $\leq 1$  in the right colon in 26.8% of cases in the right colon; 16.4% in the transverse colon, and 17.9% in the left colon.

The quality of bowel preparation was significantly associated, in univariate analyses, with gender (BBPS < 6: 37.5% men vs 26.8% women), day of the week, hour of the exam, morning/afternoon procedure (BBPS < 6: 35.0% morning vs 22.5% afternoon), endoscopist and family history of CRC (BBPS < 6: 21.8% of the exams performed because of family history of CRC vs 35.5% of the exams performed for other reasons).

On multivariate logistic regression analysis, predictive factors for quality of bowel preparation were gender ( $p < 0.001$ ), day of the week ( $p = 0.016$ ), morning/afternoon procedure ( $p < 0.001$ ) and colonoscopies performed because of family history of CRC ( $p < 0.001$ ).

**Conclusion:** In the real world, we confirmed gender, educational interventions and split dose regimens (adopted for the afternoon procedures) as factors influencing quality of bowel preparation.

**Disclosure:** Nothing to disclose

## P0890 EFFICACY AND SECURITY OF THE DOUBLE CLIP COUNTERTRACTION METHOD FOR RESIDUAL OR LOCALLY RECURRENT LESIONS IN COLONIC ENDOSCOPIC SUBMUCOSAL DISSECTION

<sup>1</sup>Hopital Edouard Herriot, Gastroenterology, Lyon, France, <sup>2</sup>Edouard Herriot Hospital, Gastroenterology and Endoscopy Unit, Lyon, France, <sup>3</sup>Hopital Edouard Herriot, Lyon, France, <sup>4</sup>CHU Limoges, Limoges, France, <sup>5</sup>Edouard Herriot University Hospital, Digestive Diseases, Lyon, France, <sup>6</sup>CHU Limoges, Hepato-Gastro-Enterology, Limoges, France, <sup>7</sup>Hospices Civils de Lyon, Gastroenterology and Endoscopy, Lyon, France

**Contact E-Mail Address:** faller.julien@gmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) for the resection of scarred colonic lesions is a feasible but challenging technique because of submucosal fibrosis. We previously reported an internal traction method using two clips and a rubber band and making ESD easier. This study

aimed to evaluate the efficacy and security of ESD using this countertraction technique (DCT-ESD) in case of residual or locally recurrent colonic lesions.

**Aims & Methods:** We retrospectively analyzed all residual or locally recurrent colonic lesions, DSM treated, in two french expert center, between august 2017 and february 2019. The countertraction technique has been systematically used.

The primary endpoint was the En bloc R0 resection rate. Secondary endpoints were en bloc resection rate, degrees of fibrosis, tumor diameter, procedure time, resection speed, secondary surgical treatment, and complication rate.

**Results:** Among the 44 patients included, there were 29 (66%) locally recurrent colonic lesions and 15 (34%) residual lesions after a primary endoscopic resection. Severe submucosal fibrosis was observed in 39 patients (88.6%) and intermediate fibrosis in 5 patients (11.4%). Mean resected specimen diameter, procedure time and resection speed were 40mm [20-65mm], 50min [6-230min], and 27mm<sup>2</sup>/min [6-95mm<sup>2</sup>/min], respectively. The en bloc resection rate was 90.9% (4 piecemeal mucosal resections conversions at the beginning of the study). This rate increases to 100% from the 11th resection due to the learning curve. Only 72.7% of all patients had negative margins (En bloc R0) often due to a hole inside the lesion. At all, 4 patients (9.1%) had needed secondary surgical treatment, three for incomplete resection and one for none curative resection criteria. Complication included three (6.8%) small intraoperative perforations endoscopic treated. There was no secondary perforation but one case of delayed bleeding. No surgery was necessary following a complication.

**Conclusion:** In cases with scarred colonic lesions, thanks to the double clip and rubber band countertraction method, ESD allows curative resection with low complication risk. This technique is an alternative to Full thickness resection (FTRD) particularly for large lesions over 3 cm.

## P0891 THE ROLE OF THE EDUCATIONAL PROJECT «QUACOL - QUALITY IN COLONOSCOPY» IN IMPROVING OF THE COLONOSCOPY QUALITY: RESULTS OF YAROSLAVL REGIONAL CANCER HOSPITAL STUDY

Nekhaykova N.<sup>1</sup>, Khusainova A.<sup>2</sup>, Kashin S.V.<sup>3</sup>, Belova A.<sup>4</sup>

<sup>1</sup>Yaroslavl Regional Cancer Hospital, Endoscopy Department, Yaroslavl, Russian Federation, <sup>2</sup>Yaroslavl State Medical University, Therapy, Yaroslavl, Russian Federation, <sup>3</sup>Yaroslavl Clinical Oncology Hospital, Department of Endoscopy, Yaroslavl, Russian Federation, <sup>4</sup>Yaroslavl State Medical University, Yaroslavl, Russian Federation

**Contact E-Mail Address:** nnv\_55@mail.ru

**Introduction:** Suboptimal quality of colonoscopy is associated with increased risk of interval colorectal cancer. It is uncertain how quality in colonoscopy might be improved. We assessed the effect of the educational project «QuaCol» on colonoscopy quality. It was performed in Russia between trials «QuaCol 1» and «QuaCol 2». We compared results of «QuaCol 1» versus «QuaCol 2».

**Aims & Methods:** We examined colonoscopies performed at the Endoscopy Department of Yaroslavl Regional Cancer Hospital (YRCH) within trial «QuaCol 1» between September and December 2014 and trial «QuaCol 2» between November 2018 and February 2019. The main quality indicators such as polyp detection rate (PDR), adenoma detection rate (ADR), caecal intubation rate (CIR) and colonoscopy withdrawal time (CWT), bowel preparation were assessed. We assessed also using of split-regimen laxative. The colonoscopies were performed by the same 9 colonoscopists during «QuaCol 1» and «QuaCol 2».

Our study divided colonoscopists into 2 groups, depending on their respective ADRs within «QuaCol 1»: low-detectors (ADR ≤ 20 %) and high-detectors (ADR > 20%). Then we assessed their ADRs in «QuaCol 2» and compared results.

**Results:** 987 patients (F 65,9%, M 34,1%; mean age 53) were included in the trial «QuaCol 1» and 1366 patients (F 71%, M 29%; mean age 55) were included in the trial «QuaCol 2». The main quality indicators were ADR (21,2 vs 29 %, p < 0,0001), CIR (92, 3 vs 96 %, p < 0,0001), PDR (40 vs 49 %, p < 0,0001), CWT > 6 min (34 vs 41,4%, p < 0,0001), adequate bowel preparation (92 vs 94 %, p < 0,05). Split-regimen was used (83 vs 94,8 %). The ADR of low-detectors increased significantly higher (16,7 vs 24,5%, p < 0.0001) than of high-detectors (31 vs 35,4 %, p < 0,01) after performing of the educational project «QuaCol».

**Conclusion:** The quality of colonoscopy in YRCH within «QuaCol 1» was recognized as suboptimal to according recommendation ESGE. Then was performed the educational project «QuaCol - Quality in Colonoscopy». The educational project included some lectures about colonoscopy quality indicators, about importance of adequate bowel preparation and factors affecting on patients complains - low-volume laxative, split-regimen, low-fiber diet. Hand-on-trainings were organized for improving of the technique and skills of endoscopists. Then «QuaCol 2» was performed. According to our study, the quality of colonoscopy in YRCH Obecame is optimal after performing of the educational project «QuaCol». Our data demonstrated that ADR is increased (it was statistically valid). CIR is increased (it was statistically valid). PDR is increased (it was statistically valid). CWT > 6 min is increased (it was statistically valid). Adequate bowel preparation is slightly increased (it was not statistically valid). Our study showed the medical educational may be a key factor of improving in colonoscopy quality. The improvement of colonoscopy quality is associated with increase prevention role of colonoscopy against colorectal cancer.

## P0892 OUTCOMES OF COLONOSCOPIC SURVEILLANCE AND MOLECULAR PHENOTYPING IN PATIENTS AT HEREDITARY RISK OF COLORECTAL CANCER

Norton B.<sup>1</sup>, Coultas J.<sup>2</sup>, Nicholas V.<sup>2</sup>, Wright T.<sup>2</sup>, Brown R.<sup>2</sup>, Monahan K.<sup>2,3</sup>

<sup>1</sup>Imperial College London, Department of Genomic Medicine, London, United Kingdom, <sup>2</sup>West Middlesex University Hospital, Department of Gastroenterology, London, United Kingdom, <sup>3</sup>St Mark's Hospital, Family Cancer Clinic, London, United Kingdom

**Contact E-Mail Address:** benjamin.norton@nhs.net

**Introduction:** An estimated 35% of cases of colorectal cancer (CRC) are due to heritable factors, and approximately 30% of the UK population has a family history of CRC. Those at hereditary risk should be effectively managed through registration, phenotypic and genotypic characterisation, and risk-stratified colonoscopic surveillance. We assessed the impact of surveillance in patients at hereditary risk of CRC managed through the Family History of Bowel Cancer Registry at West Middlesex University Hospital (WMUH). Through analysis of this registry data, we assessed the diagnostic yield of colonoscopic surveillance and assessed the role of molecular testing.

**Aims & Methods:** We analysed prospectively collected colonoscopic surveillance data at WMUH between 2010-2018. Patients were divided into five family history risk populations as defined by current British Society of Gastroenterology (BSG) guidelines. Patient demographics including age, gender and family history were collated, alongside colonoscopy findings, and molecular data including mismatch repair (MMR) status and germline testing. Impact of these variables on the prevalence of non-advanced adenomas (NAAs) and advanced adenomas (AAs) were assessed by logistic regression using SPSS software. Time to NAA or AA was determined by survival analysis and findings were compared between index and surveillance colonoscopy.

**Results:** In total, 752 colonoscopies were performed in 454 patients with 1081 years of colonoscopic follow-up. Five CRCs, 56 AAs and 204 NAAs were identified with an adenoma detection rate (ADR) of 20.01%. Time to both NAA and AA occurred at significantly earlier age in patients with LS. The prevalence of CRC, AA and NAAs in patients without Lynch syndrome (LS) was 0.46%, 7.85% and 25.04%, respectively, with no significant differences between non-LS family history populations. Although the number of affected offspring did associate with AA detection on univariate analysis ( $P = 0.038$ ), only age was significantly associated with both NAA and AA detection on multivariable analysis ( $P < 0.001$ ). A normal index colonoscopy was strongly associated with normal findings during surveillance ( $p < 0.001$ ). A family history of MMR proficient CRC was associated with an ADR equivalent to the non-LS population (22.67%). Molecular testing significantly altered surveillance strategy in 27.6% of patients through re-categorisation of familial risk.

**Conclusion:** This data emphasises the strong association of colorectal neoplasia with MMR status and the need to exclude LS in patients at familial risk. Age is independently associated with colorectal neoplasia risk in this analysis, however patients often undergo colonoscopic surveillance inappropriately early. A normal index colonoscopy is associated with a low diagnostic yield in subsequent colonoscopies in this population, and this relatively low yield may influence future guideline strategies. Finally, we believe that molecular phenotyping to risk stratify patients helps to facilitate effective colorectal cancer prevention.

### P0893 COLONOSCOPIST KEY PERFORMANCE INDICATORS IN PATIENTS WITH A FAMILY HISTORY OF COLORECTAL CANCER UNDERGOING SURVEILLANCE

Norton B.<sup>1</sup>, Coultas J.<sup>2</sup>, Nicholas V.<sup>2</sup>, Wright T.<sup>2</sup>, Brown R.<sup>2</sup>, Monahan K.<sup>2,3</sup>

<sup>1</sup>Imperial College London, Department of Genomic Medicine, London, United Kingdom, <sup>2</sup>West Middlesex University Hospital, Department of Gastroenterology, London, United Kingdom, <sup>3</sup>St Mark's Hospital, Family Cancer Clinic, London, United Kingdom

**Contact E-Mail Address:** benjamin.norton@nhs.net

**Introduction:** Colorectal cancer (CRC) accounts for over 40,000 new cases/year in the UK, and in 35% of cases CRC develops due to inherited susceptibility. Patients at hereditary risk undergo colonoscopic surveillance to reduce CRC incidence and mortality. High quality colonoscopy, measured by key performance indicators (KPIs) including adenoma detection rate (ADR), caecal intubation rate (CIR), and polyp recovery rate (PRR) may enhance surveillance outcomes.

This is particularly important for high risk patients where colonoscopy may be a one-off intervention, or where there is significant risk of interval cancers. Consequently, we assessed colonoscopy quality in a cohort at hereditary risk of CRC managed at West Middlesex University Hospital (WMUH), and determined their relationship to colonoscopist KPIs in non-surveillance cohorts.

**Aims & Methods:** We analysed prospective colonoscopic surveillance data through the Family History of Bowel Cancer Registry at WMUH between 2010-2019. A cohort of 454 patients at hereditary risk were divided into five risk groups based on current British Society of Gastroenterology guidelines. Patient demographics including age, gender and family history were collated alongside colonoscopist data, colonoscopy findings, and KPIs. Using linear regression on SPSS software, we compared findings to the ADR, CIR and PRR of colonoscopists in non-surveillance patients.

**Results:** During surveillance, 752 colonoscopies were performed by 12 clinicians. The adequacy of bowel preparation and CIR across all colonoscopists was 89.2% and 98.0%, respectively. The collective ADR during index, 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> surveillance colonoscopies was 19.6%, 15.9%, 29.3% and 25.8%, respectively. T

here was no difference in ADRs at Index, 1<sup>st</sup> and 2<sup>nd</sup> surveillance colonoscopy between familial risk groups. The average ADR for colonoscopists across all surveillance colonoscopies was 22.8% (8.6-38.1%). In the non-surveillance cohort ADR was 29.5% (13.3-40.7%), CIR 93.5% (78.8-95.7%) and PRR 95.2% (86.9-98.2%). Colonoscopist ADRs during surveillance correlated with both ADRs ( $R^2 0.738$ ,  $P < 0.01$ ) and PRRs ( $R^2 0.695$ ,  $P < 0.01$ ) in the non-surveillance cohort but not CIR.

**Conclusion:** ADR is the main indicator of efficacy during colonoscopy and a consistent independent risk factor for interval CRCs in screening colonoscopies. Colonoscopists ADRs in patients undergoing surveillance correlated with their ADRs and PRRs during colonoscopies in a non-surveil-

lance cohort. Therefore, we suggest that all surveillance colonoscopies are performed by endoscopists consistently achieving BSG colonoscopy KPI minimum standards.

**Contact E-Mail Address:** nicolau.vallejo@hotmail.com

**Introduction:** Colonoscopy is the best exploration for detection of colorectal cancer (CRC) and polyps. An adequate bowel preparation, usually defined with BBPS score  $\geq 2-2$ , is a marker of quality that should be fulfilled in at least 85% of colonoscopies. With this aim, a low-residue diet is usually recommended for outpatient colonoscopies. Compliance with bowel preparation protocol is mandatory. In this context, a free diet without restrictions may improve tolerance and adherence to the bowel cleansing protocol, especially in outpatient setting, the main scenario of colorectal cancer screening programs.

**Aims & Methods:** Our aim was to compare the quality of colonoscopy with two different diets: low-residue diet and a free diet without restrictions.

A prospective, randomized, single blind clinical trial was designed to evaluate the impact of low-residue diet and free diet without restrictions the day before colonoscopy for bowel cleansing. The BBPS scale was used, with a value of  $\geq 2-2$  defining an adequate preparation. Patients between 18 and 75 years old, scheduled for outpatient colonoscopy were included. Patients with previous colonoscopies, colorectal surgery, obesity grade II or more (BMI  $\geq 35$ ) or severe constipation without response to conventional treatment were excluded. Participants were randomised to group A (low-residue diet the day before colonoscopy) or B (free diet, including breakfast on the day of colonoscopy). Endoscopists were blinded for diet. Sodium picosulfate/magnesium citrate was used in all patients, giving the first dose 8 hours and the second dose 4 hours before colonoscopy. Sex, age, indication for colonoscopy, BMI, diabetes, diverticula, tolerance to preparation, exploration and recuperation, time of exploration and polyp detection rate (PDR) were evaluated. Results are shown as means and percentages, and analysed by chi-square and T-student test as appropriate.

**Results:** Based on previous sample size calculation, 201 patients were included (52.2% women, median age 51 years, range 23-75). Main indications for colonoscopy were CCR family history (60.1%), rectal bleeding (15.9%) and abdominal pain (6.9%). Diabetes was present in 6.5% of patients. The median BMI was  $26.7 \pm 3.88$ . Diverticula were reported in 20.8% of cases. The median procedure time was 14.5 minutes ( $875 \pm 360$  seconds). PDR was 37.8%. 108 patients (53.7%) were included in group A and 93 (46.3%) in B. An adequate bowel preparation was observed in 96.2% in group A and 87.1% in group B ( $p=0.03$ ). Only 2 procedures had to be interrupted due to poor bowel preparation, both in group A. There were no differences in age ( $p=0.99$ ), sex ( $p=0.19$ ), BMI ( $p=0.91$ ), tolerance to preparation ( $p=0.20$ ), exploration ( $p=0.32$ ) or recuperation (0.93), exploration time (0.54) or PDR (0.80). No differences were observed between patients with adequate or poor bowel preparation in sex ( $p=0.21$ ), age ( $p=0.22$ ), BMI ( $p=0.17$ ), diverticula ( $p=0.46$ ), diabetes ( $p=0.57$ ), amount of liquids ( $p=0.86$ ).

**Conclusion:** In outpatient colonoscopy without risk factors for poor bowel preparation, a free diet without restrictions for bowel cleansing is associated with an adequate bowel preparation in more than 85% of patients. The impact of a low-residue diet in this setting is statistically significant, although clinically less relevant than expected.

**Contact E-Mail Address:** veronique.vandervoort@outlook.com

**Introduction:** Endoscopic mucosal resection (EMR) is a well-established technique for removal of benign colorectal polyps. Submucosal fibrosis can cause non-lifting or insufficient submucosal lifting and is frequently encountered during EMR for recurrent or residual adenoma. It increases complexity of the procedure, because it is often difficult or even impossible to grasp non-lifting tissue in the snare. Suck-and-snare (SAS) is a modified adjunctive EMR technique using suction to grasp and snare the target area. Our aim was to describe the efficacy and safety of the SAS technique for non-lifting colorectal polyps.

**Aims & Methods:** We prospectively registered all consecutive patients in whom the SAS technique was used in the endoscopic treatment of presumed benign non-lifting colorectal polyps. With the SAS technique, the target area is suctioned into a cap (soft straight 4mm) mounted on the scope. A prepositioned snare strangulates and resects the lesion after maximum aspiration. Clinical and endoscopic data on target area, technical success, adverse events and follow-up were collected.

**Results:** From May 2016 until March 2019, 70 patients (mean age 69 yrs (SD  $\pm 8.8$ ), male 66%) were included. Non-lifting was caused by fibrosis due to recurrent or residual adenoma (n=51, including 3 also known with IBD), IBD (n=5) and other reasons (n=14). The target areas were remaining island(s) (n=35) or the entire lesion (n=35), with a median size of 15 mm (range 3-42 mm). Technical success with complete removal of polyp tissue with SAS alone was achieved in 47 patients (67%). In 20 patients (28%) at least 75% of the target area could be resected, followed by adjunctive cold avulsion and/or ablative therapy. In 3 cases  $\leq 15\%$  of the target area could be removed with SAS. Reason for incomplete removal was inadequate grasp with the snare, together with insufficient suction into the cap in 2 cases. No polyp- or procedural factors were associated with recurrence at follow-up. Benign histology was reported in 67 cases (96%). Unexpectedly, invasive cancer was found in 3 patients, of whom 2 were referred for surgery and 1 preferred surveillance. Recurrence rate after SAS for benign lesions was 26% (16/61) after median follow-up time 7 months (range 2-20). Follow-up data is pending in 6 cases. Muscle layer injury related to SAS occurred in 6 patients (11%), including 3 transmural perforations, successfully treated with clips. Delayed bleeding in 5 cases (7.5%), all could be managed endoscopically or were self-limiting.

**Conclusion:** Suck-and-snare EMR is a promising adjunctive technique with an acceptable safety profile, and seems attractive in finishing endoscopic resection for benign non-lifting fibrotic colorectal polyps.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** cmangassanjuan@gmail.com

**Introduction:** Adenoma detection rate (ADR) is the most important quality measure in screening colonoscopies because it is inversely related to the development of interval cancer and mortality. Minimum standard ADR recommended according to different ESGE Guidelines is  $\geq 25\%$ ; however, this recommendation is based in studies that evaluated the prevalence of adenomas in asymptomatic patients undergoing a primary screening colonoscopies. However, it remains unknown whether this cut-off must be the same for other colonoscopy indications.

**Aims & Methods:** The aim of this study was to describe the ADR based on procedure indication and to predict the ADR recommended cut-off for other indications.

An observational, multicenter and cross-sectional study was conducted between February 2016 and December 2017 in 14 Spanish centers. Four colonoscopy indications have been considered: primary screening colonoscopies (reference category), positive fecal immunochemical test (+FIT) (OC-SensorTM; cut-off level 20 $\mu$ g/g), post-polypectomy surveillance and gastrointestinal symptoms. The ADR was calculated by age, sex, body mass index, comorbidities and aspirin use. The ESGE Guideline published in 2017 has been considered as the reference for ADR recommendations. Logistic regression analysis was used to assess the relationship between ADR and indications, and population proportions and its confidence intervals (95%CI) were calculated using the exact Clopper-Pearson method. **Results:** A total of 14867 patients were included and the global ADR was 38%. According to procedure indications and adjusted by factors mentioned previously, statistically significant differences between ADRs were found (p-value < 0.001). The ADR in gastrointestinal symptoms was 28.1% (OR 0.67, 95%CI 0.58-0.79); 46.4% (OR 2.01, 95%CI 1.71-2.35) in FIT-based procedures; 48.2% (OR 1.41, 95%CI 1.20-1.67) in surveillance compared to 30.8% in primary screening colonoscopies. Trend lines for the ADR in each indication were calculated based on endoscopists that performed procedures in all indications and no correlation between the quality of endoscopists and the ADR was found. 95%CI calculated for ADR population proportions was 27-29.3% in symptoms, 45.1-47.7% in +FIT endoscopies, 46.1-50.3% in post-polypectomy surveillance and 28.2-33.5% in colonoscopy screening group. Finally, based in our results, we propose a formula for calculating the minimal ADR adjusted to the clinical practice of each endoscopist.

**Conclusion:** ADR significantly differs between colonoscopy indications. Policies addressing performance measures beyond colonoscopy screening procedures may be developed. According to population proportions results, two different cut-offs could be suggested as new minimum standard ADR recommendations:  $\geq 25\%$  in gastrointestinal symptoms and primary screening colonoscopies and  $\geq 45\%$  in FIT-based screening and endoscopic surveillance.

## P0897 QUALITY INDICATORS IN THE DETECTION OF COLONIC LESIONS DURING COLONOSCOPY: A SINGLE CENTRE EXPERIENCE

Missale G.<sup>1</sup>, Cannatelli R.<sup>2</sup>, Munari F.<sup>2</sup>, Uberti P.<sup>1</sup>, Ghedi M.<sup>3</sup>, Ricci C.<sup>4</sup>  
<sup>1</sup>Spedali Civili - University of Brescia, Department of Scienze Cliniche e Sperimentali, Brescia, Italy, <sup>2</sup>University of Milan, Gastroenterology, Milan, Italy, <sup>3</sup>Spedali Civili - University of Brescia, Endoscopy Unit, Brescia, Italy, <sup>4</sup>Spedali Civili - University of Brescia, Gastroenterology Department, Brescia, Italy

**Contact E-Mail Address:** cannatellirosanna@gmail.com

**Introduction:** Colorectal cancer (CRC) is the third neoplastic lesion diagnosed in males and the second one in females. The mortality for this neoplasia has decreased since the widespread of the colonoscopy as a tool in the screening. The ESGE (European Society of Gastrointestinal Endoscopy) guidelines establish the quality indicators in screening colonoscopy for the detection and differentiation of colonic neoplasia.

**Aims & Methods:** In this study, we have evaluated the experience of a single Italian centre (ASST Spedali Civili - University of Brescia) in colonoscopy. We analysed the adenoma detection rate (ADR), polyp detection rate (PDR), serrated detection rate (SDR) in the right and left colon in our Endoscopy Unit in 2017. Moreover, we evaluated the influence of bowel preparation and endoscopist's experience in the detection and treatment of colonic lesions. We divided 3077 patients who met the inclusion criteria (full colonoscopies and no colonic resections) in 4 groups: I. age  $\geq 50$  years with fecal occult blood test (FOBT) positive (n=282); II. age  $\geq 50$  years with a different indication (n=1291); III. surveillance colonoscopy for familiarity for CRC or previous history of neoplastic colonic lesions, any age (n=1100); IV. age  $< 50$  years, any indications (n=404). The bowel preparation was scored with Boston Bowel Preparation Scale (BBPS) and a score  $\geq 6$  was considered sufficient. Statistical analysis were performed with SPSS and chi-square test has been calculate.

**Results:** The bowel preparation was found sufficient in 259 (91,8%) patients in group I, in 1097 (84,9%) in group II, in 1013 (92,1%) in group III and 367 (90,8%) in group IV. The PDR was higher in the group I (52,1%) and group III (49,8%) compared to group II (37,4%) and group IV (18,3%). A similar pattern was observed for the ADR: higher in the group I (40,7%) and group III (34,6%) and lower in the group II (28,7%) and group IV (10,9%). However, the SDR was 5,7%, 5,4% and 5,7% in group I, II, and III, respectively; while, it was 2,0% in group IV. A sufficient bowel preparation does not improve either PDR, ADR or SDR. Regarding the differences between right and left colon, the PDR was superior in the left colon in all groups (41,1% vs 24,5%, 24,7% vs 21,6%, 31,3% vs 30,4% and 12,2% vs 8,1% in group I, II, III and IV respectively). The ADR was higher in the left colon in the group I (31,2% vs 18,1%), group II (16,2% vs 13,3%) and group IV (5,8% vs 5,3%), while in the group III it was superior in the right colon (24,2% vs 15,4%). On the other hand, the SDR was higher in the right colon compare to the left colon in all groups (3,2% vs 2,5%, 4,2% vs 1,5%, 4,4% vs 1,8% and 1,7% vs 0,7%). Between endoscopists, the PDR was from 24,9% to 51,5%; the ADR from 17,1% to 40,0% and the SDR from 1,0% to 9,4%; without any correlations with bowel preparation.

**Conclusion:** In our experience, the ADR, PDR and SDR were higher in patients with risk factors for having CRC (group I and III), compared to the general population (group IV). The bowel preparation does not influence these considered parameters and it is possible that they are not enough and new parameters, such as cancer interval, could be considered in a quality colonoscopy definition. ADR and PDR were superior in the left colon; while, the SDR was better in the right colon; probably, because hyperplastic polyps are more frequent in this side.

**Disclosure:** Nothing to disclose

## P0898 PREDICTORS OF ADENOMA DETECTION RATE OF POSITIVE FIT VS SCREENING COLONOSCOPY IN A URBAN SAFETY NET HOSPITAL

**Contact E-Mail Address:** drdalbir@gmail.com

**Introduction:** Fecal immunochemistry test (FIT) and colonoscopy are the first-tier colorectal cancer (CRC) screening tests recommended for average risk adults aged 50 years and above in the United States.

**Aims & Methods:** To compare the predictors of adenoma detection rate (ADR) of Positive FIT with screening colonoscopy (SC).

Individuals  $\geq 50$  years, at average risk of CRC who underwent quantitative FIT or SC as part of their routine CRC screening between 09/01/2017 and 08/30/2018 were reviewed. The quality of bowel preparation was assessed by Aronchick scale and fair/ good/excellent was considered adequate. The colonoscopy findings of the individuals following a positive FIT (FITC) were compared to those who underwent SC.

Advanced adenoma was defined as polyp  $\geq 10$  mm in size, with villous histology or high - grade dysplasia. Lesions were categorized into proximal - cecum to splenic flexure and distal - descending colon to rectum. Demographic variables, ADR, AADR, mean size of the largest polyp, adenoma per colonoscopy (APC) were compared between the two groups using chi-square test and student's T test.  $p < 0.05$  was determined statistically significant.

**Results:** 351 individuals were identified in FITC group (follow up rate was 60.16% after a positive FIT) and 1841 in SC group. The ADR was 66% in FITC and 34% in SC (odds ratio OR 3.78, CI 2.97-4.82,  $p < 0.0001$ ). AADR was 35.89% in FITC and 8.64% in SC (OR 5.92, CI 4.51-7.77,  $p < 0.0001$ ). The mean size of the largest polyp for FITC was significantly higher than SC (FITSC  $12.09 \pm 1.15$  mm, SC  $8.06 \pm 0.56$  mm,  $p < 0.0001$ ) for proximal (FITC  $10.03 \pm 1.11$ , SC  $7.37 \pm 0.58$ ,  $p < 0.0001$ ) as well as distal lesions (FITC  $12.10 \pm 1.49$ , SC  $8.89 \pm 0.92$ ,  $p = 0.0002$ ). APC was also significantly higher in FITC ( $3.31 \pm 0.50$ ) compared to SC ( $1.90 \pm 0.13$ ),  $p < 0.0001$ . Individuals who had a true positive FIT (adenoma detected) were more likely men and had a history of smoking whereas individuals who had a positive SC (adenoma

[P0898 Predictors of Adenoma Detection Rate (ADR) in Positive FIT colonoscopy (FITC) and Screening colonoscopy (SC)]

detected) were more likely to have a history of smoking, diabetes mellitus type 2, hypertension and hyperlipidemia. When individuals with true positive FIT were compared with positive SC, FIT true positives were more likely to be Non-Hispanic blacks, had a history of smoking and obesity.

**Conclusion:** As expected, the odds of detecting adenomas and advanced adenomas were more common in the FITC compared to the SC group. FIT requires larger size to detect adenomas compared to screening colonoscopy and the difference was more pronounced for distal lesions. Risk factors of CRC influenced FIT and screening colonoscopy ADRs differently except for smoking (increased odds of positive FITC and SC). Understanding the demographic predictors for a positive CRC screening test will help providers and patients select the most suitable screening method.

## P0899 DISSECTION-ENABLED SCAFFOLD ASSISTED RESECTION (DeSCAR): SAFETY, FEASIBILITY, AND EFFICACY FOR RESECTION OF RESIDUAL AND NON-LIFTING COLONIC NEOPLASIAS

Villa E.<sup>1</sup>, Stier M.W.<sup>2</sup>, Donboli K.<sup>1</sup>, Chapman C.G.<sup>1</sup>, Siddiqui U.D.<sup>1</sup>, Waxman I.<sup>1</sup>

<sup>1</sup>University of Chicago, Center for Endoscopic Research and Therapeutics, Chicago, United States, <sup>2</sup>University of Chicago, Gastroenterology, Chicago, United States

**Contact E-Mail Address:** eespee88@gmail.com

**Introduction:** Colonic lesions referred for endoscopic mucosal resection (EMR) may not be amenable to conventional snare resection due to previous manipulation or submucosal invasion or because of flat areas of visible tissue that cannot be snared. Current methods for treating residual tissue may lead to incomplete resection or not allow complete tissue sampling for histologic evaluation. In 2018, our group initially described Dissection-enabled Scaffold Assisted Resection (DeSCAR)—a technique combining circumferential endoscopic submucosal dissection (ESD) with EMR—to be a safe technique for the endoscopic resection for removal of superficial, non-lifting or residual lesional “islands” with suspected submucosal involvement or fibrosis<sup>1</sup>.

Our aim is to describe our expanded experience and follow up of patients undergoing DeSCAR and assess the efficacy, safety, and feasibility of this technique for endoscopic resection of non-lifting or residual colonic lesions.

**Aims & Methods:** Lesions referred for EMR were retrospectively reviewed. In addition to our initial cohort of 29 patients from 2015-2017, 28 additional patients from 2018-2019 were identified where lifting and/or snaring of colonic lesions was incomplete, and the DeSCAR technique was undertaken. Cases were reviewed for location, prior manipulation, rates of successful hybrid resection, adverse events, and endoscopic follow up to assess for residual lesions.

**Results:** 57 lesions underwent DeSCAR due to non-lifting or residual “islands” of tissue. Patients were 51% female and 49% male with an average age 69 (SD +/- 9.6 yrs). Lesions were located in the cecum (n=16), right colon (n=22), transverse colon (n=5), left colon (n=7), rectum (n=4), or in other locations defined by distance from the anus (n=4). Average lesion size was 27.7 mm (SD +/- 16.6 mm). Previous manipulation occurred in 54 of 57 cases (68% biopsy, 47% resection attempt, 18% intralesional tattoo injection). The technical success rate for resection of non-lifting lesions was 100%. There were two delayed bleeding episode (one requiring endoscopic intervention) and one small perforation (managed by successful endoscopic hemoclip closure at the time of perforation), but no other adverse events were observed. Endoscopic follow up was available in 25 patients (44%) with no residual adenoma noted in 23 patients (92% of those with surveillance).

**Conclusion:** Our expanded experience with DeSCAR continues to demonstrate a high safety, feasibility, and effectiveness profile as an alternative to argon plasma coagulation and avulsion for the endoscopic management of non-lifting or residual colonic lesions, providing *en-bloc* resection of tissue for histologic review. Further studies are needed to demonstrate long-term eradication and direct comparison with other currently available endoscopic techniques.

**Introduction:** Colorectal cancers are generally recognized to develop from “polyps”. This “adenoma-carcinoma sequence” theory has been in the mainstream of development of colorectal cancers. However, recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called “de novo” pathway.

Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia *in vivo*.

**Aims & Methods:** The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern and EC classification.

A total of 32025 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to February 2018.

Of these, 24704 lesions were low-grade dysplasia, 6058 were high-grade dysplasia and 1263 were submucosally invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.

**Results:** The rate of T1 carcinomas in depressed-type lesions reached to 62.7%, meanwhile that in flat-type and protruded-type lesions was 3.2% and 2.8%, respectively. Within less than 5mm in diameter, that was 10.1%, 0% and 0%, respectively. Most of the flat-type (92.3%) and protruded-type (94.5%) lesions showed type III<sub>L</sub> or IV pit pattern corresponding to adenomas, whereas 91.7% of the depressed-type lesions were characterized by type III<sub>S</sub>, V<sub>I</sub> or V<sub>N</sub> pit patterns corresponding to carcinomas. As for endocytoscopy, most of the flat- and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (37.0%) and EC3b (55.6%) corresponding to invasive carcinomas.

**Conclusion:** This study revealed the diagnostic characteristics of depressed-type lesions. They show typically type III<sub>S</sub>, V<sub>I</sub> or V<sub>N</sub> pit patterns in magnifying endoscopy and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the submucosal layer even when they are small. It is important to diagnose colorectal neoplasms according to their morphology.

**Disclosure:** Nothing to disclose

## P0901 INTERMEDIATE RISK OF APPENDICITIS FOLLOWING FULL-THICKNESS RESECTION OF ADENOMAS ARISING FROM THE APPENDICEAL ORIFICE- A RETROSPECTIVE ANALYSIS

**Contact E-Mail Address:** benjamin.walter@uniklinik-ulm.de

**Introduction:** Conventional endoscopic resection techniques of adenomas near the appendiceal orifice have certain limitations e.g. an increased risk for perforation. Endoscopic full-thickness resection (eFTR) is a novel technique for adenoma resection up to 20mm in diameter. As full thickness resection near the appendiceal orifice is associated with a subtotal appendectomy it remained unclear whether the risk for development of an appendicitis or mucocele is increased. We present the results of a retrospective analysis of 38 patients with adenomas involving the appendiceal orifice treated with the FTRD system (Ovesco Endoscopy, Tuebingen, Germany).

**Aims & Methods:** Retrospective analysis of patients treated with eFTR for adenoma near the appendiceal orifice between 2014 and 2018. 38 patients from 2 centres (Ludwigsburg, Ulm) were included, median age 68.0 (47-85) yrs., follow up-time median 11 (6-32) months. The objective was the evaluation of post treatment complications in acute and long term follow up (appendicitis, mucocele). Patients with prior appendectomy were excluded from the study.

**Results:** All patients received prophylactic antibiotic treatment for on average 3.7 days in a row started perintentionally. No acute severe adverse events were reported for the eFTR procedure. Symptoms of appendicitis occurred in 9 patients (23.7%) within follow-up. In 3 cases conservative treatment was sufficient, 5 patients were transferred to appendectomy. No development of a mucocele was reported in long time follow up.

**Conclusion:** Based on this retrospective analysis eFTR of adenomas involving the appendiceal orifice is associated with an intermediate risk for developing appendicitis and consecutive risk for appendectomy. Therefore we conclude patients must be thoroughly informed about the risks. The reason why some patients develop appendicitis should be further elucidated.

## P0902 EFFICACY AND FEASIBILITY OF FULL THICKNESS DEFECT CLOSURE USING MODIFIED ENDOLOOPS: EX VIVO STUDY IN A PORCINE COLON MODEL

Dobashi A.<sup>1,2</sup>, Rajan E.<sup>1</sup>

<sup>1</sup>Mayo Clinic, Developmental Endoscopy Unit, Division of Gastroenterology and Hepatology, Rochester, United States, <sup>2</sup>The Jikei University School of Medicine, Department of Endoscopy, Tokyo, Japan

**Contact E-Mail Address:** akira.dobashi@nifty.com

**Introduction:** To ensure a safer endoscopic full-thickness resection (eFTR), a reliable defect closure system is essential. The commercially available endoloop was modified for the purposes of a more secure closure. The aim of this study was to evaluate the efficacy and feasibility of modified endoloops for defect closure.

**Aims & Methods:** Two prototype endoloops (Olympus, Tokyo) were studied. One was an endoloop with a double-cinch and the other an endoloop with a 3mm needle at the base of the loop. Phase 1: Full-thickness colon resections measuring 2 cm in diameter were created free-hand. The closing force for each device was compared to the gold standard of a hand-sewn defect closure using leak testing. Five different closure methods were studied: 1. conventional endoloop, 2. endoloop with a double-cinch, 3. endoloop with a needle, 4. over-the-scope clip (Padlock clip; US Endoscopy, OH), 5. free-hand suturing. Phase 2: eFTR was performed to compare the closing forces of the optimal modified endoloop identified from Phase 1 to the conventional endoloop. Using endoloops, a pseudopolyp containing the entire colonic wall was created and then resected using a hot snare.

**Results:** Phase 1: A total of 17 sites were resected using the free-hand model. The median maximum pressure for leak testing in hand-sewn closure was 22 mmHg compared to conventional endoloop (21 mmHg; p=0.56),

double-cinch endoloop (47 mmHg; p=0.077), endoloop with a needle (22 mmHg; p=0.86), and over-the-scope clip (40 mmHg; p=0.13). In Phase 2: eFTRs were successfully completed in 16 colonic sites (conventional endoloop, 8 sites; double-cinch endoloop, 8 sites). The median lesion size in conventional and double-cinch endoloops were 17mm (range: 14-20) and 19 mm (range: 15-22), respectively (p=0.13). The median maximum pressure for leak testing in the conventional and double-cinch endoloops were 29 mmHg (range, 20-45) and 42mmHg (range, 34-55), respectively (p< 0.01).

**Conclusion:** A double-cinch endoloop demonstrated a significantly higher closing force compared to conventional endoloops. The median maximum pressure for leak testing was higher with the double-cinch endoloop compared to hand-sewn closure, but did not reach significance. This simple modification to a currently available and familiar device could enhance defect closure following eFTR.

**Contact E-Mail Address:** g.holtmann@uq.edu.au

**Introduction:** Simethicone is an antifoaming agent frequently added to endoscopic rinse solutions but has recently been implicated as a possible risk factor for endoscopy transmitted infections due to a potential simethicone build-up in the working channels [1-3]. However, we have previously shown that discontinuation of simethicone use has a detrimental effect on the polyp and adenoma detection rates [4, 5]. However, the build-up of a deposit in the working channels of the endoscope is likely related to the simethicone concentration in the rinse solution. Unfortunately, no data are available on the minimal effective dose of simethicone that has antifoaming effects. We therefore aimed to determine the lowest effective concentration of simethicone that retains antifoaming properties.

**Aims & Methods:** We developed an 'in vitro bubble model'. For this purpose six 100 mL test tubes filled with water for irrigation were prepared with a standard kitchen detergent (Fairy®, 1% v/v). One test tube served as control, while different doses of simethicone (Infacol®, 0.02, 0.2, 2.0, 20 and 200 mg) were added to the other 5 test tubes. Oxygen was streamed for 30 seconds into the test tube at a rate of 2 L/min. After 10 seconds, digital photos were taken and the foam or bubbles that were visible on the photos rated semi-quantitatively rated (0 = no air bubbles, 1 = isolated air bubbles not impairing the visibility, 2 = air bubbles partly covering the surface, 3 = air bubbles fully covering the surface, 4 = multi-layered air bubbles) by five independent assessors blinded for the dosing of simethicone. Sufficient suppression of air bubbles was assumed when all assessors reported a score of 1 or less.

After determining the minimal effective dose of simethicone, we implemented this into routine clinical practice and compared polyp detection rates before and after introduction of the low-dose simethicone. To control for differences in the performance of endoscopists, we compared data from the same clinicians pre and post the dose change.

**Results:** Simethicone at doses as low as 20 mg/100 mL resulted in a complete or near complete prevention of bubble formation. Thus, doses as low as 20 mg/100 mL appear to be the appropriate minimal doses of simethicone to suppress bubble formation during endoscopic procedures. We compared polyp detection rates in 1,340 patients undergoing routine colonoscopy (606 female, age 59.6±14.9 [mean ± SD]), with 1,475 patients undergoing routine colonoscopies (655 female, age 58.3±15.2 [mean ± SD]) after implementation of the low dose simethicone protocol. In the high dose, the polyp detection rate was 56.5% (53.8-59.1% [95% CI]) and in the low dose it was 56.7% (54.2-59.3% [95% CI]).

**Conclusion:** While in most endoscopy units simethicone is added *ad libitum* to rinse solutions (e.g. 200 mg/100 mL), our data suggest that doses as low as 20 mg/100 mL are sufficient to abolish or prevent the formation of air bubbles or foam. Most importantly, this low dose of simethicone resulted in no change to our polyp detection rates, indicating that it is a clinically appropriate dose.

## P0904 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) OF EARLY RECTAL NEOPLASIA USING THE TISSUE RETRACTOR SYSTEM (TRS), A NEW ENDOSCOPIC PLATFORM FOR ENDOLUMINAL EN BLOC TISSUE RESECTION IN THE GASTROINTESTINAL TRACT - FIRST RETROSPECTIVE CASE SERIES AT A GERMAN REFERENCE CENTER

Kandler J., Wessel J., Neuhaus H., Beyna T.  
Evangelisches Krankenhaus Düsseldorf, Department of Internal Medicine,  
Düsseldorf, Germany

**Contact E-Mail Address:** torsten.beyna@evk-duesseldorf.de

**Introduction:** Endoscopic resection (ER) is the curatively intended first-line therapy for early rectal neoplasia (ERN)<sup>1</sup>. Prerequisite is successful Ro resection, which cannot always be achieved with lesions >20mm by endoscopic mucosal resection (EMR). In these cases, ESD is the preferred method<sup>2</sup>. Advantages of ESD are higher en bloc resection and lower recurrence rates, while EMR is faster to perform and shows lower perforation rates<sup>3-5</sup>.

For safer and faster ER, stable device position and good view into the submucosal space are needed. Tissue Retractor System (TRS) was developed to enable this with help of mechanisms established in laparoscopic surgery with a conventional endoscope<sup>6</sup>. TRS is a novel system, consisting of flexible overtube with expandable working chamber with 2 independent instrumentation catheters. With forceps via catheters, tissue can be stretched and held in position for ER.

**Aims & Methods:** Primary objective: Technical success of TRS-ESD (complete resection of target lesion using TRS). Secondary objectives: En bloc, Ro and curative resections, adverse events (AEs).

Retrospective analysis of all TRS-ESD cases of ERN between June 2018 and February 2019 at a tertiary referral center in Germany.

**Results:** 8 patients treated with ESD using TRS were included (3 women, 5 men, mean age 67 years, range 53-82). Target lesions were therapeutic naive, located in rectum (7 distal, 1 proximal), slightly-elevated with sessile parts (laterally spreading tumors nodular mixed type) and classified as type 2a or 2b according to JNET (Japan NBI expert team) classification<sup>7</sup>. Mean diameter 45.6mm (20-80mm). Technical success (complete resection using TRS) was achieved in 87.5% (7/8). In 12.5% (1/8) positioning of TRS (distal rectum) was not successful for anatomical reasons.

However, all lesions were resected completely (100%). The single lesion, non suspicious of malignancy, where TRS positioning was not successful, was resected by EMR (piece-meal technique, PM-EMR); all other lesions (87.5%, 7/8) were resected by ESD en bloc using TRS. Histologically, adenomas were found in 62.5% (5/8: 2 low grade dysplasia, LGD, 3 high grade dysplasia, HGD) and adenocarcinomas (AC) in 37.5% (3/8).

Overall, Ro resection was achieved in 75% (6/8). All (3/3) carcinomas were resected en bloc, Ro and curatively. 2 of 5 adenomas were not resected Ro (1 PM-EMR of LGD-adenoma due to failed TRS-positioning, 1 en bloc resection with focal adenoma in horizontal margin). All HGD-adenomas were curatively resected. No intraoperative or delayed AEs occurred.

**Conclusion:** ESD using TRS seems to be feasible and safe in the rectum. En bloc and Ro resection rates were comparable to those of conventional ESD. The rate of curative ESDs in cases of AC was high with 100%, which is less explained by the use of TRS than by adequate pretherapeutic selection of lesions. Whether use of TRS could finally be helpful reducing disadvantages of ESD cannot be answered with this work.

Although perforation rate of 0% was lower than that of conventional ESD, data is limited by the small number of cases and the retrospective analysis. Duration of intervention could not be analyzed in the current retrospective

dataset, but appeared not to be shorter. A reason could be longer learning curve for this complex procedure. For final appraisal now data from large scale prospective trial is needed.

## P0905 A 3-DAY VERSUS 1-DAY LOW RESIDUE DIET TO IMPROVE COLONOSCOPY PREPARATION RESULT AND PATIENT TOLERABILITY, A RANDOMIZED, SINGLE-BLINDED, CONTROLLED TRIAL

Taveira F., Areia M., Elvas L., Alves S., Brito D., Saraiva S., Cadime A.T.  
Portuguese Oncology Institute of Coimbra, Gastroenterology, Coimbra, Portugal

**Contact E-Mail Address:** fctav@hotmail.com

**Introduction:** The European Society of Gastrointestinal Endoscopy (ESGE) recommends a low-fibre diet on the day preceding the colonoscopy, although some endoscopists suggest a 3-day diet before colonoscopy. We intended to study the influence of a 3-day (3D) versus 1-day (1D) low residue diet in bowel preparation results and the effect on patient tolerability and adherence.

**Aims & Methods:** Randomized controlled trial, single-centre, endoscopist single-blinded, consecutive outpatients scheduled for total colonoscopy. Bowel preparation was 4L split-dose of polyethylene glycol. Randomization in 2 groups (n = 206), D3 vs. D1. The primary outcome was the bowel cleansing quality assessment by the Boston Bowel Preparation Scale (BBPS) (adequate cleansing ≥ 2 points per segment) to achieve a reduction from 15 to 5% of inadequate preparation result with a 3-day regimen. Statistical analysis in intention to treat (ITT) and per protocol (PP) with descriptive analysis,  $\chi^2$  and logistic regression with 95% confidence intervals (CI). Clinical Trial register NCT02955901.

**Results:** 412 patients were included, and groups were homogeneous in relation to gender, age, colonoscopy indication and risk factors for inadequate preparation.

The inadequate bowel preparation rate (primary outcome), assessed by the BBPS, was not significantly different between groups: ITT analysis (n=412) D3 8.3% vs. D1 5.3%, p=0.24 and PP analysis (N=400) D3 6.5% vs. D1 3.5%, p=0.16.

Secondary outcomes, on ITT analysis, were similar between groups (D3 vs. D1): cecal intubation rate (95.1% vs. 98.1%, p=0.1), polyp detection (52.9% vs. 52.4%, p=0.92) and advanced adenomas detection (34.9% vs. 39.8%, p=0.45). No differences were also found between groups (D3 vs. D1) regarding adverse effects / patients complaints (55.8% vs. 60.2%, p=0.37), ease in acquiring the proposed diet (5.3% vs. 6.8%, p=0.54) and willingness to repeat the regimen (77.2% vs. 80.6%, p=0.4) but difficulty in following the prescribed diet was significantly higher in D3 group: 11.7% vs. 4.4% p=0.008, OR 2.7, 95%CI 1.3-5.8.

Non-compliance with split dose (OR 3.0, 95%CI 1.7-12.0), chronic constipation (OR 3.3, 95%CI 1.3-8.8), consumption of tricyclic antidepressants (OR 3.2; 95%CI 1.1-8.8) and diabetes (OR 3.1, 95%CI 1.2-7.9) were statistically significant factors for inadequate preparation.

**Conclusion:** The increase for 3 days of a low residue diet prior to colonoscopy did not reduced the rate of inadequate bowel preparation; similar bowel preparation quality results are obtained with only 1 day of low residue diet within the ESGE threshold and with better adhesion and tolerability by the patient, under a split-dose preparation

**Disclosure:** Nothing to disclose

## P0906 COMPARISON OF THE EFFECTIVENESS OF FOUR BOWEL CLEANSING PREPARATIONS BEFORE COLONOSCOPY - RANDOMIZED, SINGLE - BLIND STUDY

Kmochova K.<sup>1</sup>, Suchanek S.<sup>1</sup>, Ngo O.<sup>2</sup>, Majek O.<sup>2</sup>, Zavoral M.<sup>1</sup>

**Contact E-Mail Address:** klara.kmochova@uvn.cz

**Introduction:** The effectiveness of bowel preparation is an essential requirement of successful colonoscopy. Polyethylenglycol is a gold standard in bowel preparation. It's main disadvantage is high volume. Oral sulfate solution (OSS), low volume PEG + ascorbic acid (2L-PEG/Asc) and sodium picosulfate + magnesium citric-acid solution (SP/MC) are low-volume preparations that might be appropriate substitution of PEG.

**Aims & Methods:** Comparison of the effectiveness of four bowel cleansing preparations.

Randomized, single-blind study. Patients with colonoscopy from all indications (except planned therapeutic procedure) were recruited. Instructions were provided in both verbal and written version and split-dose regimen was recommended. The bowel cleansing quality was evaluated by the experienced endoscopists blinded about the type of a bowel preparation. The effectiveness was assessed by the degree of bowel cleansing according to Boston Bowel Preparation Scale (BBPS) and polyp detection rate (PDR).

**Results:** In the period from 09/2017 to 03/2019 there were 439 individuals included in the study of which 6 patients eventually did not undergo colonoscopy from different reasons and 13 patients did not have total colonoscopy. The final analyzed number of patients was 420. The numbers of individuals with each preparation were as follows: 109 PEG; 108 OSS; 103 2L-PEG/Asc and 100 SP/MC. Representation of men was 51 % and average age was 58 years for whole group. Split-dose regimen was respected by 82% of patients. Adequate bowel cleansing (BBPS total score  $\geq 6$  and sub score  $\geq 2$  in each colonic segment) was comparable for all groups (95.4% PEG vs. 94.4% OSS vs. 98.1% 2L-PEG/Asc vs. 96.0% SP/MC;  $p = 0.600$ ). Excellent bowel cleansing (BBPS total score  $\geq 8$  and sub score  $\geq 2$  in each colonic segment) was observed often in PEG and OSS group however the difference was not significant (86.2% PEG vs. 84.3% OSS vs. 80.6% 2L-PEG/Asc vs. 80.0% SP/MC;  $p = 0.580$ ). Average value of total BBPS and average sub score for each colonic segment and preparations shows table 1. Polyp detection rate was comparable for all groups (49.5% PEG vs. 50.0% OSS vs. 36.9% 2L-PEG/Asc vs. 42.0% in SP/MC;  $p = 0.166$ ). There was also no difference in detection of advanced colorectal neoplasia ( $\geq 10$  mm, high grade dysplasia or cancer): 11.0% PEG vs. 10.2% OSS vs. 9.7% in 2L-PEG/Asc vs. 15.0% in SP/MC;  $p = 0.654$ . Average size of detected polyp was 5 mm and average number of detected polyp for each person was 2.

**Conclusion:** All tested low volume solutions provide comparable effectiveness of bowel preparation as polyethylenglycol and they could be considered as it's alternative.

Supported by the projects M01012 and Progres Q28/LF1. The study is registered on ClinicalTrials.gov.(NCT03242369).

	PEG	OSS	2L-PEG/ASC	SP/MC	Total number; p - value
Number of patient	109	108	103	100	420
Excellent preparation	86.2%	84.3%	80.6%	80.0%	0.580
Adequate preparation	95.4%	94.4%	98.1%	96.0%	0.600
Average value of total BBPS (SD)	8.4 (1.1)	8.4 (1.3)	8.4 (1.0)	8.3 (1.0)	
Sub score: RC	2.6 (0.6)	2.7 (0.6)	2.7 (0.5)	2.6 (0.6)	
TC	2.9 (0.4)	2.8 (0.5)	2.8 (0.4)	2.8 (0.4)	
LC	2.9 (0.4)	2.9 (0.4)	2.9 (0.3)	2.9 (0.3)	

[Table 1.]

Excellent bowel preparation: BBPS total score  $\geq 8$  and sub score  $\geq 2$  in each colonic segment; Adequate bowel preparation: BBPS total score  $\geq 6$  and sub score  $\geq 2$  in each colonic segment; RC: right colon; TC: transverse colon; LC: left colon; SD: standard deviation.

**Contact E-Mail Address:** ckdryekd@gmail.com

**Introduction:** The rate of polyp detection and removal from the screening colonoscopy have grown tremendously in many Asian countries. However, there is a great concern for demand of surveillance colonoscopy. Despite a continuing effort to lengthen intervals for surveillance colonoscopy, a number of surveys have indicated that most doctors still recommend more frequent surveillance colonoscopy than guideline suggest. The aim of this study is to investigate the surveillance recommendations of Asian gastroenterologists after polypectomy and compare them with recommendations from international guidelines.

**Aims & Methods:** A survey study was performed among seven Asian countries from July 2018 and October 2018. An email invitation which a link provided was sent to gastroenterologists, general internal medicine and surgeons. Participants were asked to complete a survey of eight clinical scenarios designed to evaluate their potential course of action in response to screening or follow-up colonoscopy results. The US Multi-Society Task Force on Colorectal Cancer 2012 was determined as a standard guideline. We stratified participants according to their number of colonoscopy as 1) performed  $\geq 20$  colonoscopies per month [high-volume (HV)] and 2)  $< 20$  colonoscopies per month [low-volume (LV)].

**Results:** One hundred thirty-seven doctors were invited. A total of valid response were obtained from 123 doctors (89.8%). Respondents included 40 Korean gastroenterologists and 83 physicians from other Asian countries. Majority of participants (73%) practiced in a tertiary hospital and 87% were gastroenterologists. Approximately, half of participants adhered to the guideline regardless of adenomas except a combination between adenoma  $\geq 10$  mm with tubulovillous and high grade dysplasia, in which 35% of participants adhered to the guideline. Only 12% of participants adhered to the guideline of 10 years interval for no polyp in a patients with a prior high-risk adenoma. According to the stratification by colonoscopy number, 78 (64%) participants were in HV group, and 45 (36%) were in LV group. The HV group more adhered to the guideline recommendation after removal of adenoma than LV group. The reasons for non-adherence to the guideline were concern of missed polyp (59%), low cost for colonoscopy (26%), incomplete resection (25%), and medical liability (15%).

**Conclusion:** This study shows a remaining discrepancy between physician's recommendation and current guideline for post-polypectomy surveillance. Physicians in LV group frequently do not adhere to the guideline, suggesting a need for appropriate control and continuing education. Concern for quality of colonoscopy and incomplete polyp resection were mainly related to non-adherence.

**Disclosure:** Nothing to disclose

## P0908 IN PATIENTS WITH AN OVERALL CLEANSING SUCCESS THE 1L POLYETHYLENE GLYCOL NER1006 ACHIEVES MORE HIGH-QUALITY CLEANSSED SEGMENTS PER PATIENT THAN THREE STANDARD BOWEL PREPARATIONS

Bisschops R.<sup>1</sup>, Manning J.<sup>2</sup>, Halonen J.<sup>3</sup>, Álvarez-González M.A.<sup>4</sup>

<sup>1</sup>Katholieke Universiteit Leuven, Gastroenterology, Leuven, Belgium, <sup>2</sup>Borders General Hospital, NHS Borders, Melrose, United Kingdom, <sup>3</sup>Norgine, Medical Affairs, Harefield, United Kingdom, <sup>4</sup>Hospital del Mar, Barcelona, Spain

**Contact E-Mail Address:** raf.bisschops@uzleuven.be

**Introduction:** Detection of all adenomas during colonoscopy is important for patient protection against colorectal cancer. At a minimum, this requires successful pre-colonoscopy colon cleansing which is usually based

on the least clean colon segment. High-quality cleansing has however been shown to improve adenoma detection. The prospective phase 3 development programme for 1L polyethylene glycol (PEG) NER1006 (studies DAYB, MORA and NOCT) is the largest to date on colon cleansing quality [1-3]. The primary analysis revealed a higher or at least as effective adequate level cleansing efficacy of NER1006 versus sodium picosulfate/magnesium citrate (SPMC), 2L PEG + ascorbate (2LPEG), and oral sulfate solution (OSS). An improved high-quality cleansing efficacy has already been shown for NER1006 at the treatment group level, but the patient level benefits remain unclear.

**Aims & Methods:** This post hoc analysis of 1749 patients in three randomised phase 3 trials examined if the number of high-quality cleansed colon segments per patient could improve with NER1006 versus SPMC, 2LPEG or OSS. All patients with documented segmental cleansing scores and neoplasia counts were included. Treatment-blinded central readers assessed the segmental cleansing quality using the validated Harefield Cleansing Scale (HCS) scores 0-4 based on colonoscopy videos by site colonoscopists. Patients with an overall cleansing success (HCS Grades A-B) were stratified per trial and allocated bowel preparation. The mean number of attained high-quality colon segments (HCS scores 3-4) per patient was calculated. One-sided t-tests compared the mean number of high-quality colon segments per patient using NER1006 versus the comparator in each trial.

**Results:** A total of 1471/1749 patients (84%) achieved overall cleansing success (Table). With comparable split dosing regimens, overall cleansing success rates reflected the primary published results [1-3]. The mean number of high-quality colon segments per patient was greater for patients using NER1006 than any of the comparators in each respective trial. Day before split dosing with NER1006 was more effective than with SPMC: 1.13 vs 0.76;  $P=0.005$ . Overnight or morning only split dosing with NER1006 was more effective than with 2LPEG: 2.52 and 2.65 vs 1.65;  $P<0.001$  for both. Similarly, overnight split dosing with NER1006 was more effective than with OSS: 2.61 vs 2.30;  $P=0.032$ . The additional effect size for NER1006 versus its comparators ranged from 0.31-1.00 high-quality segments per patient.

**Conclusion:** These results demonstrate that despite comparable or higher adequate cleansing success, this does not prevent NER1006 from being clearly more effective than SPMC, 2LPEG or OSS in delivering more high-quality cleansed segments per patient.

	DAYB		MORA			NOCT	
	NER1006	SPMC	NER1006	NER1006	2LPEG	NER1006	OSS
Split dosing regimen	Day before	Day before	Overnight	Morning only	Overnight	Overnight	Overnight
Patients with overall cleansing success (HCS grade A-B), n/N (%)	151/229 (65.9)	133/239 (55.6)	248/256 (96.9)	242/266 (91.0)	230/250 (92.0)	231/251 (92.0)	236/258 (91.5)
High-quality segments (HCS score 3-4) per patient with overall cleansing success, mean (SD)	1.13 (1.29)	0.76 (1.07)	2.52 (1.76)	2.65 (1.81)	1.65 (1.71)	2.61 (1.80)	2.30 (1.81)

## P0909 ADENOMA PER COLONOSCOPY (APC) AND ADENOMA PER POSITIVE PARTICIPANT (APP) AS QUALITY METRICS IN SCREENING COLONOSCOPY

Mathou N.<sup>1</sup>, Papastergiou V.<sup>1</sup>, Giannakopoulos A.<sup>1</sup>, Evgenidi A.<sup>1</sup>, Schoretsanitis E.<sup>1</sup>, Lenas M.<sup>2</sup>, Apessou D.<sup>2</sup>, Paraskeva K.D.<sup>1</sup>

<sup>1</sup>General Hospital of Nea Ionia 'Konstantopoulou-Patision', Gastroenterology, Athens, Greece, <sup>2</sup>General Hospital of Nea Ionia 'Konstantopoulou-Patision', Pathology, Athens, Greece

**Contact E-Mail Address:** konparaskeva@gmail.com

**Introduction:** Adenoma detection rate (ADR; proportion of colonoscopies with at least 1 adenoma) is the most validated metric in colonoscopy quality. However, ADR is not free of limitations. These include the "one and done" phenomenon, in which endoscopists may be less vigilant after having detected their first adenoma. Alternative quality indicators considering the total number of adenomas have been proposed, although supported by scant evidence.

**Aims & Methods:** We evaluated APC (total number of adenomas divided by the total number of colonoscopies) and APP (total number of adenomas divided by the number of colonoscopies with at least 1 adenoma) as quality markers for screening colonoscopy, based on the correlation of each with the ADR and the advanced ADR (AADR; proportion of colonoscopies with an advanced neoplasm). For this purpose, consecutive screening colonoscopies conducted in a single endoscopy unit in Greece (Jan 2015-June 2018) were retrospectively reviewed. Pearson's correlation was used to evaluate the relationship between APC-ADR, APC-AADR, APP-ADR and APP-AADR.

**Results:** A total of 1505 colonoscopies performed by 6 endoscopists were analyzed. The ADRs ranged from 13.0% to 28.7% (mean, 22.7%), AADRs from 3.9% to 8.8% (mean, 6.6%), APCs from 0.18 to 0.45 (mean, 0.30) and APPs from 1.29 to 1.50 (mean, 1.38). APC showed a strong correlation with ADR ( $r=0.91$ ,  $p=0.01$ ) and AADR ( $r=0.89$ ,  $p=0.02$ ). Contrarily, no association could be identified between APP and both these parameters (ADR:  $p=0.91$ ; AADR:  $p=0.37$ ).

**Conclusion:** In our setting, APC, but not APP, demonstrated significant correlation with both ADR and AADR and may be considered as alternative quality indicator of screening colonoscopy.

## P0910 SCAR ASSESSMENT AFTER PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION - INTEROBSERVER AGREEMENT IN HISTOLOGICAL RECURRENCE PREDICTION

Silva J.C., Fernandes C., Silva A.P., Proença L., Freitas T., Pinho R., Fernandes S., Leite S., Ponte A., Sousa M., Gomes A.C., Afeto E., Carvalho J.

Centro Hospitalar Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

**Contact E-Mail Address:** catarina.rib.gomes@gmail.com

**Introduction:** It is unclear whether scar assessment after piecemeal endoscopic mucosal resection (pEMR) has to include scar biopsy in the absence suspected recurrence. Histological recurrence (HR) is an important limitation of pEMR and occurs in  $\leq 20\%$ . Currently HR assessment is routinely performed through endoscopic evaluation and scar biopsy. Advanced imaging methods such as *Narrow-Band Imaging* (NBI) may predict HR with high acuity.

**Aims & Methods:** This study aims to evaluate agreement between gastroenterologists with different endoscopic experience, in the prediction of HR based on the endoscopic scar assessment.

Patients undergoing colonoscopy 3-6 months after a pEMR of 20mm or larger non-invasive colorectal lesions were included. Scar biopsy was performed and in case of suspected endoscopic recurrence residual lesion was resected.

Thirty-eight high definition images with white light (WL) or NBI were selected, of which 18 with HR and 20 without HR. 12 participants with different degrees of experience in therapeutic endoscopy performed an offline assessment of pEMR scars. The images were randomized. Participants were blinded for the randomization and histology. Each gastroenterologist classified the images as HR or without HR, and the interobserver agreement coefficient (k) was calculated.

**Results:** Mean age was  $66 \pm 12$  years, with 60.5% male ( $n = 23$ ). The mean lesion size was  $35 \pm 15$  mm, with 60.5% 0-I-IIa ( $n=23$ ).

Endoscopic prediction of recurrence had high sensitivity (55.6%-88.9%) and specificity (85.0%-95.0%). Negative predictive value (70.4%-94.1%) and positive predictive value (82.4%-93.8%) were also calculated. Coefficient of agreement (k) between the different participants was 0.806 ( $p < 0.001$ ). In patients with recurrence k-coefficient was 0.881 ( $p < 0.001$ ). In patients without recurrence k-coefficient was 0.925 ( $p < 0.001$ ). There were no significant differences between NBI ( $k=0.769$ ;  $p < 0.001$ ) and WL ( $k=0.837$ ;  $p < 0.001$ ).

**Conclusion:** Endoscopic prediction of recurrence based on offline scar assessment under WL and NBI showed high interobserver agreement among gastroenterologists with different degrees of experience in therapeutic endoscopy.

**Contact E-Mail Address:** timo.rath@uk-erlangen.de

**Introduction:** Adenoma detection rate (ADR) is inversely related to the incidence of interval colorectal cancers and therefore serves as a benchmark criterion for quality assessment during screening or surveillance colonoscopies. Within this study, we evaluated whether additional retrograde inspection of the colon can increase ADR and the number of adenomas per patient.

**Aims & Methods:** Patients undergoing screening or surveillance colonoscopies were prospectively enrolled. During colonoscopy, each segment of the colon (Cecum and ascending colon, transverse colon, descending and sigmoid colon) were inspected first with HD standard forward view (SFV) followed by inspection of the same segment in retroflexed view (RFV) using a dedicated endoscope with a 210° retroflex angulation (Pentax Retro-View). Number of adenomas in each segment detected with SFV and RFV as well as withdrawal times with SFV and RFV were recorded.

**Results:** At the time of abstract submission, 56 patients (mean age 59.4 years, 38 male) were prospectively included. Inspection of the whole colon in retroflexion was possible in all patients. Polyp detection rate (PDR) with SFV was 36% and increased to 46% when additional RFV was performed in each segment. Likewise, ADR increased by 9% when RFV was performed (ADR SFV: 32%, ADR RFV: 41%). Adenoma per patient rate was 1.7 with SFV and increased to 2.3 with additional RV. Size of the additional adenomas found with RFV ranged from 3 to 10 mm. Withdrawal times were not significantly different between SFV and RV.

**Conclusion:** Additional retroflexion of the colon using a dedicated endoscope can significantly increase ADR and the number of adenomas found per patients. This approach should be considered during standard colonoscopy to increase ADR and to improve the quality of colonoscopy.

**Introduction:** Colorectal cancers have two development theories. One is "adenoma-carcinoma sequence". The other is "de novo" pathway, considered to emerge directly from normal epithelium, not through the adenomatous stage. We investigated clinicopathological characteristics of depressed-type colorectal carcinomas considered as "de novo" pathway.

**Aims & Methods:** A total of 34,276 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our center from April 2001 to December 2018. Of these, 1,203 lesions were T1 carcinomas. According to the morphological development classification (modified Paris classification), they were divided into 3 types: 265 lesions (22%) were depressed-type, 428 lesions (36%) were flat-type and 510 lesions (42%) were protruded-type. We investigated the clinicopathological differences of these types.

**Results:** Among T1 carcinomas, the rate of vessel invasion was 47% in depressed-type, 22% in flat-type and 21% in protruded-type, that of poorly differentiated or mucinous adenocarcinoma was 16%, 10% and 14%, that of massively submucosal invasion was 94%, 70% and 78%, and that of tumor budding was 48%, 26% and 30%, respectively. The rates of these pathological factors were significantly higher in depressed-type lesions than other types. The rate of adenomatous component was 5%, 55% and 52%, and the rate of polypoid growth was 14%, 56% and 96% respectively. It was significantly lower in depressed-type lesions than other types. The mean size of tumor of each type was 15mm, 30mm, and 19mm, and that of depressed-type was significantly smaller than other types. The rate of lymph node metastasis was 9%, 6% and 12%, respectively. The rate of distant metastasis or recurrence was 1% (10/1,203). Among these 10 cases, 5 cases were depressed-type lesions among which one showed a para-aortic lymph node metastasis and four showed lung metastases.

**Conclusion:** Depressed-type colorectal carcinomas had significantly lower adenomatous components and smaller size than flat- or protruded-types, suggesting that they follow a growth "de novo" pathway different from the "adenoma-carcinoma sequence". Depressed-type colorectal carcinomas contained worth pathological features than other types. Giving a careful attention to the morphological features is important to diagnosis the colorectal carcinomas.

**Disclosure:** Nothing to disclose

## P0913 EFFICACY AND LONG-TERM OUTCOMES OF RECTAL NEUROENDOCRINE TUMORS AFTER ENDOSCOPIC SUBMUCOSAL RESECTION WITH A LIGATION DEVICE

Takita M., Ohata K., Matsuhashi N.

NTT Medical Center Tokyo, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** mycopiasm@mail.goo.ne.jp

**Introduction:** The therapeutic strategies for the rectal neuroendocrine tumor (NET) still have not been standardized. We often use endoscopic submucosal resection with a ligation device (ESMR-L) for treatment of rectal NET. We conducted this study to evaluate the clinical outcomes of rectal NET treated by ESMR-L.

**Aims & Methods:** Between May 2002 and March 2018, 199 patients with 200 rectal NETs underwent ESMR-L in our hospital. Firstly, we investigated association between clinicopathological characteristics including endoscopic findings and therapeutic outcomes. Curative resection was defined as margin negative without lymphovascular invasion. Subsequently, the long-term outcomes after a 48-months follow-up period were also evaluated.

**Results:** The majority were male (74.5%) and the average age was 52.4 years. Most of the lesions were located at Rb (82.5%), and the average size was 4.6mm. Of the 200 lesions, 199 achieved margin negative and 125 achieved curative resection, respectively. Multivariate logistic regression analyses revealed that the tumor size  $\geq 5$ mm (OR: 2.30, 95% CI: 1.24-4.26,  $P=0.008$ ) and presence of central depression (OR: 3.72, 95% CI: 1.06-13.1,  $P=0.04$ ) are significantly associated with non-curative resection. 13 (17.3%) of the non-curative resection underwent additional surgery, among which 2 cases (15.4%) had histological lymph node metastasis. Both of them could not detect the metastasis in preoperative period. Regarding to long-term outcomes, no case had local or distant metastases during the follow-up period. With respect to complications, 13 (6.5%) cases had delayed bleeding and one (0.5%) had perforation, but they were successfully managed conservatively.

**Conclusion:** ESMR-L is a feasible procedure as an endoscopic resection for rectal NET. Since there were few patients with non-curative resection who underwent additional surgery, we cannot exclude the possible presence of clinically undetectable metastatic lesions. However, considering that there was no recurrence in those cases, observation without additional surgery in a subset of cases with non-curative resection might be allowed.

**Introduction:** Endoscopic full thickness resection (EFTR) by the Full Thickness Resection Device (FTRD<sup>®</sup>) is an invasive treatment for colorectal lesions not resectable by conventional endoscopic techniques. This study presents the first Greek experience on FTRD<sup>®</sup> procedure, assessing EFTR efficacy and safety.

**Aims & Methods:** We conducted a retrospective analysis of 21 patients consecutively treated with FTRD<sup>®</sup> at two referral centers from October 2015 through April 2019. The indications included difficult adenomas (non-lifting and/or at difficult locations), early adenocarcinomas and subepithelial tumors.

Primary endpoints were technical success (resection in one piece and macroscopically complete) and R0 resection (negative lateral and deep margins based on histological examination).

**Results:** Technical success and R0 resection occurred in 17 of 21 procedures (80.9%). In 11 patients with difficult adenomas, they were achieved in 81.8%. In the subgroup with carcinomas (n=3), technical success and R0 resection rate was 66.6% while in the subgroup with subepithelial tumors (n=7) the rate was 85.7%. In general, technical success and R0 resection were decreased significantly for lesions >20mm versus ≤20mm (p=0.005). In 21 patients a total of four adverse events occurred (19%) and one of the patients underwent laparoscopic appendectomy due to EFTR around the appendix.

**Conclusion:** Our study showed favorable results concerning EFTR feasibility, efficacy and safety, especially for lesions ≤20 mm, non-lifting adenomas, subepithelial tumors and adenomas involving the appendix. Technical success, R0 resection and adverse events rates are comparable with data reported in literature. Larger randomized studies comparing available surgical techniques with EFTR are needed to better define the clinical benefit and long-term outcomes of EFTR in selected patients.

**Introduction:** Correct estimation of colorectal polyp size is important for surveillance policy, to estimate malignant potential and to plan the method of removal<sup>1</sup>. In relation to smaller polyps, size estimation is of major importance in the 'resect-and-discard' strategy<sup>2</sup>. Currently, the gold standard of polyp size determination is the pathological measured diameter, but often is relied on visual (endoscopic) rating of polyp size. Literature shows that this visual estimation is frequently inaccurate when compared to the pathological report<sup>3,4</sup>. We aimed to assess factors which could hypothetically influence the accuracy of visual polyp size and volume estimation in a colon model.

**Aims & Methods:** We created a colon model with artificial polyps of different size, shape and volume, which were photographed using an Olympus video colonoscope (Olympus EVIS EXERA III, CF-HQ190L) at fixed distances of 1, 3, and 5cm. The pictures were presented to 15 endoscopists of three different centers, who were asked to estimate polyp diameter and volume. Polyp diameters were categorized into ≤5mm, 6-9mm and ≥10mm, as these were considered clinical relevant categories<sup>1,2</sup>. Level of agreement

between the visually estimated diameter category and the true (measured) diameter category was assessed using the Kappa test. Agreement in volume estimation was assessed using intraclass correlation.

**Results:** The Kappa for agreement of the correct category of polyp diameter was 0.41 (95% confidence interval (CI) 0.33-0.48), which equals a fair to moderate agreement<sup>5</sup>. Agreement did not substantially improve with experience, with a Kappa of 0.42 (95% CI 0.33-0.51) in the experienced group (>48 months of endoscopic experience) versus 0.39 (95% CI 0.26-0.51) in the less experienced group. Moderate agreement was observed between estimated and true polyp volume (intraclass correlation 0.69, CI 0.63-0.74). Subanalysis showed that the best distance to estimate polyp diameter was at 3cm (Kappa of 0.45, versus 0.37 at 1cm and 0.40 at 5cm). Polyps photographed at 1cm were consequently estimated larger than those photographed at 3 and 5cm, for diameter as well as volume.

**Conclusion:** In this study using a colon model with artificial polyps we found fairly disappointing results in estimation of polyp size (both diameter and volume). Our data suggests that endoscopists tend to overestimate polyp size at short endoscopic distance and underestimate polyp size at larger distance. Three centimeters seems to be the ideal endoscopic distance for optimal polyp size estimation.

Novel techniques are needed to more accurately assess polyp size during endoscopy.

## P0916 DELAYED BLEEDING AFTER COLONOSCOPIC TREATMENT IN PATIENTS TAKING ANTICOAGULANTS

Tomida H.<sup>1</sup>, Yoshio T.<sup>2</sup>, Uragami N.<sup>3</sup>

<sup>1</sup>Ehime University Hospital, Endoscopy Center, Ehime, Japan, <sup>2</sup>Cancer Institute Hospital, Gastroenterology, Tokyo, Japan, <sup>3</sup>Showa University Koto Toyosu Hospital, Digestive Diseases Center, Tokyo, Japan

**Introduction:** Delayed bleeding after endoscopic treatment in antithrombotic therapy is still a serious complication. Japanese guidelines for gastroenterological endoscopy have recommended continued warfarin treatment in patients where the INR within therapeutic range and withdrawal of direct anticoagulants (DOACs) only on the day of treatment. However these guidelines have suggested the management of anticoagulants, the differences of the influence on delayed bleeding between warfarin and DOACs, and among each DOACs haven't been clarified yet.

**Aims & Methods:** The aim of this study is to clarify the effect of anticoagulants on bleeding after colonoscopic treatment. This study was three institutions retrospective cohort study based on clinical records. We assessed 265 consecutive patients with anticoagulants who underwent colonoscopic treatment from January 2013 to December 2017. 122 patients were taking warfarin and 143 patients taking DOACs, including 33 patients on dabigatran, 58 patients on dabigatran, 39 patients on apixaban and 13 patients on edoxaban. Delayed bleeding has been defined as an event requiring emergency endoscopic hemostasis or a >2g/dL decrease in hemoglobin level after colonoscopic treatment.

**Results:** The overall delayed bleeding rate was 4.5% (12/265), and the bleeding rate was significantly higher in the DOACs group with 7.0% (10/143) than in the Warfarin group with 1.6% (2/122) (p=0.041). In DOACs, the delayed bleeding rate of each agents were 3% in dabigatran (1/33), 8.6% in rivaroxaban (5/58), 7.7% in apixaban (3/39), 8.3% (1/13) in edoxaban. Dabigatran, as direct thrombin inhibitor, had lower delayed bleeding rates than factor Xa inhibitors, but there was no significant difference. Heparin bridge therapy (HBT) after procedure was performed more frequently in warfarin group (19%) than in DOACs group (2.8%) (p<0.001), however, there was no association between delayed bleeding and HBT. Antiplatelet agents were combined in 45 cases (17%) and were signifi-

cantly higher in warfarin group (34% vs 9.7%,  $p<0.001$ ), but combined use of antiplatelet agents was not related to delayed bleeding. There was no significant differences in tumor diameter, tumor location and procedure (ESD or Polypectomy/EMR) between the two groups. The hospitalization period was significantly shorter in DOACs group (7days vs 2days,  $p<0.001$ ). Perioperative thromboembolism occurred in 1 case of DOACs group, and the patient was improved with only slight paralysis.

**Conclusion:** In colonoscopic treatment, delayed bleeding was more frequent in patient with DOACs, and the DOACs effects differed in each agent. In DOACs, the possibility of rapid onset of anticoagulant effect after oral administration was considered. We have previously reported that there was less delayed bleeding rate after gastric ESD in patients taking dabigatran. A shift from factor Xa inhibitors to dabigatran could be the option to reduce the delayed bleeding in gastrointestinal endoscopic treatment.

**Introduction:** One of the difficulties in performing endoscopic submucosal dissection (ESD) is the lack of retraction during submucosal dissection. The development of master and slave transluminal endoscopic robot (MASTER), EndoMaster EASE System, aims to enhance safety and efficacy of ESD through two flexible robotic arms for tissue retraction and dissection. This is a preclinical animal study to evaluate performance of colorectal ESD using the latest version of the EndoMaster EASE System.

**Aims & Methods:** The latest version of the EndoMaster EASE System consisted of an independently designed flexible robotic platform with build-in endoscopic imaging system with working channels for the passage of 2 robotic arms and accessories. In this animal study, the outcomes measured included operating time (from starting incision to finishing dissection), completeness of resection, procedure-related complications as well as limitation of arms manipulation in narrow working space as assessed by counting the frequency of blind cutting.

**Results:** A total of 5 colorectal ESD procedures were performed in a 66.7kg porcine model under general anesthesia [Figure 1]. The mean operative time was 73.8 minutes, and the mean size of specimen resected was 1340 mm<sup>2</sup>. There was no perforation, while profuse bleeding was encountered during one of the ESD procedures [Table 1]. Hemostasis was achieved after adequate exposure of bleeding arteriole by retracting the mucosal with robotic arm. The en-bloc resection rate was 100%

**Conclusion:** This study confirmed the feasibility and safety in performing ESD using the EndoMaster EASE System in porcine colon. This provides an important preclinical experience for the next clinical trial.

No	Weight (kg)	Location	OT time	Dissection Time (mins)	Specimen size (mm <sup>2</sup> )	Dissection speed (mm <sup>2</sup> /min)	Difficulty in manipulation	Complication

## P0918 PREVALENCE AND CHARACTERISTICS OF COLONIC POLYPS AMONG PATIENTS REFERRED FOR FAST TRACK COLONOSCOPY FOR IRON DEFICIENCY ANAEMIA

Dru R.C.<sup>1</sup>, Court E.L.<sup>2</sup>, Getachew A.E.<sup>2</sup>, El Falaha S.<sup>2</sup>, Curtis N.J.<sup>2</sup>, Francis N.K.<sup>2</sup>

**Contact E-Mail Address:** rebecca.dru@ydh.nhs.uk

**Introduction:** Iron deficiency anaemia (IDA) is a common indication for fast track referral for suspected colorectal cancer. The vast majority of these patients undergo upper and lower gastrointestinal (GI) endoscopy. Most research focuses on the incidence of colorectal cancer, but there is a paucity of published data concerning colonic polyps in this patient population.

**Aims & Methods:** The aim of this study was to investigate the prevalence and characterisation of polyps, the histological subtype, and to identify any relationship between these and the degree of anaemia in patients referred for colonoscopy via the fast track pathway.

A dedicated, prospectively populated database of fast track referrals for endoscopy was utilised. Patient demographics, polyps and/or tumour characteristics, and haematological results at the time of referral were captured. These included haemoglobin level (Hb), mean cell volume (MCV), and markers of iron metabolism (iron, transferrin, transferrin saturation, and ferritin levels). Anaemia was defined as Hb level of < 120g/L for women and < 135g/L for men. Descriptive details of patient age, sex, referral route (if not fast track), and polyp characterisation were recorded. Data was analysed using the IBM SPSS® statistical tool.

**Results:** 846 patients underwent colonoscopy for anaemia at our centre over a period of 5 years (31<sup>st</sup> March 2014 to 7<sup>th</sup> April 2019). 355 patients in the cohort were found to have polyps (42.0%) and 58 had colorectal cancer (6.9%).

In cancer patients, low Hb and MCV were statistically significant ( $p=0.014$  and  $0.008$  respectively). Hb had a negative predictive value of 0.92 for malignancy, being just 0.38 for polyps.

After exclusion of patients with cancer and those who did not have full haematological data, further subgroup analysis was carried out on a total of 217 patients. Median polyp number and size were 1 (range 1-8) and 5mm (range 1-40mm) respectively. 66.4% of those patients with IDA had a pathologically confirmed adenoma, but there was no difference in measured blood results between adenoma and non-adenoma patients ( $p$  value range 0.249 - 0.935). In addition, neither polyp size nor site correlated with any of the blood tests analysed (all  $r^2<0.15$ ,  $p>0.3$ ).

**Conclusion:** Colorectal polyps are common but incidental findings among patients who undergo colonoscopy for iron deficiency anaemia. The level of anaemia does not appear to correlate with incidence, site, or size of polyps. Further research is required to validate these findings and to investigate novel markers for patients with anaemia, as colonoscopy does not appear to identify the cause of anaemia in the majority of cases.

## P0919 LOW-DOSE RECTAL DICLOFENAC FOR THE PREVENTION OF POST-ERCP PANCREATITIS IN ELDERLY PATIENTS

Maeda N.<sup>1</sup>, Higashimori A.<sup>1</sup>, Nakatani M.<sup>1</sup>, Mizuno Y.<sup>1</sup>, Nakamura Y.<sup>1</sup>, Ikeda D.<sup>1</sup>, Hashimoto A.<sup>1</sup>, Morimoto K.<sup>1</sup>, Fukuda T.<sup>1</sup>, Fujiwara Y.<sup>2</sup>

<sup>1</sup>Minami Osaka Hospital, Gastroenterology, Osaka, Japan, <sup>2</sup>Osaka City University Graduate School of Medicine, Gastroenterology, Osaka, Japan

**Contact E-Mail Address:** natsu072407@yahoo.co.jp

**Introduction:** According to the guidelines of the European Society of Gastrointestinal Endoscopy and Japan Gastroenterological Endoscopy Society, 50-100 mg rectal dose of nonsteroidal anti-inflammatory drugs (NSAIDs; diclofenac or indomethacin) is recommended for prophylaxis of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP). However, little is known about the appropriate dose of NSAIDs to prevent PEP in elderly patients.

Moreover, the recommended dose is higher than the 25 mg dose that is commonly administered to Japanese patients, especially frail elderly patients with a low body weight or decreased renal function, who are more prone to adverse reactions.

**Aims & Methods:** The aim of this study was to evaluate the efficacy and safety of 25 mg rectal dose of diclofenac to prevent PEP in elderly patients aged over 75 years.

This was a retrospective observational study in a single institution. Between April 2013 and March 2019, 636 patients underwent 1200 ERCP procedures. Patients aged over 75 years with normal upper intestinal anatomy including Billroth I reconstruction were enrolled in this study. The exclusion criteria were as follows: 1) acute pancreatitis, 2) peptic ulcer disease, 3) contraindication to NSAIDs, 4) aspirin-induced asthma, and 5) severe kidney dysfunction with serum creatinine over 120  $\mu\text{mol/L}$ . Consequently, 303 patients with 626 procedures were included in this study. They were administered with or without the rectal administration of 25 mg diclofenac 30 min before the procedure. The primary outcome was overall occurrence of PEP. Generalized estimating equations (GEE) were used to analyze repeated-measures data. The propensity score approach with inverse probability of treatment weighting (IPTW) was used to adjust for covariate imbalance between diclofenac and non-diclofenac groups.

**Results:** Patients were assigned to either administration of 25 mg diclofenac group (59 patients with 132 procedures) or non-diclofenac group (244 patients with 504 procedures). Their average age, body-mass index, and creatinine clearance (Ccr) were  $83.5 \pm 5.5$  years old,  $21.2 \pm 4.2$   $\text{kg/m}^2$ , and  $43.5 \pm 16.8$   $\text{mL/min/1.73 m}^2$ , respectively. Patients with decreased renal function less than Ccr 60  $\text{mL/min/1.73 m}^2$  accounted for 86% (260/303). Thirty-four patients developed PEP and the incidence rate of PEP in diclofenac group (3.4%, 2/59) was significantly lower than in non-diclofenac group (13.1%, 32/244,  $p=0.037$ ). The multivariate analysis using GEE revealed that prophylactic administration of low-dose diclofenac reduced the incidence of PEP (OR, 0.226; 95% CI, 0.052–0.975;  $p=0.046$ ). Multivariate analysis using IPTW also showed that low-dose diclofenac was effective to prevent PEP (OR, 0.158; 95%CI, 0.029–0.872;  $p=0.034$ ). After ERCP, there were no adverse events related to diclofenac such as gastrointestinal hemorrhage/ulceration and acute renal failure.

**Conclusion:** A 25 mg rectal dose of diclofenac was considered to be effective and safe in preventing PEP in elderly patients aged over 75 years.

**Disclosure:** Nothing to disclose

## P0920 DOES ERCP PERFORMED FOR PATIENTS WITH ACUTE PANCREATITIS INCREASE THE RISK FOR THE COMPLICATION? A PROSPECTIVE MULTICENTRE OBSERVATIONAL STUDY

**Introduction:** Complications associated with endoscopic retrograde cholangiopancreatography (ERCP) include post-endoscopic sphincterotomy (EST) bleeding, perforation and sedation problems, in addition to post-ERCP pancreatitis. ERCP is frequently necessary in cases of obstructive pancreatitis caused by choledocholithiasis or pancreatic cancer. However, once pancreatitis develops, complications are believed to arise owing to papillary oedema or deterioration of general condition. In the present prospective multicentre study, we investigated whether pancreatitis before ERCP was performed increased the risk of complications associated with ERCP.

**Aims & Methods:** We prospectively followed 3920 patients examined by performing ERCP in five high-volume centres between April 2015 and May 2017. The outcome measures were as follows: presence or absence of pancreatitis prior to the examination, patients' backgrounds, procedures, serum amylase level after the examination and complications associated with ERCP.

**Results:** In total, 127 (3.2%) patients had acute pancreatitis before ERCP was performed. No significant difference was observed between the pancreatitis and non-pancreatitis groups in terms of age, sex and mean exami-

nation time. The ASA physical status classification score and frequency of obstructive jaundice and untreated papilla were significantly higher in the pancreatitis group ( $p < 0.001$ ). We observed that the pancreatitis group had a higher frequency of cannulation and incidence of endoscopic sphincterotomy (EST), placement of biliary and pancreatic stents, pancreatography and insertion of guidewire than non-pancreatitis group ( $p = 0.003$ ,  $p = 0.001$ ,  $p < 0.001$ ,  $p = 0.002$  and  $p < 0.001$ , respectively). No significant difference was observed in the incidence of cholangitis, cholecystitis, bleeding after EST, perforation, biliary tract injury and sedation complications. The incidences of pancreatic duct injury were higher in the pancreatitis group than in non-pancreatitis group ( $p < 0.001$ ). The frequency of post-ERCP pancreatitis was 7% (266/3650).

**Conclusion:** ERCP performed for patients with acute pancreatitis had an acceptable level of safety. We also found that the biliary cannulation rate was higher in patients with pancreatitis. However, care should be taken when inserting a guidewire to the pancreatic duct owing to an increased risk of pancreatic ductal injury.

**Disclosure:** Nothing to disclose

## P0921 CLINICAL USEFULNESS OF A CONVENTIONAL GASTROSCOPE FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY

Nakatani M.<sup>1</sup>, Higashimori A.<sup>1</sup>, Maeda N.<sup>1</sup>, Nakamura Y.<sup>1</sup>, Hashimoto A.<sup>1</sup>, Morimoto K.<sup>1</sup>, Fukuda T.<sup>1</sup>, Fujiwara Y.<sup>2</sup>

<sup>1</sup>Minami Osaka Hospital, Gastroenterology, Osaka, Japan, <sup>2</sup>Osaka City University Graduate School of Medicine, Gastroenterology, Osaka, Japan

**Contact E-Mail Address:** natsu072407@yahoo.co.jp

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy (SAGA) is technically challenging. Some studies reported that ERCP using balloon-assisted enteroscope (BAE) yield better results than previous attempts of ERCP using conventional endoscopes. However, requirement for the specific endoscopic system limits the numbers of hospitals equipped with BAE. Considering the distance from the mouth to the blind end in patients with SAGA, it would be possible to perform ERCP using a conventional gastroscope instead of BAE.

**Aims & Methods:** The aim of this study was to assess the efficacy and safety of ERCP using gastroscope in patients with SAGA. Additionally, we identified the risk factors of failure of ERCP using gastroscope.

This was a retrospective observational study in a single institution. Between April 2013 and September 2018, ERCP procedures using the gastroscope, Q260J (Olympus, Japan, working length of 1040 mm, working channel of 3.2 mm) were performed in patients with SAGA such as post-gastrectomy with Billroth-II (B-II) and Roux-en-Y (R-Y) and post-pancreatoduodenectomy with modified Child method (PD). Success rates of deep insertion, cholangiogram and treatment were evaluated. We estimated the predictive factors of failure of ERCP using gastroscope. Generalized estimating equations (GEE) were used to analyze repeated-measures data.

**Results:** Total 29 patients with 47 procedures were included, comprising B-II (10 patients with 17 procedures), R-Y (13 patients with 18 procedures) and PD (6 patients with 12 procedures). Deep insertion was successful in 41/47 procedures (87%), average insertion time was  $7.7 \pm 6.4$  min. Successful cholangiogram and treatments were obtained in 38/41 (93%) and 36/41 (88%) procedures, respectively. Overall average procedure time was  $35.3 \pm 15.5$  min. Although there was no significant difference in the success rate of deep insertion among three groups, the rate in patients with R-Y tended to be low, the rate in patients with B-II, R-Y and PD being 86% (15/17), 75% (14/18) and 100% (12/12), respectively. Complications occurred in 4/47 procedures (8.5%), and all complications were managed conservatively. There were no independent predictive factors of failure associated with our endoscopic procedures. In a separate analysis focusing on patients with R-Y, laparotomic gastrectomy was the only independent predictive factor of failure of deep insertion by multivariate logistic regression with GEE (odds ratio, 5.06; 95% confidence interval, 1.00–25.47).

**Conclusion:** Since ERCP using the conventional gastroscope was safe and effective in patients with SAGA, gastroscope could be used in place of BAE. However, because the success rate of deep insertion in patients with laparotomic gastrectomy with R-Y was relatively low, such patients should receive ERCP using BAE.

**Disclosure:** Nothing to disclose

## P0922 ERCP IS MORE CHALLENGING IN CASES OF ACUTE BILIARY PANCREATITIS THAN IN ACUTE CHOLANGITIS - AN ANALYSIS OF THE HUNGARIAN ERCP REGISTRY DATA

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is necessary in acute biliary pancreatitis (ABP) when cholangitis or common bile duct stone is present. However, the inflammation of the pancreas and the surrounding tissues might make it more difficult. This topic is not widely studied, therefore we intended to quantify this challenge for the endoscopist by analyzing 5 tertiary centers' data from the prospectively collected data of Hungarian ERCP registry.

**Aims & Methods:** 150 ABP cases and 243 acute cholangitis (AC) cases without ABP were included. Previous papillotomy, altered gastroduodenal anatomy and biliary stricture cases were excluded. The rate of biliary access, advanced cannulation method, adverse event rates, cannulation and fluoroscopy time, as well as subjective difficulty were evaluated.

**Results:** Needle-knife precut use was significantly higher in the ABP than in AC group (33% vs. 21%;  $p=0.013$ ), however, no difference was found between biliary cannulation rates of the two groups (93% vs. 91%). Significantly more pancreatic guidewire manipulation (30% vs. 16%;  $p=0.01$ ) and prophylactic pancreatic stent use (22% vs. 9%;  $p<0.001$ ) was seen in the ABP than in AC group. Moreover, longer cannulation time in the ABP patients (300 vs. 200 s;  $p=0.008$ ) but similar fluoroscopy times (90 vs. 87 s) were measured in the two groups. There was no difference between the adverse events rate of ABP vs. AC cases (immediate bleeding: 11% vs. 9%, only one case required transfusion in the AC group, all other cases were controlled endoscopically; hypoxia: 5% vs. 7%). No significant difference was found in the subjective difficulty, however, there was a trend towards easier examinations ( $<3$  on a 10-point scale) in the AC group (40% vs. 51%;  $p=0.073$ ).

**Conclusion:** ERCP in ABP cases is more challenging than in AC but does not affect the outcomes in our registry data. The increased need for pre-cutting, longer cannulation time and higher rate of pancreatic guidewire manipulations show more frequent difficult biliary cannulation in the ABP patients without worsening the biliary cannulation success rate. The level of subjective difficulty also correlates with these data. Adverse events rates were similar in the groups.

**Disclosure:** Nothing to disclose

## P0923 PERFORATION OF THE LATERAL DUODENAL WALL CAUSED BY PLASTIC BILIARY STENT DISPLACEMENT TREATED WITH OVER-THE-SCOPE-CLIP: A PROSPECTIVELY COLLECTED COHORT

Bureau M.-A., Gkolfakis P., Blero D., Devière J., Lemmers A.  
*Erasmus Hospital, Université Libre de Bruxelles (ULB), Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Brussels, Belgium*

**Contact E-Mail Address:** pgkolfakis@med.uoa.gr

**Introduction:** Duodenal perforation is a complication of ERCP in less than 1% of procedures and can sometimes be caused by the impaction of a distally migrated stent into the lateral duodenal wall. Treatment options when this occurs may include endoscopic treatment with either through-the-scope clips or over-the-scope clips (OTSC) and surgical repair.

**Aims & Methods:** The goal was to determine the incidence of duodenal perforation caused by plastic biliary stents displacement in our center and identify possible predisposing factors. We also wanted to evaluate the efficacy and safety of endoscopic closure with OTSC. To obtain data, we went over the database including all ERCPs performed and screened for duodenal perforation secondary to biliary plastic stents displacement from January 1<sup>st</sup> 2014 to March 31<sup>st</sup> 2019. We then collected individual data of the screened cases.

**Results:** Six cases of ERCP done for lateral duodenal wall perforation caused by plastic biliary stent displacement were identified during that period (0.8% of the 696 ERCPs with plastic stent placement performed over the same period). In most cases the diagnosis of perforation was done less than five days after the stent placement (4/6) and the time between stent insertion and perforation diagnosis ranged from 2 to 91 days. In the majority of these patients (5/6) biliary stenting was done with multiple double flaps straight plastic stents, in all cases the longest stent was the culprit and in most of them (5/6) the culprit stent was in the left intra-hepatic bile ducts. The length of the perforating stents ranged from 12 to 18 cm. Two patients had a history of previous stenting achieving a higher total stents diameter than what was applied at the last examination (patient 3 had a maximum total stents diameter of 18.5 Fr while the total diameter of stents in his last ERCP was of 10 Fr and patient 4 had a maximum total stents diameter of 27 Fr while the total diameter of stents in his last ERCP was of 25.5 Fr). Each patient was treated with a 12mm OTSC which permitted successful closure of all perforations (6/6; 100%) confirmed by subsequent imaging modalities. In five patients no further interventions were needed and outcome at 28 days was excellent for four of them. One patient died at day 17 after perforation closure but his death was not related to the complication. Further intervention after successful treatment was needed for another patient. This patient developed peritonitis requiring laparotomy and peritoneal lavage. The laparotomy did not show any residual leak at the perforation site but the patient eventually died of this complication at day 5 post perforation.

Patients characteristics (Gender, age)	Stenting indication	Days between stent placement and perforation diagnosis	Culprit stent informations	Immediate outcome	28 days outcome
1. M 75	Biliary leak post hepatectomy	21	Double flaps 18 cm 8,5 Fr (1/2 migrated)	Success at closure	No further interventions or complications
2. M 61	Bilioma post liver transplantation	2	BSLC 17 cm 8,5 Fr	Success at closure	No further interventions but death 17 days later (biliary sepsis)
3. F 31	Choledocholithiasis and bile duct stenosis	4	Double flaps 15 cm 7 Fr (1/2 migrated)	Success at closure	No further interventions or complications
4. M 52	Ischemic cholangitis	91	Double flaps 12 cm 8,5 Fr (2/3 migrated)	Success at closure	No further interventions or complications
5. M 72	Bile duct compression after hepatic artery embolization	2	Double flaps 13 cm 8,5 Fr (1/2 migrated)	Success at closure	Peritonitis needing laparotomy and death 3 days later
6. F 46	Anastomotic stenosis post liver transplantation	2	Double flaps 12 cm 8,5 Fr (1/2 migrated)	Success at closure	No further interventions or complications

[Table 1: Cases Summary]

**Conclusion:** Perforation of the lateral duodenal wall by a biliary stent is a rare complication of ERCP in a tertiary referral center. In this study, most cases were related to multiple straight plastic stents with double flaps. A history of maximal total stents diameter achieved before the last ERCP, use of longer stents ( $>12$  cm) and placement of stent into the left intra-hepatic bile ducts could be potential risk factors. OTSC appears as an effective treatment with a closure success rate of 100% in our cohort.

**Disclosure:** Nothing to disclose

## P0924 WHO SHOULD ADMINISTER SEDATION DURING ERCP - ANESTHESIOLOGIST, INTENSIVIST OR ENDOSCOPIST? A COMPARATIVE PROSPECTIVE STUDY

**Introduction:** The proper training in sedation and who should administer it during ERCP still unknown.

**Aims & Methods:** To compare safety and effectiveness of sedation during ERCP (sERCP) regarding which medical doctor directs it.

A comparative prospective non-randomized study done in daily practice. Consecutive patients who underwent to ERCP were collected at two centers. January 2017 - May 2018. Sedation was directed either by an endoscopist (endoscopist-directed propofol: EDP), on Monday or by an intensivist (intensivist-administered propofol: IAP), on Wednesday or by an anesthesiologist (monitored anesthesia care: MAC), on Thursday. The safety was measured by the appearance of serious adverse events (SAE) and the effectiveness, by the cancelled ERCP rate, sedation time and patient position that determined ease of ERCP and quality of radiologic images.

**Results:** 454 patients (Age: 72.7 ±15.7y; women: 54.63%); 147 into EDP group, 137, IAP group and 170, MAC group. The endoscopist had the largest experience in sERCP (>100 procedures): 98%, p=0.000 and he administered only propofol in 81.9%, the intensivist administered propofol plus midazolam in 78.7% and anesthesiologist, propofol plus other agents (i.e. opioids, ketamine) in 86.2%, p=0.000. The sedation was deepest in MAC, Observers's Assessment of Alertness-Sedation score (OAAS): 5.19 ±0.6, p=0.000. The SAE rate was 8.6%, lowest in EDP: 4.8%, p=0.042. The SpO<sub>2</sub> < 70% was the most frequent SAE: 4.5%, highest in MAC: 6.1%, p=0.085 and it had required more respiratory resuscitation measures (chin-lift maneuver, increasing of FIO<sub>2</sub> or Guedel airway insertion) in MAC and IAP than EDP, p=0.003. The tracheal intubation was most frequent in MAC: 1.8%, p=0.074. Concerning effectiveness, the highest cancelled ERCP rate was observed in MAC: 2.9%, p=0.015. Similarly, in this group the lateral decubitus position was most frequent (31.6%, p=0.000), which determined the worst radiologic image (17.8%, p=0.000). The sedation time was shortest in IAP: 44.4 ±1.8 min, p=0.023. In a multivariate analysis, the shorter training on sERCP: OR =6.56 (3.18-13.54 CI95%), Obstructive sleep apnea: OR =4.34 (2.07-9.11 CI95%) and age ≥75years: OR =2.18 (1.03-4.63 CI95%) were associated to appearance of complications.

**Conclusion:** Our data suggest that sERCP is safer and more effective when is administered by an expert nursing team directed by an endoscopist.

**Introduction:** EUS-directed transgastric ERCP is an emerging technique for pancreaticobiliary intervention in patients with a history of Roux-en-Y gastric bypass (RYGB). It can allow ERCP to be performed in a minimally invasive fashion and with a high technical success rate.

**Aims & Methods:** The aim of this study was to analyze the safety and efficacy of EDGE procedures performed at a single tertiary care center. Patients with a history of RYGB who underwent an EDGE procedure between January 2018 and April 2019 were included in the study. Patient demographics,

procedure time, technical success and complications (bleeding, infection, perforation and pancreatitis) were recorded. Total time to complete procedure and hospital length of stay was calculated by addition of the time for EUS and ERCP. Statistical analysis was performed using SPSS 23 (IBM, Armonk, NY).

**Results:** Eighteen patients were included in the study. Mean age was 61 ±11 years and 78% (n=14) were females. EDGE was performed after a failed ERCP in 22% (n=4). EDGE was performed as a same-day procedure in 33% (n=6) and access route was transgastric for 89% (n=16) vs transjugular for 11% (n=2). Technical success was 100% (n=18). LAMS was removed during the initial ERCP for 44% (n=8), follow-up EGD for 17% (n=3), elective surgery (Whipples procedure) for 3% (n=17%), follow up ERCP for 11% (n=2), follow-up EUS for 6% (n=1) and left in place for 6% (n=1). 72% (n=13) underwent spontaneous closure of the fistula, 17% (n=3) underwent closure intraoperatively, 6% (n=1) underwent closure with endoscopic mucosal clips. Post-procedural bleeding occurred in 6% (n=1). LAMS dislodgement during the procedure with successful replacement of the LAMS occurred in 6% (n=1). The mean hospital length of stay was 1.09 ±0.76 days.

**Conclusion:** EDGE is a safe and efficacious procedure that has a 100% technical success rate and short length of stay with minimal complications.

**Introduction:** Pancreatic duct (PD) stones are a common complication in chronic calcifying pancreatitis (CCP) and contribute to pain onset and pain exacerbation. (Digital) single-operator pancreaticoscopy (d-SOP) guided lithotripsy was shown to be a promising option of therapy regarding technical success (95% ductal clearance) and short-term pain relieve. However, there is only little evidence of mid-and long-term clinical success and impact on quality of life.

**Aims & Methods:** Analysis of clinical success and impact on quality of life after d-SOP guided lithotripsy in CCP in ongoing follow up. A single-center, retrospective analysis of all d-SOP guided lithotripsies (n=23) of PD stones in 20 CCP patients after introduction of next generation d-SOP (SpyGlass DS) in 2015. Clinical success was determined by a systematic questionnaire regarding pain intensity and incidence as well as quality of life after 3,6 and 12 months in an ongoing follow up.

**Results:** After d-SOP guided lithotripsy technical success (PD decompression) was achieved in a total of 19/20 cases. Clinical success (pain reduction >50 % in numerical rating scale (NRS) pain score) was achieved in 19/20 cases. In early follow-ups 95% of the patients reported major improvement in symptoms and quality of life. In the latest (12 months) follow up 2 patients were referred to a surgeon for partial pancreatectomy, one patient was lost to follow-up. Of the 17 remaining patients clinical success - as defined above - was persistent in 11 cases and 12 patients described major improvements in symptoms and disability in daily life. There was no need of further interventional therapy except subsequent stenting in case of persistent PD strictures.

**Conclusion:** d-SOP guided lithotripsy was found to be safe and effective regarding technical success and clinical outcome. Beneficial effects on symptom control and quality of life seem to last in the majority of CCP patients after a 12 months follow-up.

**Introduction:** ESGE guideline recommends using pancreatic guidewire (PGW)-assisted biliary cannulation in patients where biliary cannulation is difficult and repeated unintentional access to the main pancreatic duct occurs. However, insertion of the GW into the pancreatic duct has a risk of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis. Recently, J-tipped GW designed for improving luminal passage have been developed and reported to be beneficial in selective biliary cannulations. Although J-tipped GW was not applicable to pancreatic duct due to its large tip radius, the newly developed small J-tipped GW with a smaller loop has enabled pancreatic duct interventions.

**Aims & Methods:** The aims of this study were to evaluate the safety and efficacy of newly developed small J-tipped guidewire for PGW-assisted biliary cannulation. PGW-assisted biliary cannulation for difficult biliary cannulation with naïve papilla were performed in a total of 277 cases. We used angle-tipped GWs from January 2011 to February 2014 and small J-tipped GWs from March 2014 to September 2016. The patients were divided into two groups chronologically, according to the time period during which guidewires were used for PGW-assisted biliary cannulation: the angle-tipped GW group (from January 2011 to February 2014) and the small J-tipped GW group (from March 2014 to September 2016). Pancreatic stent was inserted after PGW-assisted biliary cannulation. The success rates and complications were evaluated.

**Results:** Success rates of PGW-assisted biliary cannulation were 81% in the small J-tipped GW group and 70% in the angle-tipped GW group, respectively. There was no statistical difference between the two groups ( $p = 0.052$ ). The rate of post-ERCP pancreatitis was significantly lower in the small J-tipped GW group compared with that in the angle-tipped GW group (6.3% vs 19.0%,  $P = 0.01$ ). Moreover, localized pancreatitis or pancreatic ductal leakage caused by injury of pancreatic duct were significantly less in the small J-tipped GW group compared to the angle-tipped GW group. Multivariate analysis showed that the use of the small J-tipped GW was the only factor reducing the risk of post-ERCP pancreatitis (OR 0.32, 95% CI 0.12-0.87,  $P = 0.026$ ).

**Conclusion:** Newly developed small J-tipped GW reduce a risk of developing post-ERCP pancreatitis in patients with difficult biliary cannulation.

**Contact E-Mail Address:** tawfik.khoury.83@gmail.com

**Introduction:** The prevalence of post endoscopic retrograde cholangiopancreatography pancreatitis (PEP) is variable and ranges from 5-25%. Fatty liver disease has been increasingly encountered in the last decade and it is already reported as a risk factor for several extra-hepatic diseases, however, it has not been reported as a risk factor for PEP.

**Aims & Methods:** We aimed to assess whether NAFLD is a risk factor for the development of PEP. We performed a retrospective multicenter study. All patients who underwent ERCP during 2014-2016 who had a diagnosis of NAFLD by abdominal imaging were eligible for inclusion. Four hundred and one patients were included, among them, thirty-eight (9.5%) were diagnosed with PEP according to clinical, laboratory and radiological criteria.

**Results:** The mean age in groups A (patients without PEP) and group B (patients with PEP) were  $61.2 \pm 20.9$  and  $67.6 \pm 19.3$ , respectively. Forty-five percent in group A and 44% in group B were males. The most common indication for ERCP in the two groups was confirmed CBD stones, cholangitis and obstructive jaundice. One-hundred twenty-four patients (34%) in group A had fatty liver as diagnosed by pre-endoscopic ultrasound (US) compared to 21 patients (55.3%) in group B,  $P=0.01$ .

In univariate analysis, several predictors of PEP were identified. Fatty liver (OR 2.363, 95% CI 1.211-4.614,  $P=0.01$ ), AST (OR 1.008, 95% CI 1.000-1.016,  $P=0.04$ ), ALT (OR 0.979, 95% CI 0.968-0.991,  $P=0.0007$ ), ALP (OR 1.008, 95% CI 1.001-1.015,  $P=0.01$ ), GGT (OR 1.014, 95% CI 1.006-1.021,  $P=0.0005$ ) and total bilirubin (OR 1.141, 95% CI 1.039-1.253,  $P=0.005$ ) were statistically significant in predicting PEP. In multivariate regression analysis, only fatty liver showed statistically significant correlation with PEP (OR 3.224, 95% CI 1.548-6.713,  $P=0.001$ ), while the other parameters showed very weak association with PEP, with ROC area under the curve (AUC) of 0.8156. Notably, no patients with dilated CBD of more than 10 mm had developed PEP.

**Conclusion:** NAFLD was shown to be a risk factor for PEP. Therefore, we suggest to consider prophylactic pancreatic stenting and/or NSAID's suppositories among these patients.

**Disclosure:** Nothing to disclose

## P0929 IS VASCULARITY ENOUGH TO PREDICT NEOPLASIA IN BILE DUCT LESIONS DURING PERORAL CHOLANGIOSCOPY?

Robles-Medrand C., Oleas R., Olmos J., Alcivar-Vasquez J., Puga-Tejada M., Baquerizo-Burgos J., Pitanga-Lukashok H. Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Gastroenterology and Endoscopy Division, Guayaquil, Ecuador

**Contact E-Mail Address:** robertoleas@gmail.com

**Introduction:** The direct visualization of the intraductal biliary system via peroral cholangioscopy (POCS) changes the clinical management in patients with bile duct lesions. Macroscopic features have been used to determine neoplasia in bile duct lesions during POCS such as the presence of masses or irregular surfaces; however, the presence of bleeding, oozing or tortuous vessels as signs of neovascularity might be most the accurate findings for neoplasia.

**Aims & Methods:** To evaluate the role of neovascularity in bile duct lesions for the prediction of neoplasia during peroral cholangioscopy.

A cohort study with prospectively collected endoscopic data of patients with bile duct lesions evaluated via POCS who was aged  $\geq 18$  years. Patients with lesions but with no subsequent histological confirmation, with less than six months of follow-up, or concomitant choledocholithiasis during POCS were excluded for analysis. POCS were performed using a digital, single-operator cholangioscopy system (Spyglass®, Boston Scientific, Marlborough, MA, USA). Neovascularity was defined as the presence of irregular or spider vascularity on bile duct lesions. The neovascularity overall diagnostic accuracy was estimated considering a six months follow-up as a gold standard. Inter-observer agreement analysis was performed between two endoscopists (JO & JAV). A  $p$ -value  $< 0.05$  was considered statistically significant. Data were analyzed in R-3.4.2 (R Foundation for Statistical Computing; Vienna, Austria).

	Total (n=95)	Neoplastic (n=52)	Non-neoplastic (n=43)	p-value
Age (years), median (range)	66 (20-93)	71.2 (37-93)	61 (20-87)	<0.001
Gender (female), n (%)	51 (53.7)	26 (50.0)	25 (58.1)	0.428
Main POCS indication (Tumor suspicion/ indeterminate stenosis), n/n	50/45	42/10	8/35	<0.001
Previous ERCP, n (%)	40 (42.1)	15 (28.8)	25 (58.1)	0.039
Bile common duct localization, n (%)	61 (64.2)	30 (57.7)	31 (72.1)	0.028
Presence of neovascularity, n (%)	65 (68.4)	49 (94.2)	16 (37.2)	<0.001
Neoplastic histology, n (%)	48 (50.0)	48 (92.3)	0	<0.001

[Table 1. Baseline characteristics between neoplastic vs. non-neoplastic groups according to follow-up.]

**Results:** Ninety-five patients were enrolled, median age 65.6 (16 - 93) years old, 56 (55%) were female. Neovascularity signs were appreciated in 65/95 (68%) of cases. The biopsies sample were adequate in 90/95 (95%) cases. Histology confirmed neoplasia in 45/61 (74%) cases; while, follow-up in 49/65 (75%).

Table 1 summarized baseline characteristics between neoplastic vs. non-neoplastic groups according to follow-up. The vascularity for predicting neoplastic lesions reached sensitivity, specificity, positive and negative predictive value (PPV & NPV), positive & negative likelihood ratio, observed and inter-rater agreement of 94%, 63%, 75%, 90%, 2.53 (95% IC 1.71 - 3.76), 0.09 (95% IC 0.03 - 0.28), 80% and 57% ( $p < 0.001$ ), respectively. The interobserver agreement analysis exhibited an excellent agreement ( $K > 80\%$ ;  $p < 0.001$ ).

**Conclusion:** Irregular or spider vascularity on bile duct lesions during POCs evaluation predict properly biliary neoplastic lesions.

**Disclosure:** Nothing to disclose

## P0930 ANALYSIS OF POST-ERCP PANCREATITIS RATE IN THE TIME TO SUCCESSFUL BILIARY DEEP CANNULATION AND OPERATOR CHANGE FROM TRAINEE TO EXPERT

Kawamoto H., Tanikawa T., Ishii K., Urata N., Nakamura J., Suehiro M., Sasai T., Nishino K., Kawanaka M., Haruma K.  
Kawasaki Medical School General Medical Center, Internal Medicine, Okayama, Japan

**Contact E-Mail Address:** hirofumi.kawamoto@gmail.com

**Introduction:** Selective biliary deep cannulation is a first step of biliary endoscopic treatment and one of the most important procedures to master for trainees. When this procedure is time-consuming, the complication risk may increase. We retrospectively analyzed the relation between biliary cannulation time and post-ERCP pancreatitis (PEP) and assumed the time to change an operator from a trainee to an expert.

**Aims & Methods:** Between April, 2011 and March, 2019, there are 996 patients with intact papilla [536 male, median of age 75 year old (IQR: 66-83)] in whom the selective biliary deep cannulation was mandatory for the endoscopic treatment. The diseases of the patients were benign in 765 cases (76.8%). ERC was usually commenced with conventional cannulation technique. Wire-guided cannulation, pancreatic guide wire method, or needle knife precut were allowed. The expert (EX) was H.K. who experienced more than 3000 ERCP cases and the other operators were defined as trainees (TR).

Although the operator change from TR to EX was within EX discretion, the time of operator change was principally within 15 minutes. The PEP was defined as severe epigastric pain and more than twice value of upper serum AMY level which were occurred in the patients within 24 hours after treatment. The degree of PEP severity was classified according to Cotton criteria. The rate of PEP was analyzed according to the first operator and time.

**Results:** The success rate of biliary cannulation was 98.9% (985/996). The median time of cannulation was 5 minutes (IQR: 2-15). PEP rate was 6.0% (60/996). The moderate PEP was noted in 5.0% (3/60) and the rest mild. The number of EX-first cases was 310 (31.1%) and that of TR-first cases 686 (68.9%). The rate of operator change from TR to EX was 31.6% (217/686). The success rate of cannulation in EX-first cases was 99.7% (309/310) and that in TR-first cases was 98.5% (676/686); ( $p = 0.11$ ). The median cannulation time was 3 minutes (IQR: 1-8.8) in EX-first cases and that in TR-first cases was 5.5 minutes (IQR: 2-14.8); ( $p < 0.001$ ). The PEP rate in EX-first cases was 4.2% (13/310) and that in TR-first cases was 6.9% (47/686); ( $p = 0.10$ ). In TR-first cases, median successful cannulation time by TR alone was 6 minutes (IQR: 2-15) and median time of operator change was 10 minutes (IQR: 7-15). Comparing the PEP rate according to successful cannulation time: within 10 minutes (short time: ST) and more than 10 minutes (long time: LT), the PEP rate was 4.4% (31/700) in ST and 9.8% (29/296) in LT; ( $p < 0.01$ ).

Compared between the first operators in ST cases, the PEP rate in EX-first cases was 3.6% (9/247) and that in TR-first cases was 4.9% (22/453); NS ( $p = 0.46$ ). In LT cases, that in EX-first cases was 6.3% (4/63) and that in TR-first cases 10.7% (25/233); NS ( $p = 0.30$ ). Compared in intra-operator time, in EX first cases, there was no significant difference (3.6% vs 6.3%:  $p = 0.34$ ) in PEP rate between ST and LT. However, compared in TR-first cases, significant increase in PEP rate was noted (4.9% vs 10.7%:  $p < 0.01$ ). In operator-changed cases, total PEP rate was 6.9% (15/217). PEP rate in

ST was 4.3% (5/116) and that in LT was 9.9% (10/101); NS ( $p = 0.10$ ). In cases that successful cannulation was achieved by TR alone, total PEP rate was 6.8% (32/468). However, PEP rate significantly increased ( $p < 0.001$ ) from 5.1% (ST: 21/412) to 19.6% (LT: 11/56).

**Conclusion:** In case of time-consuming, the more PEP rate increases, especially in TR-first cases. These data suggests that operator change may be considered in case that TR consumes more than 10 minutes to achieve successful deep biliary cannulation.

## P0931 ERGONOMIC INJURIES IN ENDOSCOPISTS AND THEIR RISK FACTORS

Kalwar H.A., Kamani L.

Liaquat National Hospital, Gastroenterology, Karachi, Pakistan

**Contact E-Mail Address:** hamidgulk@yahoo.com

**Introduction:** Endoscopists often experience musculoskeletal pain and injury (most often in the back, neck, shoulders, hands, wrists, and thumbs) that are associated with the minute and repetitive strain that is placed on these areas during endoscopic procedures. The aim of this study is to assess the musculoskeletal injuries in endoscopists and their risk factors.

**Aims & Methods: Objective:** To assess frequency of ergonomic injuries in endoscopists and their risk factors, at a tertiary care hospital, Karachi.

**Subject & methods:** This cross sectional study was conducted at the Department of Gastroenterology, Liaquat National Hospital after informed written consent on endoscopy practitioners doing endoscopies throughout the Pakistan. Endoscopists were asked to fill-up the Performa. Chi square test was used for analysis. P-value  $< 0.05$  was considered as significant.

**Results:** Out of 61 endoscopists 58 (95.1%) were male and 3 (4.9%) were female with the mean age of 44.02±7.873 years. The most common ergonomic injury noted was back pain in 25 patients (41%), leg pain in 14 (23%) and hand pain in 12 (19.7%). Ergonomic injuries were common in endoscopists with higher BMI ( $p < 0.004$ ), were seen more in endoscopists performing high number of procedures ( $p < 0.001$ ), more commonly noted in endoscopists with higher cumulative duration of GI practice ( $p < 0.001$ ) and common in endoscopists not doing regular exercise ( $p < 0.030$ ). But ergonomic injuries were not associated with mini-rests between procedures ( $p < 0.133$ ), glove size of the endoscopists ( $p < 0.102$ ) and hand dominance (right handed & left handed) ( $p < 0.182$ ).

**Conclusion:** Among endoscopists there is a increased prevalence of injuries definitely or potentially related to endoscopy. Higher procedure volume, cumulative years performing endoscopy, BMI and lack of regular exercise are associated with more work-related injuries.

**Disclosure:** Nothing to disclose

## P0932 PANCREATIC PARENCHYMA ATROPHY AND DILATED MAIN PANCREATIC DUCT CAN BE NEGATIVE PREDICTORS OF PANCREATITIS RELATED TO BILIARY SEMS INSERTION

Yamada T., Umemura M., Asai Y.

Iwata City Hospital, Gastroenterology, Iwata, Japan

**Contact E-Mail Address:** masahiro58398@docomo.ne.jp

**Introduction:** Obstructive jaundice is crucial for the patients with pancreaticobiliary malignancy. Insertion of self-expansive metallic stent (SEMS) into biliary duct is known useful to improve obstructive jaundice and quality of life (QOL) of these patients. However, post ERCP pancreatitis (PEP) after SEMS insertion across the papilla of Vater is one of the most important adverse events affect patients' QOL.

**Aims & Methods:** Ninety patients received biliary SEMS insertion for biliary obstruction due to malignancy in Iwata City Hospital from 2010 to 2018 were reviewed. We evaluated the relationship between incidence of PEP after biliary SEMS insertion and clinical factors, including age, sex, serum amylase level, tumor location, cause of obstruction, with/without EST, with/without pancreatography, diameter of main pancreatic duct (MPD), and thickness of pancreatic parenchyma.

**Results:** Mild and severe PEP were diagnosed in 11 (12.2%) and 1 (1.1%) patients, respectively. Only the thickness of pancreatic parenchyma ( $p < 0.001$ ) and diameter of MPD ( $p < 0.001$ ) showed significant difference between PEP and non-PEP groups. However, other factors did not show significant difference in the incidence of PEP. The incidence of PEP among patients

whose thickness of pancreatic parenchyma at the left side of corpus vertebræ were less than 10mm (1.7%) in computed tomography was quite lower than patients whose thickness were 10mm or more (32.2%) ( $p < 0.001$ ). Similarly, the wider (5mm or more) diameter of MPD (1.6%) reduced the incidence of PEP compared to narrower ones (30.0%) ( $p < 0.001$ ).

**Conclusion:** These results imply that pancreatic parenchyma atrophy and dilated MPD are negative predictive factor of pancreatitis related to biliary SEMs insertion.

**Disclosure:** Nothing to disclose

### P0933 PARTIALLY COVERED SELF-EXPANDABLE METAL STENTS REPLACE PLASTIC STENTS FOR MALIGNANT EXTRAHEPATIC BILIARY OBSTRUCTION: RESULTS OF A MEDICAL CENTER

Huang W.-H., Yu C.-J., Ting C.-F., Yang C.-Y., Chuang S.-C., Peng C.-Y.

**Contact E-Mail Address:** u97766.huang@msa.hinet.net

**Introduction:** Endoscopic biliary stenting has been well established as standard treatment of malignant biliary obstruction. Comparing with plastic stent, self-expandable metal stent (SEMS) has longer stent patency. However, few reports are published to compare primary SEMS placement and reintervention of SEMS to replace plastic stent.

**Aims & Methods:** The aim of this study was to assess the differences in stent patency and complications between patients with primary metal stent placement and reintervention to replace previous plastic stent.

From Jan., 2010 to Dec., 2016, patients with malignant obstruction below the common hepatic duct (CHD) confluence undergoing biliary stenting with partially covered self-expandable metal stents (PCSEMS) were retrospectively analyzed. Malignancy was diagnosed based on clinical, laboratory, imaging, and pathologic studies.

**Results:** A total of 81 patients (43 female and 38 male; mean age  $72.5 \pm 13.1$  years) with PCSEMS for malignant obstruction below the CHD confluence were included. Malignancy included pancreatic cancer ( $n=58$ , 71.6%), cholangiocarcinoma ( $n=12$ , 14.8%), ampullary cancer ( $n=8$ , 9.9%), metastatic cancer ( $n=2$ , 2.5%), and gallbladder cancer ( $n=1$ , 1.2%). Strictures were located at upper ( $n=3$ , 3.7%), middle ( $n=12$ , 14.8%), and distal extrahepatic duct ( $n=66$ , 81.5%), respectively. Average length of stricture was  $21.2 \pm 9.0$  mm. All patients underwent endoscopic sphincterotomy before metal stent placement. The length of PCSEMS was 40 mm ( $n=11$ , 13.6%), 60 mm ( $n=58$ , 71.6%), and 80 mm ( $n=12$ , 14.8%). The lumen diameter of PCSEMS was all the same (10 mm). Twenty of 81 (24.7%) patients received chemotherapy and/or radiotherapy. PCSEMS was placed as a primary intervention in 21 (26%) patients, and PCSEMS replacing plastic stent was performed in 60 (74%) patients. Overall stent patency was  $210 \pm 112$  days. During the period of follow-up ( $190.2 \pm 190.5$  days), stent complications occurred in 25 of 81 (31%) patients and included cholangitis ( $n=10$ ), stent migration ( $n=6$ ), cholecystitis ( $n=2$ ), pancreatitis ( $n=2$ ), stent occlusion ( $n=2$ ), perforation ( $n=1$ ), liver abscess ( $n=1$ ), and hemorrhage ( $n=1$ ). Although stent patency, and stent complications were lesser in reintervention (26.7%) than in primary intervention (42.9%), the differences were not statistically significant ( $P > 0.05$ ).

**Conclusion:** For patients with malignant obstruction below the CHD confluence, primary metal stent placement and reintervention with PCSEMS showed comparable stent patency and complications.

**Introduction:** European society of gastrointestinal endoscopy (ESGE) recommends (1) rectal indomethacin or diclofenac prior to endoscopic retrograde cholangiopancreatography (ERCP) as a prophylaxis for post-ERCP pancreatitis (PEP). Primary sclerosing cholangitis (PSC) is a chronic chole-

static liver disease characterized by intrahepatic or extrahepatic stricturing and markedly increased risk for biliary neoplasia (2). ESGE/EASL suggest (3) that ERCP can be done in PSC if MRC plus liver biopsy is equivocal or contraindicated in patients with persisting clinical suspicion of PSC and in addition ERCP is done for ductal sampling (brush cytology) and dilatation of significant strictures. The risk for PEP is approximately 7% in PSC (4).

**Aims & Methods:** Our aim was to evaluate the role of rectal diclofenac as a prevention of PEP or other ERCP-related complications in PSC patients. Since November 2013 all ERCP patients without contraindications in Helsinki University Hospital (HUH) Endoscopy unit in Meilahti have received rectal diclofenac before ERCP procedure. This survey was a retrospective patient-control study, where we collected the clinical data from patient records from 1000 consecutive ERCP procedures made for patients with PSC or suspected PSC at HUH Endoscopy unit and with administration of rectal diclofenac (procedures after November 2013). Control procedures ( $n=1000$ ) were with the same indication but without administration of rectal diclofenac (ERCP procedures before November 2013). Totally 2000 ERCPs were made for 925 patients between January 2009 and January 2018. Acute PEP and other ERCP-related complications were evaluated.

**Results:** PEP developed in 49 patients (4.9%) in diclofenac group and 62 patients (6.2%) in control group ( $p=0.241$ ). There was no statistically significant difference between the groups in severity of PEP or in other acute complications. Risk of PEP was slightly more elevated in patients with native papilla: 11.4% in diclofenac group and 8.7% in control group,  $p=0.294$ .

	Diclofenac group (n=1000)	Control group (n=1000)	p-value
Age* at ERCP	40 (16-73)	39 (16-79)	0.568
Female	370 (48.0)	401 (52.0)	0.168
BMI* (kg/m <sup>2</sup> )	25.0 (13.7-45.0)	24.5 (12.1-48.0)	0.222
Native papilla	193 (19.3)	358 (35.8)	0.000
Diverticulum	24 (2.4)	34 (3.4)	0.230
Duration of ERCP* (minutes)	26 (5-94)	26 (5-123)	0.953
Biliary papillotomy	214 (21.4)	409 (40.9)	0.000
Pancreatic papillotomy	41 (4.1)	80 (8.0)	0.000
Inflammatory bowel disease	743/975 (76.2)	478/944 (50.6)	0.000
Post-ERCP pancreatitis (PEP)	49 (4.9)	62 (6.2)	0.241
Severity of PEP			0.130
mild	34/49 (69.4)	36/62 (58.1)	
moderate	10/49 (20.4)	22/62 (35.5)	
severe	5/49 (10.2)	4/62 (6.5)	
Cholangitis	15/1000 (1.5)	28/1000 (2.8)	0.063
Bleeding	7/1000 (0.7)	2/1000 (0.2)	0.179
Perforation	6/1000 (0.6)	5/1000 (0.5)	1.000
Other	0/1000 (0.0)	1/1000 (0.1)	1.000
PEP in native papilla patients	22/193 (11.4)	31/358 (8.7)	0.294

[Table 1. Patient characteristics and ERCP complications. Numerical data are presented as median (range)\* or number of patients (%). \*\*Cotton et al. (6)]

**Conclusion:** In low-risk unit, diclofenac does not reduce the risk of PEP or other ERCP-related complications in patients with PSC. In addition, there is no significant difference in PEP rate in patients with native papilla compared to those with biliary papillotomy. The results of the present study are in line with our previous report in non-PSC-patients (5).

**Contact E-Mail Address:** godi.szilard@gmail.com

**Introduction:** In cases of inadvertent pancreatic guidewire cannulation, transpancreatic sphincterotomy (TPS) is a feasible alternative to achieve biliary access. We intended to compare several aspects of TPS with the standard needle-knife precut papillotomy (NKPP) using data from the Hungarian ERCP Registry

**Aims & Methods:** 76 TPS and 240 NKPP cases could be analyzed from the database. Biliary cannulation success rate, postERCP pancreatitis (PEP) rate, use of prophylactic measures, cannulation time and subjective difficulty were compared.

**Results:** Biliary cannulation achieved more frequently after TPS (70/76, 92.1%) compared to NKPP (200/240, 83.3%,  $p=0.058$ ). PEP developed at a similar rate after TPS (3/76, 3.9%) and NKPP (8/240, 3.3%). Prophylactic pancreatic stent (PPS) was inserted in 44 of 76 (57.9%) cases in the TPS group, while only in 15 of 240 (6.3%) cases in the NKPP group. Multiple pancreatic guidewire passages occurred in 26 patients in the NKPP group, but PPS was placed only in 6 (23.1%) of them. Indomethacin suppository was used in 52.6% of TPS and 49.2% of NKPP cases. Additional needle-knife precut was needed after TPS in 7 cases, 1 PEP developed in these cases. We found no statistically significant difference in the subjective difficulty on a 10- point scale between the two techniques (TPS: 5.8 vs. NKPP: 6.7) and there was also no difference in the mean cannulation time (TPS: 9.0 min vs. NKPP: 7.4 min).

**Conclusion:** TPS is an effective and safe technique in cases of difficult biliary access and also allows the use of preventive methods (e.g. PPS) easily. However, the Hungarian practice shows a serious deviation from international recommendations in this regard. One of the long-term goals of the registry is to improve the use of PEP prevention techniques in Hungary.

**Introduction:** Selective biliary duct cannulation (BDC) was analysed in our current practice based on the data from five tertiary centers according to the recent evidence-based ESGE algorithm of biliary access.

**Aims & Methods:** The prospectively collected ERCP Registry contained 1011 cases of intact papilla with biliary indications. The rate of difficult biliary access and the usage of advanced biliary cannulation methods were analysed.

**Results:** Simple cannulation (659 cases, 65.2%): Deep BDC was achieved with guidewire in 305 cases (30.2%), with papillotomy in 312 cases (30.9%), but failed in 39 cases (3.9%) due to anatomical obstacles. In 3 (0.3%) cases the BDC was not successful. The average cannulation time was 125 s, only 6.1% of the patient had longer than 300 s cannulation time. Twelve (1.9%) post-ERCP pancreatitis (PEP) occurred. Pancreatic guidewire (PGW) assisted cannulation (134 cases, 13.3%): BDC was achieved with double guidewire in 27, with papillotomy in 3, while after prophylactic

pancreas stent (PPS) insertion in 12 cases. Pre-cutting was used after PGW or PPS insertion in 12 and 33 cases, TPS was performed in 47 cases. The average cannulation time was 481 s. Biliary access failed in 18 patients (13.4%), while PEP rate was 2.2%. Needle-knife precut (NKP) (160 patients, 15.8%): BDC failed in 28 (17.5%), while PEP developed in 7 cases (4.4%). The average cannulation time was 514 s. Needle-knife fistulotomy (NKF) (58 patients, 5.7%): BDC failed in 4 (6.9%), PEP developed in 2 cases (3.4%). The average cannulation time was 466 s. The overall failure rate of BDC in our cohort was 5.2% (53/1011) excluding anatomical reasons. 42 out of 44 initially failed procedures were successfully completed later on.

**Conclusion:** Advanced biliary cannulation methods were used in our tertiary centers in more than one third of the cases. NKF had the highest BDC rate and required the shortest cannulation time. The PEP rates were similar in the different groups.

**Contact E-Mail Address:** johnkalantzis@hotmail.com

**Introduction:** Acute pancreatitis is a potentially serious complication of Endoscopic Retrograde Cholangiopancreatography (ERCP). Independent patient-related and procedure-related factors increase the risk of post-ERCP pancreatitis (PEP). Non-steroidal anti-inflammatory drugs (NSAIDs) administered mainly rectally before or immediately after endoscopy, have demonstrated an efficacy in reducing the incidence of PEP.

**Aims & Methods:** Investigating the difference in the incidence of PEP among intramuscular (IM) or rectal (PR) administration of diclofenac before ERCP, taking into account patient-related and procedure-related factors associated with PEP, as well as the intraprocedural hemorrhage during the endoscopy. The retrospective study of our department's records revealed rectal administration of diclofenac for two years 2014-15 (N = 233) and intramuscular for the consecutive two years 2016-17 (N = 283). Data analysis was performed with the SPSS statistical package.

**Results:** 516 patients (294 men, 222 women) were included in the study (mean age: 72 years). The indication was either choledocholithiasis (N=351, 68%) or benign/malignant biliary/pancreatic stenosis (N=165, 32%). The diagnosis of PEP was defined by the criteria of the Atlanta Classification. The total incidence of PEP was 4.5% (N=23), with no significant differences between rectal (N = 12, 5.2%) and intramuscular (N=11, 3.9%) route of administration ( $p=0.633$ ). The factor that appeared to be of significance was pre-cut sphincterotomy, since patients who had pre-cut sphincterotomy had a 2.67 fold higher probability of PEP ( $p=0.050$ ). Marginal significance was also revealed for the passage of the guidewire in the pancreatic duct more than once (10.8% vs 4%) ( $p=0.074$ ), as well as with the duration of cannulation attempts over 10 minutes (7.4% vs 3.3%) ( $p=0.069$ ). Younger age, female gender, history of pancreatitis or PEP, non-dilated extrahepatic bile ducts, normal serum bilirubin, pancreatic injection, biliary balloon sphincter dilation and failure to clear bile duct stones did not show statistically significant results. Intraprocedural bleeding during ERCP (N=11, 2.1%) was almost twice higher in the rectal (N=7, 3%) compared to intramuscular group (N=4, 1.4%) ( $p=0.236$ ). Although pancreatic stent was not placed in 21 of the 23 patients who developed PEP, it did not appear statistically significant in the prevention of PEP either alone ( $p=0.703$ ) or in combination with diclofenac administration ( $p=0.517$ ). The mean amylase value in PEP incidents did not show significant difference between the two NSAIDs subgroups ( $p=0.639$ ), as it did not in the mean amylase value in patients who had hyperamylasemia after ERCP ( $p=0.172$ ). In the multivariate analysis the only significant and independent factor for PEP was precut sphincterotomy ( $p=0.029$ ), with these patients displaying 2.7 times greater probability of PEP manifestation.

**Conclusion:** The results of our study did not reveal any statistically significant difference between rectal or intramuscular administration of diclofenac in the prevention of PEP, despite the opposite results of the majority of the so far published studies and meta-analysis. Some of the risk factors associated with increased risk of PEP were also confirmed

**Introduction:** Traversing the stricture with a guidewire is a prerequisite for endoscopic treatment of biliary strictures developed after living donor liver transplantation (LDLT). Percutaneous, combined (magnetic compression anastomosis) or surgical methods can be used in cases of failure. As the biliary anastomosis is performed in patients with anatomic variations, there is great diversity in the biliary strictures. In this study, we aimed to evaluate the effect of biliary anastomosis and biliary strictures on the success of endoscopic treatment and suggest a radiologic classification.

**Aims & Methods:** The cholangiographic findings of 125 biliary strictures developed among 104 patients (77 male, mean age:51 years) with right lobe LDLT and choledoch-choledochostomy, who underwent ERCP at two reference centers of Turkey between 2013 and 2019, were retrospectively reviewed. Patients with biliary leak (n=14), referred for stent exchange (n=76), with no biliary strictures (n=7), left lobe (n=13) or cadaveric transplantation (n=54), strictures traversed by percutaneous route previously (n=12) and those with missing data (n=9) were excluded. The effect of nine different types of anastomosis classified according to the number (1,2 or >2) and location (common bile duct, hepatic bile ducts or cystic duct) of anastomosis and crossing of anterior and posterior ducts, the angle between the proximal and distal sites of the anastomosis (0-30°, 30-60°, 60-90°, >90°), the contrast enhancement pattern of the stricture (passage of contrast and visualization of the anastomosis), and the anatomy of the proximal site of the choledochus (round, triangular, intermediate form, end to site anastomosis) on the success of traversing the anastomosis with a guidewire were evaluated.

**Results:** Out of 125 biliary strictures, 86 (68,8%) could be passed via endoscopic route. After excluding 6 patients in whom the strictures were traversed via percutaneous route at outside centers, the remaining 33 strictures were managed by either percutaneously (n=13; 39,4%) or magnetic compression anastomosis (n=20; 60,6%). Compared to round appearance, triangular (OR:6,5) or intermediate form (OR:17,7) of the proximal site of the choledochus and end to side anastomosis (OR:5,1) were associated with an increased chance of traversing the stricture (p< 0,001). The success of endoscopic treatment was higher in patients with passage of contrast through the stricture associated with (92%) or without (81%) visualization of the anastomosis, compared to those with no passage of contrast (20%) (p< 0,001). The success was increased as the angle between the proximal and distal sites of the anastomosis approximated to zero (0-30°:74%, 30-60°=69%, 60-90°=63%, >90°=41%). The types of anastomosis and stricture (anastomotic or non-anastomotic) and the duration passed between the transplantation and ERCP had no effect on the success of treatment.

**Conclusion:** The types of biliary anastomosis and stricture affect the success of endoscopic treatment in patients with biliary strictures after right lobe LDLT. These data may play role in making decision about the type of anastomosis during the surgery in suitable patients.

### **P0939 A NOVEL TREATMENT APPROACH IN VISCERAL ARTERY PSEUDOANEURYSM: ENDOSCOPIC ULTRASOUND GUIDED THROMBIN INJECTION**

Maharshi S., Sharma S.S.

SMS Medical College & Hospitals, Gastroenterology, Jaipur, India

**Contact E-Mail Address:** sudhir.maharshi@gmail.com

**Introduction:** Pseudoaneurysms usually occur after vascular injuries or erosions such as in trauma or inflammation like pancreatitis, and are associated with high morbidity and mortality. Digital subtraction angiography with coil embolization is the established treatment for aneurysm. There are limited data in literature on endoscopic ultrasound (EUS) guided thrombin injection for pseudoaneurysm.

**Aims & Methods:** Aim of the study is to assess the efficacy and safety of EUS guided thrombin injection in pseudoaneurysm. Prospective study was done at SMS Hospital, Jaipur from January 2018 to December 2018. All patients with symptomatic visceral artery pseudoaneurysm were enrolled consecutively. Data related to demography, laboratory parameters, radiological imaging, pseudoaneurysm and endotherapy were analyzed.

**Results:** Eight patients with median age 34(27-58) years, all males were studied. Etiology of pseudoaneurysm was chronic pancreatitis in 6(75%) and idiopathic in 2(25%) patients. Vessel was splenic artery in 5(62.5%), left hepatic artery 2(25%) and gastroduodenal artery in 1(12.5%) patients. Size of pseudoaneurysm was 2.9 cm x 2.6 cm (1.8x1.9- 4x5 cm). All patients were presented with history of gastrointestinal bleeding and two patients had hemobilia. Hemoglobin was 5.2 gm/dl (4.1-12.2 gm/dl) and requirement of packed red cell transfusion was 3(0-5) units. Thrombin requirement was 400 IU (200-500IU) for loss of doppler flow signals. Computed tomography and EUS after 3 months showed obliterated pseudoaneurysms in 7(87.5%) patients, while recurrence was seen in 1(12.5%) patient after 6 weeks of thrombin injection.

**Conclusion:** EUS-guided thrombin injection is a new option for management of pseudoaneurysm.

**Disclosure:** Nothing to disclose

### **P0940 EUS-FNB IN THE EVALUATION OF SUBEPITHELIAL LESIONS OF THE GASTROINTESTINAL TRACT: SIDE-TYPE VERSUS END-TYPE NEEDLE - WHICH ONE IS THE BEST?**

Félix C.<sup>1</sup>, Chivia J.<sup>1</sup>, Mendo R.<sup>1</sup>, Pereira I.<sup>1</sup>, Chaves Marques S.<sup>1</sup>, Bispo M.<sup>2</sup>, Cassis J.<sup>3</sup>, Chagas C.<sup>1</sup>

**Introduction:** Endoscopic ultrasonography (EUS) is the most widely used method for characterization of subepithelial lesions (SELs) arising from the gastrointestinal (GI) tract.

However, the diagnostic accuracy of fine needle aspiration (EUS-FNA) ranges widely from 46% to 93% in the evaluation of GI stromal tumors<sup>1</sup>. Recent studies have showed superior diagnostic accuracy of fine needle biopsy needles (EUS-FNB), comparing to the standard EUS-FNA needles. Nevertheless there have been little head-to-head comparative data between FNB needles.

**Aims & Methods:** The aim of this study was to compare the diagnostic yield of the side-type needles with the end-type needles in the diagnosis of SELs of the GI tract.

A retrospective cohort study was conducted, including consecutive patients with SELs of the GI tract undergoing EUS-FNB between January 2016 and November 2018. Macroscopic on-site evaluation was used to evaluate core quality and set the number of needle passages necessary to obtain a macroscopic visible core. All samples were reviewed by one expert pathologist, who was blinded to the type of needle used, and classified as diagnostic (if biopsy specimens were adequate for making a diagnosis, including immunohistochemical staining whenever necessary), suggestive (if a suggestive primary diagnosis was assigned, but a definitive final diagnosis was not achieved) and non diagnostic (if samples were primarily insufficient for diagnosis)<sup>2</sup>. Primary outcome was defined as the ability to provide a suitable sample allowing histological interpretation (diagnostic yield). Secondary outcome was defined as the number of needle passages required to obtain a proper macroscopic sample.

**Results:** A total of 21 lesions were included (stomach n=16, duodenum n=2, rectum n=2, oesophagus n=1; median of lesion size on EUS 24 mm (10-134)) from 21 patients (9 females/12 males; median age 67 years (50-79)). The procedure was technically feasible in all patients. Side-type needles were used in 10 lesions and end-type needles in 11 lesions (fork-tip needle n=3, Freensen needle n=8). Diagnostic yield was 80% (8/10) in side-type needle group and 81.8% (9/11) in the end-type needle group (pvalue 1). Median needle passages to obtain a macroscopic visible sample was 3 (IQR 1) in the side-type needle group and 3 (IQR 2) in the end-type needle group (p value 0.821). There were no intra-procedure EUS-FNB related adverse events.

**Conclusion:** In our study there were no significant difference in diagnostic yield between side-type and end-type needles. Number of passages to obtain a macroscopic visible sample were similar between EUS-FNB needles. The procedure was feasible and safe in all lesions.

<sup>1</sup>Kitasato University Hospital, Endoscopy & Gastroenterology, Sagami-hara, Japan, <sup>2</sup>Kitasato University, Endoscopy & Gastroenterology, Sagami-hara, Japan, <sup>3</sup>Kitasato University Hospital, Gastroenterology, Sagami-hara-City, Japan

**Contact E-Mail Address:** m-kida@kitasato-u.ac.jp

**Introduction:** Endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA) has become an indispensable examination in the clinical fields. Furthermore, therapeutic EUS such as pseudocyst drainage, EUS-biliary drainage, and EUS-pancreatic duct drainage, etc. have become popular year by year. Generally, it has been believed that the learning of EUS-FNA takes long time and certain number of case experiences are essential, in order to become a good endosonographer. And it is difficult to learn EUS/EUS-FNA without instructors.

Furthermore, clinical cases are not enough for training young endosonographer and hands-on training with models are able to reduce the number of performing clinical EUS-FNA on training program. Therefore, we have developed newly designed model for training therapeutic EUS-FNA procedure such as EUS-HGS and PFC drainage, and investigated its usefulness and limitations.

**Aims & Methods:** We have collaborated with Olympus Co. and made model for EUS-HGS by special plastic material (Century medical Co., Tokyo) and pseudocyst model by non-rupture-balloon (Sumitomo Bakelight Co., Tokyo) which is 8cm in diameter. This balloon is filled by lubricant, and these models are put into water tank. We have tried this model at Kitasato Interventional hands-on training workshop with 40 attendees. We have investigated whether all attendees can complete EUS-FNA of the pancreas and pseudocyst drainage or not? And how long does it take to complete the procedure? Furthermore, we have checked their impression of this model. We have employed UCT-260 (Olympus Co., Tokyo), 19G EUS-FNA needles and 7Fr plastic stent as a drainage tube.

**Results:** Concerning about EUS-HGS, all attendee have to identify B2 and B3 branch, secondly puncture B3 with 19G needle, thirdly put in a 0.035inch guidewire, and finally deploy 7Fr stent. 96% (43/45) of attendees have completed EUS-HGS model with 7 minutes in average. Concerning about pseudocyst model, attendees have to firstly look for the good position for pseudocyst drainage, secondly attendee puncture the balloon with 19G needle, thirdly put in a 0.035 inch guidewire, push a dilator into the model, and finally put a 7 Fr drainage tube in the pseudocyst model. 89% (40/45) of attendees have completed pseudocyst drainage with 8.5 minutes in average. All balloons have not ruptured during these procedures and kept the balloon size, in spite of some leakage. According to their impression, resistance of puncture and putting in a stent is less, compared with clinical cases, however it is very useful to understand EUS-HGS and EUS-guided pseudocyst drainage.

**Conclusion:** We concluded that newly designed EUS-HGS and pseudocyst model is useful to train the beginner, in order to understand the procedure. Furthermore, using these models, we can do hands-on training everywhere and there is no necessity of animal laboratory because of dry model.

**Disclosure:** Nothing to disclose

## P0943 CELIAC GANGLIA NEUROLYSIS VERSUS BILATERAL CELIAC PLEXUS NEUROLYSIS FOR MANAGING ABDOMINAL PAIN ASSOCIATED WITH PANCREATIC CANCER

Wahba M.<sup>1</sup>, Okasha H.<sup>2</sup>, Farag A.<sup>3</sup>, Fawzy M.<sup>4</sup>, El-Mazny A.<sup>5</sup>

<sup>1</sup>Cairo University, Gastroenterology, Cairo, Egypt, <sup>2</sup>Faculty of Medicine, Cairo University, Cairo, Egypt, <sup>3</sup>Cairo University, Internal Medicine, Cairo, Egypt, <sup>4</sup>Cairo University, Kasr Alainy Medicine School, Cairo, Egypt, <sup>5</sup>Faculty of Medicine, Cairo University, Internal Medicine, Cairo, Egypt

**Contact E-Mail Address:** dr.mahmoudwahba@gmail.com

**Introduction:** Abdominal pain is a common problem in patients with pancreatic cancer, present in as many as 70% to 80% of patients at the time of diagnosis. It can be difficult to treat and patients may suffer from drug-related side effects. In these patients, celiac plexus neurolysis (CPN) may be indicated.

**Aims & Methods:** To assess efficacy and safety of endoscopic ultrasound guided celiac ganglia versus bilateral plexus neurolysis using absolute alcohol for managing abdominal pain associated with pancreatic cancer. A prospective randomized study were conducted on 35 patients with abdominal pain due to inoperable cancer pancreas. They were randomly assigned into two groups of EUS-CPN (celiac ganglia or Bilateral technique). Then patients were followed up at 2 weeks, 6 weeks and 6 months after procedure.

**Results:** In Group A (23 patients; 65.7%) celiac ganglia neurolysis was done and group B (12 patients; 34.3%) bilateral technique was done. Group A & B were matched regarding age, gender, site, type of pancreatic pathology and type of analgesics used before the procedure. Both techniques achieved similar rates of successful pain relief (83.3% of patients in Group A and 82.6% in Group B) without significant difference in Visual Analogue Scale of pain at 2 weeks and 2 months post-procedure. They were also similar regarding onset on pain relief and time of pain recurrence. There were no major complications or mortalities related to the procedure, however minor complications occurred in 10 patients (28.6%) as transient hypotension and self-limiting diarrhea. The rate of complication was similar in both groups.

**Conclusion:** EUS-guided celiac ganglia neurolysis is an easy technique more feasible and comparable with bilateral plexus neurolysis in terms of overall pain relief and reduction in dose and/or frequency of analgesics needed without increase in rate of procedure-related complications.

## P0944 RELATIONSHIP BETWEEN FIRST-VISIT PATIENTS WITH DIABETES MELLITUS AND ENDOSCOPIC ULTRASOUND IMAGES OF EARLY CHRONIC PANCREATITIS

Kubo H., Tashiro N., Ogami Y., Yasuda M., Okajima T.  
Nakabaru Hospital, Internal Medicine, Fukuoka, Japan

**Contact E-Mail Address:** canoa@dune.ocn.ne.jp

**Introduction:** Early chronic pancreatic is a new clinical entity. Endoscopic ultrasound (EUS) is an essential modality to diagnose patients with early chronic pancreatitis.

However, diabetes mellitus (DM) derives from a disorder of the pancreatic function, and the relationship between early chronic pancreatitis and DM is still not clear.

**Aims & Methods:** This prospective study was conducted for 21 patients with DM. EUS was performed before medical treatment. Diabetologist were in charge of treatment and were blind to the EUS findings. We analyzed gender, age, BMI, smoking, alcohol, family history, past history, hypertension, hyperlipidemia, HbA1c, anti-GAD antibodies, insulin secretion function, complications and therapeutic discipline. In addition, we evaluated whether the EUS findings contributed to the decision on which therapeutic method to use.

**Results:** 12 out of 21 cases meet the criteria for EUS findings for early chronic pancreatitis, while the others did not. Initial treatment went well for all the patients with DM.

In the univariate analysis, age, HbA1c, and therapeutic method were significant variables to differentiate between the presence or absence of EUS findings for early chronic pancreatitis. Patients without EUS findings for early chronic pancreatitis tended to be younger ( $p = 0.030$ ), with a higher HbA1c ( $p = 0.032$ ) and higher insulin usage ( $p = 0.021$ ) than patients with early chronic pancreatitis. In the multivariate analysis, absence of EUS findings for early chronic pancreatitis was an important factor in the use of insulin for treatment ( $p = 0.016$ ).

**Conclusion:** EUS is a valuable modality to differentiate between the presence or absence of early chronic pancreatitis in patients with DM. It seems likely that an EUS can contribute to the decision on which treatment method to use for patients with DM.

**Contact E-Mail Address:** dligresti@ismett.edu

**Introduction:** EUS-guided biliary drainage procedures (EUS-BD) have been demonstrated to be effective but technically challenging and require a substantial learning curve. Both phantoms and "ex vivo" biliary dilatation models, have been described to enhance learning in this field, but they provide a limited level of realism [1,2].

Swine model is the most realistic tool for training in EUS and biliary dilatation swine models have been described. However, they provide an erratic biliary dilatation, and can also be technically cumbersome [3-6]

**Aims & Methods:** The aims of our study were to develop a swine biliary dilatation model using temperature-controlled Endobiliary Radiofrequency Ablation (EB-RFA) and to investigate feasibility of EUS-BD in this kind of model.

Seven fourteen-month-old mini pigs underwent ERCP and a dedicated biliary radiofrequency catheter with a distal temperature sensor (ELRA RF catheter, STARmend, Goyang, Korea) was used to deliver energy into the common bile duct.

With the end-point to obtain a biliary stricture EB-RFA energy was then delivered at 7 or 10W with a target temperature of 75 or 80°C for one or two rounds (ranging from 60 to 120 seconds each).

Two weeks after EB-RFA, EUS examination confirmed massive biliary dilatation and EUS-guided biliary drainage procedure (EUS-BD) was then attempted by performing a hepaticogastrostomy (HGS) or a cholecystogastrostomy (CG).

**Results:** EB-RFA was successfully performed in all 7 pigs into the distal or proximal CBD (distal CBD,  $n = 6$ ; proximal CBD,  $n = 1$ ). There were no immediate post-procedural adverse events.

After two weeks all pigs were jaundiced without clinical evidence of acute cholangitis. EUS examination revealed massive intrahepatic and extrahepatic biliary dilation in all pigs and EUS-BD was attempted in the same session. HGS was performed in 6 pigs. Technical success was achieved in five of 6 pigs. Technical failure of HGS occurred during stent deployment. CG was successfully performed in one pig with both distended gallbladder and intrahepatic and extrahepatic biliary dilatation.

On the macroscopic evaluation, fibrotic tissue has been found around the CBD stricture without any sign of damage.

**Conclusion:** Our study demonstrates that EB-RFA is an effective minimally invasive method for creating a critical biliary stricture with associated upstream biliary dilation.

Furthermore, EUS-BD was technically feasible in this model which provides excellent level of realism in comparison to procedures undertaken in humans.

**Contact E-Mail Address:** julio.iglesias.garcia@sergas.es

**Introduction:** Endoscopic ultrasound (EUS) is considered as the technique of choice for the evaluation of gastrointestinal and extraintestinal lesions, mainly for pancreatico-biliary diseases. Standard linear EUS scopes have been usually thick and stiff in the tip.

**Aims & Methods:**

Aim of our study was to compare the maneuverability and image quality of a recently developed slim linear echoendoscope to the current standard scopes in the evaluation of pancreaticobiliary diseases.

**Material and methods:** Retrospective analysis of a prospectively collected endoscopy database from a referral academic center over 4 months. Patients undergoing diagnostic EUS with the slim linear echoendoscope (with a rounded and shorter distal part, together with a shorter bending section), attached to the ultrasound system HITACHI ARIETTA-V70 (Hitachi, Tokyo, Japan) were included in the study. All procedures were performed under conscious sedation. EUS-guided tissue acquisition was performed if indicated. The maneuverability and image quality were evaluated. A descriptive analysis was performed, showing results as mean  $\pm$  SD or 95% confidence interval.

**Results:** Out of 537 EUS procedures performed in the study period, 128 (23.8%) were done with the new linear slim echoendoscope for examination of the pancreas and bile ducts, and were included in the study. Mean age was 63 years (range 22-91, 72 females). Compared with the examinations performed with the standard EUS scope, the new slim echoendoscope performed better in terms of maneuverability during esophageal intubation, pylorus traversing and accessing from duodenal bulb to the second portion. Image quality at the standard stations (esophagus, stomach, and duodenum) was also considered better with the new scope. A complete pancreatico-biliary exploration was achieved in all cases (100%). Final diagnosis was stone disease in 40 cases, chronic pancreatitis in 34, acute pancreatitis in 5, solid pancreatic tumors in 10, 9 cases with peptic ulcer disease, 1 case of retroperitoneal lymph nodes, 1 case of liver metastasis, and 17 cases presented a normal exploration. EUS-guided tissue acquisition was performed in 9 cases (7 pancreatic tumors, liver metastasis and lymph nodes), being feasible in all cases. No complications were reported.

**Conclusion:** The new slim echoendoscope showed improved maneuverability and image quality. A complete biliopancreatic exploration can be performed safely and effectively, including EUS guided tissue acquisition.

**Disclosure:** Nothing to disclose

## P0947 EUS GUIDED CHOLEDOCODUODENOSTOMY WITH ELECTROCAUTERY ENHANCED LUMEN APPOSING METAL STENT: FRENCH MULTICENTRIC STUDY AFTER LEARNING CURVE

**Contact E-Mail Address:** jeremiejacques@gmail.com

**Introduction:** EUS guided biliary drainage is indicated in case of impossibility or failure of classic biliary drainage by ERCP. Recently we reported a good efficiency of EUS guided choledocoduodenostomy using the HOT-AXIOS device (Electrocautery enhanced lumen apposing metal stent) in a retrospective multicentric study. However in this study, technical success was 88.5%. Utilization of the recommended technique (direct puncture of the common bile duct with the HOT AXIOS + using a 6 mm Stent + fistulotomy with a pure section current) was the only predicting factor of clinical success.

We decide to reevaluate this procedure one year after in the same centers.

**Aims & Methods:** French retrospective multicentric study of a prospective database including all cases of EUS guided CDS with HOT AXIOS device in the 7 centers that participate to the first study.

**Primary ENDPOINT:** technical success rate defined as the ability to correctly deploy the Hot Axios stent between the common bile duct and the duodenal bulb with visualization of bile flow.

**Secondary endpoints:** Clinical success rate (decrease in bilirubin of at least 50% at day 7 or normalization at day 30), per-procedural complication rate, short-term complications (all complications occurring between the procedure and discharge from the hospital), Recurrence of biliary obstruction during follow-up.

**Results:** 70 consecutive patients were included in this study between 01/09/2017 and 22/09/2018 by 11 operators in 9 centers.

Pancreatic adenocarcinoma was the etiology of biliary obstruction in 77% of cases. Failure of primary ERCP was due to duodenal stenosis in 44% of cases, tumoral infiltration of the papilla in 22% of cases, and failure of deep cannulation in 4% of cases.

95% of patient had 1 or 0 ERCP procedure before EUS-CDS.

The mean duration of the procedure was 5 min (+/- 3). The recommended technique (direct fistulotomy with HOT-AXIOS using a pure cut current + using a stent of 6 or 8 mm) was used in 98.5% of cases.

**Primary Endpoint:** Technical success rate was 98.5% with only one failure.

**Secondary Endpoints:** Clinical success rate: 98.4%.

**Per procedural complication:** 1.6%: one bleeding during the fistulotomy stopped by the expansion of the stent itself.

**Short term complications:** 0%.

**Recurrence of biliary obstruction:** 7 cases (11.5%) (median follow up: 151 days).

**Conclusion:** EUS-CDS with the HOT AXIOS is efficacious and safe in distal malignant obstruction of the common bile duct in cases of ERCP failure with impressive results once the expertise is acquired and the recommended technic is followed.

It should be the technique of choice in case of distal tumoral obstruction and failure or impossibility of ERCP. Moreover it could challenge ERCP in the future as a primary option for biliary drainage on case of distal malignant obstruction.

## P0948 USEFULNESS OF HISTOLOGICAL DIAGNOSIS BY PROCORE 20G NEEDLE FOR PANCREATIC SOLID TUMOR

Watanabe S., Toki M., Kitada S., Goto T., Yoshida T., Ota H., Ochiai K., Koichi G., Hisamatsu T.

Kyorin University School of Medicine, Third Department, Tokyo, Japan

**Contact E-Mail Address:** shunshun.www@gmail.com

**Introduction:** EUS-FNAB is widely used for pathological diagnosis of pancreatic solid tumor. EchoTip ProCore 20G needle (PC20) is a puncture needle useful for histopathology because it has a large diameter and forward bevel type of core trap. In this study, we examined the tissue diagnostic efficacy of PC20 in pancreatic solid mass.

**Aims & Methods:** We conducted a retrospective study of EUS-FNAB for pancreatic solid tumor that was using PC20 from the first pass performed between October 2016 and December 2018 at Kyorin University hospital.

The main outcome was to evaluate the accuracy of histological diagnosis and the positive effect that added cytology. Secondary outcome was to examine the accuracy of histological diagnosis by number of passes. In EUS-FNAB, we firstly collected specimens by suction method. In cases with bleeding, cases in that specimens were small amount to exam, and cases when the needle was broken, we added more passes, or changed to slow-pull method, or other needles. Group4,5 in histology and Class IV, V in cytology were diagnosed as malignant tumor.

**Results:** A total of 90 patients were enrolled this study. The final diagnosis were pancreatic ductal carcinoma in 81, metastasis pancreatic carcinoma in 3, neuroendocrine tumor in 3, autoimmune pancreatitis in 1, and the others in 2. The cytological accuracy in PC20 was 85.6% (77/90). The histological accuracy in PC20 was 95.6% (86/90), other four patients were diagnosed by the changing to other needle, the accuracy by combining histological and cytological yield was 98.9% (89/90). By adding cytology to histology, the total accuracy was risen 3.3%, but it was no significant difference in comparison to only histological yield (p=0.36).

In number of passes using PC20, the histological accuracy was 86.6% (78/90) in once, 94.4% (85/90) in twice, and 95.6% (86/90) in 3 or more times. There was significant difference between once and twice (p=0.05), but no difference between twice and 3 or more times.

**Conclusion:** EUS-FNAB with PC20 for pancreatic masses showed sufficient accuracy in histological diagnosis. Additional effect of passes more than twice was not proven in accuracy of histological diagnosis.

**Disclosure:** Nothing to disclose

## P0949 SLOW-PULL COMPARED TO SUCTION TECHNIQUE FOR EUS-GUIDED SAMPLING OF PANCREATIC SOLID LESIONS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Capurso G.<sup>1</sup>, Archibugi L.<sup>2</sup>, Petrone M.C.<sup>3</sup>, Arcidiacono P.G.<sup>4</sup>

<sup>1</sup>San Raffaele Scientific Institute Irccs, Pancreas Translational & Clinical Research Center, Rome, Italy, <sup>2</sup>Hospital San Raffaele, Pancreato-biliary Endoscopy and Endosonography Division, Milan, Italy, <sup>3</sup>Vita-Salute San Raffaele University, Pancreato-Biliary Endoscopy and Endosonography Division, Milano, Italy, <sup>4</sup>Ospedale San Raffaele, PancreatoBiliary Endoscopy and Endosonography Division, Pancreas Translational and Clinical Research Center, Milan, Italy

**Contact E-Mail Address:** livia.archibugi@hotmail.it

**Introduction:** The European Society of Gastrointestinal Endoscopy (ESGE) guidelines suggest to employ the suction (SU) technique for endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) of pancreatic solid lesions. However, recently some randomized controlled trials have reported that the slow-pull (SP) technique has a similar diagnostic accuracy with possibly less blood contamination. However, these results are heterogeneous and often limited to small cohorts.

**Aims & Methods:** The aim of the study was to perform a meta-analysis to compare sensitivity, specificity, accuracy and adequacy of the SU and SP techniques for FNA of solid pancreatic lesions.

A computerized bibliographic search was restricted to randomized controlled trials only. Pooled effects were calculated using a random-effects model and expressed in terms of pooled sensitivity and specificity and OR (95% CI) for accuracy and adequacy.

**Results:** Overall, 7 RCTs were included (2 conducted in the US, 2 in Korea, 1 in India, 1 in Brasil, 1 in Italy); 4 were full text publications, 3 abstracts; the RCTs investigated 646 patients (216 sampled with SP, 211 with SU, and 119

with both). The SP technique showed a slightly higher pooled sensitivity compared to SU (83.1% vs 77.2%), while specificity was similar (96.2% vs 96.4%). A non-significant superiority of SP in terms of pooled accuracy (OR 0.59; 95% CI 0.3-1.1;  $p=0.1$ ) was recorded, while adequacy was similar (OR 1.17; 95% CI 0.5-2.5;  $p=0.6$ ). Two studies reported data on significant blood contamination with a pooled rate of 10.8% for SP and 25.6% for SU. **Conclusion:** The present meta-analysis reveals non-superiority of SU over SP, with some trend toward better performance of SP with reduced blood contamination; the current recommendations regarding preferential use of suction might need to be revised in light of these findings.

**Introduction:** Endoscopic Ultrasound (EUS) guided fine needle aspiration (FNA) can be used to obtain cytology of solid organs, lymph nodes and submucosal tumors of the gastrointestinal tract. However, there is a rising demand for histology sampling for the evaluation of tissue architecture and to perform additional diagnostics. Available needles for fine needle biopsy (FNB) can provide histology in roughly 57-89% of the cases [1-3]. Considering the poor performance of FNB and the rising demand for histology sampling, new techniques are needed to increase the diagnostic tissue histology yield [4]. Recently, a new promising device was developed to increase histology yield in EUS-guided puncturing [5], with an updated design: a Nitinol 19-gauge puncture biopsy forceps (PBF; MTW Endoskopie Manufaktur, Wesel, Germany).

**Aims & Methods:** We conducted a retrospective multicenter feasibility study in 2018 with one University Hospital (Radboudumc (RU), Nijmegen, The Netherlands), one general hospital (Evangelisches Krankenhaus (EVK), Düsseldorf, Germany) and two private hospitals (New Medical Centre Specialty Hospital (NH), Abu Dhabi and Thumbay Hospital (TH), Dubai, United Arab Emirates). Data were derived from pathology and doctors' reports. Primary outcome was diagnostic yield. Secondary outcomes were safety (bleeding, perforation) and technical performance.

**Results:** Nineteen patients were included: 4 from RU, 3 from EVK, 10 from NH and 2 from TH. The majority of patients was male (12/19, 63%), the age ranged from 34-76 years of age. The PBF was used for biopsy of the pancreas in 9, GE junction lesion in 3, lymph nodes in 2, submucosal lesion in 3 (1 duodenal bulb and 2 gastric wall) and during rectal EUS in 2 patients (perirectal lesion and thickened small bowel wall). 1-5 passes per case were performed with the PBF. In 17 patients FNA or FNB with another needle was also performed.

**Primary outcome:** In 68% (13/19) diagnostic histology was obtained with the PBF. In 3 cases no diagnosis could be made with either histology or cytology. In 3 cases diagnosis was made on the cytology only and in 4 on histology from the PBF only. In 9 cases both histology and cytology were diagnostic. **Secondary outcomes:** No adverse events occurred in these 19 patients. The PBF was very sharp resulting in easy penetration. The forceps mechanism in the tip works well even after multiple biopsies in the same patient. The Nitinol tip facilitates good bridging possibilities. A lock mechanism on the handle prevents the PBF from opening during introduction. However, in one patient the PBF was accidentally opened in the shaft. In two patients the spring mechanism failed after the first pass making it unable to continue with the same needle.

**Conclusion:** The PBF is a promising device that can be used for a wide range of indications. However, technical improvement of the needle is needed to prevent technical failure. The PBF can potentially be useful in cases where cytology alone is not adequate for diagnosis or when histology is desired for additional stains, genotyping or molecular analysis. To determine the value of the PBF and its position in the diagnostic field a prospective study is needed in which the PBF is compared to other routinely used device(s).

## P0951 ENDOSCOPIC ULTRASOUND-GUIDED CHOLEDOCHODUODENOSTOMY FOLLOWED BY DUODENAL STENTING IN PATIENTS WITH MALIGNANT UNRESECTABLE BILIODUODENAL OBSTRUCTION

Kumar A., Rai P.

Sanjay Gandhi Post Graduate Institute of Medical Sciences, Gastroenterology, Lucknow, India

**Contact E-Mail Address:** ashok110@gmail.com

**Introduction:** In patients with advanced pancreaticobiliary malignancy, along with biliary obstruction, gastric outlet obstruction is a frequent occurrence. Endoscopic retrograde cholangiopancreatography (ERCP), a first line modality for palliation of obstructive jaundice is often unsuccessful in patients with combined bilioduodenal obstruction, due to inability to reach the duodenal papilla and early dysfunction of biliary self-expanding metal stent (SEMS) due to the duodenobiliary reflux enhanced by duodenal stenosis.

As an alternative, Endoscopic ultrasound (EUS)-guided choledochoduodenostomy (EUS-CDS) and duodenal stent placement has been recently described with high rates of technical and clinical success, but with limited number of studies and unclear sequence of stenting (i.e. whether biliary or duodenal stenting first).

**Aims & Methods:** We evaluated the technical success, clinical success and safety of endoscopic ultrasound-guided choledochoduodenostomy followed by duodenal SEMS placement in patients with malignant bilioduodenal obstruction.

Medical records of consecutive patients with unresectable malignant distal biliary obstruction and gastric outlet obstruction (GOO), who required biliary drainage by EUS-CDS (because of failure of attempt at ERCP) and antroduodenal stenting were reviewed. EUS-CDS was done using 6-cm, PCSEMS (Wallflex, Boston Scientific). Technical success, clinical success [biliary stent- more than 50% reduction in total bilirubin at 2 weeks post-procedure; antroduodenal stent- improvement in Gastric Outlet Obstruction Scoring system (GOOSS)], stent patency rate and adverse events (AEs) were assessed.

**Results:** Between January 2015 and January 2019, 11 patients underwent combined EUS-CDS and antroduodenal stent placement. Both EUS-CDS and antroduodenal stent placement were technically and clinically successful in all patients. Median total serum bilirubin decreased from 15.8mg/dL to 5.9mg/dL at 2 weeks post procedure. Recurrence of jaundice was not seen until 2 months post double stent placement or death.

Median GOOSS improved from 0.56 to 2.3 at 4 weeks post-procedure. All patients were able to maintain weight above 90% of baseline at 4 weeks and 72.7% of patients had weight above 80% of baseline at 8 weeks post duodenal stent deployment.

GOO did not recur in patients who were alive at 2 months. In 8 (72.7%) of the 11 patients, the biliary and antroduodenal stents were patent and functioning normally at 2 months post-procedure.

Only one patient had bile leak, which resolved with therapeutic paracentesis. There were no procedure-related deaths. Most of the patients (9/11) died of advanced cancer cachexia.

**Conclusion:** EUS guided choledochoduodenostomy followed by duodenal stenting is safe and has high technical and clinical success for palliation of malignant bilioduodenal obstruction.

**Contact E-Mail Address:** r.quispel@rdgg.nl

**Introduction:** Endoscopic ultrasound (EUS) guided tissue acquisition (TA) is the method of choice to establish a pathological diagnosis of solid pancreatic lesions. EUS guided TA is a complex multistep procedure involving efforts of both endosonographers and cytopathologists.

Reported outcomes on the quality and yield of EUS guided TA are skewed towards high-volume academic institutions. For community hospitals, in which the majority of these procedures are performed, these data are unknown. Rate of adequate sample(RAS) (the proportion of tissue samples sufficient for cytopathological evaluation) is the only quality indicator solely reflecting the work of the endosonography team.

**Aims & Methods:** The aims of this study are 1. to determine and improve the RAS of EUS guided TA in a group of community hospitals and 2. to identify determinants of RAS. From January 2015 until October 2018 five community hospitals in the Rotterdam region in the Netherlands, prospectively included procedures. The primary outcome variable was RAS. Univariate and multivariate analyses were performed to identify determinants of yield such as type and size of needle used, application of suction, presence of rapid on site cytopathological evaluation (ROSE) and the number of procedures performed by the endosonographers.

**Results:** Seventeen endosonographers, with individual EUS experience ranging from 1-14 years, performed 372 consecutive procedures over a period of 46 consecutive months. Overall RAS was 93% (ASGE ref standard: >85%)(ref 1). In a multivariate analysis the use of suction and number of procedures performed by endosonographers were statistically significantly and positively associated with RAS (p=0.01) and (p=0.04) respectively. No significant interaction was found between number of procedures and use of suction. No significant association was found between RAS and needle type, needle size, ROSE and number of passes. Seven endosonographers performed less than 20 procedures (median 9 (3-18)) accounting for 70 procedures in total. Within this subgroup RAS was 87%. The remaining seven endosonographers performed 302 procedures (median 56 (21-63)) yielding a RAS of 95%. Differences in RAS between "low-volume" and "high-volume" endosonographers were statistically significant p=0.01.

**Conclusion:** Both use of suction and higher number of procedures performed by endosonographers are associated with better outcome (RAS) of EUS guided TA in this prospective cohort in community hospitals. The quality of EUS guided TA in a community hospital may be partly influenced

by the number of procedures done. However, the quality of an individual endosonographer depends on more factors than its volume alone and requires further research.

**Introduction:** EUS-guided biopsy is a safe and accurate method for the histological diagnosis of solid liver lesions. However, few data are available on liver parenchymal diseases.

**Aims & Methods:** Aim of our study was to evaluate in an ex-vivo model the ability of different EUS needles to obtain histological samples of liver tissue.

**Material y Methods:** 7 different types of EUS biopsy needles in an ex-vivo pig liver were tested: A1: 22G Franseen type needle; L1-L3: standard cytology needles of 25G, 22G and 19G respectively; SC1-SC3: SharkCore type needles of 25G, 22G and 19G respectively. Biopsies were performed without suction and without stylet. Two passes were performed with each needle type. Samples were collected in formalin. Samples were considered satisfactory if they were at least 1cm in length and if they included at least 10 porta spaces. Fragmentation was evaluated as well.

**Results:** Table shows results obtained with each of the needles used.

CASE	N.º CILINDERS	FRAGMENTATION	MEASURE (cm)	PORTAL SPACES	QUALITY
A1	8	High	0,1-0,4	2	Non-satisfactory
L1	8	High	0,1	0	Non-satisfactory
L2	4	Medium	0,1	0	Non-satisfactory
L3	9	High	0,1-0,4	0	Non-satisfactory
SC1	9	High	70,1-0,8	7	Non-satisfactory
SC2	11	High	0,1-1	11	Satisfactory
SC3	11	High	0,1-1,4	10	Satisfactory

[Table 1]

**Conclusion:** SharkCore needles (22G and 19G) allow obtaining a core liver biopsy in an ex-vivo model, suitable for histological evaluation. These results should be confirmed in vivo.

**Disclosure:** Nothing to disclose

**Introduction:** Radiation therapy has an emerging role in the multi-modal treatment of locally advanced pancreatic cancer (LAPC). Stereotactic body radiation therapy (SBRT) is an innovative radiation technique characterized by a high prescription dose delivered in only a few fractions thus increasing the local control rate. Endoscopic ultrasound (EUS)-guided fiducial placement allows for accurate tracking of target motion during SBRT delivery.

**Aims & Methods:** The aim of this study is to present preliminary results on the feasibility and safety of EUS-guided fiducial placement using a new preloaded needle in patients with LAPC in a prospective phase II study (NCT03158779), patients with LAPC treated with induction chemotherapy according to FOLFIRINOX or gemcitabine + nab-paclitaxel schedules were then treated with an ablative dose of SBRT (54Gy in 6 daily fractions). Gold markers were implanted under EUS-guidance into the tumor at opposite edges. A new dedicated EUS delivery device was used: a 22G needle preloaded with 4 gold fiducials (0.43mm width x 5mm length). Fluoroscopy was used to confirm correct fiducial deployment. Prior to fiducial placement, patients received IV antibiotic prophylaxis and rectal indomethacin. Technical aspects of the EUS procedure and fiducial visualization were scored on a predetermined 5-point Likert scale (1 = best, 5 = worst).

**Results:** From May 2017 to March 2019, 10 patients (mean age 65.7 years) were enrolled. Before fiducial placement, all patients received induction chemotherapy with gemcitabine + nab-paclitaxel (6 patients) or FOLFIRINOX (4 patients) for a median duration of 4.6 months (range 2-7 months). At restaging, all patients still had locally advanced tumors with no regression to resectable disease. The mean tumor size was 28.5 mm. Other characteristics are listed in Table 1.

PATIENT	AGE	GENDER	LOCATION OF NEOPLASIA	DIAMETER OF NEOPLASIA	TECHNICAL DIFFICULTIES	NUMBER FIDUCIALS	ADJUSTMENT
1	72	F	HEAD	36	MILD (HARDNESS OF TISSUE)	3	YES (< 3 MM)
2	57	M	UNCINATE	42	MILD (HARDNESS OF TISSUE)	3	NO
3	54	M	BODY	42	NO	2	NO
4	71	F	BODY	31	COLLATERAL VESSELS AROUND LESION	2	NO
5	70	F	BODY	36	NO	4	NO
6	53	F	HEAD	30	RELEASE OF TWO FIDUCIALS IN ONE SHOT	4	NO
7	75	F	UNCINATE	18	NO	2	NO
8	80	M	NECK	12	COLLATERAL VESSELS AROUND LESION	1	NO
9	72	F	UNCINATE	16	NO	2	NO
10	53	F	BODY	22	NO	3	NO

[Table 1]

A total of 26 fiducials were implanted, with a mean number of 2.6 fiducials placed per patient (range 1-4). All the fiducials were successfully deployed inside the target lesion with a technical success of 100%. In 5 of 10 patients, the procedure had no technical difficulties. In the other 5 patients, fiducial placement was characterized by minor technical difficulties due to increased hardness of lesion, interposing vessels or poor control with the first marker release. EUS, fluoroscopic and CT visualization of the fiducials was rated as excellent. Patients started the SBRT protocol 10.2 days (range 6-19) after simulation CT-scan. At the beginning of the SBRT delivery, minimal movement of one fiducial (<3 mm) occurred in one patient. No severe adverse events occurred and all procedures were performed in an outpatient setting.

**Conclusion:** These preliminary results demonstrate the feasibility and safety of the EUS-guided fiducial placement using a new preloaded needle in patients with LAPC. Only minor technical difficulties (mainly due to tumor hardness or collateral vessels) were encountered that did not affect the correct placement of the fiducials.

**Disclosure:** Nothing to disclose

**Introduction:** Traditionally, when performing endoscopic ultrasound (EUS) guided biopsy, target lesions beyond vascular structures were avoided due to concerns of major bleeding complications, leaving surgery as the only option for tissue sampling. There are few case reports and series published, underlining one small case series of transaortic sampling with favorable results. Furthermore, based on previous feasibility studies, the American Society of Gastrointestinal Endoscopy (ASGE) published a review on potential applications of EUS-guided portal vein interventions which seem safe and effective.

**Aims & Methods:** Due to the limited data available, we reviewed our experience in EUS-guided biopsy using a transvascular approach to assess its safety and diagnostic performance.

A retrospective analysis was done of 15 patients who underwent, for cancer staging, an EUS-guided biopsy with a transvascular approach from July 2007 to March 2019.

Case	Sex/Age	Punctured Structure	Needle	No Lesions	No Passes	Complications
1	M/59	Aortic Arch	25 G	1	3	No
2	F/42	Vena Cava	25 G	2	1 and 2	No
3	F/42	Portal Vein	25 G	1	5	No
4	F/59	Aortic Arch	25 G	1	2	No
5	F/55	Aortic Arch	25 G	1	3	No
6	M/53	Aorta	25 G	1	2	No
7	F/35	Aortic Arch	25 G	1	4	No
8	F/63	Aortic Arch	25 G	1	3	No
9	F/48	Aorta	25 G	1	1	No
10	M/60	Aortic Arch	25 G	1	1	No
11	F/51	Aortic Arch	25 G	1	1	No
12	F/60	Pulmonary Artery and Aorta	22 and 25 G (respectively)	2	1 and 1	Minor, self-limiting hemorrhage.
13	M/61	Aorta	25 G	1	3	No
14	F/66	Left pulmonary artery	22 G	1	1	Bronchial hemorrhage, intubation and endoscopic treatment.
15	M/55	Aortic Arch	25 G	1	3	Self-limiting periaortic hematoma.

[Table 1. Cases of EUS-guided biopsy using a transvascular approach.]

**Results:** The sample has a median age of 59.93 years (Table 1). With respect to medication, 26.67% were under non-steroidal anti-inflammatory drugs, 20% aspirin and 6.67% low-molecular weight heparin. The medication was temporarily interrupted if it was necessary. Eighty percent of the patients underwent general anesthesia and 20% deep sedation with intermittent bolus of propofol.

The punctured vascular structure was arterial in 86.67% of the cases, being the aorta (80%) the most punctured. The needle used in all the cases was a 25G, except in the biopsies through the pulmonary artery in which a 22G was used, with a median of 2.27 passes for lesion. (IC 95: 1.56 - 2.75). An on-site pathologist was present in all cases. The cytology report was positive for malignancy in 86.67% of the cases and negative for malignancy in 6.67% of the cases.

In 93.33% of the cases, the procedure was performed in an ambulatory fashion. Three patients had mild bleeding; one was a self-limiting peri-aortic hematoma, another one stopped bleeding with echoendoscope compression and another one required hospital admission for observation and did not need any other intervention.

**Conclusion:** This is one the largest case series published to date. Taking into consideration the diagnostic performance and the low complication rate, we consider the EUS-guided biopsy with a transvascular approach a feasible procedure and reasonably safe in cases in which there is no other ultrasonographic window.

**Disclosure:** Nothing to disclose

## P0957 CUMULATIVE SUM ANALYSES GUIDING IMPROVEMENT OF TEAM PERFORMANCE IN EUS GUIDED TISSUE ACQUISITION OF SOLID PANCREATIC LESIONS IN COMMUNITY HOSPITALS

**Introduction:** Endoscopic ultrasound (EUS) guided tissue acquisition (TA) is a complex multistep procedure involving efforts of both endosonographers and cytopathologists. Published outcomes on the quality and yield of EUS guided TA are skewed towards high-volume academic institutions. For community hospitals, in which the majority of these procedures are performed, these data are unknown. Rate of adequate sample (RAS) (the proportion of tissue samples sufficient for cytopathological evaluation) is the only quality indicator solely reflecting the work of the endosonography team. The ASGE guideline described a performance target of 85% for RAS (Ref 1). Cumulative SUM (CUSUM) analysis is a method that can be used for quality control (Ref 2). For EUS CUSUM has been used to evaluate learning curves of trainees (Ref 3).

**Aims & Methods:** The aim of this study is to investigate whether CUSUM might be a good method to visualize and evaluate the quality of daily practice EUS guided TA of solid pancreatic lesions in community hospitals.

In Rotterdam region, The Netherlands, a group of five community hospitals formed an EUS interest group (QUEST). With three annual meetings and a regional symposium the goal of QUEST is to improve the quality of EUS in community hospitals. For this particular study, in each hospital retrospective data was collected of EUS-FNA/FNB procedures performed in the year 2014. In January 2015, a prospective registration of all consecutive EUS procedures with FNA/FNB started. CUSUM was used to identify changes in quality. With CUSUM each adequate sample contributes to an upwards slope of the CUSUM curve, each inadequate sample will contribute to a downwards slope of the CUSUM curve. Two decision limits are calculated. When a curve crosses the upper limit, the quality is good, according to literature. When a curve crosses the lower limit an intervention is needed to improve the quality. When a curve stays between the decision limits the observations should be continued until the curve will cross one of the decision limits.

**Results:** A total of 103 retrospective procedures and 372 consecutive prospective procedures were included. Values of RAS are shown in table 1.

	RAS Hospital A	RAS Hospital B	RAS Hospital C	RAS Hospital D	RAS Hospital E	RAS Total cohort
Retrospective series	70%	95%	100%	55%	78%	80%
Prospective series	88%	89%	98%	99%	91%	93%
95% CI	0.2 - 41	-13 - 16	-13 - 9	23 - 64	-4 - 34	6 - 22
p-value	0.047	0.4	0.4	<0.01	0.1	<0.01

[Table 1. Adequate sample rates and differences between retrospective and prospective series.]

With CUSUM analysis the learning curve shows a downwards slope in 2014 (retrospective series) and crosses the lower decision limit during that year. The formation of QUEST (January 2015) marked a turning point with the curve showing an upwards slope crossing the upper decision limit in December 2017. CUSUM learning curves also revealed differences in quality between the five hospitals in QUEST showing relevant positive improvements after team formation, especially for those hospitals initially underperforming.

**Conclusion:** CUSUM showed to be a valid method to measure quality of EUS guided TA of solid pancreatic lesions. It provides continuous feedback on the development (or maintenance) of TA quality and can also be used to compare hospitals. We conclude that after the formation of the QUEST group, RAS of the participating community hospitals is comparable to the ASGE guideline.

**Introduction:** EUS-guided FNA and FNB have established their place for tissue acquisition. However, the procedure has been stagnating in recent years at a level of accuracy which falls short of patient and physician hopes. In recent years, needles have been redesigned to allow for core sampling, (FNB), to allow for immune-staining of specimens.

However, false negative results for malignancy range from 4% (experts centers) to 30%. Multiple needle passes are often needed, but often slide along the same tract as the first pass, limiting diagnostic yield. An FNA approach usually requires 3-5 passes, with fewer passes for the FNB needles. Furthermore, rapid on-site cytology can lower number of passes, but the majority of centers find this to be logistically and/or financially prohibitive. Needles after repeated passes bend out of shape leading to use of a second needle, which has cost implications. Tumor composition can be a mosaic of desmoplasia, necrosis, cystic areas, and malignant cells. If the needle is in the wrong plane and the endoscopist is unable to do fanning an inconclusive diagnosis can occur. We introduce a new needle concept to improve diagnostic yield and lower false negatives, with use of a device which has five needles.

**Aims & Methods:** A multi-pass needle has been designed which ensures five specimens will be from various sites, because the five needles are all penetrating at the same time in different planes of the lesion. This needle apparatus uses the same sheath as a standard 19 gauge needle, but within the sheath it houses a five-lumen plastic tube, which separates between the central 22g needle and the four peripheral 25g needles. The ergonomically-designed handle has a two-phase mechanism which allows the endoscopist to first place the 22g needle within the target lesion, which is the same as the process done today, and to then extrude the four 25g needles, which are pre-bent so as to spread out to a diameter of about one cm,

at a distance of about 3cm from the scope. These additional needles will each, without fanning, obtain specimens near to the central needle, and therefore a greater representation of tumor tissue will be obtained, while completing the procedure in one pass, with better accuracy due to less false negatives. The two channels for suction can be attached to either the single central needle and/or to all four peripheral needles with stopcocks facilitating the maintaining of suction when so desired. Each needle has its own stylet, these may be removed at any time desired.

**Results:** We present in the accompanying figure the InstaFan, a disruptive technological advance, for the delivery of better EUS biopsies. Ex vivo studies found that the 5 needles did not cause leakage from the gut or perforation of the gut wall, and that the 5 needles delivered resulted in five distinct specimens each of which was an adequate specimen for pathological diagnostic purposes using the cell block method and paraffin slices allowing immune-staining.

**Conclusion:** Future directions of the InstaFan will be animal in vivo animal safety study followed by first trials in humans. The goal of the InstaFan will be to reduce false negatives, thus increasing optimization of tumor diagnosis.

**Disclosure:** Both authors disclose financial association with the developers of this new needle

## P0959 HIGH DIAGNOSTIC YIELD OF MUTATIONAL ANALYSIS ON EUS-GUIDED BIOPSIES USING A NEW FRANSEEN NEEDLE IN PATIENTS WITH LOCALLY ADVANCED PANCREATIC CANCER (LAPC)

**Introduction:** Genomic analyses of pancreatic cancer display a complex mutational background with few known oncogenic events in well known cancer-related genes, and many other low prevalence mutated genes. In order to conduct a genetic study of locally advanced pancreatic cancer (LAPC), bioptic samples of the primitive tumor are necessary. Endoscopic ultrasound-fine needle aspiration with cytology has led to some preliminary results, however, the quantity of cells obtained may be insufficient to perform a genetic analysis.

New histology needles have been developed to obtain more material and a better preservation of the tissues for ancillary analysis such as somatic mutations analysis and immunohistochemistry.

**Aims & Methods:** 33 patients with naïve LAPC underwent EUS- fine needle biopsy (FNB) with the new 22G Franseen needle. Bioptic samples were sent to pathological evaluation and to genetic analysis. DNA extraction was performed, and Next Generation Sequencing provided mutational profiles of the extracted DNA samples. NGS was performed with a 161 genes panel; 18 of the most prevalent genes were selected to undergo computational analysis.

**Results:** EUS- FNB allowed for a macroscopic core in 31 patients (94%), and pathological diagnosis was obtained in 100% of patients. Good quality DNA was extracted from 32 samples (97%), and NGS analysis confirmed the diagnosis in 30 patients (93.75%). The diagnostic yield of NGS analysis improved when combined with serum CA19.9 levels (97%). Results on DNA extraction and NGS analysis are depicted in table 1.

Genetic profiling obtained from NGS sequencing revealed pathogenic mutations in KRAS, TP53, GNAS, SMAD4 and CDKN2A, as well as a large number of mutations of uncertain significance. Preliminary data analysis revealed that the mutational burden of known oncogenes may be underestimated.

**Conclusion:** The tissue obtained with the new 22G Franseen FNB needle demonstrated a high diagnostic yield for the histological diagnosis of pancreatic adenocarcinoma and gave material of good quality of NGS analysis.

The ability to identify distinct mutation subsets via EUS-TA could greatly aid patient stratification and would represent a crucial step in the field of personalized medicine.

**Disclosure:** Nothing to disclose

	RESULTS	NOTES

**Introduction:** ESGE recommends placing a submucosal tattoo to mark an identified lesion and/or the deepest point of insertion during device assisted enteroscopy (1).

**Aims & Methods:** Patients who underwent a double balloon enteroscopy (DBE) during which a tattoo was placed were included. Information on repeat DBEs, second look small bowel capsule endoscopies (SBCEs) and subsequent surgeries was gathered.

**Results:** 283 patients (mean 57 years +/-15.5; 52.7% males) had a tattoo placed during DBE. Most underwent antegrade DBE (218; 77.0%). The most common indication was iron deficiency anaemia (IDA) (Table 1).

Indication	Frequency	Percentage
Iron deficiency anaemia	72	25.4
Ulcers	48	17.0
GI bleed	63	22.3
Polyp	27	9.5
Angioectasias	21	7.4
? Tumour	19	6.7
? Crohn's disease	18	6.4
? Stricture	18	6.4
Abnormal radiology	10	3.5
? Coeliac complication	8	2.8
Diarrhoea, weight loss, malabsorption	6	2.1
White tipped villi	2	0.7
Retained SBCE	2	0.7

[Table 1: Indications for DBE;]

Pathology was reached in 158 (55.8%) patients. Other patients (111; 39.2%) had a normal DBE with subsequent investigations ruling out any pathology. In 14 patients (4.9%), the pathology was not reached.

A repeat DBE was carried out in 47 patients. Tattoo from previous DBE was detected in 18 (38.3%) patients. 28 of these patients underwent a DBE using a different route. A tattoo was detected in only 6 (21.4%) of these patients and in 12 (63.2%) patients who underwent a DBE via the same route (p=0.006).

36 patients (12.7%) were diagnosed with a tumour, meckel's diverticulum or a stricture. 26 (72.2%) underwent surgery and 20 (76.9%) of these patients had the lesion tattooed facilitating surgery.

80 patients underwent a second SBCE after DBE to ensure pathology was

not missed. Of these, 53 (66.3%) had a tattoo identified. 21 of these patients (26.3%) had pathology detected beyond the tattoo requiring alternative procedures.

In those patients (14) where pathology was not reached, 5 underwent surgery, 4 patients were not for surgery due to the multiple carcinoid tumours identified and 5 patients were treated conservatively as the pathology was deemed to be benign on subsequent investigations.

**Conclusion:** Placing a tattoo can be helpful where the suspicion of pathology is high despite a negative DBE as this will help the detection of the pathology in relation to the tattoo on subsequent SBCEs. A tattoo can help pathology be localised during surgery and facilitate resection.

**Introduction:** Capsule endoscopy (CE) has a useful role in patients with established coeliac disease (CD) with new symptoms or where a complication is suspected. Similarly double balloon enteroscopy (DBE) is helpful for histological diagnosis of pathology reported on CE in conjunction with radiology.

**Aims & Methods:** Patients with established CD who underwent DBE +/- CE +/- radiological investigations were included. Information on findings, histological results and final diagnosis were gathered.

**Results:** Twenty-four patients with established CD (median age 63 years, 54.2% males) underwent antegrade (83.3%) or retrograde DBE (16.7%). Patients underwent small bowel (SB) investigations because of persistent symptoms or anaemia (11, 45.8%) or to rule out complications of refractory coeliac disease (RCD) (13, 54.2%). Patients underwent a CE (23, 95.7%) and radiological investigations (13, 54.2%) prior to DBE. Findings on CE included: mass lesion (5, 20.8%), stricture (1, 4.2%), evidence of gluten enteropathy (9, 37.5%), ulcers (7, 28.3%). Findings on radiological imaging were: abdominal lymphadenopathy (3, 23.1%), thickened SB (6, 46.2%), mesenteric mass (1, 7.7%), strictures (1, 7.7%), lymphoma (1, 7.7%). Twenty-two patients (91.7%) had positive findings on DBE. In 3 of these, findings related to CD were present. However, the suggested mass / stricture on CE or radiological imaging was not seen. Histological findings were: raised intraepithelial lymphocytes (5, 20.8%), partial (5, 20.8%), subtotal (4, 16.7%) and total villous atrophy (6, 25.0%), adenocarcinoma (2, 8.3%), changes consistent with RCD 2 (1, 4.2%), enteropathy associated T cell lymphoma (EATL) (1, 4.2%). There was a good concordance between CE and DBE ( $K=0.646$ ,  $p=0.001$ ) and between radiological investigations and DBE ( $K=0.755$ ,  $p=0.005$ ). The concordance between CE and radiological studies was lower ( $k=0.429$ ,  $p=0.070$ ). DBE revealed more severe histological changes in the SB in 7 ( $n=10$ , 70.0%) patients compared to duodenal biopsies taken during gastroscopy ( $p=0.036$ ).

CE revealed ulcers in 29.0% (7) of patients. However only 2 (28.6%) patients had the diagnosis of ulcerative jejunoileitis confirmed on DBE. One patient with adenocarcinoma had positive findings on all 3 modalities. Another patient with adenocarcinoma had positive findings on CE and DBE. The patient diagnosed with EATL had a positive MRI. DBE was confirmative of the diagnosis. CE only showed scalloping and villous blunting in the proximal SB. In another patient diagnosed with neuroendocrine tumour, both CE and CT were diagnostic.

However, the lesion was not reached during DBE.

**Conclusion:** CE has a high diagnostic yield as an initial investigation compared to radiological studies. DBE has a useful role in establishing a confirmative diagnosis of pre-malignant and malignant conditions. In patients with active disease on CE, DBE can be useful in obtaining histological specimens that can provide additional information to that obtained from duodenal biopsies.

**Introduction:** Acute pancreatitis (AP) is a significant medical and surgical problem with variable clinical course and outcomes. Severe acute pancreatitis (SAP) is one of the most dangerous illnesses, with a significant mortality as high as 8%-39%. Infection of the pancreatic necrosis is a dreaded complication during the late course and the resulting sepsis &/ or multiple-organ dysfunction syndrome (MODS) are the main causes of death. Superimposed infection in setting of pancreatitis remains both diagnostic and therapeutic challenge and may be potentially life threatening if the diagnosis is delayed. Therefore prompt non-invasive diagnosis of infection is crucial because it has pivotal influence on decision making and management. The clinical presentation, and laboratory parameters are often equivocal and the definitive proof of infection is generally obtained by performing an image guided aspiration of the collection followed by Gram's staining and culture for bacteria and/or fungal organisms.

With significant advancements in imaging techniques, we intended to explore the utility of novel imaging techniques for early non-invasive detection of infection in this clinical setting. We performed a study to evaluate the role of two newer imaging modalities i.e <sup>18</sup>F-FDG-Labelled Autologous leukocyte PET/CT and MRI (including advanced techniques like diffusion weighted imaging (DWI), spectroscopy (MRS)) in this scenario.

**Aims & Methods:** To evaluate the utility of novel imaging techniques i.e <sup>18</sup>F-FDG-Labelled Autologous Leukocyte PET/CT and MRI (including DW-MRI, MRS) in early non-invasive detection of infection in setting of acute pancreatitis.

We performed a prospective analytical study which approved by our institutional review committee in which patients of AP and suspected infection were radiologically evaluated by both <sup>18</sup>F-FDG-Labelled Autologous Leukocyte PET/CT and advanced MRI within a span of 24-36 hrs. Targeted image guided sampling and aspiration was then performed from the suspected collection, followed by microbiological assessment.

**Results:** After evaluation of 32 patients of acute pancreatitis with clinical suspicion of infection in the fluid collections, positive microbiological evidence of infection were found in 14 patients and all these patients showed restricted diffusion on MRI and increased uptake on <sup>18</sup>F-FDG-Labelled Autologous Leukocyte PET/CT. 18 patients who did not have microbiologically proven infection showed no restricted diffusion on DWI or increased uptake on PET/CT.

**Conclusion:** Advanced imaging techniques like <sup>18</sup>F-FDG-Labelled Autologous Leukocyte PET/CT and DW MRI are showing encouraging results with high sensitivity for early detection of infection in setting of acute pancreatitis. Addition of these modalities to the imaging protocols may help in early diagnosis of superimposed infection thereby improving clinical outcomes. Also both these modalities have shown comparable accuracies in our study.

## P0964 ULTRASONOGRAPHIC ASSESSMENT IN INFLAMMATORY BOWEL DISEASE PATIENTS AND FECAL CALPROTECTIN LEVELS: EMERGING TOOLS IN MONITORING DISEASE ACTIVITY

Anda L.<sup>1</sup>, Costache R.<sup>2</sup>, Gheorghe L.S.<sup>1</sup>, Gheorghe C.<sup>1</sup>

<sup>1</sup>Fundeni Clinical Institute, Gastroenterology, Bucharest, Romania, <sup>2</sup>Fundeni Clinical Institute, Bucharest, Romania

**Contact E-Mail Address:** anda\_les@yahoo.com

**Introduction:** Current guidelines recommend bowel ultrasound (BUS) besides gold standard endoscopic assessment in the management of inflammatory bowel disease (IBD) patients [1]. Sonographic measurements superpose with endoscopic findings and other imagistic methods (MRI) [2]. Faecal calprotectin level correlates significantly with endoscopic disease activity in IBD [3] and the test is useful in clinical practice for assessment of endoscopic activity and remission.

**Aims & Methods:** 42 IBD patients were included in the study (3 diagnosed with ulcerative colitis, 39 with Crohn's disease). Diagnosis was established endoscopically and histologically and both patients with active and inactive disease were included. Exclusion criteria referred to patients with superimposed infection (viral and Clostridium Difficile) and patients that had solely rectal involvement of the disease. Patients were prospectively evaluated sonographically using a 4-8 MHz micro-convex transducer and the examiner was blinded to biological data. No special preparation was needed before BUS. Data collection was performed noting 3 sonographic measurements of bowel wall thickness in each patient and the assessment of intestinal wall structure. The sonographic measurements were noted in the corresponding regions according to endoscopic observations. Mean value of BWT was calculated. Faecal calprotectin levels were obtained for each patient and the test had a cut-off value of 50 mg/kg.

**Results:** Strong correlations were observed for the three measurements of the bowel wall thickness (Spearman's equation,  $r = 0.754$ ,  $r = 0.787$  and  $r = 0.793$ ,  $p < 0.001$ ) and values of faecal calprotectin. A mean calculated value of the 3 measurements of BWT was highly correlated with the level of calprotectin too ( $r = 0.802$ ,  $p < 0.001$ ). The observation that the higher the value of the faecal calprotectin the greater the disturbance of the wall stratification (CI 95% [-710.6-359.7],  $p < 0.001$ ) suggested a relationship between the presence of a stratified wall appearance and calprotectin levels.

**Conclusion:** Sonographic findings (BWT and bowel wall structure) and faecal calprotectin levels could be used in clinical practice to evaluate disease activity in IBD patients.

## P0965 COLITIS ON CT - DOES THIS MEAN INFLAMMATORY BOWEL DISEASE?

Patel R.N., Ramakrishnan S., Veglio-Taylor E.-P., Tariq Z., King J., Besherdas K.  
Royal Free London NHS Trust, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** Cross sectional imaging is commonly used to assess the abdomen for a variety of symptoms. Colitis reported on CT has become a frequent indication for lower gastrointestinal endoscopy. The outcomes of performing colonoscopy for radiology reported colitis is not clearly known.

**Aims & Methods:** A retrospective, single centre study of patients referred for a colonoscopy with the indication of 'abnormal imaging'. Data was collected using the endoscopy software audit tool over a 12-month period (September 2017 to August 2018). Patients who had undergone an imaging modality other than CT and those with an overt colonic polyp or mass on CT were excluded from the analysis. Analyses were performed using chi-square and student t-test.

**Results:** 249 patients (183 CT (73.5%), 66 CTVC (26.5%)) underwent a colonoscopy for CT evidence of mural thickening (218 (87.6%)), fat stranding (88 (35.3%)), inflammation (104 (41.8%)) or local lymph nodes (37 (14.9%)); median age 68 (IQR 53 - 79); median time from CT to endoscopy 33 days (IQR 12.5 - 56.5). Initial indication for CT examination: Abdominal pain 112 (45.0%), Change in bowel habit 39 (15.7%), ?Malignancy 32 (12.9%), PR bleeding 13 (5.2%), Weight loss 9 (3.6%) and Other 44 (17.7%). 53 (21.3%) patients had completely normal lower GI endoscopy. 111 (44.6%) had uncomplicated diverticulosis, 11 (4.4%) diverticulitis, 20 (8.0%) haemorrhoids and 37 (14.9%) colorectal polyps.

20 patients (8.0%) had endoscopic evidence of colitis; 14 (6%) histological evidence of colitis. 10 (4%) confirmed IBD at 6 months follow up (4 UC, 6 CD).

	Normal (n=53)	Colitis (n=20)	Malignancy (n=21)	*p value
Age, mean	63.6	54.4	69.5	<0.02
Time to endoscopy (days), mean	45.3	24.5	24.9	<0.04
Mural thickening (%)	48 (90.1)	19 (95)	20 (95.2)	ns
Fat stranding (%)	14 (26.4)	12 (60)	9 (42.9)	<0.03
Inflammation (%)	16 (30.2)	12 (60)	9 (42.9)	0.06
Lymph nodes (%)	4 (5.7)	8 (40)	11 (52.4)	<0.00006
Haemoglobin (g/L), mean	128.0	123.8	112.2	0.005
CRP (mg/L), mean	29.8	55.5	68.1	0.10, <0.05

[Table 1. Comparison of endoscopic diagnoses according to CT features and blood results.]

**Conclusion:** Colitis reported on CT correlates with endoscopic colitis in only 8% of patients in this study. Less than 5% are diagnosed with IBD at 6months follow up. The correlation improves in younger patients and with shorter interval between CT and endoscopy. One in five patients had completely normal endoscopy and over 90% had a benign diagnosis. Radiological reporting of fat stranding was an independent risk factor for endoscopic colitis. Anaemia and raised CRP helps identify those at higher risk of malignancy whilst raised CRP alone shows a trend towards identifying true colitis. We conclude that the findings of 'colitis' on CT does not imply IBD in the majority.

**Disclosure:** Nothing to disclose

## P0966 USEFULNESS OF SLIM FULLY-COVERED SELF-EXPANDABLE METAL STENT FOR UNRESECTABLE HILAR MALIGNANT BILIARY OBSTRUCTION

Fujisawa T.<sup>1</sup>, Ushio M.<sup>1</sup>, Takahashi S.<sup>1</sup>, Yamagata W.<sup>1</sup>, Takasaki Y.<sup>1</sup>, Suzuki A.<sup>1</sup>, Ito K.<sup>1</sup>, Ochiai K.<sup>1</sup>, Okawa Y.<sup>1</sup>, Tomishima K.<sup>2</sup>, Ishii S.<sup>3</sup>, Saito H.<sup>1</sup>, Isayama H.<sup>3</sup>

<sup>1</sup>Juntendo University Graduate School of Medicine, Department of Gastroenterology, Tokyo, Japan, <sup>2</sup>Juntendo University, Department of Gastroenterology, Tokyo, Japan, <sup>3</sup>Juntendo University, Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** tosshay@yahoo.co.jp

**Introduction:** Endoscopic treatment for unresectable hilar malignant biliary obstruction is still difficult because intrahepatic biliary branches were independent of each other, and a standard treatment has not been established yet. We have been using slim fully-covered self-expandable metal stent (SFCSEMS) side-by-side placement method, and examined the usefulness of this method.

**Aims & Methods:** A retrospective study was conducted on unresectable hilar malignant biliary obstruction in which SFCSEMS (6mm in a diameter) were placed between December 2016 and April 2019 in our hospital. Recurrent biliary obstruction (RBO), prognosis, and adverse events were analyzed according to Tokyo criteria 2014.

**Results:** The subjects were 31 cases with first metal stent placement (19 men, average age 69.4 years), primary diseases were 10 cases of cholangiocarcinoma, 8 cases of gallbladder cancer, 2 cases of hepatocellular carcinoma, 11 cases of metastatic tumor. The subjects include many cases in advanced status of the cancer, 37% of cases with performance status (PS) 3 or higher, and 70% of cases with Bismuth classification 3 or higher. Single SFCSEMS was placed in 2 cases, two SCSEMS in 24 cases and three in 4 cases with 100% of technical success rate. The clinical success rate was 90% (27/30), and all three failure cases were PS 3 or more and Bismuth 4, all of which were considered to be in liver failure. Stent removal was attempted in all 12 cases in which RBO was occurred during the course, and all of them could be removed without any adverse events. After removal, the SFCSEMS was reinserted in 6 of 12 cases and changed into plastic stents in 5 cases, and EUS-guided hepaticogastrostomy in 1 case. Median time to RBO was 128 days, and survival was 114 days. adverse events related with the deployment procedure was only 2 cases (6.7%) in 1 case of mild pancreatitis and 1 case of cholangitis. Pancreatitis was conservatively treated and cholangitis was improved by adding another metal stent to the cause biliary branch which was obstructed by SFCSEMS.

**Conclusion:** The slim fully-covered SEMS with 6mm diameter is considered to be an effective method because it is easy to remove, and patency is equal to or more than that of other methods, and there are few incidents.

**Disclosure:** Nothing to disclose

## P0967 BILATERAL METAL VERSUS PLASTIC STENTING FOR PALLIATION OF JAUNDICE IN PATIENTS WITH UNRESECTABLE CARCINOMA GALLBLADDER

Kumar A., Rai P.

Sanjay Gandhi Post Graduate Institute of Medical Sciences, Gastroenterology, Lucknow, India

**Contact E-Mail Address:** ashok110@gmail.com

**Introduction:** Gall Bladder Cancer (GBC) is one of the most common biliary malignancy and frequently presents as locally advanced disease with jaundice. Most of these patients cannot undergo curative surgical resection and need palliative biliary stenting for biliary decompression. Endoscopic biliary drainage is well established modality for palliation of malignant lower end biliary obstruction, but it is technically challenging for hilar biliary strictures. Plastic stents (PSs) have been widely used, but Self Expanding Metal Stents (SEMSs) are becoming increasingly popular. However, the previously published studies have been heterogenous with regard to underlying disease pathology (GBC, cholangiocarcinoma and others), level of malignant block (varying from I-IV Bismuth classification) and type of biliary system drainage (unilateral or bilateral).

**Aims & Methods:** This study aimed to determine the safety and efficacy of plastic or metal stent deployment in a homogenous population of patients with type II (Bismuth classification) malignant hilar block due to unresectable gall bladder cancer.

Records of all patients with Gall Bladder cancer with hilar block who underwent endoscopic biliary drainage at our tertiary-care center between January 2013 and December 2018 were analyzed for the following outcome parameters: technical success (TS), functional success (FS), early and late complications, stent patency and survival. Patients were followed from stent insertion until death or stent occlusion.

**Results:** A total of 71 patients were evaluated, of whom 60 [mean age of 54.2 years (range: 34-79) years; men 26, women 34] underwent bilateral stent placement. Twenty seven patients had SEMS placed and 33 patients had plastic stents (PS) placed. TS was achieved in 33(100%) patients treated with PS and in 25(92.6%) patients palliated with SEMS. SEMS provided significantly higher success of biliary drainage as compared to plastic stents, on both intention to treat (81.4% vs 57.6%,  $p=0.019$ ) and per protocol analysis (88.0% vs 57.6%,  $p=0.019$ ) with a lower number of ERCP procedures (1 vs 1.58) and lower complication rates (22.2% vs 39.4%) compared with PS. SEMS remained patent for a significantly longer duration than PS [122.6 days (range 25-219) vs. 25(0-94) days, respectively,  $p=0.000$ ]. Thirty days mortality was higher (but statistically insignificant) in the PS group as compared to SEMS group [18.2% vs.7.4% days, respectively,  $p=0.222$ ]. Use of metal stents was associated with a significantly longer median survival time [126.0 days (3-266)] than in patients treated with PS [87.9 days (9-291),  $p=0.000$ ].

**Conclusion:** SEMS should be preferred over plastic stents for palliation of jaundice in malignant hilar block due to unresectable gall bladder cancer because of better adequacy of biliary drainage, higher stent patency and patient survival with lower complication rates and reduced number of total ERCP procedures with SEMS.

**Introduction:** Percutaneous transhepatic biliary drainage (PTBD) for malignant biliary obstruction is a useful alternative treatment for patients in whom endoscopic transpapillary drainage is difficult to perform. We examined the feasibility of endoscopic ultrasound-guided biliary drainage (EUS-BD) replacement of PTBD for internalization of biliary drainage.

**Aims & Methods:** This single-center retrospective study reviewed records of patients who had undergone EUS-BD replacement of PTBD between March 2017 to April 2019. We evaluated technical success; procedure time; clinical success, defined as subsequent removal of percutaneous catheter; adverse events; time to recurrent biliary obstruction; and reintervention.

**Results:** EUS-BD (EUS-hepaticogastrostomy in 9 and EUS-choledochoduodenostomy in 2) was performed in 11 patients (9 males, mean age 82 years) to replace PTBD. The median period from PTBD placement to EUS-BD was 8 (range, 3-34) days. Technical success was achieved in all cases. The mean procedure time was  $44.0 \pm 17.1$  min. There were two early adverse events, bile peritonitis in one and acute cholangitis in one. Both conditions were improved with only antibiotic administration. Clinical success was achieved in all cases with PTBD catheter removal after a median of 7 (range, 1-52) days. Median time to recurrent biliary obstruction was 100 (26-357) days. Reintervention was performed in 6 patients. Five patients were exchanged for the new stent endoscopically, and one was required reinsertion PTBD.

**Conclusion:** EUS-BD replacement of PTBD for internalization of biliary drainage is a feasible, effective and safe technique for patients in whom endoscopic transpapillary drainage is difficult. At the time of reintervention, reinsertion PTBD is not required in most cases and an endoscopic approach is possible.

**Introduction:** Fully covered self-expandable metallic stent (FCSEMS) have been used recently to treat refractory benign pancreatic stricture in advanced chronic pancreatitis. However, stent migration and stent-induced ductal change are main limitations. The aim of this study was to evaluate the usefulness of non-flared short FCSEMS that was designed to minimize ductal injury and migration for refractory pancreatic stricture in advanced chronic pancreatitis.

**Aims & Methods:** Total 25 consecutive patients with symptomatic benign pancreatic duct strictures that was unresolved with plastic stents were prospectively enrolled between August 2012 and July 2018. A short (3 or 5 cm) FCSEMS having long lasso (7 cm) used in this study has non-flared convex ends to minimize tissue hyperplasia and smaller center portion to prevent migration. The FCSEMS placement (intraductal or transpapillary) was performed across the stricture and removal was performed after 3 months.

**Results:** The technical and clinical success rates of FCSEMS placement (14 intraductal and 11 transpapillary stenting) were 100% (25/25), respectively. Stent migration was observed in 1 patients (4.0%) but improved stricture and not needed for additional intervention. Intended stent removal was

successful in 24 patients (100%) (median duration of stenting, 109 days; interquartile range, 91–126). Follow-up ERCP showed resolution of duct strictures in all patients. Stent-induced ductal change was not observed in all patients. Stricture recurrence was observed in 8.0% (2/25) during 665 days of median duration of follow-up (interquartile range, 437–1244).

**Conclusion:** Non-flared short FCSEMS may be potentially effective option for refractory pancreatic stricture in advanced chronic pancreatitis with minimizing stent-induced ductal injury and stent migration.

**Disclosure:** Nothing to disclose

## P0970 INTRADUCTAL PLACEMENT OF NON-FLARED FULLY COVERED METALLIC STENT FOR REFRACTORY ANASTOMOTIC BILIARY STRICTURES AFTER LIVING DONOR LIVER TRANSPLANTATION: LONG-TERM RESULTS OF PROSPECTIVE MULTICENTER TRIAL

**Contact E-Mail Address:** jhmoon@schmc.ac.kr

**Introduction:** Fully covered self-expandable metallic stent (FCSEMS) may be an effective modality for managing anastomotic biliary stricture (ABS) after liver transplantation. However, stent migration and stent-induced ductal injury are main limitations. The objective of this study was to evaluate the usefulness of an unflared, intraductal FCSEMS that was designed to minimize migration and ductal injury for refractory ABS after living donor liver transplantation (LDLT).

**Aims & Methods:** A total of 32 consecutive patients with symptomatic ABS after LDLT unresolved by plastic stents with or without balloon dilation at four tertiary medical centers were prospectively enrolled in this study. A short (3 or 5 cm) FCSEMS having long lasso (10 cm) used in this study had unflared convex ends to minimize tissue hyperplasia and smaller center portion to prevent migration. The FCSEMS was placed above the papilla in all patients and removed at 3–4 months after stenting.

**Results:** Technical and clinical success rates of intraductal placement with FCSEMS were 100% (32/32) and 81.2% (26/32), respectively. Early stent migration was observed in 5 (15.6%) patients. However, 3 patients with early stent migration had stricture resolution without needing additional intervention. Intended stent removal was successful in 27 (100%) patients (median, 101 days; range, 23–118 days). No stent-induced ductal change was observed in all patients. Stricture recurrence was observed in 11.5% (3/26) of patients during 639 days of median duration of follow-up (range, 366–2079 days).

**Conclusion:** Intraductal placement of an unflared short FCSEMS may be a promising option for refractory ABS after LDLT with minimal stent-induced ductal injury and stent migration.

**Disclosure:** Nothing to disclose

## P0971 INTRADUCTAL PLASTIC STENT PLACEMENT IS AN EFFECTIVE THERAPY FOR UNRESECTABLE MALIGNANT BILIARY OBSTRUCTION

Yamaguchi A., Wada K., Moriuchi R., Tao K., Konishi H., Miura R., Tamaru Y., Kusunoki R., Kuwai T., Kouno H., Kouno H.

**Introduction:** Recent reports have described the efficacy of plastic stent (PS) placement inside the bile duct for malignant biliary strictures. However, the superiority of intraductal PS placement (IS) over PS placement across the sphincter (conventional PS placement [CS]) and uncovered metallic stent placement above the sphincter of Oddi (MS) is unclear.

**Aims & Methods:** The aim of this study was to evaluate the efficacy of IS, and compare its efficacy with the efficacies of CS and MS for malignant biliary strictures. This retrospective study included 40 patients (43 procedures) with an unresectable malignant hilar or middle bile duct obstruction, who underwent IS between January 2008 and December 2018 at our institution. The indication for IS was a distance of at least 3 cm between the lower end of the stricture and the sphincter. We compared the efficacy of IS with the efficacies of CS (34 patients [46 procedures]) and MS (21 patients [21 procedures]). Among the 40 patients who underwent IS, the origins of the malignant biliary stricture were gallbladder cancers in 10 patients, intrahepatic cholangiocarcinomas in 11 patients, bile duct cancers in 6 patients, pancreatic cancers in 3 patients, and others in 10 patients. We evaluated complications associated with stent placement, the Time to recurrent Biliary Obstruction (TRBO), and stent removability at occlusion. We modified a 7-Fr Flexima biliary stent (Boston Scientific Co., Boston, MA) and attached a nylon thread (size 2/0) to the distal end for removal. If insertion was difficult due to winding or narrowing of the intrahepatic bile duct (ex. B3 and B6), we placed a Flexima nasobiliary drainage tube (7.5Fr), cut to the appropriate length, as an internal stent. Most stent placements were performed after preoperative nasobiliary drainage.

**Results:** The overall technical success rates in the IS, CS, and MS groups were all 100%. The TRBO was greater in the IS group than in the CS group (117 days vs. 45 days,  $P < 0.001$ , log-rank test); however, the TRBO was not significantly different between the IS and MS groups (117 days vs. 139 days,  $P = 0.57$ ). The predictive factors of longer TRBO in plastic stents were IS (vs CS), usage of anti-cancer drugs, and multiple stents replacement in univariate analysis and was IS in multivariate analysis ( $P < 0.001$ , Cox's proportional hazards model).

In the IS group, there were no early complications associated with stent placement; however, delayed complications were observed in 4 patients from this group (3 had cholecystitis and 1 had stent migration to the hepatic side). Additionally, in the IS group, 19 patients developed stent dysfunction. The causes of dysfunction were sludge or food deposition in 14 patients, reflux cholangitis in 1 patient, bending of the stent in 1 patient, tumor overgrowth in 1 patient, dislocation to the duodenal side in 1 patient, and migration to the hepatic side in 1 patient. In 14 patients from the IS group, stent replacement was attempted and was performed successfully. There were no complications associated with stent removal.

**Conclusion:** The TRBO is longer with IS than with CS for malignant biliary obstruction. Additionally, the TRBO tends to be shorter with IS than with MS; however, the difference might not be significant. Additionally, complications are relatively minor with IS, and the stent can be removed if dysfunction occurs. Therefore, IS is an effective option for unresectable malignant hilar and middle bile duct obstructions, and it is as effective as MS.

**Introduction:** Endoscopic ultrasonography (EUS)-guided transmural drainage has been accepted as a modality of choice for pancreatic fluid collections and gallbladder (GB) drainage. Double pigtail plastic stents, conventional tubular-shaped self-expanding metal stents (SEMS), and recently introduced lumen apposing metal stents (LAMS) are commonly used for this procedure.

However, each type of stent has its own disadvantages; plastic stent is prone to occlusion due to its small diameter, fully covered SEMS has a higher risk of migration, and LAMS has been reported to cause serious

adverse events such as bleeding and buried LAMS syndrome. There are still unmet needs in dedicated stents for transluminal drainage despite the ongoing developments.

**Aims & Methods:** This animal study aims to evaluate a newly designed fully covered metal stent with dual coiled ends for the transluminal drainage. We performed the EUS-guided GB drainage with a newly developed metal stent in 8 mini pigs with surgically induced GB distension. This stent is a SEMS with coiled ends, which is made of nitinol wire and fully covered with silicone. The diameter of the stent is 8mm and the length is 6cm. Both pigtail ends are coiled 360 degrees in order to minimize the risk of bidirectional migrations. EUS-guided GB drainage was performed as follows; First, GB was punctured with a 19-gauge needle under direct sonographic visualization from the stomach. A guidewire was inserted through the access needle and coiled inside the GB. Further puncture with a cystotome and tract dilatation with a balloon catheter was done, followed by the deployment of the stent with an 8Fr delivering catheter under the guidance of fluoroscopy, EUS and endoscopy. After the EUS-guided cholecystogastrostomy was completed, pigs were raised and monitored for certain periods before the removal of a stent; 28 days in 2 pigs, 35 days in 2 pigs, 42 days in 2 pigs, and 49 days in 2 pigs. The primary outcome was technical success rate and the secondary outcomes were adverse events, stent dysfunction, stent removability, and the successful fistula formation.

**Results:** The stent was placed successfully between the gallbladder and the stomach without any adverse event in all cases. Neither stent migration nor dysfunction was observed during the study period and all the stents were removed easily as scheduled. Successful cholecysto-gastric fistula formation was confirmed at endoscopic and histologic level in all cases.

**Conclusion:** EUS-guided transmural drainage and fistula formation using a new fully covered metal stent with dual coiled ends was technically feasible without any adverse event in this animal study. We expect this newly developed stent to be useful in EUS-guided transluminal drainage. Further clinical studies on the application of this stent in real practice are needed to evaluate the efficacy and safety.

**Disclosure:** Dr. Lee is the inventor of the newly developed metal stent used for the study. The stents were provided free of charge and financial support was provided for the study by S&G Biotech Inc.

**Contact E-Mail Address:** b\_mangiavillano@hotmail.com

**Introduction:** Esophageal cancer is the sixth most common cancer worldwide and in presence of non-surgical candidate presenting dysphagia, the placement of a self-expandable metal stent (SEMS) uncovered, partially covered (PCSEMS) or fully-covered (FCSEMS) nowadays represent a safe and effective palliative treatment for the relief of dysphagia. Esophageal stent are placed over-the-wire (OTW), under X-ray control, with or without endoscopic assistance during the stent release. Actually, there are no data in literature about the use of the new through-the-scope (TTS) esophageal stent placed for malignant dysphagia.

**Aims & Methods:** The aim of our study is to evaluate the clinical efficacy of the new TTS esophageal stent in this group of patients. 35 patients (10F and 25M - mean age: 76±9.1ys) with malignant dysphagia unfit for surgery underwent TTS esophageal stent placement (Taewoong Medical Co.) were retrospectively evaluated. 27 patients presented adenocarcinoma, 6 were squamous neoplasia, 1 neuroendocrine tumor and 1 ab-extrinsic compression by breast cancer lymphadenopathy. Length of stenosis was of 5.6±2.8 cm. 28 stenosis were located at the III distal esophagus, 6 in the middle

and 1 in the proximal. 13 stent were of 18mm diameter, 18 of 20mm diameter and 4 of 22 mm. We replaced 10 SEMS, 11 PCSEMS and 14 FCSEMS. All of the stents were placed for palliation.

**Results:** All of the 35 of the patients had completely relief of dysphagia, starting liquid and solid oral intake 24h after the procedure. No adverse events were observed during the stent placement. In one case (2.8%) the guide-wire was not used. In 12 patients a submucosal marking of the distal part of the stenosis was used (34.2%). 5 distal migration were observed (14.7%): 1 PCSEMS after three months of chemotherapy (CT) and 4 FCSEMS (28.5% of all FCSEMS), of which 1 after 45 days of CT and 3 at 1, 2 and 5 days after placement. No technical difficulties were encountered by the endoscopists during the stent placement.

**Conclusion:** The efficacy of the new TTS esophageal stent, in the relief of malignant dysphagia, is comparable to the standard OTW esophageal stent but adverse events seems to be reduced. Migration rate was higher for the FCSEMS. TTS esophageal stent allows to reduce procedure's time and the technique seems more simple if compared to the OTW. An antimigration system may diminish the migration rate of the FCSEMS.

**Disclosure:** Nothing to disclose

### P0974 EQUIVALENCE IN LONG-TERM ONCOLOGICAL OUTCOMES OF COLONIC STENTING AS BRIDGE TO SURGERY IN COMPARISON WITH SURGERY ALONE IN STAGE II AND III LEFT-SIDED OBSTRUCTIVE COLORECTAL CANCER

Ishibashi R.<sup>1</sup>, Yoshida S.<sup>1,2</sup>, Kondo R.<sup>1</sup>, Hata M.<sup>1</sup>, Hakuta R.<sup>1</sup>, Nakada A.<sup>1</sup>, Takahara N.<sup>1</sup>, Yamada A.<sup>1</sup>, Nakai Y.<sup>1,2</sup>, Koike K.<sup>1</sup>

<sup>1</sup>University of Tokyo, Graduate School of Medicine, Department of Gastroenterology, Tokyo, Japan, <sup>2</sup>University of Tokyo, Endoscopy and Endoscopic Surgery, Tokyo, Japan

**Contact E-Mail Address:** rei1484@gmail.com

**Introduction:** Endoscopic stenting with self-expanding metallic stent is considered as one of an effective treatment for intestinal decompression in obstructive colorectal cancer. However, many physicians remain hesitant to perform colonic stenting as bridge to surgery (BTS) in a curative setting, since it has been suggested to adversely affect oncological outcomes of colorectal cancer patients. The aim of this study is to verify the equivalence of colonic stenting to surgery alone for stage II and III left-sided obstructive colorectal cancer in long-term oncological outcomes.

**Aims & Methods:** This study was conducted as a retrospective chart review at a single institute in Japan. The data of patients who had operable left side obstructive colorectal cancer at first diagnosis were collected retrospectively from the clinical records of the University of Tokyo Hospital between 2007 and 2017. We defined obstructive colorectal cancer as the malignant stricture caused by colorectal adenocarcinoma that a colonoscope cannot pass and requires fasting or food restriction allowing only liquid food. We compared the patients who received colonic stenting before surgery (Stent group) and who received surgery alone without decompression treatment (Surgery alone group). Patient characteristics, pathological findings, duration of fasting, and duration of recurrent-free survival and overall survival were obtained from electric medical record.

**Results:** We identified 364 obstructive colorectal cancer patients during this period, of which 114 patients were classified as stage II or III. Among them, 23 patients received stent placement for decompression and 91 patients were received surgery alone. There was no difference between the 2 groups regarding gender, age and location of primary tumor. There were more cases of stage II in the Stent group than in the Surgery alone group (65.2 % vs 41.8%, P = 0.04). In pathological findings, although there was no statistical difference in the depth of tumor, the Surgery alone group had more patients with local lymph node metastasis (49.5 vs 34.8 %, P = 0.04) and neural invasion (72.7 vs 42.9 %, P = 0.04). Stent placement was clinically successful in all cases except one, and no perforation were observed. Duration of fasting was shorter in stent group (23.6 vs 28.8 days P = 0.03). Regarding the long-term oncological outcomes, no statistically significant difference was observed in recurrent-free survival or overall survival. In multivariate analysis of recurrence, local lymph node metastasis and neural invasion were risk factors, but stent placement was not identified as a risk factor.

**Conclusion:** Stent placement without perforation as a bridge to surgery for obstructive colorectal cancer patients does not adversely affect long-term oncological outcomes.

**Disclosure:** Nothing to disclose

## P0975 RIGHT-SIDED COLONIC STENTING IN PALLIATIVE COLON CANCER: MORE CHALLENGING BUT LOWER LATE COMPLICATION RATE AND AT LEAST EQUIVALENT SURVIVAL

Dewar D.H.<sup>1</sup>, Walker G.<sup>1</sup>, Engledow A.H.<sup>2</sup>

<sup>1</sup>University Hospital Lewisham, Gastroenterology, London, United Kingdom,

<sup>2</sup>University Hospital Lewisham, Colorectal Surgery, London, United Kingdom

**Contact E-Mail Address:** daviddewar@nhs.net

**Introduction:** Stent insertion for malignant colonic obstruction is established as a palliative measure as well as a bridge to surgery. UK guidelines on colorectal cancer (NICE CG131) specifically does not recommend placement of a stent in right-sided malignant large bowel obstruction.

**Aims & Methods:** Patients referred for colonic stenting in our centre over a 10-year period up until 2019 were included. Technical and clinical outcomes, and subsequent progress, including late complications, surgery, re-stenting, oncological therapies, and death were recorded. To assess the durability of stent benefit, we measured time to re-intervention (re-stenting, surgery, or death without re-intervention), surgery-free survival (to surgery, or death without surgery), and overall survival (to death, irrespective of any intervention).

**Results:** 135 stent procedures were undertaken for malignant large bowel obstruction - of these 105 cases were index procedures with palliative intent, comprising 80 left-sided tumours and 25 right-sided obstructing tumours proximal to the splenic flexure. The median age was 74 years (range 27-94), and 56% were male. Technical and clinical success rates were respectively 90% / 86% for left-sided stents, and 72% / 68% for right-sided stent procedures ( $p=0.04$  /  $p=0.07$ ). There was evidence of improving outcomes with time with technical success in 2009-2014 and 2014-2019 being 81% and 96% for left-sided, and similarly improving from 60% to 79% for right-sided stents ( $p>0.05$ ). Reasons for clinical failure in left and right-sided stents were inadequate bowel preparation (0% v 12%), inability to cross stricture with wire (7.5% v 16%), and failure to relieve obstruction after satisfactory luminal deployment of stent (5% v 4%). There were no complications during the stent procedures, but later complications requiring surgical intervention were 3 perforations in left-sided stent cases (day 1, day 27, day 101); 1 patient with an extrinsic cancer had early stent migration on day 4; 1 patient developed an abdominal wall abscess on day 47; 1 stent occlusion was operated on day 90. Stent migration was identified in a further 6 left-sided stent patients (day 27 palliated, day 123 and day 274 both re-stented; a further 3 patients, all undergoing chemotherapy and >6 months post stent, were noted on follow-up CT to have incidental stent migration, but no intervention was required). Stent occlusion in a further 7 cases required re-stenting at a median of 228 days (177 to 498 days). One right-sided patient re-obstructed on day 536 and had surgery but no other interventions occurred in this group. Comparing left and right-sided stents, overall complication rates in the 12 months after stenting were 25% / v 0% ( $p=0.02$ ), duration of stent benefit was 177 v 320 days ( $p=0.07$ ), surgery-free survival 223 v 320 days ( $p=0.12$ ) and overall survival 306 v 320 days ( $p=0.29$ ). Patients who had a failed palliative stent procedure had a median survival of only 75 days ( $p=0.002$ ), which was not related to any complications.

**Conclusion:** Outcome and survival after right-sided colonic stenting appears at least comparable to left-sided stenting - although technical success was statistically lower, there was a lower complication rate in the 12 months after stent insertion with no re-interventions, compared to 1 in 5 in the left-sided group. The survival of right-sided stent patients was not inferior to left-sided stent patients. We believe right-sided stenting should be a management option for patients presenting with proximal large bowel obstruction and palliative cancer.

## P0976 FACTOR ASSOCIATED TECHNICAL AND CLINICAL FAILURE OF SELF EXPANDABLE METAL STENT IN MALIGNANT COLORECTAL OBSTRUCTION

Myung D.-S., Kim K.-H., Hong J.-Y., Choi J.-H., Jung M.-W., Joo Y.-E.

Chonnam National University Medical School, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Gwangju, Korea (Republic of)

**Contact E-Mail Address:** myungdaeseong@daum.net

**Introduction:** Self-expanding metal stents (SEMSs) can be used as a palliative treatment or to decompress colon prior to definitive surgery. The purpose of this study was to investigate the factor associated clinical and technical Failure of SEMS used as palliation and bridge to surgery for malignant large bowel obstruction.

**Aims & Methods:** We retrospectively reviewed the records of patients with malignant colorectal obstruction who tried SEMS insertion in our hospital between January 2008 and December 2017. We analyzed demographic, clinical characteristics. Technical failure was defined as failure to deploy the stent across the colon stenosis site. Clinical failure was defined as the absence of resolution of obstructive symptoms and passage of gas and stool within 7 days despite achievement of technical success.

**Results:** SEMS were tried in total 466 patients. The indication of SEMS was as a bridge to surgery in 225 (48.3%) patients and as palliation in 241 (51.7%) patients. 83 (17.8%) patients were seen in right colon obstruction. 383 (82.2%) patients were seen in left colon obstruction. Technical failures were found in 50 patients (10.7%). After SEMS insertion, clinical failure was found in 23 of 416 patients (5.5%).

On univariate analysis, the rate of technical failure was high in patients with peritoneal carcinomatosis, abdominal pain (Visual Analogue Scale(VAS)  $\geq 5$ ), abdominal tenderness, C-reactive protein ( $>4.4\text{mg/dl}$ ), fever, palliative treatment, metastasis. Multivariate analysis revealed that peritoneal carcinomatosis(odds ratio: 2.43, 95% CI: 1.22-4.83,  $p=0.012$ ), abdominal pain (Visual Analogue Scale  $>5$ ) (odds ratio: 3.40, 95% CI: 1.08-10.549,  $p=0.036$ ) were a significant risk factor for technical failure.

On univariate analysis, the rate of clinical failure was high in patients with peritoneal carcinomatosis and elevated White Blood Cell(WBC) count( $>10800/\mu\text{l}$ ). Multivariate analysis revealed that peritoneal carcinomatosis (odds ratio: 3.14, 95% CI: 1.30-7.61,  $p=0.011$ ) and elevated WBC count (odds ratio: 2.55, 95% CI: 1.03-6.33,  $p=0.043$ ) were a significant risk factor for clinical failure.

Stent complication (58/466, 12.4%)	Treatment for stent complication
Perforation (15/58, 25.9%)	operation :13
	supportive care due to poor general condition: 1
	Operation refuse: 1
Migration (26/58, 44.8%)	2nd stent insertion: 11
	operation :13
	observation: 2
Re-stenosis (17/58, 29.3%)	operation: 13
	2nd stent insertion: 3
	Treatment refuse: 1

[Stent complication and treatment of complication]

**Conclusion:** Before trying SEMS insertion for malignant colorectal obstruction, endoscopist must consider patient condition. Patient with peritoneal carcinomatosis, abdominal pain (VAS $\geq 5$ ), elevated WBC count is negatively impacted outcomes of SEMS placement.

**Disclosure:** Nothing to disclose

## P0977 ANALYSIS OF THE RISK FACTORS COLONIC PERFORATIONS IN PATIENTS AFTER STENTING FOR MALIGNANT COLORECTAL OBSTRUCTION

Vodoleev A.<sup>1,2</sup>, Duvanskiy V.<sup>3</sup>, Pirogov S.<sup>4</sup>, Karpova E.S.<sup>5</sup>, Perfil'ev I.<sup>1</sup>, Kryazhev D.<sup>2</sup>, Veselov V.<sup>1</sup>, Sukhin D.<sup>1</sup>, Yarotskov I.<sup>6</sup>

**Introduction:** SEMS implantation is an effective method of decompression for patients with malignant colorectal obstruction. However, the use of colonic stenting is limited due to relatively high rate of complications. The most serious complication is perforation, requiring emergency surgery and associated with high mortality and risk of cancer cell dissemination. According to publications, rate of perforations is 2-10%, but we have very limited and unsystematic data about risk factor of perforations.

**Aims & Methods:** The aim of our research work was to analyze the factors influencing the occurrence of various types of perforation after colorectal stenting. We retrospectively carefully studied cases of 197 patients with malignant colorectal obstruction who received endoscopic SEMS insertion from December 2012 to April 2019. We divided perforations into 2 types: 1) perforation of the tumor and / or colonic wall with a stent and perforation of the proximal colon segments due to dilatation or ischemic lesion.

**Results:** The technical and clinical success rates were 98.0% and 92.3%. After successful procedure, in 11 (5.6%) patients perforation was recognized on 1-20 days. One patient has silent perforation (intraoperative finding), in 1 case - autopsy finding. Severe obstructive symptoms (11-15 points on the Colon Obstruction Score (odd ratio 7.2432; 95% confidence interval, 1.040-28.787) and 0-1 on the CROSS scale odd ratio, (odd ratio 4.439; 95% confidence interval, 0.48-0.59) were perforation-related factors for the entire sample of cases. Additionally, stage T4b was risk factor of perforation in first subgroup odd ratio (odd ratio 7.87; 95% confidence interval, 2.040-12.508), and cecum dilatation on X ray more 10 cm was significantly associated with occurrence of perforation in second subgroup (odd ratio 2.602; 95% confidence interval, 1.279 - 5.634).

**Conclusion:** Severity of obstructive symptoms was significantly associated with occurrence of perforation. In order to reduce perforation rate, clinicians should pay more attention when performing SEMS placement and monitoring patients with these risk factors.

**Disclosure:** Nothing to disclose

## P0978 ADDITIONAL SURGERY AFTER CHEMOTHERAPY FOLLOWING ENDOSCOPIC COLONIC STENTING IN THE MANAGEMENT OF OBSTRUCTIVE COLORECTAL CANCER WITH DISTANT METASTASIS

**Introduction:** Endoscopic stenting with a self-expandable metallic stent (SEMS) in patients with acute large-bowel obstruction due to CRC has been established as a palliative therapy or a bridge to surgery with more favorable rates of permanent stoma, primary anastomosis, and overall complications. In the previous study, we demonstrated that when technical and clinical successes are achieved by careful SEMS placement, chemotherapy under long-term SEMS is a feasible therapeutic option for patients with obstructive CRC. However, the outcome of additional surgery after chemotherapy under long-term SEMS placement has not been investigated.

**Aims & Methods:** The aim of this study was to evaluate outcome of additional surgery after chemotherapy following endoscopic colonic stenting by comparing that of chemotherapy following stenting without additional surgery and that of chemotherapy following surgery.

In total, 68 patients with stage IV CRC who visited the Aomori Prefectural Central Hospital for obstructive symptoms between January 2012 and March 2018 were evaluated. In this retrospective study, the patients were classified into an SC (stenting before chemotherapy) group (n = 36), comprising those who underwent chemotherapy following endoscopic colonic stent placement, and an OC (operation before chemotherapy) group (n = 32), comprising those who underwent chemotherapy following surgery. In the SC group, for comparison, the patients were further classified into those who did (n = 20) and did not (n = 16) undergo additional surgery. Patients' characteristics including age, gender, tumor location, performance status, obstructive symptom and prognostic nutritional index (PNI), adverse events and overall survival were evaluated.

**Results:** Patients characteristics in the SC and OC groups

There were no significant between-group differences in age, tumor location, performance status, obstructive symptom and PNI. Male to female ratio was significantly lower in the OC group (16/16) than in the SC group (28/8, p=0.017).

**Patient characteristics in the SC group for those who did and did not undergo additional surgery**

There were no significant between-group differences in male to female ratio, performance status, frequency of tumor locations, and response grades to chemotherapy. Patient age was significantly lower in patients who underwent additional surgery (62.9) than in those who did not (70.6, p< 0.01).

**Adverse effects in the SC group**

The frequency of procedure-related adverse events occurring after 30 post-stenting days included perforation (3.1%) at 149 days post-stenting, dislodgement and migration (21.9%) at 84 days post-stenting, and re-obstruction (12.5%) at 98 days post-stenting.

**Overall survival**

There was no significant difference in overall survival between the SC and OC groups (p = 0.371). In the SC group, patients who underwent additional surgery had an improved survival compared with those who did not (p < 0.001) and those in the OC group (p = 0.027). Furthermore, in the SC group receiving additional surgery, 8 patients with PNI increase before and after stenting had an improved survival compared with 12 patients without PNI increase (p < 0.001).

**Conclusion:** In the SC group, additional surgery was found to significantly improve overall survival which can be predicted by PNI evaluated before and after stenting. We conclude that chemotherapy under long-term SEMS with additional surgery is a feasible therapeutic option for patients with obstructive CRC.

**Disclosure:** Nothing to disclose

## P0979 THE ROLE OF EUS-GUIDED GASTROENTEROSTOMY IN THE TREATMENT OF MALIGNANT GASTRIC OUTLET OBSTRUCTION

**Contact E-Mail Address:** j.b.kastelijn@umcutrecht.nl

**Introduction:** In patients with malignant gastric outlet obstruction (mGOO) and an expected survival of at least six weeks, surgical gastrojejunostomy (sGJJ) seems favoured over duodenal stenting. (SUSTENT-study; Jeurnink et al, 2010). There is accumulating evidence that EUS-guided gastroenterostomy (EUS-GE) could be an effective and safe alternative treatment of mGOO. It is minimally invasive with fast relief of complaints, like duodenal stenting, but it also has the potential of low reintervention rates and long-lasting patency, like sGJJ. However, the exact role of EUS-GE in the management of mGOO remains unclear and evidence about its long-term durability is limited. We therefore aimed to evaluate the long-term patency of EUS-GE.

**Aims & Methods:** We performed an international, multicentre retrospective analysis of EUS-GE cases that were performed between 2015 and 2019 in six centres from four European countries. All cases concerned EUS-guided placements of a Hot AXIOS Stent (Hot AXIOS™ Stent and Electrocautery-Enhanced Delivery System, Boston Scientific Corporation, USA), as palliative treatment for mGEO, regardless of the cancer etiology. Data on patient and procedural characteristics were recorded. Endpoints were:

1. Technical success (defined as a successful placement of the Hot AXIOS stent between the stomach and an intestinal or duodenal loop),
2. Clinical success (defined as the ability to tolerate a liquid diet without vomiting after a technical successful placement of the Hot AXIOS stent),
3. Long-term patency (defined as the time to recurrence after a technical and clinical successful treatment), and 4) adverse events.

**Results:** In total 41 patients (51% female, mean age 69.5 years (range 40-90)) were included in this study. Most patients were unable to tolerate oral intake, with 21/41 (51.2%) having a GOOSS-score of 0. Etiology of mGEO included pancreatic cancer (39%), gastric cancer (15%), duodenal cancer (7%), periampullary cancer (7%), gallbladder cancer (5%), biliary tract cancer (7%), and extrinsic compression by metastases (17%). Ascites was present in 14/41 (37%) and peritoneal carcinomatosis in 13/41 (36.1%) patients.

The Hot AXIOS stent was placed using the direct technique in 32/41 (78%) patients. Balloon assistance was used in the remaining 22%. A 15 mm diameter stent was placed in 28/41 (70%) and 20 mm in the remaining 30%. Additional balloon dilation of the stent was performed in 9 (26.5%) patients.

Technical success was achieved in 35/41 (85%) patients. Stent maldeployment/misplacement was the sole reason for technical failure (n=6). Clinical success was achieved in 30/35 (86%) of the technical successful cases. In 2/30 clinical successful cases, recurrent obstructive symptoms occurred after 33 and 283 days of follow-up. Procedural adverse events occurred in 8 (19.5%) patients which concerned misplacement in seven (four resulting in a perforation), and one puncture of the colon. Postprocedural adverse events occurred in 14 (35%) patients, of which 5 were fatal.

**Conclusion:** The long-term patency of EUS-GE seems good once it is performed successfully and relief of symptoms has been achieved, with recurrent symptoms in only 6.7% of cases. This long-term durability makes EUS-GE a possible treatment option for mGEO. The high number of fatal complications due to misplacement of the Hot AXIOS stent might be a concern.

## P0980 KISSING SUTURING EFFECTIVE METHOD FOR LARGE GASTROINTESTINAL WALL DEFECT CLOSURE

Liu B.-R., Ahmed M.R., Yang H.

*The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China*

**Contact E-Mail Address:** bingrongliu@qq.com

**Introduction:** Endoscopic full-thickness resection (EFTR) has been established as a minimally invasive surgical method for en bloc resection. However, it remains a challenge to safely and efficiently close large defects left after the procedure. Successful closure of the wall defect is the key procedure for EFTR technique.

**Aims & Methods:** Our aim was to demonstrate an easy, safe and feasible technique which uses a combination of clips and nylon loops to close large defects using a single-channel endoscope, called the "Kissing Suturing" method.

We retrospectively studied 35 patients (defect size up to 2 cm in diameter) were treated at our hospital with the 'Kissing Suturing' method for large defect closure resulting from EFTR procedure. After EFTR procedure, a nylon loop of a detachable snare was fixed in the tip of the transparent cap. Then, placed the loop in the defect area and used two clips to anchor it

to the two edges of the defect. Tightening the loop produce two smaller defects which could then be closed with clips or following placing additional loops.

**Results:** A total of 35 patients (20 male, 15 female) with an average of 57.8 years old (range, 27-82) were treated with 'Kissing Suturing' method for large defect closure resulting from EFTR. The mean tumor size was 3.56 cm (range, 2-7 cm). A successful complete resection rate by EFTR was accomplished in 35/35 (100%). The mean defect size was 3.56 cm (range, 2-7 cm). Complete closure of all post-EFTR defects was succeeded in all patients (success rate 100%) with the mean time was 77.62 minute (range, 13-211 minute). There was no major complication such as peritonitis, delayed bleeding or perforation in all patients.

**Conclusion:** This study provides evidence that the use of clips and nylon loops with single-channel endoscope namely "Kissing Suturing" method for large defect closure seems to be safe, easy and feasible.

**Contact E-Mail Address:** jabadahmed88@hotmail.co.uk

**Introduction:** Colorectal cancer is the 4th most common cancer in the UK with an incidence of 41700 new cases every year.

Colonic Stenting for malignant obstruction has been used for palliation and as a bridge to elective surgery. The 2014 ESGE guidelines cautioned use in the latter group due to the risk of upstaging disease. More recent ACPGBI position statements suggest lower morbidity in the stent group compared with primary resection and survival equivalence.

**Aims & Methods:** To review the use of colonic stenting in malignant obstruction at a busy district general hospital against current clinical guidelines.

A 5 year retrospective review of patients in whom colonic stenting for malignant obstruction was attempted (Jan2014-Jan2019). Data were retrieved from endoscopy database, radiology reports and discharge summaries.

**Results:** A total of 36 patients (M:F 1:1) were identified. Mean age was 69 (SD 16, Range 32-97).

The 36 patients can be separated into 25% (9/36) with known colorectal cancer who eventually required a stent due to obstructive symptoms and 75% (27/36) who presented acutely with obstruction with a previously undiagnosed colorectal cancer.

47% (17/36) of patients were stented with a view to subsequent surgery. 53% (19/36) were stented for palliative treatment only.

Known cancer patients average diagnosis to stent time and admission to stent times were 243 and 2 days respectively.

Acute first presentation average diagnosis to stent time and admission to stent times were 6.23 and 2.53 days respectively.

Stents were placed in the sigmoid colon in 44% (16/36), descending colon in 17% (6/36) and splenic flexure in 17% (6/36).

All stents were performed by one of three experienced consultant endoscopists, in a symptomatic cohort.

They all had a contrast CT scans confirming the diagnosis and level of obstruction prior to the procedure.

No stricture dilatations were performed.

Uncovered Cook Evolution stents were used in all cases, from 6-10cm in length.

No patient in the cohort had extra colonic obstruction.

83% of patients had a phosphate enema, 6 patients who had no prep, with most reporting a good or satisfactory preparation on endoscopy report.

Only 9 of the 17 patients who were stented with a view to surgery proceeded to surgery. In the remaining 8 out of 17 a decision was made not to have surgery or no information was available. None of the proximal lesions which were stented had a subsequent resection.

Repeat CT imaging was performed on average 97.8 days after stent insertion.

The average time to elective surgery from stent insertion was 27.33 days (13-39 days).

35/36 stents attempted were successful on first attempt with remaining case succeeded on second attempt.

Stent complications were: 1 stent related perforation which occurred 4 days post insertion for a palliative indication and a partial stent obstruction managed conservatively.

47% (17/36) of patients died with an average stent to death time of 209 days. 11 of these had been stented with palliative intent whilst 6 had been stented with a view to subsequent surgery.

**Conclusion:** 1. Colonic Stenting for malignant obstruction has a high success rate, and a low morbidity and mortality rate.

2. It can provide long-term relief of obstruction in palliative patients, or provide a bridge to elective surgery.

3. The use of stenting as a bridge to surgery in potentially curable patients remains controversial but appears to be a reasonable and safe option in experienced hands.

**Contact E-Mail Address:** elbachahicham@hotmail.fr

**Introduction:** Afferent limb syndrome (ALS) or Afferent loop syndrome is a late postoperative complication of duodenopancreatectomy defined as the dilatation of the afferent limb with accumulation of biliopancreatic fluid due to the mechanical obstruction of the afferent limb usually by cancer recurrence. ALS can cause abdominal pain pancreatitis and reflux cholangitis. Standard treatment is surgery, but in patient in bad shape surgery is an invasive treatment carrying its own morbidity and mortality.

We present here an endoscopic technic for ALS managment.

**Aims & Methods:** We present here five cases of ALS treated by endoscopic entero-anastomosis by Lumen apposing metal stents (LAMS). The aim of the technique was to obtain an internal drainage of the afferent limb through the stomach or jejunum by creating an endoscopic anastomosis. The gastroenterostomy or enteroenterostomy was created under endoscopic ultrasound (EUS) and fluoroscopic guidance.

**Results:** All procedures were successful with no related complications, two patients had a complete regression of their symptoms, one experienced cholangitis recurrence after 3months, two patients died after some weeks due to their malignancies.

**Conclusion:** EUS-guided entero-enterostomy by LAMS offers a convenient and safe palliative solution for patients presenting ALS due to progressive malignancy after duodenopancreatectomy.

## P0983 LAPAROSCOPIC SURGERY FOR ACHALASIA: OUTCOMES OF 572 CONSECUTIVE CASES IN JAPAN

Fukushima N.<sup>1</sup>, Yano F.<sup>1</sup>, Omura N.<sup>2</sup>, Tsuboi K.<sup>1</sup>, Hoshino M.<sup>2</sup>, Yamamoto S.<sup>2</sup>, Akimoto S.<sup>2</sup>, Masuda T.<sup>1</sup>, Mitsumori N.<sup>2</sup>, Kashiwagi H.<sup>2</sup>, Yanaga K.<sup>2</sup>

<sup>1</sup>Jikei University School of Medicine, Surgery, Tokyo, Japan, <sup>2</sup>Jikei University School of Medicine, Tokyo, Japan

**Contact E-Mail Address:** naoko9037@gmail.com

**Introduction:** Laparoscopic Heller-myotomy with Dor-fundoplication (LHD) is the most common surgical treatment for achalasia. Recent development of surgical equipment allows less invasive procedures such as reduced

port surgery (RPS) and needlescopic surgery (NS), providing a better cosmetic results. All these techniques are available in our tertiary referral hospital in Japan. The aim of this study is to explore the outcomes of LHD including RPS and NS based on a large cohort of 572 patients diagnosed with achalasia.

**Aims & Methods:** All patients diagnosed with achalasia are entered into a prospectively maintained institutional database. After Institutional Review Board approval, we queried this database to identify patients who underwent LHD between August 1994 and May 2018. Of these, 572 patients who were followed at our clinic at least 3 months after surgery were included. The mean age was 45.6 years and 279 patients were women. The following characteristics were explored in this study: surgical procedure, operative time, blood loss, number of intraoperative complications, length of postoperative hospital stay, prevalence of postoperative reflux esophagitis, prevalence of esophageal stenosis requiring endoscopic balloon dilation, and degree of patients' satisfaction for LHD scored from 1 (disappointed) to 5 (excellent) based on postoperative interview.

**Results:** Based on Japan Esophageal Society classification of esophagogram, 453 patients had straight esophageal type, 76 patients had sigmoid type, 26 had advanced sigmoid type, and data unavailable in 17 patients. The average maximum esophageal transverse diameter was 5.1±1.6 (range, 10 to 12.5) cm grade I in 74, grade II in 327, grade III in 149, and data unavailable in 22 of them. 50 patients (9%) underwent RPS, and NS was performed in 42 (7%) patients. The average operative time was 174.8 ± 46.2 (range, 67-447) min and median blood loss was 0 ml. Intraoperative complications were observed in 98 patients (17%), which included mucosal injury on the esophagus and/or stomach in 84, the vagus nerve injury in six, piriform fossa injury in two, small intestine injury in one, and splenic injury in one patient, respectively. None but one patient (0.1%) with splenic injury required open conversion. Duration of postoperative hospital stay was 5.3 ± 3.0 (range, 3-35) days, postoperative reflux esophagitis was noted in 70 patients (12%), and endoscopic esophageal dilation was required in 7 patients (1%) due to outflow obstruction. Four patients (0.7%) underwent reoperation at 7 to 63 (mean 30 month) months after the primary surgery for postoperative stenosis, dislocation of the wrap, and delayed perforation of the small intestine. Satisfaction score for symptomatic relief was 4.7±0.6.

**Conclusion:** The rate of intraoperative complications of LHD for esophageal achalasia was relatively high, though most of them did not require open conversion. LHD had reasonable perioperative outcomes with excellent symptomatic relief.

**Disclosure:** Nothing to disclose

## P0984 LONG-TERM QUALITY OF LIFE AFTER TOTAL GASTRECTOMY VERSUS IVOR LEWIS ESOPHAGECTOMY

Jezerkyte E.<sup>1</sup>, Saadeh L.M.<sup>2</sup>, Hagens E.R.C.<sup>1</sup>, Sprangers M.A.G.<sup>3</sup>, Noteboom L.<sup>1</sup>, van Laarhoven H.W.M.<sup>4</sup>, Eshuis W.J.<sup>1</sup>, van Berge Henegouwen M.I.<sup>1</sup>, Gisbertz S.S.<sup>1</sup>

**Contact E-Mail Address:** e.r.hagens@amsterdamumc.nl

**Introduction:** Surgical treatment for gastroesophageal junction (GEJ) cancers is challenging since both a total gastrectomy and an esophagectomy can be performed. The preferred treatment is unknown given the scarce evidence regarding their effects on surgical morbidity, pathology, long-term survival and health-related quality of life (HR-QoL). The aim of this study was to investigate the difference in long-term health-related quality of life in patients undergoing total gastrectomy versus Ivor Lewis esophagectomy in a tertiary referral center.

**Aims & Methods:** From 2014 to 2018, patients with a follow-up of at least one year after either a total gastrectomy or an Ivor Lewis esophagectomy for GEJ or cardia carcinoma completed the EORTC QLQ-C30 and EORTC QLQ-OG25 questionnaires. Problems with eating, reflux and nausea and vomiting were chosen as the primary HR-QoL endpoints. The secondary endpoints were the remaining HR-QoL domains, postoperative complications and pathology results.

**Results:** 101 patients with a mean age of 63 years were included, 30 after gastrectomy and 71 after Ivor Lewis esophagectomy. The response rate was 80.2%. Median follow-up was two years (range 12-84 months). Pa-

tients after total gastrectomy reported significantly more problems with eating ( $p=0.028$ , 95% CI 0.595-10.137). Reflux and nausea and vomiting were not significantly different between the two groups. Of the remaining HR-QoL domains odynophagia was significantly worse in the total gastrectomy group ( $p=0.014$ , 95% CI 1.010-8.611). After Ivor Lewis esophagectomy patients reported significantly more insomnia, choking when swallowing and coughing ( $p=0.021$ , 95% CI -11.922 - -0.981;  $p=0.001$ , 95% CI -9.437 - -2.466;  $p=0.000$ , 95% CI -18.525 - -7.643). No significant difference was found in postoperative complications or Clavien-Dindo grade between the two groups. Significantly more lymph nodes were resected in esophagectomy group ( $p=0.008$ ), however, no significant difference in number of positive lymph nodes or radicality of surgery was found.

**Conclusion:** In light of the scarce evidence about the difference in long-term HR-QoL in patients with GEJ or cardia carcinoma undergoing gastrectomy or esophagectomy, the results of our study contribute to the promotion of knowledge on this topic. After a follow-up of more than one year problems with eating and odynophagia were more common in the gastrectomy group and insomnia, choking when swallowing and coughing in the esophagectomy group. No significant difference was found in reflux, nausea and vomiting, postoperative complications or radicality of surgery. Based on this study it is difficult to determine which procedure for GEJ cancer is preferred.

**Disclosure:** Nothing to disclose

### P0985 C-REACTIVE PROTEIN AS A PREDICTOR FOR ANASTOMOTIC LEAKAGE AFTER ESOPHAGEAL SURGERY

Hagens E.R.C., Lam W.C., Eshuis W.J., van Berge Henegouwen M.I., Gisbertz S.S.

**Contact E-Mail Address:** e.r.hagens@amsterdamumc.nl

**Introduction:** Anastomotic leakage following an esophageal resection for esophageal cancer is a severe complication, leading to more post-operative morbidity or even death. CRP is commonly used by surgeons to raise suspicion of anastomotic leakage and other infectious complications, but optimal cut-off values and diagnostic accuracy are undetermined.

**Aims & Methods:** The aim of this prospective observational cohort study was to determine the accuracy and optimal cut-off values of CRP to predict anastomotic leakage, and to determine if there is an association between the level of CRP and the severity of anastomotic leakage. Consecutive patients with an esophageal carcinoma scheduled for an esophagectomy with gastric tube reconstruction between April 2016 and October 2018 in the Amsterdam UMC, location AMC, The Netherlands were included. CRP was measured routinely on post-operative day (POD) 3, 5 and 7. Anastomotic leakage was assessed and severity was scored according to the ECG classification. Anastomotic leakage was confirmed if a defect or leakage of oral contrast was seen on a CT-scan or by endoscopy or if saliva was draining from the neck incision. The diagnostic accuracy of CRP was assessed by receiver operator curve (ROC) analysis. Youden's index was adopted to determine the cut-off value in ROC analysis with highest sensitivity and specificity for predicting anastomotic leakage.

**Results:** 200 patients were included in this study. A cervical anastomosis was created in 25 patients, of which 7 (28.0%) developed anastomotic leakage. An intrathoracic anastomosis was created in 175 patients of which 17 (9.7%) patients developed anastomotic leakage. Median CRP levels in patients with and without anastomotic leakage were 99 and 188 mg/L on day 3, 62 and 154 mg/L on day 5, and 45 and 163 mg/L on day 7, respectively ( $p<0.001$  for all days). POD 5 showed the highest area under the ROC to predict anastomotic leakage with a cut-off value of 119.5 mg/L. Severity of anastomotic leakage and level of CRP did not significantly correlate with each other on postoperative day 3, 5 and 7 ( $p=0.204$ ,  $p=0.092$  and  $p=0.161$  respectively). The optimal cut-off value for CRP to predict anastomotic leakage or any complication is shown per day in table 1 with the corresponding area under the ROC, sensitivity, specificity, positive predicting value and negative prediction value.

**Conclusion:** CRP on POD 5 has the highest diagnostic accuracy to predict anastomotic leakage, using a cut-off value of 119.5 mg/L, resulting in a negative predicting value of 96% and specificity of 92%. CRP is therefore a feasible marker to predict anastomotic leakage. However, larger studies should be conducted to confirm this finding, also taking other post-operative days into account.

	Cut-off value CRP (mg/L) <sup>a</sup>	AUCROC	P-value <sup>1</sup>	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Diagnostic values for prediction of any postoperative complication							
CRP POD-3	99.65	0.657	<b>0.000</b>	75	53	72	56
CRP POD-5	119.50	0.688	<b>0.000</b>	34	93	88	48
CRP POD-7	71.90	0.719	<b>0.000</b>	62	73	81	51
Diagnostic values for prediction of anastomotic leakage							
CRP POD-3	141.40	0.695	<b>0.004</b>	71	61	19	94
CRP POD-5	119.50	0.801	<b>0.000</b>	71	82	30	96

**Contact E-Mail Address:** soluchan@naver.com

**Introduction:** Postoperative delayed gastric emptying is one of the most common problem in the early postoperative period after distal gastrectomy and may have effects on the early recovery after surgery.

**Aims & Methods:** We evaluated several clinicopathological features associated with delayed gastric emptying and the primary aim of this study was to investigate whether the preoperative endoscopic findings could be associated with postoperative delayed gastric emptying.

A total of 39 patients underwent distal gastrectomy for gastric cancer at Seoul Medical Center between August 2016 and December 2018 were collected and reviewed retrospectively. All patients underwent an esophagogastroduodenoscopy for preoperative evaluation and the results were reviewed by a single qualified gastroenterologist. The patients underwent either open or laparoscopic distal gastrectomy along with D2 lymphadenectomy by a single surgeon performed all surgical procedures. And the reconstructive procedure was selected based on the tumor location and surgeon's preference among four types of reconstruction methods. And all patients also underwent a gastric emptying SPECT/CT in the early postoperative period for evaluation of early alimentary limb leakage and remnant gastric motility. The relationship between delayed gastric emptying and clinicopathological factors was statistically analyzed.

**Results:** Among 39 patients, 26 (66.7%) patients showed delayed gastric emptying. An average T1/2 emptying time was 244min. Reflux esophagitis was endoscopically detected in 36 patients (92.3%). 35 patients (89.7%) had an atrophic gastritis and 13 patients (33.3%) infected with Helicobacter pylori. And Helicobacter pylori infection was associated with delayed gastric emptying ( $p=0.013$ ). Reconstructive procedure was also associated with delayed gastric emptying ( $p=0.011$ ). Billroth I reconstruction showed no stasis in comparison to the other reconstruction methods.

**Conclusion:** Helicobacter pylori infection and the type of reconstruction following distal gastrectomy seem to be associated with delayed gastric emptying after distal gastrectomy.

**Disclosure:** Nothing to disclose

## P0987 THE INCIDENCE AND RISK FACTORS OF PANCREATITIS AFTER DUODENECTOMY IN FAMILIAL ADENOMATOUS POLYPOSIS

Mehta N.<sup>1</sup>, Yoon J.<sup>2</sup>, Shah R.<sup>3</sup>, Laguardia L.<sup>1</sup>, O'Malley M.<sup>1</sup>, Augustin T.<sup>3</sup>, Mankaney G.<sup>1</sup>, Church J.<sup>4</sup>, Kalady M.<sup>4</sup>, Walsh M.<sup>3</sup>, Bhatt A.<sup>1</sup>, Burke C.<sup>1</sup>

**Contact E-Mail Address:** mehtan5@ccf.org

**Introduction:** Duodenectomy is recommended in patients with Familial Adenomatous Polyposis (FAP) with Spigelman stage IV duodenal polypsis to prevent cancer. Pancreaticoduodenectomy (PD) (both pylorus-sparing and classic), pancreas-sparing duodenectomy (PSD) and segmental duodenal resections are all surgical options. PD consists of removal of the head of the pancreas, common bile duct, and gallbladder along with the duodenum. The anastomosis in PD includes a hepaticojejunostomy and pancreaticojejunostomy. A PSD preserves the pancreas and includes anastomoses of the jejunum to the biliary-and-pancreatic-duct complex.

**Aims & Methods:** We aim to evaluate the incidence and risk factors for new onset pancreatitis in FAP patients after foregut surgery. We identified consecutive FAP patients following duodenal resection (PD, PSD, segmental duodenectomy) at Cleveland Clinic, between 05/1992 and 01/2018 from the David G. Jagelman Inherited Colon Cancer Registries. A history of pancreatitis preceding the surgery or those without follow-up data were excluded. Medical records were used to determine demographics and risk factors for pancreatitis. Pancreatitis was defined as 2 out of 3: i) typical symptoms ii) lipase three times the upper limit of normal or iii) radiography consistent with pancreatitis.

**Results:** 77 FAP patients (51.9% male) with duodenal resection were identified. 24 underwent PD, 10 segmental duodenectomy, and 43 PSD [Table 1]. 10/77 patients (13%) developed new onset, post-surgical pancreatitis. 7/10 who developed post-surgical pancreatitis had undergone PSD and the remainder PD [Table 2]. 2/10 developed pancreatitis perioperatively within 30 days and 8 developed pancreatitis >30 days after surgery (range: 2-19 years after surgery). 9/10 required hospitalization for pancreatitis (median BISAP score 0, indicating likelihood of mortality at < 1%). 1 death from pancreatitis occurred perioperatively (BISAP score 3). Of the 8 with non-perioperative pancreatitis, 5 developed acute recurrent pancreatitis (4 of whom underwent PSD) prior to endoscopic intervention. 6/8 required endoscopic retrograde cholangiopancreatography (ERCP) with balloon dilation for stenosis at the pancreaticojejunal (PJ) anastomosis (range: 1-2 ERCPs for successful treatment). ERCP was successful at dilating the stenosis in 5 of 6 cases. No patients had family history of pancreatitis or significant alcohol intake (>2 drinks/day males, >1 drink/day females). 4/10 had history of cholecystectomy, 1 remotely for gallstones and 3 during PD.

**Conclusion:** FAP patients may develop pancreatitis after duodenectomy. It usually occurs years after surgery and commonly due to stenosis at the PJ anastomosis which can lead to acute recurrent pancreatitis. Evaluation of the PJ anastomosis should be considered for patients that develop pancreatitis after duodenectomy to evaluate for stenosis.

**Disclosure:** Nothing to disclose

## P0988 THE YIELD, EFFECTIVENESS AND SAFETY OF GASTROSCOPY IN MANAGEMENT OF EARLY POST-BARIATRIC SURGERY COMPLAINTS

Mari A.<sup>1</sup>, Khoury T.<sup>2</sup>, Kadah A.<sup>3</sup>, Mahamid M.<sup>3</sup>, Sbeit W.<sup>2</sup>

**Introduction:** Obesity is a worldwide epidemic affecting over 600 million individuals. There are several medical treatments for obesity, however, their efficacy are limited and most patients regain weight after losing it. Still standard bariatric surgery is the most effective method for sustained weight loss with a potential for resolution of over-weight associated comorbidities. Gastrointestinal symptoms are common in the early post-bariatric surgical period making gastroscopy is the main investigative tool.

**Aims & Methods:** The aim of our study was to assess the yield, effectiveness and safety of gastroscopy within 3-months post-bariatric surgery performed for investigating gastrointestinal symptoms. We performed a single retrospective study in EMMS Nazareth Hospital from 2010 to 2018. All patients who underwent gastric-bypass (either Roux-en-Y(R-en-Y) or Mini-gastric bypass (MGB)) and who had early gastrointestinal symptoms were included in the study.

**Results:** Four-hundred and twenty-eight (428) patients were included in the study. Among them, 154 patients (36%) underwent R-en-Y surgery and 274 patients (64%) underwent Mini-gastric bypass (MGB). Baseline characteristics were similar in the two groups. The mean age (years), male gender and the BMI were among the R-en-Y group compared to the MGB group were 42.3±10.8 vs. 42.8±11.2, 54.3% vs. 53.8% and 41.7±4.7 vs. 42.3±3.7, respectively (P=NS).

Overall, 39 (9.1%) patients from the all study cohort underwent gastroscopy due to upper gastrointestinal tract complaints during the first 3 months after surgery. Eighteen (11.6%) patients in the R-en-Y group, and 21 (7.6%) patients among the MGB group, P< 0.005.

The endoscopic findings showed normal surgical anatomy in 14 (35.8%) subjects; five patients (27.8%) in the R-en-Y group as compared to 9 patients (42.8%) among the MGB (P< 0.005). Erosive esophagitis with suspected bile reflux was documented in only one patient (5.5%) among the R-en-Y group as compared to 3 patients (14.2%) in the MGB group (P< 0.005). Notably, the upper gastrointestinal tract symptoms related gastroesophageal reflux disease (GERD) improved only in one patient (the only patient after R-en-Y), and persisted among all three patients after MGB, despite high dose proton pump inhibitors (PPI) for at least 6 months of follow-up.

Anastomotic stricture, marginal ulcer, functional obstruction due to non-absorbable sutures and gastro-gastric fistula were observed in 2,3,1,0 patients (11.1%, 16.7%, 5.5%, 0% respectively) among the R-en-Y patients and 2,2,1,1 patient (9.5%,9.5%,4.7%, 4.7% respectively) among the MGB group.

A single session of balloon dilation of the anastomotic stricture was successfully performed in all 4 patients (2 in each group) with symptomatic and endoscopic improvement; moreover, removal of surgical suture was successfully performed using endoscopic scissors in 2 patients (one in each group) also with complete resolution of patient's symptoms.

There were no procedural or sedation related complications reported during or after the gastroscopy among all patients who underwent gastroscopy.

**Conclusion:** Gastrointestinal symptoms in the early post-bariatric surgery are common with most endoscopic examination revealing normal surgical anatomy. Although gastroscopy is mostly normal in this setting in most patients, it is safe and potentially effective in treating these uncommon complications.

**Disclosure:** Nothing to disclose

## P0989 ENDOSCOPIC "SUCTION CHAMBER" TO TREAT COMPLEX DUODENAL LEAKS AFTER UPPER GASTRO-INTESTINAL SURGERY: A SINGLE CENTER EXPERIENCE

**Contact E-Mail Address:** ludovica.venezia@gmail.com

**Introduction:** Leaks from duodenal stump after upper gastrointestinal surgery are difficult to manage and usually require re-do surgery, since conservative treatments often fail.

Vacuum-assisted drainage has been already used in the endoscopic management of colorectal, esophageal anastomotic leaks and duodenal perforations [1]. However, it has never been reported to treat leaks from duodenal stump.

The use of negative pressure decreases the intraluminal pressure involved in the leak formation, induce the collapse of the fistula wall associated with granulation tissue formation and draw fluids and secretions away, decreasing bacterial load.

**Aims & Methods:** Here we report our single-center experience on the endotherapy of duodenal stump leaks after upper gastrointestinal surgery using an innovative approach. Between January 2016 and December 2018, 5 consecutive patients (M:F 3:2, mean age: 43 y.o.) were referred to our unit for complex dehiscence of the duodenal stump. Previous upper-gastrointestinal surgery included 3 subtotal gastrectomy with Roux-en-Y reconstruction (two for gastric cancer, one for stab wounds); 1 subtotal gastrectomy with Braun reconstruction (gastric cancer after liver transplantation); 1 gastric bypass (for severe obesity).

All these patients underwent a re-do surgery that failed to repair the intestinal leak.

On the basis of our expertise in the treatment of post-surgical adverse events [2-3], the rationale to treat these patients was to create a "suction chamber" to the enteral lumen: a fully-covered self-expandable enteral metal stent was inserted with the distal crown into the peritoneum through the duodenal leak.

Subsequently, the common bile duct and the main pancreatic duct were endoscopically drained inserting a biliary and a pancreatic stent through the meshes of the enteral stent. An aspirative large naso-duodenal tube, with the tip about 1-2 cm out of the enteral stent's distal crown was placed (creating the so called "suction chamber"). If present, the surgical drainage was pulled out about 3 cm away from the leak to favor the peritoneal-enteral pressure gradient than the peritoneal-atmospheric one.

**Results:** Technical and clinical success rate were achieved in all the patients (5/5, 100%).

The mean duration of aspirative patency was 36 (23-103) days with a mean duration of hospital stay of 92 (47-273) days. An abdominal CT scan check was generally performed 2 days after the procedure (to verify the reduction of the intraperitoneal fluid collections) and 30 days after the procedure to decide to stop the aspiration through the naso-peritoneal tube. Abdominal drains were removed 15 (4-26) days after the procedure, after an additional CT scan check. Stent removal was scheduled at 6 months in all the patients. Mean follow-up was 26 (13-35) months: no mortality neither long-term adverse events related to the endoscopic procedures were reported.

**Conclusion:** Endotherapy of duodenal stump leak is feasible and effective in tertiary referral endoscopy centers with expertise in the management of post-surgical adverse events. Our "suction chamber" method offers the possibility to treat complex dehiscence especially if re-do surgery failed.

**Introduction:** Since re-do surgery and interventional radiology are considered the first-line treatment for bilio-digestive anastomotic stricture, endoscopic treatment has been utilized as a minimally invasive alternative for management of these adverse event, with two critical issues:

1. Ability to reach the biliary anastomosis;
2. Perform an effective therapeutic procedure. Duodenoscope, gastroscope and pediatric colonoscope have all been used, with poor rate of biliary anastomosis achievement.

Enteroscopes (short, long, single- or double-balloon) [1] have also been utilized, with an overall technical success rate of about 76%. Finally, high success rate (around 90%) have also been described for the EUS-guided approach, which has a high morbidity (18%-50%) and mortality (1.5%) [2].

**Aims & Methods:** We proposed a totally endoscopic approach to improve the endotherapy of bilio-digestive anastomotic stricture.

From January 2014 to April 2019, 33 consecutive patients (mean age: 60 y.o.; M/F 20/13) affected by bilio-digestive anastomotic stricture treated by endoscopic enteral-enteral bypass (EEEB) and subsequent endoscopic retrograde cholangiography (ERC) were included in the present study. To reach the anastomotic site, an EEEB between the duodenal or gastric wall and the biliary jejunal loop using luminal apposing or biflanged metal stents under both fluoroscopic and endoscopic ultrasound's guidance was performed. This allowed the establishment of a short-way for therapeutic ERC procedures using large operative channel's endoscopes.

**Results:** EEEB was successful in 31 patients and therapeutic ERC was performed in all the 31 cases using multiple or single large-bore fully-covered self-expandable metal stenting (SEMS). We registered a 100% clinical success with a mean number of ERC sessions of 3. During a mean follow-up of 23 months (range: 1,5 - 59 months), two anastomotic stricture recurrences (6,4%) occurred, successfully re-treated through the EEEB. One case of post-ERC bleeding due to portal hypertension occurred and was treated conservatively. No long-term adverse events were observed.

If we briefly compare EEEB-guided ERC with other techniques, the radiological/percutaneous approach allows placement of SEMSs but not their removal, while enteroscopy does not permit use of large-bore SEMSs. In addition, selective cannulation of the bile duct with cholangiography is of paramount importance to characterized complex stenosis(es) and to drive subsequent endoscopic management. This can be only obtained by using the EEEB-guided ERC. Moreover, the EEEB allowed us to perform repeated treatments in patients with complex clinical situation or re-treat those with recurrence.

**Conclusion:** EEEB is safe, feasible, and allows a successful long-term treatment of different biliary adverse events in a tertiary referral centers with high-level experience in both ERCP and EUS.

In the setting of bilio-digestive anastomotic strictures, EEEB-guided ERC permits to use endoscopes with large operative channel to treat the stenosis(es) with large-bore SEMS, to manage case of complex strictures and multiple-ducts biliary anastomosis, to guarantee a long-lasting gradual dilation and to re-treat the patients in case of recurrence.

**Introduction:** Acute fascial dehiscence (FD) is a feared complication after laparotomy. The incidence of FD is about 3,5%, 14 - 67 % of Patients (Pat) with FD died. Known causes for FD include: wound infection, premature mobilization, increased intraabdominal pressure. However, all studies in this field are outdated. Also, we do not know the context between Vakuum Assisted Closure (VAC)-Therapy and FD. In this paper, we aim to update the database about FD and to investigate a possible therapeutic effect of VAC Therapy on FD.

**Aims & Methods:** We analyzed all patients who were diagnosed with FD within the first 30 days after a laparotomy between July 2007 and August 2016, retrospectively. We analyzed 180 patients with a FD. We excluded 67 patients with a laparotomy previously within one year.

**Results:** 113 patient (73,5% male) occurred a FD on the 10th [2;30]day after laparotomy. The main reason for FD was a wound infection (38,9%) or a

high intraabdominal pressure because of an intestinal paralysis, ileus or ascites (20,3%). A lot of pat with a FD were operated in the primary operation with an emergency indication (38,9%). They got mostly a median laparotomy (77,9%) and were closed by continuous fascia suturing (61,1%). The Pat stayed extended 33 [9;120] days at hospital. 18 patients (15,9%) died during hospitalization. 20 patients (17,7%) had a second FD. We saw that Pat with a VAC-Therapy after first FD had a significant higher risk to get a second FD ( $p=0,041$ ).

**Conclusion:** FD is serious complication and we show that VAC-Therapy has a negative influence to get a second FD, but it is to discuss whether the VAC-Therapy is the problem or the associated wound infections. It has to be investigated in future prospectiv studies.

**Disclosure:** Nothing to disclose

## P0992 ENDOSCOPIC SUTURING IS FEASIBLE FOR TREATMENT OF LOW COLORECTAL ANASTOMOTIC LEAK - EXPERIMENTAL STUDY

**Introduction:** Anastomotic leak after low anterior resection represents dreaded complication, which is associated with a significant mortality and affects both oncological and functional outcomes. OverStitch™ (Apollo Endosurgery) is an endoscopic suturing system now widely available for a variety of endoscopic procedures allowing to place full thickness sutures.

**Aims & Methods:** The aim of our study was to assess the feasibility of endoscopic repair of anastomotic leak on animal model. Secondary aim was to evaluate whether this technique prevents intraabdominal sepsis.

Model of low colorectal anastomotic leak was introduced in 28 male pigs. Laparoscopic low anterior resection was performed and the anastomosis created with 28 mm circular stapler after removing half of the staples.

Fourteen pigs had an endoscopic anastomotic repair with OverStitch™ 2 days later. A double-channel endoscope was introduced and defect closed with 2/0 prolene and secured with original knotless fixation. Three-grade scale (I - closed completely, II - closed with visible gaps, III - closure not possible) was used to assess the completion of closure. The signs of intraabdominal septic complications - IASC and anastomotic healing including burst test were assessed after animals being sacrificed on 9th postoperative day. Fourteen animals with no treatment were included in control group. Chi square test was used to compare both groups.

The protocol was approved by local ethical committee in accordance with the European Convention on Animal Protection. The study was supported by AZV 16-31806A, MO 1012.

**Results:** Endoscopic closure was technically possible in all 14 cases (gr. I - 11, gr. II - 3 and gr. III - 0) with mean procedure time of 31 (19-70) min. Two animals from suture group died due to peritonitis on 8<sup>th</sup> and 9<sup>th</sup> post-operative day. Overall IASC rate was however significantly lower compared to the control - 5/14 vs. 11/14 ( $p=0,022$ ). The autopsy confirmed healed anastomosis with no visible defect in 10/14 cases after endoscopic suturing and in 2/14 within control group ( $p=0,0023$ ). The burst test performed in 10 healed OverStitch cases confirmed sufficient closure with mean pressure of 200 (80-300) mmHg.

**Conclusion:** OverStitch™ endoscopic suturing is technically feasible for repair of low colorectal anastomotic leak. This technique reduced the rate of intraabdominal septic complications.

**Introduction:** Rectal cancer is commonly treated by chemotherapy and radiation therapy, followed by anal sphincter-preserving surgery where possible, with a temporary protecting ileostomy. Low anterior resection syndrome (LARS) is a constellation of symptoms, commonly developing following stoma reversal, which includes faecal urgency, incontinence and difficulty emptying, severely affecting quality of life of cancer survivors. Scant data exists on the natural history of LARS, and specifically on the role of anorectal physiology testing and sphincter-strengthening oriented biofeedback therapy (BF) in predicting long term symptoms.

**Aims & Methods:** To evaluate long term outcomes of sphincter-preserving surgery and it's correlation to baseline anorectal physiology testing and BF. 75 consecutive patients (49 males, age 61  $\pm$  12 yrs) undergoing sphincter-preserving surgery were studied. 43 (57%) patients participated in long term follow up (median 4 years, range 1-11). Severity indexes and quality of life measures at long term follow up were recorded and analyzed in correlation to baseline clinical characteristics, anorectal physiological studies and BF treatment.

**Results:** Baseline characteristics of the cohort are described in Table 1. On long term follow up, mean LARS score was 34 (SD 11), with 33 patients (86%) displaying severe LARS (scores >30). Mean faecal incontinence severity index was 30 (SD 19) and mean bowel frequency/day was 7 (SD 4). Mean FI-QOL was 2.2 (SD 0.9) and SF-36 total mean was 51 (SD 22). Sixty-six (88%) patients underwent anorectal manometry (ARM), 30% of them before stoma closure. Anal resting and squeeze pressures were low in 67% and 23% of patients, respectively. Balloon expulsion time was abnormal in 42% of patients. 23 (30%) patients underwent BF treatment (mean of 4 meetings, range 1-16), 32% of them before stoma closure. Lower resting pressure showed a trend towards predicting higher LARS scores at follow up ( $p=0.055$ ). BF therapy before or after stoma closure and absence of post-surgical complications were associated with higher (less) bodily pain scores on follow up SF36 (77 vs 48, respectively,  $p=0.006$ ), but did not predict symptom severity scores.

Tumor distance from anal verge - mean, cm (SD)	6 (3)
Tumor Stage (T)	
0 or 1 n(%)	23(33%)
2- n(%)	25(33%)
3- n(%)	24(32%)
4- n(%)	1(1%)
Type of surgery	
Low anterior resection- n(%)	42(56%)
Colo-anal anastomosis- n(%)	33(44%)
Post-surgery complication (including pelvic abscess, anorectal fistula and strictures)- n(%)	22(32%)
Anorectal manometry (n=66)	
Anal resting pressure- mmHg; mean(SD)	57(34)
Anal squeezing pressure - mmHg; mean(SD)	152(72)
Anal relaxation on push maneuver - %- mean(SD)	16(23)
Recto-anal inhibitory reflex - absent- n(%)	32(51%)
First rectal sensation thresholds- mean, ml (SD)	42(23)
Defaecation urge sensation thresholds- mean, ml (SD)	62(29)
Maximal tolerated volume- mean, ml (SD)	83(32)

[Table 1. Baseline characteristics of patients undergoing sphincter-sparing surgery (n=75).]

**Conclusion:** Severe symptoms and impaired quality of life persist at a median of 4 years following sphincter preserving surgery. ARM might help predict symptom severity, and BF might slightly mitigate symptoms' impact

on quality of life. Nevertheless, improvement of current treatment options, including utilization of a more comprehensive anorectal BF protocol and/or sacral neuromodulation, is critically needed in this group of patients.

**Introduction:** Treatment options for Zenker's diverticulum (ZD) include open surgery, rigid endoscopy and flexible endoscopy. Clinical success is achieved in 80-90% of cases after endoscopic septotomy, however, adverse events (AEs) occur in 14% and, importantly, symptom recurrence in up to a third of patients. Recurrence is thought to be due to incomplete septotomy. A new technique using POEM for direct visualization/complete dissection of the septum has been described; however, outcomes of POEM for ZD (Z-POEM) are not known.

**Aims & Methods:** To study the technical feasibility, safety, and efficacy of Z-POEM in the management of ZD. This is a retrospective international study involving 10 centers (2 Asia, 2 Europe, 1 Mexico, 5 USA). Consecutive patients who underwent Z-POEM for ZD were included. Technical success is defined as successful completion of the Z-POEM. Clinical success is defined as complete/near complete resolution of dysphagia (Dakkak/Bennett score of 0 or 1) without the need for repeat endoscopic/surgical interventions. AEs were categorized/ rated per the ASGE lexicon.

**Results:** A total of 75 patients (73yr, F 33) were included with an average Charlson Comorbidity Index of 4. Eleven patients had prior treatment for ZD, which included open surgery in 5, dilation in 1, and flexible endoscopy in 5. The mean size of ZD was 31.29±1.63mm (10-89mm). Most common indications for Z-POEM were dysphagia (46%) and regurgitation (29%). General anesthesia was used for all cases. The technical success rate was 97.3% (73/75). Types of septotomy device used: hybrid knife (n=44), Tri-angle tip knife (n=12), standard Stag-beetle knife (n=7), IT-2 knife (n=7), Hook knife (n=2), IT-nano (n=1), both hybrid and Stag-beetle knife (n=2). The 2 technical failures were due to inability to locate the septum and failed tunnel creation (Table. 1).

AEs occurred in 6.7% (5/75): 1 bleed (mild) conservatively managed and 4 perforations (1 severe, 3 moderate). One severe perforation was a small contained perforation requiring ICU monitoring which subsequently self-resolved. Of the 3 moderate perforations, 2 were treated using cyanoacrylate glue and 1 was closed using clips. The mean procedure time was 52.4±2.9 min and mean length of hospital stay was 1.8±0.2d. Clinical success was achieved in 92% (69/75) with a decrease in mean dysphagia score from 1.87 to 0.25 (p< 0.0001). The median length of follow-up was 291.5 days (IQR=103.5-436). At 12-month follow-up, 1 patients reported symptom recurrence.

**Conclusion:** Endoscopic management of ZD using the POEM technique is novel and feasible with promising efficacy and safety results. Long-term follow-up is needed to ensure durability of response. In addition, comparative studies with other treatment modalities are warranted.  
**Disclosure:** Nothing to disclose

	N=75

**Contact E-Mail Address:** alessandro.repici@hunimed.eu

**Introduction:** Endoscopic suturing is an alternative to surgical treatment for a broad spectrum of care, ranging from closure of mucosal or full thickness gastrointestinal tract defects to stent fixation to primary sleeve gastropasty. A growing number of academic referral centers and community hospitals worldwide are performing endoscopic suturing procedures using the OverStitch Endoscopic Suturing System (Apollo Endosurgery Inc. Austin, Texas).

**Aims & Methods:** The aim of this registry is to collect demographic, procedural characteristics and follow-up outcomes of endoscopic suturing from multiple participating centers.

A retrospective analysis of a prospectively collected series of any patient who underwent an endoscopic suturing procedure using the OverStitch device for a gastrointestinal application from 6 European centers from January 2018 to April 2019 was performed.

This registry includes five main groups:

1. Closure of full thickness defects (post-operative leaks/anastomosis dehiscence, fistula closure, perforation)
2. Closure of mucosal defects (mucosal excision defects (EMR, ESD), enterotomies (e.g. EFTR), POEM/STER mucosal entry sites, ulcers)
3. Fixation of endoprosthetics
4. Gastrointestinal Bleeding
5. Other (GERD Cardioplasty, revision bariatric procedure, any other application of the endoscopic suturing device not listed above)

The data have been entered into a secure database by an identifier known only to the physician or his/her designee(s). All information in the database is de-identified prior to entry.

**Results:** To date, 67 patients (all Caucasian, male: 37; median age: 60.8 years) have been entered into the registry. Six European centers contributed to this first collection with a varying number of procedures from each center (max: 29; min: 1). The distribution of cases for each group is shown in Table 1.

Regardless of the procedure type, there were no cases of failure to introduce the device and advance it to the target area. Furthermore, suturing was technically achieved as intended in all 67 cases. In the group of closure of mucosal defects, follow-up has been reported for 7 patients (range: 90 days-1 year) with a 100% success rate. A mean of 1.9 running sutures were used. Patients who underwent fistula closure had a follow-up range of 30 to >90 days with a success rate of 77.8% (2 patients required repeated suturing; 2 patients have no follow-up data). All cases of perforation were successfully closed initially with a continued success rate of 92.9% in follow-up (range 30-90 days). Closure of post-op leaks performed in 7 patients, with a continued success rate of 80% in those with reported follow-up of 90 days or more (in 1 patient with a follow-up of 30 days the leak wasn't resolved; 2 patients have no follow-up data). Thirteen stents (located in the esophagus, stomach and duodenum) were fixed by suturing with success in 84.6% (11 of 13) cases (follow-up range 30 to 90 days; no follow-up data for 6 patients).

**Conclusion:** This data demonstrates safety and feasibility of endoscopic suturing for several GI indications. In our opinion, this European registry is a valuable tool to pool outcomes of endoscopic suturing cases and to address future research directions.

**Disclosure:** Nothing to disclose

GROUPS	PATIENTS

## P0997 TREATMENT OF REFRACTORY HEPATIC ENCEPHALOPATHY DUE TO SPLENORENAL SHUNT IN LIVER CIRRHOSIS: OCCLUSION OR DIVERSION?

Wei B.<sup>1</sup>, Deng K.<sup>2</sup>, Huang Z.<sup>3</sup>, Wu H.<sup>2</sup>, Tang C.<sup>2</sup>

<sup>1</sup>West China Hospital, Sichuan University, Department of Gastroenterology, Chengdu, China, <sup>2</sup>West China Hospital, Sichuan University, Gastroenterology and Hepatology, Chengdu, China, <sup>3</sup>West China Hospital, Sichuan University, Chengdu, China

**Contact E-Mail Address:** allylooking@163.com

**Introduction:** Hepatic encephalopathy (HE) encompasses a spectrum of neuropsychiatric abnormalities observed in patients with liver dysfunction, after the exclusion of other brain diseases. Significant portal-systemic shunts are closely linked to the development of portosystemic encephalopathy. An effective approach for treating this type HE is the occlusion of the large shunts. However, the shunts that exist in cirrhosis patients are a physiologic phenomenon that has evolved to compensate for the presence of portal hypertension.

As a result, occluding the shunt is likely to increase portal pressure and the risk of hemorrhage. It is therefore important to consider whether occlusion is the optimal treatment for portosystemic encephalopathy in cirrhosis patients.

**Aims & Methods:** To compare the efficacy of two methods of interventional therapy for the treatment of refractory hepatic encephalopathy (HE) due to a splenorenal shunt. Fifteen cirrhotic patients with refractory hepatic encephalopathy due to splenorenal shunt were studied. Either occlusion or diversion of the splenorenal shunt was undertaken to treat HE. The shunt was occluded by coils and tissue glue in the occlusion group. Selected embolization of the spleen vein was performed between the shunt and superior mesenteric vein in the diversion group.

**Results:** Occlusion was performed in 8 patients (occlusion group) and splenic vein embolization in 7 patients (diversion). Complete resolution of HE occurred in all 15 patients without recurrences during the follow-up. Improvement of Child-Pugh score was found in both methods. A weak trend toward a smaller increase in portal pressure change was observed in the diversion method.

**Conclusion:** Hepatic encephalopathy can be effectively treated with both diversion and occlusion interventional methods. The splenorenal shunt was reserved to relieve the portal pressure change by the diversion method, comparing to the occlusion method.

**Contact E-Mail Address:** brodynad@uvn.cz

**Introduction:** Endoscopic submucosal dissection (ESD) is the therapeutic endoscopic method that allows en-bloc and radical (R0) resection of early gastrointestinal neoplasia. ESD is still a technically demanding method, which needs special training and has some risk of complications.

**Aims & Methods:** The main aim is to evaluate effectiveness of ESD and hybrid technique ESD / EMR (endoscopic mucosal resection) in the treatment of early gastrointestinal neoplasia in one tertiary endoscopic centre. Data from a retrospective registry of patients who underwent ESD and hybrid ESD/EMR from February 2015 to March 2019 were evaluated. Therapeutic results and performance related complications were analysed.

**Results:** A total of 43 ESD and ESD/EMR were analysed in 40 patients (mean age 64.5 years, 27 males). The lesion distribution was as follows: rectum (n = 30), sigmoid colon (n = 2), transverse colon (n = 1), oesophagus (n = 4) and stomach (n = 6). The mean lesion size was 30.9 mm (range 5-70 mm). En-bloc resection was achieved in 39 of 43 lesions (90.7%) and R0 resection was achieved in 35 of 39 en bloc resection (89.7%). 20 lesions (46.5%) were assessed as sessile polyps (type 0-Is according to Paris classification). The classic ESD technique was used in 32 lesions (74.4%); R0 resection in 28 lesions), hybrid technique (ESD/EMR) in 11 lesions (25.6%); R0 resection in 7 lesions). Perforation was observed in 16 cases (37.2%). However, all perforations were closed with an endoscopic method using hemoclips, in one case OVESCO clip was successfully applied. Only one delayed bleeding after ESD was observed, successfully resolved endoscopically. Surgical treatment was not necessary in any of these complications. The average inpatient time was 4.7 days (2-11 days). 24 patients (55.8%) were treated with antibiotics (Cephalosporins). Histological findings were as follows: 6 cancers (14.0%) with invasion to the upper third of submucosa (sm1), 4 intramucosal carcinomas (9.3%), 1 neuroendocrine tumours (2.3%), 1 gastrointestinal stromal tumour (2.3%), 12 adenomas with high grade dysplasia (27.9 %) and 13 adenomas with low grade dysplasia (30.2%). One patient underwent surgical resection for invasive T2 carcinoma. Follow up endoscopy was performed in 29 of 43 lesions (67.4%), all with negative findings.

**Conclusion:** Our analyses demonstrate that ESD and hybrid technique ESD/EMR are effective and safe therapeutic methods for radical resection (R0) of early gastrointestinal neoplasia. Periprocedural complications can be treated conservatively.

**Funding:** The works were supported by grants AZV ČR reg. 17-31909A and NV18-08-00246.

## P0999 PERORAL ENDOSCOPIC MYOTOMY AFTER OPERATIVE INTERVENTIONS ON THE GASTROESOPHAGEAL JUNCTION

Shumkina L., Pavlov I., Nedoluzhko I., Shishin K.

A.S. Loginov Moscow Clinical Science Center, Operative Endoscopy, Moscow, Russian Federation

**Contact E-Mail Address:** ivannedoluzhko@gmail.com

**Introduction:** Peroral endoscopic myotomy (POEM) may be a challenge in patients with previous interventions on the esophageal-gastric junction. The degree of fibrosis in submucosal space plays a key role in the feasibility and safety of tunnel technique.

**Aims & Methods:** To evaluate the safety of peroral endoscopic myotomy in patients previously operated on the esophageal-gastric junction. Between July 2014 and May 2018, 123 patients underwent POEM in the Moscow Clinical Scientific Center, including 46 (37%) patients previously operated on the esophageal-gastric junction. The group of operated patients involved 41 (89%) patients after pneumatic balloon dilation, 3 (6.5%) patients after Heller myotomy, 1 (2%) patient after previous esophagogastricoplasty, 1 (2%) after POEM.

**Results:** The POEM procedure was successfully completed all patients. The mean operative was comparable in both groups: 106 min (55-195 min) in previously operated patients and 103 min (45-180 min) in naïve patients. Fo degree was detected in 14 (30%) cases, F1 in 29 (63%), maximal fibrosis (F2) in 3 (6.5%) patients who had previously undergone pneumatic balloon dilation. In patients after Heller's myotomy and esophagogastricoplasty, the degree of fibrosis reached F1, despite the expected more pronounced fibrosis. In the group of primary patients FO, the degree was detected in 27 (35%) observations, F1 - 46 (60%), severe fibrosis (F2) was detected in 4 (5%). There were no intraoperative complications affecting the tactics of surgical intervention in one observation. There were no major bleeding episodes requiring blood transfusion in either group. In one case in the group of previously operated patients, a mucosal defect was detected after the formation of the tunnel. The lesion was clipped.

The technical success of the surgical intervention was up to 100%. There were no intraoperative complications. X-ray examination on the 1<sup>st</sup> day after intervention with a water-soluble contrast showed appropriate evacuation and no leakage. Patients were discharged the 2<sup>nd</sup> day after surgery.

**Conclusion:** The history of failed previous surgical interventions is not a contraindication to the POEM procedure and does not significantly affect the course of surgical intervention.

**Disclosure:** Nothing to disclose

## P1000 *HELICOBACTER PYLORI* INFECTION PROTECTS AGAINST CHRONIC COLITIS BY REGULATING COLONIC EPITHELIAL BARRIER FUNCTIONS

Zhang H.<sup>1</sup>, Dai Y.<sup>2</sup>, Shen H.<sup>1</sup>, Yang J.<sup>1</sup>, Zhang X.<sup>1</sup>, Wang W.<sup>2</sup>

<sup>1</sup>Hangzhou First People's Hospital, Gastroenterology, Hangzhou, China,

<sup>2</sup>Peking University First Hospital, Gastroenterology Department, Beijing, China

**Contact E-Mail Address:** hongchen\_zhang@126.com

**Introduction:** Large epidemiological studies and meta-analyses have demonstrated an inverse association between *Helicobacter pylori* (*H.pylori*) infection and the risk of developing inflammatory bowel diseases (IBD). However, the mechanisms by which *H.pylori* infection protects against IBD are still unclear. Our previous published study has found that *H.pylori* infection can affect the Th17/Treg balance in colon. Here, we explored the possible protective effects and mechanisms of gastric *H. pylori* colonization on a chronic colitis model, with focus on whether *H. pylori* exerted its effects through regulating the barrier function of the colonic epithelial cells (CECs).

**Aims & Methods:** The aims of our study is to confirm that *H.pylori* infection exerts its protective effect on chronic colitis in mice by regulating the colonic epithelial barrier function. Chronic colitis model was induced by DSS treatment. To evaluate the severity of colitis, the body weight, rectal bleeding and stool consistency were observed to generate a disease activity index score (DAI). All mice were sacrificed at 45 days. H&E staining was performed for pathological scoring of both colitis. The colonic permeability

of mice was measured by fluorescein-isothiocyanate-dextran (FITC-Dextran) method. Immunohistochemical staining for BrdU was performed to evaluate the proliferative activity of colonic epithelial cells. The expression of apoptosis associated proteins (Cleaved-caspase-3, Bcl-2 and Bax) and necroptosis associated proteins (p-MLKL, RIPK1 and RIPK3) were determined by western blotting. Western blotting was also used to detect the expression of tight junction proteins (Occludin and Claudin3).

**Results:** *H.pylori*+DSS group exhibited significantly less weight loss and DAI score, and increased survival rate during the experiment when compared with DSS group ( $P<0.05$ ). In accordance with the clinical data, the colon length in *H.pylori*+DSS group was longer than the DSS group ( $6.98\pm0.73$ cm vs.  $8.09\pm0.45$ cm,  $P<0.05$ ). *H.pylori*+DSS group had a significant decreased microscopic histological score compared to DSS group ( $7.17\pm0.75$  vs.  $4.5\pm0.97$ ,  $P<0.05$ ), suggesting that *H.pylori* infection might ameliorate the severity of chronic colitis in mouse model.

The intestinal permeability improved in *H.pylori* infected group compared with DSS-induced mice ( $1141\pm55.57$  pg/ml vs  $913.9\pm32.44$  pg/ml,  $P<0.05$ ). CECs proliferation determined by BrdU staining demonstrated that the proliferative activity was increased in *H.pylori* infected group ( $38.00\pm7.975$  vs  $135.3\pm13.56$ ,  $P<0.05$ ). The expressions of tight junction protein (Occludin and Claudin3) were enhanced in *H.pylori* infected group ( $0.15\pm0.08$  vs  $0.85\pm0.49$ ,  $P<0.05$  and  $0.11\pm0.06$  vs  $0.67\pm0.13$ ,  $P<0.05$ ). The expression of cleaved-caspase 3 and the ratio of Bcl-2/Bax decreased significantly in *H.pylori*+DSS group ( $0.60\pm0.42$  vs  $0.38\pm0.28$ ,  $P<0.05$ ;  $0.09\pm0.08$  vs  $1.43\pm0.65$ ,  $P<0.05$ ), suggesting that *H.pylori* infection might ameliorate the apoptosis of CECs.

Notably, Compared with DSS group, *H.pylori* infection inhibited the necroptosis associated proteins including RIPK1 ( $0.76\pm0.12$  vs  $0.16\pm0.04$ ,  $P<0.05$ ), RIPK3 ( $0.94\pm0.19$  vs  $0.24\pm0.08$ ,  $P<0.05$ ) and p-MLKL ( $0.90\pm0.19$  vs  $0.06\pm0.02$ ,  $P<0.05$ ), suggesting that necroptosis inhibition might be involved in the protective effects against colonic inflammation.

**Conclusion:** *H.pylori* infection can attenuate the intestinal inflammation in DSS-induced mice, which may be due to improving intestinal mucosal barrier function by enhancing the expression of tight junction protein and inhibiting the apoptosis and necroptosis of colonic epithelial cells.

**Disclosure:** All authors have declared no conflicts of interest.

## P1001 COMMENSAL FUNGI AND THEIR CELL-WALL $\beta$ -GLUCANS DIRECT DIFFERENTIAL RESPONSES IN HUMAN INTESTINAL EPITHELIAL CELLS, SUGGESTING A MECHANISM FOR MUCOSAL TOLERANCE

**Contact E-Mail Address:** irisdo@clalit.org.il

**Introduction:** Intestinal epithelial cells (IECs) are the first to encounter luminal antigens and play an active role in intestinal immune responses. Antibodies directed against fungal cell-wall glycans are associated with Crohn's disease (CD) and may represent loss of tolerance towards intestinal microorganisms. We previously reported that the receptor Dectin-1 and its major signaling mediator Syk are expressed in normal ileal and colonic IECs. Furthermore, the fungal cell-wall glycans  $\beta$ -glucans induced IL-8 and CCL2 secretion by IEC lines in a Dectin-1 and Syk dependent manner.

**Aims & Methods:** To address the mechanism of IECs response to fungi and fungal glycans.

Mucosal samples were obtained from healthy individuals and fungal recognizing C-type lectin receptors (CLRs) expression was assessed by immunofluorescence (IF). Mucosal explants and IEC lines (HT-29 and SW480) were stimulated with *Candida albicans* and *Saccharomyces cerevisiae* and the  $\beta$ -glucans zymosan and curdlan. Signaling was assessed by Western blot and IF. Chemokine secretion was assessed by ELISA.

**Results:** The CLRs Dectin-1, Dectin-2, DC-SIGN and Mincle were identified in ileal and colonic human mucosal samples as well as in IEC lines. Stimulation of mucosal explants and IEC lines with commensal fungal particles of live, heat-killed (HK)- or UV-inactivated wild-type *C. albicans*, as well as

HK- *S. cerevisiae* and  $\beta$ -glucans resulted in Syk phosphorylation. However, in IEC lines,  $\beta$ -glucans, but not fungal particles, induced phosphorylation of the MAP kinases JNK and p38 and the transcription factors c-JUN and NFkB p65.

Furthermore, only  $\beta$ -glucan stimulation induced the secretion of the pro-inflammatory chemokines Gro- $\alpha$ , GM-CSF, IL-8 and CCL2 (e.g.  $13.5 \pm 0.4$  vs.  $0.35 \pm 0.005$  ng/ml GRO- $\alpha$  in zymosan-treated vs. control HT-29 cells, respectively,  $p \leq 0.0001$ ).  $\beta$ -glucan induced chemokine secretion was sensitive to Syk (R406) and JNK (SP600125) inhibitors (e.g. 79% and 57% inhibition of zymosan induced IL-8 secretion in SW480 cells, respectively) as well as to NFkB-p65 inhibition by BAY 11-7082 (e.g. up to 90% inhibition,  $p \leq 0.01$ , of curdlan induced IL-8 and Gro- $\alpha$  secretion from SW480 cells). Notably,  $\beta$ -glucan induced NFkB p65 phosphorylation was insensitive to Syk inhibition.

Finally, co-stimulation of IEC lines with  $\beta$ -glucans and HK *C. albicans* yielded a decrease in all tested chemokine secretion compared to stimulation with  $\beta$ -glucans alone (e.g. 27% inhibition,  $p \leq 0.01$ , of zymosan induced GRO- $\alpha$  secretion in HT-29 cells and 30% and 32% inhibition,  $p \leq 0.01$ , of curdlan and zymosan induced IL-8 and GRO- $\alpha$  secretion respectively, in SW480 cells).

**Conclusion:** CLRs expressed by IECs allow recognition of luminal fungi and their cell-wall glycans such as  $\beta$ -glucans. Epithelial response to  $\beta$ -glucans includes Syk-dependent activation of JNK, p38 and c-JUN, as well as a Syk-independent activation of NFkB p65. While Syk is activated, the lack of JNK, p38, c-JUN and NFkB p65 activation and chemokine secretion upon epithelial recognition of commensal fungi may reflect regulatory signals, resulting from CLRs response to other glycans expressed by intact fungi that contribute to mucosal tolerance. This is supported by the inhibitory effect of *C. albicans* on  $\beta$ -glucan-induced chemokine secretion. Skewed epithelial response to commensal fungi may impair homeostasis, lead to loss of tolerance and contribute to the pathogenesis of CD.

**Introduction:** Proteolytic activity in the intestine is detected both in the lumen and in tissues in physiological conditions. It is increased in both compartments in pathological situations such as Inflammatory Bowel Disease (IBD) and Irritable Bowel Syndrome (IBS). The increased activity can be due to an overexpression of proteases, to a decreased expression of natural endogenous protease inhibitors, or both.

**Aims & Methods:** Our objective was to identify the disease-associated proteases and their inhibitors that are present in the intestine. We therefore developed a number of tools for that aim. First, we developed fluorescent enzymatic assays and a range of substrates to detect proteolytic activity in human tissues and feces. Next, we revealed localization of enzymatic activity by *in situ* zymography from frozen tissue sections. We used serine protease-targeted activity-based probes (ABP) coupled with mass spectrometry analysis to identify active forms of proteases present within the gut tissues of healthy individuals, patients with gastrointestinal disorders as well as in naïve mice or in mouse models of gut inflammation. Expression levels of proteases and their related inhibitors were analysed by qPCR, immunostaining and western-blotting using mouse and patient's tissues as well as 3D organoids cultures.

**Results:** We have identified different proteases such as a previously uncovered form of epithelial elastase, chymotrypsin as well as PRSS-1, 2 and 3 in gut tissues. Importantly, *in situ* zymography revealed that most of the proteolytic activity localised in the intestine originated from the epithelium. Some proteases and inhibitors had differential expression in IBD and IBS. Expression of proteases and inhibitors in epithelium were confirmed in patients' organoids culture.

**Conclusion:** Epithelial proteases and protease inhibitors appear as major actors of mucosal homeostasis. Their functional study highlights new possible therapeutic intervention for intestinal pathologies.

**Disclosure:** Nothing to disclose

## P1003 PHARMACOKINETICS AND EXPOSURE-RESPONSE RELATIONSHIPS OF USTEKINUMAB IN PATIENTS WITH ULCERATIVE COLITIS: RESULTS FROM THE UNIFI INDUCTION AND MAINTENANCE STUDIES

**Introduction:** Serum concentrations of monoclonal antibody-based biologics have been shown to correlate with their efficacy. PK, exposure-response (ER), and immunogenicity of ustekinumab (UST) were evaluated in UNIFI induction and maintenance studies in UC. Induction results were presented previously<sup>1</sup>.

**Aims & Methods:** PK, immunogenicity, efficacy & safety data were obtained from two Phase 3, double-blind, PBO-controlled trials in adult patients (pts) with moderate-severe UC. These included 1 induction study which enrolled 961 pts (UNIFI). Patients enrolled in the induction study received a single IV infusion at Week 0 of PBO, UST 130 mg, or weight-range-based doses approximating 6 mg/kg UST (~ 6 mg/kg; 260 mg for pts  $\leq 55$  kg, 390 mg for pts  $> 55$  kg &  $\leq 85$  kg, & 520 mg for pts  $> 85$  kg). Responders to a single IV infusion of UST comprised the primary study population for the maintenance study (n=523) & were randomly assigned to receive SC UST 90 mg q12w, UST 90 mg q8w, or PBO. Blood samples were collected to measure serum UST concentration and antibodies to ustekinumab. Key efficacy outcomes were based on the Mayo score and inflammatory biomarkers (C-reactive protein [CRP] and fecal calprotectin [fCal]). Relationships between serum UST concentrations & efficacy, and the incidence of selected safety events of infections, serious infection & serious adverse events (SAE) were evaluated.

**Results:** Serum UST concentrations over time were dose proportional, unaffected by concomitant immunosuppressants, & similar between pts who were biologic failures & non-failures. Median peak serum UST concentrations in the induction study were 43.2  $\mu$ g/mL & 127.0  $\mu$ g/mL for the 130 mg & ~6 mg/kg dose groups, respectively. At induction week 8, median UST concentrations were 2.51  $\mu$ g/mL & 8.59  $\mu$ g/mL, respectively. Steady-state was reached by the start of the second SC maintenance dose (16 or 20 weeks from the IV induction dose for the q8w and q12w regimen respectively). Median steady-state trough serum UST concentrations over time in the UST q8w group (2.69 to 3.09  $\mu$ g/mL) were 3-fold higher than in the q12w group (0.92 to 1.19  $\mu$ g/mL). During induction & maintenance, serum UST concentrations were positively associated with the proportions of pts achieving response & remission, respectively (Table), and there was an inverse association between serum UST concentrations and CRP and fCal levels. No relationship was observed between serum UST concentrations & the incidence of infections, serious infections or SAEs during induction or maintenance treatment with UST. The incidence of antibodies to UST through 1 year using a drug-tolerant assay was 3.4% among those receiving UST maintenance vs. 9.1% in the PBO group; no impact of antibodies on efficacy was observed.

**Conclusion:** Serum UST concentrations were approximately dose-proportional. A positive E-R of serum UST with clinical efficacy measures and an inverse relationship with inflammatory markers was observed during UST IV induction & SC maintenance treatment. Adverse events including infections did not increase with increased serum UST concentrations at the doses evaluated in induction and maintenance. These findings are consistent with those in UST for Crohn's disease.

Efficacy Outcome	Serum Ustekinumab Concentration (µg/mL)*/Proportion of Patients (%)			
	1st Quartile	2nd Quartile	3rd Quartile	4th Quartile
Clinical Response at Induction Week 8	<2.2/41.2	2.2 to <3.9/47.7	3.9 to <8.8/61.1	≥8.8/74.2
Clinical Remission at Maintenance Week 44	<0.9/29.9	0.9 to <1.9/46.2	1.9 to <3.2/46.8	≥3.2/61.5

\*Serum concentration quartiles based on ustekinumab concentration at Week 8 for the induction analysis, and average steady-state trough concentration for the maintenance analysis

[Table. Proportions of Patients Achieving Efficacy Endpoints by Serum Ustekinumab Concentration]

**Introduction:** The role of incretin hormone, glucagon-like peptide (GLP-1), in Crohn's disease (CD) is still poorly understood. GLP-1 is secreted by intestinal L cells and decreases blood glucose levels. GLP-1 is rapidly degraded by dipeptidyl peptidase IV (DPP-IV), with a half-life of less than 2 minutes. CD patients may be at a greater risk of glucose metabolism disturbances due to overproduction of proinflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that a possible mechanism of disturbances in glucose metabolism may be related to changes in the levels of incretin hormones due to inflammation.

**Aims & Methods:** The primary aim of this study was to investigate whether colitis is associated with changes in glucose metabolism. The secondary goal was to investigate potential involvement of incretin system as an underlying factor.

To develop a chronic colonic inflammation mimicking CD in humans, mouse model of colitis induced by intracolonic administration of 2,4,6-trinitrobenzenesulfonic acid (TNBS) at dose 150 mg/kg at day 0 was used. On day 7 mice were sacrificed and macroscopic score as well as ulcer score were recorded. In all mouse experiments the expression of inflammation markers: tumor necrosis factor-α (TNF-α), IL-6 and IL-17 was determined.

The effect of colitis on glucose metabolism was studied by measurement of fasting glucose levels, as well as the GLP-1, DPP-IV, prohormone convertase 1/3 (PC 1/3) and GLP-1 receptor (GLP-1R) expression. Moreover, to translate results obtained in mice, we measured the level of GLP-1, DPP-IV and expression of PC 1/3 mRNA in serum (n=11-15) and colon samples (n=5-6) from healthy controls and CD patients.

**Results:** There were significant differences in macroscopic score, ulcer score in mice with colitis compared to control mice. TNF-α was significantly higher when compared to control mice, whereas IL-17 expression was decreased. No difference in expression of IL-6 was observed between groups.

Glucose levels in mice treated with TNBS were significantly higher in comparison to control group, what was associated with non-significantly lower level of GLP-1 and significantly higher level of DPP-IV in mouse serum. In mouse colon samples, GLP-1 levels were significantly lower whereas PC 1/3 expression, an enzyme involved in processing proglucagon into GLP-1 were significantly higher in mice with colitis compared to controls. No

change in DPP-IV was observed. Furthermore GLP-1R expression was non-significantly higher in mice treated with TNBS when compared to controls. In humans, GLP-1 and DPP-IV levels were significantly decreased in the serum of CD patients in comparison to healthy control subjects. Surprisingly, GLP-1 level was significantly increased in colon samples of the same cohort of CD sufferers, when compared to control samples. Furthermore, there was no significant reduction of PC 1/3 mRNA expression in CD group when compared to control group.

**Conclusion:** Changes in incretin hormone levels in response to colonic inflammation contributes to the impaired glucose metabolism. Our data suggest that targeting incretin system by GLP-1R agonists or DPP-IV inhibitors may become a novel therapeutic option in the treatment of CD with both anti-inflammatory and anti-diabetic effect.

**Introduction:** Current therapeutic goals for inflammatory bowel disease (IBD) focus on symptomatic response, but many patients experience disease progression. There has been a movement towards tighter control of IBD, defined as deep remission. Achieving deep remission could lead to lower rates of complications, surgical interventions, and hospital visits. No consensus definition currently exists for deep remission, although clinical, endoscopic, and biochemical remissions are all components that have been proposed in the definition. We systematically reviewed the different variations of deep remission and created a classification system to provide uniformity when discussing deep remission among clinicians.

**Aims & Methods:** We performed a systematic review using the search terms ("inflammatory bowel disease" OR "IBD" OR "crohn\*" OR "CD" OR "ulcerative colitis" OR "UC" OR "colitis") AND ("mucosal healing" OR "deep remission" OR "complete remission" OR "full remission" OR "endoscopic remission") in Pubmed and EMBASE on October 1, 2018. 7,514 articles and abstracts were identified. Two authors independently reviewed the publications which defined deep remission. Publications which included pediatric patients or were published in foreign language were excluded. A total of 37 peer-reviewed publications that defined deep remission were included. A classification system for deep remission was created based on the variety of definitions.

**Results:** There were 9 different definitions of deep remission in the 37 publications, involving combinations of the following remission variables: clinical, endoscopic, biochemical, histologic, radiographic, or immunologic. The majority of definitions, 21/37 (56.7%), only included clinical and endoscopic remissions as part of deep remission. The remaining definitions for deep remission were as follows: 4/37 (10.8%) with clinical, endoscopic, and biochemical remissions; 4/37 (10.8%) with endoscopic and histologic remissions; 3/37 (8.1%) with clinical, endoscopic and histologic remissions; 1/37 (2.7%) with clinical, endoscopic, histologic, and biochemical remissions; 1/37 (2.7%) with clinical and radiographic remissions; 1/37 (2.7%) with histological remission, 1/37 (2.7%) with endoscopic and biochemical remissions, and 1/37 (2.7%) with immunologic and histologic remissions.

**Conclusion:** Given there is no consensus definition for deep remission, we propose a classification system to simplify the combinations of remission variables recognized as definitions of deep remission. Our system recognizes the most common definition of deep remission, clinical and endoscopic remission, as DR-A. However, the system allows for the flexibility of alternate definitions encompassing other remission variables. This is important as clinical treatment goals transition to tighter disease control, and physicians focus on different indicators of remission such as histologic or radiographic evidence. Future studies will likely assess greater numbers of remission variables to ensure complete dormancy of underlying inflammation in IBD patients. That transition is best represented in our classification system by DR-E. Our classification system is a stepping stone towards providing clarity amongst clinicians in discussions involving deep remission.

**Disclosure:** Nothing to disclose

Type of Deep Remission	Definition
Deep Remission A (DR-A)	Clinical Remission + Endoscopic Remission
Deep Remission B (DR-B)	Clinical Remission + Other Remission Variable (but not Endoscopic Remission)
Deep Remission C (DR-C)	Endoscopic Remission + Other Remission Variable (but not Clinical Remission)
Deep Remission D (DR-D)	2 Remission Variables (but not Clinical nor Endoscopic Remission)
Deep Remission E (DR-E)	>2 Remission Variables (any combination)
Remission Variables	Clinical, Endoscopic, Biochemical, Histological, Radiographic, Immunologic, or other remission types

[Deep Remission Classification System]

## P1006 C86/CD16 POSITIVE CELLS ACCUMULATE IN THE MUCOSA OF B3-PATIENTS AND COULD MEDIATE EMT IN CROHN'S DISEASE

**Introduction:** Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype.

**Aims & Methods:** The aim of the present study is to analyze the pattern of expression of macrophages, the expression of EMT related genes and cytokines in surgical resections from Crohn's disease (CD, n=43) patients which were categorized according to Montreal classification (B2 or B3); unaffected mucosa of patients with colorectal cancer was used as control (n=20). mRNA was isolated from intestinal samples and the expression of macrophage and EMT markers and cytokines were analyzed by RT-PCR. PBMCS were isolated from healthy donors and treated during 5 days with secretomes, from control, B2 or B3 surgical resections; the mRNA expression of macrophage markers were determined by RT-PCR. Results are expressed as mean±SEM (n≥5). Statistical analysis was performed by ANOVA + Newman-Keuls test. Correlations between data were analysed using Pearson's correlation coefficient (\*p < 0.05).

**Results:** The expression of CD16 and CD86 was significantly higher in intestinal samples from B3 CD patients (7.2 ±1.1 and 7.7±1.3, respectively) than in controls (1.4±0.2 and 2.5±0.4, respectively) or B2 CD patients (4.8±0.9 and 4.5±0.6, respectively). The mRNA expression of CD16 and CD86 were significantly higher in PBMCS treated with B3-secretomes than in those treated with B2- or control secretomes. The expression of CD16 and CD86 significantly correlated with FSP1 (r=0.74, P=0.002\* and r=0.66, P=0.003\*, respectively), VIMENTIN (r=0.60, P=0.02\* and r=0.82, P=0.001\*, respectively), SNAIL1 (r=0.61, P< 0.01\* r=0.52, P=0.04\*, respectively), IL4 (r=0.63, P=0.01\* and r=0.60, P=0.02\*, respectively) and IFNγ (r=0.56, P=0.001\* and r=0.58, P=0.01\*, respectively) in intestinal tissue from the fistulizing CD group.

**Conclusion:** A macrophage phenotype expressing CD86/CD16 may act as a source of EMT mediators in intestinal tissue from CD patients with a penetrating (B3) behavior. IL4 and IFNγ could be responsible for the increase in the number of CD86/CD16 macrophages in the B3 behavior.

**Disclosure:** Nothing to disclose

**Introduction:** The steroid-refractoriness is a common complication of ulcerative colitis (UC), which appears unpredictably. Several mechanism of action (MoA) has been implicated in corticosteroid (CS) failure, however, there are no conclusive studies on the molecular functions involved in it. Therefore, ourgroup used rectal biopsies from patients with active UC and different response to CS treatment to generate a predictive computational strategy based on Biology of Systems. Combining mRNA and miRNAs intestinal expression profiles with updated molecular information related to UC and CS, we were able to identify a MoA associated with steroid-refractoriness in UC<sup>1</sup>.

**Aims & Methods:** In order to transfer these results to clinical practice, we tried to explore the reflection of the biological activity of the intestinal mucosa into the plasma of these patients.

RNA-seq (Illumina, USA)-assessed plasmatic miRNAs (pmiRNAs) were statistical compared between responders and non-responders CS patients. Differential pmiRNAs between both groups of patients and their target proteins were identified. The resulting molecular data were compared with our previous intestinal mucosal results, following statistical approaches:

- pmiRNAs vsbiopsy differential miRNAs (bmiRNAs);
- Target proteins of pmiRNAs vs. those of the bmiRNAs;
- Target proteins of pmiRNAs vs.proteins encoded by mucosal mRNA differentials; and
- Target proteins of pmiRNAs vs. key proteins linked to steroid-refractoriness MoA.

**Results:** Four of the pmiRNA differentially expressed (miR-194-5p, miR-145-5p, miR-216a-5p and miR-224-5p) were related to biopsies findings, either sharing the same protein target with the differential bmiRNA or linked to MoA key proteins. Interestingly, the miR-145-5p targeted directly VEGF-alpha (a down-regulated MoA-protein in responder's patients<sup>1</sup>) and CDK4, an over-expressed protein at mRNA level in non-responder's patients; while miR-224-5p targeted CXCR4 (over-expressed mRNA in non-responder group) and NCOA6 (glucocorticoid receptor co-activator). Finally, another one pmiRNA (hsa-miR-487a-3p) showed differences between patients in both tissues (intestinal mucosa and plasma), over-expressed in intestinal biopsies and suppressed in plasma of non-responder's patients

**Conclusion:** In conclusion, there is a biological steroid-refractoriness-MoA reflection from the intestinal mucosa to the plasma in patients with UC, which making up interesting molecules (miRNAs and proteins) as possible biomarkers or therapeutic targets to improve CS response

**Introduction:** Ustekinumab is an effective therapy for moderate-to-severe ulcerative colitis (UC),<sup>1,2</sup> but its effects on mucosal healing (endoscopic improvement + histologic improvement) during maintenance treatment are unknown.

**Aims & Methods:** We evaluated the effects of maintenance ustekinumab on histologic and endoscopic activity in the UNIFI Phase 3 study of ustekinumab in moderate-to-severe UC (n=961). Subjects in response 8 weeks after receiving intravenous ustekinumab were randomized to receive maintenance treatment with subcutaneous (SC) placebo or ustekinumab 90 mg every 8 (q8w) or 12 weeks (q12w). Two colonic biopsies were collected from the distal colon at screening and Weeks 0 and 44 of maintenance. Endoscopic improvement (EI) was defined as a Mayo endoscopy subscore  $\leq 1$ ; histologic improvement (HI) comprised the following Geboes score-based criteria: absence of erosions or ulcerations, absence of crypt destruction, and < 5% of crypts with neutrophil infiltration. To encompass both macro- and microscopic scales, histo-endoscopic mucosal healing (MH) was defined as achieving both EI and HI.

**Results:** At maintenance Week 44, EI was achieved in 28.6%, 43.6%, and 51.1% of subjects treated with placebo, ustekinumab q12w (p=0.002 vs placebo), and ustekinumab q8w (p< 0.001), respectively. HI was achieved at Week 44 in 32.9%, 54.0%, and 59.3% of subjects treated with placebo, ustekinumab q12w, and ustekinumab q8w, respectively (p< 0.001 for both q12w and q8w). MH was achieved at Week 44 in 24.1%, 38.8%, and 45.9% of subjects treated with placebo, ustekinumab q12w (p=0.002), and ustekinumab q8w (p,0.001), respectively. HI at Week 44 (irrespective of maintenance treatment) was significantly associated with EI and MH (p< 0.001) and with both lower absolute levels and larger post-treatment changes in total Mayo score, partial Mayo score, and Mayo symptom subscores for stool frequency and rectal bleeding at Week 44. Both EI and HI following 8 weeks of ustekinumab treatment were associated with clinical remission and steroid-free clinical remission at Week 44 (p< 0.05), as well as remission through Week 44 (i.e. at both Week 8 and Week 44). For example, 26% of subjects with induction HI were in clinical remission through Week 44, versus 4% of subjects without induction HI. Induction MH was similarly associated with positive outcomes at maintenance Week 44.

**Conclusion:** Among subjects with moderately-to-severely active UC, those receiving SC ustekinumab maintenance had higher rates of EI, HI, and MH than those receiving placebo. Both EI and HI are associated with subsequent clinical remission and steroid-free clinical remission.

Clinical Outcomes	Histologic Improvement <sup>a</sup>	Without Histologic Improvement <sup>a</sup>	p-value <sup>b</sup>
Week 44	N=140	N=124	
Endoscopic Improvement	62%	47%	<0.02
Mucosal Healing	59%	43%	<0.02
Clinical Remission	54%	40%	<0.02
Steroid-free Clinical Remission	52%	39%	<0.04
Week 8 AND Week 44			
Endoscopic Improvement	31%	6%	<0.0001
Mucosal Healing	40%	0%	<0.0001

**Introduction:** Endoplasmic reticulum (ER) is responsible for the synthesis and processing of secretory and membrane proteins. The stress state of the endoplasmic reticulum (ERS) occurs due to the inability of certain proteins to adopt the appropriate conformation stage, thus leaving them unfolded within the ER. The accumulation of unfolded proteins is detrimental to the cell, which may respond by driving the proteins to degradation, pausing the transcription process or even initiating apoptosis<sup>(1)</sup>. Gene association and meta-analysis studies show that ERS possibly correlates with the pathogenesis of Crohn's disease (CD)<sup>(2)</sup>.

**Aims & Methods:** Our aim was to investigate the occurrence of ERS in the intestinal mucosa of patients with CD, and to evaluate the effect of a chemical inhibitor on its activation and modulation of pro-inflammatory cytokines. Biopsies of intestinal mucosa were collected by colonoscopy from patients with CD (CD group) and patients who did not present inflammatory bowel diseases (control group).

Cell culture was performed to evaluate the ERS and its potential resolution with chemical inhibitor. Non-parametric tests were performed for statistical analysis, with p < 0.05. The study was approved by the Research Ethics Committee.

**Results:** Samples were collected from 10 patients with active CD (CDEIS $\geq 5$ ) and 6 control patients. After cell culture, a significant difference was observed in the activation of the main ERS pathways in the CD group. A modulation in the expression of pro-inflammatory cytokines was also observed after the treatment. Treatment with a chemical inhibitor also led to a significant decrease in the expression of the genes responsible for the activation of ERS pathways and to a decrease in the main inflammatory cytokines present in CD.

**Conclusion:** The activation of the main ERS pathways suggests a role in the maintenance of the inflammatory process in CD. The use of a chemical inhibitor has been shown to be effective in significantly decreasing the activation of ERS and to modulate the inflammation in CD.

**Contact E-Mail Address:** adeak89@hotmail.com

**Introduction:** The presence of anxiety and depression is higher in patients with chronic diseases compared to the general population. A long term medical illness may become a risk factor for depression. There is important evidence that inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis (UC), is associated with higher rates of

anxiety and depression compared to the general population<sup>1</sup>. Despite this knowledge, IBD patients are not routinely screened for depression and anxiety.

**Aims & Methods:** The aim of our study was to show the prevalence of anxiety and depression in IBD patients in Albania and also to evaluate its correlation with the disease severity. This is a prospective study of IBD patients, followed-up in a 2 year period, at the University Hospital Mother Theresa, in Tirana, which represents the largest in and outpatient facility in Albania. The presence of anxiety and/or depression was determined using the Hospital Anxiety and Depression Scale<sup>2</sup>, compiled under the explanations and supervision of medical staff. Patients with known mental illness followed by Psychiatry were excluded. Patient demographics, disease characteristics and medication information were collected. Multivariable analysis was used to determine associations between patient characteristics and depression and/or anxiety. Statistical analysis was made with Chi-square (p-value, significance level: 0.05).

**Results:** We have followed 46 IBD patients (26 F : 20 M), on treatment with anti-TNF since July 2016. Of these, there were 9 patients (19%) with Crohn's disease and 37 patients (81%) with Ulcerative Colitis. 16 patients (34%) were under treatment with Adalimumab and 30 patients (66%) were under treatment with Infliximab. Among these 46 IBD patients, there were 18.7% with depression and 34.3% with anxiety, with a rate of 40.6% of patients suffering from depression and/or anxiety. Females were more likely to have anxiety with a significantly rate of 63% compared to males: 27%. Ulcerative colitis patients were also more likely to have depression and/or anxiety (84.6%) than Crohn's disease patients (15.4%). Disease activity calculated by Mayo score (for UC) and CDAI score (for CD), was found to be significantly associated with depression and/or anxiety. Correlation coefficient (r) between depression and disease activity was: - 0.314, while for anxiety, it was calculated: -0.298 (p values respectively: 0.03 and 0.04).

**Conclusion:** A significant number of patients with IBD, suffer from depression and/or anxiety and this has an important impact on their quality of life. Patients with a severe disease activity are at a higher risk for anxiety and depression and this may suggest that it can be important to start screening all the IBD patients with this questionnaire in order to evaluate them and eventually refer them to the psychiatrists.

**Introduction:** Prevalence of axial spondyloarthritis in inflammatory bowel disease (axSpA-IBD) is up to 25 times higher than in the normal population, and there is some evidence to suggest that different forms run different courses. In addition, the very strong association with HLA-B\*27 seen in axial spondyloarthritis not associated with IBD (axSpA-not IBD) is much weaker in axSpA-IBD. This difference leads us to conclude that environmental factors, particularly the *milieu* (microbiome, metabolome and inflammatory status) in the gut lumen may be important in defining the course of disease. Establishing axSpA-IBD from axSpA-not IBD is important for both management and prognostic reasons. Here we present initial analysis from proton high-resolution nuclear magnetic resonance (1H-NMR) spectroscopy, profiling human serum, urine and stool to test the hypothesis that metabolites differ between ax-SpA-IBD, ax-SpA-not IBD, psoriatic peripheral arthritis (PsA) and control cohorts (HC). We have used multivariate statistics analysis to find distinct metabolic signatures across the cohorts.

**Aims & Methods:** 1H-NMR spectra were acquired from serum, urine and stool samples of 71 patients (23 ax-SpA- not IBD, 15 ax-SpA-IBD, 16 PsA and 17 HC) in a Bruker 600 MHz NMR spectrometer, following Bruker SOP pro-

ocols. Multivariate analysis of all NMR features involved principal components analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA). NMR resonances for assigned metabolites influenced by gut microbiota were compared using Mann-Whitney U test.

**Results:** PCA revealed clustering of the groups; OPLS-DA modeling in stool metabolites was able to distinguish between ax-SpA- not IBD and ax-SpA-IBD cohorts (Q<sup>2</sup>Y 0.468, p-values for 1,000 random permutations: pR<sup>2</sup>Y= 0.102 and pQ<sup>2</sup>Y= 0.002). In this initial analysis, there was no differentiation between cohorts in urine and serum.

**Conclusion:** (1)H NMR-based metabolic profiling is able to distinguish between ax-SpA- IBD and ax-SpA- not IBD in stool. Further modeling of urine and serum metabolic profiles will be undertaken to examine whether the differences in stool are reflected in other biofluids as well as deeper analysis specific metabolites.

**Introduction:** Tofacitinib, an orally administered pan-Janus kinase (JAK) inhibitor modulating the JAK-STAT (signal transducers and activators of transcription) signaling pathway, is used for the treatment of patients with ulcerative colitis (UC). Tofacitinib effects in the intestinal mucosa are still elusive.

**Aims & Methods:** To identify tofacitinib effects in human intestinal mucosa and to decipher whether discordant responses occur in the normal or inflamed mucosa of patients with UC or Crohn's disease (CD).

Human mucosal explants were obtained from patients with inflammatory bowel disease (IBD) and normal controls. Phosphorylated STAT (p-STAT) levels were assessed using Western blot and Immunofluorescence. Lamina propria lymphocytes were isolated from explants and stimulated with anti-CD3/CD28 beads in the presence or absence of tofacitinib for 3 days. Cytokine production by CD3<sup>+</sup> T cells and cell viability were assessed by flow cytometry. T<sub>84</sub> intestinal epithelial cell (IEC) lines were cultured on transwells for 12-14 days to generate epithelial barrier, measured as transepithelial electrical resistance (TEER), and stimulated with IL-13 basolaterally in the presence or absence of tofacitinib for 24h. Permeability was assessed by TEER measurements and Claudin-2 (CLDN2) gene expression, assessed using RT-PCR.

**Results:** Mucosal explants were obtained from 11 subjects (7 controls, 4 CD). p-STAT1 and p-STAT3 expression was located mainly in the lamina propria and was higher in explants with active inflammation compared to normal controls. A dose-dependent decrease in p-STAT1 and p-STAT3 expression in response to tofacitinib was observed compared to non-treated (NT) mucosa. Normal controls and explants obtained from areas with active inflammation responded similarly. Interestingly, significantly more potent inhibitory effect on STAT1 compared to STAT3 phosphorylation was observed (100nM tofacitinib compared to NT, p< 0.0023).

Moreover, upon tofacitinib treatment, CD3<sup>+</sup> IL4<sup>+</sup> and CD3<sup>+</sup> IFN-γ<sup>+</sup> cells, isolated from normal and explants with active inflammation, were decreased in a dose-dependent manner (35.5% and 37.5% without tofacitinib; 20.1% and 25% with 10nM; 11.6% and 14.5% with 100nM tofacitinib, respectively). No significant effect on IL-17 production by T cells or on T cells mortality

was observed. In T<sub>84</sub> cells, tofacitinib prevented IL-13-induced decrease in TEER and increase CLDN2 expression in a dose dependent-manner ( $p < 0.001$  and  $p < 0.0054$ , respectively;  $n = 3$ ).

**Conclusion:** Tofacitinib was a more potent inhibitor of specific p-STAT in the intestinal mucosa of both normal controls and patients with IBD. Inflamed mucosal explants from patients with CD responded to tofacitinib by inhibiting JAK-STAT signaling pathway and cytokine secretion by intestinal lymphocytes. Furthermore, tofacitinib ameliorated epithelial barrier disruption induced by IL-13. Thus, beneficial effects are expected in CD. *Ex-vivo* examination of drug effects in the intestinal mucosa may be used as a tool for evaluation of treatment effects.

**Introduction:** Inflammatory bowel disease (IBD) often forms intractable ulcers. Self-assembling peptide hydrogel (SAPH, PuraMatrix™, 3D Matrix Co., Ltd., Tokyo) is composed of only amino acids present in the living organisms; its forms nanofibers with a diameter of 10 nm and forms a gel when it comes in contact with blood or bodily fluids or under physiological conditions. In recent years, SAPH has also been reported to promote regeneration of damaged sites in various organs. However, the tissue repair effect of SAPH in ulcers of IBD is not reported yet. In this study, we evaluated the effect of SAPH on repairing ulcers using the rat model topical trinitrobenzene sulfonic acid (TNBS) -induced colitis.

**Aims & Methods:** Seven-week-old male SD rats were laparotomized under anesthesia. The proximal colon was clamped with ringed forceps. An ethanol solution (35%; 0.2 ml) containing 0.15 M TNBS was injected into the proximal colon lumen via a needle to prepare a localized ulcer model. On the second and fourth day, SAPH ( $n = 6$ ) or saline ( $n = 5$ ) was applied to the ulcerated area under colonoscopy. On the second, fourth and seventh days, the ulcer size was measured with an endoscope. The rats were sacrificed on the 7th day, and the ulcer area of the colon, colonic weight (g / 3 cm), and histologic findings were evaluated. The tissue levels of pro-inflammatory cytokines (interleukin [IL]-1 $\alpha$ , IL-6, IL-22 and tumor necrosis factor [TNF]- $\alpha$ ) and tight junctions (claudin [Cldn]-1, Cldn-2, occludin, cadherin-1, Zo-1, Zo-3)) in tissue were determined using real time-PCR.

#### Results:

- (i) Endoscopic evaluation: SAPH group showed reduction in ulcer size as compared with that in the control group ( $P = 0.015$ ).
- (ii) Macroscopic finding evaluation: Ulcer area was significantly reduced in the SAPH group than in the control group ( $P = 0.024$ ). Colonic weight also tended to decrease in the SAPH group compared to the control group.
- (iii) Real time-PCR analysis: In the SAPH group, expression of several pro-inflammatory cytokines (IL-1 $\alpha$  and IL-6) decreased and expression of cldn-1 increased ( $p < 0.05$ ).

**Conclusion:** SAPH effectively suppresses colonic injury through the down-regulation of pro-inflammatory cytokines and the up-regulation of cldn-1. Use of SAPH has been suggested to be a potential therapeutic strategy for refractory ulcers of the intestinal tract in IBD.

**Disclosure:** Nothing to disclose

### P1014 GLUCOCORTICOID AUGMENTS EPITHELIAL PERMEABILITY IN CD PATIENT-DERIVED INTESTINAL ORGANOIDS

**Introduction:** Intestinal barrier dysfunction has emerged as a key pathogenic factor contributing to the onset and exacerbation of Crohn's Disease (CD). Exogenous glucocorticoid (GC) is a first-line therapeutic for the treatment of moderate to severe CD. Recently, GC therapy was shown to restore intestinal permeability in CD patients. However, the underlying mechanisms remain largely unknown.

**Aims & Methods:** The main aim of the study was to investigate the effect of glucocorticoid prednisolone on intestinal barrier integrity and to elucidate the underlying molecular mechanisms using CD patient-derived intestinal organoids. Hollow 3D intestinal organoids were generated from stem-cell containing crypts isolated from proximal colon biopsies of remissive CD patients (SES-CD < 3,  $n = 6$ , ethical approval NL31636.068.10). To mimic the inflammatory microenvironment, a mixture of cytokines containing TNF- $\alpha$ , IFN- $\gamma$  and IL-1 $\beta$  (20 ng/mL each) were added to the culture medium for 24 hours, with or without prednisolone (500 ng/mL) for 12 hours. Epithelial permeability of the organoids was assessed by the flux of fluorescein isothiocyanate-labelled dextran 4 kDa (FITC-D4) from the basal to the luminal compartment using confocal microscopy. Gene expression and localization of barrier junctions were analyzed by qRT-PCR and immunofluorescent staining. Cell signaling activities were analyzed using western blot. Data are expressed as means  $\pm$  SEM. Statistical significance was evaluated using one-way ANOVA and Tukey's post-hoc test.

**Results:** Exposure of the cytokine mixture significantly disrupted epithelial barrier function of the intestinal organoids, as evidenced by increased luminal/basal FITC-D4 ratio as compared to the control treatment ( $5.051 \pm 0.376$  vs  $1.000 \pm 0.098$ ,  $p < 0.001$ ). This effect was partially rescued upon prednisolone supplementation ( $1.857 \pm 0.214$  vs  $5.051 \pm 0.376$ ,  $p < 0.001$ ). Compared to the control treatment group, exposure of cytokine mixture resulted in a significant reduction of E-Cadherin and an increase of Claudin-2 on both mRNA and protein levels, and led to an increased phosphorylation of MLCK. Supplementation of prednisolone ameliorated the junctional alterations and barrier dysfunction induced by the cytokine mixture ( $p < 0.05$ ).

**Conclusion:** Using CD patient-derived intestinal organoid model, we demonstrated that glucocorticoid prednisolone has a protective effect against the cytokine-induced epithelial barrier dysfunction. Prednisolone promotes epithelial integrity through enhancing the expression of E-Cadherin and reducing the expression of Claudin-2, and inhibiting the cytokine-induced MLCK phosphorylation. Our findings provide a novel mechanism for the beneficial effect of prednisolone in the treatment of IBD.

**Contact E-Mail Address:** manubarreiro@hotmail.com

**Introduction:** Inflammatory bowel disease (IBD) is a chronic inflammation that affect gastrointestinal tract, especially small and large bowel. The pathogenesis seems to be related to environmental factors and genetic susceptibility that put together lead to the failure of functions in several immune system process like: loss of tolerance in Treg cells, detriment of

apoptosis in Th1/Th17 cells and exacerbate of proinflammatory cytokines production of TNF- $\alpha$ , IFN- $\gamma$  and IL-17. B cells are gaining interest in this inflammatory process considering that their depletion is not favourable for the disease course. Anti TNF- $\alpha$  treatment usually re-establish a fair B cell level and the monitoring of the transitional B gather the condition of a good market to follow the disease development.

**Aims & Methods:** The aim of this study is to reveal the existence of a specific immune system cell pattern; to discover T cell ability of cytokines production and transcription factor activation; among IBD patients in remission under infliximab (IFX) therapy.

A pilot case-control study was performed. Inclusion criteria were IBD patients in clinical remission under maintenance IFX treatment. After informed consent, blood samples were obtained in IBD patients just before IFX infusions and in healthy controls. Participants were classified in different groups: Healthy control (HC), Crohn's disease (CD) and ulcerative colitis (UC). Remission was defined as a Partial Mayo < 2 in UC and a Harvey-Bradshaw < 4 in CD. Blood samples were used to determine the immune cell status of patients and negative controls. To investigate the immune system cell distribution, peripheral mononuclear blood cells were isolated from fresh blood in order to characterize: monocyte, dendritic cells (DC), Th1, Th17, Treg and B cell. Cells were then incubated with a specific fluorescent antibodies' cocktails, then identified with flow cytometry. T cells ability to produce TNF- $\alpha$ , IL-17 and INF- $\gamma$  was tested by performing intra cellular staining, while T-bet, Fox-P3 and Ror- $\gamma$  expression thought intra nuclear staining, data were collected with flow cytometry. Results are shown in percentages and analyzed with Prism 5.0, for parametric data.

**Results:** Thirty participants were consecutively included, 10 CD, 10 UC, mean age of 45, all in remission under IFX maintenance therapy and 10 HC. The surface staining demonstrated differences between the group's cell subtype. CD and UC patients showed a decrease of CD25<sup>+</sup> CD127<sup>+</sup> Treg subset, vs negative control, pointing out that UC patients decrease 2%, while CD only 1%. Decrease of transitional B cell subset CD38<sup>+</sup> CD24<sup>+</sup> CD19<sup>+</sup> was observed in CD and UC patients. The cytokine production in T cell, showed a significant increase of TNF- $\alpha$  (50-60% vs 20-30% HC), especially in IL-17 (5% vs 1-2% HC), while no significant different was observed in IFN- $\gamma$  production. Regarding the transcription factor expression T-bet and FoxP3 increased significantly in CD and UC vs HC, with a clear tendency of CD patients to express more FoxP3 than UC patients, while Ror- $\gamma$  was more specifically expressed in UC than CD.

**Conclusion:** The immune system cell subset is highly modified by the IBD disease type (CD, UC) despite being in remission under anti-TNF therapy, indeed the T cell ability to cytokine production demonstrate their deregulation towards the Th1 phenotype. Transcription factors expression showed as well this unbalance leading to Ror- $\gamma$  and FoxP3.

**Introduction:** Local extracellular acidification occurs at sites of inflammation and ischemia. Protons present in an acidic microenvironment may lead to activation of pH-sensing G protein-coupled receptor GPR68, also known as ovarian cancer G protein-coupled receptor 1 (OGR1). Recent studies suggest a link between IBD and this pH-sensing receptor. We previously reported that GPR68 is regulated by tumor necrosis factor (TNF) via a NF- $\kappa$ B dependent pathway.

Further, we demonstrated that GPR68 regulates barrier function and epithelial restoration, and that GPR68 expression is enhanced in intestinal inflammation in IBD patients. We have also shown that the genetic abla-

tion of GPR68 ameliorates colitis in different murine models. In the current study, we investigated the effects of a novel GPR68 antagonist in a murine colitis model.

**Aims & Methods:** Acute colitis was induced in wild type (C57BL/6) mice by the addition of 1.5% dextran sulfate sodium salt (DSS) in the drinking water for 7 consecutive days. The small molecule GPR68 inhibitor was administered by oral gavage in a vehicle solution (methylcellulose 0.5%), twice daily (interval of 12 h). Doses used were per kilogram bodyweight per day: 25 mg, 50 mg, 100 mg (n=10 mice per group). Water or DSS control groups were gavaged with vehicle solution without inhibitor (n=10 mice per group). On day 8, mice were sacrificed and inflammatory parameters were evaluated.

**Results:** An amelioration of murine DSS-induced colitis in the GPR68 -inhibitor treated group compared to DSS-treated control animals was observed. Endoscopy revealed that GPR68 -inhibitor treated mice showed a lower MEICS score, indicating reduced inflammation compared to DSS control animals.

Macroscopically, the colon tissue of the inhibitor treated mice showed no thickening, vascularity was similar to water control mice and no fibrin was detected. However, inhibitor treated mice showed an elevated score in stool consistency. Further colon shortening was significantly reduced in treated mice, indicating an attenuation of colon inflammation.

Microscopically, H&E staining revealed that inhibitor treated mice exhibited markedly less infiltration and epithelial damage compared to DSS control mice. Immunohistochemistry (IHC) staining for the cellular proliferation markers Ki67 showed slightly enhanced proliferation in inhibitor treated mice compared to DSS control mice.

Moreover, decreased infiltration of T-cells was observed in treated mice compared to the DSS control group. However, a difference in body weight or health score could not be demonstrated among the groups treated with the inhibitor compared to controls, and MPO activity and neutrophil infiltration did not differ between groups.

**Conclusion:** The inhibition of GPR68 has an ameliorating effect on the extent of DSS-induced colitis in wild type mice. Our data suggests that targeting proton-sensing GPR68 by a specific small molecule antagonist may be a novel therapeutic approach for the treatment of IBD.

**Introduction:** Transient receptor potential (TRP) channels have been identified as cellular sensors of exogenous and endogenous environments, agents and mediators. Previous studies have focused on the expressions of these TRP channel members in colonic tissue of patients with inflammatory bowel disease (IBD), whereas no data exists regarding the expressions of these channels in peripheral blood mononuclear cells (PBMCs). We examined, for the first time, the comprehensive expression profile of TRP channels belonging to the TRPV (vanilloid) and TRPM (melastatin) channel superfamilies in PBMCs from patients with IBD.

**Aims & Methods:** PBMCs were obtained from 44 patients with ulcerative colitis (UC), 35 patients with Crohn's disease (CD), and 45 normal subjects. The mRNA levels of TRP channels and pro- and anti-inflammatory cytokines, TNF- $\alpha$ , IL-1  $\beta$ , IL-6 and IL-10, in the PBMCs were measured using a quantitative real-time-polymerase chain reaction, and the disease activities were compared according to laboratory parameters.

**Results:** Overall, the mRNAs of each of the TRP channel members were expressed at different levels in the PBMCs from patients with IBD. Compared with the levels in the PBMCs from normal controls, the expression of TRPV2 mRNA was significantly lower and that of TRPM2 mRNA was higher in PBMCs from both patients with UC and those with CD.

The expressions of TRPV3 and TRPM5 mRNAs were lower and that of TRPV4 mRNA was higher only in PBMCs from patients with CD. Comparing

the two diseases, the expressions of TRPV1 and TRPV3 mRNAs were lower and that of TRPV4 mRNA was higher in the PBMCs from patients with CD than in those from patients with UC. The expression of TRPV2 mRNA was negatively correlated with disease activity in the UC and CD groups, while the expression of TRPM4 mRNA was negatively correlated with disease activity only in the UC group.

Significant correlations between the expressions of individual TRP channel members were observed in both the UC and CD group. The expression of IL-6 mRNA, TNF-alpha and IL-1 beta mRNA, was correlated with that of TRPV1 and TRPV3 mRNA in UC and TRPM5 mRNA in both UC and CD. The expression of IL-10 mRNA was negatively correlated with that of TRPV2 and TRPM2 mRNA in UC.

**Conclusion:** The present results indicate, for the first time, that PBMCs from patients with IBD exhibit varying mRNA expression levels of TRP channel members, which may play an important role in the progression of IBD. In addition, the expression levels of these TRP channel members in PBMCs are promising markers for IBD. Further studies are needed to determine the clinical and pathogenic role of TRP channels in IBD.

### P1018 SYSTEMIC IRON DEFICIENCY IS ASSOCIATED WITH ACTIVATION OF THE HIF-1 $\alpha$ PATHWAY IN THE INTESTINAL MUCOSA OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Fagundes Rosa R.<sup>1</sup>, Bourgonje A.R.<sup>1</sup>, Barbieri R.<sup>1</sup>, Jansen B.H.<sup>1</sup>, Taylor C.T.<sup>2</sup>, Faber K.N.<sup>1</sup>, Dijkstra G.<sup>1</sup>

**Contact E-Mail Address:** r.fagundes.rosa@umcg.nl

**Introduction:** Many patients with Inflammatory Bowel Disease (IBD) exhibit extra-intestinal disease symptoms and anemia is the most common hematological manifestation affecting up to two thirds of the patients. IBD-associated anemia is considered to be the result of a combination of iron deficiency anemia (IDA) and anemia of chronic disease (ACD). In case of IDA, patients often require intravenous iron supplementation, as this is known to increase patients' disease outcome and quality of life.

However, in clinical practice, it is difficult to determine the responsiveness of patients to iron treatment. Iron homeostasis is intimately associated with oxygen metabolism in the intestinal mucosa, which is regulated by the hypoxia-inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ) pathway. Here, iron (Fe<sup>2+</sup>) is a critical cofactor to the hydroxylase reaction that targets the HIF-1 $\alpha$  protein to degradation in the presence of oxygen.

Therefore, an interplay between Fe<sup>2+</sup> levels and the HIF-1 $\alpha$  pathway regulates oxygen sensing in human epithelial cells and may be a crucial mechanism underlying IDA in IBD patients. In this study, we aimed to determine the association between serum iron status and activation of the HIF-1 $\alpha$  pathway in mucosal biopsies of IBD patients.

**Aims & Methods:** Biopsies were collected from both ileum and colon and evaluated for their inflammatory status. In addition, serum laboratory parameters of iron metabolism close to biopsy dates (hemoglobin, MCV, free iron, ferritin, TYBC, transferrin, transferrin saturation) were documented. Based on serum iron status and inflammation, patients were categorized into either a group having 'normal' iron status ( $n=81$ ) or a group having systemic IDA ( $n=29$ ). RNA sequencing data ( $n=167$  entries) from intestinal biopsies of 110 IBD patients were retrospectively analyzed for 18 HIF-1 $\alpha$  pathway genes, including *HIF1A*, *HIF2A*, HIF-hydroxylases (*EGLN1*, *EGLN2*) and HIF-1 $\alpha$  target genes (*EGLN3*, *CA9*, *PDK1*, *SLC2A1*, *MUC3*, *TFF3*, *A2BAR*, *SLC29A1*, *ADK*, *HAMP*, *SLC11A2*, *HMOX1*, *TFRC* and *TF*), some of which are involved in iron metabolism, and analyzed for differential expression with iron status.

**Results:** The HIF-1 $\alpha$  pathway was activated in inflamed ileal and colonic tissue compared to adjacent non-inflamed tissue. Moreover, IBD patients with systemic IDA showed increased expression of HIF-1/2 $\alpha$  target genes in inflamed tissue, with significantly elevated mucosal levels of ileal *SLC11A2* ( $P<0.05$ ) and *PDK1* ( $P<0.05$ ) and colonic *TFRC* ( $P<0.05$ ) levels. mRNA levels of *HIF1A*, *HIF2A* and the HIF-hydroxylases *EGLN1* and *EGLN2* were not different between patients with or without IDA.

**Conclusion:** IBD patients with systemic iron deficiency show differential expression of HIF-1 $\alpha$  target genes *SLC11A2*, *PDK1*, *SLC2A1* and *TFRC* as compared to patients with a normal iron status. These preliminary data suggest an association of systemic iron status in IBD and activation of the HIF-

1 $\alpha$  pathway in the intestinal mucosa. These data reveal a possible disease mechanism involved in IBD-associated anemia that can be modulated by treatment.

**Contact E-Mail Address:** mimarkelova@gmail.com

**Introduction:** Butyrate is an essential metabolite in the human gut, as it is the preferred source of energy for colon epitheliocytes and is known for its anti-inflammatory properties. The main source of butyrate is bacterial fermentation of fiber. It is known that the microbiota of Crohn's disease (CD) patients is characterized by reduced abundance of butyrate-producing bacteria. The four major pathways involved in butyrate synthesis are acetyl-CoA, lysine, 4-aminobutyrate, and glutarate pathways.

**Aims & Methods:** The aim of the study was to reveal the differentially abundant genes encoding enzymes involved in butyrate synthesis pathways in the gut microbiota of CD patients compared to the control group. The study included 40 CD patients and 42 healthy controls. Total DNA was extracted from stool samples and sequenced using the NextSeq 500 platform (Illumina). Reads were mapped to the ChocoPhlAn database using the HUMAnN2 algorithm to assess the representation of microbial metabolic pathways. Relative abundances of genes were calculated as "cpm" - a number of reads mapped to a gene divided by the total number of mapped reads;  $p<0.05$  was considered as statistically significant. Butyrate levels were measured in stool samples by gas-liquid chromatography.

**Results:** Butyrate levels were significantly decreased in the stool samples of CD patients ( $1.14\pm1.1$   $\mu$ g/g) compared to the control group ( $1.82\pm1.55$   $\mu$ g/g). All of the pathways mentioned above include conversion of crotonyl-CoA to butyryl-CoA catalyzed by butyryl-CoA dehydrogenase (Bcd). Abundance of the Bcd gene was not significantly different between the CD and control groups. The final stage of butyrate synthesis is transformation of butyryl-CoA catalyzed by butyryl-CoA:acetate CoA-transferase (But), or alternatively by butyrate kinase (Buk); this stage is catalyzed by butyryl-CoA:acetoacetate CoA-transferase (Ato) in the lysine pathway. Abundance of the But gene also did not differ between the groups. However, abundances of phosphotransbutyrylase (Ptb) and Buk genes coding enzymes that catalyze butyryl-CoA transformation to butyrate through butyryl-phosphate were reduced in CD patients ( $1.9\pm3.2$  cpm and  $45.9\pm30.5$  cpm) compared to controls ( $2.4\pm1.9$  cpm and  $63.3\pm21.1$  cpm, respectively). Most butyrate-producing bacteria have only one type of enzyme - But or Ptb+Buk - for the last stage of butyrate synthesis. Thus, the microbiota of CD patients is supposed to be depleted in bacteria carrying Ptb+Buk genes. The acetyl-CoA pathway is present in the majority of butyrate producers. Relative abundance of this pathway was decreased in CD patients due to a reduced number of the hydroxybutyryl-CoA dehydrogenase gene ( $19.1\pm15.2$  cpm) and the 3-hydroxybutyryl-CoA dehydratase gene ( $20.1\pm15.6$  cpm) compared to the control group, where these genes were detected by  $26.9\pm10.1$  cpm and  $27.6\pm11.1$  cpm, respectively. Stool samples from CD patients were characterized by a reduced abundance of 4-aminobutyrate pathway, in particular, by depletion of 4-hydroxybutyrate dehydrogenase gene ( $0.1\pm0.2$  cpm) compared to controls ( $0.3\pm0.2$  cpm). Ato as a part of the lysine pathway was decreased in CD patients ( $2.2\pm1.8$  cpm) in comparison to the control group ( $2.3\pm4.2$  cpm). The glutarate pathway was not significantly different between the cohorts.

**Conclusion:** Stool samples of CD patients were characterized by reduced levels of butyrate caused by a decreased number of genes coding enzymes involved in three out of four main butyrate synthesis pathways (acetyl-CoA, 4-aminobutyrate, and lysine).

**Disclosure:** The research described in this abstract was financially supported by Philip Morris International.

## P1020 INCREASED EXPRESSION OF EPITHELIAL-DERIVED GASDERMIN-B (GSDMB), A NOVEL MOLECULE THAT PROMOTES EPITHELIAL RESTITUTION AND REPAIR, IN PATIENTS WITH IBD

Rana N.<sup>1</sup>, Pizarro T.T.<sup>2</sup>

**Introduction:** The resolution of inflammation at mucosal surfaces is a basic physiological process that promotes restitution of the epithelial barrier and appropriate tissue repair, in an attempt to restore normal organ function and homeostatic conditions with the interfacing microenvironment. This process is critical for patients with IBD, wherein efficient resolution of inflammation and mucosal healing is one of the most important goals to attain in order to maintain long-term remission. Gasdermin-B (GSDMB), a novel molecule belonging to the Gasdermin family of proteins, has recently gained intense interest for its potential role in the pathogenesis and progression of chronic inflammatory disorders, particularly those that affect mucosal surfaces, including asthma and IBD. Importantly, GWAS have revealed SNPs within the gene encoding *GSDMB* as being reportedly associated to both an increased susceptibility of acquiring IBD and an increase in GSDMB expression.

**Aims & Methods:** The aim of the present study was to examine the expression pattern and functional relevance of GSDMB in the pathogenesis of IBD. Primary intestinal biopsy and isolated intestinal epithelial specimens, as well as formalin-fixed intestinal tissues, from both IBD patients and non-inflamed controls were evaluated for mRNA and protein levels by qRT-PCR and Western blots, respectively, and cellular localization was examined by IHC/confocal microscopy. Using the human colonic epithelial cell line, HT-29, CRISPR-cas9 knockout (KO) cells lacking GSDMB were generated, and used for *in vitro* XTT and cell migration functional assays. Finally, subcellular localization of GSDMB was investigated after *in vitro* stimulation with LPS and nigericin (NG) by fluorescent imaging and subcellular fractionation/Western blot analysis.

**Results:** We report for the first time a dramatic increase in epithelial-specific GSDMB expression in IBD patients (both UC and CD) compared to healthy controls. HT-29 epithelial cells stimulated with LPS and NG suggests regulation that is NLRP3-dependent, with a functional decrease in *in vitro* proliferative activity and wound repair in epithelial cells lacking GSDMB.

Additionally, we report unique subcellular localization of GSDMB primarily within the cytosolic compartment, with indication of migration towards a membrane/organelle compartment after stimulation with LPS and NG in human epithelial cells.

**Conclusion:** Taken together, our data suggests that increased epithelial-derived GSDMB during IBD is protective in function and promotes epithelial-specific proliferation. To our knowledge, this is the first report of GSDMB's functional role in IBD, and provides the rationale for the potential therapeutic use of GSDMB to obtain optimal gut mucosal wound healing towards promotion of resolution of inflammation.

## P1021 PRECLINICAL INVESTIGATIONS OF IMU-838, AN ORALLY AVAILABLE SMALL MOLECULE INHIBITOR OF DIHYDROOROTATE DEHYDROGENASE FOR THE TREATMENT OF INFLAMMATORY BOWEL DISEASE

Kohlhof H.<sup>1</sup>, Mühler A.<sup>2</sup>, Gröppel M.<sup>3</sup>, Vitt D.<sup>3</sup>

<sup>1</sup>Immunic AG, Management / PCD, Planegg-Martinsried, Germany, <sup>2</sup>Immunic AG, Clinical Development, Planegg-Martinsried, Germany, <sup>3</sup>Immunic AG, Development, Planegg-Martinsried, Germany

**Contact E-Mail Address:** hell.kohlhof@immunic.de

**Introduction:** IMU-838 is a small molecule inhibitor of DHODH (Dihydroorotate Dehydrogenase) and currently in clinical phase 2 testing for ulcerative colitis and multiple sclerosis. Inhibition of DHODH in highly activated immune cells, such as in T cells in inflammatory bowel disease, leads to induction of metabolic stress signals with immediate onset of inhibition of cytokine release of IL-17 and IFN $\gamma$  (IFN $\gamma$ ) and later on to induction of apoptosis in those cells driving inflammation in the bowel wall. We performed in-vitro and in-vivo experiments to further explore the impact

of IMU-838 on other aspects of the immune network important in inflammatory bowel disease with particular focus on regulatory macrophages and TNF $\alpha$  (TNF $\alpha$ ).

**Aims & Methods:** Efficacy of IMU-838 was tested in a 2.8% DSS induced C57BL/6 colitis mouse model in a therapeutic setting with four days of colitis induction prior to treatment start with IMU-838. The impact of IMU-838 on cytokine regulation was tested in PHA stimulated human peripheral blood mononuclear cells (PBMCs) and in a mixed lymphocyte reaction (MLR). Cytokine regulation was tested via gene expression analysis and protein secretion via ELISA technique. In the MLR assay, the impact of IMU-838 on regulatory macrophages and the synergistic effects with anti-TNF $\alpha$  Infliximab treatment were tested via FACS analysis. Therefore, isolated PBMCs from two healthy donors were pre-incubated for 48h and then incubated for another four days with IMU-838 in four different concentrations (30, 10, 3, 1 $\mu$ M) with and without anti-TNF $\alpha$  antibody Infliximab (10 $\mu$ g/ml).

**Results:** In a DSS induced colitis model, IMU-838 was administered in monotherapy with an oral low dose of 20mg/kg in a therapeutic setting. IMU-838 demonstrated improvement of the diarrhea score, the histology score and TNF $\alpha$  secretion as markers for improvement of the disease. Even though IMU-838 had no impact on TNF $\alpha$  secretion in PHA stimulated human PBMCs, a significant reduction of TNF $\alpha$  secretion in a mixed lymphocyte reaction assay (MLR) was found. Administration of IMU-838 to the MLR assay slightly enhanced the percentage of regulatory macrophages (which are known to be important for improvement in IBD under anti-TNF therapy). In MLR experiments combining IMU-838 and anti-TNF Infliximab a strong increase in regulatory macrophages and decrease in TNF $\alpha$  secretion was shown, thereby confirming a substantial synergism of the effects for the combining the two molecules.

**Conclusion:** Preclinical experiments support that IMU-838 and its mechanism of DHODH inhibition testing of IMU-838 in clinical trials for IBD patients. Beside the already known inhibition of IL-17 and IFN $\gamma$  cytokine secretion as well as apoptosis induction of highly activated T cells, these recent investigations of IMU838 also indicate a beneficial impact on regulatory macrophages and inhibition of. In addition, combining IMU-838 with an anti-TNF $\alpha$  antibody has shown a strong synergism of effects on regulatory macrophages and TNF $\alpha$  secretion, which seems to indicate that a combination trial in IBD patients suffering from insufficient or reduced efficacy of anti-TNF $\alpha$  antibodies such as infliximab should be considered.

**Introduction:** The dysregulation of immune system mediated by T lymphocyte seems to be the most important factor for progression of Crohn's Disease (CD) (Marsal & Agace, 2012). CD8<sup>+</sup> T cells (TCD8<sup>+</sup>) are a subset of cytotoxic lymphocytes that can differentiate into both central (T<sub>cm</sub>) and effector (T<sub>em</sub>) memory cells. Two animal models suggested that the destruction of intestinal epithelial cells by TCD8<sup>+</sup> is the event that lead to the disease activity proposing a role for this cells in CD pathogenesis (Westendorf et al., 2006; Nancey et al., 2006). In patients with CD that experienced relapsing or chronically active disease, an increase in T cell activation genes and a difference in TCD8<sup>+</sup> activation status was demonstrated prior to commencing treatment (Lee et al., 2011) but there is no data about the effects of Anti-TNF $\alpha$  therapy in TCD8<sup>+</sup> subpopulations.

We hypothesized that Anti-TNF $\alpha$  therapy decreased the activation levels and modulate the memory phenotype of TCD8<sup>+</sup> to better control the inflammatory process.

**Aims & Methods:** We aimed to characterize the subpopulations of TCD8<sup>+</sup> in blood and in tissue of patients with CD. The blood was collected and cells were acquired by multiparametric flow cytometry. The analysis was performed by Flowjo software. For co-expression analysis, Pestle and Spice was used. We also collected five tissue samples from patients who underwent surgery and TCD8<sup>+</sup> was quantify using confocal microscopy. Statistical analysis was performed using Prism5 [GraphPad software] and Mann-Whitney tests.

**Results:** We enrolled 44 CD patients, which 27 patients were under Anti-TNF $\alpha$  therapy and 17 patients was under conventional therapy. Among the patients, there was no difference between age, gender and several laboratories parameters (like Calprotectin and CRP) that was used to better define this cohort.

We first observed that patients receiving Anti-TNF $\alpha$  therapy had an increase in the percentage of circulating TCD8 $^{+}$  when compared to patients that are under conventional therapy ( $p = 0.0429$ ). When we analyzed the tissue lesion and healthy area from surgery material, TCD8 $^{+}$  shows no statistical difference between the two regions.

When we analyzed the expression of CD38, HLA-DR, CD73 and CD39 in TCD8 $^{+}$  in peripheral blood, we observed lower expression of CD38 ( $p = 0.0033$ ), HLA-DR ( $p = 0.0002$ ) and CD73 ( $p = 0.0021$ ) in patients with Anti-TNF $\alpha$  therapy when compared to patients receiving conventional therapy, but no statically differences was observed in the expression of CD39 between the groups.

Next, we analyzed the expression of memory subsets. Anti-TNF $\alpha$  therapy decrease the pool of T $_{cm}$  cells ( $p = 0.0007$ ) and T $_{cm}$  with coexpression of CD38 ( $p < 0.0001$ ) and HLA-DR ( $p = 0.0457$ ). On the other hand, T $_{em}$  cells ( $p = 0.0004$ ) and T $_{emra}$  cells ( $p < 0.0001$ ) shows an increase in patients under Anti-TNF $\alpha$  therapy when compared to conventional therapy. The multivariate analysis of the markers CCR7, CD45RA, CD38 and HLA-DR demonstrated that the majority of TCD8 $^{+}$  in patients receiving Anti-TNF $\alpha$  therapy lacked the expression of all markers ( $p = 0, 0002$ ). Already in patients that are under conventional therapy, we observed the co-expression of CD38, HLA-DR and CCR7 in the same population ( $p = 0, 0002$ ). In the functional analysis CD8 T cells do not demonstrated any difference in cytokine production between groups.

**Conclusion:** We conclude that Anti-TNF $\alpha$  therapy induces a profile of TCD8 $^{+}$  effector memory cells and reduces the activation levels of this cells in patients of Crohn's Disease, demonstrated the capacity for induce better immune response.

## P1023 VITAMIN D DEFICIENCY IN CROHN'S DISEASE: A SINGLE-CENTER PROSPECTIVE STUDY

Ayadi S., Ayari M., Belhadjmabrouk E., Zaimi Y., Said Y., Mouelhi L., Debbeche R.

Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia

**Contact E-Mail Address:** ayari.myriam@hotmail.fr

**Introduction:** Crohn's disease (CD) is a chronic inflammatory bowel disease (IBD), involving dysbiosis of intestinal microbiota, a dysfunction of the intestinal barrier and a dysregulation of innate and adaptive immunity on a genetically predisposed ground. In recent years, the immunomodulating effects of vitamin D have gained a huge interest in its possible pathogenic influence on the pathophysiology of IBD. However, it remains unclear if this association is a result of inflammatory process, or a cause. Therefore Interest in links between vitamin D deficiency and CD has grown substantially.

**Aims & Methods:** The aim of the study was to assess the vitamin D status in patients with CD and in healthy controls and to determine related factors associated with vitamin D deficiency in patients with CD. We conducted a prospective study over 18 months, including patients followed for a CD and age-, sex-, and socio-economic status-matched healthy controls. Serum 25-hydroxyvitamin D (25 (OH) D) concentration was measured with radio-immunoassay. Vitamin D deficiency was defined by levels  $< 30$  ng/ml and subdivided into: vitamin insufficiency:  $10$  ng/ml  $< 25$  (OH) D  $< 30$  ng/ml and vitamin deficiency:  $25$  (OH) D  $< 10$  ng/ml.

Crohn's disease activity was evaluated by a combination of clinical, biochemical, and endoscopic assessment. Crohn's disease activity index (CDAI) was calculated for each patient.

**Results:** We included 77 subjects (52 patients with MC and 25 controls). The mean age was of 38 years  $\pm 11$  [20 - 64]. The average level of 25 (OH) D was comparable in both groups ( $8.83 \pm 8.89$  ng/ml in patients and  $10.06 \pm 7.42$  ng/ml in controls;  $p = 0.554$ ), also in patients with active disease and remission ( $7.47$  ng/ml  $\pm 10.72$  and  $10.2$  ng/ml  $\pm 6.52$  respectively;  $p = 0.273$ ). Most patients and controls had suboptimal levels of vitamin D (98% and 96% respectively) including (75% and 67% respectively) with vitamin D deficiency, (25% and 33% respectively) with vitamin D insufficiency. Deficiency rates were higher in patients than controls but this difference was not statistically significant. In univariate analysis, lower serum 25(OH) D was associated with anemia ( $p = 0.002$ ), hypo-albuminemia ( $p = 0.002$ ), elevated C-reactive protein (CRP) ( $p = 0.003$ ), CDAI ( $p < 0.001$ ), ileal location ( $p = 0.04$ ) and immunosuppressive therapy ( $p = 0.01$ ). In multivariate analysis, only CDAI was significantly associated ( $p = 0.003$ ) with vitamin D deficiency (OR=9.33).

**Conclusion:** Vitamin D deficiency is common during CD and was associated with disease activity and higher CDAI. Vitamin D status should be used as a biomarker in assessing disease activity among CD patients in addition to CDAI and CRP. Supplementation could be proposed as a therapeutic to improve outcomes of the disease.

## P1024 INNATE IMMUNITY PROFILE FROM THE "NORMAL" MUCOSA OF ULCERATIVE COLITIS PATIENTS

Ramos L.<sup>1</sup>, Carrillo M.<sup>1</sup>, Alonso I.<sup>1</sup>, Hernandez-Alvarez N.<sup>1</sup>, Hernandez G.<sup>1</sup>, Hernandez Camba A.<sup>1</sup>, Martinez Blanco L.<sup>2</sup>, Gonzalez Paredes F.J.<sup>1</sup>, Quintero E.<sup>1</sup>

<sup>1</sup>Hospital Universitario de Canarias, Gastroenterology, San Cristóbal de La Laguna, Spain, <sup>2</sup>Hospital Universitario de Canarias, Pathology, San Cristóbal de La Laguna, Spain

**Contact E-Mail Address:** laura7ramos@gmail.com

**Introduction:** Innate immunity modulates the integrity of the epithelial barrier, microbial detection and autophagy which occurs during the inflammatory process presented in ulcerative colitis (UC). UC is associated with polymorphisms in the TLR2 (R753Q) and TLR4 (Asp299Gly) genes, increasing expression of TLR4 and TLR2 in the mucosa and enhances the release of proinflammatory cytokines and the activation of NF $\kappa$ B. However, the role of innate immunity associated with macroscopically normal mucosa in UC is not well known.

**Aims & Methods:** Objective: To establish the profile of gene expression related to the innate immunity of normal macroscopic (non-inflamed) mucosa in patients with UC.

Methods: Consecutive patients of UC who underwent a colonoscopy by clinical practice in a tertiary hospital were included. The total (TMS) and partial (PMS) scores were recorded according to the Mayo index at the time of the colonoscopy. The histological activity based on the Geboes scoring system was previously determined to the PCR study to stratify the samples according to the degree of colitis (inactive colitis Geboes  $< 3$ ). Colon biopsies of the inflamed (iUC) and non-inflamed (safe) (sUC) mucosa were obtained in patients with active UC, stratified as mild colitis (LsUC, TMS 1-4 / Geboes  $< 3$ ) and moderate / severe colitis (MsUC, TMS 5- 12 / Geboes  $< 3$ );  $n = 47$ ). Likewise, patients with quiescent UC (QUC, defined as TMS = 0 / pMS = 0 / Geboes,  $n = 46$ ) and a control group (non-IBD) (C;  $n = 13$ ) were included. Gene expression of innate immunity was quantified using Taqman Human Immune Assay-microfluidic cards in colonic mucosa, considering the degree of UC and the location of the samples.

**Results:** Biopsies from mucosa with quiescent colitis (qUC), as well as those from mucosa do not affect by inflammation, both in patients with mild colitis (LsUC) and moderate / severe colitis (MsUC), demonstrated an expression of genes related to innate immunity different from the control group without UC. 36, 55 and 3 genes were overexpressed and 7, 14 and 7 underexpressed genes were under-expressed in QUC, LsUC and MsUC, respectively, compared to non-IBD controls ( $p < 0.05$ ) (Table 1).

**Conclusion:** The normal mucosa, by endoscopic and histologic criteria, in patients with UC presents a differential pattern of innate immunity from that observed in non-IBD subjects, suggesting the existence of a pan-colonic inflammatory predisposition that can condition the clinical evolution of the disease.

**Introduction:** Mineralocorticoid receptor (MR) is involved in inflammation and fibrosis process from extra-intestinal organs and may thus constitutes a therapeutic target in inflammatory bowel diseases (IBD). MR is highly expressed in the colon and all components of renin-angiotensin system (RAS) are expressed within the gastrointestinal tract. RAS components are increased in IBD and Ramipril, a RAS antagonist decreased matrix metalloprotease (MMP) activities in tissues from Crohn's disease fistula. Lipocalin-2 is a MR-modulated in the pro-inflammatory and pro-fibrotic processes induced by mineralocorticoids. We aimed to investigate whether MR participates to IBD-induced inflammation and fibrosis.

### Aims & Methods:

**In vitro** study: Human colon fibroblasts CCD-18Co were incubated with 10 ng/mL of TGF-β for 24 hours to obtain an *in vitro* model of intestinal fibrosis. Cells were also induced with primary ligand of the MR (aldosterone at 10<sup>-8</sup> mol/L) or MR antagonist (spironolactone at 10<sup>-6</sup> mol/L) or Lipocalin-2 (5 to 50ng/mL) for 24 hours (n=4 independent experiments). Fibrosis markers such as α-SMA, CTGF, COL1A1, COL3A1 and MMP-9 expression were analyzed by Western Blot and RT-qPCR.

**In vivo** study: To induce colitis, mice received 2% dextran sulfate sodium (DSS) in drinking water *ad libitum* for 7 days followed by 3 days of normal water. Pharmacological MR (spironolactone, 30mg/kg, n=10) or RAS antagonists (Ramipril, 10mg/kg, n=10) were investigated in DSS colitis (DSS, n=10). Cell specific deletion of MR in smooth muscle (SM) were studied in DSS-induced SM22-MR deleted mice (n=5) and their littermate (n=3). Body weight was daily recorded. Gene expression of IL-6, MCP-1 and TNFα were evaluated by RT-qPCR. Fecal calprotectin and colon myeloperoxidase activity (MPO) were recorded.

**Results:** *In vitro*, TGF-β significantly increased α-SMA, CTGF, COL1A1 and COL3A1 mRNA levels in CCD-18 Co (p<0.01). Spironolactone inhibited α-SMA (p<0.01) while aldosterone significantly increased it in TGFβ-induced intestinal myofibroblasts (p<0.01).

*In vivo*, DSS-induced colitis led to a significative body weight loss (p<0.001) and increased inflammatory markers such as a decreased colon length (p<0.01), a higher colon MPO activity (p<0.01) and a higher fecal calprotectin (p<0.01). Ramipril significantly decreased body weight loss vs DSS or spironolactone groups (p<0.05).

Ramipril increased colon length (p<0.05) while it decreased colon MPO activity (p<0.01) and fecal calprotectin (p<0.01). Ramipril significantly decreased IL-6, TNFα, MCP-1 mRNA levels compared to DSS or DSS+spironolactone treated mice (p<0.01). SM22 specific MR deletion protected mice from DSS colitis compared to littermate mice. SM22 MR deleted mice had a lower colonic IL-6 mRNA levels (P<0.05) and a lower colon MPO activity (P=0.056).

**Conclusion:** MR antagonism decreased fibrosis markers *in vitro*. Smooth cell specific MR deletion prevented colitis. Ramipril treatment inhibited DSS-induced colitis. MR and RAS may represent novel therapeutic targets in intestinal fibrosis.

**Introduction:** Collagenous colitis (CC) and lymphocytic colitis (LC), the two main subtypes of Microscopic Colitis (MC), are chronic inflammatory diseases of the colon, characterized by watery diarrhoea, normal (or near normal) endoscopy with characteristic histopathological features, which define its diagnosis. CC is mainly characterized by the presence of a subepithelial collagen band (>10 micrometers) and LC mainly by the presence of ≥20 intraepithelial lymphocytes per 100 epithelial cells. The inflammatory infiltrate in the lamina propria has been described as increased numbers of mononuclear cells in both entities. In few studies, eosinophil infiltration has been described only in CC. However, whether eosinophils characterize one or both entities and its role in the pathophysiology of MC remains unknown.

**Aims & Methods:** Our aim is to quantify mucosal eosinophilic infiltration and describe its activation in CC and LC. Colonic mucosal biopsies (sigma region) were obtained from newly diagnosed patients with active CC (n=8) and LC (n=15), and from healthy volunteers (HV; n=8), as the control group. Lamina propria and intraepithelial eosinophils were counted per high-powered field (hpf) after eosinophil-specific major basic protein (MBP) immunohistochemical (IHC) staining. The ultrastructure of eosinophils was assessed by transmission electron microscopy.

**Results:** In HV samples, scattered mucosal eosinophils were found across the colonic tissue and identified by weak MBP signal, while in MC, eosinophils were identified in patchy areas and displayed a large cytoplasm and high MBP signal intensity. The number of eosinophils in the lamina propria was significantly higher in patients (CC: 20.1±5.50; LC: 19.9±3.30 cells/hpf) as compared with controls (HV: 1.5±0.5 cells/hpf; P<0.05).

The number of intraepithelial eosinophils was also higher in samples from MC patients (CC: 0.43 [0.0-1.88]; LC: 0.13 [0.0-4.78] cells/hpf) than from controls (HV: 0.0 [0.0-0.17]; P<0.05). Interestingly, IHC analysis revealed extracellular staining of MBP in lamina propria eosinophils from MC patients (CC: 7.7±2.1; LC: 7.6±1.3 eosinophils/hpf) while few eosinophils displayed signs of protein release in control tissues (HV: 0.6±0.2 eosinophils/hpf; P<0.05). The analysis of mucosal ultrastructure confirmed eosinophilic activation only in samples from patients. While the control group showed intact eosinophils, CC and LC samples displayed both piecemeal degranulation and eosinophil cytolysis with associated clusters of free eosinophilic granules in the lamina propria.

**Conclusion:** Despite the histological characteristics that differentiate CC and LC, mucosal eosinophilic increase and activation are observed in both, CC and LC. Further studies are needed to identify whether eosinophils play

a specific role in the pathophysiology of MC subtypes or if its contribution to mucosal inflammation is secondary to the aetiology of these diseases.

**Contact E-Mail Address:** berta.julia@merck.com

**Introduction:** Measuring patient's perceived quality of care (QoC) in Inflammatory Bowel Disease (IBD) units is becoming increasingly important. The aim of the current analysis from the IQCARO project was to assess the factors associated with the QoC in IBD units from Spain, by measuring the completion of a validated predefined decalogue of QoC indicators<sup>1</sup>.

**Aims & Methods:** A survey including a Decalogue of QoC indicators, previously developed by patients, IBD gastroenterologist and IBD nurses, was distributed through the webpage of the Confederation of Spanish Associations of Patients with Crohn's disease and Ulcerative Colitis (ACCU). The survey also included patient's sociodemographic and clinical characteristics. Patients could answer yes/no to every item of the decalogue, scoring 1/0 respectively. The final QoC index was obtained by calculating the mean of the total score of each indicator (higher score represents better QoC). Qualitative variables were presented as absolute frequencies and percentages and quantitative variables as mean and standard deviation or median and interquartile range depending on the distribution of the data. In the multivariate analysis the QoC index was dichotomized (high quality/low quality) with a cut-off point of 9.5 to be used as a dependent variable in a binary logistic regression model in order to determine the factors that can influence the evaluation of QoC as high.

**Results:** Online-completed surveys from 605 patients were considered valid for the analysis. 451 patients (74.5%) were attended by IBD specialists, 138 (22.8%) by general gastroenterologists (GG) and 16 (2.7%) by other professionals. The population included patients from the 17 Spanish autonomous communities, and 183 sites. The mean age of the patients was 42.3 years, with a mean disease duration of 13 years. 66% were women and 60.7% had Crohn's disease. The mean QoC index was 7.8/10 being significantly higher (meaning better QoC) in patients attended by IBD specialists vs GG: 8.2 vs 6.7 respectively,  $p < 0.001$ . We found no significant differences in disease activity, number of flares, hospitalizations, emergency room visits in the last year or patients' perception of controlled disease in the last two weeks, when comparing patients attended by IBD specialist or GG. When we analyzed the QoC index score as a dichotomized variable, we found that older patients, longer disease duration, routine follow-up by an IBD specialist, and a better perception of a controlled disease were all associated with high QoC while, active disease, unscheduled visits in the last year, higher number of flares, and unemployment were correlated with low QoC. The multivariate analysis showed that employment, controlled disease, low number of unscheduled visits and being attended by an IBD specialist were all associated with a high QoC. Table 1.

	coef	OR	IC95	p
IBD specialist	1.11	3.05	(1.88;4.95)	<0.001
Employed	1.09	2.97	(1.51;5.85)	0.002
Controlled disease	1.08	2.69	(1.90;4.63)	<0.001
Number of unscheduled visits	-0.20	0.81	(0.72;0.93)	0.003
ed visits Constant	-2.89			<0.001

[Binary logistic regression analysis]

**Conclusion:** The perception of the QoC received by IBD patients in Spain is good particularly when they are followed-up by IBD specialists rather than GGs. Personal and disease related aspects may influence the perception of the QoC received.

**Introduction:** Ulcerative Colitis (UC) is a chronic inflammatory disorder affecting the mucosal surface of the rectum and colon characterised by periods of relapse and remission. The increasing incidence and prevalence of UC, morbidity associated with its chronic, relapsing and remitting nature and the increasing earlier use of biological therapies, has important implications to the health economy. The lack of current data on direct and indirect medical cost of treatment and societal cost justified the urgent need to conduct a study to quantify the current economic landscape related to UC. The living with Ulcerative Colitis, identifying the socioeconomic burden in Europe (LUCID) study was a descriptive, retrospective, cross-sectional, European (France, Germany, Italy, Spain, United Kingdom, Denmark, Norway, Poland, Romania and Turkey), multi-site, bottom-up, prevalence-based Burden of Illness research study carried out by HCD Economics and the University of Chester in partnership with Crohn's and Colitis UK.

**Aims & Methods:** The primary objective of the LUCID study was to quantify the existing UC-related costs for each country and by disease severity. The study population was recruited through gastroenterologists (surveyed between Aug 2018- February 2019) and included adult patients diagnosed with UC by endoscopy and histology, at least 24 months prior the index date (date of clinical consultation). The study cohort population consisted of two arms; Arm 1: Patients with moderate or severe UC status at initiation of documentation period (12 months prior the index date) and, Arm 2: Patients with moderate or severe UC that achieved mild UC or remission at initiation of documentation period. Physician completed questionnaires (CRF) captured clinical information, direct medical costs and some direct non-medical costs. Each patient was invited to complete a corresponding public patient involvement and engagement (PPIE) form which captured further direct non-medical costs and indirect costs. Due to the descriptive nature of this study a formal calculation of sample size and statistical power was not applicable. Per-patient costs were calculated by multiplying the quantities of the resource use collected with the national unit price and then extrapolated to population level to calculate the total societal economic burden. Total costs were only calculated for patients with completed PPIE forms due to the need to add non-direct medical and indirect costs to the direct medical costs.

**Results:** Completed physician-reported forms (CRF) and PPIE forms were assessed for 1,658 patients. Of these, 1001 (60.7%) and 648 (29.3%) patients were in arm 1 and arm 2 respectively, with 9 patients unable to be assigned to either arm. Total average EU cost per patient in the last 12 months was €8,833.94 in arm 1 and €6,512.74 in patients in arm 2 with direct medical costs per patient amounting to €4381.70 in arm 1 and €3078.48 in arm 2.

Direct non-medical costs per patient were €1353.93 for arm 1 and €1128.37 for arm 2. Societal costs per patient amounted to €3098.31 of the total cost for arm 1 and €2305.89 for arm 2.

**Conclusion:** These preliminary results suggest that non-medical costs and indirect costs make up substantial proportions of the overall cost implying that the cost of treatment constitutes only a part of the overall burden of UC. Further analysis is planned to identify the drivers of costs in each arm in order to make comparisons between them.

**Disclosure:** The LUCID study was funded internationally by Pfizer and Eli Lilly and in the UK by Celgene. The study was governed by an expert reference group consisting of the authors.

## P1029 INCIDENCE OF COLLAGENOUS COLITIS AND LYMPHOCYTIC COLITIS IN TERRASSA, SPAIN, 2015-2018: A CONTINUOUS EPIDEMIOLOGIC STUDY

**Contact E-Mail Address:** ffbanares@mutuaterrassa.es

**Introduction:** The incidence of microscopic colitis (MC) has increased in several geographical areas but long-term epidemiologic data are scarce.

**Aims & Methods:** We report an incidence study of collagenous colitis (CC) and lymphocytic colitis (LC) during 2015-2018, as a follow-up of our previous studies 1993-2008.

Population-based study of residents of the catchment area of the hospital, with a new diagnosis of MC between 2015 and 2018. All patients with non-bloody watery chronic diarrhea referred for a diagnostic colonoscopy were included. Multiple biopsy specimen samples were obtained when the macroscopic appearance of the colonic mucosa was normal to rule out MC. Diagnosis of both CC and LC was based on accepted standard criteria. Patients were identified by diagnosis register of the Department of Pathology. Age- and gender-specific crude incidence rates based on the year of diagnosis were calculated. An exact rate ratio test was used to compare the incidence rates for the two time periods.

**Results:** Collagenous colitis was diagnosed in 20 patients (16 females) and LC in 27 patients (22 females). The mean annual incidence (per 100,000 inhabitants) was MC 9 (95% confidence interval: 6.6-12), CC 3.85 (2.2-5.5), and LC 5.2 (3.2-7.2). Age-specific incidence showed a peak in females older than 60 years. Female:male ratio was 14:1 in subjects < 60 years, and 3:1 in those ≥60 years. A comparison of current study period with 1993-2008 showed unchanged mean incidence of CC, but a significant increase in women with LC (Rate ratio=2.7; 95% CI, 1.5-5; p=0.001).

**Conclusion:** After a rise during early 2000s, annual incidence of CC has been stable during the last 10 years around 4/100,000 inhabitants. However, the incidence of LC, which was stable in the period 1993-2008, has significantly increased in women during the last decade.

**Introduction:** Inflammatory bowel diseases (IBD) are chronic and debilitating conditions, that can contribute to the development of anxiety and depression symptoms.

**Aims & Methods:** We aimed to assess the prevalence of these symptoms in a population of IBD patients, using Hospital Anxiety and Depression Scale (HADS), and identify predictors of these symptoms.

Unicentric, transversal cohort study, including adult outpatients with IBD. Excluded patients with psychiatric disease, severe comorbidity or malig-

nancy and those who refused to participate in the study. Assessed several clinical and analytical parameters and determined the anxiety (HADS-A) and depression (HADS-D) sub scores, which were considered positive if ≥8 points.

**Results:** Included 99 patients, 65.7% with Crohn's Disease (CD). HADS-A≥8 in 64.6% and HADS-D≥8 in 96.0%.

HADS-A score ≥8 associated with female gender (64.1% vs 40.0%, p=0.021), presence of extraintestinal manifestations (EIMs) (91.3% vs 8.7%, p=0.002) and longer disease duration (8.2±6.7 years vs 5.2±4.1 years, p=0.017). When assessing only CD patients, HADS-A score ≥8 associated with higher consumption of benzodiazepines (29.3% vs 8.3%, p=0.048), EIMs (88.9% vs 11.1%, p=0.008) and longer disease duration (8.9±6.4 years vs 4.4±4.3 years, p=0.001).

HADS-D score ≥8 associated with intravenous biologic therapy (100.0% vs 0.0%, p=0.001), EIMs (86.9% vs 13.0%, p=0.038) and ferritin and C Reactive Protein levels (113±137 vs 44±34 ng/mL, p=0.007 and 5.6±5.6 vs 2.9±0.0mg/dL, p< 0.001). In patients with CD, HADS-D ≥8 associated intravenous biologic therapy (100.0% vs 0.0%, p=0.019), EIMs (88.9% vs 11.1%, p=0.019) and calprotectin levels (366±337 vs 93±16ug/g, p< 0.001). In patients with ulcerative colitis no predictors of HADS-A or HADS-D scores ≥8 were found.

**Conclusion:** In patients with IBD, anxiety symptoms are present in nearly 2/3 of patients and depression symptoms in over 90%. Anxiety symptoms are more frequent in women and patients with long standing disease, while depressive symptoms associate with disease inflammatory activity. Presence of EIMs associated with both types of symptoms.

**Disclosure:** Nothing to disclose

## P1031 LESS INPATIENT COMPLICATIONS AND ECONOMIC BURDEN IN FEMALE PATIENTS ADMITTED WITH ULCERATIVE COLITIS

Kroner P.T.<sup>1</sup>, Kesler A.M.<sup>2</sup>, Corral J.E.<sup>3</sup>, Cangemi J.R.<sup>3</sup>

<sup>1</sup>Mayo Clinic, Gastroenterology, Jacksonville, United States, <sup>2</sup>Mayo Clinic, Jacksonville, United States, <sup>3</sup>Mayo Clinic, Gastroenterology and Hepatology, Jacksonville, United States

**Contact E-Mail Address:** thomaskroner@gmail.com

**Introduction:** Gender in ulcerative colitis (UC) is a well-studied topic with contradicting results with a slight male predominance seen in large population based studies in Olmsted County, Minnesota, while other studies have shown a slight female predominance. Yet, the relationship between UC and gender is not well-understood. Hence, it is unclear what is responsible for differences in gender.

**Aims & Methods:** The aim of this study is to assess the inpatient prevalence and inpatients outcomes of UC by gender.

Case-control study using the NIS 2016, the largest public inpatient database in the US. All patients with ICD9-10CM codes for UC were included. None were excluded. Female patients were identified within the database using the female gender indicator.

The primary outcome was determining the odds of UC in female patients compared to males. Secondary outcomes included determining inpatient morbidity, mortality, resource utilization, colectomy rates, hospital length of stay (LOS), and inflation-adjusted total hospital costs and charges.

Propensity score matching was used to create a matching population for Charlson Comorbidity Index and age. Multivariate regression analyses were used to adjust for income in patient zip code, hospital region, location, size and teaching status.

**Results:** A total of 38, 950 patients with UC were identified and propensity matched for selected covariates. The mean patient age was 45, and 47.2% were female. For the primary outcome, females had decreased adjusted odds (aOR: 0.92, p< 0.01) of being admitted for UC. For secondary outcomes, female patients displayed lower adjusted odds of multi-organ failure, being placed on TPN, and undergoing colectomy. Females also had lower adjusted mean hospital costs, charges, and length of stay (LOS). All adjusted odds and means are displayed in Table 1.

**Conclusion:** Females have lower inpatient prevalence of UC, complications, and economic burden compared to males. This reinforces the slight male predominance that was seen in the older Olmsted County population-based studies. One can speculate that the difference in complications, costs, charges, and LOS indicate that females have less severe disease course at hospital admission. Numerous studies have examined the association of gender with disease severity and outcomes, and there continues to be conflicting data.

Thus, future studies are needed to determine what contributes to the variation in disease prevalence and course by gender, and possibly better tailor treatment regimens by gender.

<sup>1</sup>Biomx, Ness Ziona, Israel, <sup>2</sup>Biomx, Killingworth, United States

**Contact E-Mail Address:** yuliam@biomx.com

**Introduction:** An abnormal intestinal microbiota (dysbiosis) is associated with the inflammatory bowel disease (IBD) phenotype and is considered to be a causal or synergistic factor, together with genetic and environmental elements, in perpetuating chronic inflammation. Recent studies demonstrated that a specific *Klebsiella pneumoniae* strain (KP2H7) isolated from the oral cavity of IBD patients causes strong TH1 immune stimulation in germ free wild type mice and colitis in germ free mono-colonized colitis-prone mice [Atarashi et al. Science, 2017]. The present study aims to validate the KP2H7 bacteria as a disease-associated target in IBD patients and to initiate development of a bacteriophage-based therapy that targets this specific bacterial strain by demonstrating ability of a rationally designed phage cocktail to significantly reduce the KP2H7 load in colonized animals. **Aims & Methods:** 300 stool samples from patients including IBD patients from France and Israel were assessed for the presence of KP2H7 strains by applying metagenomic analyses and KP2H7 isolation methods combined with strain specific qPCR, respectively. To examine the prevalence of KP2H7 in the IBD population in the United States (US), the metagenomic data released by the Human Microbiome Project group (HMP Part 2) were re-analyzed to determine its association with IBD.

In parallel, "phage hunting" techniques were applied to isolate tens of natural phage that target the KP2H7 strains from environmental and clinical samples. By combining phage with complementary characteristics (such as differences in their bacterial hosts and recognition of different bacterial surface receptors), phage cocktails were designed and tested for their ability to significantly reduce KP2H7 bacterial burden in mice that were colonized with this bacteria by oral gavage.

**Results:** A KP2H7 prevalence of about 30% was consistently observed in IBD patients across three different geographical locations (Table 1). In the subset of patients for whom deep metadata was also available, a trend in KP2H7 abundance was observed in correlation with disease severity (flare vs remission).

The phage cocktail targeting KP2H7 strains demonstrated significant reduction of bacterial burden in the stool and intestinal mucosa (5 log reduction after 3 administrations of a 5 phage cocktail) when orally administered to mice that were previously colonized with these bacteria.

**Conclusion:** The KP2H7 prevalence data collected from IBD patients offer support for the potential association of KP2H7 and similar strains with IBD, and have demonstrated the existence of a significant target population for phage therapy targeting these bacteria. The efficient eradication of KP2H7 strains by a specifically tailored phage cocktail administered orally to colo-

nized mice suggests that IBD patients carrying these strains may benefit from phage therapy. Since this new treatment modality addresses potential microbiome drivers of IBD and not just disease symptoms, it should be further evaluated as a potential disease-modifying therapy.

Country	Ulcerative Colitis n/N (%)	Crohn's Disease n/N (%)	IBD n/N(%)
Israel	19/52 (37)	17/57 (30)	36/109 (33)
United States	9/30 (30)	23/50 (46)	31/80 (39)

**Introduction:** Inflammatory bowel disease (IBD) encompasses two main life-long chronic immune-mediated disorders, namely Crohn's disease (CD) and ulcerative colitis (UC). Symptoms range from abdominal pain and diarrhoea, to fever, weight loss, and malnutrition requiring hospitalisation. IBD has a negative impact on quality of life, including private and social life. IBD is also susceptible to stigmatisation, mainly because of its symptoms, the old assumption of being a psychosomatic disorder, and because it may deeply affect sexual function. Patients affected by chronic disorders may have an impaired resilience, that is defined as the capacity of thrive in face of adversity, adapting body, mind and spirits to life circumstances, including health issues. No study has ever assessed resilience in IBD patients.

**Aims & Methods:** Aim of this study was to investigate resilience and perceived stigmatisation in an Italian adult cohort of IBD patients. Starting January 2019, consecutive IBD patients were prospectively enrolled, and were regularly followed up at the IBD tertiary medical centre in Pavia. A definite diagnosis of CD and UC was established for a duration of at least three months prior to enrolment. Over, the same period, a cohort of blood donors from the same geographic area was enrolled as healthy controls (HC) to evaluate the average level of resilience in the Italian population. Demographic and relevant clinical data were recorded at the time of the physician evaluation, and every patient was asked to fill in the perceived stigma scale (PSS) and the 25-item Connor-Davidson resilience scale (CD-RISC25). PSS included sub-scores for significant others (friends, family members, spouse or partner) and for health care providers. Disease activity was assessed through Harvey-Bradshaw Index (HBI) for CD and partial Mayo Score for UC. The study is still ongoing and patients are being recruited.

**Results:** A total of 101 IBD patients were enrolled (mean age 46.37±16.5 yrs, F:M=0.8:1), including 46 CD and 55 UC. 249 HC were enrolled (mean age 42.16±12.28 yrs, F:M=1.1:5) as controls for resilience only. The mean PSS score for significant others was 0.62±0.48, and no difference was seen between CD and UC patients. Patients with an active disease had a mean PSS of 1.27 compared to those with inactive disease (0.8, p=0.05). No difference was seen between males and females (1.02 vs 0.82; p=0.22). Mean CD-RISC25 was significantly lower in IBD patients compared to HC (62.93

vs 69.45;  $p=0.0003$ ). Also, females IBD patients had a lower mean CD-RISC25 compared to males (59.43 vs 65.63,  $p=0.06$ ). Mean CD-RISC25 was also lower in patients with active disease compared to inactive disease (48.5 vs 67.52;  $p=0.02$ ).

**Conclusion:** This is the first study showing a low resilience in IBD patients, especially in those in the active phase. Also, patients with active IBD are more likely to suffer from social stigmatisation that may negatively impact on quality of life. These results should not be overinterpreted, as the study is still underway. More studies are needed in order to evaluate possible targeted interventions for this population.

**Introduction:** The exact etiology of ulcerative colitis (UC) is unknown, however, according to the present view, the disease is the result of a chronic inflammatory reaction resulting from abnormal immune response of normal gut flora in genetically susceptible individuals.

**Aims & Methods:** The aim of our study was to determine the composition of the intestinal microbiome in UC patients after restorative proctocolectomy with ileal pouch-anal anastomosis, compared with UC patients with varying extent, FAP (familial adenomatous polyposis) patients after colectomy and IPAA surgery and healthy controls. Active and inactive UC patients who underwent on restorative proctocolectomy and IPAA formation were enrolled in the study.

To compare, active and inactive UC patients with different extent were enrolled, as well. The same number of healthy subjects was aimed to enroll as control group. Clinical data of patients, blood and fecal samples were collected. Fecal microbiota structure was determined by sequencing the V4 hypervariable region of the 16S rRNA gene. Fecal community structure was determined at genus level.

**Results:** Overall, 63 patients were enrolled: 25 UC patients with pouch, 17 UC patients, 8 FAP patients with pouch and 13 healthy control. Only 6 of UC patients with pouch received maintenance therapy (5-ASA, corticosteroids), on the contrary, only one UC patient was without medication. Significant bacterial abundance differences were observed among the examined groups.

Compared to the control, both UC groups had higher *Streptococcaceae*, *Pasteurellaceae*, and lower *Desulfovibrionaceae* abundance. Higher bacterial abundance of *Bacteroidaceae*, *Erysipelotrichaceae*, *Clostridiaceae*, *Peptostreptococcaceae*, and lower *Ruminococcaceae*, *Rikenellaceae*, *Porphyromonadaceae* were found in the UC patients with pouch group compared

to UC patients and controls. There was a significant difference between the groups regarding to the abundance of *Prevotellaceae* and *Enterobacteriaceae*. Fecal microbiome determination of FAP patients are in progress.

**Conclusion:** Changes in bacterial abundance had been observed in UC patients with and without pouch compared to healthy controls. These changes may be a part of the pathomechanism, but the consequence of intestinal inflammation in UC, as well.

**Introduction:** Despite advances in Ulcerative Colitis (UC) therapies, many patients suffer refractory defaecatory symptoms in the absence of active inflammation. For this group, treatment remains challenging, with a paucity of research and limited therapeutic options. In this prospective, ongoing study, we aim to determine the prevalence of faecal incontinence (FI) in patients with quiescent UC.

**Aims & Methods:** In a cross-sectional study, consecutive patients with UC attending Inflammatory Bowel Disease (IBD) clinics were invited to participate. Patients completed a series of validated questionnaires; including an IBD-specific FI questionnaire (ICIQ-IBD questionnaire), Hospital Anxiety and Depression Scale (HADS), the Rome IV diagnostic questionnaire, and the IBD-control questionnaire. Participants were requested to return a Faecal Calprotectin (FCP) within 2 weeks of completing questionnaires. Quiescent UC was defined as IBD-control 8 score  $\geq 13$  and IBD-control-VAS  $\geq 85$ , and/or FCP levels  $\leq 250$  (where available, FCP data were used in preference to IBD-control to classify UC activity). Data were compared between active and quiescent groups using chi-square and non-parametric tests.

**Results:** Overall, n=97 UC patients (n=50 males, mean age 48 (range 18-82) participated. ICIQ-IBD data revealed that most patients experience FI (84/97 (87%) during 'relapses'. Interestingly, 58/97 (60%) reported FI when in 'remission', and this group had higher median HADS depression ( $P=0.0002$ ), poorer QoL scores ( $P<0.0001$ ), and trend towards higher HADS anxiety ( $P=0.09$ ) scores, compared to those without FI. Disease activity data (IBD-control and/or FCP) were available for all patients, and based on these 61/97 (63%) had quiescent UC. The prevalence of FI based on ICIQ-IBD did not differ between those with active (22/36, 61%) and quiescent UC (36/61, 59%),  $P=NS$ . In those with FI on ICIQ-IBD, median IBD-FI symptom scores, IBD-FI QoL scores and HADS (anxiety:  $P=0.47$ , depression:  $P=0.18$ ) did not differ between disease activity groups. However, within the quiescent group, patients that met the more stringent Rome IV criteria for FI (n=13) had higher median IBD-FI symptom scores ( $P=0.007$ ) and HADS-depression scores ( $P=0.05$ ), a trend to worse IBD-FI QoL ( $P=0.07$ ), but similar HADS-anxiety ( $P=0.68$ ).

**Conclusion:** This study is one of the first to identify that regardless of disease activity, FI affects most patients with UC, detrimentally impacting patients' psychological wellbeing, impairing their QoL, and should therefore routinely be screened for in clinics. There is an urgent need for further research in the often neglected area of FI and quiescent disease.

**Contact E-Mail Address:** k.w.j.van.der.sloot@umcg.nl

**Introduction:** Inflammatory Bowel Disease (IBD), consisting of Crohn's disease (CD) and ulcerative colitis (UC) are chronic inflammatory diseases of the gastro-intestinal tract. The etiology of IBD is complex with an interplay between genomic susceptibility, diet, microbiome and environmental factors. Once disease develops, its course remains highly variable and unpredictable due to yet unknown disease modifiers. The role of environmental factors in etiology and disease course remain inconclusive, while the identification of modifiable risk factors is crucial for potential personalized preventative and disease modifying strategies. We executed a large population-based study evaluating known and possibly involved environmental factors in the etiology of and disease course in IBD.

**Aims & Methods:** All IBD patients of the 1000IBD cohort at the University Medical Center Groningen (UMCG), the Netherlands, were asked to fill the validated Groningen IBD Environmental Questionnaire (GIEQ). Overall, 848 environmental factors were, grouped in 15 categories.

To study etiology, patients were group-matched, based on age at diagnosis and sex, in a 1:2 ratio to participants of the population-based Lifelines cohort study, who completed a comparable questionnaire. To study disease course, data collected by the GIEQ was linked corresponding clinical data from the 1000IBD cohort. Disease complications were defined as the need for biological therapy or surgery. Logistic regression was applied to estimate the multivariable-adjusted effect of lifestyle factors on IBD (odds ratio; OR) and 95% confidence intervals. Case-control comparisons were corrected for their differences in age, sex and history of smoking for etiology, as well as disease duration for disease course. A  $p < 0.05$  was considered as nominal and Bonferroni adjusted  $p$ -value as statistically significant. A large number of environmental factors were examined, the interim results are reported.

**Results:** 728 patients of the 1000IBD cohort completed the GIEQ. There were no differences in baseline characteristics between participants and the remaining cohort ( $P > 0.2$ ). Several environmental factors were associated with statistically significant increased risk of IBD, such as the presence of more than three stressful life-events prior to diagnosis CD (OR 2.9, 95%CI 1.9-4.5) and UC (2.6,1.7-4.0); and prenatal smoke exposure for CD (1.9,1.4-2.6) and UC (1.6,1.2-2.2), but showed no effect on disease course. While living environment for the first 5 years of life showed a nominal risk increasing trend for CD and UC, an urban living environment was associated with higher odds of surgery later on (2.3,1.2-4.7). Having pets during the first year of life showed a striking protective effect for both disease (CD and UC; cat 0.4,0.4-0.5, dog 0.4,0.4-0.6), while having a pet during disease was associated with increased risk of both the need for biologicals as well as surgery in UC (2.6,1.1-6.1; 4.2,1.9-9.2, respectively).

**Conclusion:** Stress and prenatal smoke exposure were associated with significantly higher odds of developing IBD. Childhood pets were associated with less odds of IBD, whereas current pets might negatively influence disease course in established UC. Larger studies are needed to validate these findings and further evaluate the role of modifiable environmental factors and their interactions in preventive strategies and personalized treatment.

**Contact E-Mail Address:** k.w.j.van.der.sloot@umcg.nl

**Introduction:** The role of *Mycobacterium Avium* subspecies *Paratuberculosis* (MAP) in Crohn's disease (CD) is controversial. Due to many similarities between CD and Johne's disease, a chronic enteritis in dairy cattle caused by MAP, its role in CD etiology has been studied repeatedly. CD patients seem more prone to MAP infection compared to healthy controls. However, whether MAP acts as a causative agent of CD, an inflammatory trigger or as a secondary invader remains elusive. Over 200 genetic risk loci have been identified in inflammatory bowel diseases, but genetic determinants of MAP infection are poorly studied. Moreover, whether MAP exposure affects CD disease course remains elusive. In this study, we explore genetic determinants of MAP infection and the association of MAP infection with the course of IBD.

**Aims & Methods:** Detailed clinical characteristics, serum and DNA were obtained from in total 847 patients with IBD included in the prospective 1000IBD cohort. In addition, serum samples from 53 healthy controls were collected. MAP serology was determined in all available serum samples. Two conjugates (Protein A-HRP: detects IgA, IgE, IgG1,2,4 and IgM, and Protein G-HRP: detects IgG1-4) were used to measure antibody response to four different MAP antigens (Protoplasmic MAP antigen and three recombinant MAP antigens). Cut-off values according to Bernstein et al. were used to determine seropositivity with a 95% specificity. Logistic regression models, adjusted for age, sex, disease duration, history of smoking and batch effects, were used to explore the association between MAP and IBD disease course. All patients were genotyped with the Illumina Global Screening Array, and genetic data were imputed to the Haplotype Reference Consortium reference panel. A genome-wide association study (GWAS) for presence of MAP seropositivity was performed.

**Results:** Patients with IBD had similar rates of MAP seropositivity as compared to controls ( $P > 0.2$ ) and baseline characteristics were comparable between seropositive and seronegative patients. Disease location, behavior and extent, classified using the Montreal classification, were not associated with MAP seropositivity ( $P > 0.1$ ). Multivariate analyses identified MAP seropositivity for conjugate A as risk factor of a more complicated disease course in patients with CD (biological use [OR 2.19; (95% CI 1.01-4.75)] and in patients with UC (surgery [OR 2.01 95% CI 1.01-3.99]). Using GWAS, a total of 50 genetic loci were associated with MAP seropositivity at a suggestive genome-wide significance threshold ( $P < 5 \times 10^{-5}$ ). One of these loci (rs7901290 [ $P = 8 \times 10^{-7}$ ; OR=1.86]) harbors the *CAMK1D* gene, which is involved in the regulation of granulocytes. Another associated locus (rs1001792 [ $P = 4 \times 10^{-7}$ ; OR=1.92]) harbors the *TNFRSF10B* gene, which has been associated with and apoptosis induction.

**Conclusion:** Patients with IBD had similar rates of MAP seropositivity compared to healthy controls. MAP seropositivity showed no association with IBD disease location, specifically not with ileal Crohn's disease. However, seropositivity for MAP conjugate A, representative for mucosal and acute phase immunoglobulins, was identified as a risk factor of a more complicated disease course in both CD and UC. GWAS analyses show suggestive associations between MAP seropositivity and immunomodulating genes. Future studies in independent cohorts using Ig isotype specific tests are needed to validate these findings and to explore the interaction between genetic susceptibility, MAP exposure and IBD.

**Introduction:** Inflammatory bowel disease (IBD) prevalence is estimated to be rising but no detailed, recent United Kingdom (UK) data are available. The last reported prevalence rate in the UK was 0.40% in 2003.<sup>1</sup>

**Aims & Methods:** We aimed to establish the current and projected future prevalence in Lothian, Scotland.

We conducted an extensive all-age multiparameter search strategy using inpatient IBD international classification of disease (ICD-10) coding (K50/51)(1997-2018), IBD pathology coding (1990-2018), primary and secondary care prescribing data (2009-18) and a paediatric registry (1997-2018) to identify "possible" IBD cases to 31/08/18.

A team of IBD physicians manually confirmed all diagnoses through electronic health record (EHR) review as per Lennard-Jones/Porto criteria. Prevalence and incidence calculations were performed using mid-year population estimates or projections from National Records Scotland.<sup>2</sup>

Trends in incidence, prevalence and mortality over time were reported as annual percentage change, calculated by exponentiating the beta-coefficient of Poisson regression and subtracting 1. Poisson modelling was also used to calculate significance in these trends over time. Autoregressive integrated moving average (ARIMA) regression was applied to forecast prevalence to from 31/08/18 to 01/08/28.

**Results:** In total, 24,601 possible IBD cases were identified and then manually reviewed, revealing 10,499 true positives. The optimum search strategy was pathology plus mesalazine prescription and ICD-10 K50/51 coding that identified 95% true positives with 6% false negatives.

The point prevalence for all IBD in Lothian on 31/08/18 was 784/100,000 (ulcerative colitis (UC) 432/100,000, Crohn's disease (CD) 284/100,000, and IBD unclassified (IBDU) 68/100,000) (Table 1).

Year	Population of Lothian Healthboard	UC (prevalence/ 100,000)	CD (prevalence/ 100,000)	IBDU (prevalence/ 100,000)	All (prevalence/ 100,000)
2008	808,940	315	216	36	567
2009	816,510	334	224	38	596
2010	825,520	349	232	41	621
2011	836,610	359	242	43	644
2012	843,740	375	249	47	671
2013	849,720	386	258	51	694
2014	858,120	398	265	56	719
2015	867,800	411	270	59	739
2016	880,000	418	274	62	753
2017	889,450	427	278	66	772
2018	897,210	432	284	68	784

[Standardised prevalence per 100,000 population for Lothian on 31st August between 2008-18]

There was no significant change in incidence between 2008-2018 (annual percentage change 14.4%; 95% CI -0.9, +32.1%, P= 0.66), nor IBD prevalent cohort mortality (annual average percentage change 10.5%, 95% CI -18.8, +50.0, P= 0.52).

However prevalence increased by 4.3% per year over the same period (95% CI +3.7, +4.9%, P< 0.0001) (Table 1). ARIMA modelling projected a point prevalence on 01/08/28 of 1.02% (95% CI 0.97-1.07%) that will affect an estimated 1.53% (95% CI 1.37-1.69%) of those over 80 years of age.

**Conclusion:** We report a rigorously validated IBD cohort with all-age point prevalence on 31/08/18 of 1 in 125, one of the highest worldwide. Incidence has consistently exceeded mortality in our cohort for the past 10 years, exemplifying the effects of compound prevalence.

We project prevalence will rise to 1 in 98 by mid 2028, with the majority of IBD patients over 50years of age. This has significant current and future implications for IBD service delivery.

**Introduction:** Overlap and intersection exists between inflammatory bowel disease (IBD) and HIV with regards to mucosal barrier and immune cells. HIV is felt to potentially attenuate inflammation in IBD, however, very limited data exists on the development of IBD in HIV+ patients. This is of importance as treatments for IBD are being studied for HIV and treatments for HIV therapies are being studied for IBD.

**Aims & Methods:** Using Explorys (1999-2019), a HIPAA-enabled web platform that includes clinical and lab data from over 63 million unique individuals, we aimed to quantify the risk for new-onset IBD among patients who had a diagnosis of HIV versus the general population. IBD was diagnosed based on a combination of ICD-9 codes and at least one prescription for an IBD specific medication (5-ASA, immunomodulator, biologic). Relative risks (RR) with 95% Confidence Intervals (CI) are reported.

**Results:** A total of 357,950 patients tested positive for HIV, of which 10,570 developed new-onset IBD after their HIV diagnosis (3,043/100,000 persons). The risk of developing IBD among HIV positive patients was 5-fold higher than the general population (RR 5.26, 95% CI 4.81, 5.74, p< 0.001). The majority of patients developing new-onset IBD were not on anti-retroviral therapy for their HIV (89% vs. 11%, p< 0.001) and a higher proportion of new-onset IBD cases in the HIV positive patients were Crohn's disease as compared to the new-onset IBD cases in the general population (65% vs. 42%, p< 0.001).

	De-novo IBD in HIV+	IBD Group without HIV+	P
Subtypes, n [%]			
Crohn's Disease	6,840 [65]	152,580 [42]	< 0.0001
Ulcerative Colitis	3,000 [28]	128,560 [35]	< 0.0001
Indeterminate Colitis	730 [7]	85,480 [23]	< 0.0001
IBD-Associated Outcomes, n [%]			
Colectomy	1,180 [11]	44,720 [12]	0.0018
Proctectomy	30 [0]	3,840 [1]	< 0.0001
Ileostomy	3,490 [33]	18,780 [5]	< 0.0001
Fistulotomy	50 [0]	2,220 [1]	< 0.0001
All-Cause Mortality, n [%]	570 [5]	21,040 [6]	< 0.0001

[HIV+ Patients and De-Novo IBD]

**Conclusion:** We observed that HIV positive patients are at a greater risk for development of IBD as compared to the general population. The majority of new IBD diagnoses among HIV positive patients are Crohn's disease and are often not receiving anti-retroviral therapy. Further research is needed to confirm these observations and to understand how antiretroviral therapy influences the risk for development of IBD.

## P1040 THE IMPACT OF EATING HABITS ON THE OCCURRENCE OF ULCERATIVE COLITIS

Bikbayova G., M.A. Livzan, V.I. Sovalkin, D.V. Turchaninov, T.V. Tretyakova  
Omsk Medical State University, Hospital Therapy, Endocrinology, Omsk, Russian Federation

**Contact E-Mail Address:** galiya1976@mail.ru

**Introduction:** Ulcerative colitis is a chronic state, and its etiology is not currently evident. Inflammatory bowel diseases originate at the interface of inherited predisposition, impact of certain environment factors and intestinal microflora changes. Impact of nutrition factors on emergence of risk of ulcerative colitis has been discussed for many years, which was confirmed by the increased incidence of inflammatory bowel diseases in developed countries compared to developing countries. Changes in general nutrition approaches in the last years have caused the prevalence of bowel diseases to increase. It should be noted that there is an increased incidence of inflammatory bowel diseases in the countries with previously lower incidence, which is associated with the changes in the lifestyle of modern society.

**Aims & Methods:** Aim of this study was: to estimate the impact of nutrition factors on the risk of development of ulcerative colitis based on the analysis of food consumed; to evaluate the significance of consumption of certain nutrients in development of ulcerative colitis among Western Siberian population. We conducted a survey of 81 patients suffering from ulcerative colitis and 39 healthy respondents. We studied the profile of eating habits of patients with ulcerative colitis (prior to being diagnosed) compared to habits of healthy respondents. The study of nutritional patterns of patients with ulcerative colitis and healthy respondents was conducted using the standardized WHO CINDI questionnaire. The survey includes 12 questions regarding the frequency and amount of consumption of certain foods. Particular attention was paid to the consumption of milk and dairy products, meat, fruits, vegetables, carbohydrate foods and sugar. Respondents were offered to choose out of possible options.

**Results:** The diet of patients with ulcerative colitis is characterized by rare consumption and small portions of fresh and cooked vegetables and fruits prior to the first symptoms of the disease ( $U=1094,5$ ;  $Z=-2,7$ ;  $p=0,01$ ). Patients with ulcerative colitis consumed more sugar with tea and/or coffee compared to healthy respondents prior to the first symptoms of the disease ( $U=1214,0$ ;  $Z=-2,0$ ;  $p=0,04$ ). Patients with ulcerative colitis poorly tolerated milk and dairy products prior to the first symptoms of the disease ( $2I=9,72$ ,  $p<0,01$ ). There were no statistically significant differences detected between patients with ulcerative colitis and healthy respondents and their consumption of meat ( $U=1330,0$ ;  $Z=-1,4$ ;  $p=0,16$ ), spicy, fried, salty smoked food ( $U=1530,0$ ;  $Z=0,3$ ;  $p=0,78$ ), and frequency of visits to fast food outlets ( $U=040$ ;  $Z=-1,0$ ;  $p=0,33$ ).

**Conclusion:** Our study confirms the possible effect of a lack of dietary fiber and excessive sugar intake on the emergence of ulcerative colitis.

**Disclosure:** Nothing to disclose

**Introduction:** Loss-of-function (LoF) variants are one of the most interesting forms of rare functional genetic variations as they impair the function of a gene and are more likely to lead to extreme phenotypes

**Aims & Methods:** Our aim was to know the impact of functional rare variants in clinical response to anti-TNF therapy in Crohn's disease (CD).

CD anti-TNF naïve patients starting anti-TNF treatment due to active disease (CDAI>150) were included. The whole genome was sequenced using the Illumina HiSeq4000 platform. Clinical response was defined as a CDAI score < 150 at week 14 of anti-TNF treatment. Low-frequency variants were annotated and classified according to their damaging potential. The whole genome of CD patients was screened to identify homozygous LoF variants. The TNF signaling pathway was tested for overabundance of damaging variants using the SKAT-O method. Functional implication of the associated rare variation was evaluated using cell-type epigenetic enrichment analyses

**Results:** A total of 41 CD patients were included. From them, 54% were male, 75% had ileal or ileocolonic involvement, 12% had structuring and 26.8% fistulising behavior, 20% had perianal disease, 41.5% had previous surgery, 80% of them were under concomitant immunomodulators; 61% were treated with infliximab and 39% with adalimumab. At week 14, 61% had remission and 24% were primary non-responders. A total of 3,250 functional rare variants (2,682 damaging and 568 LoF variants) associated with response to anti-TNF therapy were identified. The strongest damaging impact was detected in 10 LoF SNPs (table 1). Two homozygous LoF mutations were found in *HLA-B* and *HLA-DRB1* genes associated with lack of response and remission, respectively. Genome-wide LoF variants were enriched in epigenetic marks specific for the gastrointestinal tissue (colon,  $P=4.11e-4$ ; duodenum,  $P=0.011$ ). The burden of damaging variation in the TNF signaling pathway was associated with response to anti-TNF drugs ( $P=0.018$ ); damaging variants were enriched in epigenetic marks from CD8+ ( $P=6.01e-4$ ) and CD4+ ( $P=0.032$ ) T cells

**Conclusion:** Functional rare variants are involved in the response to anti-TNF therapy in CD. Cell-type enrichment analysis suggests that the gut mucosa and CD8+ T cells are the main mediators of this response. These findings provide new insights into the underlying heterogeneity of CD, revealing the basis of TNF-dependent biological mechanisms

**Introduction:** Thiopurines are the most widely used immunosuppressants in inflammatory bowel disease (IBD), but in elderly IBD patients they are associated with an increased risk of adverse effects (AE) [Calafat M. et al, 2018]. Elderly patients with IBD are more vulnerable due to a higher rate of comorbidities, polypharmacy and changes in pharmacokinetics, and therefore have an increased risk for treatment related complication [Broekman M., 2017]. Starting thiopurines over 60 years of age should be followed by a closer monitoring. Thiopurine S-methyltransferase (TPMT) deficiency leads to an accumulation of higher levels of cytotoxic thiopurine nucleotides in patients carrying defective *TPMT* alleles and can prospectively identify patients at higher risk for thiopurines toxicity [Robert D. Nerenz, 2018].

**Aims & Methods:** To evaluate a role of TPMT genotyping in late-onset IBD patients as part of therapeutic drug monitoring. DNA samples of 127 IBD patients over 40 years old (median age 53 years; Q1-Q3=47.0-62.0) were obtained from the Genome Database of the Latvian Population. *TPMT* genotyping with a real-time polymerase chain reaction (PCR) (TaqMan Drug Metabolism Genotyping Assays) was performed for detection of rs1800462, rs1800460, and rs1142345 single nucleotide polymorphisms (SNPs). The three common non-functional *TPMT* alleles (*TPMT*\*2, \*3B, and \*3C) were determined in 57.5% women and 42.5% men. Data were collected about demographics, medication intolerance, allergies and comorbidities. Data were analysed in SPSS@23.

**Results:** Our study includes 77% (n=98) of patients with ulcerative colitis, mean age 55±11 years and 23% (n=29) of patients with Crohn's disease, mean age 57±13 years, p=0.4. 92.1% were wild-type homozygous *TPMT*\*1/\*1 genotype, 7.9 % (n=10) were heterozygous. In total four patients had history of azathioprine (AZA) adverse events: gastrointestinal intolerance (n=2), hepatotoxicity (n=1), myalgia (n=1). In total 20.5% (n=26) of patients marked allergies on different medication groups as antibiotics, analgesics, etc. The most frequent polymorphism was *TPMT*\*1/\*3A genotype in 6.3%. No patients were homozygous for any mutation. 7.9% (n=10) of

patients with *TPMT*\*1/\*1 genotype takes AZA in standard dosage 2-2.5 mg/kg without any adverse drug effects. In total 75.6% (n=96) of patients had comorbidities as cardiovascular diseases (arterial hypertension, stenocardia, chronic heart failure) and endocrine diseases (diabetes mellitus, thyroid disorders, adiposity).

**Conclusion:** We have identified *TPMT*\*1/3A as the most prevalent polymorphisms in late-onset IBD patients. TPMT genotyping is an effective method of thiopurines toxicity risk evaluation in late-onset IBD patients. Our data shows that AZA still remains effective treatment in late-onset IBD patients, however detection of TPMT status should be used as a part of therapeutic drug monitoring.

**Introduction:** The therapeutic armamentarium for Inflammatory Bowel Disease (IBD) is rapidly expanding, but inter-individual variability in response remains high, partly driven by genetic variation. Several gene-drug interactions predictive of therapeutic outcomes or adverse drug responses have been identified: genetic variants in *thiopurine-S methyltransferase (TPMT)* and *nudix hydrolase 15 (NUDT15)* are predictive of thiopurine-induced myelosuppression (TIM), the *HLA-DQA1-HLA-DRB1* haplotype is predictive of thiopurine-induced pancreatitis (TIP), and recently the *HLA-DQA1\*05* haplotype has been identified as a genetic determinant of immunogenicity of TNF $\alpha$ -antagonists. Pre-treatment pharmacogenetic testing allows personalised therapies and optimisation of therapeutic outcomes, but its uptake into clinical practice and guidelines has been slow. The aim of this study was to explore the predicted clinical effectivity of an IBD specific pharmacogenetic passport, including multiple pharmacogenetic predictors.

**Aims & Methods:** Detailed clinical characteristics were obtained from patients treated with azathioprine and/ or a TNF $\alpha$ -antagonist in an IBD specialised tertiary hospital. The presence of thiopurine toxicity and/or immunogenicity of TNF $\alpha$ -antagonists was retrospectively evaluated using stringent criteria (1,2). All patients were genotyped with the Illumina Global Screening Array. Genetic data underwent stringent quality control and were imputed to the Haplotype Reference Consortium panel. An in-house developed computational pipeline translated genetic data into an IBD pharmacogenetic passport with predicted risks for thiopurine toxicity and TNF $\alpha$ -antagonist immunogenicity for each patient. Using proposed pharmacogenetic-guided treatment guidelines, clinical effectivity estimates were calculated to show the predicted implications of pharmacogenetic pre-treatment testing in the context of IBD management.

**Results:** Among 817 IBD patients that were exposed to thiopurines and/or TNF $\alpha$  antagonists, 165 adverse drug responses were identified. An IBD pharmacogenetic passport would have predicted 59 (36%) of these adverse drug responses. For every 50 patients genotyped for *NUDT15* and *TPMT* variants prior to start of thiopurine therapy, one case of TIM would have been prevented. When including genotyping of the *HLA-DQA1-HLA-DRB1* haplotype to predict TIP, only 41 patients need to be genotyped to prevent one case of either TIM or TIP. For every 26 patients with an IBD pharmacogenetic passport, predicting all three gene-drug interactions, 10 patients would receive a positive test result. If these 10 patients subsequently receive pharmacogenetic-guided alternative treatment strategies, one case of either thiopurine toxicity or immunogenicity of TNF $\alpha$ -antagonists will be prevented, which results in a number needed to genotype of 26.

**Conclusion:** This is the first study that assesses the predicted clinical effectivity of pre-treatment pharmacogenetic testing for multiple gene-drug interactions in a large IBD cohort. Based on our findings, an IBD pharmacogenetic passport will lead to a significant reduction in potentially life-threatening thiopurine toxicity and increased TNF $\alpha$ -antagonist therapy response rates, and should be implemented into clinical guidelines for IBD treatment.

**Introduction:** Colonic localization of inflammatory bowel diseases (IBD), ulcerative colitis (UC) and Crohn's disease (CD), represents an important risk factor in the development of colorectal cancer (CRC). The risk of CRC increases 8-10 years after the diagnosis of IBD and strong evidences suggest that CRC occurs in the inflamed epithelium, according to the sequence dysplasia-carcinoma. To date, more than 200 genetic loci have been associated to IBD although none to the development of IBD related cancer.

**Aims & Methods:** The aim of this study is to clarify the role of some oncogenes and protooncogenes in the molecular mechanism that leads IBD patients to CRC. On the basis of available literature we profiled a panel of 40 genes (39 genes potentially involved in cancer predisposition and the most important gene associated to IBD, NOD2). A germline variant identification analysis pipeline was performed on the DNA of individuals with CRC diagnosis and IBD history.

Data about patients' features, disease history, disease pattern, family history, and drugs were recorded. We ranked all identified germline mutations by pathogenicity and summarized the allelic frequencies of pathogenic or likely pathogenic variants.

**Results:** We identified 25 IBD patients all consecutively enrolled in a single referral center. The mean age at diagnosis of IBD was of 43 yrs (range 20-72), and a mean age at diagnosis of cancer of 54 yrs (range 36-76). Independently to the disease phenotype status, 8 pts (32%) resulted carriers of at least one major NOD2 susceptibility variants. Multigene panel testing identified 23 mutations in 18 IBD patients (72%): 4 in APC, 3 in MLH1, BRCA1 and CHEK2, 2 in MYH and PDGFRA, 1 in MSH2, MSH3, EPCAM, POLD1, POLE, CDKN2A. Only in two cases (8%) the family history suggested a Lynch syndrome.

**Conclusion:** This study demonstrates that a high rate of pathogenic variants in CRC/IBD patients, above all in APC and mismatch repair genes. The identification of this variants move attention from duration of disease to genetic predisposition as risk factor to develop a CRC. Identification of carriers should make possible stratify patients who need an intensive surveillance regimen or an early indication to prophylactic colectomy.

**Introduction:** We believe that multi-generation IBD families have a monogenetic mechanism of inheritance.

**Aims & Methods:** To identify gene variance associated with IBD inheritance we performed whole exome sequencing (WES) in all our IBD families receiving care at Johns Hopkins IBD Center. We included 37 (35) families with IBD in our study, 17 of which were families of Ashkenazi Jewish ancestry. One hundred fifteen members were sequenced. Affected individuals diagnosed with either Crohn's disease or Ulcerative colitis underwent deep exome sequencing (1-4 individuals/family) performed by our department in collaboration with the genetic department and pediatric gastroenterology. Using PhenoDB analysis we performed individual and merge analysis to identify candidate gene for autosomal dominant or recessive inheritance.

**Results:** After we have filtered out all the non-frameshift variants and those variants with allele frequency incidence of more than 1% we detected: 0-66 variants per family with autosomal recessive compound heterozygous inheritance potential, 0-39 variants per family with autosomal recessive homozygous potential and 6-454 variants per family with autosomal dominant potential. We then performed merged analysis of all the families included in the study and we identified 35 autosomal dominant variants but none autosomal recessive variants. These 35 gene variants were selected if they met the following criteria: present in 3 or more IBD families, express loss of function, present in GWAS studies, have a high genetic score, have an OMIM phenotype.

Out of the 35 gene selected PCGL2 gene variant was noted in seven families: three families from IBD adult cohort, four families from very early onset IBD. All three adult families exhibit genetic anticipation.

**Conclusion:** PLCG2 have been found in other autoimmune diseases characterized by antibody deficiency, in immune dysregulation syndrome and familial cold autoinflammatory syndrome 3. Understanding the PLCGL2 role in IBD inheritance associated with genetic anticipation has implications for genetic counseling for children and grandchildren of IBD patients developing novel therapy.

**Introduction:** It has been seen that 30-40% of patients treated with Infliximab (IFX) who achieve an initial response to induction therapy lose this response over time with maintenance treatment. Therapeutic drug monitoring (TDM) could be used to optimize management in such situations. However, IFX serum levels are not well defined. The aim of the study was to find our cut-off range of Infliximab serum levels in Crohn's disease (CD) patients in remission in clinical practice.

**Aims & Methods:** An observational retrospective study was developed from 1st February, 2016, to 30th November, 2017, in our hospital. Patients with established CD who had been on maintenance dosing schedule of IFX were included.

IFX and antibody to IFX levels were measured before each infusion at least twice and after 6 months of treatment in all patients. All the tests were performed using enzyme linked immunosorbent assay (ELISA) with Progenika kits (PROMONITOR®). Clinical remission was defined using Harvey Bradshaw Index (HBI≤4). The interpretation of data was by cluster analysis (Silhouette measure of cohesion and separation: cluster quality >0.5\*\*).

**Results:** 105 CD patients were included in the study, 57.1% men, with a mean age of 39 (DE±12.9). The median (range) time of the disease was 11 years (7-15). The median (range) time of follow-up was 32 months (22-38). Montreal phenotypes were: 76% A2, 35.2% L2 and 53.3% B1. Perianal disease was present in 51.4%. 265 IFX levels were measured during the follow-up.

Patients who achieved remission had IFX serum levels between 4.26 - 8.26 ug/ml versus 0.06 - 1.43 ug/ml in patients who did not achieve remission (silhouette 0.72) the first time; and 2.84 - 7.75 ug/ml versus 0.05 - 2.69 ug/ml in patients who achieved remission versus those who did not achieve remission respectively the second time (silhouette 0.78) (Fig 1-2). 4.26- 7.75 ug/ml were the best cut-off range for remission (Table 1).

Time 1	Time 2	Most Restrictive interval	
0.06-1.43	0.05-2-69	0.06-1.43	No Remission
1.43-4.26	2.69-2.84	1.43-4.26	Uncertainly zone
4.26-8.26	2.84-7.75	4.26-7.75	Remission

[Crohn's Disease]

We found that perianal disease does not have any influence on IFX serum levels for achieved remission.

**Conclusion:** In our practice the best value to predict remission status in patients undergoing IFX TDM was 4 - 8 ug/ml, which was higher than in other studies.

**Introduction:** Study objective: In order to evaluate early prediction markers for the therapy response of golimumab (GLM) in ulcerative colitis, we aimed to assess the association of an detectable GLM trough serum level together with a reduction in fecal calprotectin level in week 6 (W6) with a clinical response in week 26 (W26) in patients with moderate-severe ulcerative colitis.

**Aims & Methods:** The study was designed as a prospective, single-arm, multicenter, observational study with no interim analyses in Germany between October 2014 and December 2017. Patients aged  $\geq 18$  years, with diagnosed moderate-severe active ulcerative colitis and starting GLM treatment were offered participation in this ethics approved study at ten registered IBD centers. These sites were recruited by the IBD study platform "German Inflammatory Bowel Disease Study Group" (GISG). After screening, for each eligible patient enrolled, the study duration was 26 weeks with six visits at weeks 0 (baseline), 2, 6, 14, 22 and 26.

The primary outcome was clinical response measured by Partial Mayo Scoring Index (PMS). Clinical response was defined by a Partial Mayo Score  $\leq 1$  or a reduction in the PMS by two points. Calprotectin level for response in was defined as reduction of  $\geq 50$  % in comparison to baseline. Detectable GLM trough level was defined as  $\geq 2.5$   $\mu\text{g/ml}$ .

The sample size was calculated for 61 patients (including 3 % drop-outs). Analysis of the primary outcome was done according to the Intention-To-Treat (ITT) method. Missing (outcome) data were imputed as follows: between W0 - W6 classified as therapy failure; between W6 - W26 as Last Observation Carry Forward (LOCF) Effect estimates were reported as relative risks with corresponding 95 % confidence intervals (CI).

**Results:** 61 patients were enrolled, two patients were excluded due to screening failures. During the course of the study 28 patients discontinued their participation (47,5%) due to 1. withdrawal of GLM therapy (n = 21; 35,6%), 2. withdrawal of consent (n=7; 11,9% ).

In the ITT cohort, gender distribution was almost equal (female 52,5%; male 47,5%), the median age was 40.1 (Interquartile Range: 22.1), the mean duration of ulcerative colitis was 8.7 years (95% CI, 6.5 - 10.9). Patients had moderate disease according to PMS with a mean scoring point of 5.6 (95% CI, 5.2 - 6.1). 54.2 % of the enrolled patients were anti-TNF naïve, 8.5 % had experienced a primary and 37.3 % a secondary loss of TNF-alpha therapy prior to the start of GLM therapy.

We showed that patients with an early detectable positive GLM trough level in W6 and a change in calprotectin at the same time had a 1.54 fold increase chance (RR: 0.65, 95% CI: 0.44-0.95; n=45) to achieve a clinical remission at w26 in comparison to patients who had no early detectable positive GLM trough level and no change in calprotectin in w6. On the other hand we analyzed that patients without early detectable GLM trough level and no change in calprotectin in w6 had a 3.46 fold higher risk (RR 3.46; 95% CI 0.56-22.45; p=0.1; n=45) for not achieving response in w26.

**Conclusion:** In this prospective multicenter study we were able to show the impact of fecal calprotectin and serum golimumab level at week 6 to predict the therapeutic response at week 26. Further studies are needed to confirm the statistical significance our primary result.

**Contact E-Mail Address:** [alavra@gmail.com](mailto:alavra@gmail.com)

**Introduction:** Extra-intestinal manifestations (EIM) are common in inflammatory bowel diseases (IBD) and may affect up to 50% of the patients during the course of the disease. Peripheral arthralgia (PA) is by far the most common EIM. To date, TNF-alpha inhibitors are the most established treatment for EIMs in IBD. Infliximab (IFX) trough levels (TL) and anti-IFX antibodies (ATI) are correlated with multiple outcomes in IBD such as clinical response and remission, mucosal healing, fistular healing and more. To date, a correlation between IFX TL/ATI and PA has not been evaluated.

**Aims & Methods:** This retrospective study included IBD patients followed by gastroenterology departments of Sheba Medical Center and Saint Etienne Medical Center. Patients with active peripheral arthralgia at onset of IFX treatment were included. IFX TL and ATI were evaluated at week 6, 14 and 26 and correlated with PA persistence.

**Results:** Forty nine patients (42 CD, 7 UC) with IBD associated arthralgia were included. The overall prevalence of arthralgia was 59.2% (29/49), 44.9% (22/49) and 53.1% (26/49) after 6, 14 and 26 weeks respectively. At 14 and 26 weeks of treatment, arthralgia was less prevalent in clinical responsive patients than in patients who didn't respond to IFX (8.8% vs 66.7%, p=0.004 and 35% vs 70.6%, p=0.031, respectively). IFX TL were not associated with PA at week 14 (median, 4.5 vs 3.15  $\mu\text{g/ml}$ , p=0.26) and at week 26 (median, 3.9 vs 3.6  $\mu\text{g/ml}$ , mean, p=0.84) however detectable ATI were significantly more prevalent in patients with PA than in patients without PA at week 26 (46.2% vs 13.6%, p=0.015).

**Conclusion:** In patients with IBD-related PA, IFX ATI are associated with an increased risk of persistence of arthralgia. No direct correlation was demonstrated between IFX TL and persistence of arthralgia.

### **P1049** DOES FIBROBLAST GROWTH FACTOR 19 (FGF19) LEVEL CORRELATE WITH INFLAMMATORY BOWEL DISEASE ACTIVITY?

Panek-Jeziorna M., [Mulak A.](#)  
Wroclaw Medical University, Department of Gastroenterology and Hepatology, Wroclaw, Poland

**Contact E-Mail Address:** [agata.mulak@wp.pl](mailto:agata.mulak@wp.pl)

**Introduction:** Fibroblast growth factor 19 (FGF19) is the ileal hormone providing feedback inhibition of bile acid (BA) synthesis in the liver which may serve as a surrogate marker to assess BA malabsorption. FGF19 is a key target of the farnesoid X receptor (FXR). The FXR activation inhibits intestinal inflammation. While disturbances in BA metabolism and enterohepatic circulation have been well documented in Crohn's disease (CD), still little is known about the role of these mechanisms in the pathogenesis of ulcerative colitis (UC).

**Aims & Methods:** To evaluate serum FGF19 level and its correlation with inflammatory bowel disease (IBD) activity in patients with UC and CD. Fasting serum FGF19 level was measured using ELISA test in 62 IBD patients (33 M, 29 F, mean age  $40.0 \pm 15.8$ ) and 19 healthy control subjects (8 M, 11 F, mean age:  $39.9 \pm 13.0$ ). The IBD patients were divided into 4 subgroups according to the disease form and activity: non active UC (n=15), active UC (n=16), non-active CD (n=15) and active CD (n=16). The clinical disease activity in UC patients was assessed by Rachmilewitz index, and in CD by CDAI. The endoscopic disease activity was evaluated using the Mayo Endoscopic Score in UC and SES-CD in CD. Moreover, abdominal pain intensity using visual analog scale (VAS), as well as serum CRP and fecal calprotectin levels were measured. Non-parametric statistics were used and results are expressed as median and the lower and upper quartiles [25Q-75Q].

**Results:** Median serum FGF19 level was lower in active UC (114.3 pg/ml) than in non-active UC (175.3 pg/ml) ( $p=0.093$ ). Median FGF19 level in the healthy controls amounted to 151.6 pg/ml, but there were no statistically significant differences between the patients with active and non-active UC compared to the controls. Despite the fluctuations of FGF19 level dependent on the disease activity, in the majority of UC patients it was still within the normal range. In patients with active CD, serum FGF19 level was significantly lower than that in the controls ( $56.5$  vs  $151.6$  pg/ml,  $p=0.043$ ). The lower serum FGF19 level was found in 38% of patients with active CD, and 13% of patients with non-active CD. An inverse correlation was observed between serum FGF19 and number of stools per 24 hours and Bristol Stool Form Scale score, as well as clinical disease activity in CD. No correlation between FGF19 level and endoscopic disease activity was revealed in either form of IBD. In patients with UC the inverse correlations between FGF19 level and abdominal pain intensity ( $R = -0.48$ ,  $p=0.007$ ), as well as inflammatory markers including fecal calprotectin level ( $R = -0.38$ ,  $p=0.036$ ) and serum CRP level ( $R = -0.36$ ,  $p=0.045$ ) were found.

**Conclusion:** The ELISA test for FGF19 constitutes a useful tool to evaluate BA malabsorption in the course of IBD. Serum FGF19 level, although remaining within the normal range in the majority of IBD patients, shows fluctuation dependent on the disease activity, which indicates the association between the regulatory mechanisms of BA enterohepatic circulation and IBD activity. The inverse correlations between FGF19 level and abdominal pain and inflammatory markers may imply its potential analgesic and anti-inflammatory effects - direct or due to the FXR-FGF19 axis activation. The dynamic of FGF19 level fluctuation dependent on the IBD phase suggests new therapeutic aims associated with FXR activation, which constitutes a key element of the gut-liver axis.

**Introduction:** Recent studies have demonstrated that proactive therapeutic drug monitoring (TDM) with drug titration to a target trough concentration is associated with better clinical outcomes. Moreover, dose intensification strategy based on the parallel assessment of clinical symptoms, serum and fecal biomarkers and serum infliximab (IFX) concentration may further increase therapeutic response.

**Aims & Methods:** The aim of this study is to evaluate the outcome of IFX optimisation based on proactive drug monitoring in combination with the assessment of clinical activity and biomarkers using rapid assays.

This is a prospective study of consecutive Crohn's disease (CD) and ulcerative colitis (UC) patients on IFX maintenance therapy. Blood and fecal samples were obtained from the patients at the day when subsequent IFX infusion was scheduled. C-reactive protein (CRP) and hematocrit levels were measured. Serum IFX and fecal calprotectin (FC) concentrations were benchmarked with rapid, lateral flow-based assays. Clinical activity indices were calculated. On the basis of all data, patients were assigned to 4

groups: no intervention (NI), dose increased (DI), stopping (ST) or switch. After optimisation, patients are followed for 6 months with determining all the above mentioned parameters retrospectively at every 2 months.

**Results:** Twenty-six CD and 21 UC patients were enrolled. On the basis of the rapid tests, DI was performed in 14 CD and 11 UC patients, NI in 8 CD and 7 UC patients, and ST in 4 CD and 2 UC patients. One UC patient was switched from IFX to adalimumab. In DI CD group, serum level of IFX increased, CDAI decreased significantly compared to the baseline. Level of CRP and FC did not change significantly at month 2, but CRP decreased significantly at month 4.

Twelve CD patients stayed in remission in the DI group; two relapses were observed, one patient was switched to ustekinumab and one patient received corticosteroid. In DI UC group IFX level increased significantly, CRP, pMayo and FC decreased compared to baseline.

Seven patients in NI CD group and 3 patients in the NI UC group remained in remission till the end of the follow up. None of the examined parameters, except for serum IFX level at month 4 changed significantly.

One patient in the ST group required reintroduction of therapy with adalimumab at month 2. Serum IFX concentration and FC level measured with the rapid, lateral flow-based assay and ELISA kits are correlated ( $r=0.69$ ,  $p=0.0012$ ).

**Conclusion:** Change in therapy was performed in 32 cases on the bases of benchmarked concentrations of serum IFX and FC levels. Our results suggest benefit of using rapid tests in daily practice. Results of rapid, lateral flow-based assays and ELISA kits are correlated.

**Disclosure:** Nothing to disclose

## P1051 INDIVIDUAL PATIENT-LEVEL AUTOMATIC DETECTION OF MUCOSAL INFLAMMATION ON VIDEO CAPSULE ENDOSCOPY IMAGES IN CROHN'S DISEASE

**Contact E-Mail Address:** ukopylov@gmail.com

**Introduction:** Capsule endoscopy (CE) is a well-established modality for diagnosis and monitoring of Crohn's disease (CD). Some of the drawbacks of CE technology include interobserver variability and prolonged reading time. Deep learning technology is being extensively explored in several fields of medicine and has a potential to provide efficient and automated image processing.

The aim of our study was to evaluate the patient level performance of deep learning model for detection of small bowel ulcers on capsule endoscopy images.

**Aims & Methods:** We retrospectively collected capsule endoscopy images of patients with established Crohn's disease and normal subjects. Each image was labeled by an expert gastroenterologist as either normal mucosa or containing mucosal ulcers. A Convolutional Neural Network (Xception) was trained to classify images into either normal mucosa or with mucosal ulcers.

We compared the results of the networks for randomly split images and for individual patients.

First we trained the network on five-folds randomly split images (each fold with 80% training images and 20% images testing). Then we conducted three experiments in which images from n-1 patients were used to train a network and images from a different individual patient were used to test the network. Areas under the curves (AUC) and accuracies were computed for each individual network.

**Results:** Overall, the dataset included 4,255 capsule endoscopy images from 15 patients (11 with and 4 without CD, respectively); 2,272 images contained ulcerated mucosa and 1,983 normal images.

For randomly split images the performance of CNN was excellent with AUC ranging between 0.97 and 0.99 and accuracies ranging from 96.7% to 97.8%.

For individual patient-level (patients 1,2 and 3) experiments, the AUCs were also excellent (0.97, 0.99 and 0.99, respectively). Variability was seen in the accuracies for different patients (73.2%, 88.2% and 95.6%, respectively).

**Conclusion:** Deep learning technology provides accurate automated detection of mucosal ulcers on capsule endoscopy images for both pooled and individual patient images. To simulate real life results, individual patient-level experiments must be conducted. This technology may be applicable for real-life processing of CE imaging in suspected and established Crohn's disease.

## P1052 PULMONARY FUNCTION TESTS IN ASYMPTOMATIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE: PRELIMINARY RESULTS OF A SINGLE CENTER COHORT STUDY

Fragaki M.<sup>1</sup>, Pasparaki E.<sup>2</sup>, Bibaki E.<sup>2</sup>, Kounalakis G.<sup>2</sup>, Theodoropoulou A.<sup>1</sup>, Ferdoutsis E.<sup>2</sup>, Paspatis G.<sup>1</sup>, Meletis G.<sup>2</sup>, Karmiris K.<sup>1</sup>

<sup>1</sup>Venizeleion General Hospital, Department of Gastroenterology, Heraklion, Greece, <sup>2</sup>Venizeleion General Hospital, Department of Thoracic Medicine, Heraklion, Greece

**Contact E-Mail Address:** angeliketheodoropoulou@yahoo.co.uk

**Introduction:** Pulmonary dysfunction is frequently underestimated in inflammatory bowel disease (IBD) patients. The aim of this study was to investigate pulmonary function in IBD patients and identify possible risk factors for pulmonary dysfunction.

**Aims & Methods:** Consecutive informed and consented IBD patients < 60 years old followed up in our centre underwent pulmonary function tests (PFTs) during their regular follow up visit. Measurements conducted were forced vital capacity (FVC), forced expiratory volume in one sec (FEV1) and maximal mid-expiratory flow (MMEF 75/25). Exclusion criteria were an acute or chronic respiratory disease as well as the presence of an established pulmonary extra-intestinal manifestation.

**Results:** 135 IBD patients have been enrolled so far (males: 55.6%, Crohn's disease: 63.7%, mean age at IBD diagnosis: 34.2 years [SD±11.9], median [IQR] duration of IBD: 7.5 months [0.1-34.3], extraintestinal manifestations: 36.3%). Thirty-eight patients (28.1%) had never smoked with the rest being either active (36.3%) or ex- (33.3%) smokers. Thirty-four patients (25.2%), including 7/38 (35.3%) non-smokers, revealed abnormal PFTs (males: 22/34, Crohn's disease: 25/34); 12 (35.3 %) exhibited a restrictive pattern, 12 (35.3 %) an obstructive pattern and 10 (29.4%) small airway disease. Interestingly, appendectomy was more commonly reported in non-smokers with abnormal PFTs compared to those without (p=0.002). IBD was active at baseline in 4/34 and extraintestinal manifestations were present in 15/34 patients. Anti-TNFalpha agents were administered in 17/34 (50%) patients. Six patients were under combination therapy with an IMS. There was no association of abnormal PFTs with gender, disease sort or location or behavior or activity, tonsillectomy, IBD therapy either as monotherapy or as combination therapy and the presence of anemia.

**Conclusion:** More than one fourth of our IBD patients in total and of non-smokers in particular demonstrate abnormal PFTs measured in a random outpatient visit without any symptoms, signs or history of respiratory disease. Appendectomy was associated with LFTs abnormality in non-smokers perhaps revealing an immunologic defect influencing the development of obscure primary or secondary pulmonopathy on the background of IBD. These results should of course be interpreted with caution for the time being, while awaiting those of a larger cohort.

**Disclosure:** Nothing to disclose.

## P1053 DIAGNOSTIC ACCURACY OF FECAL LACTOFERRIN AND CALPROTECTIN COMPARED TO THE RILEY SCORE AND NANCY INDEX FOR THE DETERMINATION OF HISTOLOGICAL INFLAMMATORY ACTIVITY IN PATIENTS WITH ULCERATIVE COLITIS

**Contact E-Mail Address:** j.langhorst@kliniken-essen-mitte.de

**Introduction:** This study aims to investigate the performance of Lactoferrin and Calprotectin compared to the Riley Score and especially to the Nancy index assessing the histological inflammatory activity in a cohort of patients with ulcerative colitis (UC).

**Aims & Methods:** Secondary analysis of clinical data from UC patients who were treated in the Department of Internal and Integrative Medicine at the Kliniken Essen-Mitte, Germany. Patients were included in the present study, if colonoscopy-results, biopsies and data of the fecal biomarkers Lactoferrin and Calprotectin were available. A total of 3 biopsies were taken each in the sigma and rectum and the Riley Score and Nancy index were calculated by an experienced pathologist blinded to the results of the fecal biomarkers. The histologic scores were correlated to Lactoferrin (LF) and Calprotectin (Cal) levels in stool harvested within 7 days before the endoscopic intervention. Comparisons were done for differences between biomarker levels and the grades of the Nancy index. Sensitivity, specificity, negative predictive value and positive predictive value as well as optimized cut-offs were calculated. Remission was defined as Nancy Index ≤ 1.

**Results:** 228 patients (60.1 % female, mean age 45.26 years) with diagnosed UC were included in the analysis. The Riley score and Nancy index correlated significantly with LF ( $r_s(228) = 0.43$ ;  $p < .001$ /  $r_s(228) = 0.43$ ;  $p < .001$ ) and Cal ( $r_s(228) = 0.40$ ;  $p < .001$ /  $r_s(228) = 0.38$ ;  $p < .001$ ). Median levels of LF and Cal differed significantly between the grades 0-4 of the Nancy index (both  $p < .001$ ). Subsequent post-hoc tests showed that LF differed between the grades 0 and 3 ( $z = -6.15$ ,  $p < .001$ ), 0 and 4 ( $z = -4.82$ ,  $p < .001$ ), 1 and 3 ( $z = -3.31$ ,  $p = .009$ ), 1 and 4 ( $z = -2.83$ ,  $p = .046$ ), 2 and 3 ( $z = -3.66$ ,  $p = .003$ ) and 2 and 4 ( $z = -2.88$ ,  $p = .040$ ) and Calprotectin between the grades 0 and 2 ( $z = -3.90$ ,  $p = .001$ ), 0 and 3 ( $z = -5.69$ ,  $p < .001$ ), 0 and 4 ( $z = -4.46$ ,  $p < .001$ ), 1 and 3 ( $z = -3.77$ ,  $p = .002$ ) and 1 and 4 ( $z = -3.27$ ,  $p = .011$ ). Moreover the median levels of LF and Cal differed significantly between patients in remission (Nancy Index ≤ 1) and patients with disease activity (Nancy Index ≥ 2), both  $p < .001$ . Optimized cut-off-values and the diagnostic accuracy of LF and Cal for the differentiation between active and inactive disease using the Nancy Index as reference standard are < 5.85 for LF and < 34.28 for Cal resulting in a diagnostic accuracy of .73 for LF and .76 for Cal with a sensitivity of 76.4 for LF, 64.6 for Cal and a specificity of 64.3 for LF and 78.6 for Cal. Table 1 shows the sensitivity, specificity, positive predictive value and negative predictive value of LF and Cal.

**Conclusion:** The fecal biomarkers Lactoferrin and Calprotectin correlated significantly with the Riley and Nancy index. LF and CalP differed significantly between the grades of the Nancy index. The results support the utility of fecal biomarkers for detecting active histologic inflammation in patients with ulcerative colitis.

	Cut off	SE (%)	SP (%)	PPV (%)	NPV (%)
Lactoferrin	≤ 7.25 µg/g	103/144 (71.5)	55/84 (65.5)	103/132 (78.0)	55/96 (57.3)
Calprotectin	< 50 µg/g	82/144 (56.9)	68/84 (81.0)	82/98 (83.7)	86/130 (65.3)

[Table 1. Sensitivity, Specificity, positive predictive value and negative predictive value of Lactoferrin and Calprotectin using manufactures' cut-offs]

## P1054 RED BLOOD CELL DISTRIBUTION WIDTH AND ITS DERIVATIVES AS POTENTIAL MARKERS IN THE COURSE OF ULCERATIVE COLITIS - AN OBSERVATION OF PATIENTS TREATED WITH INFLIXIMAB

Michalak A., Radwan P., Kasztelan-Szczerbinska B., Laskowska K., Cichoż-Lach H.  
Medical University of Lublin, Department of Gastroenterology with Endoscopy Unit, Lublin, Poland

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** Red blood cell distribution width (RDW) is associated with various medical conditions. Its elevated level was found to be the predictor of poor outcome in cancer, liver cirrhosis and cardiovascular diseases. RDW was also suggested as a marker of inflammation in the course of inflammatory bowel disease (IBD).

Nevertheless, it seems that a potential role of its derivatives (red blood cell distribution width-to-platelet ratio (RPR) and red blood cell distribution width-to-lymphocyte ratio (RLR)) in this field of gastroenterology has not been explored so far.

**Aims & Methods:** The aim of our study was to find out if there are deviations in RDW and its derivatives levels - RPR and RLR - in the course of infliximab (IFX) induction regimen in ulcerative colitis (UC) patients. We also looked for relationship between mentioned parameters, platelet indices and C-reactive protein (CRP). One hundred and twelve participants were qualified to the survey: 56 patients with active UC and 56 persons in control group. UC patients were treated with IFX (3 doses of standard induction therapy). RDW, RPR and RLR values were obtained in the blood of UC patients at 0, 2, and 6 weeks of induction regimen and in follow-up six weeks later. Results were compared with control group.

**Results:** RDW value in UC patients prior to the first dose of IFX was above normal range; it was also higher in comparison to control group ( $p < 0.001$ ) and normalized in follow-up ( $p < 0.01$ ). Baseline RLR level in study group compared to controls was higher ( $p < 0.001$ ) and decreased after finished IFX induction regimen ( $p > 0.05$ ); Baseline RPR value did not differ significantly; in follow up its level increased ( $p < 0.001$ ). We noticed several correlations in UC patients.

Prior to the treatment with IFX, RPR correlated positively with mean platelet volume (MPV) ( $p < 0.01$ ) and platelet distribution width (PDW) ( $p < 0.001$ ); negative correlation was observed between RPR and plateletcrit (PCT) ( $p < 0.001$ ). In follow up RPR correlated negatively with PCT ( $p < 0.001$ ) and CRP ( $p < 0.001$ ); positive correlation was noticed between RPR and PDW ( $p = 0.001$ ).

**Conclusion:** Performed study revealed that RDW, RPR and RLR values are affected by IFX therapy in UC patients and should be considered as potential laboratory markers in the course of IBD.

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** Recently, neutrophil-to-platelet ratio (NLR), platelet-to-lymphocyte ratio (PLR) and mean platelet volume-to-platelet ratio (MPR) have been proposed as potential markers in various medical disorders, e. g. cancer, cardiovascular diseases, liver cirrhosis. However, the above-mentioned indices have not been explored in inflammatory bowel disease patients so far.

**Aims & Methods:** Our goal in this survey was to assess NLR, PLR, MPR and their relationships with platelet indices and C-reactive protein (CRP) in Crohn's disease (CD) patients treated with infliximab (IFX). We included 80 participants to the study: 40 patients with active CD and 40 persons in control group. CD patients were treated with IFX (five doses of standard

therapy). NLR, PLR, MPR and their relationships with CRP, mean platelet volume (MPV), plateletcrit (PCT) and platelet distribution width (PDW) were assessed in blood of CD patients at 0, 2, 6, 14 and 22 weeks. Results were compared with controls.

**Results:** Baseline values of NLR and PLR among CD patients were higher in comparison to controls ( $p < 0.001$ ); MPR level was lower ( $p < 0.01$ ). In CD group, after five doses of IFX, a decrease in NLR ( $p < 0.001$ ) and PLR values ( $p = 0.001$ ) together with increase of MPR level ( $p < 0.001$ ) were noticed. We also observed significant correlations in CD patients, present simultaneously prior to the biological treatment and after five doses of IFX. NLR correlated positively with PLR and CRP ( $p < 0.01$ ). There was a negative correlation between PLR and MPR ( $p < 0.01$ ), together with positive association between PLR and PCT ( $p < 0.001$ ). Finally, MPR correlated positively with MPV ( $p < 0.01$ ) and negatively with PCT ( $p = 0.001$ ). In addition, CRP correlated negatively with MPR at baseline ( $p < 0.001$ ) and positively with CRP ( $p = 0.004$ ) after five doses of IFX.

**Conclusion:** CD, IFX therapy, NLR, PLR and MPR are closely related to each other. Analyzed hematological indices might be potential tools in the monitoring of CD patients.

## P1056 NEUTROPHIL-TO-PLATELET RATIO, PLATELET-TO-LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME-TO-PLATELET RATIO AS POTENTIAL HEMATOLOGICAL INDICES IN THE EVALUATION OF INFLAMMATION IN ULCERATIVE COLITIS PATIENTS

Michalak A., Radwan P., Kasztelan-Szczerbinska B., Laskowska K., Cichoż-Lach H.  
Medical University of Lublin, Department of Gastroenterology with Endoscopy Unit, Lublin, Poland

**Contact E-Mail Address:** lady.agatamichalak@gmail.com

**Introduction:** There is a growing body of evidence that new routinely obtained noninvasive blood indices could become markers of inflammation in inflammatory bowel disease patients. Nevertheless, the number of observations devoted to this field of gastroenterology is still very small.

**Aims & Methods:** We aimed in our survey to look for relationships between hematological parameters in ulcerative colitis (UC) patients treated with infliximab (IFX). One hundred and twelve participants were enrolled to the study: 56 patients with active UC and 56 persons in control group. UC patients were treated with IFX (3 doses of standard induction therapy). Neutrophil-to-platelet ratio (NLR), platelet-to-lymphocyte ratio (PLR), mean platelet volume-to-platelet ratio (MPR) and their correlations with red blood cell and platelet indices were measured in the blood of UC patients at 0, 2, and 6 weeks of induction regimen and in follow-up six weeks later. Results were compared with control group.

**Results:** NLR and PLR levels in UC patients prior to the first dose of IFX were higher in comparison to controls; MPR value was lower ( $p < 0.001$ ). NLR value decreased after finished IFX induction therapy ( $p < 0.001$ ). PLR level became lower too, however not significantly. MPR value became higher ( $p < 0.001$ ). Several correlations were noticed in UC patients. PLR correlated positively with mean platelet volume (MPV) and red blood cell distribution width (RDW) before the introduction of IFX ( $p < 0.01$ ); there were also positive correlations between MPR and both - platelet distribution width (PDW) and plateletcrit (PCT) ( $p < 0.001$ ). In follow-up after finished induction regimen PLR correlated positively with NLR and PCT ( $p < 0.001$ ); negative correlations were noticed between PLR and both MPR and PDW ( $p < 0.01$ ).

**Conclusion:** Deviations in white blood cell, red blood cell and platelet indices seem to be closely related to each other in UC patients and affected by IFX therapy. NLR, PLR and MPR are potential diagnostic tools in the monitoring of UC patients.

**Introduction:** Oncostatin M (OSM) has been implicated in the pathogenesis of inflammatory bowel disease (IBD), wherein its increased mucosal expression drives intestinal stromal cell inflammation and predicts non-responsiveness to anti-TNF therapy<sup>1</sup>. In this study we aimed to further unravel the potential of OSM as a diagnostic, prognostic and/or therapeutic biomarker.

**Aims & Methods:** We collected serum and mucosal biopsies from Crohn's disease (CD) and ulcerative colitis (UC) patients: (1) treatment-naïve newly diagnosed patients; (2) patients initiating anti-TNF or (3) vedolizumab therapy; (4) post-operative CD patients six months after ileocolonic resection with ileocolonic anastomosis; (5) multiple-affected IBD families including unaffected first-degree relatives (FDRs). For each group, matched samples from non-IBD controls were included as comparison. Serum OSM protein levels were measured using the Proseek Multiplex Inflammation panel (OLINK), and mucosal OSM expression using RNA-sequencing or microarray technology. An overview of the studied samples and the corresponding applied definitions and technologies can be found in Table 1. Wilcoxon tests (R 3.5.1) were applied to assess statistical significance, defined as a p value < 0.05.

**Results:** In newly diagnosed CD and UC patients, we observed increased colonic OSM expression (fold change (FC)=60.2, p=3.7E-09) and serological protein levels (FC=4.9, p=1.3E-11) compared to non-IBD controls, with the strongest upregulation in extensive UC and fistulizing CD. Moreover, elevated mucosal OSM (but not serum OSM) at diagnosis was associated with the need for biological therapy within one year after diagnosis (poor- vs. good-prognosis: FC=5.0, p=1.5E-03). Prior to both anti-TNF and vedolizumab therapy, colonic OSM was upregulated in future non-remitters (FC=2.5, p=5.0E-02; FC=2.3, p=1.0E-02 respectively). In contrast, baseline serum OSM could not identify future anti-TNF or vedolizumab non-remitters (FC=1.0, p=3.0E-01; FC=0.9, p=4.1E-01 respectively). In CD patients with post-operative recurrence (POR) higher serum OSM levels were found at month 6, as compared to patients without POR and to controls (FC=2.6, p=1.9E-02; FC=2.9, p=4.5E-03). Furthermore, mucosal OSM in POR CD patients did not differ from CD patients without POR (FC=1.2, 1.4E-01), but was significantly upregulated as compared to controls (FC=1.5, p=5.0E-03). In multiple-affected IBD families increased serum levels were observed in FDRs as compared to matched control families (FC=1.7, p=4.0E-04), and levels were similar to those of IBD patients.

**Conclusion:** Colonic OSM levels are increased in CD and UC patients at the time of diagnosis, and higher levels correlate with poor prognosis. In addition, upregulation of colonic OSM is associated with future anti-TNF/vedolizumab non-remitters. Therefore, OSM at the mucosal site is a surrogate marker of biological treatment-refractoriness in IBD.

### Introduction:

**Aims & Methods:** To compare the success rate between two HBV vaccines in IBD patients: the traditional (Engerix®) and a new vaccine with an adjuvant (Fendrix®). Secondary aim was to identify predictor factors of response to the vaccine.

IBD patients with negative HBV serology and without previous vaccination were included in this multicenter study (EUDRA-CT number: 2010-023947-14), and randomized 1:1 to receive double doses of Engerix® or Fendrix® or at months 0, 1, 2 and 6. Anti-HBs concentration was measured 2 months after the 3<sup>rd</sup> and 4<sup>th</sup> doses. Response to vaccination was defined as anti-HBs ≥100 IU/L.

**Results:** 173 from 180 included patients were randomized and received the first vaccine dose. 98% received the first 3 doses of vaccine and 97% completed the vaccination schedule. During vaccination, 24% of patients were under immunomodulators (IMM), 15% under anti-TNF and 24% under combo therapy (IMM and anti-TNF). 54% of patients received Engerix® and 46% Fendrix®; the main characteristics of patients (age, gender, type of IBD, treatment and proportion of drop-outs) were similar between the 2 groups.

Variables	Odds ratio	95% confidence interval
Age (>60 years vs. ≤60 years of age)	0.17	0.06-0.49
Fendrix (single dose) over Engerix (double dose)	1.8	0.8-4.1
IBD treatments		
Steroids vs. no treatment	0.03	0.004-0.3
Immunomodulators in monotherapy vs. no treatment	0.1	0.02-0.58
Anti-TNF in monotherapy vs. no treatment	0.05	0.01-0.3
Combo therapy vs. no treatment	0.02	0.004-0.1

[Table 1. Multivariate analysis of predictive factors associated with response (anti-HBs≥100 IU/L after 4 doses) to hepatitis B virus vaccine in infl]

Overall, in the per-protocol (PP) analysis, 45% of patients had response (pre-defined as anti-HBs≥100 IU/L) after the first 3 doses (168 patients received 3 doses), and 71% after the completion of the vaccination schedule (159 completed the vaccination). 47% of patients that did not respond after the 3<sup>th</sup> dose, responded to the 4<sup>th</sup> vaccine administration (p<0.0001). In the PP analysis, the response rate after the 4<sup>th</sup> dose was 75% (95%CI, 57-78%) with Fendrix® vs. 68% (64-85%) with Engerix® (p=0.3); however, considering anti-HBs≥100 IU/L (the standard threshold to define response), there was a trend towards higher success rate with Fendrix® than with Engerix® (88% vs. 77%, p=0.07). The response rate after 4 doses was significantly lower in patients under IMM, anti-TNF agents and combo therapy compared with no treatment: 77%, 63%, 45% and 96%, respectively (p<0.01 for each comparison).

In the multivariate analysis, older age, the treatment with steroids alone, IMM, anti-TNF agents and combo therapy were associated with lower probability of response to the vaccination. The type of vaccine -Engerix® or Fendrix®- was not associated with the response to the vaccination (table 1).

The proportion of adverse events probably related to the vaccine was significantly higher in patients receiving Fendrix® vs. Engerix® (17% vs. 4%), being local pain the most frequent one; all of them were mild.

**Conclusion:** We could not demonstrate a statistically significant higher response rate of Fendrix® (single dose) over Engerix® (double dose) in IBD patients. A 4-dose vaccine schedule significantly increases (over 40%) the response compared with a 3-dose regimen. Older age and IMM and anti-TNF treatment impaired the success rate of the vaccine. Both vaccines are safe in IBD patients.

## P1059 COMPLIANCE WITH INTERNATIONAL GUIDELINES ON VACCINATION AND MALIGNANCY PREVENTION AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Mellos A., Michalopoulos G., Makris K., Kapizioni C., Kourkoulis P., Koutoufaris G., Milioni K., Giannelis P., Vrakas S., Xourgias V., Tzaneio General Hospital, Department of Gastroenterology, Piraeus, Greece

Contact E-Mail Address: gmicha78@hotmail.com

**Introduction:** IBD patients receiving immunosuppressive therapy are at increased risk of developing opportunistic infections and certain types of malignancy, often associated with the type of immunosuppressive therapy. International guidelines have been published, involving vaccination protocols and malignancy screening with cervical smear, mammography and skin examination, yet adherence from patients remains low.

**Aims & Methods:** To determine self-reported compliance with influenza virus and pneumococcal vaccination guidelines, as well as malignancy screening with cervical smear, mammography and skin examination, among Greek patients with inflammatory bowel disease.

**Method:** In collaboration with the Hellenic Society of Crohn's Disease's and Ulcerative Colitis' Patients, a questionnaire was posted on the Society's website, inviting IBD patients only on immunosuppressive therapy to fill it in. The questionnaire included demographic data, disease characteristics as well as influenza and pneumococcal vaccination queries, skin examination (all patients), cervical smear and mammography screening rates (female patients).

**Results:** A total of 176 patients completed the questionnaire [CD=134 (76.14%) UC=42 (23.86%), male=57 (32.38%) female=119 (67.6%)]. Among them, 51(28.9%) patients were treated with one immunomodulator (MTX-AZA), 73 (41.4%) with anti-TNF, 19 (10.7%) with Vedolizumab, 3 (1.7%) with Ustekinumab whereas 30 (17%) patients were treated with combination therapy. According to the results, 97 patients (55.1%) received the influenza virus vaccine, 81 patients (46%) received the 13-strain PPV, whereas 14 patients (8%) weren't sure if they received the vaccine or not. Fifty nine patients (33.5%) received the 23-strain PPV and 25 patients (14.2%) weren't sure if they received the vaccine or not. Thirty nine patients (22.2%) underwent skin examination whereas 26 patients (14.8%) weren't aware of it. Twenty four patients (18.9%) had never undergone cervical smear testing and 57 (46.7%) had never performed a mammography. There was no statistically significant difference between vaccination and screening compliance rates of patients receiving monotherapy and combination therapy.

**Conclusion:** There appears to be a significant proportion of patients receiving immunosuppression therapy (>50%) that does not comply with the international guidelines on vaccination and malignancy prevention (it cannot be clarified whether this is a problem of lack of education or simply non-compliance), putting themselves at risk. Even high-risk patients (combination immunotherapy) do not seem to have better compliance rates.

**Disclosure:** Nothing to disclose

## P1060 THE HISTOLOGICAL HEALING IN ULCERATIVE COLITIS PATIENTS CAN BE BEST PREDICTED BY THE COMBINATION OF FAECAL CALPROTECTIN AND ENDOSCOPIC HEALING ASSESSED BY ADVANCED OPTICAL ENHANCEMENT TECHNIQUES

**Contact E-Mail Address:** cannatellirosanna@gmail.com

**Introduction:** Endoscopic mucosal healing (MH) is an important target of therapy and prognostic factor in Ulcerative Colitis (UC) patients. Considerable interest has been generated by reports that 18-24% of patients with endoscopic healing at white light endoscopy (WLE) are found to still have active inflammation from the histological results. Faecal Calprotectin (FC) is a widely used surrogate marker of MH. Recently, we have published and validated endoscopic MH using high definition (HD) electronic chromoendoscopy which provides fine details of mucosal and vascular patterns.<sup>1,2</sup>

**Aims & Methods:** In this study, we aim to investigate MH using Faecal Calprotectin (FCP) multiple endoscopic and histological scoring systems assessed with advanced endoscopic platforms widely available. We prospectively obtained clinical data, endoscopic scores (Mayo Endoscopic Score (MES), Ulcerative Colitis Endoscopic Index of Severity (UCEIS) PICaSSO score (Paddington International virtual ChromoendoScopy ScOre))<sup>1</sup> FCP for 51 UC patients (mean age 45y, 51% male) undergoing colonoscopy for colitis assessment or surveillance using high definition iscan optical enhancement (iscan-OE) Pentax, NBI near focus (NBI-NF) Olympus or Blue Light Imaging (BLI) Fujinon. Histologic activity was scored by Robarts Histological Index (RHI) and Nancy Index (NI). Receiver Operating Characteristics (ROC) curves were plotted to determine operating characteristics of FCP alone or in combination with endoscopic scores to predict histologic healing using modelling algorithms.

**Results:** 24 (47.1%) patients had endoscopic remission defined as MES= 0 or UCEIS (≤1) using HD-WLE. The mean (SD) of FCP was 505.5 (741.0) µg/g and 23 (45.1%) patients had FCP≤100 µg/g. 24 (47.1%) were in histologic remission, defined as RHI ≤ 6; and 21 (41.2%) patients were in histologic remission defined as NI ≤1.

ROC curves showed that the optimum cut-off of FC alone to predict histological healing with RHI was 163 µg/g with an accuracy of 82.4% (95%CI 69.-91.6) and Area Under ROC curve (AUROC) of 83.6% (95%CI 71.8-95.5). Using NI, the best threshold was 112 µg/g with accuracy of 82.4% (95%CI 69.1-91.6) and AUROC of 85.7% (95%CI 75.4-96.0).

When FC (≤100 µg/g) and PICaSSO were combined to predict histological healing, measured with RHI, the optimum cut-off was PICaSSO=3 with accuracy of 90.2% (95%CI 78.6-96.7) and AUROC of 95.5% (95%CI 90.4-100). Combining FC with PICaSSO with the formula "FC+1.5\*Picasso" the accuracy and AUROC to predict histological healing with NI at the threshold of PICaSSO=5 were 92.1% (95%CI 81.1-97.8) and 96.5% (95%CI 91.8-100), respectively.

The accuracy of predicting histological healing with RHI for the combination of UCEIS & FC (≤100µg/g) was 90.2% (95%CI 78.6-96.7) and AUROC 94.4% (95%CI 88.1-100) at the cut-off of PICaSSO=4. However, with NI, the best cut-off was PICaSSO=3, with accuracy of 92.9% (95%CI 77.5-98.0) and AUROC 92.2% (95%CI 84.7-99.7).

PICaSSO alone was able to predict histological healing at the cut-off of PICaSSO=3, with accuracy of 92.2% (95%CI 81.1-97.8) and AUROC of 95.1% (95%CI 89.1-100) with RHI. However, with NI accuracy was 90.2% (95%CI 78.6-96.7) and AUROC was 95.5% (95%CI 90.1-100) at the same cut-off.

**Conclusion:** The combination of advanced optical enhancement endoscopic scores such as PICaSSO with FC could help to identify UC patients with histologic healing (RHI or NI) with higher accuracy than FC alone. Using new advanced endoscopic technologies now widely available, endoscopic scoring and histologic scoring no longer have large discrepancies as reported before.<sup>1,2</sup>

**Contact E-Mail Address:** asmabenmed2014@gmail.com

**Introduction:** Osteoporosis and osteopenia are frequently reported in Crohn's disease, and their prevalence varies between 15 and 30%. The aim of our study was to evaluate the prevalence of bone loss in patients with Crohn's disease and to determine its predictive factors.

**Aims & Methods:** We conducted a retrospective study including patients with Crohn's disease followed from 2010 to 2016. The measurement of bone mineral density (BMD) was realized by dual energy x ray absorptiometry (DXA). BMD was evaluated by calculating bone mass expressed in g / cm<sup>2</sup> and T-score expressed as standard deviation scores (SDS).

**Results:** Sixty patients were collected. The average age was 35.7 years (19 t-70). The sex ratio M / F was 1.41 (35 men and 25 women). Twenty two patients were smokers (36.6%), the average number of pack years was 13.3 PY. The average body mass index (BMI) was 22.7 Kg / m<sup>2</sup> (12.3 kg / m<sup>2</sup> - 30.84 kg / m<sup>2</sup>). Denutrition (BMI < 18,5 kg / m<sup>2</sup>) was present in 13.33% of patients. The mean number of relapses was 2.57 (1-8). According to the Montreal classification 33.33% (20/60) were ranked L1, 13.3% (8/60) ranked L2, 50% (30/60) ranked L3, and 3.33% (2/60) classified L4. Corticotherapy was noted in 73.3% of patients, the average number of courses was 1.44 (1-5) and the average cumulative dose was 3.75 g. The average duration of the evaluation of the disease was 84 months. Twenty four patients (40%) underwent intestinal resection. Biologically, 53% of patients had an inflammatory syndrome.

BMD was normal in 24 patients (40%) and low in 36 patients (60%). Osteopenia was reported in 28 cases (46.66%) and osteoporosis in 8 cases (13.33%).

The risk factors for bone loss were an age greater than 45 years (p = 0.04), a number of corticosteroid courses > 3 (p = 0.02) and a duration of disease progression > 4 years (p = 0.045).

However, the bone loss was not related to the gender, the location of the Crohn's disease, or the history of intestinal resection.

**Conclusion:** Bone loss is common in people with Crohn's disease, hence the need for early detection to initiate specific treatment especially when Corticosteroid therapy is used.

**Introduction:** The effectiveness of colonoscopy is dependent on the quality of bowel preparation. There are multiple modifiable and nonmodifiable factors that affect the quality of bowel preparation. One recent systematic review and meta-analysis was conducted and showed that age, male sex, inpatient status, diabetes mellitus, hypertension, cirrhosis, opioid use, constipation, stroke, and tricyclic antidepressant (TCA) use were associated with inadequate bowel preparation.

However, information regarding risk factors for inadequate bowel preparation in inflammatory bowel disease (IBD) is scarce. In this population an adequate bowel preparation is particularly important for the evaluation of the endoscopic activity and for the screening of pre-malignant lesions through chromoendoscopy.

**Aims & Methods:** The aim of this study was to assess the quality of bowel preparation and the predictive factors for an inadequate bowel preparation in patients with IBD. A retrospective single-center analysis of patients with IBD who underwent colonoscopy between July 2017 and December 2018 was performed. Incomplete colonoscopy or colonoscopies performed in an emergency setting were excluded. Clinical and endoscopic activity in Crohn's Disease was assessed using the Harvey-Bradshaw Index (HBI) and the Simplified Endoscopic Score- Crohn's Disease and Rutgeerts, respectively. Clinical and endoscopic activity in Ulcerative Colitis was assessed using the Mayo score.

**Results:** 255 patients were evaluated, 51.4% male (n=131), with a mean age of  $46 \pm 15.1$  years-old. The median American Society of Anesthesiologists (ASA) score was 1 (IQR: 1-2) and the median duration of IBD was  $9.1 \pm 7.7$  years. Crohn's Disease was more prevalent 58% (n=148), and most of the patients were in clinical remission 68.2% (n=174) or under some medication 86.2% (n=220). Polyethylene glycol (PEG) was the main bowel preparation 40.8% (n=104) and 85.9% (n=219) had a previous nurse consultation. Bowel preparation was inadequate in 13.3% (n=34) of patients. In the univariate analysis, patients with poor bowel preparation had a higher proportion of a previous stroke (8.8% vs. 0.9%,  $p=0.002$ ), higher opioid use (8.8% vs. 0%,  $p < 0.01$ ), and had less frequently a nurse consultation (73.5% vs. 87.8%,  $p=0.03$ ). The bowel preparation was not associated with age, male sex, body mass index, active smoking, abdominal surgical history, diabetes mellitus, ASA score, disease duration, IBD type, IBD treatment, clinical and endoscopic activity, and type of bowel preparation. In the multivariate analysis, only a previous nurse consultation showed to be associated with an adequate bowel preparation ( $p=0.02$ ).

**Conclusion:** The quality measure of bowel preparation ( $\geq 90\%$ ) was not reached in this study. In this study, only a previous nurse consultation was shown to be associated with an adequate bowel preparation.

**Introduction:** Infliximab (IFX), adalimumab (ADL) and golimumab (GLM) are anti-TNF inhibitors of IgG1 class which do not cross the placenta until the 3rd trimester of the pregnancy; therefore, they are considered a safe treatment for the foetus during the 1<sup>st</sup> and 2<sup>nd</sup> trimester of the pregnancy. Infants born from IBD mothers exposed to anti-TNFs during this period of pregnancy did not exhibit higher rates of congenital abnormalities, early life infections, or any adverse events to early vaccinations. However, at usual dosing regimens blood levels of IFX are higher in pregnant compared to non-pregnant IBD female patients. Furthermore, IFX levels may be detected in the newborn's circulation despite cessation of IFX scheduled treatment in the mother before the 22<sup>nd</sup> week.

**Aims & Methods:** We aimed to assess the short and long-term effects of IFX, ADL and GLM on the maturation of the immune system, response to vaccinations and development of serious illnesses in offsprings of IBD females exposed to these anti-TNFs until the 26<sup>th</sup> week of pregnancy. Prospective, single center study. Data on somatic and mental development, serious illnesses, adverse events to vaccinations and general health state of children were recorded. The source of information was information from mothers, the child's health-book (a full record of child's somatic and mental development, vaccinations and any illness necessitating a visit to the family paediatrician or a hospital) and direct or phone contacts to the family paediatricians.

**Results:** Data were collected for 19 children (11 female) born from 14 mothers [7 with CD (3 after right hemicolectomy), 7 with UC (4 extensive, 3 left-sided disease)] on monotherapy with IFX (10), ADL (3), GLM (1) at conventional doses from the beginning of the pregnancy until between the 19<sup>th</sup> and 26<sup>th</sup> gestational week. Three women had conceived by in vitro fertiliza-

tion, and 4 women had  $>1$  pregnancy. Two women reported a prior spontaneous abortion. All infants were born full-term with normal somatometric data. At birth, low levels of IFX were measured in 3 children (1, 1.5 and 2  $\mu\text{g/ml}$ , respectively), whose mothers had stopped treatment at 24<sup>th</sup>, 26<sup>th</sup> and 19<sup>th</sup> gestational week, respectively. Levels of ADL and BLM were undetectable. All mothers resumed anti-TNF treatment after 1-3 months postpartum. 18/20 children received regular vaccinations uneventfully but 2/20 have not yet completed all vaccinations. 4/20 children were not breast-fed but only 1/4 for fear of anti-TNF treatment. 11/20 children are aged 3-10 years. None of these has developed any serious autoimmune, allergic, or malignant disease, and have responded satisfactorily to vaccinations and have normal rates of somatometric development.

**Conclusion:** In this small, single-centre, prospective study, treatment with IgG1-anti-TNF agents until the 26<sup>th</sup> gestational week does not seem to be related with later development, response to vaccinations, or any later adverse life events.

**Disclosure:** Nothing to disclose

## P1064 ASSOCIATION BETWEEN SERUM AND TISSUE PROTEIN PROFILES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: THE ASCERTAIN STUDY

**Introduction:** Molecular markers to facilitate personalized treatment of inflammatory bowel disease (IBD) are needed. Intestinal tissue might be the optimal matrix for biomarker discovery as the affected intestine contains high concentrations of inflammatory proteins. However, the use of tissue is limited due to the invasive nature of biopsy procurement. Therefore, matched validation of candidate markers in serum is an attractive approach.

**Aims & Methods:** The objectives of this study were to (i) investigate the correlation between the proteomic profile of intestinal biopsies and serum of patients with active IBD and (ii) to identify proteins that discriminate IBD from non-IBD and Crohn's disease (CD) from ulcerative colitis (UC). In this prospective multicentre cross-sectional study, consecutive IBD patients and controls were included between April 2017 and May 2018. Patients with IBD had active endoscopic disease defined by the presence of  $\geq 0.5$  cm in size in CD or an endoscopic Mayo score  $\geq 1$  in UC. Non-IBD controls were matched in age and had a normal colonoscopy. In all patients, five biopsies were procured. In CD patients, biopsies were taken from the edge of the most prominent ulcer. In UC, biopsies were taken from inflamed mucosa between 20-25 cm from the anal verge or the nearest inflamed region. In non-IBD controls, biopsies were taken between 20-25 cm from the anal verge. A predefined set of 92 inflammatory proteins was measured in both intestinal biopsies and serum using a proximity extension assay (OLINK, Uppsala, Sweden). Adjustments for multiplicity were performed using the Benjamini-Hochberg approach. Statistical significance was set at an adjusted  $P$  value  $< 0.05$ .

**Results:** In total, 41 patients with CD, 39 with UC and 10 controls were included. Forty-three (47.8%) patients were male and the mean (SD) age was 39.6 years (13.3). Median [IQR] CRP and faecal calprotectin values in IBD patients were 8.1 [4.2 - 22.3] (mg/L) and 452.5 [303.4 - 736.5] ( $\mu\text{g/g}$ ), respectively. Median SES-CD score [IQR] was 8 [5 - 13] in CD. In the UC group, 20 (51.3%), 16 (41%) and 3 (7.7%) patients had an endoscopic Mayo score of 3, 2 and 1, respectively. A significant positive correlation was observed between tissue and serum in IBD patients for IL17A ( $r = 0.44$ ), TGF- $\alpha$  ( $r = 0.42$ ) and IL6 ( $r = 0.39$ ). In serum, 29 proteins could discriminate IBD from controls (adjusted  $P < 0.05$ ) of which IL17A was most discriminative. No differences in protein abundance were observed between UC and CD in serum. In tissue, none of the proteins differed between IBD and controls after adjustment for multiple testing.

When comparing intestinal tissue between UC and CD, significantly higher concentrations of five distinct proteins were observed in UC (IL-17A, IL13, CCL4, LIF and CCL3) while the CCL25 level was higher in CD than in UC (adjusted  $P < 0.05$ ).

**Conclusion:** Of 92 inflammatory proteins, only IL17A, TGF- $\alpha$  and IL6 showed moderate positive correlation between tissue and serum. Twenty-nine serum proteins could discriminate between IBD and non-IBD. Six tissue proteins differentiated CD from UC. The most consistently implicated protein was IL17A. Overall, a poor correlation between tissue and serum proteomic profiles in IBD was found. Ongoing research will focus at the intestinal tissue transcriptome compared to circulating proteins.

**Introduction:** The possible role of histological activity in clinical management of Ulcerative Colitis (UC) is undefined.

**Aims & Methods:** In a prospective study, we aimed to assess the role of histological activity as a predictive marker of clinical relapse in a cohort of UC patients (pts) undergoing colonoscopy and followed up for 1 year (yr). Secondary aim was to assess in the same cohort of UC pts, the correlation between clinical, endoscopic and histological scores of activity. From Feb. 2016 to Feb. 2017, consecutive UC pts with clinical indication for colonoscopy were prospectively enrolled. Inclusion criteria:

- 1) Diagnosis of UC;
- 2) Age >18 and ≤80yrs;
- 3) Regular follow up;
- 4) Indication for colonoscopy;
- 5) Compliance to clinical follow up at 1 yr.

During colonoscopy ≥2 biopsies were taken from ≥1 macroscopically involved area and possibly, from ≥1 uninvolved area. All colonoscopies were performed by the same IBD-dedicated gastroenterologist. The day of colonoscopy clinical activity was assessed by the Mayo partial score (activity ≥3)(1), endoscopic activity by the Mayo endoscopic score (activity ≥2)(1). Histological activity was assessed by the same IBD-dedicated pathologist using the Geboes Simplified Score (GSS) for UC (activity ≥3.1)(2). Scores were blindly assessed by the 3 investigators. Data were expressed as mean

[range]. Spearman's correlation coefficients were used to investigate the association between different scores of activity. Cox proportional hazards regression model was used for both univariate and multivariate analyses to identify the predictors of clinical relapse at 1 year (Odds Ratio, OR [95% CI]).

**Results:** The study cohort included 77 UC pts with clinical, endoscopic and histological assessment at baseline, clinically followed up for 1 year. Clinical characteristics of the 77 UC pts: 43 M (55.8%); age 51 [24-80] yrs; UC duration 14.7 [1-48 yrs]. UC extent included (%): pancolitis in 33 (42.8%), left sided in 24 (31.2%), proctitis in 20 (26%) pts. The day of colonoscopy UC was clinically active in 15 (19.4%), inactive in 62 (80.6%) pts. Endoscopic activity was observed in 39 (50.6%) pts and histological activity (GSS ≥ 3.1) in 37 (48%) pts; 5 of these 37 pts were in endoscopic remission. Moderate correlations were observed between clinical and endoscopic scores ( $r=0.439$ ;  $p<0.0001$ ), clinical and histological scores ( $r=0.32$ ;  $p=0.0045$ ), endoscopic and histological scores ( $r=0.653$ ;  $p<0.0001$ ). During the clinical follow at 1 yr, clinical relapse of UC occurred in 24 (31%) pts while 53 (69%) pts maintained clinical remission. At baseline 11 out of 24 (46%) UC pts were clinically active, 15 out of 24 (63%) pts showed endoscopic activity, and 16 out of 24 (67%) pts histological activity. Among the 5 pts showing endoscopic remission and histological activity at baseline, 1 pt developed clinical relapse within 1 yr. Univariate analysis identified clinical activity (OR 4.82 [2.15-10.82];  $p<0.001$ ) and histological activity (OR 2.599 [1.11-6.08];  $p<0.027$ ) as predictive factors for clinical relapse at 1 yr. The multivariate model retained only histological activity as predictive marker of clinical relapse (OR 2.44 [1.04-5.75];  $p<0.041$ ). We estimated that, after controlling for age and gender, pts with histological activity (GSS ≥ 3.1) have 2.44 fold risk of clinical relapse at 1 yr compared to pts with histological remission (GSS < 3.1).

**Conclusion:** Histological activity provided independent information for clinical relapse in a cohort of UC patients prospectively followed up for 1 year. Histological activity had a moderate correlation with the endoscopic and clinical activities.

**Introduction:** Among immunocompromised patients who respond to the HBV vaccine, clinically significant HBV infection has been documented in those who do not maintain anti-HBs concentrations > 10 IU/L.

**Aims & Methods:**

- 1) To understand the kinetics of the anti-HBs titers over time in IBD patients who have initially responded to the vaccination.
- 2) To identify predictive factors of negativization of anti-HBs titers over time.

This multicenter study included IBD patients vaccinated in the COMVI-B trial (EUDRA-CT number: 2010-023947-14), where patients with negative HBV serology and without previous vaccination against HBV were randomized 1:1 to receive Fendrix® or double doses of Engerix® at months 0, 1, 2 and 6. Patients with anti-HBs > 10 IU/L 2 months after the 4<sup>th</sup> dose were followed-up. Anti-HBs titers were then measured at 6 and 12 months. When anti-HBs titers were < 10 IU/L during the follow-up, they were considered negatives. Long-term maintenance of positive anti-HBs titers was

estimated using Kaplan-Meier curves. Cox-regression analysis was performed to identify potential predictive factors for losing anti-HBs protective titers during follow-up.

**Results:** A total of 131 patients had anti-HBs  $\geq 10$  IU/L after completing vaccination; from them, 117 patients (90%) accepted to be included in the follow-up study. From those, 55% were male, 54% had ulcerative colitis and 90% had anti-HBs  $\geq 100$  IU/L after vaccination. With respect to IBD treatments, 2.6% received solely steroids during follow-up, 29% immunomodulators in monotherapy, 15.4 anti-TNF in monotherapy and 19% combo therapy (immunomodulators plus anti-TNF agents). Fifty percent of patients received each of the vaccines (Engerix® or Fendrix®). There were no differences in the main characteristics (age, anti-HBs concentration after complete vaccination or IBD treatment) between the study groups (Engerix® or Fendrix®) but the proportion of patients exposed to anti-TNF was superior among patients vaccinated with Fendrix® (43 vs. 25%,  $p < 0.04$ ). The cumulative incidence of negativization of the anti-HBs titers was 13% after 6 months and 20% after 12 months of follow-up. In the multivariate analysis, to have had anti-HBs  $\geq 100$  IU/L (vs.  $< 100$  IU/L) after the vaccination was the only factor that was associated with a higher probability of maintaining anti-HBs titers during the follow-up (HR=9.8, 95%CI=4-23,  $p < 0.0001$ ). The type of vaccine administered, patient's age or immunosuppressive treatment during follow-up were not associated with the risk of negativization of anti-HBs titers.

**Conclusion:** A high proportion of IBD patients with protective anti-HBs titers after vaccination loose them over time (20% of patients after 1 year). The risk of losing protective anti-HBs titers is dramatically increased in patients achieving anti-HBs below 100 IU/L after the vaccination. Thus, anti-HBs  $> 100$  IU/L should be the threshold to consider HBV vaccination success in IBD patients. Once the patient has responded to the vaccine, patient's age or immunosuppressive treatment during follow-up seems to have no impact on the maintenance of anti-HBs titers.

**Contact E-Mail Address:** marie-munk@gmx.de

**Introduction:** Inflammatory bowel disease (IBD) is a chronic destructive disorder deteriorating the functional status of the affected patients.

**Aims & Methods:** The aim of our study was to test a new tool for measuring patient-reported outcomes, the IBD Disk invented to assess disability in patients with IBD under biological treatment. Patients attending the outpatient clinic were administered the self-completion 10-item visual scale of IBD Disk. Features of interest included abdominal pain, body image, education and work, emotions, energy, interpersonal interactions, joint pain, regulating defecation, sexual functions, and sleeping. Disease activity scores (CDAI or Mayo) were assessed by the treating physician.

**Results:** In total, 90 patients with IBD were evaluated (75 and 15 cases of Crohn's disease [CD] and ulcerative colitis [UC], respectively). The IBD Disk total score in CD was higher for active disease (score of  $49.5 \pm 27.7$  compared to  $25.5 \pm 19.5$  for inactive disease,  $p = 0.013$ ) and for female gender ( $32.6 \pm 23.8$  vs  $24.0 \pm 19.9$  for men;  $p = 0.08$ ). There was a significant, positive correlation of moderate strength between IBD Disk total score and disease activity ( $\rho = 0.521$ ;  $p = 0.023$ ), while the score showed no association with age, disease duration, concomitant disease and previous surgeries. Interestingly, patients with inactive disease ( $n = 54$ ) had severe ( $> 50$ ) or marked (31-50) disability (13% and 9.3%, respectively). The highest scores were achieved in the subgroups evaluating energy, body image, and emotions ( $4.5 \pm 2.8$ ,  $3.6 \pm 3.1$  and  $3.3 \pm 3.0$ , respectively).

**Conclusion:** IBD Disk was easy to administer in everyday practice while the application of the score allowed the rapid and representative assessment of patients' health-related quality of life.

**Introduction:** Even though it is known that fecal calprotectin levels correlate with inflammatory activity in inflammatory bowel disease (IBD) patients, some limitations were described, including fecal collection, sample delivery and processing (Meuwis 2013), high within-day variability (Lassan 2014) and the subsequent uncertainties on the optimal time for sampling (Calafat 2015). Recently, some authors proposed that serum calprotectin may be useful in disease activity evaluation in rheumatologic patients (Hammer 2010). Accordingly, we measured serum calprotectin levels in IBD patients in comparison with both patients with irritable bowel syndrome (IBS) and healthy volunteers, in order to test whether this blood biomarker could separate organic from functional disorders.

**Aims & Methods:** We enrolled 21 Crohn's disease (CD), 14 ulcerative colitis (UC) and 22 IBS patients as well as 20 healthy volunteers, comparable for age and gender (30 Females, age  $35 \pm 6$  yrs). We selected 18 patients in remission (10 CD and 8 UC), 7 mildly active (4 CD and 3 UC), 9 moderately active (7 CD and 2 UC) and 1 severely active (UC), according to Harvey-Bradshaw index for CD and partial Mayo score for RCU. Serum calprotectin was determined for each patient, after an overnight fast (Calprest, Eurospital, Italy). Fecal calprotectin was also measured, by means of ELISA test.

**Results:** As expected, after a logarithmic transformation, in IBD patients serum calprotectin levels were significantly higher than in IBS patients (1.37 mg/ml; 95% confidence interval (IC) 0.86-2.1 mg/ml in IBS vs 4.54 mg/ml 95%IC 2.09-7.1 mg/ml in IBD;  $p < 0.001$ ) and healthy volunteers (1.15 mg/ml; 95% IC 0.87-1.5 mg/ml in healthy volunteers vs 4.54 mg/ml 95%IC 2.09-7.1 mg/ml in IBD;  $p < 0.001$ ). Building a ROC curve, we could identify 2.42 mg/ml as the threshold level to distinguish IBS from IBD (area under the ROC curve 0.8;  $P < 0.001$ ) with 67% sensitivity and 88% specificity. There was no correlation between fecal and serum calprotectin nor in the whole sample, nor in the different groups. We found no significant difference between serum calprotectin level among UC and CD patients.

**Conclusion:** The results of our study suggest that serum calprotectin could be a promising biomarker providing an accurate separation between IBD patients and IBS or healthy patients. The lack of correlation between fecal and serum calprotectin levels suggests that in the future this new biomarker could improve the accuracy of IBD diagnosis: in patients with abdominal symptoms of unknown origin, the combination of fecal and serum calprotectin could be helpful in identify those patients who need invasive procedures.

Moreover, in IBD serum calprotectin seems not to be influenced by the site of the disease involvement, suggesting its potential role in monitoring IBD patients.

## P1069 FAECAL CALPROTECTIN LEVELS IN LYMPHOCYTIC AND COLLAGENOUS COLITIS

Cooney J., Naughton T., Hanna M.  
University Hospital Lewisham, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** josephcooney@doctors.org.uk

**Introduction:** Microscopic colitis (MC) is comprised of lymphocytic (LC) and collagenous (CC) subtypes, and its diagnosis is dependent on clinical symptoms of chronic watery diarrhea in addition to well-defined histological criteria [1]. Faecal calprotectin (FC) is known to be a useful non-invasive biomarker in the investigation of inflammatory bowel disease [2] but there are few published data describing FC in MC.

Previous small studies have shown that FC is elevated in 73% MC [1] and that in active CC the median FC is 48-80 µg/g [3, 2], but to the best of our knowledge no previous studies have assessed FC in LC and CC comparatively.

**Aims & Methods:** The two main objectives of our study were to establish whether faecal calprotectin levels are elevated in microscopic colitis and if there is a difference between faecal calprotectin levels in microscopic and lymphocytic colitis.

Electronic patient records were reviewed from our hospital to obtain FC levels measured at the time of diagnosis, for all patients with a histological diagnosis of MC between 01/01/2014 and 06/10/2017. Median and range FC levels were calculated for CC and LC as well as MC overall. The Mann-Whitney U-test was used to ascertain whether there was a difference between FC level in CC and LC, with a p < 0.05 considered to be statistically significant. FC level of > 16 µg/g was considered to be elevated.

**Results:** 70 patients had a histological diagnosis of MC between 01/01/2014 and 06/10/2017; 25/70 (36%) had FC checked at diagnosis. The average age was 60 years for LC (range 29-88 years, 4 male: 11 female), and 75 years for CC (range 50-89 years, 1 male: 9 female). 20 of these 25 patients with MC (80%) had an elevated FC, while 5 (20%) patients had a faecal calprotectin level of < 16. Table 1 shows median and range FC in LC and CC independently, and also in LC and CC combined (microscopic colitis overall).

	LC	CC	Microscopic colitis overall (LC and CC combined)
Number of patients	40	30	70
Number of patients with FC tested	15	10	25
Median FC (µg/g)	63	324	148
Range FC (µg/g)	<16 to 476	86 to >1800	<16 to >1800

[Table 1]

The Median FC in Microscopic colitis overall was elevated at 148 µg/g. The Median FC was 324 µg/g for CC and 63 µg/g for LC, which showed statistical significance using Mann-Whitney U-test (p = 0.01078)

**Conclusion:** This has been the first study to compare faecal calprotectin values in Collagenous and Lymphocytic colitis. This showed a statistically significant difference towards higher levels of FC in collagenous colitis. The main reasons for the higher calprotectin level in CC are unclear, but as faecal calprotectin is a predominantly a marker of neutrophils [4] and as damage to the surface epithelium has been shown to be more common and pronounced in collagenous colitis compared to lymphocytes [5], this could be a possible explanation.

In addition, FC was elevated in 80% of patients with MC suggesting a correlation between calprotectin levels and microscopic colitis. However, it is noteworthy that the 20% of patients in our cohort had undetectable calprotectin indicating that faecal calprotectin alone is insufficient to exclude microscopic colitis and should be used in conjunction with lower GI endoscopy and colonic biopsies, in particular in cases with a high index of clinical suspicion of microscopic colitis.

<sup>1</sup>Pennine Acute Hospitals Trust, Gastroenterology, Manchester, United Kingdom, <sup>2</sup>Blackpool Victoria Hospital, Gastroenterology, Blackpool, United Kingdom, <sup>3</sup>Pennine Acute NHS Trust, Gastroenterology, Bury, United Kingdom, <sup>4</sup>Manchester University, Institute of Inflammation and Repair, Manchester, United Kingdom, <sup>5</sup>Manchester Metropolitan University, Gastroenterology, Manchester, United Kingdom

**Contact E-Mail Address:** anirudh.bhandare@nhs.net

**Introduction:** The UK Bowel Cancer Screening Programme (BCSP) was launched in 2006 to cover the population of England and Wales. It screens individuals aged 60-69 years with a Faecal Occult Blood test (FOBT) followed by a screening colonoscopy if FOBT positive. We report 7-year follow up of our cohort of patients with an incidental ("asymptomatic") diagnosis of IBD first reported in 2011.

**Aims & Methods:** We report 7-year follow up of our cohort of patients with an incidental ("asymptomatic") diagnosis of IBD first reported in 2011. A retrospective review of BCSP outcomes was conducted at our centre from its launch in 2008 until 2011. Screening data included the number of patients invited, number screened (FOBT outcome "normal" or "abnormal") and number of colonoscopies performed. Of 136,811 patients invited, 67,485 were screened (uptake of 49.33%; FOBT positivity 2.02%). Colonoscopy was performed in 1401 patients (female 523), polyps detected in 630 (41.37%), cancer in 134 (8.80%) and 469 (30.79%) had a normal exam. Of 16 patients diagnosed with IBD and confirmed at histology, clinical data including demographics, disease characteristics, treatment and outcomes were recorded and follow-up data is presented until 31 May 2018.

**Results:** Of 16 patients, 2 died from metastatic prostate cancer and post-operative complications following colectomy. One patient was lost to follow up.

11/13 patients had UC (E1=3, E2=5, E3=3) and 3 patients had Crohn's disease (A3L2B1).

At last follow up, 2 patients with E1 UC progressed to E2 and E3 disease respectively. CD phenotype did not change.

9 of 11 patients with UC were in clinical remission and 2 patients had active disease (pMayo 3 and 4 respectively) and received anti-TNF therapy. All 3 patients with CD remained in clinical remission. Of 11 UC patients, 8 continued 5-ASA therapy, 1 received Vedolizumab (following antibody mediated loss of response to anti-TNF), 1 patient received anti-TNF with Methotrexate and another is on no treatment and in clinical remission. In the CD cohort (n=3), 2 patients were on Adalimumab monotherapy, and 1 on 6-Mercaptopurine.

**Conclusion:** An incidental diagnosis of IBD is not uncommon. With the advent of endoscopic bowel cancer screening this number is set to increase. Incidental IBD appears to follow an indolent course over age 60 with a stable disease phenotype. This subset of patients may present an important model for study of early disease providing novel insights into disease pathogenesis and evolving treatment paradigms.

**Introduction:** Thiopurines (TPs) are frequently used as monotherapy to maintain remission in patients with inflammatory bowel disease (IBD). The red-cell 6-Thioguanine Nucleotide (6-TGN) biomarker is commonly measured to guide dosing. While there is scanty prospective data to support 6-TGN-directed therapy, efficacy is inferred from observed rates of remission in patients with higher levels, but the link between TP dose and TGN level is not clear [1,2].

**Aims & Methods:** The aim of our study was to determine the value of 6-TGN measurements in predicting treatment escalation in patients with IBD on azathioprine monotherapy at 12 months post treatment initiation, in whom the dose was not modified during the aforementioned period.

We carried out a retrospective review of all IBD patients initiated on azathioprine monotherapy between December 2010 and July 2018, at a single specialist centre in the UK. Electronic patient records were used to collect: sampling date, Sex, Age, 6-TGN result (between 2-6 months post treatment initiation), MMP, MMP:TGN Ratio, Azathioprine dose (Mg), Weight (Kg), Azathioprine dose per kilo (Mg/Kg), disease, previous medications, adverse events, and treatment escalation. Treatment escalation was defined as the addition of a steroid, 5-ASA, biologic, or surgery within 12 months of azathioprine treatment initiation.

A series of hierarchical regression experiments was carried out based on a probabilistic prediction framework, described in detail elsewhere [3,4]. In effect, variables were added in sequence to determine whether they improve the out-of-sample probabilistic prediction error (i.e. brier score) of a linear regression model with a logit-link function. 95% confidence intervals for each of the aforementioned performance metrics were calculated using a Jackknife estimator of variance algorithm. Statistical significance assessed using the Wilcoxon signed-rank test, with the significance threshold set at 5%. All predictive modelling was performed using the *R* (v 3.2.0) statistical software suite and the *mlr* (v 2.7) machine learning library.

**Results:** 298 individuals were identified that met the inclusion criteria (139F; mean age 36.1±14.0y; 152 UC; 146 CD). Median azathioprine dose was 125mg (Range: 25 - 250), and median weight-adjusted dose was 1.83 mg/kg (Range: 0.3 - 3.2). Median TGN response was 313.5 (Range: 5 - 1.705). Using demographic data (i.e. sex, age, weight, diagnosis, and previous medications) as a baseline model, the resulting Brier score was 0.183 (S.E. 0.039).

**Conclusion:** This study is one of the largest retrospective studies [1] examining the efficacy of TGN monitoring in azathioprine monotherapy. The results suggest that metabolite data, including both TGN and MMP, does not appear to contain any additional information about the probability of requiring treatment escalation at 12 months above that of demographic information. Given the contradictory evidence in the literature, definitively recommending a 6-TGN-based dose-optimisation strategy would require prospective study.

**Contact E-Mail Address:** farrag@gmx.de

**Introduction:** Iron deficiency and iron deficiency anemia are the most common extra-intestinal manifestations of chronic inflammatory bowel disease (IBD), significantly impairing patient's quality of life. Since the diagnostic value of ferritin as an acute phase protein (aPP) in IBD is therefore limited<sup>1</sup>, the simultaneous determination of the C-reactive protein (CRP) is recommended for interpretation in the context of inflammation<sup>2</sup>. Since the CRP and ferritin have distinctly different half-lives, the WHO recommends α<sub>1</sub>-acid glycoprotein (AGP) as a second biomarker<sup>3</sup>.

**Aims & Methods:** The aim of our study was therefore for the first time to interpret the inflammatory increase of ferritin in IBD patients by CRP and AGP, individually and in combination.

By 03/2019, 118 IBD patients (45.48 ± 15.25 years, 47.46% f.) (38 with Crohn's disease, 47 with ulcerative colitis, 33 controls) were enrolled. In addition to the Hb value, ferritin (cut-off 30 µg/mL), CRP (cut-off 5 mg/L) and AGP (cut-off > 0.65 g/L) were determined in all patients.

**Results:** When CRP alone was used, 29.76% (25/84) had an inflammatory increase in ferritin, and 82.14% (69/84; p < 0.05) when using AGP or both. Increased AGP levels were more common in patients with ulcerative colitis (60 vs. 11.11%) than in patients with Crohn's disease (57.63 vs. 32.20%) compared to elevated CRP levels. Serum ferritin levels correlate with CRP (0.420 p = 0.002), but not with (0.022, p = 0.876).

There was no specific correlation between CRP and AGP (0.098, p = 0.487). The assumption that most patients with high CRP levels also have high AGP concentrations and vice versa was confirmed by our data only in 55% of cases.

There were 11 patients with complete iron deficiency when CRP alone was used, 18 patients with functional iron deficiency, one with chronic anemia (ACI) and one with mixed-type anemia. Functional iron deficiency was found in 28 patients using CRP and/or AGP (+ 55%, p < 0.05) and 5 patients had ACI (according to (4)).

**Conclusion:** Our data underline the problem of determining ferritin also with the aid of CRP in the diagnosis of iron deficiency in IBD. We were able to demonstrate that the determination of CRP and/or AGP significantly improves the diagnostic accuracy of serum ferritin levels in IBD patients.

**Introduction:** Ulcerative colitis patients with endoscopic mucosal healing by white light endoscopy may still have histologic inflammation. Electronic chromoendoscopy (PicaSSO-Paddington International Virtual Chromoendoscopy ScOre)<sup>1</sup> may better predict mucosal healing. We investigated the

relationship between mucosal healing (MH) defined by PICaSSO, and histological index (RHI). We specifically explored the magnitude of difference between endoscopy and histology defined mucosal healing using refined endoscopic assessments.

**Aims & Methods:** A prospective study enrolling 82 UC patients (M 66%) was conducted. Mayo subscore (MES), PICaSSO mucosal and vascular endoscopic score were recorded. High definition electronic virtual chromoendoscopy was used in all patients. Histological score (Robarts histopathology index-RHI) was used to score histological inflammation. Receiver operating characteristic (ROC) curves were plotted to determine the best cut-off threshold for PICaSSO scores that predicted histological healing according to the RHI. We then validated the PICaSSO score against histology (RHI) in an independent cohort of 70 UC patients (M 52%); and sensitivity, specificity, and accuracy were calculated.

**Results:** A PICaSSO of  $\leq 4$  predicted histological healing at RHI  $\leq 6$ , with accuracy of 92.8% (95% CI: 84.8, 97.3). The accuracy of MES in predicting histological healing with RHI was inferior at 84.2% (95% CI: 74.4, 91.2). The corresponding AUROCs were 98.9% (95% CI: 97.6, 100) and 92.0% (95% CI: 85.9, 98.6) respectively.

In the validation cohort, PICaSSO  $\leq 4$  predicted histological healing at RHI  $\leq 6$  with sensitivity 96.6% (95%CI 82.2-99.9), specificity 68.3% (95%CI 51.9-81.9) and accuracy 80.0% (95%CI 68.7-88.6). PICaSSO  $\leq 3$  predicted histological healing by RHI with sensitivity 96.6% (95%CI 82.2-99.9), specificity 92.7% (95%CI 80.1-98.5) and accuracy 94.3%.

**Conclusion:** The histological healing by RHI is accurately predicted by PICaSSO at threshold values of  $\leq 3$  in a validation cohort of UC patients. Advanced electronic endoscopic techniques are able to predict histologically proven MH with high accuracy. Large prospective studies are necessary to ascertain whether, with new endoscopic technologies such as readily available VCE, histology can still provide additional information about course of UC.

## P1074 THE REAL WORLD USE OF FECAL CALPROTECTIN HOME TESTING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER MAINTENANCE TREATMENT WITH ADALIMUMAB

Orfanoudaki E., Theodoraki E., Foteinogiannopoulou K., Mantaka A., Koutroubakis I.  
*University Hospital of Heraklion, Gastroenterology, Heraklion, Greece*

**Contact E-Mail Address:** elina\_or@yahoo.gr

**Introduction:** Fecal calprotectin (FC) has been suggested as an important biomarker for the management of patients with inflammatory bowel disease (IBD). It is an indirect index of disease activity and plays a crucial role in the treat-to-target strategy. Consecutive measurements of FC in patients in clinical remission can predict a disease relapse and lead to an early treatment optimization. We aimed to present our real world experience using the FC home testing in the management of IBD patients under maintenance treatment with adalimumab.

**Aims & Methods:** Consecutive IBD patients under maintenance treatment with adalimumab were studied retrospectively based on prospectively recorded data in a registry. The study period was from 10/2016 until 3/2019. Inclusion criteria was at least one available FC measurement (ELISA, Bühlmann fCAL Home test). During this period patients' compliance in the FC home test as well as all the treatment modifications including adalimumab intensification, change of biologic agent or IBD related surgical intervention were assessed.

**Results:** From a total of 72 IBD patients under maintenance treatment with adalimumab, 63 (87.5%) who had good compliance performing the home FC test [median number of measurements 3 (1-10)] and complete follow-up data were included in the study. Patient characteristics are presented in Table 1. In 21 of them (33.3%) treatment modification (10 adalimumab intensification, 1 de-escalation, 8 change to other biologic agent, 2 surgeries) has become necessary during the study period based on the evaluation of consecutive values of FC (mean FC value 718  $\mu\text{g/g}$   $\pm 314$ , 45% of pts had values  $>1000 \mu\text{g/g}$ ), mostly after endoscopic confirmation of disease flare (18/21). The rest 42 patients who remained on stable treatment had mean FC levels 272  $\mu\text{g/g}$   $\pm 236$ , (57.1% of them had values  $< 250 \mu\text{g/g}$ ) sig-

nificantly lower than the first group  $p < 0.0001$ . Twenty three out of these 42 patients underwent a colonoscopy and mucosal healing was confirmed in 7/23 (30.4%) while FC was  $< 50 \mu\text{g/g}$  in 9/23 (39.1%).

**Conclusion:** The IBD patients' compliance rate of performing the FC home test is high (87.5%). Moreover, our results confirm the important role of consecutive FC measurements at home, in combination with the endoscopic evaluation for the optimization of treatment in IBD patients receiving maintenance treatment with adalimumab.

**Introduction:** Digestive Endoscopy, besides the diagnosis and surveillance of ulcerative colitis (UC), is also interesting to establish the severity of the disease by using the UCEIS score which assess vascular pattern, bleeding, and ulcers.

**Aims & Methods:** The purpose of our work is to demonstrate the items of the score that are most associated to the severity of the flare-ups. This is a retrospective study conducted from January 2013 to January 2018 including 480 patients with UC. The endoscopic severity was assessed by UCEIS score and the clinical activity by the Modified Truelove & Witts score. The statistical study was performed using SPSS20.0. A logistic regression analysis was performed as multivariate analysis. The binary dependent variable is the severe flare-up and the independent variables were the 3 items of UCEIS score. Statistical significance was established at  $p$  values of less than 0.05

**Results:** The clinical assessment revealed that the flare-ups were mild in 22.08%, moderate in 48.05% and severe in 28.57%. The study of the 3 items of UCEIS score revealed a patchy obliteration vascular pattern in 66.23%, obliterated in 27.27%, and normal in 6.49%, bleeding was absent

in 46.8%, mucosal in 42.9%, luminal mild in 37.7% and luminal severe in 1.3%, ulcers were absent in 18.2%, < 5mm in 37.7%, > 5mm in 19.5% and deep in 24.7%. Thus, the UCEIS score was as followed 6.5% were in remission, 33.8% were in mild, 49.4% were moderate, 3.9% were severe. The multivariate logistic regression analysis revealed that vascular pattern and the presence of ulcers were significantly associated and predictive of severe flare-ups (p=0.038, 0.049 respectively).

**Conclusion:** By studying and analyzing the UCEIS score, vascular pattern and the presence of erosions/ulcers are the items associated and predicting the clinical severity of the flare-ups.

**Disclosure:** Nothing to disclose

## P1076 EVALUATION OF PAIRED AND SEPARATED ENDOSCOPIC READS AT BASELINE AND WEEK 14 IN THE EXPLORATORY BERGAMOT INDUCTION COHORT

**Contact E-Mail Address:** oh.young@gene.com

**Introduction:** Treatment guidelines recommend that Crohn's disease evaluation and treatment decisions should include endoscopic evaluation in conjunction with clinical and laboratory assessment (1,2). Previous work found that an adjudicated central read model (CRM) for evaluating Simple Endoscopic Score for Crohn's Disease (SES-CD) that included a local reader and at least 1 central reader reduced placebo rates, variability and increased treatment response rates versus single reader models (3). This study explored the impact on scoring by blinded reading of paired endoscopic reads versus unpaired reads scored by the CRM model.

**Aims & Methods:** To compare the total SES-CD as evaluated by paired readings of the week 0 and week 14 endoscopies (i.e. simultaneous assessment of pre- and post-induction treatment endoscopic videos) by the same central reader versus scores based on unpaired readings by the CRM. Patients in this analysis (n = 63) were a random subset from the exploratory BERGAMOT induction cohort, who were randomised 2:2:1 to receive subcutaneous etrolizumab 105 mg every 4 weeks (with placebo at week 2; n = 24); etrolizumab 210 mg at weeks 0, 2, 4, 8, and 12 (n = 24); or placebo (n = 15). Three central readers performed the paired endoscopy readings. The unpaired reads were evaluated using the CRM and included a pre-defined sliding threshold to trigger adjudication of discordant scores by a second central reader as reported previously. All readers were blinded to treatment arm, timing of the endoscopy, and the other reader's assessments.

**Results:** In the overall population, 48% had ileo-colonic disease, 30% had colonic disease and 22% had disease restricted to the ileum. Prior treatment for Crohn's disease included anti-TNFs (73%), oral corticosteroids (49%), or non-biologic immunosuppressants (27%). In general, the mean baseline and week 14 SES-CD evaluated by the paired read model were higher than those assigned by the CRM. Differences between models in assigning categorical thresholds were more varied (Table). The placebo rates of ≥50% SES-CD decrease from baseline, SES-CD ≤ 4, and SES-CD ≤ 2 were similarly low (0%-6.7%) with either the unpaired CRM or the paired endoscopy model. More patients achieved ≥50% SES-CD decrease from baseline with etrolizumab treatment using the CRM compared to the paired read model (21% vs 13%, respectively).

	Placebo n = 15		Etrolizumab 105 mg n = 24		Etrolizumab 210 mg n = 24		Etrolizumab 105 mg and 210 mg n = 48	
	Paired	CRM	Paired	CRM	Paired	CRM	Paired	CRM
≥50% decrease from baseline at week 14	0	0	3 (13%)	5 (21%)	3 (13%)	5 (21%)	6 (13%)	10 (21%)

[Table. SES-CD ≥ 50% decrease from baseline at week 14 by paired and unpaired (CRM) endoscopic read models.]

**Conclusion:** Based on data generated by experienced central readers in a small subset of patients, both paired and unpaired central reading of CD endoscopic videos resulted in very low placebo response rates. However, unpaired central reading resulted in increased treatment response rates compared to a paired read paradigm.

## P1077 STATUS OF SERUM VITAMIN B<sub>12</sub> IN PATIENTS WITH CROHN'S DISEASE

Ben Mohamed A., Mouelhi L., Ayadi S., Zaimi Y., Jery K., Said Y., Kheher S., Salem M., Debbeche R.

Faculty of Medicine, Tunis, Tunisia

**Contact E-Mail Address:** asmabenmed2014@gmail.com

**Introduction:** Vitamin B12 is an essential vitamin for hematopoiesis. Its absorption mainly occurs at the terminal ileum. Crohn's disease (CD) primarily involves the intestinal tract and can affect vitamin absorption. This study was designed to assess the prevalence of vitamin B<sub>12</sub> deficiency in patients with CD, and to identify the risk factors associated with abnormal serum vitamin B<sub>12</sub> levels.

**Aims & Methods:** Aim of the work: Evaluate plasma vitamin B12 level in patients with Crohn's and identify risk factors for any vitamin B12 deficiency. It was a descriptive and cross-sectional study successively enrolling over a period of 3 months (from May 2015 to November 2015) all patients with Crohn's disease. Standard blood tests together with determination of serum vitamin B12 concentration were performed at baseline.

**Results:** In multivariate analysis, a terminal ileum resection segment length >50 cm and both penetrating and stricturing behavior were the independent predictive factor for vitamin B12 deficiency in these patients. Eighty-eight patients were included with a median age of 42.45 ± 13.81 years and a sex ratio of 0.87. Crohn's disease was located at the ileum in 30% of patients, the ileum and right colon in 40% of cases. CD was inflammatory in 41% of cases, stenosing in 35% of cases, penetrating in 6% of cases and both stenosing and penetrating in 18% of cases. Forty nine percent of patients were treated by azathiopurin, 7% by anti TNF α and 13% by combination therapy.

The rate of intestinal resection was 42%. Ileal resection was noted in 37% of cases with an average resection length of 35.73 ± 20.79 cm [4-115 cm]. Nine patients had an extended resection (>50 cm). Vitamin B12 levels were normal (≥ 200 ng/L) in 69 patients (78%) and decreased (< 200 ng/L) in 19 patients (22%). Clinically, no patient with vitamin B12 deficiency showed clinical signs of vitamin B12 deficiency.

In univariate analysis, a resection segment length >50 cm (p=0.012; HR=9.06; 95% CI [1.62-50.60]) and both penetrating and stricturing behavior (p=0.002, HR= 7.59; 95% CI [2.15-26.79]) were significantly associated with vitamin B12 deficiency. However, vitamin B12 deficiency was inversely associated with the inflammatory behavior (p=0.002, HR=0.12, 95% CI [0.026-0.056]) and the history of corticosteroid therapy (p=0.004, HR=0.32; 95% CI [0.10-1.00]).

**Conclusion:** Vitamin B12 deficiency in Crohn's disease patients is quite common (22%). Only a terminal ileum resection segment length over 50 cm and both penetrating and stricturing behavior predispose to vitamin B12 deficiency. Annual monitoring of serum vitamin B12 or preferably holotranscobalamin II in these patients will detect deficient patients, which should be supplemented with vitamin B12.

## **P1078 THE ROLE OF SMALL BOWEL CAPSULE ENDOSCOPY IN DIAGNOSIS AND MONITORING OF CROHN'S DISEASES VERSUS RADIOLOGICAL INVESTIGATIONS: A DISTRICT HOSPITAL EXPERIENCE**

Mir N.<sup>1</sup>, Anjum M.R.<sup>1</sup>, Rafique H.<sup>2</sup>, Shah A.<sup>1</sup>, Perry I.<sup>3</sup>

<sup>1</sup>The Royal Wolverhampton NHS Trust, Gastroenterology, Wolverhampton, United Kingdom, <sup>2</sup>The Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom, <sup>3</sup>The Royal Wolverhampton NHS Trust, Gastroenterology, WOLVERHAMPTON, United Kingdom

**Contact E-Mail Address:** nmir887@gmail.com

**Introduction:** A single gold standard for the diagnosis of CD is not available. In clinical practice, it is diagnosed by clinical evaluation and a combination of endoscopic, histological, radiological and biochemical investigations. Studies have explored the role of small bowel capsule endoscopy (SBCE) in diagnosing Crohn's disease. We collected the data retrospectively of patients at Royal Wolverhampton NHS Trust to analyze local data of Crohn's patients and the sensitivity of SBCE versus radiology to diagnose small bowel Crohn's.

**Aims & Methods:** We carried this study retrospectively based on data over 3 years period (2014-2017) of patients enrolled at The Royal Wolverhampton NHS Trust. Retrospective data was collected from SBCE data base, which included 90 cases. Cases were identified further who had been diagnosed with small bowel Crohn's disease either based on the results, or who had capsule for prognostic values/monitoring of established Crohn's disease. Further stratification gave us cohort of 90 patients who had both SBCE and some form of radiological investigation done for same symptoms, namely: Computed tomography (CT) Scan, CT Enterography (CTE), CT Colonography (CTC), Magnetic Resonance Enterography (MRE). Data was tabulated, and analysis was done using SPSS v20.

**Results:** Total 59 patients were included in the study. 38 (64.4%) were female and 21 (35.6%) were males. Age range was from 18 to 79 years with a median age of 45 years. 36 (61%) were diagnosed as new diagnosis of Crohn's disease while 23 (39%) had established diagnosis but underwent investigations based of ongoing symptoms. Except for 4 patients, rest had colonoscopy as initial investigations. Out of these 4, two were diagnosed many years ago and report couldn't be chased, while other two had new diagnosis of Crohn's, but refused colonoscopy. Frequency of radiological investigations done was follows: CT 15 (25.4%), CTC 5 (8.5%), CTE 2 (3.4%), MRE 37 (62.7%). Decision about different investigations was dictated by urgency of situation. CTC was done as initial test in patients who described mainly large bowel symptoms. Out of 59 patients, 17 (28.8%) had evidence of small bowel inflammation on both SBCE and radiology. In 2 (3.4%), diagnosis of Crohn's was made on radiology while SBCE was non-diagnostic (1 established Crohn's patient, 1 new diagnosis of Crohn's). In 40 (67.8%) patients, SBCE was diagnostic while radiology was non-diagnostic. SBCE had sensitivity of 96.61% while radiology had sensitivity of 32.20% in our study population.

**Conclusion:** SBCE and radiology are complementary methods for diagnosing small bowel Crohn's disease. In our study, SBCE has shown better sensitivity in diagnosing small bowel Crohn's disease as compared to radiology.

## **P1079 SPECIALIST PHARMACIST LED IMMUNOMODULATOR SERVICE REVIEW - 1 YEAR OUTCOME IN A UK DISTRICT HOSPITAL**

Richards A., Daughney R., Henshall A., Saeed S., Kong C.  
Stockport NHS Foundation Trust, Gastroenterology, Manchester, United Kingdom

**Contact E-Mail Address:** anneliese.richards@nhs.net

**Introduction:** Immunomodulators are widely used to achieve and maintain remission for Inflammatory bowel disease (IBD) patients<sup>1</sup> however these medications require regular close monitoring in order to optimise patient care. With a constant stretch on NHS resources it can be challenging to have a robust system in place to facilitate this. The introduction of an IBD specialist pharmacist clinic has the potential to improve patient outcome and disease stability. This study aims to review the impact this clinic has had on a district general hospital following its initiation in 2017.

**Aims & Methods:** Data was retrieved from the pharmacy patient record for the immunomodulator clinic for 2017, exclusion criteria were those with autoimmune hepatitis. General demographics including age and gender, number of referrals, cause of referrals, wait time, drug treatment, number of phone calls and patient outcomes at one year were all recorded. The 1 year outcomes were divided into four categories: stable/shared care with the general practitioner, escalation of therapy, de-escalation or discontinuation (this category comprised of adverse medications side-effects, patient movement out of area and dis-engagement from NHS services).

**Results:** For the year 2017, 68 referrals were made to the immunomodulator clinic. 40 (59%) had Crohn's disease, 22 (32%) had Ulcerative Colitis (UC) and 6 (9%) had IBD-unspecified. Mean waiting time from point of referral was 26.1 days. Patients who needed escalated therapy had associated longer mean wait time of 30.29 days. Those with stable or de-escalated disease at one year had a mean wait time of 21.9 days.

The most common drug was azathioprine 48 patients (70.5%) of which 4 were also receiving combination therapy with allopurinol; Methotrexate 13 patients (19.2%) and mercaptopurine 7 (10.3%) of which 1 patient was also being treated with allopurinol.

At one year 30 patients achieved stabilisation of disease (35%), 9 needed escalation of treatment (13%), 6 had their treatment de-escalated (9%) and the remaining 23 were discontinued from the clinic (35%). Discontinuation was mainly due to side-effects (15/23 patients) or disengagement from NHS services (4 patients). All patients on combined therapy with allopurinol (5 patients) had stable disease at one year. The drug treatment with the lowest proportion of patients needing escalation of therapy was methotrexate with 7.7%, mercaptopurine required 14.2% to be escalated and azathioprine required 14.6%.

On average 7.1 calls were made to patients in one year, ranging from 0-20 calls. Those who required escalation of therapy were called on average 3 times prior to escalation, de-escalated patients were called 5 times a year and those who had stable disease at one year needed on average 9.5 calls a year to achieve this. The small number of calls for escalation of therapy is felt to be due to the rapid escalation of management compared to the traditional clinic model.

**Conclusion:** The pharmacy immunomodulator clinic provides a robust and essential service to manage IBD patients who may otherwise deteriorate as well as providing a database for means of auditing. Being seen sooner in the clinic is associated with better outcomes in this study - illustrated by a higher rate of de-escalated and stabilised patients, however was not statistically significant (p value 0.55). Stability of patients is also associated with more phone calls per year to fine tune management, again reflecting the impact of a dedicated immunomodulator service on patient outcomes. Larger studies and multi-centre sites would help in sharing experiences.

## P1080 BENEFITS OF IMPLEMENTING A RAPID ACCESS CLINIC IN A HIGH VOLUME INFLAMMATORY BOWEL DISEASE CENTER: ACCESS, RESOURCE UTILIZATION AND OUTCOMES

Nene S.<sup>1</sup>, Goncz L.<sup>2</sup>, Verdon C.<sup>1</sup>, Reinglas J.<sup>1</sup>, Kohen R.<sup>1</sup>, Bessissow T.<sup>1</sup>, Afif W.<sup>1</sup>, Wild G.<sup>1</sup>, Seidman E.<sup>1</sup>, Bitton A.<sup>1</sup>, Lakatos P.L.<sup>1,2</sup>

<sup>1</sup>McGill University Health Center, Division of Gastroenterology, Montreal, Canada, <sup>2</sup>Semmelweis University, First Department of Internal Medicine, Budapest, Hungary

**Contact E-Mail Address:** kislakpet99@gmail.com

**Introduction:** Emergency situations in inflammatory bowel diseases (IBD) put significant burden on both the patient and healthcare system. Emergency department (ED) attendance is high among IBD patients.

**Aims & Methods:** We aimed to prospectively measure indicators of Quality-of-Care after the implementation of a new 'rapid access clinic' service (RAC) at the McGill University Health Centre (MUHC) tertiary care IBD center. Furthermore, to compare the resource utilization, outcomes and costs, in patients presenting via the RAC to that of the MUHC Emergency Department IBD related visits. The RAC provides patients opportunity to receive urgent evaluation by an IBD specialists, thus potentially avoiding the ED visit. The RAC service was structured by providing an emergency contact information to the patients, with a specific document explaining the pertinent symptoms that merit utilization of this access avenue. Each email/telephone contact was reviewed by a specialized IBD nurse or physician. Patient access, diagnostic procedures, resource utilization and outcome parameters were collected consecutive patients who contacted the RAC service between July 2017 and March 2019. For the comparative analysis data was retrieved from ED visits by patients not having access to RAC services between January 2018 and January 2019.

**Results:** 488 patients (41.3% men, mean age: 39 years, CD: 68.4% / UC: 31.6%) with valid medical reason for contacting the RAC clinic and 135 patients (60.7% men, mean age: 45 years, CD: 71.1% / UC: 28.9%) accessing the ED were included. 85.8% of the requests were deemed appropriate for a rapid appointment at the IBD clinic. The reason for RAC appointment was potential disease flare in 71.6% of patients. The median time to RAC visit with MD was 2 days (IQR: 0-6 days) following the first contact. Patients had a fast-track evaluation with objective laboratory (CRP (90.9%) and fecal calprotectin (73%)) and clinical assessment. Endoscopy and imaging was only performed in 17.9%, 6.7% (colonoscopy and flexible sigmoidoscopy) and 6%, 2.1% (CT and MRI). Clostridium difficile stool test and stool culture test were performed in 43.1% and 41.9. Medical therapy was changed in 54.4% of patients. ED visits within 30 days following RAC occurred in 8.8% of all patients (unplanned ED visit rate: 5.9%). Diagnostic procedures and overall resource utilization at ED visit was substantially different from the RAC visits: abdominal CT was performed in 65.7%, multiple specialists consults (gastroenterology, surgery, internal medicine). Average medical cost estimates per patient was 403.3 CAD vs 1885.5 CAD, with 64.4% of patients at ED requiring at least one day hospital admission.

**Conclusion:** Implementation of an IBD RAC improved patient care by facilitating easier access to IBD specific medical care as well as by avoiding unnecessary ED visits. Patients underwent fast-track evaluation with optimized utilization of diagnostic tests and lower costs compared to ED visits.

**Disclosure:** Nothing to disclose

## P1081 ARE RANDOM BIOPSIES STILL REQUIRED DURING IBD SURVEILLANCE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Lord R.<sup>1</sup>, Khan A.<sup>2</sup>, Burr N.<sup>3</sup>, Subramanian V.<sup>3</sup>

<sup>1</sup>Leeds Teaching Hospitals NHS Foundation Trust, Leeds, United Kingdom,

<sup>2</sup>Leeds Teaching Hospitals, Leeds, United Kingdom, <sup>3</sup>University of Leeds, Leeds, United Kingdom

**Contact E-Mail Address:** asif.khan12@nhs.net

**Introduction:** Patients with colonic IBD have an increased risk for developing colorectal cancer and surveillance is recommended. There is still debate on the role of random biopsies. Studies using newer generation endoscopes and dye based chromoendoscopy have suggested that most dysplasia is endoscopically visible. A recent retrospective study found that 1 in 8 patients with dysplasia were detected by random biopsies alone(1) and a meta-analysis has shown an increased risk for developing advanced neoplasia in patients with endoscopically invisible dysplasia (2). Random biopsies however are felt to be laborious, time consuming with poor yield

and targeted biopsies alone has been advocated. The aim for this systematic review/meta-analysis was to determine what proportion of patients with dysplasia are identified by random biopsy alone and to identify if specific advanced endoscopic technologies used or the cohort's risk has an effect on this rate.

**Aims & Methods:** Following PRISMA guidelines, we conducted a literature search using the electronic databases MEDLINE/EMBASE. Two independent reviewers screened citations and extracted data. Data analysis was performed with STATA13. Random-effects model was used to calculate pooled proportions with 95%CI. The primary outcome was the overall pooled proportion of patients with dysplasia who were identified by random biopsy only. A subgroup analysis was performed with studies pooled according to the different endoscopic technologies used (standard definition white-light (SDWL), standard definition chromoendoscopy (SDCE), high definition white-light (HDWL), high definition chromoendoscopy (HDCE), virtual chromoendoscopy (VCE), autofluorescence and full-spectrum endoscopy) and according to the risk of cancer in the populations enrolled in the studies (high-risk defined as having either included only patients with extensive colitis, or >9% of the cohort having PSC or >20% of the cohort previously having colonic dysplasia). Heterogeneity was assessed using I<sup>2</sup> statistic.

**Results:** 36 studies met our inclusion criteria. 14 RCTs, 14 prospective and 8 retrospective studies. 13.05% (95%CI 7.28-19.87%) of patients with dysplasia were identified by random biopsies alone; I<sup>2</sup>=81.2% (p< 0.001). Subgroup analysis showed HDCE having one of the smallest proportion of patients with random biopsy only dysplasia at 4.94% (95%CI 0.00-16.10%) (I<sup>2</sup>=55.9% (p=0.03)) whilst SDWL had the highest pooled proportion for patients with random biopsy alone dysplasia, 20.39% (95%CI 10.70-31.79%) (I<sup>2</sup>=80% (p< 0.001)). The pooled proportion of patients with dysplasia identified by random biopsy alone within the high-risk group was more than double, 14.19% (95%CI 7.43-22.29%) (I<sup>2</sup>=81% (p< 0.001)), when compared with that of the low-risk group, 6.42 (95%CI 0.04-18.45%) (I<sup>2</sup>=79% (p=< 0.001)).

**Conclusion:** This is the first meta-analysis looking at factors associated with the rate of detecting endoscopically invisible dysplasia. There was marked heterogeneity and overlapping confidence intervals reflecting the varied nature of included studies and risk groups enrolled. HDCE was associated with the least rates of endoscopically invisible dysplasia among all subgroups with at least 2 or more studies included. Random biopsies may still be required when surveillance is performed in high-risk populations. We propose that future prospective studies should undertake targeted and random biopsies along with capturing established risk factors for each individual. This will provide more robust evidence when attempting to define a subpopulation more likely to be harbouring endoscopically invisible dysplasia.

## P1082 FECAL CALPROTECTIN (FCAL) IN IBD: AN USEFUL AND NON INVASIVE PREDICTOR OF MUCOSAL HEALING AND CLINICAL RELAPSE

Sambuelli A.<sup>1</sup>, Gil A.<sup>1</sup>, Negreira S.<sup>1</sup>, Tirado P.<sup>1</sup>, Huernos S.<sup>1</sup>, Goncalves S.<sup>1</sup>, Chavero P.<sup>1</sup>, Goldberg G.<sup>1</sup>, Litwin N.<sup>2</sup>

<sup>1</sup>Hospital Bonorino Uadondo, IBD, Buenos Aires, Argentina, <sup>2</sup>Laboratorio de Investigación en Gastroenterología, Buenos Aires, Argentina

**Contact E-Mail Address:** alicia.sambuelli@gmail.com

**Introduction:** FCal emerged as useful tool for IBD management, but different assay methods, cut-offs, scenarios, patient phenotypes and populations may influence the clinical usefulness.

**Aims & Methods:** Two substudies were designed for the IBD population from a Latin-American center:

1) To investigate the value of FCal in mucosal healing (MH) prediction (optimal cut-off, specificity, sensitivity, VPP, VPN) and thresholds for clinical activity and phenotypes,

2) To evaluate the ability of FCal monitoring in IBD in remission to predict relapse.

FCal was determined with Bühlmann fCAL®ELISA.

Substudy-1 (MH prediction and activity/pattern of IBD): Included 100 IBD pts: (44 UC 56 CD), who underwent routine colonoscopy (VCC) with categorization by IBSEN score (Frøslie KF, Gastroenterol 2007) "MH" (scores 0-1) and "non-MH", collecting FCal samples within previous week. Optimal FCal cut-off for "MH" prediction (opt-MH cut-off) was calculated (ROC analysis). Substudy-2 (Prediction of relapse): included 50 UC and 50 CD in clinical remission ( $\geq 3$  months), FCal: basal,  $\geq$ biannual, VCC basal/final. Analysis: Kaplan Meier survival analysis for FCal levels above and below opt-MH cut-off. Mean follow-up 23.0 $\pm$ 11.8 months. Global definitions of clinical activity: Partial Mayo (UC), HBI (CD), Location/Extent (Montreal).

#### Results:

Substudy-1: FCal levels (Mean $\pm$ SD) in pts. with "MH" (25 UC, 30 CD) were significant lower vs. "Non-MH": UC (191.3 $\pm$ 174.6 vs. 621.1 $\pm$ 368.3,  $p=0.0001$ ) and CD (237.0 $\pm$ 196.9 vs. 618.5 $\pm$ 319.3,  $p<0.0001$ ) Kruskal-Wallis. Opt-MH cut-off was 242 $\mu$ g/g, AUC 0.84 (95% CI 0.753-0.906)  $p=0.0001$ , sensitivity: 76.4%, specificity: 84.5%, PPV: 85.7%, NPV: 74.5%. By clinical criteria FCal was lower ( $p<0.0001$ ) in remission vs activity in UC (165.7 $\pm$ 14.1 vs. 630.3 $\pm$ 349.6) and CD (276.4 $\pm$ 250.1 vs. 662.1 $\pm$ 289.9), but FCal cut-off was higher (284  $\mu$ g/g) than opt-MH cut-off. In endoscopically active CD pts, FCal levels in colonic CD were higher 851.9 $\pm$ 232.0 vs. other locations 544.4 $\pm$ 313.3 ( $p=0.04$ ).

Substudy-2: Cumulative probabilities of clinical relapse at 6, 12, 18, 24 months of pts. with FCal $>$ 242  $\mu$ g/g (n 34) were 20.6%, 38.2%, 44.7%, 51.6%, and with FCal $\leq$ cut-off (n 66) rates were 1.5%, 3.1%, 5.1% and 7.9% respectively, HR: 14.22 (95% CI 6.18 to 32.72),  $p<0.0001$ , sensitivity: 85%, specificity 82.7%, VPP: 67.7%, VPN: 93.9%. Globally, relapsed 15 (30%) of UC and 12 (24%) of CD (NS). Clinical relapses with FCal $>$ 242 were 67.7% vs. 6.1% ( $\leq$  than cut-off), endoscopic relapses (available in 91 pts.) with FCal  $>$ 242: 75% vs. 6.8% ( $\leq$  than cut-off), both  $p<0.00001$

#### Conclusion:

1) FCal was a good predictor of MH in UC and CD according opt-MH cut-off (242  $\mu$ g/g), Sensitivity: 76.4%, Specificity: 84.5%, PPV: 85.7%, PNV: 74.5%.  
2) FCal values were significantly lower in remission vs. activity, in UC and CD, but in endoscopically active colonic CD, FCal was higher vs. other locations,

3) FCal showed to be an effective tool to predict relapse for levels above opt-MH cut-off.

## P1083 ANXIOUS, DEPRESSED, PHYSICIAN-CRITICAL BUT LOTS OF COMPLAINTS - PERSONALITY CHARACTERISTICS OF CAM USERS IN PATIENTS WITH IBD

Klaus J.G., Rauschek L., Schulte L., Kretschmer M., Berthold J., Sularz M. Universitätsklinikum Ulm, Ulm, Germany

**Contact E-Mail Address:** jochen.klaus@uniklinik-ulm.de

**Introduction:** Many patients ask to combine complementary and alternative medicine (CAM) with guideline-based state of the art therapy in inflammatory bowel disease (IBD). In line with this, the new German S3 Guideline for the treatment of Ulcerative Colitis (UC) published in 2018 gives an update of how to use or not to use CAM in UC. In our study, we investigated the use of CAM in a cohort of IBD patients and various personality characteristics of patients to describe differences between CAM-users and non-users.

**Aims & Methods:** 291 German IBD patients filled in an anonymous questionnaire including 88 questions on the underlying IBD itself, on disease activity (HBI in CD and pMS in UC), QoL (SIBDQ), on CAM and CAMs used. Psychological tests (Hospital Anxiety and Depression Scale (HADS), State-Trait-Anxiety Inventory (STAI), Social Support Questionnaire (F-SozU), Complaints-list (BL-R'), NEO-Five-Factor Inventory (NEO-FFI)) were used to record differences in personal attributes between CAM-users and non-users.

**Results:** 138 (47.2%) male and 151 (52.8%) female patients, 183 (62.9%) with Crohn's Disease (CD) and 108 (37.1%) with UC completed the questionnaires. HBI in CD was 5.4 ( $\pm$  4.6) and pMS was 2.29 ( $\pm$ 2.4) in UC. 127 (43.6%) patients admitted intended use of CAM in the past or the present. Phytotherapies (117(92.1%)) were most frequently used, followed by probiotics (82(68.3%)), relaxation techniques (76(64.4%)) and homeopathy (59(52.2%)). We were able to identify significant differences between CAM

users and non-users with regard to depression and anxiety levels, number of complaints, patient type and personality. CAM users have significantly higher values on the depression scale (HADS,  $p=0.027$ ), more disease complaints ( $p=0.040$ ) and more often very severe anxiety symptoms ( $p=0.009$ ). CAM users personality is characterized by higher values in openness to experiences ( $p=0.011$ ), tolerance ( $p=0.037$ ) and conscientiousness ( $p=0.038$ ) according to NEO-FFI. In addition, CAM users reported significantly higher rates of a physician-critical patient type ( $p<0.001$ ). We could not detect any significant differences between CAM users and CAM non-users in quality of life, values of STAI anxiety scales, social support, and personality traits extraversion and neuroticism according to NEO-FFI.

**Conclusion:** German IBD patients widely use CAM. CAM is mainly used by patients who have higher levels of depression, more disease complaints and very severe anxiety symptoms. Since CAM users are primarily physician-critical patient types, attending IBD physicians should identify and approach such patients as early as possible, ask them about the use of CAM, and provide them with their best advice on CAM. By incorporating evidence-based CAM into conventional therapies, physicians could probably benefit from a better collaboration with physician-critical patient types.

Division of Gastroenterology, Calgary, Canada, <sup>5</sup>Institute of Translational Medicine, Birmingham, United Kingdom

**Contact E-Mail Address:** runetw@gmail.com

**Introduction:** Objective markers of disease activity are of paramount importance for evaluation of treatment response in Crohn's disease. Intestinal Ultrasonography (IUS) is long acknowledged for this indication, with recognized limitations, and Contrast Enhanced IUS (CEUS) shows promising results in showing blood flow response. However, the optimal timing for reduction in mural perfusion is as yet unknown.

**Aims & Methods:** We aim to investigate reduction in wall thickness and mural perfusion in inflamed bowel treated with Corticosteroids, Biologics or a combination of both. This observational study includes patients with known CD experiencing a flare with the need of medical treatment escalation or initiation. Patients were examined with CEUS if greyscale IUS showed bowel wall thickness (BWT)  $> 3$  mm, as part of standard of care. Follow-up varied with treatment choice: at week (W) 1 and W4 for steroids, W4 and W12 for biologics and W1, W4 and W12 for combination, using W1 as baseline for start of biologics. CEUS was performed using the microbubble contrast agent, perflutren lipid microspheres, 0.3 ml followed by saline flush. The US machine and all parameters were constant during and between scans. Time intensity curve analysis was performed and Peak enhancement (PE), area under the curve (AUC) and Wash-in Slope (WiS) were analyzed. Blood samples and fecal calprotectin were collected at baseline, W4 and W12 for the steroid group, and baseline and W12 for the biologic group. As part of standard of care, most patients underwent endoscopy at baseline and at follow-up after W12. W12 Response to treatment was evaluated with combination endoscopy (SES-CD  $< 3$  OR reduction from baseline  $> 50\%$  OR Rutgeerts io-i1) and laboratory markers (CRP  $< 8$  AND Calpro  $< 250$ ).

**Results:** 46 treatment patients include steroids n=14, biologics n=25, and combination n=7. Mean age 35.1 years [range 19.7-77.1], 45.7 % females, BMI 25.1 [16.9-51.3]. No difference between groups although a trend to larger BWT with increasing treatment intensification 7.3 mm [3.5-11.0], 8.3 mm [4.0-13.5] and 9.8 mm [7.0-12.0] respectively,  $p = 0.14$ . Responders experienced a greater reduction in BWT after 4W of any treatment -2.2 mm (95% CI -3.1 to -1.4) vs. non-responders -0.9 mm (-1.8 to 0.1) respectively,  $p=0.049$ . Moreover 6 patients (13 %) achieved transmural healing (BWT  $\leq 3$  mm) within W4. Also patients responding to biologics alone reduced BWT by -2.2 mm (-3.2 to -1.3) vs. non-responders -0.3 mm (-2.1 to 1.4) at W12,  $p=0.037$ . CEUS analyzes showed a trend towards response at W4 for steroid responders, however only for diminishment of WiS -7.00 dB/s (-11.5

to -2.5) vs. -4.00 dB/s (-4.5 to -3.5),  $p=0.09$ . Same trend towards response was found in the biological group at W4 -3.3 dB/s (-5.3 to -1.4) vs. 0.4 dB/s (-5.5 to 6.3) for non-responders,  $p=0.09$ . At W12 all three parameters were significantly different for responders vs non-responders, WiS  $p=0.011$ , PE  $p=0.026$ , AUC  $p=0.029$ .

**Conclusion:** At 4 weeks, IUS can already show reduction in bowel wall thickness, and for some even transmural healing, predicting week 12 responders to steroid and/or biological therapy. CEUS shows significant perfusion reduction at 3 months confirming endoscopic and/or biochemical response in those with successful biologic therapy. Our study did not achieve enough power to show reduction in perfusion already after 4 weeks.

## P1085 INTRINSIC BRAIN ABNORMALITIES IN UC PATIENTS AND EFFECT OF ANXIETY AND DEPRESSION

Liu C.<sup>1</sup>, Wang F.<sup>2</sup>, Zhang L.<sup>2</sup>, Qi R.<sup>2</sup>

<sup>1</sup>Jinglin Hospital, Nanjing University, Gastroenterology and Hepatology, Nanjing, China, <sup>2</sup>Jinglin Hospital, Nanjing University, Nanjing, China

**Contact E-Mail Address:** liuchang\_gi@163.com

**Introduction:** We have discovered that patients who suffered from ulcerative colitis (UC) may also accompany with anxiety and depression, which affect the quality life. According to previous researches, anxiety and depression are usually along with brain functional changes. In order to observe the relationship between brain functional changes and anxiety, depression especially in UC patients, a functional magnetic resonance imaging (f-MRI) technology was applied to conduct the study. The purpose of this study was to investigate the spontaneous brain activities and influence factors in UC patients compared with healthy people.

**Aims & Methods:** 27 patients diagnosed as UC were recruited from jinglin hospital, 17 of them and 17 matched healthy controls with similar gender, age and years of education were underwent a functional magnetic resonance imaging (f-MRI) 3.0T scan. Regional homogeneity (ReHo) was used to measure the synchronism of regional brain activities. T test, Chi-square test, pearson correlation were used to analyse the data.

**Results:** On one hand, a significant decreased ReHo values in Parietal\_Inf\_L (except supramarginal gyrus and angular convolution) and Parietal\_Sup\_L were found in UC patients compared with healthy controls. Moreover, there were significant negative correlations between ReHo values and SAS scores (Pearson correlation,  $p=0.019$ ,  $<0.05$ ,  $r=-0.3997$ ), however no statistical significance was found between ReHo values and SDS scores (Pearson correlation,  $p=0.086$ ,  $>0.05$ ). On the other hand, there is statistical significance in SAS ( $42.72\pm12.543$ ) and SDS ( $38.75$  ( $33.75-53.13$ )) scores between UC patients and healthy controls.

Moreover, years of education revealed statistical significance in SAS scores ( $c2=9.047$ ,  $p=0.009$ ,  $<0.05$ ) between UC patients and healthy controls. No statistical significance was found in SDS scores between several factors in UC patients and healthy people.

**Conclusion:** Abnormal brain functional changes exist in UC patients and they are more likely to be anxious and depressed than healthy people. These findings provide evidence that the disorder in brain-gut axis (BGA) may exist in UC patients.

**Disclosure:** Nothing to disclose

## P1086 THE CORRELATION BETWEEN CHEST X-RAY AND CHEST CT FOR THE DETECTION OF LATENT TUBERCULOSIS DURING INFLAMMATORY BOWEL DISEASE

Naji S.<sup>1</sup>, Boubker S.<sup>1</sup>, Khannoussi W.<sup>1</sup>, Ismaili Z.<sup>2</sup>, Kharrasse G.<sup>3</sup>

<sup>1</sup>Mohammed VI University Hospital, Hepato-Gastro-Enterology, Oujda, Morocco, <sup>2</sup>Medical School, Hepato-Gastro-Enterology, Oujda, Morocco, <sup>3</sup>Faculty of Medicine Oujda, Avicenne, Oujda, Morocco

**Contact E-Mail Address:** sihamnaji@hotmail.com

**Introduction:** Over the last decade, Anti-Tumor Necrosis Factor (anti-TNF) agents have shown great effectiveness in the treatment of inflammatory bowel disease (IBD). Nevertheless, their use exposes the patient to an increased risk of opportunistic infections, particularly tuberculosis. For this reason, the pre-therapeutic check-up is important in order to detect latent tuberculosis.

**Aims & Methods:** The aim of our study was to evaluate the correlation between chest X-ray and chest CT for detection infection.

This is a descriptive retrospective study done in the Hepato-Gastroenterology unit of our university hospital, over a period of 4 years from September 2015 to December 2018 and collected all patients with IBD requiring an anti-TNF treatment. All patients had chest x-rays and chest CT scans.

**Results:** Sixty-seven patients were included in our study. The average age of our patients was 35.37 years. There were 22 women (32.85%) and 45 men (67.15%) with a sex ratio M/F: 2.86. 56% of patients were followed for Crohn's disease, 11.9% for Ulcerative Colitis and 1.49% for indeterminate colitis. Respiratory symptoms were found in only 3 patients (4.47%). Chest X-ray revealed lesions in favour of latent tuberculosis in 2.9% of cases ( $n=2$ ), including interstitial syndrome. Thoracic CT scan revealed lesions in favour of tuberculosis in 13.43% of cases ( $n=9$ ), including micronodules in 55.55% of cases and a focal of alveolar condensation in 44.44% of cases. The Quantiferon assay was also performed in patients with positive CT; it was positive in 88.88% of cases ( $n=8$ ). The diagnosis of pulmonary tuberculosis was confirmed in 9 patients. The correlation between chest CT and chest radiography was calculated using the Pearson score which showed a low correlation ( $r=0.048$ ). In addition, the correlation between thoracic CT and Quantiferon, calculated using the Pearson score, was higher with a statistically significant  $p$  ( $p<0.001$ ).

**Conclusion:** In our series of sixty-seven patients candidate for an anti-TNF treatment, the correlation between chest X-ray and chest CT for the detection of latent tuberculosis during inflammatory bowel disease was very low ( $r=0.048$ ). CT Scan should be concurred reference diagnostic tool to detect latent tuberculosis. However, the correlation between chest CT and Quantiferon must be well studied with a larger sample.

## P1087 USING MAGNETIC RESONANCE ENTEROGRAPHY GLOBAL SCORES (MEGS) TO ASSESS RESPONSE TO USTEKINUMAB IN CROHN'S DISEASE

Honap S.<sup>1</sup>, Griffin N.<sup>2</sup>, Nicolescu A.<sup>2</sup>, Irving P.M.<sup>1</sup>

<sup>1</sup>IBD Centre, St. Thomas' Hospital, London, United Kingdom, <sup>2</sup>Department of Radiology, St. Thomas' Hospital, London, United Kingdom

**Contact E-Mail Address:** honap@hotmail.co.uk

**Introduction:** Magnetic resonance enterography (MRE) is a key modality in diagnosing and monitoring Crohn's disease (CD). MEGS, a quantitative MRI index of inflammatory burden in CD, has been previously validated against Harvey Bradshaw Index (HBI), C-reactive protein (CRP) and faecal calprotectin (FC). It has also been shown to reflect clinical response to anti-TNF therapy and clinical classification of disease activity<sup>2</sup>.

**Aims & Methods:** To evaluate the utility of MEGS in assessing radiological response to ustekinumab, a monoclonal antibody targeting IL12/23. Patients established on ustekinumab, with a baseline and follow up MRE (at least three months after ustekinumab induction), were retrospectively reviewed. Clinical data, including HBI, CRP and FC, were collected to establish disease activity at baseline and at the first follow up MRE. Two consultant gastrointestinal radiologists, without clinical data, analysed images to calculate MEGS. Statistical analysis was performed using Graph-Pad Prism version 8.0.

**Results:** Sixteen patients (median age 37, 50% male) with moderate to severe CD at baseline, according to a Physician Global Assessment (PGA), were identified. Median time to first follow up MRE was 10 months (range 5-18). 3/16 were responders according to PGA, and although MEGS decreased in each case (44, 16.3 and 8.5 to 38, 15.5 and 5.5 respectively), this did not reach statistical significance. 13/16 were non-responders and pre-induction median MEGS increased (21 (range 2-79.5) vs. 26 (5.5-85.5),  $p<0.002$ ), reflecting increasing symptom burden and biochemical parameters despite therapy. The overall interobserver agreement between reporting radiologists was good with a mean difference between the two observers' MEGS of -3.95 (Bland Altman Limit of Detection (-16.48 to 8.57)).

**Conclusion:** Quantitative MRI scores for Crohn's disease activity are increasingly being used in clinical practice, and our study demonstrates good interobserver agreement. Whilst our data is suggestive of a correlation between change in MEGS and PGA in this complex, prior biologic refractory patient population, larger protocolised studies are needed.

**Introduction:** Endoscopic remission has become a major goal of treatment in patients with ulcerative colitis. Few endoscopic data are available in patients with steroid-refractory acute severe ulcerative colitis (ASUC) requiring a second-line medical therapy. The aim of the present study was to describe the evolution of endoscopic lesions in patients with ASUC responding to infliximab (IFX) or cyclosporine (Cys).

**Aims & Methods:** All patients enrolled into the CYSIF trial (1), that was an open-label comparison between IFX and Cys in patients admitted for a steroid-refractory ASUC, were eligible for inclusion in the present endoscopic sub-study. Only patients who achieved clinical remission at day 98 were included in this sub-study. Flexible sigmoidoscopies were planned during the study at baseline, day 7, 42 and 98. They were locally read and the presence of pre-specified endoscopic lesions was recorded per segment. Mayo endoscopic subscore (MES) was reported; UCEIS and its components, vascular pattern (VP), bleeding (B) and ulceration/erosion (U), were post-hoc calculated from endoscopic reports. Endoscopic remission (ER) was defined as MES or UCEIS at 0. Remission for each UCEIS component was defined by VP, B or U at 0. Remission rates were compared

between VP, B and U components in the whole cohort at each time-point through paired chi-square test. Using the same method, ER rates and remission of each UCEIS component were compared between rectum and sigmoid segments. ER rates and remission rates of each UCEIS component were compared between patients treated with IFX and those receiving Cys through chi-square test or Fisher exact test when necessary. According to the numerous tests performed, significance was achieved for a p-value less than 0.01.

**Results:** From the 115 patients included in the trial, 63 have been included in the present endoscopic sub-study (32 IFX and 31 Cys). Mean $\pm$ SD of UCEIS and MES was respectively 7.0 $\pm$ 1.2 and 3.0 $\pm$ 0.2 at baseline, 5.3 $\pm$ 1.7 and 2.9 $\pm$ 0.5 at day 7, 2.3 $\pm$ 2.1 and 1.6 $\pm$ 1.2 at day 42 (n=62), 1.1 $\pm$ 1.3 (n=58) and 0.9 $\pm$ 1.0 (n=59) at day 98. When comparing to ER rates on VP at day 7 (3%), at day 42 (29%), at day 98 (50%) in the whole cohort, ER rates on B and on U were higher at day 7 (21% and 8%, p=0.001 and p=0.38), at day 42 (63%, p< 0.001 for both) and at day 98 (76% and 83%, p< 0.001 for both). There was no observed difference in ER rates between sigmoid and rectum whatever the assessment used. ER rate at day 98 was significantly higher in patients treated with IFX than in those treated with Cys (66% vs. 24%; p=0.002), whereas no difference was observed at baseline, day 7 or day 42. This observed difference at day 98 was related mainly to the VP component.

**Conclusion:** In this prospective cohort of steroid-refractory ASUC patients who achieved clinical remission at day 98, UCEIS endoscopic remission started with absence bleeding, followed by ulceration/erosion and then by restoration of the vascular pattern. Endoscopic remission was similar in rectum and sigmoid. IFX provided a significantly higher rate of endoscopic remission than Cys at day 98.

**Introduction:** The UNIFI induction study evaluated the efficacy and safety of ustekinumab (UST) in patients with moderately to severely active ulcerative colitis (UC) after a single intravenous infusion. In this analysis, we evaluated the rapidity of the onset of the treatment effect.

**Aims & Methods:** Eligible patients were randomly assigned to placebo (PBO) or UST 130 mg or ~6 mg/kg. Patients recorded stool frequency and categorized rectal bleeding daily for the 7 days before each visit. Partial Mayo scores were calculated at baseline and Week 2 using the average of the stool frequency and rectal bleeding scores from the most recent consecutive 3-day period before the visit and the physician's global assessment score recorded at the visit. C-reactive protein (CRP) and fecal biomarkers were measured at baseline and Day 14.

**Results:** At baseline, the mean 3-day average daily stool frequency was 7.0 in the PBO group, 6.9 in the UST 130-mg group, and 7.0 in the UST ~6-mg/kg group. Patients receiving UST showed greater reductions in the daily number of stools compared with PBO as soon as the first assessment time point at Day 7. Mean changes from baseline in daily stool frequency were -0.7 for PBO, -1.0 for UST 130-mg (p=0.098), and -1.2 for UST ~6-mg/kg group (p=0.018) by Day 7, respectively, and -0.9, -1.6 (p< 0.001), and -1.9 (p< 0.001) by Day 13, respectively. The percentage of patients with no blood in their stool at baseline and Day 14 were 13.5% and 26.0%, respectively, in the PBO group, 10.9% and 32.5% in the UST 130-mg group, and 12.1% and 37.3% in the UST ~6-mg/kg group. Patients receiving UST showed

significantly greater improvement from baseline to Day 14 in partial Mayo score and CRP (Table,  $p < 0.001$  for all comparisons of UST vs PBO). Differences between the UST and PBO treatment groups in mean changes from baseline to Day 14 in fecal calprotectin did not reach significance (PBO -33.96 mg/kg, UST 130 mg 79.12 mg/kg [ $p = 0.875$ ], UST ~6 mg/kg -412.68 mg/kg [ $p = 0.152$ ]). However, patients receiving UST showed significantly greater improvement in fecal calprotectin at Week 4 (mean changes from baseline: PBO -226.78 mg/kg, UST 130 mg -881.22 mg/kg [ $p = 0.013$ ], UST ~6 mg/kg -802.75 mg/kg [ $p < 0.001$ ]). Similar results were observed for fecal lactoferrin.

**Conclusion:** The effect of UST began rapidly after induction, with symptomatic improvement and reduction of systemic inflammation seen as early as the first assessments at Days 7 and 14, respectively.

	PBO IV	UST IV 130 mg	UST IV ~6 mg/kg
Primary efficacy analysis set	319	320	322

**Introduction:** Inflammatory bowel disease (IBD) and Psoriasis are chronic inflammatory conditions with an organotropic preference, where the influence of innate and adaptive immunity seems to play a crucial role. This shared pathologic process explains the use of similar therapeutic strategies like corticosteroids, immunomodulators and monoclonal antibodies. Psoriasis can be associated to IBD as an independent entity, as an extraintestinal manifestation of IBD, or even as a paradoxical event of anti-tumor necrosis factor (TNF) therapy. Their co-occurrence adds complexity to the challenge of patient management.

**Aims & Methods:** Our main goal was to review our experience of patients treated with TNF $\alpha$  inhibitors regarding the occurrence of dermatological lesions, namely, psoriasis. We retrospectively analyzed data regarding a cohort of patients with the diagnosis of IBD and submitted to anti-TNF therapy, from January 2000 until the end of January 2019. We included patients observed by the dermatology department due to suspicious lesions during treatment with anti-TNF therapy. Data was retrieved from clinical registries.

**Results:** 422 patients were analyzed. Suspicious dermatological lesions were found in 111 patients (24%) and a diagnosis of psoriasis was made in 34 (8%). The prevalence was higher in the females (26 vs 8). Among patients with Psoriasis, the predominant IBD type was CD (only 1 patient with UC). The majority of the former presented ileocolonic disease (46%), a non-stricturing non-penetrating behavior (49%) and were diagnosed between 16-40 years old (79%). Psoriatic lesions were found mainly in scalp (n=13), trunk (n=10) and palmoplantar regions (n=7). 35% of the patients were diagnosed while being treated with combined therapy with

immunosuppressive drugs (4 with methotrexate and 8 with azathioprine). 41% of patients were treated with two or more biologic drugs. The diagnosis of psoriasis preceded the use of anti-TNF therapy in 7 patients. 27 patients were on treatment with TNF $\alpha$  inhibitors at the time of psoriasis diagnosis. The mean time from anti-TNF exposure until development of psoriasis was 28 months with a mean follow up time of 7 years. Psoriatic lesions were controlled in 4 patients by switching infliximab to adalimumab. The discontinuation of anti-TNF therapy due to psoriasis occurred in 12% (n=4/34) of patients. 50% swapped to ustekinumab or vedolizumab with good skin disease control.

**Conclusion:** In our cohort there was an incidence of psoriasis in IBD patients treated with anti-TNF of 8%, resulting in alterations in the management of IBD therapy. The majority of our patients improved their skin condition with anti-TNF switch, despite lack of studies regarding this.

The incidence of this lesions on IBD patients treated anti-TNF therapy (6-11%) is consistent with that found in other diseases like rheumatoid arthritis. Psoriatic lesions were more frequently identified in patients with CD than in UC patients, with gender being identified as a risk factor. The paradoxically occurrence of psoriatic skin lesions, is an emergent issue in the context of anti-TNF drugs use. Effective drugs on psoriasis and IBD, targeting different pathways than anti-TNF, are changing the reality allowing further control over both diseases. Nowadays a good control of intestinal and skin inflammation can be achieved without compromising the outcomes expected for each. A multidisciplinary approach is of utmost importance in managing IBD treatment and potential complications.

**Disclosure:** Nothing to disclose

## P1091 CLINICAL EFFECTIVENESS OF FIRST-LINE ANTI-TNF THERAPIES AND SECOND-LINE ANTI-TNF THERAPY POST-VEDOLIZUMAB DISCONTINUATION IN PATIENTS WITH ULCERATIVE COLITIS OR CROHN'S DISEASE

**Introduction:** Real-world data is needed to understand outcomes in patients with ulcerative colitis (UC) or Crohn's disease (CD) who discontinue first-line (1L; biologic-naïve) vedolizumab (VDZ) treatment (Tx) and go on to receive subsequent anti-tumor necrosis factors (anti-TNF) Tx.

**Aims & Methods:** The objective was to compare the clinical effectiveness of second-line (2L) anti-TNF Tx post 1L VDZ and 1L anti-TNF use in patients with UC or CD. This was a real-world, multi-country, retrospective chart review study in adult ( $\geq 18$  years old) UC and CD patients treated with 1L anti-TNF or 2L anti-TNF after discontinuation of 1L VDZ for any reason (received May 2014 to March 2018). Patients were included from sites across Canada, Greece and the United States. Anti-TNF therapies included: adalimumab, infliximab, golimumab and certolizumab pegol. The index date was defined as date of 1L Tx initiation. Clinical effectiveness data were collected from 1L or 2L Tx initiation to earliest of death, chart abstraction date or 6 months post-1L Tx discontinuation (Canada only). Cumulative rates of Tx persistence, clinical response, and clinical remission were estimated using the Kaplan-Meier method for UC and CD (separately and combined) over 6 months. Cumulative rates of clinical response and clinical remission were assessed using pre-defined hierarchical algorithms of standard disease measures as reported in the medical records. P-values were generated using the log-rank test.

**Results:** This analysis included 579 anti-TNF patients (1L: 497 [UC: 224; CD: 273]; 2L: 82 [UC: 58; CD: 24]) from 36 sites. The proportion of patients in each cohort were: adalimumab (1L: 41.4%; 2L: 19.5%), infliximab (1L: 52.7%; 2L: 79.3%), golimumab (1L: 4.8%; 2L: 1.2%) and certolizumab pegol (1L: 0.8%; 2L: 0.0%). Mean (SD) age at index date: 1L, 39.6 (15.2); 2L, 49.4 (18.6) years, male: 1L, 49.9%; 2L, 61.0%, median (range: min-max) disease duration: 1L, 2.0 (< 0.1 - 49.0); 2L, 3.7 (0.1 - 54.0) years. At 6 months, cumulative rates of Tx persistence (1L: 83.9%; 2L: 83.6%), clinical

response (1L: 49.5%; 2L: 65.6%) and clinical remission (1L: 29.5%; 2L: 31.4%), were similar between 1L and 2L patients (Table 1). Results were similar when data were stratified by UC and CD, albeit sample sizes were small (Table 1).

**Conclusion:** Cumulative rates of Tx persistence, clinical response and clinical remission observed in the first 6 months of Tx were comparable between 1L anti-TNF patients and those who switched to a 2L anti-TNF following the discontinuation of 1L VDZ. This suggests that 1L VDZ may not impact the effectiveness of subsequent anti-TNF Tx in real-world clinical practice. As 2L sample size was limited, these hypothesis-generating data warrant further study.

Outcomes	Overall		Ulcerative Colitis		Crohn's Disease	
	First-Line N=497	Second-Line N=82	First-Line N=224	Second-Line N=58	First-Line N=273	Second-Line N=24

**Contact E-Mail Address:** l.cheng@ptgx-inc.com

**Introduction:** The regulatory approval of ustekinumab (targeting IL-12/IL-23 in Crohn's Disease) and clinical data for several anti-IL-23 monoclonal antibodies support targeting the IL-23 pathway for treatment of inflammatory bowel disease (IBD). PTG-200 (also known as JNJ-67864238) is an oral peptide, that acts locally in intestinal tissues to block IL-23 signaling by selectively binding the IL-23 receptor (IL-23R). *In vitro* studies confirmed PTG-200 is a potent, selective, and competitive IL-23R inhibitor. The GI-restricted nature of PTG-200 is demonstrated by marked drug concentrations in GI tissues and feces, and limited systemic blood exposure in animal models. PTG-200 therapeutic potential was established in a rat model of TNBS-induced colitis, where the threshold concentration of PTG-200 in colonic tissue and luminal feces for efficacy and pharmacodynamics was determined.

**Aims & Methods:** The objectives of this first-in-human (FIH) Phase 1 study were to assess safety, tolerability, and pharmacokinetics (PK) including food effect and fecal exposure of orally administered PTG-200. This FIH Phase 1 study was a single-center, randomized, double-blind, placebo-controlled trial comprising single ascending and 14-day multiple ascending dose (SAD and MAD) oral administration in 82 male normal human volunteers. Doses ranged from 150 mg to 900 mg once daily (QD, fasted or fed) or twice daily (BID, fed). Subjects were monitored for safety and tolerability. PK in plasma, urine and feces was evaluated, including plasma PK profile following a high-fat meal.

**Results:** Oral administration of PTG-200 was well-tolerated. There were no serious adverse events, dose-limiting toxicities, or clinically significant adverse events. PTG-200 plasma exposure was low (Table 1), below that expected to result in systemic biological activity. Following single-dose oral administration under fasted conditions, peak plasma concentration (C<sub>max</sub>) exhibited a dose-related increase with a median T<sub>max</sub> at 2.0 h. Administration of a high-fat meal prolonged the median T<sub>max</sub> to 4.0 h and had a modest effect on C<sub>max</sub> and estimated overall exposure. Repeat dosing led to dose-related increase in plasma exposure. Consistent with a terminal half-life of ~1.5 h in plasma, PTG-200 showed no evidence of accumulation except in the 900 mg BID group (2.75-fold). PTG-200 was detected in urine only at 900 mg BID. Fecal concentrations in several cohorts met or exceeded the targeted preclinical threshold concentration which was established using the rat TNBS-induced colitis model.

Cohort	Dose and Frequency	Feeding Status	Day	C <sub>max</sub> (ng/mL)	AUC <sub>0-∞</sub> (ng*hr/mL)
4	150 mg, QD	Fed	Day 1	0.33 ± 0.26	0.89 ± 0.81
4	150 mg, QD	Fed	Day 14	0.39 ± 0.12	0.97 ± 0.57
5a	300 mg, QD	Fed	Day 1	0.61 ± 0.60	1.79 ± 1.23
5a	300 mg, QD	Fed	Day 14	0.56 ± 0.26	1.69 ± 0.81
5b	150 mg, BID	Fed	Day 1	0.23 ± 0.08	0.80 ± 0.30
5b	150 mg, BID	Fed	Day 14	0.23 ± 0.07	0.62 ± 0.25
6	900 mg, QD	Fed	Day 1	1.16 ± 0.85	3.92 ± 3.00
6	900 mg, QD	Fed	Day 14	1.11 ± 0.72	3.11 ± 1.59
7	900 mg, BID	Fed	Day 1	0.48 ± 0.25	2.52 ± 1.92
7	900 mg, BID	Fed	Day 14	1.06 ± 0.70	5.15 ± 3.09

[Table 1. Plasma PK (C<sub>max</sub> and AUC<sub>0-∞</sub>) of PTG-200 in MAD. C<sub>max</sub> and AUC<sub>0-∞</sub> are presented as mean ± standard deviation. ]

**Conclusion:** Orally administered PTG-200 was well-tolerated in this FIH study. PK was consistent with the GI-restricted design of PTG-200. These safety and PK characteristics, combined with fulfillment of preclinical fecal drug threshold concentrations, support further clinical development of PTG-200 for the treatment of IBD. A Phase 2 study in patients with moderate-to-severe Crohn's disease has been planned.

**Disclosure:** Nothing to disclose

## P1093 THE EFFECTS OF CANNABIS EXTRACTS ON INFLAMMATORY BOWEL DISEASE (IBD) EXPLANT BIOPSIES

**Contact E-Mail Address:** shaul.pery@clalit.org.il

**Introduction:** Cannabis treatment improves chemical induced Colitis in mice as well as clinical disease burden in human measured by the Lich-tiger score. The mechanism by which cannabis affected Disease score is unknown. In IBD the inflamed microenvironment damages the epithelial barrier. Following damage, a process of barrier restitution begins, which depends on epithelial cell proliferation.

**Aims & Methods:**

**Aim:** To analyze the effect of cannabis on cultured colon biopsies from IBD patients and on human colon epithelial cell line exposed to soluble IBD microenvironment.

**Methods:** Biopsies (3-5, ~10mg/biopsy) were collected during endoscopy from inflamed and uninfamed colon areas of IBD patients, cultured for 5-6hr with medium, cannabis-extract (C2F, 50/100µg/ml) or methanol (C2F-solvent) and analyzed using immunohistochemistry and manually cell count or QuPath digital software for:

1) Epithelial and stromal cell proliferation and apoptosis (Ki67 and cleaved-caspase-3 expression, respectively) 2) Epithelial-cell-number/crypt-diameter. The secretomes of the cultured biopsies were analyzed for MMP9/2 activity (impair epithelial permeability, by Zymogram test) or added to colon epithelial cells (CC841) for 48hr. Following culture CCD841 cells were analyzed for viability (by Alamar-blue), cell-number and death (automatic cell-counter and trypan blue) and PCNA expression (proliferation marker, western-blot).

**Results:** Cannabis extract increased epithelial cell proliferation in all biopsies ( $p < 0.05$ , 12-31%), seen in both digital and manual cell-count. In correspondence with this, cannabis (100µg/ml) increased the number of epithelial cells in crypt circumference in all biopsies (~ 32%,  $p < 0.05$ ). Similarly, secretomes collected from C2F treated inflamed biopsies increased CCD841 proliferation (45%↑ cell-number and 41-380%↑ PCNA expression) compared to inflamed secretomes. Whereas, secretomes collected from untreated inflamed biopsies reduced CCD841 cell number (22%) and viability (16%) compared to secretomes of uninfamed areas ( $p < 0.05$ ). Exposure of CCD841 directly to C2F (100µg/ml) reduced their viability (80%↓,  $p < 0.05$ ). Cannabis extract also increased Ki-67 expression in the stromal cells of the inflammatory tissue (in 5/6 experiments), yet, had no effect on epithelial and stromal cell-apoptosis. While as the cannabis (50µg/ml) reduced MMP9/2 activity in the uninfamed secretomes in 4/5 patients, it increased the MMP9 level in the inflamed secretomes (5/6 patients).

**Conclusion:** Cannabis facilitates colon epithelial proliferation in ex-vivo and in-vitro human models and thus may facilitate mucosal healing. However, it had a complex and area dependent effect on the MMPs activity, reflecting the complexity of cannabis anti-inflammatory effect.

**Disclosure:** Nothing to disclose

### **P1094 ASSESSMENT OF BUDESONIDE MMX® EFFECTIVENESS FOR ACTIVE, MILD-TO-MODERATE ULCERATIVE COLITIS IN THE POLISH SUB-GROUP OF THE PROSPECTIVE MULTI-CENTER OBSERVATIONAL STUDY CORE PRACTICE**

<sup>1</sup>Central Clinical Hospital of the Ministry of Interior and Administration, Gastroenterology with IBD Subdivision, Warsaw, Poland, <sup>2</sup>Jan Kochanowski University, The Faculty of Medicine and Health Science, Kielce, Poland, <sup>3</sup>Ferring Pharmaceuticals Centre S.A., Global Medical Affairs, Saint-Prex, Switzerland, <sup>4</sup>Humanitas Clinical and Research Center, IRCCS, IBD Center, Rozzano, Italy, <sup>5</sup>Ferring Pharmaceuticals Poland, Medical Department, Warsaw, Poland

**Contact E-Mail Address:** maciej.jesionowski@ferring.com

**Introduction:** Budesonide MMX® is approved for induction of remission in mild-to-moderate active ulcerative colitis (UC) in adults, where 5-ASA is not sufficient. There is lack of data on its effectiveness and safety in clinical reality.

**Aims & Methods:** This was the Polish sub-group of multi-center prospective observational study CORE Practice. The proportion of patients with clinical benefit, clinical remission, symptoms resolution, endoscopic healing, endoscopic remission, fecal calprotectin normalization, change in quality of life, treatment satisfaction, change in economic parameters as well as tolerability, treated with Budesonide MMX® for mild-to-moderate UC in a real-life setting were evaluated. Patients were prescribed Budesonide MMX® 9mg in accordance with the terms of the SmPC, within a 5 days' time window before the enrolment. The primary endpoint was the clinical improvement of Budesonide MMX® defined as the percentage of patients achieving ≥3-point decrease in the UCDAI score at the end of induction treatment.

**Results:** The data from the Polish sub-group cohort of 181 patients with mild-to-moderate UC were analyzed. Clinical improvement ≥ 3-point in UCDAI at the end of treatment induction was achieved in 72.2% patients. Clinical remission defined as UCDAI clinical subscore ≤ 1-point was observed in 61.4% of patients at the end of induction treatment. Symptoms resolution at the end of treatment, defined as rectal bleeding = 0 and stool frequency ≤ 1 was observed in 72.2% patients. Full symptoms resolution (rectal bleeding = 0 and stool frequency = 0) at the end of the Budesonide

MMX® treatment was achieved in 52.3% of patients. The significant improvement of quality of life was observed according to the SIBD-Q ( $p < 0.001$ ), compared with baseline, achieving increase in mean SIBD-Q total score from 40 to 56 points. The highest treatment satisfaction level (VAS score 10) was observed in 40.2% of patients. One patient discontinued Budesonide MMX® due to an adverse event that was related to the study drug, what counts for less than 1% of patients.

**Conclusion:** The data from the Polish sub-group of the real-life study CORE Practice confirms the clinical efficacy of Budesonide MMX® 9 mg in the majority of patients with active mild to moderate UC. Budesonide MMX® was safe, well tolerated and showed beneficial effect on patient's quality of life.

**Contact E-Mail Address:** yoram.bouhnik@bjn.aphp.fr

**Introduction:** SB2 is approved in the EU as an infliximab (IFX) biosimilar, having demonstrated bioequivalence and similar efficacy, safety and immunogenicity as the reference. There is limited real-world evidence published on persistence or immunogenicity of SB2, either in IFX-naïve patients or in those transitioning from originator or another IFX biosimilar. PERFUSE is an ongoing non-interventional study intending to enrol over 1,000 patients receiving SB2 as routine therapy.

**Aims & Methods:** To describe clinical characteristics, immunogenicity and treatment persistence over 12 months in patients initiating SB2 in routine clinical practice at 8 specialist gastroenterology sites across France.

Eligible adult patients have a diagnosis of Crohn's Disease (CD) or Ulcerative colitis (UC) and initiated SB2 in routine clinical practice after September 2017, either as their first IFX or transitioning from treatment with IFX originator or another IFX biosimilar. Data are captured prospectively and/or retrospectively from patient records obtained during routine clinic visits for up to 12 months (M12) following initiation. Outcome measures include persistence on SB2, clinical characteristics at baseline (time of initiation of SB2), disease scores (Harvey-Bradshaw Index (HBI), Simple Clinical Colitis Activity Index (SCCAI)), trough levels (TL) and anti-infliximab antibodies (ADA).

**Results:** This interim analysis (IA) includes 575 IBD patients (446 with CD, 129 with UC); 273 patients with CD and 78 with UC reached M12 by data extraction date, with persistence on SB2 being 95.6% (95% CI 92.4, 97.7) and 93.6% (95% CI 85.7, 97.9) in CD and UC respectively. In the 522 patients with prior IFX, no clinically relevant difference in disease score from baseline to M12 was observed; mean individual change was -0.34 (95% CI -0.72, 0.04) and -0.22 (95% CI -0.89, 0.44) in CD and UC respectively. Baseline ADA assay was performed on 241 (50.6%) patients, showing mean total ADA concentration below 1µg/mL, with no increase over the observation period.

**Conclusion:** This IA indicates that patients with IBD can be successfully transitioned from originator or biosimilar IFX to SB2, with no loss of disease control and without immunogenicity concerns. Over 90% of patients initiated de novo or transitioned from originator or another IFX biosimilar continued SB2 treatment at M12 post-initiation.

**Introduction:** Anti-tumor necrosis factor (TNF) therapy revolutionized the treatment of inflammatory bowel disease. However, a major concern is the increased risk of developing tuberculosis (TB), which requires diagnosis and treatment of latent TB infection (LTBI) before initiation of anti-TNF agents. Currently, no recommendations exist regarding the need to regularly re-test patients for latent TB during treatment.

**Aims & Methods:** We aimed to assess the incidence and to identify risk factors for newly acquired TB infection in patients under anti-TNF. Adult patients under anti-TNF for over 12 months were retrospectively assessed. Patients with a negative pre-treatment interferon-gamma releasing assay (IGRA) that repeated IGRA during anti-TNF treatment were reviewed. Patients with a pre-treatment positive IGRA were excluded.

**Results:** Out of 244 patients under anti-TNF (124 infliximab, 120 adalimumab), 87 patients were included. Patients had a mean age of 40±14 years, 64.4% were females, 93.1% were under infliximab and 64.4% had Crohn's disease. Positive repeat IGRA was identified in 9 patients (10.3% of our sample, 3.7% of all patients under anti-TNF in our center), of which 3 had active tuberculosis and 6 had LTBI.

When comparing patients with and without positive repeat IGRA, no differences were found regarding age (39.6 years vs 36.7 years, p=0.991) or gender (10.7% females vs 9.7% males, p=0.999). Patients with repeat positive IGRA more frequently had close contact with patients with TB (22.2% vs 0.0%, p= 0.010), however no differences were found regarding travels to TB-endemic areas (11.1% vs 7.7%, p=0.548), professional risk for TB infection (11.1% vs 9.0%, p=0.999), concomitant treatment with immunosuppressants (77.7% vs 71.8%, p=0.999), use of systemic steroids during anti-TNF treatment (33.3% vs 35.9%, p=0.999), diabetes mellitus (11.1% vs 5.1%, p=0.429) or active smoking (22.2% vs 20.5%, p=0.999). Also, no differences were found regarding the duration of treatment at the time of repeat IGRA (30.2±26.7 months vs 42.5±30.1 months, p=0.640).

**Conclusion:** In patients under anti-TNF, at least 3.7% of patients have a positive repeat IGRA after starting treatment. In our sample, only close contact with patients with TB was associated with a positive repeat IGRA. Therefore, considering that infection during treatment is present in a non-negligible percentage of patients, and most of the classical risk factors can not be used to identify at-risk patients, physicians may consider routine repeat IGRA in patients under anti-TNF.

**Introduction:** Ustekinumab (UST), an IL12/23 blocker approved for Crohn's disease, was effective in Phase 3 induction and maintenance studies of patients with moderate-severe ulcerative colitis (UC). Since discontinuation of corticosteroids (CS) is an important goal of therapy in UC, this analysis aims to further describe the CS sparing effects of ustekinumab treatment through Week 44 of the UNIFI trial.

**Aims & Methods:** Responders to UST IV induction entered maintenance and were randomized to UST 90mg SC (q12wks or q8wks), or PBO. During the induction and maintenance studies, oral CS were not to be initiated or increased beyond baseline. At Week 0 of the maintenance study, a scheduled taper was recommended for all patients receiving CS. CS-free Clinical Response (CSR) and remission (CSRem) rates (at Week 44, and for >90 days prior to Week 44) were calculated for the overall population and for the subset of patients on CS at maintenance baseline. Among the subset of patients on CS at maintenance baseline, the mean prednisone-equivalent (P.Eq) CS dose (mg/day) through Week 44 were calculated as were the rates of subjects who were CS-free at Week 44 and for >90 days prior to Week 44

**Results:** Overall 50.6% (265/523) of patients in the primary analysis population were receiving CS at maintenance baseline. The proportions of patients who were receiving concomitant CS at maintenance baseline were 52.3%, 47.7%, and 52.3% in the UST q8w, UST q12w and PBO groups, respectively. As detailed in Table 1, in the overall population, CSR and CSRem rates were significantly higher for patients who continued on UST therapy during maintenance compared with placebo. Among the patients who achieved CSR or CSRem at Week 44, the majority achieved these endpoints

and eliminated CS use at or up to 90 days prior to Week 44. Similar results were observed in the subset of patients on concomitant CS at maintenance BL. In this group, the mean daily P.Eq CS dose at maintenance BL was approximately 15.0 mg/day for all treatment groups. Mean decrease in average daily P.Eq dose at Wk 44 was more pronounced and the proportion of patients who were CS-free was greater in the UST maintenance arms. **Conclusion:** UST maintenance therapy, with both q8w and q12w dosing regimens, is effective in reducing and eliminating the use of CS in patients with UC; the majority of patients (>90%) who achieved clinical response or clinical remission were able to eliminate corticosteroids.

**Introduction:** One of the new promising methods of treatment of patients with ulcerative colitis (UC) is biological therapy using bone marrow mesenchymal stromal cells (MSC). In some cases, simultaneously with MSC, patients receive concomitant anticytokine therapy. Currently, a new strategy for UC therapy is to achieve a deep remission of the disease. To compare the level of immunobiological and histological markers of inflammation—C-reactive protein (CRP), the Geboes Score (GS) and faecal calprotectin (FCP) – in patients with UC receiving cell therapy MSC, anti-integrin therapy with vedolizumab (VDB), and combined therapy of bone marrow MSC and VDB. **Aims & Methods:** To compare the effectiveness of combined therapy of mesenchymal stromal cells and vedolizumab with monotherapy MSC and VDB. 45 patients with total ulcerative colitis of moderate severity were di-

vided into groups depending on the therapy. The first group of patients with UC aged from 19 to 51 years (Me-29) (n=15) received anti-inflammatory therapy with the use of the culture of 2 million MSC/kg according to the scheme the second group of patients with UC (n=15) aged 23 to 50 years (Me-38) received VDB in accordance with the recommended scheme, the third group of patients with UC (n=15) aged 24 to 56 years (Me-31) received the MSC+VDB. The level of CRP, PCF and is was assessed 26 weeks after initiation of therapy. The baseline CRP was 24.6 $\pm$ 1.8; 25.5 $\pm$ 2.0 and 24.8 $\pm$ 2.1 mg/l, respectively. Baseline GS in the groups of patients was 4.6 $\pm$ 0.4; 4.35 $\pm$ 0.25 and 4.5 $\pm$ 0.3 points, respectively. The initial level of the FCP made 1090 $\pm$ 88.8; 1000 $\pm$ 83.9 and 1010 $\pm$ 120.5  $\mu$ g/g, respectively.

**Results:** After 26 weeks from the start of therapy in the first group of patients, the level of CPP was 7.8 $\pm$ 2.1 mg/l, in the second group 7.4 $\pm$ 1.3 mg/l, in the third group 7.5 $\pm$ 1.0 mg/l ( $p > 0.05$ ). After 26 weeks from the start of therapy in the first group of patients, the level of FCP was 98.8 $\pm$ 9.3  $\mu$ g/g, in the second group 90.6 $\pm$ 7.5  $\mu$ g/g, in the third group 82.8 $\pm$ 6.3  $\mu$ g/g ( $p < 0.05$  compared with the 1-st and 3-d groups). After 26 weeks from the start of therapy in the first group of patients with GS was 0.7 $\pm$ 0.1 points, in the second group 0.65 $\pm$ 0.1 points, in the third-0.35 $\pm$ 0.06 points ( $p < 0.001$  compared with the 1-st and 3-d groups).

**Conclusion:** Combined mesenchymal stromal cells and anti-integrin therapy with vedolizumab contributes to a more pronounced reduction in the degree of inflammation of the intestinal mucosa.

**Disclosure:** Nothing to disclose

## P1099 HIGH INCIDENCE OF HYPERGLYCAEMIA IN STEROID TREATED HOSPITALISED INFLAMMATORY BOWEL DISEASE (IBD) PATIENTS AND ITS RISK FACTORS IDENTIFIED BY MACHINE LEARNING METHODS

Harris R.<sup>1</sup>, McDonnell M.<sup>1</sup>, Mills T.<sup>1</sup>, Dharmasiri D.<sup>2</sup>, Downey L.<sup>1</sup>, Felwick R.<sup>1</sup>, Phan H.<sup>3</sup>, Borca F.<sup>3</sup>, Cummings F.<sup>1</sup>, Gwiggner M.<sup>1</sup>

**Introduction:** Glucocorticoids (GC) have been first line treatment for hospitalised inflammatory bowel disease (IBD) patients for over 60 years, despite the introduction of biologic therapy. The use of steroids in IBD inpatients is common and remains prominent in international guidelines. IBD patients often have systemic inflammation complicated by malnutrition leading to metabolic stress. The frequency and specific risk factors for hyperglycaemia in hospitalised IBD patients receiving GC are unknown

**Aims & Methods:** 100 consecutive IBD inpatients receiving intravenous hydrocortisone (IVH) for acute flares had capillary blood glucose (CBG) monitoring automatically triggered by the electronic prescription. CBG, biomarkers, IBD severity scores (Harvey Bradshaw, partial Mayo) and weight loss were prospectively recorded. Undiagnosed Diabetes Mellitus (DM) was defined as baseline HbA1c  $>48$  mmol/mol. Machine learning (random forest regressor, RFR) was applied to the data to evaluate risk factors of hyperglycaemia.

**Results:** 55% of hospitalised IVH treated IBD patients had a CBG meeting the WHO criteria of DM ( $>11$ mmol/L), while 21% and 7% had a CBG  $>14$ mmol/L and  $>20$ mmol/L, respectively. Only 7 patients had pre-existing DM, which was confirmed by admission HbA1c. RFR indicated disease severity score, duration of IVH, HbA1c and electrolyte imbalances (which affected 64%) were best predictors of hyperglycaemia.

50% were started on or switched biological therapy during hospitalisation. 59% were discharged on prednisolone, 14% on budesonide and 28% on no GC. 47 patients had HbA1c checked at 3 month follow-up of which 4 were in the diabetic range. 1 had known DM with elevated CBG during admission treated with insulin titration, 2 had elevated CBG as inpatients with no prior DM and were discharged on anti-diabetic medications (1 gli-clazide, 1 insulin) and 1 was on long-term steroids for asthma who did not have CBG  $>11.0$ mmol/L as an inpatient. 4 patients discharged on gli-clazide for steroid induced DM had documented repeat HbA1c recorded, which were all in the normal range.

**Conclusion:** Our data demonstrates that hyperglycaemia is common in IVH treated inpatients, therefore CBG monitoring should be routine practice. Predictive modelling (RFR) identifies more severe disease activity, duration

of IVH treatment and HbA1c as risk factors for hyperglycaemia. The importance of IVH duration suggests hyperglycaemia risk may be physician-modifiable.

Alternative treatment strategies such as earlier introduction of biologics (which were used in half of the cohort), rapid steroid taper and nutritional therapies could be used to minimise medication associated metabolic instability in high risk patients. Limited follow-up HbA1c data suggests oral hypoglycaemic medication may be effective to mitigate further hyperglycaemia.

**Introduction:** Mirikizumab (miri; LY3074828) is a humanized monoclonal antibody directed against the p19 subunit of IL-23, with efficacy demonstrated in psoriasis, ulcerative colitis, and Crohn's disease (CD). The effect of miri on health-related quality of life (HRQoL) as measured by the Inflammatory Bowel Disease Questionnaire (IBDQ) was examined as part of a Phase 2, multicenter, randomized, parallel-arm, double-blind placebo (PBO)-controlled trial (NCT02891226) in patients with moderate to severely active CD.

**Aims & Methods:** At baseline, subjects (N =191) were randomized in a 2:1:1:2 ratio across 4 treatment arms (PBO, 200, 600, and 1000 mg miri administered intravenously [IV] at Weeks 0, 4, and 8). The IBDQ, a 32-item patient-completed questionnaire that measures 4 domains (bowel and systemic symptoms, emotional and social function), was analyzed at Weeks 0, 4, and 12, with higher scores indicating a better quality of life. IBDQ score change from baseline (BL), IBDQ response, and IBDQ remission were assessed. Treatment comparisons were made using mixed effects for repeated measures analysis for continuous endpoints and logistic regression with nonresponder imputation for categorical endpoints

**Results:** Patients who received 600 or 1000 mg miri had greater change from BL in IBDQ scores at 4 weeks compared to PBO (PBO: 15.18±3.30; miri 200 mg: 24.16±4.83; 600 mg: 27.08±4.77; 1000 mg: 25.52±3.36; 600 and 1000 mg miri p< 0.05 vs PBO). At 12 weeks, all miri groups had greater change from BL in IBDQ scores compared to PBO (PBO: 16.23±3.65; 200 mg: 41.14±5.18; 600 mg: 45.50±5.22; 1000 mg: 41.22±3.64; all p< 0.001 vs PBO). Similarly, at Week 12 IBDQ response was achieved in 58.1%, 68.8%, and 68.8% of patients in miri 200, 600, and 1000 mg groups, compared

to 45.3% in the PBO group (600 mg p< 0.1, 1000 mg p< 0.01), and IBDQ remission was achieved in 35.5%, 53.1%, and 42.2% of patients in the miri 200, 600, and 1000 mg groups, respectively, compared to 15.6% in the PBO group (200 mg p< 0.1, 600 and 1000 mg p< 0.001).

**Conclusion:** Miri treatment produced statistically significant and clinically meaningful improvements in HRQoL as measured by IBDQ after 12 weeks in patients with CD, with clinically relevant changes noted as early as 4 weeks.

**Disclosure:** This study was funded by Eli Lilly and Company.

**Introduction:** TNF-alpha blockers increase the risk of tuberculosis (TB) infection. This risk is especially important in countries which have a high rate of TB infection. The incidence of TB infection in Turkey was reported as 15.2 / 100.000 in 2017 which shows that in our country we should be alert about the risk of TB infection in inflammatory bowel disease (IBD) patients who receive immunosuppressive treatment.

**Aims & Methods:** The aim of this retrospective study is to determine the rate of latent and active tuberculosis infection in IBD who received biologic treatment in our center.: 349 IBD patients who received TNF-alpha antagonist treatment from 1998 to 2018 were included in the study. Information about the demographic data, IBD type, previous and current treatment, latent TB screening results, duration of isoniazid (INH) prophylaxis treatment, lung imaging results, and diagnosis of active TB infection was obtained from patients' files and electronic data system of our hospital.

**Results:** A total of 349 patients (56.4 % male, mean age 42 ± 14 years) were included in the study, the mean disease duration was 10 ± 6 years, 76.5% had Crohn's disease. Taking into account that some of the patients had received more than one type of anti-TNF alpha agent; 77% of the patients (n = 269) received infliximab, where 48.1% (n = 168) received adalimumab, 5.7% (n = 20) received certolizumab, 5.4% (n = 19) received vedolizumab, and 1.1% (n = 4) received golimumab. Latent tuberculosis infection screening was positive in 171 (48.9%) patients (157 tuberculin test > 5 mm and 14 positive Quantiferon test), 96.4% (n = 165) of these patients had received INH treatment for latent TB. Incidence of active TB development was 1.7% (n = 6). Two of them had received INH treatment. In two latent tuberculosis screening was negative. The remaining two patients were inadequately screened: one of them had a negative tuberculin test but Quantiferon test was not obtained, the other patient had a borderline positivity of Quantiferon test. In three patients with active TB infection, pulmonary TB was accompanied by extra-pulmonary infection (Table). Two patients had TB infection after 4 years of TNF-alpha antagonist treatment, which can be the result of a new TB exposure. In 2 patients anti-TNF treatment was initiated again after then tuberculosis treatment was completed. None of these 2 patients developed tuberculosis reactivation. No association was found between the risk of developing TB and gender, age, disease type, type of TNF-alpha antagonist agent used and concomitant immunosuppressive therapy.

Treatment at the diagnosis of TB	INH treatment for latent TB infection (months)	PPD (mm)	Quantiferon test	Duration of TNF-alpha antagonist treatment before the diagnosis of TB (months)	Location of TB infection
AZA CS 5-ASA ADA	-	0	Negative	7	Lung+spleen+peritoneum
AZA ADA	9	6	Negative	48	Lung
5-ASA IFX	-	0	Negative	44	Lung
AZA IFX	-	NA	undetermined	2	Lung
AZA IFX	-	0	NA	7	Lung+lymph nodes
AZA ADA	6	9	NA	3	Lung+spleen

[Patients who had TB infection]

Abbreviations for the table : AZA: azathioprine ADA: Adalimumab CS: Corticosteroids IFX: Infliximab INH: Isoniazide NA:Not available TB: Tuberculosis

**Conclusion:** Active TB infection was detected in 1.7% (n = 6) of the 349 IBD patients who had biologic treatment during a period of 20 years. Two of these 6 patients have had isoniazid treatment for latent TB, in 2 of them screening for latent TB was negative. As a result although latent tuberculosis screening and treatment are recommended by guidelines, this modality may not be sufficient to eliminate the risk of TB infection in patients who receive biologics agents in countries with high incidence of TB infection.

**Contact E-Mail Address:** naegeli\_april\_n@lilly.com

**Introduction:** The efficacy and safety of mirikizumab (miri), an IL-23p19 antibody, has previously shown efficacy and health-related quality-of-life (HRQoL) improvement in patients with moderate-to-severe ulcerative colitis (UC) at 12 weeks in a phase 2, randomized, double-blind, placebo-controlled trial (AMAC, NCT02589665).

**Aims & Methods:** This analysis evaluated the effects of maintenance treatment with miri on clinical response, clinical remission, endoscopic healing, and HRQoL improvement in UC patients. Patients with moderate-to-severe UC (Mayo score 6-12; Endoscopic subscore ≥2) treated with miri during the induction period and who achieved clinical response or better at week 12 were re-randomized to miri 200 mg administered subcutaneously every 4 weeks (Q4W) (N=47) or every 12 weeks (Q12W) (N=46) through week 52. HRQoL was measured by the Inflammatory Bowel Disease Questionnaire (IBDQ) and evaluated using a mixed-model repeated-measures analysis. The percentage of patients at week 52 with clinical response,<sup>1</sup> clinical remission,<sup>2</sup> endoscopic healing,<sup>3</sup> IBDQ total score ≥170, and IBDQ improvement ≥16 were also assessed.

**Results:** At week 52, IBDQ scores significantly improved from baseline in both miri treatment groups (Table). In each treatment group, at week 52, ≥80% of patients had an improvement in IBDQ total score ≥16 points from baseline and ≥67% achieved IBDQ total score ≥170. Similarly, ≥76% of patients demonstrated a clinical response, ≥37% demonstrated clinical remission, and ≥48% demonstrated endoscopic healing at week 52.

**Conclusion:** Maintenance treatment with miri resulted in HRQoL improvement as well as clinical response, clinical remission, and endoscopic healing at week 52 in patients with moderate-to-severe UC. These are the first data in UC to demonstrate the longer-term effects of an IL-23p19 antibody on the HRQoL of patients with UC.

**Disclosure:** Study was funded by Eli Lilly and Company.

**Introduction:** Inflammatory Bowel Disease (IBD) is a chronic, severely debilitating disease which cannot be pharmacologically controlled due to ineffective activity or serious side effects of current therapies. In the search for new treatment options, we examined the anti-inflammatory potential of two preparations of silver particles in vitro in lipopolysaccharide (LPS)-stimulated RAW264.7 cells and in vivo in murine dextran sulphate sodium (DSS)-induced colitis model.

**Aims & Methods:** The nanoparticles were obtained with the use of black-currant extract exploiting the reducing and stabilizing potential of poly-phenols, ascorbic acid and anthocyanins. The concentration of polyphenol compounds equaled 75 mg/dm<sup>3</sup> and the extract showed high capacity for free radicals binding, as evidenced by 1,1-Diphenyl-2-picrylhydrazyl (DPPH) radical reduction assay. Based on UV-VIS analysis, the obtained, round nanoparticles show homogenous distribution and are well-dispersed within suspension. Two formulations were prepared, with final silver nanoparticle concentration equal to 100 and 500 mg/dm<sup>3</sup> and the mean particle diameters of 95 nm (Ag95) and 213 nm (Ag213), respectively. Higher silver concentration was associated with larger particles.

**Results:** In vitro, Ag95 and Ag213 did not show any significant cytotoxicity in RAW264.7 cells up to 1 and 2.5 ppm, respectively, as evidenced in Neutral Red Uptake test. Opposite to the model drug, 10 uM budesonide, the preparations did not increase viability of LPS-stimulated cells. However, Ag95 at 1 ppm and Ag213 at 2.5 ppm were more effective in NO production inhibition, as evaluated by Griess test.

In vivo, both suspensions of silver particles showed anti-inflammatory properties in DSS-induced murine model of colitis. The studied preparations inhibited weight loss, decreased macroscopic score and colon shortening. Additionally, Ag95 and Ag213 reduced neutrophil infiltration assessed by myeloperoxidase activity assay. When tested at the same dose (0.4mg/kg, once daily, i.c.), Ag213 was more effective than Ag95. Higher dose (2 mg/kg) further improved Ag213 performance.

**Conclusion:** The anti-inflammatory action of silver preparations may be useful in IBD treatment. The objective is to maintain high anti-inflammatory potential, simultaneously minimizing the risk of side effects. The tested formulations Ag95 and Ag213, showing good bioavailability and activity, meet these requirements, which warrants further characterization.

**Introduction:** Inflammatory bowel disease (IBD) patients in Western countries frequently experience suboptimal response to anti-tumor necrosis factor (TNF) therapy. The EXPLORE study aimed to assess the incidence and indicators of suboptimal response to first-line anti-TNF agents in IBD patients in real-world practice in newly industrialized countries, where data are currently limited.

**Aims & Methods:** A retrospective chart review study was conducted in Asia-Pacific (APAC; South Korea, China, Taiwan, Singapore), Latin America (LatAm; Argentina, Colombia, Mexico) and Russia-Middle East (RME; Russia, Saudi Arabia, Turkey) in adult patients diagnosed with ulcerative colitis (UC) or Crohn's disease (CD), who initiated anti-TNF treatment between March 2010 and March 2015. The cumulative incidence (CI) of suboptimal response (Kaplan-Meier method) was assessed over the first 24 months of treatment, as the occurrence of a first indicator of: IBD-related hospitalization, dose escalation (increase in frequency and/or dose), discontinuation including switch to another anti-TNF, non-biologic therapy augmentation, or IBD-related surgery. Primary non-response (PNR) and secondary loss of response (SLOR) were defined as any suboptimal response indicator at < 4 and ≥ 4 months after anti-TNF initiation (excluding PNR patients), respectively.

	Overall		APAC		LatAm		RME	
	UC (N=570)	CD (N=1104)	UC (N=173)	CD (N=497)	UC (N=99)	CD (N=86)	UC (N=298)	CD (N=521)
Overall frequency of suboptimal response, n (%)	188 (33.0)	454 (41.1)	81 (46.8)	253 (50.9)	36 (36.4)	40 (46.5)	71 (23.8)	161 (30.9)
Cumulative incidence of suboptimal response, %								
12 months	24.4	30.0	34.4	40.4	25.9	30.7	18.2	19.9
24 months	32.9	41.2	45.1	54.1	38.2	42.5	23.8	29.5
Cumulative incidence of PNR <sup>a</sup> , %	13.6	16.9	20.2	26.5	11.4	10.8	10.5	8.6
Cumulative incidence of SLOR <sup>b</sup> , %								
12 months	12.6	15.8	17.8	18.9	16.4	22.4	8.5	12.4
24 months	22.3	29.2	31.2	37.5	30.2	35.6	14.8	22.9
First indicator of suboptimal response <sup>c</sup> , n (%)	UC (N=188)	CD (N=454)	UC (N=81)	CD (N=253)	UC (N=36)	CD (N=40)	UC (N=71)	CD (N=161)
Anti-TNF dose escalation	23 (12.2)	65 (14.3)	3 (3.7)	34 (13.4)	12 (33.3)	9 (22.5)	8 (11.3)	22 (13.7)
Non-biological therapy augmentation	57 (30.3)	108 (23.8)	25 (30.9)	68 (26.9)	15 (41.7)	14 (35.0)	17 (23.9)	26 (16.1)
Anti-TNF discontinuation including switch	45 (23.9)	42 (9.3)	31 (38.3)	18 (7.1)	5 (13.9)	4 (10.0)	9 (12.7)	20 (12.4)
IBD-related surgery	7 (3.7)	79 (17.4)	2 (2.5)	35 (13.8)	2 (5.6)	8 (20.0)	3 (4.2)	36 (22.4)
IBD-related hospitalizations	62 (33.0)	164 (36.1)	20 (24.7)	99 (39.1)	6 (16.7)	5 (14.6)	36 (50.7)	60 (37.3)

APAC: Asia-Pacific; CD: Crohn's Disease; IBD: Inflammatory Bowel Disease; LatAm: Latin America; RME: Russia-Middle East; TNF: tumor necrosis factor; UC: Ulcerative colitis. <sup>a</sup>Cumulative incidence at 4 months. <sup>b</sup>SLOR among patients who did not experience PNR and who are still on anti-TNF at 4 months. <sup>c</sup>6 UC and 4 CD patients had more than one suboptimal response indicator on the same day.

[P1104 Table 1. Cumulative Incidence and Indicators of Suboptimal Response to First-Line Anti-TNF Therapy in IBD Patients in Newly Industrialized Countries]

**Results:** Overall, 1674 first-line anti-TNF treated patients (570 UC; 1104 CD) were included: male, UC 56.1%, CD 61.2%; median (min-max) age (years), UC 39.0 (18-82), CD 31.0 (19-83); median (min-max) disease duration (years), UC 3.0 (0-34), CD 1.0 (0-33); median (min-max) follow-up (months), UC 45.9 (24-60), CD 46.5 (14-60). At 24 months, the CI of suboptimal response to first anti-TNF treatment was 32.9% in UC and 41.2% in CD patients (unadjusted log-rank:  $p < 0.01$ ); the APAC region had the highest CI (UC 45.1%; CD 54.1%) (Table 1). The CI of PNR was 13.6% and 16.9% in UC and CD patients, respectively. The CI of SLOR was 22.3% in UC and 29.2% in CD patients at 24 months. The most frequent first suboptimal response indicator was 'IBD-related hospitalization' (UC 33.0%; CD 36.1%) followed by 'non-biologic augmentation' (UC 30.3%; CD 23.8%) (Table 1).

**Conclusion:** Suboptimal response to first-line anti-TNF agents is common in IBD patients in newly industrialized countries and is more frequently experienced in CD than in UC. Observed regional differences in the rates of suboptimal response, PNR and SLOR, may reflect local practice variations and restrictions in the management of anti-TNF treated patients.

**Disclosure:** The study was funded by Takeda Pharmaceuticals Company Ltd.

### P1105 VEDOLIZUMAB INDUCES DEEP REMISSION AND IMPROVES QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES: THE ANCONA EXPERIENCE

Quatraccioni C., Annulli G., Daretti L.M., Antuono S., Calzolari M., Guardati P., Benedetti A., Di Sario A.

**Introduction:** Vedolizumab (VDZ) is an  $\alpha 4\beta 7$  integrin antagonist approved for the treatment of adult patients (pts) with moderate to severe ulcerative colitis (UC) and Crohn's disease (CD).

**Aims & Methods:** The primary outcome of the study was to evaluate the effect of VDZ on clinical response in pts with UC and CD at the 14<sup>th</sup> week. Secondary outcomes were to evaluate clinical remission, mucosal healing, deep remission, steroid-free remission and quality of life at different time points (14<sup>th</sup> week, 6, 12 and 24 months).

We retrospectively evaluated 39 pts who referred to our Inflammatory Bowel Disease Unit and received VDZ for moderate-severe UC (26 pts) and moderate-severe CD (13 pts). As concerns the UC and CD outcomes, clinical response was defined by a reduction in Mayo score  $\geq 3$  points and in Harvey-Bradsaw index (HBI)  $\geq 3$  points, clinical remission by a Mayo score  $\leq 2$  and by a HBI  $< 5$  and endoscopic remission by endoscopic Mayo subscore  $\leq 1$  and by endoscopic SES-CD score  $\leq 2$ , respectively. Steroid free-remission was evaluated in UC pts only. Deep remission was defined, in both diseases, as clinical, endoscopic and biochemical remission. Serum C-reactive protein (CRP) and faecal calprotectin (FC) were evaluated in pts at all time points. Quality of life (QoL) was evaluated by the 32-item version of Inflammatory Bowel Disease Questionnaire (IBDQ-32).

**Results:** UC pts: 12 out of 26 UC pts had previously failed anti-TNF therapy; clinical response at the 14<sup>th</sup> week was observed in 77% of the pts and no significant differences were found between naive and anti-TNF treated pts. Non-responder pts showed a more severe Mayo endoscopic subscore (2.8 vs 2.2;  $P < 0.02$ ). Clinical remission occurred in 60%, 64%, 67% and 75% of pts at the 14<sup>th</sup> week, 6, 12 and 24 months, respectively. Steroid-free remission was 85% (17/20) at the 14<sup>th</sup> week and 75% at 24 months. Mucosal healing was above 70% at all time points. In pts who had a clinical response, FC levels decreased from 529.15 mg/kg at baseline to 103.7 mg/kg at the 14<sup>th</sup> week and was always less than 50 mg/kg after 6, 12 and 24 months. Similarly, CRP levels decreased from 1.85 mg/dl at baseline to 0.9 mg/dl at the 14<sup>th</sup> week, and were within the normal range ( $< 0.50$  mg/dl) after 12 and 24 months. Deep remission was 35% at the 14<sup>th</sup> week and 75% at 24 months. QoL in responder pts was  $131 \pm 34$  at baseline, significantly increased after 14 weeks ( $171.9 \pm 29$ ;  $P < 0.001$ ) and remained stable over time.

CD pts: 12 out of 13 pts had previously failed anti-TNF therapy; clinical response at the 14<sup>th</sup> week was observed in 46% of the pts, whereas clinical remission rates were 100%, 80%, 100% and 100% at the 14<sup>th</sup> week, 6, 12 and 24 months, respectively. Mucosal healing was observed in 25% of pts at 12 months and in 100% of pts at 24 months, whereas deep-remission was achieved in 25% and 50% of pts at the same time points. In responder pts, FC, CRP and QoL showed a significant improvement starting from the 6<sup>th</sup> month.

Advers events were observed in 5/39 pts: psoriasis (2 pts), joint symptoms (1 pt), arterial hypertension (1 pt) and mild urticaria (1 pt); however only 1 pt with psoriasis had to discontinue the treatment.

**Conclusion:** VDZ was effective and safe for induction and maintenance of deep remission and of steroid-free remission in pts with UC, and significantly improved their QoL; serum CRP and FC levels correlated with clinical response. Even if data in CD pts are limited, VDZ appeared effective for induction and maintenance of clinical and endoscopic remission also in these pts, although the improvement in biochemical indices and in the QoL required at least 6 months.

**Introduction:** Crohn's disease (CD) remains an incurable condition despite expanding therapeutic options. Treatment are randomly initiated and switched in case of insufficient response. Biomarkers that allow prediction of response offering guidance for treatment selection are lacking, leading to poor disease control and complications. Epigenetics, mainly DNA methylation patterns, have been shown to predict CD behavior and recurrence. We investigated the predictive power of peripheral blood (PB) methylation profiles in CD patients treated with infliximab (IFX) or vedolizumab (VDZ).

**Aims & Methods:** We identified CD patients who were distinct responders (R) and non-responders (NR) to IFX and VDZ based on clinical and endoscopic criteria who were prospectively sampled in the biobank Future-IBD at Amsterdam UMC. DNA was isolated from PB at baseline and 8 weeks into treatment. Methylation screening was performed using the Infinium® Methylation EPIC Bead Chip (850K) by Illumina (San Diego, CA). Response assessment was performed after 12-16 weeks.

**Results:** In this pilot study we analyzed 12 CD patients treated with IFX (6 R and 6 NR) and 12 with VDZ (5 R and 7 NR). Analysis of differentially methylated positions (DMPs) between R and NR both before and after induction treatment yielded 38 DMPs for IFX and 9 DMPs for VDZ, both at a Benjamin-Hochberg adjusted  $\alpha$  of 0.05. For IFX, all DMPs showed a complete separation of responders and non-responders and a striking mean methylation difference of at least 10% between responders and nonresponders. Similar results, but for distinct loci, were obtained in the VDZ cohort. The largest effect size with complete separation of R and NR to VDZ showed a methylation difference of  $> 30\%$ .

**Conclusion:** DMPs associated with response/nonresponse to IFX and VDZ were mutually exclusive indicating that both marker sets are specific for each treatment. We observed large methylation differences between R and NR which is exceptional in complex diseases like CD. These observations open the road to personalized treatment selection in CD. Further validation of these markers is ongoing.

**Introduction:** Developing a new drug for treating ulcerative colitis (UC) is challenging. More challenging is the clinical trial design.

**Aims & Methods:** We highlight the phase 3 trial design of a new 5ASA drug (TP0503) and compare it to the latest EMA "guideline on the development of new medicinal products for the treatment of Ulcerative Colitis" from 2018. We also compare TP0503 to another recent mesalazine trial (SAT25). We also compare TP0503 to another recent mesalazine trial (SAT25). Each item in the EMA guideline was compared to TP0503 protocol (Mesalazine 1600 mg vs. Mesalazine 400 mg; NCT01903252) and SAT25 (Mesalazine 1000 mg vs. Mesalazine 500 mg; NCT01745770). This comparison covers the patient selection (section 4 of EMA guideline), efficacy assessment (section 5) and study design (section 6). Safety aspects (section 7) and the risk management plan (section 8) were well-respected by both trials.

**Results:** As per EMA guideline, patient selection in TP0503 and SAT25 was based on symptoms, endoscopic and histologic findings. Patients with malignancy and Clostridium D. infection were excluded from TP0503. Patients with malignancy were not clearly excluded from SAT25. While both trial designs relied on endoscopic score to include or exclude patients, SAT25 used Rachmilewitz Endoscopic score (EI) which is less widely used than the Mayo Endoscopic Score (MES). SAT25 included patients with EI≥4 (mild to severe) without relying on central reading. All TP0503 patients had higher endoscopic score with MES≥2 (moderate to severe). MES was assessed by one central reader. TP0503 is one of the first trials that used central reading for inclusion and efficacy assessments.

For the efficacy assessment, TP0503 respected each item of the guideline looking at the symptomatic and endoscopic remission as a treatment goal for induction and maintenance of remission in UC. In TP0503, the primary endpoint (PEP) was a co-primary endpoint at week 8 of clinical remission and endoscopic remission as defined by MAYO≤2 without any subscore>1. SAT25 PEP, was less stringent and used clinical remission as the only PEP. SAT25 did not report a combined PEP of clinical and endoscopic remission, diverging from the EMA guideline.

For the study design, TP0503 respected each item of the guideline except for two. For ethical reasons, it was not possible to randomize UC patients to a placebo arm therefore TP0503 trial was a non-inferiority trial. Nor were they stratified according to prior treatment. While the SAT25 study group didn't include any placebo arm or stratify to prior treatment, they also, didn't perform any long term trial to evaluate the efficacy of the Mesalazine 1000 mg in maintenance.

With regards to missing data, TP0503 considered all missing data as failures, unlike the SAT25 trial where the LOCF was used to manage some missing data. Patients on topical co-medication were excluded from both trials. Looking at safety aspects, beside the exclusion of acute severe colitis and patients with pouchitis, which are not part of the mesalazine indications, TP0503 and SAT25 respected all other criteria.

**Conclusion:** TP0503 had more up-to-date design than SAT25 with more stringent criteria. It mostly adhered to the 2018 EMA guideline even though it was designed 5 years prior.

	EMA Guidelines (2018)		TP0503 (2017)		SAT25 (2018)	
	Maximum score per guidelines		Scoring	(%)	Scoring	(%)
Patient selection	7		6.5	92.9%	6	85.7%
Assessment of efficacy	21		17	81.0%	12	57.1%
Study design	25		14.5	58.0%	10	40.0%
Safety aspects	7		6	82.7%	6	82.7%
Total	60		44	73.3%	34	56.7%

## P1108 ANTI-TNF TREATMENT EFFECTIVELY REDUCED RATE OF HOSPITALIZATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE WITH OR WITHOUT EXTRAINTestinal MANIFESTATIONS: REAL WORLD DATA IN GERMANY

Bettenworth D.<sup>1</sup>, Lee W.-J.<sup>2</sup>, Clark R.<sup>2</sup>, Rath S.<sup>3</sup>, Yang M.<sup>4</sup>, Cook E.E.<sup>4</sup>, Vavricka S.<sup>5</sup>

**Introduction:** Extraintestinal manifestations (EIMs) are prevalent among patients with inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC). However, the impact of EIMs on healthcare resource utilization is not well understood. Tumor necrosis factor inhibitors (TNFi) have shown to be effective in reducing risk of hospitalization and reducing EIMs in IBD patients.

**Aims & Methods:** This study assessed the prevalence of hospitalization in patients with IBD stratified by the presence of concomitant EIM(s) and evaluated the effect of TNFi on hospitalization in the real world. This study used the InGef database (2011-2017), containing anonymous claims from statutory health insurance in Germany. Adults with ≥2 CD or UC claims, ≥2 TNFi claims, and continuous enrollment for at least 12 months before (baseline) and 15 months after the first TNFi prescription (index date) were included. The rate of all-cause and IBD-related hospitalizations during baseline were compared to the 12-month period starting 3 months after the index date (follow-up). The first 3 months were excluded to allow time for the treatment to take effect.

**Results:** A total of 1,658 IBD patients who received a TNFi were identified (CD: 1,108; UC: 550). Over 50% (845/1658) had ≥1 all-cause hospitalization at baseline, and 90% (765/845) of the events were IBD-related. During baseline, over one-third of patients (35%) had at least one EIM (CD: 34%; UC: 38%). More patients with EIM(s) had at least 1 hospitalization compared to those without an EIM (all-cause: 56% vs. 48%,  $p < 0.01$ ; IBD-related: 50% vs. 44%,  $p < 0.05$ ), and the majority resulted from an emergency room (ER) visit (all cause: 34% vs. 28%,  $p < 0.01$ ; IBD-related: 30% vs. 25%,  $p < 0.05$ ). Patients with EIM(s) also had a greater mean number of hospitalizations than patients without an EIM (all-cause: 1.2 vs. 0.9,  $p < 0.001$ ; IBD-related: 1.0 vs. 0.7,  $p < 0.01$ ). During the TNFi therapy follow-up period, the proportion of patients with ≥1 all-cause hospitalization decreased by ≥17% in both groups, and almost all were IBD-related (EIM:  $\Delta=17\%$ ; no EIM:  $\Delta=18\%$ , both  $p < 0.001$ , Table).

		With EIM* (N=581)			Without EIM* (N=1077)		
		Pre-Index	Post-Index	P-value	Pre-Index	Post-Index	P-value
All-cause	% with ≥1 hospitalization, n (%)	324 (55.8%)	224 (38.6%)	<0.0001	521 (48.4%)	335 (31.1%)	<0.0001
	% with ≥1 hospitalization resulting from ER, n (%)	199 (34.3%)	118 (20.3%)	<0.0001	301 (27.9%)	181 (16.8%)	<0.0001
	# hospitalizations, mean ± SD	1.2 ± 1.5	0.8 ± 1.4	<0.0001	0.85 ± 1.18	0.55 ± 1.04	<0.0001
	Length of stay, days, mean ± SD	11.7 ± 22.7	7.6 ± 19.6	<0.0001	7.6 ± 16.1	5.9 ± 19.7	<0.0001
IBD-related	% with ≥1 hospitalization, n (%)	288 (49.6%)	187 (32.2%)	<0.0001	477 (44.3%)	282 (26.2%)	<0.0001
	% with ≥1 hospitalization resulting from ER, n (%)	176 (30.3%)	99 (17.0%)	<0.0001	272 (25.3%)	147 (13.6%)	<0.0001
	# of hospitalizations, mean ± SD	1.0 ± 1.4	0.6 ± 1.2	<0.0001	0.7 ± 1.1	0.5 ± 0.9	<0.0001

EIM, extraintestinal manifestation; IBD, inflammatory bowel disease; ER, emergency room; SD, standard deviation.

\*EIMs included bone manifestation, bronchopulmonary disease, hepatobiliary disease, mucocutaneous disease, musculoskeletal disease, ocular disease, oral disease, pancreatic disease, renal disease, or cardiovascular events.

[Hospitalization before and after initiating a TNFi therapy among patients with IBD by EIM status]

Hospitalizations resulting from an ER visit decreased during follow-up (EIM:  $\Delta=14\%$ ; no EIM:  $\Delta=11\%$ , both  $p < 0.001$ ), and almost all of the reduction was IBD-related (EIM:  $\Delta=13\%$ ; no EIM:  $\Delta=12\%$ , both  $p < 0.001$ ). The mean number of all-cause hospitalizations (EIM:  $\Delta=0.4$ ; no EIM:  $\Delta=0.3$ , both  $p < 0.001$ ) and length of stay (EIM:  $\Delta=4.1$  days; no EIM:  $\Delta=1.7$  days, both  $p < 0.001$ ) was also reduced after TNFi use.

**Conclusion:** Hospitalization is highly prevalent among patients with IBD, especially among those with concomitant EIM(s) who had higher rates of hospitalization and ER visits than those without an EIM. TNFi treatment is effective in reducing all-cause and IBD-related hospitalizations, and this effect appeared to be comparable in both patients with or without a prior EIM.

**Introduction:** Efficacy of vedolizumab (VDZ) has been confirmed in Crohn's disease (CD), but there is limited data on mucosal healing, a combination of endoscopic and histological remission. In the LOVE-CD (LOw countries Vedolizumab in CD) trial we explored this novel endpoint in patients with active CD receiving VDZ for 52 weeks.

**Aims & Methods:** The aim of this exploratory analysis was to assess mucosal healing, the combination of endoscopic and histological healing, through week 26 in CD patients treated with VDZ. We included patients who had centrally read endoscopy at week 0 and 26 and paired biopsies at the same time points. Only patients with active histological inflammation at baseline (Robarts Histopathology Index (RHI) score  $> 7$ ) were studied.

All patients had active CD (Crohn's Disease Activity Index (CDAI)  $> 220$  and presence of mucosal ulcerations at baseline endoscopy) and were treated with VDZ 300 mg infusions at week 0, 2, 6 and every 8 weeks thereafter to week 52, with an additional infusion at week 10 in the absence of clinical response. Mucosal biopsies were collected from the edge of the most prominent ulcer in the terminal ileum and 4 colonic segments (ascending, transverse, descending colon and sigmoid and rectum), or from the most severely affected area if no ulcers were present.

If a segment was completely normal, two biopsies were taken at random per segment. Histopathology was assessed blindly using the RHI, which represents a reproducible and responsive index that incorporates four histologic descriptors (i.e. severity of chronic inflammatory infiltrate, the number of neutrophils in the lamina propria, the number of neutrophils in the epithelium and the severity of erosions or ulceration), each of which is graded from 0 to 3 (Mosli M et al. Gut. 2017;66(1):50-58). In case more than one biopsy was available per segment, the biopsy sample with the maximum RHI score was used for further analysis.

**Results:** Paired biopsies from the same segment were available in 65 patients, 40 of which (62%) had active histological inflammation (RHI score  $> 7$ ) at baseline. Out of these patients, 35/40 (88%) failed on prior anti-TNF therapy and median disease duration was 8 (4-18) years. Fourteen out of these 40 patients (35%; 95% CI (0.21, 0.52)) achieved mucosal healing at week 26 (SES-CD  $< 4$  and RHI  $\leq 6$ ). Endoscopic remission at week 26 was observed in 17/40 (43%) and histologic remission in 23/40 (58%).

**Conclusion:** Mucosal healing was achieved in 35% of CD patients with active histological inflammation at baseline after 26 weeks treatment with VDZ. These outcomes show that VDZ is able to induce both endoscopic and histological healing in therapy-refractory CD.

**Introduction:** Psychosocial stress can have a negative impact on the course of disease in ulcerative colitis. A comprehensive lifestyle-modification program that includes stress management techniques addresses this unmet need.

**Aims & Methods:** In this randomized controlled trial, 97 patients with ulcerative colitis in remission and reduced quality of life were randomly assigned to a 10-week LSM program or a one day work-shop as control (Table 1). Perceived stress, anxiety, depression, and flourishing were measured before and after the intervention and after 24 and 48 weeks.

In an exploratory sub-study, 16 female patients (8 intervention and 8 controls) additionally underwent an acute psychosocial stress paradigm, the Trier Social Stress Test (TSST) which is a validated laboratory procedure to induce stress in human participants. Here, cardiovascular responses, blood parameters, and state anxiety were captured at baseline, stress, recovery 1 (+20min), and recovery 2 (+55min).

**Results:** Comprehensive lifestyle-modification significantly decreased patients' perceived stress compared to control ( $p < .001$ ) at time point post intervention. Flourishing was significantly increased at 48 weeks ( $p = .006$ ). No effects on anxiety ( $p = .075$ ) or depression ( $p = .146$ ) were evident (all  $p < 0.05$ ). TSST induced a rise of stress parameters in both groups. Significant differences were evident for pulse ( $\Delta=6.99$ bpm;  $p=.015$ ), adrenaline ( $\Delta=-19.07$ pg/ml;  $p=.037$ ) and on a ten percent level for state-anxiety ( $\Delta=9.026$ ;  $p=.066$ ) at stress and for systolic blood pressure ( $\Delta=-10.24$ mmHg;  $p=.05$ ) and on a ten-percent-level for adrenocorticotrophic hormone at ( $\Delta=2.53$ ng/ml;  $p=.067$ ) at recovery 2. Cortisol, noradrenaline, leukocytes, thrombocytes, lymphocytes, monocytes or neutrophils showed no differences.

**Conclusion:** A Comprehensive lifestyle-modification program significantly decreased patients' perceived stress and increased flourishing in patients with UC. Those changes in stress perception were supported by results of the TSST under laboratory experimental conditions.

**Introduction:** Acute severe colitis is a serious complication of inflammatory bowel disease. It can lead to colectomy and death. Its medical treatment has been step forward within the last decades, based on infliximab or cyclosporine as second medical therapy.

**Aims & Methods:** The aim of this study is to precise the impact of infliximab on the short and long term prognosis of acute severe colitis not responding to corticosteroids.

All patients admitted for acute severe colitis have been retrospectively enrolled, between the years 1994 and 2018. Standard therapy based on intravenous corticosteroids was initially led in all patients. We particularly interested in patients failed to steroids and hence treated with infliximab as second line medication, and we studied the rate of avoiding colectomy in the short and in the long term as well as the rate of clinical and endoscopic remission.

**Results:** 69 patients with acute severe colitis were reviewed (median age: 34y. (15-64y.); 38 females and 31 males). There were 61% with ulcerative colitis, 33% with Crohn's disease and 6% with indeterminate colitis. 32.9% of patients (n=22) failed to corticosteroids. Among them, 9 patients have been treated with Infliximab infusions (5mg/Kg) . 88.8% of them avoided urgent colectomy and where discharged within 4 weeks. All pa-

tients experienced clinical remission within a median follow up of 64,96 mo [6 -234]. 4 patients have undergone a colonoscopy during follow up. Endoscopic remission was noticed in 3 patients and a mucosal healing without complete remission was reported in one patient. Nine other patients have been subsequently treated with Infliximab for active chronic disease. No adverse event was reported during follow up. Colectomy-free survival rates were better in the group of patient treated with infliximab but not significatively (p=0.695)

**Conclusion:** Infliximab is an efficient treatement for corticoreistant acute severe colitis as a second line treatment and as a remission promoting factor. It diminished the urgent and distant colectomy without serious adverse effects.

**Disclosure:** Nothing to disclose

## P1112 PEAK USTEKINUMAB CONCENTRATION AFTER INTRAVENOUS LOADING DOSE PREDICTS FAECAL CALPROTECTIN NORMALISATION IN CROHN'S DISEASE: POTENTIAL ROLE FOR THERAPEUTIC DRUG MONITORING?

**Contact E-Mail Address:** david.drobne@gmail.com

**Introduction:** Up to one third of patients with Crohn's disease do not respond or respond partially to the intravenous loading dose of ustekinumab. This was partially explained by low ustekinumab concentrations during maintenance phase (1). However, exposure-response relationship during induction, particularly during the first 4 weeks following intravenous loading, has not been sufficiently studied in the real-life setting yet.

**Aims & Methods:** We prospectively investigated the association of ustekinumab induction drug levels to calprotectin normalisation (defined as levels < 100 mg/kg) after intravenous induction in Crohn's disease in a real-life setting.

Ustekinumab drug levels (ELISA assay) at 4 prespecified time points during induction (one hour post-infusion (peak level), week 2, week 4 and week 8) were correlated to faecal calprotectin (Calprest assay) levels at weeks 8, 16 and 24 of starting ustekinumab. We recruited 52 consecutive patients who started ustekinumab due to active Crohn's disease at a tertiary referral university centre. All patients received an intravenous loading dose of ustekinumab (approximately 6 mg/kg as per label, infused over 60 min) followed by 90 mg q 8 weeks maintenance. Median disease duration at start of treatment was 15 years (IQR: 8-23), most patients (35/52 (67%)) had failed previous biological treatment (25 anti-TNF, 9 vedolizumab, 1 both). At inclusion 8/52 (15%) were on systemic steroids. Mann-Whitney U-test and ROC analysis were used to test for differences and identify optimal cut-offs of ustekinumab drug levels to predict calprotectin normalisation.

**Results:** Median calprotectin decreased from 134 (IQR:72-235) to 80 (IQR: 26-173) by week 8, to 65 (IQR:32-188) by week 16 and 66 (IQR: 35-203) by week 24 of start of ustekinumab. Faecal calprotectin was normal in 27/47 (57%), 23/42 (55%), 26/41 (63%) of patients at week 8, 16 and 24, respectively. Median ustekinumab drug levels were higher at all assessed time points in patients with normal calprotectin at weeks 8, 16 and 24 compared to those with increased calprotectin levels (Table 1). Ustekinumab levels of >94 (sensitivity 85%, specificity 65%, PPV 74%) 1-hour post-infusion, >25 (sensitivity 90%, specificity 56%, PPV 69%) at week 2, >20 (sensitivity 60%, specificity 100%, PPV 100%) at week 4, and >7 (sensitivity 60%, specificity 95%, PPV 94%) at week 8 were identified as optimum cut-offs for calprotectin normalisation at week 8, with similar values for weeks 16 and 24. Importantly, these cut-offs had a high negative predictive values (at 1h post-infusion: 71% and at week 2: 70%) for calprotectin normalisation at 6 months.

**Conclusion:** Our data indicate that induction concentrations of ustekinumab after an intravenous loading dose, as early as 1 hour after infusion, predict faecal calprotectin normalization during the first 6 months in Crohn's disease. These data indicate that therapeutic drug monitoring of ustekinumab during induction could potentially improve outcomes by identifying patients in need of early proactive dose optimisation.

Ustekinumab concentration (µg/mL), median (IQR)	Faecal calprotectin at week 8		P value	Area under the ROC curve (95% confidence interval)
	<100 mg/kg	≥100 mg/kg		
Peak (1 h after infusion)	111 (98-124)	92 (83-116)	0.033	0.73 (0.56-0.91)
Week 2	32 (28-36)	25 (21-30)	0.005	0.77 (0.61-0.92)
Week 4	20 (16-24)	12 (7-17)	<0.0001	0.82 (0.68-0.96)
Week 8	7 (4-11)	3 (2-5)	<0.0001	0.84 (0.71-0.97)

**Contact E-Mail Address:** calvo.marta@gmail.com

**Introduction:** Ustekinumab (UST) is a fully human monoclonal antibody against IL-12/23. It has shown efficacy in inducing and maintaining clinical remission in patients with Crohn's disease (CD). To date UST is approved in Spain only in refractory to AntiTNF CD patients, but information about clinical benefit of UST in patients previously exposed to several biologics in real-life practice is limited.

**Aims & Methods:** Retrospective cohort study in a tertiary hospital in which 73 CD patients received UST from April 2010 to April 2019 were evaluated. Those who received intravenous dose due to active disease (Harvey-Bradshaw index score [HBI] >4) were considered for the analysis. The maintenance schedule every 8 or 12 weeks was at physicians' discretion. The clinical benefit was defined by the HBI score and evaluated at week 8, 24 and 48.

**Results:** 68 patients included; median follow up was 5 months (IQR: 1-12). Characteristics of the study population are summarized in Table. All patients were exposed at least one biological treatment (98% anti-TNFα agent and 16% vedolizumab), and 69% more than two.

At week 8, 33% and 45% experienced clinical response and clinical remission, respectively. 41 patients reached 6 months of follow up: 24% and 71% achieved clinical response and clinical remission, respectively. 22 patients reached 12 months of follow up, 18% and 82% experienced clinical response and clinical remission, respectively. During follow-up, 8 patients (15%) required intensification at 90mg sc every 4 weeks (median: 12 months; IQR: 11-13). Of these, 4 had clinical benefit (50% response and 13% remission). Clinical evaluation still pending in 3 cases.

Patients who received UST after failure of only one biologic agent obtained better outcomes than those who received UST after 2 or 3 biologics, although it did not achieved statistical significance (p=0.09).

Withdrawal of UST occurred in 6 (9%) patients along the follow up, due to lack of efficacy in all cases. No adverse event recorded.

Clinical use of UST increased through time: among all patients included 18 (26%) received UST in 2017, 29 (42%) in 2018, and 21 (31%) in the first

trimester of 2019. Moreover, 5 (29%) of patients included in 2017 had previously failed 3 or 4 biologic agent, 7 (24%) in 2018 and 3 (14%) in the first trimester of 2019.

**Conclusion:** Our real-life clinical experience confirms favorable data of clinical efficacy and safety of UST in refractory CD patients and showed a trend towards an increasing and earlier use of UST.

**Contact E-Mail Address:** dnaessens@its.jnj.com

**Introduction:** We evaluated the effect of ustekinumab (UST) on work productivity and daily activity in patients with moderate-severe active ulcerative colitis (UC) in the UNIFI induction and maintenance studies.

**Aims & Methods:** In the induction study, patients were randomized to a single intravenous (IV) dose of placebo (PBO, n=319), UST 130 mg (n=320), or UST ~6 mg/kg (n=322). Patients who were in clinical response 8 wks after receiving UST IV induction were eligible for the maintenance study and randomized to subcutaneous (SC) PBO (n=175), UST 90 mg q12w (n=172), or UST 90 mg q8w (n=176). Work productivity was assessed using the Work Productivity and Activity Impairment Questionnaire (WPAI), a validated tool that assesses work time missed (absenteeism), reduced job effectiveness (presenteeism), overall work impairment, and daily activity impairment due to health over the previous week. The impact of UC on overall daily productivity at home, school, and work was assessed using a visual analog scale (VAS, 0 to 10, 0=no impact at all, 10=impacts very much).

**Results:** At induction baseline, patients had a mean percent work time missed ranging from 17.7% to 19.3%, impairment while working from 39.1% to 45.3%, overall work impairment from 43.7% to 49.1%, and activity impairment from 51.8% to 52.8%. At Wk8, patients who received UST IV had significantly greater improvement in WPAI domains and daily productivity VAS compared with PBO (Table).

In the maintenance study, UST-treated patients generally maintained or numerically improved WPAI scores, while scores for patients in the PBO group worsened. The mean changes from baseline to Wk44 in work time missed was 4.7% in the SC PBO group, -2.0% (p=0.133) in the SC UST 90-mg-q12w group, and 2.1% (p=0.172) in the SC UST 90-mg-q8w group, impairment while working was 7.4%, -1.6 (p=0.017), and -6.4% (p<0.001),

respectively; overall work impairment was 7.7%, -2.2% ( $p=0.013$ ), and -6.1% ( $p<0.001$ ), respectively; and activity impairment was 9.3%, 0.8% ( $p=0.002$ ), and -4.2% ( $p<0.001$ ), respectively. Mean changes from baseline to Wk44 in daily productivity VAS scores were 1.0, -0.2 ( $p<0.001$ ), and -0.5 ( $p<0.001$ ), respectively.

Domain	PBO IV	UST IV 130mg	UST IV ~6mg/kg
WPAI % work time missed due to health	-3.7% (30.41%)	-5.9%* (31.39%)	-9.1%** (23.84%)
WPAI % impairment while working due to health	-6.9% (21.89%)	-15.1%* (29.17%)	-20.4%† (24.11%)
WPAI % overall work impairment due to health	-8.0% (24.83%)	-17.2%** (30.36%)	-21.8† (26.26%)
WPAI % activity impairment due to health	-10.9% (28.66%)	-17.7%** (29.45%)	-20.8%† (26.27%)
Impact on daily productivity at home, school and work VAS (0-10)	-1.3 (2.95)	-2.3† (3.03)	-2.3† (2.84)

\* $p<0.05$ , \*\* $p<0.01$ , † $p<0.001$

[Mean (standard deviation) changes from baseline to Wk8 in WPAI and daily productivity VAS results during the induction study]

**Conclusion:** Patients who received UST IV induction reported significantly greater improvement in work productivity and daily activity compared with PBO. In patients who responded to UST IV induction, those who received UST SC maintenance through Wk44 sustained or improved the levels of work productivity and activity that were achieved during induction.

## P1116 MANAGEMENT AND OUTCOMES OF ANTI-DRUG ANTIBODIES TO INFLIXIMAB, A LONG-TERM OBSERVATIONAL STUDY

McGettigan N.<sup>1</sup>, Harkin G.<sup>2</sup>, Moran C.<sup>1</sup>, Harewood G.<sup>1</sup>, Patchett S.<sup>1</sup>, Cheriyan D.<sup>2</sup>, Boland K.<sup>1</sup>, O'Toole A.<sup>2</sup>

<sup>1</sup>Beaumont Hospital, Gastroenterology, Dublin, Ireland, <sup>2</sup>Beaumont Hospital, Dublin, Ireland

**Contact E-Mail Address:** neasamcgettigan@hotmail.com

**Introduction:** Secondary loss of response (LOR) to Infliximab (IFX) occurs in up to 40% of IBD patients. One of the causes of LOR is the development of anti-drug antibodies (ADAs) which neutralize IFX. At present, evidence regarding the optimal management of ADAs is lacking.

**Aims & Methods:** This is a long-term retrospective observational study of adult patients receiving IFX who developed ADAs >8mg/L over a study period of 3 years. This study reviewed the optimisation of Infliximab therapy and subsequent outcomes in patients who developed ADAs. The primary aim of this study is to identify the best practice of management of ADAs to IFX to avoid discontinuation of therapy/LOR and to identify predictors of development of ADAs. Secondary aims include review of adverse outcomes following development of ADAs.

**Results:** 132 patients with IBD and 1 patient with collagenous colitis are included in the study. Baseline characteristics include 54% male, mean age of 39.4, mean IFX drug trough level 4.7 mg/L, mean ADA level 103 mg/L, 25% were on a previous biologic and 26% were on combination therapy prior to the development of ADAs.

52% of patients discontinued IFX- 72% due to LOR, 16% due to clinical remission, 12% due to infusion reaction.

Both an increase in IFX and adjustments to combination therapy (increase in IFX + addition/increase in immunomodulator) were associated with lower rates of discontinuation of treatment vs no intervention ( $P$ -Value < 0.001,  $P$ -Value < 0.001 respectively). No difference was seen with adjustment of immunomodulator therapy alone ( $P$ -Value= 0.62). An increase in IFX resulted in a significant difference in ADAs and IFX trough levels pre and post intervention ( $P$ -Value < 0.001,  $P$ -Value = 0.032).

There was a significant reduction in ADAs overtime for the entire cohort (Mean of 103 mg/L vs mean of 55 mg/L on follow-up,  $P$ -Value= 0.008) and a correlation was noted with ADAs and low drug trough levels ( $P$ -Value= 0.056). No significant correlation was found between the presence of ADAs and CRP, fecal calprotectin or serum albumin. 15% were admitted

to hospital, 11% underwent surgery, 19% required steroids. 32% switched to another biologic- 63% of patients were switched to Adalimumab.

**Conclusion:** A high percentage of patients who develop ADAs to IFX experience LOR. A reduction in ADA levels was seen due to proactive drug monitoring. Both escalation of IFX alone and combination therapy resulted in lower rates of LOR. Our most common practice post LOR due to ADAs was to switch within drug class.

## P1117 THIOPURINE WITHDRAWAL DURING SUSTAINED CLINICAL REMISSION IN CROHN'S DISEASE

Sanchez-Aldehuelo R., Sanchez Rodriguez E., Rodriguez de Santiago E., Mesonero Gismero F., Fernandez C., Albillos A., Lopez-Sanroman. A. Hospital Universitario Ramón y Cajal, Servicio de Gastroenterología y Hepatología, Madrid, Spain

**Contact E-Mail Address:** ruben.sanchez.aldehuelo@gmail.com

**Introduction:** Cessation of thiopurines (TP) in patients with Crohn's disease (CD) in clinical remission (CR) is controversial.

**Aims & Methods:** To describe the evolution of CD patients who discontinued TP and to detect predictors of reactivation after withdrawal. An observational unicentric retrospective study was conducted including CD patients in clinical remission who discontinued TP.

**Results:** We included 39 patients with CD in remission (51.3% females; 26 inflammatory, 8 stricturing and 5 penetrating behaviour; 9 with terminal ileum involvement, 4 colonic, 26 ileocolonic, and 11 with perianal disease). TP were indicated to maintain remission after steroids in 27 (69.2%), to prevent postoperative recurrence in 8 (20.5%), and to induce remission as part of a combination therapy in 4 (10.3%).

Median azathioprine dose was 150 mg/day. Median duration of TP treatment was 5.3 years (p25-p75: 3.3-7.2) and of steroid-free remission 60.9 months (p25-p75: 32.4-76.6). Reasons for TP withdrawal were patient's choice/request in 10 (25.6%), physician proposal in 27 (69.2%) and drug-related adverse events in 2 (5.15%). By the time of TP discontinuation, median C reactive protein (CRP) was 2.5 mg/L (p25-p75: 1-3.8), faecal calprotectin (FC) 37 µg/g (p25-p75: 16-80) and mean Harvey-Bradshaw Index (HBI) 0.2.

Relapse was observed in 17 patients (43.6%), after a median follow-up of 47 (p25-p75: 26.2 - 81.5) months. Median time until relapse was 17 (p25-p75: 7-33.2) months. At relapse, median CRP was 6.6 (3-18) mg/L, FC 429 (340.5-479.5) µg/g and mean HBI 5.5. After relapse, 4 (21.1%) patients restarted TP; 4 (21.1%) were prescribed one single course of CE without further therapy; 2 (10.5%) one course of CE and TP reintroduction; 2 (10.5%) CE and a biological agent; 1 (5.3%) CE, a biological agent and mesalazine, 1 (5.3%) methotrexate; 1 (5.3%) low dose TP with allopurinol and CE and 1 (5.3%) underwent surgery.

During follow-up, 3 (17.6%) patients received another single course of CE, 1 (5.9%) needed surgery and 2 (11.8%) both. Mean follow-up of non-relapsing patients was 30.4 (13.9-49.2) months. TP treatment duration of shorter than 5 years before discontinuation, was associated to a higher risk for relapse (HR 3.69  $p<0.01$ ).

**Conclusion:** TP withdrawal is possible in patients with CD in sustained clinical remission; however, almost half of them can relapse.

**Disclosure:** Nothing to disclose

**Introduction:** Thiopurines are the most commonly used immunosuppressants in inflammatory bowel disease (IBD), but their main limitation is the high rate of drug-related adverse events (AE) and treatment discontinuation. Switching to a second thiopurine may be an alternative in these cases, but series published up to now, include a limited number of patients. In a previous study, we demonstrated that starting thiopurines in elderly age is associated with a higher incidence of AE.

**Aims & Methods:** Our aim was to evaluate the tolerance of switch to a second thiopurine as well as the persistence of treatment and the factors associated with it. Based on the ENEIDA registry (a large, prospectively maintained database of the Spanish Working Group in IBD -GETECCU), adult IBD patients that switch to a second thiopurine due to AE were identified. Two cohorts were selected regarding the age at the beginning of thiopurine treatment: between 18-50 years, and over 60 years. The rate and concordance of AE that occurred with the second thiopurine, treatment discontinuation due to AE and the overall persistence of the second thiopurine were evaluated.

**Results:** Of the 17,371 patients who started a first thiopurine in these two cohorts, 3,903 patients discontinued thiopurine treatment due to AE. In 1,278 of them (32%) a switch to a second thiopurine was performed (93% to mercaptopurine, 7% to azathioprine). 1,105 patients below 50 years of age and 173 over 60 years. The AE of the first thiopurine were: digestive intolerance 60%, hepatotoxicity 13%, myelotoxicity 6%, acute pancreatitis 2%, other 19%. The rate of post-switch AEs was 58%, leading to the discontinuation due to AE of the second-thiopurine in 46% of cases. In those patients who presented post-switch AE, the most likely AE was the same that occurred with the first thiopurine, particularly digestive intolerance (61%). The cumulative probability of post-switch treatment discontinuation due to AE was 40%, 43%, 47% and 50% at 6 months, 1-3-5 years, respectively. The persistence of post-switch treatment was 44%, 40% and 34% at 1-3-5 years, respectively. The multivariate analysis showed that the only independent risk factors of treatment discontinuation due to AE were the switch over 60 years (53% vs. 45%, OR 1.5: 95% CI 1.1-2.1), having developed digestive intolerance (48% vs. 41%, OR 1.4: 95% CI 1.1-1.8) or pancreatitis (83% vs. 45%, OR 6.8: 95% CI 2.6-18.2) with the first thiopurine.

**Conclusion:** In the largest series reported to date, we observed that switch to a second thiopurine is a valid strategy except in the case of pancreatitis. Close monitoring is advisable among elderly IBD patients switching to a second thiopurines because of AEs.

**Disclosure:** Nothing to disclose

## P1119 LONG-TERM OUTCOME OF ACUTE SEVERE ULCERATIVE COLITIS RESPONDING TO INTRAVENOUS STEROIDS: A MULTICENTRE COHORT STUDY

**Contact E-Mail Address:** robert.salameh@yahoo.com

**Introduction:** Acute severe ulcerative colitis (ASUC) is a life-threatening condition that occurs in up to 25% of patients with UC. Intravenous steroids (IVS) are effective in nearly two-thirds of patients. Few data are available on long-term outcomes of patients responding to IVS. ECCO guidelines recommended maintenance therapy with thiopurine in thiopurine-naïve patients and a biological agent in patients with previous thiopurine-failure.

**Aims & Methods:** We performed a retrospective observational study of consecutive patients with UC, hospitalized for ASUC (as defined by Truelove and Witts' criteria), among four tertiary centres in Paris area, between January 2006 and December 2017. Patients included responded to IVS. Relapse was defined as partial Mayo Clinic score  $\geq 3$  and/or any subscore  $>1$  and the initiation of second line therapy. Patients with Crohn's disease or inflammatory bowel disease unclassified, and those in whom biologics were initiated before response to IVS could be assessed were not included. Disease activity was assessed using the Lichtiger index and the partial Mayo Clinic score. Endoscopic activity was assessed using partial Mayo Clinic endoscopic subscore and UCEIS. Relapse-free and colectomy survival was studied with Kaplan-Meier method, log-rank test and Cox regression model.

**Results:** 142 patients (70 (49.3%) male; median age: 33.9 [IQR 25.5-48.1] years; UC duration 1.4 [0.1-4.3] yrs; 79 (55.6%) patients with pancolitis; 100 (70.4%) with no history of immunomodulator and biological agent use) were included in this study. At inclusion, patients had a mean total Mayo Clinic score of  $10.0 \pm 1.0$ , a mean Lichtiger index of  $13.1 \pm 2.2$ , a CRP serum level of  $91.9 \pm 75.4$  mg/L and a mean UCEIS of  $4.8 \pm 1.2$ . Deep ulcerations were observed in 24.3% of the cases. Median hospital stay was of 8 (6-10) days. Maintenance therapy included 5-ASA in 59 (41.5%) patients, immunomodulators in 54 (38.0%), anti-TNF agents in 18 (12.7%) and vedolizumab in 5 (3.5%). More patients were treated with 5-ASA in the naïve group (54.0% vs. 11.9%,  $p < 0.001$ ) and with biological agents in the failure group (47.6% vs. 3.0%,  $p < 0.001$ ) whereas no difference was noted for immunomodulators (40.5% vs. 43.0%,  $p = 0.85$ ). After a median follow-up of 4.8 (2.6-7.3) years, 90 (63.4%) of the 142 patients relapsed and 12 (8.5%) required colectomy. The probabilities of relapse-free survival were 58.1%, 47.8%, 45.5%, 41.9% and 39.8% at 1, 2, 3, 4 and 5 years, respectively. The multivariate analysis demonstrated that patients treated with 5-ASA (HR=1.59, 95%CI[1.01-2.49],  $p=0.04$ ) were more likely to experience failure whereas patients with  $< 6$  stools/day at day 3 (HR=0.40, 95%CI[0.21-0.77],  $p=0.006$ ) and partial Mayo Clinic score  $< 2$  at day 5 (HR=0.48, 95%CI[0.30-0.77],  $p=0.003$ ) were less likely to experience failure. There was no difference in failure-free survival between the naïve and failure group. The probabilities of colectomy-free survival were 95.8%, 95.0%, 93.2% and 92.1% at 1, 2, 3, 4 and 5 years, respectively. The multivariate analysis demonstrated that patients with Lichtiger index  $> 12$  (HR=10.1, 95%CI[1.30-78.55],  $p=0.03$ ) were more likely to experience colectomy.

**Conclusion:** In patients with ASUC responding to IVS, there was a high failure rate of the initial maintenance therapy with only 40% of patients still in clinical remission at 5 years. Conversely, the colectomy rate was less than 10% at 5 years. Improvement in maintenance therapy after ASUC responding to IVS is needed.

**Introduction:** Inhibition of cellular activation of lymphocytes, macrophages, and dendritic cells via interference between cluster of differentiation 40 (CD40) and its ligand (CD40L) represents an attractive target in inflammatory bowel disease (IBD). In chronic inflammatory conditions, non-hematopoietic, tissue-resident cells, such as epithelial and endothelial cells, can also express CD40, and its stimulation contributes to tissue damage. Preclinical studies with anti-mouse CD40 antagonist and agonist monoclonal antibodies (mAbs) have demonstrated that CD40 signaling is required to induce and maintain intestinal inflammation in mouse models of IBD. We developed a humanized anti-CD40 mAb antagonist, ravagalimab, as a potential therapeutic in IBD.

**Aims & Methods:** To test the ability of ravagalimab to block the development of T cell-dependent responses, we immunized cynomolgus monkeys with keyhole limpet hemocyanin (KLH) and assessed suppression of anti-KLH immunoglobulins M and G (IgM and IgG). In addition, healthy volunteers received single or multiple doses of ravagalimab and the functional effect of CD40 receptor blockade on CD40L-mediated induction of p38 phosphorylation was analyzed ex vivo in B cells.

**Results:** Ravagalimab exhibited exclusive antagonist activity in vitro. It exhibited immunosuppressive pharmacology when evaluated for T-cell-dependent antibody response in cynomolgus monkeys, completely inhibiting formation of KLH-specific IgM and IgG when compared with vehicle-treated animals. CD40 receptor occupancy on B cells from healthy subjects increased rapidly following intravenous administration of ravagalimab, reaching maximum occupancy of >90% within 1 to 3 days. This maximum receptor occupancy was maintained for up to 4 weeks (in a dose-dependent manner) after the last dose of ravagalimab. During maximum receptor occupancy, ravagalimab was able to fully inhibit CD40L-mediated induction of p38 phosphorylation in B cells from healthy subjects. Importantly, when full receptor occupancy was lost, CD40L-mediated induction of p38 phosphorylation was completely restored, indicating that the inhibition is reversible. Based on these translational studies, a clinical study to evaluate efficacy, safety, and pharmacokinetics of ravagalimab as a treatment for patients with moderately to severely active ulcerative colitis (UC) is presently conducted as a multicenter proof-of-concept study (clinicaltrials.gov, NCT03695185). The primary endpoint is the proportion of patients with endoscopic improvement (Mayo endoscopic subscore of 0 or 1) at week 8 as assessed by central endoscopy reading.

**Conclusion:** Translational evidence from an animal model and human cell assays strongly supports testing of the anti-CD40 antagonist mAb ravagalimab in a phase 2a study in patients with UC.

**Disclosure:** Stefan Schreiber has received consulting fees and/or lectured for AbbVie, Amgen, Biogen, Bristol-Myers Squibb, Boehringer, Celltrion, Janssen, Merck, Pfizer, Roche, and Takeda. **Contact E-Mail Address:** hunter\_theresa\_marie@lilly.com

**Introduction:** This study compared healthcare resource utilization (HCRU) among Crohn's Disease (CD) patients currently prescribed biologics and CD patients not currently prescribed biologics.

**Aims & Methods:** Adult (18+ years) patients with ≥1 CD diagnosis code (ICD-9: 555.x; ICD-10: K50.x) from January 1, 2017 to December 31, 2017 were included in this retrospective analysis of medical and pharmacy claims data from the IBM MarketScan Commercial, Medicaid, and Medicare-Supplemental Claims database. Patients with an Ulcerative Colitis diagnosis were excluded from this study. Subgroups analyses were conducted to compare CD patients prescribed biologics and CD patients not prescribed biologics during 2017. A two-sample t-test was conducted to compare continuous variables and chi-squared tests were used to compare categorical variables.

**Results:** A total of 49,292 CD were included in this analysis; 16,613 (33.7%) were prescribed a biologic and 32,679 (66.3%) were not prescribed a biologic. Biologic users were more likely to be male (46.7% vs. 41.0%; p<0.001) and younger (mean age: 40.51 vs. 46.79 years; p<0.001) when compared to patients not prescribed a biologic. Biologic users were more likely to be prescribed immunomodulators (21.9% vs/ 13.3%; p<0.001) and corticosteroids (40.8% vs. 34.3%; p<0.001), while patients not receiving biologics were more likely to be prescribed 5-ASAs (29.9% vs. 16.5%; p<0.001). Biologic users were also more likely to have gastroenterologist visits (75.1% vs. 52.2%; p<0.001). Patients not prescribed biologics were more likely to have ER visits (38.8% vs. 32.0%; p<0.001) and inpatient hospital visits (20.6% vs. 17.3%; p<0.001).

**Conclusion:** Medication use was higher among CD biologic users, however CD patients not prescribed biologics had higher HCRU.

**Disclosure:** Nothing to disclose

## P1122 OLAMKICEPT (SGP130FC) DEMONSTRATES TARGET ENGAGEMENT AND INTERLEUKIN-6 PATHWAY INHIBITION ASSOCIATED WITH CLINICAL EFFECTIVENESS IN AN OPEN LABEL TRIAL (FUTURE) IN ACTIVE IBD

**Introduction:** Interleukin-6 (IL-6) is a master regulator of inflammatory responses. Immediate IL-6-mediated effects are attributed to classic signalling, following binding of IL-6 to a membrane bound IL-6 receptor complex. In contrast, chronic inflammation is mediated by trans-signalling, in which a complex of circulating soluble IL-6R isoforms (sIL-6R) together with IL-6 can engage virtually every body cell by binding to the ubiquitous gp130 co-receptor. The fusion protein olamkicept (sgp130Fc, FE 999301, TJ301, ola) is a cytokine trap that selectively neutralises IL-6/sIL-6R complexes and hence intercepts trans-signalling(1). In clinical Phase I, ola showed target engagement and excellent tolerability without systemic immune suppression in >50 healthy and patient volunteers. Here, we report the first administration of ola to patients with active IBD in an open label study (FUTURE).

**Aims & Methods:** FUTURE was a Phase 2a open label study, in which 20 adult patients with active IBD were included (baseline endoscopies) and 16 patients (UC=9, CD=7) were dosed with ola (600 mg iv q 2 weeks for up to 12 weeks plus 42-day safety follow-up). Patients had moderately to severely active UC (Mayo score max. 11 and endoscopic sub-score ≥2) or ileocolonic CD (CDAI 220-500, SES-CD>7), immunologically active inflammation (CRP >5 mg/L), had failed conventional therapies, and had received no more than 2 prior biologics (limited to anti-TNFs and/or vedolizumab). Primary endpoint was the proportion of patients with reduced mucosal expression of a predefined 6-gene score measured by RNA sequencing. Objective assessments included centrally read endoscopies, histology and

various explorative molecular parameters and inflammatory biomarkers. The trial was sponsored and conducted by the University Medical Center Schleswig Holstein under prior approval of the medical faculty's ethics committee and the Paul-Ehrlich Institute (EUDRA-CT 2016-000205-36). Ola was provided by Ferring Pharmaceuticals A/S.

**Results:** Ola was well tolerated. AEs were unspecific in nature and showed no signs of immune suppression. There were no life-threatening or potentially ola-related SAEs. Activity scores were in the moderate-severe range (Mayo 10, CDAI 330) with high inflammation markers [median CRP/FCP 29.6/1,795 (UC) and 16.4/2,098 (CD)] and with median disease duration of 5.3 (UC) and 6.9 (CD) years. Pharmacokinetic studies showed stable and sustained exposure in plasma concentrations. Target engagement of olamkicept was confirmed by whole-blood STAT3 phosphorylation assays in all patients. Overall, 55% of patients with UC responded (5/9) and 22% (2/9) reached remission (Mayo), and 28% (2/7) CD patients responded with 14% (1/7) reaching remission. All patients in clinical remission also showed endoscopic healing. The primary endpoint was achieved in 12.5% (n=2/16) patients and was highly predictive of later clinical endoscopic and histologic remission. Blood transcriptome analysis showed early molecular anti-inflammatory signature (as early as 4 h after treatment) in all patients, irrespective of treatment outcome.

**Conclusion:** The first human efficacy data with ola indicate anti-inflammatory efficacy of IL-6 trans-signalling inhibition in patients with IBD. This preliminary signal appears to be stronger in UC than in CD. A larger, placebo-controlled, multinational Phase II study examining olamkicept (TJ301) in moderately to severely active UC is currently conducted in China and other East Asian countries (NCT03235752).

**Contact E-Mail Address:** manubarreiro@hotmail.com

**Introduction:** Dose escalation is often recommended for loss of response in patients with inflammatory bowel disease (IBD) under maintenance treatment with anti-TNF, but this strategy considerably increases the costs. A new presentation of adalimumab (ADA) 80 mg has been approved with a similar price per unit in our hospital as the ADA 40 mg presentation.

**Aims & Methods:** The aim of this study was to evaluate the efficacy, safety and cost-efficiency of ADA 80 mg every other week (eow) in IBD patients under intensified treatment with ADA 40 mg every week.

**Material and methods:** A prospective and observational study was performed. Inclusion criteria were all IBD patients under intensified maintenance therapy with ADA 40 mg every week. Patients were informed about the reasons (cost and convenience) for switching to ADA 80 mg eow and asked for their consent. Follow-up time was 6 months. The Harvey Bradshaw index (HBI  $\leq 4$ ) and the Mayo partial index (Mayo partial index  $\leq 2$ ) were used to evaluate clinical remission in Crohn's disease (CD) and ulcerative colitis (UC) patients, respectively. Adverse events were monitored. Faecal calprotectin (FC) and C reactive protein (CRP) were evaluated at baseline (week 0, before first dose of subcutaneous injection of ADA 80mg) and at months 1, 2 and 6. Biological remission was defined as clinical remission, together with FC < 250 µg/g and CRP < 5 mg/dL. Trough drug concentrations and drug antibodies were measured at baseline and

at months 1, 2 and 6 by ELISA (Promonitor). Trough levels < 5 mg/L were considered as infratherapeutic. A descriptive analysis was performed and data are shown as percentage, median and range. Cost-efficacy analysis was also performed.

**Results:** Sixteen patients were included (15 CD and one extensive UC, median age 40 years, 56.3% male, 37.5% non-smokers and 31.3% ex-smokers). In CD, 46.7% had ileal disease, 13.3% colonic disease and 40% ileocolonic disease. 46.7% CD patients presented fistulising behaviour. At baseline, 86.7% of patients were in clinical remission and 92.3% were in clinical remission after 1 month. Median FC concentration and CRP concentration from baseline to month 6 are shown in Table 1.

	At month 0	At month 1	At month 2	At month 6
Median fecal calprotectin (µg /g) (range)	317 (6-1900)	223 (10-3754)	92 (32-4527)	82 (7-3772)
Median C reactive protein (mg/dL) (range)	0.14 (0-19)	0.44 (0.01-2.94)	0.41 (0.01-6.95)	0.16 (0.01-1.08)

[Median faecal calprotectin and C reactive protein in IBD patients under maintenance treatment con adalimumab 80 mg every other week]

60%, 53.3% and 68.8% of patients were in biological remission at month 0, 1 and 2, respectively. No adverse events were registered. No significant differences in trough levels concentrations were observed from baseline to month 2, but 7% of patients had trough levels < 5 mg/L. At month 6, three patients withdrew ADA 80mg treatment because of relapse, none of them were in biological remission at inclusion. The remaining patients maintained clinical remission; 61.5% of them were in biological remission. After six months, including only patients in remission that completed the treatment, a total of 114,000 € were saved with the new schedule of treatment.

**Conclusion:** Changing to a single dose ADA 80 mg eow is an effective, safe and efficient strategy in IBD patients under intensified maintenance therapy with ADA 40 mg every week.

**Disclosure:** Nothing to disclose

## P1124 SPERMIDINE TREATMENT AMELIORATES EXPERIMENTAL COLITIS in vivo

Niechcial A.<sup>1</sup>, Katkeviciute E.<sup>1</sup>, Hering L.<sup>1</sup>, Wawrzyniak M.<sup>1</sup>, Schwarzfischer M.<sup>1</sup>, Baebler K.<sup>1</sup>, Atrott K.<sup>1</sup>, Scharl M.<sup>1,2</sup>, Spalinger M.R.<sup>1</sup>

**Introduction:** Genetic variants within the gene locus encoding protein tyrosine phosphatase non-receptor type 2 (PTPN2) are associated with an increased risk for inflammatory bowel disease (IBD). In the intestine of IBD patients, cellular levels of the natural polyamine spermidine are reduced. We have already demonstrated, that spermidine activates PTPN2 and thereby suppresses pro-inflammatory effects *in vitro* and *in vivo*. These effects are even further enhanced in immune cells derived from PTPN2 variant IBD patients, however the molecular mechanisms underlying the anti-inflammatory properties of spermidine remain poorly defined.

**Aims & Methods:** The aim of this study was to investigate the effect and molecular mechanisms of spermidine treatment in a T-cell mediated mouse colitis.

To induce intestinal inflammation, Rag2<sup>-/-</sup> immunodeficient mice were injected intraperitoneally with wild-type (WT) or PTPN2-deficient (KO) naive T-cells. Spermidine (3mM) was administered in the drinking water throughout the experiment. Colitis severity was evaluated by using mouse endoscopy, histological analysis of the colon, and myeloperoxidase activity. To assess T-cell subsets, flow cytometry was performed on lamina propria lymphocytes (LPL).

**Results:** Spermidine treatment significantly ameliorated colitis symptoms, as observed by decreased weight loss (p < 0.001), reduction of endoscopic colitis scores (p < 0.001), absence of colon shortening (p < 0.01) and lower signs of inflammation in histological assessment of the terminal colon (p < 0.001) in mice receiving WT T-cells and KO T-cells. In addition, myeloperoxidase activity, a measurement of infiltrating myeloid cells was signifi-

cantly reduced ( $p < 0.001$ ) in mice receiving spermidine when compared to untreated mice. Furthermore, administration of spermidine resulted in a significant reduction of CD4<sup>+</sup> T-cell numbers ( $p < 0.01$ ) in LPL of mice receiving WT T-cells, but not in mice receiving KO T-cells. Interestingly upon spermidine treatment, relative abundance of neither IFN- $\gamma$  T helper (Th) 1 cells, IL-17<sup>+</sup> Th17 cells nor IL-17<sup>+</sup>IFN- $\gamma$  Th1/17 was affected in mice receiving WT T-cells or KO T-cells.

**Conclusion:** Our results demonstrate that spermidine treatment significantly ameliorates T-cell induced colitis. Interestingly, the mode of action of spermidine is not dependent on presence of PTPN2 in T-cells, which implicates that spermidine treatment might have a local effect on the mucosa and/or other stromal cells. Nevertheless, our findings indicate that spermidine administration might be a promising novel therapeutic strategy for IBD treatment.

<sup>1</sup>University Hospital Leuven, Gastroenterology, Leuven, Belgium, <sup>2</sup>AbbVie Inc., Worcester, United States, <sup>3</sup>KU Leuven, Leuven, Belgium, <sup>4</sup>AbbVie Inc., Chicago, United States, <sup>5</sup>Istituto Clinico Humanitas, Milan, Italy

**Contact E-Mail Address:** severine.vermeire@uz.kuleuven.ac.be

**Introduction:** The CELEST study (NCT02365649) evaluated the selective Janus kinase-1 (JAK-1) inhibitor upadacitinib (UPA) in patients with moderately to severely active Crohn's disease (CD). Improvements in clinical and endoscopic outcomes and a safety profile consistent with that reported in rheumatoid arthritis trials were observed.<sup>1,2</sup> Here we report pharmacodynamic profiling of serum inflammatory mediators in CELEST patients with the aim of understanding UPA mechanism of action in CD and linking biomarkers to intestinal inflammation, abdominal pain (AP), and stool frequency (SF).

**Aims & Methods:** CELEST was a Phase 2, multicenter, randomized, double-blind, placebo (PBO)-controlled study designed to evaluate the efficacy and safety of multiple dosing regimens of UPA versus PBO in adult patients with an inadequate response or intolerance to immunomodulators and/or TNF inhibitors.<sup>1,2</sup> Serum samples from the baseline (BL) visit and the end of the induction period (Wk 16) were analyzed by the OLINK® inflammation panel (92 proteins) and by Singulex immunoassay for interleukin-17A (IL-17A), IL-17C, IL-17F, IL-22, and IL-23p19. Protein level changes (BL-Wk 16) were analyzed by an ANCOVA model where the BL protein level was adjusted as a covariate and the treatment effect was considered significant when a false discovery rate  $< 0.10$  was observed after multiplicity adjustment on F-test p-values. Spearman rank correlation coefficients ( $r_s$ ) were used to determine relationships between BL levels or BL-Wk 16 level changes of serum biomarkers (also including serum C-reactive protein and fecal calprotectin) and improvements in Simple Endoscopic Score for CD (SES-CD), AP, and SF.

**Results:** Paired BL and Wk 16 serum samples were available from 104 patients (UPA 3 mg twice daily [BID], n=18; 6 mg BID, n=19; 12 mg BID, n=13; 24 mg BID, n=18; 24 mg once daily, n=18; and PBO, n=18). UPA treatment significantly reduced expression of serum pro-inflammatory mediators (Table) that are associated with immune cell migration, type I/II interferon (IFN) responses, T cell activation, T helper cell-1 (Th1) responses, and CD8<sup>+</sup> T cell responses. Additionally, numerical changes for modulation of mediators of macrophage and dendritic cell activity, hematopoiesis, and neuroprotection were observed. UPA treatment did not significantly modulate expression of IL-23/Th17-related serum cytokines in CD. Correlations were observed for BL-Wk 16 changes in serum proteins and SES-CD, AP, or SF. Importantly, oncostatin-M reductions correlated with SES-CD ( $r_s = 0.35$ ,  $p = 0.02$ ) and with SF improvement ( $r_s = 0.33$ ,  $p = 0.04$ ), suggesting similar drivers of these aspects of disease. AP improvement correlated with reductions in CSF-1 ( $r_s = 0.37$ ,  $p = 0.01$ ), TNFRSF9 ( $r_s = 0.34$ ,  $p = 0.03$ ), IL-12B ( $r_s = 0.31$ ,  $p = 0.07$ ), CXCL9 ( $r_s = 0.31$ ,  $p = 0.07$ ), and CD8A ( $r_s = 0.31$ ,  $p = 0.09$ ), which are all associated with the Th1/CD8/IFN- $\gamma$  pathway.

**Conclusion:** This analysis of inflammatory mediators in serum of CD patients from CELEST identifies potential pharmacodynamic biomarkers and mechanistic insights for the JAK-1 inhibitor, UPA. These data suggest that

UPA has a differentiated mechanism from therapies targeting IL-12/23 p40 and IL-23 p19. Correlations between biomarker changes and changes in signs, symptoms, and intestinal inflammation of CD suggest that UPA may drive improvement of these aspects of CD through distinct mechanisms.

## P1126 PREGNANCY OUTCOMES IN WOMEN EXPOSED TO GOLIMUMAB - UPDATE

Esslinger S.<sup>1</sup>, Gabriel S.<sup>2</sup>, Otero-Lobato M.<sup>1</sup>, Clark M.<sup>2</sup>, Sheridan P.<sup>2</sup>, Geldhof A.<sup>1</sup>

<sup>1</sup>Janssen Biologics B.V., Medical Affairs, Leiden, Netherlands, <sup>2</sup>Janssen Research & Development, LLC, Horsham, United States

**Contact E-Mail Address:** sesslin1@its.jnj.com

**Introduction:** Rheumatologic disorders and inflammatory bowel disease (IBD) can affect women of childbearing potential. Golimumab (GLM) is approved for rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), non-radiographic axial spondyloarthritis (nr-axial SpA), polyarticular juvenile idiopathic arthritis (pJIA) and ulcerative colitis (UC). To characterize pregnancy outcomes in patients treated with GLM, data obtained from maternal exposure to GLM are presented.

**Aims & Methods:** This dataset includes individual patient cases reported to the manufacturer through 06 April 2018. Cases retrieved included prospectively reported (ie, pregnancy outcome not known when first reported) and retrospectively reported (ie, pregnancy outcome known when first reported) maternal exposures to GLM during pregnancy or within 2 months prior to conception, and a reported pregnancy outcome. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries.

**Results:** Two hundred nine pregnancy cases with reported outcomes (113 rheumatological, 37 UC, and 59 others) were identified. Of these 209 cases, 128 were prospective and 81 were retrospective. Overall, 9 congenital anomalies were reported (1 in UC). A total of 50 spontaneous abortions were noted (23.9%). Of these, 22.0% (11/50) received GLM in combination with MTX. Detailed outcomes are provided in Table 1.

**Conclusion:** The rates of congenital malformations and spontaneous abortions were consistent with published background rates for the general population. Limitations of this analysis included the lack of a direct com-

parison group, the variable amount of data available in the reports, and the possible bias towards reporting more negative outcomes in retrospective cases.

Pregnancy Outcome

**Introduction:** The anti-integrin monoclonal antibody vedolizumab (VDZ) has been approved for the treatment of moderate to severe ulcerative colitis (UC). There is a need for evaluating the clinical efficacy of VDZ in real-world clinical settings. In addition, the effect of VDZ on the endoscopic activity of UC and its ability to induce mucosal healing are still being explored.

**Aims & Methods:** We aimed to report the clinical and endoscopic response to VDZ in a large cohort of Greek patients with UC who were refractory to previous therapies. Patients were recruited from 11 tertiary Greek IBD centers. VDZ was administered according to standard induction and maintenance protocols. Short-term response was evaluated at week 12 and defined according to the Gemini 1 criteria (reduction in the Mayo Clinic score

of at least 3 points and a decrease of at least 30% from baseline, with a decrease of at least 1 point on the rectal bleeding subscale or an absolute rectal bleeding score of 0 or 1). Long-term efficacy was evaluated at week 54. Persistence of treatment at week 54 was considered as an indicator of clinical efficacy. The Gemini 1 Criteria for remission at 54 weeks (full Mayo score of 2 or lower and no subscore higher than 1) were also independently applied. Mucosal healing was defined as endoscopy Mayo score of 0.

**Results:** In total, 97 patients with UC [males=57, mean age: 45, (range: 17-79 years)] have been included in the study. Three patients had proctitis (E1), 37 left-sided colitis (E2), and 57 extensive disease (E3). Twenty-three patients (23.7%) had at least one active extraintestinal manifestation at VDZ commencement. There were 53 anti-TNF naive patients. We present herein data from the 78 patients who have completed at least one-year from initiation of VDZ treatment.

**Short-term response data:** At wks 12-14, 17/78 patients (21.8%) exhibited no response, while 61/78 (78.2%) fulfilled criteria for clinical response. Twenty-two patients (28.2%) were on concomitant treatment with corticosteroids and 13 (16.7%) with azathioprine/6-mercaptopurine. A colonoscopy at 12-14 wks was performed in 48 patients; 27% had complete mucosal healing (endo Mayo score=0), whereas an additional 48% had partial endoscopic response (decrease in endoscopic Mayo Score). We observed statistically significant improvement in patient-reported outcomes (PRO) from week 0 to week 12 of treatment with VDZ. In particular, PRO-UC1/rectal bleeding decreased from  $1.22 \pm 0.98$  to  $0.32 \pm 0.65$ , ( $P < 0.0001$ ) and PRO-UC2/number of bowel movements from  $2.69 \pm 1.12$  to  $1.51 \pm 0.78$ , ( $P < 0.0001$ ), whereas SIBDQ score increased from  $43 \pm 13$  to  $55 \pm 10$ , ( $P < 0.0001$ ).

**Long-term response data:** At week 54, 52/78 patients were still on VDZ therapy (drug persistence: 68%). Less than 10% of patients were receiving concomitant steroids and 15% azathioprine/6-mercaptopurine. Of the patients who had a colonoscopy at week 52 (n=30), 30% demonstrated complete mucosal healing and another 43% had a partial endoscopic response. At wk 54, PRO-UC1/rectal bleeding decreased from  $1.34 \pm 1.03$  to  $0.31 \pm 0.6$ , ( $P < 0.0001$ ) and PRO-UC2/number of bowel movements from  $1.82 \pm 1.12$  to  $0.67 \pm 0.88$ , ( $P < 0.0001$ ), whereas SIBDQ score increased from  $41 \pm 16$  to  $50 \pm 13$ , ( $p=0.056$ ).

**Conclusion:** In this national multicenter study, VDZ demonstrated high response rates both in the short- and long-term evaluations. Satisfactory outcomes were obtained at the clinical and endoscopic measurements combined with improved quality of life. Our study adds to other published data on real-world evidence and supports the notion that VDZ is a reliable therapeutic option for patients with UC.

**Disclosure:** This study has been funded by an IISR from Takeda to G.B. and G.P.

Immunologie, Ludwigshafen, Germany, <sup>10</sup>Amsterdam UMC, Amsterdam, Netherlands

**Contact E-Mail Address:** jasmina.kalabic@abbvie.com

**Introduction:** Efficacy and safety of the IL-23 inhibitor risankizumab (RZB) have been previously assessed in pts with moderate-to-severe Crohn's disease (CD) following induction and maintenance treatments.<sup>1,2</sup> Pts who

responded to RZB in the Phase 2 induction and maintenance study<sup>2,3</sup> could enroll in an open-label extension (OLE).<sup>4</sup> Interim safety and efficacy of RZB maintenance treatment, up to 3 yrs, are reported from this ongoing OLE.

**Aims & Methods:** Pts who achieved clinical response (decrease from BL in CD Activity Index [CAI]  $\geq 100$ ) without remission (CAI  $< 150$ ) after Period 2 (Wk 26) or clinical response and/or remission after Period 3 (Wk 52) of the preceding study<sup>1</sup> were enrolled to receive open-label 180 mg s.c. RZB every 8 wks for up to 206 wks.<sup>4</sup> Pts who lost clinical response or remission after completing the preceding study were re-induced with open-label 600 mg i.v. RZB at Wks 0, 4, 8. Pts receiving re-induction treatment could only receive subsequent 180 mg s.c. RZB every 8 wks if they regained response or remission following re-induction treatment. Ileocolonoscopy with central reading was performed yearly. Treatment-emergent adverse events (AEs) were collected throughout the study up to 20 wks after the last dose of study drug or the data cut-off date of Feb 04, 2019. Efficacy data (clinical remission [CR] and endoscopic remission [ER] [CD Endoscopic Index of Severity (CDEIS)  $\leq 4$  or CDEIS  $\leq 2$  for pts with isolated ileitis at baseline]) are reported to Wk 104 in the OLE, when all pts enrolled in the OLE had the opportunity to reach the visit date before the interim cut-off date. Non-responder imputation (NRI) was used for binary endpoints.

**Results:** A total of 65 adults with CD were enrolled, including four pts who were re-induced. Median age was 34 yrs (range 19-67 yrs) and median disease duration was 10 yrs (range 2-38 yrs). Sixty pts (92.3%) were previously exposed to TNF antagonists; 13 pts (20%) and 21 pts (32.3%) were receiving corticosteroids only and immunomodulators only, respectively, and 9 (11.8%) pts were receiving both, prior to BL of the preceding study. At the data cut-off date, mean (SD) exposure to RZB was 866.8 (316.6) days, and 18 (27.7%) pts had prematurely discontinued from the study. At Wk 0 of the current study, 47/65 (72.3%) pts were in CR and 27/63 (42.9%) pts had ER based on the observed data. Both CR and ER were sustained up to Wk 104 (Table). After a median follow-up of 31 months, AEs were reported for 58/65 (89.2%) pts; 22 (33.8%) experienced serious AEs. The most common AEs were nasopharyngitis (29.2%), gastroenteritis (20.0%), fatigue, abdominal pain, and worsening CD (18.5% each), and arthralgia (15.4%). Serious infections were reported in six pts: anal or subcutaneous abscess (1 pt each), *Campylobacter* infection (1 pt), viral gastroenteritis (2 pts), and peritonitis (2 pts). No events of tuberculosis were reported, and no malignancies or deaths occurred.

**Conclusion:** In this 3-yr interim analysis, both clinical and endoscopic remissions were sustained in pts with CD receiving long-term open-label RZB treatment. The safety profile of RZB remains consistent with previous results.<sup>2</sup> No new safety signals were identified.

	Clinical remission n/N (%)	Endoscopic remission <sup>a</sup> n/N (%)
Week 0 <sup>b</sup>	47/65 (72.3)	27/65 (41.5)
Week 8	48/65 (73.9)	—
Week 16	46/65 (70.8)	—
Week 48	46/65 (70.8)	35/65 (53.9)
Week 104	41/65 (63.1)	28/65 (43.1)

All patients in the OLE had the opportunity to reach the Week 104 visit before the cut-off date. <sup>a</sup>Data are from central reading. <sup>b</sup>Visits in OLE.

<sup>1</sup>Amsterdam UMC, Gastroenterology and Hepatology, Amsterdam, Netherlands, <sup>2</sup>Imelda GI Clinical Research Center, Gastroenterology, Bonheiden, Belgium, <sup>3</sup>Academisch Medisch Centrum, Surgery, Amsterdam, Netherlands

**Contact E-Mail Address:** matheeuwsen\_1@hotmail.com

**Introduction:** Crohn's disease (CD) is a complex disorder characterized by intestinal inflammation leading to progressive bowel damage. Treatment goals have evolved over preceding years from clinical remission to prevention of structural bowel damage. It is unknown which treatment options/sequences lead to the most optimal outcome in patients with newly diagnosed CD.

**Aims & Methods:** The aim of this study was to compare different treatment strategies and associated outcomes in early CD. We performed a retrospective study including adult patients with newly diagnosed CD at the Academic Medical Center of Amsterdam (The Netherlands) (September 2013-September 2018) or at the Imelda hospital in Bonheiden, Belgium (January 2009-January 2019). Based on first-line treatment choice, patients were assigned to one of the five pre-defined management groups. Primary outcome was time to treatment failure, defined as a switch to another treatment, escalating CD treatment, need for endoscopic balloon dilation or surgery, CD-associated hospitalization or a new perianal fistula. Kaplan-Meier survival analysis was used to estimate the median treatment survival per group.

**Results:** One hundred and forty-nine patients were included: treatment with corticosteroids only as first treatment (group 1) was started in 24 patients, immunomodulators (azathioprine, 6-mercaptopurine or methotrexate; group 2) in 70 patients, biological therapy (infliximab, adalimumab or vedolizumab; group 3) in 22 patients, biological therapy in combination with an immunomodulator (group 4) in 21 patients and 12 patients underwent early surgery (group 5).

Baseline characteristics (CRP, CD Endoscopic Index of Severity, Simple Endoscopic Score for CD, smoking status) were similar between treatment groups. Group 5 had significantly more patients with stricturing (Montreal B2) and penetrating (Montreal B3) disease subtypes (Table 1).

Log-rank test revealed significantly longer median treatment survivals in group 5 (215 days; 95% CI 25, 405), group 4 (863 days) and group 3 (321 days; 95% CI 184, 457) compared to median treatment survival in group 2 (119 days; 95% confidence interval (CI) 85, 152) ( $p \leq 0.01$ ).

Median treatment survival in group 4 (863 days) was significantly longer compared to group 1 (195 days; 95% CI 139, 251) ( $p < 0.01$ ) (Table 1).

	Group 1. (n=24)	Group 2. (n=70)	Group 3. (n=22)	Group 4. (n=21)	Group 5. (n=12)	Significance
Baseline (at diagnosis)						
Age (years, mean, [SD])	39 [19]	35 [16]	28 [12]	37 [16]	39 [16]	p=0.15
Active smoker (%) <sup>*</sup>	35 (n=20)	47 (n=53)	47 (n=15)	36 (n=14)	27 (n=11)	p=0.85
CRP (mg/L, mean, [SD]) <sup>*</sup>	22 [28] (n=15)	29 [33] (n=38)	21 [21] (n=12)	23 [16] (n=10)	65 [79] (n=7)	p=0.51
CDEIS (mean, [SD]) <sup>*</sup>	17 [5] (n=2)	9 [4] (n=14)	13 [4] (n=6)	10 [5] (n=5)	8 [5] (n=6)	p=0.06
SES-CD (mean, [SD]) <sup>*</sup>	18 [14] (n=3)	13 [5] (n=16)	18 [6] (n=6)	13 [8] (n=6)	10 [6] (n=6)	p=0.27

Montreal B1 (%)	54	61	68	71	8	p<0.01
Montreal B2 (%)	8	14	9	24	67	p<0.01
Montreal B3 (%)	8	9	5	5	50	p<0.01
Outcome						
Treatment survival (days, median, [95% CI])	195 [139, 251]	119 [85, 152]	321 [184, 457]	863 days **	215 [25, 405]	p<0.01

[Table 1. <sup>\*</sup>% based on available data indicated by n=(x) <sup>\*\*</sup>Median survival not reached after median follow-up 751 days; hence 95%-CI cannot be calculate]

**Conclusion:** These real-world data show superiority of biological treatment, combination therapy and early surgery in newly diagnosed CD patients.

**Disclosure:** Nothing to disclose

**P1132 UTILITY OF VEDOLIZUMAB DRUG LEVEL MONITORING IN IBD PATIENTS - REAL LIFE EXPERIENCE: PILOT STUDY**

Belvis Jiménez M.<sup>1</sup>, Guerra Veloz M.F.<sup>2</sup>, Argüelles-Arias F.<sup>3</sup>, Sáez A.<sup>4</sup>, Maldonado Perez B.<sup>4</sup>, Castro Laria L.<sup>4</sup>, Benítez Roldán A.<sup>4</sup>, Caunedo Álvarez Á.<sup>4</sup>

<sup>1</sup>HUV Macarena, Gastroenterology, Sevilla, Spain, <sup>2</sup>HUV Macarena, Gastroenterology and Endoscopy Unit, Sevilla, Spain, <sup>3</sup>HUV Macarena, UGC DIGESTIVO, Sevilla, Spain, <sup>4</sup>HUV Macarena, Sevilla, Spain

**Contact E-Mail Address:** mariabelvisjimenez@gmail.com

**Introduction:** Therapeutic drug monitoring has become an accepted tool in the therapy management in Inflammatory Bowel Disease (IBD). The assessment of trough levels and neutralising anti-drug antibodies are widely used to optimise the therapeutic management, and its usefulness has been more studied in anti-TNF therapies especially in situations of treatment failure. However, there is not enough data published on the usefulness of the measurement of vedolizumab (VDZ) levels in IBD patients, with no established cut-off points. The objective of our study was to evaluate the correlation between VDZ level at induction and maintenance treatment with the clinical response in patients with IBD.

**Aims & Methods:** This is a retrospective observational, single center study. We included adult patients with UC and EC treated with VDZ between January and December 2018, VDZ serum levels were prospectively collected before induction at 6, 14 and 24 weeks. Clinical and biochemical response was collected at 14 and 24 weeks. Data was analyzed by classification tree model to establish variables related with remission.

**Results:** 12 patients were included, 58.3% with UC and 41.7% with CD. 69.2% were women with a mean age of 41 ± 12 and a mean disease duration of 11.5 ± 8.15 years. 91.7% were treated with anti-TNF therapy previously. The median VDZ level was 33.4 mg/ml (26.7 -39.1), 10.3 mg/ml (7.26-12.8), 11.2ug/ml (8.47-14.45) at baseline, week 14 and week 24 respectively.

Clinical remission was achieved in 33.3% (4/12) at week 14, and 41.6% (5/12) at week 24. 33.3% (4/12) in patients who had VDZ level at week 6 between 35 - 47.4 ug/ml.

The only variable that was correlated with the remission at weeks 14 and 24 in the tree model CRT was the VDZ level at week 6 (induction therapy) (Table 1).

Clinical remission Week 14 and 24	VDZ level week 6 (ug/ml)	Prediction certainty (%)
Yes	35 - 47.4	100
No	<35 // >47.4	100

[Table 1]

**Conclusion:** In our cohort, the only variable that was correlated with the remission at weeks 14 and 24 was the VDZ level at week 6. VDZ level at week 14 and 24 were not correlated with clinical remission.

**Disclosure:** Nothing to disclose

**Introduction:** Ustekinumab (UST) is in Belgium increasingly used in moderate to severe Crohn's disease (CD). The goal of the current study was to describe the real-life experience with UST in our tertiary center.

**Aims & Methods:** A retrospective monocentric study was performed in patients with CD who were started on UST between December 2017 and December 2018. All patients received an initial intravenous dose of 6 mg/kg followed by subcutaneous UST (90 mg, q8). The clinical, biological, endoscopic and radiological response were assessed after the induction (week 4-8) and during the maintenance phase. The clinical, endoscopic and radiological response was based on the physicians' assessment. A biological response was defined as a decrease of ≥50% in C-reactive protein (CRP) and/or fecal calprotectin (FC), remission as a normalization of the parameters.

**Results:** A total of 51 patients were included, of which the majority was refractory to TNF inhibitors and/or vedolizumab (table 1). The median duration of follow-up was 45 weeks (IQR 24-69). UST was discontinued in 11 patients (21.6%) after a median of 26 weeks (IQR 10-34). Reasons for discontinuation were a loss of response, including 2 patients who were in need of surgery (n=5), primary non response (n=4), malignancy (n=1) and patient's wish (n=1).

The clinical response at short term (4-8 weeks after the initial IV induction), could be assessed in 43 patients: 27/43 patients (62.8%) had a response and 4 patients (9.3%) were in clinical remission. In 12 patients (27.9%) no response was seen. During the maintenance phase patients were assessed at a median of 26 weeks (IQR 23-39). A clinical response in the maintenance period was seen in 25/51 patients (49%) and an additional 12 patients (23.5%) reached remission.

A biological response was achieved in 8/37 patients (21.6%) and biological remission in 16/37 (43.2%), the remaining patients (35.1%) showed no response. Endoscopy was performed in 20 patients and an endoscopic response was confirmed in 10/20 patients (50%), remission in 2 patients (10%). The other 8 patients (40%) had no endoscopic response. Radiological evaluation was performed in 21 patients of which 12 showed no response (57.1%), 7/21 (33.3%) had a response and 2 (9.5%) were in radiological remission.

Ten patients (19.6%) were hospitalized for IBD-related complications, most of them for surgery (9/10). Other AEs occurred in 11 patients, most often arthralgia. One patient developed a flare of an underlying spondyloarthropathy and UST was discontinued. A paradoxical worsening of psoriasis was observed in one patient.

**Conclusion:** In this population of refractory CD patients, UST was efficacious to induce and maintain clinical remission. Endoscopic and radiological response in these preliminary analyses were modest.

**Introduction:** Ustekinumab (UST) has proven to be an efficient maintenance therapy for moderate to severe Crohn's disease (CD). However, a significant percentage of patients treated with subcutaneous maintenance UST experience a secondary loss of response (LOR) or partial response. We evaluated the clinical, biological and endoscopic response to UST optimization including IV re-induction (intravenous UST at a dose of 6 mg/kg) and/or shortening of the dosage interval (mainly every 4 weeks) in this context.

**Aims & Methods:** A retrospective, single-center study was performed including patients with CD who were treated with maintenance UST and received either IV re-induction and/or shortening of the dosage interval for a partial response or LOR. The clinical and endoscopic response was based on the physician's assessment. A biological response was defined as a decrease of ≥50% in C-reactive protein (CRP) and/or fecal calprotectin (FC); remission as a normalization of these parameters.

**Results:** Eighteen out of the 51 (35.3%) UST-treated CD patients needed optimization of UST: 2 patients only received IV re-induction, 9 patients only shortening of the dosage interval and 7 patients received both IV re-induction and intensification.

The median time to optimization was 34.5 weeks (IQR 20.3-42.3). Response to dose optimization was assessed at a median of 15.5 weeks (IQR 6.8-19.3).

One of the 2 patients who underwent re-induction alone experienced a good clinical and endoscopic response; the other patient had no clinical, biological nor endoscopic response and UST was discontinued.

A combined re-induction and shortening of the dosage interval was performed in 7 patients. Of these, 6 experienced a clinical response and 1 patient had no response. Biological remission was confirmed in 3/6 patients, whereas the other 3/6 had no biological response. Endoscopic response was observed in 1/3 patients. Despite optimization, UST was ended in one patient due to a persistent LOR.

Nine patients underwent intensification alone, which was successful in inducing a clinical response in 3/9 (33.3%) and a clinical remission in 4/9 (44.4%). Two patients (22.2%) had no clinical response. Biological remission was observed in 4/7 patients (57.1%) and 3/7 patients had no biological response (42.9%). Endoscopic evaluation in 4 patients showed a response in 2/4 and no response in the other 2. In 2/9 patients (22.2%) UST was stopped; one due to LOR and the other patient due to an adverse event (flare of underlying spondyloarthropathy).

Other adverse events (AEs) were seen in 2 patients: 1 patient had arthralgia and 1 patient developed a rash, both AEs were mild and UST could be continued.

**Conclusion:** About a third of patients treated with maintenance UST underwent optimization. Of these 18 patients, 10 (55.6%) regained a good clinical response and 4 (22.2%) were in clinical remission. UST could be continued in the majority of patients.

**Introduction:** Therapeutic drug and anti-drug antibody monitoring (TDM) of infliximab (IFX) is used with increasing regularity as a tool to optimize outcomes in inflammatory bowel disease (IBD). Trough levels (TL) of 2-8 mcg/ml are recommended during maintenance IFX treatment. The introduction of biosimilar infliximab (BI) in 2015 lead to widespread switching of patients from originator infliximab (OI) to BI. The value of TDM when switching to BI has not been defined. This study aimed to assess the impact of TDM testing before and after a managed switch to BI.

**Aims & Methods:** Individuals with IBD treated with OI and demonstrating a satisfactory response to treatment, were entered in to BI switch programme in Dec 2016. Pre-switch information was provided to patients, virtual or face to face clinical assessment was undertaken and it was recommended that all patients had pre-switch TDM performed. After switching patients returned to routine clinical care. Further TDM was performed at clinician discretion with recommendation to follow published TDM testing guidance (1). Virtual review of all patients was undertaken 2 years post-switch. Demographics, pre and post switch TDM data, OI and BI dosing regimens and other IBD related medications were recorded along with clinical outcome data. Comparative analysis of pre-switch and most contemporary TDM results was performed.

**Results:** 76 individuals considered to be clinically responding to OI were entered in to the BI switch programme. 70/76 (92%) had TDM at < 3 months pre-switch. OI was discontinued prior to switch in 2 patients. 74 people were switched from OI to BI. 52/74 (70%) were on 5mg/kg 8 weekly OI pre-switch, 38 (51%) were on immunomodulators.

Of 69/74 with pre-switch TDM, 32/69 (46%) had subtherapeutic TLs (< 2mcg/ml). Median pre-switch TL was 2.2 mcg/ml (IQR 1.1-3.4 mcg/ml). Pre-switch TL review lead to 37/74 (50%) receiving an increased dose of BI at switch. In total 47/74 had ≥1 dose escalation at the time of or subsequent to switch.

58/74 (78%) had TDM testing in the 2 years after switch (median no. tests 2; range 1 - 5) at which point 54/74 (73%) remained on BI with sustained clinical response. 49 out of 54 still on BI had both pre and post switch TDM with results demonstrating a statistically significant increase in mean TLs (2.1 vs 6.3 mcg/ml; p< 0.001); only 6% had persisting sub-therapeutic TLs.

**Conclusion:** High rates of sustained clinical response were observed to occur following a BI switch supported by the use of pre and post switch TDM. TDM dose escalation resulted in a statistically significant increase in TLs, this may account for the rates of continued clinical response.

**Contact E-Mail Address:** meadesc@yahoo.co.uk

**Introduction:** The clinical utility of vedolizumab (VDZ) trough levels (VTLs) is not well established.

**Aims & Methods:** The aim of this study was to determine if there is a correlation between VTLs and clinical and biochemical outcomes. We performed a prospective, cross-sectional study to examine the association between VTLs and clinical and biochemical outcomes. VTLs immediately prior to VDZ infusion were collected simultaneously with CRP and Harvey Bradshaw index (HBI)/Simple Clinical Colitis Activity index (SCCAI) (for Crohn's disease, CD, and ulcerative colitis, UC, respectively). Biochemical remission was defined as CRP  $\leq 5$  mg/L and clinical remission was defined as HBI  $\leq 4$  or SCCAI  $\leq 2$ . Combined remission was defined as those meeting criteria for both clinical and biochemical remission. Fishers exact and Mann-Whitney U tests were used to compare groups and ROC analysis to identify a therapeutic threshold.

**Results:** 45 samples with matched clinical and biochemical data were collected for 43 patients (24 UC, 15 CD and 4 inflammatory bowel disease-unclassified). Approximately equal numbers of patients had 4-weekly VDZ infusions (n=21) compared to 8-weekly (n=22). 25 out of 43 patients (58%) were on concomitant immunomodulation. The median trough level was 18.3  $\mu$ g/mL (range < 2 - 44.7  $\mu$ g/mL) and anti-VDZ antibodies were not detected in any patient. No significant difference could be detected between median VTLs for active disease vs combined remission (24.1  $\mu$ g/mL vs 16.4  $\mu$ g/mL, p=0.84).

In the UC subgroup, there was a difference in median VTLs between those in biochemical remission compared to those with active disease (24.5  $\mu$ g/mL vs 7.3  $\mu$ g/mL, p=0.088). ROC analysis did not identify an optimal therapeutic threshold to achieve combined remission [AUC (95% CI) 0.52 (0.32-0.72)]. However, in the UC cohort a potential therapeutic threshold was identified [AUC (95% CI) 0.76 (0.41-1.0)]. A VTL of 10.7  $\mu$ g/mL differentiated those with a normal CRP from those with a raised CRP. A comparison (using Fisher's exact test) of the highest vs lowest VTL quartiles did not show a significant difference in the proportion of patients who were in remission vs active disease.

**Conclusion:** A correlation between VTLs and clinical and biochemical markers of disease activity was not shown. However, in the UC cohort a level of 10.7  $\mu$ g/mL differentiated those in biochemical remission from those with active disease. This is a preliminary, small sample size study and analysis of VTLs for our entire VDZ cohort is being conducted.

**Introduction:** Vedolizumab (VDZ) is an approved biological treatment for moderate to severe Crohn's disease (CD) and ulcerative colitis (UC). Patients who lose response on VDZ 300 mg every 8 weeks (Q8W) during maintenance therapy may benefit from dose intensification to VDZ 300 mg every 4 weeks (Q4W). Our aim was to assess the effect of VDZ dose intensification on serum trough levels (TL) and regain of response.

**Aims & Methods:** We performed a multicenter prospective study from June 2017 through December 2018 including patients with loss of response to VDZ Q8W during maintenance therapy, defined as a total Mayo score  $>6$  for UC, and a HBI score  $>4$  with evidence of inflammation (C-reactive protein (CRP)  $> 5$  mg/L, faecal calprotectin  $>250$  mg/kg or confirmation on endoscopic or radiological imaging) for CD. Blood samples (TL and CRP) and clinical variables (partial Mayo and HBI score) were collected at T0 (last infusion of Q8W interval and start of Q4W dosing), T1 (week 4 after dose escalation) and T2 (week 8 after dose escalation). Biological response (CRP  $\leq 5$  mg/L or decrease of  $>50\%$  in patients with a CRP  $> 5$  mg/L at baseline) and clinical response (decrease of partial Mayo  $\geq 2$  points for UC or decrease of HBI  $\geq 3$  points for CD) were assessed at T1 and T2. VDZ TL were measured using the vedolizumab ELISA from apDia. Non-parametric and correlation analyses were performed comparing T0, T1 and T2.

**Results:** A total of 62 patients (34 UC and 28 CD) were included with 28% on concomitant corticosteroids, 11% on azathioprine or 6-MP and 2% on methotrexate. After dose escalation, median (IQR) TL increased from 8.8 (5.1-13.5)  $\mu$ g/mL (T0) to 19 (11.9-22.9)  $\mu$ g/mL (T1) and 23.1 (15.5-28.4)  $\mu$ g/mL (T2) (all p<.0001) with a similar evolution in UC and CD (Table).

UC (n=34)	T0	T1	T2
Median (IQR) TL ( $\mu$ g/mL)	8.1 (4.8-11.6)	17.4 (10.8-21.6)	21.3 (14.3-25)
Median (IQR) CRP (mg/L)	5.8 (1.4-9)	5.7 (1.7-15.4)	3.9 (1.9-11)
Median (IQR) partial Mayo	5 (5-6)	3 (3-5)	3 (1-5)
CD (n=28)	T0	T1	T2
Median (IQR) TL ( $\mu$ g/mL)	9.1 (5.2-16.6)	21.2 (12.4-28.1)	23.6 (19.7-31.7)
Median (IQR) CRP (mg/L)	7.2 (2.8-14.2)	6.4 (2.9-15.1)	4.9 (2.7-9.4)
Median (IQR) HBI	8 (5-13)	4 (1-6)	3 (1-4)

[Table]

In UC patients, partial Mayo score significantly decreased from T0 to T1 (p=0.002) with a trend for further decrease from T1 to T2 (p=0.08). In CD patients, HBI score significantly decreased from T0 to T1 (p=0.002) with a trend for further decrease from T1 to T2 (p=0.07). The decrease in CRP from 6.4 (1.9-12.6) mg/L at T0 to 5.8 (2.1-15.2) mg/L at T1 and 4.4 (2.7-10) mg/L at T2 was not significant (all p>.05) and similar in UC and CD (Table). Also for patients with a CRP at baseline of  $>5$  mg/L, the decrease in CRP from 11.6 (7.2-18.9) mg/L at T0 to 10.1 (5.2-16.7) mg/L at T1 and 8.8 (4.1 - 15.3) mg/L at T2 was not significant (all p>.05) and similar in UC and CD. Biological and clinical response was achieved in 30% and 51% at T1 and 44% and 59% at T2, respectively. The median increase in TL between T0 and T2 was similar between biological responders and non-responders (12.3 (8.3-14.8) vs. 12.4 (7.6-16.1), p=0.78) and clinical responders and

non-responders (14 (10.3-17.4) vs. 12.2 (6.9-14.6),  $p=0.12$ ). No correlation was found between increase in TL between T0 and T2 and change in CRP, partial Mayo or HBI scores.

**Conclusion:** Dose escalation of VDZ 300 mg from Q8W to Q4W in UC and CD patients with loss of response results in higher TL at 4 and 8 weeks. Regain of biological and clinical response was observed in 44% and 59% of patients respectively but was not associated with an increase in TL.

### P1138 ELECTRICAL CONDUCTIVITY IN *BIFIDOBACTERIUM ANIMALIS* SUBSPECIES *LACTIS* BB-12

Bozkurt H.S.

Maltepe University Medicine Faculty Internal Medicine, Gastroenterology, Istanbul, Turkey

**Contact E-Mail Address:** sancarb79@gmail.com

**Introduction:** BB-12 is technologically well suited, expressing fermentation activity, high aerotolerance, good stability and a high acid and bile tolerance[1,2]. Because of high redox potential in the colon flora ecosystem, BB-12 is highly resistant bacteria in distress condition. The BB-12 cell envelope is an electrical and physical barrier that can be overcome by pathways that consist of redox proteins. Bacterial cellular electron transfer systems (CET) are defined microbial bioelectrochemical processes in which electrons are transferred from the cytosol to the membrane of the cell[3]. Although the strength of BB-12 in the event of stress has been shown previously[2], CET features of BB-12 are not completely identified. Here we first describe that the probiotic bacteria *Bifidobacterium animalis subsp. lactis* BB-12 strain features of CET under the various atmosphere.

**Aims & Methods:** Mean gut bifidobacterial count of 5 billions ( $5 \times 10^9$ ) cfu of *Bifidobacterium animalis subsp. lactis*-BB12 (Chr Hansen) were used for the experiment in Yildiz Technical University, Davutpaşa Campus, Science and Arts Faculty, Physics Department. This *Bifidobacterium* dissolved in 5 millilitres of distilled water and prepared sample

**Results:** Charge transport behavior and the effect of the RH level on it in the BB-12 film have been investigated by means of I-V measurements. Within water moisture environment, electrical conductivity of the BB-12 increased more than six decades while under  $N_2$  environment conductivity returns to the initial current value (Figure-1). This behaviour in conductivity modulation was reversible at least in the three cycles

**Conclusion:** This experimental findings showed us that there was no structural transformation under relative humidity. On the other side, increase in the conductivity was interpreted by the increase in the population of charge carriers, supplied by the interaction BB-12 with the water moisture, monitored by amine and carboxyl group through FTIR and Zeta potential measurements. The type of surface charge of *Bifidobacterium animalis subsp. lactis* BB-12 was found to be negative by zeta potential measurements, claiming that electrons were the charge carriers. Overall, obtained result in this study indicated that *Bifidobacterium animalis subsp. lactis* BB-12 has a great potential for humidity sensing device at room temperature

**Introduction:** Probiotics are live microorganisms that, when administered in adequate amounts, confer a health benefit on the host. These benefits can include impacts on digestive health, the host immune system, and the gut-brain axis. Increasing evidence supports a relationship between the gut microbiota, inflammation, host response and health [1-3]. More recently, a number of studies have investigated the potential of heat-treated microorganisms to confer a benefit on humans or animals; these have often been referred to as 'pharmabiotics' [2,4,5].

The therapeutic application of heat-treated microorganisms could be considered to have a number of advantages over living organisms, such as longer shelf life, no cold chain requirements, ease of storage and transport and therefore also potential applications in less developed regions, no risk of infection in vulnerable individuals, no translocation of bacterial-virulence or antibiotic-resistance cassettes if the genetic material has been destroyed by the inactivation step, and no loss of activity when used in conjunction with antibiotics or anti-fungal agents [4-6].

**Aims & Methods:** We have demonstrated that supplementing the diet with heat-treated *Lactobacillus* LB is capable of subtly modifying both the microbiota and behavior in healthy male mice [6]. In this study we set out to elucidate the role of heat-treated *Lactobacillus* LB in female mice, particularly focusing on the impact on the development of colitis following *Citrobacter* infection. Female mice [N=48] were divided into two groups, one fed standard chow, and one fed chow with a *Lactobacillus* LB preparation (5%). The *Lactobacillus* LB preparation consists of a heat-treated fermentate generated by two *Lactobacillus* strains, *L. fermentum* and *L. delbrueckii*. After four weeks we implemented a *Citrobacter rodentium* infection strategy that is used as a model for several important human intestinal disorders, including Crohn's Disease, Ulcerative Colitis and colon tumorigenesis [7]. Infection with *C. rodentium* results in the colonisation of the large intestine and subsequent mild inflammation that is maintained after the pathogen has been cleared [8]. This allows us to study the effect of the *Lactobacillus* LB preparation on both infection and inflammation. Throughout the experiment samples were collected for 16S rRNA analysis of microbiota, virome analysis, SCFA, and inflammation markers.

**Results:** Diet supplementation with the *Lactobacillus* LB preparation caused subtle but significant changes in the murine microbiota, with less abundant taxa being most affected. Prolonged consumption had no adverse effect on murine health. The *Lactobacillus* LB preparation did not provide protection against *Citrobacter* infection. However, a reduction of the length of small intestine which occurred in the control-fed *Citrobacter* infected animals was prevented by the supplemented diet. An increase of colon crypt length in control-fed *Citrobacter* infected animals was also prevented. Overall, our results suggest that the *Lactobacillus* LB preparation diet has a reproducible effect on microbiota composition and diversity, as well as limiting the effect of *Citrobacter* induced inflammation in animals.

**Conclusion:** This study provides evidence for the effect of heat-treated bacteria (and their metabolites) on the murine microbiota, on infection-induced inflammation and on the behaviour of healthy mice. Preparations containing heat-treated microorganisms, or pharmabiotics, can be safe and effective interventions to impact on the microbiome and on host health.

**Contact E-Mail Address:** anna.prossomariti2@unibo.it

**Introduction:** Surgical treatment represents the gold standard for Familial Adenomatous Polyposis (FAP) patients with profuse disease. Most FAP patients undergo proctocolectomy with j-pouch, and pouchitis is emerging as a recurrent post-surgical complication. Alterations in the intestinal microbial community play a pivotal role in intestinal inflammation and have been found in UC patients with pouchitis. However, the impact of intestinal dysbiosis on pouchitis onset in FAP patients remains poorly characterized.

**Aims & Methods:** In this pilot study, we aimed to characterize the mucosal microbiome structure in FAP patients and to establish whether intestinal dysbiosis may contribute to the development of pouchitis in these patients. Sixteen patients with a clinical and genetic diagnosis of FAP (age > 18 years) were enrolled. Microbiome analysis was performed by 16S rRNA gene sequencing using an Illumina platform on DNA samples extracted from intestinal biopsies. Microbiome characterization was available for fifteen out of sixteen FAP patients. Active pouchitis was defined as a Pouchitis Disease Activity Index (PDAI)  $\geq 7$ . We first analyzed differences in taxon relative abundance among patients with intact colon (n=6) or those who underwent hemicolectomy with ileocolic anastomosis (n=1) (Group 1; n=7) and patients who underwent proctocolectomy with ileal-pouch-anal-anastomosis (IPAA) (n=6) or those who underwent colectomy with ileo-rectal-anastomosis (IRA) (n=2) (Group 2; n=8). Moreover, among patients belonging to the Group 2 we analyzed differences between patients with healthy pouch (Group 2A; n=5) and patients with pouchitis (Group 2B; n=3).

**Results:** According to the PDAI score 3 out of 8 patients within the Group 2 received a diagnosis of chronic and active pouchitis. Microbiome sequencing demonstrated a reduction in the relative abundance of Actinobacteria (4.39% vs. 0.52%) and Bacteroidetes (28.95% vs. 10.11%) phyla (Families: Coriobacteriaceae and Bacteroidaceae, respectively) associated with increased levels of Proteobacteria (34.05% vs. 59.32%) phylum (Family: Pseudomonadaceae) in patients within the Group 2 compared with Group 1. Among patients belonging to the Group 2, patients with pouchitis (Group 2B) showed decreased abundance of Bacteroidetes (15.95% vs. 0.36%) and Firmicutes (31.58% vs. 8.83%) phyla and had a microbiota almost entirely represented by Proteobacteria (46.08% vs. 81.39%) (mainly Oxalobacteriaceae and Pseudomonadaceae families) compared with healthy pouch patients (Group 2A).

**Conclusion:** Our findings suggest that alterations in the mucosal microbiota could be involved in the development of pouchitis in FAP patients subjected to proctocolectomy with j-pouch and that gut microbiota characterization in these patients may help clinicians determining the efficacy of antibiotic therapies. Further studies are warranted on larger series to confirm these data.

### **P1141 THE STUDY ON THE CHANGES AND ROLES OF INTESTINAL BACTERIA MICROBIOTA IN CORONARY HEART DISEASE COMPLICATED WITH NONALCOHOLIC FATTY LIVER DISEASE**

Zhang Y.<sup>1,2</sup>, Xu J.<sup>1,2,3</sup>, Wang X.<sup>1,2</sup>, Liu Y.<sup>1,2</sup>

<sup>1</sup>Peking University People's Hospital, Department of Gastroenterology, Beijing, China, <sup>2</sup>Peking University People's Hospital, Clinical Center of Immune-Mediated Digestive Diseases, Beijing, China, <sup>3</sup>Peking University People's Hospital, Institute of Clinical Molecular Biology & Central Laboratory, Beijing, China

**Contact E-Mail Address:** yi.wen.zhang@foxmail.com

**Introduction:** Previous study reported that patients who suffered coronary heart disease (CHD) complicated with non-alcoholic fatty liver disease (NAFLD) had worse cardiac function and clinical outcomes than patients with CHD only. Notably, the mechanism was still unclear. Previous study focused on the role of metabolism in CHD patients complicated with NAFLD (CHD-NAFLD) and evidence showed that the microbiota was an important factor in metabolism. Therefore, this study aimed to investigate the characteristics and effects of intestinal bacteria microbiota in CHD-NAFLD patients.

**Aims & Methods:** People were recruited and divided into three groups, including CHD patients (without NAFLD), CHD-NAFLD patients and healthy controls (HCs). Each group contained 24 people. Fecal samples and clinical information from three groups were carefully collected. The Illumina sequencing of 16S rRNA gene V3-4 region amplicons sequencing was applied to profile the overall structure of the fecal bacterial microbiota. Based on the Operational Taxonomic Units (OTUs), the characteristics of the bacterial microbiota of the sample and the correlation with clinical indexes were analyzed.

**Results:** In analysis of clinical information, CHD patients showed an increase in uric acid and triglycerides compared with HCs. The CHD-NAFLD patients showed a further increase in BMI, uric acid and triglyceride. In investigation of bacterial profile, we firstly compared the overall CHD patients (including CHD-NAFLD patients and CHD patients) with HCs. As a result, there was a significant reduction in the abundance of *Parabacteroides* and *Collinsella*. We further analyzed the difference of bacterial composition in between CHD-NAFLD and CHD patients. The intestinal bacterial microbiota in CHD-NAFLD patients showed an increase in the abundance of *Coprococcus* and *Veillonella*, and a reduction in the abundance of *Parabacteroides*, *Bacteroides fragilis*, *Bifidobacterium longum subsp. infantis*, *Ruminococcus gnavus* and *Bacteroides dorei*. Among them, the abundance of *Ruminococcus gnavus* and *Bacteroides dorei* was significantly lower than that in CHD patients. Additionally, spearman's correlation was performed to clarify the correlation between bacterial microbiota and clinical indexes. BMI was positively correlated with the abundance of *Coprococcus* and negatively correlated with the abundance of *Bifidobacterium longum subsp. infantis*. The abundance of *Veillonella* was positively correlated with LDL-C and AST. The abundance of *Bacteroides dorei* was negatively correlated with ALT, AST and LDL-C. These data indicated that the abundance of intestinal bacterial microbiota was closely related to the changes in clinical indexes.

**Conclusion:** Changes of intestinal bacterial microbiota in CHD-NAFLD patients may be important factors affecting the degree of metabolic disorder, which may be one of the important reasons for the worse clinical outcome and disease progression in CHD-NAFLD patients than in CHD patients.

### **P1142 THE STUDY ON THE CHANGES AND ROLES OF INTESTINAL FUNGAL MICROBIOTA IN CORONARY HEART DISEASE COMPLICATED WITH NONALCOHOLIC FATTY LIVER DISEASE**

Xu J.<sup>1,2,3</sup>, Zhang Y.<sup>1,2</sup>, Wang X.<sup>1,2</sup>, Liu Y.<sup>1,2</sup>

<sup>1</sup>Peking University People's Hospital, Department of Gastroenterology, Beijing, China, <sup>2</sup>Peking University People's Hospital, Clinical Center of Immune-Mediated Digestive Diseases, Beijing, China, <sup>3</sup>Peking University People's Hospital, Institute of Clinical Molecular Biology & Central Laboratory, Beijing, China

**Contact E-Mail Address:** yi.wen.zhang@foxmail.com

**Introduction:** Patients who suffered coronary heart disease (CHD) complicated with non-alcoholic fatty liver disease (NAFLD) were reported to have worse cardiac function and clinical outcomes than patients with CHD only. However, it was not clear about the mechanism. Previous study focused

on the role of metabolism in CHD patients complicated with NAFLD (CHD-NAFLD). Lots of evidence showed that the metabolism could be regulated by the microbiota. The research on gut microbiota mainly focused on bacteria, and there were few studies related to fungi. Therefore, this study aimed to investigate the characteristics and effects of intestinal fungal microbiota in CHD-NAFLD patients.

**Aims & Methods:** People were recruited and divided into three groups, including CHD patients (without NAFLD), CHD-NAFLD patients, and healthy controls (HCs). Each group contained 24 people. Fecal samples and clinical information were carefully collected. The microbial genome DNA was extracted and the internal transcribed spacer (ITS) 3-4 rDNA was amplified. Illumina sequencing platform was used for high-throughput sequencing analysis. Based on the Operational Taxonomic Units (OTUs), the characteristics of the fungal microbiota of the sample and the correlation with clinical indexes were analyzed.

**Results:** In analysis of clinical information in recruited subjects, CHD patients showed an increase in uric acid and triglycerides compared with HCs. The CHD-NAFLD patients showed a further increase in BMI, uric acid and triglyceride. In investigation of fungal profile, we firstly compared the overall CHD patients (including CHD-NAFLD patients and CHD patients) with HCs and found the significant reduction in the abundance of *Exophiala attenuata* and *Malassezia restricta*. We further analyzed the difference of fungal composition in between CHD-NAFLD and CHD patients. The intestinal fungal microbiota in CHD-NAFLD patients showed an increase in the abundance of *Preussia*, *Xylodon* and *Cladophium*, and a reduction in the abundance of *Candida glabrata* and *Ganoderma*. Among them, the abundance of *Ganoderma* was significantly lower than that in CHD patients. Additionally, we used spearman's correlation to clarify the correlation between fungal microbiota and clinical indexes. The ejection fraction was negatively correlated to the abundance of *Xylodon*. Uric acid was positively correlated with the abundance of *Cladophium* and *Preussia*. These data indicated that the abundance of intestinal fungal microbiota was closely related to the changes in clinical indexes.

**Conclusion:** Therefore, these changes of intestinal fungal microbiota in CHD-NAFLD patients may be important factors affecting the degree of metabolic disorder. But there are few reports on these fungi. More studies are needed to confirm the effects of these fungi on human.

**Disclosure:** Nothing to disclose

## P1143 THE EFFECT OF BILE ACIDS AS A MAJOR REGULATOR OF INTESTINAL MICROBIOTA, ESPECIALLY ON DIFFERENT PARTS OF THE MICE COLON

**Introduction:** Bile acids are the end products of hepatic cholesterol metabolism, assembled in the liver and they are the major regulators of intestinal microbiota. Human bile acids are mainly occupied by cholic acid(CA), chenodeoxycholic acid(CDCA), deoxycholic acid(DCA) and lithocholic acid(LCA). Since most of the bile acids secreted into the intestine are reused through the enterohepatic circulation, continuous oral administration of certain bile acids result in an increased composition ratio in the bile acid pool.<sup>1</sup> Each of bile acids have a varying degree of hydrophobicity and pH, so the influence on microbiotas also varies.<sup>2,3</sup> Rodent cecum is largely developed and there is a large amount of microbiotas in it, so food is known to be kneaded and digested here. That is why many animal experimental studies use and analyze the strain of rodent cecum as an alternative of human. However, since cecum is not developed in humans, it is necessary to confirm that the same results are obtained in the cecum and the rest of colon of rodents.

**Aims & Methods:** We examined the effect of each bile acids on various microbiotas in vitro and tried to find out whether similar changes occurred in the intestines by artificially increasing the fraction of specific bile acids, especially on different parts of colon.

1. We analyzed the effects of each bile acids on the various microbiotas using the disk diffusion method commonly used for microbial susceptibility test.

2. The 6 weeks-old-male C57BL/6 mice were treated with five bile acids(CA, CDCA, DCA, LCA, UDCA (ursodeoxycholic acid) and vehicle). In six groups each bile acids were delivered at a dose of 15 mg/kg/day via the transgastric rout. Fecal samples were collected every week and also the feces directly from the colon were collected on the day of the sacrifice and were separated from the cecal feces. The bacterial population was analyzed by real-time PCR and general population of bactereias were measured by universal bacterial primer.

**Results:** As a result of the test for susceptibility to bile acids, the inhibitory effect on the microbiotas of each bile acid was various, and the microbiotas found in the bile or intestinal tract were less inhibited overall than the strains found in other organs. Most of the repressed strains were inhibited by DCA and CDCA, but were also affected by other bile acids and were not consistent.

When the remainder of the rest of colon and the cecum were analyzed separately, it was reported that the total number of strains were increased in the CA and LCA administration groups in the colon except the cecum, but it was reported to be reversed in the cecum. In rest of colon, Firmicutes, a phylum known to be associated with obesity, were found to be lower than Phylum Bacteroidetes, but higher in cecum.

The results of the microbial susceptibility test for a major strains of mice were somewhat in agreement with the number of microbiotas in rest of colon, but not in the cecum.

**Conclusion:** Bile acids have a remarkable inhibitory effect on intestinal microbiotas, which varies according to the type of strain and bile acid. The effect of bile acids on microbiotas in the intestinal tract is similar to that of microbial susceptibility tests and this result was significant in the colon except the cecum. The artificial control of bile acid composition can read to change the environment of bowel microbiotas. Examinations of animal models to replace human beings may be more meaningful in colon except cecum.

**Introduction:** Colorectal carcinoma (CRC) is the third most frequently diagnosed malignancy in males and the second most common malignancy in females. There were 1,006,000 new CRC diagnoses in males and 794,900 in females in 2018 worldwide. Bacteriocins are small proteins, which are produced by the *Enterobacteriaceae* bacteria, especially by *Escherichia coli*. Bacteriocins are divided into more groups, colicins and microcins are the most important ones. Colicins and microcins do possess not only antibacterial, proapoptotic and probiotic properties, but some of them have shown significant biological activity against different cancer cells *in vitro* and *in vivo* conditions. In general, colorectal neoplasia are more frequent in males.

**Aims & Methods:** The aim of this prospective study was to evaluate natural colicin and microcin production by large intestinal mucosal bacteria at each stage of colorectal neoplasia in males and females.

A total of 63 patients with colorectal neoplasia and 20 controls were enrolled into the study. Three groups of patients with colorectal neoplasia were included: individuals with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 63±10), patients with advanced

colorectal adenoma, a-A (13 men, 7 women, mean age 65±9) and subjects with CRC (12 men, 10 women, mean age 70±10). Advanced colorectal adenoma fulfilled the following criteria: an adenoma with low grade dysplasia larger than 10 mm and/or containing high grade dysplasia being of any size and/or adenoma of any size with villous component. Control group consisted from 7 men and 13 women (mean age 57±14) with normal findings on screening colonoscopy and with negative history of colorectal neoplasia. We used the original methodology reported by our group. After appropriate microbiological culture bacteriocin production by each strain was investigated by PCR methods.

**Results:** A total of 239 mucosal biopsies were taken (52 controls, 63 non-a-A, 60 a-A, 64 CRC) and samples were further investigated. A total of 522 *Escherichia coli* and related strains were investigated for bacteriocin production.

There was a significantly higher colicin production in each group of colorectal neoplasia compared to controls,  $p < 0.01$ .

There was a significantly higher microcin production in each group of colorectal neoplasia compared to controls,  $p < 0.05$ .

Colicin production in men increased dramatically at the stage of CRC and differed significantly compared to production of colicins in females at the stage of CRC,  $p < 0.001$ .

There was a later onset of increased production of microcins observed during the adenoma-carcinoma sequence in men compared to women: statistically higher production of microcins was observed in females compared to males at the stage of a-A,  $p = 0.001$ . Subsequently, microcin production decreased in females and increased in males at the stage of CRC, when males produced microcins significantly more frequently compared to females,  $p = 0.023$ .

**Conclusion:** Strains isolated from the large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonoscopy.

Fundamental differences in colicin and microcin production have been confirmed between males and females.

**Introduction:** *Clostridium difficile* is gram-positive, anaerobic, and a spore forming, a common bacterium of the human intestine. Over the past decades, the incidence and severity of *C. difficile* infection (CDI) have increased.

Despite the clinical trial, treatment of patients with refractory CDI and those with multiple CDI recurrences is limited, and there is an ongoing for continued research to improve the outcomes these patients

Fecal Microbiota Transplantation (FMT) as an alternative treatment has been shown to be an effective treatment for recurrent and refractory CDI. However, its mechanism and a key bacteria were still unknown. In this study, we investigated the intestinal isolates to inhibit the growth of *C. difficile*.

**Aims & Methods:** Intestinal bacteria strains were isolated from fecal sample and identified by the 16S rRNA gene analysis. Each isolate and *C. difficile* was sub-cultivated in the broth media at 37 °C under anaerobic conditions. *C. difficile* culture was spreading on the agar plates and sterilized disc laid on the plate. Then, impregnated on the disc with the culture supernatant which removed bacteria. The plate was observed after 48hr incubation in anaerobic environment.

**Results:** More than forty genera including *Enterococcus*, *Clostridium*, *Bacillus*, *Lactobacillus*, *Bifidobacterium*, *Eubacterium* were isolated from human fecal sample. Among them, 5 strains of *Lactobacillus* and 4 strains of *Bifi-*

*dobacterium* were shown to suppress *C. difficile* growth. These belonged to *B. longum*, *B. pseudocatenulatum*, *B. adolescentis*, *B. dentium*, *L. ruminis*, *L. rhamnosus*, *L. sakei*, *L. salivarius*, and *L. gasseri*. Also, we confirmed *Coprococcus* and *Ruminococcus* species can inhibit *C. difficile* growth.

**Conclusion:** We found some of *Bifidobacterium* species and *Lactobacillus* species from human feces could partially suppress against *C. difficile* colonization. These results suggested a potential that some of *Bifidobacterium* species and *Lactobacillus* species could be helpful in preventing CDI. Therefore, these bacteria will be anticipated to play a crucial role in FMT for CDI treatment in the future.

**Introduction:** With emergence of microbial resistance and superbugs, there is a crucial need for safe, highly effective antimicrobial treatments with broad applicability to invasive pathogenic bacteria and fungi. Ultraviolet-C light (200-280 nm) is germicidal but associated with neoplastic transformation in humans. Ultraviolet-A (UVA, 320-400 nm) phototherapy reduces (epi)dermal inflammation without significant adverse effects but has not been evaluated in internal viscera. We aimed to assess the *in-vitro* bactericidal efficacy and *in-vivo* safety of intracolonic UVA using a novel light delivery system.

**Aims & Methods:** Customized optical rods (D=4mm, L=40mm) were designed to homogeneously side-emit UVA. A mercury vapor lamp served as light source (Asahi Max-303), and UV bandwidth/irradiance peaks were assessed (Ocean Optics; Extech). UVA intensities used in this study were less than natural sunlight. (Table 1) *In-vitro* tests were performed using microbial liquid cultures of various enteric pathogens. Cultures exposed to UVA at 20-min intervals were compared to unexposed control cultures and transferred to solid medium plates for CFU counts. *In-vivo* testing of UVA effects on normal colon were performed using BALB/cJ mice (n=10, male=5). Under anesthesia, 5 mice underwent colonic UVA exposure (2,000 µW/cm<sup>2</sup>) for 30 minutes via an optic rod introduced anally up to the splenic flexure as compared to 5 mice treated with the same technique with an unlit optic rod. Rigid endoscopy (Olympus A37027A) was used to evaluate the mucosa before and serially after UVA exposure. Endoscopic videos were blindly interpreted by two gastroenterologists with expertise in animal model endoscopies. Full thickness microscopic assessments were performed by a blinded pathologist on Swiss-roll preparations of the whole colon.

**Results:** Exposure to UVA was associated with a significant reduction in concentrations of various microbes, including *Clostridioides difficile* and *Candida albicans* (Table 1). The germicidal effects increased with greater time of exposure. *Proteus mirabilis* and *Pseudomonas aeruginosa* did not reveal any growth after 20 and 40 minutes of exposure, respectively. During *in-vivo* tests no perforation or fatalities were seen after light exposure. No evidence of erythema, mucosal friability or bleeding was observed during endoscopies. No chronic inflammation or dysplasia was seen on examined full-thickness colonic specimens exposed to UVA.

**Conclusion:** UVA light exposure exhibits significant *in-vitro* bactericidal effects in array of clinically important bacteria, including *C. difficile*. UVA is also effective against *C. albicans* which may prevent fungal bloom following antibacterial treatment. In this first study of intracolonic UVA application, UVA exposure is not associated with endoscopic or histologic injury. UVA therapy can potentially provide an effective and safe novel antimicrobial approach to the treatment of enteric infections and inflammation. Future studies are required to assess the antimicrobial and anti-inflammatory effects of UVA phototherapy on internal organs.

## P1147 COLORECTAL CANCER SCREENING AND CHOICE OF THE POSITIVE CUT-OFF LEVEL. ARE FRENCH DECISION MAKING CRITERIA OPTIMAL IN RELATION TO A PERSON'S EQUAL ACCESS TO COLONOSCOPY IN REGARDS TO ADVANCED NEOPLASIA RISK?

**Kaufmanis A.**, Koivogui A., Vincelet C., Deyra J., Ait Hadad H., Delattre H., Brixi Z., Bercier S., Le Trung T.  
 CRDC-IDF, Paris, France

**Contact E-Mail Address:** a.kaufmanis@adc77.org

**Introduction:** Many European countries use fecal immunochemical test (FIT) as a test for colorectal cancer (CRC) screening using different Cut-off levels ranging from 15-80 μHb/g [Réf-1, 2]. In France the selected level is 30μgHb/g. These levels are generally adjusted to existing capacity to provide colonoscopies for the persons with positive tests. The Netherlands and England provide colonoscopy for positive test within a fixed number of days by a gastroenterologist dedicated to the screening program. In these countries the screening capacity pool is separated from the general colonoscopy pool. In France any gastroenterologist performs a colonoscopy for a person with a positive test. There is no system of prioritization in place. In France organised CRC screening program and access to screening by FIT is advised for persons with "average CRC risk". Individuals with identified two fold risk (first degree family history, adenoma history) are excluded from screening and directly prescribed a colonoscopy. [Réf-3].

**Aims & Methods:** Our aim was to compare, within the French screening programme, the risk to detect advanced-adenoma (AA)/CRC in persons with different Hb cut-off levels in the previous campaign and who were currently considered negative and the AA/CRC general risk. If the risk within certain cut-off levels is twice that of general population should they not have direct access to colonoscopy as do others with comparable risk? Study included a reference group of 602 731 "average risk" inhabitants of Parisian region aged 50-74 years who did their FIT test in 2015-2016 (1st FIT campaign: R1). Two years later (R2) we examined the probability to detect cancer by a FIT test for those who were negative within this R1. Different subgroups of Relative-Risk (RR) analysis were formed, based on the haemoglobin cut-off during the R1 campaign. We compared these subgroups with a reference group.

**Results:** A total of 602 731 people (55.02% women, average age: 61.3 years for women and 60.9 for men) participated in the R1. Of them 4.6 % had a positive test. In this group AA and CRC detection rate was 13.0 ‰ and

2.9 ‰ respectively. Among those who had a negative test in R1, 330,469 (57.5%) (55.7% women, average age: 63.2 years for women and 63.0 years for men) performed a second test during R2. Among them 3.3% were positive, with an increased risk of positivity (2.9 ‰ -16.2 ‰) correlating to Hb level in R1. Compared with individuals of reference group R1 4644 individuals with R1 [20-30] μgHb/g level were 3.0 times more likely to have a positive R2 test, 2.6 (CI, 2.3-3.1) times more likely to have AA and 2.6 (CI, 1.9-3.7) times more likely to have CRC. At the moment of study colonoscopy results were known for 52.4% of those who tested positive in R2. The available data show an increased risk of AA and CRC correlating with the results of the faecal haemoglobin cut-off in R1.

**Conclusion:** The probability of detecting colorectal cancer within the second round of FIT based screening program for those who were negatives but above 20μgHb/g level, is more than two fold if we compare with the reference group who represents the average risk population of the Parisian region. This increase of risk could not be explained just by aging of 2 years. This strongly suggests that this Hb concentration level during the first test may be an equal or more important risk factor than for instance the first degree family history. Additional studies (early second test or colonoscopy based) should be conducted to confirm this hypothesis. If this hypothesis is confirmed, the French program should lower the cut off level.

**Introduction:** Patients with cryptogenic pyogenic liver abscess (PLA) do not have a definite source of infection and it could be a manifestation of compromised colonic mucosal barrier due to colorectal cancer (CRC). Association of PLA and CRC is unclear. Evidence is weak and limited to small sized studies. As a result, the need for colonoscopy in PLA patients is debatable.

**Aims & Methods:** We conducted a comprehensive search of multiple electronic databases and conference proceedings (from inception through January 2019) to identify studies that reported on the prevalence of CRC in PLA patients. Our goals were to evaluate the pooled rate of CRC in patients with cryptogenic PLA.

**Results:** 12 studies were included in the analysis. Majority of them were from East Asian countries. 18,607 patients were diagnosed with PLA in the study group and 60,130 patients were in the control group. 63% were males in the age range of 56 to 94 years. 90.5% of the lesions were left sided and 93.1% were positive for *Klebsiella pneumoniae*. A total of 18,607 PLA patients were reported, of which 17,906 patients underwent screening for CRC. A total of 713 colorectal lesions were found, of which 648 were diagnosed with CRC. 60,130 patients were used as control group, of which 509 patients were diagnosed with CRC. The pooled rate of prevalence of CRC was 7.9% (95% CI 5-12.1, I<sup>2</sup>=92.4, relative risk=6.6) in patients with PLA, as compared to 1.2% (95% CI 0.3-5.7, I<sup>2</sup>=93.4) in control, with statistical significance (p=0.001). Relative risk = 6.6.

**Conclusion:** Although limited by heterogeneity, our study demonstrates that patients with cryptogenic PLA are at a 7-fold risk of having CRC when compared to patients without PLA. Based on our results a screening colo-

noscopy should be considered in East Asian population with cryptogenic PLA, especially when positive for *Klebsiella pneumoniae*.

## P1149 A NATIONWIDE ANALYSIS OF READMISSION RATES AFTER COLORECTAL CANCER SURGERY IN THE US

Kim J.W.<sup>1</sup>, Mannalithara A.<sup>2</sup>, Singh G.<sup>3</sup>, Ladabaum U.<sup>2</sup>

<sup>1</sup>Inje University Ilsan Paik Hospital, Internal Medicine, Goyang, Korea (Republic of), <sup>2</sup>Stanford University Medical Center, Division of Gastroenterology and Hepatology, Redwood City, United States, <sup>3</sup>Institute of Clinical Outcomes Research and Education, Woodside, United States

**Contact E-Mail Address:** jongman12@gmail.com

**Introduction:** Hospital readmission after surgery constitutes a serious burden for patients as well as health systems and payers. Data on readmission rates after colorectal cancer (CRC) surgery are scarce. We analyzed US national rates of, and factors associated with, 30-day readmission after CRC surgery.

**Aims & Methods:** We queried the National Readmissions Database (NRD) from 2010 to 2015 to calculate national estimates of 30-day readmission rates after CRC surgery, and the causes for readmission. Patients included had non-subepithelial CRC, were aged 18 years or more, and survived the index admission. Patients with appendiceal or anal cancer were excluded. In order to allow follow-up of 30 days, patients who were discharged in December were excluded, because patients are not tracked across years. We also analyzed potential factors associated with readmission, first using non-adjusted and ultimately multivariable-adjusted logistic regression. All results were weighted for national estimates. Joinpoint analysis was performed to test for changes in temporal trends.

**Results:** The US national estimate for the number of overall index cases of CRC surgery during the study period was 616,348. Among these patients, 90,555 (14.7%) were readmitted within 30 days of discharge. During our study period, the readmission rate showed a decreasing trend from 15.5% in 2010 to 13.5% in 2015 (p-trend < 0.001, Table 1). Joinpoint analysis did not show any significant change in this trend over time. The most frequent diagnoses for readmission were gastrointestinal (54.8%), infectious (10.6%), and cardio-/cerebrovascular (6.3%).

The three most common gastrointestinal diagnosis codes for readmission were postoperative, post-traumatic, other device infections (11.9%); mal-function, reaction & complication of GI device or procedure (8.7%); and intestinal obstruction (5.9%). After adjusting for covariates, rectal resection (odds ratio [OR], 1.372 [95% confidence interval {CI}, 1.324-1.422]), longer length of stay (OR with log-increase in 1, 1.395 [95% CI, 1.358-1.432]), metropolitan teaching hospital (OR vs metropolitan nonteaching, 1.109 [95% CI, 1.072-1.147]), non-routine discharge including transfer to a short term hospitals (vs routine, OR, 1.617 [95% CI, 1.336-1.957]), elective admission (OR, 1.072 [95% CI, 1.034-1.111]), open laparotomy (OR, 1.172 [95% CI, 1.134-1.212]), and higher Elixhauser comorbidity score (OR for increase in 1, 1.009 [95% CI, 1.008-1.010]) were potential risk factors for subsequent readmission.

Advanced cancer (OR, 0.304 [95% CI, 0.288-0.321]), and older age (OR for >84 y vs 18-44 y, 0.790 [95% CI, 0.727-0.858]) and female gender (OR, 0.941 [95% CI, 0.916-0.966]) were associated with decreased odds for readmission.

Year	2010 (n, %)	2011 (n, %)	2012 (n, %)	2013 (n, %)	2014 (n, %)	2015 (n, %)	Overall (n, %)
Not readmitted	89,882 (84.5%)	88,371 (84.5%)	87,968 (85.2%)	86,557 (85.8%)	86,444 (85.8%)	86,571 (86.5%)	525,793 (85.3%)
Readmitted	16,480 (15.5%)	16,274 (15.5%)	15,331 (14.8%)	14,708 (14.5%)	14,275 (14.2%)	13,486 (13.5%)	90,555 (14.7%)
Total	106,362 (100%)	104,645 (100%)	103,299 (100%)	101,265 (100%)	100,719 (100%)	100,057 (100%)	616,348 (100%)

[Table 1. 30-Day readmission rate by year, US national estimates]

**Conclusion:** In a US national analysis, we found that the 30-day readmission rate after CRC surgery was 14.7% in the period from 2010 to 2015, with a decreasing trend from 15.5% in 2010 to 13.5% in 2015. Some associations appear as expected, such as increased odds of readmission with rectal resection, and some appear surprising and require further study, includ-

ing the decreased odds of readmission with advanced cancer and in older patients. It remains to be determined whether any of the predictors of readmission can point to modifiable factors that can decrease readmission rates after CRC surgery.

## P1150 FIT POSITIVE COLONOSCOPY PERFORMANCE AT A LARGE HMO SHOWS HIGH RATES OF PERFORMANCE AND OF ADVANCED ADENOMAS

Thurm T.<sup>1</sup>, Egger D.<sup>2</sup>, Ash N.<sup>2</sup>, Kariv R.<sup>2,3</sup>

<sup>1</sup>Tel Aviv Medical Center, Gastroenterology, Tel Aviv, Israel, <sup>2</sup>Maccabi Health Care Services, Health Care Division, Tel Aviv, Israel, <sup>3</sup>Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

**Contact E-Mail Address:** revitalk@tlvmc.gov.il

**Introduction:** Annual FIT at 50-75Y is currently the national screening program for CRC in Israel. FIT is considered to be effective for CRC early diagnosis but not a CRC preventive measure compared to colonoscopy. Positive FIT indicates the need for prompt colonoscopy due to a relatively high rate of advanced neoplastic lesions in the colon, while time to colonoscopy up to 6 months has been shown as effective in advanced cancer prevention.

**Aims & Methods:** To review colonoscopy performance among FIT positive cases and its timing after FIT. To identify factors for lack of colonoscopy performance in FIT positive cases and to study the profile of neoplastic findings in FIT positive colonoscopies performed in a large HMO in Israel. Maccabi Health care services (MHS) is an Israeli HMO with 2 million members. All MHS members aged 50-75 during 2018 were included in the analysis. MHS database was searched for FIT and colonoscopy associated parameters. CRC registry was crossed with FIT positive cases. Time between FIT performance and colonoscopy was calculated. Colonoscopy and pathology reports were individually studied for specific endoscopic lesions and corresponding histological findings, respectively.

**Results:** During 2018, 523,530 members were at the age group of 50-75y. among them- 134,542 performed FIT with 6,925 having positive results. For those, colonoscopy was performed after 3, 3-6, 6-9 months from FIT testing in 4035(58%), 337(5%), 49(0.7%), respectively. A survey in a subsample of 430 cases who did not perform colonoscopy up to 9 months post FIT showed that 74% did perform a colonoscopy in a private setting, 7% were still in workup, 4% refused and 8% agreed and performed colonoscopy through the survey. In another subsample of 536 colonoscopies, polyps were reported in 164/536(31%) cases and cancer in 20/536(4%). The records of cases with polyps were searched for endoscopic and histologic findings. Cases with adenomas- 95/536(18%) with 27 non-advanced and 68 advanced (5% and 13% of total sample; 28% and 72% of adenoma cases, respectively). Advanced polyp by histology (villous of HGD) was found in 23/68 and advanced size or number in 45/68. The rate of hyperplastic polyps was 3.5%.

**Conclusion:** Colonoscopy performance after FIT positive test is satisfactory and mostly performed within 3 months of FIT testing according to the quality parameters of MHS. The rate of advanced adenomas is higher in about 2 folds than in average Israeli risk population (1), thus making FIT a CRC preventive measure. Rate of cancer is 3.5 folds of the rate at average risk screening colonoscopy.

**Introduction:** Colonoscopy is the golden standard for detecting colorectal cancer (CRC). The prevalence of post-colonoscopy CRC (PCCRC), a CRC detected within 6-36 months after a negative colonoscopy examination, has been recognized as a quality measure. Mechanisms for PCCRC either might be missed or incompletely excised lesions or CRC developed de novo since the initial colonoscopy. Little is known about histopathological features and low-risk family history for CRC in PCCRC compared to detected CRC (dCRC).

**Aims & Methods:** The aim of the study was to compare PCCRC and dCRC regarding different tumour morphology parameters and family history for CRC. From The Swedish low-risk CRC study 1,535 individuals operated for CRC during the years 2004-06 were included. All had data on family history for CRC (defined as at least one first degree relative with CRC) and the tumours were thoroughly histologically reviewed. Data from the Swedish patient inward and outward as well as causes of death registers were collected. Those who had performed a colonoscopy within 0-36 months before the cancer diagnosis were included for analysis. Cancers were divided into PCCRC and dCRC, with CRC diagnosis within 6-36 and 0-6 months after the colonoscopy, respectively. Statistical analysis included Chi-2 test, Students' T-test and logistic regression.

**Results:** There were 476 CRCs included in the analysis. Of these, there were 29 PCCRCs and 447 dCRCs. The mean age was 66.1 years in the PCCRC group and 69.2 years in the dCRC group (p=0.07). When controlling for sex and age, there was no significant difference between the two groups in five-year mortality, 34% in PCCRC and 28% in dCRC (p=0.334). The results of the logistic regression analysis are summarized in the table.

**Conclusion:** In this small Swedish cohort study, low-risk family history for CRC was not a significant risk factor for PCCRC. Crohn-like peritumoral lymphocytic reaction was less frequently seen in PCCRC compared to dCRC. This might be an indication of different prognosis for PCCRCs compared to dCRCs.

Covariate	OR	p-value	95% CI
Sex (female vs male)	0.91	0.845	0.37-2.25
Age (continuous)	1.00	0.854	0.95-1.04
Localisation (right vs left)	0.77	0.565	0.31-1.89
T-stage (T3/T4 vs T1/T2)	4.11	0.067	0.91-18.66
N-stage (1, 2 or 3 vs 0)	1.58	0.311	0.65-3.85
Peritumoral lymphocytic reaction (yes vs no)	0.40	0.030	0.18-0.91
Vascular growth (yes vs no)	0.19	0.110	0.02-1.46
Medullary type (yes vs no)	2.21	0.357	0.41-11.95
Family history CRC (yes vs no)	1.20	0.755	0.38-3.75

**Introduction:** Implementation of the FIT-based colorectal cancer (CRC) screening program in 2014 has led to an increased detection of T1 CRCs in the Netherlands. Current risk stratification is based on non-screen-detected T1 CRCs. However, it is unknown whether screen- and non-screen-detected T1 CRCs have a comparable risk of adverse outcomes such as lymph node metastasis (LNM) and recurrence.

**Aims & Methods:** In this study we compared screen-detected and non-screen-detected T1 CRCs. A multicenter retrospective observational cohort study was performed, identifying all consecutive T1 CRCs diagnosed between 2014 and 2017 in 8 hospitals in the Netherlands. Data on whether a T1 CRC were screen-detected or non-screen-detected, together with polyp characteristics, histological risk factors, treatment approach and clinical variables such as age, gender and co-morbidities were collected. Differences in LNM were evaluated by using multivariate logistic regression analysis, adjusting for clinical variables, polyp characteristics and histological risk factors.

**Results:** A total of 1101 T1 CRCs (median follow-up 21.7 months (IQR 19-30)) were included in the study, of which 693 (62.9%; 34.2% female) were screen-detected and 408 (37.1%; 42.4% female) were non-screen-detected. Screen-detected T1 CRCs were smaller (mean size of 20.0 mm (SD 11.5) vs. 22.5 mm (SD 13.2), p=0.005), more frequently located in the left-sided colon (61% vs. 54%, p=0.02), and patients were younger (67.2 (IQR 63-71) vs. 69.3 (IQR 62-78) years, p< 0.001) compared to non-screen-detected patients with T1 CRC. Within the group of patients referred for surgery, screen-detected T1 CRC was associated with a higher risk of LNM than non-screen-detected T1 CRC (16.4% vs. 10.4%; adjusted OR 1.78, 95% CI 0.93-3.34; p=0.08). This difference was mainly attributable to a higher LNM risk in non-pedunculated screen-detected T1 CRCs (18.8% vs. 10.5%, p=0.03), as there was no significant difference in LNM risk in pedunculated T1 CRCs (9.1% vs 8.3%). Within the group of non-pedunculated T1 CRCs (n=669 (65% of total), of which screen-detected n=427(64%)) there was no difference between screen- and non-screen-detected T1 CRCs regarding histological features such as lymphovascular invasion (14.8% vs 11.1%, p=0.35) and poor differentiation (6.3% vs. 5.3%, p=0.49). However, positive (R1) or inconclusive (Rx) resection margins were more frequently present in screen-detected patients (46.9% vs. 34.7%, p=0.002), although this feature was not independently associated with LNM in this cohort (p=0.094). While non-screen-detected patients were referred for primary oncologic surgery more often than screen-detected patients (65% vs 53%, p=0.003), there was no difference in overall surgical referral rate (56.2% vs. 62.8% p=0.10).

Interestingly, the major difference in LNM in non-pedunculated T1 CRCs was found within the primary surgery group (screen-detected 17.6% vs. non-screen-detected 6.2%, p=0.008), and not in the secondary surgery group (screen-detected 20.2% vs. non-screen-detected 21.4%, p=0.871).

**Conclusion:** Non-pedunculated T1 CRCs detected within the FIT-based screening program have a higher risk for synchronous lymph node metastasis compared to non-screen detected T1 CRCs. This difference is most pronounced in patients referred for primary surgery, suggesting that these

polyps may have alarming malignant features with optical diagnosis. This increased risk should be kept in mind, now that local minimally invasive treatments such as full thickness resections are becoming more widely available.

**Disclosure:** Nothing to disclose

## P1153 OUTCOMES OF COLORECTAL CANCER SCREENING STARTING AT THE AGE OF 45 IN AVERAGE-RISK, ASYMPTOMATIC PATIENTS

Chalifoux S., Tsai F., Strum W.

*Scripps Clinic, Gastroenterology and Hepatology, La Jolla, United States*

**Contact E-Mail Address:** sarachalifoux@gmail.com

**Introduction:** Colorectal cancer (CRC) is the fourth most common cancer diagnosed among adults in the United States and most guidelines recommend colorectal cancer screening for average-risk individuals starting at age 50. Since 1994, there has been a 51% increase in CRC among individuals younger than 55. Updated guidelines from the American Cancer Society (ACS) in May 2018 recommend starting colorectal cancer screening for all individuals at age 45. T

these recommendations are based on modeling studies and there are limited data on the effectiveness and outcomes of colorectal cancer screening in average risk individuals younger than 50.

**Aims & Methods:** The aim of this study was to compare the rates of adenomas and advanced adenomas detected in average risk patients undergoing screening colonoscopies between the ages of 45-49 versus 50-54. In this retrospective study, a total of 3,760 patients undergoing colorectal cancer screening from June 2018 to December 2018 were reviewed, with 1,447 patients excluded based on active digestive symptoms, anemia or personal history of CRC. The rates of adenomatous lesions and advanced adenomatous lesions in each cohort were compared. Advanced adenomas were defined as any adenoma  $\geq 10$  mm in size, high-grade dysplasia, villous or tubulovillous histology, and adenocarcinoma. The locations of advanced adenomas were also compared.

**Results:** In the 45-49 cohort, there were a total of 190 patients who underwent screening colonoscopy, of which 47.7% were women. In this cohort, 73 (38%) patients had non-advanced adenomas (adenoma size < 5 mm in 27, and 5-9 mm in 46). A total of 10 (5%) patients had advanced adenomas based on advanced histology (polyp size 5-9 mm in 3, and  $\geq 10$  mm in 1) and size (adenomas  $\geq 10$  mm in 6). One 49 year old patient had an adenocarcinoma found on screening colonoscopy.

In the 50-54 cohort, there were a total of 2,123 patients who underwent screening colonoscopy, of which 52.4% were women. In this cohort, 870 (41%) patients had non-advanced adenomas (adenoma size < 5 mm in 443, and 5-9 mm in 427). A total of 119 (5.6%) patients had advanced adenomas based on histology (polyp size < 5 mm in 2, 5-9 mm in 13, and  $\geq 10$  mm in 17) and size (adenomas  $\geq 10$  mm in 87). No patients had adenocarcinoma found on screening colonoscopy in this cohort.

The adenoma detection rate was 44.2% in the 45-49 cohort and 46.6% in the 50-54 cohort ( $p=0.53$ ). The advanced adenoma detection rate was 5.8% in the 45-49 cohort and 5.6% in the 50-54 cohort ( $p=0.91$ ). Advanced adenomatous lesions were most frequently found in the ascending colon for both cohorts (Table 1).

45-49 cohort		50-54 cohort	
Location	Number	Location	Number
Cecum	1	Cecum	20
Ascending	7	Ascending	30
Transverse	1	Transverse	20
Sigmoid	0	Sigmoid	18
Rectosigmoid	0	Rectosigmoid	6
Rectum	2	Rectum	18

[Table 1: advanced adenoma locations]

**Conclusion:** This study provides preliminary data on the outcomes of CRC screening starting at the age of 45 in a Southwestern population since the updated ACS screening guidelines were released in May 2018. Our results show that asymptomatic patients between the ages of 45-49 who undergo screening colonoscopy have adenomas and advanced adenomas detected

at rates similar to patients screened between the ages of 50-54. Additionally, one adenocarcinoma was discovered on screening colonoscopy in a patient before the age of 50. These findings support consideration of colorectal cancer screening at age 45.

**Contact E-Mail Address:** anna.forsberg@ki.se

**Introduction:** The rate of post-colonoscopy colorectal cancer, PCCRC, a cancer detected 6-36 months after a colonoscopy in which no cancer was found, has been recognised as a key quality indicator of colonoscopy. Mechanisms for PCCRC might be either missed or incompletely excised lesions or de novo cancer developed after the index colonoscopy.

**Aims & Methods:** The aim was to evaluate the PCCRC rates and associated risk factors for PCCRC during a 10-year period. Data was collected from the Swedish patient registries on individuals  $\geq 18$  of age. All unique individuals who had undergone at least one colonoscopy during the years 2003-15 were identified. Those with a CRC diagnosis prior to inclusion in the study were excluded. The rest was individually linked to the Swedish Cancer Registry and the Swedish Cause of Death Register. CRCs within 0-6 months of a colonoscopy examination were considered as detected cancers and CRCs diagnosed within 6-36 months as PCCRCs. Colonoscopies performed 2003-12 were included in the analysis. The PCCRC rate was analysed with colonoscopies as the denominator (1). Statistical analyses employed Poisson regression analysis with cluster-robust standard errors. Covariates included were age, sex, comorbidities, procedure, location of the CRC, T-stage, time-period and the geographical location of the diagnosing hospital.

**Results:** There were 461,031 colonoscopies performed on 349,129 (56% on women) individuals included in the study. The mean age at the first examination was 59.4 years. Of these, there were 19,178 individuals with a CRC diagnosis 0-36 months after a colonoscopy. There were 1,329 PCCRCs, which is equal to the number of colonoscopies that failed to detect a CRC. The number of colonoscopies that detected a CRC was 18,480. The PCCRC rate for the ten-year period was 6.7%. The rate was 8.1% in 2003 and 5.9% in 2012. Gender, younger age, right-sided CRC, comorbidities, previous history of colorectal polyps as well as polypectomy during the procedure and the first time-period were associated with a significantly increased risk of PCCRC.

Main group	Covariate	RR	p-value	95% CI
Sex	Male vs female	0.87	0.007	0.79-0.96
Age group	Age 18-30 years	1.40	0.128	0.91-2.18
	Age 30-40 years	1.35	0.052	1.00-1.83
	Age 40-50 years	1.31	0.028	1.03-1.66
	Age 50-60 years	1.06	0.529	0.88-1.29
	Age 60-70 years	1.12	0.134	0.97-1.29
	Age 70-80 years	1.06	0.419	0.92-1.21
Comorbidity	Age > 80 years (ref)	1.00		
	Ulcerative colitis Yes/No (No=ref)	5.12	<0.001	4.48-5.85
	Crohn's disease Yes/No	3.85	<0.001	3.01-4.92
Procedure	Prior polyp diagnosis Yes/No	1.84	<0.001	1.50-2.26
	Polypectomy Yes/No	2.01	<0.001	1.68-2.41
Location CRC	Left- vs right-sided CRC	0.56	<0.001	0.49-0.64
	Undefined vs right-sided CRC	0.62	0.014	0.42-0.91
T-stage CRC	T1/T2 vs T3/T4	1.27	<0.001	1.15-1.41
	Undefined vs T3/T4	0.66	<0.001	0.55-0.80
Time period	2008-12 vs 2003-07	0.87	0.008	0.79-0.96

[Table. Multivariate Poisson regression analysis for post-colonoscopy versus detected colorectal cancer with colonoscopy as the denominator]

In the table, the multivariate analysis for the risks of PCCRC is shown. The covariates Diabetes, Diverticulosis, Ischemic Heart Disease, COPD, Heart Failure and Geography were controlled for but results not shown.

**Conclusion:** The PCCRC rate is slowly decreasing in Sweden. The strongest risk factors for PCCRC were UC and Crohns' disease. Increased effort for detecting CRCs in risk groups is of concern.

**Introduction:** Patients referred under the 2-week wait (2WW) pathway for gastrointestinal cancer with iron deficiency anaemia (IDA) are investigated in our centre with colonoscopy, upper GI endoscopy and CT scanning. It is necessary to justify these investigations given the burden they place upon radiology and endoscopy services.

**Aims & Methods:** Our aim was to examine the predictive role of ferritin in such referrals and to assess whether this might be used to better streamline investigations.

Referrals to the upper and lower GI cancer pathway over a period of one year were screened for referrals made exclusively for IDA. Data was collected on ferritin level, age, gender, cancer detection and modality of cancer detection. Low ferritin was defined as < 15µg/L. Categorical variables were compared using a chi-squared test.

**Results:** 3669 referrals to the upper and lower GI cancer pathway between May 2017 and May 2018 were screened for inclusion. 377 patients were referred for IDA of which 52 (13.8%) were found to have a malignancy. This compares to a national cancer detection rate of 7.6% for all referrals to 2WW pathways.

191 patients (52.0%) had a low ferritin. There was no statistically significant difference between rate of cancer detection in the low and normal ferritin groups (10.4% vs 20.8% p=0.06). Males were more likely to have a cancer detected than females (21.8% vs 6.9%, p= 0.00003). The cancers detected included several non-GI malignancies in both low ferritin and normal ferritin groups (5/20 vs 10/30, p=0.53) (See table).

CT scanning missed the malignancy in 7 cases of colorectal cancer subsequently detected on colonoscopy. 6 cancers were detected using upper GI endoscopy and all of these had been visible on CT scanning. In addition, all of the upper GI malignancies had normal ferritin levels.

	Low Ferritin	Normal Ferritin
Colon	14	11
Pancreas	1	2
Renal	1	1
Prostate	1	2
Other	Breast (1) Adrenal (1) Bladder (1)	Lung(4) Stomach (2) Oesophagus (2) GOJ (2) Lymphoma (1) No primary (1) Cholangiocarcinoma

[Cancer detection]

**Conclusion:** This study demonstrated a high rate of cancer detection for anaemia referrals but there was no statistically significant correlation between ferritin level and detection of cancer. Ferritin may not be a helpful marker in screening anaemia referrals. These results challenge the use of upper GI endoscopy in the investigation of anaemia on the cancer pathway since all cancers were seen on CT.

**Contact E-Mail Address:** b9002007@hotmail.com

**Introduction:** Colorectal cancer (CRC) is the third most common tumor in men and the second in women, resulting in the fourth most common cancer-related cause of death in the world. In 2010 WHO classification system divided serrated lesions in colorectum into three types: hyperplastic polyp, traditional serrated polyp, and sessile serrated adenoma/polyp (SSA/P). Among them SSA/P is an important premalignant precursor of CRC. However, the true prevalence of SSA/P and its relationship to CRC are still unknown due to unaccepted bowel preparation, detection difficulty, and poor discrimination within endoscopists and pathologists.

**Aims & Methods:** The aim of this systemic review and meta-analysis is to evaluate the true prevalence of SSA/P and its relationship to synchronous colorectal advanced neoplasia.

A comprehensive, computerized research was performed on PubMed published from 1 January 2010 to 6 July 2018 to search relevant articles without language limitation. Clinical trials were included in narrative systemic review if they matched the following inclusion criteria:

- (1) published as case-controlled study, cohort study or cross-sectional study;
- (2) defined objectively for diagnosis of SSA/P within studies;
- (3) addressed the prevalence and characteristics of SSA/P.

Within these trials if they met additional criteria involving reported outcome of risk of advanced neoplasia in relation to SSA/P they were enrolled into meta-analysis.

**Results:** The prevalence of all SSA/Ps in this review ranged from 0.038 to 20.23% and pooled prevalence was 2.7% (95%CI, 1.9-3.9%). In subgroup analysis the overall prevalence of SSA/P between period of 2010-2014 and period of 2015-2018 showed 2.7% (95%CI, 1.2-6.0%) and 2.8% (95%CI, 1.9-4.1%) respectively.

We calculated the pooled data on the risk of SSA/P and synchronous advanced neoplasia in patient with SSA/Ps available from 8 trials resulting in pooled OR of 3.53 (95%CI, 2.39-5.20, *P*=4%) without detection in heterogeneity test.

**Conclusion:** In this systemic review the prevalence of SSA/P was 2.7% (95%CI 1.9-3.9%) and was no difference between the period of 2010-2014 and 2015-2018. Besides SSA/P is associated with increasing risk of synchronous advanced neoplasia in colorectum.

**Introduction:** Colonic polyps, both adenomatous and hyperplastic (HP), have been shown to be associated with red and processed meat consumption and with smoking habits. Recently, we have shown that red and/or processed meat consumption and pack years are inversely associated with RAGE soluble receptor (sRAGE) for advanced glycation end products. In addition, sRAGE levels have been shown to be associated with the risk for colorectal cancer (CRC) in male smokers and in post-menopausal women. However, further evidence is lacking as for the modifying effect of smoking on the association between red and/or processed meat or sRAGE levels with different types of colonic polyps.

**Aims & Methods:** The aims of this study were to assess the association between red and/or processed meat or sRAGE levels and different types of colonic polyps and to test the possible effect modification of smoking habits. This was a case-control study, among consecutive subjects aged 40-70 years, undergoing colonoscopy during 2010-2015.

Cases with colorectal polyps were compared to controls with no past or present polyps. Detailed information was gathered regarding polyp histology, anatomic location and lifestyle habits including smoking. Smoking was defined as ordinal variable with three levels; never smokers, light smokers (pack years under the median of the total sample corresponding to 19.75) and heavy smokers ( $\geq 19.75$ ).

Serum sRAGE levels were measured and red and/or processed meat consumption was calculated by food frequency questionnaire (FFQ). High red and/or processed meat consumption was defined as consumption above the sample median ( $>0.33$  portions/week) and low sRAGE defined as levels under the sample first tertile ( $< 1013.42$  pg/ml).

**Results:** A total of 789 participants were included (cases with colorectal polyps  $n=403$ , controls  $n=386$ ), 743 subjects had sRAGE measurements. Among the entire sample, high red and/or processed meat consumption was significantly associated with higher odds for adenomatous polyps throughout the colon and with distal HP (OR=1.41, 95% CI 1.00-1.97,  $P=0.048$ ; OR=2.04, 1.02-4.05,  $P=0.043$ , respectively), but the association with total polyps was not significant (OR= 1.36, 95%CI 0.99-1.88,  $P=0.057$ ).

However, stratification by pack years, revealed a significant association of red and/or processed meat consumption with total polyps among heavy smokers (OR=1.96, 95% CI 1.01-3.80,  $P=0.048$ ). Moreover, low sRAGE levels were significantly associated with higher odds for HP, specifically with proximal HP (OR=2.03, 95% CI 1.06-3.89,  $P=0.032$ ; OR=2.96, 1.20-7.33,  $P=0.019$ , respectively).

**Conclusion:** High red and/or processed meat consumption is associated with adenomatous polyps throughout the colon, with distal HP and among smokers also with total polyps. Low serum sRAGE is associated with HP, especially proximal. These results may aid in designing prevention recommendations for colonic neoplasia as well as open a new frontier in understanding CRC pathogenesis.

## P1158 FAECAL DNA TEST IN COMBINATION WITH FAECAL IMMUNOCHEMICAL TEST FOR HAEMOGLOBIN IS USEFUL FOR DETECTION OF COLORECTAL ADVANCED ADENOMA

Suehiro Y., Yamasaki T.

Yamaguchi University Graduate School of Medicine, Oncology & Laboratory Medicine, Ube, Japan

**Contact E-Mail Address:** ysuehiro@yamaguchi-u.ac.jp

**Introduction:** The main approach to colorectal cancer screening worldwide is the faecal immunochemical test for haemoglobin (FIT). Although the sensitivity of the FIT for the diagnosis of colorectal neoplasia is about 90% for colorectal cancer, it falls to about 30% for the detection of advanced adenoma. To avoid this disadvantage, more sensitive methods are required.

**Aims & Methods:** As TWIST1 methylation is specific to colorectal neoplasia, detection of TWIST1 methylation from faeces samples might be useful for colorectal neoplasia screening. However, because the content of human DNA in faeces is very small, it is very difficult to detect TWIST1 methylation by conventional bisulphite-based methylation assays. Therefore, we developed a new methylation assay without bisulphite treatment and evaluated its sensitivity and specificity in combination with and without FIT for detection of colorectal neoplasia from faeces samples. DNA was treated with three methylation-sensitive restriction enzymes and an exonuclease, followed by measurement of TWIST1 methylation level by droplet digital PCR. The FIT and faecal DNA test were performed on 71 control individuals and 372 patients with colorectal neoplasia including 40 with non-advanced adenoma, 127 with advanced adenoma, and 205 with colorectal cancer.

**Results:** Sensitivity of the FIT was 7.5% for non-advanced adenoma, 32.3% for advanced adenoma, and 93.7% for colorectal cancer, and specificity was 87.3%. Sensitivity of the faecal DNA test was 27.5% for non-advanced adenoma, 47.2% for advanced adenoma, and 44.3% for colorectal cancer, and specificity was 91.5%. Sensitivity of the FIT and faecal DNA test combined was 35.0% for non-advanced adenoma, 68.5% for advanced adenoma, and 95.6% for colorectal cancer, and specificity was 80.3%.

**Conclusion:** Combination of the faecal DNA test with FIT may provide an alternative screening strategy for colorectal neoplasia, especially for potentially precancerous lesions.

**Introduction:** Common low-penetrance genetic variants (SNPs) has been consistently associated with colorectal cancer (CRC) risk, but the risk conferred by each of these variants is usually modest. The relevance of these SNPs in the development of colorectal adenomas has been scarcely evaluated.

**Aims & Methods:** To evaluate the potential of a genetic risk score (GRS) to identify individuals with an increased risk of colorectal adenomas.

Patients were selected from the Spanish colorectal cancer screening registries in Aragon and The Canary Islands. Patients with hereditary non-polyposis CRC, familial adenomatous polyposis, history of CRC or inflammatory bowel disease were excluded. We included 858 patients with no precancerous colorectal lesions and 642 with adenomas. Genomic DNA from participants was genotyped by the MassArray™(Sequenom) platform for a panel of 99 SNPs previously associated with CRC risk. We derived a GRS based on the 11 SNPs significantly associated with adenoma development in our study. The number of risk alleles was coded as 0, 1 or 2 for each SNP assuming a log-additive genetic effect. To test the relevance of our score, we estimated the impact of having each additional risk allele by computing the odds ratio (OR) and the associated 95% confidence interval (95%CI). In addition, the predictive value for colorectal adenoma risk was calculated as the area under the ROC curve (AUC). PredictABEL R package was used to compute the genetic risk score.

**Results:** Five SNPs were identified using a multivariate logistic model that included the 11 SNPs that were associated with colorectal adenomas in our study: rs10505477, rs11255841, rs13181, rs4779584 and rs8180040. We observed that the risk of developing adenomas increased with the number of risk alleles (per-allele OR=1.209, 95%CI 1.122 to 1.302  $p < 0.001$ ). Five risk alleles were considered as reference since it was the median number in patients without adenomas. See Table 1.

No of risk alleles	Patients n (%)	Without lesions n (%)	With adenomas n (%)	OR (95% CI)	p-value
$\leq 2$	30 (2.1)	19 (2.3)	11 (1.8)	0.894 (0.401-1.993)	0.783
3	112 (7.8)	73 (8.8)	39 (6.4)	0.844 (0.536-1.331)	0.466
4	225 (15.6)	142 (17.1)	83 (13.5)	0.968 (0.679-1.380)	0.858
5	366 (25.4)	229 (27.6)	137 (22.3)	1 (reference)	
6	364 (25.8)	199 (24.0)	165 (26.9)	1.431 (1.054-1.941)	0.021
7	228 (15.8)	118 (14.2)	110 (17.9)	1.621 (1.147-2.292)	0.006
$\geq 8$	117 (8.1)	49 (5.9)	68 (11.1)	2.500 (1.616-3.869)	0.000
Total	1442 (100.0)	829 (100.0)	613 (100.0)	1.209 (1.122-1.302) per allele	p trend <0.001

[Risk of colorectal adenomas associated with increasing number of risk alleles in five selected SNPs in study population]

Individuals with  $\geq 8$  risk alleles had a 2.5-fold increase in adenoma risk compared with those with 5 risk alleles. The GRS adjusted by sex and age showed a discriminating power of 66% (AUC = 0.657, 95%CI 0.628 to 0.685).

**Conclusion:** An increased GRS based on CRC-associated SNPs was associated with increased prevalence of colorectal adenomas. These findings may help to identify better a subgroup of patients with increased risk of adenomas who would benefit from stricter cancer screening programs.

**Disclosure:** Nothing to disclose

**Introduction:** Chronic inflammation is a well-established risk factor for colorectal cancer. Interleukin-10 (IL-10) is a cytokine whose main biological function is to limit inflammatory responses and is crucial to maintain immune homeostasis of the gastrointestinal tract. Some single nucleotide polymorphisms (SNPs) of IL-10 have been associated with cancer risk.

**Aims & Methods:** To evaluate the role of SNPs rs1800896, rs1800872 and rs1800871 of IL-10 in Mexican mestizo patients with rectal cancer. A prospective study was conducted in which 53 patients with rectal cancer and 52 healthy controls were included. Information was collected focused on the demographic, clinical, biochemical characteristics; CT, MRI and histopathological reports of each patient, by reviewing the clinical files. SNPs rs1800896, rs1800872 and rs1800871 of IL-10 were genotyped by RT-PCR with Ab3130 kit.

**Results:** We identified that the AA genotype of rs1800872 behaved as a protective factor for invasion of regional nodes [OR0.14 (IC95% 0.02-0.80)  $p < 0.04$ ], presence of distant metastasis [OR0.30 (IC95% 0.10-0.83)  $p < 0.01$ ] and for the development of a late stage of the disease (CS III-IV) [OR0.14 (IC95% 0.02-0.79)  $p < 0.04$ ]. The CC genotype of rs1800871 was a protective factor for the presence of distant metastasis [OR0.33 (IC95% 0.12-0.94)  $p < 0.03$ ], whereas its CT heterozygous form was at risk for greater local infiltration (T3-T4) [OR1.11 (IC95% 1.01-1.22)  $p < 0.001$ ].

The genotypic GG frequency of rs1800896 was a risk factor for non-response to neoadjuvant therapy [OR4.0 (IC95% 2.82-5.65)  $p = 0.005$ ], whereas the AG genotype represented a protective factor for non-response to neoadjuvant therapy [OR0.25 (IC95% 0.17-0.35)  $p < 0.005$ ]. The allelic frequency A [OR0.22 (IC95% 0.08-0.58)  $p = 0.001$ ] and the AA genotype [OR0.20 (IC95% 0.06-0.64)  $p = 0.003$ ] of rs1800872 were protective factors for non-response to therapy neoadjuvant, while the allelic frequency C [OR4.42 (IC95% 1.70-11.44)  $p = 0.001$ ] and the CC genotype [OR6.77 (IC95% 2.86-17.90)  $p < 0.001$ ] of the same polymorphic site were found as risk for the no response to neoadjuvant. As for the rs1800871, the allelic frequency C [OR0.27 (IC95% 0.11-0.69)  $p = 0.004$ ] and the CC genotype [OR0.20 (IC95% 0.06-0.60)  $p = 0.004$ ], were protective for the non-response to neoadjuvant, whereas the allelic frequency T [OR3.6 (IC95% 1.44-8.99)  $p = 0.004$ ] and TT genotype [OR6.0 (IC95% 2.10-17.12)  $p < 0.001$ ] resulted in risk for non-response to neoadjuvant therapy.

Of the patients included who underwent surgical procedures, we found a protective factor for post-surgical complications at the allelic frequency A [OR0.34 (IC95% 0.12-0.97)  $p < 0.04$ ] and the AA genotype [OR0.18 (IC95% 0.04-0.75)  $p = 0.01$ ] of the rs1800872, while its allelic frequency C [OR2.86 (IC95% 1.02-8.04)  $p = 0.04$ ] behaved as a risk for postoperative complications. rs1800871 is also involved in post-surgical complications, its allelic frequency C [OR0.30 (IC95% 0.10-0.86)  $p = 0.02$ ] and homozygous CC genotype [OR0.18 (IC95% 0.04-0.75)  $p = 0.01$ ] were protective factors for the development of post-surgical complications, however, its allelic frequency T [OR3.26 (IC95% 1.15-9.18)  $p = 0.02$ ] and TT genotype [OR6.0 (IC95% 2.10-17.12)  $p < 0.001$ ] represented a risk factor for postoperative complications.

**Conclusion:** IL-10 SNPs could impact in different aspects in evolution of rectal cancer, particularly in tumor infiltration, progression, treatment response and post-surgical outcomes. This is the first study worldwide that associate IL-10 SNPs with neoadjuvant response and post-surgical outcomes exclusively in rectal cancer patients.

**Introduction:** Inflammatory cells such as neutrophils and macrophages are infiltrated in the tumor microenvironment (TME). The macrophages found in the TME are often referred to as tumor-associated macrophages (TAMs), which are classified into two types: M1 and M2. M1 macrophages exhibit high bactericidal and tumoricidal capacity. In contrast, M2 macrophages promote tissue repair, regulate immune function, and are involved in tumor progression. It has been reported that TAMs often have a M2 phenotype form and are associated with a poor prognosis in some cancers, such as melanoma. In contrast, some reports show a positive correlation of high number of macrophages with better prognosis in colorectal cancer (CRC) patients. The role of TAMs in progression of CRC is still controversial. Although most studies report an association between TAMs and an advanced CRC, there is no report on the detail about association between TAMs and early-stage colorectal neoplasia. The aim of this study is to elucidate the distribution and function of TAMs in early-stage colorectal neoplasia.

**Aims & Methods:** The subjects were 40 patients of early-stage colorectal neoplasia (20 submucosal invasive cancer and 20 dysplasia, including 10 low and 10 high-grade dysplasia) treated at our hospital from 2011 to 2018. The phenotype and distribution of macrophages were assessed by double immunofluorescent staining of CD68 as a marker for total macrophages and CD163 as a marker for M2 macrophages. M1 macrophages were defined as CD68 positive and CD163 negative. The number and phenotype of macrophages were evaluated as the most representative area at each part, including center, lateral periphery, and deepest part of the tumor (invasive edge), in addition to the non-neoplastic mucosa adjacent to the tumor. Five representative high-power fields (1 HPF = 0.0988 mm<sup>2</sup>) for each part were chosen and analyzed.

**Results:** When comparing dysplasia and submucosal invasive cancer, the number of total macrophages in submucosal invasive cancer was significantly higher than that in dysplasia at each part, and the number of total macrophages at the deepest part of the tumor was higher as compared to that at the other parts in both dysplasia and submucosal invasive cancer. With regard to the phenotype of macrophages, in dysplasia, most macrophages were of M1 type with only a few of M2 type at each part and the number of M1 macrophages at the deepest part of the tumor was significantly higher as compared to that at the other parts. In contrast, in submucosal invasive cancer, the number of both M1 and M2 macrophages at the deepest part of the tumor was significantly higher as compared to that at the other parts. Additionally, the number of M1 and M2 macrophages at the deepest part of tumor in submucosal invasive cancer was significantly higher as compared to that in dysplasia. Especially, the difference in the number of M2 macrophages between dysplasia and submucosal invasive cancer was remarkable at the deepest part of the tumor.

**Conclusion:** In submucosal invasive CRC, the number of macrophages, especially M2 macrophages was significantly higher at the deepest part of tumor. These findings suggested that macrophages differentiate into M2 macrophages by interaction with tumor cells and hence promote the progression of CRC.

**Disclosure:** Nothing to disclose

## P1162 A PROSPECTIVE COHORT STUDY ON THE BENEFIT OF PREOPERATIVE ULTRATHIN COLONOSCOPY FOR COLORECTAL CANCER PATIENTS WITH STENOSIS

Ito S., Hotta K., Imai K., Kishida Y., Kakushima N., Takizawa K., Kawata N., Yoshida M., Yabuuchi Y., Ishiwatari H., Matsubayashi H., Ono H.  
Shizuoka Cancer Center, Division of Endoscopy, Shizuoka, Japan

**Contact E-Mail Address:** sa.ito@scchr.jp

**Introduction:** Preoperative colonoscopy for colorectal cancer (CRC) with stenosis is often insufficient because of poor preparation or incomplete colonoscopy. There is no large cohort study to clarify the usefulness of ultrathin colonoscopy for CRC with stenosis, although data after colon stent placement using a small diameter scope have been reported.<sup>1</sup>

**Aims & Methods:** This prospective cohort study aimed to evaluate the ability of an ultrathin colonoscope (UTC) to pass through stenosis and to detect synchronous neoplasms proximal to the stenosis. If the passage of a standard colonoscope (PCF-H290ZL: outer diameter 11.7 mm) was not feasible because of the stenosis, UTC (PCF-PQ260L: outer diameter 9.2 mm) was used. A total of 100 patients in whom UTC was used were prospectively registered from September 2017 at the Shizuoka Cancer Center (UMIN000028505). Patients with stent placement, who had undergone neoadjuvant chemotherapy, and who needed right hemicolectomy were excluded.

After colonoscopy, data on the tumor location, possibility of cecal insertion, grade of bowel preparation (according to the Boston Bowel Preparation Scale), presence of synchronous neoplasms, and day of surgery were recorded. Primary endpoints were the pass-through and cecal insertion rates. The detected synchronous neoplasms (adenomas and cancers) and their pathological findings after resection were also examined.

**Results:** Of 650 patients with advanced stage CRC who underwent preoperative colonoscopy during the recruitment period, 193 could not undergo complete colonoscopy using a standard colonoscope. After the exclusion of 93 patients, including 15 with stent placement, 21 who had undergone neoadjuvant chemotherapy, 21 indicated for right-hemicolectomy, and 40 others, a total of 100 patients who underwent ultrathin colonoscopy were enrolled in this study until February 2019 and analyzed.

The mean age of the 100 patients was 65.6 ± 10.8 years, and 59% of the patients were male. The pass-through and cecal insertion rates were 67% (67/100) and 58% (58/100), respectively. Synchronous lesions located proximal to the stenosis were detected in 65.5% (38/58) of the complete colonoscopies, with a total of 76 lesions, including 18 advanced neoplasms with three advanced stage CRCs. The bowel preparation score in the complete colonoscopy was 6.4 ± 2.6. The number of median waiting days for surgery was significantly longer in the pass-through of the UTC group (14 days vs. 10 days, *P* = 0.022). Two patients (6.1%) in the non-pass-through group required abdominal decompression by transanal ileus tube insertion before surgery.

**Conclusion:** Ultrathin colonoscopy for CRC with stenosis improved insertability compared to that in standard colonoscopy. Moreover, preoperative ultrathin colonoscopy for patients with stenosis has the potential to change the treatment strategy by predicting the risk of intestinal obstruction and detecting synchronous neoplasms.

## P1163 QUALITY OF ONLINE MEDICAL INFORMATION ON COLORECTAL CANCER SCREENING

Ong Y.L.<sup>1</sup>, Namasivayam V.<sup>2</sup>

<sup>1</sup>National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, <sup>2</sup>Singapore General Hospital, Gastroenterology & Hepatology, Singapore, Singapore

**Contact E-Mail Address:** ongyanlings@gmail.com

**Introduction:** Colorectal cancer (CRC) screening improves CRC mortality. The uptake of CRC screening is influenced by patient motivation which in turn is influenced by online health information. The Internet is a widely-used resource by patients to support healthcare decisions.

However, online content is not subjected to peer review and may be of variable quality.

**Aims & Methods:** The aim of the study is to determine whether the quality of online information on CRC screening varies according to the source of information. As many patients will not search beyond the first page of 10 hits[1], we also assessed whether higher quality hits are found in the first page of searches.

Google search was performed to identify English websites providing online information on CRC screening. The following keywords were searched: "colorectal cancer screening", "colon cancer screening", "rectal cancer screening", "colonoscopy", "FIT/FOBT", "CT colonography", "stool DNA", "colon polyp screening", "flat polyp screening", "nonpolypoid colorectal neoplasm screening". The first 2 pages for each keyword search were compiled. Scientific papers, advertisements, newspaper articles, publicly modifiable pages, videos, sites requiring subscription and duplicate websites were excluded. Websites were classified as professional society, hospital, government agency or patient advocate group. The quality of online information was assessed by the primary author using the DISCERN instrument, a validated 16-point questionnaire (total score 16-80) that evaluates the quality of written information[2]. DISCERN scores were graded as excellent (68-80), good (55-67), fair (42-54), poor (29-41) or very poor (16-28). The proportion of websites with excellent or good grading in each category was compared. Standard tests of statistical significance were used.

**Results:** The search identified 191 websites of which 40 were eligible for inclusion. Sixteen (40.0%) were written by professional societies, 15 (37.5%) by hospitals, 4 (10.0%) by government agencies and 5 (12.5%) by patient advocate groups. The overall median DISCERN score was 44.5 [23.0-67.0]. The median DISCERN scores were 51.5 [30.0-67.0] vs 36.0 [23.0-67.0] vs 44.5 [41.0-52.0] vs 42.0 [40.0-45.0] respectively. None of the websites had an excellent DISCERN score. The proportion of websites with at least excellent or good grading was significantly higher in websites from professional societies compared to hospitals, government agencies and patient advocate groups (25.0% vs 13.3% vs 0.0% vs 0.0%, *p*=0.005) (Table 1). Twenty five websites appeared on the first page of search results and 15 appeared on the second page. The median DISCERN scores were 46.0 [28.0-67.0] vs 43.0 [23.0-55.0] respectively. There was no significant difference in the quality of online information between websites appearing on the first and second page of search (20.0% vs 6.7%, *p*=0.515).

**Conclusion:** The quality of online information on CRC screening is highly variable. Professional societies provide higher quality of information than other sources but their websites might not be found in the first page of searches. While patients should be directed to online sources that provide high quality information, there remains an unmet need to improve the quality of online information on CRC screening.

Grading based on DISCERN score	Professional societies (n=16)	Hospitals (n=15)	Government agencies (n=4)	Patient advocate groups (n=5)
Excellent or good	4 (25.0%)	2 (13.3%)	0 (0.0%)	0 (0.0%)
Fair, poor or very poor	12 (75.0%)	13 (86.7%)	100 (100.0%)	100 (100.0%)

## P1164 CLINICOPATHOLOGICAL FEATURES AND THERAPEUTIC STRATEGY FOR LEFT-SIDED SESSILE SERRATED ADENOMA/POLYPS

Takeuchi Y.<sup>1</sup>, Shigita K.<sup>2</sup>, Nagata S.<sup>1</sup>, Asayama N.<sup>1</sup>, Aoyama T.<sup>1</sup>, Fukumoto A.<sup>2</sup>, Mukai S.<sup>1</sup>

<sup>1</sup>Hiroshima City Asa Citizens Hospital, Department of Gastroenterology, Hiroshima, Japan, <sup>2</sup>Hiroshima City Asa Citizens Hospital, Department of Endoscopy, Hiroshima, Japan

**Contact E-Mail Address:** yukari-ogawa@nms.ac.jp

**Introduction:** Although sessile serrated adenoma/polyps (SSA/Ps) are considered premalignant lesions and their clinicopathological features have been previously reported, the differences based on lesion location (left- and right-sided) have not been clarified.

**Aims & Methods:** This study aimed to investigate the clinicopathological features and therapeutic strategy for left-sided SSA/P. In this study, 666 consecutive patients with lesions diagnosed as SSA/P by experienced endoscopists after endoscopic examinations (white light, narrow-band imaging, and pit pattern) and resected endoscopically in Hiroshima Asa Citizens Hospital between August 2010 and March 2017 were enrolled. The pathological diagnosis of each SSA/P was evaluated by two pathologists on the basis of the following Japanese Society for Cancer of the Colon and Rectum criteria: (1) crypt dilation, (2) irregularly branching crypts, and (3) horizontally arranged basal crypts (inverted T- and/or L-shaped crypts). When at least two of the three criteria were met in  $\geq 10\%$  of the lesion area, the serrated lesion was diagnosed as SSA/P. Resected lesions were classified into four groups (left-sided SSA/P: 173, left-sided HP: 94, right-sided SSA/P: 340, and right-sided HP: 59). Evaluated endoscopic and pathological findings of left-sided SSA/P were compared with those of left-sided HP and right-sided SSA/P. SSA/P with cytological dysplasia (SSA/P-CD) was defined as a SSA/P with conventional adenoma-like dysplasia, and serrated dysplasia (SSA/P-SD) was defined as a SSA/P showing proliferation of atypical cells that are more cuboidal in shape and have eosinophilic cytoplasm, enlarged round nuclei with open vesicular prominent chromatin, and prominent nucleoli in addition to increased mitoses.

**Results:** The proportion of lesions with size  $\geq 10$  mm, mucus cap, varicose microvascular vessel, and type II open pit was significantly higher in the left-sided SSA/P group than in the left-sided HP group (35% vs 6%, 35% vs 10%, 48% vs 22%, and 53% vs 18%, respectively;  $p < 0.01$ ). The proportion of females and lesions with size  $\geq 10$  mm, flat morphology (0-IIa), mucus cap, and type II open pit was significantly lower in the left-sided SSA/P group than in the right-sided SSA/P group (23% vs 39%, 35% vs 53%, 25% vs 50%, 35% vs 70%, and 53% vs 77%, respectively;  $p < 0.01$ ). Although there was no significant difference in crypt dilation and irregularly branching crypts in the left- and right-sided SSA/Ps, the proportion of horizontally arranged basal crypts was significantly lower in the left-sided SSA/P group than in the right-sided SSA/P group (62% vs 84%;  $p < 0.01$ ). Twenty-seven cases (5%) of SSA/P-CD and 43 cases (8%) of SSA/P-SD were included in this study. The independent endoscopic finding of SSA/P-CD was an adenomatous pit pattern accompanied by type II/open II pit pattern in the multivariate analysis. No significant endoscopic findings of SSA/P-SD, except for lesion size, were found in either the left- or right-sided SSA/Ps. The proportion of right-sided SSA/P-SD increased with larger lesion size ( $< 5$  mm: 0%, 5–9 mm: 8%,  $\geq 10$  mm: 15%), while that of left-sided SSA/P-SD was low, regardless of lesion size ( $< 5$  mm: 6%, 5–9 mm: 4%, and  $\geq 10$  mm: 3%).

**Conclusion:** The endoscopic and pathological features of left-sided SSA/P are different from those of right-sided SSA/P. Lesions with an adenomatous pit pattern accompanied by type II/open II pit pattern should be treated, but the lesion size of left-sided SSA/P is not an important indication of resection unlike that of right-sided SSA/P.

**Disclosure:** Nothing to disclose

## P1165 THE CLINICAL IMPACT OF MRI FOR DETECTING EXTRA-PERITONEAL FINDINGS IN COLORECTAL CANCER PATIENTS CONSIDERED FOR CRS/HIPEC

Engbersen M.<sup>1</sup>, van 't Sant-jansen I.<sup>1</sup>, Aalbers A.<sup>2</sup>, Lambregts D.M.J.<sup>1</sup>, Kok N.<sup>2</sup>, Lahaye M.J.<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Radiology, Amsterdam, Netherlands, <sup>2</sup>The Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands

**Contact E-Mail Address:** mj.lahaye@gmail.com

**Introduction:** Part of the clinical value of MRI is not only to describe the peritoneal disease load but could also be to detect extra-peritoneal metastases that contraindicate cytoreductive surgery and hyperthermic chemotherapy. The purpose of this study is to evaluate whether a preoperative wholebody MRI for assessing peritoneal disease also has led to additional extra-peritoneal findings not described with earlier imaging.

**Aims & Methods:** Between February 2016 and October 2017, patients with colorectal peritoneal metastases considered for CRS/HIPEC who underwent a dedicated peritoneal MRI for preoperative staging were included. The MRI was performed additionally to standard diagnostic work-up of a preoperative CT chest/abdomen. The MRI protocol consisted of diffusion weighted, T2 weighted and contrast enhanced imaging of the chest, abdomen, and pelvis. The peritoneal MRI images were evaluated by one of two radiologists with experience with diffusion-weighted imaging and whole-

body MRI and all extra-peritoneal findings were scored. The reference standard was histology. The results of the MRI were compared with all other, already available, clinical and imaging data to determine whether findings of the MRI were new.

**Results:** Of the 86 candidates with a peritoneal MRI, CRS/HIPEC was attempted for 55 patients and was successfully in 52. All patients had undergone CT chest/abdomen imaging prior to the MRI scan and 9 patients a PET/CT was performed. The mean days between CT and MRI imaging was 28.5 (standard deviation:  $\pm 30.9$ ). Five patients had liver metastases and four patients had lung metastases detected with regular diagnostic work up (CT/CTPET). MRI detected in 3/86 patients new liver metastases and in 2/86 patients new lung metastases. Of the 5 (5.8%) patients with one or more additional extra-peritoneal findings, 4 were deemed ineligible for CRS/HIPEC at an MDT meeting and 1 at surgical exploration (laparotomy) for histology.

**Conclusion:** For patients considered for CRS/HIPEC, additional peritoneal MRI including diffusion-weighted body imaging can detect additional malignant extra-peritoneal lesions such as liver and lung metastases. Per-operative imaging with peritoneal MRI can not only contribute to staging of the peritoneal disease load but can also detect contra-indications that were not seen on prior imaging and thereby prevent a potentially futile CRS/HIPEC effort.

**Disclosure:** Nothing to disclose

## P1166 MR IMAGING TO PREDICT COMPLETE CYTOREDUCTION AND SURVIVAL IN COLORECTAL PERITONEAL METASTASES IN PATIENTS CONSIDERED FOR CRS/HIPEC

Engbersen M.<sup>1</sup>, van 't Sant-jansen I.<sup>1</sup>, van Eden H.<sup>2</sup>, Lambregts D.M.J.<sup>1</sup>, Aalbers A.<sup>3</sup>, Velzing J.<sup>1</sup>, Kok N.<sup>2</sup>, Lahaye M.J.<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Radiology, Amsterdam, Netherlands,

<sup>2</sup>The Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands, <sup>3</sup>The Netherlands Cancer Institute, Amsterdam, Netherlands

**Contact E-Mail Address:** mj.lahaye@gmail.com

**Introduction:** Selecting colorectal cancer patients with peritoneal metastases for CRS/HIPEC remains a big diagnostic problem. In order to prevent under or overtreatment an invasive surgical staging system, the Peritoneal Cancer Index (PCI), was introduced. In order to avoid these invasive staging surgeries this study assesses the performance of the PCI determined with preoperative peritoneal MRI (MRI PCI) to predict successful cytoreductive surgery (CRS), disease free survival and overall survival in HIPEC candidates. Can MRI replace surgical staging?

**Aims & Methods:** Between February 2016 and October 2017, 86 patients with colorectal peritoneal metastases considered for CRS/HIPEC who underwent a dedicated peritoneal MRI for preoperative staging were included. The MRI protocol consisted of diffusion weighted, T2 weighted and contrast enhanced imaging of the thorax, abdomen, and pelvis. Peritoneal MR images were evaluated by two readers, independently and retrospectively, to determine the Peritoneal Cancer Index (MRI-PCI). Relevant patient characteristics were obtained from patient files. Receiver characteristic operator (ROC) analysis was used to determine the performance of the MRI-PCI to predict successful CRS/HIPEC and Cox regression analysis to determine to prognostic value of MRI for disease free survival and overall survival.

**Results:** CRS/HIPEC was attempted for 55 patients and was successfully in 52. The median follow-up from MRI was 18.30 months (1<sup>st</sup>-3<sup>rd</sup> Quartile: 12.73-24.33). The mean (standard deviation) MRI-PCI of reader 1 and 2 was 11.8 (8.46) and 10.5 (8.59), respectively. An area under the curve was found of 0.83 (95% confidence interval: 0.74-0.93) for reader 1 and 0.86 (95% confidence interval: 0.77-0.94) for reader 2 to predict a complete resection. For the patients who received successful CRS/HIPEC and complete resection, the MRI-PCI showed prognostic value for disease free survival for both readers ( $p < 0.05$ ). The MRI-PCI of reader 1 showed a prognostic value for overall survival ( $p = 0.01$ ), independently of whether complete resection was achieved, while reader 2 was borderline significant ( $p = 0.05$ ) in this patient cohort.

**Conclusion:** MRI can predict whether successful CRS/HIPEC can be achieved and shows prognostic value for disease free and overall survival. This means that MRI is an accurate tool for selecting CRC patients which may benefit from CRS/HIPEC. Surgical staging should be reserved for borderline cases after MR imaging.

## P1167 RISK OF METACHRONOUS NEOPLASIA ON SURVEILLANCE COLONOSCOPY IN YOUNG AND OLD AGE GROUPS AFTER POLYPECTOMY

Laish I.

Sheba Medical Center, Ramat Gan, Israel

**Contact E-Mail Address:** ido.laish@gmail.com

**Introduction:** Few reports exist that address the appropriate colonoscopy surveillance interval for individuals < 50 years old. We compared the risk of metachronous neoplasia among young (< 50 years), adult (50-74 years) and old ( $\geq$  75y) age groups.

**Aims & Methods:** This is a single center retrospective cohort study. Subjects were eligible if they underwent their first colonoscopy with polypectomy between 2005 and 2014 and had at least one surveillance colonoscopy after 3-5 years. Exclusion criteria included known genetic syndromes, inflammatory bowel disease, previous colectomy, incomplete procedures and the occurrence of cancer or multiple polyps at baseline. Patients were stratified at baseline according to adenoma characteristics into low-risk adenoma (LRA) and advanced adenoma groups. The primary outcomes were the occurrence of overall and high-risk neoplasia at surveillance colonoscopy in each age-group.

**Results:** At baseline (N=495), young patients were more likely to have smoking exposure and to report a family history of CRC whereas aspirin use and diabetes were more frequent in the adult and old age-groups. In the baseline LRA- group (N= 201), the 5-year risk of metachronous high-risk neoplasia was 12.5%, 15.2% and 22.5% (P= 0.426) in the young, adult and old age-groups, respectively. In the baseline advanced adenoma group (N= 294), the 3-year risk of metachronous high-risk neoplasia was 13.3%, 14.8% and 25.3% (P = 0.041), respectively. All interval cancer in this group - 3 cases, developed in the old age-group (3.8%, P = 0.027). In multivariate analysis, after adjusting for baseline risk factors, the only risk factor for metachronous high-risk neoplasia was old age-group (old vs. young age groups: OR 2.191, CI 1.099-4.373; P= 0.026; old vs. adult age groups: OR 1.876, CI 1.087-3.238; P= 0.024).

**Conclusion:** Considering the comparable risk of metachronous high-risk neoplasia in young and adult patients, surveillance recommendations after polypectomy should not differ. Since this risk is higher in the old age-group, a more frequent surveillance is warranted and should be counter-balanced with the higher complication risk and comorbidities.

**Introduction:** Colonoscopy enables screening and prevention of colorectal cancer (CRC) by removing adenomatous polyps. Adenoma detection rate (ADR) is the proportion of screening colonoscopy patients who are found to have at least one adenoma. ADR should be used as a measure of adequate inspection at screening or diagnostic colonoscopy in patients aged 50 years or more. ADR has been inversely associated with the risk of CRC and death. However little is known about the correlation of the adenoma detection rate and the detection of other non-neoplastic findings.

**Aims & Methods:** The aim of this study was to evaluate if ADR is associated with a higher detection of non-neoplastic findings. We retrospectively analyzed patients undergoing colonoscopy by three endoscopists at our center (A, B, C). Patients with an incomplete colonoscopy were excluded as well as colonoscopies performed in the setting of overt gastrointestinal bleeding, inflammatory bowel disease or polypectomy/mucosectomy. Angiodysplasia, diverticula, nonspecific inflammation, erosions or ulcers or subepithelial lesions were considered non-neoplastic findings.

**Results:** A total of 229 colonoscopies were analyzed. The mean age was 64  $\pm$  13.1 years-old. 54.6% were male (n=125). The median ASA score was 2 (IQR: 1 - 3). The mean indication was post-polypectomy surveillance 25.8% (n=59), followed by CRC surveillance 27.1% (n=62) and screening for CRC 20.5% (n=47). The indication for colonoscopy was significantly different between groups (p=0.04): CRC surveillance was higher in endoscopist B (31.9%, n=23) and C (36.5%, n=23), and post-polypectomy surveillance was higher in colonoscopies performed by endoscopist A (A: 59.6% vs. B: 48.6% vs. C: 19%, p< 0.01). The global ADR was 36.2% (n=83) and was not significantly different between endoscopists (A: 42.6% vs. B: 36.1% vs. C: 27%, p=0.14). The ADR was not associated with higher detection rate of non-neoplastic findings (31.3% vs 30.1%, p=0.88), even when concerning each endoscopist (A: 27.5% vs 33.3%, p=0.65; B: 38.5% vs 23.9%, p=0.28 e C: 29.4% vs 32.6%, p=0.81).

**Conclusion:** In our study, ADR was not associated with a better detection of other non-neoplastic findings in the total sample and by endoscopist.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** mmalagon@idibgi.org

**Introduction:** Colorectal cancer (CRC) is the third most common cancer in men and the second in women worldwide, and a leading cause of mortality. Guidelines recommend routine screening for CRC in asymptomatic adults starting at age 50. The most extensively used non-invasive test for CRC screening is the faecal immunochemical test (FIT). Although its overall sensitivity for CRC is around 61-91% and for advanced adenomas (AA) between 27-67%, these figures still imply a high false-positive rate and a low positive predictive value (PPV).

**Aims & Methods:** The aim of this work was to develop a new non-invasive CRC screening tool based on faecal bacterial markers capable of decreasing FIT false-positive rate in FIT-positive population. Analysis of the relative abundance of eight CRC-associated bacterial markers (B10, B46, B48, *G. morbillorum*, *P. stomatis*, *B. fragilis*, *B. thetaiotaomicron*, *R. intestinalis*) and four associated to IBD (*F. prausnitzii*, *F. prausnitzii* phylogroups I and II, *E. coli*) was performed.

The bacterial signature (RAID-CRC Screen) was defined in a proof-of-concept with 172 individuals and the obtained results were validated in an external cohort of 327 subjects. All study participants had joined the national CRC-screening program.

**Results:** In the proof-of-concept study, regardless of the colonoscopy result, the most prevalent bacteria were butyrate producers (B10, B46, B48, *F. prausnitzii*, and *R. intestinalis*), with abundance values of 19%, 16%, 18%, 16%, and 12%, respectively. *P. stomatis* and *B. fragilis* were significantly more abundant in CRC than in individuals with normal colonoscopy (p=0.002 and p=0.017, respectively).

The development of RAID-CRC Screen algorithm was focused on the reduction of false positive results for Advanced Neoplasia (AN; CRC+AA) among the FIT-positive subjects, while maintaining 100% sensitivity for CRC. The combination of *F. prausnitzii*, B46, B48, *G. morbillorum*, *B. fragilis*, and the total bacterial load led to the achievement of an algorithm with sensitivity of 95%, specificity of 26%, PPV of 50%, and a negative predictive value of 86%, for AN. These results lead to a decrease in the false positive rate up to 30%.

In the clinical validation of RAID-CRC Screen a sensitivity of 84% and specificity of 16% were obtained for the detection of AN. While with FIT 20  $\mu$ g/g there were 184 false-positive results, RAID-CRC Screen reduced this value to 154, implying a reduction of the false-positive rate of 16%, which confirms the robustness of the defined bacterial signature.

**Conclusion:** RAID-CRC Screen test would allow reducing up to 20% of the colonoscopies that are performed unnecessarily in FIT-positive participants of CRC-screening programs. Thus, it becomes a good complement to be implemented in a CRC screening scenario.

	Characteristics	CRC	Advanced adenoma	Non-advanced adenoma	Normal colonoscopy
Proof-of-concept	n (%)	11 (6.3)	67 (39.0)	38 (22.1)	56 (32.6)
	Age (mean, range)	61 (50-69)	61 (50-69)	60 (50-69)	59 (49-69)

### P1170 FABP4 PROMOTES INVASION AND METASTASIS OF COLON CANCER BY REGULATING FATTY ACID TRANSPORT

Xia M., Tian W., Zhang W., Zhan Q., An F.  
Wuxi People's Hospital Affiliated to Nanjing Medical University, Gastroenterology, Wuxi, China

**Contact E-Mail Address:** xmzb1013@163.com

**Introduction:** Colon cancer is a common malignant tumor and it is estimated that about 1,200,000 new cases are reported every year. Recent studies have shown that FABP4 can participate in tumor invasion and metastasis.

**Aims & Methods:** In order to explore the effects and mechanism of Fatty acid-binding protein 4 (FABP4) on proliferation, migration, invasion and energy metabolism of colon cancer cells. We measured the distribution of fat, the content of triglyceride and the level of FABP4 mRNA in colon cancer and adjacent normal tissues. At the meantime, the adipose tissue extract was co-cultured with human colon cancer cell line HCT-8 and the cells were divided into three groups: Control, Co-culture, Co-culture + inhibitor group. And we detected the proliferation, migration and invasion of HCT-8 cells. Then we analyzed the content of ATP, LDH, glycerol and fatty acid by specific kits. In addition, we used FABP4 overexpressed adenovirus to infect HCT-8 cells, and then detect cell proliferation, migration and invasion. Meanwhile, we measured the levels of intracellular metastasis related protein MMP-2, MMP-9 and energy-related protein p-Akt.

**Results:** The content of fat in colon cancer tissues was significantly higher than that in adjacent normal tissues and the level of FABP4 mRNA in colon cancer tissues was significantly higher than that in adjacent normal tissues. Besides, the adipose tissue could promote the migration and invasion of human colon cancer cells in vitro. Moreover, the content of intracellular ATP and LDH, glycerol and fatty acid in culture supernate were decreased significantly after co-culture and FABP4 overexpression could promote migration and invasion of cancer cells and the levels of intracellular MMP-2, MMP-9, p-Akt were increased.

**Conclusion:** FABP4 may promote the transfer of fat from adjacent normal tissues to cancer tissue and co-culture with adipose tissue promoted the migration and invasion of colon cancer cells and cellular energy metabolism. Overexpression of FABP4 could promote migration and invasion and increased the levels of MMP-2, MMP-9 and p-Akt protein. This may provide a new idea for the diagnosis and treatment of colon cancer.

**Introduction:** Gastrointestinal symptoms are a common reason for patients to consult primary care physicians. Most of these patients have no relevant pathology, but in an effort not to miss colorectal cancer (CRC), precancerous lesions or inflammatory bowel disease (IBD) many of them undergo colonoscopy. Faecal biomarkers have been proposed as useful diagnostic tools in this setting. Quick faecal tests, which can be performed by patients and give immediate results, may be a useful strategy to determine which patients need rapid investigation and also the ones who have low risk of significant pathology.

**Aims & Methods:** To evaluate the diagnostic accuracy of a one-step combo card test for the simultaneous semi-qualitative detection of human haemoglobin (hHb), human transferrin (hTf), human calprotectin (hCp) and human lactoferrin (hLf) in stool samples of symptomatic patients.

**Methods:** Symptomatic patients referred for colonoscopy, who returned stool samples and completed colonic examinations, were prospectively recruited. Certest FOB+Transferrin+Calprotectin+Lactoferrin® (Certest Biotec S.L, Zaragoza, Spain), a coloured chromatographic immunoassay for the simultaneous semi-qualitative detection of hHb, hTf, hCp and hLf, was performed. Cut-off values of the test are 5.1 µg/gr for hHb, 0.4 µg/gr for hTf, 50 µg/gr for hCp and 10 µg/gr for hLf.

CRC, advanced adenoma (>10mm, >3 adenomas, villous component, high grade dysplasia), IBD, angiodysplasia and microscopic colitis were considered as relevant pathology.

Positive and negative predictive values (PPV, NPV), sensitivity and specificity for each marker and for the different combinations were calculated.

**Results:** 482 patients (251 - 52.1% female, median age 63 years, IQR: 51.5-74.5) were included. The most frequent indications for colonoscopy were recent history of rectal bleeding (128/482, 26.6%), chronic diarrhea (99/482 -20.5%), abdominal pain (85/482 - 17.6%), and anemia/iron deficiency (79/482 - 16.4%). Colonoscopies were mainly requested by primary care level (315/482 - 65.4%), and by Gastroenterology outpatient's clinics (117/482 - 24.3%).

Relevant pathology was found in 115/482 (23.9%) patients. CRC was diagnosed in 24/482 (5%) patients. IBD was detected in 14/482 (2.9%) patients. Diagnostic accuracy of hHb, hTf, hCp and hLf for relevant colonic pathology are summarized in Table 1.

162/482 (33.6%) patients had negative results of all 4 biomarkers. 151/162 colonoscopies of this group have no relevant pathology (NPV 93.2%). This 11 patients with pathology were 9 advanced adenomas and two microscopic colitis, so no case of CRC or IBD would have been potentially missed (NPV 100%). 29/482 (6%) patients had all 4 biomarkers positive, 13/29 (44.8%) were diagnosed with CRC and 7/29 (24.1%) with IBD (PPV 68.9% for CRC + IBD).

Test	Negative test	Positive test	PPV	NPV	Sensitivity	Specificity
hHb	362	120	57.5%	87.3%	60%	86.1%
hCp	183	299	33.1%	91.2%	86.1%	45.5%
hTf	380	102	47%	82.4%	41.7%	85.3%
hLf	417	65	53.8%	80.8%	30%	91.8%

[Table 1.]

**Conclusion:** This semi-quantitative rapid self-made faecal combo test may be a useful and quick diagnostic tool to avoid unnecessary colonoscopies and to prioritize high risk symptomatic patients.

**Contact E-Mail Address:** borispekarek@yahoo.com

**Introduction:** Colorectal carcinoma is the most common type of cancer in Slovakia. Recognition and successful removal of the early forms of colorectal carcinoma reduces morbidity and mortality caused by this disease. When removing early neoplastic lesions in the rectum "en bloc", we have a choice between endoscopic submucosal dissection (ESD) and transanal endoscopic microsurgery (TEM).

**Aims & Methods:** The aim of this study was to compare the outcomes of endoscopic submucosal dissection (ESD) and transanal endoscopic microsurgery (TEM) in a cohort of patients with neoplastic rectal lesions in our hospital (National Cancer Institute in Slovakia). We retrospectively analyzed the cohort of 100 patients consecutively treated for neoplastic colorectal lesion by ESD (60 patients) or TEM (40 patients) in the National Oncology Institute in Slovakia.

We collected clinical, endoscopic and histological data including the diameter of removed lesions, duration of the procedures, histopathological types of lesions, the rates of "en bloc" and R0 resections, the rates of acute and late complications, the length of hospital stay and the rate of recurrence.

**Results:** The average diameter of lesions removed by ESD were significantly greater when compared to TEM (45,6 mm vs. 34,9 mm;  $p < 0,01$ ). We observed higher rates of "en bloc" resections (95 % vs. 75%;  $p < 0,01$ ) and R0 resections 93,3 % vs. 67,5%;  $p < 0,001$ ) in the ESD group. The average length of hospital stay was significantly shorter in ESD group. (5,6 vs. 8,8 days;  $p < 0,0001$ ). The average duration of procedure was significantly shorter in the TEM group (151,1 vs. 77,7 min;  $p < 0,001$ ).

**Conclusion:** ESD and TEM have both proven to be effective and safe for treating neoplastic lesions of rectum. In our hospital, ESD was more effective in achieving "en bloc" resection, R0 resection and was also associated with shorter hospital stay. However, in our conditions, the average duration of ESD was longer than TEM.

**Introduction:** Endoscopic mucosal resection (EMR) is established as a safe, effective, efficient and definitive first line therapy for the management of large (>20mm) laterally spreading colonic lesions (LSL). 4 % of referred LSL contain covert submucosal invasive carcinoma (SMIC), which is only detected after EMR. Although en bloc resection is ideal, when this has not occurred, at present, there are no established guidelines on the optimal management for these patients. Surgery is usually advised but such patients are often elderly with multiple co-morbidities and surgery is more expensive, resource intensive and morbid.

**Aims & Methods:** To determine outcomes in patients with covert SMIC within a large prospective multicentre cohort.

Patients within the Australian colonic endoscopic resection (ACE) cohort were prospectively followed, and cases with SMIC were identified. Overt SMIC cases, where EMR was not attempted due to clear malignancy, were excluded, and only those in whom EMR was completed and cancer was subsequently diagnosed (covert) were included. Surgical and histologic outcomes were recorded and presence of residual local malignancy (defined as either lymph node involvement or residual carcinoma in the resection specimen) was determined.

**Results:** From a prospective cohort of 3372 cases of LSL, 225 cases of SMIC were identified. 74 overt SMIC cases were excluded. Of 151 covert SMIC cases, complete outcomes were available in 124. 95 patients proceeded to surgical resection (77%), while 29 were managed conservatively (23%). Patients managed conservatively were older ( $p=0.001$ ) and had higher ASA scores ( $p=0.001$ ). Based on the EMR histology, 57 (46%) had Kikuchi SM1 disease and 67 (54%) had Kikuchi SM2 or 3 disease. Overall, residual local malignancy was detected in 32 of 95 cases (34%). Of 56 with SM1 disease, 37 (66%) proceeded to surgical resection. Within this group residual luminal cancer was detected in 6 cases (16%) and nodal disease in 2 (5%), in both cases the tumour was poorly differentiated. Of 19 SM1 cases managed conservatively (due to advanced age in 3, co-morbidities in 7 and patient preference in 9), follow up colonoscopy was performed in 14 (74%). Recurrence was detected in 1 case, who subsequently underwent successful surgical resection. Over a median follow-up of 36 months (range 5-95 months) 1 death occurred due to cardiac disease, and the other 18 remain alive and disease free. On multivariate analysis with stepwise backward regression, independent risk factors associated with subsequent residual surgical disease, were presence of SM2 or 3 invasion (odds ratio 3.4 (95% CI 1.3-9.3),  $p=0.015$ ), and presence of submucosal fibrosis (SMF) (odds ratio 2.5 (95% CI 1.1-6.1),  $p=0.041$ ).

**Conclusion:** The majority of patients with covert SMIC proceeding to surgical resection have no residual local disease. This risk is increased with deeper submucosal invasion at initial EMR histology (SM2 or SM3) and presence of submucosal fibrosis. In patients with disease confined to SM1 where no SMF is present, the need for surgery needs to be balanced against the patient's age and co-morbidities. Further data are needed to more precisely inform this decision process.

**Contact E-Mail Address:** tminamid@east.ncc.go.jp

**Introduction:** Surveillance colonoscopy is strongly recommended after surgical resection (SR) of colorectal cancer (CRC) or endoscopic resection (ER) of adenoma because of their risk of metachronous colorectal neoplasia. However, there is little evidence about metachronous lesions following resection of submucosal invasive CRC (SM-CRC), for which both surgical and endoscopic resection can be chosen.

**Aims & Methods:** The aim of the present study was to clarify the incidence of metachronous advanced neoplasia (AN) after SM-CRC resection. This retrospective observational study reviewed consecutive patients who underwent surgical or endoscopic resection of SM-CRC at the National Cancer Center Hospital East, Kashiwa, Japan, between January 2005 and December 2013. We included patients who underwent:

- (i) histopathologically-proven complete resection of SM-CRC by SR or ER as the first-line treatment;
- (ii) resection of all other colorectal neoplasia; and,
- (iii) one or more surveillance total colonoscopies after resection of SM-CRC.

The overall and cumulative incidence of metachronous AN detected at surveillance colonoscopies were calculated using the Kaplan-Meier method and compared by the log-rank test. The Cox proportional hazards model was used to analyze risk factors of incidence of metachronous AN.

**Results:** A total of 343 patients were eligible for inclusion. The median age was 65 years (range, 33-87), and 219 (63.9%) were male. The location of SM-CRC was right-sided colon in 100 (29.2%), left-sided colon in 131 (38.2%), and rectum in 112 (32.7%). 93 (27.1%) underwent only ER (ER group), and 250 (72.9%) underwent ER followed by SR or only SR for SM-CRC (SR group). The median follow-up period was 61.7 months (range, 12.6-151.6), and the median number of surveillance colonoscopies was 3 (range, 1-12). The median follow-up period of the SR group was 61.9 months, whereas that of the ER group was 60.5 months. The median number of surveillance colonoscopies of the SR group was 2, whereas that of the ER group was 4.

The overall incidence rate of metachronous AN was 8.5% (29/343 patients; 95% confidence interval [CI], 5.7-11.9). The overall cumulative incidence rates at 3 and 5 years were 4.8% and 6.0%, respectively. The cumulative incidence rate was significantly higher in the ER group than in the SR group ( $P < .001$ ); in the colon group than in the rectal group ( $P = .021$ ); and in the group with synchronous AN than in the group without synchronous AN ( $P < .001$ ). The multivariate analysis identified ER (hazard ratio [HR], 2.90; 95% CI, 1.26-6.68) and synchronous AN (HR, 4.37; 95% CI, 1.96-9.73) as significant risk factors for metachronous AN.

**Conclusion:** ER and Synchronous AN were significantly associated with incidence of metachronous AN after SM-CRC resection. Intensive surveillance colonoscopy should be considered after ER of SM-CRC and patients with synchronous AN.

**Disclosure:** Nothing to disclose

## P1177 A LONG WAY FROM HOME: LIGHTS AND SHADOWS OF THE COLON-RECTUM LEARNING CURVE IN ESD EN BLOC RESECTION

**Introduction:** In the last decade ESD has shown very promising results, but the technique is still burdened by complications, depending mostly on endoscopist experience. Organizational options such as preventive hospitalization seem to play a role too, but no clear guidelines are available on this issue. In Eastern Countries, an endoscopist is considered an expert with more than 80 ESD performed in the stomach (in general, gastric lesions are easier to remove with this technique). In Western Countries, a low incidence of gastric lesions makes ESD very difficult to be learned by professionals, and, actually, the learning curve of this procedure is longer and performed mostly in the colon-rectum tract.

**Aims & Methods:** Aims are: 1.to estimate the number of ESD procedures to be performed by a single operator to learn proficiently the technique in a Western country; 2.to establish if the patient has to be hospitalized when performing ESD compared to other resection techniques and which are main complications. From 2012 to 2019 in a urban hospital, all mucosectomies >2 cm of a single operator were collected to draw the ESD learning curve. The cumulative summation analysis (CUSOM) was calculated to establish ESD learning curve for *en bloc* resection parameter.

Information was collected on preventive hospitalization, complications (perforation; acute and delayed bleeding), hospital length of stay, neoplasm relapse at follow-up. The results were compared with EMR and EFTR (performed using the Full Thickness Resection Device (FTRD®)). Statistical analyses: chi squared and t Student tests were performed for comparison, setting statistical significance  $p < 0.05$ .

**Results:** 311 procedures were collected (128 ESD, 152 EMR and 31 EFTR). 81.6% were hospitalized with a mean length of stay of  $2.7 \pm 2.04$  days (range 1-13). 54.8% were females (M:F=171/311) with a mean age  $66.4 \pm 11$  yrs. 160 patients made a regular follow-up (mean follow-up  $18.6 \pm 15.6$  months). The CUSOM curve for *en bloc* parameter after 128 ESD showed a decrement of the curve without reaching the inferior limit (-1.23), we estimated that further 10 consecutive ESD procedures are needed to complete the curve (138 in all). ESD sites: rectum (59), colon sx (31), colon dx (22), stomach/esophagus/duodenum (16). EMR sites: rectum (17), colon sx (25), colon dx (90), stomach/esophagus/duodenum (20). EFTR sites: rectum (4), colon sx (7), colon dx (16), stomach/esophagus/duodenum (4). No significant differences were found in hospital length of stay (EMR  $2.74$ -ESD  $2.85$ -EFTR  $2.23$  p=ns). Perforation was significantly higher in ESD technique (ESD  $26/128$  20.3% vs EMR  $5/152$  3.2% vs EFTR  $0/31$  0%,  $p < 0.05$ ). The mean recovery stay was longer in patients with perforation  $3.5 \text{ days} \pm 2.9$  Vs no perforation  $2.5 \pm 1.8$  (p=ns), no perforation underwent surgery. No differences were observed for acute or delayed bleeding according to the endoscopic technique (acute: ESD  $3/128$  2.3%; EMR  $4/152$  2.6%; EFTR  $2/31$  6.4%, p=ns; delayed: ESD  $8/128$  7.8%; EMR  $7/152$  4.9%; EFTR  $1/31$  3.4%, p=ns). All the delayed bleedings happened after patients discharge. During the follow-up were observed 20 neoplasms relapse (20/160 pts in regular follow up -12.5%): 12 (15.6%) in EMR; 8 (10.4%) in ESD, 0(0%) in EFTR. Relapses were associated with margins R1+ in *en bloc* resections in 23.1% of cases ( $p < 0.05$ ). Margins R0 showed 2.8 % relapses.

**Conclusion:** In our experience, to become expert in ESD in the colon nearly 140 procedures need to be performed. Patients need to be hospitalized only if a perforation occurs during the procedure. Delayed bleeding is rare and in our casuistry it happened always after discharge.

**Disclosure:** Nothing to disclose

## P1178 IMPACT OF OBESITY IN COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

**Contact E-Mail Address:** tachijun1989@gmail.com

**Introduction:** The difficulty in insertion of colonoscope, the poor maneuverability, or the abundant fat tissue in submucosal layer sometimes occur during colorectal endoscopic submucosal dissection (ESD) in patients with obesity. However, association between obesity and colorectal endoscopic submucosal dissection (ESD) has not been investigated. In this study, we evaluated the clinical impact of obesity in patient who underwent colorectal ESD.

**Aims & Methods:** We retrospectively reviewed 543 patients who underwent colorectal ESD at Omori Red Cross Hospital from April 2012 to February 2019. Patients that we could not confirmed BMI records, we discontinued the ESD, or had recurrent lesions were excluded. The remaining 536 patients (599 lesions) were divided two groups based upon body mass index (BMI, kg/m<sup>2</sup>): obesity group (BMI $\geq$ 25) and non-obesity group (BMI<25).

**Results:** 120 patients (132 lesions) were in obesity group and 416 patients (467 lesions) were in non-obesity group. There is no significant difference between both groups in mean age (67.8 $\pm$ 9.9 vs. 68.5 $\pm$ 12.4), lesion diameter (27.1 $\pm$ 14.5mm vs. 26.4 $\pm$ 13.1mm), location (C/A/T/D/S/R= 18/34/31/12/18/19 vs. 66/108/101/36/68/88) and macroscopic type (I/IIa/IIc/combined/SMT=.21/107/0/3/1 vs. 78/371/5/7/6). In short term clinical outcomes, there is no significant difference in procedure time (47.2 $\pm$ 43.7min vs. 42.0 $\pm$ 34.7min), en bloc resection rate, curable resection rate, and pathological diagnosis. While the amount of sedative (flunitrazepam) per body weight was significantly lower in obesity group (1.62 $\times$ 10<sup>-2</sup> $\pm$ 0.85 $\times$ 10<sup>-2</sup>mg/kg vs. 1.92 $\times$ 10<sup>-2</sup> $\pm$ 0.95 $\times$ 10<sup>-2</sup>mg/kg), cases in which reduction of percutaneous arterial oxygen saturation occurred were significantly more in obesity group (46.7% vs. 29.8%). The procedure time by trainee (less than 100 cases of colorectal ESD experience) was significantly longer in obesity group (58.8 $\pm$ 48.1min vs. 48.1 $\pm$ 31.3min).

**Conclusion:** This study showed colorectal ESD could be performed safely and effectively in obese patients. However, ESD in patients with obesity requires attention to changes especially in respiratory condition.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** jerome.winkler@hotmail.fr

**Introduction:** Lymph node risk assessment has become a major issue to recommended additional surgery with lymph node dissection after endoscopic resection (ER) of a superficial colorectal cancer. This risk is based on histological criteria (depth invasion, differentiation, lymphovascular invasion, budding, positive margins) and their presence is an indication for additional surgery at this time. The challenge is to determine if there are any subgroups for which surgery could be avoided.

**Aims & Methods:**

**Aims:** Evaluate the relapse-free survival rate in all patients and in specific subgroups, measure the lymph node and/or metastatic risk of colorectal adenocarcinoma pT1sm2 and evaluate the morbidity rate of endoscopic resections for tumor pT1sm2.

**Methods:** Patients with endoscopic or surgical resection of colorectal adenocarcinoma pT1sm2 between 2012 and 2018 at Institut Paoli Calmettes (Marseille, France) and Edouard Herriot hospital (Lyon, France) were retrospectively included. We evaluated two predefined groups of patients. First group was "supposedly good prognosis" patients (SGP) including ER alone with no pejorative histological criteria, patients with ER and additional surgery with favorable histology (pT0No) or primary surgery with adenocarcinoma pT1sm2 and no pejorative criteria. The second group was "supposedly effective endoscopic resection" (SEER) including ER alone with no pejorative criteria, ER with additional surgery, histologically pT0No and negative deep margins. At last we studied patients treated by ER alone. For each group, free-recurrence survival rate (FRS) at 12 and 24 month and complete remission (CR) rate (defined as absence of local or metastatic recurrence in the first 12 months, excluded local recurrence treated by endoscopy) were assessed. The rate of histological lymph node invasion, adverse events of endoscopic and surgical treatment were recorded.

**Results:** 74 patients were included (38 women and 36 men) with a median age of 68 years (51-88). The mean hospitalization length was 2 days (1-7) and the median follow-up was 16 months (0-81). 33 tumors were located in the descending colon, 18 in the ascending colon, 4 in the transverse colon and 18 in the rectum. All tumors were well differentiated, 49 % had budding, 2.7% vascular invasion, 5.6% lymphatic invasion and 40% had positive deep margins. 68 patients had ER: 22 patients alone and 46 had additional surgical treatment with lymph node staging. 6 patients were operated without previous endoscopic resection. During the follow-up, 4 patients died. No deaths were related to cancer. There were 4 local recurrences and 3 were treated by a new ER and 1 by endocavitary radiation therapy. In the general population, the FRS rate was 98% at 12 months and 97% at 24 months. CR rate at 12 months was 98%. In the "SGP" group, the FRS rate was 100% and 97% at 12 and 24 months respectively. The CR rate at 12 months was 100%. In the SEER group, the FRS rate at 12 months was 100% and 94% at 2 years and the CR rate 100%. In the "endoscopic resection alone" group alone: 8 patients had no pejorative criteria, 14 had at least 1 and the FRS rate was 100% and 90% respectively. The lymph node invasion rate was 6.4% with a mean number of lymph nodes examined of 15 (7-30). The complication rate for endoscopic resections was 11% (all treated by endoscopy) and 9.5% for surgical complications.

**Conclusion:** Endoscopic resection of pT1sm2 adenocarcinoma without histological pejorative criteria might be a good candidate to avoid additional surgery. However longer follow-up and more patients are needed to confirm this approach.

**Disclosure:** Nothing to disclose

## P1180 RISK OF CANCER BETWEEN FAMILY MEMBERS OF PATIENTS WITH PROBABLE LYNCH SYNDROME

**Introduction:** Lynch syndrome (LS) is one of the most frequent causes of hereditary colorectal cancer (CRC). However, there is a group of patients who develop CRC or tumors of the LS domain in which microsatellite instability and / or loss of expression of DNA repair genes are observed in the tumor, but without evidence of pathogenic mutation. This group of patients is known as Lynch-like syndrome (LLS) and they represent approximately 30% of all patients with unstable tumors. There is no consensus about follow-up and management of relatives of LLS patients.

**Aims & Methods:** Our aim is to compare risk of cancer in first-degree relatives (FDR) in a large cohort of LLS and LS patients. Patients who met criteria for LLS diagnosed with CRC were included, when their tumors showed immunochemical loss of MSH2, MSH6, PMS2, or loss of MLH1 with BRAF-wild type and/or no MLH1 methylation and absence of pathogenic mutation in these genes, and was compared with those with confirmed LS and CRC. Neoplasms were followed in patients diagnosed with LS and LLS and among their relatives. Based on this information, we calculated the standardized incidence ratios (SIRs) for CRC and other neoplasms associated with LS, among FDR of patients diagnosed with LLS and compared it with SIRs among FDR of patients with LS.

**Results:** A total of 205 families with LS and 126 families with LLS had complete pedigrees, including the ages of relatives without cancer. A total of 1896 FDRs were included: 1198 from families with LS and 698 from families with LLS. FDR of patients with LLS have a high incidence of CRC (SIR 2.11; 95% CI, 1.59-2.75), that was significantly lower than in FDR of confirmed cases of LS (SIR 4.28; 95% CI, 3.69-4.93;  $p < 0.001$ ). The risk of development neoplasms associated with LS (other than CRC) was also observed increased among relatives of patients with LLS (SIR 2.04; 95% CI, 1.44-2.80), but lower than the risk presented among family members of patients with LS (SIR 5.10, IC95%: 4.35-5.94;  $p < 0.001$ ).

**Conclusion:** Relatives of patients with LLS have a high risk of developing CRC, although this risk is lower than that of families with Lynch syndrome. FDR of patients with LLS should be managed taking into account this increased risk of CRC.

**Disclosure:** Nothing to disclose

## P1181 WAS "LEAVE-IN-SITU STRATEGY" FOR DIMINUTIVE ADENOMAS WELL TOLERATED?

**Introduction:** Colonoscopy with polypectomy of adenomas reduces the incidence and mortality of colorectal cancers (1). With recent increment of the number of screening colonoscopies, it is reported that eradication of adenomas during colonoscopy can be a big burden for endoscopists (2). On the other hand, some studies suggest the safety of following diminutive polyps up without removal might be sufficient (3,4). According to the Japanese Society of Gastroenterology guidelines (5), diminutive adenomas which has no evidence of carcinoma in their appearance are allowed to be left in situ, provided strict surveillance colonoscopies within 3 years ("leave-in-situ strategy") are conducted, which is different initiative from the European or American guidelines(6,7). However, the tolerability of the "leave-in-situ strategy" of diminutive adenomas are unknown.

**Aims & Methods:** The aim was to consider tolerability of the "leave-in-situ strategy" of diminutive adenomas by retrospectively assessing its safety and compliance. Patients whose diminutive adenomas were not resected at the initial colonoscopies between April 2001 and November 2015 at a referral center were chosen as the subjects. All the subjects were asked to receive surveillance colonoscopies within 3 years. The primary outcome measure is the incidence rate of index lesions (ILs) at the surveillance colonoscopy within 3 years. The ILs were defined as follows: adenomas  $\geq 10$  mm, high grade dysplasias, villous adenomas, and invasive cancers. The secondary outcome measures included the rate of patients who received the 3-year surveillance colonoscopies and the number of the diminutive polyps which were detected at both the initial and surveillance colonoscopies.

**Results:** A total of 4816 patients were left untreated of diminutive adenomas (n=2502) at the initial colonoscopies. The incidence rate of index lesions at the surveillance colonoscopies was 2.3%(36/1543; 12 adenomas  $\geq 10$  mm, 22 high grade dysplasias, and 2 invasive cancers). The rate of patients who underwent 3-year surveillance colonoscopies was 32.0% (1543/4816).

**Conclusion:** "Leave-in-situ strategy" of diminutive adenomas can be acceptable whose rate of ILs in the surveillance colonoscopies is limited to 2.3% which is similar to those in the National Polyp Study (8). However, strict instruction to the patients is indispensable considering the low receiving rate of surveillance colonoscopies.

**Contact E-Mail Address:** kimgijssbers1992@gmail.com

**Introduction:** The incidence of submucosal invasive (T1) colorectal cancers (CRCs) has increased with the implementation of the national screening program. In case of endoscopic resection of a T1 CRC with histological risk factors for an adverse outcome, the guidelines advise adjuvant surgical segmental resection. For various reasons (comorbidity, perceived low risk of residual cancer, risk of surgery), an additional resection may not be carried out and patients wish to have regular follow-up. A standard protocol for surveillance of these patients is unavailable.

**Aims & Methods:** In this national survey, an inventory has been made of the surveillance strategy for patients after endoscopic resection of a high-risk T1 CRC who refrain from additional surgery. Dutch gastroenterologists and surgeons participating in the Dutch T1 CRC Working group were asked to participate in an online survey. They were questioned on demographics, baseline staging after detection of a T1 CRC and surveillance protocols.

**Results:** In total, 69/130 (53%) physicians (87% gastroenterologist) participated in the survey. In case of an unexpected malignancy after polypectomy, 36/69 (52%) performed full oncological staging, the remainder only in case of high-risk features in the endoscopically removed specimen. Pathology criteria used to determine high risk status were; lymphovascular invasion (100%), resection margin not free/indeterminable (93%), poor differentiation (90%), malignancy  $\leq 1$  mm from resection margin (78%), tumor budding grade 2/3 (57%), and submucosal invasion depth  $>1000$   $\mu$ m (47%).

A local protocol was available in 30% of participating centers only. We recorded 61 different surveillance strategies in 63 participants, using 19 different combinations of diagnostic tests. Most common used combinations were endoscopy only (n=9); endoscopy and rectal MRI (n=8); endoscopy, rectal MRI, liver ultrasound, chest X-ray and CEA (n=7) and endoscopy, rectal MRI, abdominal CT and CEA (n=6). Endoscopy was used in all schedules, in 50 of 63 strategies (79%) at least twice in the first year. 48/63 (76%) used MRI in case of a rectal T1 CRC. 30/63 (48%) used abdominal CT and 22/63 (35%) abdominal ultrasound for surveillance, of which 6 physicians used a combination of both. 23 of 63 physicians performed chest imaging, 60% used serum CEA. Mean follow-up time was 36 months (95% CI 31.5-40.5) for endoscopy, 26 months (95% CI 20.0-31.6) for rectal MRI and 30 months (95% CI 21.7-37.7) for abdominal CT (all varying 3 - 60 months). The interval between surveillance investigations differed from 3-monthly in the first year to  $>1$  year. Peaks were seen at 3, 6, 12, 24, 36 and 48 months for each modality. Most physicians experienced none (27/69), or 1-3 (28/69) recurrences.

**Conclusion:** There is a high inter-practitioner variety in the follow-up of patients with an endoscopically resected high-risk T1 CRC who refrain from adjuvant surgery. A prospective study to evaluate the efficacy and safety of strict surveillance is needed.

## P1183 CLINICAL AND ONCOLOGICAL OUTCOMES OF LATERAL LYMPH NODE DISSECTION USING BOTH TRANSABDOMINAL AND EXTRAPERITONEAL APPROACH

**Introduction:** Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for lower rectal cancer in Japan. However, ME alone is the international standard surgical procedure for rectal cancer and complete LLND is difficult because of the narrow visual field in the pelvic cavity and the complicated anatomical structure.

**Aims & Methods:** Our LLND using a transabdominal and extraperitoneal approach provides a wider visual field through the paravesical space and enables us to perform complete lymph node dissection of these regions.

Herein we introduce our LLND procedure and report the clinical and oncological outcomes.

After ME, bilateral hypogastric nerves were separated to be preserved. Firstly, common iliac nodes were dissected; aortic bifurcation nodes and median sacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum through a transabdominal approach. Secondly, after external iliac nodes dissection was performed to the peripheral side by the abdominal approach as possible. Proximal internal iliac nodes were removed and superior vesical artery was separated.

Subsequently, the paravesical space was opened widely via an extraperitoneal approach, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall and sciatic nerve. Finally, distal internal iliac nodes from the coccygeal muscle (Alcock's canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries.

**Results:** Between 2008 and 2018, we performed ME with LLND for 239 patients with cStageI-III lower rectal cancer. The median operative time was 380 min, and the median blood loss was 620 ml. Postoperative complications developed in 124 (51.9%) patients, and the most frequent one was pelvic cavity infection (including lymphocele) in 51 (21.3%) patients. Temporary urination disorder developed in only 19 (7.9%) patients, and persistent urination disorder required intermittent urethral catheterization developed in only one woman. Lateral lymph node metastasis was pathologically found in 57 (23.8%) patients after LLND. The 5-year local-recurrence-free survival was 84.3% and the numbers of patients with local recurrence were 14 (5.9%), respectively. Overall 5-year survival rate excluding cStageIV patients was 89.1%.

**Conclusion:** Our LLND provides a wider visual field in the pelvic cavity by using both transabdominal and extraperitoneal approach, and results in favorable clinical and oncological outcomes.

We introduce our procedure of LLND. However LLND is invasive procedure which needs longer operative time and greater blood loss. So we show laparoscopic LLND as our new procedure securing equivalent range of lymph node dissection.

**Disclosure:** Nothing to disclose

## P1184 FACTORS INFLUENCING INTERRUPTION OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION FOR DETERMINING THERAPEUTIC STRATEGIES

**Introduction:** Although the colorectal endoscopic submucosal dissection (ESD) procedure is standardized worldwide, the difficulty of the procedure is well known. However, there have been no studies on the causes of treatment interruption.

**Aims & Methods:** The present study aimed to evaluate the factors involved in interruption of colorectal ESD. We retrospectively analyzed 1116 consecutive superficial colorectal neoplasms of 1012 patients who were treated with ESD between August 2008 and September 2018. The clinical and pathological characteristics and treatment outcomes were analyzed.

**Results:** Interrupted ESD was reported for 16 lesions (1.4%) of the total study population. Univariate analysis of clinical characteristics indicated that age, 0-I macroscopic-type tumor, and tumor location on the left side colon were risk factors for interruption. Multivariate analysis revealed that 0-I macroscopic-type tumor was the sole preoperative independent risk factor for interruption. Univariate analysis revealed that the presence of muscle-retracting sign (MRS), deep submucosal tumor invasion, and intermediate invasive growth pattern represented the etiology of interruption.

Multivariate analysis indicated MRS to be the sole independent cause of interruption. Additionally, the resectability and curability of 0-I type tumors were significantly inferior to those of predominantly lateral spreading tumors. Observations of 0-I macroscopic-type tumors, MRS, and submucosal deep invasion were significantly more frequent in interrupted

cases. Conventional endoscopic images without magnification endoscopy were more associated with interruption than irregular surface or Vi pit pattern in cases with 0-I type tumors.

**Conclusion:** Endoscopic submucosal dissection of 0-I type tumors is highly disruptive, and undiagnosable submucosal infiltration can reduce the curability.

**Disclosure:** Nothing to disclose

## **P1185** ARTIFICIAL INTELLIGENCE PREDICTS THE LYMPH NODE METASTASIS OF T2 COLORECTAL CANCER - PROPOSAL OF A NOVEL INDICATION FOR FULL-THICKNESS ENDOSCOPIC RESECTION

**Introduction:** Although all T2 colorectal cancers (CRCs) undergo surgical colectomy with lymph node dissection, they actually show approximately 30% of lymph node metastasis (LNM)-positivity. Thus, the remaining 70% patients have an option of receiving local resection such as full-thickness endoscopic resection. However, accurate pre-operative prediction of LNM of T2 CRCs has been considered impossible. The aim is to investigate whether artificial intelligence (AI) can predict LNM-positivity of T2 CRCs.

**Aims & Methods:** A total of 511 consecutive patients with T2 CRCs that were surgically resected in 2001-2016 were retrospectively analysed. We divided patients at a ratio of 3:1: data from 383 patients were used for machine learning for the AI model, and the remaining 128 patients were included for model validation. The AI model analyzed 37 clinicopathological factors and then predicted LNM-positivity or LNM-negativity on support vector machine which is a representative machine learning method. Operative specimens were used as the gold standard for the presence of LNM. The AI model was validated by calculating the sensitivity, specificity, and accuracy for predicting LNM.

**Results:** The rate of LNM-positivity in validation dataset was 28% (36/128). The AI model showed a sensitivity of 100% (95% CI, 86%-100%), specificity of 20% (12%-29%) and accuracy of 42% (34%-51%), respectively.

**Conclusion:** The AI model accurately predicts 20% of the LNM-negative T2 CRCs. Such patients can be good candidates for the local resection without lymph node dissection such as full-thickness endoscopic resection.

**Contact E-Mail Address:** liptak@fmed.uniba.sk

**Introduction:** Irritable bowel syndrome is the most common functional gastrointestinal disorder (FGID). The pathophysiological mechanisms of FGID are complex. Accumulating evidence indicates that autonomic dysregulation contributes to FGID. The symptoms of IBS are often triggered by stress, however, the mechanisms of autonomic dysregulation in IBS, especially in response to stress are incompletely understood.

**Aims & Methods:** The aim of this study was to assess potential changes of vagal and sympathetic regulation in patients suffering from IBS in response to distinct types of stressors (active mental stress vs. passive physical stress).

**Methods:** Studied population included 12 patients diagnosed with IBS and 12 sex- and age-matched healthy controls. All patients were diagnosed according to ROME IV criteria for functional gastrointestinal disorders. Blood

pressure (BP) and heart rate were continuously recorded using Finometer MIDI (FMS, Netherlands) at rest and during two distinct stressors - mental arithmetic test and cold pressor test (cooling of forearm in 1-3°C water bath for 5 min). Evaluated parameters:

1. baroreflex sensitivity (BRS, calculated from spontaneous heart rate variability and BP variability) reflecting reflex of vagally-mediated heart rate regulation in response to changes of BP,
2. spectral power in low-frequency band of systolic BP variability (LF-SBP) reflecting sympathetic alpha-adrenergic stimulation of vascular smooth muscles,
3. systolic and diastolic BP, and;
4. mean heart rate.

**Results:** BRS (reflecting vagal reflex function) in patients with IBS was substantially reduced compared to controls at rest and in response to both mental arithmetic test and to cold pressor test ( $p < 0.01$  for all comparisons). In contrast, LF-SBP (reflecting sympathetic function) was normal at baseline, but significantly increased in IBS compared to controls during cold pressor test ( $p < 0.05$ ). No differences were found in systolic and diastolic BP and heart rate.

**Conclusion:** Our data show impaired dynamic sympatho-vagal balance in patients with irritable bowel syndrome at rest and in response to different types of stressors. The vagal function was reduced both at baseline and during stress, while exaggerated sympathetic response is evoked predominantly by stress. These findings support the hypothesis of altered autonomic regulation during stress as a potential mechanism worsening the symptoms of IBS.

We suggest that comprehensive evaluation of stress response using non-invasive analysis of distinct autonomic effectors could help to better understand the role of autonomic dysregulation in functional gastrointestinal disorders.

**Contact E-Mail Address:** nikolaos.lazaridis@nhs.net

**Introduction:** Our aim was to investigate the underlying etiological mechanisms in the development of irritable bowel syndrome (IBS). Recent studies implicate the involvement of innate immune system dysfunction and low-grade inflammation in the pathogenesis of IBS. Toll-like receptors (TLRs) are a family of transmembrane innate immune receptors that recognize various bacterial and viral cell components and regulate immune response. TLR-signaling alterations have been suggested as an underlying factor in the manifestation of the syndrome.

**Aims & Methods:** A total of 44 IBS patients and 25 healthy controls were included in the study population. All participants underwent colonoscopy and right-sided colonic biopsies were obtained from 31 patients. TLR expression was measured with real-time quantitative Reverse Transcription PCR (RT-qPCR).

Total RNA was isolated and was reversed transcribed to cDNA and quantification of TLR2 and TLR4 mRNA levels was achieved by RQ-PCR. Quality of life questionnaires, Rome III criteria and stool pattern questionnaires were completed by all participants.

**Results:** There were no significant differences between healthy controls (HC) and IBS patients regarding age, body mass index and gender. IBS patients were subdivided in constipation group (23%), diarrhoea (57%) and mixed type (13%). TLR2 and TLR4 mRNA expression were increased in IBS patients compared to controls though there was no statistical significance. IBS-D patients had elevated TLR4 expression ( $p = 0.008$ ) compared to HC and IBS-C patients had decreased TLR4 ( $p = 0.027$ ). Furthermore, IBS-D patients presented with increased TLR2 and TLR4 mRNA expression compared to IBS-C patients ( $p = 0.018$  and  $p = 0.005$ ).

**Conclusion:** Expression of TLR2 and TLR4 was investigated in IBS patients and HC. Increased levels of TLRs were documented in the IBS group although there was no significant difference to the HC group. TLR4 was over-expressed in IBS-D patients and on the contrary IBS-C patients presented with decreased expression of TLR4. TLR2 and TLR4 were increased significantly in IBS-D patients compared with IBS-C subgroup.

**Introduction:** There are multiple reports of persons with depression have displayed elevated levels of pro-inflammatory cytokines compared to healthy controls, but the origin of the inflammation is not determined. Eosinophils are normal in the GI tract (except in the esophagus). We have found subtle increased duodenal eosinophilia is linked to mood changes in dyspepsia, and have identified increased colonic eosinophils in a subset with IBS diarrhea.

**Aims & Methods:** Given the abundance of mucosal associated lymphoid tissue present in the gut and evidence of gut-brain axis communication, we hypothesised that there may be a direct association between colonic eosinophilia and depression. The random population based colonoscopy study (PopCol) was performed 2002-2006 and included colonoscopies with biopsies on 745 individuals from the general population (Kjellström et al Eur J Gastro Hep 2014). Eosinophils (per 5 high power fields) have been counted in 161 out of the 745 individuals. Current depressive symptoms were reported on HADS at a baseline visit before the colonoscopy, 6 individuals (4 %) had a HADS depression score of 11 and above. Incident depression was defined as a Stockholm County registry recording of health care visit with an ICD-10 code F32 or F33 during 2006-2015 in individuals with HADS score below 11 at the baseline investigation. The cross sectional association between eosinophil counts and depressive symptoms were calculated using linear regression bootstrapped with 2000 replications. The association between baseline eosinophil counts and incident depression (17 cases, 138) was calculated using logistic regression.

**Results:** There was an association between eosinophil counts in transverse (beta: 0.23, p=0.028) and sigmoid colon (beta: 0.28, p=0.001), but not terminal ileum (beta: -0.08, p=.44), caecum (beta: 0.06, p=0.49) and rectum (beta: 0.16, p=0.27), and HADS depression scores, independent of smoking, age and gender. No association was found between eosinophil counts and incident depression (p's>0.13). Adjusting for IBS status (32.9 % had IBS) did not change the results.

**Conclusion:** The present result supports a direct association between colonic eosinophilia and depressive symptom severity in a general population. Future studies are needed to elucidate if this is a causal association.

### **P1189 PHENOTYPICAL CHANGES IN ENTERIC GLIAL CELLS AND THEIR ASSOCIATIONS WITH THE NEURONAL PROCESS ELONGATION STIMULATED BY NEUROMODULATORS FOR ENTERIC NERVOUS SYSTEM**

Tominaga K., Fujikawa Y.

Wakakusa-Daiichi Hospital, Gastroenterology, Higashiosaka, Japan

**Contact E-Mail Address:** tominaga\_0717@yahoo.co.jp

**Introduction:** Enteric glial cells (EGCs) present at the submucosal plexus and myenteric plexus change own phenotype by themselves and bring by-directional and functional roles with adjacent neurons. Such phenomena occur under the stress circumstances in accordance with chemical mediators closely related to the pathogenesis of irritable bowel syndrome. However, direct mechanism(s) of these glial changes remains to be elucidated especially for effects of neuromodulators. Although some reports suggest

the significance of neuronal process elongation in visceral hypersensitivity, effects by above neuromodulators and associations between the neuronal process elongation and glial efficacy are also unknown.

**Aims & Methods:** For screening of phenotypical changes in EGCs and neurons, we investigated the cellular proliferation and morphology of EGCs and neurons such as cytoplasmic shape, process elongation, and connections after stimulation with chemical mediators including expressions of nerve growth factor (NGF), and GAP43 in EGCs. We also evaluated phenotypical changes in neurons after stimulation with the conditioned medium of EGCs. EGC (CRL-2690 purchased from ATCC) and PC12 (CRL-1721.1) were used for the consequent experiments after reaching to sub-confluent condition. Morphological changes of these cells were evaluated by immunofluorescence with F-actin (a cytoskeletal marker) and S100β (a marker of glial cell) or PGP9.5 (a marker of neuron) antibody after stimulation with each mediator (NGF: 50 ng/ml, corticosterone: 1 μM, 5-HT: 1 μM, ATP: 1 μM, and tryptase: 1 μM) for 24 hours. We evaluated expressions of NGF in the EGCs after stimulation with tryptase. To evaluate interaction between EGC and neuron, we collected the condition medium of EGCs after stimulation with tryptase for 6 hours, and evaluated morphological changes of PC12 by immunofluorescence with F-actin or GAP43 and PGP9.5 after incubation with the condition medium for 24 hours. We measured cell number for cellular proliferative evaluation.

**Results:** In a screening of each mediator affecting phenotypical change of EGCs, NGF (2-fold) and tryptase (1.8-fold) significantly induced cell proliferation of EGCs. In glial morphology, NGF did not affect cell body of EGC from the basal culture condition (a star-shaped form). However, NGF markedly induced irregularly branched processes with dense connecting with adjacent EGCs. On the contrary, corticosterone and 5-HT significantly changed cell body of EGC from star-shaped form to fibrous or spindle form (thin cytoplasm) with long-branched processes with freely connecting with other EGCs. Tryptase slightly extended cytoplasm of EGCs, and ATP induced long-branched processes with dense and free connecting with adjacent EGCs as well as corticosterone and 5-HT. On the other hand, NGF and corticosterone increased neuronal proliferation. In neuronal morphology, these mediators extended cytoplasm of neurons and increased intracellular F-actin and extracellular spicule formation in parallel with process elongation. However, 5-HT, ATP, and tryptase did not affect neurons including proliferation and morphology. Expression of NGF was increased in EGCs stimulated with tryptase but not corticosterone. Conditioned medium of EGCs stimulated with tryptase caused neuronal process elongation similar to the effect of NGF stimulation, and increased GAP43 proteins.

**Conclusion:** These neuromodulators induced phenotypical changes in EGCs more prominently than neurons. Phenotypical changes in EGCs may result in neuronal process elongation mediated by NGF.

**Disclosure:** Nothing to disclose

### **P1190 IMPACT OF MUCOSAL GLIAL CELLS AND SUBMUCOSAL GLIAL CELLS ON ENHANCEMENT OF NEURONAL NETWORK MEDIATED BY NERVE GROWTH FACTOR IN A RAT MODEL OF VISCERAL HYPERSENSITIVITY**

Fujikawa Y., Tominaga K.

Wakakusa-Daiichi Hospital, Higashiosaka, Japan

**Contact E-Mail Address:** yoshi\_zb@yahoo.co.jp

**Introduction:** Neuronal elongation toward the epiderm is caused by an imbalance of nerve attractive factors such as nerve growth factor (NGF) and nerve repulsive factors such as semaphorin 3A (Sema3A). The phenomenon is partly responsible for itch sensitization (so called somatic hypersensitivity) in patients with atopic dermatitis. Previously, we reported that hyperplasia of myenteric glial cells contribute to hypercontraction in an irritable bowel syndrome (IBS) model. In addition, abnormalities of enteric neuron and glial cells observed in the colonic mucosa are reported to contribute to the pathogenesis of IBS. However, it is unknown how glial cells and nerve elongation factors change and associate with the neuronal network formation both in the mucosa and submucosa layer of IBS.

**Aims & Methods:** We evaluated the changes in the neuronal network separately in the mucosa and submucosa and the dynamics of glial cells and neuronal elongation factors in an IBS model. We used Wistar Kyoto rats (WKY) which are genetically instable to anxiety, and prepared an IBS models after intracolonic injections of acetic acid (2 mL, 0.6%) to these rats. Distal colonic segments were obtained from control (Wistar rats), WKY, and IBS models, and each layer (mucosa, submucosa, and muscle) were sepa-

rately striped from the whole colonic tissues. Between the mucosal and submucosal layers, we compared mRNA expression of NGF and Sema3A by real-time RT-PCR. To evaluate the morphological changes of glial cells and neuronal network formation, whole mount submucosal plexus tissues were prepared for immunohistochemistry with glial fibrillary acid protein and PGP9.5 (pan-neuronal marker) antibodies. To evaluate the neuronal outgrowth in the mucosa, frozen colonic tissues were prepared for immunohistochemistry with GAP43 antibody. We also evaluated the localization of NGF and Sema3A in the mucosa and submucosa layer.

**Results:** mRNA expressions of NGF (2.3-fold) and Sema3A (3.1-fold) were significantly increased in the submucosal layer in the WKY group compared to the control, while there were no change in the mucosa between both groups. In the IBS group, mRNA expression of NGF initially begun to increase in the submucosal layer, and its increase was subsequently observed in the mucosa. Sema3A mRNA expression was increased in the submucosal layer, but decreased in the mucosal layer. Submucosal glia exhibited hyperplasia of their processes that apparently overlapped with the neurons and changes in bulbous swelling of terminals in the IBS group. Neuronal network was dramatically enhanced in the submucosal layer of the IBS group, whose change gradually appeared from the outer submucosal plexus toward the inner submucosal plexus. As well as submucosal plexus, nerve fiber outgrowth (GAP43 positive neuron) was increased in the mucosal layer. NGF was localized in the both submucosal and mucosal glial cells but not mast cells in this model.

**Conclusion:** Enteric glial cells are associated with enhanced neuronal network both in the mucosa and submucosa mediated by the coordination of NGF and Sema3A in the IBS model. These findings may underlie in the pathogenesis of visceral hypersensitivity in IBS.

<sup>1</sup>IRCCS Fondazione Policlinico Universitario Agostino Gemelli, Università Cattolica del Sacro Cuore, Department of Internal Medicine and Gastroenterology, Rome, Italy, <sup>2</sup>Catholic University of Rome, Female Pelvic Medicine & Reconstructive Surgery Center, Rome, Italy

**Contact E-Mail Address:** fabianalopalco93@yahoo.it

**Introduction:** Interstitial Cystitis/Bladder Pain Syndrome (IC/BPS) is a debilitating chronic, inflammatory disorder of the bladder characterized by variable degree of pain, frequency and urinary urgency, with a negative impact on the Quality of Life (QoL). BPS patients are often affected by gastrointestinal symptoms such as abdominal pain, dyspeptic symptoms, constipation and diarrhea, often consistent with a diagnosis of IBS. Severe chronic abdominal pain is sometimes treated with opioids. Furthermore, patients introduce many dietetic restrictions in order to improve their symptoms.

**Aims & Methods:** This study aimed to evaluate the effects of chronic opioid treatment on abdominal pain, gastrointestinal symptoms and QoL. It also aimed to better understand how a weight control strategy can influence IBS/BPS patients' psychological state. A two-year study was conducted in the Multicentric Interstitial Cystitis Referral Center of the Catholic University in Rome, in a population of 44 female, aged 25-78, affected by IC/BPS according to the "European Society for the Study of Interstitial Cystitis (ESSIC)" criteria. Patients were categorized into groups according to opioid use and BMI: 17 "opioid users (at least 1 month)" and 27 "non-opioid users (in the last month)"; normal BMI group (BMI: 19-24.9) including 20 patients, underweight group (BMI < 18.9) including 8 patients and overweight group (BMI > 25) including 16 patients. All subjects were asked to fill our Psycho-Gastroenterological Questionnaire (PGQ), which includes Visual Analogue Scale (EQ-VAS), Bristol Stool Chart (BSC), Gastrointestinal Symptoms Rating Scale (GSRS), State-Trait Anxiety Inventory (STAI Y-1, STAI Y-2), Psychological General Well-Being Index (PGWBI), Hospital Anxiety and Depression Scale (HADS), General Self-Efficacy Scale (GSE), Connor-Davidson Resilience Scale (CD-RISC). Differences between groups were evaluated by Student's t test and considered significant for  $p < 0.05$ .

**Results:** Compared to opioid users, non-opioid users had a higher EQ-VAS score ( $46.7 \pm 14.9$  vs  $29.7 \pm 21.6$ ,  $p = 0.004$ ), a lower grade of stypsis on BSC ( $3.4 \pm 1.7$  vs  $1.6 \pm 0.9$ ,  $p = 0.0002$ ), and a lower GSRS score ( $14.2 \pm 6.5$  vs

$19.9 \pm 6.1$ ,  $p = 0.006$ ). Within the GSRS, "abdominal pain" ( $1.1 \pm 0.8$  vs  $1.9 \pm 0.8$ ,  $p = 0.002$ ), "heartburn" ( $0.9 \pm 0.7$  vs  $1.7 \pm 1.0$ ,  $p = 0.003$ ), "acid regurgitation" ( $0.7 \pm 0.7$  vs  $1.2 \pm 1.0$ ,  $p = 0.05$ ), "nausea and vomiting" ( $0.7 \pm 0.9$  vs  $1.4 \pm 0.9$ ,  $p = 0.01$ ), "hard stools" ( $1.2 \pm 1.0$  vs  $1.8 \pm 0.9$ ,  $p = 0.05$ ), and "feeling of incomplete evacuation" ( $0.7 \pm 0.8$  vs  $1.8 \pm 1.1$ ,  $p = 0.0004$ ) were significantly lower among non-opioid users. On the other hand, there were no differences between groups in the other scores. Compared to pathologic BMI group (underweight plus overweight patients), normal BMI group has a higher EQ-VAS score ( $44.3 \pm 21.0$  vs  $36.7 \pm 18.3$ ) and a lower GSRS score ( $15.9 \pm 7.0$  vs  $16.8 \pm 6.9$ ), but these differences were not statistically significant. On the other hand, all psychometric scores are significantly better among normal BMI group: STAI Y-1 ( $48.6 \pm 11.5$  vs  $55.6 \pm 12.5$ ,  $p = 0.06$ ), STAI Y-2 ( $42.1 \pm 11.3$  vs  $51.7 \pm 10.3$ ,  $p = 0.005$ ), PGWBI ( $61.0 \pm 20.5$  vs  $47.3 \pm 17.2$ ,  $p = 0.02$ ), HADS-A ( $7.1 \pm 4.4$  vs  $11.0 \pm 5.1$ ,  $p = 0.01$ ), HADS-D ( $5.8 \pm 3.6$  vs  $9.4 \pm 3.3$ ,  $p = 0.001$ ), CD-RISC ( $70.2 \pm 16.9$  vs  $56.6 \pm 12.3$ ,  $p = 0.003$ ).

**Conclusion:** Our study demonstrates that chronic opioid treatment increases abdominal pain and worsens gastrointestinal symptoms and QoL in subjects with IC/BPS+IBS, configuring a condition of NBS. On the other hand, weight control can strongly improve patients' QoL. Further studies in larger samples are required to establish the influence of potential confounders.

**Contact E-Mail Address:** info@ggpp.ch

**Introduction:** Fructose intolerance is common in patients with Functional Gastrointestinal Disorders (FGID) and is typically attributed to intestinal malabsorption. However, fructose is also known to invoke systemic metabolic changes, including modulation of the tryptophan (TRP)-kynurenine (KYN) pathways. This modulation has been associated with low-grade inflammation and cognitive changes, both of which are reported to be common in FGID and may be effected by either host or microbiome pathways (1-3).

**Aims & Methods:** Plasma TRP, KYN and further systemic metabolites were quantified in FGID patients after fructose ingestion and related to measures of fructose intolerance and malabsorption. Thirty-one male and female FGID patients, defined by Rome III criteria, were prospectively enrolled into a double-blind, randomised, crossover study (4). Blood, breath samples and symptom ratings were collected at 0, 0.5, 1 and 2h post-ingestion of 35g fructose or the blinded placebo, 3.9mL cyclamate/saccharine sweetener or water. Plasma TRP and KYN were quantified via liquid chromatography mass spectrometry, while other systemic metabolites were profiled via gas chromatography time-of-flight mass spectrometry.

**Results:** The KYN/TRP ratio (KTR) increased from 0h to 2h after fructose ingestion ( $p < 0.001$ ) in all FGID patients, and the change in KTR was significantly higher following fructose than water ( $p < 0.01$ ) and cyclamate/saccharine ( $p < 0.01$ ). Twelve other metabolites were significantly different (Variable importance in projection > 1,  $p < 0.005$ ) between fructose and water interventions, including long-chain fatty acids (myristic acid, oleic acid, palmitic acid, palmitoleic acid, stearic acid) and pro-inflammatory mediators (linoleic acid, arachidonic acid). Breath hydrogen and methane concentrations and symptoms did not correlate significantly with the changes in KTR.

**Conclusion:** Ingestion of fructose resulted in acute changes in the tryptophan-kynurenine axis and in fatty acid metabolism in patients with FGID. These changes do not appear to be specifically associated with malabsorption or intolerance of fructose and may rather be related to tryptophan metabolism and the recently highlighted link to the aryl hydrocarbon receptor and downstream effects on microbiome and host neuroimmune

function (5). Fructose stimulation may consequently be useful for further mechanistic assessment of the known immune activation and neural sensitization in FGID.

**Introduction:** Before colonoscopy, adequate bowel preparation is mandatory to achieve high-quality observation for entire mucosa. Several previous studies have reported factors associated with inadequate bowel preparation, including an older age, obesity, and diabetes mellitus. We investigated the predictive factors for bowel preparation.

**Aims & Methods:** We evaluated 800 colonoscopies performed from March 2016 to Jun 2019 to analyze the degree of bowel preparation using the Boston Bowel Preparation Scale (BBPS) and assessed the predictive factors for inadequate bowel preparation. All patients received low-volume (2 L) polyethylene glycol solution with ascorbate (MoviPrep®) before colonoscopy. The potential predictive factors for inadequate bowel cleansing were older age ( $\geq 75$ ), male gender, obesity (BMI  $\geq 25$ ), constipation, laxative use, a history of abdominal surgery, single- or split-dose intake preparation, diverticulosis and diabetes mellitus. Inadequate bowel preparation was defined as a BBPS  $\leq 5$ . We excluded patients with a diagnosis or history of colonic stricture, inflammatory bowel disease or prior colectomy.

**Results:** The median (range) patient age was 68 (27-84), and 43% were women. The median (range) number of bowel movements per week was 5.7 (1-11). The median (range) BBPS score was 8 (3-9), and the rate of adequate bowel preparation (BBPS  $\geq 6$ ) was 94.3%. A univariate analysis of the factors associated with inadequate bowel preparation were obesity ( $P = 0.007$ ), diabetes mellitus ( $P = 0.005$ ) and constipation ( $P = 0.0428$ ). A multivariate logistic regression analysis showed that obesity (OR 2.76 [95% CI 1.07-7.23],  $p=0.035$ ) and diabetes mellitus (OR 3.65 [95% CI 1.32-9.64],  $p=0.0133$ ) were independent factors related to inadequate bowel cleansing.

**Conclusion:** Using the BBPS score to evaluate colon cleansing, the predictive factors associated with inadequate bowel preparation were obesity (BMI  $\geq 25$ ) and diabetes mellitus.

**Disclosure:** Nothing to disclose

## P1194 A NOVEL METHOD FOR CHARACTERISING POSTPRANDIAL INTESTINAL CONTRACTIONS, EFFECTS OF GLUCAGON AND RECTAL DISTENTION IN DOGS

**Contact E-Mail Address:** s1603938@ed.ac.uk

**Introduction:** Motility disturbances are frequently implicated in functional gastrointestinal disorders. Current options for assessing intestinal motility provide limited information on the propagation pattern of the intestines.

**Aims & Methods:** This study aimed to investigate the validity of a new method for examining and quantifying intestinal motility. Seven healthy female dogs were operated on to have a cannula placed in their duodenum. The canine intestinal motility was studied under three sets of experiments (postprandial; glucagon injection and rectal distention, RD). A solid-state 4.2 mm manometric catheter with 10 sensors spaced at 1-cm intervals was inserted into the intestinal lumen via the cannula. The luminal contractile signals were converted into electrical signals by the pressure transducer and saved for further analysis. A special software was developed to analyse the data collected. The intestinal motility was evaluated by frequencies of antegrade, retrograde and simultaneous contractions, motility index (MI), propagation pattern (percentages of antegrade, retrograde and simultaneous contractions), propagation distance and velocity of antegrade and retrograde contractions.

**Results:**

1. Feeding did not induce changes in the frequencies of different contractions. The frequencies of postprandial contractions (numbers per min, npm) were  $8.1 \pm 1.4$  npm for antegrade contractions;  $3.5 \pm 1.0$  npm for retrograde contractions; and  $8.9 \pm 0.7$  npm for simultaneous contractions. MI also remained unchanged ( $11.8 \pm 0.5$  vs.  $11.4 \pm 0.2$ ,  $p = 0.19$ ). Postprandially, the dominant propagation pattern was antegrade ( $45.0 \pm 8.1\%$ ), followed by simultaneous ( $34.5 \pm 5.2\%$ ) and retrograde ( $20.5 \pm 2.0\%$ ). The average distance propagated was  $4.8 \pm 0.8$  cm with the antegrade contractions,  $4.4 \pm 0.3$  cm with the simultaneous contractions and  $2.3 \pm 0.2$  cm with retrograde contractions. The propagation velocity of the antegrade contractions was  $12.1 \pm 0.4$  cm/min and  $10.7 \pm 0.5$  cm/min for retrograde contractions.

2. Post glucagon injection, the frequencies of antegrade contractions decreased from  $7.6 \pm 1.0$  to  $4.3 \pm 0.6$  npm ( $p = 0.001$ ), the frequencies of other contractions did not change significantly. MI was reduced slightly ( $11.5 \pm 0.4$  vs.  $10.6 \pm 0.2$ ,  $p = 0.013$ ). The dominant propagation pattern became simultaneous ( $42.0 \pm 2.9\%$ ), followed by antegrade ( $34.6 \pm 2.8\%$ ) and retrograde ( $23.1 \pm 3.7\%$ ). The average distance propagated by antegrade contractions decreased to  $3.6 \pm 0.5$  cm/min ( $p = 0.0287$ ). The propagation velocity was not altered by glucagon injection.

3. RD did not significantly disrupt the intestinal contractile and propagation patterns.

**Conclusion:** Our method was able to differentiate between antegrade, retrograde and simultaneous contractile and propagation patterns. Clinically it can be used to quantify the dynamic intestinal propagation process and pinpoint whether the motility issue is due to antegrade, retrograde or simultaneous contraction. This could greatly enhance the clinical use of manometry in investigating the cause of intestinal dysmotility.

## P1195 AFFECTIVE DETERMINANTS OF SYMPTOM SEVERITY IN IBS PATIENTS

Sanda P.<sup>1</sup>, Tkalcic M.<sup>2</sup>, Troskot Peric R.<sup>3</sup>, Blazic F.<sup>4</sup>, Hauser G.<sup>5</sup>

<sup>1</sup>Faculty of Humanities and Social Sciences, University of Rijeka, Rijeka, Croatia, <sup>2</sup>University of Rijeka, Department of Psychology, Rijeka, Croatia, <sup>3</sup>Clinical Hospital Sveti Duh, Zagreb, Croatia, <sup>4</sup>Clinical Hospital Centre, Rijeka, Croatia, Gastroenterology, Rijeka, Croatia, <sup>5</sup>Clinical Hospital Centre, Rijeka, Croatia, Department of Internal Medicine, Division of Gastroenterology, University of Rijeka, Faculty of Medicine; Faculty of Health Studies, Rijeka, Croatia

**Contact E-Mail Address:** goran.hauser@medri.uniri.hr

**Introduction:** Irritable Bowel Syndrome (IBS) is one of the most common and challenging disorder confronting gastroenterologist. Symptoms include abdominal pain associated with altered bowel habits. The disorder is characterized by heightened anxiety and depression. Even IBS patients with no comorbidities have higher, although still subclinical levels of anxiety and depression. There are many aspects of anxiety that can possibly contribute to IBS symptom perpetuation, but perhaps the most illness specific one is visceral anxiety.

**Aims & Methods:** The aim of this study was to test the predictive value of trait anxiety, depression and visceral anxiety in the prediction of IBS symptom severity.

A total of 39 Rome IV-diagnosed IBS outpatients at tertiary care centre (79.4% F, M age = 49.4 years) were recruited. They completed a set of questionnaires, including State-Trait Anxiety Inventory (STAI-T), Beck Depression Inventory (BDI-II) and Visceral Anxiety Inventory (VSI). They also

kept a diary for 14 days which, among other aspects, involved completing a short symptom intensity scale. The total symptom intensity was calculated for each day and a final average of 14 days was used for each participant.

**Results:** Symptom severity was positively correlated with trait anxiety ( $r=.37^*$ ), depression ( $r=.35^*$ ) and visceral anxiety ( $r=.58^{**}$ ). Hierarchical regression analysis showed that in the final model only visceral anxiety was a significant predictor ( $\beta=.51^{**}$ ) of symptom severity and the model explained a total of 35.8% of symptom severity variance. Considering that trait anxiety significantly predicts symptom severity ( $\beta=.37^*$ ) when entered in the model alone and that adding depression ( $\beta=.17$ ) in the second step reduces that effect to non-significant ( $\beta=.24$ ), and finally adding visceral anxiety in the third step completely nullifies that effect ( $\beta=.08$ ) there are indications that depression partially and visceral anxiety fully mediates the trait anxiety - symptom severity relationship.

**Conclusion:** The obtained results indicate that trait anxiety and depression might be related to symptom severity via visceral anxiety, which emphasizes the importance of using this simple, yet very informative measure of illness-specific anxiety in IBS patients.

**Disclosure:** Nothing to disclose

## P1196 IS THERE A LINK BETWEEN IBS AND STUTTERING? PRELIMINARY RESULTS

Hauser G.<sup>1</sup>, Novosel Herceg T.<sup>2</sup>, Sanda P.<sup>3</sup>, Nosel D.<sup>2</sup>, Benjak I.<sup>4</sup>, Tkalcic M.<sup>5</sup>

<sup>1</sup>Clinical Hospital Centre, Department of Internal Medicine, Division of Gastroenterology, University of Rijeka, Faculty of Medicine, Faculty of Health Studies, Rijeka, Croatia, <sup>2</sup>ValMOD, Varazdin, Croatia, <sup>3</sup>Faculty of Humanities and Social Sciences, University of Rijeka, Rijeka, Croatia, <sup>4</sup>County Hospital Varazdin, Gastroenterology, Varazdin, Croatia, <sup>5</sup>University of Rijeka, Department of Psychology, Rijeka, Croatia

**Introduction:** Theories of stuttering have described the role of anxiety in several ways, from treating it as the main cause of the disorder to a mere by-product of stuttering. Most studies have detected a positive correlation between anxiety and stuttering severity, with higher levels of anxiety in the stuttering population compared to healthy persons. Irritable Bowel Syndrome (IBS) is one of the most common and challenging disorder confronting gastroenterologist. Symptoms include abdominal pain associated with altered bowel habits. The disorder is characterized by heightened anxiety and depression.

**Aims & Methods:** The aim of this study was to examine the prevalence of IBS in a sample of people who stutter and to explore the relationship between several anxiety measures and IBS symptom frequency among people who stutter. A total of 57 people who stutter (73.6% M, M age = 32.4 years) and were treated for stuttering at ValMod rehabilitation centre were recruited. During their regular holistic multidimensional logopaedic treatment they completed the Rome IV diagnostic questionnaire, a short questionnaire on the frequency of 6 IBS symptoms, State-Trait Anxiety Inventory (STAI-T), Visceral Anxiety Inventory (VSI) and Anxiety Sensitivity Index ASI.

**Results:** Only 8 participants (4F, 4M) fit the IBS criteria (Rome IV), which is a somewhat lower prevalence rate compared to the general population. It needs to be pointed out that the sample consisted of almost three times as many men than women. If we look at women alone, the prevalence rate is around 26% which is close to prevalence in the general population. People who stutter, but do not fit the IBS criteria, have higher STAI scores ( $M=44.53$ ;  $SD=9.34$ ) than a normative age group of healthy persons ( $M=35.55$ ;  $SD=9.76$ ), which is in line with previous studies (Ezrati-Vinacour & Levin, 2004;  $M=46.00$ ;  $SD=8.80$ ). People who stutter and fit the IBS criteria have even higher ( $t=2.59$ ;  $df=9.62$ ;  $p<.05$ ) STAI scores ( $M=53.99$ ;  $SD=9.41$ ). Their STAI score seems to be higher than the score obtained for the regular, non-stuttering IBS population, previously published in our other studies ( $M=46.30$ ;  $SD=9.63$ ).

People who stutter and fit the IBS criteria have higher scores in VSI scores ( $t=2.26$ ;  $df=8.34$ ;  $p<.05$ ), ASI scores ( $t=2.76$ ;  $df=8.34$ ;  $p<.05$ ) and the frequency of IBS symptoms ( $t=4.67$ ;  $df=8.18$ ;  $p<.01$ ) than those who don't fit the IBS criteria. In the total sample of people who stutter, IBS symptom frequency is correlated with all three anxiety measures (STAI  $r=.42^{**}$ ; VSI  $r=.52^{**}$ ; ASI  $r=.67^{**}$ ), with VSI explaining 27.4% of symptom frequency variance.

**Conclusion:** It seems IBS is not more frequent in people who stutter. However, it seems that stuttering aggravates anxiety in IBS. Patients who stutter and have IBS seem to have more pronounced anxiety than people who stutter but don't have IBS and people who have IBS but don't stutter.

## P1197 THE ASSOCIATION BETWEEN JOINT HYPERMOBILITY SYNDROME AND ROME IV FUNCTIONAL GASTROINTESTINAL DISORDERS: A CASE-CONTROL STUDY OF PREVALENCE, QUALITY OF LIFE IMPAIRMENT, HEALTHCARE UTILISATION AND NON-GI SOMATIC SYMPTOMS

Lam C.<sup>1</sup>, Palsson O.S.<sup>2</sup>, Whitehead W.E.<sup>2</sup>, Sperber A.D.<sup>3</sup>, Törnblom H.<sup>4</sup>, Simrén M.<sup>2,5</sup>, Aziz I.<sup>1</sup>

**Contact E-Mail Address:** imy\_aziz9@yahoo.co.uk

**Introduction:** Individuals with joint hypermobility syndrome (JHS) are increasingly encountered within gastroenterology services and pose complex clinical challenges. Limited data suggests a high prevalence of functional gastrointestinal disorders (FGIDs) in JHS, with non-GI somatic symptoms a potentially relevant confounder. However, no study has addressed the prevalence and associations for FGIDs in subjects with JHS against age and sex-matched general population-based controls.

**Aims & Methods:** An Internet based cross-sectional general health survey was completed by 642 subjects with JHS - recruited with the help of the charity organization Ehlers-Danlos Support UK - and 642 age/sex-matched population controls from the UK. The mean age was 39 years (SD 13) and 96% were female. The survey enquired for FGIDs using the Rome IV diagnostic questionnaire, non-GI somatic symptoms, quality of life, and healthcare utilisation. FGID prevalence data was compared between the groups, with subsequent logistic regression models (adjusting for the number of non-GI somatic symptoms) used to determine the associations for FGIDs and healthcare utilisation in subjects with JHS compared to the general population.

**Results:** Nearly all subjects (98%) with JHS fulfilled symptom-based criteria for any Rome IV FGID compared with 46% of the general population. The parts of the digestive tract most commonly affected by FGIDs in JHS and control subjects were the bowel (90% vs. 39%, respectively), gastroduodenal (70% vs. 13%) and anorectal (54% vs. 10%) regions. Moreover, those with JHS were more likely than the general population to have FGIDs in  $\geq 2$  regions (84% vs. 16%). Subjects with JHS reported a higher number of non-GI somatic symptoms (9 vs. 4.4), poorer mental and physical quality of life scores, and greater healthcare utilisation such as physician consultations, abdominal surgeries, use of opiates (84% vs. 28%) and neuromodulators (43% vs. 20%). Following adjustments for non-GI somatic symptoms, the association of FGIDs and healthcare utilisation in subjects with JHS was reduced by up to fourfold and in some instances eliminated.

**Conclusion:** This large case-control study shows that individuals with JHS report a very high prevalence of Rome IV FGIDs and incur considerable health impairment and health care utilisation. These associations are drastically reduced when controlling for non-GI somatic symptoms. Hence, reducing non-GI somatic symptoms should be considered as an early therapeutic target in JHS.

**Disclosure:** Nothing to disclose

## P1198 DIFFERENCE OF THE DEFECATION DESIRE BETWEEN CONSTIPATED PATIENTS AND NON-CONSTIPATED PATIENTS: A LARGE-SCALE INTERNET SURVEY

Ohkubo H.<sup>1</sup>, Takatsu T.<sup>1</sup>, Misawa N.<sup>1</sup>, Yoshihara T.<sup>1</sup>, Ashikari K.<sup>1</sup>, Fuyuki A.<sup>1</sup>, Matsuura T.<sup>1</sup>, Higurashi T.<sup>1</sup>, Yamamoto K.<sup>2</sup>, Nakajima A.<sup>1</sup>

<sup>1</sup>Yokohama City University Hosp., Dept. of Gastroenterology, Yokohama, Japan, <sup>2</sup>Yokohama City University, Biostatistics, Yokohama, Japan

**Contact E-Mail Address:** ohkuboh@yokohama-cu.ac.jp

**Introduction:** Chronic constipation (CC) is a functional bowel disorder with a high prevalence worldwide. However, treatment satisfaction and quality of life (QOL) is low, and several clinical problems remain unresolved today. Loss of defecation desire (LODD) is presumed to be one cause of impaired QOL; however, it is still unknown whether LODD is more common in patients with CC than those without. Understanding the difference of the defecation desire between constipated patients and non-constipated controls is important to help solve the clinical problems.

**Aims & Methods:** To compare the rate of LODD between patients who had self-recognition of constipation and actually met the Rome-IV criteria (CC arm) and age-sex-matched controls who have no symptoms of constipation and do not meet the Rome-IV criteria (non-CC arm), we performed a nationwide internet questionnaire survey in March 2019 targeting the Japanese adults (aged 20-79 years old) registered in the large-scale panel on the website owned by Rakuten Insight, Inc.

We used an original online questionnaire which collected information about sex, age, presence or absence of defecation desire, stool form, constipation score, and whether meeting the Rome-IV constipation criteria or not. Degree of defecation desire is stratified into the following four scales; 'never', 'rarely', 'usually', and 'always', then 'never' and 'rarely' are defined as LODD.

**Results:** A total of 20990 subjects, 9669 with self-recognition of constipation and 11321 without any symptoms of constipation, were included during the 10 days investigation period. Of the 9669, 26.8% (n=2591) met the Rome-IV criteria and were selected as CC arm. Rate of LODD in CC arm and non-CC arm was 57.4% and 8.0%, respectively (p< 0.001, OR:15.4 [13.1-18.1]). LODD was observed evenly from young to old people in CC arm.

**Conclusion:** This study confirmed that patients with CC are much more likely to decrease or lose defecation desire than non-constipated controls regardless of age. To improve the problematic clinical situations in this field, physicians should pay more attention to 'defecation desire' as an indicator of treatment effect in daily clinical practice.

**Contact E-Mail Address:** olafur\_palsson@med.unc.edu

**Introduction:** Functional bowel disorders (FBDs) are defined based on different combinations of abdominal pain, bloating/distension, and abnormal bowel habits, i.e. diarrhea or constipation. Which of these symptoms patients consider most bothersome varies between individuals.

**Aims & Methods:** We aimed to examine how the most bothersome bowel symptom differs between different FBDs and how this relates to health care utilization, quality of life, non-GI symptoms and demographic factors in the general population. A community sample of 6,300 adults 18 years and older in the US, United Kingdom (UK) and Canada (2,100 in each country) completed a secure online survey. Quota-based sampling was used to ensure equal proportion of sex and age groups across countries, and to control education distributions. The survey included the Rome IV diagnostic questionnaire for adults, the Short Form - 8 (SF-8) quality of life questionnaire, the Patient Health Questionnaire - 12 (PHQ-12) for non-GI somatic symptoms, questions on health care utilization, abdominal surgery, use of medications, and question about the most bothersome of the four symptoms defining FBD in the past three months.

**Results:** Data from 5,931 individuals were retained for analysis (49.2% female; mean age 47.4 (range 18-92) years) after 369 inconsistent responders were eliminated. Rome IV criteria for FBDs were fulfilled by 27.8% of subjects. The symptoms most commonly reported to be most bothersome by FBD subjects were "watery or mushy stools, or having many bowel movements in a day" (29%), and "hard stools or going several days without having a bowel movement" (25%), followed by abdominal bloating or distension (21%) and abdominal pain (17%). The most commonly reported most bothersome symptom among individuals with IBS was abdominal pain (40%), in functional constipation and in opioid-induced constipation it was hard and infrequent stools (44% and 61%), and in functional diarrhea and functional abdominal bloating/distension all patients reported that the symptom defining each disorder (loose stools and bloating/distension, respectively) was the most bothersome. For men with FBDs, loose, frequent stools were the most common most bothersome symptom (36%), whereas this was hard, infrequent stools for females (27%). FBD individuals with different most bothersome symptoms also differed regarding healthcare utilization, quality of life, and overall somatic symptom severity (Table 1): Those with abdominal pain as their most bothersome symptoms had the poorest quality of life and highest non-GI somatic symptom burden, and had the highest proportion of frequent health care users (doctor visits ≥ once a month). The abdominal pain group also had the highest proportion of subjects regularly taking medications for nausea, acid reduction, and pain (OTC), whereas regular use of constipation and diarrhea medications, respectively, was most common among individuals with those symptoms as their most bothersome bowel symptoms.

**Conclusion:** The most bothersome bowel symptom differs among individuals meeting Rome IV FBD criteria, and this influences health care utilization, medication preference, quality of life and overall somatic symptom severity. Targeting the most bothersome symptom when treating FBDs seems relevant to improve health care outcomes.

	Abdominal pain (n=285)	Loose, frequent stools (n=483)	Hard, infrequent stools (n=412)	Abdominal bloating / distension (n=343)	p-value
Mental QOL (SF-8)	42±12	44±12	45±12	42±13	0.004
Physical QOL (SF-8)	44±10	46±11	45±12	47±10	0.001
Non-GI Somatic symptoms (PHQ-12)	7.9±4.4	6.2±3.5	6.5±3.3	6.3±3.5	<0.0001
Doctor visits 1+ times a month (%)	19%	12%	14%	12%	0.03
Abdominal surgeries (%)	31%	29%	28%	29%	0.86

[Table 1. Different Most Bothersome Symptoms and Associated Factors]

## P1200 THE INTESTINAL GAS QUESTIONNAIRE (IGQ): PSYCHOMETRIC VALIDATION OF A NEW INSTRUMENT FOR MEASURING GAS RELATED SYMPTOMS AND THEIR IMPACT ON DAILY LIFE AMONG GENERAL POPULATION AND IBS

Duracinsky M.<sup>1</sup>, Archbold S.<sup>2</sup>, Lobo Alvarez B.<sup>3</sup>, Bessonneau P.<sup>1</sup>, Guagnozzi D.<sup>3</sup>, Santos J.<sup>4</sup>, Coffin B.<sup>5</sup>, Azpiroz F.<sup>6</sup>, Whorwell P.<sup>7</sup>, Chassany O.<sup>1</sup>

<sup>1</sup>University Paris-Diderot & AP-HP, Patient-Centered Outcomes Research Unit, Paris, France, <sup>2</sup>Wythenshawe Hospital, Neurogastroenterology Unit, Manchester, United Kingdom, <sup>3</sup>Hospital General Vall d'Hebrón, Research Unit Gastroenterology Department Funda, Barcelona, Spain, <sup>4</sup>Institute de Recerca Vall d'Hebrón, Department of Gastroenterology, Barcelona, Spain, <sup>5</sup>Hopital Louis Mourier, Departement de Gastroentérologie, Colombes Cedex, France, <sup>6</sup>University Hospital General Vall d'Hebrón, Gastroenterology Department, Barcelona, Spain, <sup>7</sup>University of Manchester Wythenshawe Hospital, Medicine, Manchester, United Kingdom

**Contact E-Mail Address:** duracinsky.m@gmail.com

**Introduction:** Gas-related symptoms (GRS) are common among the general population and patients with functional gastrointestinal disorders. There is no patient-reported outcome covering these symptoms and their

impact on daily life. We first performed interviews in 3 countries among IBS patients and general population (GP) (1). This resulted in a 43-item pilot questionnaire (17 symptom items with 24h recall period and 26 impact items with 7-day recall).

A psychometric validation study is reported here.

**Aims & Methods:** One hundred subjects (60 IBS, 40 GP) complaining of GRS had to be included in each of the 3 countries (UK, Spain, France) to ensure reliable item statistics. IBS patients fulfilled ROME IV criteria with IBS-SSS scores between 150-300. Subjects completed the IGQ, The functional Digestive Disorders Quality of Life (FDDQL) score (0-100, higher = better quality of life) and the generic EQ-5D. Among the 100 subjects, 30 were asked to repeat the IGQ after a 7-day interval on paper or electronically. After item analysis and reduction, convergent/divergent (IGQ vs FDDQL and EQ-5D) and known-group validity (IGQ vs IBS-SSS) and test-retest reliability (intraclass correlation, ICC) were checked.

**Results:** 305 subjects were included (UK: 105; Spain: 100; France: 100), with 186 IBS (IBS-C: 68; IBS-D: 61; IBS-M: 57), and 119 GP. Mean age was 42±14 yrs, 69% were female. Mean IBS-SSS was 252±41 among IBS. FDDQL total score was 45±13 (IBS) vs 59±19 (GP). Factorial analysis (n=304) resulted in a 6-factor structure, bloating symptom items loading on the first factor. The structure was similar among IBS and GP. Twenty-six items (10 symptom and 16 impact items) were deleted (high floor effect or inter-item correlation, cross-loading or no clear loading).

The confirmatory factorial analysis on the remaining 17 items (7 symptom and 10 impact items) among 302 subjects, with no missing data, yielded a 6-factor structure explaining 67% of the variance with respectively bloating (6 items), flatulence (3), belching (2), bad breath (2), stomach rumbling (2) and difficult gas evacuation (2). Scores from 0 to 100 (worse) were computed: for each of the 6 symptoms, a total score and a score gathering the 5 other symptoms except bloating.

Scores were worse among IBS vs GP, e.g. 75±19 vs 66±22 for total score ( $p < 0.001$ ). IGQ total and bloating scores were correlated with the FDDQL global, Discomfort and Diet dimension scores ( $r$  between 0.42-0.68). Logically there was no correlation between IGQ and EQ-5D. IGQ total score got worse in parallel with IBS-SSS ( $r = 0.24$ ,  $p = 0.0006$ ): 59±34. ICC of IGQ scores was between 0.47-0.84, except for flatulence (0.27) among the 67 subjects who were considered stable at the 2<sup>nd</sup> visit after an interval of 7.3±0.9 days.

Similarly, the correlation between the completion of IGQ in paper vs electronic among these 67 stable subjects was high (ICC: 0.77 for global score).

**Conclusion:** The IGQ is a robust instrument for capturing and measuring gas related symptoms. The final 17-item questionnaire has good psychometric properties and is available in paper and electronic versions in 3 languages.

**Contact E-Mail Address:** ikaraujo@clinic.cat

**Introduction:** Chronic idiopathic constipation has a favorable response with conservative measures in most cases, but in a small proportion of patients surgical strategies may be necessary, having inconsistent results. Sacral nerve stimulation (SNS) is a potential alternative, and as a temporary device is used previous to a definite implantation, other possible treatments are not excluded if the result is not as expected. Results in current published data vary, probably due to the design of the studies, small number of patients and the inclusion of different types of constipation.

**Aims & Methods:** The main objective was to evaluate the short and long-term efficacy of sacral neuromodulation (SNS) in patients with chronic slow transit constipation (CSTC). Secondary outcomes were to evaluate adverse effects of implantation of the device and to correlate the efficacy with transit time and anorectal manometry (AM) data.

**Methods:** a multicenter, controlled, crossover randomized, double-blind trial was designed. Patients with CSTC (< 2 bowel movements (BM)/week; refractory to maximum conservative available treatment) were included for 4 weeks of peripheral nerve evaluation (PNE), the ones with response in BM (>3times/week), decreased intake of laxatives (reduction >50 % of laxatives or enemas/week) and subjective improvement (VAS), were implanted with SNS. Patients were randomly included in a 6-week ON and OFF stimulation period separated by a 2-week washout phase. After the randomization all stimulators were left in ON. A stool diary (4 weeks), visual analog scale (VAS), Cleveland Clinic Constipation Score (CCCS), Short Form Health Survey (SF-36) and a local validated survey for constipation (CVE-20) were evaluated at 6 and 14 weeks, every 3 months during the first year and then once a year. CTT and AM were performed after 6 months and subsequently every year.

**Results:** 19 out of 26 patients met inclusion criteria (18 women, median age 52.74 years). 13 (68%) responded to PNE and underwent permanent SNS implantation, mean follow-up of 25.98 ± 12.65 months. When analyzing ON and OFF periods, significant improvement in successful BM (21.64 vs 15.18)  $p < 0.01$ . During the follow-up and at the end of it, 9 out of 15 variables of the stool diary improved significantly compared to baseline, as well as CCCS (27.66 vs 10.99,  $p < 0.001$ ) and VAS (92.79 vs 47.71  $p < 0.001$ ). Quality of life evaluated by SF-36 improved except in social impairment and with CVE-20, specific for constipation, it improved in most aspects except in emotional aspects.

Anal pressures did not change, whereas rectal sensitivity for urgency decreased significantly. Changes in CTT (Fig 2) were also significant (171 +/- 9 vs 116 +/- 23,  $p < 0.004$ ). No severe adverse events were registered, only mild sacral/anal pain or in the implantation site.

**Conclusion:** In a selected group of patients with CSTC, SNS implantation can be an effective treatment and is associated with an improvement in CTT.

## P1202 METAGENOMIC ANALYSIS OF INTESTINAL MICROBIOTA AND MYCOBIOTA AMONG DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME PATIENTS FROM ARGENTINA

Bustos Fernandez L.<sup>1</sup>, Man F.<sup>2</sup>, Dorribo C.<sup>1</sup>, Lasa J.S.<sup>1</sup>

<sup>1</sup>CMBF, Buenos Aires, Argentina, <sup>2</sup>Gastro, Buenos Aires, Argentina

**Contact E-Mail Address:** luisbustosfernandez@gmail.com

**Introduction:** It has been suggested intestinal microbiota is associated with the development of diarrhea-predominant Irritable Bowel Syndrome (IBS-D). There is scarce evidence regarding this aspect among IBS-D patients from a South American population. Additionally, intestinal mycobacteria has not been exhaustively studied on this patients

**Aims & Methods:** To describe bacterial and fungal composition of intestinal microbiota among Argentinean patients with IBS-D.

Adult patients with IBS-D (Rome III criteria) from Buenos Aires, Argentina were consecutively enrolled. One fecal sample per patient was collected for microbiota and mycobacteria analyses. Patients completed the IBS Symptom Severity Scale (IBS-SSS). Demographic features were assessed as well as stool consistency via the Bristol Stool Scale. After genomic DNA extraction and purification, bacterial and fungal composition of fecal samples

were analyzed based on 16S rDNA and ITS2 sequencing respectively. Correlation between microbial and fungal abundance and the clinical features was assessed by Pearson correlation test.

**Results:** 71 patients fulfilling inclusion criteria were enrolled. *Firmicutes* was the predominant phyla (73.61%), followed by *Bacteroidetes* (13%). A relatively elevated proportion of *Proteobacteria* (8%) was identified. *Alis-tipes* was the most represented genus. When analyzing correlations between microbiota composition and different clinical features, we found a negative correlation ( $r = -0.5$ ,  $p = 0.003$ ) between stool consistency score and butyrate-producing microorganisms, such as *Butyricicoccus* and *Lach-nospiraceae* UCG010 genera. Symptom severity assessed by IBS-SSS was positively correlated with the abundance of *Victivallaceae* uncultured or-ganisms, *Synergistes* and *Ruminococcus gnavus* groups genera ( $r = 0.42$ ,  $0.33$  and  $0.32$  respectively,  $p = 0.05$ ). ITS2 DNA sequences analysis showed that the predominant fungal phyla was *Ascomycota* (89.12%), followed by *Basidiomycota* (2.78%); *Saccharomyces*, *Debaryomyces* and *Candida* were the dominant genera. No significant correlation between mycobiota com-ponents and clinical features was found.

**Conclusion:** We describe the bacterial and fungal composition of intestinal microbiota in IBS-D patients from Argentina. Although certain significant correlations were identified between microbiota composition and clinical features such as symptom severity, the clinical implications of such find-ings deserve further research.

**Disclosure:** Dr. Luis Bustos Fernandez is member of the Latin American Board of Biocodex

## P1203 THE AGEING GUT: SYMPTOMS COMPATIBLE WITH FUNCTIONAL GI DISORDERS IN OLDER ADULTS IN THE GENERAL POPULATION

**Contact E-Mail Address:** olafur\_palsson@med.unc.edu

**Introduction:** Little is known about changes in symptoms compatible with Functional GI Disorders (FGID) with increasing age at the population level, since most published studies have used clinical samples, and mostly focus on younger individuals.

**Aims & Methods:** A community sample of 6,300 individuals age 18 and older in the US, UK and Canada (2,100 in each country) completed a secure online survey. Quota-based sampling was used to ensure equal propor-tion of sex and age groups (40% aged 18-39, 40% aged 40-64, 20% aged 65+) across countries, and to control education distributions. The survey included the Rome IV Diagnostic Questionnaire, demographic questions, questionnaires measuring overall somatic symptom severity and quality of life, and questions on health care utilization, medications and surgical history.

**Results:** 6,300 individuals completed the survey. 374 were excluded due to inconsistent responses, leaving 5,926 (49.2% female; mean age  $47.4 \pm 17.1$  years) for our analyses; of these 4,700 were 18-64 years and 1,226 aged 65+. Symptoms compatible with at least one FGID were less prevalent in 65+ (32.9%) than in subjects aged 18-64 years (41.3%) ( $p < 0.0001$ ). This difference was significant in females (38.1% vs. 49.7%;  $p < 0.0001$ ), but not in males (29.0% vs. 32.6%;  $p = 0.08$ ), and in the US (31.0 vs. 42.2%;  $p < 0.0001$ ) and the UK (29.4% vs. 39.3%;  $p < 0.0001$ ), but not in Canada (38.1% vs. 42.4%;  $p = 0.12$ ). For symptoms compatible with upper FGID (esopha-geal and gastroduodenal), lower prevalence for most disorders was noted in the 65+ group (see Table).

For lower FGID (bowel and anorectal) a different pattern was seen, with lower prevalence for irritable bowel syndrome (IBS), functional abdominal bloating/distension and proctalgia fugax in 65+, no differences in preva-lence for the functional bowel disorders defined by abnormal bowel hab-its, i.e. functional constipation, functional diarrhea and opioid-induced constipation, whereas fecal incontinence was the only FGID that was more common in 65+ (Table). Regarding other factors, subjects aged 65+ re-ported less severe overall somatic symptoms, better mental, but worse

physical quality of life, had undergone abdominal surgery more frequent-ly, consumed more acid-reducing and pain medications, but less psycho-tropic medications, and used health care more frequently than younger adults ( $p < 0.0001$  for all).

**Conclusion:** In general, symptoms compatible with FGID decrease in older adults at the population level, with the exception of fecal incontinence which increases, and bowel habit disturbances, which remain unchanged in prevalence. This pattern needs to be taken into account when planning GI health care for a growing population of older adults.

Upper GI Disorders:	18-64 years	65+ years	p-value	Lower GI Disorders:	18-64 years	65+ years	p-value

## P1204 INCIDENCE OF POST-INFECTIOUS IRRITABLE BOWEL SYNDROME AND FUNCTIONAL DYSPEPSIA AFTER A NOSOCOMIAL NOROVIRUS GASTROENTERITIS OUTBREAK

Serra K., Surís G., Arjol C., Orobitg J., Camps Aler B., Gilabert P., Ibáñez-Sanz G., Ruiz-Cerulla A., Rodríguez-Alonso L., Rodríguez-Moranta F., Guardiola J. Bellvitge University Hospital, Gastroenterology, Barcelona, Spain

**Contact E-Mail Address:** katja.serra@bellvitgehospital.cat

**Introduction:** Bacterial and parasitic intestinal infections are well-known risk factors for development of post-infectious irritable bowel syndrome (PI-IBS), but the natural history of viral gastrointestinal infections is poorly understood. In May 2017, an outbreak of Norovirus gastroenteritis (GE) was reported at Hospital de Bellvitge, with 250 affected workers. In order to determine the incidence and risk factors of functional gastrointestinal dis-orders (FGID) after a Norovirus GE, we conducted this prospective cohort study with control group.

**Aims & Methods:** By e-mail, during the 4 weeks after the GE outbreak, we invited all hospital workers to participate, both the affected cases and those who not (controls). Questionnaires evaluating digestive symptoms using the Rome IV criteria for IBS and functional dyspepsia (FD) were sent at baseline and at 6 and 12 months. The severity of the GE episode was also assessed using the Vesikari scale.

**Results:** 71 cases and 84 controls answered the questionnaires. Baseline characteristics of cases and controls were similar. Prior to the infectious episode, the prevalence of IBS and FD was identical in both groups (IBS: 6% and 6% respectively; FD: 17% and 17% respectively,  $p = 0.9$ ). Excluding individuals with previous FGID, after 6 months of the GE the proportion of individuals who developed IBS or FD was higher in the case group than in the control group (IBS: 14% and 5% respectively,  $p=0.06$ ; FD: 18% and 3% respectively,  $p=0.006$ ). After 12 months, there were no differences in prevalence of IBS and FD between cases and controls (IBS: 5% and 4% respectively,  $p=0.7$ , FD: 9% and 6% respectively,  $p=0.5$ ). Independent predictors of FGID were the GE severity assessed by Vesikari scale (OR 1.32 IC95% (1.05-1.65),  $p=0.017$ ) and smoking (OR 3.9 IC95% (1.01-14.9),  $p=0.048$ ).

**Conclusion:** Functional gastrointestinal disorders are common after Norovirus gastroenteritis but they are often transient. The risk is determined by the severity of the infectious episode.

**Disclosure:** Nothing to disclose

## P1205 PREVALENCE AND IMPACT OF SELF-REPORTED CONSTIPATION IN THE GENERAL POPULATION

Pannemans L.<sup>1,2</sup>, Van den Houte K.<sup>1</sup>, Fischler B.<sup>3</sup>, Piessevaux H.<sup>4</sup>, Carbone F.<sup>1</sup>, Vanuytsel T.<sup>1,2</sup>, Tack J.<sup>1,2</sup>

**Contact E-Mail Address:** jasper.pannemans@kuleuven.be

**Introduction:** Chronic constipation, as defined by the Rome IV criteria, is a highly prevalent functional bowel disorder. However, as the criteria impose strict diagnostic thresholds, the prevalence of self-reported constipation is considerably higher, and there is major overlap with other bowel disorders, especially irritable bowel syndrome. We therefore conducted a pooled-analysis to evaluate the presence of self-reported constipation in the general population, its association with other bowel symptoms and its health-economic impact.

**Aims & Methods:** We used an internet survey (Medistrat internet panel, representative of the national adult population) to collect information on bowel symptoms' prevalence and their impact. In this analysis, we focused on patients who reported constipation symptoms over the last 12 months. First, we compared participants who experienced constipation to those who reported other bowel symptoms. Second, subjects reporting constipation were subdivided in painful constipation (PC), and those who did not experience abdominal pain (NPC).

**Results:** 1012 subjects (mean age 45.2±0.5 years, 62% females), of whom 217 (21%) reported constipation, completed the survey. Subjects reporting constipation experienced more other bowel symptoms than those without constipation [3(2-6) vs. 2(1-4),  $p<0.0001$ ]. The constipation group reported higher prevalence's of abdominal pain, altered stool frequency, alternating bowel habits and bloating (all  $p<0.05$ ). Further, constipated subjects reported higher symptom occurrence ≥3 days per month (65.9% vs. 52.9%;  $p<0.01$ ). Furthermore, the days of symptom occurrence significantly differed between the constipated participants and those with other bowel movements. Those with constipation had symptoms 1-2 days/week (28.6% vs. 22.7%), while those with other bowel movements experienced symptoms >2 days/month more often (35.7% vs. 24.9%); ( $p=0.036$ ). Finally, in total 44% of participants with constipation reported taking laxatives for their complaints, compared to just 8% of those whom reported other bowel symptoms ( $p<0.001$ ).

Of those with constipation, 134 patients reported NPC compared to 83 patients with PC (43±14.29 and 41±14.46 years, respectively). Women were significantly more represented in the group reporting constipation compared to those reporting other bowel symptoms (81.57% vs. 56.60%,  $p<0.0001$ ). Thirty-eight out of 83 PC patients (45.24%) fulfilled the Rome IV IBS criteria.

More patients with NPC compared to PC marked constipation as their most bothersome symptom (75% vs. 44%,  $p = 0.014$ ). In addition, excessive gas was experienced more frequently in the NPC compared to the PC group (64% vs. 39%,  $p = 0.044$ ). PC patients also reported more consultations with a medical doctor (40.24% vs. 14.29%,  $p<0.0001$ ), and more visits to specialists (50% vs. 10%, 95% CI 1.8-44.9), but not to general practitioners or other doctors in the past 12 months. Concerning medication, the use of anti-spasmodics was significantly higher in the PC-group compared to the NPC-group (38.24% vs. 12%,  $p=0.025$ ).

**Conclusion:** Self-reported constipation, often associated with other bowel symptoms, is a highly prevalent condition in the general population. Especially when abdominal pain is present, this generates major healthcare costs.

**Disclosure:** Nothing to disclose

## P1206 EXTRA-GASTROINTESTINAL SYMPTOMS CHARACTERIZE CLUSTERS OF FUNCTIONAL GASTROINTESTINAL DISORDERS THAT ARE NOT READILY DISTINGUISHED BY ROME III CRITERIA

Wilder-Smith C.H.<sup>1</sup>, Mohr Drewes A.<sup>2</sup>, Olesen S.S.<sup>2</sup>, Materna A.<sup>1</sup>

<sup>1</sup>Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland, <sup>2</sup>Aalborg University Hospital, Dept. of Gastroenterology and Hepatology, Aalborg, Denmark

**Contact E-Mail Address:** info@ggpp.ch

**Introduction:** Functional gastrointestinal disorders (FGID) are defined according to the Rome criteria by the grouping of non-specific GI symptoms without demonstrable underlying organic pathology. These definitions do not consider extra-GI symptoms or extra-GI pathology. The non-specific GI symptoms accompany a wide range of pathologies, including some without primary GI origin.

**Aims & Methods:** The aim of this large single-centre study was to characterize subgroups of FGID patients based on GI and extra-GI chronic symptom profiles using cluster analysis. Furthermore, the relationships between retrieved clusters and different Rome III groups of FGID were assessed. Successive male and female patients over 18 years of age referred to our GI practice for investigation of FGID and without evidence of organic disease were included. Patients completed a standardized, extensive GI and extra-GI symptom questionnaire focusing on their long-term symptom profiles and FGID was classified according to the Rome III criteria. The long-term symptom profile data were subjected to latent class analysis to identify unobserved clustering in the patient population and to find meaningful groups that were similar in their clinical assessment parameters. For each patient cluster, the prevalence of irritable bowel syndrome (IBS), functional dyspepsia (FD), functional bloating (FB), functional diarrhoea (FDa) and functional constipation (FCo) was determined.

**Results:** In 2083 patients with FGID (mean age 39.7 years, 70% females), the optimal number of clusters was 6. Face validity was apparent, with some distinctions seen between clusters in distributions of GI symptoms, but more apparent differences seen for distributions of extra-GI symptoms. GI fermentation-type symptoms were present across all 6 clusters and exclusively characterized Cluster 1 (35% of patients). The further clusters were distinguished by additional reflux-like (cluster 2: 19%), allergy-like (cluster 3: 6%), central nervous system (cluster 4: 17%), musculoskeletal (cluster 5: 10%), and generalized extra-GI (cluster 6: 14%) symptoms. Us-

	Cluster 1 GI fermentation-like (n=736)	Cluster 2 fermentation + reflux-like (n=117)	Cluster 3 fermentation + allergy-like (n=391)	Cluster 4 fermentation + central nervous system (n=348)	Cluster 5 fermentation + musculoskeletal (n=208)	Cluster 6 fermentation + generalized extra-GI (n=283)	p-values
Irritable bowel syndrome	195 (26)	35 (39)	138 (35)	126 (36)	68 (33)	110 (39)	0.001
Functional dyspepsia	605 (82)	91 (78)	373 (95)	319 (92)	182 (88)	269 (95)	<0.001
Functional bloating	67 (9)	12 (10)	7 (2)	8 (2)	9 (4)	5 (2)	<0.001
Functional diarrhoea	248 (34)	35 (30)	149 (38)	118 (34)	69 (33)	107 (38)	0.42
Functional constipation	89 (12)	16 (14)	67 (17)	75 (22)	34 (16)	63 (22)	<0.001

[P1206 Patients numbers (%) defined by Rome III subgroups in symptom clusters. There is considerable overlap between Rome groups.]

ing Rome III criteria, the prevalence of the FGID subtypes differed significantly between the 6 symptom clusters (see Table): IBS (26-39%;  $p=0.001$ ), FD (78-95%;  $p<0.001$ ), FB (2-9%;  $p<0.001$ ), FDa (30-38%;  $p=0.42$ ) and FCo (12-22%;  $p<0.001$ ). The differences in prevalence of FGID subtypes across the symptom clusters were statistically significant, but mostly not clinically relevant (see Table).

**Conclusion:** Patients with FGID fall into distinct subgroups based mainly on their extra-GI long-term symptoms. The Rome III definitions did not readily distinguish between subgroups of FGID across the clusters. Inclusion of extra-GI symptoms in the classification of FGIDs may be helpful in identifying subgroups with distinct underlying pathologies and thereby therapeutic possibilities.

## P1207 DOES INTESTINAL MICROBIOTA COMPOSITION DIFFER BETWEEN DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME PATIENTS WITH OR WITHOUT AN ALTERED LACTULOSE BREATH TEST?

Bustos Fernandez L.<sup>1</sup>, Man F.<sup>2</sup>, Dorribo C.<sup>1</sup>, Lasa J.S.<sup>1</sup>

<sup>1</sup>CMBF, Buenos Aires, Argentina, <sup>2</sup>Gastro, Buenos Aires, Argentina

**Contact E-Mail Address:** luisbustosfernandez@gmail.com

**Introduction: Background:** It has been suggested that the intestinal microbiota is associated with the development of diarrhea-predominant Irritable Bowel Syndrome (IBS-D). A significant proportion of such patients exhibit abnormal hydrogen excretion on lactulose breath tests, which could be associated with small intestinal bacterial overgrowth (SIBO). Patients with IBS-D and an abnormal lactulose breath test may show a different intestinal microbiota profile, which could be associated with such alterations in gas excretion.

**Aims & Methods:** To compare the bacterial and fungal composition of intestinal microbiota of IBS-D Argentinean patients with or without SIBO. Adult patients with IBS-D (Rome III criteria) were consecutively enrolled. One fecal sample per patient was collected for microbiota and mycobiota analyses. Furthermore, patients undertook a lactulose breath test (LHBT). An increase of at least 20 ppm in hydrogen excretion before 100 minutes was considered to be a criterion for SIBO. After genomic DNA extraction and purification, bacterial and fungal composition of fecal samples were analyzed based on 16S rDNA and ITS2 sequencing respectively.

**Results:** 71 patients were enrolled; mean age was  $43.5 \pm 14.5$  years and 62% were female. 76% were SIBO positive. No significant differences were found in terms of demographic features between SIBO-positive and SIBO-negative patients. 16S rDNA alpha and beta diversity analyses showed comparable microbiota composition between SIBO positive and SIBO negative. However, Akkermansia genus and upper-related taxa were significantly more abundant (+672%,  $p=0.009$ ) in SIBO negative patients. Furthermore, Turicibacter genus and upper-related taxa were also more abundant (+535%,  $p=0.04$ ) in SIBO negative patients. Cloacibacillus genus was greatly increased in SIBO negative patients (+8463%,  $p=0.0006$ ). On the other hand, Ruminococcaceae UCG 003 and Ruminoclostridium 9 genera were decreased in SIBO negative patients (-70% and -46.6%,  $p=0.003$  and  $0.0007$ , respectively). Mycobiota analyses showed no major difference.

**Conclusion:** Differences in terms of bacterial and fungal composition of intestinal microbiota were found between SIBO-positive and SIBO-negative IBS-D patients. Clinical implications of these findings require further investigation.

## P1208 THE INTRA-INDIVIDUAL VARIABILITY OF FECAL CALPROTECTIN IN HEALTHY INDIVIDUALS

Netzer S.<sup>1</sup>, Netzer P.<sup>1,2</sup>

<sup>1</sup>GastroZentrum Netzer AG, Bern, Switzerland, <sup>2</sup>Lindenhofspital, Bern, Switzerland

**Contact E-Mail Address:** serainanetzer@rocketmail.com

**Introduction:** Fecal Calprotectin (FC) is a marker for intestinal inflammation, which allows the clinician to distinguish between functional and organic intestinal illnesses, as well as to evaluate the activeness of disease

in chronic inflammatory bowel disease (IBD). There are singular studies that report day-to-day variability in FC concentration measured in patients with IBD. If such a variation also exists in healthy individuals has not been evaluated as of yet.

**Aims & Methods:** Our aim was to determine the intra-individual day-to-day variability of FC in the intestinally healthy. The results could influence the further management of patients with intestinal discomfort. To achieve this, 163 healthy volunteers without gastrointestinal symptoms, colitis related manifestations or intake of NSAID gave three stool samples of the morning bowel movement on three consecutive days. The samples were sent via mail. The FC-analysis was made by enzyme-linked immunosorbent assay (ELISA) method after Bühlmann (Rothen Medizinische Laboratorien AG Basel).

Material was financed by Netzer AG, analysis by MCL Laboratorien Niederrangen. The threshold to pathological FC-values was  $50 \mu\text{g/g}$ , as recommended in Switzerland. Volunteers with elevated values were investigated further, only those remained in the study who had no signs of organic gastrointestinal disease.

**Results:** 163 volunteers (aged 17-66y, mean 37y, median 32y,  $f=100$ ), showed a range of FC-values of 3 -  $2142 \mu\text{g/g}$ . The first measurement showed a range of 3 -  $587 \mu\text{g/g}$ , mean value 44.5, median 20, standard deviation (sd) 75.1. The second measurement showed a range of 6 -  $2142 \mu\text{g/g}$ , mean value 60.3, median 22, sd 183.4. The third measurement showed a range of 9 -  $699 \mu\text{g/g}$ , mean value 41, median 18, sd 73.7. Every one of the three measurement series showed only two values  $>400 \mu\text{g/g}$ . Of all 163 volunteers, 114 (69.9%) showed FC-values of  $50 \mu\text{g/g}$  and lower in all three samples, thus having inconspicuous results throughout. 49 volunteers (30.1%) showed at least one value deemed pathologic. Of these 49, 40 (24.5%) showed both normal and elevated ( $>50 \mu\text{g/g}$ ) values and 9 (5.5%) showed elevated values throughout. By applying a cut-off of  $100 \mu\text{g/g}$ , 26 volunteers (15.9%) showed at least one elevated measurement and only 4 (2.5%) had values consistently over  $100 \mu\text{g/g}$ .

**Conclusion:** The presented data show a high variability of FC in a short amount of time in a third of the healthy volunteers. This suggests several measurements of FC to be adequate to reach a decision if further investigation (e.g. endoscopy) is necessary. The mean value of three measurements could show a higher correlation to actual intestinal inflammation and could help reduce unneeded interventions. Further investigations in a non-healthy population are recommended. The data also support the question, if raising the cut-off to  $100 \mu\text{g/g}$  would be appropriate to keep the rate of false positive results low without missing relevant disease, as several investigators have recommended already.

**Contact E-Mail Address:** m.rostami@gmail.com

**Introduction:** The major dilemma in medical practice is the gluten tolerance assess in IBS patients and evaluation of symptoms in different dosage of gluten challenge. For this purpose, we designed a single-blind free diet controlled gluten challenge to report a true NCGS prevalence among IBS patients

**Aims & Methods:** In this trial, 40 participants were asked to follow low FODMAP+ strict gluten free diet for 6 weeks. Then, all patients were randomly allocated to one of the following groups:

Group A: patients received special bread containing of 8 g/ gluten for 2 weeks. Those who had tolerance to prescribed dose received 16 g/d for more 2 weeks. Then tolerated patients took 32 g/d for further 2 weeks; Group B: continued gluten free diet for more 6 weeks; Group C: received regular gluten containing diet for 6 weeks.

At the end, participants were asked to fill VASs scale to evaluate the improvement of symptoms, SF-36 and Zung questionnaire.

**Results:** After 6 weeks of following gluten free and low FODMAP diet, all IBS symptoms, except for defecation frequency, were significantly improved. In group A: 25% tolerated up to 8 g 20% to 16 g, and 55% to 32 g gluten. At the end of the study, no significant difference was found between groups in terms of pain, bloating, satiety, impact on community function, defecation and total score. In regard to SF-36 questionnaire, significantly lowest bodily pain was found in group C (A:  $3.93 \pm 1.44$ , B:  $4.71 \pm 2.33$  and C:  $3.29 \pm 0.95$ ) ( $p=0.02$ ). Borderline significant difference was detected for social functioning score ( $p=0.049$ ). There was significant reduction regarding nervous and anxiety score ( $p=0.021$ ), calmness ( $p=0.047$ ), dry and warm hands ( $p=0.02$ ) and easily asleep ( $p=0.01$ ) in group B compared other groups.

**Conclusion:** Most patients with irritable bowel syndrome have tolerance to gluten. But following gluten free diet would decrease anxiety in IBS patients.

**Disclosure:** Nothing to disclose

## P1210 OSTEOPONTIN HAS NO ROLE AS A DIAGNOSTIC BIO-MARKER IN IRRITABLE BOWEL SYNDROME (IBS)

Mostafa H.<sup>1</sup>, Zaghoul M.<sup>2</sup>, Khalil G.I.<sup>3</sup>, Dwidar F.I.<sup>4</sup>

<sup>1</sup>Alexandria University, Medical Research Institute, Internal Medicine, Alexandria, Egypt, <sup>2</sup>Kafrelsheikh University, Faculty of Medicine, Hepatology, Gastroenterology and Infectious Diseases, Alexandria, Egypt, <sup>3</sup>Alexandria University, Medical Research Institute, Chemical Pathology, Alexandria, Egypt, <sup>4</sup>Alexandria University, Medical Research Institute, Alexandria, Egypt

**Contact E-Mail Address:** mariam\_zaghoul@med.kfs.edu.eg

**Introduction:** Osteopontin (also known as early T lymphocyte activation Eta-1), a cytokine which promotes Th1 immune responses. Several recent reports have suggested an important role for osteopontin in the pathogenesis of inflammatory bowel diseases as well as its possible use as a bio-marker. It has been proposed that inflammation may play a role in IBS, based on several lines of evidence.

**Aims & Methods:** The aim of this work was to find out the diagnostic potential of osteopontin as bio-marker in irritable bowel syndrome. 40 patients, who were fulfilling Rome IV criteria for IBS, were investigated. As well as 20 healthy subjects were enrolled as controls. All subjects were subjected to: medical history taking, thorough physical examination and laboratory investigations which included: Routine laboratory tests, fecal calprotectin assessment and serum osteopontin assessment. Colonoscopy and histopathological examination of biopsies from the colon were done for patients only after informed consent.

	IBS Cases (n = 40)	Control (n = 20)	t	p
ESR at 1st hrs (mm/hr)				
Mean $\pm$ SD	12.13 $\pm$ 2.05	11.80 $\pm$ 2.38	0.548	0.586
Median	13.0	13.0		
ESR at 2nd hrs (mm/hr)				
Mean $\pm$ SD	24.55 $\pm$ 3.17	23.25 $\pm$ 4.38	1.315	0.194
Median	25.0	23		
CRP (mg/l)				
Mean $\pm$ SD	4.44 $\pm$ 1.53	4.13 $\pm$ 1.10	0.791	0.432
Median	4	4		
Calprotectin (mg/kg)				
Mean $\pm$ SD	28.60 $\pm$ 19.24	21.75 $\pm$ 9.08	1.872	0.066
Median	19	20		
Osteopontin (ng/mL)				
Mean $\pm$ SD	2.92 $\pm$ 0.91	2.50 $\pm$ 0.78	1.748	0.086
Median	2.80	2.25		

[Comparison between the two studied groups according to the markers of inflammation]

**Results:** Out of 40 patients (group I); 20 were IBS-D (diarrhea predominant), 14 IBS-C (constipation predominant) and 6 IBS-A (alternating diarrhea and constipation). Both group I and group II were matched as regard age and sex. There were no statistical significant difference between the two studied group in routine laboratory investigations. Stool analysis was

normal in all subjects. No statistical significant difference between the two groups as regard the mean erythrocytes sedimentation rate (ESR) at the first and second hour [ $p = 0.586$  &  $0.194$  respectively]. Also no statistical significant difference between the two groups as regard the mean C-reactive protein (CRP), the mean fecal calprotectin level and the mean serum osteopontin level [ $p = 0.432$ ,  $0.066$  &  $0.086$  respectively]. As regard colonoscopic findings in IBS patients: Hyperemia was found in 4 patients, polyps were found in 2 patients, diverticulae, ulcers and mass were not found in any patients. Regarding histopathological findings of colonoscopic biopsies in IBS patients: Non specific colitis was found in 30 patients and 10 patients were normal. Lymphocytic colitis was not found in any of the patients group.

**Conclusion:** Osteopontin has no role as a diagnostic bio-marker in IBS. Further work on a larger patients sample will be required to study the probability of the use of osteopontin as non invasive bio-marker in the differentiation between functional and inflammatory gastrointestinal disorders.

**Contact E-Mail Address:** mike.jones@mq.edu.au

**Introduction:** An objective method of differentiating functional gastrointestinal disease (FGID) from health remains an elusive goal although there has been some promising work using biomarkers<sup>1</sup>. Another potential avenue comes from work showing that FGID individuals have altered central (brain and central nervous system) processing of visceral stimuli relative to healthy controls<sup>2</sup>. Further, FGID individuals appear to have selective attention to gastrointestinal words<sup>3</sup> suggesting an attentional bias towards GI-relevant terms. Individuals meeting criteria for FGIDs have also been shown to exhibit exaggerated threat perception<sup>4</sup>. Previous work has taken either an experimental approach, eg fMRI studies of acute, regional brain activation in response to noxious stimuli, or an epidemiological approach based on measuring symptom experiences by questionnaires or daily diary record. How well gastrointestinal disease might be differentiated from health based on a combination of these distinct objective and subjective profiles is lacking in the literature.

**Aims & Methods:** This study aimed to determine whether a combination of objective responses to experimental stimuli (EEG, below) and subjective but prospectively recorded, naturalistic responses to daily events (EMA, below) can differentiate symptomatic and asymptomatic individuals. 28 GI symptomatic and 27 asymptomatic individuals were recruited from the community. Organic pathology and current mood disorders were ruled out by self-report. All subjects viewed 20 GI-illness-related words, 20 negatively-valenced words, and 20 neutral words from a validated word bank six times in a randomised order. Attention was measured through ERP peak amplitude in the Occipital region measured via an electroencephalograph (EEG) in the P100 period (75-125 milliseconds after word stimulus presentation), as this clearly corresponds to pre-attentional processing. Average level and variability in gastrointestinal and non-gastrointestinal pain

as well as mood were recorded prospectively using ecological momentary assessment<sup>5</sup> (EMA) via a smartphone app over a 14-day period. Total GI symptom burden was measured through the gastrointestinal symptom rating scale<sup>6</sup> (GSRS). Discrimination between symptomatic and asymptomatic subjects was evaluated through the area under the ROC curve (AUC).

**Results:** GI symptomatic subjects yielded a higher average P100 response to all stimulus categories than asymptomatic subjects ( $b=1.28$ , 95% confidence interval 0.74, 1.82,  $p<.001$ ), consistent with enhanced threat perception but not limited to GI concepts. A combination of increased P100 response amplitude, higher average level and greater variance in current mood and higher average level and greater variance in GI pain and higher average level and greater variance in non-GI pain yielded strong discrimination between symptomatic and asymptomatic subjects ( $AUC=0.90$ ) which increased to  $AUC=0.93$  if total GI symptom burden is included.

**Conclusion:** In contrast to a large body of past work which has used an individual's recall of past symptom experience to classify individuals as diseased or healthy, this study demonstrated prospectively that FGID individuals have a distinct day-to-day experience of both GI and extra-GI pain and respond to experimentally-induced stimuli differently to asymptomatic individuals. The combination of these responses provide good differentiation of symptomatic individuals from healthy controls. The use of non-invasive, inexpensive stimuli offers a promising avenue of investigation for objective diagnostic testing.

**Introduction:** Current treatment for FGIDs categorise patients based on symptoms and attempt to target potential biological disease mechanisms, yet extensive literature suggests FGIDs result from interactions between biological, psychological and social factors. Therefore, a biopsychosocial framework for treatment for FGIDs should be considered. We have previously demonstrated that an Integrated Care Clinic (ICC) approach incorporating a multidisciplinary integrated treatment program in the setting of a gastroenterology outpatient department (OPD) significantly reduces overall gastrointestinal (GI) symptom burden in FGID patients. This study aimed to identify whether the effect of the intervention is moderated by the severity of GI symptom burden at baseline, to help identify predictors that may characterise a patient's response to a multidisciplinary integrated treatment program.

**Aims & Methods:** This study explored total GI symptom burden at baseline as a predictor of reduction in total GI symptom burden post intervention. 51 consecutive gastroenterology outpatients recruited to the ICC were included. These patients received a team-based integrated care approach including individualised assessment and treatment sessions with a gastroenterologist, general practitioner, psychologist, dietician and exercise physiologist, as deemed necessary by the team to meet the patient's needs.

Patients were grouped into total GI symptom burden-stratified subgroups according to baseline gastrointestinal symptoms severity as measured using the validated Structured Assessment of Gastrointestinal Symptoms scale (SAGIS) which measures the intensity of 22 upper and lower gastrointestinal symptoms, 0 = no problem to 4 = very severe problem for a maximum score 88 points. Stratification groups were based on mean baseline score ( $M = 27$ ): low for total SAGIS score below 27 and high for total SAGIS score above 27. Within-subject changes were compared using a paired sample t-test and change scores between GI symptom severity strata were compared using an unpaired t-test.

**Results:** Mean age was 41.7 (SD=14.90) years with 84% females. In total, 53% of patients had irritable bowel syndrome, 10% had functional dyspepsia, and 37% had overlap of both. The mean baseline score was 27 and the overall mean change in total GI symptom burden post intervention was 9 units; by total GI symptom burden strata the mean was 4 units for the GI symptom burden low group and 14 units for the GI symptom burden high group. Total GI symptom burden significantly decreased from baseline ( $p < 0.015$  by paired t-tests within both groups).

However, the decrease was higher in the GI symptom burden high group than the GI symptom burden low group ( $p = 0.002$  comparing the change scores between the two groups using an unpaired t-test). Clinically significant reductions in total SAGIS score were present in 70% of the total GI symptom burden high group compared to 33% of the total GI symptom burden low group.

**Conclusion:** These results indicate that total GI symptom burden independent of varying GI total symptom burden is reduced by a multidisciplinary integrated treatment approach in FGID patients. However, the reductions were substantially greater in patients with more severe manifestations of FGID, and this will need to be considered in future studies on the cost-benefit analysis of multidisciplinary treatment approaches.

**Introduction:** Recruitment can be a major challenge to randomized clinical trials, and failure to achieve recruitment goals can endanger the overall quality of the study and lead to costly delays and non-completion [1]. In functional bowel disorder (FBD) studies, recruitment rates are particularly low and many studies fail to recruit patients on time and within budget [2]. Several factors attribute to this failure. Although FBD is relatively common, patients are often discharged quickly and have limited chance to build a rapport with the research team. Conversely patients who are not discharged often have severe refractory symptoms, rendering them far from ideal for most trials. Patients are often reluctant to come off laxatives/anti-diarrhoeals, thus are not keen to risk being on placebo, and are less willing to undertake the trial burden compared to studies of higher mortality conditions.

**Aims & Methods:** Our aim was to design a study for irritable bowel syndrome with diarrhoea (IBS-D) that was both deliverable and would maximise recruitment potential. The trial RELIEVE IBS-D, is currently recruiting 430 patients in 27 sites in the UK studying the effectiveness of the intestinal adsorbent Enterosgel for the treatment of IBS-D. We developed a study that was suitable for primary and secondary care recruitment, and that included pragmatic (real life) inclusion / exclusion criteria with low screen thresholds. Patient involvement (PPI) was used in both study design and all patient-facing documentation. An open label phase was included so that all patients received the intervention, as it is known that obtaining a form of personal gain through participation is a primary factor influencing participation in clinical trials.

Rescue therapy was only restricted for baseline and a re-screening phase was introduced to compensate for the variable nature of the condition [3]. Patient burden was restricted with a reduced visit number, low questionnaire number and an online daily diary with text-based reminders and limited number of questions. Following the guidelines, participants were encouraged to adjust their daily dosage during both phases based on their symptoms to better imitate "real world conditions" [4].

Several recruitment strategies are being employed. We use primary care patient identification centres for hospital sites to reduce attrition rates [5] and we contact eligible patients through the new ContactME IBS registry that enrolls patients who have expressed an interest in research participation. A number of sites are also leveraging Clinithink Inc software that allows extensive mining of hospital records for eligible patients. We have used various forms of advertising through social media to gain a good representation of the clinical profile of IBS patients in the general population.

**Results:** The study began in October 2018 with recruitment starting in November, as of end of March 2019, 94 patients have been consented and 41 randomised. These rates are expected to increase as the main recruitment strategies will be employed in April to coincide with IBS awareness month.

**Conclusion:** Although recruitment is still a challenge, careful consideration during study design and employment of a comprehensive range of recruitment strategies can go some way to mitigate any potential issues from failure to recruit.

**Introduction:** Irritable bowel syndrome (IBS) is one of the most common functional gastrointestinal (GI) disorders with a prevalence of 5-10%. Previous evidence shows that GI symptoms can be triggered by dietary intake, resulting in patients avoiding certain foods in order to relieve these symptoms.

**Aims & Methods:** We aimed to enhance our understanding of food intake as trigger for symptom generation by correlating habitual dietary intake and symptom outcomes. Two IBS cohorts were included, using the first cohort for exploratory (hypothesis-generating) and the second for confirmatory (hypothesis-testing) purposes. Patients kept 4-day food diaries of

their habitual food intake and simultaneously filled out symptom questionnaires, including information about bowel habits (Bristol stool form scale), quality of life (IBS-QOL), and IBS symptom severity (IBS-SSS and GSRS-IBS). Nutrient intake was calculated using dedicated software, and additionally FODMAP intake in the exploratory cohort, and health-consciousness of the diet in the second cohort were determined. We tested linear correlations between dietary variables and symptom variables and conducted a principal component analysis (PCA) with two principal components of the dietary intake data of both cohorts. Moreover, we tested mediation in the association between total calorie intake and IBS symptom severity.

**Results:** The exploratory cohort (N=112, 75% female, aged 33.5±11.3 years, body mass index (BMI) 23.1±3.8 kg/m<sup>2</sup>, IBS-SSS 310.5±83.7, 23% IBS-constipation (IBS-C), 44% IBS-diarrhea (IBS-D), 7% IBS-mixed (IBS-M), 26% IBS-unsubtyped (IBS-U)) and confirmatory cohort (N=76, 81% female, aged 42.2±16.4 years, BMI 24.3±3.8 kg/m<sup>2</sup>, IBS-SSS 308.1±66.1, 39/16/3/42% IBS-C/D/M/U patients) demonstrated various statistically significant food-symptom correlations. Total caloric intake correlated with overall GI symptom severity (GSRS-IBS) (exploratory (e): R=-0.213, p=0.026; confirmatory (c): R=-0.274, p=0.018), fiber intake with hard (R<sub>e</sub>=-0.217, p<sub>e</sub>=0.027) and loose bowel movements (BM) (R<sub>c</sub>=0.247, p<sub>c</sub>=0.037), and legume intake with quality of life (R<sub>e</sub>=-0.296, p<sub>e</sub>=0.002; R<sub>c</sub>=-0.269, p<sub>c</sub>=0.029). In the PCA, PC 2 was negatively correlated with the IBS-SSS score (R=-0.27, p<0.001). PC 2 was characterized by a higher intake of calories (loading: 0.54) and legumes (loading: 0.38), but a lower intake of diet drinks (loading: -0.40), and less nighttime consumption (loading: -0.40). No significant correlations were found between FODMAP intake and IBS symptom severity, nor between the health-consciousness of the diet and IBS symptom severity or quality of life. The negative association between total calorie intake and IBS symptom severity was mediated by not eating and not being hungry due to symptoms.

**Conclusion:** Based on this analysis of two IBS cohorts, we were able to demonstrate associations between dietary intake and GI symptoms as well as disease-specific quality of life. Patients with severe IBS may have reduced energy intake because of GI symptoms. Further characterization of food-symptom associations can lead to the development of personalized dietary advice in the management of IBS.

**Introduction:** Irritable Bowel Syndrome (IBS) is a disorder of brain-gut interaction characterised by chronic and recurrent abdominal pain, altered defecation and sensitivity to stress. One of the important advances in the knowledge of the origin of IBS is the common finding of a dysfunction of the intestinal barrier (permeable barrier) associated with structural and molecular alterations in the intercellular junctions and the presence of immune activation and low-grade mucosal inflammation, particularly in IBS-diarrhea (IBS-D). Mucoprotectants such as the combination of xyloglucan + pea protein and tannins + xylo-oligosaccharide (XPPTX) may be useful to control permeability changes induced by life stress.

**Aims & Methods:** Our hypothesis is that XPPTX, through the establishment of a mucus-associated biofilm, exerts a direct local protective effect capable of preventing the increase of intestinal permeability and the immunoinflammatory response triggered by acute experimental stress in patients with IBS-D. Therefore, we aimed to:

- To determine the effect of the administration of XPPTX on intestinal permeability induced by acute stress in the jejunum of patients with IBS-D, and to
- Evaluate the effect of the administration of XPPTX on changes in tight junctions and intestinal microinflammation induced by acute stress in the jejunum of patients with IBS-D.

**Methods:** We designed a randomised, double-blinded, placebo-controlled pilot study in patients with IBS-D. In a first step, 28 healthy subjects (15 F) were included to determine control baseline small bowel permeability (SBP) using the lactulose/mannitol test for 2 h. In a second step, we evaluated SBP in 104 patients with IBS-D (70 F). Out of these, thirty three IBS-D showed values of baseline SBP over percentile 75 of healthy (188,4 mg/L of mannitol). Twenty-two were randomised to receive 7 days of oral (b.i.d.) XPPTX (n=10, 6 F) or placebo (cornstrach)(n=12, 8 F), followed by a determination of SBP after 15 min of acute experimental stress (cold pressor test) and a jejunal biopsy using Watson's capsule. Biopsies were processed for histology (H&E staining), mast cell (CD117), intraepithelial lymphocytes (CD3) & eosinophil counts (H&E), mucus evaluation (PAS-Alcian blue), and transmission electron microscopy (TEM). In addition, background stress levels (tests of Holmes-Rahe & Cohen), depression (Beck's inventory) and severity of IBS (IBS-SSS) were also evaluated.

**Results:** There were no differences in baseline demographics, background stress, psychological characteristics and IBS-SSS between XPPTX and placebo groups. We did not identify any difference in mucus evaluation, mast cell, lymphocytes and eosinophil counts between groups. Compared to baseline, both placebo (26.8±39.6%) and XPPTX (31.1±21.2%) reduced significantly SBP ( $P < 0.0001$ ) after cold stress but without differences between them ( $P=0.79$ ). Response to XPPTX was much more consistent and homogeneous than placebo. Mean (Placebo=23.1±3.3 nm; XPPTX=23.5±1.6 nm) and maximum (Placebo=28.3±5.7 nm; XPPTX=28.4±1.9 nm) intercellular space at the level of apical tight junctions was similar in both groups, though again response to XPPTX was much more consistent and homogeneous than placebo. No correlations were found between permeability and clinical and psychological parameters.

**Conclusion:** The mucoprotectant XPPTS significantly reduces post-stress intestinal permeability in IBS-D but is not superior to placebo in this small pilot study. Future studies with higher number of patients are needed to determine the efficacy of XPPTX in controlling SBP in IBS-D and its potential clinical benefit.

**Disclosure:** This study has been funded by Novature S.L.

## P1216 THE EFFECT OF LACTOBACILLUS PLANTARUM ON SYMPTOMS AND THE MICROBIOME IN SUBJECTS WITH IRRITABLE BOWEL SYNDROME

Önning G.<sup>1,2</sup>, Robertson A.-K.<sup>1</sup>, Larsson N.<sup>1</sup>, van de Walle V.<sup>3</sup>, Boekhorst J.<sup>4</sup>

<sup>1</sup>Probi AB, Lund, Sweden, <sup>2</sup>Lund University, Pure and Applied Biochemistry, Lund, Sweden, <sup>3</sup>PreCare Trial & Recruitment, Beek, Netherlands, <sup>4</sup>NIZO, Ede, Netherlands

**Contact E-Mail Address:** gunilla.onnng@probi.com

**Introduction:** Irritable bowel syndrome (IBS) is a complex condition with variable symptomatology involving a broad range of both physiologic and psychological symptoms, such as mucosal integrity and function, gut function, visceral perception and brain-gut dysregulation. Intake of a probiotic bacteria is one alternative to improve IBS.

**Aims & Methods:** The aim of the study was to investigate if *Lactobacillus plantarum* DSM 9843 (LP) could improve symptoms and affect the faecal microbiome in subjects with IBS.

After a 2-week run-in period, subjects with IBS according to Rome III criteria, were randomized to receive either LP or placebo capsules for 4 weeks. A total of 197 male and female patients with IBS were included at two sites in the Netherlands (PreCare Trial & Recruitment). An irritable bowel severity scoring system (IBS-SSS) form was filled in at each visit (Day -14, Day 1 and Day 28). Abdominal pain, frequency of bowel movements and stool consistency were reported daily. Faecal samples were collected before and after the intervention and the microbiome analysed with 16S rRNA gene profiling (NIZO).

**Results:** There was no significant difference in abdominal pain, IBS-SSS, bloating, frequency of bowel movements and stool form when comparing subjects that consumed LP or a placebo product. However, a subgroup analysis on the subjects that had IBS with predominant constipation (IBS-C, 25% of the subjects), showed that IBS-SSS was reduced significantly

in the LP group compared with the placebo group (Table 1). The IBS-SSS form is validated and includes five questions: abdominal pain (severity, frequency), abdominal distension, satisfaction with bowel habits and how IBS affects and interferes with the life in general (Francis *et al.* 1997). The maximum score is 500 (100 scores/question) and a reduction with 50 scores indicates an improvement.

	LP (n=20) Mean (SE)	Placebo (n=27) Mean (SE)	P-value between treatments, t-test
Before treatment	249 (10)	260 (8)	
After 4 weeks treatment	183 (19)	251 (17)	
Change	- 66 (20)	- 9 (16)	0.027

[Table 1. Change in IBS-SSS after intake of *Lactobacillus plantarum* DSM 9843 or placebo. Subgroup with IBS-C.]

Analysis of the faecal microbiome showed that the family Lactobacillaceae was more abundant in the group that consumed LP than in the placebo group, reflecting the presence of the given *Lactobacillus plantarum* strain in the faeces. Furthermore, the genus *Oscillospira* was significantly higher in the LP group compared to the placebo group. A lower abundance of this genus has earlier been found in infants suffering from Crohn's disease (Kaakoush *et al.* 2012) and in patients with flatulence (Manichanh *et al.* 2014).

**Conclusion:** A beneficial statistically significant effect of treatment with LP as compared with placebo on symptoms associated with IBS could not be demonstrated. Subgroup analysis of subjects with IBS-C showed a beneficial effect on the total IBS-SSS score after consumption of LP. Minor changes in the microbiome were found except an increase of the given bacteria and of *Oscillospira* after intake of LP. Further studies are suggested to investigate the mechanism behind the beneficial effect on IBS symptoms shown after consumption of LP in subjects with IBS-C.

**Contact E-Mail Address:** shuwen.tay@mohh.com.sg

**Introduction:** Irritable bowel syndrome (IBS) is a prevalent condition which negatively impacts quality of life and places a large burden on health-care globally. Current pharmacological treatment has variable efficacy and often has unsatisfactory results. Traditional Chinese Medicine (TCM) is widely accepted in Asia and many seek it as alternative therapy. To date, attempts to characterize TCM efficacy universally suffer from poor scientific

method or they do not faithfully replicate authentic TCM best practice. We sought to address these deficiencies combining the best of TCM practice with western medicine in this study.

**Aims & Methods:** This was a randomised, double blind, placebo controlled parallel group study carried out in a single centre in Singapore. Patients who fulfilled ROME III criteria for IBS-Constipation predominant subtype (IBS-C), and the TCM syndrome of Liver Qi stagnation (LCS) were recruited. To reflect typical TCM practice, LCS diagnosis can be further “modified” into 3 subtypes based on a standardised TCM diagnostic criteria. TCM treatment consist of a standardized core herbal formula specific for treatment of LCS or a modified formula based on the LCS subtype. After a 2-week run in, subjects were randomised (1:1) to receive the prescribed TCM treatment or placebo with 10% of active core ingredients for 8-weeks. The primary endpoint was change of IBS-Symptom Severity Score (IBS-SSS) at end of treatment compared to baseline. Secondary outcomes include change in individual gastrointestinal symptoms, Bristol stool scale, bowel movement, psychological scale, quality of life and adverse events. Analysis was performed based on Intention to treat using 2-sided T test and chi-squared as appropriate. Ethics Board review was obtained. The trial was registered on Singapore and international (ClinicalTrials.gov) trial registries prior to recruitment.

**Results:** 59 patients were screened, 40 were randomized and 39 patients with valid data were analysed. Patient characteristics and primary outcome is shown in table 1. Patient characteristics were similar in both arms. There was a non-significant benefit in IBS-SSS in the TCM group vs the control group with adjusted difference by baseline of -28.0 (95% CI = -84.9, 28.95; p=0.325). TCM was well tolerated, there was no serious adverse events in both arms, only 2 patients from the placebo arm withdrew from the study. One due to body ache which resolved after cessation of treatment, another due to hair loss. There was no significant difference in the other secondary outcomes.

	TCM			Control			p-value
Female (%)	90			74			0.19
Mean Age (years)	43.3			42.7			0.90
Race							
Chinese (%)	95			84			0.24
	Baseline	End of Treatment Response	Change	Baseline	End of Treatment Response	Change	
IBS-SSS mean (SD)	256.2 (101.0)	205.4 (103.8)	-50.8 (49.83)	227.3 (102.6)	215.6 (118.9)	-11.7 (106.99)	0.32

[Patient Characteristics and Primary Outcome]

**Conclusion:** A TCM treatment regime which allowed for subtype modification reflecting typical TCM practice showed a non-significant benefit in patients with constipation predominant irritable bowel syndrome in a randomised, double blind, placebo-controlled study design. The treatment was well tolerated with minimal side effects. Larger RCTs should be conducted to further validate this.

**Disclosure:** Nothing to disclose

## P1218 THERAPY OF IRRITABLE BOWEL SYNDROME AND OTHER FUNCTIONAL GASTROINTESTINAL DISEASES WITH STW 5 IN A SELF-MEDICATION SETTING

**Contact E-Mail Address:** careen.fink@bayer.com

**Introduction:** Surveys on everyday life therapeutic use and patient satisfaction are important tools to gain real life evidence and understanding of patients' needs for medicinal products [1].

The herbal combination preparation STW 5 has been available in the German market for more than 58 years [2]. Its scientific evidence for treatment of functional gastrointestinal diseases like irritable bowel syndrome and functional dyspepsia includes a multitude of clinical, pharmacological and toxicological studies [3].

**Aims & Methods:** Up to now, few data on self-assessed usage behavior, perception of effectiveness and tolerability for STW 5 are available. Therefore, pharmacy customers with product desire or recommendation for STW 5 were asked whether they would participate in a survey on the product. Patients received a questionnaire regarding demographic data, gastrointestinal complaints, effectiveness, tolerability and satisfaction with the product. They were asked to answer it during the next few days and send it back to a contract research institute within a week.

**Results:** Data from 843 patients were evaluated. 29.4 % were male and 70.6 % female. The majority was in the 30-49 age range. In 384 patients, complaints were related to the upper, in 139 to the lower abdomen, in 311 patients to both regions. In 7.3 % of the 384 patients a functional dyspepsia had been diagnosed, in 16.9 % of the 139 patients an irritable bowel syndrome. Up to 64% of the patients specified a good or very good improvement of the respectively predominant symptom with treatment of STW 5. Symptom relief was perceived as fast and covered the comprehensive spectrum of complaints. Tolerability was rated good to very good in 97.4 % of all patients and did not differ between patient groups. Correspondingly 93.2 % of the users were “very satisfied” or “satisfied”. 91 % of the customers would recommend STW 5 to others for treating their complaints.

**Conclusion:** Overall, it can be concluded that this patient survey gives a reliable picture of the behavior of users of STW 5 in a self medication setting, with high satisfaction values as well in irritable stomach as in irritable bowel syndrome and single symptoms. The favorable tolerability ratings confirm the ratings from the clinical studies on the product.

**Introduction:** Over half of patients with irritable bowel syndrome have either diarrhoea (IBS-D) or a mixed stool pattern (IBS-M). The relative ef-

ficacy of pharmacological therapies in IBS-D and IBS-M is unclear in the absence of head-to-head trials. We conducted a network meta-analysis to resolve this uncertainty.

**Aims & Methods:** We searched MEDLINE, EMBASE, EMBASE Classic, the Cochrane central register of controlled trials, and clinicaltrials.gov through January 2019 to identify randomised controlled trials (RCTs) assessing the efficacy of pharmacological therapies in adults with IBS-D or IBS-M. Trials included in the analysis reported a dichotomous assessment of overall response to therapy at 8 to 12 weeks of follow-up, and data were pooled using a random effects model. Efficacy and safety of all pharmacological therapies were reported as a pooled relative risk of remaining symptomatic with 95% confidence intervals (CIs) to summarise the effect of each comparison tested. Treatments were ranked according to their P-score.

**Results:** We identified 21 eligible RCTs (7 alosetron, 5 ramosetron, 2 cilansetron, 1 ondansetron, 2 rifaximin, 4 eluxadoline), containing 10654 patients. With the exception of ondansetron, all drugs were superior to placebo, according to the Food and Drug Administration (FDA)-recommended endpoint of improvement in both abdominal pain and stool consistency for trials in IBS. Alosetron 1mg twice-daily ranked first for efficacy, based on this composite endpoint (RR = 0.69; 95% CI 0.60 to 0.80, P-score = 0.95), as well as for effect on global symptoms of IBS (RR = 0.62; 95% CI 0.52 to 0.75, P-score = 0.95). With respect to effect on stool consistency all drugs, including ondansetron 12mg once-daily, were superior to placebo, but alosetron 1mg twice-daily was again ranked first (RR = 0.70; 95% CI 0.60 to 0.81, P-score = 0.85). Ramosetron 2.5mcg once-daily was ranked first for effect on abdominal pain (RR = 0.74; 95% CI 0.65 to 0.85, P-score = 0.89). Total numbers of adverse events were significantly greater with alosetron 1mg twice-daily, compared with placebo. Rifaximin 550mg three times daily ranked first for safety, with ondansetron 12mg od ranked second (P-scores 0.74 and 0.68, respectively). Constipation was significantly more common with all drugs, except rifaximin 550mg three times daily and ondansetron 12mg once-daily.
