Working from home

Project success

Multi-method study

ABSTRACT

With the COVID-19 pandemic, Scrum teams had to switch abruptly from a traditional working setting into an enforced working from home one. This abrupt switch had an impact on software projects. Thus, it is necessary to understand how potential future disruptive events will impact Agile software teams' ability to deliver successful projects while working from home. To investigate this problem, we used a two-phased Multi-Method study. In the first phase, we uncover how working from home impacted Scrum practitioners through semi-structured interviews. Then, in the second phase, we propose a theoretical model that we test and generalize using Partial Least Squares-Structural Equation Modeling (PLS-SEM) surveying 138 software engineers who worked from home within Scrum projects. We concluded that all the latent variables identified in our model are reliable, and all the hypotheses are significant. This paper emphasizes the importance of supporting the three innate psychological needs of autonomy, competence, and relatedness in the home working environment. We conclude that the ability of working from home and the use of Scrum both contribute to project success, with Scrum acting as a mediator.

1. Introduction

With the recent COVID-19 pandemic, millions of people around the world were suddenly forced to either work from home or not at all, and companies were forced to allow their employees to work from home where possible in order to keep their businesses afloat (Venkatesh, 2020). Remote work has always been an alternative to being present in an office, especially within Software Development. A global survey shows that 56% of companies allow remote working and 52% of employees work from home at least once a week (Labs, 2018). With the rapid spread of the virus globally, countries imposed specific guidelines and restrictions regarding, for example, the number of people allowed in indoor spaces and their conduit, policies that, in this case, made working from home the only viable solution for many companies. However, despite apparent advantages such as reducing commute time and being able to spend more time with the family (Butler and Jaffe, 2021), working from home is not an easy endeavor. It requires personal skills that allow professionals to organize and carry their work without any form of direct supervision and that the job, i.e., the workplace, has a culture that supports and encourages remote work (Baruch, 2000).

Within Software Development, the rise of Agile methodologies in the latest decades has changed how people perceive and go about their work, as well as how companies encourage their employees to behave (Hoda et al., 2018). According to the annual State of Agile report, Scrum was the most practiced Agile framework of all, and many companies already had some form of distributed Scrum within their organizations (Digital.ai, 2021). Furthermore, the rate of project success using Scrum was reported to be 60% higher than projects utilizing the traditional approach (Johnson, 2018; Taufiq et al., 2020). However, the pandemic caused many companies to adapt to a fully remote work environment, putting Scrum practices under different strains.

Notably, this investigation provides a unique perspective on the project success of using Scrum when abruptly forced to switch from a traditional office-based setting to a home-office based one. Since we carried out this research during the lockdown, our findings are not generalizable for post-COVID. Nevertheless, understanding how Scrum is impacted by working from home provides very important insights in case of possible further extreme events, such as environmental disasters, geo-political events, or also future epidemics or pandemics.

We started this research journey by studying the existing literature, we found that Scrum used for remote work has mainly been studied in the context of Distributed and Global Software Development, the focus being on how Scrum can be adapted to support a distributed working environment, commonly among co-located teams (Vallon et al., 2014). However, the literature is

scarce on how Scrum and the projects' success were affected by organizations switching to working fully from home to adhere to the new pandemic restrictions. That being said, our study aims to identify the impact that working from home had on software project success through Scrum practices. In our paper, the terms *remote work* and *working from home* are used interchangeably, as there is no other way of remote working than working from home during the pandemic. Hence, we want to clarify that throughout this study, our focus is on working from home rather than remote working.

Through a pragmatic Multi-Method approach, we performed interviews with people working from home within software development Scrum projects to understand the phenomenon better. We proposed a theoretical model that we attempt to generalize through a quantitative survey with 138 Scrum IT professionals using Partial Least Squares Structural Equation Modeling.

We employed this research design to address the following research question:

RQ. *How Scrum practices affect software project success while working from home?*

In the remainder of this paper, Section 2 discusses related work. First, the research design is presented in Section 3, illustrating the methodology this paper is based on. After that, Section 4 summarizes the qualitative phase, which refers to the data collecting and analysis for the qualitative study. Followed by the quantitative phase in Section 5, where the model is constructed and evaluated. Next, the findings of our study are presented in Section 6, together with its limitations. Finally, Section 7 discusses future work as well as our conclusions.

2. Related work

In the Scrum Guide, Schwaber and Sutherland (2020) do not mention if Scrum can or cannot be used in the context of remote working. However, the literature on the topic argues that Agile practices, including Scrum, are meant for co-located working environments and that they present challenges in a distributed context, causing the necessity to adapt Scrum accordingly (Fani-ran et al., 2017; Seckin and Ovatman, 2018). Moreover, prior research has shown that “only a small number of guidelines are systematically followed, and that some guidelines are rarely followed consistently” (Hassani-Alaoui et al., 2020), suggesting that each organization's Scrum implementation might differ from the guideline recommendations.

Prior research investigating Scrum concerning remote work targets distributed projects, also called Distributed Software Development and Global Software Development, where the focus is on how Scrum can be adopted and why it can be a good fit considering its benefits and challenges (Paasivaara et al., 2008; Jalali and Wohlin, 2010). The majority of papers discuss the challenges that distributed work creates in software engineering and how Scrum, with or without modifications, can address and mitigate these challenges (Ghosh, 2012). The predominant theme is centered around co-located teams, mainly providing offshore software development services, which commonly implies working from different geographical locations within different time zones (Sutherland et al., 2007; Pries-Heje and Pries-Heje, 2011). This requires Scrum to be adapted to support the coordination of the teams despite the challenges bridged by the geographical dispersion and the size of the projects (Gupta and Reddy, 2016; Bannerman et al., 2012; Paasivaara and Lassenius, 2011).

Another general topic in the literature is how Scrum can be scaled for Global Software Development since it generates

new challenges such as communication and coordination overhead (Lous et al., 2017). Some of the solutions found for mitigating the issues, as mentioned above, between multiple teams include: adding new events such as Scrum of Scrums for larger teams (Paasivaara et al., 2009), regularly visiting other sites for better process alignment (Ghosh, 2012), using online tools for keeping the backlog and documentation up to date within teams (Therrien and LeBel, 2009) and conducting meetings online or via phone between remote teams (Paasivaara and Lassenius, 2011).

Throughout the literature, researchers display ways of adapting and expanding Scrum practices to mitigate the challenges generated by distributed software development of geographically dispersed co-located teams (Hossain et al., 2009). However, the perspective of everyone involved in a Scrum project working remotely, even within co-located teams, is missing from the literature. Some papers bring forward suggestions that could be adapted for this situation, such as virtual meeting rooms and fully remote Scrum events (Ghosh, 2012). However, how the Scrum practices were impacted by the entire company working remotely remains to be thoroughly researched. For example, a recent action research study within a Brazilian start-up portrays how they managed to migrate to being fully remote to accommodate the COVID-19 restrictions (da Camara et al., 2020), yet a theoretical model remains to be developed and evaluated.

Moreover, most of the literature on distributed Scrum focuses either on successfully adapting or adopting the framework in a remote context, without accounting for the project's success. For example, Hassani-Alaoui et al. (2020) argue that “if Scrum is easy to learn but difficult to master, Scaled Scrum is even more difficult to master, and conducting it improperly could have consequences for project success”, suggesting that the adjustments made to accommodate the remote context may alter the project success.

Shared understanding, a challenge seen in the remote Scrum contexts caused by the communication impediments, has a significant effect on project success (Hummel et al., 2016). However, Hummel et al. (2016) “did not find a significant moderation effect of team distribution on the effect of shared understanding on project success”, indicating that co-location is not necessary for effective communication as long as the proper tools are in place. This finding suggests that besides the adaptations to Scrum, organizations must provide appropriate technological resources for remote contexts (Sonjit et al., 2021).

Thus, our study differentiates from the existing literature by analyzing how Scrum practices are related to project success and what is the impact caused by the sudden change to remote working, which imposed everybody on working from home and eliminated the possibility of a co-located working environment.

3. Research design

Our study aims to get a better understanding of the impact of working from home on Scrum and if it affects the project's success. For that, we employ a Multi-Method research approach, consisting of two phases as seen in Fig. 1. The benefit of using a Multi-Method approach is profiting from a research strategy's advantages while mitigating its weaknesses through the usage of another strategy (Ågerfalk, 2013).

For Phase I, we employed a qualitative study approach consisting of semi-structured interviews with Scrum practitioners. As the prior knowledge about the topic under research is limited, the inductive technique is suitable (Elo and Kyngäs, 2008). We aim to collect enough data in order to understand the phenomenon and quickly draw our findings directly from the responses (Cho and Lee, 2014). The semi-structured approach allows us to respond to and then ask further questions regarding what the interviewees answered, instead of completely following a predefined set of

Fig. 1. Design of the two-phased study.

questions (Rubin and Rubin, 2011). The responsive dynamic of semi-structured interviews aids in connecting with the interviewees and treating them as conversational partners rather than research objects. To synthesize and analyze our findings, we use the Gioia Methodology (Gioia et al., 2012) as a data analysis technique. The qualitative phase is detailed in Section 4.

Phase II complements and validates the qualitative study from the first phase by developing a theory and evaluating it through a quantitative survey (Stol et al., 2017). Within this phase, we employ a theory-building method to construct on the findings of the qualitative study as well as the literature, culminating in a theoretical model consisting of a set of hypotheses that are evaluated using Partial Least Squares - Structural Equation Modeling (PLS-SEM) (Russo and Stol, 2021). The hypotheses are evaluated on a quantitative survey consisting of 138 IT professionals using Scrum. During this stage of research, the researcher is distanced from the observed constructs and statistically examines them. As the investigation's point of view is objective, and the hypotheses have been empirically validated, the study's findings are generalizable and independent of time, and context (Nagel, 1989). We discuss the quantitative phase in Section 5.

4. Phase I: Qualitative study

This section presents the qualitative data collection and analysis.

4.1. Qualitative data collection

The data is comprised of 12 interviews with professionals working remotely with Scrum within software development departments during the COVID-19 pandemic lockdown. To find developers interested to participate in our study, we devised a small sign-up questionnaire which was used as screening tool. It was meant to both filter out people who did not meet one of the requirements. Specifically, our requirements were (i) developing software using Scrum, and (ii) working remotely on a software project during the lockdown. Additionally, participants could choose afterwards their preferred interview time in case they passed the requirements. Questions on the participant's years of experience and role within Scrum were also included in this screening phase.

The questionnaire was completed by 26 potential informants, out of which four did not meet the requirements to participate and ten qualified people received personal invitation e-mails but chose not to participate. An overview of the 12 eligible participants can be seen in Table 1. The interviews lasted between 20–35 min and were conducted and recorded via Zoom or Microsoft Teams, and then transcribed for analysis using Konch.¹ The transcripts were all further manually checked for possible errors created by the software, such as misinterpreted or missing words.

The interview questions were designed to cover all aspects of Scrum – artifacts, events, and roles in comparison with working

Table 1
Participants distribution in the qualitative study.

P#	Scrum Role	Years of Scrum experience	Country
1	Scrum master	1–3	India
2	Developer	1–3	Romania
3	Developer	1–3	Denmark
4	Scrum master	3–5	Indonesia
5	Scrum master/Product owner	5+	USA
6	Developer	1–3	Denmark
7	Developer	1–3	Denmark
8	Developer and Scrum master	3–5	Denmark
9	Developer	5+	Hungary
10	Developer	<1	Romania
11	Developer	1–3	Spain
12	Developer	1–3	Denmark

from home and on-site. Within the interviews, all the participants were asked about themselves, their workplaces and to describe their usual way of working with Scrum. To do so, we asked them to describe an exemplary sprint happened before the pandemic. After that, to assess changes, we asked to describe an exemplary sprint during the pandemic. The interview structure can be found in Appendix A.

4.2. Qualitative data analysis

To analyze the data, we used the Gioia Methodology (Gioia et al., 2012) as a data analysis technique. However, given the exploratory direction of our research, throughout the process, we did not iterate between data collection and analysis or used theoretical sampling (Baltés and Ralph, 2022). Instead, we aimed to investigate how working from home affects Scrum projects inductively. For this reason, our goal in employing Gioia is to provide a systematic strategy that proved effective when performing our study and to assist readers in perceiving the rigor of our concept creation and progression to our conclusions.

We have begun the analysis by iteratively going through the transcripts and condensing information from the text in medium-sized codings while keeping informant terms (using participant's own words in the codings) to construct the 1st order concepts. The transcripts were coded with the research question in mind, focusing on what the participants voiced impacted their Scrum project the most while working from home. As such, each code summarizes the actual impact the interviewees observed, felt, or experienced remote work had regarding any role, event, or artifact of Scrum, as compared to how these practices were enacted before the COVID-19 pandemic.

During the 2nd order analysis, we begun to look for similarities and contrasts across the several concepts in order to reduce their amount to a more manageable number. The emerging themes will help us describe and explain the phenomena we observe. Our analysis yielded a set of 17 2nd order themes seen as the underlying impacted areas, which were further distilled into six aggregate dimensions. The result is a data structure presented in Figs. 2 and 3. The data structure not only helps us to construct our data into an understandable visual aid, but it also

¹ <https://www.konch.ai>

gives a graphic depiction of how we proceeded from raw data to 1st order concepts, 2nd order themes and aggregate dimensions while completing the analyses, which represents an important component of proving rigor in qualitative research (Gioia et al., 2012).

For example, some of the participants stated that they had been using online tools for communication and task management long before the pandemic forced everyone to work from home:

We had everything online (before having to work fully remote) of course, we used Jira. (P9)

This quote was coded into a 1st order concept – “using Jira for task management”. Together with other 1st order concepts that share the same similarities, such as “using Slack for communication” and “using EasyRetro for Retro meetings” they emerged as a 2nd order theme entitled *Online tools*. Finally, this theme was reduced into the *ability of working from home* aggregate dimension.

The use of Scrum, project success and ability of working from home were each compiled as different dimensions (Fig. 2) together with three additional ones (Fig. 3) which reflect the impact of working from home on the individual through three innate psychological needs, further identified within the Self-Determination theory (Ryan and Deci, 2000) i.e., need for autonomy, need for competence and need for relatedness, that represent the extent to which these three needs are fulfilled.²

We uncovered that the impact of remote work was most visible on the Scrum Team, more specifically on the individuals comprising the Scrum Team. This finding allowed us to look at the events and artifacts through a different lens, making it clear that what the participants voiced about events or artifacts were simply manifestations of the affected individuals. In addition, we uncovered that the impact felt at the individual's level had implications in how the events were carried out, which also contributed to how the individuals were affected, creating a cycle that either positively or negatively affected Scrum as a whole. The analysis made it more evident that working from home involves challenges for the individual, portrayed as the extent to which three innate psychological needs are fulfilled: autonomy, competence, and relatedness. Russo et al. identified the exact three needs to be predictors of well-being and productivity among software developers working from home during the COVID-19 pandemic (Russo et al., 2021b). Moreover, together, the three psychological needs are “essential for facilitating optimal functioning of the natural propensities for growth and integration, as well as for constructive social development and personal well-being” as defined by Ryan and Deci (2000) in their Self-Determination theory. Thus, the impact of working from home on the individual can be rightfully reflected through the three psychological needs.

Furthermore, the three dimensions related to the psychological needs indicate that the ability of working from home had a considerable effect on the individual, which is emulated into the use of Scrum and the project's success. Therefore, the remainder of this subsection details each dimension individually.

² To be consistent with the terminology proposed by Deci & Ryan (1980) and by the subsequent social psychological literature, we will still use Need for Autonomy, Cognition, and Relatedness. However, they do not represent an individual's need for autonomy, relatedness, or competence. Instead, they indicate the extent to which the individual's need for autonomy, relatedness, or competence are satisfied or fulfilled.

4.2.1. Ability of working from home

For many people, before COVID-19 caused everyone to work from home, they would not have an appropriate designated space for a home office setup, making it harder to accommodate remote working at first. For this reason, people had to create a setup from where they can adequately do their job. Depending on their household situation, some people were forced to improvise an office and work from their sofas, beds or even kitchen tables (Ralph et al., 2020a). However, even though ergonomics are not significantly related to well-being or productivity (Russo et al., 2021b), improving comfort can help avoid future health issues. More importantly, to do their job, employees must have access to the proper virtual tooling.

Since our way of working was already entirely digitized, we had a digital Scrum board, held meetings online, and so on, it was not big of a change. (P6)

Most organizations were already using online tools for communicating and task management, which made the transition to working from home smoother (Newman and Ford, 2021). However, one big challenge of working from home is to avoid getting distracted and stay motivated (Russo et al., 2021b).

If I am on a call, we will do our sprint planning, and just trying to get everybody's attention for more than an hour is hard. You have kids working at home, you know, on their schoolwork. You have dogs barking and all kinds of noises. Doorbell's ringing Amazon deliveries. So it is a lot more distracting, and then it is harder to get everybody back together if we have questions or need more information. (P5)

The participants voiced that it is difficult to avoid being distracted by what is going on around them unless they live alone or can appropriately seclude themselves from the rest of the people in their house. Everyone is focused on working at the office; however, this does not apply to home working. The distractions can deteriorate the communication between the team members and have consequences on the overall project success. Another effect of the way people communicate when working from home is an increase in the number of formal meetings (Russo et al., 2021b), as time has to be better managed between people who only see each other through online tools. Meetings became more formal and scheduled to accommodate the asynchronous way of communicating online and avoid overlapping schedules. This gives people the impression that the number of meetings has increased because the previously ad hoc conversations have now become a time slot in their calendar.

And then you also, of course, have the people that are late because they have children and their children have to go to school, or maybe they are arriving home, so they have to break it up in the middle of the daily stand up. (P7)

The formal meetings are very defined on a topic and have to be scheduled to accommodate everyone's household duties schedule, particularly for the individuals living with their family. Another challenge brought up by working from home is the disruption of the work-life balance.

I have had colleagues who said that they liked going to the office because it made it easier for them to have a schedule, and it brought more balance in their work and personal life in the sense that when they were working from home, they lost track of time. And most often, they worked too much, and they did not realize that it was eight p.m. and they were still working. (P10)

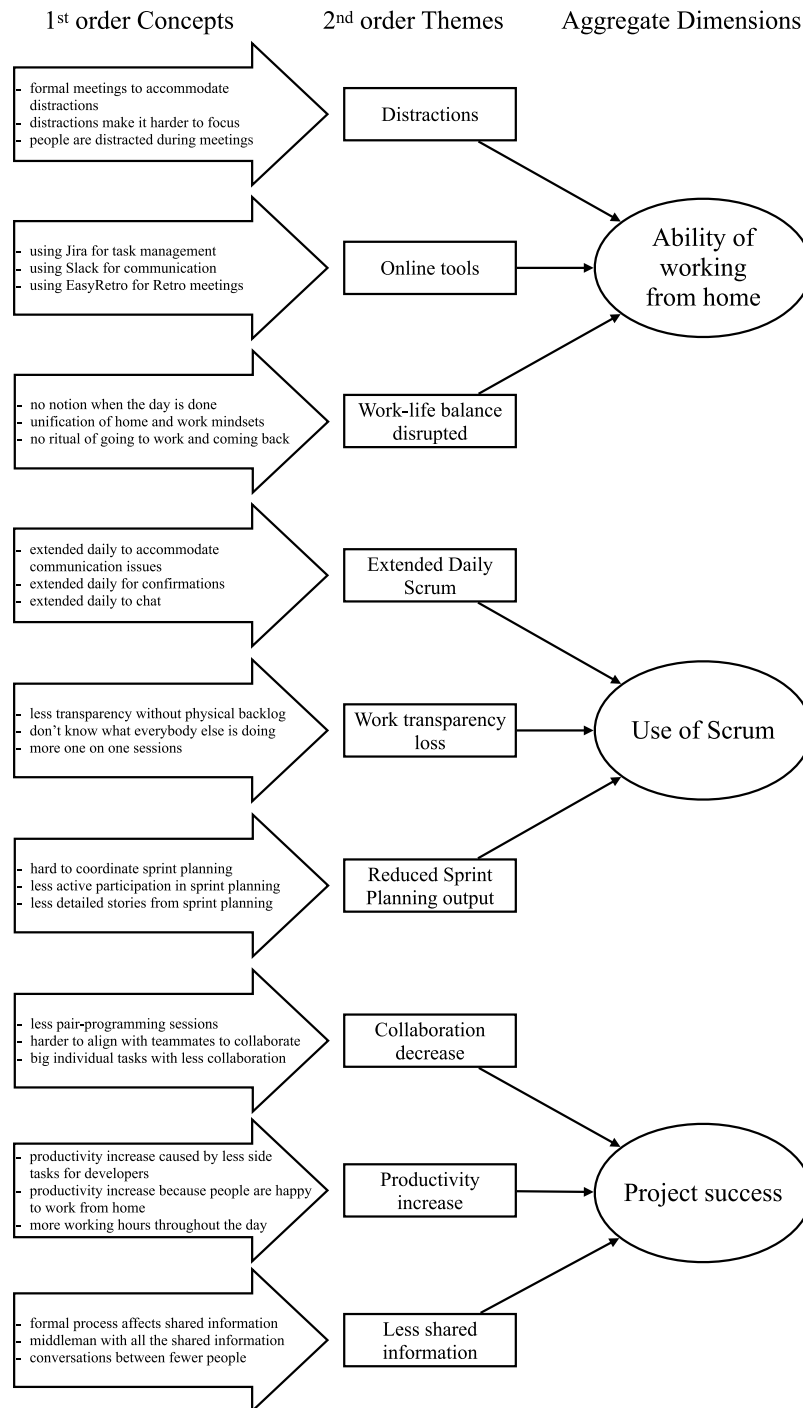

Fig. 2. Data structure of use of Scrum, project success and ability of working from home during the COVID-19 lockdown.

More particularly, without a clear working schedule, people got sucked in their work and stopped keeping track of how much they are working or used working as a coping mechanism for the ongoing pandemic (Russo et al., 2021b). This produced a spike in their perceived productivity as they were completing more tasks, but it affected their work-life balance. The ritual of having to commute to work and back was a clear delimiter for when to stop working for the day, yet it lacks in the home working environment.

4.2.2. Use of Scrum

It cannot be generalized how the Scrum practices were impacted by working from home, as most companies have different

ways of implementing and using Scrum within their organization (Masood et al., 2020). However, many interviewees voiced that their Daily Scrums were extended compared to the on-site version, which can be seen as a generalizable finding.

Since the pandemic, the team decided to extend the time for daily Scrum. So after 15 min, they will close the daily Scrum and have extended 15 min to have a discussion as a confirmation session. (P4)

While some companies only extended the scheduled duration of the Daily Scrum, other added additional events. The common reason being to enforce team communication and maintain the

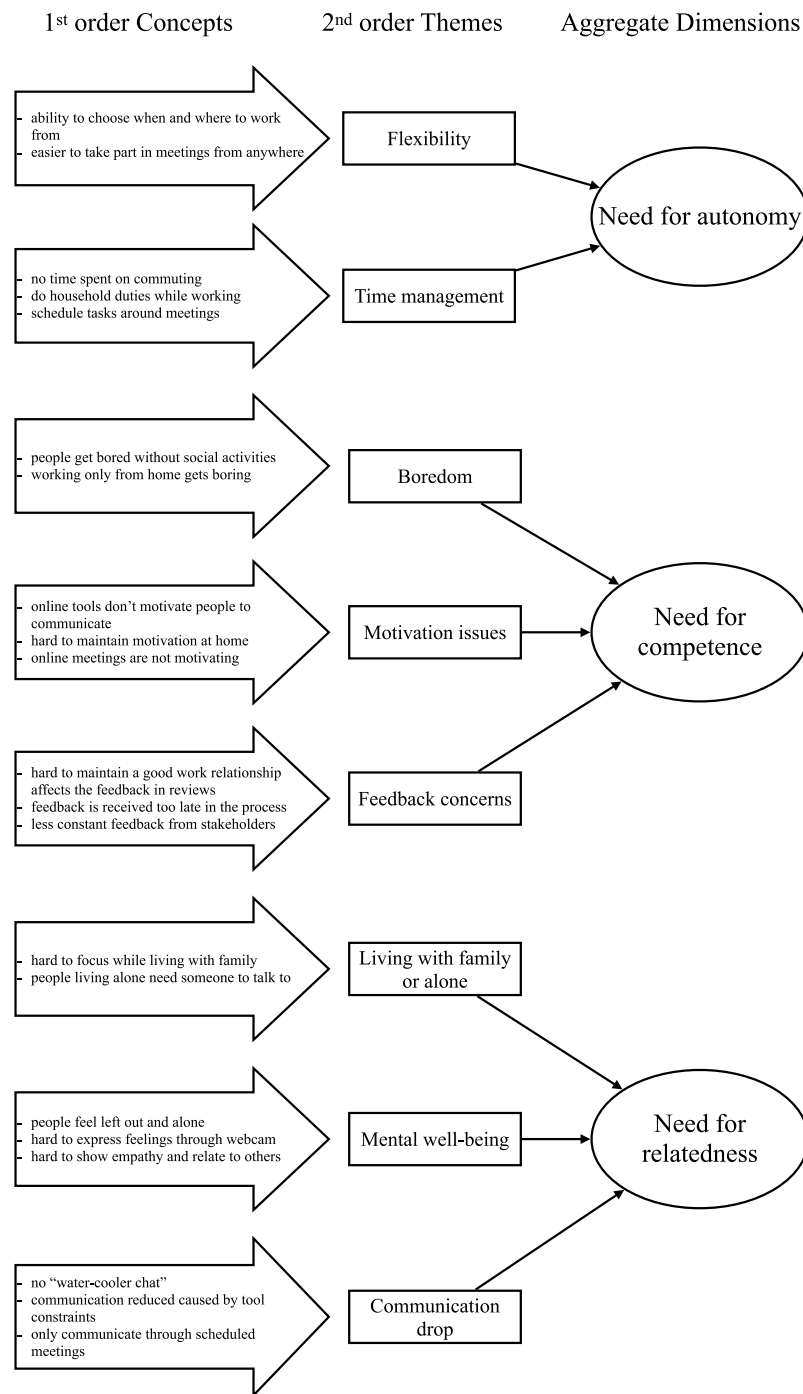

Fig. 3. Data structure of the three innate psychological needs during the COVID-19 lockdown.

transparency of what everybody is doing, which is one of the three pillars of Scrum (Schwaber and Sutherland, 2020). Other reasons include allowing people from different teams to see each other using additional events such as Scrum of Scrums or just giving people the possibility of having an informal conversation before starting the workday. Although seen as something new as an effect of the sudden change to remote working by many people, additional and extended Daily Scrums are a common adaptation of using Scrum in a remote context, as noted in the literature (Hossain et al., 2009). Furthermore, daily Scrums are an essential part of a healthy Scrum implementation; they “improve communications, eliminate other meetings, identify impediments to development for removal, highlight and promote

quick decision-making, and improve the Development Team’s level of knowledge” (Schwaber and Sutherland, 2020).

There are days in which I have been maybe working from home where out of the three people in the team, maybe with one or two of them, we did not talk at all in the rest of the day after the daily. (P11)

Given that the communication between the co-workers decreased throughout the day (van der Lippe and Lippényi, 2020), Daily Scrums became even more critical as some people would only get to communicate and share their progress through this event.

Regarding the other events, the interviewees perceived that their output was affected because of the decreased engagement and motivation of the participants. More particularly, the online experience of the Sprint Retrospective was not as pleasant as the on-site version for many interviewees. The ability of working from home does not provide the same setting that encourages people to speak up and express themselves as part of the Sprint Retrospective. For this reason, Scrum Masters had to improvise and create new games to motivate the Development team and keep them engaged during the event.

Um, I do not like that (remote Retrospectives). We have done it a couple of times using online tools. But there is a component missing for me, like the human aspect, where you want to be honest and you got to express your feelings and all that. (P12)

Moreover, the Sprint Planning meetings were also affected by the decreased engagement of the Development Team caused by the communication channel. Some interviewees voiced that their planning meetings were not as detailed as before because people would not pay attention.

You can hide easier and do something else when you are remote and when you are here (on-site office), you kind of have some sort of obligation to listen to the people in front of you. (P12)

The biggest challenge of the remote events perceived by the individuals is maintaining their focus on the topic and trying to engage in the conversation while looking at or talking to a screen. Whereas in the on-site environment, the engagement is kept by a face-to-face conversation between the team, when working from home, it is very easy to get distracted and do something else on your machine while the other participants are talking.

The increased number of meetings had equally impacted the Product Owner and the Scrum Master.

What impacted me as Scrum Master. The level of my confidence dropped because I feel like I do not contribute anything to the company. And this happened because I need to have more meetings than before. For example, I cannot do something big because I have to accompany my product manager to have an ideation session. [...] So most of my days, I have a call rather than create something or observe the process. (P4)

Both roles struggled to accommodate the new communication channels, which initially caused an increase in scheduled meetings. This, in turn, caused people to lose their confidence when unable to perform their role's duties due to the increased amount of meetings required to carry to support the business. Remote work has had a multi-sided impact on the Developers, consisting of many different underlying impacted areas. One element that was consistently missed by the participants is the physical interaction provided by sharing office spaces. Some argued that the interaction between the Developers changed because of working remotely:

There was less interaction or less direct interaction, and you could not always see what everyone was doing, and they could not see what we were doing. Sometimes we had to wait until the demo or until the daily stand up next day to see progress. (P3)

This has also resulted in a decrease in the quality of shared information and transparency among Developers, which has resulted in a decrease in the quality of the ambient knowledge intrinsic within teams.

Despite the product and sprint backlogs being two different artifacts within Scrum, no participant differentiated the two in our discussions. For most participants, the terms were interchangeable, and working with either backlog was also interchangeable due to the backlogs being in digital format in Jira or Trello. This is also why many participants felt no difference in interacting with the backlogs, as they were using online tools for managing their backlogs since before remote working, even though everybody used to have physical backlogs. However, some individuals miss the physical activity of interacting with the backlog, as having it in a digital format prevents them from having some sort of physical activity within a desk-job, as well as keeping them from quickly seeing a status of the Sprint, what each member is working on and who is available:

I can see that there was a difference being done to physical activity like an on-site used to perform. I mean, sticking on the board, seeing what everyone was doing, like story points. [...] So that is the part which is missed. (P1)

Before, in office, I created a physical board, right? So we can see other people, what they are doing—and moving the ticket, so they have some physical activity. But during this pandemic, they cannot see other people—what are they doing at this time? And when they need help, it is hard to get. (P4)

Thus, the impact that working from home had on the use of Scrum is requiring the Scrum Team to consolidate and adapt the events, roles, and artifacts to mitigate the challenges caused by the remote context. Teams and individuals were given a lot of freedom, which led to the adaptation of a variety of hybrid Scrum processes, most of which were inspired by what was feasible in the home working environment. The adaptations regarding extended events, introducing new ones such as Scrum of Scrums, and employing online tools for task management are similar with the ones seen in the distributed Scrum literature (Ghosh, 2012). This implies that Scrum can be applied to remote projects with no significant changes as long as people adhere to the framework's values and principles, but the official guidelines must be modified to better depict how Scrum can be used in a remote context.

4.2.3. Project success

The project success was also affected by the communication impact, as online communication is not as expressive as face-to-face, people had to optimize the way they share information between them. The communication became more formal and had to be more efficient and on point, but it affected some individuals' feelings. Especially making it harder for introverts to be included in social events as the former casual conversations and water cooler banter almost disappearing in the remote environment (Russo et al., 2021b).

The backend developers, we are cooperating less because someone is always working from home. We are not doing a lot of pair-programming, and we started taking on bigger tasks individually and working on those alone during the Sprint because then you do not really need to communicate a lot to each other. (P7)

Since the communication between people was affected, their collaboration also presented some discrepancies. Popular on-site pair-programming sessions are less common remotely because people may better focus on their job and may no longer require assistance or find it more difficult to reach out to others for help. The collaboration discrepancies directly impact the project's success, as the shared feedback between co-workers decreased due to always having to communicate and collaborate through

an online communication tool. When people are not in the same office, they tend to reach out less often for help as they never know what their colleagues are doing at that time (van der Lippe and Lippényi, 2020). Even if they do seek assistance, there is no way of predicting when the recipient will respond due to the asynchronous nature of the communication.

I do not have to drive into the office anymore. I mean, I can turn my laptop on at seven a.m. and, you know, some days I finish off at four, some days I just work, maybe do not take a lunch. I mean, where am I going to go? So I think people are more productive because they can dedicate more time to working. (P5)

People also observed a productivity improvement when working from home, which can be explained in various ways. A big struggle for most remote workers was to separate their work, and personal life (Russo et al., 2021b). Working from home created a shift in their work-life balance, and some people felt so connected to their work that they did not know when to stop working for the day. When working from the office, there is a clear distinction of when the workday ends, but working from home allows for more flexibility, which was hard to manage. Thus, one reason for the productivity spike is that people worked more hours (Arntz et al., 2019) and the overall productivity of the project increased. However, this cannot guarantee if people were actually more productive or they had to work more to achieve the same results. Another reason is that working from home provides for better time management and helps employees to organize their work better. Because there were fewer work interruptions, the planned meetings, rather than ad hoc discussions, helped people focus on work for longer periods of time.

The productivity even has increased because the colleagues are even happier while working from home and are given more hours. (P1)

I am more productive, that is for sure. These two things are connected because I am more productive, which might boost myself because I have got this much amount of work done, and then I will work more because I am boosted by this experience. (P9)

Moreover, people felt better when they worked from home, and because well-being is related to productivity, the home environment had an influence on people's productivity, which is strongly tied to project success. One obstacle that can endanger the project's success is the reduced amount of shared information resulting from the collaboration discrepancies.

I think you are more prone to be the middleman where you kind of you write something to someone, and then you get a response and you write something to someone else and then you are the one sitting with all the information. (P12)

Especially in a Scrum project, where transparency is one of the framework's pillars (Schwaber and Sutherland, 2020), the decreased amount of shared information can negatively affect its success. On the other hand, a streamlined communication method in which shared information is clear to all team members decreases the odds of errors and does not prolong the feedback process, boosting the quality of the development process and the project's likelihood of success.

4.2.4. Need for autonomy

The need for autonomy is an important aspect of having motivated employees. An autonomy-supportive context allows the individuals to feel competent, related, and autonomous, positively affecting their performance (Ryan and Deci, 2000). In addition, working from home brings more flexibility over how and when the employees are completing their tasks, which is related with more productivity and more engaged work to reward the employer for the flexible work arrangement (van der Lippe and Lippényi, 2020).

I am more relaxed when I get up in the morning, and this seems weird, but there is the option where you can say "I'm working from home", and then you can sleep one more hour because that is usually what you would spend to go to work. I think actually it gives you like a nice space buffer in your head saying like "OK, I'm going to work from home today because it seems like it's pretty windy". (P12)

Many people are forced to work outside of their prime hours by having to be present in the office at predefined hours, but working from home offers the freedom some seek in managing their own schedule and working when they feel more inclined to.

I see a huge time saving by not having to commute because it usually adds up to almost two hours every day. So, well, then I save two hours from my life every day. (P6)

Something as simple as having 40 min of commute either way. And so those 40 min are spent working when I work from home. (P8)

Many interviewees voiced that working from home saves precious time each day, which can be used for either working or doing something else not work-related. For those whose commuting time takes more than two hours, it eventually adds up to at least 10 h spent on work-related activities in a day. Thus, working from home brings a great benefit by removing commuting altogether from the equation, allowing people to have more time for their personal life. Moreover, the flexibility and better time management resulted from working from home allows people to intertwine work and family life, giving them an advantage in meeting household needs (Osnowitz, 2005).

On the other hand, working from home hinders the individual's interaction with their co-workers and the ability of the management to monitor the employees, creating more significant opportunities for work avoidance (van der Lippe and Lippényi, 2020). Thus, organizations should ensure contextual supports of autonomy for their employees and portrait working from home as an alternative to on-site development, rather than an escape from a controlled environment (Ryan and Deci, 2000).

4.2.5. Need for competence

Together with optimal challenges, contexts related to social events, such as feedback and communication that aid the feeling of competence while working on a task, can intensify the motivation to complete the task (Ryan and Deci, 2000). Working from home impacted the individual's motivation and feeling of achievement, challenging their perceived competence levels. As part of the Self-Determination theory, the need for competence and need for autonomy facilitate the vital expression of human growth tendency (Ryan and Deci, 2000).

My confidence level dropped because I feel like I do not contribute something to the company, and my work is becoming smaller and smaller. (P4)

The reduced amount of social interactions made people feel disconnected from the process and project objectives, leading them to detach even more from their work which they believed is insignificant. Other people perceived their tasks as boring when having to do them from home.

They were bored at home; they could not work from home anymore. They needed the office. (P2)

For some people, the seclusion makes them lose interest and motivation to complete their tasks and perceive their work as boring (Russo et al., 2021b). This is understandable for those working in functions or projects that require continuous communication, but it is also understandable for those who are lonely at home and miss the social context of the office, as lonely people report higher levels of boredom (Farmer and Sundberg, 1986). Either way, boredom is a result of their reduced motivation which affects their perceived competence.

I ask one person all the time and then imagine I make some code that is causing a problem. And it is not until the moment when this other person in the team, that knows about these corner cases, has to review it, and then he would give his feedback, and I would need to go back and redo and then show again. [...] It is more difficult to gather all the knowledge or all the feedback that you need until you know that the product is good. (P11)

The async communication between fewer people impacts the individual's perceived competence, as the feedback during working from home presents concerns compared to the pre-pandemic times. The struggle to gather all of the necessary information and the late feedback received throughout the completion of a task delays and obstructs the entire process of formulating and solving a task, perceived as difficult by the individual whose sense of competence is hampered.

4.2.6. Need for relatedness

The need for relatedness was challenged for some remote workers. Individuals are more likely to carry out activities that present interest for them or other individuals with whom they relate to (Ryan and Deci (2000)). While working from home, most people perceived a great impact on the communication with their colleagues, which spawned different discrepancies in their usual way of working. Some people, for example, were unable to effectively focus and relate to their peers since their attention was drawn to what was happening in their household.

If you have a person that you can clearly see has a difficult time concentrating because things are going on, you are not going to address them or ask them a bunch of questions because you want to be nice to them. It is harder to focus if you are the one that has screaming children running between your legs. (P7)

Moreover, the ad-hoc conversations from the office became more formal. Given that just tapping on someone's shoulder and asking for help was no longer possible, meetings had to be scheduled and sustained through an online communication tool. Another observed impact was on individuals feeling left out or alone or needing someone to talk to. The Developers started initiating one-on-one meetings with their peers, but also with the Scrum Master or Product Owner in an attempt to maximize their well-being as individuals.

We have more regular one-on-one sessions; even between the teams, they create a regular session with their peers. Before, when working from the office, they have rarely done that. I think they have one on one sessions because they need someone to talk to. (P4)

The number of people an individual would have a conversation with during the day decreased to only a few close colleagues, or superiors (van der Lippe and Lippényi, 2020), forming more closed circles and increasing the bond between some people. However, affecting the overall transparency and the quality of the project's shared information while also discouraging individuals from starting conversations with other people outside their close circle. Moreover, some Developers' way of relating to the Scrum Master has also been changed compared to the on-site environment.

There were times when he (Scrum Master) would have meetings and stuff like that, and he would just disappear from our place. This made us feel like he was way more superior or something like that, the fact that he could always leave the office. But during working from home, I did not get that feeling at all because I was not seeing anyone around to notice if they are missing. (P2)

As previously mentioned, while working from home, the individual interacts less with their co-workers (van der Lippe and Lippényi, 2020), making the perceived superiority of other people hinder as the individual is more focused on their work and also creating a sense of equality among the co-workers (O'Connell and Russell, 2005). Another form of equality was brought up by the whole team communicating through telecommunication tools from their home, which made people relate more to their peers by having a small glimpse into everybody else's private life through seeing their home office set-up. Thus, the social aspects present in the office were diminished by people working from their homes.

The findings are also supporting the literature, as the Self-Determination Theory requires, besides the autonomy and competence fulfillment needs, a third innate psychological need for relatedness to produce motivation (Ryan and Deci, 2000). These three needs, characterize how every professional shapes, works, and interacts with the home working environment. Self-Determination Theory has been also defined as the "innate psychological needs that are the basis for their self-motivation and personality integration, as well as for the conditions that foster those positive processes" (Ryan and Deci, 2000) and is, as such, a crucial aspect of our professional lives.

5. Phase II: Quantitative study

In the second phase, we used existing Scrum literature and previous phase findings to develop a set of hypotheses that are integrated into a single theoretical model to improve our understanding of the relationship between working from home and the success of Scrum projects. The model is evaluated using Partial Least Squares- Structural Equation Modeling (PLS-SEM) following Russo and Stol (2021) guidelines. The goal is to use quantitative analysis to triangulate the findings of our qualitative phase. This section depicts the specification of the model and its assessment using a quantitative survey and PLS-SEM.

5.1. Theory development

The first goal of the quantitative phase is to specify the theoretical model by defining a set of hypotheses. The hypothesis formulation draws from both the literature and the qualitative study.

The working environment has an impact on the individual's motivation and productivity (Korzynski, 2013; Awan and Tahir, 2015). Working from home has both positive and negative aspects. The positive ones include enabling employees to focus more on their tasks, as the contact with their co-workers is

significantly reduced (van der Lippe and Lippényi, 2020). Research shows that while working from home, employees are interrupted less often (Bailey and Kurland, 2002). Furthermore, teleworking gives employees more flexibility in terms of where they work from, how much work they do, and how they organize their time to complete their tasks even outside of office hours (Kossek and Thompson, 2016). The results of the first phase show that employees felt more productive while working from home, which can be attributed to the autonomy that teleworking provides (Vega et al., 2015). While the findings from the qualitative study show that some employees did not feel motivated when working from home, this can be seen as a result of the ongoing pandemic and the sudden change to enforced home working (Russo et al., 2021b). Studies show that mixing online and offline working environments can help increase employees' motivation and engagement and that online communication tools are seen extremely well, especially by the Millennials who are now joining the workforce (Korzynski, 2013). This unprecedented context together with the lack of an adequate working space and other household impediments, affected the ability of working from home for some employees which is reflected through the three psychological needs. As such, the hypotheses relating to the extent these three needs are fulfilled through the ability of working from home are:

Hypothesis 1a. Ability of working from home is positively related with the Need for autonomy.

Hypothesis 1b. Ability of working from home is positively related with the Need for competence.

Hypothesis 1c. Ability of working from home is positively related with the Need for relatedness.

The findings of the qualitative study show that working from home impacted the use of Scrum, particularly on some of its events. The literature on the topic argues that Agile practices, including Scrum, are meant for co-located working environments and that they present challenges in a distributed context, causing the necessity to adapt Scrum accordingly (Faniran et al., 2017; Seckin and Ovatman, 2018). As previously mentioned, the adaptations of Scrum events undergone while people had to work from home are similar to the adaptations that a distributed Scrum team has to enforce to support the communication between geographically dispersed co-workers (Gupta and Reddy, 2016). The working environment plays a big role in how people interact with each other, and working from home impacted the transparency between the people in the Scrum team, causing Daily Scrums to be extended or even requiring better documentation practices, effects also seen on distributed Scrum projects (Hossain et al., 2009). The ability of working from home has repercussions on the freedom and frequency of communication between team members, growing the chance of individualism, which is detrimental for the use of Scrum (Ozierańska et al., 2016). Moreover, working from home brings difficulties related to teamwork, collaboration, and collective responsibility (Ozierańska et al., 2016). The 2nd hypothesis is:

Hypothesis 2. Ability of working from home is negatively related with the Use of Scrum.

Project success is an important theme in project management literature, but it lacks a widely agreed definition of what success is. Traditional criteria such as time, budget, and quality, forming the "iron triangle", can be a good representation of the success of the management of the project but cannot necessarily reflect the success of the project itself (Ika, 2009). Shrnur et al. (1997)

argue that between the three traditional dimensions of project efficiency (time, budget, and scope), the scope has the largest contribution in shaping the success of a project. Thus, besides scope being an aspect of project efficiency, it also has an impact on the customer, and their satisfaction (Serrador and Pinto, 2015). In software development, the success metrics can also include stakeholder success (Davis, 2014, 2018), including satisfaction of the customer (Shenhar et al., 2001), team, meeting organizational goals (Belassi and Tukel, 1996) and strategic success/value (Shenhar et al., 2001). According to a global report (Johnson, 2018), it was found that the percentage of project success using the Scrum approach was 60% greater than projects that use the traditional approach in 2018 (Taufiq et al., 2020). While the above metrics are important to define the success of a project formally, the success factors of an Agile project might be nuanced differently as indicated by Russo (2021).

In an Agile project, such as Scrum, the success factors include Product Owner involvement, Scrum Master leadership, top management commitment, and Developers' skills (Russo, 2021). Ken Schwaber and Jeff Sutherland, the creators of Scrum, promote that "the essence of Scrum is a small team of people" (Schwaber and Sutherland, 2020) and that Scrum is "a framework within which people can address complex adaptive problems, while productively and creatively delivering products of the highest possible value" (Schwaber and Sutherland, 2020). There is no silver bullet recipe for implementing Scrum, and each company can have varied ways of using Scrum (Hossain et al., 2009). Moreover, even though there should be a Scrum Master to promote and support the good use of the framework within the project, the self-organizing Development Team (Developers) is responsible for managing their own work (Schwaber and Sutherland, 2020). Thus, the use of Scrum within a company is related with the project success, stemming the 3rd hypothesis:

Hypothesis 3. Use of Scrum contributes to Project success.

The ability of working from home influences the way employees sustain their day-to-day work activities, which may, in turn, affect the project success. Building on the qualitative study, the communication, and collaboration between employees present challenges when people are working from home, findings also confirmed by the literature on remote Scrum projects (Paasivaara and Lassenius, 2011; Ghosh, 2012). However, working from home is not always seen as a challenge for software engineers (Russo et al., 2021b), which was also the case for the people interviewed who indicated increased productivity while working from home. Moreover, people spend more time working instead of commuting when they are remote, which is directly affecting project success (Barrero et al., 2021). Thus, the 4th hypothesis states:

Hypothesis 4. Ability of working from home contributes to Project success.

The literature suggests that using Scrum can help mitigate the challenges brought by remote contexts (Pries-Heje and Pries-Heje, 2011), indicating that the use of Scrum can be seen as a mediator between the ability of working from home and project success, rising the 5th hypothesis:

Hypothesis 5. Use of Scrum mediates the relationship between Ability of working from home and Project success.

Fig. 4 presents our theoretical model, where ovals represent the constructs and the hypotheses are represented by single-headed arrows.

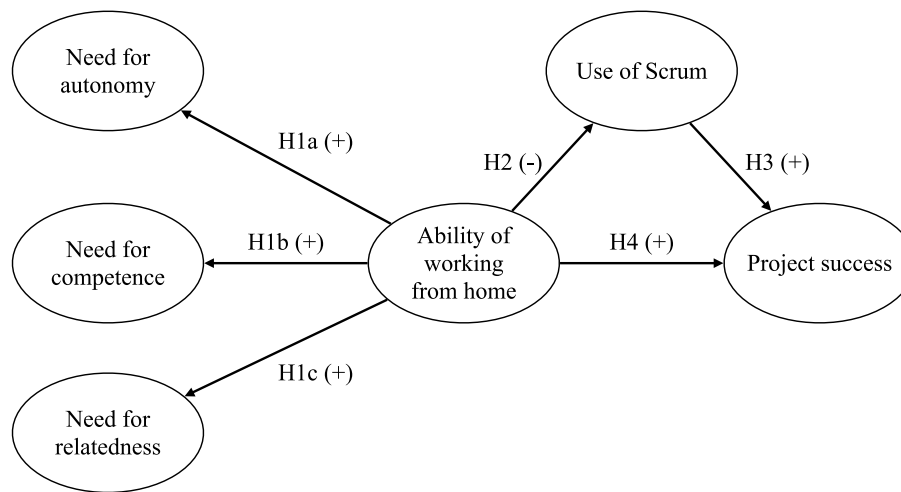

Fig. 4. Theoretical model.

5.2. Partial Least Squares-Structural Equation Modeling

Partial Least Squares-Structural Equation Modeling (PLS-SEM) is a multivariate statistical analysis used to evaluate latent and unobserved variables, also called constructs, using multiple observable indicators or items (Chin et al., 1998). It is an emerging inquiry approach in empirical software engineering (Russo and Stol, 2021; Sharma and Stol, 2020; Russo, 2021) and is best suited for exploratory theory development investigations (Russo and Stol, 2019).

Every PLS-SEM model has two sub-models: a structural model and a measurement model. The structural model is made up of several constructs and their relationships define the research hypotheses. The latent variables might be exogenous (predecessor), endogenous (target construct) or mediators. The items are measured through the measurement model using data collected, most often, through a survey.

We chose PLS-SEM for this study given its suitability for exploratory studies (Russo and Stol, 2019) and to allow us to not only observe the direct relation between our constructs but also understand what causes the relation. Furthermore, we can evaluate the mediation effects between our latent variables, making PLS-SEM the best choice for our study.

5.2.1. Specification of the structural model

The first step in PLS-SEM is to specify the structural model by defining a set of hypotheses. The structural model is represented by the theoretical model established in Section 5.1 and depicted in Fig. 4.

5.2.2. Specification of the measurement model

The second step is to specify the measurement model, that is, identify suitable measurement instruments for each non-observable variable. The model's constructs are defined below, indicating what each construct entails and what is its measurement instrument. The complete list of each construct's items together with the references used to frame the questions can be found in Table B.11 in the Appendix.

All the responses were given on a 7-point scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Need for autonomy, need for competence and need for relatedness. Fulfillment of autonomy, competence and relatedness needs of the Self-Determination theory (Ryan and Deci, 2000) were measured using the 18-item balanced measure of psychological needs scale (Sheldon and Hilpert, 2012).

Ability of working from home. The ability of working from home construct concerns distractions, noise, comfort, ergonomics, ambient, tooling, office set-up, and the social aspect of working from home. It is measured using nine items adapted from The Work Design Questionnaire (WDQ) (Morgeson and Humphrey, 2006), Danielsson and Bodin (2009) study of office environment satisfaction and Russo et al. (2021b) study of predictors of well-being and productivity of software professionals to reflect the home working environment.

Use of Scrum. The use of Scrum concerns the implementation within an organization of Scrum's roles, events, and artifacts as defined in the official guide. It is measured using 15 items created from the Scrum Guide (Schwaber and Sutherland, 2020). The responses reflect the extent to which the participants' Scrum implementation relates to the statements.

Project success. The project success construct concerns the process, deliverable, and business success. It is measured using three items from the Russo (2021) Agile Success Model.

5.3. Quantitative survey

After specifying our research model, we can concentrate on the empirical confirmation of our study hypotheses. Thus, we conducted a quantitative survey, which is the best research strategy for generalizing a research model (Stol and Fitzgerald, 2018).

5.3.1. Survey data collection

We used G*Power (Faul et al., 2009) to do a *priori power test* to determine the minimal sample size. According to this analysis, the smallest size for six predictors with an effect size of 15%, significance of 5% and power of 80% is 98 (Fig. C.6).

Prolific,³ a data collection platform meant for academic purposes with over 130,000 active users, was used to gather the data using a cluster sampling approach (Gravetter and Forzano, 2018). Prolific offers various benefits over other data collecting platforms, such as email lists, replicability, data quality, and reliability (Palan and Schitter, 2018; Peer et al., 2017), and is widely used in computer science as a data collecting platform (Russo, 2021; Russo et al., 2021a). To reduce response bias, the survey was conducted using Qualtrics⁴ with randomized questions

³ <https://www.prolific.co/>

⁴ <https://www.qualtrics.com/>

within their blocks (Gravetter and Forzano, 2018; Paulhus, 1991). Following The Day Reconstruction Method (DRM) by Kahneman et al. (2004), the questions within the survey were phrased such that people would reflect on their last project where they used Scrum while working from home.

To ensure the quality of the data, we added competence screening questions and random attention checks. The competence screening part included questions from Danilova et al. (2021) and aimed to filter out people who do not meet the software engineering knowledge requirement. Attention checks were randomly inserted between questions to ensure the reliability of the answers. From a total of 200 completed responses, we filtered out 62 candidates who either failed the attention checks or the competence screening, summing up to 138 valid responses, which is above the minimum sample size.

5.3.2. Sample description

Appendix C presents a detailed overview of our sample description. The gender distribution of the 138 respondents (Table C.12) includes one non-binary respondent, while women make up 18.1%, which is slightly higher than earlier sample studies that reported just 10% of women participants (Qiu et al., 2019; Vasilescu et al., 2014). According to Table C.13, the great majority of the participants are from Western Europe.

In terms of Scrum, 86.2% of the participants are part of the Development team (Table C.14), and most of them have more than one year experience of working in Scrum teams, $\approx 60\%$ even having at least three years experience (Table C.15). This suggests that our participants are somewhat experienced with the Scrum practices. Moreover, Table C.16 shows that most participants first started working from home when the COVID-19 pandemic restrictions were enforced. This benefits the study, allowing us to oversee the early impact that switching to working from home had on Scrum and the individuals of companies used to practice Scrum in an on-site environment.

5.3.3. Assessment of the reflective measurement model

Following Russo and Stol (2021) recommendations, the measurement model is evaluated before the structural one to ensure variables' reliability and robustness of the results. This section discusses internal consistency reliability, convergent validity, and discriminant validity.

Internal consistency reliability. The tests ensure that the latent variables are measured in a *reliable* and *consistent* manner across their items. It aims to determine if the correlations between the items are high enough, indicating resemblance between the items of the same construct. We performed the Cronbach's alpha (Cronbach, 1951), Composite Reliability (Werts et al., 1974) and Consistent Reliability Coefficient (rho_A) (Dijkstra and Henseler, 2015) tests. Values between 0.6–0.7 are acceptable in exploratory researches, while values between 0.7–0.9 are recommended for more mature research (Hair et al., 2019). On the other hand, values below 0.6 indicate a lack of internal consistency reliability, and values above 0.95 indicate that the items are similar, decreasing validity (Russo and Stol, 2021). As seen in Table 2, most constructs' tests fall within the recommended range of 0.7–0.9. The only exceptions are need for autonomy and use of Scrum with a Cronbach's Alpha and rho_A above 0.6. Although this last result is still considered acceptable for an exploratory investigation like this one, we are not fully satisfied with the results, since need for autonomy might be misinterpreted by informants and use of Scrum seems not to fully capture the its actual theoretical meaning.

Table 2
Construct reliability and validity.

Construct	Cronbach's Alpha	rho_A	Composite Reliability	AVE
Need for autonomy	0.600	0.620	0.831	0.712
Need for competence	0.808	0.828	0.885	0.720
Need for relatedness	0.709	0.741	0.836	0.632
Project success	0.725	0.731	0.845	0.645
Use of Scrum	0.611	0.612	0.793	0.561
Ability of working from home	0.789	0.803	0.862	0.610

Convergent validity. This validity assessment measures the degree to which different items of the same construct correlate positively with one another (Russo and Stol, 2021). Given that all the model's latent variables are reflectively measured, the items should share a significant proportion of variance, meaning that they converge. To assess this assumption, two tests were performed: Average Variance Extracted (AVE), which calculates the grand mean value of the squared loadings of the latent variable's indicators, and another one to check if the outer loadings of each construct share at least 50% of their variance using the indicator's reliability (Russo and Stol, 2021). The AVE should score higher than 0.5 (Fornell and Larcker, 1981) and the outer loading of an item onto its construct should be higher than 0.7 (Chin et al., 1998). Several items did not share a proper amount of variance and were removed in a stepwise manner. Hair et al. suggest discarding all the items with an outer loading below 0.3 and consider discarding the ones with values between 0.4–0.7 if it leads to an increase in the AVE (Hair et al., 2016). Therefore, in turn, each lowest scoring indicator was discarded, then the model was re-run and verified that indeed the AVE value improved. We repeated this process until all the outer loadings passed the 0.7 threshold. Table 2 shows that all AVE values are above the 0.5 threshold and Table 3 displays the retained indicators' reliability scores, also passing the 0.7 threshold, through the cross-loadings.

Discriminant validity. This final validity test measures to which extent each construct uniquely captures different concepts about other constructs. We assessed this using the Heterotrait–Monotrait ratio of correlations (HTMT), which has been proven to outperform other tests, such as the Fornell–Larcker criterion (Henseler et al., 2015). It can be seen in Table 4 that all the cut-off values are below 0.9, which is the suggested threshold (Henseler et al., 2015), indicating that each construct is capturing a different phenomenon.

5.3.4. Assessment of the structural model

We can conclude, from assessing the measurement model, that all our latent variables are reliable. The next step is to assess the structural model by discussing the predictive power and the significance of the relationships between the constructs. This evaluation is important for accepting or rejecting the proposed hypothesis.

Collinearity. Our structural model consists of six constructs, out of which three are exogenous (need for autonomy, need for competence, and need for relatedness). The correlation between the exogenous variables with the endogenous ones should be independent; for that, we assess their collinearity using the Variance Inflation Factor (VIF) (Miles, 2014). A widely accepted cut-off value for VIF is 5, but Hair et al. suggests a more conservative cut-off value of 3 (Hair et al., 2016), as collinearity issues may appear between VIF values of 3 to 5. We report VIF values ranging from 1.000 (between Use of Scrum and Home Working Environment) to 1.398 (between Home Working Environment and Need for Competence), which are below the more conservative cut-off value, indicating that our model does not present collinearity issues.

Table 3
Cross loadings of the retained items on the constructs.

Item	Need for autonomy	Need for competence	Need for relatedness	Project success	Use of Scrum	Ability of working from home
AN_3	0.804	0.295	0.268	0.232	0.100	0.286
AN_5	0.881	0.323	0.220	0.264	0.215	0.360

Table 4
Heterotrait–Monotrait ratio of correlations (HTMT).

	Ability of working from home	Need for autonomy	Need for competence	Need for relatedness	Project success
Need for autonomy	0.546				
Need for competence	0.641	0.524			
Need for relatedness	0.526	0.419	0.627		
Project success	0.557	0.454	0.469	0.365	
Use of Scrum	0.368	0.306	0.354	0.274	0.664

Significance and relevance of path relations. The hypothesized relationships among the constructs are represented by path coefficients, which have standardized values ranging from -1 to 1 (for highly negative or positive correlations, respectively), while values close to 0 indicate a weak relation (Russo and Stol, 2021). Because PLS-SEM does not make any distributional assumptions, parametric tests cannot be used to determine significance. For this reason, we used a 5000-subsample bootstrapping approach with replacement, reported in Table 5, where the bootstrapping coefficient, mean, standard deviation, T statistics, and p -values are displayed for each of our seven hypotheses.

Hypothesis 4 proposed that use of Scrum mediates the relationship between ability of working from home and project success. To evaluate mediating relationships, we must compare the mediators' suggested indirect paths to the direct paths (Zhao et al., 2010; Nitzi et al., 2016). Variables can have no mediating impact (the indirect effect is insignificant), a partial mediating effect (if the direct effect is significant), or a full mediating impact (if the direct effect is insignificant) (Sharma and Stol, 2020).

Both the direct ($p=0.000$) and indirect ($p=0.007$) paths are significant, indicating that use of Scrum has a partial mediating effect between ability of working from home and project success. Moreover, all the relations have p -values less than 0.05 , and the T statistic is more than 1.96 (for a significance of 5%) (Hair et al., 2016). We conclude from this analysis that all our hypotheses are significant, thus supporting our research model.

Coefficients of determination and predictive relevance. In this step of the analysis, we are interested in the endogenous variables' predictive qualities, depicted in Table 6. The R^2 value, or the coefficient of determination explained variance, is an essential metric in PLS-SEM since it determines the model's explanatory ability by determining how much of the variance is explained by each endogenous variable (Russo and Stol, 2021). Because the

Table 5

Path coefficients, bootstrap mean, standard deviation, T statistics and p -values (NA = Need for autonomy, NC = Need for competence, NR = Need for relatedness, WFH = Ability of working from home, US = Use of Scrum, PS = Project success)

Hypothesis	Coefficient	Mean	STDEV	T	p
Direct Effects

Indirect Effects					
H5: WFH \rightarrow US \rightarrow PS	0.097	0.104	0.036	2,715	0.007

Table 6

Coefficients of determination and construct crossvalidated redundancy.

Construct	R^2	R^2 Adjusted	Q^2
Need for autonomy	0.149	0.142	0.094
Need for competence	0.270	0.265	0.181
Need for relatedness	0.164	0.158	0.088
Project success	0.308	0.298	0.186
Use of Scrum	0.073	0.067	0.035

R^2 value is proportional to the model size, it is a good practice to account for the Adjusted R^2 criteria, which adjusts the R^2 value based on the model size (James et al., 2013). The resultant number, which ranges from 0 to 1 , indicates the amount of explanatory power. Threshold values are impossible to supply since they are dependent on the subject matter and the model's complexity (Russo and Stol, 2021). We also computed Stone–Geisser's Q^2 to see how predictive a given endogenous construct

Table 7
Constructs prediction summary.

is (Cohen, 2013). Finally, a blindfolding procedure was applied to compute Q^2 (Hair et al., 2016). The Q^2 must be greater than 0 to be relevant (Cohen, 2013), which is the case for all endogenous constructs in our study. As a result, we draw the conclusion that our model is both predictively relevant and accurate.

Predictive performance. To evaluate the predictive performance, we used the *PLS predict* algorithm developed by Shmueli et al. which provides an assessment regarding a model's predictive power by mimicking the evaluation of the predictive power for out-of-sample data (Shmueli et al., 2016). The process consists of dividing the data into k equal-sized subsets, out of which $k - 1$ are used to train the model, then its predictive power can be evaluated to assess whether the model can predict the k th subset (Russo and Stol, 2021). The goal of *PLS predict* is to see if the model can outperform the most naïve linear regression benchmark (referred to as Q^2 predict). Thus a Q^2 predict value greater than 0 indicates that the PLS path model's prediction error is less than the naïve benchmark's prediction error (Russo and Stol, 2021). We divided our sample into 10 folds and used 10 repetitions to compute the *PLS predict* statistics, following the guidelines by Shmueli et al. (2019) to analyze the results. The predictive performance of the constructs is shown in Table 7. The positive values of Q^2 suggest a meaningful predictive performance of the entire model. Moreover, all the indicators of the endogenous constructs were checked using the mean absolute error (MAE) as the prediction error, then double-checked using the root mean squared error (RMSE) against the naïve benchmark, and our conclusion does not change. Thus, the PLS prediction error for all items is lower than the naïve benchmark. As a result, we conclude that our model as a whole has a meaningful predictive performance.

Predictive stability. The final assessment considers the model's predictive stability by analyzing the effect sizes (f^2). Table 8 displays the effects of the different relations in the model. The effect size thresholds are 0.02, 0.15, and 0.35 for small, medium, and large effects, respectively (Cohen, 2013). As such, the effect sizes in our model are all relevant, since we report that all relationships have at least medium effect sizes.

Throughout this section, our research model was confirmed and validated through a PLS-SEM analysis. The computed model can be seen in Fig. 5.

6. Discussion

The first phase (Section 4), consisting of the qualitative research, helped us in better understanding how working from

home affects the individuals within Scrum teams and how this translates into an impact on project success. We drew from these findings, together with the literature on software engineering, social and organizational psychology, and project success, to develop our theoretical model in the second phase (Section 5). Our model illustrates how these constructs relate to each other and helps us understand the role of Scrum within projects where people are working from home. Finally, we performed a quantitative survey to generalize our findings and test our hypotheses. Following the most recent guidelines for software engineering research by Russo and Stol (2021), we analyzed the collected data through a PLS-SEM analysis as it is well-suited for evaluating a model's predictive abilities.

Here, we are discussing the implications for theory and practice, summarized in Table 9 and our limitations.

6.1. Implications for theory and practice

Starting at looking to the **direct effects**, we found support for the hypotheses ($H1a$, $H1b$, $H1c$) which proposed a positive relation between the ability of working from home and the satisfaction of the three innate psychological needs. All needs had significant relationships (0.38–0.52) with medium effect sizes (0.17–0.37). Need for autonomy had the weakest relationship (0.38) and lowest effect size (0.17), which may be explained by the fact that the need for competence involves the need for autonomy (Russo et al., 2021b). It is simpler to satisfy one's demand for competence while remaining relatively autonomous (Ryan and Deci, 2000). Moreover, the weaker relationship of the need for relatedness can be explained by the fact that, while working from home, people are less in contact with their peers (van der Lippe and Lippényi, 2020). Organizations must ensure that their employees' working environments, whether at home or on-site, support the fulfillment of three needs, according to the suggestions of the Self-Determination theory by Ryan and Deci (2000). Such an environment should encourage autonomy rather than control, offer employees the resources and training they need to feel competent about their work and make everyone feel heard and involved in the process.

We found a positive relationship between ability of working from home and use of Scrum, which does not support the proposed negative relation of $H2$. This finding confirms that Scrum can be adapted for distributed projects (Paasivaara et al., 2008) and it helps mitigate the challenges brought by the remote context (Ghosh, 2012). Even though 72% of our survey participants first worked from home during the COVID-19 lockdown, most of them reported having the needed equipment and software to do their work, which suggests that the maturity of home working within the company is not related to the use of Scrum. Instead, it is crucial to have the right online tools in place, such that the employees have a smooth transition to remote working (Deshpande et al., 2016). Moreover, the findings are consistent with the latest version of the Scrum Guide (Schwaber and Sutherland, 2020). The Scrum Guide became less prescriptive with the 2020 version, allowing more flexibility. For this reason, our paper contributes to the Scrum community by supporting the experience-based update of the framework. We recommend that businesses encourage their staff to experiment with various internet tools before deciding on the best ones. This is necessary to guarantee that the employees who work remotely are determined and find it simple to utilize these technologies to conduct their jobs.

As expected, we found a considerable positive contribution of the use of Scrum on project success. This finding is consistent with the literature, which shows that Scrum projects have a higher success rate than other traditional methods (Serrador and Pinto, 2015; Johnson, 2018). However, as also emphasized earlier,

Fig. 5. Measurement and Structural model with outer loadings, R^2 , and path coefficients (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$). Each construct's items can be identified using their id (ex: WFH_2) within Appendix B.

with the Scrum Guide being less prescriptive in terms of its practices and knowing that many organizations do not fully adhere to or adapt the practices, it is essential to follow the framework's values and pillars. Hassani-Alaoui et al. (2020) suggest that "teams that frequently respected the pillars and values of Scrum, even when modifications were made, appeared to achieve better outcomes" in terms of project success.

Ability of working from home also has a considerable positive contribution on project success. This can be explained through the satisfaction of the three innate psychological needs, which are also positively related with ability of working from home. Ryan et al. state in their Self-Determination theory that "employees' experiences of satisfaction of the needs for autonomy, competence, and relatedness in the workplace predicted their performance and well-being at work" (Ryan and Deci, 2000). Moreover, Russo et al. (2021b) found that, among other predictors, need for autonomy and need for competence predicted the well-being of software developers during the pandemic. Thus, the ability of working from home must offer a suitable setting in which developers may thrive, and enterprises should place a greater emphasis on improving their employees' working environments to achieve project success. Similarly, Agren et al. stress the importance of avoiding any coercive behaviors from organizations to teams, as it is particularly detrimental for psychological safety (Agren et al., 2022).

Finally, regarding exploring the **indirect effects**, we found a partial mediating effect between ability of working from home and project success through the use of Scrum. These findings support the literature's contention that Scrum aids in mitigating the difficulties related with remote working (Hossain et al., 2009) while maintaining high rates of project success (Hassani-Alaoui et al., 2020). Using a framework, such as Scrum, has the benefit of regulating the organization's process and, in the home working environment, it supports the employees to structure and plan their work around Scrum's events. This is important because employees could quickly lose focus and slack more while working from home without a straightforward process and defined goals. However, a controlled context hinders the competence and autonomy fulfillment needs, affecting the performance of the employees (Ryan and Deci, 2000). One way to cultivate a beneficial setting is to ensure that the current Scrum implementation within the projects adheres to the framework's core values (commitment, focus, openness, respect, and courage) (Schwaber and Sutherland, 2020), which support the three needs. As described in the Scrum Guide, "the Scrum Team members are open

about the work and the challenges; respect each other to be capable, independent people; and are respected as such by the people with whom they work and dare to do the right thing, to work on tough problems" (Schwaber and Sutherland, 2020). In other words, the ideal Scrum Team is made up of autonomous, competent people who can take on challenging tasks and collaborate to reach their planned goal and attain project success. As a result of its flexibility in implementation and ability to accommodate changes, Scrum is well-suited to creating a beneficial home working environment that contributes to project success, as long as its values and pillars are followed.

6.2. Threats to validity

Both qualitative and quantitative validity paradigms are used to discuss the limitations of the study concurrently, as suggested by Russo et al. (2018, 2017). First, the qualitative dimension is analyzed by considering the credibility, transferability, dependability, and confirmability following the Criteria for assessing the trustworthiness of naturalistic inquiries (Guba, 1981). Second, for the quantitative dimension, its evaluation investigated the statistical conclusion, internal, construct, and external validity as suggested by Wohlin et al. (2012).

Credibility. Our findings are based on a qualitative study approach as described in the ACM SIGSOFT empirical standards (Ralph et al., 2020b), consisting of 12 semi-structured interviews with individuals from three continents and seven countries, with various Scrum experience levels, working in all existing Scrum roles. The participants were screened before the survey, and those who did not meet the requirements of working from home within a Scrum project were filtered out. Additionally, the sample size is in line with other studies applying a Mixed Methods approach (Russo, 2021).

Transferability. According to Gioia et al. the findings of a study based on this methodology are transferable as long as the study "generates concepts or principles with obvious relevance to some other domain" (Gioia et al., 2012). Although we only used Gioia as a data analysis technique, based on this notion, the findings within this paper, while limited in its sample size, can be considered transferable, as the underlying impacted areas discovered throughout the study are human-centric, therefore branching out into other sciences such as social sciences, psychology or anthropology. As such, the findings of this study can be used as a basis

Table 9
Summary of findings and recommendations.

Hypothesis	Findings	Recommendations
H1a: Ability of working from home → Need for autonomy	Supported. With a medium path coefficient (0.38) and medium effect size (0.17), Ability of working from home is positively related with Need for autonomy.	The autonomy of working from home can result in more productivity and more engaged work. Organizations should ensure an autonomous context, rather than a controlling one.
H1b: Ability of working from home → Need for competence	Supported. This relationship is stronger than H1a, with a higher path coefficient (0.52) and a high effect size (0.37).	While working from home, people took on more individual tasks which challenged their competence. Organizations should establish a streamlined feedback process with high degree of shared information.
H1c: Ability of working from home → Need for relatedness	Supported. The relationship between the Need for relatedness and Ability of working from home has a medium path coefficient (0.4) and medium effect size (0.19).	People did not relate as much with their colleagues when working remotely. Organizations should devise more social events to keep people connected.
H2: Ability of working from home → Use of Scrum	Not supported. Ability of working from home is not negatively related with Use of Scrum. However, there is a positive relation through a moderate path coefficient (0.27) with small effect size (0.08).	Scrum can successfully be adapted for remote working. Organizations have to accommodate the remote challenges by adopting and training their employees to use online communication and task management tools.
H3: Use of Scrum → Project success	Supported. Use of Scrum has a statistically significant and considerable positive relation with Project success (path coefficient of 0.35 and moderate effect size of 0.17).	Scrum comes in many flavors depending how it is used to achieve project success. However, organizations must ensure that their Scrum implementation respects the pillars and values of Scrum.
H4: Ability of working from home → Project success	Supported. Ability of working from home also has a statistically significant and considerable positive relation with Project success (path coefficient of 0.34 and moderate effect size of 0.15).	Software engineers' experience in achieving the needs for autonomy, competence and relatedness predicts their work performance and well-being. Organizations can do better by enhancing their employees' ability of working from home.
H5: Ability of working from home → Use of Scrum → Project success	Supported. Use of Scrum has a partial mediating effect between Ability of working from home and Project success (path coefficient 0.09, $p = 0.007$).	Using Scrum helps mitigate the remote working challenges which could hinder project success. Organizations should consider using Scrum within their remote teams to take advantage of the framework's benefits which are also reflected on Project success.

for further investigation of similar matters, therefore enriching the academic understanding of how working from home impacts Scrum IT professionals. However, we acknowledge that this study only focuses on Scrum practices during the COVID-19 lockdown; thus, we cannot make any assumptions for projects using other Agile frameworks or a combination. Similarly, our finding do not hold in a post-pandemic setting as such, but are precious evidence for possible future extreme events. Organizations might benefit from our investigation to develop a set of procedures about managing possible lockdowns.

Dependability. The research process is consistent, and the data is stable. An external auditor can examine the process following the “audit trail” (Guba, 1981) consisting of documentation gathered by the authors throughout the process, along with the actual data.

Confirmability. We guided ourselves by the ACM SIGSOFT empirical standards (Ralph et al., 2020b), which provided a broader understanding of what a qualitative study entails, allowing us to be less constrained in our analysis process. As such, our study provides a transparent explanation of our analysis process, with a clear chain of evidence from the participant (data) to the proposed concepts.

Internal. We used a cluster-randomized probability sampling strategy to validate our model (Gravetter and Forzano, 2018). Thus, we only used a cluster, namely the Prolific community, instead of the entire world population, which would not be feasible. We recognize that cluster sampling is less precise compared to random sampling, but it is far more cost-effective than other sampling strategies (Russo, 2021). Furthermore, we added screening questions and random attention checks to filter out inadequate responses to enhance the data quality. With this strategy, we filtered out 62 candidates out of 200 who did not meet our requirements, concluding to 138 valid responses. However, as most of our informants are from Europe, we recognize that our sample is not representative of the software engineering population employing Scrum.

External. Because sample studies are ideally suited for theory generalization, the fundamental goal of the PLS-SEM study has been the generalization of our findings (Stol and Fitzgerald, 2018). We received 138 valid responses, which was more than acceptable given the results of the *priori power test* we conducted using G*Power (Faul et al., 2009) before the data collection (suggesting a sample size of 98 participants). However, our model only

accounts for Scrum projects, thus cannot be generalizable for projects using other Agile frameworks. Moreover, our sample is mostly composed of professionals living in Western countries, which limits our external validity.

Construct. Is the most critical limitation to this investigation. Using a single-informant approach, the latent variables were measured to reflect the professional's perspective. We solely employed self-reported metrics, asking our informants to rate their level of agreement with literature-derived indicators. Considering the limited time we had to perform this investigation and its exploratory nature, we did not control for Common Method Bias. To compensate for questions not being correctly answered, we added random attention checks to filter out dishonest candidates. Furthermore, we adapted existing measurement instruments from the literature and also created the use of Scrum measurement instrument from the official Scrum Guide (Schwaber and Sutherland, 2020), as no validated scale was identified. For this reason, 26 out of 45 indicators were discarded from the model due to their poor loadings. For future research, we recommend of not using this scale due to its poor performance. We also acknowledge that although we used a validated a scale for Need for Autonomy, its reliability is just above threshold.

Statistical conclusion. The survey findings were computed using the Partial Least Squares-Structural Equation Modeling method with the well-known statistical tool SmartPLS (v. 3.3.7), which has been used in over 1,000 peer-reviewed studies (Russo, 2021; Ringle et al., 2015). Furthermore, all statistical techniques and tests utilized in the PLS-SEM analysis are in accordance with the most recent recommendations in our community (Russo, 2021; Russo and Stol, 2021).

7. Conclusion

Using Scrum can help mitigate the challenges brought by the remote context. The literature already focused on the best adoption and adaptation strategies towards distributed Scrum. However, the pandemic generated a context where the entire organization is working remotely, which has yet to be researched. Therefore, our study aimed to uncover the impact of working from home on the success of Scrum projects.

We employed a two-phased Multi-Method approach to better understand the impact through multiple interviews with Scrum practitioners who worked remotely. Then, we formulated a theoretical model drawing from our findings and the literature. We evaluated the model using Partial Least Squares-Structural Equation Modeling through a quantitative survey of 138 participants to generalize our findings. We found that the ability of working from home nurtures the satisfaction of the three innate psychological needs of the employees' autonomy, competence, and relatedness, making them perform better while working from home. Moreover, the use of Scrum mediates the ability of working from home and project success, suggesting that remote projects using Scrum have higher chances of attaining project success.

This study contributes to the limited literature within software engineering on working from home and its relation to Scrum and project success. While our investigation was purely exploratory, future research can build on our findings to create more fine-grained theories to fully understand the impact of working from home on the current software engineering community. Moreover, it would be insightful to expand our model other Agile methodologies, to capture a broader understanding of the current phase of the industry. Finally, future studies might build on our findings by assessing the relationship between Scrum's values and principles and the three innate psychological needs to provide further suggestions on creating a beneficial working environment for employees, which also reflects in project success.

Appendix A. Interview structure

For each Scrum Event in Table A.10, three questions were always asked for both On-site and Remote contexts:

1. What is the process?
2. How long does it take?
3. Who participates?
4. What is the output? Is there a difference between the contexts?
5. How do you feel about doing this event in this context?

Appendix B. Items description

See Table B.11.

Appendix C. Quantitative survey

See Fig. C.6 and Tables C.13–C.16.

Table B.11

Items description. Those prefixed with (*) were dropped because of their insufficient loading onto their latent variable.

Construct	Item ID	Questions	Reference
Need for autonomy	AN_1	(*) I was free to do things my own way.	Ryan and Deci (2000)
	AN_2	(*) I had a lot of pressures I could do without.	Ryan and Deci (2000)
	AN_3	My choices expressed my "true self".	Ryan and Deci (2000)
	AN_4	(*) There were people telling me what I had to do.	Ryan and Deci (2000)
	AN_5	I was really doing what interests me.	Ryan and Deci (2000)
	AN_6	(*) I had to do things against my will.	Ryan and Deci (2000)
Need for competence	CN_1	I did well even at the hard things.	Ryan and Deci (2000)
	CN_2	(*) I experienced some kind of failure, or was unable to do well at something.	Ryan and Deci (2000)
	CN_3	I took on and mastered hard challenges.	Ryan and Deci (2000)
	CN_4	(*) I did something stupid, that made me feel incompetent.	Ryan and Deci (2000)
	CN_5	I was successfully completing difficult tasks and projects.	Ryan and Deci (2000)
	CN_6	(*) I struggled doing something I should be good at.	Ryan and Deci (2000)
Need for relatedness	RN_1	I was lonely.	Ryan and Deci (2000)
	RN_2	I felt a sense of contact with people who care for me, and whom I care for.	Ryan and Deci (2000)
	RN_3	I felt close and connected with other people who are important to me.	Ryan and Deci (2000)
	RN_4	(*) I felt unappreciated by one or more important people.	Ryan and Deci (2000)
	RN_5	(*) I felt a strong sense of intimacy with the people I spent time with.	Ryan and Deci (2000)
	RN_6	(*) I had disagreements or conflicts with people I usually get along with.	Ryan and Deci (2000)
Ability of working from home	WFH_1	(*) My home is free from excessive outside noise.	Morgeson and Humphrey (2006)
	WFH_2	My job takes place in a clean environment.	Morgeson and Humphrey (2006)
	WFH_3	(*) The climate at my home is comfortable in terms of temperature and humidity.	Morgeson and Humphrey (2006)
	WFH_4	The seating arrangements at my home are adequate (e.g.: ample opportunities to sit, comfortable chairs, good postural support).	Morgeson and Humphrey (2006)
	WFH_5	My home offers an environment where I can easily focus on my work	Danielsson and Bodin (2009)
	WFH_6	There is enough space for work material and equipment at my home.	Danielsson and Bodin (2009)
	WFH_7	(*) At home, I have the technical equipment to do my work (e.g.: PC or laptop, printer, webcam, microphone).	Russo et al. (2021b)
	WFH_8	(*) The internet connectivity is fast and reliable at my home.	Russo et al. (2021b)
	WFH_9	(*) On the computer or laptop I use while working from home I do have the software and access rights I need.	Russo et al. (2021b)
Use of Scrum	US_1	(*) The Product Backlog is always prioritized.	Schwaber and Sutherland (2020)
	US_2	(*) The Scrum Team consists of Product Owner, Scrum Master and Developers (Development Team), composed of 3 to 10 people.	Schwaber and Sutherland (2020)
	US_3	(*) Within my Scrum Team, there are no sub-teams or hierarchies.	Schwaber and Sutherland (2020)
	US_4	(*) Only the people within the Scrum Team internally decide the work on the Sprint.	Schwaber and Sutherland (2020)
	US_5	The Product Owner is the only person responsible of creating and ordering items in the Product Backlog while estimating the items is the Developers' responsibility.	Schwaber and Sutherland (2020)
	US_6	(*) The Scrum Master is responsible to facilitate all the Scrum events.	Schwaber and Sutherland (2020)
	US_7	(*) Sprints have fixed lengths that do not exceed one calendar month.	Schwaber and Sutherland (2020)
	US_8	(*) Sprint planning is completed at the beginning of each Sprint and the resulting plan is created by the collaborative work of the entire Scrum Team.	Schwaber and Sutherland (2020)
	US_9	(*) Daily Scrum is time-boxed to 15 min and it is held every day of the Sprint.	Schwaber and Sutherland (2020)
	US_10	(*) During the Sprint Review, the Scrum team and the stakeholders collaborate on what was done in the Sprint and what to do next.	Schwaber and Sutherland (2020)
	US_11	(*) The Sprint Retrospective occurs after the Sprint Review and prior to the next Sprint Planning and The Scrum Team discusses what went well during the Sprint, what problems it encountered, and how those problems were (or were not) solved.	Schwaber and Sutherland (2020)

(continued on next page)

Table B.11 (continued).

Construct	Item ID	Questions	Reference
	US_12	Each artifact contains a commitment to ensure it provides information that enhances transparency and focus against which progress can be measured (Product Backlog - Product Goal, Sprint Backlog - Sprint Goal, Increment - Definition of Done).	Schwaber and Sutherland (2020)
	US_13	(*) Only the Development Team can update the Sprint Backlog during the Sprint.	Schwaber and Sutherland (2020)
	US_14	(*) Refinement of the Product Backlog items is done at least once each Sprint.	Schwaber and Sutherland (2020)
	US_15	Each Increment is checked if it meets the Definition of Done before being deployed.	Schwaber and Sutherland (2020)
Project success	PS_1	In light of new business requirements that arose during project execution, the project delivers all desirable features and functionality.	Russo (2021)
	PS_2	In light of new business requirements that arose during project execution, the Scrum-developed software meets key project objectives and business needs.	Russo (2021)
	PS_3	In light of new business requirements that arose during project execution, the Scrum-developed software overall is very successful.	Russo (2021)

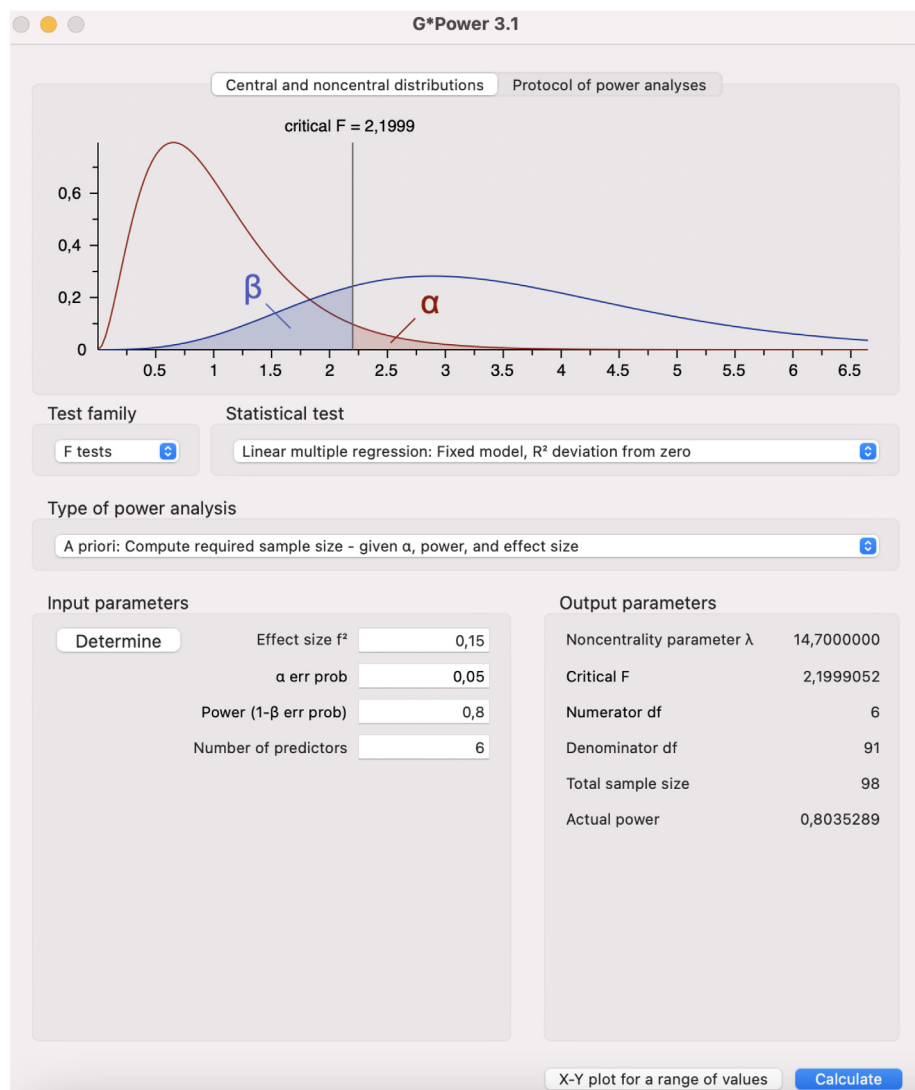

**Fig. C.6.** Sample size estimation based on statistical power of 80%.

Table C.12

Population divided per gender.

	Frequency	Percent (%)
Man	112	81.2
Woman	25	18.1
Non-binary	1	0.7
Total	138	100.0

Table C.13

Country of residence.

	Frequency	Percent (%)
Portugal	37	26.8
United Kingdom	24	17.4
Poland	16	11.6
Italy	11	8.0
Spain	7	5.1
Mexico	6	4.3
Canada	6	4.3
Greece	4	2.9
South Africa	4	2.9
Chile	3	2.2
Austria	2	1.4
Czech Republic	2	1.4
Denmark	2	1.4
France	2	1.4
Germany	2	1.4
Norway	2	1.4
United States of America	2	1.4
Slovenia	2	1.4
Belgium	1	0.7
Hungary	1	0.7
Latvia	1	0.7
Netherlands	1	0.7
Total	138	100.0

Table C.14

Scrum role.

	Frequency	Percent (%)
Developer (Development team)	119	86.2
Product Owner	7	5.1
Scrum Master	6	4.3
Other	6	4.3
Total	138	100.0

Table C.15

Scrum experience in years.

	Frequency	Percent (%)
Less than 1 year	39	28.3
1-2 years	40	29.0
3-5 years	43	31.2
6-10 years	15	10.9
11-20 years	1	0.7
More than 21 years	0	0.0
Total	138	100.0

Table C.16

Start working from home.

	Frequency	Percent (%)
During the COVID-19 lockdown	100	72.5
Before the COVID-19 lockdown	38	27.5
Total	138	100.0

Adrian-Alexandru Cucolaş holds a Master's degree in Computer Science from Aalborg University, Denmark. Currently, he is working as a full stack developer for a startup company in Copenhagen.

Daniel Russo is an Associate Professor of Computer Science at Aalborg University in Copenhagen, Denmark. His research and teaching interests are in the broad area of Empirical Software Engineering. His research has been published in the broader area of computing e.g., *ACM Computing Surveys*, *ACM Transactions on Management Information Systems*, *Semantic Web Journal*, as also in the Proceedings of the International Conference on Human Factors in Computing Systems (ACM CHI). Nevertheless, his main focus is on Software Engineering, with papers published, among others, in *ACM Transactions on Software Engineering and Methodology*, *IEEE Transactions on Software Engineering*, *Empirical Software Engineering*, and in the Proceedings of the International Conference on Software Engineering (ACM/IEEE ICSE). His research specializes in studying the effects of the COVID-19 pandemic on IT professionals, Agile software development, and research methodology. He is also PI or co-PI of several research projects and collaborates with large professional organizations, defense agencies, and multinational banking institutions. Web: www.danielrusso.org.
