Huangling County is located at the southern edge of the Loess Plateau, with the eastern loess area being part of the Luochuan tableland, and the western mountainous area belonging to the loess hills and soil and rocky mountains; since soil erosion is more serious in the eastern area, more than 70 percent of the increase in ecological space in Huangling County in the period 1995-2020 under the impetus of the grain for green project will be concentrated in the eastern side of the county. Local fast-growing tree vegetation, mainly acacia, is more suitable for planting and simple to maintain, so through long-term forestry activities in the eastern part of Huangling County, a relatively single vegetation structure dominated by trees has been formed, which has greatly reduced the species richness in the eastern part of the county, and for a long time, not only are the ecological differences caused by the topography and soil environment faced by the eastern and western parts of the county, but also the dichotomy of species diversity resulting from the grain for green project has also become more and more obvious. These factors have intensified the formation of the ecological border zone, and the development of the ecological space located in the ecological junction zone in the central part of Huangling County has obviously stagnated. In the future, the growth of ecological space will be further concentrated on the eastern side of the county, which will lead to more obvious ecosystem differentiation, and the overall stability of ecological space will continue to decrease(Figure 6).

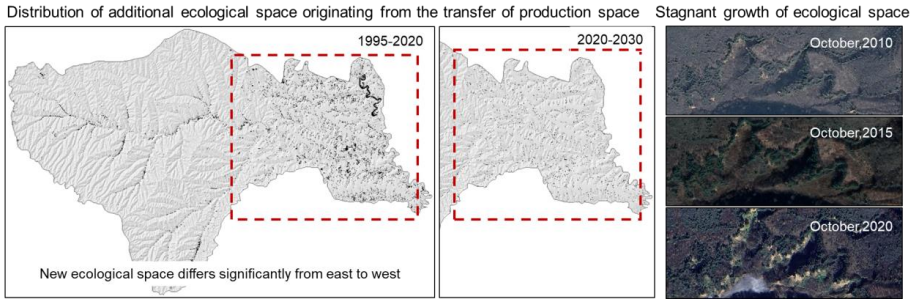

Fig.6. Binary polarisation of ecological space.

4 Spatial collaborative governance strategy for Huangling County

4.1 Connecting production space to improve the quality

In Huangling County's long-term development process centred on urban construction, a large amount of high-quality cultivated land has been replaced by construction land, and the quality of cultivated land has inevitably declined in the production space. Aiming at the scattered distribution of new cultivated land and the intermittent abandonment of cultivated land, which has led to the reality of the evolution of the fragmentation of the production space, the study puts forward the strategy of connecting production space to improve the quality.

Firstly, taking the territorial spatial planning of Huangling County as the basis, integrating and optimising the overall pattern of production space, higher quality cultivated land in the valley area should be prioritised into permanent basic farmland to strengthen the protection of high-quality cultivated land, and when cultivated land has to be occupied for urban expansion, less suitable cultivated land should be selected first, while cultivated land with higher cost of use and higher ecological risk should be designated into the ecological protection red line, and cultivated land will be launched in an orderly manner, so as to continuously harmonising the interrelationships among the “production-living-ecological" space. Secondly, the policy of "cultivated land requisition-compensation balance" needs to be linked to the construction of agricultural infrastructure. On the one hand, new cultivated land must adhere to the principle of "quantity-quality-ecology" balance in the selection of replenishment areas, and compensation measures need to be proposed for the phenomenon of "occupying the best and replenishing the worst". On the other hand, the relatively poor quality cultivated land in loess gullies and loess tableland borders need to invest more public resources in the construction of agricultural infrastructure to improve the conditions for the use of the production space continuously. Finally, it is necessary to optimise the rural settlement system, adjust the distribution relationship between population and arable land, and guide the integration of fragmented cultivated land resources for contiguous development.

4.2 Saving living space and making it suitable for the location

The rapid expansion of living space has long been spreading in the form of a long and narrow belt, which not only causes the inefficiency of living space, but also has a serious negative impact on the production and ecological space in the vicinity. Aiming at the unstable development of living space and thus leading to the decline of spatial coordination, the study proposes the solution strategy of saving living space and making it suitable for the location.

Firstly, the expansion of living space needs to strictly comply with the requirements for the coordination and integrity of the “production-living-ecological” space, and in the dual evaluation stage of territorial spatial planning, the key protection areas of production and ecological space should be identified in advance, so as to take the lead in protecting them and preventing the disorderly encroachment of living space. Secondly, the ever-expanding living space needs to respect the natural geographical conditions of the Loess Plateau region. On the one hand, the urban construction should be adjusted from a long and narrow belt to a continuous group, forming a relatively independent and complete living space, changing the current inefficient development mode, and gradually forming a "finger" urban structure by linking up the surrounding gully areas through the newly built roads. On the other hand, the grouped spaces should be interspersed with continuous ecological and production spaces, so as to reduce the environmental risks in the valley area. Thirdly, in the process of rapid development, there are a lot of inefficient urban spaces in Huangling County that need to be improved, so it is

important to actively promote urban renewal to ensure the efficient use of the stock of living spaces.

4.3 Regulating the ecological space into a stable and healthy system

The evolution of ecological space needs a long time process to appear the effect, for a long time Huangling County grain for green project to relatively single fast-growing vegetation planting forestry activities, although a significant increase in the total amount of ecological space, but at the same time, also greatly changed the overall stability of the ecological environment, for the construction of ecological space ignoring the ecological functions of the local adaptability, thus leading to the development of ecological space binary polarisation of the reality of the problem, the study proposes a solution strategy for the regulating the ecological space into a stable and healthy system.

In terms of technical support, Huangling County is located at the southern edge of the Loess Plateau, and its topography, soil and climate are all special to the area, so the construction of ecological space needs to set up a special research team, and on the basis of the ecological zoning of the territorial spatial planning, it should adjust the proportion of planting structure of trees, shrubs and grasses based on native plant species according to the actual conditions, so as to ensure stable and healthy development of the ecological space. In terms of policy support, the construction of ecological space requires long-term and stable local policies and regulations. The government of Huangling County should carry out long-term planning for the development of ecological space, and allocate funds in instalments according to the construction period and the maintenance period, so as to guarantee the funding requirements for long-term coordinated management. For the ecological space located in the ecological border zone, its own vulnerability is high, so it is necessary to reduce the intervention of external factors through planning, on the one hand, to reduce the concentration of new cultivated land in these areas, and at the same time, put forward more stringent control measures for the production activities; on the other hand, to minimise the intervention of short-term human activities in plantation areas through the closing hillsides to facilitate afforestation.

5 Conclusion

The construction of “production-living-ecological" space with harmonious integration of production, living and ecology is an inevitable requirement for urban development in the context of ecological civilisation, and also a key issue for the transformation of urban development in Huangling County in the new period. The analysis of the “production-living-ecological" space in Huangling County in a long time sequence can not only clarify the implementation of the previous plan, but also has practical significance in identifying the problems of urban development. Although there are some limitations, this paper conducts collaborative governance research based on the spatial and temporal evolution of the “production-living-ecological" space, which provides a guideline for the optimisation of the “production-living-ecological" space in Huangling County in the future, and also provides a scientific reference for the transformation of urban development in the Loess Plateau region.

Abstract
The paper addresses the complex and multifaceted issue of how planners, public administrations and scholars can approach high-tech transitions, and more generally the governance of transition to desired futures beyond techno-solutionism. The paper first presents the results of the Torino2050 project, which addressed the issue of governing the transition to autonomous driving. It then discusses how a collaborative backcasting approach will be applied in the recently launched ToMove project, which will test an autonomous public transport shuttle and a robot for last-mile delivery in a quasi-superblock testbed area. The project is promoted by the Municipality of Turin and the authors are involved in setting up a participatory scenario planning process. The project is a useful opportunity to actively involve the public administration in the scenario planning process, taking stock of the lessons learnt in the previous Torino2050 project.

Keywords:
scenario-planning, backcasting, autonomous vehicles, public administrations

1. Introduction

The salvific power of urban smartification should not be taken for granted, nor should its sustainability (Cugurullo et al., 2023). Whereas techno-solutionism which dominates the smart city discourse highlights the potential of new technologies (including AI) for urban efficiency and performance, a passive laissez-faire approach from public administrations can lead to undesired, unexpected and ungovernable outcomes. The deployment of Autonomous Vehicles (AVs), being a dominant manifestation of the emergence of AI in the management and development of cities, fully encapsulates these dilemmas.

The advent of AVs is likely to produce significant changes in how we move and live. Yet, when, how and to what extent these changes will take place is unclear, due to several dimensions of uncertainty. Not only is there high uncertainty about when full automation will reach significant market penetration, but also the direction and intensity of the potential impacts of AVs are

related to how public administrations will intervene in their diffusion. Public administrations need to deal with this challenge, in the short and medium term, but they are often reluctant to take up the challenge (Curtis et al., 2019). This is due to various factors, such as the high levels of uncertainty, the long horizon – much longer than the timeframe of administrative and political offices, for instance – and the lack of sufficient "actionable" information to direct investments or planning priorities. Scenario planning methods (Ariza-Álvarez et al., 2022; Tori et al., 2023) can be very helpful to support public authorities in dealing with these issues, but they rarely enter planning routines.

Aiming to stimulate discussion on these issues, this paper refers to two projects. Firstly, it summarises the results of the Torino2050 project, aimed to address the issue of governing the transition to autonomous driving, defining, through a collaborative backcasting, a policy pathway toward urban liveability and sustainability in Turin (Vitale Brovarone & Staricco, 2023). The process involved public and private actors, and shed light on three very important issues. The first is the power of anticipatory visions and the importance of defining concrete propositions to govern the technological transitions, beyond techno-determinism and towards desired urban futures. The second is the opportunity to ride the wave of the seductive power of technological innovation to promote goals of liveability and reduction of vehicle traffic within urban neighbourhoods. The third is the challenge of actively involving public administrations in the scenario planning processes (Vitale Brovarone et al., 2021).

Secondly, it discusses how backcasting is going to be applied in the recently launched ToMove project, that will test an autonomous public transport shuttle and a robot for last-mile delivery in a quasi-superblock testbed area. The project is promoted by the Municipality of Turin, and the authors, as part of the FULL-Future Urban Legacy Lab of Politecnico di Torino, are involved to set up a participatory scenario-planning process. In this case, the public administration is leading the process, and has accepted the researchers' proposal to use backcasting as a tool to envision a desired future and govern the transition to it, seeing AVs as just a small part of a desired future. The project is therefore a useful opportunity to actively involve the public administration in the scenario-planning process, taking stock of the lessons learnt in the Torino2050 project.

2. Scenario planning

In recent years, scenarios have been increasingly used to support decision makers to engage with uncertainty. For example, in the transport sector scenario planning is a well-known method to help solve future mobility challenges of cities (Tori et al., 2023). Nevertheless, as Cordova-Pozo and Rouwette (2023: 1) point out, three main challenges "limit the spread and the usefulness of scenario planning: conceptual confusion, methodological chaos, and scarcity of evidence on its effectiveness". Moreover, visions and scenarios are often acontextual as they do not refer to real case studies. This can be seen in the literature on AVs, where scenario planning frequently does not refer to the real spaces in which these vehicles will be circulating and parking (Staricco et al., 2019).

The process of scenario building foresees the delineation of a number of scenarios (generally three), including the reference scenario (usually referred to as the 'Business as Usual' or 'BAU scenario'), that is used to compare desirable futures. An important part of scenario building process is also the identification of key factors, which "may determine qualitatively different paths for the socio-economic environment" (Stead & Vaddadi, 2019: 127). The timeframes of scenarios can vary: they can be developed for both the medium term (e.g. 5-10 years) and the long term (10 years or more).

According to Stead and Vadaddi (2019), scenarios can be quantitative or qualitative. However, both quantitative and qualitative scenario methods seem to carry a certain number of disadvantages. For example, Weimer-Jehle (2006) argues that the complexity of quantitative methods often makes it difficult to involve stakeholders in a scenario building process. To counter these disadvantages, mixed-methods approaches, such as the cross-impact balance (CIB) development of socio-technical scenarios could be used (Tori et al., 2023).

Stead & Vaddadi (2019) identify three main approaches to scenario construction: (i) the forecasting approach; (ii) the exploratory approach; and (iii) the backcasting approach. The forecasting approach is often quantitative, where substantial change is not expected and current trends continue in the future. The exploratory approach is usually interactive and involves the identification of key independent and dependent variables. The backcasting approach is a widely known normative scenario method, which formulates future visions and goes backwards to define the actions needed to achieve them. It is often used to look at long-term futures, examining the way in which the desirable future can be reached. To do this, expert stakeholder participation is expected throughout the various phases of the analysis. It then delineates a set of criteria and policy pathways to support decision makers.

In the following sections, this paper presents, examines and discusses how a backcasting scenario planning approach is being applied to a real context in the City of Turin.

3. The case study of Turin

The case study focuses on the City of Turin, located in the north-west of Italy. Known as the 'city of the car', the city has deep roots in its economic specialization in the automotive sector. Although its economy is no longer centred on the automotive industry, today the local population is largely car dependent and presents high ownership rates, among the highest in Europe. The public transportation system is underused, as well as the bicycle and car sharing networks and services. Nevertheless, the presence of a technologically advanced public infrastructure for the management of the local mobility has led to the designation of Turin among the first cities in Italy for the national experimentation of the 'Torino Smart Road' project.

In 2018, it was the first Italian city to have launched a pilot project, the 'Torino Smart Road', to experiment with the circulation of AVs on public roads. One of the most significant results of the initiative was the definition of a 35 km urban circuit on which innovative autonomous and sustainable mobility solutions could be tested on a real road network (Figure 1). This real-world experiment has helped to place Turin at the forefront as regards the transition to AVs.

Figure 1. A road in Turin equipped with technologies needed to test autonomous vehicles (Source: Scudellari et al., 2020).

In 2021, the City adopted its Sustainable Urban Mobility Plan, which will regulate actions and interventions with a time horizon of ten years (up to 2030), developing a vision of the mobility and transport system that could improve the quality of life of citizens. Moreover, the City of Turin is one of the 100 European 'Mission Cities' that is committed to reducing emissions by 2030, i.e. it is a hub of experimentation and innovation in the climate sector.

4. The Torino2050 project

This section summarises the results of the Torino2050 project[1], which addressed the issue of governing the transition to autonomous driving in the City of Turin. In particular, the research project focused on the possible impacts of the diffusion of AVs, as well as the policy strategies and instruments (e.g. transport and land use policies) that should be adopted to govern them. In fact, one of the aims of the project was to provide policy guidelines that the public administration could implement in the short, medium and long term, to guide the transition of autonomous driving towards a future scenario based on the sustainability and liveability of the urban environment. To do this, the research adopted a collaborative backcasting approach, involving both public and private stakeholders, in order to define a future vision and the actions needed to achieve it. In particular, the project involved the participation of the various stakeholders (e.g. public administration, private companies, non-profit associations) throughout all of the phases of the project. This strong collaboration allowed the research group to deepen the technical knowledge of autonomous driving systems, as well as the understanding of the potentials and risks of these new means of travel (Scudellari et al., 2020). Finally, the project defined a policy pathway toward urban liveability and sustainability (Vitale Brovarone & Staricco, 2023), where the diffusion of AVs could be managed in an integrated and sustainable way.

[1] The project "Governare l'impatto spaziale e territoriale della diffusione di Veicoli a Guida Autonoma" was carried out by the Interuniversity Department of Regional and Urban Studies and Planning (DIST) of the Politecnico di Torino.

As mentioned above, the study adopted a backcasting approach, formulating future visions and going backwards to define the actions needed to achieve them. The visioning exercise was carried out in three different phases (Staricco et al., 2019): (i) the development of three visions by the research group; (ii) the validation of the three visions through a focus group with expert stakeholders, and (iii) the selection of the most advisable vision through a set of more than 50 interviews with expert stakeholders. The first two steps were based on a think-tank model, whereas the third was grounded on a participatory model.

In the first phase, three long-term visions (2050) for the city of Turin were delineated:

(i) a 'business as usual' scenario (Vision 1), in which the diffusion of AVs would not be explicitly governed, not their positive or negative impacts;

(ii) an optimistic and technology centred scenario (Vision 2, strong deregulation), which assumed that the impacts of AVs on the city would be largely positive;

(iii) a pessimistic scenario (Vision 3, strong regulation), which presumed that the negative impacts of AVs on the city would prevail if not properly managed.

The three visions were defined with reference to fourteen items: i) road hierarchy, based on the articulation into main roads and local roads; ii) limitation to vehicle circulation; iii) parking areas, with a specific focus on roadside parking and areas to pick-up/drop-off the passengers, multilevel parking, and intermodal parking; iv) local public transport, with specific focuses on the main lines, feeder capillary network and reserved lanes; v) shared mobility, differentiated between motorised and non-motorised services (e.g. bike-sharing); vi) pedestrian areas; vii) bicycle facilities; and viii) modal split.

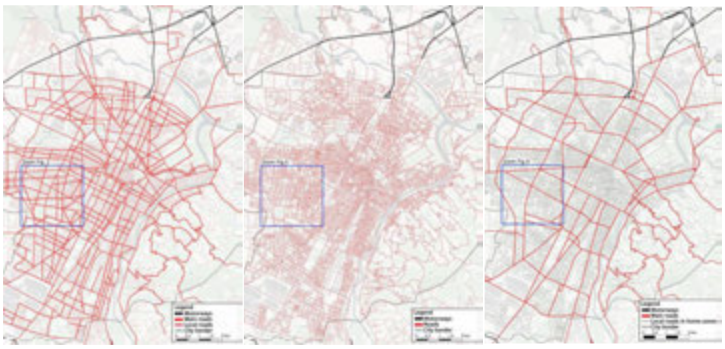

Figure 2. Road hierarchy in the three visions (Source: Staricco et al., 2019: 9, 11 and 13).

In the second phase, a focus group was organised and seven local experts in the transport sector (e.g. from the municipal and metropolitan administration, public transport authority, and third-sector associations) were invited to discuss and validate the three visions and assess their advisability and sustainability.

In the third phase, the seven experts who participated in the focus group and 44 other local stakeholders were interviewed to identify the most advisable of the three validated visions. The stakeholders were chosen in order to cover a wide range of actors interested in the possible future impacts of AVs in the City, such as: automotive companies, research centres, public administration, and environmentalist or professional associations. Finally, Vision 3 (strong regulation) was considered to be the most advisable, Vision 1 (business as usual) ranked second and Vision 2 (strong regulation) was deemed the least advisable.

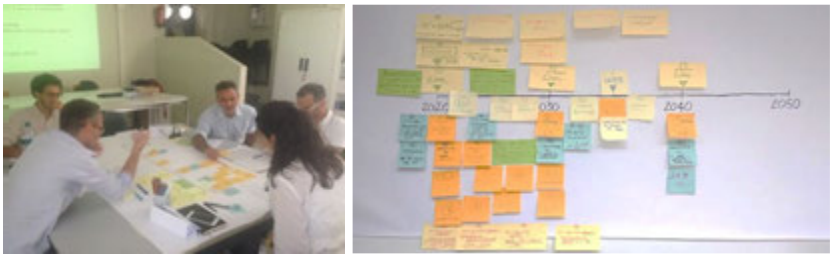

Figure 3. Policy pathway outcome of the Torino2050 collaborative backcasting (Source: Staricco et al., 2020).

The project has shed useful light on three very important issues. The first is the power of anticipatory visions and the importance of defining concrete propositions to govern the technological transitions, beyond techno-determinism and towards desired urban futures. The second is the opportunity to ride the wave of the seductive power of technological innovation to promote goals of liveability and reduction of vehicle traffic within urban neighbourhoods. The third is the challenge of actively involving public administrations in the scenario planning processes (Vitale Brovarone et al., 2021).

5. The ToMove project

Building on the lessons learnt in the Torino2050 project, this section looks at how backcasting is going to be applied in the recently launched ToMove project. The project is led by the City of Turin, and funded with 7 million euros by the National Recovery and Resilience Plan. The overarching aim of the ToMove project is to test an autonomous public transport shuttle and a robot for last-mile delivery in a quasi-superblock testbed area of the City of Turin. To do this, the project foresees a Living Lab, which focuses on the co-design of innovative and sustainable autonomous mobility solutions. As mentioned above, the project is promoted by the Municipality of Turin, and the authors, as part of the F*UL*L (Future *Urban Legacy* Lab) of the Politecnico di Torino, are involved in setting up a participatory scenario-planning process. The public administration has accepted the researchers' proposal to use backcasting as a tool to envision a long-term desired future and govern the transition to it, thus seeing AVs as just one part of a desired future. The project is therefore a useful opportunity to actively involve the public administration in the scenario-planning process. The aim is to actively involve the public administration from the beginning and throughout the various phases of the scenario planning process, thus facing one of the challenges which emerged from the previous Torino 2050 project.

Starting from the test area of the autonomous public shuttle of the ToMove project, envisaged near the Einaudi Campus of the Università di Torino, the scenario planning activity intends to look at a larger urban area, which can experiment with various different integrated forms of mobility. Referring to the approaches of organizing the urban fabric into superblocks (as in the well-known case of Barcelona, which many other cities are taking inspiration from), the area subject to experimentation includes the Vanchiglietta district and its immediate surroundings (Figure 4). The objective is to stimulate a broader reflection on the future of this part of the city, where important urban transformation projects are currently being implemented (e.g. projects involving green and blue infrastructures, redesigning public spaces, addressing climate neutrality, etc.). The study also takes into consideration current and future urban transformations in the test area and its surroundings, such as the former Italgas gasometer area

and the transformations along the riverside areas and the related parks, like the Meisino Park and the Fausto Coppi Motovelodromo.

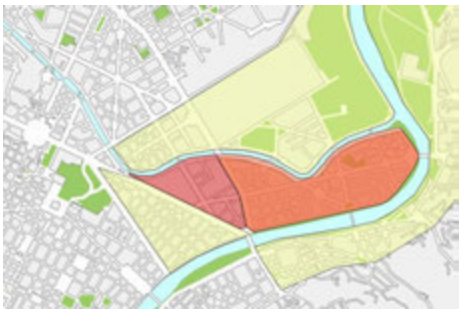

Figure 4. The testing area (in red), the Vanchiglietta area (in orange) and the interface areas (in yellow). Source: own elaboration.

There are various considerations underlying this choice, partly morphological and partly concerning the transformative urban potential. First, the area is contiguous with the autonomous mobility experimentation area around the block within which the Einaudi Campus is located. The extension of the area will provide access to a greater urban area in which to outline strategic transformation scenarios. Second, the spatial conformation of the area along its main road (Corso Belgio), an ogive shape surrounded by the rivers Dora and Po, which is relatively isolated with less than a dozen accesses via bridges lends itself to a reflection on the overall transformation. Third, there are various transformation processes already underway, in particular around the Einaudi Campus of the University of Turin and a former gasometer site. Fourth, the interface area extends north to the city's important monumental cemetery, partly because it is an attractor at an urban scale and partly because the area between the cemetery and the Dora is also relatively isolated. Fifth, the area offers possible solutions to support a redesign of mobility strategies on a larger scale, also through MaaS (Mobility as a Service) solutions. Moreover, this urban area is ideal for supporting a greater valorisation of the area along the rivers, as well as for integrating soft mobility routes.

The scenario planning activity goes beyond the experimental dimension carried out through autonomous driving tests, seeing AVs just as a part of a desired future. In fact, it aims to accompany a reflection on the future of this part of the city from various aspects, such as: innovative mobility (e.g. public transport, sharing mobility, bike lanes), urban regeneration (e.g. urban transformation projects, the redesigning of public spaces) and environmental sustainability (e.g. energy transition, circular economy, urban greening). The ToMove Living Lab also pursues the objectives of energy and environmental sustainability in line with the commitments undertaken within the European programme "100 Climate-Neutral Cities by 2030 - by and for Citizens", in which the City of Turin participates (see Section 3 above). It could be interesting, moreover, to exploit the momentum of Climate-Neutral Cities, where the concept of new mobility with MaaS services would be more visible on both a larger and smaller scale.

In order to co-design a new innovative mobility, the project involves the introduction of the concept of superblock, and the rethinking of public spaces, according to a principle of integration and diversification. In particular, these are the interventions that could be discussed with the various stakeholders and citizens: (i) the rethinking of vehicular traffic by concentrating it on some key sections; (ii) the possibility of using limited transit or pedestrianised areas; (iii) the connection with the areas along the river; (iv) the rethinking/connection with public transport lines; (v) the connection with MaaS systems,

creating exchange hubs; (vi) the taking into consideration of some of the major urban attractors (Einaudi Campus, former Italgas hub, monumental cemetery, etc.) and the customization of travel plans and integrated modes; (vii) indications for the redesigning of public spaces gained through the rethinking of vehicular transit spaces.

The project also looks at the overall normative framework, such as urban planning regulations: the comprehensive plan (Piano Regolatore Generale, PRG) and the various sectoral plans, such as the Sustainable Urban Mobility Plan (SUMP, Piano Urbano della Mobilità Sostenibile) of the Metropolitan City of Turin. Moreover, the test area, due to its particular location, offers the possibility of thinking about possible partnerships with carpooling systems, for innovative mobility services. Finally, the scenario planning will also consider how to integrate the topic of last mile logistics within the area. The scenario planning activity will be carried out within a CityLab[2], adopting the collaborative backcasting method, indicated in the literature as particularly suitable for supporting local authorities in the definition of transition pathways and policy packages towards desired visions for the medium and long term in contexts characterised by multiple elements of uncertainty.

As explained in Section 4 above, the collaborative backcasting method has already been tested by the research group as part of the "Torino2050 – Governing the impacts of the transition towards autonomous driving" project (Scudellari et al., 2019; Vitale Brovarone et al. 2021). The involvement of stakeholders will be based on the experience of the research group and the most recent indications from the scientific literature on scenario planning (Ariza-Álvarez et al., 2022; Tori et al., 2023). The backcasting approach is divided into different temporal and spatial levels (test area / extended area; ten-year scans) and is organised in five work phases:

i) a preliminary phase of identifying stakeholders;

ii) a visioning phase, with a pre-configuration of the different scenarios (there are usually three alternative visions of desirable futures, including the business as usual scenario) and of the transformation drivers;

iii) an interaction phase with experts and stakeholders (focus groups, interviews) to validate the scenarios, evaluate their strengths/weaknesses and select the desired scenario, to which the subsequent backcasting phase refers;

iv) a backcasting phase, for the definition of a policy pathway and the identification of different policy packages, i.e. sets of integrated policies to support the transition towards the desired future. These policy packages will then be evaluated against a series of criteria (e.g. environmental, social and economic). The backcasting operation will be conducted collaboratively, with the direct involvement of the stakeholders, followed by the re-elaboration and systematisation of the results by the research group.

v) a collective public restitution event. The results will be collected in a report that can inform and support the strategic plans and the definition of general (e.g. urban development policies) and sectoral (e.g. SUMP) guidelines of the City of Turin.

As regards the stakeholder involvement, four macro-categories of stakeholders will be involved in the process: (i) public administration; (ii) mobility and ICT services; (iii) research and consultancy; (iv) citizens' associations.

[2] Method already tested in Turin for the project financed by the Compagnia di San Paolo "Mover La Movida", proposed by the Municipality of Turin, and reported in the research report "Vivere, convivere, far vivere la notte a Torino" (Mangione et al., 2023).

6. Conclusions and future directions

As pointed out in the Introduction, today smart cities are dominated by techno-solutionism, pressing for more urban efficiency and enhanced performance. At the same time, the current advent of AVs is bringing a high level of uncertainty to urban areas. Public administrations and decision makers need to face this rising challenge but are often reluctant to do so (Curtis et al., 2019), which may lead to undesired, unexpected and ungovernable outcomes. Nevertheless, scenario planning seems to effectively support public authorities to deal with uncertainty, as well as to plan in such a long-term timeframe.

Both the Torino2050 and the ToMove (even if the latter is currently at an early stage) projects have shed light on a number of relevant issues as regards the application of scenario planning in the City of Turin. First, the governance structure of the urban environment is of fundamental importance to guide the future transition of cities. The urban normative framework, such as planning regulations and sectoral plans (e.g. the urban mobility plan), has a key role in shaping the desired future development of cities. As seen in the Torino2050 project, the "regulation of AV circulation and parking is likely to play an important role in governing the impacts of this innovation on the city" (Staricco et al., 2019: 17). Second, scenario planning seems to be a very useful instrument for decision makers in order to plan uncertainty. Moreover, as González-González et al. point out "in contrast with more commonly used forecasting approaches, backcasting provides a way of imagining a desirable future and identifying a set of core goals on which key decisions can be made" (2019: 153). It also seems that an active involvement of the public administration (as well as expert actors) during the different phases of the scenario planning processes helps the delineation and the evaluation of future scenarios. Finally, the literature on scenario planning seems to be mostly acontextual and a high number of studies seem to focus more on mobility issues rather than general planning issues. The case study of the City of Turin aims to help fill this gap and it is hoped that the ongoing implementation of the collaborative backcasting approach in the scenario planning will provide further fruitful results and considerations that can then be usefully applied in other contexts.

Projecting The Future:

Scenario Building and Storytelling for Holistic Perception of Future Context.

Abstract

In this paper, hybrid use of scenario development and storytelling tools is discussed to enhance the design process and how they can be used in the field of urban design to create solutions to the wicked problems of the future.

The workshop in which the proposed scenario building and storytelling processes were experienced was presented and how the methodology used in this study was developed, its findings and outcomes were introduced. As a result, it was determined that by integrating these tools into the design processes, the needed common idea development platform was created and design teams from different disciplines were enabled to holistically define the unpredictable context of the future and accordingly, a positive contribution was obtained in the development of the design idea.

Keywords: Scenario building, storytelling, future context, design education, wicked problems.

1. Introduction

The aim of this paper is to demonstrate how urban space can be considered within a holistic contextual proposal to build a vision of the future and confront possible wicked problems by using the scenario building and storytelling tools.

Based on the prediction that wicked problems such as climate change, whose global effects we have begun to encounter, will turn into continuous phenomena rather than isolated events, there is a need to define a new future context (IPCC, 2018). The concern that the idea projects produced through the analysis and synthesis of existing data for the problems of today and the near future cannot provide solutions to the wicked problems of the distant future is the starting point and basic question of this paper. Therefore, this paper explores the need to develop tools for interdisciplinary discussion of the uncertain and unpredictable new context of the future, especially in the field of education, at professional scales ranging from planning to architecture and other disciplines related to urban space.

Within this scope, the positive effects of the use of scenario building and storytelling tools were first examined through the development of the design idea in the historical process, the qualities that can be transferred to the current design process were determined. A redeveloped and interrelated hybrid process of using these tools collectively was tested in a workshop with mixed groups of undergraduate and graduate students from different disciplines working on urban space, and the findings were shared and discussed. When the results obtained are evaluated, it is determined that by using scenario building and storytelling tools together, it is possible to establish a common working platform that is necessary for interdisciplinary work and thus, it is possible to define the context of the future holistically in a part-whole relationship to support the design education process.

2. Design Problematic in The Presence of Crises

Although the act of design is simply defined as a fundamental problem-solving process (Archer, 1965), underlying this simplicity is the system approach that has developed since the late 19th and early 20th centuries, when scientific approaches developed and discussed the design problematic in relation to other disciplines. The necessity of considering the internal and external contexts starting from the individual who is the subject of the design to the society and community and their environment, as the whole system to which the problem belongs, and the need to analyse the diversified scales in relation to each other has been revealed (Bertalanffy, 1968).

The emergence of this awareness can be explained by a process in which past practices were inadequate, social problems requiring urgent solutions were fed by increasing crises and the need for *the new* and thus the need to refer to scientific methods became a necessity. In parallel with the change in production systems with the industrial revolution and the transition to globalisation, the identification and diagnosis of problems with all their components in a comprehensive context has become the main focus of the problem-solving process. Eventually, this approach brought the concept of *context* to the center of design problematic. The need for a new cross-scale approach has emerged in design education, which was once associated with only arts and crafts and should be evaluated together with different fields of specialization (Giedion, 1959).

The inadequacy of a single point of view in defining the problem and developing proposals for solution in the field of design, reveals the necessity of new approaches in education at the end of the 19th century. Beginning in the early 1920s, the shift from the arts and crafts movement based education system of the early Chicago School in the United States to a model supported by functional utility and knowledge gained from laboratory experience can be cited as an example (Jaffee, 2005, p. 42). Similarly, it is claimed that the strong development of the *Ecole Polythecnique* system in France from the beginning of the 19th century, alongside the classical *Beaux-Art* education, arose from the need to produce urgent solutions to the problems encountered in contemporary practice, in the sense of bringing together life and design. (Giedion, 1959, p. 211). The fact that the attempts to *search for the new* gained strength and increased after the First World War which were stimulated by economic and political crises, reveals the view that design is a tool that is questioned again especially in times of crisis. Giedion (1959, p. 291) defines this period as *infected atmosphere* and attributes the differentiation that emerged in design in two basic conditions. These were the abandonment of historical methods and the adoption of the principle of fitness for purpose in creativity. The salvation of the city from the individual citizen to the society and building to the urban structure

took a new breath in Germany at the beginning of the 20th century with the innovative design model brought by Bauhaus, bringing all disciplines together for the human needs.

The new crisis that started with the Second World War and the design approach that developed afterwards, by introducing new rational methods, proposes a systematic city that is distinguished with precise lines where people can live faster while accelerating production processes (Le Corbusier, 1927). Against this crisis of *standardisation*, it is possible to see models such as the Doorn Manifesto of 1954, which proposes different design approaches to achieve liveable urban areas and to reunite people, cities and nature with all their differences (Mumford, 2002, p.239). It is understood that the efforts of the reformist, innovative approach, which continued with TEAM 10 in the continuation of the Doorn Manifesto, addressing the design problem together, starting from the individual to the urban scale, could not prevent the space from becoming an object of consumption (Urry, 2016, p.104). As an example of this, it is possible to read the meeting of the city with the automobile, starting from the design object, through the way it affects the city, the individual, the society and its interaction with the social, political and economic context (Sheller and Urry, 2000). It is not surprising that a linear design approach was adopted to find solutions to the crisis of demand hunger encouraged by the economic system of the consumer society, while the real crisis of hunger, which has no material equivalent, was ignored. Therefore, it is possible to define the basic method of the design process in this economic boom period as the transformation of the idea into a design product within a basic approach that extends from analysis, synthesis, projection, concept design and production.

Design process carried out with such a limited analytical evaluation may also have lack off creative dimension and visionary perspective (Cross, 2004). However, it should not be ignored that the search for alternative solutions brought to the design process by temporary economic-based problems such as the oil crisis in the 1970s has enabled approaches that we define today as nature-based solutions or passive architecture (Wright, 1978). Similarly, collective architecture or place-making practices, the integration of participatory methods from planning to architecture, or the search for alternative transportation solutions have become tools of a design approach that seeks new ways to overcome the crisis of consumer society.

Based on these arguments, it is possible to say that starting from the 19th century, the design process was shaped by social conditions and crises that radically changed the production of space. it is seen that in the presence of crises that develop within defined contexts, it is accelerated to adapt to the current situation or to produce solutions to mitigate the effects of the crisis. Such a determination shows that crises that can be reduced to defined problems are effective in creating new methods that strengthen the design process until today.

On the other hand, in a situation such as the climate crisis, which poses a threat on a global scale and whose unpredictable effects cannot be reduced to defined problems, the design methods we have implemented until today can be considered inadequate. Distinction between *time ahead* and *upcoming prospects* conveys an important caution. *Time ahead* conveys a chronological sequence and linear flow of phenomenon mostly about a predictable near future, while *upcoming prospects* includes problems of distant future that are the focus of this paper such as certain outcomes conditional to significant societal events, natural hazards or public action plans (Ghimire, 2018). What we expect from design today is not only to produce solutions to current problems or the needs of today or the near future, but also to produce solutions to the unpredictable context that awaits us in the distant future.

3. The Need for A Tool to Predict the New Future Context

In the early 1970s, teams working in the technological field developed ideas on how methods such as operations research and systems analysis could be transferred to find solutions to urban problems. In this period, innovative methods were introduced to address the newly encountered *wicked problems* (Rittel and Webber, 1973) in social, technological and scientific fields within a systems approach (Skaburskis, 2008).

The definition of wicked problems also coincides with the *infected atmosphere* used by Giedion (1959) to describe the crisis where the design process has failed to produce innovative solutions. Today, wicked problems are recognised as the global problems emerging with the climate change, the parameters of which we cannot yet define precisely, but the consequences of which we may face in the short, medium and long term (IPCC, 2018). The consequences of problems such as overpopulation, urbanisation in the process of sudden spatial transformation, change of coastal areas, lack of biodiversity, transformation of agricultural lands, urban heat island effect can be listed as wicked problems (Neil, 2020). The main challenge is to identify wicked problems for which conventional solutions are insufficient in the framework of an unknown future context and in the presence of new complex problems, including issues that were not on the agenda of the last century. The systems thinking approach of looking at the wicked problems through patterns, provides important guidelines for holistically envisioning the contextual relations of the future. Senge (1990) defines systems thinking as the discipline of seeing the whole and emphasises that it is a framework for understanding interrelationships rather than singular elements, an approach to recognising patterns of relational change rather than momentary static fixations. According to Senge, an intuitive intelligence is needed to deal with complexity. While the intuitive side of problem solving is neglected in conventional educational theories, the role given to intuition by the systems thinking approach has the potential to make a significant difference.

The tendency towards the approach of interdisciplinarity in the design process can be considered as a result of the need to discuss the adaptation and interaction of changing space typologies in different time uses and contexts, and to consider different scenarios in the presence of uncertainties. Criticizing the design approach of the past, reveals that thinking across scales and establishing connections in the part-whole relationship cannot be reduced to a single point of view or a specific profession. When complex systems such as urban space are subject to design, it is recognized that interdisciplinary, participatory, holistic approaches that are open to discussion and questioning as much as possible require interdisciplinary, participatory and holistic approaches. The existence of program requirements in the accreditation of architecture schools, which state that the criteria for the evaluation of the social, economic, ecological, technical, artistic and cultural dimensions of design all in harmony, shows today's tendency towards a multidimensional and interdisciplinary approach to design education (UNESCO-UIA, 2023).

Despite of this tendency, in the field of education, the existence of tools that will enable different fields of expertise to work together in order to produce creative solutions by comprehending the complexity of the problems, uncertainties and the complex structure of the city as a whole is questionable. It can be said that the plan and project production processes applied today are limited within the problem and potential orientated design process, which is developed on a very linear and rational cause and result relationship to serve the current production and consumption systems coming from the legacy of the modern period.

Considering these current remarks and the approaches to the design problem defined from the beginning of the 20th century to the present day, it is possible to see that we are facing a different urban phenomenon and the problems it brings. Although the components that constitute the multiple structural layers and form of the city have changed slightly since the modern period of 1950's, it is seen that the scale relationship, socio-economic and political factors that constitute the parametric structure of this complex system have changed on a local and global scale. Especially the increase in the speed and accessibility of information flow compared to previous periods has brought a different dimension in reading and understanding this complex structure. While obtaining and synthesising the information needed from this complex pool of data requires the development of new areas of expertise in relation to the field of planning and design, it also shows that no single voice in the field of planning and design can be authorised to project ideas for the new context of the future. Consequently, this has led to a new wave of complexity-oriented urban science (Lepri et al., 2015). Especially in the field of planning and design education, it is becoming increasingly important how these data can be evaluated.

4. Scenario Building and Storytelling as The Unifying Tool for Interdisciplinary Studies

Based on the problems and potentials defined at section two and three, it is understood that the starting point of the design idea in complex systems such as cities is not the subject-object relationship based on a single problem, but the dilemma of finding a way in a chaotic situation. While dilemma often draws an unpredictable, ambiguous future, the design team consisting of different expertise are expected to produce creative thinking system in order to deal with today's complex set of problems.

Contemporary approaches suggest that planning and design processes should be evaluated in a multi-layered and interdisciplinary or even transdisciplinary structure, in the interaction of complex systems with the natural and artificial environment, and by considering the changing human perception (Gallotti, Sacco, & Domenico, 2021). Among these dimensions, perhaps the most striking emphasis is the difficulty of human perception to perceive this complex structure. Therefore, the need for conceptual tools to abstract this complex structure is particularly important. Today, as the climate crisis being a part of our daily lives, it is understood that the future predictions or plans and projects put forward by conventional methods are insufficient. Although the priority is to find resilient city solutions and to mitigate the impacts of climate change for developing short, medium, and long-term interventions, on the other hand the scenarios of adaptation to the new facts and new contexts for a future proof city needs to be considered. From this point of view, it is thought that the scenario building method (Chermack, 2011; Kahn and Wiener, 1967; Martelli, 2014) can be re-considered and developed in the field of planning and design education and can be evaluated as a tool to create a mutual platform that will bring together students dealing with urban space at different scales.

The philosopher and futurist Gaston Berger, with his discourse *la prospective*, is mentioned to have used the concept of scenario not only as a tool for imagining but also as a tool for understanding the future and making long-term predictions (Martelli, 2014). The concept of scenario building, which has found a wide implementation area today, was defined as a series of hypothetical events that aim to focus our attention on decision-making processes and was developed by Kahn and Wiener (1967). Urry (2016, p.97) states that *scenario workshops* play a role in determining the events and processes that are expected to occur at the chosen time of the defined scenario, and that future alternatives can be evaluated in the light of scientific data based on yesterday and today's information. In this sense, according to Urry, scenario building

enables the creation of a characterisation of the economy or society for a future time in the light of known trends, the main sources of change and possible patterns of economic and social life.

At present, scenario building tools are used in a wide range of perspectives, especially in the field of planning and design, from the development of country and regional development strategies to urban design and architecture (UN-Habitat, 2023; Merrie *et al*., 2018; Abou Jaoude *et al*, 2022). Considering these implementations, it is important to note that scenario building tools are actually considered as learning tools, as they are used to develop alternative proposals about the future context. This emphasises the importance of using this tool in the field of education (Berkhout *et al*., 2002; Brown and Castellazzi, 2014).

Among the actual scenario building tools that can be applied with multiple participants from different disciplines, the quad matrix (2x2 prediction matrix) created in the x and y coordinate plane with concepts representing extreme case oppositions finds a widespread implementation area. Although this tool is considered inadequate because it only allows the discussion of four alternative future scenarios, it is preferred as a practical application tool for short-term workshops for the development of design ideas. In order to establish the basic concepts to be discussed on the matrix, a preliminary study is required to identify future uncertainties and trends. This process can be developed through group discussions and debates and considered as a broad platform where the participation process can be conducted. While defining concepts of extreme cases to be placed on the matrix, the discussion of trends and uncertainties through political, economic, social and technological data constitutes the infrastructure for the development of scenarios with scientific data.

It is important to remember while developing scenario building tools that scenarios are stories about the future and should be presented as a narrative (Martelli, 2014). When Calvino's (1978) Invisible Cities is considered, it is possible to see that the abstraction technique and power of narratives have always been used as a valuable tool to conceptualise, represent and communicate the complexity of urban environments (Mukhija, 2015). In addition to Calvino's storytelling through text, it is also possible to see examples of how this approach can be used in the design process of storytelling through visualisation. In the context of the standardisation brought about by modernism, it can be said that the Archigram team (Cook, 1999), which questioned the urban space in the 1960s and emerged with a new manifesto, used the method of designing and transferring through storytelling, going beyond the strict architectural language and making the idea of design a source of inspiration for different disciplines. The competition, which brought together the experiences on sustainable and liveable urban development and aimed to project Metro Manila's future vision of the city by 2050, is an example of thinking, designing and communicating through storytelling in the current period (Manila Bulletin, 2020). Espinosa's work titled *Broken But Still Beautiful*, which won the grand prize, is noteworthy for narrating the urban context of the future through storytelling in a part-whole relationship.

When the changing perception of design in the historical process, its interaction with crises and interdisciplinary dimension are evaluated, it is seen that the utilization of scenario building and storytelling together can be evaluated as a tool to produce potential solutions to the new wicked problems we face with climate change. It shows that scenario building and storytelling have the potential to be developed as a tool that will enable the evaluation of the environment in a part-whole relationship and the creation of interdisciplinary collaborations, starting from the upper scale context in which all design fields from urban to architecture, and industrial design are involved. This holistic approach does not aim to uniformise and standardise cross-scale

approaches, as has been experienced in the historical process, but to foresee the conditions for a common future context that prioritises diversity and to encourage the development of different creative solutions to wicked problems.

It is argued that crises are the driving force for the development of innovative approaches in the design process. However, it is seen that the innovative pursuits that emerge in the aftermath of crises develop manifestos that form their basic discourse by first conceptualizing and questioning past and present trends. It is noteworthy that these manifestos use storytelling tools to convey how they transform the space for the future and to develop the idea of design. Although scenario development and storytelling tools seem to be communication tools, the idea that they can also be used as design development tools stands out as a potential model to be developed.

5. Construction of the Ideathon

In this framework, the combined use of scenario building and storytelling approach was tested through a workshop focusing on the coastal areas of Istanbul for the year 2100 and aiming to re-think the urban context when the sea level rises through different scenarios. Thus, the theme of the workshop was selected as *Sea Level Rise Due to Climate Change* as it is a contemporary theme with a multi-layered data set in terms of future projections in various fields. Based on this approach, the aim of the workshop is to develop design methodology in the presence of wicked problems and new crises and to test the use of innovative tools in the field of education as a supportive element of the design process.

5.1. Methodology and Work Structure

The workshop was organised in an ideathon format, bringing together different disciplines and creating an atmosphere of an idea marathon. The structure of the workshop has been developed to combine the process of performance-based scenario building with the process of stimulating creativity, generating different future ideas based on analytical data and developing design thinking through storytelling. The use of scenario building and storytelling tools, proposed as the main tools of the Ideathon, were utilised to allow participants to develop holistic and multi-layered approaches through quick thinking and high concentration. The scenario building tool, involving of a basic 2x2 prediction matrix, was used to present extreme opposite conditions and thus develop ideas about four alternative future scenarios to be used in the workshop. The groups to be formed by the students were asked to build their original scenarios by choosing one of these four conceptual frameworks.

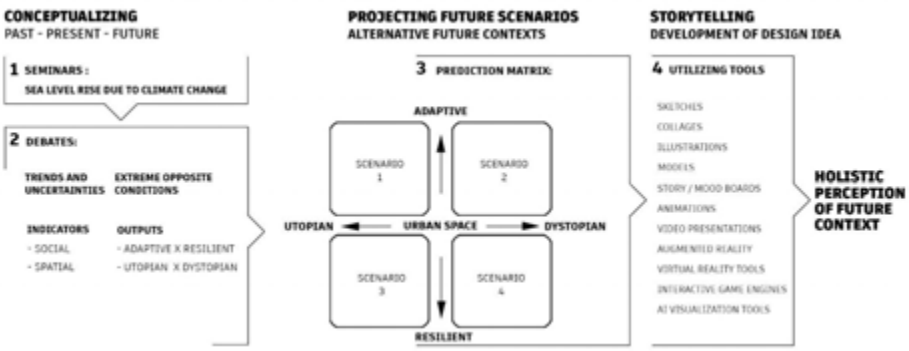

Figure 1. Methodologic approach to integrate scenario building and storytelling tools into the design process.

The methodologic approach that framed the workshop was applied in three phases over three days to bring participants together on a common platform and integrate scenario building and storytelling tools into the design process to create a holistic perception of the future context (Figure 1). These three phases were defined as *conceptualizing* the past, present and future, *projecting future scenarios* as alternative contexts and *storytelling* as development process of the design idea. The fourth day, which includes the jury evaluations and the closing panel, can be considered as the final phase that reveals the outcomes of the work.

The establishment of common conceptual structure for the discussion of the future context is important for the evaluation of the workshop outcomes. Therefore, there is a need to identify and conceptualize the variables that drive collective thinking in a short-term workshop with participants from different disciplines. The professional diversity of invited lecturers for seminars, jury members for evaluations and mentors to guide idea projects is as important as the diversity of participants in ensuring interdisciplinarity. In this way, different scenario proposals based on technical and scientific data can be developed, different storytelling tools can be introduced, and the final products can be evaluated equally. Therefore, experts from different fields of expertise in planning, design and art have been invited to participate to the workshop. On the other hand, student participants who will produce idea projects were invited through an open call to all undergraduate and graduate students who produce ideas related to urban space. Submissions evaluated according to the applicants' motivation letters, workshop experiences and other areas of interest. The Ideathon was attended by 27 students from the fields of architecture, urban planning, urban design, interior design, photography, painting, software engineering, sociology, graphic design, public administration, computer engineering, from various institutions. Mentors to assist the student groups during the workshop and jury members to evaluate the final products were selected from the fields of urban planning, urban design, visual arts and entrepreneurship, writing, stage design and scenic arts, and public administration.

5.2. Flow

On the first day, the first two phases of the Idethon process were addressed. In order to establish basic mutual understandings, debates on trends and uncertainties related to effects of sea level rise have been guided through political, economic, social and technological indicators. Since the workshop is a spatial inquiry and an inter-scaled study in the context of urban design, these multiple data set used in scenario building was categorized in two groups as *spatial and social indicators*.

After the thematic lectures and debates, lecturers and mentors highlighted the following concepts that emerged from all discussions, which were then used to identify extreme conditions for scenario building. These concepts can be grouped under the following headings.

- Adaptation
- Climate crisis and crisis response
- Planktonic approach
- Scenario building
- Balance

- Harmony
- Utopia
- Dystopia
- Sustainability
- User-centered design

The two main pairs of opposing concepts to be developed on the 2x2 prediction matrix were selected as a result of the clustering made in accordance with the connections established between the concepts.

- Adaptive and Resilient
- Utopian and Dystopian

The second day involved the scenario development phase. In this phase, four different future scenarios defined by the selected extreme condition concept were identified to form the 2x2 prediction matrix. Each group was asked to develop one of the four different future scenarios: Adaptive dystopian, resilient dystopian, adaptive utopian or resilient dystopian urban contexts. With the support of mentors, 8 groups of 2 to 5 students, decided which concepts in the scenario building matrix would intersect to envision the urban space of the future. Accordingly, they chose a coastal area on the Bosphorus and started to envision how the spatial and social qualities of this area would be shaped within the scope of the future scenarios they chose. This phase stands out as the phase where the part-whole relationship was questioned, supported by brainstorming, discussions and sketching. It is also the phase where storytelling tools suitable for narration were selected.

The third day involves the use of storytelling as a tool for developing the design idea. The groups were directed to narrate how the scenario they had identified affected the social organization and spatial structure from the individual to the community and society, how it changed and transformed coastal areas, and how these areas could become *liveable urban spaces*. Each group adopted their own narrative tools and defined their proposed *new urban system* in a *part-whole relationship*. It is important for the storytelling to question the proposed fictional context with continuous feedback. In this way, the feedback process needed in the design process is also implemented.

On the fourth day, the completed team works were evaluated by the jury members. The presentations and evaluations were announced through an open call and scheduled to be visible to anyone who wanted to participate online or in person.

5.3. Evaluations

Eight groups made their final presentations in a public session in front of the audience and jury. Presentations finalized with a question and answers session. The jury evaluated the proposed idea projects on the basis of the following five criteria, taking into account their ability to present a holistic and coherent new urban space.

Evaluation criteria of the idea projects:

- Consistency of the constructed idea.
- Scenario built through different perspectives.
- Multi-layered elaboration of the fiction of Istanbul.
- Originality of the idea.

- Quality of the visual presentation.

	CONSISTENCY OF THE CONSTRUCTED IDEA	SCENARIO BUILT THROUGH DIVERS PERSPECTIVES	MULTI-LAYERED ELABORATION OF THE FICTION OF ISTANBUL	ORGINALITY OF THE IDEA	QUALITY OF THE VISUAL PRESENTATION
GROUP 1	●	●	●	●	●
GROUP 2	●	●	●	●	●
GROUP 3	●	●	●	●	●
GROUP 4			●		
GROUP 5		●	●	●	●
GROUP 6	●	●	●		
GROUP 7		●	●	●	●
GROUP 8				●	

Figure 2. Evaluation of the idea projects.

According to the evaluations (Figure 2), 88 percent of the groups built their scenarios considering the perspectives of different disciplines in addition to architecture and planning. The diversity of the workshop offered a perspective that brought together social sciences, art and technology in the design process and made the proposals unique and innovative. The predominance of projects that emphasize how different species can coexist in interaction in urban space, can be considered as a result of this diversity. Generating a common vision from the perspectives of different disciplines increases the comprehensiveness of the design process.

75 percent of the idea projects developed creative ideas to confront wicked problems beyond conventional spatial project proposals. This can be associated with the fact that while developing the story, the proposed solutions evolve along with the narrative, and that all actors, from the individual to the community and all elements interacting with the space, are included and considered in the story. In this way, the problem is no longer just a *structural design* problem.

The relatively low presentation quality of the stories, at 65 percent, can be explained by the inadequate use of scenario tools and the fact that only one day was allocated to narration. The group discussions focused on the production and elaboration of the original scenario so that there was not much time for visualization due to time constraints. This situation shows that more time should be allocated to storytelling in similar workshops, and that rapidly developing artificial intelligence tools should be used more effectively to support design processes. On the other hand, it has also been observed that scenario development and storytelling may potentially risk *becoming an objective* rather than *a tool* to support design thinking. This can be considered similar to the problem of *Rendering Architecture* overwhelming the idea of architectural design. Therefore, it was seen how important the support and guidance of mentors is for establishing a balance in the use of these tools.

As a brief summary of the evaluations, it can be said that the participants were asked to imagine the future with multi-layered aspects of daily life in a limited time and that the program was supported with conceptual and technical lectures to increase creativity. So, the participants worked in a highly concentrated process. The outcomes of Ideathon aim to define the space and its components contextually, rather than using technical norms and standards as in a

conventional workshop. Although the theme of the climate change and the new crises was chosen with reference to a dark future, most of the groups proposed creative solutions and holistic proposals that carry hope for the future. This can be considered as an effect of promoting new inclusive methods, comprehending the problem in the whole context and developing creative ideas first, rather than looking for solutions to singular spatial problems. The components that construct the space and future habitat were proposed in a comprehensive and interrelated manner instead of being analysed in a fragmentary manner. It was observed that all idea project presentations developed a system proposal based on a liveable future. Hence, even if the future is a dystopia, the necessary conditions for adaptation can be achieved and that the power of imagination and holistic thinking by establishing inter-scale relations contribute to the re-establishment of ecological balance on a global scale. Different disciplines have different ways of problem solving. The integration of scenario building and storytelling tools for the development of design ideas has created a platform that brings these differences together to create solutions in a collaborative way.

6. Conclusion

The complex problems of today are indicators that we may face more complex problems tomorrow. It can be said that the role and responsibility of the designer and conventional design processes have to change in the presence of an unpredictable future context.

The method proposed in this study aims to improve the process, not the design itself. It enables the definition of a future context that minimizes uncertainties before moving to a design solution. The priority here is to project the future context and, accordingly, the design concept and the set of criteria for solving wicked problems (Figure 3). The hybrid scenario building and storytelling process guides the interdisciplinary design team to abstract the uncertainties of the future and imagine a coherent and holistic urban space through co-creation and conceptualization. In urban design, this hybrid methodology emphasizes the social, political, economic and ecological values of urban space, thus transforming the perception of urban design from a simple relationship of form and function.

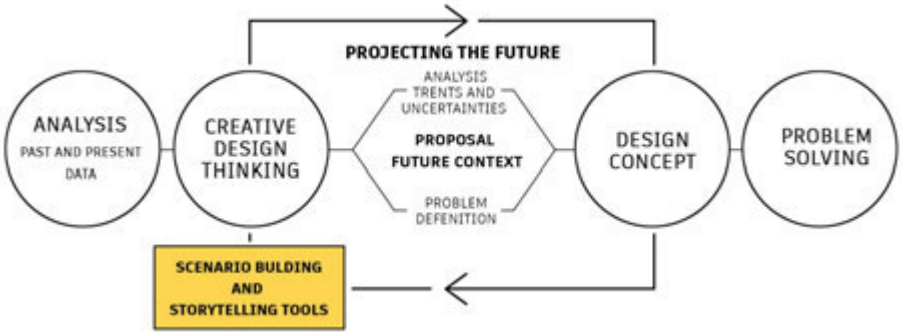

Figure 3. Problem solving process integrated with hybrid use of scenario building and storytelling tools.

The Ideathon format workshop is designed as a meeting, learning and idea generation environment for students from different disciplines to support their education. It aims to provide a creative exercise that emphasizes the diversity of scientific and artistic approaches to design

and a systems approach. Instead of defining a problem through limited analysis and synthesis data in a focused area, it is built on the development of a holistic perspective and creative design thinking that emphasizes understanding the trends and uncertainties at the source of the problem and thus the context of tomorrow.

A general evaluation of the study reveals that today it is increasingly difficult to predict the future in complex systems such as cities, and the negative impacts of constructing urban space through a single discipline or individual expertise. The need for an interdisciplinary perspective in education is clearly seen in order to prevent these difficulties. In professional practice contexts shaped by the conventions of the past, singular project-oriented thinking cannot devote sufficient time and energy to such endeavours of visioning. Similarly, in short university education, practices for vision and strategy development may be limited or there is not enough time to realize the idea of bringing together different disciplines, which is an important tool for achieving this. In order to design the future urban space, there is a need to develop an interdisciplinary and multi-perspective approach, which requires the interaction, exchange and co-creation of the knowledge and experience of different fields of expertise.

As in the experience shared in this paper, it is seen that supportive tools can be developed to close this gap by encouraging mixed studies, such as the hybrid use of scenario building and storytelling tools through short-term workshops. In the development of creative and innovative projects in design education, regardless of their theme and scale, it is important to evaluate them in the interaction of time and space with all their components, from the unit to the whole, from the individual to the society. This method has an important potential to perceive and comprehend the context of the future holistically and to produce solutions in the face of unexpected, wicked problems.

Abstract
Islands and island archipelagos, as typical peripheral areas, are of particular interest for both researchers and spatial planners. In this research the importance of the scenario method, especially in the education of future spatial planners is emphasised. The Zadar Island archipelago in Croatia was chosen as a case study for which eight possible scenarios were proposed. According to the evaluation the best rated scenario was developed in the long-term vision. Necessary activities in the form of different models (housing, transport, economy, green infrastructure) and related development projects were proposed for a period of next 25 years. Proposed models, with some modifications could be applicable to areas with similar characteristics.

Keywords: development vision, education, islands of the Zadar archipelago, scenario planning, strategic thinking and planning

1. Introduction

Peripheral areas of Europe as well as areas with geographical specificities, including islands and island archipelagos, are particularly interesting and challenging for both researchers and planners. Since the inner peripherality is the result of multiple combinations of features and processes in the space and different development dynamics, such spaces can also have significant development potential limitations. Conventional peripherality, as a result of physical geography and remoteness, is strong and in fact difficult to improve. As peripherality is determined also with non-spatial processes and factors, it is necessary to comprehensively look at and conceive appropriate development strategies, as well as policies and measures in order to achieve better accessibility, better economic potential and access to services of general interest, and consequently a better demographic situation for such areas (ESPON, 2017; ESPON, 2019).

Based on the sustainable development goals of the UN Sustainable Development Programme 2030, the Republic of Croatia created the *National Development Strategy of the Republic of Croatia until 2030* (2021), which determined four development directions (Sustainable economy and society; Strengthening resilience to crises; Green and digital transition and Balanced regional development) and thirteen related strategic goals, as a contribution to global sustainability goals. (Figure 1)

Figure 1. Connection between the Strategic Framework of the National Development Strategy of the Republic of Croatia until 2030 and the UN Sustainable Development Goals. Source: Official Gazette (2021)

In accordance with European development policies for balanced regional development, the Republic of Croatia wants to reduce internal differences in the level of development and make all parts of the country better and more desirable, while achieving permanent growth, demographic recovery, strengthening social justice and social trust. Goal 12 "*Development of supported areas and areas with developmental peculiarities*" is aimed on undeveloped areas, which refers to areas with developmental peculiarities - hilly and mountainous areas and islands. The main development of such areas is related to the unfavourable economic structure (weak role of the private sector and large presence of the state sector, insufficiently developed human capital, low entrepreneurial culture, insufficiently efficient institutions), depopulation, emigration and aging of the population. In addition, islands and hilly-mountainous areas are faced with specific challenges such as insufficient transport connections and seasonal infrastructure overload.

The national development strategy envisages *Development of smart and sustainable islands*. The concept is based on an integrated approach to the development and digitisation of island resources and management, taking into account the specifics in terms of traffic, energy, security and risk prevention, as well as the availability of infrastructure and public services. The goal is to encourage integrated passenger transport, interconnecting of the islands and their connections with the mainland. The planned structural changes of the island economies aim to strengthen the island's capabilities and capacity to implement innovative solutions in response to key social challenges (climate change and environmental protection, clean energy and traffic,

health and quality of life). In order to revive the island economy and vitality, emphasis is placed on the digital economy, tourism, availability of public services, renewable energy sources, fishing, food production and processing. Investments in the development of digital infrastructure are supported as a prerequisite for successful digitisation and digital transformation of island communities. Strategic connection of the islands with entrepreneurs and universities is planned in order to define and implement sustainable solutions for specific problems, including the concept of "smart islands".

The National Development Strategy (2021) sets the following policy implementation priorities on development of smart and sustainable islands:
• smart and sustainable management of island resources and environment, fight against climate change and risk prevention
• sustainable development and structural transformation of the island economy
• smart mobility and connectivity
• development and construction of optical broadband infrastructure and high-capacity communication networks
• improvement of life quality through development of public infrastructure (utility, water supply, transport, business and social infrastructure), support of housing and public services development.

In order to choose the most suitable development direction for islands and island archipelagos, it is necessary to consider the national and regional development plans, think strategically about the space and look at the long-term needs of inhabitants, as well as possibilities and spatial potentials on the local level.

The aim of this work is to emphasise the importance of the scenario method in planning as a par excellence tool for the future development. Its importance in the education of future spatial planners is pointed out so that they can think strategically about space, and to design and valorise possible scenarios of cities and regions in the 21st century (ECTP-CEU, 2013).

2. Education of Spatial Planners and Scenario Method in Spatial Planning

According to the UNECE (2008) spatial planning is a key instrument for establishing long-term, sustainable frameworks for social, territorial, and economic development both within and between countries. Its primary role is the enhancement of the sectors integration, and the improvement of national and local systems of urban and rural development, while taking into account environmental considerations.

As ECTP-CEU (2013) point out spatial planning, as a discipline, operates at different scales, from European, transnational, national, regional to local plans. Therefore, the principal education of spatial planners must be conceived in the way they get the abilities to cope with different scales and different levels of territorial planning.

As cross-disciplinary, spatial planning involves different professionals and actors. The planner’s role responds to planning developments in society and laws and policies. Primary focus of spatial planning is on the interest of society, the settlement and the region, and their development in long-term. The spatial planners are committed to protect the general interest of society. They analyse, draft, implement and monitor development strategies, supporting policies, programmes and key projects. They are engaged in the various phases and scales of the planning process. In planning, the role of the planner as a mediator is important, because

planning is not only concerned with plan preparation, but is part of the process where public and private interests need to be balanced. Ability to mediate and to negotiate are therefore important in planners' education. In order to support and guide the public planning process, the planner's role requires increased design, synthesis, managerial and administrative skills. Besides it demands a scientific approach, the achievement of social dialogue and agreements. The challenges of the 21st century require planners to undertake the commitments as leaders of change, political advisors, designers, urban managers and scientists in order to lead the way in making the changes that are needed for cities and regions to achieve the Vision and to apply the principles for sustainable development. (ECTP-CEU, 2013)

According to the ECTP- CEU the planners' core commitments, embodied in the Charter of European Planning, include research and analysis, advocacy and mediation, the ability to envision, evaluate and promote potential future options for urban, spatial, and territorial development. University-based recognised planning courses for spatial planner are combining scientific and creative conceptual thinking with practical approaches in order to harmonise society and environment at various territorial levels. The ECTP- CEU (2017) has identified the framework of guidance based on three needs and the related eight core competences of spatial planners:

- Critical thinking and understanding of the rationale of planning and its theoretical and legal basis (The Rationale od Planning)
- An understanding of the spatial systems (Socio-economic systems, The Built Environment, Environmental systems)
- Technical and creative competence needed to engage in planning practice (Planning Techniques, Planning Instruments, Planning "Products" and Independent Research).

Spatial planners therefore must have a range of core competences and a commitment to ethical standards of conduct. Understanding, knowledge and skills of the following are required: the economic, social and environmental spatial context for planning decision; the political and legal framework within which decisions are taken; the ability to initiate and implement plans and policies; analytical, design and communications skills to inform choices, including the application of research knowledge; and the ethical challenges including the need for inclusive approaches and reflective learning; and the ability to collaborate and in co-working. (ECTP-CEU, 2017)

As it can be seen on the Figure 2 that the planning process is continuous and cyclical because spatial systems change, and planning needs to adapt to these changes. Further the preparation of the planning product is informed by research into socioeconomic, built, and natural spatial systems. The planning product is implemented by the use of legal, financial and administrative instruments. That will have an impact on the spatial systems as these change as a result of planning intervention. Those changes in the nature of the spatial systems will require renewed intervention, or changed intervention that will require updating planning policies. Since planning is more than an administrative or bureaucratic process, planning intervention is not always necessary and must be justified. (ECTP-CEU, 2017)

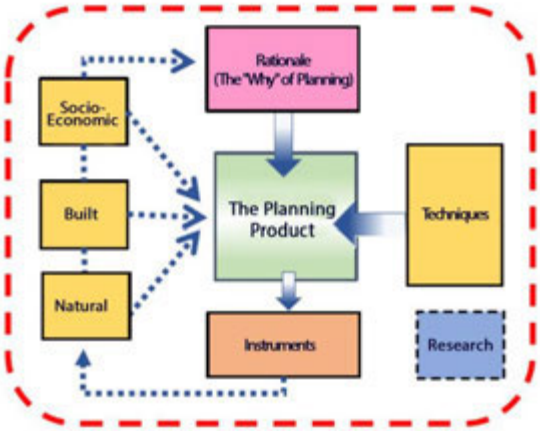

Figure 2. Aspects of Planning Practice. Source: ECTP- CEU (2017)

In order to determine the future development possibilities of a certain area the scenario method is used as a par excellence tool in planning especially regarding encouraging strategic thinking and helping overcoming thinking limitations. As the scenario method is the subject of numerous research, there are many definitions depending on the authors and their areas of application. The founders of future studies and scenario planning, Kahn and Wiener (1967) define scenario as "a set of hypothetical events set in the future constructed to clarify a possible chain of causal events as well as their decision points". Scenario is also perceived as a description of the future state and the sequence of events leading to the future state (Godet and Roubelat, 1996). Shearer (2005) points out that the scenario is a mean to achieve the desired state, and not a "variant of the future".

After the WWII, the use of the scenario method expanded, when it was linked to military planning at the RAND Corporation. During 1960s the methodology was used for the purposes of social forecasting, public policy analysis and decision making. In the 1970s, scenario planning gained a new dimension especially in the private sector. Bradfield et al., (2005) point out that during the last decades, the use of scenario method has particularly increased also in the field of spatial planning.

Depending on the level of spatial planning, Kok et al. (2006a, 2006b) stress that scenarios created for lower levels are based on scenarios from higher levels. Higher-level scenarios are usually developed by scientists and stakeholders on the regional and national levels, while local scenarios are developed by local stakeholders. Scenarios can be presented in textual and graphic form as pictures, graphs, maps, etc. that enables better perception and understanding of the future (Rothman (2008). Ljubenović et al. (2014) stress that quantitative numerical accuracy is typical for simulations, while scenario planning usually provides a more qualitative description of how the present will evolve in the future. They point out that in the scenarios the range of possible outcomes resulting from uncertainty is explored, while creating a vision builds a picture of desired future together with strategies for achieving goals. Friedmann et al. (2004) believe that how we are questioning the future for optimal decisions in the present that have to

be based locally. In order to enable the assessment of the outcomes and effects on different aspects of sustainability, in the context of different assumptions or scenarios a detailed investigation of strategic issues is necessary. Radeljak Kaufman (2016) points out that the scenario method is useful in spatial planning because of the creation process during which knowledge about development trends and spatial elements is expanded, but also because of the final results that are important for management strategies and measures.

In the education process, students as future spatial planners are directed to strategic thinking and the use of the scenario method, that presents an efficient tool to articulate concepts of an uncertain and complex future. This tool serves as a basis for defining an integrated vision of development of cities and regions. The application of scenario planning based on Intuitive logics school, which does not use any mathematical algorithms, stimulate students′ intuition and creativity, which is the methodology proposed by Stanford Research Institute International (SRI). The advantage of the SRI approach is the development of flexible, internally consistent scenarios from an intuition and logical perspective (Huss and Honton,1987). Besides the importance of flexibility in the process of creation of a spatial development vision, has to be taught as well as the need to create at least four scenarios which enable an open discussion and the combination of different interests of stakeholders in the process of defining the preferred model and creating a common development vision (Vogelij, 2010).

In the process of education, students are directed to elaborate strategic visions that are considered as the basis for creating high quality places and delivering a more sustainable future for communities as well as to achieve their long-term needs. Using comprehensive planning, as an effective tool for enabling communities to formulate strategic visions of their future development goals, future spatial planners are taught to apply the integrative approach that allows an evaluation of the strengths and challenges of the specific area, the definition of opportunities and scenarios, and selection of optimal vision and spatial policies for the future development.

At the Faculty of Architecture of the University of Zagreb during the Undergraduate and Graduate Studies in Architecture and Urbanism students encounter various tasks in the field of urbanism and spatial planning. On the third semester of the Master Study in Architecture and Urbanism students have the opportunity to choose between fourteen workshops led by professors from the Faculty of Architecture. Workshop 3 - Spatial planning is one of three workshops led by professors of the Department of Urban Planning, Spatial Planning and Landscape Architecture. The main goal of the course is to propose a vision of the spatial development of chosen area (region or city) based on the principles of sustainability and the proposed topic depending on the academic year. The first stage of students′ assignment includes a consideration of theoretical starting points and a detailed analysis of the existing situation, spatial planning documentation and strategical document, which ends with a SWOT analysis as a basis for the second stage. They are directed to perceive spatial strengths, weaknesses, opportunities, and threats considered from different perspectives, immersing themselves in the different roles played by various actors. Besides they are encouraged to use surveys to determine the key issues and needs of residents and users of the subject area. In the second stage, students independently or in group research conceive various scenarios for the future development, taking into account complex systems and numerous processes. Based on the set criteria, the evaluation of development scenarios is made and development vision as well as a concept for the subject area (graphics, model) is proposed. In the third stage, a more detailed elaboration of the program for the selected location and the proposal of strategic and development projects are made.

3. Case Study: Islands of the Zadar Archipelago

For this research, the islands of Zadar archipelago were chosen as a case study, because of its specific geographic characteristics as well as socio-economic processes, as depopulation and emigration, and the relatively old population. The project was made within the Workshop 3 – Spatial Planning in the Academic year 2022 / 2023 (students: Lucija Kustić and Marta Marelić, mentor: Associate Professor Lea Petrović Krajnik). The goal of this project is to set up a revitalisation model for (Croatian) islands, that is, to create a model that is applicable to other areas with similar characteristics and similar challenges.

Figure 3. Position of Zadar County and Islands of the Zadar Archipelago. Source: Kustić and Marelić (2023)

3.1. Specificities of Zadar County and Islands of Zadar Archipelago

The Zadar County (area 7,276.23 km² and 159,766 inhabitants) is located in the central part of Adriatic Croatia and has an important role in transport connections within the country, but also on the European level, since it is located at the intersection of two important transport routes (the pan-European transversal North - South and the future Adriatic - Ionian longitudinal) and is the location of the shortest international ferry connection with Italy. (Figure 3)
Zadar County includes 34 local self-government units, of which six are cities and 28 municipalities. The largest city and administrative centre of the county is Zadar, the fifth largest city in Croatia (70,779 inhabitants). Zadar is the urban centre of northern Dalmatia and the administrative, economic, cultural and political centre of the region.

Zadar County is specific for the number of islands, the indented coast, the fertile zone of Ravni Kotari and hilly - mountain area. It is made up of seven spatially developmental and geomorphological units regarding its natural-geographic features (Zadar urban region, Zadar islands, Ravni Kotari coastal area, Sub-Velebit channel area, Bukovica, Lika-Poun area and a part of the island of Pag). One of the units is the islands area, which is formed by the northern

fragmented group (Silba, Olib, Premuda, Ist, Škarda, Molat te Tun), the Ugljan-Pašman group (Ugljan, Sestrunj, Rivanj, Ošljak, Pašman, Babac te Vrgada), and the Dugi otok group (Ravu, Iž, Zverinac, Lavdaru te Katinu). The island archipelago represents one of the most sensitive and endangered areas of the county with specific demographic and developmental problems of aging and displacement of the population and the consequent decline of economic activities. (Ministry of Economy and Sustainable Development, 2024)

The *Spatial plan of Zadar County* (2023) and the medium-term strategic planning act of importance for Zadar County, *Zadar County Development Plan* (2022), which defines special goals for the implementation of strategic goals from long-term strategic planning acts were used as the basis for the analysis of existing and planned situation, development needs and potential of the county and the determination of development goals.

The analysis of the demographic structure of the population of Zadar County indicates that settlements on the mainland have a better ratio between old and young population, while all the islands of the archipelago have less than 20 percent of young population. This trend was evident in three previous population censuses. One of the reasons for such a trend is centralisation, which encouraged the emigration from the islands, and represents one of the most significant topics.

The road infrastructure on islands varies depending on the size, the number of inhabitants, tourism development and other factors. Due to unplanned development, some areas are not equipped with sufficient transport infrastructure, there is a deficit of parking space, which is often organised in inappropriate locations, and public transport is insufficient. The island of Silba is an example of an island where cars are prohibited. Ferry and boat connections to the island depend significantly on the number of permanent residents and tourists, and the number of lines is significantly higher during tourist season. The maritime connection between islands is weaker because all lines are primarily directed towards Zadar and some of these lines interconnect different islands in order to be more profitable.

The total of 34.48 percent of county's area is covered by the NATURA 2000 ecological network, of which Public institution Natura-Jadera is responsible for 25.33 percent. Conservation areas important for birds cover 26.4 percent of county's surface and conservation areas important for species and habitat types cover 24.76 percent. There are several protected categories of nature on islands, one of which is the Telašćica nature park, three special reserves on Pag and one on Dugi Otok, significant landscapes on Dugi Otok, the island of Pag and the island of Ošljak. The natural environment of islands of the archipelago is well preserved because of their partial isolation.
The geographical position of the county and climate conditions favour the production of energy from renewable sources. The area of Zadar County is exposed to strong winds, especially in the area at the foothill of Velebit, where 8 wind farms have been built, which make up 23 percent of the total power of all wind farms in Croatia. In addition, out of twenty small hydropower plants in the Republic of Croatia, four of them are located in the county. The largest is HPP Velebit located in Zadar County, which is also the second largest hydropower plant in Croatia. In order to realise the plan of the Republic of Croatia to increase the share of renewable energy sources to more than 50 percent by 2030, the planning and construction of solar panels and the use of solar energy, which the country is abundant of, began. Zadar County has almost 2,500 hours of sunshine per year, which significantly favours the use of solar energy. Out of a total of nine large, non-integrated solar power plants built or planned so far, two of them are located in Zadar County - Obrovac and Stankovci.

In significant economic indicators, the economy of Zadar County accounts for approximately 2.5 – 3 percent of the economy of the Republic of Croatia, except in sectors of tourism (where the share is up to 14 percent), maritime transport (up to 40 percent) and mariculture with over 70 percent of country's total capacities. The structure of the Zadar County economy according to total income, in addition to other activities, is dominated by trade, processing industry, tourism, fishing and mariculture (although limited by natural resources and legal catch limits) and shipping. In addition to the food industry based on raw materials from the sea and Ravni Kotari, the export-oriented processing industry relies on the production of metal components for the automotive and pharmaceutical industries.

In the area of Zadar County, according to data from 2015 / 2016 there are 80 kindergartens, 38 primary schools, 79 regional schools/facilities, 21 high school and one high school dormitory (in Zadar). Almost 80 percent of the total number of schools are located in the city of Zadar, while the rest are located in the cities of Biograd na Moru, Benkovac, Obrovac, Pag and the municipality of Gračac. Pag is therefore home to the only high school on the island in the county. There is one university in Zadar County - the University of Zadar, with a total of 25 departments, four research centres and two teaching centres. Primary School Zadarski otoci - Zadar has three regional departments on the islands (Veli Iž, Silba and Olib). A preschool program also takes place on islands Veli Iž and Silba.

There is a potential for development of numerous adventure sports on islands, both for the purpose of tourism and for the local population. Analysis of existing sports and recreation infrastructure indicates that only larger settlements have certain sports facilities mostly football and/or basketball and handball fields, and less often tennis courts.

Based on detailed research a SWOT analysis was created as a database for further scenario planning. In addition, the conclusion of the analysis is given, and there are certain topics that have a distinct mutual influence and indirectly related topics (Figure 4).

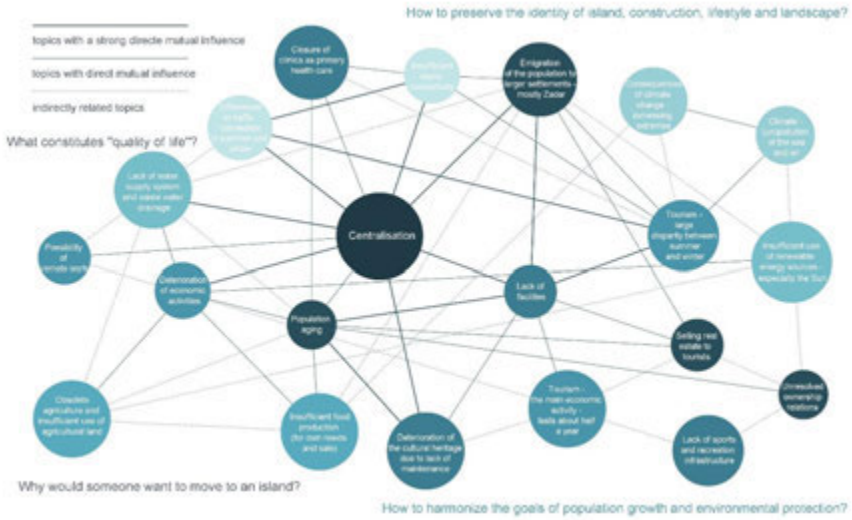

Figure 4. Main Topics for Consideration and Problematic Issues. Source: Kustić and Marelić (2023)

3.2. Development Scenarios of Islands of the Zadar Archipelago

Taking into account the goals of sustainability, the current situation, and the inhabitants needs, the basic goals to be achieved in the long term by the project were to limit the emigration and aging of the population, to offer new facilities, modernise life on islands, but also to recognise the quality that this way of life offers, with an emphasis on (self)sustainability which is to be achieved through the integrity of the approach to planning future development.

Based on the detailed analyses, eight scenarios were proposed as possible directions of development. (Figure 5)

The "Status quo" scenario continues the current trends in the area characterised by the aging and emigration of the population. All island settlements will continue to gravitate towards Zadar as the centre. The islands will remain–poorly connected by traffic, so there would be no cooperation or complementing each other with facilities, which would be an undesirable and unsustainable scenario.

The scenario "Strengthening the existing island centres" - Pag, Ugljan, Dugi Otok and Pašman, is based on the idea of partial decentralisation of Zadar, because the centres are formed around larger settlements. Residents primarily move to these places and to these islands, which results in smaller islands becoming abandoned and available for conversion and renovation with the appropriate purpose - agricultural, production, tourist, cultural or recreational islands.

The "Networking" scenario - the islands as a whole - the city, envisages interconnection - both in terms of traffic and various facilities, at the level of all the islands of the observed area. The intention of this scenario is for the islands to be seen as neighbourhoods within a larger whole - the "island-city", which aims to increase the availability and sustainability of the facilities and attract residents to permanently move to islands and to be less dependent on Zadar.

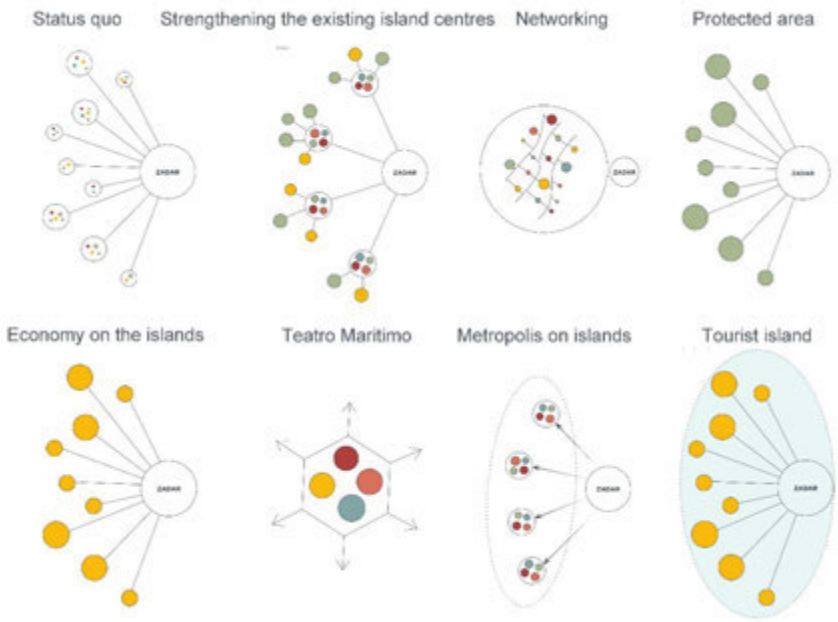

Figure 5. Eight Possible Scenarios for the Islands of the Zadar Archipelago. Source: Kustić and Marelić (2023)

The "Protected area" scenario envisages the relocation of residents and facilities to Zadar. In this way, islands would be natural protected oases. All the islands of the archipelago would become part of Zadar, and would represent a protected landscape used for research purposes, sports and recreation, and tourism.

The "Economy on the islands" scenario predicts further development of Zadar as a centre, due to which the population moves to the city, while islands remain abandoned. Islands of the archipelago with great potential become a part of Zadar economic zone intended for development of clean industry, modern agriculture and energy production from renewable sources. The number of permanent residents is decreasing, as well as the aging trend, as the necessary workforce is immigrating.

The "Teatro Maritimo" scenario is based on Aldo Rossi's idea of a floating theatre, i.e. public facility that floats to the user, instead other way around. In this way, the number of necessary daily commuting would be reduced, and at the same time the availability and profitability of the facility would be increased (due to larger gravity).

The "Metropolis on islands" scenario is based on the premise that life in existing cities becomes so poor and/or even impossible (due to pollution and the consequences of climate change) that the population moves to islands in search of better living conditions. The islands of the archipelago become cities where the necessary infrastructure, facilities, residential construction are built, and existing ones are renovated. This scenario is the riskiest (out of the above) as it could result in devastation and environmental pollution.

The "Tourist island" scenario is based on the idea of turning islands of the archipelago into Zadar tourist zone, due to further centralisation. It is based on the assumption of year-round tourism, various supporting facilities and the necessary infrastructure. It is characterised by complete subordination to tourism. Permanent residents of islands are necessary for the maintenance of the entire infrastructure, while the rest of users travel to islands for work.

Figure 6. Comparison of Eight Scenarios. Source: Kustić and Marelić (2023)

Eight scenarios were rated based on 19 elements (population, housing, quality of life, economy, tourism, energy, food production, traffic, climate, risks, environmental protection, waste, dependence on a larger centre, waste, health, water supply, education, culture, administration and politics) and compared with each other. The graphs (Figure 6) show the evaluation of individual scenarios. The scenarios, although extreme, have some good elements that could be used in further planning. Based on the comparative analysis of the effects, the comprehensive "networking" scenario was chosen as the optimal. In the following, the scenario was elaborated into a vision in which some elements of other scenarios were included.

3.3. Development Vision - Spatial Interconnecting for the Sustainable City of Tomorrow

The vision of development is based on networking which implies interconnection - both in terms of traffic and various facilities, at the level of islands of the Zadar archipelago. The islands are seen as neighbourhoods within a larger whole - the "island-city". In this way, an effort is made to increase the availability and sustainability of facilities, and to attract residents to permanently move to islands, which would result in less dependence of island residents to the

city of Zadar. On each island there are facilities necessary for its function. Certain islands are assigned with one "main" purpose, resulting in creation of a larger centre (an "island-city"), which is well connected to other islands. The mutual traffic connection of islands is realised by public shipping and a network of autonomous electric boats that enable accessibility within the archipelago. (Figure 7)

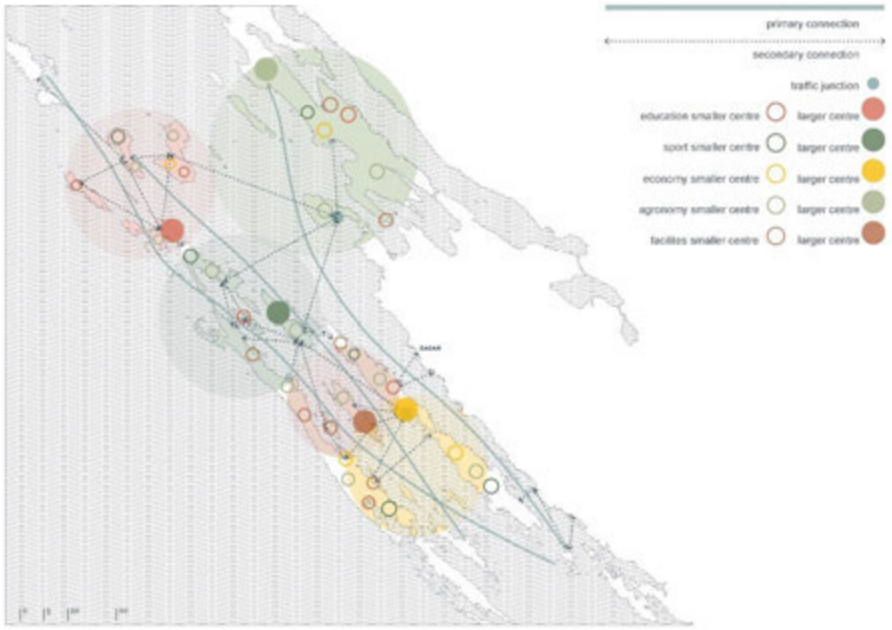

Figure 7. Development Vision for Islands Archipelago. Source: Kustić and Marelić (2023)

In order to enable the realisation of the vision for development of islands of the archipelago, four models were set as a part of the elaboration, namely: housing; traffic; economy; green infrastructure and facilities.

The housing model is based on the idea of flexibility, in order to meet the housing needs of people of different ages. In contrast to the usual acquisition of a housing unit that meets the needs of only a certain part of life, the model of rental housing is proposed. The first step is the valorisation of existing construction in order to determine which is suitable for renovation and reuse. After the energetic and structural-architectural renovation, the application process for residential unit begins, and units are allocated according to the needs, at acceptable housing prices. This would enable satisfying the needs and wishes of the residents. In the second step, there is a construction of new residential buildings according to the principles of bioclimatic approach and sustainability - modular, flexible and adaptable construction with the use of renewable energy sources and given location (e.g. solar energy for passive heating, greenery for passive cooling, sea water for cooling/ heating, rainwater, etc.). The model aims to create a community with facilities like urban farming, i.e. shared gardens, spaces for socialising and recreation, shared transportation, etc. This approach would reduce the unnecessary expansion of the construction area, and thus further devastation of valuable space. (Figure 8)

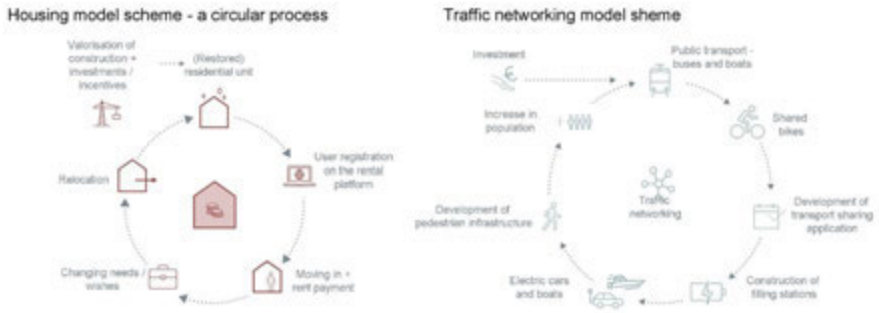

Figure 8. Housing and Traffic Model Schemes. Source: Kustić and Marelić (2023)

The concept of development of islands in the archipelago is based on their networking and observation of the entire area as a city. The transport solution is designed with two modes of transport - public and shared. Public transport includes electric autonomous (mini) buses and (fast) electric semi-autonomous boats, which get their energy from renewable sources. Another form is shared transportation, which includes bicycles, electric bicycles and scooters, cars and (small) electric boats. The boats used in the system are autonomous, although users still need a permit. The system is based on application which enables reservation and pick-up of a vehicle. In this way, the cost of living is reduced because the need to own a personal car and a boat on the island is significantly reduced. A long-term increase in the population is predicted, which will require further development of the transport network and an increase in the number of lines that would become more profitable in the future. This solution frees up areas used for parking, which are often located by the sea, and is repurposed into walkways and bike paths, areas for recreation and green infrastructure. (Figure 8)

The economy model is focused on the development of several economic areas. It is based on transport connections, since islands create a whole in terms of production process in which tourist, agricultural and other economic activities are distributed. A "clean" industry with as little negative impact on the environment as possible is planned by incentives awarded to entrepreneurs. The development of technology enables online jobs, for which a good network connection is a basic prerequisite. Renovated buildings house specialised research institutes that attract experts and (future) entrepreneurs. Thanks to good traffic connections, it is possible to link tourist attractions into a network, creating a good basis for the development of year-round tourism. Agriculture is planned to be modernised, to ensure an easier and more favourable distribution of products, which is also contributed to by the concept of "urban farms" on islands where the local population grows food on a smaller scale. The production of electricity on islands of the archipelago implies the creation of producer communities, energy infrastructure renovation and construction, which reduces energy needs. In addition to wind energy, thanks to the large number of sunny hours, the construction of solar farms is encouraged. (Figure 9)

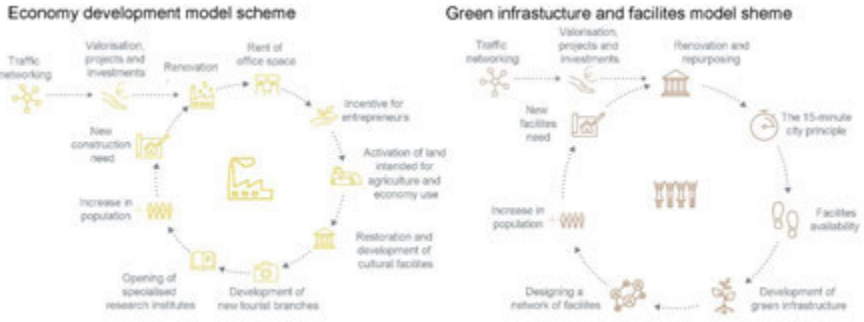

Figure 9. Economy and Green Infrastructure and Facilities Model Schemes. Source: Kustić and Marelić (2023)

The green infrastructure and facilities model is based on the creation of island and inter-island green networks. First, the arrangement of the existing green infrastructure is planned, and in the second step, the development of a new one. Outdoor sports and recreation facilities are directly linked to the green infrastructure arrangement plan, along with planning indoor sports and recreational facilities. This vision of development of islands of the archipelago increases its gravitational area, so public and social facilities become more sustainable and profitable. Development of new facilities continues on previous networking and is primarily based on the renovation and repurposing of existing construction stock. The archipelago was designed according to the principle of a 15-minute city and is based on the premise that each island should have facilities necessary for everyday life, upgraded by the "system" of public and social facilities in the archipelago. (Figure 9)

4. Discussion

Whether it is planning at the regional or local level, special attention should be directed both to protected areas and to areas with developmental peculiarities, i.e. peripheral areas, such as hilly and mountainous areas and islands and island archipelagos, and the planning itself should be approached with utmost sensibility. With conventional peripheries resulting from physical geography and distance, which is a factor per se, what needs to be considered are non-spatial processes and factors, and it is necessary to approach them comprehensively in order to design appropriate development strategy, policy and measures. Documents and studies on European level provide a guidance on how to enable better accessibility, better economic potential and access to services of general interest, and consequently a better demographic situation.

In addition, national strategic documents, such as the *National Development Strategy of the Republic of Croatia until 2030*, emphasise the importance of such areas and strive to ensure balanced regional development by planning activities in those areas. In the National Development Strategy of the Republic of Croatia, one of the strategic goals is "*Development of supported areas and areas with developmental peculiarities*" which, along with other challenges of depopulation, aging population and less favourable economic structure, face insufficient traffic connections and seasonal infrastructure overload. With the concept of *Development of smart and sustainable islands*, priorities for the implementation of policies related to the management of island resources, the transformation of the island economy, the establishment of smart mobility and connectivity, the provision of modern electronic

communication networks and the provision of public infrastructure and services to raise the quality of life have been set at the national level. National and regional strategic goals become the basis for further considering and planning development of the area in question.

In addition to gathering theoretical knowledge, future planners should be involved in practical activities. The education of future planners is based on a combination of scientific and creative conceptual thinking and a practical approach, and through practice courses, such as the spatial planning workshop, the ability of research and analysis, advocacy and mediation, the ability to envision, evaluate and promote potential future options for urban, spatial, and territorial development is learned. Working in a group develops the ability to cooperate and work together, which is a necessity for planning. Students are encouraged to think critically and understand the logic of planning and its theoretical and legal basis. They are taught to understand spatial systems that, in addition to the built and natural environment, include socio-economic systems. During the planning process they improve the technical and creative skills necessary for their inclusion in the planning practice. Above all, the workshop is a place where, through the planning process, the importance of strategic thinking and planning on different levels is pointed out.

The use of the scenario method in the education process, as a practical application in workshops, is particularly significant because it encourages strategic thinking, development of intuition and helps overcoming thinking limitations. Development of several possible scenarios is particularly important in order to enable a comprehensive overview of the needs and possibilities, aspirations of various stakeholders, and an open discussion and flexibility in the process of creating a spatial development vision.

In this case study, eight possible scenarios for future development of the island archipelago are proposed. Creation of various scenarios enables a better overview of spatial possibilities, while the appropriate selection of criteria and their assessment in accordance with the initial goals develops the ability to make decisions that will influence further development of the area. Conceiving scenarios based on the sustainability goals indicates an awareness of the importance of development based on global trends, which through planning and intervention at lower levels contribute to the achievement of global goals.

This paper shows how the work which was focused on the local and regional development and revitalisation scenarios for islands of the Zadar Archipelago is focused in the next step on the development vision and the elaboration of models that enable its realisation. The vision of development and revitalisation of the islands of the Zadar archipelago set a broader framework for planning development of smaller settlements on islands. Based on knowledge about the specificity of islands as peripheral areas, with respect for national guidelines for such areas defined by the *National Development Strategy of the Republic of Croatia until 2030*, separate models that refer to important topics (highlighted at the national level as priorities for policy implementation related to the concept of *Development smart and sustainable islands*) have been set. The intention is to set up models that can be applied with minor modifications on other islands and island archipelagos with similar spatial systems and characteristics. The realisation of strategic and development projects in accordance with the proposed vision and models (housing, transport, economic and green infrastructure and content) in a period of 25 years would lead to revitalisation of settlements and improvement of quality of life at the local level, the revitalization of economic activities in the region, while at the national level it would contribute to the achievement of one of the strategic goals of national development – "*Development of supported areas and areas with developmental peculiarities"*.

5. Conclusion

In addition to the theoretical knowledge of spatial planning acquired during studies, practical application is necessary in order to prepare the future planner for the roles that await him in professional practice. The spatial planning workshop is one of the platforms where students in the final phase of their studies practically apply the knowledge and skills they have acquired. On different scales, they practice strategic thinking, research, analysis, synthesis, critical thinking and understanding of spatial systems, forecasting and planning development of selected area.

The methodology of scenario planning is used in the education of spatial planners in order to enable them to deal with the complexity of predicting the future development of cities and regions, and to see the possible consequences of spatial interventions. In addition, this is an opportunity to use a tool that encourages creativity and intuition and enables future planners to think one or more steps further into the future. The grounding of projects on European documents on sustainable development as starting points, and consideration of national, regional and local strategies and plans, as well as existing spatial planning documentation, is the basis for further consideration and planning. Through education, the continuity and cyclicality of planning processes and changes in spatial systems that require adaptation and flexibility is pointed out.

Students are encouraged to take a comprehensive look at spatial systems and other elements of the development process and to determine the criteria for evaluation of scenarios as a basis for development of a long-term vision concept. Working in a group allows critical thinking and questioning of planning decisions, while understanding causes and results of concrete development projects serves as a basis for creation of new spatial planning documents. In order to harmonise all requirements and their changes over time with the long-term development goals and the legislative framework, flexibility in planning is insisted upon in order to achieve the overall long-term sustainability of the selected area, both on the local and the regional level.

Utopias as a design-thinking key for counter-hegemonic ecological transitions

Abstract (up to 125 words)
Present times are marked by structural crises and social alternatives appear increasingly implausible. Planetary urbanisation intertwines global society and ecosystems amidst social, ecological and rational crises accounting for unprecedented challenges. Discourses shift from reform versus revolution to ecological transition and resilience approaches within a scenario of turmoil. A workshop taking place in Goias City, Brazil, employed 'utopias' as lens and delved into counter-hegemonic urban ecological relationships. Concepts, such as Neoliberal contradictions, Decolonial approaches, Coexistence, Ethics of Care, Mobility of frontiers and Co-poiesis of Nature were assessed and led to three dialectical utopias — Queer planet, Matriarchal Society and Afrofuturism. Design thinking was used to envision alternative futures by integrating these concepts to utopian experiments addressing contemporary contradictions and societal trends.

Keywords: ecological transition; utopian imagination; design-thinking.

1. Introduction

We are witnessing times of structural crises when no alternatives to the current system seem reasonable. On the one hand, planetary urbanisation connects global society and earth ecosystems in a series of crises. This is an unprecedented social crisis that opens room for rising social inequalities. Yet, lack of confidence in political institutions tears apart old compromises. There is an ecological crisis experienced as we enter the *capitalocene*, which threatens us with climate change, mass extinction and environmental disasters. On the other hand, there is a rationality crisis that cannot acknowledge non-instrumental ways of thinking. At the same time, fake news, robots, and artificial intelligence threats undermine science as the way to structure society.

Besides this context of great changes and social unrest, environmental changes are inevitable, society fails to produce viable alternatives and to implement new approaches to social changes. In any case, changes will happen due to collapse or adaptation. The old polemics between reform or revolution, meaning light social adjustments or complete social transformation, are now dominated by the ecological transition theory, which highlights circular economy, energy efficiency and sustainable practices towards a new social-natural contract. However, we still lack viable images for future changes. The main theories available in environmental thinking, such as Resilience, Nature Based Solutions, Ecosystem Services, among others, deal with how

to best adapt to unknown eminent changes. Nonetheless, they are stuck in the pragmatic reform paradigm and in an apolitical approach. Accordingly, the only question is whether the environmental collapse will be handled, overcome or creatively explored. Are there ways to overcome the reform-revolution paradox?

The aim of the present article was to explore an action research carried out during a one-week workshop in Goias City - Brazil. 'Utopias' were used as keys to read counter-hegemonic urban ecological relationships capable of providing possible images of alternative futures. We developed six main approaches to the contemporary condition to explore other ways out of this paradox, namely: Neoliberal contradictions, Postcolonial approaches, Coexistence, Ethics of Care, Mobility of frontiers and the Co-poiesis of Nature, as well as developed three dialectical utopias: Queer planet, Matriarchal Society and Afrofuturism. That was done to rearticulate new possibilities in a world filled with blind fields.

2. Goias City and the urban nature paradoxes

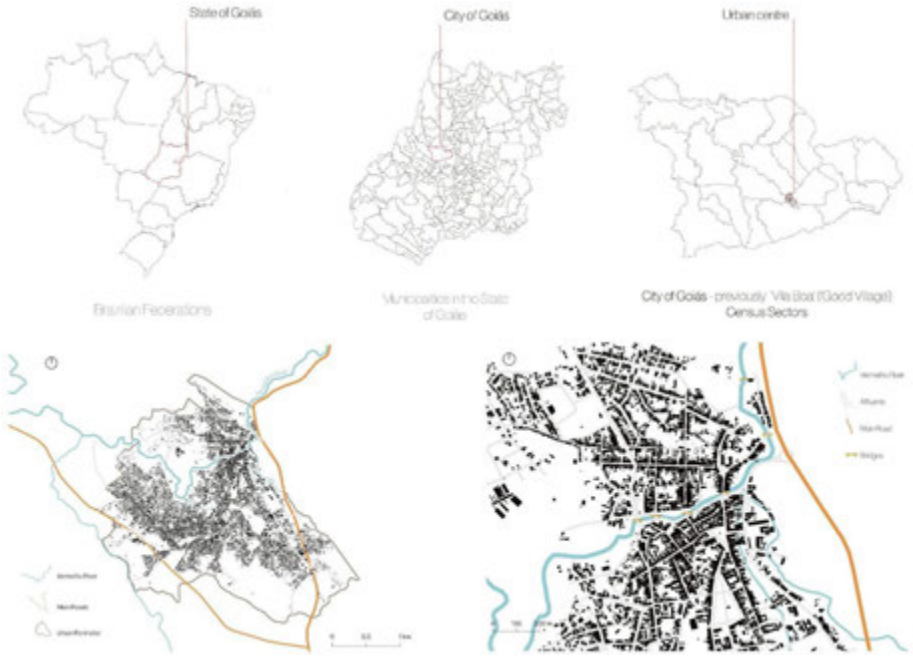

Image 01: Goias City and Vermelho River

Goias City was founded in 1727 as an 'arraial' (village) and thrived on gold mining along its riverbanks in the first years of its existence. The city developed far from the river due to hazardous conditions and slave labour. It became the capital of 'Capitania de Goiás' in 1748 and witnessed urban expansion and the construction of key infrastructure. Nature was viewed as both menacing and divine in the colonial era. On the one hand, wild landscape was denied and the city was an 'anthropized' space with no greenery. On the other hand, orchards and gardens were carefully controlled in private backyards.

Gold production declined from the 1780s onwards. Brazil proclaimed its independence right after that, in 1822. A series of governmental policies aimed at establishing a new order for the new Brazilian empire were implemented in the 19th century, and social attitudes towards nature shifted. These interventions led to modern labour practices and introduced green spaces as leisure places. Although the city shifted from gold to livestock farming, its space remained unchanged for one century, but an idyllic nature meant for pleasure and bucolic landscaping became accepted in urban spaces.

In 1869, a new road to the Central Market changed the city's river connection. Before that, a line of backyards would be the transitional space between the city and the river. Nowadays, the urban space is wide opened to the river. However, the road remained mostly empty, with few modern buildings by it. Later on, in 1999, the Environmental Film Festival was launched and, in 2001, the city and mountain ranges were designated as UNESCO Heritage Sites. This title highlighted the river's ecological significance. Contemporary environmental concerns have reshaped perceptions about urban nature and residents have adopted new practices and attitudes towards them. The river has become a central point in the city and it attracts new businesses and stands out as one of its main images.

Thus, we are dealing with a very peculiar situation: the same city and the same nature took different social performances. Although the environment was the same, it was differently perceived; it had different values and propelled different interactions. At first, the Natural elements were seen as dangerous, diabolic and as something to be explored, but also as God's gifts. Now, they are objects that could be manipulated to generate idyllic delights for free subjects and as complex ecosystems to be preserved, beyond human interests. This is one phenomenon among many phenomena we might call 'metamorphosis of nature'. However, it does not simply mean that our interpretations change. Nature assumed a political role because it reinforced subjectivities and structured habits.

Here an external example might help understanding this paradox. Hilary Angelo (2021) presented the German River Ruhr case, exploring the interconnections among concepts of nature, space production and political subjectivities. In the Industrial Revolution, the Essen region became a network of cities structured around the river as source of energy and natural resources. On the one hand, nature became an instrumental object explored to its limits. The dominant logic was human centred and it maximised investments and outputs without taking the ecosystem into consideration. On the other hand, a series of Garden Cities were built for the working class; they were refuges from industrial spaces' contradictions. These idyllic places, nonetheless, had specific rules for the use of nature creating healthy habitats for workers.

The impact on nature was paradoxical, since nature was seen both as an economic externality and as a controlled good used for individual delight in backyards. This was a one-directional double objectification of nature. On the one hand, in concrete terms, it meant a maximum exploitation of both things and humans, without any regard to environmental logic. On the other hand, in abstract terms, it became an utopian ideal to impose a social life on workers and to normalise modern social behaviours. Although the spirit of the time is the same, it does encompass contradictory feelings towards nature, both disregarded and valued. These paradoxes underline different instrumental subjectivity towards nature.

According to Hilary Angelo (2021), the global order changed in the postwar period and the region faced a deindustrialisation process. Production moved to global peripheries and factories were abandoned; this process was followed by economic decay and unemployment. New

paradoxes emerged. On the one hand, local communities started to organise themselves based on community initiatives and informal work. Backyards in old Garden Cities underwent a radical metamorphosis and, from places of bourgeois delight, they became places of rural production. Chickens, pigs, and vegetable gardens dominate the landscape. On the other hand, urban planning evolved and became a comprehensive tool. This region was then viewed as an integrated system of social, economic and natural spaces. Propositions aimed at controlling development, protecting nature and to keep Garden Cities as heritage.

Comprehensive knowledge clashed with community reality. In addition, another conflict emerged between the abstract view of Garden Cities as heritage landscape and the living reality of people who (re)appropriate gardens as community-based alternatives for economic survival. Nature became a field of multiple dimensions, a palimpsest and not simply a fixed stage where different actors play free roles upon. Actually, nature became a plastic field changing from the inside out, a field of possibilities engraved through different times, upon which history, culture, and knowledge can act upon to reveal new potentials.

Yet, according to Hilary Angelo (2021), when we moved towards the neoliberal context, nature once more changed its roles. The new configuration of global markets made the cities' image key elements for attracting investments in an international network of competition. Thus, abandoned factories became parks and nature started occupying old industrial ruins to create new bucolic scenarios. Punctual interventions aimed to create landmarks with global identity. The shift from comprehensive planning to strategic planning saw a new mix of spectacle and 'Disneyfication' of leisure and tourism, and nature became a commodity for marketing. The financialisation of spatial production meant that regions had to build brands to attract the global capital. Flexible work features, communication and transport technologies gave the regions a new potential to expand to vast territories and to get connected through new infrastructures.

Traits of this green gentrification also appeared in Goias City. As access to nature turns from right to commodity, a new dilemma exacerbates social inequalities. This phenomenon not only commodifies green spaces but also perpetuates disparities by deepening the division between socio-economic classes. This phenomenon overstates existing inequalities in Goias City, displacing local inhabitants from the city centre to its peripheries by pricing out marginalised communities. Consequently, we are transitioning from the right to nature to market-driven privileges. New residents moving in further raised real estate values and the proliferation of second-hand homes emptied the city centre. This displacement involves environmental injustice matters, since it does not only deprive communities from access to new green spaces but also disrupt their social networks and community ties.

According to Matthew Gandy (2022), we need new approaches to deal with these urban roles of nature. Positivist approaches based on absolute universals cannot handle their social metamorphoses and roles. *Neovitalists* are non–humanist, although they are always trapped in pseudo-ecocentric approaches. Object-oriented ontologies are both neo-romantic and animist. Relational anthologies take one step further, but they might submit to relativism. Arguably, we should go beyond modernism contestation and move away from language-oriented post-structuralism, which is lost in endless semiotic hermeneutics, and we should head towards a post-positivist evidence-based creative (poetic) materialism.

Matthew Gandy (2022) sees Eyal Weizman's forensic architecture theory as a way to 'give voice to things that nature gave no Voice' to. We could see Earth itself as a global scale 'crime scene' by advancing Bruno Latour's (2004) role of scientists as political representatives of

nature in a new politics that includes non-humans. This process means going beyond human sensorium and social spectacles. The environment can be seen as a recording device engraved with social history, although it is messed in entangled traces. This approach to the environment as material traces shifts the focus on individual humans as subjects of knowledge to men as aesthetic observers. This perspective changes the causality issue as the environment becomes an indirect, distributed and extended field of casualties that are spread over space and time.

Arguably, this neonature filled with urbanised reminiscences pictures a multilayered matter. It depicts both symbolic and spectral distances, whose past and future manifest themselves here and now. If the way we see nature has political consequences and frames how people interact with themselves and with the environment, the construction of a new aesthetics focused on nature will play the role of building new social-environmental arrangements. In order to do so, we need to understand the transitions we want, how they change our understanding of nature and what kind of images they may project to the future.

3. Approaching context and desires, and the nature of co-poiesis

We developed a series of lectures to approach the specific context of Goias City and its relationship with nature. The topics were addressed in flipped classroom assignments, which counted on six main concepts to observe the current contradictions between cities and nature, namely: Neoliberal Contradictions, Decolonial Approaches, Coexistence, Ethics of Care, Mobility of Frontiers and the Co-poesis of Nature.

Interactions among these concepts aimed at elaborating a critical cartography of the observed web of conflicts. Neoliberal Contradictions highlight tensions inherent to the context. Decolonial approaches are both lens and procedure to challenge dominant narratives and power structures. Mobility of Frontiers establishes physical and conceptual borders' fluidity and dynamism. These mobile borders shape human interactions with both society and the environment. Coexistence as an axiom aims at overcoming the traditional gap between human and non-human entities by fostering the need of thinking about the global integrated dependence among them. Ethics of Care foregrounds the direction nurturing empathy and responsibility that, in their turn, should guide all actions. Finally, the Co-poesis of Nature underscores the interconnectedness and co-creative dynamics of social and environmental systems. Together, these concepts plot a 'critical' cartography, an ecology of knowledge, which is featured by integration, interaction and conflict.

The aim of this cartography is to challenge conventional understandings of power, knowledge and nature. It provides an alternative framework for envisioning and navigating our relationship with the environment. This critical cartography invites us to engage in complexity, to embrace diversity and to confront the systemic injustices and inequalities shaping our societies and the environment.

3.1. Neoliberal Contradictions

Although the neoliberal contradictions exceed the scope of the current article, they help better understand the current moment and better see nature as a field of possibilities and conflicts. We aimed at unveiling the contradictions and at tracing counter-hegemonic sensibilities by drawing on critical theory approaches (David Harvey, ; Henri Lefebvre, ; Michel Foucault, ; Jason Moore, ; among others) and decolonial thoughts (Arturo Escobar, ; Frantz Fanon, 1961; Achille

Mbembe, ; Donna Haraway, 1988; Glissant, 1990; Mignolo, 2007; Enrique Dussel; among others).

Contemporary spatial production derives from a series of entailed processes linked to sensibilities and concepts that, in their turn, result in concrete practices and spatial devices. The idea was to get a grip on the hegemonic cultural logic - such as the instrumental logics, the parasitic exploitation of nature, the commodification and objectification of both nature and subjects, the financialization, consumerism, individualism and spectacle - only as strategy to imagine counter-hegemonic configurations.

According to Williams (1973), in Gramscian terms, hegemony is the dominant culture in action at a given society. It is rooted in 'common' sense, rather than in something singular. This prevailing way of thinking is experienced and embodied in daily life; moreover, it influences people's expectations and perceptions of reality. The hegemonic thinking reinforces the perspectives of dominant classes, institutions, and individuals, as well as continuously adapts to the social frameworks. According to Williams (1973), culture is a continuous of residual (traces of past events) and emergent cultures, which may either get integrated to the hegemonic culture or remain excluded from it. Consequently, new cultural elements can show regressive and progressive tendencies. Moreover, the term ‘alternative’ simply highlights ‘differences’ and it can be embodied as hegemony by the cultural discourse. Williams conceives ‘counter-hegemony’ as critical cultural practice aimed at being oppositional to the dominant culture.

Lefebvre (1976) argued that capitalism has managed to avoid crises by reproducing the social relationships of production. This reproduction is achieved by both destroying traditional spaces and reproducing the instrumental logics into new spaces. Several authors, among them, Marx (1996), Adorno and Horkheimer (1996), and Lukács (1971), have discussed this instrumental logic. According to Lukács, this way of thinking builds 'facts' and forms a pragmatic discourse about truth. It operates by asserting the *status quo* and the existing objects as natural absolutes. It demands overlooking social processes and the historicity of social relationships, turning what 'exists' into unconditional mythologies (Lukács, 1971). Thus, even those who want to protect the environment reproduce the parasitic exploitation of nature. If we understand nature as an external object, we can only act on it in terms of distant protection or exploitation.

The second key contraction of the neoliberal condition is a simulacra condition. Jean Baudrillard (1994) famously advocated that we live in a hyper-real world where reality is nothing but simulations. We only create new false representations of reality when we try to unveil the mask of ideology that hides reality. Although this approach leads to a sort of contradiction in terms (since any theory of reality is nothing but simulation), it also allows critically approaching the construction of reality. Although authors like Jacques Ranciere (2005) and Henri Lefebvre (1967) developed the idea of nature as socially created (poiesis), a critical approach can also enable seeing that it is at the same time a simulacrum (hiding its artifices) and a creative force developing new potentials to reality. Thus, we nowadays live in a world of fake news and spectacles that outspread instrumental views of nature and, simultaneously, financialisation and individualism are fantasies that have concrete and direct impact on the production of new social inequalities. Arguably, we should explore further the creative alternatives to this condition.

3.2. Decolonial approaches

Decolonial approaches provide a more nuanced framework to assess the intricate cross-sections of human society and the environment. These approaches provide a unique perspective that unveils contradictions, vested interests and power dynamics underlying the environmental discourse. Spatial concepts shape distinct realities that are tailored to specific contexts. However, new concepts can emerge from encounters between different knowledge systems and preserve the diversity of perspectives. For that, it should emerge from the 'here and now' of encounters and collisions between knowledge paradigms to preserve differences between subjects. These encounters highlight the lack of universal agreement and emphasise the need of acknowledging and managing divergent epistemic practices. Negotiating agreements amidst conflicting visions and paradigms does not rule out collective differences, but rather brings them to light.

The decolonial project represents a realm of divergence where disagreements remain. Entities do not want to relinquish what they deem crucial in conflicts over shared objects or interests. Spatial knowledge within the decolonial project embodies this divergence and acknowledges that common objects like rivers or mountains are inevitably influenced by several interests, perspectives and desires in contexts where multiple collectives and spatial production practices converge. The integration between knowledge practices and entities should maintain the dimensions of excess, misunderstanding and divergence.

The concept of ‘Dark Ecology’ in this realm, as articulated by Timothy Morton (2016), delves into the obscured and often unsettling aspects of ecological discourse, emphasising uncertainty, ambiguity and the unforeseen consequences of human actions. This is particularly important because it acknowledges that our knowledge is always imperfect, and the blind fields of our current epistemologies might lead to new social-environmental alternatives. Accordingly, the exchange of different scientific and traditional knowledge types gains a new and reinforced role. Morton's concept challenges traditional notions of nature as something separated from humanity. It rather highlights the entanglements and complexities inherent to ecological systems. Dark Ecology underscores the urgency of acknowledging and addressing the planet's ecological crises. These decolonial analyses can allow insights in the complexity of environmental issues and the dynamics of power at play by focusing on the unknown elements within our approaches to ecology (i.e. dark ecologies).

Mary Douglas (1992) outlined several 'nature myths,' including the 'myth of capricious nature', the 'myth of strong nature' and the 'myth of fragile nature'. The fragile nature is encompassed by spatial policies that rely on technical-scientific methods to manage interactions between society and the environment. Ecopolitics, like all forms of politics, is linked to entitlement, obligation, enforcement of rights, and decision-making authority issues. In a world characterised by both diverse spatial landscapes and significant social disparities, decisions and actions have disparate impacts on different people and places. Decolonial thinking does not focus on the decolonization of colonialism; it rather focuses on addressing the enduring condition of coloniality. Coloniality is not colonialism, it is the ‘dark side’ of modernity.

A whole variety of new endeavours have emerged in recent years, notably in the Ecuadorian Amazon, and they have deeply influenced the environmentalist discourse. These initiatives include agro-forestry projects, efforts to revive degraded forests, sustainable harvesting and sales of forest products, as well as adopting innovative forest management techniques. Simultaneously, there has been the trend to implement ecotourism policies and attempts to register indigenous territories. These actions have led to the creation of tourism zones with clearly defined boundaries. Tourism has been increasingly viewed as a means of economic

opportunity for indigenous communities since the 1990s. It fosters the hospitality industry and traditional crafts' growth. However, these shifts have resulted in different outcomes: some clans prospered from their engagement in such activities, whereas others have experienced impoverishment or displacement to remote jungle areas.

If one thinks of decoloniality in terms of existence and space, it means imagining it as an archipelago of enunciation points, as a constellation of micropolitics, and as experimental arenas shaped by subjective positions and cultural dispositions. Decolonization entails acknowledging that reality can be kaleidoscopic, fragmented and inherently ambiguous by defying simplistic representations through fixed cartographic projections. It transcends mere perspectivism to focus on points of action and enunciation places. Hence, the decolonial project is inherently linked to the sense of coexistence.

3.3. Coexistence and dependence

Peter Sloterdijk's (2011) concept of Coexistence provides a fresh perspective on the intricate web of relationships defining our contemporary society. It explores the dynamics of living together by highlighting the cohabitation and interdependence of several entities within shared spaces. This framework not only makes the understanding of diversity and the complex relations inherent to modern society easier, but also acknowledges the deep interconnections between human and non-human processes. We should think in terms of "terrestrials" rather than of oppositions, such as human/non-human and artificial/natural, to propose a new theory of inter-dependencies between society and nature, and to emphasise our embeddedness within broader global processes.

Dependency is an ethical issue, and a fact. We depend on Earth's habitable conditions, and the assumption that we could free ourselves from this reliance is a simple matter of fantasy. According to Peter Sloterdijk (2011), modern knowledge paradigms draw identifiable and manageable segments of the world within socio-spatial configurations. Social and ecological interdependencies in modernity have been overcome by isolated entities or 'spheres of independence' that are often seen through binary lenses. However, by taking Earth's overflowing of life into consideration, it is possible stating that this vitality stems from interconnected relationships among entities, subjects and ecologies. The shift from independence to the establishment of interdependent spheres within project practices means we need to attempt a transgression of current modes of imagination.

The idea of dependency in the social studies field has been commonly used to analyse non-Western societies as means to highlight a model of the subject who opposes the Western liberal idea of supposedly autonomous individuals. The concept of dependency has recently become a central topic in anthropological theory. The work by Ferguson (2013; 2015) has disclosed the contrast between specific European desire for autonomous freedom and alternative concepts that define systems of dependency as the very basis of being.

Dependence is not about living in harmony, in empathy with natural agents. One should acknowledge the dependence on various agents, without seeking universal agreement by avoiding the misconception, according to which, living in empathy and harmony with all things is feasible. According to Latour (2017, pp. 290-29), modern humans saw themselves as continuously emancipated from past constraints. As an alternative, one should not aim at reduction or harmony, but at expanding the list of involved agents and the interests in them. Thus, we should think about all terrestrials in general, exploring their limits together.

The concept of DELINKING aims at generating a series of disjunctive synthesis, as argued by Viveiros de Castro and Roy Wagner (2017). Accordingly, divergence and distance are their causal factors, rather than similarity or identity. Coexistence and interconnection entail separation and differentiation, rather than mere blending and fluidity. The objective is to delineate contact zones between various ecological forms of spatial production within a 'pluriverse' framework and to explore the potential of 'multi-situated' and networked life practices. Therefore, coexistence is not synonymous with harmony. It resembles language in its requirement for noise, messiness, fuzziness, granularity, vagueness, and slipperiness, so meanings can emerge. Similarly, the space of coexistence between differences must be closely articulated in itself, as well as present abundant fuzzy situations and mediating devices. Thus, by envisioning the unfamiliar coexistence we need a new concept of thresholds and blurred spaces.

3.4. Mobility of frontiers

Gilbert Simondon's (2013) concept of frontiers is linked to the differentiation process within complex systems. According to him, frontiers are not merely static divisions but dynamic interaction and transformation zones where entities undergo becoming and differentiation processes. Simondon views frontiers as tension, exchange and integration sites; thus, they are not fixed delimitations, but fluid interfaces of ongoing evolution and adaptation. Simondon's concepts emphasise the interconnectedness between adjacent domains, and it highlights the continuous information, energy and matter flow, which is a key element in the shaping and the emergence of new structures.

The Mobility of Frontiers concept (Hissa, 2002) expands Simondon's concepts by highlighting the interconnectedness between human society and its environments, since it suggests that frontiers are not only shaped by physical geography but by cultural factors, as well. Simondon's concepts tend to focus more on the material aspects of borders, often neglecting their historical and cultural construction. Hissa's framework points out that frontiers are historically constructed by our epistemology and aesthetics. This profile builds a non-binary framework that acknowledges the complexity of the society/ecology dialectics. Cássio Hissa's (2002) fluid interaction zones acknowledge a continuous historical movement and negotiation through the borders, and it challenges the traditional sense of fixed territorial divisions.

Similarly, Descola (2013) empirically and conceptually questions the dichotomy between nature and culture. This division is rooted in modern thinking and works as an ideological construct employed by Western societies to categorise and dominate other cultures and non-humans. Descola asserts that many cultures do not adopt the distinction between human (deemed superior) and non-human (seen as exploitable). In addition, chemist James Lovelock and sociologist Bruno Latour have similarly questioned the sense of an Earth system by arguing that the biosphere is a delicate mix of many conflicting complexities. Latour (2017: 87) describes Earth as an 'anti-system' composed of agents that resist unification into a single cohesive entity.

Decolonial thinking operates from the epistemic frontiers of modern thinking by questioning Eurocentric or Western spatial planning and design forms. Accordingly, the concept of Border Thinking (Anzaldúa, 1987) becomes relevant, mainly when it comes to design practices. Border thinking (Mignolo, 2007) is understood as situations where subjects, collectives and social groups living on the margins produce knowledge to be transferred from one place to another,

which is seen as a way of escaping modernist binary thinking. Therefore, decolonising the project means looking for where "frontier thinking" can question hegemonic knowledge and paradigms departing from externalisation paradigms. Anzaldúa (1987) investigated the contradictions and material conditions of life "on the borders and the margins", and revealed the joy that can be derived from so much suffering: the sensation of being part of something alive, the change of identity that awakens areas of otherwise dormant awareness, which is never felt at ease, but nevertheless at home.

3.5. Ethics of Care

The Ethics of Care allows refraining from individualistic approaches and acknowledging the role of others, both human and non-human, in fostering a caring society aware of diversity and collective risks. Interdependence and relationality are rooted in empathy, and this ethical framework prioritises subjects' well-being within their social and environmental contexts. This perspective emphasises nurturing relationships, mutual support, and responsiveness to others' needs by challenging traditional moral theories centred on abstract principles or rights. However, the Ethics of Care underscores the importance of context, emotions, and concrete actions in ethical decision-making. It advocates for an inclusive and compassionate approach to address social injustice and ecological challenges.

Sociologist Donna Haraway suggests that all knowledge and research are "situated" (Haraway 1988). This understanding encompasses not only the cultural context of research but also what Shawn Wilson refers to as the axiology of researchers, which encompasses morals, values, and ethics. These factors play crucial roles in shaping research processes and in influencing the selection of research questions, methodologies, design strategies, and dissemination modes.

However, when urban discourse (research/design) is influenced by issues, such as feminism, black studies, subaltern studies, queer thought, decolonial theories, body, and indigenous thoughts, it faces the challenge of establishing new legitimacy and authority for a given project. This process leads to questioning the Western project, design, research, and teaching practices. Contrary to the traditional goal of rationally organising the environment, this line of thinking views urban projects as more akin to chemistry - a discipline focused on studying changes, modifications, decompositions, and transformations.

3.6. Co-poiesis of Nature

In a seminal essay, Arturo Escobar (1996) clarified the social construction of our concepts of nature. He emphasised how these perspectives, which are featured by the political aesthetics and social enactments of nature, can actively reshape both society and the natural world. Bruno Latour (2004) has reinforced this theoretical understanding by acknowledging the hybrid nature of objects and relationships and by bridging the gap between the natural and the artificial.

The co-poiesis approach develops Maturana's concept of auto-poiesis to acknowledge how nature is produced in a political aesthetic. Copoiesis emphasises a collaborative and dynamic process of co-creation between human and non-human entities. It involves the mutual shaping and transformation of agents within a complex system, by emphasising interconnectedness and interdependence. Copoiesis highlights the active role of both human and non-human elements in shaping the environment, by fostering a deeper understanding of reciprocal relationships and emergent properties within ecosystems.

According to Lefebvre (1967), poiesis refers to an idea's ability to shape reality. Unlike praxis, which belongs to practical experiences; and mimesis, which deals with ideal representations in the mind, poiesis involves the generation of tangible experiences through conceptual frameworks. This understanding emphasises how ideas can actively change reality by focusing on the underlying principles, processes, and decisions involved in creating truth or reality. Lefebvre argues that the driving force behind changes in reality lies in building new possibilities. He compares this process to that of a seed, whose potential to become a tree transcends its current state; this process illustrates the significance of its virtual reality - the possibility of transformation. He argues that every epistemology has 'virtualities' and 'blind fields' (Lefebvre, 2003b, pp. 23-44) and, furthermore, he (1967, 375-377) advocates that poiesis creates a new reality by operating in residual fields that were left untouched by previous epistemologies.

The aforementioned process implies exploring unique capabilities of each epistemology, whereas certain aspects of reality might remain undiscovered. These unexplored aspects represent potential actions that have not been articulated, so far, although they work as the boundaries for any form of reasoning. From this perspective, poiesis reveals the hidden and obscure parts of reality, thereby reshaping it. Consequently, epistemology's limitations catalyse the rise of potential new realities. Arguably, the role of design-thinking can be conceived as exploring the gap between blind-fields and virtualities – i.e. to both visualise reality anew and to conceive future solutions. The next section uses the concepts discussed, so far, to recombine environment and subject, what resulted in three dialectical utopian experiments (Queer planet; Matriarchal Society; Afrofuturism) aimed at exploring current contradictions and at formulating new imaginaries of what could be the alternatives to current social trends.

4. Reimagining futures

The classic study by Ernst Bloch (1986) argues that utopia is fundamental because it is a 'principle of hope': once one understands that the reality of 'things' is not as natural as it seems, then hope can create a different reality for things. In his book 'Spaces of Hope', David Harvey (2001) advocated for the concept of dialectical utopias, which avoids the simple 'imagination' of alternative worlds. This perspective would be conceived as counter-utopia, as a device negatively related to reality that allows imagining future alternatives rooted in concrete reality.

Similarly, in his book, 'The Right to the City', Henri Lefebvre (2000) proposes an experimental utopia developed in an intellectual operation called by him 'transduction': the theoretical production of possible objects taken as references, as strategy designed to transform society - 'urban revolution' was his most famous 'possible object'. Accordingly, the aforementioned workshop aimed at investigating the role of design and architecture in developing immanent possibilities and social-environmental alternatives. It explored design-thinking methods to visualise the hidden aspects of urban nature through cartographies, critical representation, diagrammatic interpretation and photographic *dérives*, as well as to envision new possible futures through a transductive utopian imagination.

This Utopia emerges from perception and imagination convergence, according to which, the lens of present reality meets the canvas of an idealised reconfiguration. This convergence transcends the mere spatial and social revolutions, and delves into the depths of societal vulnerabilities, while aspiring towards collective improvement. Inspired by writers, such as Octavia Butler, and by the contemporary Solarpunk movement, utopias represent our right to

collective existence to envision worlds where flaws are acknowledged, vulnerabilities are embraced and community engagement thrives.

These utopias focus on the dialectical nature of relationships. Conflict is not an obstacle, but a catalyst for collective imagination to flourish by steering society towards community engagement and transformative action. Indigenous writer Ailton Krenak (2019) advocates that 'postponing the end of the world' is urgent. We need to rethink our relationship with the environment and embrace the most diverse ways of living. Integrating traditional practices and worldviews to modern solutions is imperative to navigate the socio-ecological goal of surviving the impending catastrophe.

However, the journey towards utopia is fraught with challenges, mainly because of entrenched capitalist paradigms and the ecological crises. Despite advances in quality of life, the continuous-growth narrative perpetuated by capitalist systems masks existential threats and perpetuates dystopian imaginaries. Yet, it is within the cracks of this dystopian reality that literature and fiction illuminate pathways to utopian futures by providing resilience, adaptation and societal transformation narratives.

One of the Workshop activities aimed at conceptualising and imagining utopias to explore the relationship between humans and non-humans in urban environments based on the fiction's ability to incorporate utopianism into crooked realities. Participants were divided into three groups and asked to apply the main concepts of design-thinking methods. They used the brainstorming technique to unravel the intricate intersections between human societies and the environment by exploring the contradictions, power dynamics and spatial concepts shaping distinct realities.

Results showed the need of converting concepts into imaginaries, which had to be represented in textual narratives and collages of three utopias, namely: Queer Planet, Afrofuturism and Matriarchal Society. Each group provided a free mix of theoretical concepts into immanent worlds by addressing complex socio-ecological challenges through playful explorations. These utopias made participants engage in critical reflections on the pressing issues of our times rather than just envisioning alternative futures.

4.1. Queer planet

The Queer Planet prioritises individuals' well-being within their intricate social and environmental contexts by embodying the ethics of care. This perspective nurtures symbiotic relationships and reciprocal support networks anchored in empathy and relational elements by transcending conventional moral frameworks entrenched in abstract principles. The Queer Planet utopia sought an inclusive and compassionate *ethos* aimed at addressing prevalent social inequities and ecological imperatives by embracing innate diversity and collective vulnerabilities inherent to the human condition.

The Queer Planet boldly challenges the entrenched senses of fixed territorial demarcations by embracing the dynamic concept of mobility of frontiers. It sets the concept of frontiers as fluid and permeable zones of interaction and transformation, where new configurations emerge from both conflict reconciliation and the fusion of diverse elements. This utopia propels co-evolutionary dynamics between human society and its surrounding environments by stressing the multifaceted historical, cultural and epistemological dimensions disclosing the different perspectives of the world.

The profound concept of co-poiesis of nature lies on the very core of the Queer Planet where the collaborative and dynamic interplay between human and non-human entities holds paramount significance. The active agency of human and non-human elements in shaping the environment is duly acknowledged by fostering reciprocal relationships and engendering emergent properties within ecosystems. The Queer Planet decisively challenges the rigid nature versus culture and human versus nonhuman dichotomies by presenting a visionary portrayal of reality as intricate and interconnected tapestry of life, which is rich in complexity and interdependence.

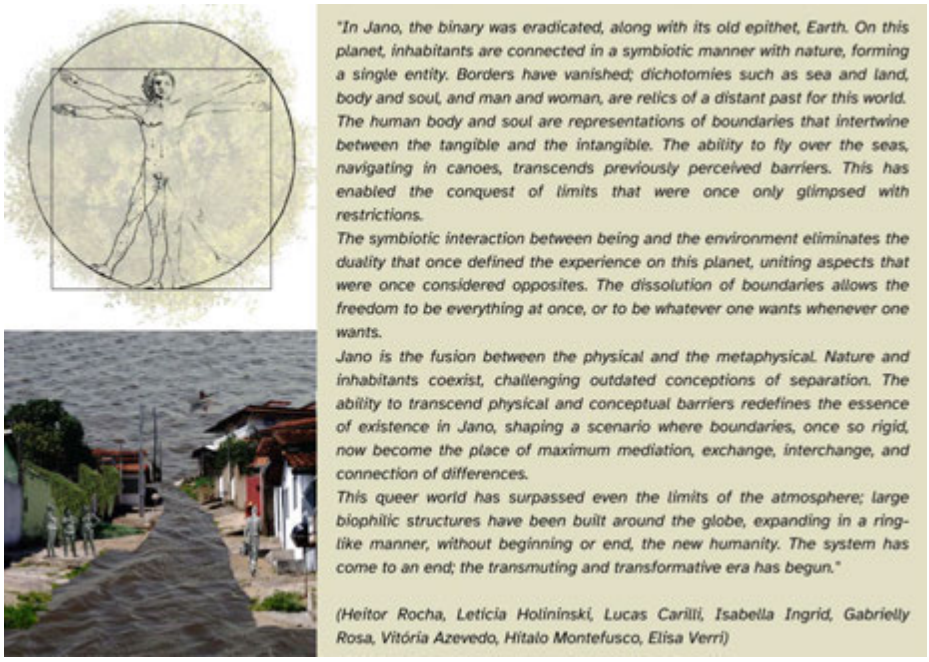

Image 02: Queer Planet Utopia

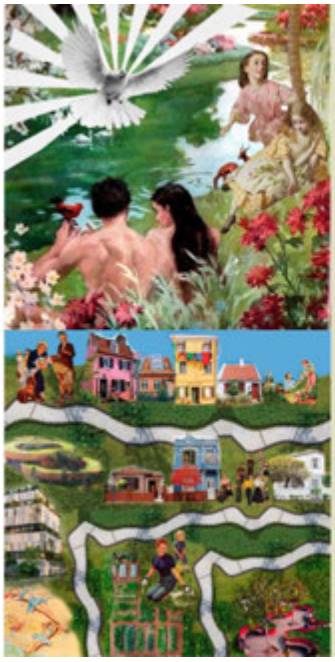
4.2. Matriarchal Society

The Matriarchal Society utopia embodies the *ethos* of care as a fundamental principle. Individuals' well-being in their intricate social and environmental contexts takes precedence. Nurturing relationships and mutual support networks are not only encouraged but intricately woven into the societal fabric. This paradigm challenges traditional hierarchical structures by advocating for empathetic and relational modes of governance that prioritise collective well-being over individual gains. Care, in this utopian construct, transcends the mere virtue of becoming a guiding principle capable of shaping every aspect of social interaction and decision-making

Acknowledging coexistence and dependence is in the centre of the Matriarchal Society utopia. These elements underscore the interconnectedness between humans and the environment, as well as among different human communities. Mutual respect and reciprocity work as fundamental values of this coexistence by guiding relationships. Individuals acknowledge their

strong dependence on the natural world and strive to live in symbiotic relationships that sustain both human society and the ecosystem. Humans coexist with non-humans as stewards, rather than as dominators in this utopia; they nurture biodiversity and ecological resilience through reciprocal interactions.

The Matriarchal Society embraces the concept of co-poiesis of nature by engaging in the collaborative and dynamic process of seeding, rather than in that of creating. Humans actively participate in the environment in this utopia by acknowledging their role as caretakers, rather than as exploiters. They contribute to the flourishing of ecosystems by fostering biodiversity through these reciprocal relationships. This approach transcends traditional nature/culture dichotomies by fostering the sense of interconnectedness for all living beings in the intricate web of life.



"In a world shaped by patriarchal norms and structures, the Matriarchal Society emerged as a beacon of hope and transformation. For centuries, the voices and experiences of women, non-binary individuals, and marginalised genders were silenced and overshadowed. But within the embrace of the Matriarchal Society, a new narrative unfolded—a narrative of empowerment, equality, and communal care.

Gone were the days of hierarchical dominance and oppressive systems. Instead, the Matriarchal Society thrived on principles of inclusivity, cooperation, and respect for all beings. Women, long relegated to the sidelines of history, took centre stage as leaders, innovators, and visionaries. Non-binary individuals found acceptance and affirmation, their identities celebrated rather than erased. Together, they forged a society where every voice mattered, decisions were made collectively, and where the well-being of the community was paramount.

Nature flourished under the stewardship of the Matriarchal Society, as humanity embraced its role as caretakers rather than conquerors. Sustainable practices and reverence for the Earth guided every aspect of life, from agriculture to architecture. The wisdom of indigenous cultures was honoured and integrated, offering a blueprint for harmonious coexistence with the natural world. In the heart of every village and city, lush green spaces and vibrant ecosystems thrived, serving as reminders of humanity's interconnectedness with all living beings."

Image 03: Matriarchal Society Utopia

4.3. Afrofuturism

The Afrofuturism utopia emphasises the struggles and complexities of concrete life. Thus, the **decolonial approach** provides the lens through which to scrutinise the dynamics of power and knowledge. Afrofuturism challenges dominant narratives and Eurocentric standards by fostering spaces for marginalised voices to express themselves. Encounters between diverse knowledge systems unveil contradictions and power dynamics by highlighting the need of managing divergent epistemic practices in this utopian vision. Afrofuturism disrupts colonial legacies and preserves the most diverse perspectives by envisioning a world where alternative futures can flourish by embracing African diasporic perspectives.

Peter Sloterdijk's concept of coexistence echoes the intricate web of relationships defining society through the Afrofuturism utopia. His narrative depicts a world where entities cohabit and are dependent on one another. The Earth itself becomes a central character embodying both dependence and agency. Afrofuturism rejects the fantasies of emancipating from this interdependence and embracing the vision of interconnectedness and mutual reliance. It challenges binary divisions and presents an alternative to simplistic narratives on harmony through cohesive sets of functions and movements.

The Afrofuturism utopia also lies on the concept of co-poiesis of nature, which emphasises the collaborative and dynamic process of co-creation between human and non-human entities. Thus, nature is not a passive element, it is dialectically shaped by human actions and cultural dispositions. Afrofuturism fosters reciprocal relationships and emergent properties within ecosystems. Based on Arturo Escobar's sense of social construction of nature, Afrofuturism actively reshapes society and the natural world by providing a visionary portrayal of the environment as contextualised reality.

"Within a world of conflicts and divergences, the figure of the oppressed has always been exploited, and mystified to justify the myths of charity and meritocracy. One day, after many days, after centuries and hours of negotiation, little was done and almost nothing changed. Everyone spoke and few listened; there were so many layers of omission, resentment, and dander that reaching any consensus seemed impossible, and indeed it was.

Even within the unity of the oppressed, the pursuit of consensus was fading, but the desire for disruption grew. The Global South rebelled, not in wars or endless conflicts, but through conscious disdain and irony that stripped the system of its inability to see and control everything. Unlike Diogenes, blacks, Arabs, Latinos, women, queers and workers no longer wanted to seek out an honest man to save them, instead, they engaged to seek their autonomy, to accept blurred divergences while exposing inconsistencies and developing new ways of living.

The oppressed bodies retreated into the quiescency of nature and cast new standards of comfort in new ways of life. They developed free and authentic technologies, dialogued with the transparency of a cynic, and overthrew sheriffs and coronels by asserting their sincere ideology in contrast to absolute truths. From within entropy, they created small syntropic utopias, which, during heatwaves, vibrated in green and freshness."

(Heitor Rocha, Leticia Holininski, Lucas Carilli, Isabella Ingrid, Gabrielly Rosa, Vitória Azevedo, Hitalo Montefusco, Elisa Verri)

Image 04: Afrofuturism Utopia

4.4. Discussion: Theorising Experience

Arguably, effective counter-hegemonic ecological transitions cannot be defined without developing innovative ways of knowledge production capable of engaging actors, entities, collectives with experience of struggle. As Santos clearly states, an "epistemological shift" (de Sousa Santos, 2018) is needed to reinterpret the world through dialogue between producers of different types of knowledge.

The fuzzy concepts of 'co-creation' and 'co-production' are increasingly present in our disciplinary lexicon (Voorberg et al., 2015). One of the main aims of our approach is to

reconceive Co-Creation as a method of collaborative knowledge production by seeking to develop 'dense narratives' to enhance our understanding of spatial justice and social inclusion. This production is linked to Chantal Mouffe's (2007, 2013) notion of "agonism", in which agonistic actions and projects have the potential to open "cracks in the system" and allow for the establishment of forms of relationships different from those to which we are accustomed" (Mouffe, 2013: 97). Our hypothesis is that through the adoption of different points of view and 'ways of knowing', an agonistic understanding can be developed that has the potential to think about and configure more socially inclusive spaces and environments.

Therefore, a key innovation in our approach requires the active engagement of all participants, both academic researchers and members of local communities, in a practice of knowledge production that challenges the hierarchy between researcher and 'researched', as well as the rigid binaries between established knowledge/popular knowledge. This is not to deny that there may be power asymmetries deeply rooted in Brazilian society, which it is, of course, necessary to acknowledge. Although Co-Creation is underpinned by notions of equality and inclusion, its practice inevitably takes place in an arena of diverse and sometimes conflicting interests.
.
A further issue for the co-creation of an ecology of knowledge is the need for all participants to consider the positionality, as well as the reflexivity, knowledge production and power relations that are inherent in research processes. If successfully executed, this approach to co-creation recognises the tensions and power relations that are likely to exist between participants and can create an environment of mutual trust. These experiences illuminated the importance of having awareness of both the links and possible conflicts between socially engaged collaborative practice and project action, and the potential tensions between the many ways of producing knowledge.

We therefore argue, in line with Chantal Mouffe, that the ultimate goal is to promote "agonistic spaces", i.e. public spaces in which "conflicting points of view confront each other without any possibility of final reconciliation" (Mouffe, 2013: 92). In 'agonistic spaces' the different perspectives of actors are brought to the fore and contested, not with the aim of an 'antagonistic clash between enemies' but rather an 'agonistic encounter', a struggle between adversaries, in respectful conflict with each other (Landau, 2019: 16).

Design and politics are two inextricably interconnected domains. Design practices participate in the constitution and maintenance of a given symbolic order or its questioning, and thus can play a critical role by fostering agonistic public spaces in which to launch counter-hegemonic struggles against neoliberal hegemony. It is necessary to make visible what the dominant consensus tends to obscure and erase, in giving voice to all those who are silenced within the framework of the existing hegemony so as to disarticulate the framework in which the dominant identification process takes place (Mouffe, 2013: 93).

The agonistic approach to place-making is thus an innovative way of addressing conflicts around the relationship between dwelling and nature, between territory and practices, by involving residents and local actors in activities foregrounding alternative representations of places, communities, collectives. Thus, we argue that these agonistic and disruptive place-making practices can be important components of action and change in the relationship between city and nature, as they generate a deeper understanding of different perspectives on space, ecologies, and ultimately social justice. In short, the endeavour aimed to produce new ways of political thinking and practice.

5. Final considerations

Current systems appear inadequate, in a world grappling with interconnected challenges and structural crises. Planetary urbanisation intertwines societal, ecological and rationality crises that escalate social inequalities and the ecological *Capitalocene*. In this context, the present article reported an action research carried out in Goias City, Brazil, which delved into the concrete aspects of these crises by employing utopias as lenses to explore counter-hegemonic urban ecological alternatives. Based on the six herein addressed concepts, we strived to forge pathways towards alternative futures in a landscape fraught with uncertainty.

This co-poietic hiper-nature is intertwined with urbanised reminiscences, besides being a complex tapestry embodying both a field of symbolism and spectral presences, and a field of obscure possibilities and political intentions engraved in different times. Thus, shaping perceptions of nature holds political significance, since it influences societal interactions with the environment. Embracing a new aesthetic towards nature is pivotal for fostering new social-environmental frameworks that require understanding the desired transitions and their implications to our relationship with the environment.

Here, the key element is the experimentation provided by these utopian exercises. By revisiting the question of experimentation through the lens of an operational field defined by the six key concepts, an ecology of knowledge was created in an agonistic dimension, as conceptualised by Chantal Mouffe (2013). This approach discussed in Goias City did not seek immediate and universal solutions for managing the river and its nature, but it rather aimed at revealing the conflicting nature arising from diverse desires and imaginaries projected onto these elements.

This imaginary interweaving seeked to establish non-extractive utopian images by delving into methodologies such as the sociology of absences and emergencies, the ecology of knowledge, and the craftsmanship of practices. The perspective it aimed at creating heads towards the decolonization of environmental thinking and towards the prioritisation of cognitive justice. This process regards adopting an epistemological transition towards solidarity to those seeking to change the terms with which we have traditionally known the world.

Integrating Metaphors for a Planning Ecology. Evaluating the Work of a Local Quality Platform

Jan Schreurs
Affiliation: KU Leuven, Belgium
Email: jan.schreurs@kuleuven.be

Biographical Note

Jan Schreurs is Emeritus professor at the Department of Architecture, University of Leuven (KU Leuven). He graduated as engineer architect, urban designer and spatial planner. His research interests are grounded in the will to enhance socio-spatial qualities of man-made environments. His PhD focused on the role of visual metaphors in creative design practices. His research has always been interwoven with practice: as designer, as director of Physical Planning at KU Leuven, as expert in numerous public commissions. As member of the Management Team Urban Policy (*Regieteam Stedenbeleid*) in Flanders, he is actively involved in managing 'concept studies'. He is appointed as external project director by the city of Beringen and is chairing the quality platform.

Integrating Metaphors for a Planning Ecology. Evaluating the Work of a Local Quality Platform

Jan Schreurs

Abstract

Multi-actor collaboration is a major condition within planning situations which include not only analysis, research and design, but also action programs, communication, and implementation. For the sake of integration, five metaphors are introduced to frame a major change in an ongoing planning process, to guide projects towards coherence, and to offer a medium for coordination. The installation of a quality platform offered opportunities for transdisciplinary action research. Through the lens of a *planning ecology* the paper focusses on the fabric and dynamics of correspondence between contextualized planning actors.
After introducing theme, approach and method, the paper elaborates on the notion of 'planning ecology', then problematises the case Beringen-Mijn, next reflects on findings concerning metaphors mobilized for and of collaboration. Conclusions reflect on the findings and evaluate the relevance of 'planning ecology' as approach.

Keywords
collaboration, metaphor, planning ecology, correspondence

1 Introduction

1.1 Collaboration As Challenge

Reflecting on means and ways of managing local change must investigate 'collaboration'. Multi-actor collaboration is a major condition within planning situations which include not only analysis, research and design, but also operational aspects such as action programs, communication, and implementation. Actors have to work in processes of joint problematization and building shared meanings (De Blust, Devisch and Schreurs, 2019). 'Co-creation and co-production also relate to the broader challenge of combining different types of knowledge and experiences in collective learning trajectories' (Medina-Garcia, 2024, p.14). Indeed, many stakeholders need to be informed, motivated and mobilised before they are prepared to invest their creativity, time, money… in realising a project. Their diversity in terms of values, knowledge, resources, means, experience, … does not help to bring stakeholders easily on the same track. Moreover, actual (global) turbulences urge planners to include and integrate knowledge and goals from an increasing number of specialist fields of research and practice: climate, biodiversity, water, energy, health, food, justice…. In addition, within participatory processes, stakeholders arrive with diverging models and images of what it means 'to collaborate': To be part or to take part? To work in a complementary way? To invest (care) in a common project? Different attitudes, aims, interests and (knowledge of) means only reinforce tensions between those images.
Collaboration is co-laborious. Nevertheless, during the complex quest for concepts, strategies and instruments, collaboration is a crucial factor. Rightfully, it is promoted by many scholars and professionals (Albrechts, 2012). But the practice of collaboration is not obvious. The circulation of a multitude of terms collaboration is dealt with in literature (co-creation, co-production, collaborative, coalition, collective….) is an indication of some confusion concerning meaning, relevance, and applicability of this concept.

1.2 Collaboration Is Interaction

Let's explore a promising image of (and for) collaboration. Since a bunch of threatening environmental and social issues provokes the need to plan more effectively, we need to understand better the interactions within and between biophysical and human ecosystems. Many ideas, proposals, reflections, and discussions about making a better – more healthy, resilient, robust, enduring, sustainable, just – environment, appeal to 'ecology' (cfr. References for e.g.). Advocating that 'urban, design and ecological thinking emerge as important disciplinary threads that need to be intertwined' (McGarth, 2013, p.9), clearly indicates both the importance of ecology and the intensity of the interaction needed.
In planning, even the best ideas (concepts, scenarios, designs…) need to be 'processed' within intricate constellations of many, diverse actors. To process not only means to innovate and articulate, but also to exchange, combine, negotiate and deliberate, and thus always involves qualified interactions with others. Understanding better the logics and mechanisms behind actors' (ex)changing interactions can help to get good ideas and concepts implemented. Within the available research, not much attention has yet been paid to the fabric and dynamics of interactions between contextualized planning actors, in other words, to what I will call a 'planning ecology'.
Convinced that local change is heavily depending on productive collaboration, central questions are thus:

- How can we stimulate diverging lines of attitude, thought and action to converge during collaborative planning processes?
- (How) can the notion of *planning ecology* contribute to generate insights into collaborative dynamics?

1.3 Metaphor As Art Of Integration

As a hypothesis, answers to these questions can be generated by focussing on metaphors, for three reasons. As creative device, metaphors create similarity (Lakoff and Johnson, 1980). They make us see sameness notwithstanding difference (e.g. *argument is war*, *ideas are objects*). Thus, metaphors integrate by making connections between unlikely ideas, aspects or objects, often in a novel and unexpected way, creating new understanding. As framing device, metaphors can serve to reframe thoughts and practices (e.g. learn to see *argument as dance* and not *as war*), thus offering a similar perspective to different actors in a coordinated way. As epistemological device, metaphors can be integrative because of the unifying character of their 'vehicle' or referent that conveys the comparison (e.g. 'love is a collaborative work of art').
For the case analysed in the paper, generative metaphors (Schön, 1979) will help to look in a systematic way to the planning ecology at stake. Five referents will be metaphorically mobilised. *Learning ecology* and *meshwork* generate perspectives to analyse the case. *Ship*, *beacon* and *wayfaring* generate frames which played a role within the planning ecology of the case. These are introduced to respectively frame the intended change of the planning process, to guide diverse projects towards coherence, and to offer a medium for coordination of ideas and activities.

1.4 Participant Observation As Action Research

Looking for answers to the central questions, a case is analysed. In a medium Belgian town, Beringen, a public-private-partnership (PPP) was founded to restore, renovate, and repurpose

a former mining site. Looking for a 'director of projects', the local government asked me to take the responsibility to mediate between private developers, city government and administration, Flemish Government Architect, heritage associations and inhabitants. Moreover, as chair of a multi-disciplinary quality platform (with external experts representing the disciplines industrial heritage, architecture, urban design, landscape design, strategic planning, mobility, participation, local governance), which helps to mediate the planning process in terms of steering for coherence, I'm sitting in the first row to observe and assess what is going on in a real-life instance of collaboration.
This situation offers opportunities for transdisciplinary action research. Because of the setting – PPP and quality platform – every project within the case develops according to the string: action-observation-evaluation-reflection-action… Within each (part of a) project, steps can be intentionally induced because of my tasks and responsibilities. Whenever appropriate, transformational imaginary (e.g. 'mine-landscape') or co-creative actions (e.g. research by design) could be introduced to generate change of ideas or practices. Resulting dynamics are at least partially motivated by such steps in the projects. Linking those effects to infused imaginaries and actions allows to learn for next (steps in) planning processes.
This action research is partially self-induced within the case: learning by doing and understanding in practice. Therefor an objectifying counterpart was created by an initiative of self-evaluation by the quality platform. Several drafts and successive discussions iteratively evolved into an informal evaluation document. After completion, this was discussed with key stakeholders (mayor of Beringen, director of development company NV be-MINE, director of investment vehicle LRM, municipal strategic manager of environment & city development, and local coordinator inclusivity) to learn from their experiences with the quality platform. This assessment started after two and a half years and was finished within half a year. The paper firmly builds on that evaluation, which is enriched by a metaphor-based analytical frame of reference.
The paper first elaborates on the notion of 'planning ecology', then problematises the main lines of the ongoing case, next reflects on findings concerning metaphors mobilized *for* and *of* collaboration. Conclusions reflect on the findings and evaluate the relevance of *planning ecology* as approach.

2. A Lens On Planning Ecology

While turning the centennial page, 'ecology' became a dominant discursive term within man-environment-studies. One could argue that 'ecology' replaced 'sustainability' as a leading idea behind arguments favouring much needed transitions (Waldheim, 2016). In search for complex interventions, science, politics, activism, and professional disciplines such as urban design and planning, seemed to find common ground in 'ecology' (Niemelä, 1999).
Without going into detail, three aspects of mobilising ecology in this case-study should be touched upon. To avoid misunderstandings, it makes sense to explicitly differentiate the vested term *ecological planning* from *planning ecology*. Furthermore, in preparation of the case discussed, a central concern needs to be highlighted: bringing coherence between projects, and productive coordination between stakeholders. Finally, perspectives on improving coherence and coordination are created by generative metaphors that serve interaction and integration.

2.1 Ecology As Logic Of Interactions

Ecology is no longer solely interpreted in the original, biology-focused way as 'the study of the complex relations between organisms and their environment' (Lister, 2010, p.536). In a

certain way, ‘ecology’ has even become an empty signifier because the term has been overdetermined. Niemelä (1999) identifies at least four different meanings of ‘ecology’. As science, ecology investigates interactions within nature's ‘economy' (flows of matter and energy or distribution and diversity of organisms). As nature, ecology has become the resource base for humans and an object of science. As movement, ecology refers to ‘green’ political attitudes and activities focusing on ecological and environmental issues. As concept, ecology views human existence in relation to the science ecology (e.g. ‘human ecology‘). Consequently, a clear meaning of the term ‘ecology’ is lacking. Using the term ecology does not hint in an evident way towards intentions, expected roles, nor its agency. Thus, a focus is needed.
As a key-concept within the biological sciences, ‘ecology’ has given impetus to the broader science of living systems. Relationships between humans and their various environments – natural and constructed – became a plausible subject. With ‘urban ecological design’ in mind, Palazzo and Steiner include human species, noting: ‘Ecology involves the relationships of all organisms, including humans, to one another and to their environments’ (Palazzo & Steiner, 2011, p.18). As noted by Lister (2010), ecology can be even broader ‘used in the vernacular plural to describe human relationships with everything from urbanism, culture, and religion, to food, fear, and pizza’ (Lister, 2010, p.536). For our purposes, ecology will be primarily used as metaphor or as model for social and conceptual interactions.

2.2 Planning Ecology And Ecological Planning

Evidently, as disciplines with a focus on the environment, urban design and spatial planning are at the front of harvesting concepts on the ‘ecology’ field. The term ecology has pervaded academic literature in the field of urban and landscape design and planning. Lister notes e.g. ‘Ecology is now central to the vocabulary and language of the contemporary landscape.’ (Lister, 2010, p.536; cfr. also References) As Waldheim notes, ‘ecological planning’ is a ‘long-standing tradition of planning the city through ecological knowledge’ (Waldheim, 2016, p.6), and stands for ‘environmentally and ecologically informed planning practices’ (Waldheim, 2016, p.8). According to Palazzo and Steiner:

> ‘Ecological planning may be defined as the use of biophysical and sociocultural information to suggest opportunities and constraints for decision making about the use of the landscape’ (Palazzo and Steiner, 2011, p.18)

A similar concern to combine environmental and sociocultural knowledge can be found within ‘ecological urbanism’ that develops ‘the capacity to incorporate and accommodate the inherent conflictual conditions between ecology and urbanism’ (Mostafavi, 2010, p.17), by developing frameworks ‘through the conjoining of ecology and urbanism’ (Mostafavi, 2010, p.13). *Ecological planning* can be defined as a projective culture, focusing on interactions among living species and between living species and their environment, combining environmental and design knowledge.

Looking for *planning ecology* instead, literature is sparse. According to Browne and Keil, ‘[p]lanning ecology is understood as an exercise in planning democratic participation.’ (Browne and Keil, 2000, p.159) This definition is broad and vague. Also their ambition to ‘yield a set of sharp tools to understand urban environmental politics in Los Angeles‘ (Ibidem) shows their focus on (political) environmental issues, which makes the concept too small and sharp for our purpose. Focussing on ecology to help understand conditions and ways of decision making within urban design and planning processes, seems like studying an

ecology of knowledge. No wonder that Star's definition of 'ecologies of knowledge' comes close to what I have in mind:

> Ecologies of knowledge […] means trying to understand the systemic properties of [planning] by analogy with an ecosystem, and equally important, all the components that constitute the system. This is not a functional (or functionalist) approach, with a closed-system organic metaphor at its core. As Sal Restivo (1988) notes in his description of science as a social problem, we want to approach [planning] as a set of linked interdependencies inseparable from "personal troubles, public issues and social change agendas. (Star, 1995, p.14; [planning] = my intervention)

Since science as well as planning thrive on knowledge, it is not surprising that replacing 'science' by 'planning' in this quote, simulates rather accurately my imaginary of the term 'planning ecology'. Interestingly, public, social, but also personal issues enter such an ecology. This offers room for an approach which considers persons in complex situations. I stick to the term 'planning ecology' however, because the singular focus on knowledge would distract from the intense interactions within and between several ecological registers: environmental processes, social relations, and human subjectivity (cfr. Guattari, 2000; Lister, 2010; McGrath, 2013), within spatial, social, and temporal contexts. Thus *planning ecology* further refers to (interactions between) multiple ecological processes between diverse actors within a specific, multidimensional planning context. Different from *ecological planning*, *planning ecology* would rather invite a research culture focusing on how 'ecological logics' (Ellin, 2013, pp.61-63), and systemic dynamics, both of 'natural' and human ecosystems, play a role within projective cultures, such as urban and landscape design and planning.

2.3 Integrating Metaphors For A Quality Platform

As an analytical frame, this investigation uses a composite lens to describe, analyse and asses the *planning ecology* in a case. This lens is composed of metaphors, because metaphors make us see, albeit in a certain way (Lakoff and Johnson, 1980). Ecology is the basic metaphor. Looking at a planning process as an ecology makes us see only part of it. Because ecology is all about interaction, this lens will make us primarily look for relations. This will help to focus on major challenges of the case study: collaboration of people and coordination of projects. To see different aspects of that planning ecology, the lens can be polished into several facets. These facets offer different perspectives, which might help to articulate a planning ecology more precisely. For the case study, two perspectives are used: 'reading' the context and 'writing' interventions.
The reading perspective, in section 3, will explain the case Beringen-Mijn in an essential problematisation. To reveal different perspectives on coherence and coordination, *learning ecology* is mobilised as main metaphor, and *meshwork* as subordinate one. These metaphors are mobilised *for* the case, not *in* the case. They are part of my theoretical framework, and thus available before the analysis.
The writing perspective, in section 4, recalls three main attempts to stimulate coherence and coordination *in* the case Beringen-Mijn. According to the project director and the quality platform, three metaphors frame respectively: the favourable way of working, (*projects are a fleet*), the goal every project should reach for (*mine-landscape is a beacon*), and ways to find common ground for coordination and coherence (*designing is wayfaring*).

2.3.1 Learning Ecology

In this reconstruction and assessment of a planning case, ecology is evidently the driving metaphor. Eager to better understand how planning works, we look at the situation as (if it is) an ecological system. This is similar to Lynch, who describes a neighbourhood as 'local system of social groups, behaviour, mental images, and physical form' (Lynch, 1981, p.330). His reflections on how to make 'Good City Form' with these components, rely on the view of a city as an 'ecosystem of human groups', or as a 'learning ecology' (Lynch, 1981, pp.328,115). Indeed, 'cities are the product of beings who can learn' (Lynch, 1981, p.97). Thus, they can learn to care for continuity and connection as basic conditions for a qualitative learning ecology:

> So that settlement is good which enhances the continuity of a culture and the survival of its people, increases a sense of connection in time and space, and permits or spurs individual growth: development, within continuity, via openness and connection. (Lynch, 1981, pp.116-117)

Being open to development, a good city is an 'evolving "learning ecology"', richly characterised by Lynch:

> To the familiar ecosystem characteristics of diversity, interdependence, context, history, feedback, dynamic stability, and cyclic processing, we must add such features as values, culture, consciousness, progressive (or regressive) change, invention, the ability to learn, and the connection of inner experience and outer action. (Lynch, 1981, pp.115–116)

2.3.2 Lines And Meshwork

If 'change, invention, the ability to learn' are characteristic for a learning ecology, this must be a living ecology. But what does it mean 'to live'? One of L's returning themes develops 'the idea of life as lived along lines, or wayfaring' (Ingold, 2011, p.xii). To give this a more concrete, and collective dimension, his key concept is 'meshwork, understood as a texture of interwoven threads' (Ibidem). This concept replaces the strongly distributed idea of network of connected points. In the 'web of life' (Ingold, 2011, p.63), this 'meshwork of wayfaring, […] the lines of the meshwork are not connectors. They are the paths along which life is lived.' (Ingold, 2011, p.151)

> Proceeding along a path, every inhabitant lays a trail. Where inhabitants meet, trails are entwined, as the life of each becomes bound up with the other. Every entwining is a knot, and the more that lifelines are entwined, the greater the density of the knot. (Ingold, 2011, p.148)

It is easy to see an ecology in this web of life. But how then, do inhabitants learn in that learning ecology? Learning involves exchange of knowledge. Misguided by the famous 'conduit' metaphor, we take it for granted that ideas are objects (Lakoff and Johnson, 1980), which can be transferred as a product from one person to another. But true learning needs learning *with* and *from* (Ingold, 2013, p.2). Knowing, and broader, learning and being cannot be separated. Knowing 'belongs, at the heart of being' (Ingold, 2013, p.6). Since life develop along lines, so does learning. We take it that an ecology of learning is developing along interacting lines, with others on entwining trails, meeting into a meshwork of relational interactions.

2.3.3 Correspondence

Thus, as a metaphor, *learning ecology* highlights complex planning processes as the weaving together of storylines about better environments, from engaging actors, enacting ideas, programs, and values into collective practices of correspondence. From that perspective, *planning ecology* turns out to be the generation, transformation and survival of knowledge, actions, and attitudes of all relevant stakeholders. In the words of Ingold, it is 'an ecology of correspondence' (Ingold, 2015, p.155)

3. Problematising A Case: Beringen-Mijn

One way of grasping the accuracy of 'collaboration' in a critical way, is to learn from cases. Since collaboration is a practice as well as a principle, valuable lessons can be learned from dialogues between facts and frames. Therefore, the paper looks at a specific PPP planning practice, where collaboration is a structural condition, reflecting on ongoing practices developed during several years. This case is 'Beringen-Mijn', a district in a moderate Belgian city, developed out of a huge coal mining plant. From motor of prosperity, this miner's district became a monumental burden in terms of physical problems (large derelict land, empty impressive industrial buildings, abandoned heritage, a worn-out garden city, …), social tensions (spatially isolated and socially divided communities of migrants and newcomers, …), and mental disruption (loss of work and collective ethos, traumatic history, emptied signifiers, …). Typically, such burdens also have a huge potential for new developments. To capitalize on this potential, a specific multifaceted planning approach has been introduced by the city government. Typical for this approach, the idea of integration steers the heart, head, and hand of the stakeholders.

3.1 A (Re-)quest For Coherence And Coordination

Desperately seeking someone to interrelate and coordinate ongoing and upcoming interventions in the historically important former mine site, was probably the reason why I received an email form the administration of Beringen, in august 2020. Would I be available for co-operation with the city government of Beringen, a town of 50.000 inhabitants, with an enormous, valuable mine-heritage? Three weeks later, after a site-visit, together with the mayor and the strategic manager city development, my role as 'director of projects' was outlined, and the installation of an ambitious 'quality platform' ('*kwaliteitskamer'*) was prepared. Both decisions were formalized in October.
These decisions of the Municipal Executive (Board of Mayor & Aldermen; in Dutch: *College Burgemeester & Schepenen*, or *CB&S*) had a context. As a result of a tumultuous trajectory, the development of one of Europe's most important mine sites had to prepare for a drastic turn. Now, three and a half years later, my experiences offer much to reflect upon how to approach a strong change in regime. Essentially, development had to shift from fragmentation to coherence, and from autonomy to coordination.

3.2 Coal Washing Plant As Stumbling Stone

On October 28th, 1989, status, conditions and perspectives of the historical mine site tilted. Its enormous heritage became a heavy financial burden in the pockets of the central government, who had to take care for the social passive, and for buildings and infrastructures. Dwellings in the 'cité', the miner's garden district, were sold rather cheaply, preferentially to renting inhabitants. The empty industrial buildings and warehouses deteriorated while being 'mined'

by copper thieves and urban explorers. From dynamic productive machine, the mine turned into a complex of massive buildings, listed in 1993 and 1994. Considerable amounts of subsidies became available for this protected heritage, but this came with an ambitious vocation. Indeed, from the seven coalmines in the Flemish Campine region, Beringen was selected as the only lasting complete testimony of former grandeur, technical functioning, and socio-spatial organization. Being listed as a heritage implied conserving a coherent image of a complete mine plant, enabling to demonstrate, to explain and to experience its former role and functioning. This huge expectation was motivated by the production unit's representativity, age, completeness of buildings and installations, architectural and technical value of interventions, state of preservation, compactness, clarity, present complementary activities, the presence and location of two slag heaps (Team Vlaams Bouwmeester, s.d. [2019]). The immense coal washing plant was the main reason for this entrusted vocation. With its four parts, it was formally and functionally the heart of the industrial complex (Figure 1), and Beringen was the only place of preservation.

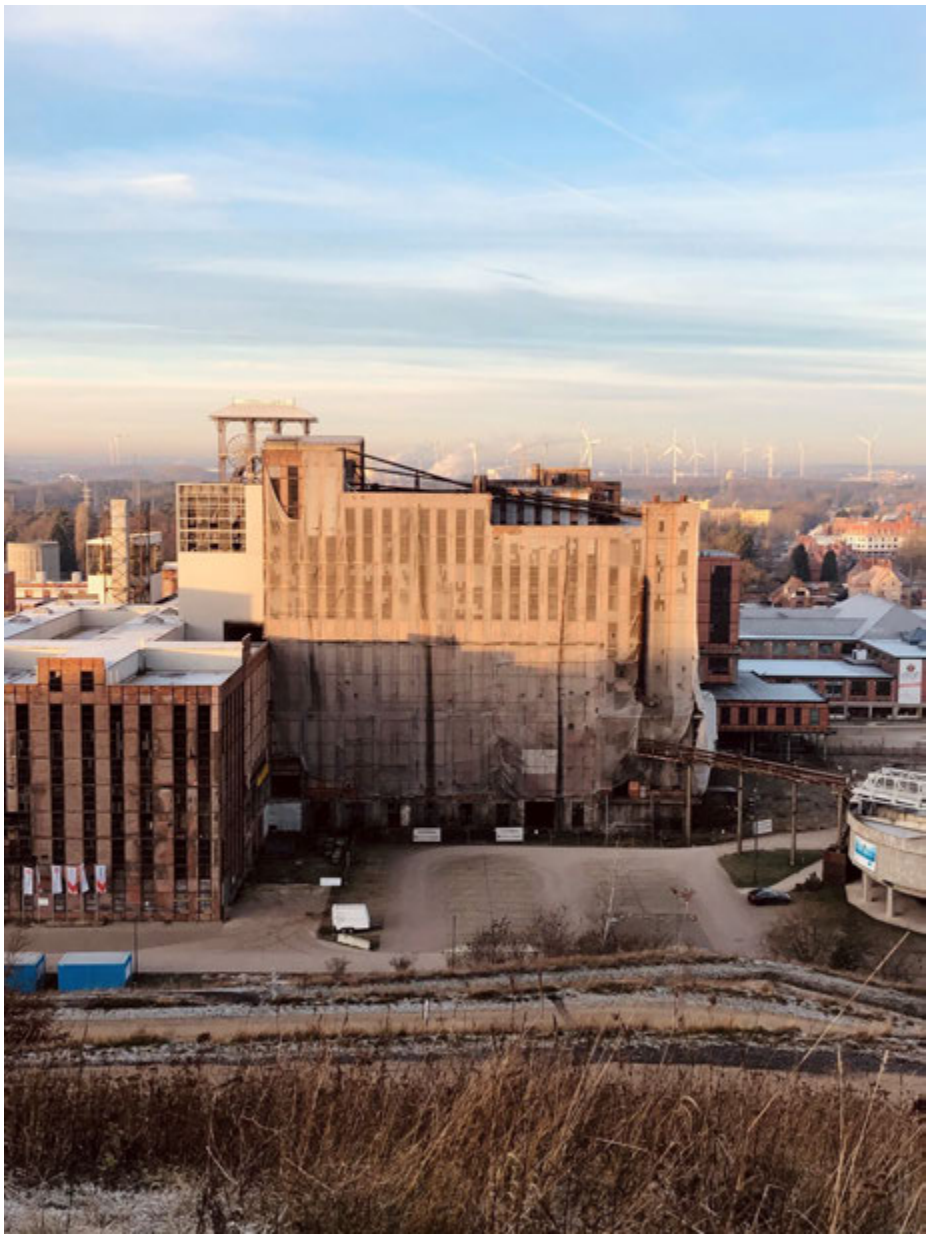

Figure 1. Part of mine site with huge coal washing plants

To implement this vocation, a reconversion plan was made by a PPP, formalised as a public limited company, named NV be-MINE. From then on, the vocation of the mine site was labelled as a touristic-recreational project. It had to comply with a local legally binding plan (Bongaerts, 2000) that defined the location as zone for urban development. The restauration

and re-use of the plant was gradual implemented. When the PPP asked the responsible minister to drop the heritage label for two of the four parts of the coal washing plant, the project took a dramatic turn in December 2018. According to the developer, lifting the conservation status was necessary because the combination of lamentable physical conditions and complicated spatial situations made reconstruction not affordable. The entailed compulsory public investigation provoked a gulf of national and international protest and pressure, and resulted in 1.311 notices of objections. Instead of coming to a head using legal procedures, the minister preferred to find common sense amongst the development consortium and heritage associations.

3.3 Coal Washing Plants As Pars Pro Toto

To find a way out, in May 2019 Minister Geert Bourgeois asked the Flemish Government Architect, Leo Van Broeck, to play a mediating role in this open conflict. He was asked to guide a participatory trajectory with all relevant stakeholders, trying to find consensus. Bilateral and collective discussions ended up in a hopeful report (Team Vlaams Bouwmeester, s.d. [2019]). Van Broeck perceived common support for a scenario of principles. Further designerly research and stabily studies would be needed to find out if that consensus would withstand.
Together with this optimism, the Flemish Government Architect ventilated severe critique on the way the PPP was managed. His report assessed lack of coherence and of coordination between the stakeholders and their initiatives as one of the major objectionable matters of the ongoing development on the mining site (Team Vlaams Bouwmeester, s.d. [2019]). Precisely this argument convinced the Municipal Executive of the city of Beringen to take bold measures. Enlarging and qualifying drastically the former '*kwaliteitskamer'* (quality chamber) and installing a '*projectregisseur'* (project director) explicitly aimed at fully integrated development in coproduction (CB&S, 2020a). In line with the advice of the Government Architect, success should be built upon two pillars. Synergy and added value should be found within an overall long-term vision on a larger scale. Coherence between projects should be steered on a systematic base by an overall vision and supported by all relevant actors. It would be the project director's responsibility to guard sufficient coherence among all current and future projects, both content- and timewise, while pursuing cross-pollination and societal added value (CB&S, 2020b). By this decision of the Municipal Executive, a trajectory of redirection was launched, and the direction was clear. A long-term vision for the larger scale focussed on a much broader work field than the coal washing plants and was extended towards the complete mining site. Simultaneously the Executive enumerated a list of at least 15 projects that waited for coordination. The Government Architect's plea for coherence and coordination did not fall on a cold stone.

3.4 The Ex-mining Territory Fragmented

The Government Architect's evaluation quite precisely assessed the situation on the field. The ex-mining territory had been compartmentalised into lots, while the fragments were declutched under separate ownerships. About 11 ha. were split off to realise 'Houtpark', serving a new housing district for approximately 600 houses, apartments, and service flats. On plots around the listed historic buildings, a private swimming pool, a restaurant and a shopping boulevard had been constructed. Besides the existing tourist reception and small mine museum, parts of the old mine buildings had been reused for nursery classes, a climbing hall, a banquet hall, a bike shop, and offices. The former thickener of the coal-washing process had been transformed into a diving centre. The largest part of the listed buildings was

still empty. However, plans were already on the table. The main spaces would be used for an experiential museum, focusing on the 'path of the miner', to be run by the province of Limburg. The technically worst part would be partly opened to invite trees, light and rain ('re-NATURE'), and partly turned into a casco to be sold piece by piece. Depending on the partial project on the site, 'ownership' was already given to different stakeholders: NV be-MINE, province of Limburg, city of Beringen, region of Flanders, social housing company, school community, private families, investors. Only NV be-MINE had a clear development model: restore listed buildings supported by subsidies, find a new, fitting program, transmit (part of) the building to third parties, by selling or establishing a long term right in rem (e.g. long lease). Despite all those realisations and plans, the PPP expected to be confronted with a large unused (and probably unusable) surface in the coal washing plants at the end of the development term. Without doubt this would become a burden for a yet-to-be-created management structure. Without intervention, the demonstration of a complete and coherent coal-mining history, as the minster was expecting when listing the building, would not be the obvious result of the ongoing development.

4. Diving Into A Planning Ecology

4.1 Projects As Ships

From section 3.4 we learn that levers for easily steering on the coherence of all projects, were already gone when the project director could start to remedy. Because of the distributed 'ownership', the situation was an amalgam of actors, each with 'own' goals, means and trajectories. To cope with this situation, I suggested a twofold approach to the Municipal Executive: conceptual and process oriented. It combined Hajer's conviction that socio-spatial transitions need a shared 'imagery' (Hajer, 2016), with Bruggemans' three-step approach for a 'sabbatical detour' (Brugmans, 2016). Therefore, I conceptualised the diverging projects as individual *ships*, with autonomous commanding officers. These should instead think and act as a *fleet*, heading for a common destination: to realise the vocation of the ex-mine site, each for his part. To reach out for the same *beacon*, would demand a decisive 'turn', a specific twist in each ship's trail. The suggestion of the Government Architect to instrumentalise the 'power of designerly research', (Team Vlaams Bouwmeester, s.d. [2019]), would find a productive 'locus' in three successive workshops with the crucial stakeholders. Each workshop would deal with one of three cohesive questions. First: What do we aim at? How do we look at the city-district Beringen-Mijn (including the ex-mining site)? Second: What can we aim at? How can we together discuss and articulate the qualities aimed at for Beringen-Mijn? Third: What will we do? How will we work together, while developing Beringen-Mijn? This proposal was approved as a working program by the Municipal Executive (CB&S, 2020b).

4.2 Mine-landscape As Beacon

At the first meeting of the quality platform, developing shared imaginaries as 'beacons' to co-orient the 'noses' of 'ships' was presented and discussed as success factors for coproduction. As guide for a qualitative development of Beringen-Mijn, the quality platform formulated a mission-and-vision statement concerning the expedient rectification of ongoing trails of the *ships*. In line with the Government Architect's suggestions, this text expresses enduring concerns about a mutual attuning of projects, in space and time. That mission is taken up by a vision which promotes to work within interdisciplinary, integrating frameworks. The basis of their articulation is the explicit ambition to work towards sustainable development and socio-

spatial qualities, but first and foremost towards a coherent *mijnlandschap* (mine-landscape), articulated at different levels of scale. Open spaces, heritage and community are seen as its most important facets. The focus is on links between and within these facets, both on short term (masterplan, project) and on long term (strategy, management). The text also formulates an unambiguous intention: 'The quality platform's way of working should lead to incorporating its vision as an evident dimension of ideas and practices of crucial stakeholders and actors' (Kwaliteitskamer Beringen-Mijn, 2021). This ambition to share ideas was actualised by many long conversations and dialogues, while constructing stories about interaction, coherence and coordination, and by designerly research, while drawing and representing imaginative mine-landscapes. Analogous to the idea of *landscape*, elements were systematically situated within their context, and not given meaning without that larger picture. E.g. as a result, one of the coal washing plants was systematically valued as a complement to the three others. And the relevance of building new dwellings was explained in terms of what the housing quarter will receive from, and what it will offer to the lager environment.

4.3 Design As (Co-creative) Wayfaring

An always uncompromising practice of priorities and agendas was responsible for a less strict scheme than the 'sabbatical detour' had in mind. The trajectory of the projected 'turn' involved more than three steps. Although aims did not really change, partners did fluctuate, depending on evolving dossiers, progressing insights, and personal affinities. In practice, the three thematic questions (aims, articulations and actions) intertwined, functioning in an iterative way, thus in-betweening for correspondence. This was not unexpected: gradually formulating qualities more clearly, and reshuffling coalitions of practice, can lead to different ways of seeing the territory and its vocation, as well as each other's ambitions and attitudes. Nevertheless, two factors were kept constant: the middle of the table was always occupied by maps and plans, pencils and pens, while the landscape was never obliterated.
During the first, internal workshop, the quality platform prepared a vision framework. Inspiration was found in a situation scan prepared by the team of the Government Architect (BUUR, 2021). This is a tool offering a socio-spatial diagnostic to local governing bodies, highlighting spatial and executive strongholds and weaknesses about the communal territory. Stimulating a local agenda-setting of projects and policies, the scan articulates potential strategic projects. The most appropriate of these projects - *augmenting living quality and improving the spatial structure of Beringen-Mijn* - was assessed and evaluated. Collective brainstorming produced alternative design ideas suggesting new green connectors at the scale of Beringen-Mijn, which would also strengthen cohesion between green and blue structures to the East and West of the central nucleus. (Figure 2)
As a next step, a week of design and dialogue was organized. Developers, associated designers, inhabitants, external experts, administrations, and aldermen collectively contributed by offering ideas for and comments upon the strategic project. (Figure 3) Simultaneously *designerly imaginations* produced a first version of what would be elaborated later into a spatial structure sketch for Beringen-Mijn. The central landscape structure contains two parallel north-south axes: a functional urban boulevard with services, and a recreational green connector for soft mobility. This idea was complemented by a set of possible actions to interconnect these axes and the surrounding cité (Figure 4).

Figure 2. Quality Platform collectively generating ideas for Beringen-Mijn
Figure 3. Design presentation and dialogue during design week

Figure 4. Structure sketch for Beringen-Mijn (© BUUR PoS)

Next, a series of advisory *design workshops* was organized, bringing together NV be-MINE, city administrators and representatives of the quality platform. Spread over several months, this group developed innovative but feasible proposals for use and lay-out of coal washing plants number 1 and 3. Breaking away the worst parts of the structure should enable to incorporate nature, enjoying it while growing. Although invasive, this intervention would serve later as flag and symbol for a 're-nature' strategy, ambitiously framed as philosophy and essence of the whole redeveloped ex-mining site.
Finally, intensive *research by design* played a decisive role in an intensive program of meetings and workshops, aiming to complete the necessary plan for receiving a permission to develop the new living quarter Houtpark. Starting with a declaration of intent, signed by NV be-MINE and the city of Beringen, these partners launched a steering committee, also incorporating members of the quality platform. After ten months of coproduction, the result was 'Houtparkboek', a well-illustrated quality-guideline. With its qualifying descriptions and visual references, this book gives designers and administrators tools to grasp wanted qualities of buildings and generous landscape connectors between the existing cité and the new quarter.
Although turbulent at times, the results of the 3-year process show progress. Two projects, formerly heavily criticised, the reconversion of two listed coal-washing plants and developing a new living quarter, were given formal permission to start implementing. According to the quality platform, aspects of social and spatial sustainability improved substantially. The design-and-dialogue week was emblematic. A co-produced structure sketch shows opportunities for strengthening spatial and functional coherence between new projects and the district of Beringen-Mijn. Actions needed to operationalise those opportunities were identified. Moreover, designing the structure sketch demonstrated dimensions of the new mine-landscape: industry, infrastructure, city, suburbanisation, heritage, centrality… and the open heath landscape were all this settled. Innovative ways of interacting between developers, city, inhabitants, external experts, and the quality platform, established intensive coproduction: a design week, collective biking, visiting coal washing plants and relevant projects, designing with the Government Architect. Words and images of many participants were carried along entwining flight lines, by open ideas and reflections, not necessarily meeting in a final design. They rather develop along and with each other, in an ongoing dialogue, sometimes converging, sometimes not, meeting as interweaving lines, a meshwork as memory of collective learning.

5. Conclusions: About the Relevance of 'Planning Ecology'

The paper describes the rationale of an ecology-inspired approach to urban planning, assesses the way it is accomplished in a case study, and evaluates its results.
As 'director' of projects within an ex-mining city, I describe a local *planning ecology* as it has been developing over the last three and a half years. The motivation to do so is twofold. Primarily it is an attempt to assess and evaluate the mediating role of a quality platform, and its results. Such evaluation is useful, especially in case the city decides to continue this process. Second, I hope this assessment also reflects the relevance of using the concept 'ecology' as metaphor and model within processes of urban planning and design. The following conclusions reflect on the findings and evaluate the relevance of 'planning ecology' as approach.

5.1 Reflections

This investigation is based on a case study. It involves a meaningful confrontation between abstract frames of reference and concrete processes in the field. Investigating a process by someone with personal involvement has pros and cons. According to Ingold, participant observation is 'knowing *from the inside*', opening up 'our perception to what is going on there, so that we, in turn, can correspond to it' (Ingold, 2013, pp.5-7). This subjective relation of '*correspondence*' receives a compensating inter-subjective check by also relying on an evaluation by the quality platform, which brings this information *of* the world back *into* the world.

Conclusions are preliminary. First because the projects discussed are not finished yet. At this moment, they only recently received a building permit or a go to start developing. The relative positive results might be tempered after detailed designs and constructions. Second, the approach is young and hesitant: I have no previous experience in diving into the intricate interactions of a planning ecology. Thus conclusions concerning the agency of metaphors and the characterization of planning ecology are tentative.

5.2 Relevance of Approach

Problematising collaboration in planning generated as first research question: *How can we stimulate diverging lines of thought and action to converge during collaborative planning processes?* Since metaphors have integrative power, two sets of metaphors are mobilized as theoretical framework. Together, they form a composite lens to describe and analyse the case Beringen-Mijn. *Learning ecology* and *meshwork of lines* act as generative metaphors *for the case*. Together they help to read the contextual situation (city, actors, projects, …) and modes of interaction between actors. They provide a guide for focusing on socio-spatial coherence. A second set of metaphors, *projects are ships*, *(mine-)landscape is beacon* and *designing is wayfaring* have been deliberately brought *into the case*. They serve specific but varied intentions: to offer an imaginary for the dynamics of projects, an image for the feasibility of converging autonomous projects, and a medium for correspondence between diverse actors.

Many converging and constructive interactions could be identified within the planning process. The intended 'sabbatical detour' was incorporated within the decisions of Municipal Executive, as articulation of the transformative *fleet* imaginary. This imaginary was presented and discussed during the first meeting of the quality platform. The mission-and-vision text prepared by the quality platform articulated the 'mine-landscape' as *beacon* for that *fleet*, and explicitly formulated that imaginary as an evident goal to be incorporated in every project or action. Several long trajectories of designerly research and dialogues amongst overlapping groups of actors, effectuated a productive correspondence within a *meshwork* of activities. As result of a collective design-and-discuss week, a structure sketch was produced, synthesising the concerns and wants of a broad array of various participants. This sketch is constantly referred to within the following projects.

Thus, three 'functional' metaphors have helped converge Municipal Executive, developers, quality platform and – indirectly other stakeholders. The hope that the project leaders, the captains of *ships* would implement the 'turn' needed to orient all projects towards a coherent whole, was redeemed for the projects described in the paper. Coproduction amongst stakeholders of the two most delicate and precarious projects gradually improved. All stakeholders finally agreed with the plans made up during and after many dialogues on the quality platform. However, one important project never surpassed the consultation stage, and fell out of the fleet.

The second research question, *if and how the notion of 'planning ecology' can contribute to generate insights into collaborative dynamics?* is harder to answer. This question was launched with the aim to better understand how collaboration works at the micro-level of

urban design and planning. Although the condition of transdisciplinary research based on participant observation was promising, the available time, and the rather closed character of some niches in the planning ecology, were limiting factors. Investigating at the micro-level needs time to observe and interview many actors, many times. Availability, mutual understanding (literal and figurative), and – more important – mutual trust, are necessary conditions, which can only be realised relatively late in the process.

The sphere where these conditions are fulfilled rather well, are intense occasions of research by design. Design-week, substantial and/or successive workshops, where ideas and designs gradually try to correspond, without the need to come to a conclusive decision, offered favourable conditions for creating multiple collective trails, and offer valuable insights about density and intensity of active meshworks. At least, design proved to serve the intention of making lines of thought intertwine.

A conclusion from these observations also is, that continuous lines are the better trails. During the process, several persons changed position, disappeared or entered the scene. The consequences of such discontinuities are sometimes dramatic because they hamper trust. Moreover, because ideas are not objects which can be handed over to someone else, but results of correspondences amongst multiple lines of thought, discontinuity hinders imagination and ambition.

Unravelling a sustainability vision in the national spatial plan

Antti Roose, Pille Metspalu
University of Tartu
Antti.roose@ut.ee; pille@dge.ee

Abstract
There is an increasing demand for a new generation of planning frameworks capable of delivering long-term sustainability outcomes amidst the escalating uncertainties (Becker 2023, Kivimaa 2023). European policies reshape the territorial dimension at the national level, fostering policy debates through downscaling emerging initiatives and measures (Böhme et al., 2022b). Estonia's National Spatial Plan has undergone a significant transformation, shifting from traditional growth paradigms to a sustainability vision. The research evaluates the plan's inception and framework, addressing challenges posed by climate change, regional disparities, and national security while striving for a resilient and sustainable future. The inception phase establishes principles, selects themes, and outlines impact assessment methodologies, along with identifying necessary studies. Rethinking climate policy, particularly in the land-use sector, involves aligning policies with decarbonisation, climate and biodiversity implications, simply minimizing land take and acknowledging spatial scarcity. The plan should set clear land use priorities, providing conditions and guidelines for local comprehensive plans, seeking climate-proof and low carbon land uses and enforcing brownfield development for reducing aggressive land take. A nuanced approach incorporates cross-cutting planning principles and sustainability dilemmas, plus national deference urgencies. The research highlights potential gaps in the plan's adaptability to the transition mode and underscores uncertainties regarding high territorial dynamism, navigating tensions between flexibility and stability. This initial phase of national planning is crucial as it sets the ethos and tone for the entire planning system and process.

Introduction

European nations reassess their national strategies and planning frameworks in light of pressing sustainability concerns. It is compounded by the importance of innovative and automated planning methods with Big Data and AI as well manifesting a deliberate participatory governance paradigm for civic society (Oldbury and Isaksson 2023). In addition, the convergence of COVID-related disruptions, energy crises, and geopolitical tensions has accelerated deglobalisation trends, prompting nations to reassess their reliance on global supply chains and trade networks (Böhme et al 2022a). This shift reflects a growing emphasis on regional self-sufficiency and economic resilience in the face of heightened uncertainties and vulnerabilities in the global landscape related to the economic and energy transition (Sivonen and Kivimaa 2024). Research community claims rethinking the relationship between humans and the environment through a systemic perspective that encompasses dynamic inclusion, vitality, purpose, and value (Davelaar 2021). Transitioning to a new sustainability paradigm requires new foresight and strategic planning schemes as well replacing conventional systems thinking with a comprehensive metaphor of nested leverage points. The 'beyond growth' debate expands examining economic and socio-ecological challenges replacing economic primacies. European policies aim to mitigate negative growth impacts, focusing on innovation, and the

European Green Deal. Additionally, beyond growth relates to social challenges emphasizing concepts like justice, fairness and sufficiency. The EU discussion papers highlight obstacles for EU policymaking and underscores the importance of values and implications of globalisation in transitioning towards sustainability (Jensen 2023). In addition to degrowth thinking, another neologism narrated recently and tackling regional gap at European and county scale territorial strategies is 'left behind' places (Fiorentino et al 2024).

Thus, old problems need new solutions to all-for-all wicked problems: climate change, national security, urbanisation, resource depletion, poverty. While current trends and uncertainties may paint a rather pessimistic picture the planners have begun looking outside of the box, challenge our traditional assumptions, and stop trying to solve the same problems with the classic approach and tools. Larger, targeted sets of projects and policies create new socio-technical realities (Berglund-Snodgrass et al 2020). Contemporary research stresses the importance of governing with intent, i.e., with clear objectives and an understanding of the anticipated impacts of new strategies, business models, services. e.g based on digitalisation and platformisation (Oldbury and Isaksson 2023).

Böhme et al 2022 discuss the need for increased territorial resilience in the face of rapid changes and uncertainties. Emphasizes the importance of navigating under 'new' uncertainty, a shared sense of direction, and supporting territorial resilience has become a priority in strategic territorial visioning in European Union, channelling discussions on Territorial Agenda 2030. This can be achieved through capacities such as foresight, the ability to react and transform, and a willingness to change, as well as through cooperation, coordination, and a common vision for Europe's future. There is an increasing demand for a new generation of planning frameworks capable of delivering long-term sustainability outcomes amidst the escalating uncertainties, in worst case shocks and declining security (Becker 2023, Farinós 2020, Kivimaa 2023). It concerns also national and regional territorial agendas as elaborated below.

Estonia's National Spatial Plan has undergone a significant transformation, shifting from traditional growth paradigms to a sustainability vision. The 2012 concept of low-density urbanized space, integrating compact cities, suburbs, and traditional villages to support diverse urbanized lifestyles, is proposed to be replaced by an optimised, densified cohesive pattern centred around cities. The research evaluates the plan's inception and framework, addressing challenges posed by climate change, regional disparities, and national security while striving for a resilient and sustainable future.

The inception of national spatial planning

The inception phase of the planning establishes principles, selects themes, and outlines impact assessment methodologies, along with identifying necessary studies. The national spatial planning is positioned in both the spatial planning system and the strategic planning at the national scope (Fig 1). The critique of spatially blind strategic planning has been mitigated by strengthening spatial principles, territorialisation, and targeting regional gaps in the national

spatial planning process and methodology.

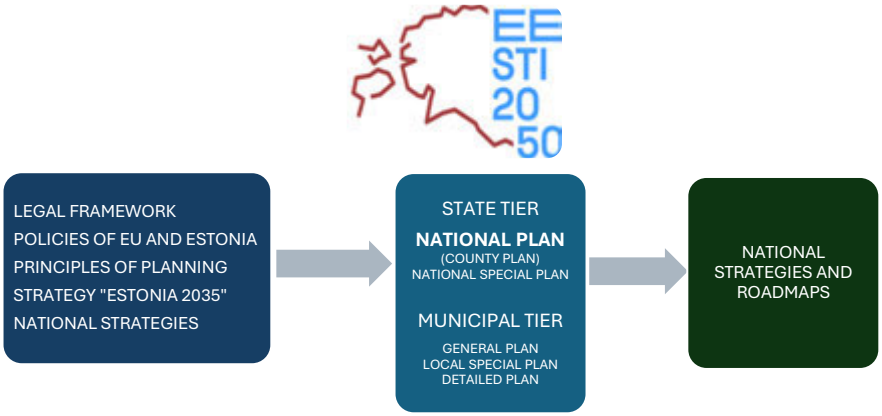

Figure 1. The strategic planning process – the scope of national spatial plan.

The starting point for national spatial planning is the emphasis on sustainability paradigm. This holds significant symbolic importance in the current stage of societal development in addition to emerging strict and ambitious legislative obligations. The pro-sustainable themes dominate in the plan's structure (Fig 2).

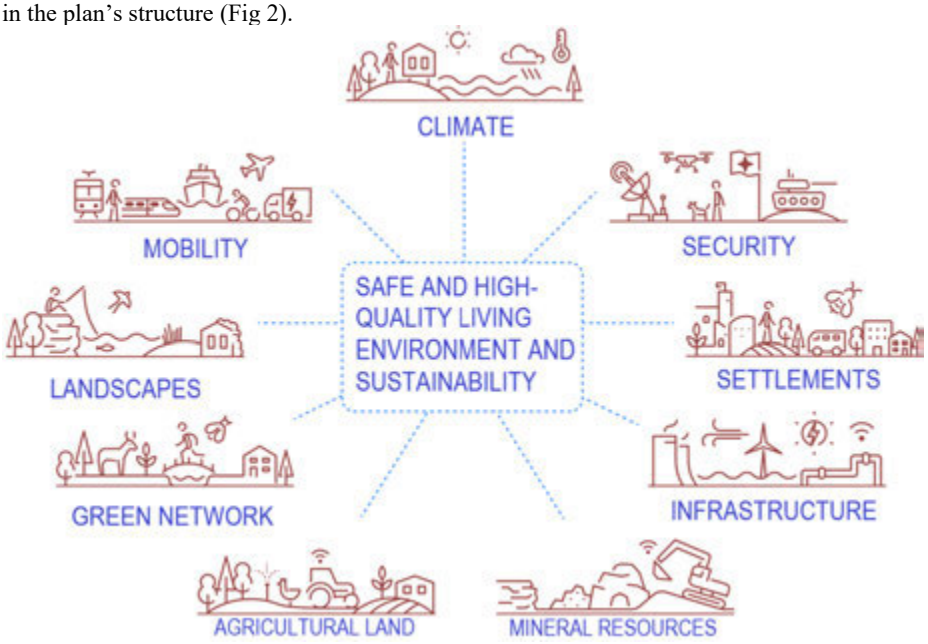

Figure 2. Focus themes of the national plan.

In light of the climate crisis and imperatives of heightened national security, there has been an intensification of spatial rivalry of land uses – conflicting interests regarding land use both in specific locations and in contrasting spatial networks of residential areas effects (Li et al 2024). Despite Estonia being sparsely populated compared to most European countries, competing interests of land use occur. National spatial plan prioritizes land use changes based on national interests. Climate policy and the limitation of natural resources, including the loss of biodiversity, will increasingly and significantly shape land policy and regionalisation. Furthermore, attention must be paid to the temporal axis of spatial processes, their sudden acceleration. Also, the plan determines the fundamentals of settlement pattern. It relates to the services, mobility, infrastructure, natural resources, ensuring the preservation of cultural heritage, sustainability, and the environmental burden. Based on settlement trends, guidelines are provided for shaping sectoral spatial networks and combining them to seek positive synergies and effects. National plan should serve as a basis for drafting sectoral development plans and other strategic development documents.

In regard the Estonia's geography and size, the plan intends to strengthen Estonia's position internationally. The planning process unpacks the spatial impacts of international agreements. The planning process supports Estonia's competitive advantages by focusing on a safe and high-quality living environment that considers all needs as an export commodity. Additionally, it identifies and activates the international economic networks in relation to territorial principles. The national plan accepts Estonia's maritime spatial plan, including Pärnu and Hiiu county maritime plans.

Traditionally, strategic territorial plans have mostly been based on land use-based approach, simplifying territory in robust two-dimensional terms. Recent planning practice introduces network-based approach, based on the systemic relations on territorial phenomena and theme, launched already by the Torremolinos Charter in 1983. In addition, the discourse of high-quality living environment has become prominent.

The evolving the sustainability context

The most significant global megatrends affecting Estonia and their impacts are addressed in the national spatial plan prioritise climate crises and green policies. This relocates the economy and activities, emphasis in nature conservation and resulting migration pressures, limits the use of fossil energy and mitigates negative impacts on land take. Digitalization means territorial polarisation, both concentration and dispersion, deepening regional competition, while also re-setting technological progress for more dispersed life and economic activities. In Estonian case, geopolitics should be number one in global trends, causing multitude of new globalisation and regionalisation outcomes, creating new walls and barriers in the territories. Cultural turn intensifies the struggle for quality space, with growing multiculturalism, generation etc divides in civil society. Convergence and trends of welfare society continue in Estonia as the Nordics set the pathways.

The EU Green Deal aims to drive the transition to a sustainable and climate-neutral economy across member states, while the Climate Law sets binding targets for reducing greenhouse gas emissions, fostering climate resilience, and promoting sustainability (Dupont et al 2023). Despite massive progress since 1990s during the transition decades, decarbonisation aims fall short of the target set by the Climate Law. Estonia needs to implement additional measures in various sectors to bridge the gap in meeting Effort Sharing and LULUCF Regulations targets.

Renewable energy's share in final energy consumption is expected to increase significantly by 2030, covering the total internal electricity demand. Energy security is highly important also in terms territorial development, as detailed plans for diversification are elaborated. While efforts to phase out fossil fuels, in particular oil shale for energy generation are underway, Estonia is increasing commitments on climate and biodiversity. Draft climate law of Estonia claims that nature conservation area should increase up to 30% from current 22% (Fig 3).

The sustainability domain of the national plan aims to create liveable environments across Estonia, addressing regional disparities. The Planning Act aims for rational, feasible, and sustainable land use, participatory planning and public hearing with the wide public, balancing and integrating interests, multifunctionality of land uses and evidence-based planning and adequacy of information.

Rethinking climate policy, particularly in the land-use sector, involves aligning policies with decarbonisation, climate and biodiversity implications, simply minimizing land take and acknowledging scarcity and availability of land resources despite the low population density and seemingly unlimited agricultural, forest and wetland land. This paradox on land conversion limits progressive and cohesive planning for multifunctional uses.

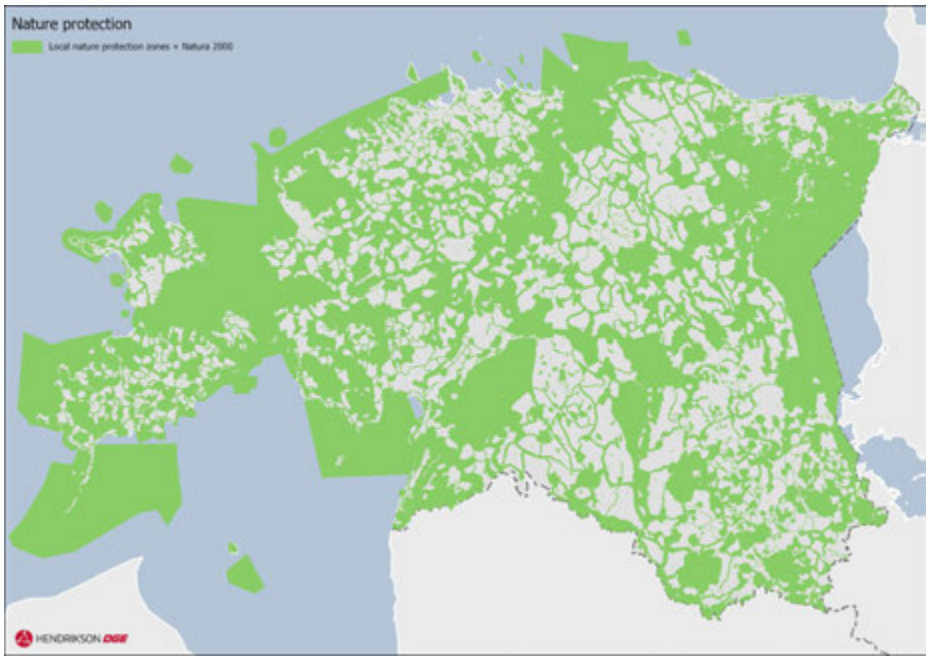

Figure 3. Nature protection areas (Data: Environmental Agency).

The plan should set clear land use priorities, providing conditions and guidelines for local comprehensive plans, seeking climate-proof and low carbon land uses and enforcing brownfield development. Fulfilling climate and biodiversity goals sets heightened expectations for the functioning of green networks, including urban green areas. At the same time, there is increasing pressure from construction activities on green network areas, especially near large cities. Nature conservation, more sustainable land management, and the restoration of forests

and other ecosystems offer the greatest economic potential for buffering and mitigating climate change, with immediate benefits from preserving carbon-rich habitats such as wetlands and forests on peatlands. Though, the discursive contestation and decision-making practices are shaped by political logics of levelling up or growth and ecological logics on climate change and biodiversity (Fearn 2024).

Aligning regional specialization with energy transition imperatives will be challenging in the deindustralised oil shale mining region as well in the wind powered western Estonia. Energy transition causes phase-out of oil shale industry and diffuses the energy system and infrastructure. The plan must also develop a climate resilience model for various urban areas and their vulnerabilities. A nuanced approach incorporates cross-cutting planning principles that comprehensively account for climate risks across sectors and land uses.

Resetting new regional structure in urban and rural territorialities

Besides improvement of the living environment the Planning Act aims for rational, feasible, and sustainable land use, participatory planning and public hearing with the wide public, balancing and integrating interests, multifunctionality of land uses and evidence-based planning and adequacy of information.

Estonian spatial policy takes into account positive net migration leading to population growth, which is accompanied by population aging and increasing cultural diversity. Continued concentration of population and economic development in the capital region, metropolisation of Tallinn continues causing the several major territorial changes (Fig 4). The future work and pastime trends guide towards micro-mobility and mobility as a service. It is also a challenge to ensure security throughout Estonia in the light of global trends. Spatial mobility, multi-location living and expanding home-work commuting areas increases due to remote work facilitation and security considerations, leading to the use of previously abandoned residences in rural and small-town areas (Fig 5).

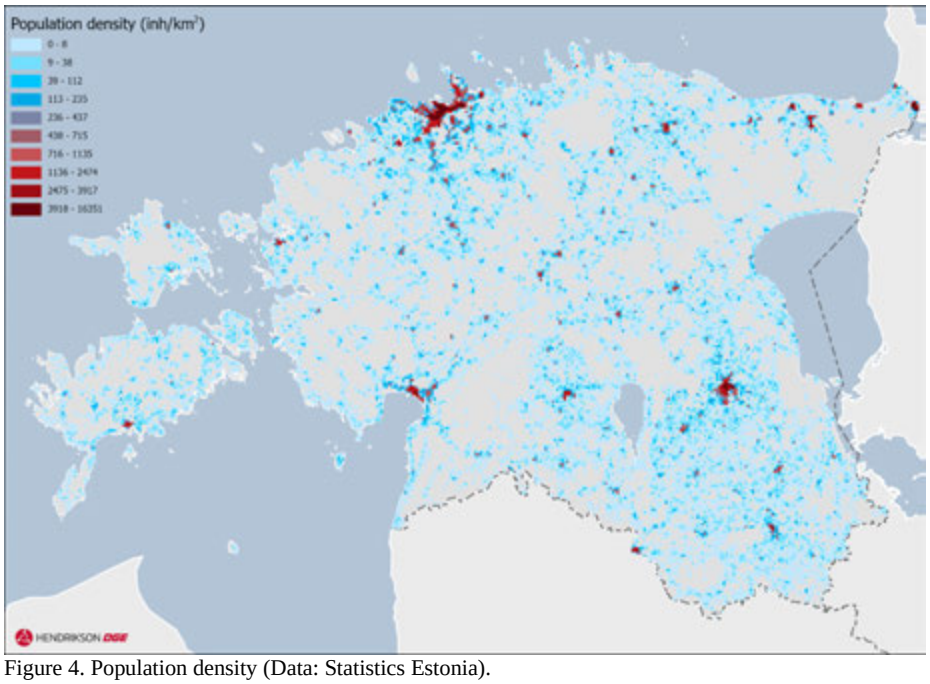

Figure 4. Population density (Data: Statistics Estonia).

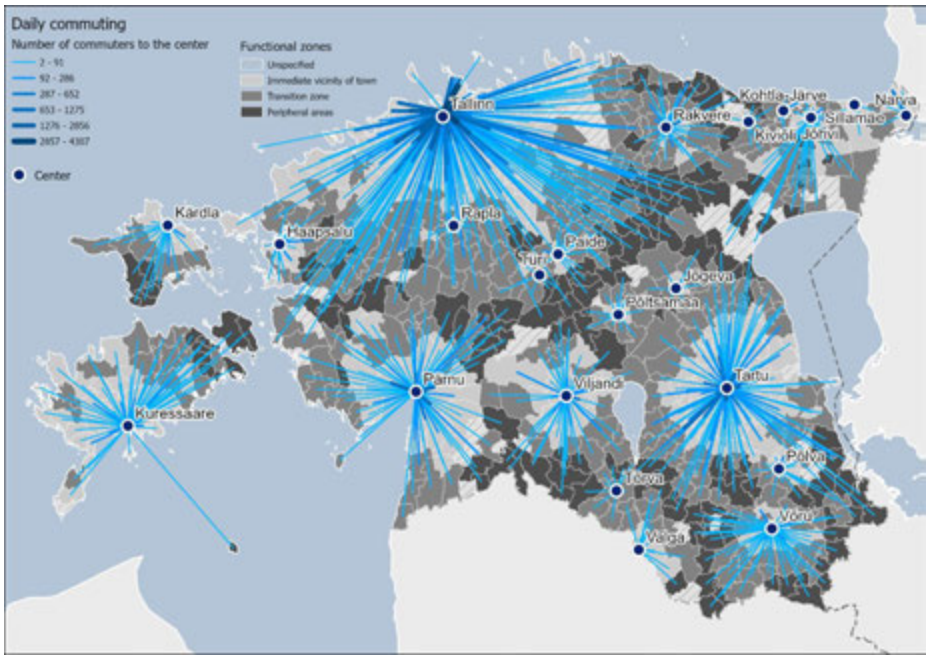

Figure 5. Daily job-related commuting (Data: Statistics Estonia).

The analysis of settlement scenarios and strategic solutions define the generic principles for directing the regional development, and the hierarchy of functional regions and settlement systems. The plan elaborates on the nature of a quality living environment across different types of settlements, the basis for land re-use and brownfield development. It defines centres based on territorial capacities, regional strengths and other networked principles. The major city regions are set for the international competitiveness. Also, the shrinking is strongly addressed in the plan.

Defence priorities

Escalation of the security situation in Estonia as a border state disrupted territorial tiers eastwards. The main challenge is to propose strong guidelines and find a territorial solution for ensuring national defence and the impact of national defence activities on people's well-being (Fig 6).

The plan intends to provide guidelines for determining land use for national defence, military training grounds 40,000 ha extended in Nursipalu, Sirgala and Klooga extensions), in addition, extended risk areas for tactical exercises in the state forest areas. The use of weapons and ammunition need further land allocations. Considering this, the expansion of the opportunities for practicing long-range weapons is preferably done as an extension of the existing training grounds. Land uses for marine-coastal exercises should be designated. Relevance of renewable energy restrictions resulting from national defence is another major discussion.

Figure 6. Overview map of national defence and safety (Data: Ministry of defence, Rescue Board).

Based on those implications, cross-cutting themes and conditionalities emphasised across the national plan to be multidimensional spatial approach, quality space, ensuring security and

safety, improving international competitiveness, mitigating contradictory trends in demography, mitigating climate impacts and enhancing biodiversity.

As a result of the above stated principles and growing dynamism and uncertainties in key themes, the professional stakeholders identified the needs of targeted research, which should refine settlement pattern and scenario, enhance green and blue network, redefine valuable landscapes and set contemporary innovative territorial monitoring and assessment framework.

Discussion

European policies reshape the territorial dimension at the national level, fostering policy debates through downscaling emerging initiatives and measures (Böhme et al. 2022b). Critique extends to contextualizing national territorial policies within the European climate ambition and cohesion policy (Farinós-Dasí 2023). While advocating for experimentation and adaptation to uncertainties, the study questions the feasibility of new approaches and planning solutions. Sustainability demands a more robust vision and an empowerment of the planning instruments, incorporating policy making, foresight, mapping and communication techniques (Berisha et al 2021). Climate targets and sustainability ambitions are not necessarily evaluated in relation to land uses and current functions in human activities, economic and technical infrastructure, energy security as well nature conservation. Sivonen and Kivimaa (2024) argue challenges of reducing reliance on Russian fossil fuel imports as well compromising climate policies in promoting renewable energy production while emphasizing national security and sustainability. The planning solutions highlight potential gaps in the plan's adaptability to the transition mode and underscores uncertainties regarding high territorial dynamism. This initial phase of national planning is crucial as it sets the ethos and tone for the entire planning system and process.

In terms of plan qualities, the content of the plan, as well as its spatial solutions, must be based on universally understood and consistently considered principles of societal development. Considering the global and EU strategic, regulatory, and business environment, as well as the choices made in the Estonia 2035 strategy, these fundamental principles should revolve around the principles of sustainable development. This includes the need to plan for sustainability, abandon inefficient land use, densify built environments, and reduce the area of artificial spaces. Plan intends to define temporally territorial interventions at the strategic scales to amplify positive trends. The plan takes into account game-changers associated to conditional territorial interventions. It defines criteria to determine whether a planning and land use condition is met. One of the game-changers as emerging policy streams, it can be metaphorically labelled as flipping the hourglass, is net zero land take.

Spatial plan is a vision document, defines the basis for the entire spatial development and policy in Estonia, and implements a wide range of planning instruments. Territorial visions for different regions is to be consistently presented, along with measurable objectives. A suitable selection of other planning instruments is made based on the nature of the theme, answering the question of how to most appropriately direct the development of a territorial part in the spatial plan.

There is a risk that public bodies fail to address the primary governance and planning challenges posed by new climate policies introduced by new economic models, circularity, platformisation (Oldbury and Isakkson 2023). This could allow market actors' agendas or controversially NIMBY activists to dominate instead. To ensure greater and committed involvement of public actors, strategic planning at national scale should actively acknowledge the competing and conflicting scales inherent in these processes, multitude of factors, to be settled by ad hoc and

flexible decision-making and planning schemes. Strategic planning needs to contain a clear attempt to recognise competing and contradictory dimensions of scale in these processes.

Reflecting the change in the planning paradigm of Southern Europe, austerity and crises create under pressures territorial policies and planning cases that favours inequality, aggravates left behind places, is market-oriented stronger than before against cohesion. If quick direct instruments are used, regulation is frowned upon, and strategies excluded or revised flatly (Tulumello et al 2020). A similar understanding tends to spread in Estonia and across Eastern Europe in 2020s with deepening tendency (Nowak et al 2023). At the same time, climate and biodiversity issues inevitably require a higher level of regulation and concise decisions (Dupont et al 2023).

This research reveals that national spatial plan, rather than serving as flexible coordinating intermediaries, legitimize their role in territorial and regional development processes across arenas, sectors and territorial units. This outcome creates possibilities for agreements, compromises, new ways of planning as well clear-cut trade-offs. The variance of solutions and window of opportunity can be extended. While beyond the scope of this paper, the quest for stronger legitimacy and institutional framework raises questions about the strengths and strategic power of national spatial plan. The findings in the inception phase of national planning illuminate trends, pathways and priorities of territorial transformations in Estonia at the external border of European Union. These spatial transitions and regional transformations reflect differing perspectives across society and sectors in the contemporary uncertainties. The national spatial plan will navigate tensions between flexibility and stability within the national and sub-national context.

Abstract
Designing 3D urban scenes for Virtual Reality (VR) offers the opportunity to transfer future scenario narratives to multiple publics involved in urban planning. Nevertheless, there is a current lack of conceptual frameworks to produce VR environments out of future scenarios. This research explores how scenarios might be enhanced and communicated through VR narrative environments. It elaborates and test the Scenarios-to-Scenes' framework, encompassing three steps: (i) generation of future stories; (ii) real/virtual places; and (iii) VR experiences. The framework was tested with urban planners, academics, and media communication experts in two collaborative workshop settings. This process illustrated the frameworks' capacity to enable the expansion of scenario contents out of diverse participants' interpretations and to transfer key narrative and design elements for the VR scenes.

Keywords: scenario prototyping, Virtual Reality, narrative environments, 3D urban scenes

1. Introduction

Urban planning is an activity deemed to the co-production of endurable future by multiple actors. Scenario writing, as the dominant technique for representing futures in scenario planning methods, offers the potential to engage the natural ability of humans for making sense of stories (Burnam-Fink, 2015), creating a common understanding about urban change. But it is the design of narrative environments (von Stackelberg and Jones, 2014), using a wider array of forms to experience the future –perceptually, cognitively, emotionally–, which may foster the transferability and usability of scenarios across different professional and non-professional domains in urban planning.

The concept of scenario prototypes encompasses all those narrative forms – i.e. stories of the future – that bring abstract or partial ideas/images of conventional future-scenario narratives into a present experience of such future. The here called *narrative prototypes* use fictional/speculative stories as mechanisms to explore and tests complex concepts. In science-fiction prototyping, such concept probing depends on how scenario narratives deploy one *novum* or multiple *nova*, that is, "primary points-of-reference" that make readers to distinct fictional futures from their home reality (Raven, 2014): e.g. disruptive technology, concept, event... Immersive Virtual Environments are being explored as the ultimate means of producing scenario prototypes, combining Virtual Reality (VR) capacity for sensory immersion and spatial presence with the natural capacity of humans for building their own stories about places (Stepanovic and Ferraro, 2020).

The production of VR 3D urban scenes using scenarios to transform present places into virtual futures offers the opportunity to expand scenario narratives towards richer narrative

environments. Nevertheless, there is a current lack of conceptual frameworks to deal with two main challenges of VR scenario prototyping: interpreting scenario narratives in multiple geographical contexts, enabling its localisation; and adapting scenario contents to visual communication of VR scenes, balancing "spectacular" realism with efficient 3D-scenes design.

The first challenge has been addressed from a narratological perspective. How futures are experienced from multiple audience is mediated through narrative elements embedded in scenario prototypes (Raven and Elahi, 2015). The first element is the *story-world*, or the spatial and temporal setting of the events. Beyond a mere "context for the story", future changes can be translated into a sequence of spatially and temporally relevant places in the synthetic VR space (Vallance and Towndrow, 2022). The second element is the *story* or "plot", as the sequence of contingently related actions having an identifiable beginning, middle, and end (Shearer, 2004) – typical "story arc". The focus on "actions" and "actors" and finite story arcs may contribute to create interpretative frames for explaining complex causation underlying future change – e.g. motivations, triggers, contingencies… (Derbyshire and Wright, 2017). The third element, *narration/storytelling*, involves the form of the narrative discourse – i.e., the explanation of why something happens (Shearer, 2004) – in connection to alternative narrative strategies (Raven, 2014; Raven and Elahi, 2015). On one hand, strategies focusing on realism though comprehensive worldbuilding connects better with the paradigmatic forms of presentation (i.e. exposition, argumentation) of technical/academic environments. On the other hand, those strategies highlighting the story rely on the description of actors and their actions, in line with narrative presentation (von Stackelberg and Jones, 2014).

The second challenge involves how previous narrative elements are translated to the codes and languages of VR scenes. Despite urban scene ontologies offer a full menu of choices based on functions and architectural typologies (Berta, Caneparo and Rolfo, 2020) or identified objects (Zhang *et al.*, 2018), such ontological frameworks are not enough to anticipate the multiple meanings captured by scenario narratives (Wu *et al.*, 2022). Interpretative frameworks may require the adoption of semiotic approaches to VR, which distinguish between previous *syntaxis/sematic* levels of communication, capturing the structure and meaning of content to be decoded by the user (i.e. the 3D scene model), from the *pragmatic* level, or how VR users "decode" such content (Barricelli *et al.*, 2016). Highlighting the later, VR scene production (as other computer interface designs) is a generative process, that is, it creates a representation of the message together with a "model user" able to interpret it (Barr, Biddle and Noble, 2004). Classic narrative semiotic models based on actors' participation into actions (as subjects, objects, senders, receivers, helpers, opponents… in Greimas' actantial model) may become useful tools, in combination to the abovementioned narrative strategies, for anticipating how publics create meaning through key transformations (Hebert and Eveaert-Desmedt, 2011). In the same fashion, virtual environments deploy a set of affordances and visual stimuli (i.e., a perceptual map) that guides VR users through a set of discoveries, barriers and rewarding experiences. The same grammars used for analysing narrative strategies in 3D games and virtual environments can turn into generative systems to produce them (Fencott, 2001).

Considered the previous challenges, semiotic principles and analytic tools, this research aims to design and test a framework for converting *Scenarios to Scenes* (StS framework). This framework relies on expanded scenario narratives and 3D urban scene concepts as prototypes for creating immersive VR narrative environments, as explained in Section 2. In addition, the applicability of the StS framework was tested in 2 sequential collaborative workshops (see Section 3), exploring contributions and limitations of the StS process from three main dimensions (see Section 4): the capacity of participants to translate original narratives into a set of specific changes, events, and actors; their capacity to connect the narrative with real and/or

virtual places; and their capacity to elaborate communication strategies that explicitly consider how users interact with given places in order to gain understanding about the original narrative.

2. Designing The Scenario-to-Scenes (StS) Framework For Prototyping Future Scenarios

The aim of the *StS framework* is to support the use of any conventional scenario narrative to elaborate full-fledged narrative strategies based in the production of VR narrative environments. The framework relies on the design of two complementary narrative prototypes: the expanded scenarios and the 3D-scene concepts. *Expanded scenarios* consist of more detailed account of key future events and actions, as a future story illustrating main scenario changes in specific places and moments. The *3D urban-scene concepts* (henceforth "scenes") encompass a set of visual and logical specifications of the model representing the place, mapped by a set of visual stimuli and interactions of an imagined VR user's experiences. The StS framework guides the design of both prototypes by enabling three generative processes[1] triggering each other (Figure 1): the future story generation, the place generation, and the VR experience generation. Each process is interpreted through alternative *story models*, as described below.

The future-stories generation process rise the general question "What happens in the scenario World?" It aims at the generation of future themes (henceforth *themes*) capturing how the original scenario narratives represents their underlying image of the future (in the mind of scenario authors). Themes are "controlling ideas" that help to elicit the shape, value – intrinsic, instrumental, symbolic– and direction of narratives (von Stackelberg, 2011). Using archetypical Greimas' actantial roles[2] as interpreters (Hebert and Eveaert-Desmedt, 2011), we translate the generation of future themes through the 3 types of associations between actors. The *action themes* refer to an *agent* introducing a key *change* for understanding the future – i.e., *novum*: e.g., a pedestrianisation project (change) proposed by city planners (agent). The *transformation themes* define the nature of change, in connection to two actors: the *system* receiving the change, and the *regulator* motivating the agent to perform it. In the previous example, car congestion problems (regulator) motivate city planners to perform the pedestrianisation of some commercial street (system). The regulator has the role of activating and deactivating the agent at the beginning and the end of the story. The *transition themes* define how the agent performs the change, as enabled by *helpers* and hindered by *barriers* to change: e.g. the plan faces retailers and car-drivers complains (barriers), that address by increasing environmental awareness (helpers). Each theme enables a new interpretation of original scenario narrative, which can be expanded into new future stories.

The *place generation* process consists of representing future stories through complementary "where" questions. Place concepts (from now, "*places*") are those settings required to interpret abstract thematic actors as concrete symbols, icons, indexes, or metaphors that can be apprehended by a figurative observer. According to the meaning transferred, places encompass (Agnew, 2011; Zhang *et al.*, 2018): *locations*, as generic or specific sites of reference where key changes of the story happen (e.g., the city centre streets in the previous example); and *story locales*, as concrete urban entities – workplaces, homes, shopping, streets, people, vehicles –

[1] While conventional semiotics studies the interpretation of signs, generative semiotics revert the semiosis process to generate signs. The current approach is based in the infinite semiosis process described through the Pierce semiotic triangle: object, representant, interpretant (Barr et al., 2004).

[2] The Greimas' actantial model defines 6 pairs of complementary roles that can be taken by actants (disregarding their figuration: i.e., human or non-human, material or abstract): *subject/object*, *sender/receiver*, and *helper/opponent*. Any archetypical story takes a subject that gets some object of value, motivated by a sender, to take it to the receiver. The success of the quest is supported by helpers and hindered by opponents.

representing main actors' states, activities or behaviours (e.g., the pedestrian areas representing the plan). Places can be direct references to the elements that will be represented in 3D urban scenes (virtual places), so they can extent location with a set of details aimed at building a sense of reality through future routines. Narratively, such *sureties* will act as reinforcers of *surprises* in VR experience generation (Fencott, 2001). The expansion of places may encourage the generation of new future stories.

The *VR experiences generation* process is driven by the question "what happens in the VR scene?" VR experiences define alternative stories on how imagined VR users interpret previous places by interacting with them. The VR user's story model uses the actantial model in combination with the *surprises* of the Perceptual Opportunities model (Fencott, 2001) to define 3 types of *VR experiences* in the 3D scene. The *exploration experiences* are based on a VR user *activity* reaching some *reward*, namely a memorable opportunity for immersion, presence, and embodiment: e.g., for the previous future story, discovering that people in a near street are not moving because heavy traffic. *Discovery experiences* use *attractors* that direct users towards the activity (*retainer*); e.g., user sees/hear a distant crowd waiting. Attractors can be just calls for attention or work as more complex retainers of the reward (being also a rewarding experience by themselves). *Navigation experiences* (E3) create *connectors* - paths, movements, challenges and decision points - taken by user-explorers in their progression toward the reward; e.g. main street axis, people moving from/towards reward's direction. VR experiences are final interpreters of the whole StS process, so they may trigger re-interpretations of places, themes, and even original narratives.

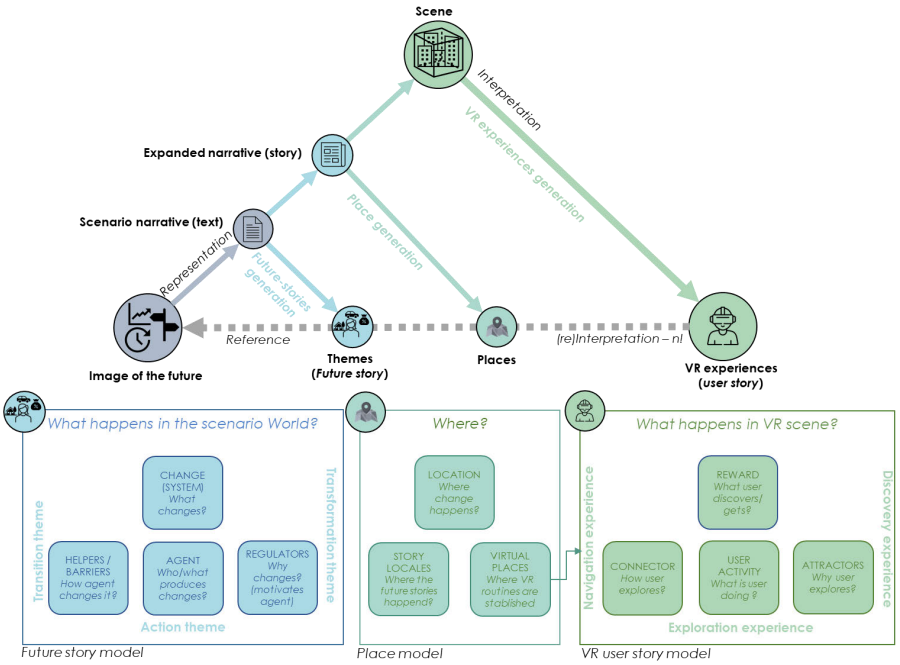

Figure 1. StS Framework overview for producing VR narrative environments.

3. Implementing And Testing The StS Framework

This research aims at assessing the applicability of the StS framework for building VR narrative environments enhancing scenario communication. The StS was tested in 3 participative workshops of 2-hours length (approx.), with 4 participants each. The aim of those workshops was to generate expanded narratives and VR experiences' concepts based on the development of VR scenes from Project TRANSURBAN's narratives. Those narratives addressed the original project's aim of generating disruptive scenarios about land use and transport integration scenarios for the Henares corridor in 2050. For convenience, only one of the three different future-scenario narratives, *High levels of insecurity in urban areas*, summarised in Soria-Lara et al. (2021, p. 8):

> [The future] is strongly affected by a high level of insecurity in urban areas. Walking and cycling are not advisable. The modal split would be drastically altered, with the private car dominating all daily trips –work, shopping, and leisure. There would be also preferences for increasing the level of car sharing, as well as for the promotion of clean and autonomous vehicles with zero emissions. Public green areas would be removed and recovered for car infrastructures. There would be a preference by high-income families for living in the city periphery in private communities. Land uses would be highly segregated in homogenous areas connected by motor[ised] infrastructure. City centres would be mainly transformed into work destinations, with most employees commuting from the city's periphery. Low-income families would also tend to live in those insecure city centres.

Two types of workshops were planned in sequence. The first kind, here-called *consultancy workshops*, focused on the future story and place generation processes before conceptualising VR experiences; and the second kind, called *VR production workshops*, focused on validating and expanding proposed VR experiences from consultancy workshops according to their communication opportunities. Participants' engagement was equally directed to experts and practitioners familiarised and not familiarised with the geographical context of the scenario narratives, integrating both at the end. None of them knew the TRANSURBAN scenario narratives, to ensure their genuine interpretation.

Two consultancy workshops were held independently, one involving academics (Workshop 1), and the other, practitioners and policymakers (Workshop 2). In each case, participants' expertise covered either urban and transport planning areas (or both). The central activity consisted of selecting and developing future stories and potential locations out of the reading of TRANSURBAN's narrative, creating newspaper future headlines to capture it in a future story, and voting them either by credibility, relevance, or degree of surprise. Participants used the future story model to analyse the most voted news and to expand actors and themes. Then, they proposed place models connected to previous themes, adopting the perspective of a future photographer illustrating the headline's story. A first unstructured attempt to ideate VR experiences was made, creating chains of routines and surprises for imagined VR users' interactions. Participants were encouraged to agree on central actors, locations, and avatars before enriching stories and connecting elements.

The results of consultancy workshops fed a *VR production workshop* (Workshop 3) targeting VR/3D environment designers and visual media communicators. This workshop was focused on the intricacies of developing the VR experience and the 3D scene prototype. Dynamics for this workshop mostly consisted of the selection, validation, and refinement of ideas from previous workshops. Firstly, facilitators presented participants with a synthesis of 2 VR user stories resulting from the first workshops, consisting of a set of story maps pointing at relevant interactions and decision points. Then, facilitators asked them to suggest main messages, interesting places, and moments of each user story. After comparing user stories with the

original future stories, presented as conceptual maps similar to Figure 2 (see section 5.1.), participants chose 1 story and focused on elaborating VR experiences using the complete VR user story model. Finally, results were synthesised on a raw storyboard representing potential user pathways and key scene elements.

During all workshops, the research team acted as facilitators, guiding participants through the StS process, moderating discussions and providing with different materials: templates, boards and post-its and pins to place over them. The team recorded the audio and video and collected the filled materials. The analysis of all these contents consisted of the writing of ethnographical notes describing key events in the interaction of participants with the assumptions, models, and processes of the StS framework (see previous section); this process was supported with the elaboration of more structured conceptual maps representing the story models (see Figures 2 and 3 at the end of Section 4), and semantic maps representing elicited connection between themes, places, scene elements and VR experiences (not included in this publication, but used internally to offer some of the insights of section 4).

4. The StS Framework In Practice: First Insights And Learnings

4.1. Interpreting And Expanding Future Scenario Narratives

For the first stage of the StS framework, the *future-stories generation process*, we tested the capacity of consultancy workshops' participants (W1 –academics– and W2 –practitioners–) to translate original narratives into a set of actors and themes. Future story models were expected to work as flexible narrative structures capturing how participants interpreted as a group what is happening in the world of the original scenario narrative.

Participants read original scenario-narrative at the beginning the abovementioned workshops and were encouraged to focus on certain aspects to individually create news' headlines about the Henares Corridor in 2050. Most of the proposed headlines offered paradigmatic presentations of social changes depicted in the original narrative. In W1, the most voted headline was titled "The new urban walls", highlighting spatial segregation into "two cities", based on social class differences. In W2, participants chose the headline "Health issues increase due to lack of contact with outdoor environments", which brought isolation and public space deterioration as core themes. Both choices were influenced by its perceived credibility, and, in W1, also by its relevance.

The selection of headlines clearly shifted the thematic focus of the narrative towards social issues, which occupied the centre of the analysis and development of both headlines. Figures 2 and 3 (upper part) show the future story models proposed in W1 and W2, respectively.

Looking at the action themes (i.e. agent-change axis), social dynamics were seen as cause of the main future change in W1, the "urban wall" concept. Similar social dynamics (encapsulated in "society" as an actor) became the agent of W2's change: citizen isolation. The agent in W1 was defined by merging other headline proposal ("Delocalised"): a "disruptive technological innovation" exacerbating class differences in access to services. Nonetheless, the nature of this disruption was not defined until the place generation stage. Defining the central change was especially difficult in W1, where one of the participants (well familiarised with scenario-planning methods) resisted the linearity of the model and highlighted the complex feedback loops between social, economic, and technological systems. Similar dilemmas on causal loops between insecurity, isolation, and public-space deterioration rose in W2. This time, facilitators amended some of these issues by improving the explanation of the whole model, offering narrative examples based on a popular tale, and by emphasising the idea that, for convenience,

the choice must accept the perspective of the headline, even if there are "many ways to tell the same story".

Concerning the transformation themes (i.e. regulator-change axis), regulators were mainly depicted by organisations, collectives, and institutions (policymakers and planners). The interpretation of the "regulator" role was fitting in W1, where participants defined a new world order led by tech companies as the motivator of the technological disruption. Conversely, in W2, the figure of the regulator was connected to multiple sources of regulation and decision-making without too much reflection on its implication in a society becoming isolated. Playing with the flexibility of the story model, this problem was fairly solved by implying that such organisations are part of society at large. But the lack of connection to action probably influenced failed attempts to portray such regulators in place generation.

Transition themes depicted a wide range of helpers and barriers connected to central social transformations. Central topics of the original scenarios, such as insecurity, transport, and telematic activities were included here. Interestingly, the topic of civic insecurity was extended to other sources of insecurity in W2, such as climate change and heat waves making public spaces unsafe and abandoned. In both consultancy workshops, the negative connotation of the central change made participants to struggle with the connotations of the "helpers" (positive) and "barriers" (negative) to such change. As in the case of the regulators, this had to do with the choice of name for the actantial roles. With the facilitators' support, participants interpreted barriers as positive aspects, such as good public space design, social policies, or the regulation of tele-activities, whose absence explained the central changes.

In this phase, participants took advantage of the flexibility of the story model, allowing actors to adopt multiple roles and shapes. On the positive side, participants openly referred them as "characters" of the story, reinforcing abstracts and non-human forces (e.g. climate change) as narrative figures. Technology and society were placed as protagonists of change, which recalls the central novum of classic science fiction stories. In W2, the model also opened interesting reflections of the accountability and agency of actors in those scenarios. On the negative side, actor choices were often too abstract and symbolical, making next StS stages more difficult. This was associated with the resistance to abandon argumentative modes, particularly high in W1, instead of offering a simple narration and description of actors of the future story-world. A possible reason is that the scenario references (e.g. inequality as a source of crime and insecurity) and auto-referential concepts ("the Wall") emerging in discussions building the alternative world were mixed with multiple external referents: professional experience and dilemmas, cases from other geographical contexts, theoretical models (5-helix innovation, 15' cities…).

4.2. From Themes To Places: Localising The Scenario Narrative

The StS potential to enable the representation of future stories through real and/or virtual places was also tested in consultancy workshops during the *place generation process*. Reciprocally, our analysis pay attention to how place generation expanded and nuanced original themes, despite time limitations in workshops leave no room for encouraging this exercise. Figures 2 and 3 (middle part) summarise main locations and locales.

The location-locale relationship was more flexible that the story model and subjected to variations between W1 and W2. Firstly, participants agreed some locations giving a common perspective for the imagined photographer illustrating the news headline; then, they proposed locales (place objects, events, activities…) observable from the photographer's position, connected to central themes. Facilitators proposed a rule limiting photographer's movements, so to keep the exercise focused. Nonetheless, many locations emerged as parallel referents of

discussions. Those referents included real locations and locales in the geographical context (e.g. emblematic cites and architectural elements, places of innovation), city models (e.g. suburban models, Latin-American cities), and even fiction works (e.g. Stephen Kings's *The Dome*, the *Snowpiercer* show). Some of those places were early introduced as referents to themes as well.

In W1, the urban wall concept quickly led to the idea of private spaces and gated communities (also referenced in the original narrative as "segregated residential areas"), defining a conceptual location called: "new fortified urbanisations". The physical wall and security access control system (i.e. camera control, security guards) were the main locales defining this location. Other important locales represented the disruptive technological innovation: autonomous delivery systems based on drones and autonomous vehicles. Discussions at this stage helped to clarify the nature of the technological disruptor, described as a change in food production based alternatively on private facilities for self-supplying food (such as private greenhouses) or on pills for easily carry all nutritional needs to citizen. The class-differences theme started to gain prevalence at this point of the discussion. On parallel, urban borders of Alcalá de Henares inspired a sub-location of "transition between two cities", happening along a "segregator element" (e.g. road, change of urban pattern). This transition concept was expanded during VR experiences generation, defining locales by contrast inside and outside the residential area. Abandonment and isolation, as well as physical public-space design were added to the themes at this point, after proposing some locales reflecting urban space abandonment (e.g. abandoned children play area, degraded local retail…).

In W2, changes in social dynamics and isolation were quickly referred to an image of social meeting areas already described by the author of the selected headline. The selected location was the Alcalá de Henares' Town Hall square desolated at noon on Saturday. This specific spatial and time reference was an interesting choice if compared with W1's. Some indexes of voluntary lockdown, such as close commerce and empty bar terraces, easily represented the central action. The sub-location of an empty park permanently sealed off by police was finally included to represent the barrier associated with the lack of public space improvements and its abandonment. E-commerce's influence was represented by a futuristic image of historic streets full of autonomous vehicles and drones making deliveries, following a similar pattern than W1. These elements also signified, according to participants, distances, and digitalisation themes, together with companies as regulators related to mobility (a relationship somewhat forced during the workshop dynamic). Climate change was represented in combination to a degraded bus marquee with a thermometer showing extreme temperatures, a decision that manifests the participant efforts to make efficient choices. In this phase, a central theme of the original narrative emerged with an interesting interpretation: how car mobility dominates public space and cause its abandonment, with public insecurity as a reinforcement of this process.

The future photographer dynamic and the location-to-locales concept worked better in W2, where participants gave quick impressionistic and intuitive images after agreeing a point of observation. In W1, there was still a tendency to discuss and analyse conceptual urban settings. Challenges to represent abstract or conceptual actors (distances, disruptors, climate change…) were better solved in this phase. Some locations, such as parks, were given alternative definitive interpretations in each workshop, as a luxury (W1) or as abandoned place (W2).

4.3. From Future Stories To VR-User Stories

The potential of the StS framework to help anticipating how VR users (adopting an avatar perspective and role) might interact with places so to capture central themes was tested in all workshops. In the consultancy workshops, this final stage aimed at validating and completing previous themes and places, while the VR production workshop (W3) focused on the user story itself, improving opportunities for its communication, selecting key moments from proposed

experiences and mapping potential "game mechanics". Figures 2 and 3 (bottom part) show the main paths proposed by workshop participants between different VR experiences.

In W1, the use of the simplified routines-surprises model encourage participant to select and expand locales, this time perceived from the perspective of two avatars: a resident of the fortified urbanisation; and a visitor wanting to access inside but prevented by the wall's security measures. As observed in Figure 2 (bottom part), this unstructured array of experiences was an opportunity to stress the contrast between the luxury world inside the urbanisation and a conflictive neighbourhood in the city outskirt. Near the end of the W1, a coherent user-story idea emerged where the resident leaves the security provided by the residential area and gets lost in the conflictive neighbourhood, where she hears gunshots in the distance or sees evidence of drug dealing. An interesting experience was the need to get assistance from locals to return home, overcoming the fear of an apparent hostile environment before setting out to explore empty spaces in an old commercial street while looking for help.

In W3, after the initial reading of the story map elaborated by the research team, participants found this urban-transition concept appealing, despite the motivation of the resident to get out the "bubble" was missing. Other important aspect was the lack of markers of being in the future. "This could be United States in the 1980's" some participant pointed out. It seems that the participants did not capture the idea of the gated community as a transformed location in Alcalá de Henares. Most amendments tried to highlight the technological disruptor theme or the new technological order, both missed in the user story, by adding car and house technologies: access panels or a trademarked AI-assisted car navigation system.

W2's participants elaborated more lineal user stories (Figure 3, bottom part), encouraged front the beginning by a "Yes… and" improvisation dynamic that did not work in W1. The first story took the perspective of a journalist with the mission of making photographs, moving through selected places but finding nobody. The second story featured a delivery android trying to reach its destination, facing delays and conflicts with other vehicles, and finally breaking down due to over-heating. At the end, participants hardly distinguished from routines and surprises. As a result, most proposals depicted inflection points in the user stories, or just offered a tour through the already generated places. Both user stories stressed at some point conflicts of mobile avatars experimenting different modes of transportation, in line with the expertise of some participants. Ideas for advanced game mechanics appeared at the conclusion of the workshop, along some reflection on the dehumanisation linked to digitalisation. Participants showed some preference for the journalist story but recognised the potential of an encounter between the 2 avatars. This inspired the research team to create a story with a mixed proposal.

Conversely, W3's participants found that the journalist's mission was "difficult to translate to 2050", whereas the point of view of the android avatar was original and suggested a message of "abuse" of technology, clearly aligned with W2's themes. Nonetheless, the presence of technology reflected solitude, but also freedom, which conflicted with the core theme of insecurity. In this case, the presence of "too advanced technology" caused concerns about the overall credibility of the depicted world. The leaps between traditional city locations and advanced logistics hubs were also confusing.

Because of previous issues, W3's participants agreed on working with W1's user story. The dispersion of experiences and the problem of "where do you want the user to look at?" anticipated the need to emphasise "call to actions" for motivating exploration, which aligned with the purpose of the VR user-story model. A proposal was inspired from the experience of looking a sad child in a window wanting to go out. In this new proposal, the child is trapped inside the house after the failure of some access control system, which demands the parent to

find help outside of the residential area. This solution portrayed a moment when the resident experiments technology as a wall itself. The VR-user-story model assisted in creating a tensional sequence around the main activity (accessing the house) and the reward (saving the child). The attractor was interpreted as the "problem" or initial "call-to-action": the child calls to the avatars' mobile. Connectors deployed challenges during exploration (i.e. go out with the car and getting some technology to repair the car and the house), which quickly led to sub-stories (e.g. the broken car) not easy to structure under the story model (see Figure 2, bottom part). Even in the preparation of storyboards, when participants were expected to thematically enrich the background with new scene elements, they were still solving emerging conflicts and gaps in the narrative structure of the story. Consequently, most scene elements obeyed only to this purpose. Some technical aspects of VR, such as movement methods, and the interface format were discussed at this point.

In consultancy workshops, the VR experiences generation encouraged participants to abandon paradigmatic presentations to propose places and interactions from a more creative approach. The choice of imagined avatars helped them to build the story-world. Nonetheless, the main issue was the difficulty to contain brainstorming and counteract the path-dependency of some ideas deviating from central themes (e.g. the technological disruption theme disappearing from W1's user story). In the VR production workshop, the inversion of the StS process – i.e. reading the experience first and comparing it with the original future stories later –, created some confusion, but helped to recall central problems of interpretation. The map showing the future story models (i.e. themes and actors) was found particularly helpful by communicators for keeping the central messages, detecting the actors that were missed. The VR user-story model triggered appropriate questions along the process: "how do we point at where the solution is?", "is this a reward or not?" Although the story model was not able to capture complex sub-stories, it aligned to participants emphasis on the importance of planning the scene exploration, using narrative elements to produce it.

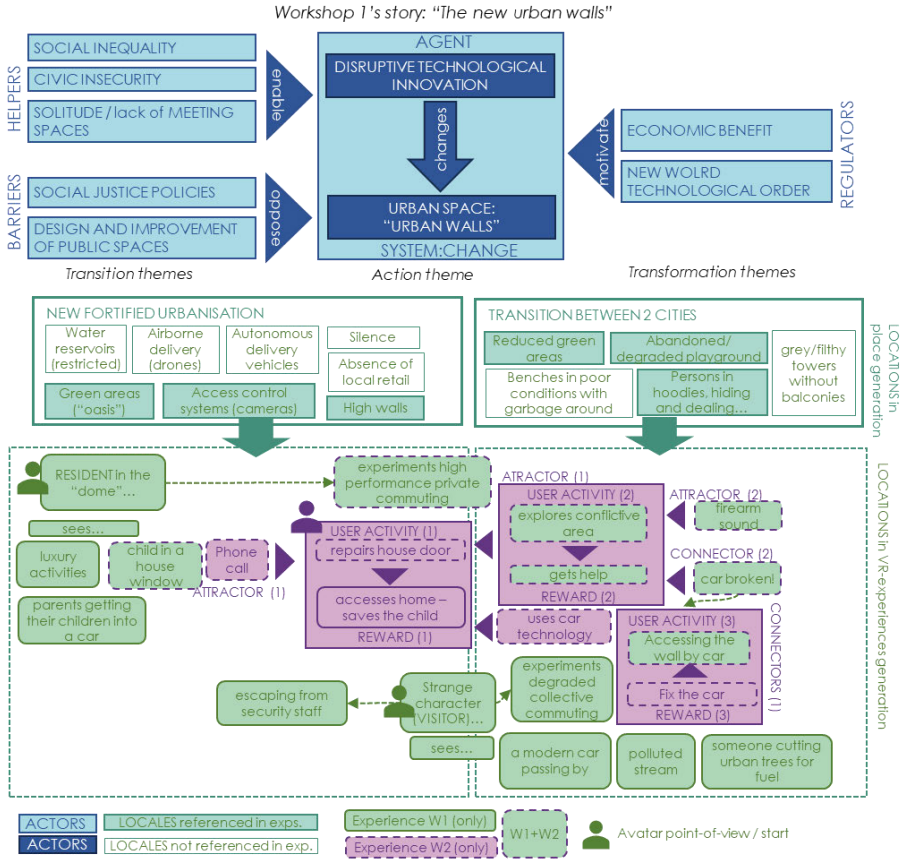

Figure 2. Synthesis of future stories, places and VR-user story models proposed by W1's participants and expanded by W3's participants.

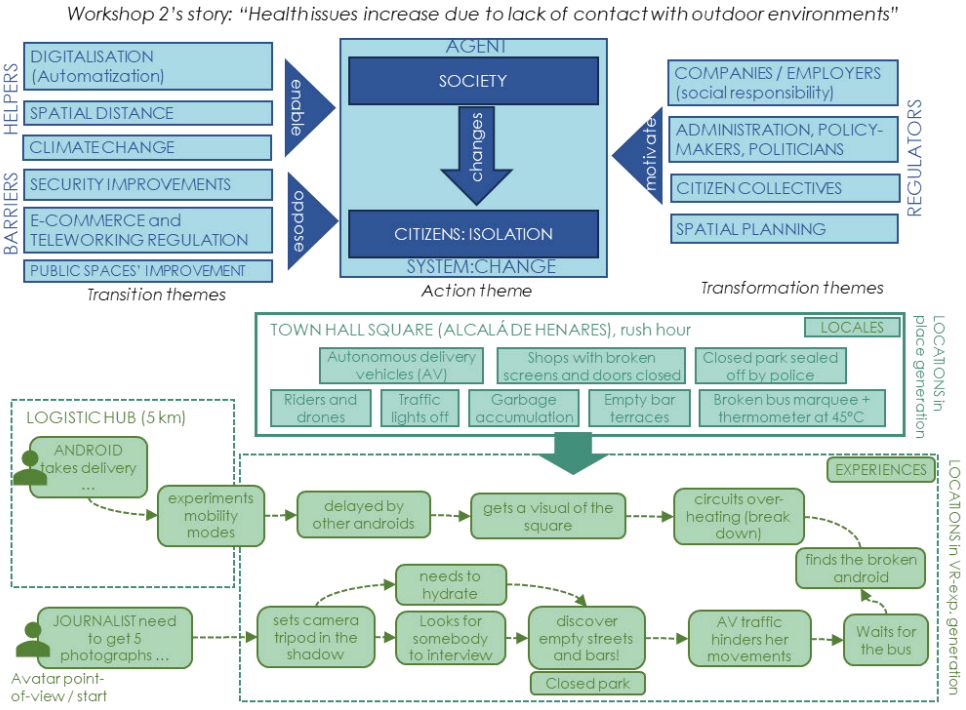

Figure 3. Synthesis of future stories, places and VR-user story models proposed by W2's participants.

5. Conclusions

This research explored how conventional scenario narratives might be enhanced and communicated by using Virtual Reality Environments through the production of 3D urban scenes. A Scenarios-to-Scenes (StS) framework was proposed as way to build scenario prototypes expanding and consolidating a narrative environment. Three expected contributions of the StS framework were tested in participative workshops with urban-planning practitioners and academics (consultancy workshops), media communicators and VR experts (VR production workshops): (1) the translation of original narratives into a narrative structure connecting scenario transformations and actors along specific themes and stories; (2) the localisations of such stories in a map of specific real and virtual places; and (3) the integration of the VR experiences and user stories in the narrative environment.

Firstly, concerning the translation of the original scenario to a narrative structure, the StS framework proved effective and flexible enough to bring out alternative interpretations of the original future narrative, materialised in participants' discussions about the nature and role of actors. These discussions, at the end, contributed to expand the original narrative and bridged some important gaps (e.g. social inequality as a cause of insecurity). Although the use of the future story model in consultancy workshops showed a slow learning curve, the effort paid off in sharing key aspects of the story-world with the VR production workshop. Both urban experts and communicators converged in underlining conflicts between technological and social actors, a narrative structure already used in other narrative prototyping experiences (Burnam-Fink, 2015). Secondly, the localisation of future stories helped in defining the nature and shape of previously identified actors, in part meeting its purpose of mediating between the previous

phase and the VR-experiences' generation. Nonetheless, places and VR experiences complemented each other to build a structured "story-map". Lastly, the VR experiences reinforced visualisation and emphasis on storytelling through the avatars' roles but failed to capture potential "model VR users" (publics, audiences….) connecting to the central message. Probably, this perspective-taking exercise should have been done earlier, along the pre-definition application contexts proposed by participants at the end of workshops: e.g. educational purposes, and urban project/plan showcases embedding narrative elements.

Some of the limitations of the StS process may be addressed by testing them in processes longer than 2-hours workshops, with frequent validation and revision of materials (as represented in the cycle of Figure 1). In the future, the StS framework is expected to guide procedures and protocols for prototyping Virtual Reality Environments by keeping track of main design hypotheses and testing them with real VR users. To that end, the story models need some amendments in the naming and its communication must be improved to understand their contribution to the VR production process.

Abstract
In spring 2023, the PBL Netherlands Environmental Assessment Agency published the research project *Spatial Outlook 2023* with four spatial scenarios for the Netherlands in 2050. In this multidisciplinary scenario study, a combination of story lines, maps and other forms of visualisations is used to explore and describe how the country could look like after the transition towards a climate-neutral and circular society. This paper describes the method of how the scenario story lines and the related land use maps were developed by applying a new mixed methods approach that combines participatory and multidisciplinary scenario development, GIS-based land use modelling and creative tools of research by design. Moreover, the paper discusses the use of spatial scenarios in the context of regional and national spatial planning.

Keywords:

Spatial planning; Scenario method; Sustainable land use; Research by design; Multidisciplinary research

1. Introduction

The Netherlands faces a number of major challenges in the fields of spatial and environmental planning. Social, political and economic changes and unpredicted events, such as the COVID-19 pandemic and the war in Ukraine, are contributing to increased levels of complexity and uncertainty. In order to help policymakers and planners deal with a growing level of uncertainty and to shed light on possible spatial interventions, the PBL Netherlands Environmental Assessment Agency (PBL) has developed four spatial scenarios for the Netherlands in 2050 (see Figure 1) in the project *Spatial Outlook 2023* (PBL, 2023). In this multidisciplinary scenario study, a combination of story lines, maps and other visualizations was used to explore and describe how the country could look like after the transition towards a climate-neutral and circular society.

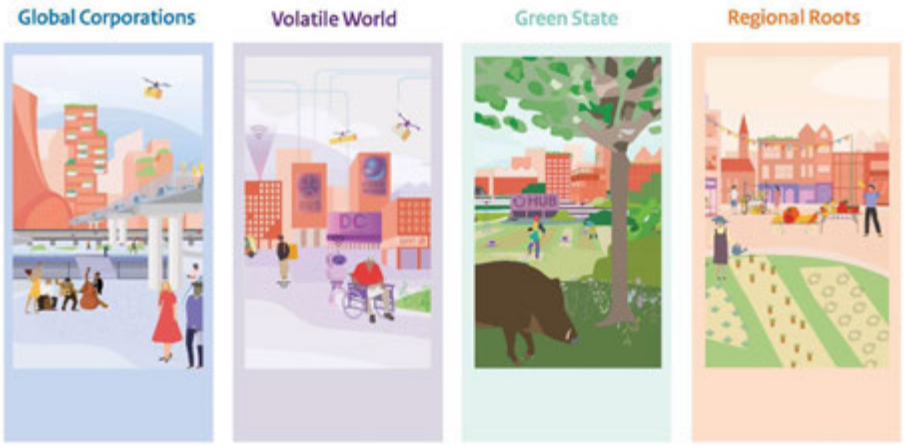

Figure 1: Impressions of the four spatial scenarios, source: PBL.

The four scenarios of the study show how land use in the Netherlands might look like in the year 2050, specifically looking at the following questions: Where do spatial conflicts arise? Where do opportunities lie? Who will take the lead? Policymakers can use these scenarios to respond to the uncertainty inherent in long-term policymaking. Using the scenarios, policymakers can explore robust strategies: which approaches fit into multiple scenarios? They can also explore the possibilities for adaptive policies: what adaptation options are available and conversely, how can 'lock-in' situations be avoided? These scenarios of the *Spatial Outlook 2023* enable policymakers and planners to understand, explore and discuss advantages, disadvantages and possible conflicts of spatial choices related to the scenarios.

The development of the story lines of the scenarios and the related maps was an interactive and participatory process together with experts and stakeholders, including policymakers from national, regional and local level. However, it is important to mention that the scenarios and maps should not be seen as blue prints for future developments. The scenarios can be further developed and adapted for different spatial contexts or serve as an inspiration for policymakers. To support this after the publication of the scenario study, the PBL project team organised numerous presentations and workshops with municipalities, provinces and different departments of ministries.

This paper describes the method of how the scenario story lines and the related land use maps of the *Spatial Outlook 2023* were developed by applying a new mixed methods approach that combines participatory and multidisciplinary scenario development, GIS-based land use modelling and creative tools of research by design. Moreover, the paper reflects on experiences with using spatial scenarios in the context of regional and national spatial planning.

2. Complex Spatial Challenges In Times Of Uncertainty

2.1 Old And New Planning Tasks Accumulate

In the Netherlands, a range of spatial challenges accumulate on a limited territory. The Netherlands is a relatively small country, which is threatened by rising sea levels and has ambitious national policy goals to become a circular and climate-neutral society by 2050. While there are traditional short-term spatial planning tasks, such as creating and maintaining space for living and working as well as protecting nature and improving the environmental and landscape quality, new planning tasks have emerged concerning long-term transitions related to climate adaptation, energy transition and the circular economy. The accumulation of urban, rural and infrastructural developments on the same relatively small territory contributes to the country's increasing difficulties in achieving all of its goals.

2.2 Growing Uncertainty

In addition to the above-mentioned spatial challenges, there are other developments that have an influence on spatial planning. For instance, rapid technological developments are taking place in information, communication and transport technology. These technological developments influence daily lives as well as institutions (Van Dijck, Poell and Waal, 2016; Crang and Graham, 2007). In addition, social, political and economic changes take place, all of which increase the level of uncertainty facing policymakers and planners.

More recently, the COVID-19 pandemic and the war in Ukraine have shown us that unexpected events on top of the more structural changes and developments contribute to even greater spatial challenges. The war in Ukraine and the related effects on energy prices and security might be a turning point that leads to an acceleration of the energy transition with an increased demand for wind farms, solar farms and energy-related infrastructure. Furthermore, the war in Ukraine has led to increased migration flows and a re-evaluation of military areas in the Netherlands. Whereas in the past decades, military areas were reduced and transformed to other functions, in the future, they might need to be expanded for increasing military activities.

2.3 A Complex Puzzle

Addressing the spatial challenges in times of uncertainty is a complex puzzle for policymakers and planners in the fields of spatial and environmental planning. After all, suitable land has to be found and designed for very diverse functions with often mutual, and possibly conflicting, interactions. The following questions highlight this: How can residential areas not only be built quickly, but also in such a way that they use less energy and can withstand longer periods of drought, heat and heavier rainfall? How can the transformation of agricultural land contribute to both reducing nitrogen deposition in natural areas and addressing desiccation? And how can wind turbines and solar panels be given a place without damaging landscapes to a certain extent, while simultaneously receiving public support?

An answer to questions such as these will require a balancing act from policymakers in the near future. As the balance has tilted increasingly in the past decades towards the economic use of space, the carrying capacity of the ecosystem (e.g. soil, water, and biodiversity) has come under great pressure. For example, the construction of large suburban residential areas (so-called VINEX-locations), commercial areas and logistic parks has contributed to increased soil sealing and more car use and traffic congestion. Some of the recent urban developments are located in areas below sea level that are vulnerable to soil subsidence. In this respect, the spatial development of the Netherlands is far from being future-proof. In addition, there is too little attention paid to how citizens experience space. Their perspective does not always align with that of policymakers and planning professionals, and their opinions are not necessarily taken into account in spatial decision-making processes. Especially now that the Netherlands is facing major challenges, there is an increasing need to strengthen society's support for major spatial interventions, both in residential and rural areas.

3. Scenarios As A Tool To Deal With Complexity And Uncertainty

Complexity and uncertainty are facts when considering future developments. Acknowledging this can make policymakers and spatial planners feel uncomfortable, as they often argue that their day-to-day planning tasks are complicated enough. Having to take into account the uncertainty of new developments (e.g. working remotely from home), possible discontinuities of trends (such as shifts in mobility patterns), and changes in the outlook on urban and spatial developments (related to migration and uncertain demographic prognosis) make spatial planning processes even more complex. The complexity can make it tempting to ignore uncertainty in the development of spatial planning strategies. However, not exploring possible new challenges, views and policy options will only yield 'present-proof' policies rather than 'future-proof' ones. In this regard, future-proof policies are defined as policies that lead to spatial developments that contribute to a circular and climate-neutral society and are resilient to possible changes and risks in the long term.

In order to help policymakers and planners to develop future-proof policies and plans, it is necessary to gain insight into and anticipate a diversity of plausible future developments. Therefore, the PBL Netherlands Environmental Assessment Agency has developed four spatial scenarios for the Netherlands (see Figure 1). In these scenarios, we explore what the Netherlands might look like if all planning tasks were to be addressed. Where do spatial conflicts arise? Where do opportunities lie? Who will take the lead?

Policymakers can use these scenarios to respond to the uncertainty inherent in long-term policymaking. Using the scenarios, policymakers can explore robust strategies: which approaches fit into multiple scenarios? They can also explore the possibilities for adaptive policies: what adaptation options are available and conversely, how can 'lock-in' situations be avoided?

Before we describe the scenarios in more detail in the second part of this paper, we will summarise the characteristics of spatial planning and the main spatial challenges in the Netherlands in the following section.

4. Spatial Planning In The Netherlands

4.1 The Most Planned Country In Europe

The Netherlands has an internationally acclaimed reputation for comprehensive and effective spatial planning, often referred to as 'comprehensive integrated approach'. According to Dutt and Costa (1985), the Netherlands is the 'most planned country in Europe'. The performance of the Dutch planning system has been attributed to a strong national consensus on a set of interrelated and enduring notions on spatial configurations and development strategies, and how they should be implemented. In the synthesising report of the 1990s EU Compendium project, the Dutch system was characterised as "…a very systematic and formal hierarchy of plans from national to local level, which coordinate public sector activity across different sectors…" (Commission of the European Communities, 1997, p. 36).

4.2 Decentralisation Of Spatial Planning …And Back To Stronger National Coordination

However, in the past 25 years, the strategic national spatial planning culture that had emerged in the post-war era gradually came to an end. The coordination of spatial planning and the protection of natural areas were mostly decentralised to regional and local authorities. Besides this, the role of planning in Dutch society also seems to have changed in this period. General trust in government and faith in expert opinion has diminished, not unlike developments in many other countries (Albrechts, 2006). Citizens have become more vocal, and civil society more polarised. And finally, the growing importance of the regional and EU levels has led to an increasing questioning of the national level as the locus of spatial planning (Zonneveld, 2016).

In recent years, however, there has been a resurgence of demands for a more directive national spatial planning. Although some of the issues facing the Netherlands can be tackled regionally, some developments require decisions in conjunction with the national level (PBL, 2019). Advocates point to the complexity and urgency of national spatial issues such as the acceleration of housing programmes, the energy transition, climate adaptation, and environmental protection.

The current national policy for spatial planning is contained in the NOVI: the National Strategy on Spatial Planning and the Environment (BZK, 2020). With the NOVI, the national government wants to give direction to the major tasks that will radically change the face of the country over the next 30 years. This policy document shows a sense of urgency but does not yet make sufficient substantive choices. Decisions on a number of spatial issues are needed, including concrete and coherent implementation strategies. Currently, the NOVI is in the process of being elaborated in collaboration with the 12 Dutch provinces, with a special focus on 16 designated so-called NOVEX areas where complex spatial challenges accumulate. PBL's spatial scenarios can be used to explore regional options for coherent future-proof developments and can help to develop a comprehensive spatial vision for the Netherlands.

5. An Overview Of Spatial Challenges In The Netherlands

In the first phase of the scenario study, we have analysed and described the spatial challenges concerning five main themes that are mentioned as central themes in the NOVI (PBL, 2021). These central themes are urban development in cities and regions, vibrant rural areas, climate adaptation, energy transition, and sustainable economy (see Figure 2). In the following sections, we address the main challenges for each theme and the implications they have for future spatial developments.

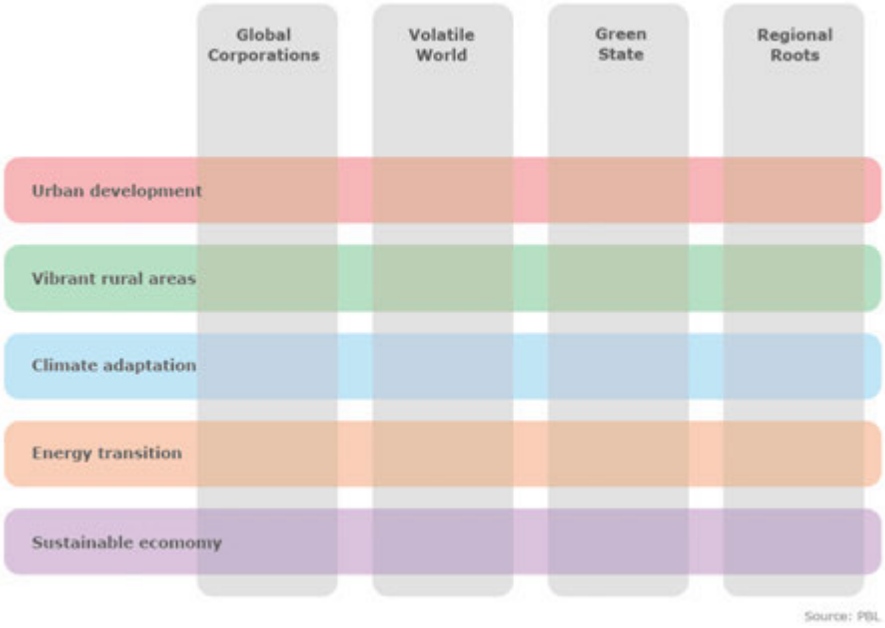

Figure 2: Four scenarios and five themes, source: PBL.

5.1 Urban Development

The Netherlands has a major urbanisation challenge. The affordability of houses is under pressure and the government wants to increase housing production. However, there is limited suitable land, a lack of skilled workers and construction prices are rising. Yet increasing the housing production in urban areas – linked to urbanisation – raises other issues, including those concerning the nature of economic development, soil conditions, rainwater and river water use, traffic congestion, the relationship between urban and rural areas and various social themes. For example, in order to create a future-proof spatial development, the limited available land must simultaneously accommodate economic activities apart from housing, without neglecting soil conditions and traffic congestions.

Not surprisingly, the spatial distribution of housing and economic activities is a central spatial topic here, both across as well as within regions in the Netherlands. This involves, for example, a decision to concentrate living and working in existing urban areas in the western part of the country or, on the contrary, their dispersion in and around smaller towns throughout the country. The distribution of living and working also has consequences for the required infrastructure. Currently, there is discussion about possible plans for new large-scale suburban residential areas, some of which are located on vulnerable soil conditions.

5.2 Climate Adaptation

Climate change is accompanied by rising sea levels, more extreme rainfall and longer droughts. The layout of cities and rural areas has not yet been designed to cope with the effects of climate change. Further climate change will increase the need to adapt spatial planning in the country and the various areas within it. One issue that arises with climate adaptation is where and to what extent soil and water conditions should act as guiding principles in the spatial planning of cities and rural areas. The extent of climate change is uncertain but climate adaptation measurements such as higher dyke systems and larger flood protection areas might require a lot of extra space.

5.3 Energy Transition

As a result of the global climate agreements of Paris and Glasgow, the Dutch government is aiming for a climate-neutral society by 2050. Energy transition is an important part of this. The transition involves fundamental changes in energy generation, energy storage, transmission networks and energy consumption. These will include: local electricity storage (batteries), regional generation of clean electricity (wind and solar parks), large-scale, national electricity generation (offshore wind) and international connections of transport networks. Conflicting spatial interests on a limited territory, however, make the realisation of such goals more complex. For example, local residents might oppose the construction of wind parks in spatial proximity to their homes for reasons that concern the surrounding landscape aesthetics.

Recently, the war in Ukraine has put the Dutch planning of the energy transition under extra pressure. In the short run, there is the risk of a setback as a result of an increase in the use of coal for electricity production. In the long run, however, higher (fossil) energy prices can make renewable energy production more attractive. The spatial effects of the energy transition will vary depending on the prioritisation of the main goals of energy supply and the scale at which energy systems are optimised.

5.4 Sustainable Economy

The Dutch government is striving to create a sustainable economy. An important part of this is the transition from the linear to a circular economy by 2050. The circular economy involves the use of raw materials in production and consumption processes – and the effect the entire life cycle of products has on the living environment, both inside and outside the Netherlands. In the linear economy, many raw materials are wasted, and pollutants are emitted, leading to mountains of waste, climate change and biodiversity loss. With rising global demand for raw materials, the raw materials problem is becoming increasingly urgent. Moreover, geopolitical supply risks and the risk of price fluctuations are increasing. One issue that arises is what spatial effects the transition to a circular economy will have. It is not only about the spatial effects arising from the transition, but also about which spatial-economic structure policymakers are aiming for, as well as the spatial scales (from regional to global) of the life cycles of products. What is important is which priorities policymakers set: reduce waste and emissions, strengthen the competitive position of companies, or reduce supply risks and price volatility.

5.5 Vibrant Rural Areas

There are different kinds of urgent tasks in rural areas. Climate change requires climate adaptation and mitigation, the tense relationship between agriculture and nature requires balanced choices in land use, and ongoing (sub)urbanisation requires additional space. The issues are multiple: greenhouse gas emissions, nitrogen precipitation, increasing drought,

biodiversity loss, subsidence, and salinisation. This shows that the limits of the physical system of water, soil and ecology have been reached and sometimes far exceeded. Policymakers face the task of setting new priorities and making choices, including spatial choices. One of the questions that needs to be answered is in what cases and in which areas prioritisation of space use is needed, and in which cases multiple space use (combining functions) is possible, the latter providing opportunities for synergy.
Conflicts and challenges in land use

To summarise, the living environment in the Netherlands is under a lot of pressure. There are all kinds of conflicting spatial interests that often cannot be solved in isolation. This makes it increasingly difficult to find space for traditional land use functions, such as living and working, but also for new functions related to renewable energy and climate adaptation. Intensive use also puts pressure on the resilience of the ecosystem in the Netherlands. In many cases, soil and water conditions were neglected, causing problems such as desiccation and eutrophication. In socio-economic terms, uneven distribution of demographic and economic growth has increased regional disparities. This is also the case within regions, for example, between more and less affluent neighbourhoods. The COVID-19 crisis has shown not only how vulnerable we are in terms of public health, economy and social interaction, but also how important the living environment is to us. For example, the lockdowns and spending more time at home has increased awareness and appreciation for street life, park life and the vibrancy that defines the city with its public, semi-public and private spaces (Sepe, 2021).

5.6 Spatial cohesion

A key topic in discussions on sustainable spatial planning relates to the concept of spatial cohesion. Activities that policymakers can undertake to achieve spatial cohesion include aligning the land use of sectoral functions, aligning interests at different spatial scales and synchronising the allocation of functions (or making them follow each other at logical points in time). These kinds of activities help to resolve spatial conflicts, exploit spatial synergies, avoid spatial lock-ins, and implement so-called spatial ‘no-regret’ actions. ‘No-regret‘ actions are actions by institutions and communities that can be justified from economic, and social, and environmental perspectives whether natural hazard events or climate change take place or not (Hallberg, Siegel and Jorgensen, 2009). These actions can be achieved by involving a wide range of actors, including citizens, in the formulation and implementation of spatial and environmental planning processes.

6. Methodological Underpinnings Of The Scenarios

As mentioned in the first section of the paper, PBL has developed four spatial scenarios for the Netherlands in 2050 (see Figure 3). These scenarios enable policymakers and planners to explore possible solutions to the problems mentioned in the previous section and to discuss advantages, disadvantages and possible conflicts of certain spatial choices. The scenarios and the maps of the *Spatial Outlook 2023* have been developed in a two-year long process between 2021 and 2023 with a multidisciplinary team of the PBL in collaboration with experts from Wageningen Environmental Research (WUR), Deltares and other advising offices. The transition to a circular and climate-neutral society plays a central role in all four scenarios. The year 2050 was chosen because there are specific policy ambitions to reduce carbon emissions and the use of natural resources significantly by 2050. Furthermore, the project could make use of existing demographic and economic projections for 2050, which were an important input for the GIS land use modelling that was applied to develop the maps.

6.1 Societal Values

The four scenarios of the *Spatial Outlook 2023* are based on four different sets of societal values, previously published by PBL in the report *Rehearsing The Future* (PBL, 2020). In the research underlying the four scenarios, existing developments were traced back, interpreted and extended into the future. Also, new trends were identified as well as so-called ´weak signals´ to indicate possible changes in trends. The research included expert interviews, a literature review and media analysis from newspapers, magazines, websites and social media. Depending on society's preferences, the transition paths and spatial patterns emerge differently. And because sustainable development does not happen by itself, specific institutional changes were assumed in each of the four scenarios.

6.2 Mapping The Scenarios

Whereas the report *Rehearsing The Future* didn't include maps of the possible future spatial land use, the ambition of the *Spatial Outlook 2023* was to create four integral maps of how the land use of the Netherlands could look like in 2050, including all five main themes of the research and also including the Dutch parts of the North Sea which is often neglected in spatial studies of the future. Maps, with their ability to convey spatial relationships and patterns, are powerful tools to develop spatial scenarios and to help to communicate and discuss the content of the scenarios with policymakers, planners and the public (Salewski, 2012).

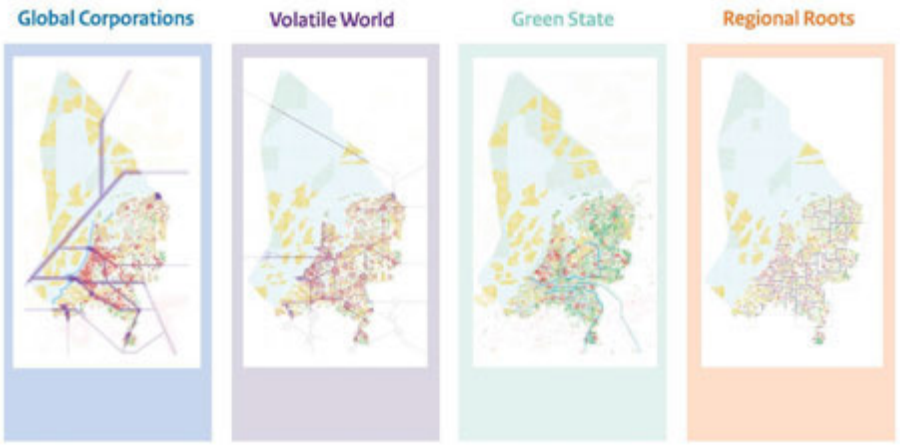

Figure 3: Conceptual maps of the four spatial scenarios, source: PBL.

At an early stage of the research, sketch maps for the four scenarios were drawn with colour pencils on top of printed base maps of the country. These initial rough sketch maps helped to communicate basic spatial developments and features related to the story lines of the scenarios in meetings with the project team and in the national workshops with stakeholders. After the initial phase with the sketch maps, detailed maps were generated based on land use modelling by applying the models Land Use Scanner (PBL)and the Model for Nature Policy (WUR). And finally, the detailed maps derived from the GIS modelling were enriched, edited and graphically stylised by a team of urban designers to create comprehensive and readable maps.

The central ambition for the scenario maps was to give general input for the national spatial and environmental planning strategy as well as more detailed map information for local and regional planning strategies. Therefore, the decision was made to create two types of maps for the publication: detailed maps and conceptual maps (see Figure 3). After the detailed maps were produced by a combination of GIS land use modelling and research by design methods, the designers made a strongly simplified and stylised version of the maps. These conceptual maps have a more iconic character and only show the most important spatial elements. That makes the them more easy to read for policymakers and the general public.

6.3. Participation In The Development Process Of The Scenarios

The development of the story lines of the scenario's and the maps was an interactive and participatory process together with experts and stakeholders, including policymakers from national, regional and local level. In a series of national and regional workshops, preliminary scenario narratives and maps where tested, discussed and refined (see Figure 4). After the workshops, the project team finalised the narratives of the scenarios and the maps for the publication of the project in a book and a website with an interactive map viewer.

Figure 4: A scenario workshop in progress, source: PBL.

7. Characteristics Of The Four Scenarios

In the following paragraphs the main societal, economic and spatial characteristics of the four scenario are described. All four scenarios have advantages and disadvantages, and show possible conflicts and dilemmas.

7.1 Global Corporations

According to the Global Corporations scenario, Dutch society in 2050 has a strong performance-oriented, hedonistic and individualistic character. Dominant values are work, success, pleasure, self-development, self-reliance and personal responsibility (PBL, 2020). In terms of sustainability, it is more about 'prosperity' than 'people' and 'planet'; the Netherlands is prosperous in a material sense. There is high prosperity and spatial inequality, but there is a minimum level of welfare and quality of life for all. Because of agglomeration effects, large international companies concentrate mainly in central business districts, main ports and green ports, but they operate in extensive global networks. There is a big contrast between the extended Randstad area (the most urbanised part of the Netherlands) and the periphery.

7.2 Volatile World

In the Volatile World scenario, Dutch society is fragmented. Different lifestyle communities live parallel lives. The groups organise themselves digitally. They arise quickly, but also change and disappear quickly. The communities therefore have not only a dynamic but also a volatile character. Depending on the group, 'prosperity', 'people' or 'planet' is paramount. There is great confidence in technology, also for sustainable solutions. The Netherlands is prosperous, but the differences between digital groups are large and changeable. For many people, the virtual world is more important than the physical world, which has a somewhat messy and ever-changing character.

7.3 Green State

Green State is a scenario in which people see themselves as part of nature and see sustainability challenges as a collective public mission. Ecological boundaries are respected, and the social base is well maintained. 'Planet' has priority. Natural solutions dominate. Technology should contribute to ecosystem improvement. Achieving green goals justifies limiting individual freedom of consumption. The Netherlands is prosperous, but not primarily in a material sense. Building is concentrated around major public transport hubs. There is multifunctional use of space here. Due to compact urbanisation and nature-inclusive agriculture, there is plenty of space for nature and recreation. Water and soil have a high priority in this scenario.

7.4 Regional Roots

In the Regional Roots scenario, local and regional communities call the shots. Continuity and security are important. Profits must not come at the expense of community spirit and ecology. The concept of 'people' comes before 'planet' and 'prosperity'. Communities take care of nature, primarily understood as beautiful, recreational landscapes in geographical proximity to people's homes. Society focuses on local and regional self-sufficiency, as far as possible. Urban development takes place throughout the country. Large cities have expanded on a small scale, smaller towns and villages have grown organically and the functions of living and working are mixed as much as possible.

8. Using Scenarios In Long-term Spatial Planning

8.1 Towards A New Balance

The war in Ukraine is having a strong impact on economic developments and migration flows in Europe and the Netherlands. It is unknown how long the war will last and how large the spatial effects will be. However, in the long term, the biggest challenge will be to find a new balance between urbanisation and economic growth and a sustainable and healthy living environment. In the Netherlands, the physical living environment is being used more and more intensively. So intensively that both ecological sustainability and social appreciation of the living environment are under pressure. A new balance is required between the utility value (economic use), amenity value (citizen's perspective), and future value (ecological sustainability) of space in the Netherlands (PBL, 2021). Policymakers and planners are faced with the task of incorporating new land use in their environmental policy (and coordinating it with existing land use), while at the same time improving the quality of the environment, and increasing citizens' involvement in the policymaking and planning process.

The major transitions facing the Netherlands are guaranteed to span several legislative periods. By considering the transitions using a scenario approach, administrators and policymakers can seek different paths to robust future-proof policy choices and adaptability. Based on the four perspectives developed in our scenario study, we make recommendations to this end. In the following two sections, we give an example of two recommendations. Firstly, one in respect of the soil and water system and, secondly, one concerning citizen participation.

8.2 Soil And Water System As Structuring Principle For Spatial Planning

The current urban and rural areas in the Netherlands are not designed to cope with climate change. This is already having serious negative economic, ecological and social consequences, and these will increase further without adaptation to worsening conditions. The ever-increasing drought problem, especially in areas with sandy soils, is a case in point. Also, failure to meet internationally agreed targets inhibits economic development, for example the exceeding of the nitrogen limit values in vulnerable, protected natural areas, which has already caused a construction freeze in several sectors, including housing, infrastructure and industrial areas. If more attention is not paid to the carrying capacity of the ecosystem, the risk of ecological and economic damage increases. The carrying capacity of the ecosystem should therefore be more central to future policy. Given that urbanisation, climate change, nature, water management and agriculture share soil and water as a common substrate, the preconditions set by the water and soil system for spatial interventions and the points of leverage from that same system for climate adaptation should be much more central to spatial and environmental policy than it has been in past decades. Indeed, all four scenarios also show a need for this.

8.3 Improving Participation Processes

Spatial and environmental policy not only encounter physical boundaries, but social boundaries as well: one only has to think of protests (e.g. against wind farms), inadequate citizen participation (in planning), and the 'dropping out' of population groups (e.g. due to distrust in government). In addition, signals from citizens about 'system failures' do not always get through to government and policy in time. Examples of this are the stalled consultations with local residents on the noise pollution of Schiphol Airport in the Amsterdam region and the painstaking process of building repair and financial compensation in the wake of the earthquake damage caused by gas extraction in the province of Groningen. Citizens feel unheard or sometimes even misled. There is also an issue of justice here: some citizens experience the distribution of benefits and burdens as skewed. For example, in the case of the benefits and

burdens of wind turbines, citizens simply feel that big companies gain, whereas local communities lose.

Involving society in the formulation and implementation of spatial and environmental policy will therefore require extra attention in the future. Public support for the necessary spatial interventions requires a substantial government effort, on all spatial levels. Citizens' involvement and trust in government policy require long-term goals, clear frameworks, and an in-depth understanding of the living environment from a citizen's perspective in various policy domains.

9. Conclusions: Spatial Scenarios As A Useful Tool For Spatial Planning

In times of growing uncertainties, working with scenarios helps to create greater awareness the necessity to explore multiple long-term perspectives in spatial policymaking and to develop future-proof spatial strategies that can be adapted in the case of unforeseen developments. In this paper we have discussed the major spatial challenges in the Netherlands and the development of four spatial scenarios and how the scenarios can enable policymakers and planners to take into account future uncertainties. The current Dutch national planning strategy already contains many ambitions and starting points for finding a new balance in spatial and environmental policy. However, some of these ambitions are still quite vague and need to be worked out for specific regions and cities in the Netherlands. In this process, we can expect discussions about spatial options to arise. The spatial scenarios that we have developed in the *Spatial Outlook 2023* enable policymakers, planners and stakeholders to explore and discuss the advantages and disadvantages of a variety of spatial choices, at both the national and the regional scales.

However, it is important to mention that the scenarios and the related scenario maps should not be seen as blue prints or simple solutions for the future developments. The scenarios can and need to be further developed and adapted for different spatial contexts or just serve as an inspiration for policymakers. To support this after the publication of the scenario study, the PBL project team held several lectures and organised numerous workshops with municipalities, provinces and different departments of ministries. In the lectures and workshops, the use of scenario maps had an important function to explain the spatial patterns and to explore the scenarios in different spatial contexts with stakeholders. The maps made complex planning concepts more accessible, fostering greater understanding and transparency about the scenarios and the related spatial patterns.

The PBL Netherlands Environmental Assessment Agency is the Dutch national institute for strategic policy analysis in the fields of the environment, nature, and spatial planning. The institute contributes to improving the quality of political and administrative decision-making by conducting outlook studies, analyses, and evaluations in which an integrated approach is considered paramount.

Track 13: Theories

THEORIES - PLANNING THEORIES AS A GAMECHANGER?

Chairs:

- Ben Davy, TU Dortmund University
- Xavier Desjardins, Sorbonne Université
- Luciano Pana Tronca, Istituto Universitario di Studi Superiori, Pavia

Keywords: *planning theories, planning practices, planning academia, theory-building, planning*

This track invites the bold explorers of the game-changing potential of planning theories to share their ideas on creative destruction, disruptive knowledge, inventive borrowing, and turbulent polyrationality with respect to spatial planning theories. Leaving behind the final frontier of a Pure and Unified Theory of Planning, the track normalises and mediates a wide variety of theoretical approaches to planning. Moreover, it welcomes reflections on how planners employ or are disappointed by theories that address the methods, processes, and substances of planning.

Planning theories are the expression and foundation of planning knowledge and planning performance. However, these theories are not static but inspire constant change and development. The track highlights how planning theories change the game in favour of just and sustainable regional and urban developments. This track expects that questions of planning and theory will be raised and discussed in all tracks: it specifically encourages:

- unfolding the different meanings of planning and theory as object and subject of planning theories,
- contributing to a better understanding of the interconnections between planning practices, planning theories, and planning academia,
- understanding the strategies and dynamics of theory-building in planning theories,
- deconstructing the relationships between truth, the political, and ideology in planning theories, as well as
- stimulating a debate on the suitability of planning systems and approaches to encounter today’s big topics and raise awareness for needful changes.

This track offers experienced as well as young planning academics an opportunity to engage with plural planning theories in a turbulent world. Their contributions will examine the scope of planning theories, the integrated or fragile knowledge shared by planning theorists, and the obstacles within planning theories. Recognising that theoretical narratives often are lost in translation and have vague meanings, the track also invites to improve quality through more precise and explicit language in planning theories.

Theorizing State Dispossessive Planning vs. Community Self-Determinative Planning: The Case of the Al-Bostan Palestinian Community Struggle against the Israeli Planning in East Jerusalem

Yosef Jabareen
MEI, Columbia University, NYC
Email: jabareen@technion.ac.il; yj2818@columbia.edu

Abstract (up to 125 words)
The Jerusalem Municipality recently launched the King's Garden Plan to transform Al-Bustan, a Palestinian neighborhood in the heart of East Jerusalem. The Plan called for demolishing Al-Bustan's buildings, displacing its residents, and constructing a park, named after the Biblical King David. The Al-Bustan community objected fiercely to the Plan, resisting it through a political campaign, preparing an alternative plan, and undertaking various measures to prevent their displacement and ensure their continued presence. This paper investigates what I call dispossessive planning, contrasting it with the self-determinative planning developed by communities in response. Dispossessive planning is a regime of practices that dispossesses and displaces relatively disadvantaged groups, weakening the material foundations of their affective and existential security, as it deliberately constructs a new reality. In response, self-determinative planning, as I conceptualize it, involves the development of forms of autonomy in their place, as dispossessed urban populations assert their right to produce and control their spaces of existence autonomously.

Keywords: Planning theory, Palestine, Israel, Jerusalem, Displacement

Introduction

In 2009, the Municipality of Jerusalem launched the King's Garden Plan, to transform Al-Bustan, a Palestinian neighborhood in the heart of East Jerusalem. The Plan called for demolishing Al-Bustan's buildings, displacing its residents, and constructing a park, named after the Biblical King David. The Al-Bustan community objected fiercely to the plan, resisting it through a political campaign, preparing an alternative plan, and undertaking various measures to prevent their displacement and ensure their continued presence.

This paper is based on a longitudinal study that incorporates observation and data collection from 2009 to the present, concerning this spatial conflict between the Palestinian residents and the Israeli Jerusalem Municipality. This paper raises some critical questions regarding state and community planning, the state's planning, and the encounter and conflict between it and the community. It asks what accounts for their differences and interactions. Elaborated with respect to the same place, they present different and conflicting visions of future planning and development, and in some ways are negations of each other. How can we best understand a type of state planning that directly involves the harassment, dispossession, and displacement of disadvantaged groups? And how to best understand the spatial, political, and social actions and protests of the communities facing the state planning, and the encounter between them?

Planning literature has a long history of criticizing the dark side of planning, holding that zoning and land use policies are in many cases unjust, discriminatory or exclusionary, disempowering or disenfranchising, or otherwise doing other harm to, various population groups (i.e. Flyvbjerg, 1996; Gaffikin & Morrissey, 2011; Howitt & Lunkapis, 2010; Huxley, 2010; Rothwell &

Massey, 2009; Scott 1999; Shertzer & Walsh, 2015; Wilson et al., 2008; Yiftachel, 2006). There are also many discussions of alternative planning approaches, such as "advocacy planning" (Davidoff, 1965), "radical planning" (Grabow and Heskin, 1973), "insurgent planning" (Miraftab, 2009), "hegemonic planning" (Jabareen, 2017), and "insurgent informality" (Jabareen and Switat, 2019). However, there is a necessity for more elaboration on how to comprehend best the political, spatial, and social actions and protests of the communities facing state tyrant planning and the encounter between them.

Thus, this paper aims to conceptualize contradictory planning approaches for the state and community, taking into account that they usually are at work simultaneously, in the same place, and in conditions that are deeply conflictual ethnically and politically. It then proposes a methodological framework for capturing, analyzing, and conceptualizing an alternative planning approach rooted in community practices of autonomous self-determination.

I suggest that these respective planning approaches each involve their own specific and coherent 'regime of practices', which can be captured through interrelated 'logics', which function independently to reach convergent ends. By a 'logic' I mean to indicate a specific "kind of statements that we make about phenomena." Thinking through such logics enables us to investigate the "possibilities of phenomena" disclosed in their domain and the statements that can then be made about them in various spatial and temporal contexts (Glynos and Howarth, 2007: 134). In discussing the two types of planning, I will aim to distill their respective logics. Tracing that logic allows us to understand the central ideas and practices involved in the respective type of planning. This means that one goal of empirical work is to identify these logics. Understanding them can certainly help us grasp how the differing approaches relate to each other, what the problems are with currently dominant ones, and what the alternatives might look like.

In this paper, I consider state planning as *dispossessive planning*; it displaces and dispossesses people from their properties (land and dwellings), as it transforms and capitalizes on them through the planning endeavor. Communities encountering the state planning approach may engage, often in response to the former, in *self-determinative planning,* involving (collective) political practices that often begin with, and may aim at, protecting the community from the tyranny of state actions taken through its planning activities. I argue that each of these approaches involves a *specific coherent regime of practice*, which can be understood through its interrelated logics. These logics, as will be seen, are political, spatial, aesthetic, and economic.

The next section of this paper presents the context of the study. The second section deconstructs the state planning currently involved in Al-Bustan, and the third describes the planning efforts developed by the community of residents in response. The fourth section conceptualizes dispossessive and self-determinative planning and presents their logics. The final section discusses the findings and elaborates further on the framework of the architecture of dispossession.

Context of the study and data collection

The case study involved here focuses on Al-Bustan, a Palestinian neighborhood located in East Jerusalem, in the part of the city that was occupied in 1967 by Israel. The 1948 war over Palestine resulted in the establishment of the state of Israel and the displacement of some 780,000 Palestinians (Abu-Lughod, 1971). Jerusalem was divided, West Jerusalem coming under the control of Israel, while East Jerusalem, including the Old City, fell under Jordanian

rule. In 1967, Israel occupied Palestinian East Jerusalem, and in 1980, annexed it through its "Basic Law: Jerusalem, the Capital of Israel," which formally declared the "whole and united" area of East and West Jerusalem to be "the capital of Israel." In response, the U.N. Security Council unanimously adopted Resolution 478, which declared the annexation to be in violation of international law (Mayer and Mourad, 2008).

Jerusalem is thus a divided and conflicted city, and is highly segregated along ethnic lines between Palestinians and Jews. It is a frontier city subject to a deep bi-ethnic conflict around sovereignty, identity, narrative, and territoriality (Bollens, 2000; Jabareen, 2010). Israel's institutional planning, and its judicial and other national institutions, have been working to transform the demographic and territorial structures of East Jerusalem, aiming at control of the eastern part of the city, united under Israeli laws (Jabareen, 2017b; Jabareen et al., 2019; Yacobi, 2015). Since 1967, Israel has converted about 66 percent of the territory of East Jerusalem into open green lands and new neighborhoods built for Jews (Jabareen, 2020). The demography of this part of the city has been dramatically changed, such that about 40 percent of the population today is Jewish (CBS, 2024).

Al-Bustan, a Palestinian neighborhood that is home to 1,500 residents, is located in East Jerusalem near the Old City of Jerusalem, in the city's Holy Basin. The Old City of Jerusalem and the "Holy Basin," which has a rich history involving the three religions (Judaism, Christianity, and Islam), has been a major target for spatial and demographic transformation sine its occupation in 1967. This paper traces the Israeli institutional spatial planning of Al-Bustan and the reaction of its community to these plans, from the occupation of East Jerusalem in 1967 up today (2024).

It does so based empirically on an extensive data collection undertaken over a long period of time. This includes: (a) an analysis of all institutional spatial plans relating to the Al-Bustan neighborhood between 1967 and 2024; (b) an analysis of the alternative spatial plans developed by the Al-Bustan community; (c) a review of collected documents and protocols related to Al-Bustan planning. The sources of data and documents are as follows: (a) the Department of Planning and Infrastructure Administration of Jerusalem Municipality; (b) the Jerusalem Local Planning and Building Committee; (c) the Jerusalem District Planning and Building Committee; (d) the City Engineer of the Jerusalem Municipality; (f) the Al-Bustan Popular Committee, which was established in 2005; (g) the protocols regarding the meetings between the lawyers and planners of the Al-Bustan Popular Committee and the Jerusalem Municipality's representatives; (h) observations from four meetings between the representatives of the Al-Bustan Popular Committee and two consecutive Mayors of the Jerusalem Municipality; (i) observations of community reactions to the Israeli plans for Al-Bustan, which took the form of public meetings and protests in Al-Bustan's Tent of Protest.

The King's Garden Plan

In this section, I discuss the state planning endeavors in the Al-Bustan neighborhood, and specifically the King's Garden Plan, in order to understand the logics behind the planning approach.

Excluding the residents

Between 1948 and 1967, East Jerusalem was controlled by Jordan. During this period, the Municipality of East Jerusalem prepared a Master Plan for the entire eastern section of the city, which designated the area of Al-Bustan for residential use (Rapoport, 2005). However, since its occupation, the Israeli national, district, and local planning institutions, along with the

Jerusalem municipality, the Ministry of the Interior, and the Justice Ministry, have been engaged in concerted efforts to demographically and territorially transform East Jerusalem and its historic areas, including the Holy Basin, where Al-Bustan is located. The idea is, indeed, to ensure a solid Jewish presence in this section of the city.

In 1976, the Jerusalem District Planning and Building Committee approved the plan, 'EM/9-Local Master Plan for Ancient Jerusalem and its Surroundings' (State Controller, 2009: 688). The aim of this plan was to tighten, and put restrictions and obstacles on, the housing and economic development of the Palestinian residents, in order "to protect the urban landscape, and the religious properties of the Jewish religions and others, and to preserve the archeological sites within the area of the plan" (EM/9, 1977: 3). According to the EM/9 Plan, as Figure 1 shows, Palestinian neighborhoods, including Al-Bustan, were designated as "green open spaces" even though they were in fact inhabited (mostly by Palestinians).
Figure 1. Plan no. EM/9

Capitalizing on dispossession
In 1995, the Jerusalem Municipality decided to capitalize on the dispossessed space and make a profit from it. Accordingly, the Jerusalem Municipality and the Ministry of Tourism

established a Steering Committee for Tourism Development in Jerusalem to prepare the city for the "3000 years of the establishment of Jerusalem."[i] The main recommendations were to develop tourism in Jerusalem to transform the city into "the most important tourist center in the Middle East" and make it "an economic lever for tourism development throughout the country" (2015: p. 30).[ii] The committee proposed a plan called *King's Garden: 3000 Years of Jerusalem* (p. 108). About a decade later, the City Engineer of Jerusalem decided to implement the *King's Garden* plan and, thus, to destroy the entire Al-Bustan neighborhood, under the excuse of ending "illegal building in the Garden." The idea was to empty the neighborhood of housing and allow the municipality and the private sector to capitalize on the dispossessed neighborhood, instead of allowing the residents themselves to enjoy and share the benefits of its economic development.

On September 9, 2009, the Knesset's (Israeli parliament's) Finance Committee approved a budget of NIS 600,000 to promote a plan to build a national park in the King's Garden following Safdie's plan. Accordingly, Nir Barakat, the Mayor of Jerusalem, launched *The King's Garden Plan* on March 2, 2010. The plan has been called "a first-class national project" (Jerusalem Municipality and Jerusalem Development Authority, 2010, 5).[iii] Since then, the Jerusalem Municipality and local planning institutions have been striving to promote this plan despite the objections of many residents of the Al-Bustan neighborhood, who were almost unanimously opposed.

The *King Garden's Plan* (2010: 6) makes claims regarding a religious Jewish "history," integrating it with the capitalization of the spaces, considering the space as the site of a *business initiative*, and mixing this with a reinvented historical narrative in order to colonize what was then an authentic Palestinian space in Eastern Jerusalem:

> As part of its vision to develop the city, the Municipality of Jerusalem is making every effort to preserve and restore these green areas as part of this commitment and responsibility to the values of nature and environment, *a historic commitment*, which the inhabitants of Jerusalem have stood by steadfastly in the past, and that we will continue in the present for the future. (*King's Garden Plan*, 2010: 9)

The Plan presents as its overriding objective "to restore the King's Garden to its historic state as a major world and tourism site"; the "Plan's vision is to turn the King's Garden into a blossoming park that will flourish alongside a residential neighborhood, in which there will be restaurants, artists' studios, souvenir and local-art shops and more" (*King's ;Garden Plan*, 2010: 14-15).

Aesthetic justifications

The King's Garden Plan involves a specific aesthetic discourse that justifies the dispossession of the residents and the demolition of the neighborhood. It uses Biblical language to describe the neighborhood as an ancient landscape:

> Traditionally, it was in this place that the kings of Israel established their gardens. It is commonly believed that this is where King Solomon planted his garden, and where, sitting in the shade of its trees, he wrote the book *Ecclesiastes*. (*King's Garden Plan*, 2010: 9).

The Mayor of Jerusalem, Nir Barakat, claimed that:

> The initiative to restore the area of the King's Garden to its ancient glory is part of our fundamental commitment and responsibility to preserve and safeguard Jerusalem, its landscapes and vistas, historic and scenic sites for the sake of future generations. For thousands of years, the King's Garden was an island of green, a site of agriculture and water, as part of systems of valleys and wadis that surrond the Old City – ancient Jerusalem. (Jerusalem Municipality and Jerusalem Development Authority, 2010: 5)

Self-determinative planning in practice

The Al-Bustan community had been opposing the state's King's Garden Plan since it was first launched by the Jerusalem Municipality. This section analyzes the community's reaction to the plan, based on an ethnographic longitudinal study. (This included in-depth interviews with Palestinian residents, and members and leaders of local community and grassroots organizations, which I was unable to publish, because quoting them would have a great potential to endanger them and also lead to the immediate demolition of their homes. It should be noted that since the eruption of the current war between Hamas and Israel, on 7 October 2023, the Jerusalem Municipality has increased the demolition of houses in the neighborhood and in the city. As Hasson and Solomon (2024) have reported in their article aptly titled "Israeli Demolitions of Palestinian East Jerusalem Homes Spike amid War," there was "a 60% surge in demolished homes reported in 2023." I also had to decide not to use in their entirety any texts from the WhatsApp group in the community that I am part of. Alternatively, I have used the Arabic and international media, and observations from the community meetings, which were publicly held.)

Becoming a political community

The Palestinian Al-Bustan community had not been collectively organized and did not have a grassroots organization until the rise of the new threat to demolish their neighborhood, and from the beginning of its occupation in 1967 to 2005, there was almost no collective mobilization against the state planning and the housing demolition policy. In 2005, the residents of the neighborhood decided to establish a grassroots organization called the Al-Bustan Popular Committee. The people of the neighborhood elect seven representatives to constitute the committee, which then represents the community's residents as a group. The Popular Committee has been responsible for the community, social, and planning actions that are related to the city plan of King's Garden.

As a result of the decision of the Municipality to destroy the neighborhood, the residents of Al-Bustan submitted a new plan to the District Planning and Building Committee in 2005. The Popular Committee hired an architect to prepare a zoning plan for their neighborhood. At the end of 2005, they submitted City Plan Scheme #11641 to the District Committee (District Planning and Building Committee, 2005). In 2009, the District Planning and Building Committee rejected the plan, arguing that "the plan is situated under City Plan AM/9, which designates the site as a public open green area; there is no room for qualifying the illegal buildings; the area of the plan is located in part of the sequence of open spaces," which "should not be allowed to be harmed, given their scenic sensitivity and their great importance due to their location." Furthermore, the committee claimed that the area has a "a scientific and tourism potential," and "sensitive open space," where the existing Palestinian "buildings that were built without a permit" should not be allowed to remain. Furthermore, the representative of the city stated that "the position of the City Engineer is that the plan should be rejected, since it proposes construction in the valleys, in violation of the planning policy and the Master Plan.

In 2009, when the Jerusalem Municipality launched the King's Garden Plan, the Al-Bustan Popular Committee members realized that it would not be enough to submit a plan to the Israeli planning institutions, and that they needed a new approach to oppose the city's new plan and the effects it would have on their neighborhood. Thus, they moved from a simple resistance to a plan for a new mobilization strategy. The community of Al-Bustan decided to take a wide-range of planning, social, and political actions aimed at opposing the King's Garden plan and constructing a new reality.

The struggle for recognition

In response to the city's plan, the Popular Committee established a Steering Committee in 2009 to manage the case and advise the Popular Committee on legal and planning issues. The committee includes members of the Al-Bustan Popular Committee, leading political figures from Jerusalem, and representatives of grassroots organizations. The Steering Committee included political figures and civil society leaders, in order to construct a consensus around the activity of the Popular Committee and provide it with political legitimacy. In addition, the committee assigned a Chief Planner, who headed a team of practitioners and was asked to prepare an alternative detailed plan for Al-Bustan. In addition, three lawyers were selected to legally advise the planning team and the Steering Committee. The overriding objective of the Popular Committee was to achieve statutory recognition through promoting a three-part strategy: achieving political reach, developing an alternative plan, and building local self-determination and autonomy.

Political reach

The first strategy was to put international political pressure on the Mayor of the Jerusalem Municipality and the Israeli government to halt the proposed plan and stop the demolition of the neighborhood. Obtaining international support was crucial in this. Since its establishment, the Popular Committee has also been updating United States Congress members, Senators, the Secretary of the State, and many other European governments political leaders. As East Jerusalem is considered by the international community a city under Israeli occupation, the United States and other Western countries consider themselves somehow obliged to protect the rights of Palestinians in the city and prevent Israeli territorial and demographic transformations (Badran, 2023).

In this regard, when the Jerusalem Municipality launched the King's Garden Plan in 2010, the Al-Bustan Popular Committee occupied a public building in the neighborhood, built a large tent on the roof, and announced that the building was 'The Tent of Protest." This occupied building, considered an illegal building by the Israeli legal and planning institutions, has remained the communal site of social, cultural, religious, and political activities (Photos 1-3).

On March 2009, US Secretary of State Hillary Clinton, visiting Jerusalem and the Palestinian Tent of Protest, intervened in an effort to prevent the demolition. As a headline put it, "Clinton criticised Israel's plans to demolish dozens of homes in Arab East Jerusalem," stating, "Clearly this kind of activity is unhelpful and not in keeping with the obligations entered into under the 'Road Map'," and that "[I]t is an issue that we intend to raise with the government of Israel and the government at the municipal level in Jerusalem" (McCarthy, 2009).

Clinton refused to meet the Mayor of Jerusalem, Nir Barakat, because of his announced plan to demolish Palestinian homes to make way for a tourist park. In an expression of support for the Al-Bustan community, she chose instead to visit the Al-Bustan Tent of Protest. Jerusalem's mayor "became embroiled in a high-profile conflict with Secretary of State Hillary Clinton over his intention to demolish the homes" (Hasson, 2010). There was then pressure from Europe and the U.S. to prevent Israel demolishing the neighborhood.

The alternative plan

The creation of an alternative plan for Al-Bustan was based on wide public participation within the community. The city's planning and its results were presented in the Protest Tent. The alternative plan was eventually approved by the Al-Bustan Committee and the people of the neighborhood attending a community convention, establishing what was called the Popular

Community. In part to obtain recognition, the Popular Community proposed the renovation and beautification of the neighborhood, making use of the professional terminology of planning:

> Our vision is to create a socially, culturally, economically, environmentally and spatially vibrant and sustainable community at Al-Bustan and promote a place that enriches, uplifts, and inspires the human spirit (The Plan Report, 2010).

The plan would implement an aesthetics based on local Palestinian and historic Islamic architecture in Jerusalem. This would mean a landscape based on gardens and green routes, flowing water in canals, and a focus on protecting the environment. These features are meant to enhance the community environmentally and aesthetically as well as economically, and are a response to the recognition that the community's struggle concerns social and spatial conditions that it could aim at improving, while hoping to end the state's antagonism towards it.

Constructing autonomy

The Popular Community (PC) has been sustaining and strengthening the Al-Bustan community socially, physically, and environmentally, constructing a type of urban autonomy aiming to serve the central goal of preventing the demolition of the neighborhood and achieving recognition and approval for the alternative plan. Community cohesion, solidarity, and collective action have become central to the political and planning cause of the neighborhood. A sense of shared risk, feelings of deprivation, and national pride created conditions for mobilization and collective action that had been in a standstill since the city launched its plan in 2010.

The PC has conducted activities on a wide social, cultural, and environmental spectrum**.** Since the Jerusalem Municipality does not provide any services to the neighborhood, the Popular Community promoted various projects to improve the living conditions of the residents, including renovating the neighborhood's narrow paths, constructing a children's playground, painting the walls of the buildings facing the main road, drawing graffiti paintings to present the story of the neighborhood and show its durability, renovating a building for a kindergarten, cleaning the neighborhood streets, and building a mosque.

In fact, the community has taken the place the place of the municipality in providing municipal services. The occupied building became a community center for cultural and social activities, in which the committee provides courses and public lectures for residents. The building has its own "Tent of Protest" on its roof. This tent has been used for collective meetings, and is a popular site for visitors from elsewhere in the city as well as international diplomats.

Conceptualizing dispossessive vs. self-determinative planning

In analyzing the framework of the planning of dispossession, I am looking at the *logics* of the regime of practices of the architecture of dispossession. Each "logic" is meant to grasp specific aspects of the architecture of dispossession, which they together constitute (Glynos and Howarth, 2007). Based on the underlying empirical work, this study identifies as three logics involved in dispossessive planning *accumulation by dispossession*, the logic of *exclusion*, and the logic of *aesthetics*.

The logic of *accumulation by dispossession* captures the economic aspects and capitalization of the dispossession through spatial planning practices. Harvey (2001, 2003, 2008) proposes that "[w]hat accumulation by dispossession does is to release a set of assets (including labour power) at very low (and in some instances zero) cost," following which, "over-accumulated

capital can seize hold of such assets and immediately turn them to profitable use" (Harvey, 2003, 149). *Accumulation by dispossession*, Harvey contends, is "the mirror-image of capital absorption through urban redevelopment," a process of displacement that lies at the core of urbanization under capitalism. This process is backed by the strong state, and state power is always a major player in accumulation by dispossession. At present, most policies of dispossession are what are widely called neoliberal policies. Accumulation by dispossession occurs in many ways, including displacement of people, privatization (converting public assets into private property rights), and commodification of cultural forms. Thus, following Harvey, the logic of accumulation by dispossession suggests that spatial strategy and capitalization interact to ensure both the alteration of a space and its use for capitalization and profit.

Thus, the state in Al-Bustan first demolishes the buildings on the grounds of the illegality of land uses, then confiscates the land, displaces the residents, and launches a new development project, aimed at tourism, in the dispossessed place. Dispossessive planning involves uses of planning in two ways: first, to legally justify the demolition and displacement, and secondly, to propose a new plan of economic development. In this way, planning serves the state in justifying the displacement of people and rationalizing future economic development of the dispossessed assets.

The *aesthetic logic* captures the politics of the aesthetic of transformation of places; specifically, the way in which dispossessive planning uses aesthetics to justify its *creative destruction strategy*. Aesthetics in this case is a matter of appearance. Rancière (2010) suggests that what is called "art" is always political, because in proposing ways of seeing reality, which can include the arrangement or rearrangement of spaces, it is engaged in the construction of (contingent and contested) "forms of life." The effort to construct an aesthetically pleasing, and thus valuable, new or renovated "reality" through changes to a place provides one way of understanding planning through dispossession and accumulation: the place and its uses are transformed, and increased in "value" in a sense that can both be appreciated and enjoyed, and be financially profitable.

In this case, the King's Garden Plan neglects the existing aesthetic qualities of the Al-Bustan neighbourhood, dismissing the fact that the residents protect, sustain, and use its running water, and have made the neighborhood greener than most, if not all, other neighborhoods in Jerusalem. Al-Bustan, which means "the garden" in Arabic, is instead represented as a collection of illegal houses, built on public lands, whose designation as a green park is contrary to its proper uses. Furthermore, the aesthetic images used in the official plan involves an untrue historic narrative, lacking any archaeological evidence, and plainly ideological, in claiming that "[t]raditionally, it was in this place that the kings of Israel established their gardens," and that it is where "King Solomon planted his garden, and where, sitting in the shade of its trees," whose ancient glory is even described in mythically paradisiacal terms as the place of the "Gates of the Garden of Eden" (The King Garden Plan, 2009: 9).

The *logic of exclusion* captures the way dispossessive planning excludes the very presence of the dispossessed, the excluded "others." In *The Politics of Dispossession*, Edward Said describes the use of concepts of absence/presence in which the dispossessor's presence is justified by the supposed absence of the dispossessed, an absence that has been conceptually transformed from a displacement into a supposed non-reality. Similarly, Butler (2013) conceptualizes dispossession as involving a dialectic of presence/absence "whereby presence (or a presence-effect) is produced by being constantly haunted by its spectral absences or (mis-)recognized presences" (Butler 2013, 16). The presence to be removed is represented as an

absence, but it is also haunted by it, since its negation is an uncertain, and troubling because troubled, project. Furthermore, "being dispossessed refers to processes and ideologies by which persons are disowned and abjected by normative and normalizing powers that define cultural intelligibility and that regulate the distribution of vulnerability" (Butler 2013, 2). The dispossession is normalized by a discourse that denies the existence of what it violently attacks.

Dispossession can be thought of as a way in which human bodies are de-materialized through these practices (Hirsh, et. al., 2020; Jabareen et. al., 2017). It is both a reality and a process, and it involves both a material process and a resulting sense of being "deprived of the ability to have control over their life" (Butler 2013, 3). Accordingly, dispossession, "whether it be colonial or neocolonial, capitalist, and neoliberal, endures by reproducing … the violence inherent in improper, expropriated, and dispossessed subjectivities" (pp. 18-19).

Exclusion through the process of dispossessive planning is a violent act, whose effects on the dispossessed include the creation of an ontological insecurity . In Al-Bustan case, the people living there must spend their days and nights under the threat of the demolition of their homes. On any given morning, officers of the Jerusalem municipality may come with the police to demolish a house. The residents are often asked to participate, by demolishing their own houses, failing which the Israeli authorities will destroy them and the displaced must pay the demolition costs.

Dispossessive planning is a coherent regime of spatial, aesthetic, legal, economic, and socially exclusionary practices of dispossessing and displacing a disadvantaged group of people in order to construct a new and "better" reality. The aesthetic logic of dispossessive planning represents this as creating a pleasing and attractive place for tourists and settlers. The logic of *accumulation by dispossession* captures the capitalization of dispossession through spatial practices of place alteration for economic redevelopment. The *exclusionary logic* captures the reasons given for the exclusion of specific people and places, which may be based on social differences and antagonisms. Dispossessive planning is a form of state violence that understands itself in these three analogous and convergent ways.

Conceptualizing self-determinative planning

Self-determinative planning is a regime of practices that normally emerges to counter the apparent injustice of institutional planning policies. Central to self-determinative planning is the *logic of becoming a political community*, which may arise through efforts to cope with actions that are interpreted as destructive of the community that is then substantially formed in response. The community may become constituted politically in the context of 'friend-enemy ' relations, in this case provoked by the opposition of the state. This has been found to occur in many places around the world where states have displaced communities for the sake of redevelopment and urbanism. In this case, the state has been antagonistic to Palestinian communities in Jerusalem, in various spheres including planning, housing, development, and issues of citizenship.

Dispossessive planning itself depends on a friend/enemy formation. It follows the logic identified by Schmitt (1932: 26), according to which "the phenomenon of the political can only be grasped by referring to the real possibility of friend and enemy groupings," which are the most intense and extreme political antagonisms (1932: 23). For Schmitt, the state is an organized political unit that depends on a friend-enemy decision. In East Jerusalem, the state has made a decision to clearly distinguish between two ethnic groups, Israeli Jews and Palestinians. The resulting antagonism "manifests itself in all sorts of tactics and practices"

(Schmidt 1932: 23), including, in urban development, what we can recognize as *dispossessive planning*. Thus, political community arises when its members collectively make a distinction between friend and enemy, the one expressing "inward" relationships and the other "outward" ones. For the community in this case, this means, internally, constructing a collective political identity in the face of the antagonism of the state's projects. Schmitt argues that every political community requires a substantive collective identity, which is independent of, and can exist outside, the established framework of constitutional rules, or the state itself (Vinx, 2015).

Under these circumstances of severe state antagonism, a community becomes political in aiming to mitigate, or dismantle and dissolve, the tyranny of the state and its institutions and policies over spatial production. It may even be thought that the antagonism of the 'friend-enemy 'divide constitutes the ontological foundations of self-determinative planning.

In our context, collective identity and solidarity derive from the shared common interests recognized among the community members, and these common interests are necessarily recognized in opposition to the state political authority, which opposes them and brings them together as a community sharing this situation. The community collectively produces, out of a sense of grievance, a collective "we" facing a "they," in this case the Israeli state, which is held responsible for its grievances. Becoming political is a response to the actions of a state apparatus as an "enemy" that is poised to do (and does) harm to the community. In the literature of collective action and protest, identity, injustice, and efficacy are sometimes said to be among the core concepts of social psychology of protest, with group identification fostering protest participation (Klandermans, 2002). The shared sense of becoming an urban political community provides its members with opportunities to take control over its spaces, conferring meaning on the choices and tasks involved. Self-determinative planning supports a sense of autonomy, solidarity, of belonging to the place, and destiny.

A logic of recognition reflects some of the political ends of the self-determinative planning approach. One objective of the community is achieving recognition for its demands, including its alternative plans regarding its space planning and production. Fraser (2000) conceives recognition as a question of social status, where the demand for recognition is about the status of individual group members to become full partners in social interaction. Thus, misrecognition involves not only the depreciation and deformation of a person's group identity, but also social subordination—in the sense of being "prevented from participating as a peer in social life" (p. 113). Understanding the important role of recognition as such, some scholars have called for more "substantial forms of recognition," without which, in one way or another "our lives are at risk," as Judith Butler put it (quoted in Willig, 2012: 139). Thus, Eizenberg et al. (2021) propose a framework of *urban space of recognition to* foster a more just and inclusive society.

A logic of autonomy or self-management describes the political settings of self-determinative planning. A political community embodies a collective identity it has constructed, originally, around the friend/enemy divide, and the sense among the community's members that it is a political entity that may have real power either to influence elites and state powers or of direct self-governance. If they find that they have some real strength in local, national, and sometimes international, contexts, they may then be able to oppose themselves to the state authority of the larger society.

Henri Lefebvre proposes, in his case by reworking the Marxist concept of the "withering away of the state," with its implication that this would equally involve "the decline of the Party as a centralized institution that monopolizes decision-making" (Brenner and Elden, 2009: 136), the

concept of self-management *(autogestion)*, which he takes as implicit and incipient each time a social group "refuses to accept passively its conditions of existence," and consequently forces itself "not only to understand but to master" those conditions (p. 135). This makes it a means of struggle that is also a "means for reorganization of society" (p. 149). This can force the state in reply to submit some of its own power "to 'grassroots' democratic control." The ideal or utopian character of this, which Lefebvre calls "the opening toward the possible," may be "only one element of a political strategy," though it may be significant in being, as he believes, the only way "members of a free association can take control over their own life" (p. 150).

The logics I have identified as involved in state dispossession are countered in those involved in the framework of what I call *self-determinative planning*, which may be provoked by them. Dispossession both wields and invokes an inescapable friend-enemy divide. In this context, people who have begun to organize themselves together in resistance may develop new forms of autonomy (as well as strengthening old ones), as well as seeking recognition, including from the state that acts otherwise as enemy, for their own demands and plans they are forced to develop as alternatives.

Self-determination as a social and political ideal can be rooted in liberal political theory as well as elsewhere. Classical liberal theory is based on the rights of individuals. Governments are expected to provide protection for those rights, failing which, people have the right to resist, as well as to emigrate or secede (Freeman, 1999). In radical versions of liberal theory, self-determination is justified when necessary to ensure liberty or protect civil or human rights (Beitz, 1979; Freeman, 1999). Similarly, psychological theories of self-determination ground its desirability in personal "needs": people are said to have needs for autonomy or self-governance, a sense of mastery or competence, and a sense of belonging and connection, that are best met by collective processes of self-management (Ryan & Deci, 2020). It may be held that "individuals experience greater psychological well-being through the satisfaction of these three psychological needs, and conversely feel highly fragmented, isolated, and reactive when their needs are not met" (Chiu, 2021). People may thus be seen as possessing rights to collective political self-determination that are grounded intrinsically either in their nature as human beings or in the extant political formations to which they are already subject. Thus, forms of urban planning that are manifestly destructive of these very principles may facilitate their assertion in part precisely because they were implicit to begin with.

Kymlicka (2012) suggests that "national minorities and indigenous peoples typically view themselves as 'peoples' or 'nations' and, as such, as having the inherent right of self-determination. They demand certain powers of self-government," and "they want to govern themselves in certain key matters to ensure the full and free development of their cultures and the best interests of their people." While it may appear that ethnic or national identity is here the basis on which the desire for self-government is founded, it may also be that the latter is prior or that the two are "given" together. National communities may derive some of their importance from the fact that they are the most available sites for possible collective self-government. At the same time, cultural "accommodation rights" that depend on minority status, may remain important as long as there are persistent cultural differences at the same time that governance remains linked to an ethnic or cultural identity that is held in common.

Self-determinative planning is a form of self-determination that involves a community's production and reproduction of its member's individual and collective property rights, and its physical space, which they may normally expected to be guaranteed by the state, and that may

be defended against if it is violated (including by or involving the state itself). In this way, planning may come to mean collectively seeking a mastery over the conditions of people's lives, in opposition to a state tyranny that undermines or threatens them. Self-determinative planning may thus be undertaken by members of a community that sees its interests as in an antagonistic relationship to state activities and institutions.

Conclusion

Planning literature includes frameworks that can be found useful by planners opposed to official state planning, such as "radical planning," "advocacy planning," and "insurgent planning." This paper conceptualizes the dominant state planning as a coherent regime of practices that function together, serving the political and economic purposes involved in the dispossession of an extant "foreign" population, in this case Palestinian citizens and residents of a neighborhood in East Jerusalem. A corresponding approach of self-determinative planning should, I am suggesting, be similarly composed of integrated political, economic, and aesthetic practices that are oriented to the local (Palestinian) community's continued residence rather than dispossession, autonomous self-governance, and maintenance of a satisfactory quality of life in the lived environment consistent with these ends. An appropriate regime of planning practices in situations and places like this would be the complementary contrary of the current one of dispossessive planning, and it is this whose coherent deployment I have called self-determinative planning.

As we have seen,, dispossessive planning involves a distinct and coherent regime of practices, which can be conceptualized through three interrelated logics. The aesthetic logic describes the way the dispossessive planning manipulates reality and creates a new reality through spatial, design, and aesthetic practices that are intrinsically political. The logic of exclusion is that of a violent practice that excludes the very presence of the dispossessed, negating their very existence. The logic of accumulation by dispossession describes the capitalization of the dispossessed spaces and places, which are then appropriated for profitable uses. Thus, displacing the poor or specific racial groups from specific sites in cities aims, in many cases, not only to create profits but also to 'clean' urban areas from undesired others. The purposes aimed at are functionally convergent, though through distinct "logics" with independent rationales.

Urban self-determinative planning must challenge dispossessive planning, on account of the uneven and distorted relationship between the planning apparatus of the state and affected disadvantaged communities. This tends to mean that it depends upon the community's resisting what must seem to it as state tyranny, and that resistance requires its becoming political by building specific forms of autonomy, if at first only to support the struggle for recognition of its members' needs and rights by the state. Planners attentive to the rights and needs of disadvantaged and minority populations to produce and control their very spaces of existence, a notion that the urban planning profession can hardly to fail recognize, as it would otherwise have to abandon all pretense of democratically being rooted in or responsive to the needs and interests of the inhabitants of the spaces being planned, perhaps in favor of something amounting to or approximating an act of war, must recognize the priority to their activity of the autonomous self-determinative political processes in the affected communities.

Abstract:

In the 60 years since *Image of the City* was proposed by Lynch, it has been widely applied while also receiving various critiques and queries. However, recent developments of internet have led to new theoretical frameworks and research paradigms based on the classical *Image of the City*. To explore application transformation of *Image of the City* in urban planning over the past 20 years, this paper conducts qualitative and quantitative analyses based on 126 articles selected from the China National Knowledge Infrastructure (CNKI) and 244 articles selected from the Web of Science (WOS). It outlines an overview of research hotspots, trends, and significant changes in the study of *Image of the City* within the field of urban planning. The study reveals that Kevin Lynch's foundational work has been expanded to incorporate digital and cultural dimensions into *Image of the City* researches. Furthermore, it highlights the adoption of "big data," "images," and other relevant data, alongside advanced technologies such as "deep learning" and "convolutional neural networks." These technologies have progressively replaced traditional cognitive mapping and questionnaire methods in the study of *Image of the City*. This shift not only marks a significant methodological evolution but also broadens the scope of research in capturing and analyzing the complexities of urban environments.

Keywords: Lynch, Image of the City, CiteSpace, Applications and prospects

1 Introduce

The theoretical approach to urban imagery originates from the perceptual research methods proposed by Lowenthal (1961), yet it is widely acknowledged that Lynch's seminal *Image of the City* has become emblematic of the concept itself (Gu and Song, 2001). In the six decades following Lynch's publication, while his theory has been extensively utilized, it has also encountered numerous critiques and challenges. These criticisms have catalyzed the ongoing expansion and evolution of the *Image of the City* concept. In the digital age**,** the cognitive patterns, subjects, and theoretical underpinnings of the *Image of the City* are progressively transforming, prompting the development of new theoretical frameworks and research paradigms based on the original theory. Consequently, there is a pressing need to summarize and review the recent shifts in the theoretical content and research paradigms related to the *Image of the City* within urban planning.

To address this, the present paper utilizes CiteSpace as a bibliometric analysis tool, drawing on core journals from the China National Knowledge Infrastructure (CNKI) and the Web of Science Core Collection databases (WOS) to pinpoint research hotspots and trends in *Image of the City* studies over the past two decades. From this analysis, the paper delineates the shift in

Image of the City research paradigms within urban planning.

2 General Progress In Image Of The City Research

2.1 Data Resources

To gain a deeper understanding of the research progress on *Image of the City* in urban planning within both Chinese and international contexts, we conducted searches and downloads of basic data from CNKI and WOS, restricting the publication period to between 2000 and 2022.Utilizing the CNKI journal database, the search parameter SU='城市意象' (Image of the City) yielded 273 papers from SCI or EI indexed journals, Chinese core journals, CSSCI journals, and CSCD journals. To specifically focus on urban spaces, studies concerning urban imagery in literature and film were manually excluded, ultimately resulting in 126 relevant documents. In the WOS Core Collection, the search was conducted using TS="urban image", focusing on journal articles and conference papers, which initially provided 245 core journal papers. After an examination to remove irrelevant publications, 244 papers remained. This paper employs CiteSpace 6.1.R6 software to perform foundational bibliometric analysis.

2.2 Volume Of Publications

From the perspective of publication volume, Chinese scholars’ engagement with *Image of the City* studies in the field of urban planning appears limited, exhibiting a fluctuating trend with a slow rise and decline in recent years. Conversely, international scholars have demonstrated a steady increase in their research on *Image of the City*, particularly after 2016. This indicates a period of heightened activity and growing interest in the subject (Figure 1).

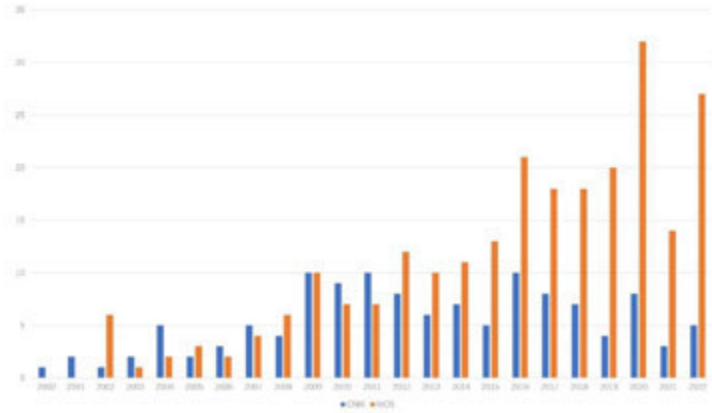

Figure 1. Comparison of year-to-year changes in the number of publications in CNKI and WOS papers

2.3 Research Hotspots

A co-occurrence keyword graph is instrumental in analyzing research hotspots and their evolution. In such graphs, each node represents a keyword, with larger nodes indicating higher frequencies of occurrence, thus highlighting the current hot topics in *Image of the City* within the field of urban planning. In Chinese research, besides fundamental topics like "spatial imagery" "cognitive maps" and "imagery maps" the main research topics include "urban

design" "urban tourism" "urban characteristics" and "big data" (Figure 2), focusing on the application of *Image of the City* theory in urban planning and design, such as identifying urban characteristics. Similarly, international studies on *Image of the City* also focus on "urban design" "urban planning" and "urban development," and like Chinese studies, show a notable interest in new big data-related technologies such as "deep learning" and "convolutional neural networks." However, international research differs by also emphasizing exploration of specific historical urban districts, with a focus on "urban historical district renewal" and "urban historical heritage preservation" (Figure 3).

Centrality in the keyword graph indicates the degree of connection between keywords, with higher centrality suggesting stronger links with other keywords. As shown in Table 1, besides primary nodes with high centrality such as "urban image " "Image of the City", keywords like "space syntax" "big data" and "deep learning" are emerging as secondary important nodes in both Chinese and international research spectra, indicating significant future research trends. Since 2016, related data such as "big data" and "images," along with new technological methods like "deep learning" and "convolutional neural networks," have been increasingly applied in *Image of the City* research, replacing traditional cognitive mapping and survey questionnaires, showcasing high centrality and becoming significant nodes within the research field. Thus, the paradigm of *Image of the City* research is shifting from traditional surveys and cognitive sketches involving small samples to utilizing computer algorithms to mine information from big datasets.

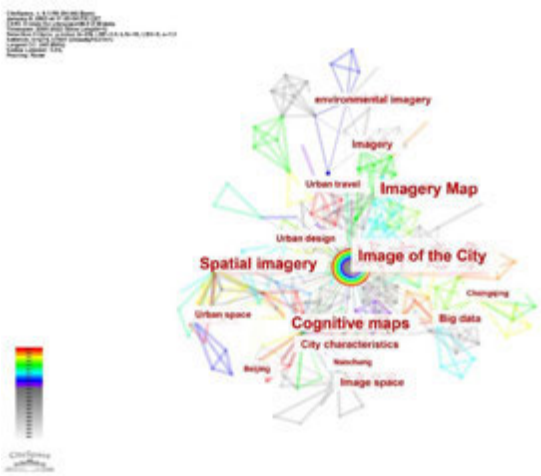

Figure 2. Co-occurrence keyword mapping in Chinese *Image of the City* researches

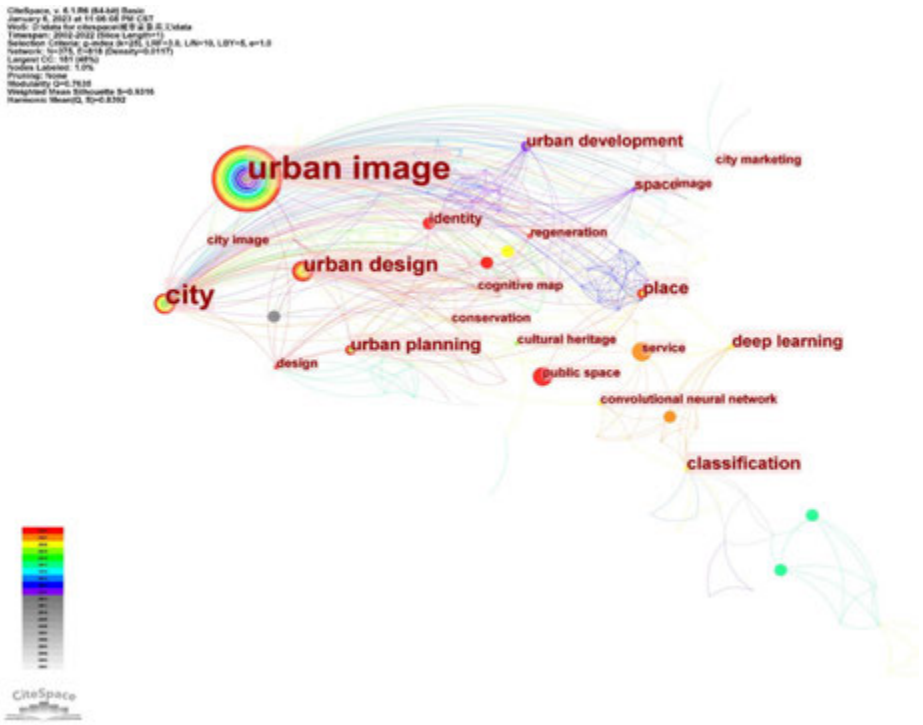

Figure 3. Co-occurrence keyword mapping in international *Image of the City* researches

2.4 Research Trends

Chinese scholars' research on *Image of the City* can broadly be divided into three stages (Figure 4). The first stage (2000-2010) focused on applying and empirically testing classical methodologies of *Image of the City*. The second stage (2010-2015) centered on enhancing these classic methods through the integration of theories from environmental psychology and semiotics. The third stage (2015-present) has seen the adoption of multidimensional data such as online text, internet images, street view images, and big data. This data is analyzed using deep learning techniques to categorize and deconstruct in order to explore subjective perceptions alongside objective environmental analyses.

Internationally, research on *Image of the City* can be divided into two stages (Figure 5). The first stage (2000-2010) was characterized by keywords such as social capital, cultural capital, regional renewal, and negative imagery, applying classic *Image of the City* methodologies to the fields of regional renewal, city branding, and urban transformation. This phase emphasized enhancing distinctive urban features and employing city branding as a robust image-building strategy, which subsequently led to the exploration of creative cities and urban personality planning. The second stage (2010-present), similar to developments in China but starting earlier, utilizes images, remote sensing imagery, and other data sources, analyzed using deep learning, convolutional neural networks (CNN), and convolutional autoencoders (CA). This phase places a greater emphasis on culture, focusing on the cognition of urban culture, the protection of urban cultural heritage, and the preservation of historical urban environments.

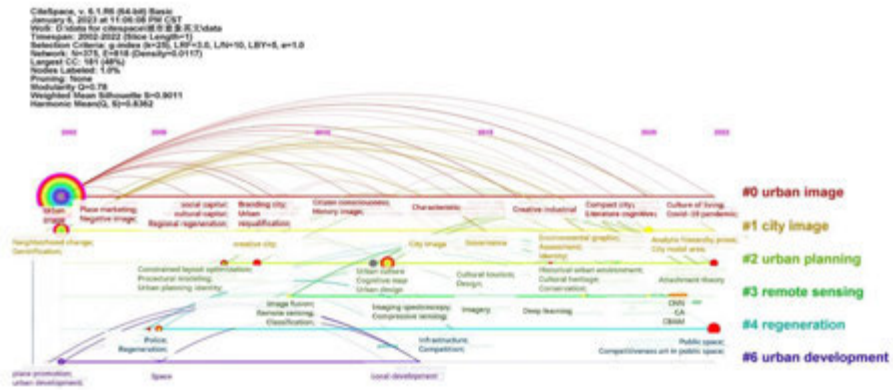

Figure 5. Time series map of keyword changes in international *Image of the City* researches

3 Paradigms Shifts In Image Of The City Research Within Urban Planning Studies

3.1 Evolution Of Theoretical Content Of Image Of The City

(1) Limitations of *Image of the City* theory

Kevin Lynch, in his seminal work "Image of the City", provided a comprehensive set of theories and methodologies related to urban imagery. Lynch posited that urban imagery results from the interaction between the environment and individuals, where perceptions are influenced by urban environments to create spaces of experience, either directly or indirectly. These perceived images, which residents can recall, constitute the "subjective environmental" spaces in their minds. Thus, individuals can organize and attribute meaning to everything they perceive. Lynch's research across cities like Boston, Jersey City, and Los Angeles distilled urban imagery into five structural elements: paths, edges, districts, nodes, and landmarks. And he proposed that residents construct mental maps of the city through path-dominated or space-dominated approaches (Lynch, 1960). Cognitive mapping and social survey techniques have been commonly used to obtain these mental maps of urban imagery, with studies varying in scale from city-wide (Xiong et al.,2011) to region (Miao,Li and Xu,2010) ,and campus levels (Topcu and Topcu,2012).

However, as a product of the 1960s, the suitability of Lynch's *Image of the City* theory for exploring subjective spatial perception in contemporary urban environments has been widely debated. First, Lynch's structural elements of urban imagery are focused on tangible aspects of urban design, leading to highly similar findings about urban characteristics that often appear repetitive and generic (Xu, 2012). Second, cognitive maps, as abstract schematic structures, detach from the cultural essence of the city itself, serving primarily for directional purposes and overlooking the motivations behind behaviors, thus failing to genuinely represent the holistic urban structure and to uncover the city's true character (Shen, 2004). Third, the sample bias in surveys does not reflect the perceptions of millions of urban dwellers but only those of a few

individuals (Wang, 2003).

(2) Expansion of *Image of the City* Connotations

With the transformation in information technology and transportation, *Image of the City* perception now integrates more culturally and emotionally valuable media. The cognitive models of *Image of the City* have evolved to combine visual and virtual cognition, with the objects of *Image of the City* cognition shifting towards urban spaces popularized by online platforms like TikTok and social media (Zheng et al.,2020). People's perceptions of the real world are influenced not only by physical experiences but also by interactive recommendations on social media, and by the rapid dissemination of literature, cinema, and short videos, gradually forming more fixed urban imagery within the digital realm. Gradually, the study of *Image of the City* has moved beyond just the interaction between observer and environment, focusing increasingly on the role of media imagery. In the digital domain, the transfer of digitized images eliminates physical distances between subjects and objects, making geographical traversal unnecessary for path-finding cognition, thus giving *Image of the City* perception an instantaneous and geographically unbounded sharing quality (Zhao and Chen, 2023).

3.2 Perception And Recognition Of Urban Image Based On Multivariate Data

Since the internet has become a common medium for large groups to share photos, information, and feelings, the images and text found online can reflect people's subjective perceptions of the physical environment to some extent. The advancement of digital technologies, artificial intelligence, and network information technology has significantly transcended the traditional "cognitive map" route for identifying *Image of the City*, shifting towards research that leverages "network media" to perceive *Image of the City*. Consequently, images and text are increasingly replacing small-sample data obtained through cognitive maps and survey methods as the primary data sources for urban imagery research (Table 2).

(1) Identifying Urban Imagery Based on Image Data

Long and Zhou (2025) introduced "Pictorial Urbanism," advocating that image data not only embodies the objective world and subjective perceptions but also can be applied on a large scale quantitatively in urban studies. Images, reflecting static visuals inherent in human vision, are extensively used to identify *Image of the City* elements and assess their features. Depending on their origin, images are categorized as online images (from the internet), street view images (from services like Baidu Maps, Google maps), and attributes of images (from photographic metadata).

Online images are widely utilized to explore the composition of *Image of the City* and identify its characteristics (Zhao, Xu and Li, 2015; Cao, Long and Yang, 2017; Li et al., 2017), street view images are employed for perceiving street spaces (Xu, Jiang and Chen, 2018). These image datasets are often analyzed using deep learning and machine learning technologies to recognize content, categorize features, and conduct quantitative analyses.

Attribute information such as shooting location, uploading practices, description tags, exposure parameters, and geographic information in the image can also be utilized to mine *Image of the City*. For example, Bahrehdar, Adams and Purves (2020) used a combination of user-generated

content from Flickr and street network data from OpenStreetMap to investigate urban perception and city elements such as paths, landmarks, districts, edges, and nodes.

(2) Identifying Urban Imagery Based on Text Data

Online texts, as mediums conveying daily thoughts and emotions, effectively express individuals' emotional and preferential responses to entities. Researchers have used online texts as raw data to analyze *Image of the City*. In China, sources of online textual data include Weibo, Baidu Tieba, and Dianping.

Research in this area often focuses on the imagery preferences of various demographic groups (Feng et al., 2011; Zhao and Liu, 2012) and the urban imagery of specific regions (Xie et al., 2017). Text data carries limited information, confined to content and coarse geographic details, making it less capable of extracting detailed information and suitable only for broad, qualitative spatial perception descriptions. Thus, research solely based on text data for identifying urban spatial imagery is uncommon. Text data primarily aids in enhancing urban imagery perception studies, for instance, Fan and Zhang (2022) used POI density to gauge functional perception, street view images for visual perception, and textual notes to extract emotional perceptions.

Table 2. Data basis of *Image of the City* perception and recognition in Chinese

Data categories	**Sub-categories**	**Combined with other data**	**Research content**	**Source**
Image	Online images	None	Identifying the composition, dominant direction, characteristic degree and similarity of *Image of the City* elements in 21 Chinese cities	Cao, Long and Yang, 2017
	Online images	Combining questionnaires and cognitive maps	The basic elements of the *Image of the City* Composition of Dingxing Ancient City	Fu et al., 2017
	Night Scene Web Image	Nighttime remotely sensed light intensity data	The main spatial characteristics of Zhuhai's urban nightscape Imagery and the tendency of popular Choice	Li et al., 2017
	Online images	None	Evaluation of feature recognition of 21 Cities in Guangdong province	Zhao, Xu and Li, 2015
Street view images	Baidu Street View map	None	Perceived safety of public space in Shanghai streets	Xu, Jiang and Chen, 2018
Online texts	word frequency of Weibo hot area	None	Image of the Beijing City	Xie et al., 2017

	microblogging text	None	Similarities and differences in chinese and western tourists' perceptions of Beijing's urban Imagery	Feng, 2011
	Economic news text, Baidu posting geographical term frequency	None	Differences and similarities between the media and the public on urban imagery of Shanghai's downtown area	Zhao and Liu, 2012

3.3 Reanalysis Of Urban Imagery Structures Based On New Computational Methods

The development in big data and computing has continually fostered new models for understanding Image of the City. Deep learning and machine learning, key branches of artificial intelligence, provide tools for extracting objective environmental imagery and the subjective perceptions of the public. These technologies are extensively applied in urban planning and related research. The primary significance of deep learning and machine learning in urban imagery lies in their ability to "mimic human learning" processes, autonomously learning from large datasets to derive patterns, particularly in analyzing image, text, and spatiotemporal data. Consequently, numerous scholars have attempted to employ these methods to develop new models for exploring *Image of the City*.

For example, Cao, Yang and Long (2019) used Weibo data comprising photos, texts, and location tags, combined with big data and deep learning techniques, to construct a model that deeply characterizes urban imagery across three dimensions: structure, types, and evaluation. Zheng (2021) utilized street view big data, machine learning, and both subjective and objective quantitative evaluations to quantify the objective environmental components and primary perceptual outcomes in Nanjing's central urban area, proposing a new set of five urban imagery elements different from Kevin Lynch's model: core, node, corridor, layer, and blind spot.

Internationally, Doersch et al (2012) based their study on large-scale street view data, using unsupervised computer recognition algorithms to identify elements representing Paris's urban environment. Their findings indicate that Paris's urban imagery elements are embedded in everyday culture rather than unique urban landmarks or structures. Liu et al (2016) applied deep learning techniques to categorize and classify photo content from Panoramio and Flickr by elements (e.g., green visual imagery, water visual imagery), exploring the *Image of the City* element types and spatial distribution characteristics in seven cities. Zhou et al (2016) used deep learning to identify and classify geographical photo data from 21 cities, investigating each city's urban imagery features and spatial characteristics, and further exploring the differences among these cities.

4 Summary

Image of the City is summarized in two adjustments in urban planning research:

(1) Theoretical Contributions and Expansions

Kevin Lynch's foundational work has been expanded to integrate digital and cultural dimensions into the study of *Image of the City*. The original elements of paths, edges, districts, nodes, and landmarks have been adapted to include digital interactions and cultural perceptions. This expansion is crucial as it acknowledges the changing urban experiences in the digital age,

where physical and virtual spaces converge. The incorporation of more culturally and emotionally charged elements into the study of *Image of the City* is a significant theoretical advancement. By acknowledging the influence of media and digital platforms, current research captures a more holistic view of how urban residents perceive their environments. This approach reflects a shift from a purely functional view of urban spaces to one that includes emotional and experiential dimensions.

(2) Methodological Innovations

The use of big data analytics, deep learning, and convolutional neural networks marks a substantial methodological shift. These technologies have enabled researchers to analyze large datasets of images and texts, providing a broader and more nuanced understanding of *Image of the City.* This approach contrasts sharply with the traditional methods of surveys and cognitive mapping, which often relied on smaller, less diverse samples. The transition to multivariate data analysis allows for a more comprehensive examination of *Image of the City.* By utilizing both image and text data sourced from the internet, researchers can capture a wide array of perceptions and interactions that were previously inaccessible. This methodological shift enhances the ability to analyze complex urban dynamics and understand the multifaceted nature of urban imagery.

5 Conclusions

This paper outlines the overall research progress on *Image of the City* within the field of urban planning and summarizes the research hotspots and trends. It further categorizes changes in research content, dividing it into the expansion of the connotation of *Image of the City*, perceptual identification of *Image of the City* based on multivariate data, and the re-discrimination of *Image of the City* structures using new computational methods. The study reveals that Kevin Lynch's seminal work has been expanded to incorporate digital and cultural dimensions into *Image of the City* research. Moreover, in terms of methodology, data related to "big data" and "images," along with new technological approaches like "deep learning" and "convolutional neural networks," have progressively replaced traditional cognitive mapping and survey questionnaires. Looking ahead, using deep learning, convolutional neural networks, and other computer algorithms in conjunction with large datasets such as text and images to further analyze *Image of the City* remains a key research direction. Applying these methods to historical heritage preservation, urban design, cultural tourism, and city branding holds significant potential. However, the complexity of online information and whether it can truly replace the perceptions of the majority of urban populations remains a topic for further debate and investigation. Therefore, future research should focus on enhancing the explanatory power of digital information for *Image of the City* theory.

Abstract
The philosophical work of Cornelius Castoriadis on the imaginary institution of society can inform planning theory today at a juncture of major transitions, unprecedented global urbanisation, multiple crises, and conflict. Planning as magma constitutes a dynamic world of social imaginary significations, which goes beyond plans, legal frameworks, administrative processes, and professional practices. This highlights the political dimensions of planning as thinking and doing interwoven with consensual or conflictual social dynamics, representations, desires, finalities, and affects. Derivative values such as indetermination, infinite potentiality, inexhaustibility, multiplicity, and difference may open paths to self-reflection, self-transformation, and radical imagination. Planning as magma means to elucidate planning goals and orientations, to conceive new social imaginary significations, and to constitute new methodologies, epistemologies, policies, and practices, toward sustainability and justice.

Keywords: planning theory; spatial planning; philosophy; magma; Cornelius Castoriadis

Introduction
In this paper, I find inspiration in the work of the Greek-French philosopher Cornelius Castoriadis to inform theoretical approaches to spatial planning. My emphasis lies on institutions (in the broader sense of the term) and current challenges in times of neoliberal globalisation, multiple crises, and conflict. Planning theory has often identified diversified connections of planning to philosophical and sociological endeavours developed in France around the 1970s, which revolutionised and radicalised social sciences in the context of wider social unrest, and critical dispute (often coined as May '68). Inspiration has been found in neo-Marxist political economy approaches on the right-to-the-city from the work of Henri Lefebvre (Chiodelli, 2013); in poststructuralist approaches on power and governmentality from the work of Michel Foucault (Flyvberg, 1992); or in psychanalysis, desire, and phantasy from the work of Jacques Lacan (Gunder, 2005). I wish to contribute to this thread within planning theory by suggesting ideas and concepts from the work of Cornelius Castoriadis.[1] Drawing from philosophy and psychanalysis, his work, as developed in France in the 1970s and 1980s, revolves around the notion of *institutions* and introduces key concepts such as the *imaginary institution of society*, *autonomy*, and the *magma of social imaginary significations*. I argue that Castoriadis's socio-historical lenses on institutions and radical imagination may provide helpful

[1] Cornelius Castoriadis (1922-1997) was a philosopher, an economist, and a psychoanalyst. Born in Constantinople (1922), lived in Athens (1922 -1945) and Paris (1945-1997). In 1945 he got aboard the ship Mataroa, together with other Greek intellectuals, writers, and artists, in order to escape from anti-communist prosecutions at the outbreak of the Greek Civil War, and migrated to Paris where he spent the rest of his life. He was the founder of the group and journal Socialisme ou Barbarie (1949-1966); worked as an economist at the Organisation for Economic Co-operation and Development OECD (1948-1970); joined the psychoanalytic group Quatrième Groupe; and worked at the Faculty of École des Hautes Études en Sciences Sociales (EHESS). He died in 1997.

insights into institutional approaches to planning with particularly relevant theorisations. We can derive notions that elucidate our understanding of today's critical challenges, transitions, and crises. They also suggest theoretical paths to imagine creatively beyond current trends and limitations.

Neoliberal planning paradigms

In a recent article, Benjamin Davy, Meike Levin-Keitel and Franziska Sielker (2023) suggested to 'cherish the diversity of planning' and spoke of 'plural planning theories' as necessary to deal with huge present transitions and a simultaneity of overlapping crises. In recent decades, in the era of neoliberal globalisation, planning has shifted orientation in its objectives and content. The accelerated flows of capital, people, goods, and information, the radical technological innovations, the unprecedented pace of global urbanisation, and, gradually, a succession and acceleration of crises mean sweeping changes for space and society. The emergence of global governance networks and the gradual expansion and dominance of a neoliberal ethos and policies have decisively influenced planning. *Spatial planning* emerged in the 21st century as a dominant planning paradigm in much of Europe (Gunder, Madanipour and Watson, 2018a, p. 5) through these sweeping changes intertwined with globalisation, albeit with significant variations among regions and contexts. Ideas and planning practices of growth, competitiveness, entrepreneurship, governance, strategic selectivity, and flexibility gradually formed a planning paradigm, which stood in contrast to 20th-century planning paradigms in the West, the East, and the South. Spatial planning, as a neoliberal planning paradigm, diffused globally throughout a post-modernist, post-socialist, and post-colonial world as a reform, good practice, and a factor in shaping planning cultures (Sanyal, 2005).

Institutional turn and planning

Not without reason, institutions and institutional reforms got inextricably entwined with the era of globalisation. In the political arena, terms such as 'institutional reforms', 'institutional change', 'institutional adjustment', and 'institutional development', became an integral part of discourses and policies initiated by international organisations and national governments (Verma, 2007). Planning literature speaks of a 'changing relationship between the institutions of power and the society and environment' (Gunder, Madanipour and Watson, 2018a, p. 2) while also mentioning an *institutional turn* (Moroni, 2010) in intellectual thought. This turn 'recognizes the centrality of institutional framework when dealing with social and economic phenomena' (ibid., p. 275) and has profoundly influenced planning theory (Salet, 2019). André Sorensen (2018) writes thoroughly about *new institutionalism*, highlighting the importance of theorising institutions to planning theory. He mentions different (and often overlapping) branches of institutional approaches, including (a) rational choice institutionalism, which connects to New Institutional Economics; (b) historical institutionalism, which emphasises path-dependency and embeddedness, development pathways, origins and genealogies, endogenous, and incremental process; and (c) sociological institutionalism, which connects to organisational sociology and brings to the fore social norms and conventions, cultural and normative settings, even legitimating myths. As can be noted, the notion of *institution* can have multiple meanings and contents. Following Douglass North's well-known distinction (North, 2010), an institution may refer to formal rules (written law, property rights, regulations) or informal settings (conventions, codes of conduct, unwritten laws, customs, and habits) that shape social behaviour, as well organisations (political, economic, social, religious, educational bodies) or groups of people bound by a common cause. A series of questions arise here. How does planning theory and practice change, towards where, and why? How is planning reformed, and why? How do planning reforms link to broader institutional transitions?

Reflecting on Cornelius Castoriadis

Initiating from the problematisation of *institutions*, in the most profound sense of the term, I will delve into the work of Cornelius Castoriadis on the *imaginary institution of society*, with a particular focus on the notions of the *social imaginary significations* and the *magma*. The philosophical universe of Castoriadis's ideas and concepts has been the focus of interest for an ever-growing body of philosophical, psychanalytic, and political science literature (Adams, 2014; Kioupkiolis, 2012; Ktenas and Schismenos, 2018; Memos, 2014; Schismenos, 2013; Stavrakakis, 2002; Tovar-Restrepo, 2012). In this text, I revisit some of Castoriadis's original works (translated into English) from a planning perspective while building on relevant theorisations in Greek-language planning literature (Mantouvalou, 2020; Triantis, 2020a). My theoretical endeavour wishes to contribute to the discussion on planning theories in the AESOP congress 'Game Changer? Planning for Just and Sustainable Urban Regions', held in Paris in 2024. At the same time, this pays homage to Cornelius Castoriadis, who developed his philosophical thought while living in Paris.

Reading Castoriadis: the magma of social imaginary significations

Social imaginary significations

In his seminal work, The Imaginary Institution of Society, Castoriadis challenges the functionalist-economic causal explanations of the creation of institutions, arguing that the understanding of institutions cannot be limited to fulfilling a society's functional needs. He argues that society's needs are historically and culturally constructed and that societies invent and define new ways of fulfilling their needs or creating new ones. Besides functionalist-economic explanations, he claims that societies also get instituted in imaginary ways. Institutions contain, all along, an imaginary part together with a functional part:

> The institution is a socially sanctioned, symbolic network in which a functional component and an imaginary component are combined in variable proportions and relations. (Castoriadis, 1975/1987, p. 132)

From this perspective, institutions are not abstract ideas discovered by society at any given time but, instead, are created each time by society, and are constantly under transformation through time. Castoriadis identifies the source of institutions in what he names *social imaginary*. This stands for the capacity each society has for creation. The *social imaginary* is this element

> which gives a specific orientation to every institutional system, which overdetermines the choice and the connections of symbolic networks, which is the creation of each historical period, its singular manner of living, of seeing and of conducting its own existence, its world, and its relations with this world, this originary structuring component, this central signifying-signified, the source of that which presents itself in every instance as an indisputable and undisputed meaning, the basis for articulating what does matter and what does not, the origin of the surplus of being of the objects of practical, affective and intellectual investment, whether individual or collective. (ibid., p. 145)

The *social imaginary* contains the *social imaginary significations*. The very existence of any society is interwoven with the creation of *social imaginary significations*. These hold together a society and answer fundamental questions the society poses to itself, its needs, and the world. Individuals (being always part of their society) incarnate or challenge the social imaginary significations of their societies. Castoriadis clarifies that *social imaginary significations* are *not* simply individual representations, ideas, or thoughts, but something much deeper which links

to the society, the individual, and even the *psyche*/soul. These form an integral part of what makes individuals members of society by all different means – from social learning to conflict:

> Significations *are* obviously not *what* individuals represent to themselves, consciously or unconsciously, or *what* they think. They are that by means of which and on the basis of which individuals are formed as social individuals, capable of participating in social doing and representing/saying, capable of representing, acting, thinking in a compatible, coherent, convergent manner, even if this be in the form of conflict. (ibid., p. 366)

Elsewhere, in the collection The Rising Tide of Insignificancy (texts: The Greek and the Modern Political Imaginary, and Culture in a Democratic Society), Castoriadis insists on the deep and complex theorisation of the social imaginary significations, and distinguishes a threefold role, which refers to representations, desires (or finalities), and affects:

> The role of these social imaginary significations […] is threefold. They are what structure the *representations* of the world in general, without which there can be no human beings. […] Second, these significations designate the *finalities* or ends of action; they dictate what is to be done and not to be done, what is good to do and not good to do. […] Thirdly, and it is this point that is undoubtedly the most difficult to discern, these significations establish the types of *affects* that are characteristic of a society (Castoriadis, 1996/2022, pp. 167-8).
>
> Signification […] is not a simple matter of ideas or representations, for it must gather together – bind in a form – representation, desire, and affect. (ibid., p. 272)

Subsequently, understanding a society's *social imaginary significations* is key to understanding society itself and its institutions. In different societies and times, social imaginary significations are different. This means that even similar institutions may have a different meaning as they link to different significations:

> Apparently similar 'institutions' can be radically other, since, immersed in another society, they are caught up in other significations. (Castoriadis, 1975/1987, p. 368)

For instance, when writing about capitalism in Western societies, Castoriadis identifies the centrality of the economic imaginary signification (ibid., p. 363). The institution of a capitalist society provides that *commodity* becomes an imaginary signification of crucial importance. As stated in Anthropology, Philosophy, Politics (The Rising Tide of Insignificancy):

> No one has ever seen a commodity: one can see a car, a kilo of bananas, a meter of fabric. It is the social imaginary signification commodity that makes these objects function in a commercial society. (Castoriadis, 1996/2022, p. 151)

The economic imaginary signification of the commodity links to capitalist *affects* such as the 'perpetual restlessness, constant change, a thirst for the new for the sake of the new and for more for the sake of more (ibid. 169). Nonetheless, although dominant, the economic signification is not the only one. In The Crisis of the Identification Process (The Rising Tide of Insignificancy), Castoriadis identifies two central significations that are in principle *antinomical* to each other: the capitalist, economic signification on the one hand, and, on the other, the signification of individual and social autonomy:

> On the one hand, there is the signification of the unlimited expansion of an allegedly rational alleged mastery over everything, nature as well as human beings. This signification corresponds to the capitalist dimension of modern societies. On the other hand, there is the signification of individual and social autonomy, of freedom, of the search of forms of collective freedom, which correspond to the democratic, emancipatory, revolutionary project. (ibid., p. 171)

At the same time, every society maintains the capacity to creation: *radical imagination* and the *social imaginary*, which is again theorised in ontological and psychanalytic terms:

> There is the radical imagination of the psyche – namely, perpetual upsurge of a flux of representations, of affects, and of desires, all three indissociable each from the others. (ibid., p. 145)

In turn, the notions of *radical imagination* and the *social imaginary*, along with the *antinomical* significations and conflict, the representations, the desires, the affects, and the idea of *autonomy* can further be elucidated through the notion of *magmas*.

> Every society creates its own world in creating the significations that are specific to it. Indeed, it creates a magma of significations. (ibid., p. 167)

The logic of magmas

Castoriadis introduces the notion of *magma* in The Imaginary Institution of Society. Although the term is mentioned earlier in the book, in the final chapter named Social Imaginary Significations (section i, The Magmas), he expresses his will 'to go beyond merely negative ontology and open up a path (or several paths) in order to think what is without confining ourselves to saying how it is not be thought' (Castoriadis, 1975/1987, p. 340). He then provides a theoretical conception of the magma:

> A magma is that from which one can extract (or in which one can construct) an indefinite number of ensemblist organizations but which can never be reconstituted (ideally) by a (finite or infinite) ensemblist composition of these organizations. (ibid., p. 343)

We can here mark some values of the magma, such as ontological positivity, openness, and indetermination. Another value he insists on is *multiplicity*. In that case, multiplicity is not conceived as a sum of singularities but rather as constituents inextricably assembled, interwoven, or bundled together:

> We have to think of a multiplicity which is not one in the received sense of the term but which we mark out as such, and which is not a multiplicity in the sense that we could actually or virtually enumerate what it 'contains' but in which we mark out in each case terms which are not absolutely jumbled together. Or, we might think of an indefinite number of terms, which may possibly change, assembled together by an optionally transitive pre-relation (referral); or of the holding-together of distinct-indistinct components of a manifold; or, again, of an indefinitely blurred bundle of conjunctive fabrics, made up of different cloths and yet homogeneous, everywhere studded with virtual and evanescent singularities. (ibid., p. 344)

In another point, Castoriadis explains his choice to employ magma as a metaphor, thus bringing to the fore values such as motility, liquidity, contingency, impetus, and alternation:

> [In the magma] there are flows that are denser, nodal points, clearer or darker areas, bits of rock caught in the whole. But the magma never ceases to move, to swell and to subside, to liquify what was solid and to solidify what was almost inexistent. (ibid., p. 244)

In a later piece of his work, The Logic of Magmas and the Question of Autonomy, Castoriadis (1983/1997) revisits the notion of magmas. He underlines the different logic that magmas have in relation to ensemble theory and mentions initial experimentations with other terms such as cluster [amas] and conglomerate before concluding with *magma*. He then specifically defines magma by the five following properties (ibid., p. 297):

Properties of magmas

M1	If M is a magma, one can mark, in M, an indefinite number of ensembles
M2	If M is a magma, one can mark, in M, magmas other than M
M3	If M is a magma, M cannot be partitioned into magmas
M4	If M is a magma, every decomposition of M into ensembles leaves a magma as residue
M5	What is not a magma is an ensemble or is nothing

Source: Castoriadis, 1983/1997, p. 297

Derivative values from these properties are, respectively, an 'indefinite potentiality', an 'inexhaustibility of modes of being (and of types of organisation)', an 'impossibility of separation', and an 'inexhaustibility of decomposability' (ibid., pp. 297-8). Among them, Castoriadis marks as most important and decisive property M3, namely that a separation of a magma is impossible and irrelevant. Two more theorisations are of particular interest to this paper. First, the 'absolutely universal' theorisation of magmas, which allows us to think about how the logic of magmas can apply to different epistemological fields and contexts: 'We can call magmatic every non-ensemblistic-identitary mode of being/mode of organization that we encounter or can think of' (ibid., p. 298). Second, the persistent clarification that the magma's indetermination is not a 'state of ignorance' or a 'statistical situation' but a possibility for creation:

> No state of being is such that it renders impossible the emergence of other determinations than those already existing. […] It is creation, namely, emergence of other determinations, new laws, new domains of lawfulness. (ibid., p. 308)

The quest for 'the new' and for 'creation' is crucial for Castoriadis and allows for political connotations. What becomes evident is that the notion of *magma* has a profound *political* content, which links to *radical imagination* and the *imaginary institution of society*. A central argument, which comes back in various wordings throughout Castoriadis's work, links *magma* to the *social imaginary significations* and the institution of society/the world. From this perspective, the *magma of social imaginary significations* is inextricably interwoven with the *doing* (*ποιείν/πράττειν*) and the *representing/saying* (*παριστάνειν/λέγειν*) of any given society, feeding pretty much everything from the soul and personal existence and behaviours to social cohesion and law legitimacy.

> The institution of society is what it is and as it is to the extent that it 'materializes' a magma of social imaginary significations, in reference to which individuals and objects

> alone can be grasped and even simply exist. Nor can this magma be spoken of in isolation from the individuals and the objects that it brings into being'. (Castoriadis, 1975/1987, p. 356)
>
> The institution of society is in each case the institution of a magma of social imaginary significations, which can and must call a world of significations. (ibid., p. 359)

Castoriadis' notion of the society's institution refers to processes of continuous transformation through complex and unequal social dynamics and 'an undetermined number of particular ends' which moves on implicitly and is not overdetermined by any superior structure or power – although sometimes perceived as such:

> The institution operates implicitly, is intended as such by no one, is realized through the pursuit of an undetermined number of particular ends, which are present and can be presented only in the social sphere, […] which subsequently prove to be overdetermined by this central signification, in the process of being instituted. The latter thus allows itself to be grasped, after the fact, as the non-real condition of the real coexistence of social phenomena. (ibid., pp. 363-4)

Within this philosophical universe, Castoriadis develops the idea of *autonomy*,[2] adding a distinct thread to similar theorisations within philosophy and political science. Although an approach of Castoriadis's idea on social and individual autonomy falls out of the scope of this paper,[3] I am interested in marking *autonomy*'s connection to *magma*. It is through the notion of *magma* Castoriadis enters the concluding chapter of the Imaginary Institution of Society to introduce the concepts of a *radical imaginary* and an *instituting society* – namely an *autonomous* society that institutes itself. In the ending sentence of his seminal book, he writes:

> The self-transformation of society concerns social doing – and so also politics, in the profound sense of the term – the doing of men and women in society, and nothing else. Of this, thoughtful doing, and political thinking – society's thinking as making itself – is one essential component. (ibid., p. 373)

This idea of autonomy is necessarily democratic, tragically risky, and essentially political. Autonomy is an 'opening', rather than a closure,

> a 'radical rupture, an ontological creation, the emergence of societies that put into question their own institutions and significations – their 'organization' in the most profound sense of the term. (Castoriadis, 1983/1997, p. 310)

The notion of a free and reflective society that *creates* its own institutions through *radical imagination* is central to Castoriadis's idea of *autonomy* and the notion of *magma*. Castoriadis names this radical, revolutionary notion of autonomy as *self-institution* (*αυτοθέσμιση*), *self-constitution* (*αυτοσυγκρότηση*), or *self-transformation* (*αυτομεταχσηματισμός*), in opposition to *heteronomy* and beyond the notion of *self-organisation* (*αυτό-οργάνωση*). What I want to stress is that the conception of a self-instituting, autonomous society is possible precisely because its institution materialises a *magma* with all these values mentioned above: 'indefinite

[2] Coming from the Greek word αυτονομία=autonomy and αυτόνομος=autonomous [αυτό/auto=self and νόμος/nomos=law], meaning one who has/makes their own law.
[3] Castoriadis is frequently mentioned as the 'philosopher of autonomy'. See: Kioupkiolis, 2012.

potentiality', 'inexhaustibility of modes of being (and of types of organisation)', 'impossibility of separation', multiplicity, indetermination, and so on. This point serves as the connecting link to issues of planning.

Selective influences on planning theory

Castoriadis's thought has been distinctively influential in various disciplines and social fields, academia, and activism, even to those interested in space and planning. Ideas about space, place, and the *City* (Polis) can be found in various parts of his work. For instance, in the subchapter The Philosophical Institution of Time/The Social Historical in The Imaginary Institution of Society, he theorised space as inseparable from time and rejected any philosophical distinction between them. For him, an important attribute of space is *difference*: 'If there were no *place*, not *topos*, how could what is different exist?' (Castoriadis, 1975/1987, p. 191). And further on: 'Space is the possibility of the difference of the same from the same without which there is nothing at all' (ibid., p. 194). Moreover, in the part Polis of The Rising Tide of Insignificancy (among others), Castoriadis employed the notions of *political imaginary* as essentially interwoven with a democratic society and the political institution of the City, also bringing to the fore issues of public and private spheres, and citizenship, having as reference the Athenian classical democracy.

Although Castoriadis's concerns were far from planning theory and his work does not directly mention planning, influences from his work can be traced down to various planning contexts and traditions. Jean Hillier (2005, p. 276) recognised Castoriadian thought among theories that 'have been rooted in what are fundamentally transcendent notions' along with those of Habermas, Lacan, Zizek, and Lefebvre). In Latin American contexts, a body of literature has found inspiration in the concepts of *social imaginary* and *autonomy* to explore the prospects of autonomist urban planning and management. Marcelo Lopes de Souza (2000) links these notions to examples of radical urban management, conflictual decision-making, and participatory budgeting in Brazil. Alexandre Bomfin (2019) turns to Castoriadis's idea of radical imagination to discuss the notion of a 'spatial imaginary'.

In South-European contexts, architect-planner Maria Mantouvalou – herself part of Castoriadis's social circle in Paris and Athens – has introduced Castoriadian ideas in her (Greek-language) work. In a text about the problematics of city centres, social inequality, and cultural difference, Mantouvalou (1996) employed Castoriadis's threefold distinction of public and private spheres, namely the Athenian *oikos* (private sphere), the *agora* (private/public sphere), and the *ekklesia* (public sphere) (Democracy as Procedure and Democracy as a Regime from The Rising Tide of Insignificancy), to discuss the changing socio-spatial organisation and public-private relations in European city centres. From a South-European perspective, she subsequently, advocated for urban policies and planning that maintain and foster social diversity/difference and cultural heterogeneity.

In her more recent text, Institutions, 'Overturns', and Stakes of Spatial Planning (2020), Mantouvalou further implies two connections between planning and Castoriadian thought. The first builds on the discussion on *institutions,* emphasising the catalytical influence planning may have on everyday life, ideas, social values, perceptions, cultures, administration, and institutions – in the broader sense. In times of neoliberal globalisation and the dominance of the capitalist social imaginary, she theorises spatial planning and planning reforms as a catalyst to wider institutional overturns and broader social changes (namely the neoliberal institution of the society), as entwined to factors that contribute to a continuous process of educating, changing, and transforming people and their relations. The second one reflects on the notion of

magma of social imaginary significations and reads it in parallel to the notion of *palimpsest* (a concept also used in urban design and planning), which links to values of multiplicity, diversity, co-existence, openness, and interweaves individuals and groups with particular places, social-historical layers, and social imaginary significations. She claims that the notion of planning as a *magma of social imaginary* significations highlights the political dimension of planning and brings to the fore social dynamics that either work together or are in conflict with each other. The magma ought to be understood along with the notion of creation and may elucidate the need for critical and reflective actions and the perspectives of the potentially new.

In dialogue with Mantouvalou's theorisations, I explored how the Castoriadian thought may enrich our understanding of spatial planning and institutions (Triantis, 2020a). I examined planning transitions in a post-socialist East European context, by focusing on fieldwork in Albania as a paradigmatic case study, to explore the interrelations of changing planning cultures and practices with institutions, social dynamics, and the production of space. I then attempted to summarise my research findings and theorise about planning in the era of neoliberal globalisation by reflecting on the work of Cornelius Castoriadis. My research particularly discussed the changing *social imaginary significations* of the post-socialist era. As became evident, the 'restitution' of private property, privatisations, the prevalence of exchange values, and the penetration of free market relations tended to render the *commodity* and *private property* as social imaginary significations of supreme value, guiding the transition towards the capitalist, neoliberal institution of society (Triantis, 2018). Various social and cultural norms and settings got destabilised: land and property relations, land use, organisation and management, the public and the private, what is socially accepted and what is not, individual and collective affects, needs, and desires, social problems and objectives, the very meaning of family and kinship, state, economy, and labour – all the above were changing in the whirl of the transition. At the same time, new significations were created (e.g. growth, competitiveness, entrepreneurship, development, consumption), and new social subjects were being formed, also shaped through trans-local networks of communication, information, technology, education, migration, and labour. These have been significant qualitative changes between space and society (Triantis 2020b), supported by institutional reforms but, in fact, referring to broader institutional transitions.

In this troubling, transitional context, spatial planning emerged as a contested field and a stake in institutional reforms and overturns. Understanding spatial planning as *magma*, following the Castoriadian thought, meant going far beyond planning reforms, the making of laws and administrative frameworks. This meant understanding planning as a dynamic, inseparable, indefinite, indeterminate, and inexhaustible entity of global trends and local particularities, discourses, perceptions, experiences, social dynamics, formal and informal practices, governance patterns, power relations, formal institutional settings and unwritten laws, customs, and relations of trust, and imaginary significations – along with their social and historical layers and in time and fragments from past eras. Within this magmatic condition, planning was understood, on the one hand, to virtually normalise – *in terms of normativity and normality* (Triantis, 2020a) – capitalist, neoliberal imaginary significations around land and property development along with broader and deeper social and institutional transformations. On the other hand, this magma contained contradictions across different geographical scales that permeated policies, perceptions, and social practices also including planning alternatives: From informality or conflict to critical reflection and the creative challenging of dominant imaginary significations.

Suggestions on the imaginary institution of planning

I will conclude with two suggestions that attempt to link the selective reading of Castoriadis's work on The Imaginary Institution of Society to planning theory. If we admit that planning is an institution, we may follow the Castoriadian thought to argue that, pretty much like other institutions, planning is instituted in imaginary ways. As should be noted, these are initial thoughts that would require further elaboration.

Suggestion 1: Revisiting planning imaginary significations

As academic literature has shown, planning is an institutional apparatus that links to diversified values and imaginaries (Gunder, Madanipour, and Watson, 2018a). In countries of the West during the post-war era of the 20th century, planning was intertwined with the Keynsian welfare state, redistributive policies, liberal democracies, and centralised state authority, and imaginary significations of modernisation, rationality, scientific efficiency, productivity, order, gendered divisions and social stratifications. Planning in the former socialist countries of the East formed an integral part of centralised economic programming and bureaucratic state authority, much more due to the limitations on private property. It was entwined with imaginary significations quite similar to the Western ones, while also associated with state provision and socialist ideas of equality, and social justice. Planning in formerly colonised countries of the South was assembled with colonial oppression, racial discrimination, orientalism, the transfer of Western institutional settings, and the imaginaries of Westernisation, modernisation, rationalisation, and Europeanisation.

In the era of globalisation, spatial planning emerged as a dominant planning paradigm, coined with neoliberal, capitalist imaginary significations of the commodity and the private property as supreme values, privatism, commodification, free market growth, consumption of natural resources, entrepreneurship, and competitiveness (Cahill *et al.*, 2018; Dardot and Laval, 2010/2017). Planning became a 'carrier' of neoliberal agendas (Davoudi, 2018), by introducing a neoliberal ideology and ethos through tools like public land privatisations, laissez-faire policies, city marketing, Urban Development Projects (UDPs), Public-Private Partnerships (PPPs), and entrepreneurial spatial management (Baeten, 2018), gradually transplanted across the globe. In this neoliberal context, spatial planning has often normalised certain principles, objectives, typologies, and modes of spatial organisation, development, and governance, along with commodity relations and the economic imaginary significations with which these are interwoven (Triantis, 2020a). This normalisation has been twofold. First, in terms of *normativity*, as spatial planning shapes rules, development, and building regulations and restrictions, it often translates to binding or guiding policies, legal documents, and maps. Second, in terms of *normality*, as spatial planning tends to create norms that serve as socially accepted principles, values, and standards for the organisation, development, and management of space. In this way, spatial planning contributes to the gradual change of deeper relationships between space and society, its representations, desires, and affects. To paraphrase Margaret Thatcher's infamous saying about economics: Planning could be a 'method; the object is to change the heart and soul'.

Yet, in the 21st century, threads of theory and practice question the legacies of this post-modernist, post-colonial, post-socialist, and profoundly neoliberal world. Suggestions to decolonise planning imagination (Miraftab, 2018), feminist and queer approaches, ecological and post-human theorisations, and also post-neoliberal manifestos like *Common* (Dardot and Laval 2019), *Care* (Care Collective, 2020), and a Green Democratic Revolution (Mouffe, 2022) open up new horizons to planning theory and practice. Following Castoriadis's notion of *social imaginary significations*, these 21st-century evolutions can be understood to be in principle *antinomical* to dominant neoliberal planning paradigms. From this standpoint, we could revisit

planning imaginary significations, in terms of representations, desires, and affects. Such an approach would possibly open up several paths to autonomous creation – doing, and thinking – in the Castoriadian magmatic sense of radical imagination and democratic self-transformation.

Suggestion 2: Planning as magma

Since the end of the 20th century, in much of Europe and other parts of the world, ideas about communicative and collaborative planning (Healey, 1997) have had a major impact on planning theory and practice. By drawing on Jürgen Habermas's notion of *deliberative democracy*, they were focusing on consensus building, the reconciliation of diverging agendas, the democratisation of planning processes, and the promotion of citizen participation. More recently, these theories have received criticism, which questioned the meaning and content of consensus insofar as this ignored power relations, exclusions, and structural limitations. Today, in times of multiple crises, armed conflict, rapid digital and material transformations, and a plurality of truths on the internet and social media, planning meets the challenges of goals and orientation, social legitimacy, post-truth validity, and multiple methodological and epistemological biases (Davy, Levin-Keitel, and Sielker, 2023). In post-colonial, global South contexts, and elsewhere, notions of *insurgent planning* and *insurgent citizenship* (Holston, 2008; Miraftab, 2018; Watson, 2012; Swyngedouw, 2018)) have explored alternatives of radical planning practices and new paradigms of citizenship which could be counter-hegemonic, transgressive, inclusive, emancipatory, and imaginative (Miraftab, 2009). Other threads of planning theory have turned to the thought of political theorists and philosophers like Alain Badiou, Ernesto Laclau, Chantal Mouffe, and Jacques Rancière to discuss neoliberal planning and governance as depoliticised, *post-political*, and *post-democratic* (Davoudi, 2018; Swyngedouw, 2018). A distinct thread (Metzger, 2018; Ploger, 2018) has specifically found inspiration in the work of Chantal Mouffe. Beyond the critique on consensus building and the post-political condition, these theorists have drawn attention to Mouffe's suggestions towards a democratically productive *agonism*, *agonistic pluralism*, a *conflictual consensus*, or a conflict-oriented model of radical democracy.

These notions of agonism, conflict, insurgency, and emancipation in a 'world struggling with a lack of consensus' (Davy, Levin-Keitel, Sielker, 2023, p. 2) can be understood as supportive of a need to *re-politicise* planning and bring us back to Castoriadis's political notion of *magma of social imaginary significations*. Castoriadis's logic of *magma* constitutes an open-ended path of thinking and doing with political connotations. Planning as a *magma* responds to an indeterminate, infinite, inexhaustible multiplicity of interwoven elements: ideas, discourses, perceptions, politics, social dynamics and practices, processes, and politics, from the local to the global level. It is much broader than laws, plans, and administrative frameworks. The elements that constitute the *magma* are not stable or equal; they do not hold the same power or significance and do not necessarily coexist in balance. They are bundled with power relations and unequal social dynamics; they contain contrasts and contradictions, contingencies, tensions, or even conflicts.

Interestingly enough, Mouffe (2022) recalls Castoriadis's notion of the *social imaginary significations* to develop her argument on the power of common *affects* and *passions* and the necessity of *identification politics* for what she names the 'green democratic revolution'. She acknowledges the critical affectual power of the democratic social and political imaginary, and she claims that ideas need to connect to what Castoriadis calls *social imaginary significations* to wake up affects that fuel politicisation and urge people to act. To understand planning as *magma* refers to an open-to-change scheme in which we can identify certain characteristics but

cannot prescribe its future course. Although influenced by dominant actors or power structures, it is not necessarily predetermined by them. It is rather created within social reality through multiple, complex, heterogeneous, and unequal social dynamics, being consensual or conflictual. Understanding planning as magma elucidates its political dimensions, which are inherent in (and constitutive of) democratic conditions. It further creates conditions for self-transformation through critical self-reflection, self-constitution (as *autonomy* rather than *heteronomy*) radical imagination, political thinking, and doing.

Conclusion

In this paper, I tried to show that the work of Cornelius Castoriadis can critically enrich our understanding of planning at a juncture of major transitions, unprecedented global urbanisation, multiple crises, and conflict. In a post-modernist, post-socialist, post-colonial, and profoundly neoliberal world we can rethink planning theories and practices as inextricably intertwined with institutions, broader ideas and conceptualisations, social dynamics, as well as different experiences of countries and regions across the globe. Castoriadis's notion of *magma* speaks of a dynamic and indefinite universe of *social imaginary significations*, which shapes on a case-by-case basis the institution of society with unique characteristics relevant to representations, desires, finalities, and affects. *Planning as magma* goes beyond plans, legal frameworks, administrative processes, and professional practices. It constitutes an open-to-change, under constant transformation, incremental, and complex outcome of multiple, heterogeneous, unequal, yet interconnected, interwoven dynamics: imaginaries, ideas, concepts, policies, social dynamics, and practices, which either work together or confront each other. This highlights the political dimensions of planning as thinking and doing. Derivative values such as indetermination, infinite potentiality, inexhaustibility of modes of being and types of organisation, multiplicity, difference, and vigorousness may open up future alternatives of creative questioning of norms and assumptions, self-reflection, self-determination, and radical imagination. In times of poly-crisis and perma-crisis, rapid global urbanisation, climate vulnerability, rising inequalities, and neoliberal governmentalities, to think of institutional change and institutions (in the most profound sense of the term) means challenging dominant planning imaginaries and paradigms. Planning as magma means to elucidate values, goals, and orientations, to conceive inclusive, post-colonial, feminist, post-human imaginary significations, and to constitute methodologies, epistemologies, policies, and practices, opening up a horizon of alternatives toward sustainability and justice.

Elli Papastergiou (https://orcid.org/0009-0000-3477-7633) is a Ph.D. candidate at the School of Spatial Planning and Development, Faculty of Engineering, AUTh. She holds a Diploma (MEng) in Spatial Planning and Development Engineering and an MSc in Spatial Planning for Sustainable and Resilient Development from the same institution. Her research focuses on subjective well-being in contemporary urban environments, quality of life and socio-psychological dimensions of urban space. Additionally, she is dedicated to sustainable and resilient urban development, with her Ph.D. research, which exploring the impact of urban green spaces on well-being. In 2022-2023, she served as a visiting Ph.D. student at Northeastern University in Boston, supported by Marie Skłodowska-Curie Doctoral Fellowship (TREnD Project, Horizon 2022 EU Program).

Dr. Athanasios Kalogeresis (https://orcid.org/0000-0003-2421-6925) is Associate Professor at the School of Spatial Planning and Development, Faculty of Engineering, Aristotle University of Thessaloniki, where he teaches economic geography, urban and regional development, and globalization. His research interests and recent work evolve around two main themes, namely, local and regional development and various aspects of the organization of production (spatial, social, institutional and cultural). Within these broad themes, he has worked and published in several specific areas, such as small and micro entrepreneurship; the creative economy; the analysis of new forms of (multinational) organization of economic activities; the role of multinational production and trade in knowledge spillovers; relations between international and local productive systems, the sources of regional disparities and the role of human capital and human capabilities.

Dr. Georgia Pozoukidou (https://orcid.org/0000-0002-8497-0420) is an Associate Professor of Urban Planning, Policies and Land Use Models, Faculty of Engineering at the Aristotle University of Thessaloniki, Greece. She holds an engineering degree in Spatial Planning and Regional Development (University of Thessaly, GR). Before her appointment as a faculty member, she worked in the private and public sectors in the USA and Greece, gaining significant experience on the issues of land use planning, urban modeling, protection and management of the natural and cultural landscapes, as well as participatory planning practices. Her scientific interests focus on spatial planning with emphasis on spatial models and the use of quantitative methods to understand land-use transport interactions. Most recently she has been exploring the idea of 15-minute city and cities of proximities as an alternative narrative to the dominant mobility oriented urban development strategies. She has published more than 70 scientific papers.

Abstract

This paper explores the relationships between place and subjective well-being. Despite the substantial growth in studies on this topic across multiple disciplines, there is still a long road ahead for urban planning theory. This work introduces a novel conceptual framework that illustrates in a structured manner the interrelations between place and subjective well-being, uncovering the mediating role of sense of place and highlighting the transformative potential of micro- and small-sized businesses in shaping urban neighbourhoods' sense of place. The study emphasizes the significance of understanding subjective well-being at the neighbourhood scale for informed urban planning and policy making, contributing to the theoretical discourse on people-place relations.

Keywords: subjective well-being; neighbourhood; sense of place; social well-being; micro and small-sized businesses

1. Introduction

People and places are inseparable. Gifford (2014, p. 543) argues that an individual's whole life is interlaced with a place; "we are always nested within layers of place." This complex and dynamic relationship has bidirectional links: places are shaped by people, while where individuals spend their time shapes them (Ballas, 2021; Gifford, 2014; Healey, 2005; Stephenson, 2010). According to Gehl (2010, p. 9), "First we shape the cities – then they shape us."

The first part of this process (people shaping places) is often visible and direct. Consider this hypothetical scenario: one morning, you pass by a street that rarely crosses your path, a degraded district in the city. A few decades ago, several stores related to garment production would pile up here, and people would walk down the street. However, those days belong to the past. Today, this area is soulless and filled with shutdown stores, a void in the periphery of some busy streets. A month later, your journey takes you down this street again -it's always morning; as soon as the sun sets, you do not even think of passing from here. A pleasant change catches your eye: a pizzeria operates in one of the corners. Two people -most likely employees- are standing outside the store, chatting beside a couple of food counters decorated with a few flowers. A few weeks later, you return to the street with a couple of friends. This time, a crowd is enjoying their pizza, music is playing in the background, and people are chatting and laughing. This is not the gloomy street you used to know, and you notice that a handmade jewellery store has popped up across the street. This simple narrative underlines one of the many ways people may transform a place, change its meaning, and redefine an area's milieu.

On the contrary, how places shape people may be more difficult to comprehend. Often, these effects might be indirect, invisible or it might take time to show. The interaction between people and places may take multiple forms and be determined by numerous factors. Moreover, the experience and perception of this interaction may vary among individuals or social groups (Relph, 1976; Tuan, 1975), making it highly subjective. In recent years, the impact of place on people's subjective well-being (SWB) is increasingly recognized (Aslam and Corrado, 2012; Ballas and Dorling, 2013; Morrison, 2007). Fleury-Bahi et al. (2017) suggest that a person's satisfaction, expectations, and hopes, as well as frustrations and experiences, vary along urban contexts. Similarly, Ballas (2021) argues that the level of SWB is affected by the dynamics developed between personal circumstances, social interrelations, and geographical characteristics in proximity.

Exploring the relations between people and places within the urban setting is -or should be- at the limelight of the urban planning and development field. Yet, for years, the people dimension received limited attention (Gehl, 2010; Stephenson, 2010). Traditionally, the spatial dimension of subjective well-being, the focus of the herein study, has been overlooked (Morrison, 2007). Only recently have studies started to investigate this relationship, while only a paucity of these interweave the discussion simultaneously around the constructs of place, sense of place, and subjective well-being (Erfani, 2022). Ergo, there is an opportunity to delve deeper into the nuances of people-place relations. As we live at the peak of the urban era, we argue that investigating subjective well-being within the framework of cities, specifically the neighbourhood scale, is considered crucial for urban planning theory, applications, and policy making.

This paper investigates the relationships between place and subjective well-being. The theory synthesis methodology is adopted (Jaakkola, 2020), aiming to articulate the links and propose new relationships among these constructs. The relevant literature streams are critically reviewed, unravelling the key components of the concepts that allow the identification of common grounds. In attempting to achieve integration across the theories, concepts are being decomposed and re-approached through new theoretical lenses. The domain theory in this paper is subjective well-being. The method theories relate to the themes of place, sense of place, and micro- and small-sized businesses (MSBs) as components of the urban landscape. Despite today's expanded connectivity between people, we focus on the urban neighbourhood scale, as it remains the immediate socio-spatial context for most individuals (Agnew and Duncan, 1989).

More precisely, we explore the interrelations among the constructs of urban *'place'* and *'subjective well-being'* -we argue that the former impacts the latter*, 'sense of place'* -we argue that it has a mediating role in the aforementioned relationship- and *the role that MSBs play* -we argue that they have transformative potentials in developing sense of place at the neighbourhood level. The study introduces a conceptual framework, synthesizing and theorizing previously unconnected pieces of knowledge. Therefore, this work is expected to contribute to theoretical debates, expanding the frontiers of knowledge related to people-place relations and stimulating debates on the role of MSBs in urban form and development. It is expected to shed light on the spatial dimensions of SWB in cities, and ultimately facilitate planning and development processes and outcomes. The ethos guiding this endeavour is reflected in Jane Jacobs' 1958 article "Downtown is for People": "There is no logic that can be superimposed on the city; people make it, and it is to them, not buildings, that we must fit our plans." (Jacobs, 1958, p. 127).

2. From 'Space' to 'Place'

The notion of *'place'* became central to geography and urban studies during the 1970s. The perceptible difference between abstract space and the specific place is the meaning that people ascribe to the former, thus, transforming it into the latter. A 'meaningful location' could also be an alternative description for place. According to Cresswell (2004, p. 7), these are the locations that people are "attached to in one way or another", embodying their relationships with the world. Agnew (1987) argues that every space interpreted as a meaningful location is constructed by three structural elements: (a) *'location'*, i.e., where the place is; (b) *'locale'*, i.e., its palpable dimension where social activities develop; and (c) *'sense of place'*, which he interprets as the subjective and emotional attachment with a place. Locations exceed their tangible dimension and gain meaning when people give them names, identify them, and represent them (Cresswell,

2004; Gieryn, 2000). Thus, places are recognized in terms of their physical elements, but they also have a social and a psychological dimension as they can be "interpreted, narrated, perceived, felt, understood and imagined" (Soja, 1996, cites Gieryn, 2000). As Casey underscores, a "place brings with it the very elements sheared off in the planiformity of site: identity, character, nuance, history" (Casey, 1997, p. 14).

Cities, the "centers of meaning" according to Tuan (1975, p. 156), perfectly embody the concept of place as they are possibly the only environments created exclusively for human use. The motivation driving their development is the organization and facilitation of people's everyday lives. Cities are formed by smaller scale units, the neighbourhoods. This construction is considered one of the most important scales of research and intervention in urban studies and other place-related disciplines, constituting the "optimal level of abstraction" (Lewicka, 2011, p. 212). This is evident as a great amount of research related to people-place themes refers to the neighbourhood scale (Giuliani, 2003; Hidalgo and Hernández, 2001; Lewicka, 2011, 2010). According to Hallman, "a neighborhood is a limited territory within a larger urban area where people inhabit dwellings and interact socially" (Hallman, 1984, p. 3). Lee et al. define them as "social constructions named and bounded differently by numerous and diverse individuals" (Lee et al., 1994, p. 252). The above approaches imply that in neighbourhoods we found social connections and networks, attributes inherent also to the notion of community (Chaskin, 1997).

Accordingly, when hearing the word *'community'*, most people possibly understand that it refers to a concept incorporating a territorial dimension (i.e., the built and natural environment, but not limited to that), a social dimension (i.e., the people who live, work or are active in this setting), as well as the ongoing interactions between these two (i.e., the links, flows, and networks that develop) and the processes of collective actions (Farmer et al., 2016; Wilkinson, 1991). In fact, according to most definitions, three basic assumptions must apply to refer to a human community: first of all, it requires a group of people who are involved in interactive activities; second, these activities are expected to take place within the framework of a geographic territory; and third, often enough the involved people share some common values, beliefs or behaviours (Hillery, 1955). Even though the notion of community can be variously interpreted and understood, especially as we currently live in a globalized and virtually interrelated world that could situate the territorial element under dispute, it is our strong belief that the territorial dimension is present in every kind of human communities, even if not perceived in a traditional fashion.

Synthesizing the above, the current study approaches the *'neighbourhood'* as a concept that denotes *proximity*, *compositionality*, and *community*. *Proximity* is a spatial dimension that can be understood in both objective and perceived terms. The term *compositionality* reflects the unique mosaic of a neighbourhood where the "juxtaposition of the dissonant" (Massey, 1997, p. 213) and the similarities co-exist. It may refer to a variety of things, including the built and natural environment (e.g., the architectural style and infrastructures, the environmental characteristics, etc.), and the socio-economic environment (e.g., the demographic composition, the accessibility to jobs and services, the social networks and the alterity). It may also refer to the cultural or intellectual composition or other identity-related characteristics that infilter a place, as well as the composition of different narratives about it. The *community* represents the dynamic entity of people that formulates through the ongoing social interactions, the networks, and the flows formatted while at a place and in interaction with the place itself. The neighbourhood can often be experienced differently, at different times by different individuals or social groups.

3. Exploring Sense of Place

As mentioned above, the concept of *'sense of place'* is inextricably linked to the construct of a meaningful location, given that each place is related to people and their ability to produce and consume meaning individually and as communities. While an acknowledged phenomenon (Duggan et al., 2023), it remains a nebulous one as there is yet no universal consensus on the definition and theory behind it (Nelson et al., 2020; Williams, 2014), or whether there is meaning to measure it (Shamai, 1991). It could be loosely described as the multidimensional attitude people hold towards a place and the emotional bond they form with it (Guthey et al., 2014; Lewicka, 2011; Nelson et al., 2020; Rajala et al., 2020; Relph, 1976). Nonetheless, this remains a broad and abstract description of the concept. Despite its complexity, the dynamic and subjective nature of sense of place becomes apparent. It is anchored in the individual's and collective sensory and cognitive experiences and develops over time (Relph, 1976; Shamai, 1991) and in relation to time (Jackson, 1995). According to Tuan (1975, 1997) the experiential processes a person undergoes at and with a place serve as the paths for the development of emotional bonds with it. However, it is argued that sense of place is not limited to that.

Datel and Dingemans (1984, cites Shamai and Ilatov, 2005) emphasize that people, either consciously or unconsciously, ascribe to localities all sorts of complex meanings, symbolic representations, and attributes, and the amalgamation of all these represents sense of place. Entrikin (1997) and Eisenhauer et al. (2000) illustrate the mediating role of the cultural dimension in the experience of a place and the social phenomenon that it is, highlighting the impact of collective narratives in the formulation of sense of place. Often, it is not just an individual's experience but responds to a shared structure of feelings that are shaped and reshaped among groups and generations (Pred, 1983). As people change so does the way they make sense of place (Anderson, 2004). Following the approach of the social construct of space, some studies (Allen et al., 1998; Rose, 1995) argue that it is crafted through power and inequality. Considering that places can serve as means of inclusion and exclusion (Madanipour, 2015; McGregor and McConnachie, 1995), separating 'us' from 'others', the experience of a place and thus sense of place differentiates for 'us' and 'others'.

Sense of place is different from 'genius loci' – the spirit of place, though closely related. Genius loci denotes the character that a place has while sense refers to the perspectives and bonding a person develops about a place and its spirit (Meetiyagoda et al., 2024). At the other end of the spectrum, we find the concept of 'placelessness' introduced by Relph (1976). This concept represents the lack of any such bond with a place that, according to Relph (1976), is caused as a result of standardized landscapes that lack distinctiveness and authenticity and are subjugated by a homogenizing effect (e.g., suburbia). The intellectual discourse around the topic becomes quite perplexing as scholars often use the term sense of place interchangeably with that of place identity, place dependence, and place attachment (Duggan et al., 2023; Nelson et al., 2020). However, the recent literature recognizes them as three separate dimensions that clarify the essence of the overarching notion of sense of place and are often used to measure it (Domingues et al., 2021; Jorgensen and Stedman, 2001; Nanzer, 2004).

The concept of *'place identity'* was introduced during the 1970s in environmental psychology, defined as "a substructure of the self-identity of the person" (Proshansky et al., 1983, p. 59). According to Proshansky it is shaped in relation to people's physical environment and involves their "conscious and unconscious ideals, beliefs, preferences, feelings, values, goals, and behavioral tendencies and skills" (Proshansky, 1978, p. 155). This definition highlights the impact of a place's (and its attributes) interpretation on an individual's identity. Brown-Saracino

and Parker (2017) approaches it as "a collection of attributes or an identity assigned to a place, and as a collective self–understanding that rests on a particular locale". This stresses further the interplay between self-identity (or collective) and the perception of a particular place. Places may reflect a particular aspect of a person's (or a group's) identity (Anderson, 2004): given that an individual's self-identity develops around conscious (and subconscious) beliefs, interpretations, and evaluations of oneself, place identity constitutes an aspect of a person's identity (Nanzer, 2004). From the above emerges that place identity is found at the intersection between a person's (or group's) identity and the perceived understanding and interpretation of their surrounding environment. This convergence is the output of the experiences of a person (or a group) that involve interaction with a place. As the interaction changes the sense of place identity may change too (not necessarily in a positive way). At the neighbourhood scale, elements that may contribute to the formation of its identity could be the built and natural environment, the infrastructures, the residents, and their activities, as well as the meaning they produce, the institutions, and the commercial entities operating in the area, but also the memories and the narratives about the neighbourhood.

'Place dependence' responds to the more functional dimension of sense of place (Meetiyagoda et al., 2024). The notion reflects the connections and dependency developed with places on the basis of the activities, behaviours, and goals they facilitate (Jorgensen and Stedman, 2001; Stokols and Shumaker, 1982). Places are evaluated as important in accordance with the conditions they provide that enable and support these specific uses, goals, etc., and their ability to adequately provide these specific uses (Nanzer, 2004; Schreyer et al., 1981). Place dependence primarily focuses on whether a particular environment enables individuals to accomplish their objectives more effectively in comparison with known alternatives (Nanzer, 2004; Suntikul and Jachna, 2016). Inextricably this concept introduces comparability. To a degree, people's assessments of whether a place can support their choices and goals are made compared to other existing alternatives (Dameria et al., 2020; Nanzer, 2004; Stokols and Shumaker, 1982). Lastly, *'place attachment'* reflects the affective dimension of sense of place and constitutes a "complex, multifaceted concept" (Farnum et al., 2005, p. 3). According to Tuan, (1997, p. 159), "attachment of a deep though subconscious sort may come simply with familiarity and ease, with the assurance of nurture and security, with the memory of sounds and smells, of communal activities and homely pleasures accumulated over time". Low and Altman (1992), assert that place attachment is generated and maintained through interactions with the environment and affected by interconnected biological, environmental, psychological, and sociocultural processes. It may emerge individually or collectively through spending time in places and engaging in deeper local relationships (Bonaiuto et al., 1999; Cuba and Hummon, 1993; Suntikul and Jachna, 2016). Therefore, the length of residency influences the sense of place attachment (Bonaiuto et al., 1999).

4. Subjective Well-Being Beyond the Individual Level and the Impact of Place

Traditionally, subjective well-being (SWB) was appraised as an aspatial conception. However, multiple studies have challenged this view over the past decades, highlighting the role of place-related determinants (Aslam and Corrado, 2012; Ballas, 2013; Morrison, 2007). In fact, the inclusion of the spatial dimension in models has been found to enhance their explanatory power (Brereton et al., 2008; Oswald and Wu, 2010). According to Diener (2006), SWB encompasses all the different cognitive evaluations -positive and negative- people make over their life and its aspects, being an "umbrella term" that despite its "subjective" character its manifestations can be objectively observed. In the same fashion, the Organisation of Economic Co-operation and Development (OECD) argues that SWB is taken to be "good mental states, including all of

the various evaluations, positive and negative, that people make of their lives and the affective reactions of people to their experiences" (OECD, 2013, p. 10). OECD identifies demographics (including geographic information and urbanization), material conditions, quality of life indicators, and psychological dimensions as the broad categories of variables that could be impactful to the levels of one's well-being.

According to Manderson (2005), well-being is socially contingent, which implies a geographical dimension given that the immediate social context of people's lives is found in geographical proximity (Agnew and Duncan, 1989). Multiple efforts have been conducted to understand SWB beyond the individual level. Keyes (1998) referred to social well-being which is described as the perceptions of people related to the quality of their relationships with others, their neighbourhood, and their community. More recent literature identifies it as community well-being (CWB). According to Lee and Kim (2015), it refers to a group of people who are geographically linked. Often, they are the dwellers in a locality, such as a neighbourhood or a city, involved in direct or indirect interactions with each other (Lee and Kim, 2015). Whereas, one might assume that it is simply the aggregation of individual well-being assessments or simply a "sum of community and well-being" (Lee and Kim, 2015), social well-being is a multifaceted and complex construct. It captures individuals' well-being as nested within social and community contexts (Rollero and De Piccoli, 2010), incorporating numerous factors that can have a direct or indirect effect, while also impacting one another (Christakopoulou et al., 2001).

Chanan (2002, cites Lee et al., 2015, p. 2) highlights the complexity and abstraction that the notion involves:

> When community is identifiable with a locality, CWB/the quality of community life is intimately connected with: how well that locality is functioning; how well that locality is governed; how the services in that locality are operating; and how safe, pleasant and rewarding it feels to live in that locality.

Another indicative approach is that of Wiseman and Brasher (2008, p. 358), according to which community well-being is "the combination of social, economic, environmental, cultural, and political conditions identified by individuals and their communities as essential for them to flourish and fulfill their potential". This definition also emphasizes the contextual character of the notion defined by the population's evaluations and the place. Atkinson et al. (2017) argue that the conceptualization of community well-being must incorporate the experience of "being well together", i.e., the shared resources and experiences, that could include the provided services and the availability of public open spaces, the sense of safety and belonging, etc.

It becomes apparent that the concept is linked to a territorial dimension. However, only a scant of studies have investigated the connection between sense of place and subjective well-being beyond the individual level. Whereas, there are studies that indicate a connection between well-being and place influenced by the territorial sense of community (Albanesi et al., 2007; Cicognani et al., 2008) or place attachment (Afshar et al., 2017; Rollero and De Piccoli, 2010), there is still a long road ahead. Recently, there has been some effort in studying the links between sense of place and SWB (Li et al., 2023; Ng et al., 2022).

5. The Role of Micro- and Small-sized Businesses

It is universally acknowledged that micro- and small-sized businesses (MSBs) (together with medium-sized) constitute the 'backbone of the economy', representing around 90% of businesses, 60% of employment, and 50% of GDP at a global level, according to the World Trade Organization (2016). Apart from their role as drivers of economic development (Davidsson et al., 1995; Kuratko and LaFollette, 1987; Ribeiro-Soriano, 2017), they could also be described as cornerstones of the community and social life (Ayalu et al., 2022; Farmer et al., 2016; Fitzgerald and Muske, 2016; Ribeiro-Soriano, 2017). Additionally, the crucial role of MSBs in achieving the 2030 Agenda for SDGs has been identified by the United Nations General Assembly through adopting Resolution (A/71/279). The key idea underpinning this statement is that since MSBs and the networks of people involved, nurture and thrive within urban neighbourhoods, they inescapably contribute to shaping their visual and cultural identity while forming gathering places that enhance social bonds, capital, and resilience (NALCAB, 2019; Oldenburg, 1999).

Research suggests that when defining a neighbourhood's identity, its commercial character is equally, or even more (Felder and Pignolo, 2018), important to its residential qualities (Meltzer and Capperis, 2017). Being the "visible face of the neighborhood" (Zukin et al., 2016, p. 12), local MSBs have a fundamental role in driving the place's identity, but also reflecting it (Deener, 2007; Lloyd, 2010; Martucci, 2019). People often spend considerable time in businesses consuming products or services. This is particularly prevalent in locations with a shortage of public spaces appropriate for socializing (Gomez et al., 2015), adverse conditions (such as prolonged winter periods), or places where spending time in public spaces is not the norm. Consequently, they have a highly symbolic role as parts of the urban landscape. Local businesses contribute to residents' feeling of ownership (Martucci, 2019), generate a sense of familiarity and belonging (Duyvendak, 2011; Martucci, 2019), and add to the social and cultural capital of the neighbourhood (Fitzgerald and Muske, 2016; Oldenburg, 1999).

Further, Jacobs (1961) argues that local businesses are sources of safety and security in the neighbourhood ("eyes on the street") while Oldenburg (1999) places them at the heart of democratic participation and community vitality. Felder and Pignolo (2018, p. 98) concretely presented the essential role of local businesses in the neighbourhood: "shop's visible and concrete presence materializes the struggle over place identity". Their symbolic and highly important role within a neighbourhood is also reflected in the inclusion/exclusion regulatory power that businesses can have on a given street or area (Clark, 2003; Jacobs, 1961; Lamont and Molnár, 2002; Martucci, 2019; Zukin and Kosta, 2004). Messages are being communicated via aesthetic choices, prices, and the provided products, reflecting in that way specific lifestyle standards (Martucci, 2019). This results in excluding specific social groups from accessing the provided resources and opportunities in the given location (Clark, 2003; Lamont and Molnár, 2002; Zukin and Kosta, 2004). Additionally, the way MSBs are nested in the urban form, (e.g., pedestrian-oriented streets or drive to plazas or malls) also impacts the health and well-being of individuals (Gomez et al., 2015).

6. From Place to Subjective Well-Being: Developing a Conceptual Framework

The preceding discussion leads to the development of a conceptual understanding, framing the relationship between subjective well-being (SWB) and place. In attempting to advance this discourse, the study proposes a four-dimensional conceptual framework (Figure 1). This framework serves as an explanatory medium, unravelling the integration across the concepts and revealing their multidimensionality. It illustrates the relationships between place and SWB in a structured manner, facilitating understanding and unfolding what is expected to be

discovered through empirical research. In the proposed framework, each concept plays a distinct role. The first dimension, namely the place - neighbourhood, is presented as the explanatory element of SWB (second dimension) which in turn, is approached as the response phenomenon in the framework. The third one represents the micro- and small-sized businesses (MSBs) and illustrates the transformative potentials they have over sense of place (moderating role). The fourth dimension is sense of place. We argue that the relationship between place and SWB is mediated by the construct of sense of place through its three manifestations. It is approached as a holistic concept that glues together the concepts of place, SWB, and MSBs.

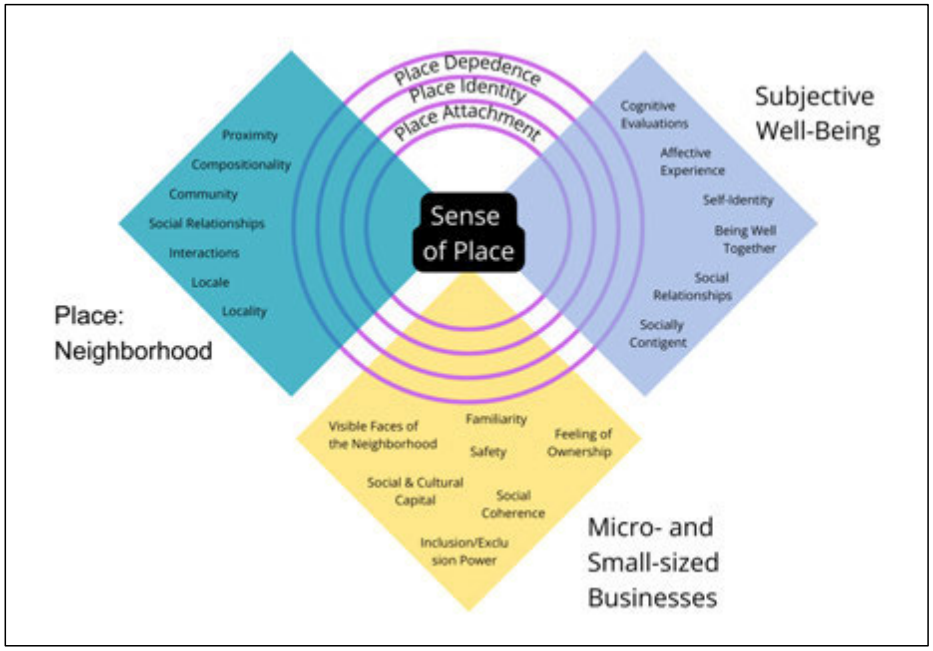

Figure 1. The proposed four-dimensional conceptual framework illustrates the interrelations between SWB, Place, Sense of Place, and MSBs

Neighbourhood (place) and sense of place: Our analysis identifies the neighbourhood as a meaningful location (place), denoting proximity, compositionality, and a sense of community. This suggests that the neighbourhood may influence sense of place, affecting how people relate to its environment and with each other. A neighbourhood's unique mosaic -encompassing a blend of the physical and built environment attributes and the social fabric- shapes people's cognitive understanding and experience of the place (meanings, feelings, narratives), thus, cultivating a distinct place identity (Bernardo and Palma-Oliveira, 2016). The physical and sensory engagement of individuals with their surrounding environment elicits perceptions and appreciations of its uniqueness (or lack of it), and the aesthetic, environmental and/or geological value (or lack of it). Through synergies and active participation, communities reshape places leading to an enhancement of the sense of attachment to the community and to place (Fang et al., 2016; Silberberg et al., 2013). Place attachment is further enhanced through the spatial opportunities provided for building networks and engaging in interactions with both other people and with the neighbourhood's environment (Fang et al., 2016; Low and Altman, 1992). Additionally, the duration of residency and the time spent engaging in activities in the

neighbourhood contribute to the sense of safety and belonging, leading to the enhancement of place attachment (Brown and Raymond, 2007; Lewicka, 2011; Mesch and Manor, 1998). The attributes a locality holds, creating the premises for individuals and groups to functionally satisfy their needs and accommodate their lifestyles may determine the sense of place dependence. Place dependence may also be subject to enhancement or retardment by the neighbourhood's capacity to support individuals or social groups in achieving their goals and engaging in desired and diverse activities (Jorgensen and Stedman, 2011). Collectively, the above neighbourhood dimensions may contribute to a strong (or a weak) sense of place, as well as satisfaction with the neighbourhood.

MSBs and sense of place: The proceeding analysis provided an overview of how MSBs can significantly influence all three manifestations of sense of place. The obvious is the functional aspect of MSBs that can support everyday life and the fulfilment of needs. This may influence the sense of place dependence by determining how well the neighbourhood meets the residents' needs and supports their lifestyles. Additionally, MSBs have a symbolic role and may play a distinctive role in formulating the sense of place identity in a neighbourhood. As indicated through literature, MSBs determine and act as a reflection of the neighbourhood's identity, cultural and social ethos (Felder and Pignolo, 2018; Martucci, 2019). Further, the symbolic role of MSBs and their impact on place identity is manifested through their inclusion or exclusion regulatory power, influencing who feels included in or excluded from the neighbourhood (Lamont and Molnár, 2002; Zukin and Kosta, 2004). Finally, MSBs contribute to the feeling of ownership and generate a sense of familiarity and belonging in a neighbourhood (Duyvendak, 2011; Martucci, 2019). They are at the heart of community vitality, serving as places where residents interact, strengthening social bonds, and creating shared experiences, while MSBs support the neighbourhood's safety, enhancing in these ways place attachment.

Sense of place and subjective well-being: SWB involves cognitive evaluations of life and its various dimensions and affective experiences. Among the various determinants, SWB is sensitive to place of residency (Aslam and Corrado, 2012; Morrison, 2007). Thereby, an individual's evaluations of their neighbourhood are expected to impact their overall SWB. Evaluation of residential satisfaction involves "residents' attitude toward their living space" and "feelings of gratification from living in a specific space" (Sirgy, 2012, p. 303). It is argued that sense of place affects the levels of SWB both through its influence on residential satisfaction and evaluations related to quality of life, including social life, and through their affective experiences. Empirical evidence (Li et al., 2023; Ng et al., 2022) demonstrates that individuals with a stronger sense of place experience higher levels of SWB. Since place identity constitutes an aspect of a person's identity, it is expected to influence their affective experiences. Further, how well a place accommodates a person's lifestyle, goals, and expectations (place dependence) is expected to interfere both with their cognitive evaluations of life as a whole or aspects of it, and their daily affective experience given that spatial competence relates to people's physical and psychological well-being (Kaplan, 1983). Moreover, SWB is highly affected by the social relationships people develop with their community (OECD, 2007), but also with their physical environment and social structures (Maricchiolo et al., 2020). This extends SWB beyond the individual level. 'Being well together' involves strong community ties which are among the major social predictors of place attachment (Lewicka, 2011, 2010). Inversely, place attachment may increase the willingness to get involved with the community and the neighbourhood (Shamai, 1991).

7. Concluding Remarks

The study of place and subjective well-being poses a challenge due to the complex and multifaceted nature of these constructs. This paper delves into an analysis that contributes to the enhancement of the conceptual understanding behind this relationship, revealing the mediating role of sense of place. Recently, there has been some empirical research investigating the links between place and SWB through the lenses of sense of place. The novelty of the herein contribution lies in the fact that it theorizes and illustrates in a structured manner the interrelations between place and subjective well-being, acknowledging the mediating role of sense of place. Additionally, it introduces in the discussion the transformative potentials of MSBs in shaping sense of place.

These interrelations require to be further investigated on a theoretical level and to be validated at the empirical level. However, it is argued that the development of this framework marks the first step in contributing to the theoretical debates and expanding the frontiers of knowledge regarding people-place relations in urban planning discourses. This framework may also have various implications for the application and policy making of urban planning. Gehl (1987) underscored the significance of urban planning in curating public spaces conducive to social interaction. Through creating the premises for experiential processes and social engagement, the role of urban planning can be pivotal to the development of individual and collective sense of place over time (Cartel et al., 2022; Erfani, 2022), which in turn can enhance subjective well-being at the individual level and beyond. To achieve this, it is considered imperative that a comprehensive understanding of the spatial dimensions of SWB in cities and urban neighbourhoods is achieved.

Funding: This paper has been prepared within the framework of the 'Very Small and Small Businesses and Urban Development (VeSBUD)' research project which received funding from the Hellenic Foundation for Research & Innovation (H.F.R.I.) under grant agreement No 4371, 2nd Call for H.F.R.I.'s Research Projects to Support Faculty Members & Researchers.

Since when has regional planning been vague?

An analysis of textual data from 7 regional master plans of Ile-de-France region between 1939 and 2019

Abstract

This paper explores whether discursive vagueness has been used for a long time in planning documents, in the case of the Ile-de-France region. To do so, we analyzed seven main regional plans between 1939 and 2019, with the help of textometry. What emerges is a major pivotal moment in the way regional planning is formulated, between the late 1960s and the mid-1970s. Two phases can be distinguished: (1) a "before" phase in which discourse and rules are intrinsically linked, in a normative and regulatory approach; and (2) an "after" phase in which regional discourse aims above all to support the actions of the various players, largely abandoning normativity and the definition of clear rules. We interpret these results as the reflection of a major change in the planning system in France in the late 1960s, as well as an evolution in the way urban planning norms are written.

Keywords: planning discourse analysis, regional planning, Ile-de-France region, planning norms, discursive vagueness

1. Introduction

Recent planning research has highlighted a strategic dimension of plans that had previously been rather overlooked: discursive vagueness (Buhler and Lethier, 2020; Chesneau, 2023). “Discursive vagueness” refers to a series of discursive devices such as the use of concessionary wordings, or the elimination of time and space references. This allows actors, and particularly local authorities, to deal with a subject imposed (often by their central government) without making too strong of a commitment when it is not intended (Kaza and Hopkins, 2009; Buhler, 2021)[1].

Vagueness in contemporary planning discourse may seem paradoxical at first sight, since the plan no longer functions (for some subjects) as a way of saying "what is planned", but as a mean for creating blurred zones, subjects where negotiation and other less "publicized" modalities of action take over (Kaza and Hopkins, 2009). These vague elements of discourse can also be interpreted as ways to maintain room for negotiation in order to avoid conflict with municipalities, landowners and developers (Levy, 2015).

This does not mean that any attempt to plan a city is doomed to end in vagueness. As Charles Hoch (2007, p. 21) puts it: “*plans that say little about how to turn policy into projects may be said to lack means-ends coherence*.” Rather, vagueness is one of the components of the plans' discourse, and its proportion has increased in the case of French local plans since the 2000s (Buhler and Lethier, 2020; Buhler, 2021). From this finding, two questions emerge: (1) is this growing use of vagueness also observed in other national contexts?; and (2 - if we restrict the focus to the French context) for how long these (vague) discursive devices have been in use? In this paper, we address this second question, which calls for a diachronic approach on planning documents themselves.

Indeed, several research originating from the “plans as signals” approach have identified that plans themselves are an ideal material for analyzing discourse and interactions between actors (Hopkins, 2001; Hopkins and Knaap, 2018, 2019). In the context of plan making, and for various subjects, these actors are seen as being able to either: (1) contribute, sometimes fully and transparently, to the discourse setting up, sometimes (2) in a rather encrypted way, or (3) not to contribute at all, in order to retain certain information. Following this theoretical framework, it seems that tracking a series of comparable plans over time enables us to distinguish discursive evolutions (stylistic, lexical …) that reflects institutional and political changes.

Constructing a diachronic reading of plans over a long period of time make it thus possible to test two hypotheses. We can assume (a) that use of vagueness in planning is recent and is explained by governance changes related to the emergence of neo-liberalism in spatial planning; or we can assume (b) on the contrary, that vagueness always has been present in planning discourse, because it is part of the broader genre of institutional discourses in which vague terms and devices are a major component.

To this end, we propose to examine the ways in which discourse is made in regional planning documents on a rather long period of time (80 years) taking as an example the capital region of

[1] The issue of vagueness/fuzziness in urban planning is not entirely new, since it has been the subject of previous developments, essentially focused on the objective of minimizing it during exchanges between planning actors (De Roo, 2007; Porter and De Roo, 2007).

France, Ile-de-France, through a corpus of 7 regional planning documents and their revisions (between the 1939 PARP plan to the latest 2019 SCoT-M).

The regional development plans for the capital region were chosen because they are - in France at least - one of the rare examples of temporal continuity (over a long period of time) in the development of plans that are made at on a comparable geographical scale[2]. These documents have of course changed in form (development plan, master plan) and have been embedded in different political contexts (Saez, 2021). However, these dissimilarities do not prevent their structural proximity: all these documents provide access to a diagnosis, orientations, statements, and arbitrations established among various stakeholders (Chesneau, 2023). The documents (see the list of plans considered in section 2.1) analysed in this paper are therefore comparable with each other. The corpus thus appears consistent and is suitable for examining how planning discourse have evolved over time in the Ile-de-France context using systematic tools, such as textometry.

In this paper, we will first present the methodology developed, including a detailed presentation of the corpus considered and the method developed. Then we will present the results obtained which convergently signal a major change in the regional planning discourse between the end of the 1960s and the mid-1970s. We then organize a discussion around several analytical hypotheses, with a specific focus on the long-term evolution of the written formulation of the “norm” in regional plans.

2. Corpus and Method

To answer the question of how long has vagueness been in use in the planning prose, we have compiled a series of urban planning documents that have shaped regional planning in the Ile-de-France region, from the first development plan for Paris region (PARP) in 1939 to the “Schéma de cohérence territoriale de la Métropole du Grand Paris” (SCoT-M) in 2019. Although urban planning in France dates back to the Cornudet Acts (1919 and 1924), we have excluded this tradition of municipal planning from our analysis and focused exclusively on regional plans and schemes[3].

2.1. A corpus of seven urban planning documents

The first plan considered is the " Plan d'aménagement de la région parisienne" (PARP) of 1939. It was drawn up at the end of the 1920s under the direction of Henri Prost, chief architect and

[2] Naturally perimeters are not exactly the same as the urban region has spread in the meantime.

[3] This series has been extracted from a textual database covering urban planning in the Ile-de-France region from 1919 to 2019. The database contains more than 355 digitised documents, 15% of which have been transcribed. Each town planning document is linked to the preparatory documents and discussions that took place during their preparation. This network of texts is the result of documentary research based on several sources: parliamentary documents published in the *Journal Officiel* (1919-1935), seven inventories of the ministries responsible for planning between 1910 and 1990 (National Archives), archives of the Ile-de-France Regional Council and Internet data for the latest documents. These textual data are currently being deposited on Nakala (IR* Huma-Num) and will soon be available to the public: Chesneau (2024). *Collection: Ile-de-France urban planning corpus 1919-2019*, NAKALA, DOI: 10.34847/nkl.78d52zja.

town planner of the “Comité supérieur de l'aménagement et de l'organisation de la région parisienne" (CSAORP). The two main aims of the plan were to replace the *laissez-faire* approach of the past, and to curb the region's urban growth, which was considered “monstrous”. Five years after its approval, the PARP plan was revised, but the war and the occupation prevented its completion. In 1950, the Minister for Reconstruction and Town Planning, Claudius Petit, presented a major report to the Council of Ministers entitled *Pour un plan national d'aménagement du territoire*, in which he announced the entire policy to be followed until the mid-1960s. Because of the importance of this text and the strong state control of planning at the time, we have considered it to be a quasi-revision of the PARP and have therefore included it in the corpus. The PARP was not revised until 1956, mainly by the urban planner Pierre Gibel, under the direction of Pierre Sudreau, the commissioner for reconstruction and urban planning for the Paris region.

After the election of Charles de Gaulle in 1958, and the establishment of the Fifth Republic, the government prescribed a “Plan d'Aménagement et d'Organisation Générale de la Région Parisienne” (PADOG) but left the existing institutions untouched. The same people who had drawn up and revised the PARP therefore set to work on this new plan. In fact, the PADOG was quickly validated in 1960, in line with the previous plans. One of the main contributions of this plan was to advocate a new form of governance for the development of the Île-de-France region and to encourage the creation of "a single regional authority capable of acting on behalf of both the central government and the local authorities" (Alduy, 1979).

A new team led by Paul Delouvrier created the “Institut d'aménagement et d'urbanisme de la Région Parisienne” (IAURP) in 1960 and the “District[4]” of Paris in 1961. This dynamic led to the drafting of a preliminary two-decade program for the Paris region in 1963, known as the “Livre blanc”, which served as the explanatory memorandum for the third document in our corpus, the “Schéma directeur d'aménagement et d'urbanisme de la région de Paris” (SDAURP) of 1965. In the history of development plans for the Paris region, this master plan represented a major doctrinal shift. The State took the view that it should voluntarily organize the distribution of the population in the region, in particular by creating “New Towns” (“villes nouvelles”). However, it was not officially approved in 1965 and, from a legal point of view, it did not officially abrogated PADOG. It was not officially approved until 1976, under the name SDAURIF, after two failed attempts of revision (1969, 1971).

From the 1980s onwards, planning falls out of favor. Shortly before the 1981 presidential elections, the government decided to revise SDAURIF, whose data were no longer up to date. However, the new government did not take up the initiative and it was not until 1986 that the Ile-de-France region relaunched the project. The Regional Council entrusted IAURIF with this task and, at the beginning of 1989, adopted the regional planning project entitled “Ile-de-France 2000”. Although the 1988 presidential elections did not change the political context, the government of Michel Rocard wanted to assert the predominant role of the State in the development of planning policy in the Ile-de-France region. After a long struggle between the State and local authorities, the SDRIF was finally approved by decree on 26 April 1994.

Following the adoption of a series of major laws between 1995 and 2000 (LOADT, LOADDT and SRU), the 1994 SDRIF was revised by decree in 2005, after it had being criticised as a kind of "super POS" that slowed down development rather than encouraging it. Regional workshops were then organised to bring the State into dialogue with local authorities and major public

[4] Districts are a past form of intermunicipal bodies.

institutions in the Paris region. On the basis of a consolidated draft SDRIF, the public consultation was launched at the end of 2007. However, following the legislative changes introduced by the Greater Paris Act (June 2010) and the Grenelle I and II Acts (July 2010), the "Conseil d'État" issued a negative opinion. Planning objectives, including regional objectives, had changed: the project is not part of sustainable development, to which France had committed itself in Rio in 1992, and the Greater Paris project required a rethink of planning scales.

After several unsuccessful attempts a new revision process was launched in 2011, starting with a consultation process known as the "Regional Territorial Conference". In 2012, the Ile-de-France Regional Council adopted the update of the SDRIF, entitled "*Objectif: Ile-de-France 2030*". As a preamble, the Council drew up a new version of the "Regional Vision", which was presented as "the social project that the Region wishes to build with all its partners, in the near future (tomorrow) and in the distant future (2030)". After receiving the opinions of the State, departmental councils, consular chambers, etc., and a public consultation, the project was adopted in autumn 2013 and approved by the Council of State in December 2013.

Finally, the 7th document in the corpus is the "SCoT Métropolitain" (2019). In the Ile-de-France region, the planning documents architecture was radically overhauled with the creation of the "Métropole du Grand Paris". It is now structured around the SDRIF, the "SCoT Métropolitain" and several intercommunal land-use regulatory plans called "PLUi". From a legal point of view, the SDRIF is binding on the SCoT-M, which must be compatible with it, but in practice the revision of the SDRIF in 2013 has been delayed by the current preparation of the SCoT-M. Although the boundaries are different, the planning issues overlap. In order to be able to cover the end of the 2010s, we have considered this plan[5].

Over these 80 years, these documents have changed form, from development plans to master plans, and have had different types of speakers. What they all have in common, however, is that they present, each in its own way, the broad development guidelines for a more or less distant future (5, 10 or 15 years, depending on the period), based on a diagnosis. Despite their differences, they have a number of similarities (Pincemin, 2012) and their "polyphony" (Perrin, 2004) can be seen as a means of collective representation.

2.2. Textometric reading

We used textometry for analysis the corpus, with the help of TXM software. The advantage of this software is that it can be used to describe and compare the formal characteristics of words and/or sentence segments and to model diachronic variations within the different partitions of the corpus. The semantic meaning of a theme then emerges from the confrontation between, on the one hand, global views derived from statistical processing (i), and, on the other hand, consultation of local contexts of enunciation, at a finer scale (ii). By combining quantitative and qualitative processing in this way, this method enables the identification of new information that would otherwise be inaccessible to the human eye (Rastier, 2011, p. 13).

Our work is based on this method in order to gain insight into the evolution of planning documents in the Ile-de-France region through a back-and-forth movement between the texts themselves and statistical data. To do this, we'll begin by observing the construction of discourse through the study of sentence components to better understand how writing has evolved in these documents over time. We will then look at their lexicon, in particular pronouns, which show

[5] We have not been able to integrate the SDRIF-E, which is currently being approved.

whether or not a speaker or writer is in charge of the discourse, as well as verbs (all tenses and modes) and common nouns, both of which provide information on the content and description of the elements highlighted in each document.

3. Results

To determine a possible chronological evolution in the discourse of plans, we have partitioned our working corpus into 7 parts (table 1), each corresponding to an urban planning document and, when applicable, its revisions.

Table 1: The corpus of planning documents from 1919 to 2019 divided into 7 groups

Corpus partition	Number of words
PARP and revisions 1950 and 1956	27 844
PADOG 1960	57 349
SDAURP 1965	84 000
SDAU 1976	63 464
SDRIF 1994	84 638
SDRIF 2013	61 887
SCoT-M 2019	103 232

The volume of these texts can fluctuate from one to four times their size, but they are still of a comparable scale, which makes the use of textometry possible. Furthermore, the statistical tools we use take this discrepancy into consideration, as they are based on the relative share of a given graphic form/term category in each document.

3.1 A discourse that becomes increasingly nominal

The analysis by grammatical categories enables us to study the construction of the discourse and avoid a reading guided only by circumstances and the lexicon. Indeed, the lexicon is dependent on current events and the circumstances of a particular period. It carries information – and we'll look at this later – but it is also the product of an era and its events.

So, to begin with, we observed the distribution of the various grammatical categories that make up discourse, according to the documents (i.e. plans) considered. CFA can be used to visualize a collection of numerical data linked to lexical units, generally organized in double-entry tables (also named contingency tables). These tables present words or categories of terms in rows and external categorization modalities in columns, such as year, author, title, category, etc. The CFA then provides a synthetic representation of the vocabulary distribution.

In a CFA, the proximity of a row point to a column point means that there is "an attraction between that row and that column" (Cibois, 2007, p. 28)[6]. Furthermore, "the closer a point is to

[6] All quotations translated by us.

the center, the weaker its attractions or oppositions. When a point is strictly at the center, this means that it is in a situation of independence with all the other modalities" (*ibid*.: 34).

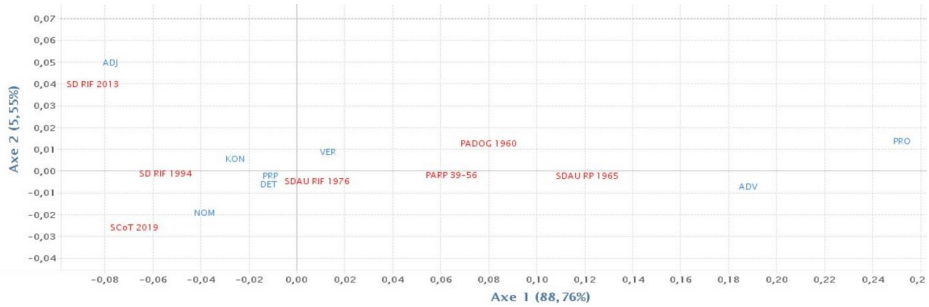

Figure 1: Distribution of grammatical discourse categories by documents (CFA)

We can observe a diachronic evolution in the construction of sentences in urban planning documents, dividing the corpus into two parts (see Figure 1) : on the right of the graph, the years 1939 to 1965 (PARP and its revisions, PADOG and SDAURP) present a discourse with a verbal consistency as evidenced by the presence of verbs (“VER” on the CFA), adverbs (“ADV”) and pronouns (“PRO”), while the years 1994 to 2019 (the two SDRIFs and the SCoT) present a more nominal discourse with an over-representation of nouns (“NOM”), determiners (“DET”), adjectives (“ADJ”), prepositions (“PRP”) and conjunctions (“KON”). The year 1976 (with the SDAURIF plan) stands out as a pivotal year, on the ordinate axis.

The shift from verbal to nominal discourse is typical of the evolution of institutional discourse (Krieg-Planque, 2012). Nominalization is an argumentative tool, presenting the relationship between two terms (noun + noun complement) as necessarily existing. In other words, it imposes a pre-construct, referring to an "object of the world already there, pre-existing the discourse" (Sitri, 1996), and has the "effect of erasing the agent, verbal aspect and modality of the previous statement" (ibid.). This evolution of urban planning discourse thus demonstrates a desire for enunciative erasure (Rabatel, 2004): the discourse is disembodied and no longer carried by a defined speaker or group of speakers.

3.2 A discourse that gradually avoids clear expression of the speaker's identity

This observation is confirmed by the use of subject personal pronouns in the corpus:

Figure 2: CFA of the distribution of personal pronouns by corpus documents

Chronologically, the pronouns *je* and *on* (*you/one* or *we/they/people*) attract the first part of the corpus (1939-1976) to the left-hand side of the graph, while the two SDRIFs (1994 and 2013) are polarized by the pronouns *il*, *Elle*, *Elles* and *Ils (he, she* and *they*) (see Figure 2).

Although axis 2 contributes less to understanding the distribution of pronouns within the CFA, the particular case of the 2019 SCoT leads us to return to the text to observe the uses of the pronoun *nous* (*we*). Thus, the examples below show that the use of *nous* in this part of the corpus does not reflect an enunciative assumption of responsibility but presents a general value corresponding to the population of the territory concerned:

> 'We are all metropolitans, we live at the pace and scale of the Metropolis, we travel through it every day, we live here, work and study there, we take part in cultural or sporting activities elsewhere, and we use all kinds of means of transport to come and go.' [7]

> 'No matter where **we** are in the metropolis, being able to find a job, suitable housing, but also the services, shops and facilities **we** need on a daily basis should be a matter of course.' [8]

[7] The authors' translation for the following paragraph : "**Nous** sommes tous métropolitains, **nous** vivons au rythme et à l'échelle de la Métropole, **nous** la parcourons chaque jour, **nous** habitons ici, travaillons et étudions là-bas, **nous** pratiquons des activités culturelles ou sportives ailleurs et **nous** utilisons pour cela toutes sortes de moyens de transport pour aller et venir."
[8] The authors' translation for : "Quel que soit le lieu où nous sommes dans la métropole, pouvoir trouver un emploi, un logement adapté, mais aussi les services, les commerces, les équipements dont nous avons besoin au quotidien doit relever de l'évidence."

The gradual elimination of 'I' variants, offset by the emergence of more frequent uses of 'we' and 'he/she/it', marks a transition towards: (1) more frequent use of passive voice, as well as (2) more descriptive sentences and (3) pronouns that allow first-person speech without precisely defining the speaker ('we' and related written forms). This last feature is characteristic of institutional discourse, which endeavors to formulate a discourse 'emanating from a collective entity presented as indivisible while being the product of negotiation among various points of view'

3.3 Prescription and rule-setting gradually fade away

To observe this diachronic evolution in greater detail, we have analyzed the use of verbs and common nouns in the corpus.

With regard to verbs, whose lemmas[9] we have observed at least ten times in the corpus - in order to avoid hapax[10] that could distort the results - the calculation of specificities[11] shows an opposition between the PARP, the PADOG and the SDAU RP, i.e., the oldest documents on the one hand, and the SD RIF and the SCoT on the other. The 1976 SDAU RIF again finds itself in an in-between position, close to neutrality. Thus, between 1939 and 1965, we see a discourse with several aspects:

- a cognitive dimension, with verbs such as *foresee, understand, interest, envisage, suppose, justify* or *predict*;
- a discursive dimension, with *ask, detail, decline, indicate, tell, propose, accuse, reveal, etc.*;
- a normative dimension, with *prohibit, authorize, grant, impose, admit, submit, execute, must, should, may, order*.

The following extract illustrates the highly prescriptive and normative form of the plans in the first half of the corpus.

> 'These easements prohibit building or exceeding a certain height, and forbid enclosing properties with anything other than hedges or clear fences that do not obstruct views.' (PARP, 1939, Programme général, chapitre 5)[12]

In the plans for the years 1994–2019, three other dimensions predominate:

- a dimension of action, with the overuse of verbs such as *structure, mesh, protect, undertake, house, irrigate, decongest, artificialize, feed, count, produce* or *manage*;

[9] A lemma is the canonical form, or the dictionary form, of a set of word forms. For verbs, the lemma corresponds to the infinitive form. For nouns (and, in French, adjectives), it's the masculine singular form.

[10] A hapax is a word that occurs only once in a corpus.

[11] The calculation of specificities allows us to observe the distribution of the forms studied in the different parts of the corpus. Specificity is positive when these forms are overused (their frequency is higher than the expected theoretical frequency) and negative when they are underused (their frequency is lower than the expected theoretical frequency) (Leblanc, 2005: 66).

[12] Original excerpt : « Ces servitudes interdiront de bâtir ou de dépasser une certaine hauteur de construction et défendront de clore les propriétés autrement que par des haies ou des clôtures à claire voie ne masquant pas la vue. »

- a dimension of support and "working together": *welcome, involve, support, protect, watch over, associate, caution, accompany, participate, link, connect, contribute* or *mobilize*;
- a more political dimension, involving the enhancement of what has already been done and the continuity of what is planned: *improve, enhance, consolidate, pursue, grow, strengthen, perpetuate, renew, maintain, promote, increase, optimize, promote, evolve, adapt, initiate, etc.*

The following extract is typical of this shift towards a more partnership-based, less prescriptive/injunctive approach to formulating future actions.

> 'The undeveloped land located in Tremblay-en-France, to the south of the airport, is naturally destined to host new world-class activities. It is important that they be developed through a selective location policy, involving the State and local authorities and avoiding premature waste of this regionally important land asset.' (SDRIF, 1994, Annexe : Le Schéma Directeur en huit départements) [13]

The chronological opposition between the two "halves" of the corpus thus seems to reside in the way planning is approached: on the one hand, before 1976, planning was approached from the angle of **prescription and rule-setting**; on the other hand, after 1976, it is a question of **valuing action** - and in particular joint action - and what is **achieved** by the institution.

3.4 Fewer references to objects and concrete items, offset by more themes covered

If we take a closer look at the common nouns overrepresented in the various documents, the same chronological pattern emerges. In the first part of the corpus, we find an overrepresentation of numerical or accounting data (*dwelling, a billion, width, height, m³, year, worker, surplus, purchase, kilometer, inhabitant, building, etc*.). , but also very concrete elements linked to the territory and its issues (*area, municipality, road, development, grouping, hygiene, sewer, evacuation, junk, recycling, core, conurbation, location, aerodrome, industry, center, axis, city, leisure, highway, shore, valley, intra-muros, vehicle, poverty, employment, etc.*). Finally, the notion of rule or norm is also over-represented (*article, non aedificandi, property, program, proposal, government, order*).

The second half of the corpus also presents elements that make up the challenges of regional planning, but these are no longer the same: *university, IUT, heatwave, protection, drought, biodiversity, health, energy, crisis, inequality, mobility, cycling, precariousness, school, climate, green, consumption...* The interests and objectives have therefore shifted towards education on the one hand, and the environment on the other.

A number of factors suggest that a major shift in Ile-de-France regional planning discourse took place between 1965 and 1976. This division into two major halves allows us to identify specific lexical and stylistic features (see Table 2).

Overrepresentation of …	First half of the corpus (1939-1976)	Second half of the corpus (1976-2019)

[13] Original excerpt : Les terrains non urbanisés situés sur Tremblay-en-France, au sud de l'aéroport, sont naturellement destinés à accueillir de nouvelles activités de niveau international. Il importe qu'ils soient valorisés par une politique sélective d'implantations, associant l'État et les collectivités territoriales et évitant de gaspiller prématurément ce patrimoine foncier d'enjeu régional.

… types of sentences	Verbal sentences	Nominal sentences
… pronouns	'Je'	'Il'/'elle' + 'nous'
… nouns	Prescriptive and normative assertions Numerical data, norms, concrete elements	Valuation of partnership action and of already achieved results New topics (higher education, environment)

Table 2: summarized results of regional plans discourse analysis

Apart from the addition of new topics, which seems obvious given the evolving legal framework, the rest of the features indicate a discourse that is increasingly approaching the institutional genre, moving away from more injunctive and regulatory forms. These results indicate that, over the long term, regional planning documents, particularly those relating to the Ile-de-France urban region, are gradually losing their normative substance.

4. Discussion

We assumed two specific hypotheses at the beginning of this paper. First, we assumed that (a) the emergence of vagueness in planning prose could be linked with the emergence of a neo-liberal model of urban planning. However, the results do not seem to support this assumption, as the major change in terms of discourse occurred chronologically earlier, at the end of the 1960s. In the case of the Ile-de-France region, this involved a general overhaul of the planning system, giving a new role to regional planning.

4.1 The changing role of regional planning

The evolution of regional planning discourse in region Ile-de-France seems to chronologically follow the establishment, in France, of a 'hierarchy of standards' in spatial planning through the LOF-Act (1967). This law introduced a new national planning system where two main plans played a central role: (1) the POS[14] (a regulatory urban planning plan) at the municipal level which defined the land-use permissions and prohibitions at the plot scale, and (2) the SD[15], strategic plan made up at the built-up area level.

In 1967, this new division of institutional competences therefore define the municipal level as the scale for town planning rules, leaving a more strategic and guiding role for higher order documents, such as the regional planning documents analysed in this paper.

4.2 Writing the rule: from command to recommendation

At the beginning of the paper we also formulated (b) the idea according to which urban planning, being linked to the genre of institutional discourse, would always have been (at least partly) vague. This second hypothesis also seems rather false. Indeed, the first part of our corpus (1939-1976) shows a planning discourse much closer to legal and political genres than to institutional one.

[14] 'Plan d'occupation des Sols'
[15] 'Schéma Directeur'

As we have seen in our analysis, the rule of law in urban planning describes a norm that "consists in modalising actions by means of obligations, authorisations or prohibitions" (Alland and Rials, 2003, p. 1080)[16]. It should be seen as a set of explicit reference models for action. While obligations, permissions or prohibitions are actions that are at the core of urban planning norms, their development has a social purpose (Weber, 2019). The main objective is to use institutional rules to coordinate the decisions of decentralised actors operating at the local level. Development plans and master plans can therefore be seen as texts that act as 'operators mediating regulatory relations' (Smith, 2018, p. 24). The specificity of this regulation is that it is carried out primarily through texts, in which words encode both a reading of the current state of the city and the expectations of the state with regard to its development (Chesneau, 2021). It is through this agentivity of words that the link between institutions and everyday urban planning practices is established and that negotiations can take place in the event of disagreement (Lascoumes, 1990).

Our results seem to show that the prescriptive nature of the rules set out in them gradually fades over time, and today they are little more than flexible or vague guidelines. This observation leads us to a better understanding of the way the norm is constructed in these different texts by focusing on their characteristics that emerge from our analysis. In our case, spatial planning plays the role of a flexible and strategic framework rather than a document that "says what will be" and would be prescriptive for the lower institutional levels.

An analysis of the plans shows that before 1976, norms were commanding, mandatory and directive in nature - in particular by setting out technical and numerical standards - and aimed to standardise behaviour by resorting to prohibition. After this date, norms evolved towards recommendations. Its aim is to reconcile diverse and even divergent interests. It therefore becomes more conciliatory, flexible and permissive. In a spirit of accommodation, its function is less to achieve quantitative objectives than to recognise the possibility of certain hitherto unacquired rights to be asserted or supported. This is expressed, for example, as follows:

> "**Recognise** a certain number of establishments, currently classified as short-stay, for their actual medium-stay activity, particularly geriatric" (SDRIF 94)[17]
>
> "Each area of the Île-de-France region will be **recognised** in the same way as the major centres, as parts of the city that need to be developed. Because real centralities, points of concentration of greater urban intensity, will have been created, the agricultural, wooded or natural areas of the Île-de-France's peri-urban or rural zones can be preserved. This spatial organisation will offer different ways of living in response to the diverse needs of Île-de-France residents" (SDRIF 2013)."[18]

[16] Original quote : « consiste à modaliser des actions par l'obligation, la permission ou l'interdiction »
[17] Original excerpt : « **Reconnaître** à un certain nombre d'établissements, actuellement classés en court séjour, leur activité réelle de moyen séjour, notamment gériatrique »
[18] Original excerpt : « Chaque territoire de l'Île-de-France sera **reconnu** au même titre que les grandes polarités comme des morceaux de ville à aménager. Parce que de véritables centralités, points de concentration de plus grande intensité urbaine, auront été créées, les espaces agricoles, boisés ou naturels des zones périurbaines ou rurales de l'Île-de-France pourront être préservés. Cette organisation spatiale offrira des façons différentes de vivre en réponse aux besoins divers des Franciliens »

> "Forest identified and preserved under the Forestry Code for its ecological, heritage and/or cultural characteristics. This **recognition** is evidenced by a classification and by strong protection that prohibits any change in land use."[19] (SCoT-M 2019)

The shift that takes place over time shows that the norm is not removed from urban planning documents over the decades, but that it is expressed differently, by erasing pronounced linguistic markers, opening the way to another way of constructing the relationship between urban planning and law.

This transformation took place between 1965 and 1976, at a time when the territorial basis of town planning law was completely changed by the “Loi d’orientation foncière” (LOF). From a legal point of view, this transition from plans to master plans corresponded to the establishment of a hierarchy of rules that was strengthened at the top and extended at the bottom. At the top, the master plan must comply with general rules that apply to the whole of the national territory. These rules are imposed by the “Code de l’urbanisme”, which in 1973 got rid of the provisions concerning building and housing contained in the first “Code de l’urbanisme et de l’habitation” of 1954. Downwards, at the municipal level, land use rules were henceforth set by land use plans (POS). This means that each municipality must define the precise rights attached to each plot of land within its territory, in accordance with the urban policy guidelines set out in the master plan. The corollary of this transfer of powers is that there is no longer any need for the master plan to include a detailed description of the organisation of the urban fabric of each municipality in the region, specifying the purpose of the buildings, the density, the location of reserved areas, etc. It is up to the local authorities to define the rights attached to each plot of land. Ultimately, it is up to the building permit officer to interpret the application of the main principles of urban policy in minute detail.

4.3 Injunctive vagueness or worded texts?

As can be seen, the organisation of the principles of planning law follows an easy-to-understand logic: at the top of the hierarchy are the most general rules and at the bottom the most contingent. The consequence of this organisation is that no text is autonomous; it forms part of a linear structure which, according to François Ost and Michel Van de Kerchove, has become circular over time, based on a tangled hierarchy made up of "strange loops" (1987, p. 183–253). The result is that the higher up in the hierarchy of norms the planning rules are, the less detailed they are. What we have called vagueness could be interpreted as a mark of maturity of planning law, where the norm is not systematically expressed in prescriptive terms.

Paradoxically, this essentially qualitative approach to the norm (i.e. vague language) is nevertheless legally prescriptive. The master plans are binding on the schéma de cohérence territoriale (Scot), the plan local d'urbanisme (PLU), the plan de déplacements urbains (PDU) of the Île-de-France region and the plan métropolitain de l'habitat et de l'hébergement (PMHH), while, as we have pointed out, leaving local authorities a margin of interpretation. If this gradual nominalisation of these texts does not contradict their mandatory nature, it might be because of the principle of compatibility, which requires that the lower rule does not contradict the higher rule. In reality, this legality is assessed in the light of the planning principles and objectives defined in a very comprehensive manner, including the "regulatory" and "cartographic" guidelines that make up the prescriptive provisions of the SDRIF. The master plans can

[19] Original excerpt : « Forêt identifiée et préservée au titre du Code forestier pour ses caractéristiques écologiques, patrimoniales et/ou culturelles. Cette **reconnaissance** est actée par un classement et par une protection forte qui interdit notamment tout changement d’affectation du sol. »

therefore be seen as 'outsourcing' the legal content of the planning guidelines to the municipalities (Sulpice, 2023), as shown by the litigation on this issue (JurisClasseur Collectivités territoriales, 2021).

Although planning law has become increasingly complex over the years, it is still based on the need to control land use in order to better control the dynamics of urban growth in a region, the forecast and planning of housing quantity, and (3) the distribution of economic and other activities over the considered area. Since the Grenelle I and II Acts, this framework has also been directly linked to ecological transition policies, such as land-use planning to reduce land consumption (zero net artificialisation by 2050) and transport needs, or to preserve biodiversity. All of these objectives require the use of quantified measures to reduce (CO_2, hectares of built up area, etc.) or increase (biodiversity, energy savings, etc.), just as the PARP or the SDAU 1965 required the most accurate quantification of building needs at the time.

The hierarchy of norms we have described has undoubtedly had the effect of diluting the current imperatives of ecological transition. As Frédéric Rolin points out, 'the legal cascade effect between the different levels of implementation of the national energy transition policy means that it is simply ineffective in imposing precise targets on urban planning documents'. He adds: "We know that for several decades the Conseil d'État has pursued a policy of relaxing [the relationship of compatibility] between two norms" (Rolin, 2021), a principle that no longer guarantees the prescriptive nature of the norm as such.

5. Conclusion

This textometric study of regional planning documents in the Ile-de-France region between 1939 and 2019 reveals a pivotal moment in their evolution. This change, which took place in the 1960s-1970s, corresponds in fact to the implementation of the LOF, enacted in 1967, which established a comprehensive system of planning documents in France, and imposed the strategical coordination at the inter-municipal level.

The corpus shows a shift from verbal to nominal discourse, as evidenced by the distribution of the grammatical categories that make up discourse, and the gradual erasure of the enunciative endorsement in the documents. We move from a discourse that gives pride of place to the pronoun “I” to one that gives more space to pronouns characterizing the use of the passive, description and vagueness concerning the speaker.

Observation of the lexicon overrepresented in the corpus shows that the pre-LOF period presents, (1) a normative dimension, in the sense that the norm is clearly expressed by precise terms (prohibit, authorize, etc.) together with (2) a more concrete aspect, with lexis linked to measurement, quantities and precise locations.
In the later period, both the action carried out and planned are highlighted and valorized, as well as the joint work involved by the diversity of actors.

All of these results invite us to think that the use of vagueness in the planning prose is primarily linked - in the French case - to the reshaping of the planning system which took place at the end of the 1960s. This seems to better explain chronologically, the emergence of such a discourse register, much better than hypotheses of urban neo-liberalism or of a planning discourse that would have always been vague.

In terms of perspectives, these results invite us to analyze the presence and evolution of vague discourses in other urban and national contexts. To do so, our results show the importance of considering (when conducting diachronic analyses) a set of planning documents, covering various scales. This would make it possible to track the shifts of certain parts of the document (in our case, the most normative, concrete and precise aspects towards the lower level). With this in mind, we follow recent developments reclaiming for analyses of "networks of plans" (Hersperger et al., 2024).

The author has graduated from the University of Helsinki (practical philosophy) and worked as a researcher at Aalto University.

Reconnecting Planning Theory with Urban Design: Public Space as a Social and Architectural Concern

Abstract

Today's planning theory is largely procedural and remains abstract in urban design terms even when formally content-oriented, as when treating the just city. The theory reflects Anglo-Saxon weak planning conditions. While this explains the felt need to reinvent the role of planning and its theory, it threatens to break planning theory's tie to *town* planning. Especially, it becomes inadequate for comprehending the workings of architect-led, still powerful and proactive planning organisations. Such exist even where academics contribute to mainstream theory, producing a gap in the understanding of real-world planning among students, practitioners and non-practising researchers. My purpose is to help reintroduce an urban design focus into planning theory, integrating the latter's social scientific interests with an understanding of the social significance of urban design traits.

Key words: planning theory, public space, urban design

1 Introduction

Planning theory, despite its all-inclusive designation and its often procedural or abstract nature, usually refers to town planning (urban planning or city planning) or regional planning (Beauregard, 2020, p.3). The field is dominated by Anglo-Saxon academia, non-Anglo-Saxon planning often being neglected (eg, by Fainstein and DeFilippis (2016, pp.5f)). Along with the professionalisation of the theory and the transformations in planning practice since the rise of neoliberalism, the theory has metamorphosised. Yet, the traditional sense of its research object as involving a professional (rather than just a politically-economically defined) physical-functional aspect should be taken seriously, inter alia, for planning theory to be generally relevant for European planning systems (cf. Newman and Thornley, 1996; ARL, 2024). From this viewpoint, it is problematic that planning theorists tend to restrict their treatment to the planning procedure, focusing on communication and participation, and to abstract or radical social thinking. Nonetheless, despite the changes, planning theory does retain a tie to traditional town planning, helping to distinguish the discipline from, for example, political economy, history and philosophy, at whose crossroads Fainstein and DeFilippis (2016, p.4) situate it. They quite reasonably note that planning is not *only* (rather than not at all) about planning places as it also involves communication et cetera. In any case, many de facto difficulties with the theory's idealism, partisanship and vague generality in respect of urban issues relate to its unclear research object and concomitant unclarities regarding its fundamental research interests.

Nonetheless, there is hardly any return to traditional town planning theory, for example of the British post-war kind (Taylor 1998). Its concreteness and straightforward applicability could not compensate for its lacking comprehension of the socio-economic presuppositions and consequences of suggested solutions. Yet, such naïve technocratic theory coupled with a rationalistic understanding of the planning procedure is not the only possible kind of substantial

planning theory. Already in the 19th century, Ildefons Cerdà presented an elaborate alternative to the separation of societal and design thinking (cf Dovey and Pafka, 2016). Jane Jacobs (1961), for her part, advanced a socially based criticism of the technocratic planning of the time, with far-reaching implications for how to design urban environments. She did this without prescribing the architectural realisation of her planning rules in any detailed manner. Presumably, neither kind of thinking needs to be anachronistically categorised as either planning theory or urban design theory. Could the kind of synthesis they represent, instead, be re-effected today?

While there is no reason to oppose a pragmatic division of work between researchers closer to urban design and those more abstractly engaged in urban issues, for planning theory to preserve its tie to town planning – with an emphasis on both *town* and *planning* –, some noteworthy architectural effects should in most cases, as with Jacobs, follow from theorisation. This seems natural, if the task of planning theory is to 'find a leeway within the larger social structure to pursue the good city' (Fainstein and DeFilippis, 2016, p.4). A lack in the theory's applicability has been perceived by observers (Goosen and Cilliers, 2020). Also, the sordid reflections from the inside on the future of planning theory (Beauregard, 2020, pp.115ff), makes a re-evaluation of its focus urgent. Nonetheless, tying social theorising to design is not trivial. As a gap easily appears between urban design practice and academic reflection on urban conditions due to the nature of the tasks and the highly differing education required, it is particularly important to take *this* challenge, internal to the academic project, seriously in theoretical reflection. Planning theory, however, guarding its social scientific credibility, makes few concessions to the practical interests of urban design. On the other hand, urban design theory, although more down-to-earth, contains societal references in line with planning theory, making a reintegration possible.

There are at least two reasons for the need of a rapprochement between abstractly procedural theory and theory studying or guiding urban design. First, in some countries where theoreticians deal with mainstream planning theory, as in Finland, planning still works in the traditional way, planners being experts in physical planning rather than facilitators. This is hidden from view, inter alia, as researchers currently seldom cite studies done by their Scandinavian colleagues if not available in English (this was not the case only a few decades ago). In any case, for this region, to put it starkly, planning theory does not in fact theorise planning. Instead, it treats the occupationally unestablished and rather marginal domain of (non-architect) facilitators ('interaction planners').[1] This easily results in confusion as students, practitioners and, at least, researchers not practising or lacking a background in architecturally focused town planning may get a false understanding of the nature of local real-world town planning.

Second, even where planning conditions have changed to the point of justifying a new professional identity for planners, the question how urban design solutions affect social life remains. As neoliberalism, with its deregulation and larger space for private initiative, has largely shifted responsibility for urban design to consultants, it has become more difficult to

[1] Such officials were hired for the once ambitious participatory endeavour initiated by the powerful architect-led town planning of Helsinki. Its purpose, to be sure, was to increase the communicative competence and responsiveness of the planning organisation, yet doubtless also to let architect-planners concentrate on their key responsibility, namely town planning (in its long-established sense).

steer planning in a democratically desirable direction. Planning theorists have therefore extended their research into domains like governance, and called for even more radical, participatory forms of democracy to regain control. In contrast, the role of urban design and planning expertise in forming a socially well-working environment has been downplayed to a surprising degree, sometimes even being dismissed as 'expert ideology' (Beauregard, 2020, pp.21, 26). After having lost their trust in the omniscient maestro planner, planning theorists today instead seem convinced of the infallibility of laypeople's views (individual strivings apparently being coordinated by an invisible hand). The impression is that urban design knowledge is regarded as irrelevant for grasping complex, perhaps futile, issues such as how legibility affects the urban experience or how physical-functional and symbolical architectural traits condition daily life and social relations. Here planning theory joins hands with libertarianism.

As a response to the problems of planning theory's one-sided attention to the planning procedure, abstractions and the lacking tie to urban design, the intention here is, first, to explore how planning theoretical concerns may be concretised by connecting them to urban design.[2] Second, to suggest how urban design theory might be more closely brought together with planning theoretical reflection. Tying planning theory to urban design with the help of the concept of public space facilitates the clarification of the existence, status and significance of the urban design problems and knowledge that needs to be confronted. The urban design literature used is P. Panerai et al.'s *Urban Forms: The death and life of the urban block* (2004 [1975]), M. Carmona et al.'s *Urban Places, Public Spaces* (2010), J. and C. S. Tarbatt's *The Urban Block* (2020).

2 Back to Basics: What Kind of an Urban Environment do we Want?

Assuming that planning theorists are still, after all, interested in how to achieve a socially well-working and ecologically sustainable urban environment (rather than just in its political-administrative conditions, in popular planning intervention or in planners' action as facilitators), the burden of proof seems to be on those holding urban design to be irrelevant for planning theory. How could the breaking of the tie between procedural and social theorising, on the one hand, and concrete planning goals, on the other, possibly be justified within this practice-oriented domain? The move taken by those denying the importance of urban design

[2] Texts explicitly containing both viewpoints are not quite as readily available as one might think considering general reflections on the tasks of planning theory in standard introductions. These may mention public space as a key goal 'that planners hold dear' (Fainstein and DeFilippis, 2016, p.12). Yet, eg, Philip Allmendinger (2017) touches on public space only abstractly in relation to politics. In Gunder et al. (2018), it is mentioned in a treatment of the public interest; in an article on justice (by Fainstein) in relation to diversity and favouring the poor; as pertaining to ethnic and racial diversity; finally, in the context of complexity, as a task for actors. In Beauregard (2020), it is brought up once, again in relation to justice. In Fainstein and DeFilippis's *Reader*, public space figures in relation to global uncertainties, the planning procedure and justice. In none of these contexts is it more than fleetingly mentioned nor tangibly related to urban design concerns. A Scopus search (09/05/2024) with the keywords 'planning theory' and 'public space' resulted in 29 hits.

focused planning is essentially one from an interest in expertise to an interest in politics, following from changed assumptions about their respective significance for planning and its results. Communicative theorists suppose that optimal planning results can be achieved by considering all relevant needs and viewpoints, which is secured by the involvement of all interested parties in a procedure ideally approaching an unconstrained dialogue. Post-structuralists find such a belief in open exchange of ideas unrealistic, instead presupposing an agonistic constellation, where it should be acknowledged that actors have fundamentally conflicting interests and unequal resources. In both cases, planners become facilitators (or even, in the latter case, political activists), while substantial planning knowledge, especially urban design related knowledge, is devalued.

Instead of criticising these current planning theoretical standpoints, I shall go straight to a positive defence of the possibility of rejoining planning theory with urban design with respect to social goals. The basic question then is: what kind of a built environment do we want? Disregarding, consequently, the currently popular planning theoretical view that the 'we' is misplaced in the context and that common goals cannot exist, except as meaningless empty signifiers, different levels on which consensus and dissensus can be identified may instead be discerned. One should also be clear about what disagreement means. If a deliberatively democratic ideal is accepted, a common understanding should be based on the best available arguments and knowledge. To present a dissenting opinion, it is not enough, then, just simply to say no.

A problem – here planning theorists' worries must be taken seriously – is that this not only concerns resourceful actors, who need to make their strivings transparent and commonly acceptable, partly by making concessions to what (contra a 'post' view) may, at least in clear-cut cases, be described as the public interest, but also by presenting valid arguments. The same goes for weak actors, whose needs, 'fragile knowledge' and viewpoints must be teased out by benevolent but non-patronising planners or mediators and translated into expert language. Real betterments for marginalised people may still basically require the application of valid urban design knowledge in the face of possible resistance by powerful interests, which seems to be conceded by Susan Fainstein (2018, p.139) in her contribution to the *Handbook*, where, in the context, popular initiative and political struggle is otherwise emphasised.

What, then, are the key characteristics of a commonly desired urban environment? The answer must be conventional not to be controversial: at least, it should be ecologically sustainable and socio-economically well-working, as well as of high aesthetic quality. These purposes are non-distributive in the sense of being general and meant for all. This does not mean that justice would not need special attention, only that before pondering on how to distribute urban goods, one should be clear on what they are. Possibly, though, starting out from the above obvious planning purposes might be held only to postpone the real issue, as planning theorists of a post bent will be quick to point out. Nevertheless, as a starting point for planning and urban design, it is not insignificant to identify such goals as basic. It already outlines what may be conceived as a public interest, thereby refuting the view that everything is contestable. What is further needed is a more precise description of the key goals as well as their status in relation to each other and other possible goals.

As to the first task, 'ecologically sustainable' must certainly mean, at least, an environment that helps mitigate climate change and counteract the reduction of *global* biodiversity (eg, by lessening urban sprawl). To be socio-economically well-working, the built environment must, at least, enable users to be and feel safe, offer different kinds of spaces, both commercial and non-commercial, organised in a functionally and symbolically sensible way, satisfying varying needs and enabling the regulation of social relations (implying a hierarchy of privateness–publicness). An aesthetic environment not only carries artistic intrinsic value but also satisfies the needs for beauty and environmental experiential stimulation of users. As to the second task, the fundamental characteristics of the urban environment must not be regarded as just any goals to be considered but, instead, as forming boundary conditions for each other and further objectives. This does not necessarily mean that the key goals should be satisfied completely, only to a reasonable degree. Again, both the specification of the desired environmental characteristics and the exact extent to which they should be realised leaves space for argument. The point is that there in fact is some political-professional agreement on the prioritisation of planning aims.

The omnipresence of politics and agonistic struggle is not necessarily refuted by conceding such a hierarchical view. At each step of the concretisation of ends and means, there is space for reasoning and, in practice, for bargaining. One should note that conflicts may remain on a basic level. Thus, eco-fundamentalists might, coherently in view of their background understanding, hold that urban development should be halted and society reorganised in a work-intensive rather than energy-intensive manner. Radical critics of capitalism may as consistently claim that the unsustainability of urban development, like socio-economic development generally, stems from capitalistic contradictions that need to be solved before other measures can have any effect. In such cases, academic and political discussion is to be solved on a 'more fundamental' or general level, or one must accept that not all involved may be part of an agreement. This should not leave content-oriented professional action by urban designers or planners without any guidelines. True, part of the political struggle takes place in the theoretical sphere. In any case, advances in theory, even of social, planning and urban design theory, more contestable than natural science backing up requirements to act in an ecologically sustainable way, creates an onus of proof for those challenging it.

3 Public Space and Urbanity

While the focus of and the themes treated by urban design theory vary, public space is central to all the sources used. It is a suitable starting point for reconciling planning theoretical concerns with those of urban design and its theorisation since its vulnerable position in current urban development equally worries planning theorists (cf. Fainstein and DeFilippis, 2016, p.4). A discussion of urbanity, which is both tightly interwoven with public space and central to urban designers, then easily follows. To play a mediating role between the two lately separated theoretical realms, public space should be specified in relation to both its design features and its social properties. As there are many kinds of urban space with variable publicness and other features, threatening to make one particular characterisation appear idiosyncratic, it is appropriate to aim at an exemplar. The street (or square) space in (the centre of) the traditional European city is such an instance, defining a standard recognised by all. It may at the same time

be conceived as the paramount example of the urban in the architectural sense and as the archetypal setting of the urban in the social sense.

In fact, public space has simply been conceived as *the* object of urban design (eg, Cuthbert 2007). This, however, is certainly not literally true, as urban design includes various opposites of the definitively public, namely private spaces, suburban environments and other areas, such as parks and even forests, with varying degrees of publicness. More credibly, the design of urban environments may be contrasted with the architectural task of designing individual buildings or situating them in a rural setting, or in the wilderness, as well as planning on an abstract enough level, which may possibly justify a (partial) disregard of urban design features, even if no such delimitations can be sharp.

As to planning theory, which primarily focuses on urban issues in a more general sense and with varying relevance to urban design and architecture,[3] public space is still a central issue, relating to many social issues such as equal access and freedom of use of the city, or to the privatisation and commercialisation of urban space. There is not only a need to concretise planning theorisation and make it more readily applicable, as pointed out above. Urban designers, often working pragmatically in the crossfire of various needs and demands, may in their turn profit from a theory that systematically reflects on questions of equality, justice, sustainability, et cetera, in relation to specific types of solutions.

To elaborate on the cross-fertilisation of urban design and planning theory, with the prototypical public space of the traditional city serving as a mediator, the essential architectural and social traits of the latter should first briefly be outlined. Architecturally, this public space is formed by its strict delimitation by building walls, ground floors communicating with the street, numerous plots making for small building units, and detailed façades that contribute to a rich architectural impression. In social terms, public space makes up a theatre for various social occurrences that play a symbolic, political and socially integrative role. Although in modern society, political and social life is not wholly dependent on common physical locations, places where people can meet in person still form a backbone of it, as testified by the recent anaemic human existence in forced isolation under a pandemia.

4 Planning Theoretical Concerns: Justice, Plurality and Public Space

Several, perhaps most, of the content-oriented planning theoretical concerns thus require urban design measures to be fully met even when town planning is not (tautologically, in the context) understood in its traditional sense as architecturally focused. Sometimes, however, these actions are trivial from a design perspective in being immediately comprehensible and realisable without any genuine architectural effort despite formally containing a design aspect (eg, the demand to secure spaces for businesses and other activities on the ground floor). Yet in other cases, the link between the goals proposed in the abstract and their architectural realisation is not inconsequential. Everything may then depend on exactly how the physical interventions called for are carried out as to their dimensioning, their detailed architectural-symbolic

[3] Fainstein and DeFilippis (2016, 1) mention characterisations according to its object, that is, 'producing and regulating the relations of people and structures in space' and according to its method, namely, 'the process of decision making as it relates to spatial development'.

properties and their functional coordination with other environmental traits. For this link to be theoretically catered for, an urban design theoretical extension of what today is the preserve of planning theory is needed.

Depending on the viewpoint, this vital connection to urban design holds for both justice and pluralism (or difference), which are both prominent themes in planning theory. Undeniably, in the manner justice is treated in planning theory, the urban design aspect may sometimes be justifiably avoided. For example, the issue whether there is enough subsidised housing to provide for poor people's needs seems a political-administrative question, which might not be an issue for the old-style town planning office. This changes once attention is turned to environmental features, for instance relating to needs specific to less resourceful people (or more important to them), to be spatially integrated with other functions. In her treatment of justice, Susan Fainstein (2018) thus, in her practice-oriented conclusions, touches on design-related aspects of a just urban environment, such as provision of basic amenities in the ground floors of subsidised housing.

The currently salient theme of avoiding segregation, also treated by Fainstein, likewise relates to justice and, at the same time, to pluralism. Non-segregation is brought to the fore on several levels of urban development. Flagrant segregation should be avoided not the least on a regional and district level. Segregation may easily arise under conditions of unequal distribution of income and wealth as some urban areas are generally more valued than others, for example due to assets such as a seashore or lakeshore, parks or architecturally interesting historical surroundings. Once such 'natural' segregation occurs, it may easily take on a self-enforcing character since people who can choose, often prefer to live not only at a location with favourable environmental qualities as such but also at addresses with high status. (Hence, homes with a less attractive location within a valued area might be overpriced from the 'objective' point of view.)[4]

On the micro level, on the other hand, a clearcut form of counteracting segregation, which does not necessarily involve urban design measures, is to mix the forms of tenure of a building, an urban block or a district. (Such methods are also relevant on the level of the whole city, as inserting subsidised housing at least somewhere within affluent areas lessens the extreme one-sidedness of supply.) As environmental psychologists have pointed out, however, it matters in what way different socio-economic, age or ethnic groups are mixed on the micro level of the urban block, as differences in lifestyles might cause tensions, whereas possibilities to meet on 'neutral ground' may enrich local life and benefit everybody. Again, sociologically informed building architecture and urban design might be decisive for non-segregating but diversity-generating planning to be realised.

These points are elucidated by Mokarram Abbas and Bas van Heur (2014), whose research is situated in the context of Palestinian urbanity. It emphasises the importance of spatial organisation for both the persistence of and the possibilities to intervene in perceived social and political problems in town planning by urban design means. The theoretical perspective is that

[4] It is important to note, though, that not all people have the same environmental preferences (not even if the notion of preference is not mixed up with the ability to pay). This calls for balancing the planning objective of levelling differences of a segregating kind with that of creating precondition for urban diversity on the meso-level by a differentiation of districts.

of feminism in relation to women and planning, while the object of study are the socio-spatial features of women's urban life in the town of Nablus, where attitudes towards women's presence in society are conservative. A central issue raised by the authors is what line to take to a culture that is discriminating in some sense, when these features will have an even more oppressing effect if not taken into account (whether out of principle or due to naïve generalisation of Western standards) in designing the environment. In the investigated town, where women prefer small semi-public spaces in which they are better tolerated and less exposed to male control and incivilities, the case studies for the research (including both interviews and observation of the sites) indicate that design features of such spaces, such as walls and vegetation limiting the view from the outside, notably complement formal (not strictly enforced) rules restricting the access of men into the area.

Again, the proposed means, as such, are not especially demanding from an urban design viewpoint once comprehended, although sophisticated architectural thinking in the realisation may add to the success of the spaces. A suitable further planning undertaking might be to provide for such small-scale semi-public spaces all over a city, while one may imagine – without knowledge of the cultural conditions – urban design complementing with the use of feminine symbolism and other traits, perhaps in the end even making female, neutral and male dominated spaces meet to secure the female world ever more safe visibility and influence. Here, of course, the danger of architectural naivety lurks as soon as one deceives oneself with an exaggerated belief in the capacity of environmental traits as such to change social behaviour, thus ignoring its structural conditioned nature. Therefore, any efforts of further integrating women into society with design means should certainly be done parallel with non-architectural policy measures and inclusive democratic deliberation.

Another case, where even the nature of the issue depends on urban design related clarification, is that of gated communities or (the possibly less strictly fenced off areas) enclosed residential domains. David Hamers and Joost Tennekes (2015) discuss the effects of the latter on the public realm in the Netherlands in relation to the invigorated debate about gated communities. At the same time as their study, in a most ambitious planning theoretical manner, is based on analysing how alternative positions in social theory and philosophy affect the perception of the empirical case studied, they observe that taking up a stand to the issue requires a detailed analysis of the morphology of the developments making up the research object.

Hence, it seems necessary to clarify what the research object is. The city, its districts and urban blocks consists of a pattern of stepwise or clearly differentiated private and public spaces, which may be so either formally in terms of law or visually-functionally, depending on legibility and factual use. For example, perimeter blocks articulate the difference between public and private space in a rather definite way, while such differentiation is often more difficult in suburban areas, such as in a 'buildings in a park' settlement. There, signs frequently appear to mark out boundaries that urban design has left diffuse. Now, few people would criticise the enclosing of courtyard areas of private houses or reserving perimeter block courtyards for the residents, even when such urban blocks are large and thus lessen the permeability of a district. The situation changes dramatically if a whole network of streets, seemingly forming an integrated part of the city, are suddenly fenced off by cast iron gates across the street, as can be observed in, for instance, the 16th arrondissement in Paris. The reason has to do with the legibility of the city, more precisely with breaches against what we have learnt to expect in an urban environment.

Functionally, it also means that some people are not possible to reach without an appointment, which is certainly part of the plot but somewhat foreign to the traditional functioning of a city.

5 Urban Design Concerns

Most urban design, at least in principle, aims at producing a good urban environment for all, as if architectural town planning were carried out from behind a veil of ignorance, rather than being tailored for some specific social group. Not the least in welfare societies such as the Nordic, more or less the same recipe is applied in all cases, the planners not necessarily knowing what groups will move in. Variation instead stems from the location of the site and environmental values specific to it. When planning for decisive urbanity and well-working public spaces, the purpose is exactly the synergetic integration of different activities, social groups and urban functions (which should not, of course, exclude directing special attention to special needs). Nevertheless, for marginalised or vulnerable groups, an urban environment that is socially well-working in general terms may be particularly important (cf. Fainstein, 2018, p.139) since such groups may not be as self-sufficient as to space and equipment or have the resources to reach services at distant locations.

The urban design literature treated varies as to its concreteness and social or societal references. As the urban design task intrinsically involves the social, the issue is whether broader social goals, preconditions and consequences are discussed and whether the literature accounts for conflicting interests and political views on the preferred design solutions. The need for social engagement varies depending on the specificity of the themes treated. The danger in the urban design context are textbooks and handbooks that neglect the relevance of interests and political awareness, favouring instead a conventional pragmatic approach serving the status quo, even though for example the climate crisis would demand radical action.

Tarbatt and Tarbatt's *The Urban Block*, to a great extent restricts itself to a systematic classification and characterisation of different urban block types, explaining morphology and dimensioning by needs that have produced them (eg, large depths of buildings being tied to, inter alia, the requirements of a parking garage). The book often mentions the pros and cons of different solutions in terms of properties such as legibility (eg, relating to the private or public character of the space). Differing expert views that ultimately might take a political shape may then possibly be overlooked. Still, the comments provided should mostly be taken to reflect the professional ability to see the consequences of specific solutions produced by specific needs or aesthetic preferences for the urban whole. The primary need in the context is not to criticise urban development or to politicise the treatment in other respects. Still, in drawing attention to properties that according to a certain professional consensus make for a good built environment, the authors provide planners with well-grounded arguments as against private interests in profit. At the same time, the explicit formulation of the knowledge behind often pragmatic design may contribute to avoiding haphazard results of democratic decision-making ignoring the best available arguments and knowledge.

Panerai et al.'s *Urban Forms* also treats the theme of the urban block, yet from an even more specific viewpoint. The two foci of the book are, first, the urban block as a building block for the city, forming a critical mediating meso-level structure between the separate buildings and plots, on the one hand, and the district and larger urban structure, on the other. The second is

the traditional morphology of this entity as such: its perimetral character, division into plots, clearcut separation of private and public spaces as well as its multifunctionality. The classical perimeter block is then compared to modern developments of it. For the authors, the social uses and patterns that the traditional urban block enables are as important as its architectural features. They are critical of critics of modernity, including post-modernists, for ignoring the social dimension in instead focusing on formal architectural features. Thus, while architects have tried to reinvent the city after a period of suburban growth, according to the authors, they have often failed as they have not paid enough attention to the classical urban fabric on the level of urban block.

Carmona et al.'s *Urban Places, Public Spaces*, is the most general discussion of city building from the viewpoint of public space. Yet, like *The Urban Block*, its aim is to provide a comprehensive overview of the broad theme treated rather than, as *Urban Forms* does, take a definite stand to a neglected a problem. A background is provided of the meaning of and traditions within urban design (visual-artistic, social usage, place-making) as well as of writing focusing on it since Jane Jacobs. In justifying the endeavour, the authors use examples to illustrate cases where a holistic view on the urban environment is lacking and where an uncoordinated provision for pragmatic needs, not the least of parking spaces, may result in a clearly unattractive urban environment. They discuss urban development both as to its results and to its drivers and situate newly arisen ideals, such as various urbanisms, in this societal context. Also, they account for how governmental organisation and action affects the preconditions of urban design. Here, there are obvious shared interests with present-day planning theory.

In covering dimensions of urban design, first of all urban morphology, including the urban block structure and plot division, Carmona et al. take a critical stand to the development, in line with Panerai et al., without therefore advancing a definite thesis. The critical stance rather follows from what today is commonly regarded as the basic tasks of urban design as well as from contemporary strivings, for example towards decisive urbanity. In this way, again, the importance of the treatment lies, except for the vital task of providing students, practitioners and researchers with a comprehensive understanding of the field, in enabling them to argue for the urban design perspective as such (rather than for specific solutions) in various contexts of urban development.

Whereas the aim of *The Urban Block* is to introduce, in an easily graspable if comprehensive form, the urban block alternatives at the disposal for the urban designer/town planner architect in developing different parts of the city, *Urban Forms* more clearly articulates a consistent critical perspective, favouring one type of urban block structure, largely for social reasons. The approach of *Urban Places, Public Spaces* can be situated in between these as its scope is broad, bringing societal aspects to the fore, but still aims at a balanced viewpoint, acceptable to most actors within the field. (This may have come true for *Urban Forms* as well since the mainstream has moved in the direction recommended by the authors, if not, perhaps, heeding its detailed prescriptions, making all the difference for them.) If the urban design literature treated, and comparable literature, provides a substantial knowledge basis for actors involved in urban development (cf. Moudon 1992), there are several aspects in which the ideas may be developed in a planning theoretically pertinent fashion.

For example, a nuanced discussion is called for about whether the urban block structure favoured by Panerai et al. might be enrich in a way partly accommodating post-modernist and contemporary ideas about semi-private and semi-public space by manipulating rigid divisions effected by classical spatial arrangements within and adjacent to the perimeter block. Such may be the provision of a semi-public courtyard as well as semi-private forecourts, when suitable in view of the urban environment. This does not depend on breaking down the morphological features of the perimeter block. The discussion may be tied to basic interests of planning theory, as regards the integration of various social groups defined by age, gender, class, ethnicity et cetera.

Also, once understanding the critical features of the classical block and its contemporary variants, a main urban design endeavour should be to coordinate the urban development, allowing for morphological and associated social diversity, simultaneously restricting the ecologically disastrous effects of urban sprawl. Could New Urbanist ideas about a Transect logic be employed without necessarily accepting their detailed design principles? A main benefit would be an increased legibility and identity as well as possibilities of enjoying public space and neighbourhood services in suburban environments containing small town qualities.

6 Discussion

In my treatment, I have pointed to ambiguities in the core of planning theory concerning its research object and research interests. As to the first, there is the division into procedural and content-oriented theory, where procedural theory has come to deal with participatory democracy (rather than the technical planning process) and content-oriented theory focuses on relatively abstract social goals, where the connection to specific spatial-architectural traits of the built environment at best remains vague. In addition, the theorising is often partisan, rather than building on consensual starting points. Although radical theory is not reprehensible as such, one might expect the primary question to be why nominally consensual objectives, such as mitigation of climate change or a socially-economically well-working urban environment, are not reached, for example, by means of currently favoured decisive urbanity. If, for some theorists, the answer seems clear (eg, due to capitalist interests), to be able to understand the causal and structural mechanisms, it would be necessary to clarify the goals. What is, for example, a socially well-working city? Switching for a moment to a deeper theoretical level, one may suspect some power/knowledge mechanisms producing conceptual muddle even in cases where the needed action should be relatively easy to grasp, such as in relation to ecological sustainability. Anyhow, specification of goals regarding the built environment is not easy without studying how architectural traits interact with social interaction on different levels, from that of the home to the urban region. Therefore, the missing link between planning theory and urban design theory is problematic.

The treatment is partly based on looking more closely [if definitely not closely enough] at both planning theory and urban design theory. One intersection between their interests is in public space. Although this may be both more or less public and inclusive, depending on its qualities and location, it is clearly one of the main urban qualities for planning theorists, enabling free social interaction, integration, political activism and lingering in the city without necessarily consuming. It is relevant from both a justice and pluralism (difference)

perspective. Yet again, it remains a vague notion without a description in urban design terms. It also admits for interesting discussions from the viewpoint of other cultures and current important theoretical perspectives, such as feminism. It is at centre stage in topical debates, such as that of gated communities. Again, however, one should specify the morphological properties of the urban structure for wholly comprehending what is at stake from a social viewpoint and what is common for contextually varying developments.

It is admitted that there are different levels of urban design relevant treatment of planning issues. In some cases, the issue is abstract enough not to necessitate any architectural dimension. The problem is if one is left with the impression of a missing link to urban design, which might make a highly abstract treatment both comprehensible and implementable. There is therefore no problem with abstract theory as such: the structurationism of both Bourdieu and Giddens, or the architectural thinking of Foucault, to mention a couple of eminent social theorists whose main interest is not town planning, may help comprehend the spatial dimension of social life and applying a fruitful theoretical perspective.

Abstract
Adaptive planning aids in addressing nonlinear urban changes through dynamic adjustments. This study employs knowledge mapping and meta-analysis methods to examine the progress and effectiveness of adaptive planning research in China over the past two decades. The results indicate that China has focused on the application of adaptive planning in environmental areas, gradually expanding to territorial spatial planning. Key areas of focus include ecological protection, urban renewal, and transportation development. The overall effectiveness of adaptive planning implementation in China has been positive, though attention is needed on developing multiple alternative plans, enhancing community participation, and increasing long-term investment in adaptive processes. This study identifies adaptive issues and response strategies within the Chinese planning context, aiming to enrich the global research system of adaptive planning.

Keywords
adaptive planning; Chinese practice; research progress; implementation effectiveness

1. Introduction

Global cities are facing profound uncertainties in economic development, environmental climate, public health, infrastructure, and other aspects, posing unprecedented challenges for urban planning. Adaptive planning, as an innovative planning concept, is increasingly receiving attention in academia. Due to its dynamic evolution and the involvement of multiple stakeholders, adaptive planning can assist cities in overcoming short-term uncertainties and create sustainable long-term futures through dynamic adjustments.

In recent years, international research on adaptive planning has been gradually increasing, encompassing diverse disciplines, theoretical foundations, and technological levels. Apart from the typical adaptation to climate change studies(Ahern, 2011; Cai and Wen, 2017), other research focuses on adaptive governance of urban built environments. From the perspective of community participatory planning, discussions revolve around governance strategies concerning sea-level rise(Vella *et al.*, 2016), policy logic(Urwin and Jordan, 2008), ecological resilience in urban design(Ahern, 2013), and the adaptive governance process in comprehensive urban transportation planning(Shin and Lee, 2017).

Other studies aim to innovate theoretical frameworks, emphasizing adaptive capacity in spatial planning(Kruse and Pütz, 2014), survival health(Zhang and Puterman, 2013), and climate change(Fu, 2020), along with discussing adaptive strategies and actions in transportation planning(Chow *et al.*, 2011), community governance(Zandvoort *et al.*, 2019), and disaster impact sectors(Nohrstedt *et al.*, 2022). Additionally, cutting-edge research focuses on adaptive planning application methods such as building adaptive models(Marsal-Llacuna and Fabregat-Gesa, 2016), algorithms(Chen and Yu, 2020), and scenario planning(Lempert *et al.*, 2006; Abou Jaoude, Mumm and Carlow, 2022).

In May 2022, the Chinese government issued the "National Climate Adaptation Strategy 2035," marking adaptive planning as a primary approach for China's climate issues in the new era. In China, adaptive planning is gradually becoming a focal point in academia, potentially offering more Chinese insights to global adaptive governance. Chinese researchers emphasize integrating adaptive processes with local planning characteristics, such as aligning with China's rural revitalization strategy(Yu, Qi and Gong, 2019) or integrating adaptation into unique Chinese planning policies like overall planning(Zhan and Sheng, 2014), and detailed planning(Yao, 2011).

Moreover, Chinese researchers excel in establishing adaptive systems within spatial planning contexts(Wu, 2021; Yue, Wei and Chen, 2021; Wang *et al.*, 2023), expanding to diverse planning scales. At smaller scales, discussions focus on the adaptability of parks(Li, Fan and Ma, 2018) and neighborhoods(Wang and Zang, 2018). At larger scales, exploration extends to area morphology(Chen, Sun and Li, 2021), green space systems(Xiao, Cao and Li, 2020), water space(Du and Tang, 2015), and cultural heritage sites(Song, Zhang and Xu, 2011), aligning with urban spatial adaptation. Additionally, research examines how adaptive methods can better serve population(Neumann *et al.*, 2015), public health(Leng and Li, 2021), and comprehensive transportation planning(Huang and Xu, 2019).

However, there are two shortcomings in the review analysis of adaptive planning: firstly, most reviews focus on climate change, lacking attention to the essence of "adaptation." Secondly, as mentioned subjectively, most reviews are qualitative, making it challenging to effectively reveal domain hotspots, structures, and implementation effects.

Therefore, this study focuses on indigenous Chinese adaptive planning research and practices. The second part defines the conceptual connotations of the study, the third part delineates the research progress of Chinese adaptive planning, the fourth part proposes issues and corresponding action plans, the fifth part studies the effectiveness of action implementation, and the sixth part discusses the practical insights of Chinese experience on global adaptive planning. We hope that through adaptive research on China's multi-element, multi-scale urban-rural complex systems, we can provide relatively objective experiential references for global researchers in adaptive planning (Figure 1).

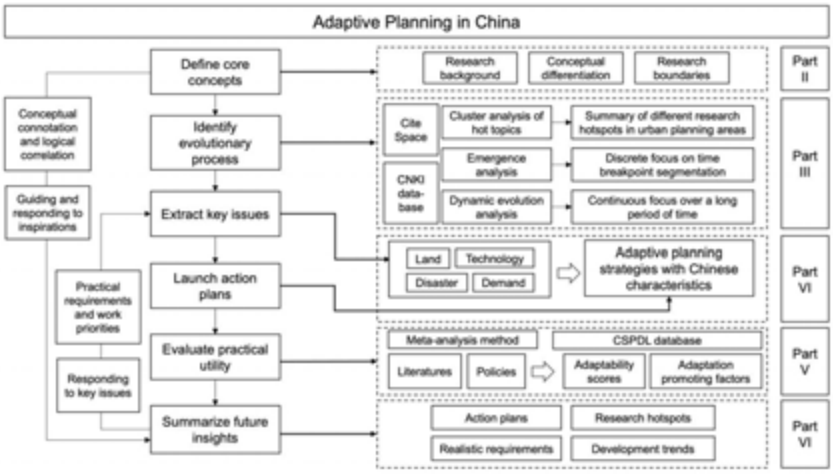

Fig.1 Research Framework

2. Concept: Understanding Adaptive Planning in China

A thorough understanding of the conceptual boundaries of adaptive planning is essential. "Adaptation" generally refers to continuous change and achieving balance with the environment.

This study considers multidimensional urban research and defines adaptive planning as "a proactive and dynamic approach to addressing uncertainties in urban development." Unlike traditional static and long-term planning, adaptive planning emphasizes pre-planning, rehearsal, and simulation for all scenarios, setting planning goals and specifics within shorter timeframes. During implementation, new events are continuously integrated, multi-stakeholder democratic decision-making is employed, and planning content is iteratively adjusted.

In the Chinese planning context, adaptivity has broader theoretical characteristics. First, adaptation is a tool for mitigating uncertainty. Chinese planning agencies conduct comprehensive surveys across transportation, social, and cultural domains, leveraging interdisciplinary perspectives to counter urban uncertainties and maximize planning benefits.

Secondly, adaptation is a dynamic process. Influenced by the Chinese philosophical concepts of "harmony between man and nature" and "non-action," Chinese adaptive planning

sets long-term development goals for each city and continuously monitors progress, aligning with the natural development patterns and effectively meeting the dynamic nature of planning.

Lastly, adaptation results in meeting individual needs. Guided by the "benevolent governance" philosophy of "Ren," Chinese planning emphasizes individual adaptation, addressing a wide range of ecological, cultural, transportation, social, disaster, and health needs. This approach is closely linked to the framework of Chinese planning disciplines.

3. Progress: Summarizing the Research Trajectory of Adaptive Planning in China by Knowledge Graphs

3.1 Methodology and Data Source

This study utilizes CiteSpace, a software developed by Professor Chaomei Chen, for scientometric and visualization analysis of Chinese literature. The software uses nodes, links, and colors to visualize the frequency, connection strength, and time intervals of literature, alongside keyword clustering analysis, burst detection, and dynamic evolution analysis.

Data is sourced from the China National Knowledge Infrastructure (CNKI) database, covering the past 20 years (2004-2024). After filtering the search results, 267 Chinese articles were selected for analysis.

3.2 Results

3.2.1 Analysis of Hotspot Keyword Clustering

Over the past 20 years, the most frequent keywords in China have formed three major clusters: "adaptation" + "urban planning," "climate change" + "territorial spatial planning" + "landscape architecture," and "urban rail transit" + "planning" (Figure 2). Adaptive methods have increasingly dominated planning theory and practice.

On the theoretical level, research has focused on the origins of complex adaptive planning(Sun *et al.*, 2016) and sustainability(Ahern, 2011), ecological civilization(Du, He and Bao, 2018), resilient cities, and improving living environments(Cai and Wen, 2017; Chen and Li, 2023).

Practically, studies have examined the adaptability of master planning(Zhan and Sheng, 2014), regulatory planning(Yao, 2011), and the evaluation of planning implementation(Tang *et al.*, 2021). Territorial spatial planning(Wu, 2021; Yue, Wei and Chen, 2021; Wang *et al.*, 2023), urban spatial structure and morphology(Chen, Sun and Li, 2021), along with urban renewal(Li and Zhao, 2021) and old neighborhood renovation(Zhang *et al.*, 2023; Zhao and Liu, 2023) have also been explored.

Additionally, research has focused on international experiences in adaptive planning(Jiang, Yuan and Yu, 2021), health risks(Zhou, Wang and Wang, 2021; Chen, Wu and Lai, 2023), public policy and governance models(Qin, 2022), as well as rural and urban landscapes(Li, Fan and Ma, 2018; Ding and Ji, 2020) and transportation systems(Huang and Xu, 2019; Cui and Liu, 2023).

The focus of Chinese adaptive planning over the past 20 years has been closely linked to the development of traditional planning modes, evolving to address subcategories such as "spatial morphology, landscape green spaces, rail transit, and planning implementation" in response to the requirements of territorial spatial planning. However, the extensive knowledge network covered by these research clusters still requires theoretical and methodological innovations driven by "cross-disciplinary integration" keywords.

Fig.2 Co-occurrence of Hot Keywords and High-Frequency Information

3.2.2 Analysis of Emerging Hot Keywords

The strongest keyword emerging in China over the past 20 years is "territorial spatial planning," which has been emerging since 2021 (Figure 3). In May 2019, the Chinese government specified the establishment of a territorial spatial planning system and supervision implementation, achieving "integrated multiple plans into one." Provinces across the country have successively launched the compilation of 2021-2035 national spatial plans, coinciding with the starting period of related research emergence.

"Territorial spatial planning" also dominates with an emergence intensity coefficient of 5.73, becoming a recent research hotspot alongside topics like transportation development(Huang and Xu, 2019; Cui and Liu, 2023) and spatial renewal(Li and Zhao, 2021). Keywords such as "landscape architecture" and "urban planning" also reflect the characteristic of adaptive planning serving related disciplinary studies.

The emergence of "urban spatial structure" lasted for six years from 2011 to 2017, experiencing extensive, large-scale, and gray construction processes. China's urbanization construction focuses on urban spatial form structure(Wang and Zang, 2018; Yan *et al.*, 2018; Chen, Sun and Li, 2021), making refined adaptive adjustments and becoming a topic of sustained attention in recent years. Keywords like "urban renewal"(Li and Zhao, 2021), "urban governance"(Gu, Wu and Dai, 2021; Qin, 2022), and "rural revitalization"(Yu, Qi and Gong, 2019) had the latest starting time for emergence, reflecting recent research priorities in Chinese adaptive planning.

China's cities are gradually entering an era of stock urban renewal, requiring attention to urban-rural integration, ecological protection, industrial economy, and other diverse planning entities for flexible governance adjustments. It is evident that China's adaptive planning has gradually shifted its focus from climate change and disaster management to specific urban issues and adaptive implementation in recent years, providing a significant inspiration for international planning research.

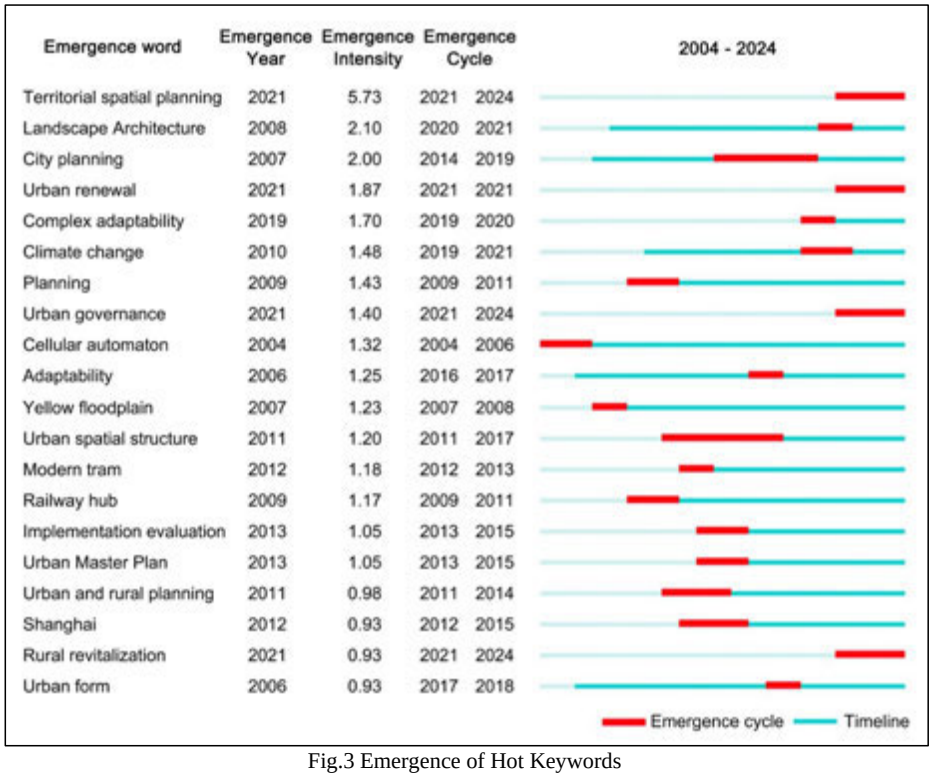

Fig.3 Emergence of Hot Keywords

3.2.3 Dynamic Evolution Analysis of Hot Keywords

Over the past 20 years, the hot keywords in China's adaptive planning have formed multiple generalized clusters such as climate change, urban rail transit, and spatial structure, indicating a dynamic evolution in three stages (Figure 4, Figure 5).

From 2004 to 2010 was the initial exploration period of China's adaptive planning, with relatively dispersed research content focusing on planning simulation, compilation, and multi-element adaptive planning involving urban form, water systems, and hub facilities.

From 2010 to 2020 marked the integration period of China's adaptive planning with climate change response. As global climate change issues unfolded, Chinese researchers actively engaged in climate adaptation as the main theme, exploring multi-element adaptive planning including public transportation, urban form, open space, cultural heritage, and public participation control.

Chinese literature during this period tended to discuss sustainable slowing and adaptation in the urbanization evolution process of the living environment and the dialectical relationship between planning development and protection.

After 2020, China entered a development phase where adaptive planning was incorporated into spatial planning, reflecting the era characteristics of Chinese planning. Based on territorial spatial planning, related research conducted adaptive governance studies on participatory planning, supply-demand optimization, public service facilities and space disaster reduction, urban renewal, etc., implementing spatial planning adaptation requirements of "comprehensive, all-element" and "step-by-step conduction."

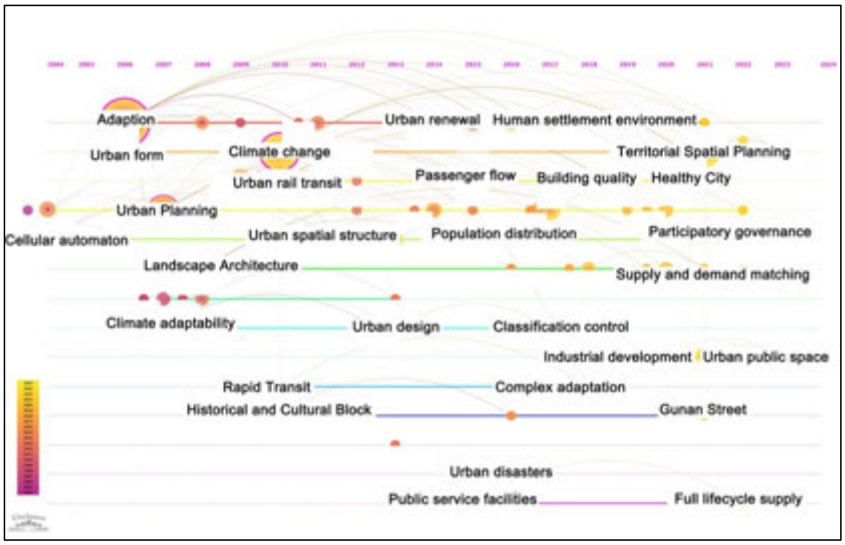

Fig.4 Timeline of Hot Keywords

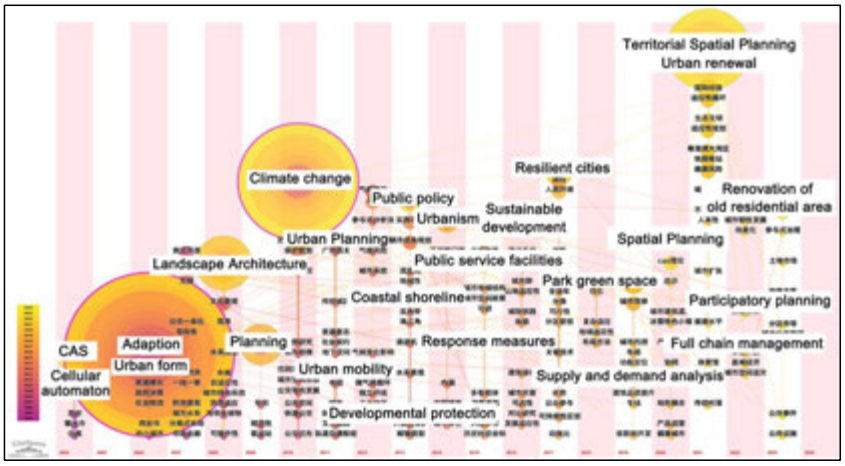

Fig.5 Time Zone of Hot Keywords

4. Issues and Actions: Addressing Adaptive Planning Challenges with Chinese Approaches

4.1 Key Issues in the Transformation of Urban Adaptive Planning in China

The concepts of urban planning in China are undergoing a transformation due to adjustments in national government structures and the introduction of territorial spatial planning policies. Based on a review of the past 20 years of research on adaptive planning in China, several key issues in this transformation have been identified.

On the research front, planning theory lags behind practice. China aims to integrate national strategic policies with theoretical and practical applications to enhance effectiveness. The efficient functioning of state machinery relies on the execution advantages of various administrative levels, necessitating that adaptive planning actions spatially respond to strategic directives.

Spatial planning must adapt to the processes and outcomes of top-level strategies proposed by the Chinese government, such as "ecological civilization," "a community with a shared future for mankind," "carbon peaking and carbon neutrality goals," and "a country with strong transportation network."

In practice, planning has yet to robustly address urban uncertainties. China is designing adaptive toolkits for different scales, adopting spatially adaptive resource management actions to handle urban nonlinear changes. For instance, in the later stages of urbanization, new technologies like autonomous driving and artificial intelligence are leveraged to meet diverse individual needs.

Guided by these key issues, China is exploring an action path for adaptive planning, leveraging its institutional and execution advantages to facilitate a shift in thinking.

4.2 Adaptive Planning Actions Addressing Key Issues

The most prominent feature of China's adaptive planning, and its most effective action plan, is the integration of territorial spatial planning with multi-scale and multi-objective adaptability.

At the national and regional levels, strategic planning is spatially implemented to manage gradual or drastic changes in urban development, ensuring controlled and positive development in the medium to long term. At the city and community levels, multi-objective comprehensive adaptation and the realization of citizen will be emphasized, ensuring iterative adjustments throughout the lifecycle of planning, akin to "moving targets" for stationary objectives.

This process is often driven by specialized administrative bodies, benefiting from top-down administrative execution and long-term construction. An efficient policy implementation system ensures that national intentions are accurately reflected spatially, responding to top-level strategic designs. This facilitates effective linkage and practical implementation of adaptive planning at various scales in China.

Additionally, China's adaptive planning employs cross-disciplinary research methods and legally integrated planning processes, providing multi-domain feasibility and responding to the comprehensive theoretical core of China's adaptability.

Collaboration between experts from academia and industry has yielded various contingency plans for different urban types and emergencies, such as shrinkage planning and refined governance for high-density cities, smart growth and urban-rural integration for developing cities, and the use of emerging technologies for planning autonomous driving lanes, simulating residential patterns, or identifying ecological risks.

Moreover, community participatory governance effectively meets individual needs. China has implemented a legally recognized and protected system where experts with planning backgrounds serve as responsible planners for specific urban communities. This ensures that different urban areas can genuinely adapt to local characteristics during development and that higher-level administrative directives are implemented more normatively and efficiently. Additional examples include adaptive spatial planning strategies that cater to children, the elderly, and people with disabilities, as well as promoting pedestrian and cycling-friendly environments.

5. Effectiveness: Quantifying the Implementation Outcomes of Adaptive Planning in China Using Meta-Analysis

5.1 Methodology and Data Sources

Firstly, we conducted a comprehensive literature review of Chinese adaptive planning, selecting cases through abstract and full-text analyses to finalize our dataset.

Given China's political system, many adaptive planning implementations are enforced through government policies, either mandatorily or non-mandatorily. Consequently, we also collected relevant policies and administrative announcements from the State Council Policy Document Library, the official repository designated by the Central People's Government of the People's Republic of China.

The rigorous nature of official documents resulted in a limited number of relevant records from a single search. Therefore, we broadened our data collection scope to include documents related to adaptive planning in areas such as climate and environmental protection, social equity and inclusion, disaster resilience, transportation and infrastructure, public health, and urban preservation and renewal.

The criteria and process for selecting literature and policies are illustrated in Figure 6.

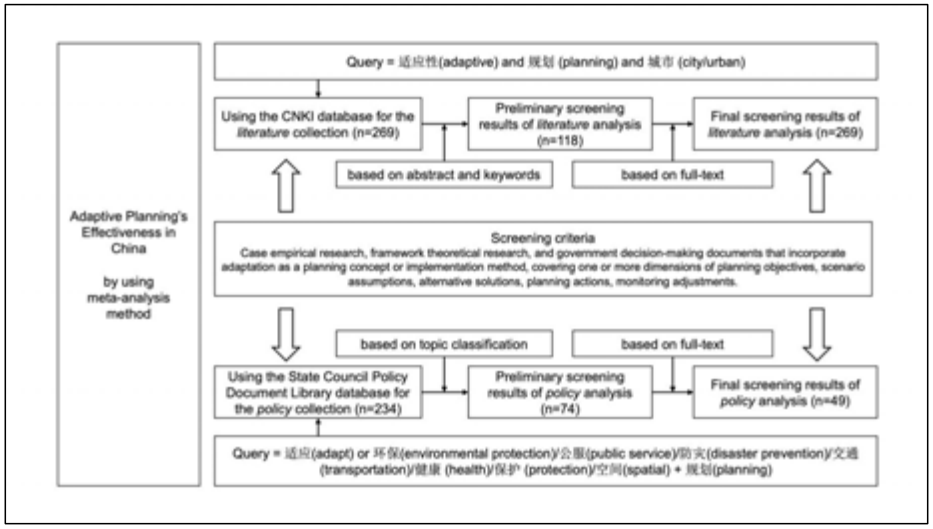

Fig.6 Selection Criteria for Meta-analysis Records

Next, we adapted a methodology from similar studies by Shirin Malekpour and Jens Newig (2020). Drawing from literature reviews by Jeuken et al. (2015), Quay (2010), and Walker et al. (2013), and tailored to China's context, we adopted evaluation dimensions including goals, scenarios, plans, actions, and monitoring. These dimensions were employed in a meta-analysis to assess and statistically evaluate the collected records. The formula used is as follows:

$$U = \sum_{k=1}^{N} S_k$$

$$S_k = \sum_{i=1}^{n} W_i * F_i$$

Where:

U represents the total adaptability score for all records.

N is the number of collected records.

S_k represents the total adaptability score for the k^{th} case, $S_k = \{0,0.5,1,1.5,2,2.5,3,3.5,4,4.5,5\}$.

n is the number of evaluation factors, which in this study is 5.

W_i is the weight of the i^{th} evaluation factor, which is set to 1 based on relevant literature (Shirin Malekpour and Jens Newig).

$F_i$is the adaptability score of the i^{th} evaluation factor, $F_i = \{0,0.5,1\}$.

The specific meanings and scoring standards are detailed in Table 1.

Tab.1 Definition and scoring criteria of evaluation factors

Evaluation factor	**Code**	**Definition**	**Score**		
			0	**0.5**	**1**
Planning objectives	F_1	Expectations for the outcomes of adaptive planning should include both quantifiable and non-quantifiable results.	Not any Planning objectives.	Goals may be vaguely defined or not easily quantifiable.	A list of clear and quantifiable objectives has been established.
Scenario assumptions	F_2	Various future planning scenarios and their potential outcomes should be hypothesized.	Not any Scenario assumptions.	One or two planning scenarios or hypotheses in different application areas have been proposed.	Three or more planning scenarios or hypotheses across different application areas have been proposed.
Alternative solutions	F_3	Multiple flexible planning actions should be proposed, with at least one plan adopted at each planning stage.	Not any Alternative solutions.	One or two alternative plans have been suggested.	Three or more alternative plans or phased implementations have been suggested.
Planning actions	F_4	There should be a conceptual or framework explanation for achieving the goals of adaptive planning, accompanied by concrete actions.	Not any Planning actions.	Conceptual or framework guidance for planning assumptions and alternative plans has been provided, but no concrete actions have been taken yet.	Clear and quantifiable action plans for the planning assumptions and alternatives have been provided, or concrete actions have already been taken based on existing plans.
Monitoring and adjustment	F_5	Continuous monitoring of any critical changes is essential, with proactive measures taken when necessary.	Not any Monitoring and adjustment.	Conceptual or framework methods for future monitoring and adjustments have been proposed, but no monitoring	Clear monitoring and adjustment goals have been established for existing plans, or ongoing monitoring and dynamic adjustments are being conducted.

				actions have been implemented yet.	

Finally, based on the attributes of the Promoting Factors in each record, we calculated the total score for all Promoting Factors from the evaluation results. This analysis identified the most critical driving factors for the implementation of adaptive planning, which can provide valuable governance insights for future research and practice in adaptive planning in China. The formula is as follows:

$$P_j = \sum_{k=1}^{N} S_k * \frac{1}{T_k}$$

Where:

P_j represents the adaptive score of the j^{th} Promoting Factor.

T_k represents the total number of adaptive Promoting Factors summarized from the k^{th} record.

N, k, and S_k have the same meanings as previously defined.

5.2 Results

5.2.1 Overall adaptability

Based on the aforementioned evaluation criteria, the overall status of completed or ongoing adaptive planning cases in China is relatively favorable, with an overall adaptability score of 2.32. Specifically, for individual evaluation factors with a total score of 1 point, these cases performed well in Planning Objectives, Planning Actions, and Scenario Assumptions, with average scores of 0.68, 0.60, and 0.61, respectively. However, there is room for improvement in Monitoring and Adjustment and Alternative Solutions, with average scores of 0.25 and 0.17, respectively (Figure 7).

In the various fields of adaptive planning in China, the highest number of records, 64, is in urban and rural planning and construction. Transportation and climate fields have 13 and 11 records, respectively, while other fields have fewer than 10 records. The average adaptability scores across different fields are relatively high. Notably, the disaster and climate fields achieved impressive average scores of 2.63 and 2.59, respectively (Figure 8).

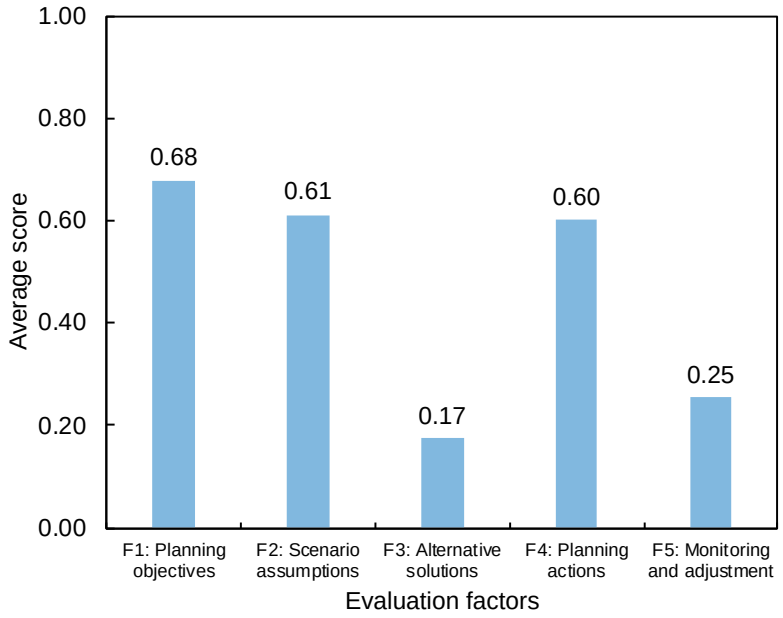

Fig.7 Average Adaptability Scores under Five Evaluation Factors

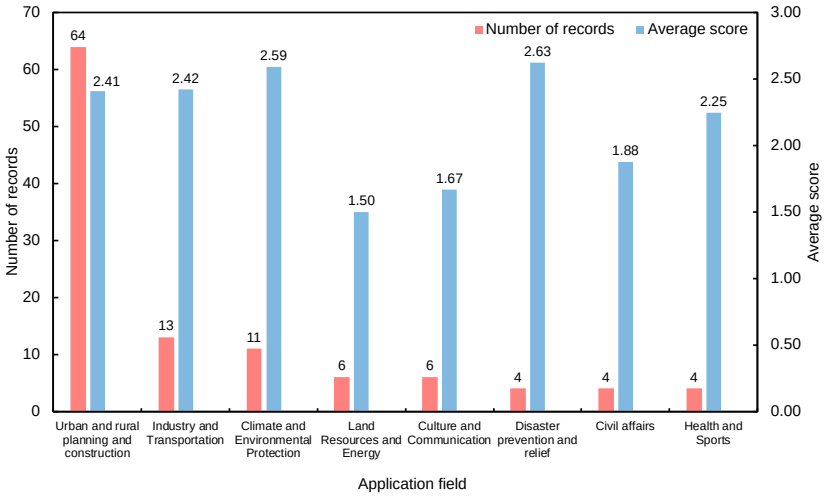

Fig.8 Number and Scores of Adaptive Planning Records in Different Fields

5.2.2 Promoting Factors of Adaptive Planning

We also identified ten key Promoting Factors for the adaptive planning process based on the content of the selected records (Figure 9). It is evident that top-down administrative orders

and interdisciplinary research are the most effective Promoting Factors, with 59 and 49 records respectively, and average scores of 0.41 and 0.36. Continued efforts are needed to promote community participation and public support, as well as investment activities involving related enterprises, as these factors have relatively low numbers of studies and average scores. According to the t-test results, administrative orders and community participation significantly impact the overall adaptability scores.

Regarding the effects of Promoting Factors on different evaluation factors (Figure 10), top-down administrative orders effectively promote the completion of planning objectives, actions, and subsequent monitoring, which is related to the Chinese government's public authority. Interdisciplinary research facilitates the use of scenario assumption methods, while cutting-edge technology supports the development of more alternative solutions, likely due to the academic community's application of theory and methods to practice. Additionally, interdisciplinary research and theoretical expansion play critical roles in meeting planning objectives and achieving overall adaptability results.

6. Reflection: What Can We Learn from China's Adaptive Planning?

6.1 Insights from China's Adaptive Planning Research and Practice

Over the past 20 years, three major research focuses in China's adaptive planning can provide valuable references for the international community.

Firstly, the "timeliness" of adaptation is crucial. Addressing climate change and technological advancements remains a continuous priority for urban adaptability in China. Global climate issues significantly impact international politics and economics, while big data and artificial intelligence can effectively solve complex urban models. Future global adaptive planning should focus on strategies for various types of disasters, regions, and urban computing methods.

Secondly, the "people-centered" nature of adaptation is emphasized. Multi-disciplinary and cross-sectoral approaches that cater to individual needs are particularly important. China's adaptive planning research includes perspectives from culture, communication, industry, transportation, and health, all aiming to meet diverse human needs.

The adaptation of the built environment through spatial layout and policy control effectively integrates rational and emotional decision-making to comprehensively meet these needs. Future global adaptive planning should prioritize individual-centric values, considering citizens' primary needs concerning the environment and health.

Lastly, the "authoritativeness" of adaptation stands out. China's adaptive planning research highlights the characteristics of its political system, effectively utilizing consistent governmental power while considering citizen opinions and community participation. The government rigorously delineates specialized departments for natural resources, housing, and

transportation, which coordinate horizontally under the State Council's unified leadership to issue adaptive planning policies. These policies are directly and efficiently transmitted vertically to subordinate city departments and strictly adhered to. This long-term adaptive planning framework ensures effective future responses.

On one hand, city departments have detailed divisions of labor to collaboratively produce adaptation outcomes in various fields. On the other hand, the procedural basis of this process is legally grounded, ensuring implementation effectiveness. China's adaptive planning leverages these advantages at the macro level, with chief urban planners driving territorial spatial planning, and at the micro level, with community responsibility planners ensuring thorough stakeholder participation and adaptation implementation. These institutional strengths and methods are valuable for international reference.

6.2 Current Requirements, Development Trends, and Adaptive Action Framework for Global Adaptive Planning

Currently, academic attention on adaptive planning is predominantly focused on climate change and disaster risk. The core requirement is to expand research directions and develop localized adaptation strategies with regional characteristics. For instance, China has recently diversified its research content around territorial spatial planning.

The academic community should pay more attention to urban transportation, supply-demand matching, community governance, tourism development, and ecological protection in the context of population mobility, economic development, and technological innovation, forming a comprehensive adaptive planning research network.

Moreover, a clear goal-oriented approach to address pressing national issues is essential for identifying effective adaptive planning pathways. Examples include flood management in the Netherlands, green building initiatives in Singapore, and improved transportation planning in London.

Additionally, supporting adaptive principles with spatial intelligence technology, formalizing participatory planning into legislation, and applying it to decision-making at all levels to meet human-centered needs like social equity and resident health is also crucial.

Therefore, this study attempts to outline future development trends in adaptive planning. There is a systematic integration trend in existing global climate adaptation planning research. Future efforts should establish a reusable response mechanism through cross-disciplinary collaboration.

There is a trend of theoretical expansion in adaptive planning, requiring a clearer definition of its broad and narrow cores according to national strategic needs, specifying its covered fields, and proposing dynamic action plans to meet specific field requirements, which necessitates strong political measures.

Finally, adaptive planning exhibits a trend of multi-dimensional integration, serving the public. Combining foundations from engineering, management, social sciences, and intelligent tools will create more comprehensive and scene-specific adaptive planning methods, focusing adaptation efforts on individual needs.

Based on these trends, we propose a theoretical framework to guide future governance actions in adaptive planning (Figure 11).

Fig.11 Governance Action Framework for Adaptive Planning

7. Conclusion and Discussion

Based on defining the essence of adaptive planning, this study retrospectively reviews the progress and implementation effectiveness of adaptive planning in China using knowledge graph analysis and meta-analysis methods. The research indicates that the theoretical and practical aspects of adaptive planning in China have seen substantial development over the past 20 years, categorized into stages of planning adaptation exploration, climate adaptation dominance, and spatial adaptation development. Research hotspots like "Territorial spatial planning" and "Urban Renewal" with Chinese characteristics have been explored.

Concurrently, administrative orders and interdisciplinary research are the primary driving factors of adaptive planning in China, demonstrating significant implementation effects across multiple sectors and administrative departments. Within China's spatial planning context, studies have gradually moved away from a singular focus on climate change adaptation, instead exploring more localized adaptive pathways, potentially providing insights and ideas for adaptive planning globally.

However, there are shortcomings in this study, such as incomplete literature and policy collection, and subjective dimensions and methods in meta-analysis evaluations. The literature and policies of adaptive planning in China exhibit distinct characteristics, and future research will optimize data and evaluation methods for more detailed discussions.

Through "no-regret" short-term planning and dynamic adjustments involving multiple stakeholders, adaptive planning serves as a methodological guide for planners in China, effectively addressing rapidly evolving urban issues. Spatial planning needs proactive adaptation to promote equitable resource allocation, infrastructure, and public services,

addressing urban population, land, transportation, and environmental issues while fostering urban-rural integration and economic development.

This process requires the participation of planners, government, and the public, as well as supportive policies and regulations concerning land use, environmental protection, and planning standards. It also necessitates promoting optimized resource allocation across administrative regions, harmonious development, and collective adaptation, embracing the future of urban-rural changes with dynamic, flexible, and forward-looking adaptive planning methods.

Track 14: Policy Mobility

POLICY MOBILITY - Planning models, circulation and learning across boundaries

Chairs:

- Divya Leducq, Université de Lille
- Chandrima Mukhopadhyay, UN-Habitat India
- Marcela Alonso Ferreira, Sciences Po Paris

Keywords: *Mobile urbanism, international exchange, environment, urbanization, green-city models, planning practices, postcolonialism, gender lens, urban strategy, policy transfer, local assemblage, global age, placemaking, traveling theory…*

Within a more interconnected world, urban professionals through their references and practices are contributing to the international circulation of ideas and policies in and around spatial planning, experimenting with solutions to environmental and social challenges. Track 14 “Policy Mobility” aims to critically examine not only the circulating planning ideas, both in theory and practice, but also the transnational circuits of knowledge (how do ideas travel?), international benchmark, local experimentations, urban production that result from them, and urban resistance towards them. The session will focus on the political-economic, institutional, ethical, and methodological issues of international exchange in the planning field (process of diffusion). While the circulation from Norths to Souths - and reverse (even though limited) - of ideas and policies (such as: Olympic urbanism, transition towns, smart cities, Green European Capital, Transit-Oriented Development, 15-minutes city, etc) is not a new topic, new debates have emerged: hybridization of models, entrepreneurial urbanism, adaptive urbanism, decolonization of planning practices, provincialization of policy, etc.

We invite contributions from different intellectual traditions such as the history of planning ideas, international development studies, urban studies, the globalization and postcolonial literatures and the policy transfer and social learning fields. The session will look into North-North, North-South, South-North as well as South-South circulation of ideas and policies. So, we call for studies from various contexts such as Europe, North America, and also Asia, Africa, Middle East.

We welcome studies on roles of international networks, actors and agencies and their expertise and ethics (e.g. ICLEI, UN-Habitat, C40…) in transferring such ideas and policies. While the presentations would discuss land use planning, transportation planning, basic services, and infrastructure planning, we are interested in learning which

policy traveled to what context and by whom, and to what extent it was successfully implemented and why.

Contributions to this track might cover the following urban planning issues (although this list is not exhaustive):

- ??Assemblage and hybridization of planning models; adaptation process
- Provincialisation of planning theories, ideas and policies; situating planning practice
- Planning culture/ Culture of practice
- Institutional changes in sustainability transitions
- Role of epistemic communities
- Role of civil societies in either promoting or resisting international ideas
- Tracing policy mobility and policy networks
- Transnational circuits of knowledge
- Carriers of ideas and Struggle of local experts to adopt; urban resistance
- Outside observer and Insider practitioner; reflective practitioner.
- Local ambitions, policy experimentations
- Sustainableplanning models, new urbanism, European Green Capital, European Capital of Culture, Olympic urbanism, Smart-city, compact city, 15-minutes city, transition towns, TOD, gender mainstreaming strategies...

For all these themes, one might wish to discuss: theoretical perspectives, methodologies and empirical contributions exploring shared urban models, ideas and practices and stakeholder involvement, including activists, across as well as key results/impacts achieved or not achieved such as environmental planning policies, local development, spatial justice or better territorial cohesion.

Exportation of the Parisian's urban knowledge (1976–2005)

Florence Bousquet

Affiliation : Université Paris 1 Panthéon-Sorbonne

Email : florencebousquet@free.fr

Abstract

From 1976 to nowadays, 'Atelier parisien d'urbanisme' (APUR), which is an urbanism organisation partially financed by the Paris Municipality, was involved in projecs out of Paris, especially in Global South countries. This communication will focus on APUR's networks all over the world to highlight the way of the French way-of-thinking urbanism have been diffused abroad. We will analyse especially the APUR's projects for the reconstruction of the city centre of Beirut (1976–1977), the projets for Phnom Penh (1992–1998) and for Jakarta (1996–1998) and Cairo (2001–2004) in which APUR was involved.

Keywords

Urbanism ; History ; City planning ; Global South

From 1977 to nowadays, 'Atelier parisien d'urbanisme' (APUR), which is an urbanism organisation partially financed by the Paris Municipality, led a programme to disseminate its urbanistic knowledge abroad, especially in Global South countries.

APUR was created in 1967. The architects of this organisation designed many new residential areas in Paris since the mid 1970s and worked on public spaces projects or transportations issues. The urban forms they created was called 'postmodern urbanism' by Nan Ellin (1996), refering to the 'traditional city'. Over the years, these architects acquired skills in urban planning and town-planning design, especially in dense cities with an important heritage, like Paris.

Considering these achievements, APUR was involved in projects worldwide since the end of the 1970s. Thereby several architects from the organisation began to travel in order to work on urban studies in big cities. Therefore, in France, APUR is not the only one urbanism city organisation to lead programmes abroad : Clément Orillard (2017) also highlighted many projects (more or less 150) realised by the 'Institut Paris Region' (previously called 'Institut d'aménagement et d'urbanisme de la région parisienne' (IAURP)) in many cities over the world.

This dissemination of APUR's knowledge began in 1977 when the city of Beirut asked APUR to work on the reconstruction of the downtown of the city after the 'two years war' (1975–1976). Then, after 1986, projects abroad were declined in different ways : urban studies or projects (for cities like Jakarta, Santiago de Chile or Phnom Penh), exhibitions about new Parisians districts or involvement in international conferences about urban planning.

We will analyse how the Parisian architects applied some existing practices in other cities, and what was the process to think these projects abroad, knowing that the 'philosophy' of the APUR was to take into account the specificities of each territory. So we will wonder how the expertise of the Parisian urban planning organization has been applied in various territories ? This analyse will help us to understand how the APUR sometimes places itself in the position of an expert, while at the same time enabling it to enrich its know-how by creating new situations. What is the balance between the parisian way-of-thinking urban planning and each specific site ? Ensentially, if the APUR's methods, approaches and analyses are different for each project, is the final declension is so different ?

We will analyse the APUR's strategical proposals on urbanism, methods and tools using for projects. But we will not focus on how this suggestions were applied, neither the final realisation of projects. This submission will show APUR's networks all over the world to highlight the way of the Parisian way-of-thinking urbanism have been diffused abroad. Also it demonstrates that some countries were asking for an occidental know-how in urbanism. We will first list the cities and the type of events or projects in which the APUR was involved, especially in the 1980s. Then, we will analyse two diffrent types of interventions : the first ones in which APUR's was involved that apply a map strategy based on a precise analyse of the city landscape (throught the case of the reconstruction of Beirut downtown (1976–1977) and Phnom Penh (1992–1998)) ; and in a second part projects developed later with a more *strategical* approach (Jakarta (1996–1998) and Cairo (2001–2004)).

1. APUR and the gradual establishment of an international activity

Created in 1967, APUR organisation was involved first in thinkings of the Parisian new master plan, in the 1970s. Paris approved a masterplan for the city called 'Plan d'occupation des sols' (POS) in 1977. This masterplan is based on a precise analyse of the city landscape, based on

each plot and its relationship with streets (this type of regulatory plan exists in all the French citites but it is particularly precise in Paris). Also, APUR is carrying out projects to enhance some Parisian sites, notably as part of the 'Plan programme de l'est parisien' launched in 1983 : creation of *Coulée verte*, enhancement of the *Halles de la Villette* and *canal de La Villette*, and development of *Bois de Boulogne* and *Bois de Vincennes*.

In 1977, the new mayor of Paris, Jacques Chirac, encouraged APUR to be involved in the design of the new parisians districts (which are called 'Zones d'améagement concerté' (ZAC)). Six APUR's architects were thus involved in designing new residential areas in Paris, and they realised 42 of its between 1977 and 2000. They mostly studied at the Beaux-Arts School in Paris and most of them in the Louis Arretche's workshop in this school. Over the years, these architects acquired skills in urban planning and town-planning thought, especially in dense cities. The best known ZAC are the *Bercy* one (1992–1994), *Reuilly* (1986–2000) and the *Paris Rive Gauche* (1995–2024). Pierre Micheloni was the architect involved in the design of these three districts and also in several projects abroad. In the book *Postmodern urbanism*, Nan Ellin (1996) highlights the importance of the past trails, the heritage and the history of the city, which the new building's forms refered. In these ZAC projects, the public space is very important, as well as parks. The design of the new streets was created in continuity with the neighbourhood's surrounding roads and the buildings are designed to match the scale of the surrounding buildings. Some blocks, whose size, layout and form have evolved over time, are inspired by 'traditional' Parisian blocks, meaning buildings aligned on the street and inner courtyards.

In 1976, the Lebanese government asked APUR to carry out its first international mission for the reconstruction of Beirut city centre. This mission, which included other urban planners and members of the French Ministry of Public Works, was led by APUR, and in particular by its director, Pierre-Yves Ligen, for the first part of the mission. Other APUR's urban planners, such as Philippe Mathieux, were involved in the city's development proposals after the first step of the city analysis.

In the 1980s, APUR gave a lot of presentations about the projects it had recently implemented in Paris, as conferences in Berlin (called 'Politiques d'aménagement à Paris et Berlin', 11-12 december, 1985) and Istanbul ('Conférence des principales villes mondiales', november, 1987). In the 1980s, the mayor of Paris, Jacques Chirac, also suggested to the mayors of several big cities a collaboration or a technical support of APUR's architects. Therefore, it didn't immediately lead to any assignments (for example, the city deputy mayor of Brazzaville, Mr Okabando, asked for a study of the Poto-Poto/Est District, in 1986). This type of project abroad was quite new in the mid-1980s and the APUR's director was wondering about the conditions of this type of mission. Even though no office or urban planner in APUR had ever been assigned to carry out international projects.

At the end of the 1980s, several technicians or civil servants involved in urban planning from cities in the Middle East came to Paris to study the municipality's working methods and achievements. Officials from the city of Amman in Jordan came to Paris in May 1986, as also the president of the Riyadh city development centre. In 1988, a travelling exhibition called 'L'urbanisme parisien' was organised in Middle East (first in Doha and then in eleven cities : Amman, Sanaa, Abu-Dhabi, Aden, Baghdad, Damascus, Doha, Khartoum, Kuwait, Cairo, Manama, Muscat, Riyadh) focusing on Parisian ZAC in the 1980s. It was the *ZAC Reuilly* and *ZAC Bercy* that the APUR's architect Pierre Micheloni presented as references for the project

of the occupation of abandoned railways in Roma during a consultancy assignment he was given in 1966 for the redevelopment of railways in the Appio-Latino-Tuscanola sector.

It was in the 1990s that APUR really began to get involved in several missions out of France, with a first project carried out in Phnom Penh in 1992. In the 1990s and 2000s, APUR has been requested to assist on technical matters. However, no specific office or division was set up in APUR. Therefore, the same APUR's architects worked on the abroad projects : Christiane Blancot in South-East Asia and Pierre Micheloni for a lot of projects in Europe and South America. André-Marie Bourlon, project manager for the transportation team, often accompagnied them. More or less 25 projects have been done abroad by APUR since 1976 (first project in Beirut) and 2010. Except two projects in Roma and Budapest, most of the projects have been carried out in countries in the Global South. These missions are miscellaneous, and have either been the subject of a cooperation agreement with the City of Paris or the French State ; or APUR is acting under contract or in response to calls for tender.

While IAURIP was called upon for the creation of new towns, APUR was mainly asked for its expertise in drawing up or suggesting improvements to master plans or development plans in cities with a major heritage. Other French urban planning agencies were also called upon for missions abroad. Sometimes, APUR and IAURIP may collaborate together on different assignments in the same cities. It happened in Budapest (1994), Buenos Aires (1998), Teheran (2004) and Rabat-Salé (2007). APUR had also been called upon for its expertise in heritage conservation (Santiago de Chile, Phnom Penh, Budapest) and enhancement of public spaces (Hanoï), and for its technical support, particularly in transportation field and GIS matter, and for its methodology, regulatory and administrative know-how. Finally, urban projects on specific sites were also designed, especially by Pierre Micheloni, as in Rio de Janeiro for the Porto Maravilha District (2004), the development of the eastern corridor of Amman (2005), or the development plan for a district of the city centre of Tbilisi (2013).

Dates	City	Country	Mission	APUR's architect(s)
1976-1997	Beyrouth	Lebanon	Reconstruction of the city centre after the "two-year war" (1975-1976).	
1992-2009	Phnom Penh	Cambodia	Study of architectural and urban heritage. Technical assistance to the Municipality of Phnom Penh. Assistance in setting up the sewerage network (with the engineers of the City of Paris). In January 1992, APUR presented the development challenges of Phnom Penh. Technical training for urban planners of the BAU. Proposals for town planning regulations in 1997.	Christiane Blancot
1994	Budapest	Hungary	Expertise of the master plan of the city of Budapest. Development of heritage.	
1994-2000	Santiago de Chile	Chile	Heritage and protection study of the Santiago-Poniente district.	
1996-1998	Jakarta	Indonesia	Expertise in the revitalization of Jakarta's old centre and the renovation of Jakarta's museums. Opinions on projects submitted and recommendations.	Christiane Blancot and Christian Dupavillon
1996-1998	Roma	Italia	Advisory mission on the development of railway rights-of-way in the Appio-Latino-Tuscolano area.	Pierre Micheloni
1997-1998	Hanoi	Vietnam	Assist the AIMF in arranging the premises for hosting the International Francophonie Summit in 1998 around the Hanoi Opera.	Christiane Blancot
1998	Brazzaville	Congo		
1998-2006	Tunis	Tunisia	Establishment of a real estate and land observatory and a geographical reference for Greater Tunis. Urban Development Monitoring Mission, Documentation and Communication.

Table 1 : Missions abroad carried out by APUR between 1977 and 2013.

2. First international projects: reconstruction of downtown Beirut (1976–1977) and revitalization of downtown Phnom Penh (1992–1998)

These first two APUR's projects abroad are similar in the urban project method : a precise analysis of the existing city first, and then a city-wide cartographic regulation based on these surveys with the aim of conserving and enhancing city's landscape.

2.1 Reconstruction of downtown Beirut (1976–1977)

APUR was commissioned to carry out its first mission abroad : the reconstruction of Beirut city centre in 1976, accompanied by three french architects (Henry Bernard, Jacques-Henri Labourdette and Charles Delfante). IAURP had already been involved in international projects, starting in 1971 (implementation of Buenos Aires master plan). After the lebanese 'two-year war' (1975–1976), the city centre was partially destroyed and APUR carried out an aerial survey to visualise building heights and the statement of the buildings, in conjunction with a Lebanese team, in order to plan the restoration of the buildings, particularly the remarkable ones. As it was made for Paris urban knowledge, APUR first mapped the city precisely (including for example land-use coefficients) in order to identify areas to be rebuilt or rehabilitated based on these analysis (areas 'to be redeveloped or significantly remodelled', 'likely to be redeveloped in the long term but to be maintained in the immediate future', 'to be improved in their current state'). Far from a *tabula rasa* policy, APUR is thinking in terms of restoring and maintained three quarters of the existing city. A specific attention was paid to public spaces, as in Paris. These analyses led to a 'development plan' and a 'traffic plan'. APUR's expertise in Beirut consisted especially in methodological approach and thinking about urban development as an overall, based on very detailed analysis of what already exists and what can support improvements.

APUR's project, drawn up between 1976 and 1977, proposed the enhancement of the seafront and the creation of a vast public garden in front of it. APUR also suggested the creation of a new thoroughfare from the Grand Serail, the seat of government, to the sea ; the extension and renovation of the existing 'souks' between Place de l'Étoile and Place des Martyrs ; the development of the grand hotel district ; and the creation of a modern port and two new districts in the south and west of the port. There were also regulations, inspired by the Parisian POS, regarding the creation of new roads, public spaces and private spaces (layout, alignment, etc.). Scale models and master plans were drawn up. The report of what they made was published in 1977 and the plan was approved by the municipality on 15th April, 1978 but the resumption of fighting prevented it from being carried out.

The master plan (Fig.1) shows a pre-dimension of blocks to be built in line with each other and a high concentration of pedestrian areas in the north of the town. Wider streets are surrounded by tree lines, and a number of squares have been designed at the crossroads of some streets in several parts of the city. Voluntarily, no major architectural artwork is proposed and the new constructions will have to integrate as well as possible in the city.

Nevertheless, Jad Tabet (1991), a Franco-Lebanese architect highlighted the limits of this APUR's masterplan :

Over and above the architectural and urban qualities of the project, the following are revealed the limits of the "cultural urbanism" that underpins the plan to rebuild the city centre. City

centre: the centre is being reinvested, rehabilitated in delicate pastel tones, and pedestrianised. But these new spaces are not the start of an overall redevelopment of urban space. The most that can be done is to recreate the myth of the bazaar, the primitive souk or that of the Mediterranean cities wrapped around their old port; a certain climate, an atmosphere. Because the fundamental question of town centre development is not asked: what urban organisation should be used? What kind of urban organisation will it be? In the final analysis, this project, which was not carried out in the end because another war interrupted its implementation, was strongly inspired by Parisian principles of enhancing public spaces.

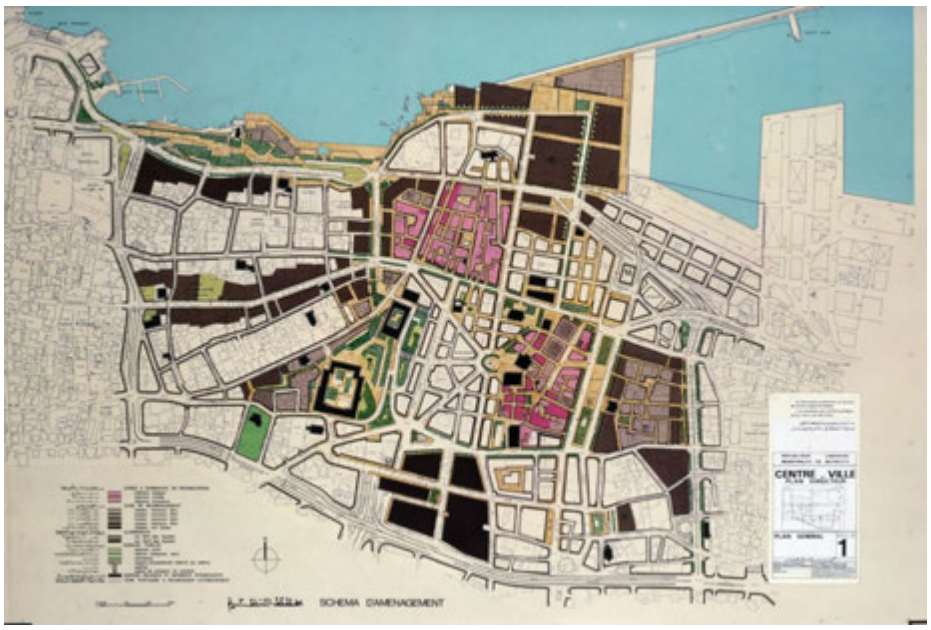

Figure 1 : Masterplan of Beirut, 1977, courtesy : APUR.

2.2 A new masterplan for Phnom Penh (1992–1998)

Phnom Penh is the first abroad project in which APUR has been involved after the project of the downtown Beirut. Since 1990, APUR has been involved in technical cooperation with the cambodian municipal services (that Jacques Chirac, the mayor of Paris, visited in 1994). This

technical cooperation was extended to the field of urban planning in 1991 and 1992 at the initiative of Jacques Chirac. Thus, in January, 1992, APUR presented the challenges of the development of Phnom Penh : to protect and enhance public spaces and their plantations ; to create new planted public esplanades ; to enhance the river and lakes by creating a continuous public promenade on the embankment ; to preserve the airy and sparsely populated nature of the centre ; to enhance the overall landscape of the city along the river ; to enhance the quality of Phnom Penh's public buildings, respecting their architecture and urban integration, and to encourage their rehabilitation.

After the establishment of the Royal Government of Cambodia in May, 1993, the State Minister for Urban Planning suggested the establishment of an Urban Affairs Bureau (BAU), an operational urban planning unit, composed of city's and Cambodian's technicians, assisted by APUR and a 'Transfer of Knowledge Through Expatriate Nationals' (TOKTEN) consultant. During six months, in 1993, the TOKTEN's architect managed a study on squats and formal and informal markets in Phnom Penh. In 1993, technical parisians services were involved in Phnom Penh in setting up the city's sewerage network. In addition, the BAU's urban planners received a technical training. APUR was then associated with this service to ensure the training of city officials and to make a lot of missing documents needed for urban project management (city plans, etc). Christiane Blancot was the main architect of APUR invested in Cambodian projects. As part of the BAU, APUR team in Phnom Penh, led by Ms. Aline Hetreau-Pottier, architect, leaded a study on the city's architectural and urban heritage. These studies are based on surveys of Khmer houses, but also of streets surveys, in section, and also of the templates and location of buildings in relation to the streets, types of islets and their parcel division, with a typo-morphological method (Fig 2). In addition to a survey of typical Khmer houses or complexes, a mapping was carried out to characterize the existing fabric. This first tool, which was primarily geared towards heritage conservation, served as a tool for the development of subsequent regulatory plans.

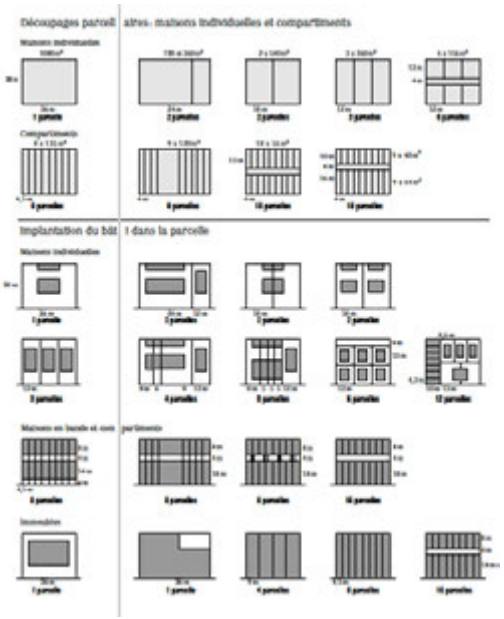

Figure 2 : Subdivision of parcels in Phnom Penh, courtesy : APUR.

In 1995, Phnom Penh issued a law prohibiting the demolition of all old buildings in Phnom Penh, and the preservation of a number of buildings of definite heritage interest was the priority of BAU and APUR. This law was supplemented by an urban regulation by blocks and plots for the Daun Penh area, known as 'servitudes d'urbanisme et de constructions', drawn up in 1996, refering to the Paris POS, but it was simplified. It shew on a plan urban spaces, heights of existing buildings, margins of retreat and the method of siting and the ground clearance of the buildings (Fig. 3). These easements are based on the analytical mapping carried out earlier. These Servitudes were done, discussed and finalized by a Technical Commission which brought together all relevant municipal technical services – cadastre, town planning and construction, environment, culture, public works, industry and the Office of Urban Affairs. These four main areas of development were divided into several sub-sections. In the case of building and non-building land, the first step was to protect the area of public garden streets and to delimit their right of way to prevent private encroachment on them, to protect public facilities and pagodas, and to prohibit construction on plots of less than four metres of façade. With regard to the maximum building heights and the right-of-way of buildings, the aim was to highlight the city's landscape. Around sites of exceptional character, the heights of the facades were erected in order to respect the heights surrounding the site, to take into account the building habits related to the climate, and to preserve the gardens. Considering the architectural aspects of new buildings, they need to maintain the traditional systems of protection against rain and sun and the use of colours and materials in harmony with existing buildings (using of entirely glazed facades, facade tiles, masonry brick or masonry stone coatings was prohibited and the colours white, ochre, yellow and garnet were imposed). Finally, the last priority concerned the importance of regulating the rejuvenisation of public spaces and plantations.

Figure 3 : Map of easements of town planning, 1997, courtesy : APUR.

As with the reconstruction of the city centre of Beirut, an analysis of the city was carried out on a city scale in order to make an overall mapping according to several parameters. In Phnom Penh, however, the heritage and morphological study proved to be even more advanced. While in Beirut these cartographic analyses led to project proposals, in Phnom Penh it led to a proposal for a regulation based on very European principles for the development of public space and respect for the existing landscape, while at the same time establishing architectural easements that value the use of local techniques and materials.

3. The Kota neighbourhood in Jakarta (1996–1998) and the Sayeda Zeinab neighbourhood in Cairo (2001–2004): new strategies

During the 1990s and 2000s, APUR was called upon to work on urban projects in several cities around the world, especially because of its expertise in sites with high heritage value such as in Paris. Most of projects falled within the scope of heritage presentation and multiple, small-scale interventions in cities concerning the development of public spaces. The projects in Jakarta (1996–1997) and Cairo (2001–2004) are interesting to study because APUR and local urban planners needed to thing entirely about how intervene in each city/district, and the proposed solutions were sometimes indenticals and sometimes differents. In Jakarta, projects were made especially on the Kota district and the city's museums, and in Cairo, in the area of Sayeda Zeinab, which are two old districts in these two cities.

3.1 Create the 'image of the city' of Jakarta (1996–1998)

In Jakarta, APUR was involved in urban project by the Ministry of Foreign Affairs in 1996. Christiane Blancot was in charge (she had already been involved in the Phnom Penh project for a long time) of this mission in APUR with Christian Dupavillon, architect and General inspector of Culture at the Ministry of Foreign Affairs. The advisory mission, which was planned at the request of the Governor of the City of Jakarta, consisted of advising on the future projects planned for the city, and especially on expertising Jakarta's old centre projects and the renovation, programming and management of Jakarta's museums.

After the visit of the two French architects in 1996, they formulated guidelines and established a programme and schedule of works. The interventions were interesting because they were not based on city-wide mapping or regulations, but on a series of actions to be carried out in a short term, inspired by Parisian actions to embellish the city.

Regarding the development of the city centre, the district of Kota was especially studied, as the most interesting district in terms of history and heritage, on which attention was focused. The french's architects guidelines decreed that 'Kota has lost its *raison d'être*'. This district was a power one until the 19th century. After it was abandoned in favour of newer district located in the south of the city. The canals would have been a memory of the transport of goods have been covered or blocked, the great street of the district, Kali Besar, has also disappeared and was cut off by railway lines and motorways and in Jajah Mada, ancient islets have been destroyed and replaced by towers and shopping malls. The aim was thus to affirm the history and identity of this district, Kota, at the same time as the memory of khmer people, in order to increase tourism and give an 'image' to the city of Jakarta based on this district linked to the history of Indonesia. The Christian Dupavillon's and Christiane Blancot's report also specified that 'Kota has all the aesthetic and historical elements as in Paris'.

With this in mind, Christian Dupavillon and Christiane Blancot suggested actions to be done quickly, in six months, before embarking on deeper reflections on the Kota district. The quick actions to be implemented in the short term were : the rejuvenisation of public spaces, starting with the building of pavements in all streets and the planting of trees ; the animation of Fatahillah Square by reducing car traffic and setting up open-air cafés ; the installation in some abandoned warehouses of artists or architects ; the organisation of events such as flower markets, fish markets, parades, concerts and the creation of a green space on the site of the old Dutch citadel with the highlighting of archaeological traces. In this district of Kota, they also recommended the enhancement of some of the more 'picturesque' districts such as those of Montmartre or the Marais in Paris, as well as the enhancement of the canal system, which was poorly maintained or no longer maintained. The reference examples are once again European : the *Canal Saint-Martin* in Paris or the canals of Bruges, adding that 'in a few years we will visit the canals of Jakarta as well as those of Venice'. These proposals have been complemented by urban traffic proposals in order to link the different parts of this district.

After these proposals, a working programme was proposed for the implementation of these actions in 1998, with the involvement of several Parisian experts, as well as for the development of canals, which required expertise in the drainage of rainwater and wastewater, or the restoration of buildings, which required the expertise of a specialist architect. Gilles Sensini, architect at APUR, lived in Jakarta for one year. An urban design guideline for a longer-term production was also drawn up in 1997 for Kota district : restoring the physical links between the different parts of the neighbourhood, cut off by transport infrastructure ; highlighting the original Kali Besar axis of Kota and valorise the original district composition affirming and highlighting the significant buildings (maritime museum, lighthouse, fish market, railway

station square) from a very Aldo Rossi's perspective. Other matters were proposed in order to strengthen the links between the centre of Kota and the old suburbs ; thinking about improving pedestrian circulation, especially crossings, and highlighting some monumental hotspots. Also, in order to include the inhabitants of Kota in the urbanization of their neighbourhood, it is suggested to create a house of 'information and exchange' with the inhabitants : the 'Kota House', located in a restored building, to be an example of restoration for the owners and to show to the owners the potential of their cambodian's houses. These projects, carried out in accordance with the guidelines (particularly along the main Kali Besar canal (Fig. 4) where pavements and plantations have been built and the canal has been cleaned) have made it possible to regularize and harmonize this part of the city.

Figure 4 : Kali Besar today in Jakarta, 2024, Google street view.

In Jakarta, it's the rehabilitation of the image of the city that prevails. To aim this goal, Christian Dupavillon and Christiane Blancot proposed faster interventions to revitalize some neighbourhoods. The references were European and Parisian projects and the *touch* of Christian Dupavillon was felt in the proposals. In fact, h has worked on the staging of specific events and has been interested in the rehabilitation of industrial sites into creative sites, proposes quick interventions, not necessarily architectural but more programmatic, allowing to obtain an immediate effect on the uses and image of the city. It seems that in Jakarta, the two architects gave free rein to their imaginations, but proposed projects inspired by European models.

Thus, the ways of city development suggested in 1996 were more precise than those in 1992 for Phnom Penh. The method of intervention was also different. While in Phnom Penh it was

through cartography and regulations that an intervention was primarily linked to the preservation of heritage and the protection of landscapes, a regulation based on the existing one ; in Jakarta, the axes led to the secondment of French personalities attached to neighbourhoods and projects on certain specific aspects (rehabilitation of disused buildings, restoration of canals), in a vein of *tactical urban planning*. It was only later that several districts of Kota were planned with specific urban guidelines.

3.2 *Stategic urbanism* in Cairo (2001–2004)

In 2001, the city centre of Cairo was deteriorated. The governor of the city, who had been bound by a friendship pact with the city of Paris since 1985, called on the city in 2001 for its expertise in the rehabilitation of historic areas and the procedures created to involve the population in the development of neighbourhood projects. The district of Sayeda Zeinab, located in the south of the city, was chosen as a testing ground for methods and tools adapted to its transformation. As a partner of the City of Paris in this decentralized cooperation programme, APUR helps define studies and urban projects on this district. Each proposal had to lead to the definition of a concrete operation, which could be carried out by mobilizing local expertise and resources, under the authority of the governorate services. The approach had to be pragmatic and the result of the work could be transferred to other areas of Cairo.

In December 2002, a mission of experts carried out an initial diagnosis of the neighbourhood. It identified the most critical problems and outlined the actions to be taken. During 2003 summer, young academics managed the research needed to continue the study : surveys and field surveys. At the end of the year, plans were drawn up and the Governor validated the general principles of action to be taken. The first concerned ‘Abdel Meguid al-Labbân Street (Fig. 5), which was selected as a pilot project for the development of public space. The second concerned the rehousing of the mechanics of ‘Abu ad-Dahab Street. The third was focused on the rehabilitation of the built heritage. In 2005, the scope of the study was extended to the neighbourhood of Qal’at al-Kabsh and its connection with the lower city.

As in Jakarta, in Cairo was done strategic interventions, small-scale ad hoc projects, which were supposed to change the image of the city and have a generating action. Two main lines of action were decided : the rehabilitation of existing buildings and the redevelopment of streets. So it is first the streets, squares, dead ends and passages that were renovated. The houses and residential buildings were renovated, the facades first and the structures consolidated, the sanitary and electrical installation network secured. In older districts of Sayeda Zeinab, Qal'at al-Kabsh and Tûlûn, urban development was being proposed through, among other things, the installation of better flooring, quality urban furniture and tree plantations, encouragement of rehabilitation through financial assistance and technical support for the inhabitants, and the reuse of unused plots. More specific projects were planned, such as the rehabilitation of Abu ad-Dahab Street, surrounded by mechanics' workshops that could be optimised in their use, or the creation of a public staircase in the Qal'at al kabsh neighbourhood.

Figure 5 : Plans and sections of the Abdel Meguid Al-Labbân street in Cairo, 2005, courtesy : APUR.

These different projects highlight the way APUR has transposed its tools and methods in the cities in which it has intervened : through a variation of the POS in the oldest cases and through more localized strategies more recently. However, the same conclusions emerge : the enhancement of public spaces, water spaces, and the rehabilitation and enhancement of the existing buildings.

Post Covid19 topiography: Prospects of the polycentric operational model for a Greek city.

K. Christoforaki, Dr. Architect Engineer – Urban Planner
Affiliation : School of Architecture, National Technical University of Athens, Greece
Email: ka.christof@gmail.com

Abstract
The COVID-19 pandemic prompted a reevaluation of urban dynamics worldwide, impacting economic, social, and daily life aspects. This shift, coupled with the imperative to combat climate change, has led to a reconsideration of modern city functioning. The polycentric city model emerges as a solution, integrating technological advancements to create user-centric, environmentally friendly urban spaces. Research demonstrates the feasibility of this model, emphasizing its economic, environmental, and social benefits. Greek cities, with their manageable scale and existing neighborhood structures, are particularly suited for this transition, offering a favorable cost-benefit ratio. Case studies aim to validate the effectiveness of the polycentric model in Greece, reinforcing its potential for sustainable urban development. This paper evaluates the prospects of the polycentric operational model for the city of Ilioupolis in Athens, Greece

Key words: post-pandemic city, urban environment sustainability, social inclusion

Introduction

Covid pandemic served as a benchmark for the reconsideration of the way users operate in the urban environment. The shifts that happened rapidly not only in the economic sector and the social activities but also in day-to-day life, leading to a global reconsideration of the way developed cities function under these new circumstances. In addition to this, the demands of the strategy towards battling climate change, promote the research for the optimal operational model of the modern city, regarding trivial functions and needs, car use, networking, and communication.

The model of a polycentric city formation is promoted as an answer to these challenges. This contemporary polycentric city theory is enhanced with the technological advancements and oriented towards the city user, aiming to create a greener environment-friendly urban space, that promotes the battle against climate change. Given the turn towards a more viable sustainable environment with a more user-friendly city formation that subjects to the principles of sustainable mobility, as well as the technological means available, the implementation of a structure with multiple centres, a mix of functions and extended networking, can produce a new urban topiography that derives from the environmental principles of the 21st century.

This paper follows previous research where this polycentric city model was evaluated using the economic theory, and specifically a cost-efficiency analysis, to establish a foreseeable outcome and determine and quantify the possible benefits on an environmental, economic, and social level. The analysis applied an ex-ante evaluation and uses simulation techniques and indicators to define the cost-effectiveness ratio, combined with mental mapping activities, in order to promote people inclusion in the decision-making process.

The findings showed that the cost that needs to be allocated to implement a polycentric model of operation in Greece, although dynamic and varied from case to case, is relatively low compared to the benefits that come as a result. In fact, the most of said benefits are linked to the European Sustainable Development Goals, the promotion of which is a strategy all European countries and cities are already committed in following.

The main reason why the cost may appear lower for Greek cities to shift to a polycentric model, is that Greek cities in particular, are characterised by a small scale of the urban fabric and a variety of uses, both equally important when implementing this model of operation. The formation of neighbourhoods is thus favoured and, on a first level, already present, which gives the Greek city an advantageous starting point regarding the possible cost of rearranging the city from scratch.

This paper builds on the previously established evaluation model and employs a case study to validate the evaluation method and furthermore produce a series of observations and results regarding the actual costs and benefits of polycentric city operations in Greece.

The polycentric city establishing the 15minute city

The polycentric city constitutes a development model that has been examined in various variations in urban planning theory since the last century. In contemporary discussions within urban planning, the concept evolved to the 15-minute city that emerged as a compelling vision aimed at fostering more livable, sustainable, and resilient urban environments. Essentially, the 15-minute city model advocates for reconfiguring cities to ensure that residents can conveniently access essential services, amenities, and job opportunities within a 15-minute walk or bike ride from their residences. This vision signifies a reappraisal of conventional urban development patterns, which typically prioritize automobile-centric infrastructure, towards a structure with multiple small scale centralities within the urban fabric.

Among the European cities, the city of Paris has been leading in the implementation of the 15-minute city concept, leveraging its distinctive urban layout and cultural heritage to redefine how urban life is organized spatially. Through strategic interventions and policy measures, Paris seeks to cultivate compact, polycentric neighborhoods where everyday needs can be met within close proximity. This approach aims to decrease reliance on cars, encourage active transportation, and improve overall quality of life.

Nevertheless, the 15-minute city model poses several threats along with its benefits. As pointed out in previous work [1] implementing the 15-minute city model in Paris, or any urban setting, presents both achievements and obstacles. While Paris has demonstrated notable adaptability in capitalizing on opportunities arising from the COVID-19 pandemic to advance its urban agenda, uncertainties persist regarding the applicability and efficacy of certain strategies, particularly in diverse urban contexts characterized by varying scales and socio-economic dynamics.

After drawing insights from Paris' experience, this paper aims to delve into the complexities of implementing the 15-minute city model and assess its implications for urban planning practice in the Greek city. By critically examining both the successes and limitations of Parisian initiatives, valuable lessons can be gleaned for other cities embarking on similar urban transformation endeavors. The chosen case study is the city of Ilioupolis, a municipality in southeast metropolitan Athens, with a characterizing urban plan similar to the 19th century garden city. The city is organized around several roundabouts that have become very closely related to the identity of Ilioupolis. In this paper, these roundabouts become the core of the proposed scenario of the 15minute city model.

The uniqueness of the urban design of the area predisposes and promotes centralities at the points where we encounter the roundabouts. When exploring the case study, the already existing

trend of centralization development at these points is taken into account, a trend that seems to have accelerated after the COVID-19 pandemic. In this way, the proposed centralities of the 15-minute city examined in this research are the product of bottom-up processes and not predetermined top-down locations, as in the case of Paris, for example. Moreover, this paper emphasizes the importance and necessity of flexible, context-sensitive approaches to urban planning that prioritize both equity and sustainability, both of which are significantly boosted via community engagement.

Ultimately, through a comprehensive analysis of the case study of Ilioupolis, this paper aims to contribute to the ongoing discourse surrounding innovative urban planning strategies and their potential to shape more inclusive, resilient, and vibrant Greek cities for the future.

Case study: The Municipality of Ilioupolis - Urban fabric characteristics

Ilioupoli is a municipality that was developed to meet the increased housing demands created by the large refugee influxes to Greece following the Asia Minor Disaster of 1922. It is a suburb of Metropolitan Athens, located in the southeastern part of the basin. It is situated at the foothills of Mount Hymettus and is only a few kilometers away from the center of Athens. It was declared a municipality in 1963 (Government Gazette 45/A/19-4-63). It has always been crossed by several streams, the most significant being 2-3 branches of the Pikrodafnis stream, most of which are now covered. In the area where the municipality of Ilioupoli is now developed, there was a small estate during Ottoman rule, called the "Kara estate." The buyer in the following years was A. Nastos, who later sold the land initially required for the construction of the Municipality of Ilioupoli.

In 1925, the "Greek Company for Urban and Rural Settlements Drandakis - Pagkalos, and CO" was established with the aim of constructing the settlement according to the plan of Aristomenis Valvis, as modified in 1928 after its first approval in 1925. Ilioupoli initially targeted a wide range of residents. It had a rural section, a semi-rural section, and a general population section, which were distinguished from each other based on the size of the available plots of the settlement. In the general population section, the size of the plots reached that of the center of Athens. The smallest acceptable plot size was set at 112.5 sq.m. and remained so until 1940. Along the way, the rural section was abolished as buyers could not afford it financially. According to the "General Guide to Ilioupoli" (1960), anyone "...found a place for a home, the rich and the poor, the scientist and the professionals, the employees and the workers...".

Figure 1. Plan of Ilioupolis (1925) [2]

The original plan by Valvis for the settlement of Ilioupoli was characterized by a clear effort to mimic the principles of a garden city. Strong curves, numerous concentric circles and roundabouts lead to the creation of small building blocks. This initial plan underwent modification with evident signs of improvement in 1928 (Government Gazette 227/1928).

In 1930, the "Anonymous Construction and Industrial Company of Ilioupolis Athens" was founded, a company that, along with the "Greek Company for Urban and Rural Settlements Drandakis, Pagkalos, and CO" and with the "Anonymous Transportation Company of Ilioupolis," undertook the execution of the plan.

However, the image of the city of Ilioupoli in its early years was not very encouraging regarding the completion of the plan and its settlements. Nevertheless, it was widely advertised in newspapers, urging buyers to invest in land purchases, which (according to said advertisements) would not lose their value, and thus the investors would profit from a potential devaluation of the currency (a practice not uncommon in 20th century Greece). The main service networks of the city were ultimately completed after World War II, a period during which the Municipality began to grow systematically.

Locating the city centralities

Existing centralities

In Ilioupoli, the General Urban Plan (GUP) was approved in 1988 (Government Gazette 407/D/1988, reissued Government Gazette 1225/D/1994) and is still in effect, defining the allowed land uses of the city (Fig.2). The GUP includes the entire current area of the Municipality, along with the successive expansions after the initial approval of the city plan. The same GUP separates 14 neighborhoods - Urban Units as they appear on the map below (Fig. 3). The division of neighborhoods seems to have been made based on geometric characteristics of the town plan and with the intention of an equal distribution of the covered area per unit. There does not appear to be an intention to create independent centers per

neighborhood, and the circular nodes are, in most cases, not placed at the center of each unit, but seem to serve as meeting points for two or more neighborhoods. Given that the already defined neighborhoods have a maximum distance range of 1.5 kilometers from each boundary, this distance can work perfectly with the scenario of the 15-minute city and promote accessibility using bicycles, walking, or other non-motorized vehicles.

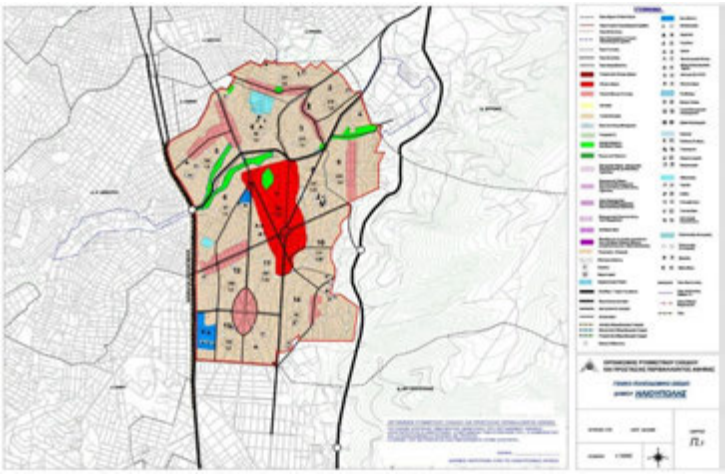

Figure 2. General Urban Plan of Ilioupoli [3].

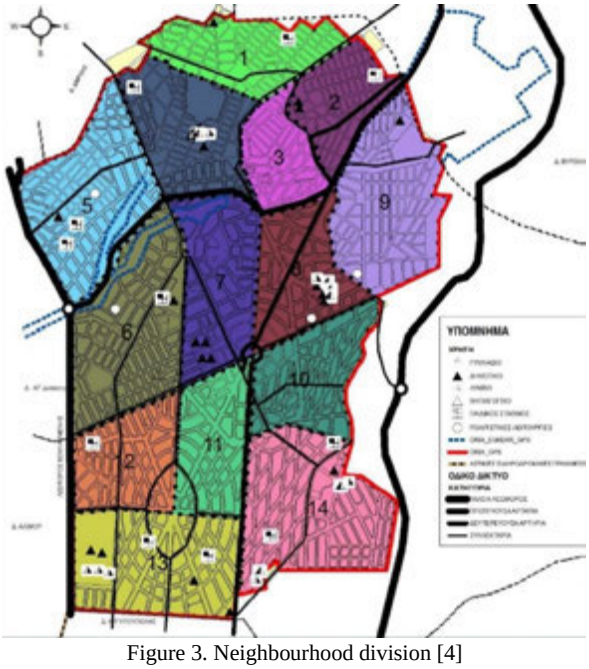

Figure 3. Neighbourhood division [4]

For many years, and up until the end of the 2010s, when the economic crisis changed the density of commercial uses, Ilioupoli developed commercial and recreational activities mainly around

Ethnikis Antistaseos Square, which is the central square of the Municipality and located at the intersection of neighborhoods 7-8-10-11. This development aligns with the General Urban Plan of the city, which designates the square and part of the axes leading to it as the "city center," differentiating it from other adjacent squares in other neighborhoods designated as "neighborhood centers."

Another secondary center of smaller scale was developing at Independence Square in neighborhood 1, just before the intersection of neighborhoods 1-3-4, while with lower intensity and uses related only to commerce, two more centralities were found, located, one at Karaiskaki Square (Kanaria) at the intersection of neighborhoods 4-5-6-7 and one at 28th October Square in the heart of neighborhood 8.

We can observe that, unlike the central square of Ilioupoli, the secondary centers created initially did not follow the current General Urban Plan regarding the determination of the neighborhood centers. The General Urban Plan placed these units mainly along axes and not on circular nodes, not exploiting the centrality they provide due to their layout.

Emerging centralities

After the economic crisis, new centralities began to emerge, mainly around the development of commercial and leisure activity zones in areas that showed less interest until 2010. This trend strengthened towards the end of the economic crisis around 2019, and despite the slowdown experienced during the period 2019-2021 due to the pandemic, it accelerated at a faster pace in the last two years (Table 1).

The newly created centralities also tend to indeed move along axes, as initially predicted by the General Urban Plan (GUP), but still concentrate on those connecting the most developed squares of the Municipality. Thus, we observe a new center at 25th March Square at the intersection of neighborhoods 6-7-11-12, another one at Agia Paraskevi Square at the intersection of neighborhoods 11-12-13, and one more at Agia Mavra Square at the intersection of neighborhoods 8-9-10. The commercial and leisure uses also tend to expand on the axes between squares as shown in the consolidated map below (Fig.4).

CENTRALITIES \NUMBER PER USES	RETAIL			LEISURE			MARKET		
YEAR	2014	2019	2024	2014	2019	2024	2014	2019	2024
25th March Square	12	14	**15**	3	4	**7**	2	2	**2**
Agia Paraskevi Square	2	2	**2**	2	6	**6**	4	4	**4**
Agia Mavra Square	4	2	**2**	3	4	**6**	0	1	**2**

Table 1. Uses per centrality

The above-mentioned businesses are found either on the square or within a radius of less than 100 meters from it. The nearly doubling of leisure establishments along with the increase in retail and food market shops are trends encountered in all three cases. This trend was not -yet- present in other squares of the Municipality.

Proposed centralities

Examining the distribution of existing and emerging centralities in the Municipality, along with a 500meter radius of service for each centrality, we observe that there is a significant overlap across its entire extent of the city, with only two neighborhoods having room for improvement.

The first one is Neighborhood 14. The prominent topography of the neighborhood, located precisely at the foot of Mount Hymettus, as well as the strong boundary formed by Kyprou Avenue, which serves as the main and high-speed axis for vehicular traffic coming from Alimou-Karea Av. towards south Athens, dividing the neighborhood from the rest of the Municipality, result in the relative isolation of the neighborhood. Therefore, it is suggested to explore the creation of a local center in around the Ilioupolis municipal swimming pool, as the pre-existing use already establishes a degree of centrality to the area. The proposal aims to further strengthen this centrality and accommodate the part of the city that is relatively separated from the rest of the municipality.

The second point of low coverage from the existing and emerging centralities is the boundary between Neighborhoods 2 and 3, along which the General Urban Plan (GUP) initially established the use of the neighborhood center. While there is a market operating in the area with some shops, the intense adjacency with Alimou-Karea Av., the increased traffic, and the wide width of the road at this part of the city, have not favored cohesion in operations and the creation of a cohesive centrality up until today.

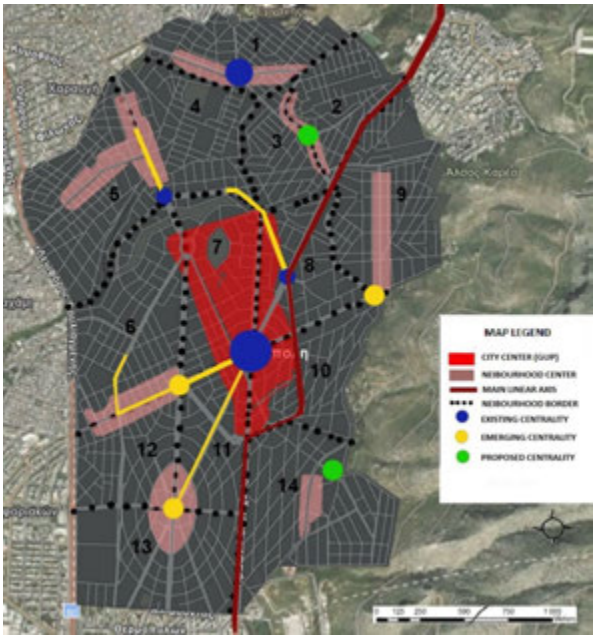

Figure 4. Centralities per type

Model implementation cost and effectiveness assessment

The centralities identified in the study area create a dense network capable of covering the entire Municipality with a service radius ranging from 500 to 700 meters. A total of 7 centralities were identified, and two more were proposed. In proportion to the city's population, which, according to the 2021 census, stands at 76,730residents, this means that approximately 8500 residents are

served per centrality. During the implementation of the 15-minute city model, it is important to protect specific established features defined by urban planning legislation. This means that the new proposed centralities are not intended to compete with the current commercial center of the Municipality. The Ethnikis Antistaseos Square, representing the municipal center, retains its primary central character in any case, as reflected in the intense overlap of service radius of the neighboring centralities under examination. The goal is to strengthen smaller local units that can maintain a degree of differentiation among them in terms of character, functions, and size.

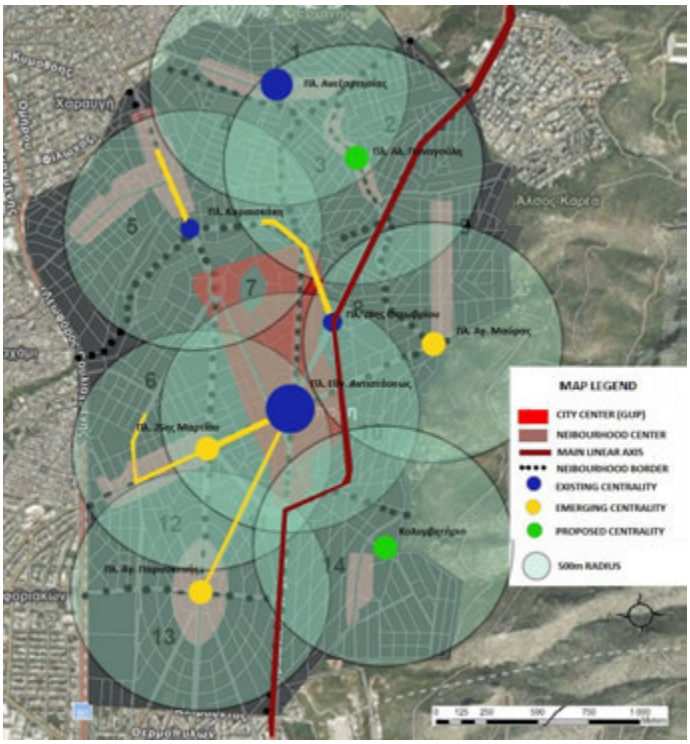

Figure 5. 500m radius per centrality

In this section, we proceed to the parameterization of the centralities according to the desired outcome. This means determining the expected character of each centrality, the desired functions per point, while assessing the degree of satisfaction of the desired condition from the current situation. This comparison will highlight the necessary interventions needed to achieve the predetermined goal for each centrality. These requirements can then be evaluated in terms of cost and effectiveness.
Building upon the functions introduced by the model of K. Moreno for Paris, where the key operating axes were proximity, mixed-use, density, repetition, we observe a high degree of satisfaction of these conditions in the case of the Municipality of Ilioupoli. The city is indeed characterized by a dense fabric with mix of uses and its small scale favors proximity to each center.

In terms of proposed uses, K. Moreno positioned schools at the center of neighborhoods and set the six basic uses that need to be satisfied: residence, work, market, education, health, and

recreation. In the present context, we choose to set open spaces/squares as the center of the unit, which already demonstrate a dynamic concentration of mixed functions. Additionally, while in the case of Paris, where the stronger separation of uses and the size of the city are evident, residence needs to be defined as a default requirement, in the context of the Municipality of Ilioupoli (and the broader Greek cityscape), the function of residence is considered to be satisfied throughout the examined area. Specifically, in the Municipality of Ilioupoli, according to the Operational Program of the Municipality of Ilioupoli [5], which drew data from the 2011 Census, out of a total of 11,885 buildings, only 677 are not used for residential purposes (exclusive or mixed use).

On the contrary, given the inadequate public transportation network in the greater Athens area, which results in increased use of private vehicles mainly for commuting to and from work, it appears that additional public service points and remote working opportunities are much more necessary in the present context.

During the pandemic, three points were highlighted regarding remote work and public service in Greece: a) remote operation without the requirement for physical presence is largely feasible and effective, b) remote work burdens employees with the need to secure a workspace at home, which is not always feasible in terms of living conditions, space, and equipment, and c) there is an inevitable shift of operational costs from businesses to employees.

In this case study, the proposal for municipal remote work operational centers (hubs) ensures a safe environment close to home, allowing employees to have a fully equipped workspace in a common working space open to the public and businesses. The available space can be a public or private building, and private capital can be leveraged with incentives provided to private enterprises. The successful development of such a structure within the Municipality will achieve a reduction in private vehicle usage, decrease commuting time to and from work, create job opportunities for single-parent households and/or young parents, and improve the user's quality of life. All of these are Sustainable Development Goals as adopted by the EU.

However, in the case of examining central Athens or any other city with significant tourist interest, the aspect of residency should revert to the parameters, while the demand for remote work structures would decrease. It should be noted that the exclusion of residency from this specific parameterization does not imply that protective measures for residency should not be considered to the extent that it is estimated that the proposed interventions will affect it (e.g., to avoid the phenomenon of gentrification). These measures should be examined during the stage of establishing the institutional framework for the implementation and execution of the 15minute city model in Greece.
Table2 presents the coverage of functions (YES/NO) per identified centrality in the Municipality of Ilioupoli. The indication "+" is used in case of desired enhancement of the specific use:

CENTRALITIES/USE	RETAIL	LEISURE	MERKET	GREEN SPACES	EDUCATION	HEALTH CARE	REMOTE WOKRING
EXISTING							
Eth. Antistaseos Sq.	N	N	N	N	N	O	O
Aneksartisias Sq	N	N	N	N	N	O	O++
Karaiskaki Sq.	N	N	N	N	N	N	O
28th October Sq	O	N+	N	N	N	O++	O

EMERGING/TO BE ENHANCED							
25th March Square	N+	N	N	N	N	O	O++
Agia Paraskevi Sq	N+	N	N+	N	N	O++	O
Agia Mavra Square	N+	N+	N	N	N	O	O++
NEW PROPOSALS							
Al. Panagouli Sq.	N+	N+	O	N	O	O	O
Swimming complex	O	O	O	N	N	O	O

Table 2. Coverage of functions (YES/NO) per identified centrality

To save resources, specifically concerning public service/healthcare facilities and remote working spaces, a larger radius per central point can be utilized. It is thus proposed a service clustering every three centralities. In this case study, remote working spaces may be established at 25th March square, at Anexartisias square, and at Agias Mavras square, while healthcare/public service facilities may be located at 28th October square and Ag. Paraskevis squre, in addition to Karaïskaki square, which is in close proximity to the existing municipality's healthcare infrastructure. Even with this proposed clustering for these specific functions, the user's commute will not exceed the one-kilometer limit. Data on employment in the municipality of Ilioupolis, sourced from the Operational Program of the Municipality of Ilioupolis. report that out of a total of 30,527 employees in the municipality, 84.79% are employed in the tertiary sector of services [5]. This implies that even if there is a possibility of remote work for 1 out of 3 employees in the service sector, over 8,500 commutes to and from work are prevented per user.

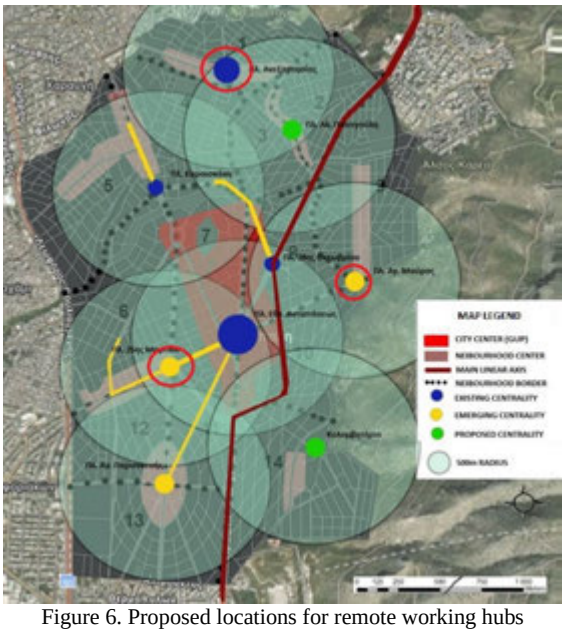

Figure 6. Proposed locations for remote working hubs

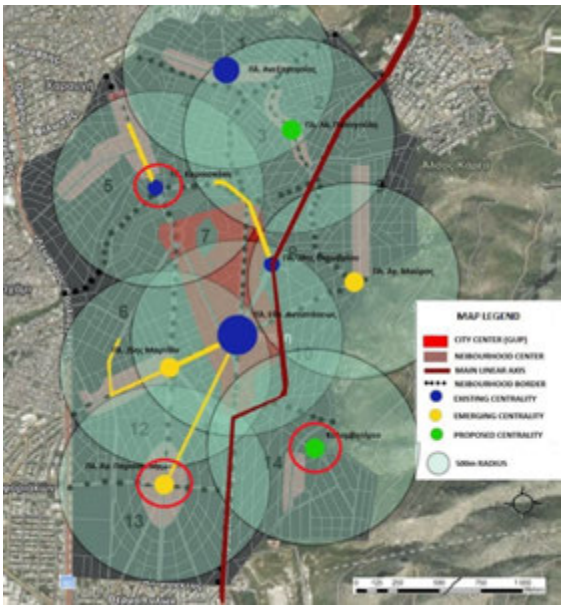

Figure 7. Proposed locations for healthcare facilities

In the previous section, the goals and needs for the operation of centralities in the Municipality of Ilioupolis were outlined. From the table that presented the coverage of functions (YES/NO) per identified centrality in the Municipality of Ilioupolis, we observe that the actual requirements of the local centers mainly involve enhancing existing functions and uses rather

than adding new ones. This ensures that the proposal follows a dynamic already present in the area and guarantees a reduction in potential disruption of balance, as well as an increased likelihood of acceptance by the public.

Specifically, as concluded from the above, the following are required:

Enhancement of existing use:

Retail in 4 centralities
Leisure in 3 centralities
Market in 1 centrality

Installation of new use:

Remote working facilities in 3 centralities
Healthcare/public service in 2 centralities

It should be noted, however, that an exact estimation of the level of enhancement needed is not yet possible, given that both remote work and public service/healthcare facilities are expected to attract daily users to the proposed locations, thus boosting retail and leisure uses to some extent either way. Furthermore, requirements for enhancing uses overlap with the installation of the new uses in all cases except for Panagouli Square, meaning that the city interventions can and will have multiple impact on several sectors.

According to the above analysis, the actions that the Municipality of Ilioupolis should take to support the above scenario are as follows:

Δ1. Enhancement of commercial, leisure and market uses in the designated areas.
Δ2. Establishment of 2 healthcare/public service facilities and 3 remote work facilities.
Δ3. Development of a network between centralities with safe routes that comply with the sustainable mobility principles.
Δ4. Modernization of regulatory framework to facilitate proposed interventions.

In the table below, we have defined the minimum requirements for promoting the scenario of multiple centralities in the case study of Iioupoli Municipality. We observe that, apart from the need for equipping, leasing, and/or adapting municipal buildings to accommodate the new uses of healthcare/public service and remote working facilities, there is a strong overlap of requirements per set Action. This implies increased efficiency of the resources allocated to meet each predetermined requirement.

Actions	Δ1	Δ2	Δ3	Δ4

Costs/Requirements				
Leasing of building infrastructure				
Adapting building infrastructure				
Technical equipment				
Operating costs/Consumables				
Operating costs/Energy				
Incentives for private individuals				
Urban equipment				
Creation/upgrading of pedestrian traffic network				
Upgrade/Enhancement of green network				
Enhancement of public transportation				
Consultation organization				
Person-hours for consultation				
Diffusion of results				

Table 3. Requirements/costs per Action

Furthermore, we observe that overall, the requirements consist of mild-scale interventions that are either explicitly included in existing strategic priorities of the Municipality (e.g., the Operational Program of the Municipality of Iioupolis 2015-2019) or are part of the requirements arising from compliance with European Sustainable Development goals. This fact, on the one hand, makes such interventions a constant target of the municipal authority and, on the other hand, entails the possibility of securing funding from European sources that will not burden the municipal budget.

It is therefore estimated that the substantial burden that the exploration of the 15-minute city model will impose on the Municipality of Ilioupolis will be small and mainly focused on issues of strategic development and management, consultation organization, resource leverage, and incentive development. In terms of efficiency however, this cost, besides being a constant need of Greek local government at all levels, is estimated to be much smaller in comparison to the benefits that the city and the user will derive in terms of daily living, resilience, risk management, as well as in relation to today's requirements for environmental protection.

Concluding observations

In summary, the examination of the polycentric operation implementation within the Municipality of Ilioupoli, advocating for the 15-minute city model, offers valuable insights into the multifaceted implications of this urban development strategy. By meticulously scrutinizing the identified functions and requirements of the centralities, the study reveals a nuanced understanding of how the proposed approach harmonizes with the existing fabric of the community and aligns with strategic priorities. This alignment not only mitigates potential disruptions but also garners widespread public acceptance.

Furthermore, the delineation of requisite measures to bolster this initiative underscores the municipality's steadfast dedication to fostering sustainable urban growth. Leveraging both established strategic frameworks and available European funding avenues, the municipality demonstrates a proactive stance towards realizing its vision. Despite projections of a modest upgrade in administrative and organizational demands, the anticipated benefits for residents—ranging from enhanced quality of life to heightened resilience and ecological preservation—far outweigh any associated costs.

In essence, the pursuit of the polycentric 15-minute city model epitomizes a forward-looking urban planning practices that places paramount importance on safeguarding the well-being and sustainability of the Ilioupoli community. This progressive approach not only sets a precedent for the region but also holds promise for emulation in other Greek cities, signaling a potential paradigm shift in urban development practices nationwide, if evaluated and implemented correctly and according to the needs of every case study.

It's important to note that the findings presented above are part of an ongoing research endeavor, and as such, the results are not final. While the insights gleaned thus far shed valuable light on the potential benefits and challenges associated with the implementation of the polycentric operation in the Municipality of Ilioupoli and the promotion of the 15-minute city model, they represent only a preliminary analysis. Further in-depth examination and data collection are necessary to fully understand the complexities of this urban development approach. In the subsequent stages of this research, more detailed observations will be made, providing a comprehensive understanding of the implications and outcomes of adopting the polycentric model. Thus, these initial findings serve as a foundation for future exploration and refinement of urban planning strategies in Ilioupoli and beyond.

[2] Tongji University, College of Architecture and Urban Planning, Shanghai, China.
*yue.zhang@students.iaac.net

Abstract:
Amid China's ongoing initiatives to enhance industrial land efficiency and promote urban upgrading, high-tech innovation parks emerge as crucial policy zones driving urban economic development. These parks are increasingly integrated into the fabric of urban districts, reflecting their growing role as key components of city functions. This paper specifically examines Chengdu Xinchuan High-tech Innovation Park, exploring strategies for managing land resource allocation and efficient supply to support the park's swift and transformative development. An analysis of the functional configurations from exemplary parks like Shenzhen Nanshan High-Tech Park, Shanghai Zhangjiang Hi-Tech North Park, and Chengdu Tianfu Software Park informs the proposed optimization for Chengdu Xinchuan. The initial planned distribution of 32% residential, 28% industrial, and 40% commercial functions is recalibrated to 32% residential, 43% industrial, and 25% commercial. This adjustment is aimed at creating a more balanced development conducive to both economic vitality and community sustainability. Drawing on the successes of these benchmark parks, the study outlines a tailored functional ratio scheme, providing actionable insights and strategic guidance for similar transformations in other urban high-tech industrial parks.

keywords: Functional optimization, High-tech innovation parks, Benchmark analysis, Land function

1.Introduction

The rapid economic transformation of China over the past few decades has been significantly influenced by the strategic development of high-tech industrial parks (Hu, 2007). These parks are pivotal in fostering innovation, attracting foreign investment, and catalyzing regional development. The Chinese government's emphasis on upgrading industrial structures and enhancing technological innovation capabilities has further propelled the evolution of these parks (Zhang and Wu, 2012). In Chengdu, the push towards establishing a high-tech zone reflects broader national trends aimed at integrating advanced manufacturing and information technology industries. Chengdu's strategic location in southwestern China adds to its potential, positioning it as a gateway for technological and economic interactions between China and South Asia.

Chengdu's commitment to technological advancement is exemplified by the development of Chengdu Xinchuan High-tech Innovation Park. Launched as part of a larger initiative to transform the region into a center for technological innovation, the park is designed to support cutting-edge industries such as IT, biotechnology, and new energy. This development is underpinned by China's national policies advocating for

the intensive use of industrial land, which aims to optimize land use efficiency and support sustainable urban growth (Tu, Yu, and Ruan, 2014).

Since its inception, Chengdu Xinchuan High-tech Innovation Park has made significant strides in attracting high-tech firms and contributing to the region's economic growth. However, the park faces several challenges that hinder its potential to become a leading innovation hub. One of the primary issues is the mismatch between land supply and the specific demands of high-tech industries. This misalignment often leads to inefficient land use and underutilization of available resources, which can stifle the growth of resident companies and reduce the park's overall competitiveness.

Another significant challenge is the functional imbalance in land use, where the proportions of land designated for industrial, residential, and commercial uses do not optimally support the park's goals. This issue is exacerbated by rigid planning policies that fail to adapt to the dynamic needs of high-tech enterprises, which require flexible environments that can rapidly adjust to technological advancements and market changes.

This study aims to address these challenges by:

1. Analyzing the current land allocation and functional configuration at Chengdu Xinchuan High-tech Innovation Park to identify core issues in land management and usage efficiency.

2. Benchmarking against successful high-tech parks nationally to derive actionable insights and best practices that could be adapted for Chengdu Xinchuan.

3. Proposing strategic interventions to optimize land resource allocation and functional configuration, ensuring that the park not only meets the current needs of its tenants but is also poised for future growth and innovation.

The ultimate goal is to redefine the urban space within Chengdu Xinchuan High-tech Innovation Park to better serve its function as a catalyst for technological innovation and economic development, contributing to the broader objectives of Chengdu's urban and economic planning strategies.

2.Literature Review

2.1 Industrial Land Use Policies in China

The transformation of industrial land use policies in China has been profound over the last few decades, reflecting the nation's shift towards a more sustainable and economically productive use of its urban and peri-urban land. The Chinese government has introduced several policies aimed at promoting the efficient use of industrial land, particularly in the context of rapid urbanization and the growing need for innovation-driven economic zones. Notably, the "National Land Use Policy" (2008) and subsequent amendments emphasize the intensive and efficient use of industrial land. These policies support the development of high-tech parks by stipulating that such areas must incorporate sustainable practices and efficient land use to foster innovation while minimizing environmental impacts (Ministry of Natural Resources of the People's

Republic of China, 2008).

Further reforms were introduced with the "Guidelines on Promoting the Economical and Intensive Use of Land" (2015), which set specific targets for the utilization rates and densities of industrial parks. These guidelines are designed to ensure that new developments, like Chengdu Xinchuan, align with national sustainability objectives while supporting high-tech industries (Ministry of Natural Resources of the People's Republic of China, 2015).

2.2 Case Studies on Land Resource Management in High-tech Zones

Several high-tech zones in China and globally offer valuable insights into effective land resource management practices. For instance, the Suzhou Industrial Park and the Shanghai Zhangjiang High-tech Park have been highlighted for their innovative approaches to land use and management. These parks have implemented mixed-use development strategies that integrate residential, commercial, and industrial spaces, allowing for greater functional integration and resource efficiency (Holländer, Wu and Duan, 2009).

Examining high-tech zones within Asia provides valuable insights into the effective management of land resources. Alongside China's Suzhou Industrial Park and Shanghai Zhangjiang High-tech Park, Singapore's One-North is a leading example of a science park that exemplifies best practices in land resource management. One-North has been designed to be a hub for research, innovation, and entrepreneurship, integrating business parks, biomedical sciences, and infocomm technology zones. The park's development strategy has prioritized flexibility in land use and zoning to adapt quickly to the needs of dynamic sectors, enhancing its appeal to international and local companies (Yuen, 2016).

In Japan, the Tsukuba Science City represents another significant case of strategic land use. Tsukuba's planning framework was designed to facilitate close interaction between research institutions and private companies, fostering collaboration and innovation. The city's layout includes dedicated spaces for different scientific fields, residential areas, and commercial services, creating an integrated environment that supports both professional and personal needs of its community.

In Europe and America, examples such as the Research Triangle Park in North Carolina, USA, and the Cambridge Science Park in the UK demonstrate the importance of flexible land use policies that adapt to the evolving needs of high-tech companies. These parks focus on creating environments that foster collaboration and innovation while providing the necessary infrastructure to support high-tech development (Bakouros, Mardas and Varsakelis, 2002).

2.3 Impact of Functional Configuration on Urban Development

The configuration of land use functions within high-tech zones significantly impacts urban development. Properly balanced functional areas can lead to enhanced economic performance, improved environmental sustainability, and increased quality of life for residents and workers within the zone. Research has shown that the integration of green spaces, residential areas, and commercial services within industrial parks not only

supports sustainability but also boosts the attractiveness and competitiveness of these areas (Qu et al, 2015). In Chengdu Xinchuan, the challenge lies in optimizing this functional mix to match the specific needs of high-tech industries while supporting urban development goals. Effective functional configuration can facilitate better traffic management, reduce environmental stress, and create more livable urban spaces, contributing positively to the broader urban fabric of Chengdu (Yang Wu and Dang, 2017).

3.Research subjects and methods

3.1 Background Of Chengdu Xinchuan High-Tech Innovation Park

The Chengdu Xinchuan High-tech Innovation Park, located in the Chengdu High-tech Zone, integrates industrial, residential, and commercial functions (Figure 1). Since its establishment in 2012, the park has attracted numerous industries, primarily focusing on information technology, biotechnology, and new materials. In 2018, the policy document titled "Several Policies for Further Relieving the Non-Core Functions of Central Urban Areas and Enhancing the Quality of Urban Capacity in Chengdu" was issued. This policy mandates further optimization of land use functions in central urban areas, promoting the reform of industrial land supply side, and accelerating the improvement of land use efficiency and management levels.

In the context of this policy framework, the land management strategies of Xinchuan urgently require reevaluation. Currently, under the management of floor area ratio (FAR), Chengdu Xinchuan High-tech Innovation Park still has a potential total buildable volume of 14.687 million square meters. According to statistics, the scale of buildable new-type industrial buildings is estimated to be between 8.75 and 9.5 million square meters, residential buildings between 3.6 and 5.14 million square meters, and commercial buildings between 0.7 and 1.45 million square meters. This data demonstrates significant flexibility in land use adjustment.

Figure 1. Construction Status of Chengdu Xinchuan High-tech Innovation Park

3.2 Research Approach

This study employs a case comparative analysis method to investigate the development trajectories and land management strategies of high-tech industrial parks with successful operational experiences. It aims to summarize and collate the functional configuration combinations and proportions used across different parks, deriving general principles of spatial requirements for high-tech industrial parks. Based on these findings, the study proposes land use configuration strategies for Chengdu Xinchuan High-tech Innovation Park.

3.3 Method of Case Selection

This study selects parks for comparison based on their similarities in function (focusing on high-tech industries), challenges (urban integration and sustainable development), and their successful experiences in overcoming these challenges through innovative land use planning. Chengdu Xinchuan High-tech Innovation Park, with a land area of 10.34 km^2, was ultimately chosen for analysis alongside three other cases: Shenzhen Nanshan High-Tech Park(11.52km^2), Shanghai Zhangjiang Hi-Tech North Park (12.13km^2), and Chengdu Tianfu Software Park (9.55km^2). These comparisons aim to draw actionable insights based on the similarities and distinctive approaches of each park.

4. Case Study Analysis

4.1 Shenzhen Nanshan High-Tech Park

Shenzhen's Nanshan district, home to the renowned Shenzhen High-Tech Industrial Park, represents a model of successful high-tech park development through distinct phases of growth. There are three stages of development as follows.

Firstly, in initial industrialization phase (1985-1996), the Shenzhen Science and Technology Industrial Park, the predecessor of Shenzhen Nanshan High-Tech Park, rapidly achieved industrialization through a strategy known as "three supplies and one compensation". This phase focused on drawing in investment and technology through favorable policies, creating a somewhat isolated development model with designated land separating it from surrounding cities. Secondly, in rapid construction and innovation gathering phase (1996-2006), the High-tech Park shifted its focus towards aggregating innovative resources and fostering leading enterprises. This was a time of intensive land and industrial park development, seamlessly integrating property development with industrial expansion. The approach evolved from solely enhancing physical infrastructure to cultivating a comprehensive environment that supported all aspects of high-tech industry growth. And thirdly, in world-class park development phase (2006-present), the emphasis has been on promoting industrial transformation and upgrading to enhance indigenous innovation capabilities. The park's relationship with surrounding cities has become increasingly centered on human capital needs. This intercity collaboration extends to urban services such as university campuses, commercial centers, high-end residential areas, and the Shenzhen Bay Sports Center, significantly strengthening the integrated urban service framework that supports the

high-tech park.

Today, Nanshan hosts major companies like Tencent and Huawei and has developed a robust ecosystem that supports innovation across various sectors including telecommunications, biotechnology, and digital media. The park's enduring success is attributed to its strategic location, superior infrastructure, and the thoughtful integration of commercial and residential areas which enhance the livability for employees and their families (Cheng et al., 2014). This approach to functional mix and land use optimization provides valuable insights into creating a sustainable and integrated urban environment conducive to high-tech development.

The land use within the Shenzhen Nanshan High-Tech Park has been meticulously categorized to highlight the functionality of different areas as shown in Figure 2. Spanning an extensive site area of 11.52 square kilometers, the park features a total built-up area of 22.36 million square meters. It is predominantly designated as M0 new-type industrial land, accounting for 67% of the total area, which underscores its focus on fostering cutting-edge technological and industrial development. Additionally, commercial and residential lands make up 3% and 30% of the area respectively.

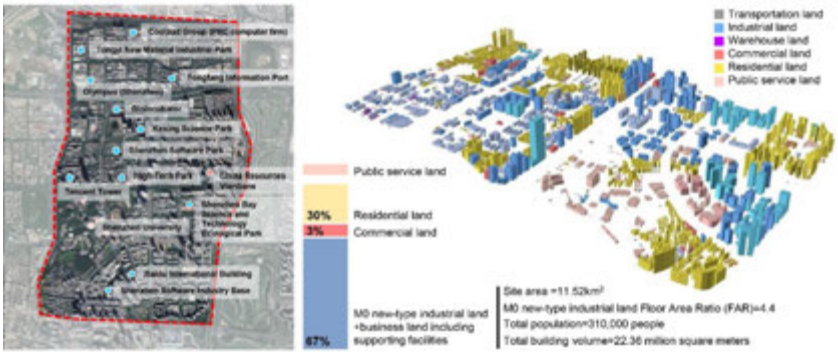

Figure 2. The proportions of different land use functions in Shenzhen Nanshan High-Tech Park

4.2 Shanghai Zhangjiang Hi-Tech North Park

Located in the Pudong district, Shanghai Zhangjiang High-tech Park is often referred to as China's Silicon Valley. Since its inception, the park has undergone several pivotal development phases as follows.

The period from 1992 to 1995 constituted the initial setup phase. The Park was meticulously planned, outlining the functional composition and zoning of the technology area. It established biopharmaceuticals, electronic information technology, and optomechatronics as the three leading industries. The construction of the park's incubators began, and expert and advisory committees were formed to guide development. Then, the period from 1995 to 1999 marked the Consolidation Phase for Zhangjiang. During these years, the area encountered substantial challenges in

attracting investments. In response, the municipal government strategically pivoted to emphasize high-tech development, designating the park as a national biopharmaceutical and technology industry base in Shanghai. This strategic shift included the establishment of national key laboratories, which laid the essential groundwork for the subsequent development of a comprehensive national science center. From 1999 to 2005, during the Aggregation Phase, Zhangjiang witnessed a significant integration of industry, education, and research. The establishment of an industrial base development and operation service company and the completion of a large-scale integrated circuit manufacturing base marked major milestones. Additionally, the groundwork was laid for the burgeoning cultural and creative industries. This phase seamlessly transitioned into the Upgrade Phase from 2005 to 2012, where Zhangjiang was among the first to propose the "Triple Services Strategy" in development zones, which included development and operation, integrated services, and industrial investment. This strategic evolution continued into the current phase, beginning in 2012, where Zhangjiang has been designated as a National Independent Innovation Demonstration Zone. This phase accentuates the dual engines of "function and innovation," rapidly integrating these elements into the park's development agenda, ensuring continual progress and enhancement of its industrial and research capabilities.

Throughout these phases, Zhangjiang High-tech Park has been instrumental in advancing China's pharmaceutical and IT industries. The Park benefits from strong governmental support and boasts a comprehensive service system that promotes research and development activities. Its development has been characterized by a strong emphasis on research and development facilities, which are complemented by residential and commercial spaces designed to foster a balanced work-life environment. The park's planning has been particularly effective in facilitating collaboration between research institutions and businesses, which has been a key factor in its success (Zhang and Wu, 2012).

Similarly, the land use within the Shanghai Zhangjiang Hi-Tech North Park has been carefully analyzed to ascertain the functionality of different areas, as depicted in Figure 3. The Park spans a total site area of 12.13 square kilometers and features a total built-up area of 10.16 million square meters. The distribution of land types includes 74% allocated to M0 new-type industrial land, 5% to commercial land, and 21% to residential land.

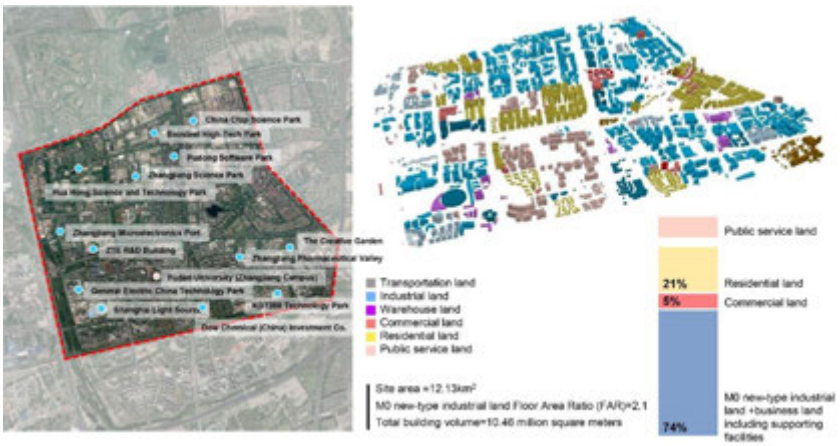

Figure 3. The proportions of different land use functions in Shanghai Zhangjiang Hi-Tech North Park

4.3 Chengdu Tianfu Software Park

Chengdu Tianfu Software Park, located in the heart of the Chengdu Hi-tech Zone, epitomizes a strategic approach to high-tech park development through clearly defined growth phases. Since its official opening in 2005, the park has undergone significant evolution, reflecting the broader ambitions of China's software and service outsourcing industries. Initially, from 2005 to 2007, it focused on establishing a strong foundational structure to rapidly cultivate a professional environment conducive to software development and IT outsourcing. This initial growth phase enabled the park to quickly attract major companies, leveraging Chengdu's burgeoning status as a tech hub. In the next phase, from 2008 to 2011, the park expanded its infrastructure from 800,000 square meters to over 1.3 million square meters, diversifying its industry mix to include business software, digital entertainment, and telecommunications. This expansion facilitated an ecosystem that supports both large corporations and small-medium enterprises. The most recent phase, from 2012 to the present, has centered on sustainability and internationalization. The Park has focused on creating a sustainable and culturally vibrant environment that attracts international investments, enhancing global connectivity and cultural offerings to improve the quality of life for its 30,000 employees and foster a balanced work-life environment.

The land use distribution within Chengdu Tianfu Software Park is detailed in Figure 4. Spanning a site area of 9.55 square kilometers, it is the smallest in size among the three cases discussed. Despite its smaller area, the park boasts a significant total building volume of 17.94 million square meters, ranking just behind Shenzhen Nanshan High-Tech Park. In terms of land allocation, 62% is dedicated to M0 new-type industrial land, underscoring its focus on technological and industrial development. Additionally, commercial land makes up a modest 3%, while residential land comprises 35% of the park. This layout strategically balances industrial growth with residential and commercial spaces, enhancing the overall functionality and livability of the area.

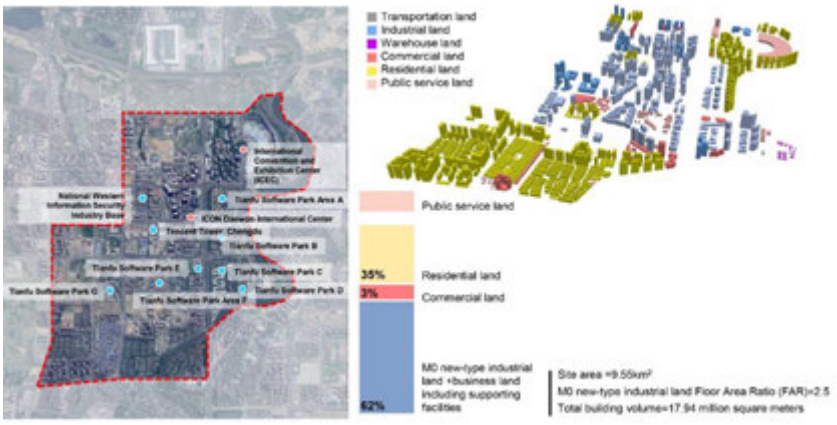

Figure 4. The proportions of different land use functions in Chengdu Tianfu Software Park

4.4 Summary

Although there are clear differences in the total building volumes among the three case study areas, the proportion of industrial, residential, and commercial land use demonstrates a general pattern (Figure 5). M0 new-type industrial land generally accounts for about 60%-75%, residential land comprises 20%-35%, and commercial land falls within the range of 3%-5%. This pattern provides a reference of successful experiences for the functional distribution in Xinchuan.

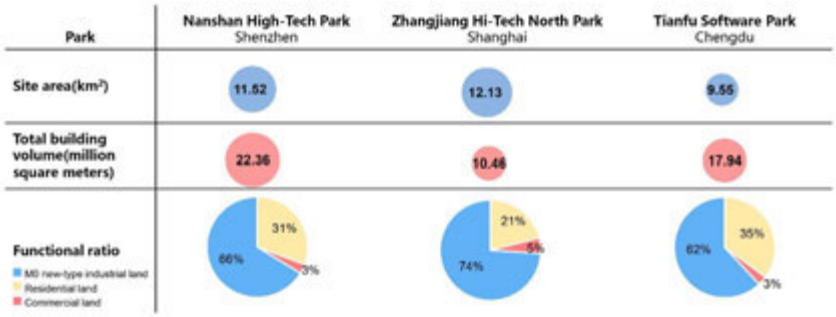

Figure 5. Comparison of land function proportions in the three high-tech industrial parks

5. Strategies and Recommendations

Considering the successful strategies employed by benchmarked parks, it is recommended to strategically reallocate resources within Chengdu Xinchuan High-Tech Innovation Park to foster its development into a leading high-tech hub (Figure 6). To achieve a more optimal functional mix, it is advised to adjust property function allocation to 60-75% for 'Industry + Office', which should include accommodation and small commercial support facilities. Residential areas should then comprise 25-35%, with retail space occupying 3-5% of the total area. Additionally, adjustments in the building ratio are necessary, aligning with the successful innovation parks' experiences

to significantly increase the share of industrial space. This includes accommodating up to 10% of the industry space for service facilities as ancillary rooms, which enhances functionality without overwhelming the industrial character. The proposed changes would maintain the residential space at 470.7 million square meters, increase industrial space from 398.9 million to 631.0 million square meters, and decrease commercial space from 589.5 million to 356.3 million square meters. Finally, the comparison of total building volume by land use type for Xinchuan Park before and after adjustments is shown in Figure 7.

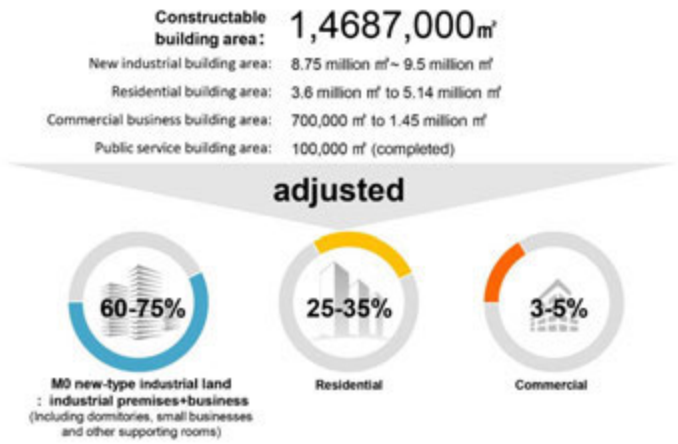

Figure 6. Schematic diagram of land functional ratio adjustment for Chengdu Xinchuan High-tech Innovation Park

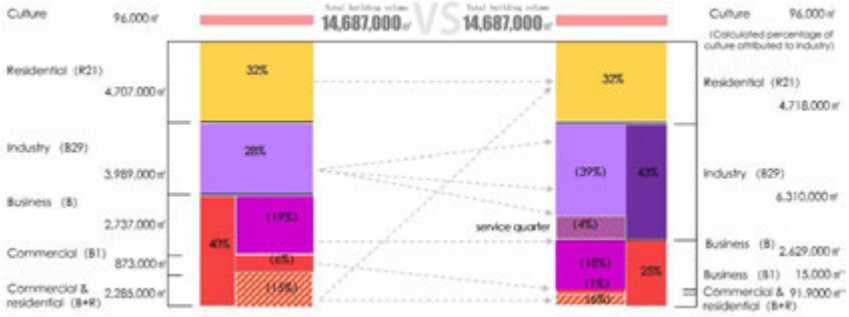

Figure 7. Comparison before and after adjustment of total building volume by land use type

6. Conclusion

This paper analyzes the functional configurations of successful parks such as Shenzhen Nanshan High-Tech Park, Shanghai Zhangjiang Hi-Tech North Park, and Chengdu Tianfu Software Park to derive general principles for land use functional ratios in high-tech industrial parks. It concludes that industrial land typically comprises 60%-75%, residential areas account for 20%-35%, and commercial spaces make up 3%-5% of

these parks. These findings provide empirical guidelines for adjusting the land use layout in Chengdu Xinchuan Innovation Technology Park, aiming to facilitate its transition from a traditional industrial area to an integrated urban district. As a result, this study redefines the urban space of Chengdu Xinchuan High-Tech Innovation Park by adjusting the original planning of 32% residential, 28% industrial, and 40% commercial functions to 32%, 43%, and 25% respectively. This adjustment better positions the urban space to serve as a catalyst for technological innovation and economic development. Although the derived ratios are based on successful parks, the limited number of comparative cases means these guidelines are not yet universally validated and require further substantiation.

Ligurian transfer: when territorial constraints may hamper mobility policies replicability

Daniele Soraggi and Valentina Costa

Email:daniele.soraggi@edu.unige.it

Abstract
Within EU, policy transferability is pivotal. Nevertheless, best-practices' approach has proved ineffective for fragile and peculiar regions. In terms of mobility policies, Sustainable Urban Mobility Plans constitute one of the main EU-led tools larger cities were provided to define context-based actions, later spreading to wider regions, according to the reading of EU system as a polycentric intertwined network, where main hubs connect higher and lower layers. Nevertheless, not all EU regions show this territorial model. Liguria, North-Western Italy, does not: its geo-morphological asset has deeply influenced urban and infrastructural development. The definition of a user-centred perspective, turning from a case-study to a use case approach, contributes shaping inductively tailored solutions. Present perspective may contribute to identify similarities in needs and requirements, thus supporting policies up-scaling.

Key-words: mobility policies, user-centred, use case methodology, place-based

1. Introduction
As the official motto states – *United in diversity* (European Union, 2000) – European Union strategic mission as policy maker is to build shared background, structures and policies able to both respect Member States peculiar cultures and identities as well as define a common approach towards challenges they all need to face.
Best-practices transfer appeared to be, in this direction, the most suitable initiative to meet similar double-layered goal. Descending from private business' world where in the 1960's companies aimed at enhancing performances and consolidating competitive advantage (Jarrar Y. and Zairi M., 2000), similar approach was later extended to support replicability of solutions, policies, actions or procedures within different territorial contexts facing comparable issues, especially whenever planning and mobility initiatives are concerned (Macmillen and Stead, 2014).
Similar choice did not aim only at supporting policy transferability, but played also a significant role in the implementation of evidence-based actions, thus legitimating public decision-making and governance (Ettelt, Mays and Nolte, 2012). Best-practices replication appears indeed to be extremely suitable also in terms of public expenditure rationalisation, thus reducing variability and uncertainties related to experimental steps (Marsden, 2011). This territorial "legacy" supports therefore regions and cities in policy-making processes to capitalize on foreign successes and avoid mistakes repetition (Stead, De Jong and Reinholde, 2008). Exchange network and formats therefore boosted within EU borders, later defined as a "massive transfer platform" (Radaelli, 2000). Increased efficiency and evidence-based approach guided indeed deeply different contexts and regions to reproduce winning experiences implemented elsewhere (Blake *et al.*, 2021), thus providing best-practices a unprecedented pivotal role among policy-making tools (Vettoretto L., 2009).
Nevertheless, their de-contextualizing effect has been also harshly criticized (Vettoretto L., 2009), since actions' effectiveness has been more and more related to context-specific features (Stead D., 2012).

In this direction, progressive EU extension East-ward increased inter-regional differences and variety, so that policy-transfer approach needed to be updated (Hospers, 2005). Regional peculiarities progressively gained relevance in this mechanism, so that innovation and competitiveness started to be promoted and boosted through local features valorisation, following the concept of the so-called *learning regions* (Morgan, 1997). Regional identities gradually acquired indeed larger spots both referring to policies and politics spaces (Salone, 2010), thus increasing structural resources to locate themselves on the map.
After policy transfer and replication showed their weaknesses, networking among cities and regions seemed consequently the most proper way to foster local innovation and development (Stuck, Broekel and Revilla Diez, 2016), thus contrasting isolation risk. Main hubs and secondary nodes were therefore identified to support territorial complementarity in driving regional competitiveness.
As far as transport and mobility policies, similar reasoning may be found at the basis of both infrastructural (TEN-T network) and governance (SUMPs) initiatives.
Large cities are therefore required to drive smart and green transition of their reference region, thus relying on smaller centres supporting progressive spreading of the actions. Nevertheless, not all regions show similar territorial and urban structure, where both vertical and horizontal complementarities contribute in achieve effectiveness performance thresholds.
Ligurian regional asset and structure for instance show not to match present model.
Is it therefore possible to conceptualize different approach towards mobility and transport policies for those contexts where unusual spatial patterns hamper policy up-scaling?
Present contribution aims indeed at highlighting how user-centred approach may help fragile and peculiar regions towards sustainable mobility goals. In details, conceptual shift from a case-study to a use-case methodology will be addressed.
To this aim, mobility policies and EU-led initiatives will be investigated in terms of territorial governance and implementation mechanisms (Section 2), in order to evaluate potential mismatches with Liguria and Genoese asset (Section 3), thus framing potential benefits coming from the shift from a case-study to a use-case approach. In this direction, potential system requirements would be pointed-out (Section 4) to finally evaluate how similar user-centred approach could contribute to overcome existing barriers in terms of mobility policies up-scaling (Section 5).

2. Mobility policies and territorial complementarities

Since the very beginning of common transport and mobility policies, large urban areas have been targeted as key-actors to face EU strategic challenges. Similar responsibilities were mainly due to their weight in terms of socio-economic phenomena, related traffic flows attraction and generation, as well as of energy consumption and emissions production (Harris *et al.*, 2020).
Increasing commitment of EU to mitigate transport-related externalities, supporting sustainable transition of territorial systems, met a significant change in 2013 when both *Guidelines for the development of the Trans-European Transport Network* (European Union, 2013) and *Urban Mobility Packages* (European Commission, 2013) -and consequently *Sustainable Urban Mobility Plans* (SUMPs)-were introduced.
It is therefore evident that on the infrastructural as well as on the governance and planning side, urban hubs were targeted as main drivers of EU-scaled transport and mobility initiatives. Their strategic intertwining was therefore remarked in 2021 when

TEN-T network was revised, and 400 cities constituting the nodal structure of the network were required to design and approve SUMPs in order to ensure transport infrastructures full and effective implementation (European Union, 2021).
As far as sustainable mobility planning is concerned, EU initiative -initially launched in 2009 (European Commission, 2009), supporting progressive consolidation of SUMPs- aimed at collecting experiences descending from voluntary commitment of European cities to foster subsequent best-practices transfer.
Nevertheless, EU monitoring of the databases showed that smaller municipalities (counting less than 100,000 inhabitants) had weakly participated in SUMP programme, due to limited human and material resources to be dedicated (EU Urban Mobility Observatory, 2021). In this direction, White Paper in 2011 (European Commission, 2011) suggested that municipalities over that threshold should be required to draft SUMPs on a mandatory basis, thus conditioning the allocation of regional and cohesion funds (Torrisi *et al.*, 2020).
Specific guidelines for small municipalities were later published, to support widespread transfer of best practices, at the same time topic guide for metropolitan implementation of SUMPs (Chinellato and Morfoulaki, 2019) was introduced, thus stating that similar up-scaling is not feasible through standardized, *one-size-fits-all* solutions. It is therefore evident that present transfer strategy relies on the potential of larger cities to design innovative actions to be later extended to wider metropolitan and regional contexts. Nevertheless, past SUMPs history has shown that not all territorial *milieu* prove to be equally successful (Klausen and Szmigiel-Rawska, 2017).
In this direction, potential explanation could be derived from different territorial networks model. While Christallerian and interconnected networks (Dematteis G., 1994) benefit from both vertical and horizontal complementarities among smaller and larger centres (Figure 1), thus feeding regional hub and spoke system, territorial contexts where strong polarisation is present may face significant challenges (Lang *et al.*, 2022).

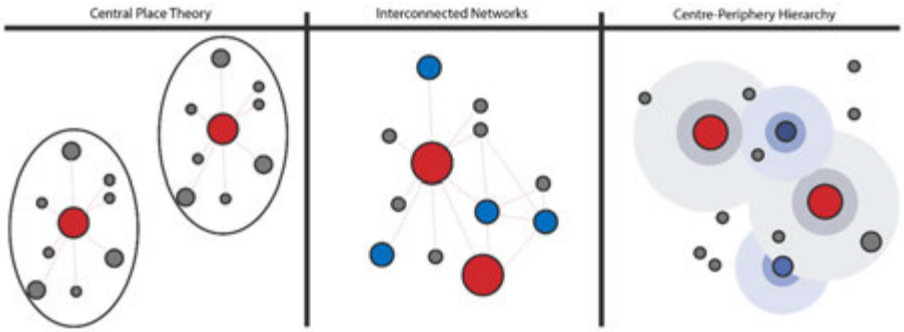

Figure 1. Territorial networks model

In parallel, it is necessary to point-out that SUMPs programme identify several mobility enablers, in order to support multi-modal integration, green and digital transition. Among these several bottom-up mechanisms (such as Mobility Management and Mobility-as-a-Service) are targeted to support bottom-up mechanisms whenever top-down approach fails in the up-scaling of policies (Timms, 2011). User-centred perspective is indeed gaining relevance to overcome planning barriers related to

administrative boundaries, layered and complex urban flows management, conflicting interests and prevision.

3. Genoa: using case-studies or studying use cases?

In this section we introduce the case study: the city of Genoa, Italy, and its role in determining travel in Ligurian Region. Through the experiences gained from the pilot projects and policies implemented in the metropolitan city area, strengths and weaknesses in the scalability on a regional scale will be identified.
To that purpose, through the models of networks and territorial nodes, limitations in the regional development of mobility policies in Liguria are traced.
Finally, a use-case methodology is introduced through which to structure the proposal in the next section.

3.1 Case Study And Regional Mobility

The case study that is the subject of this paper is the municipality of Genoa and by extension of mobility policies the region of Liguria, located in the north-west of Italy. Genoa is the main city of Liguria and with more than 500,000 inhabitants it accounts for more than 35 percent of the regional population.
Liguria is an Italian region consisting of four provinces: Imperia, Savona, the Metropolitan City of Genoa and La Spezia (Figure 2). To the north and south, it is delimited by two physical boundaries: the Ligurian Sea and the Alpine-Apennine arc. This territorial conformation also determines the compressed shape that Liguria possesses and explains its infrastructural systems, with a coastline and three pass lines to the north.
The region's main urban centres are located along the coastline and, in line with the classification provided by the National Strategy for Inner Areas (Agenzia di Coesione Territoriale, 2013), 43% of Ligurian municipalities are unable to reach an urban pole capable of providing the necessary services in less than 20 minutes (Istat, 2021). Moreover, in terms of employment rate they achieve significantly lower percentage values than urban centres - poles, inter-municipal poles and belt poles (Istat, 2021).

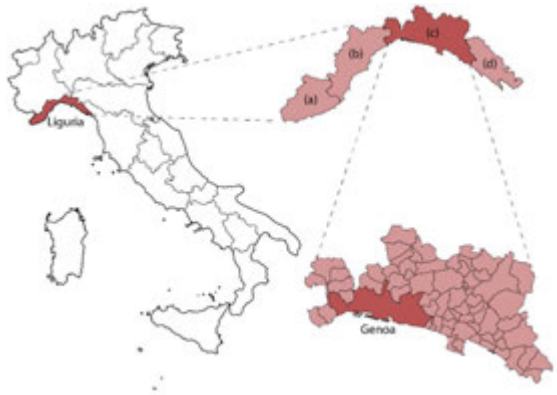

Figure 2. Case study location in relation to Italy. Imperia province (a), Savona province (b), Genoa Metropolitan Area (c) and La Spezia province (d).

Administratively, Liguria borders France to the west, Piedmont and Emilia Romagna to the north and Tuscany to the east. The infrastructure network - motorway and railway - converges on the Genoa node where the presence of the port - freight and cruise - is a determining factor in the Genoese and regional economy (Autorità Portuale di Genova, 2017). In fact, the induced industries activated by the port sector generate over 10 percent of added value and 8 percent of regional employment (Autorità Portuale di Genova, 2017).
All these factors turn out to be decisive in the definitions of the mobility habits of Ligurian citizens, strongly dependent on the need to reach Genoa, a city that plays a barycentric role in the determination of daily travel motives. The Liguria Region itself has published a report analysing regional mobility through data processed by the Vodafone Analytics service(Regione Liguria, 2020). Although the report describes a pre-pandemic situation, it can be considered representative of the current situation, not in numerical terms but in the definition of descriptive trends.
As emerges from the histograms shown in Figure 3, Genoa assumes a centralising role in mobility because it generates and attracts travel numbers hardly comparable to those of other Ligurian destinations, both in the off-season - November - and in the peak-season - August. It is interesting to point out that the city of Genoa exceeds one million trip-days; therefore, relating this number to the number of inhabitants makes the central role more evident than the whole Ligurian population.

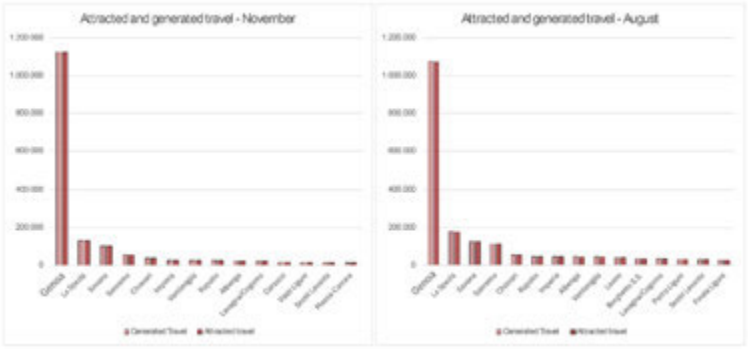

Figure 3. Number of travels generated and attracted in one day by Ligurian municipalities in November and August. Source Regione Liguria (2020), graphic reworking by the authors.

This is most evident when reading the desire lines, the tracks that indicate the movements according to the origin-destination pattern and assess their extent. In Figure 4, the month of November 2019 is taken as a reference and some singularities are highlighted: two areas of disconnection, one between the provinces of Imperia and Savona and one between the Metropolitan City of Genoa and La Spezia; furthermore, the city of Genoa centralises the displacements.
The Metropolitan City of Genoa adopted a SUMP in 2019 (Città Metropolitana di Genova, 2019), through which it determines the strategies and actions to be pursued and monitored in the following years. One part of the proposed actions focuses on the mobility of goods and people within Genoa's urban boundaries. A second part concerns strategic actions to optimise commuting to Genoa. In the latest version of the PUMS the line of strengthening and adapting the urban transport network for people and goods continues, with a strongly focused vision on local public transport (Città Metropolitana di Genova, 2023). In addition, MaaS - Mobility as a Service -

experiments are mentioned for the entire Metropolitan City of Genoa in order to stimulate the development of technologically advanced solutions for travel management and the various mobility services in the area (Città Metropolitana di Genova, 2023).

Figure 4. Map of Liguria's desire lines in November, line size and colour are proportional to the number of travel-days. Source Regione Liguria, (2020), graphic reworking by the authors.

Finally, it is recorded that the city of Savona is beginning the process to adopt its own SUMP (Comune di Savona, no date) and the city of La Spezia has adopted a municipal SUMP (Comune di La Spezia, 2018). In both cases it is emphasised how, despite the non-compulsoriness imposed at national level for the adoption of PUMS, the two municipalities represent two virtuous attempts to adapt to the new sustainable mobility standards. However, it must be emphasised that they are limited to the municipal territory and do not include the entire province in the planning of strategies.
Hence, it can be stated that the mobility policies at stake mainly concern the Metropolitan City of Genoa and describe localised actions on the main urban system and promote its accessibility. Therefore, the successful attempts found at the urban level have not been activated at a larger scale, so the areas surrounding the large urban centres are excluded from the provincial and regional scaling up of mobility actions.

3.2 Regional Limitations

In the previous subsection, actual shortcomings in the transition of mobility policies and winning actions from the urban - Genoese - to the larger - provincial and regional - scale were highlighted.
In line with what has been described by Dematteis (1994), it is demonstrable that Liguria can be ascribed to a polarised model in which Genoa is the centre around which the other municipalities gravitate, for different reasons. Therefore, service levels decline with distance from the centre and actions produced and designed for the centre are hardly redistributed.
Through Figure 5 we describe the territorial limitations in the direct application of the theoretical model of territorial development just specified. In fact, in Liguria, in the first

instance morphological limitations invalidate the regular extensibility of policies; to these are added the borders and administrative subdivisions. The presence of the Ligurian Sea to the south and the mountain arc to the north limit the distribution and incidence of policies and services from a circular model to a west-east linear model.
This theoretical simplification has a representation in reality if the infrastructure structure endowed to the region and described above is visualised.

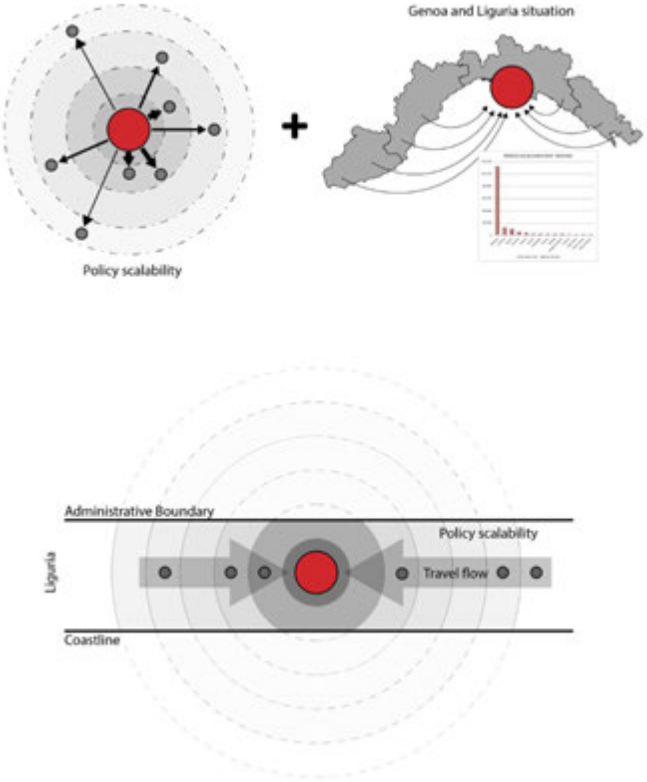

Figure 5. Theoretical application of the polarised model to the Ligurian case. The result is a limited linear distribution against the mobility towards Genoa.

According to the literature, the increased responsibility attributed to metropolitan cities in the exportability on a territorial scale of their policies faces resistance from other levels of governance that attempt to maintain their decision-making autonomy (Chinellato and Morfoulaki, 2019). This is evident from the administrative composition of Liguria, a border region composed of four provinces each dependent on its capital, as a point of convergence of the shifts that emerged from the desire lines (Figure 4). Therefore, it can be said that the greater the distance from Genoa, the more difficulties there will be in the exportability of mobility policies adopted at the local Genoese level. This is more apparent if one adds to the territorial description also the travel trends described in the previous section. In fact, Genoa plays the pivotal role in daily travel motivations from all over Liguria.

Consequently, it emerges how the trend of mobility in Liguria takes place in the opposite direction to the ideal scalability of mobility policies produced by the central pole (Figure 5).

3.3 Use-case Methodology

To motivate the proposed approach for mobility management on a regional scale in the following section, in this section we introduce the Use-case Methodology (UcM).
UcM was developed in 1992 by computer scientist Ivan Jacobson as a language useful for modelling and preliminary design of software and digital tools (Jacobson, 1993).
Use cases are understood to be the description of the individual of a set of interactions between a user and a system that enable the user to achieve a goal or perform a task. In addition, it can be said that through the analysis of the interaction pattern of use cases, the external characteristics of a software system are defined from the user's point of view (Schneider and Winters, 2001).
Hence, UcM can be represented as a whole within which individual use cases are positioned which, if completed, allow the achievement of the objective for which UcM was used.
Although this methodology was born for IT, in this paper we attempt to re-propose it to support regional mobility planning in a territory with particular boundary conditions such as Liguria. So, in our case the object described by UcM is 'Ligurian Transfer', that is the possibility of reaching any destination from any origin in Liguria.
While individual interactions are represented by users who need to make a journey. In conclusion, it will be the individual user who will be the solution to the need to move and the interaction he or she generates with the mobility service will be addressed, in this sense the idea behind UsM in which the user is an element external to the project will be overturned (Figure 6).

4. Proposed approach

As shown by the authors in the previous section, Ligurian urban and infrastructural asset, as well as territorial inequalities and unbalances hamper mobility policies up-scaling. Administrative boundaries, as well as polarised accessibility, act as barriers to best-practices transfer.
At the same time, recent MaaS experiences suggest that both bottom-up and user-centered perspective may contribute to overcome existing limits.
Use-case approach requires the preliminary setting of the operational question. In details, moving across Ligurian Region through sustainable alternatives is therefore main aim of proposed approach. In this direction, origin and destination of the journey deeply affect individual mobility potential. General framing of travel demand implies indeed to further investigate users' mobility patterns, choices and needs to support sectorial policies design independently from territorial boundaries and constraints (Figure 6).
Operational question needs to be detailed then according to travel purposes, being them study/work commuting, personal non-systematic reasons, free time/holiday (Manfredini and Dilda, 2012).
Once travel sub-systems are defined, thus setting travel frequency, purposes and respective elasticity on a general basis, users' individual features require to be identified.

In this direction, it is particularly relevant to define which variable may affect more significantly users' behaviors and attitudes (Lenormand *et al.*, 2015). Similar user-centered perspective is the one leading MaaS offer where transport services combination (and consequent fares) target specifical users' segment.
Starting from demographic and socio-economic profile of regional population, is therefore possible to identify tailored measures to be implemented.
Proposed approach is to profile several "personas" able to orient policy design, not only on a territorial basis, but including also individual features and behaviors.
According to recent studies linked to MaaS experiences (Ye, Zheng and Yi, 2020; Smith, Sochor and Karlsson, 2022), main individual features influencing mobility choices are related to i.age; ii.gender; iii.work conditions; iv.driving licence; v.vehicles ownership.

4.1 Potential Impacts Assessment

4.1.1 Accessibility Improvement

Combinations of similar sets of features may guide policy makers to identify relevant gaps in terms of transport supply as well as in terms of territorial accessibility.
Turning from a strictly sectorial mobility approach to the wider look of activity-based accessibility (Ferreira and Papa, 2020) could represent a turning point for a more integrated and inclusive planning. Defining mobility policies inductively may contribute to meeting widespread needs, more than territorial-scaled top-down initiatives. Similar approach indeed may constitute a win-win solution both for users –provided with tailored services- and policy makers – developing effective and efficient policies supporting sustainable and digital transition.

4.1.2 Planning Prioritization

At the same time, shaping planning and policies following a UcM, may support indeed the analysis of potential synergies among different clusters of users: de-contextualizing mobility needs and data from a standardized territorial-driven basis, may help policymakers to identify different users' segment converging into similar preferences and necessities. In this direction, transport measures replicability and transferability could be further boosted beyond traditional administrative and services boundaries.
In this direction, similar recognition and assessment could prove particularly relevant for public administrations and planners in order to point out priorities among mobility interventions and actions, thus tracing potential economy of scales within a wider context. Instead of consolidated approach where urban-led actions are supported in the name of local competitiveness and efficiency, while non-urban initiatives belong to territorial cohesion field, the potential intersection among the two contexts on a users' needs basis contributes to the clear and effective individuation of mobility patterns, thus making it easier to cluster them and respond them in a targeted way.

4.1.3 Stronger Regional Coordination

Finally, the shift to a user-centered approach –due to the massive requirements in terms of data collection- may lead to an up-scaling of strategic mobility planning, thus providing within the wider framework of regional coordination, significant support to

smaller municipalities, historically unable to cope with EU-initiatives requirements and prescriptions (as SUMPs experience has recently shown).

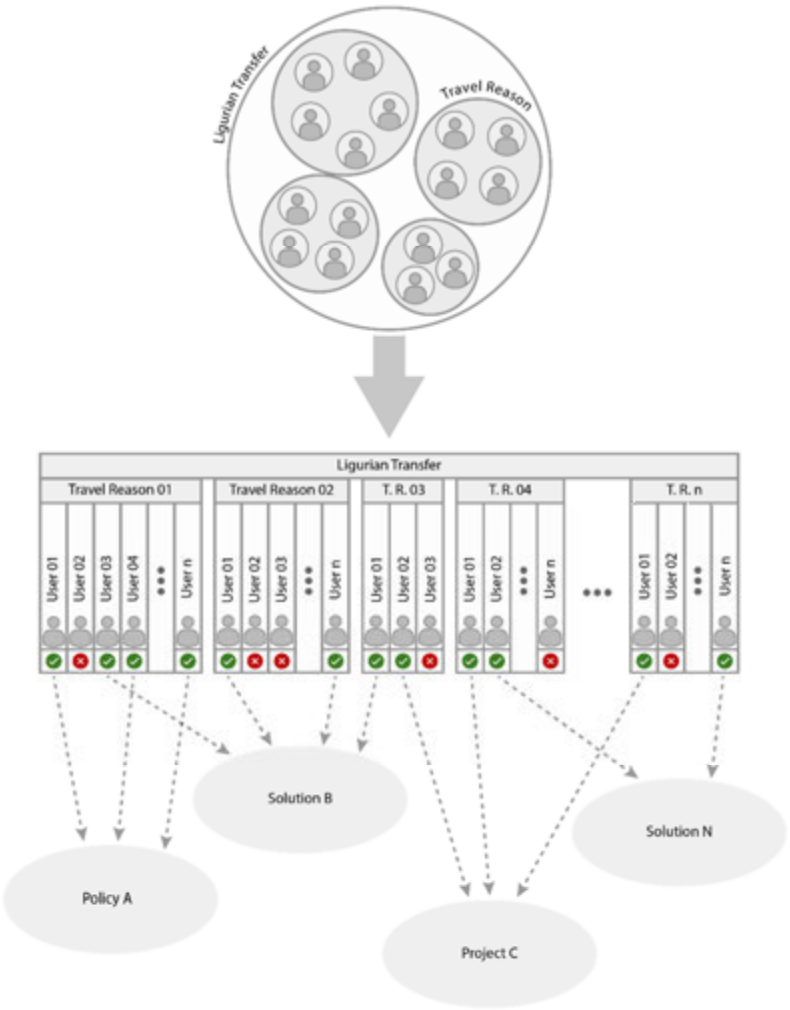

Figure 6. Representative and simplified diagram of the proposed solution based on the UcM and the possible identification of mobility solutions in Liguria.

4.2 Limitations

Nevertheless, some criticalities on the planning level require to be highlighted.

4.2.1 Massive Data Collection

As previously stated –also capitalizing MaaS-related recent experiences- user-centered mobility planning requires massive data-collection, thus constituting relevant

barrier both in terms of users' privacy protection and ICT structures for public administrations. Significant legislative issues are currently under EU investigation to balance tailored mobility experiences and individual privacy guarantee.

4.2.2 Planning Competencies Allocation

Transport and mobility competencies are allocated to different administrative levels. Despite Regional role in strategic transport and mobility planning, mobility basins, as well as public transport networks, are scaled on a provincial/metropolitan basis, transport-related initiatives may be finally defined within municipal borders. In this direction, greater coordination among them is necessary to feed user-centered system, both in terms of data collection and intervention prioritization. Mobility Agencies may for instance constitute key-actors of similar processes, especially in guiding transitional steps.

4.2.3 Strategic Planning Relevance

Policies' fragmentation on a user-centered basis may hamper holistic and integrated mobility planning. Particular attention should be paid to strategic planning in order to orient user-centered initiatives within a wider sustainable mobility framework. Tackling the risk of a vertical planning, thus ignoring interactions among different users' segments and dedicated strategies, general coordination of the entire process should be provided to assure that the sum of individual interests effectively equals the pursue of collective sustainability goals.

5. Conclusions

Best-practices approach towards mobility policies transfer has been for long the prevailing approach within EU boundaries. Increasing variability and complexity of urban flows and dynamics have later required to fine-tune initial approach. After SUMPs were firstly introduced, it was therefore evident that smaller municipalities faced strong criticalities in reproducing mobility initiatives implemented elsewhere. In this direction, plans up-scaling proved particularly difficult whenever territorial assets and network do not develop vertical and horizontal complementarities. Polarised configurations (such as the Ligurian one) are not able to support effective spreading of sustainable mobility planning and experiences.

The definition of a Use-case Methodology may contribute indeed to shift mobility planning inductively, thus tailoring policies through a user-centered approach.

Similar de-contextualized planning and policymaking could represent potential solution to the need of policies mobility and replicability within EU context becoming more and more variegated and changing.

It needs to be pointed out that user-centered perspective, thus potentially driving a more conscious and effective approach towards transport planning, somewhat overlaps best-practices premises in terms of practices replicability and de-contextualization. Nevertheless, decades of EU policies have shown that despite not all regions may develop similar networks, structures and sensibilities, all communities and citizens show comparable needs to join socio-economic opportunities and share similar basic needs.

The shift from a mobility-driven approach towards a more accessibility-centered way to look at passengers-dedicated transport policies and planning could constitute the

turning point to a widespread and effective upscaling of EU initiatives towards a more sustainable mobility.

From Global North to Global South: Exploring Creative City Policy Mobilities and Their Urban Impacts

Author's Name: Ludmila Kolouchova
Affiliation: Faculty of Environmental Sciences, Czech University of Life Sciences Prague

Abstract
An increasing number of cities of the global South are introducing the creative city policy and pledging to adopt creativity as their main developmental focus to improve the living conditions of their population. Although European cities have long used this policy (Scott, 2014), many have been unsuccessful (Rius-Ulldemolins, Hernàndez I Martí and Torres, 2016). Since developing countries of the Global South are participating in such international models, more research is needed to address a gap in the literature on the urban planning effects of creative city policy in the Global South. This study presents a theoretical framework of creative cities focusing on the urban regeneration of cities in developing countries by rehabilitating cultural creativity, diversity, and social inclusion. The research may provide a valuable knowledge base for international exchange of experience in the planning field.

Keywords: creative city policy, policy mobility, global South, urban planning

Introduction

Creative city policy is a well-established approach to urban development (Costa *et al.*, 2007). This article interconnects research on global urban aspects of creative city policy and policy mobilities.

In the past decades, much research has focused on creative cities and policy mobilities of the global North[1] (Bunnell, 2015; Molho *et al.*, 2020). Western cities have long used creative city policies to reposition themselves in the global urban hierarchy and to tackle their problems of rising social inequalities and tensions in the urban context (Scott, 2014). Its roots are in the 1990s, primarily Europe, North America, and Australia (O'Connor, Gu and Kho Lim, 2020). However, some policies have been unsuccessful in creating amenities, requiring massive financial investment and land consumption, like in Barcelona and Valencia (Rius-Ulldemolins, Hernàndez I Martí and Torres, 2016).

Nowadays, an increasing number of cities in the global South (Molho *et al.*, 2020) are introducing the creative city policy and pledging to adopt creativity as their main developmental focus. They rely on Western theoretical frameworks to research the cities and use homogenising scripts of creative cities to interpret the cultural policies (Molho *et al.*, 2020; O'Connor, Gu and Kho Lim, 2020). That calls for further investigation due to different

[1] I use the term 'global North and South'. It refers to the regions of Latin America, Asia, Africa, and Oceania. Most countries maintain low incomes and marginalised cultures and politics, although emerging BRIC countries (Brazil, Russia, India, and China) complicate the division. As (Dados and Connell, 2012) state, 'The term Global South functions as more than a metaphor for underdevelopment. It references an entire history of colonialism, neo-imperialism, and differential economic and social change through which large inequalities in living standards, life expectancy, and access to resources are maintained.'

socioeconomic and cultural backgrounds. Among others, the relationship between culture and urban development (Russo and Van Der Borg, 2010).

My study aims to close the literature gap by creating a theoretical framework within which practitioners and academics can approach these questions: How is creative city policy evaluated globally? Who and what moves the policy? What are the stages of policy mobility from the global North to the South? What are the key features of urban planning effects of creative city policy on recipient cities?

Literature Review

Creative City Policy

Its History and Emergence

The evolution of creative city policies spans the time of the post-industrial crisis, globalisation and the rise of neo-liberal ideologies. In response to these shifts, cities became entrepreneurs in a competitive market striving to attract capital and investors (Pratt, 2011).

This transformation was preceded by the crises of Fordism (Florida 2005, Landry 2008), characterised by mass production technologies predominant in the Western industrialised world until the early 1970s. These changes affected cities such as Detroit, Chicago, the English Midlands, the German Ruhr district, and parts of northern Italy.

The transition from Fordism led to the emergence of more flexible and specialised production models, altering industrial organisation and inter-firm relations. The trend was to liberalise institutional restraints on market competition and weaken the welfare state (Harvey, 1989), (Brenner and Keil, 2014).

These shifts also influenced the spatial patterns of growth (Brenner and Keil, 2014). Industries, like cinema (Storper and Christopherson, 1987), were increasingly clustering in metropolitan areas to improve the efficiency and competitiveness of entrepreneurs and lower production costs. This was possible due to the availability of a specialised and skilled workforce, reduced transaction costs, face-to-face problem-solving, and sharing of skills.

Costa (Costa *et al.*, 2007) suggests five origins for the increasing interest in creativity:

1. 'Creative city' concept developed by, amongst many others Charles Landry (2000), Peter Hall (2000), and Ralph Ebert et al. (1994) in connection with an analysis of 'creative industries' and practical applications via policies
2. Launch of 'Creative Europe' by European research institutions or the project of 'Creative Cities network' by UNESCO in 2004
3. 'Creative class' (Florida, 2002), as a critical driver of competitiveness and urban regeneration processes due to its talent, tolerance and openness
4. 'Creative industries' within the economic analysis originate from the industrial economic tradition, and a similar approach is 'creative economics'. It analyses their organisation in an institutional context, taking their particularities into consideration
5. The importance of creation and artistic creativity, leading to the study of not only the demand side but also the supply (Throsby, 2004)

While the definition of creative cities and creative economies varies (Costa *et al.*, 2007), most authors agree that creative industries include film, music, radio, television, publishing and

advertising along with the support infrastructure (organisational or material) (Pratt, 1997). Despite the substantial economic contributions of creative economies, evaluating their impact can be challenging due to their nature, which has both financial and cultural value (the process of creation is also essential, not only the outcome) (Pratt, 1997; Evans, 2005).

In practice, creative city policies aim to enhance the quality of life for urban inhabitants through targeted interventions in three main areas: (a) economic development, (b) social welfare/inclusion, and (c) urban development (Bianchini and Parkinson, 1995; Rato, Roldão and Mühlhan, 2009). There are benefits in combining all three perspectives (Boddy and Parkinson, 2004; Costa *et al.*, 2007). Figure 1 below gives an overview of the combination of approaches and typical examples of cities.

(a) Economic development is usually the central focus of creative city policies, with the primary objective being the job creation and formulation of industrial and creative strategies.

(b) Social welfare programmes focus on social inclusion or community character.

(c) Urban development plays a central role in shaping the city's physical landscape. It includes renovations and reconstructions to improve the image of the city, even a recreational strategy. These approaches are usually more or less modified and combined (Bianchini and Parkinson, 1995; Rato, Roldão and Mühlhan, 2009).

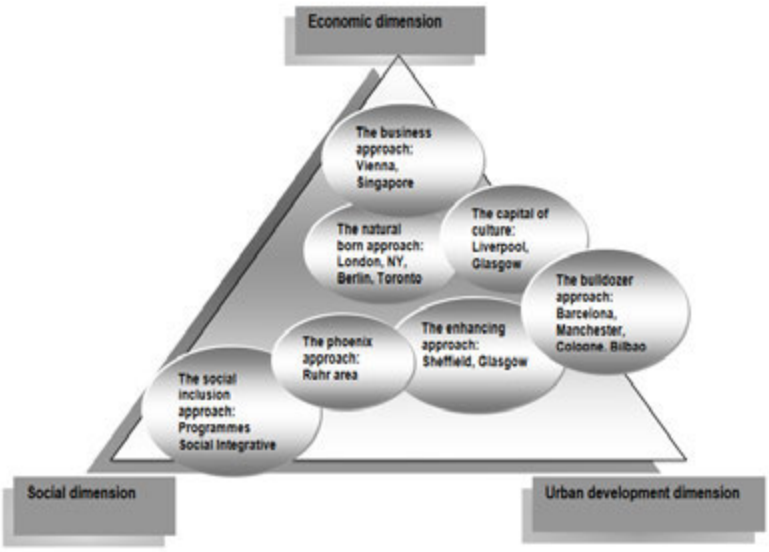

Figure 1 Typology of creative cities (Rato, Roldão and Mühlhan, 2009)

The paradigm shifts from focusing solely on the economic benefits of the arts to sustainability (in terms of physical, social and economic well-being) and distributive equity. From short-term to long-term impacts (Evans, 2005). From building flagship projects to incorporating small-scale public art projects with the stress of everyday use, social inclusion, and design quality (Boddy and Parkinson, 2004) to battle gentrification associated with high art venues and large redevelopment projects. Inclusion of local communities, engagement and consultation. Cultural activity should be incorporated as one key indicator of a city's quality of life (Evans, 2005).

Limitations and Contradictions

There are numerous limitations and contradictions to this neo-liberal urban policy. Much of the critique is centred on the fact that researchers predominantly focus on theoretical and empirical research on the global North and the lack of investigation of a broader range of contexts of different countries (Molho *et al.*, 2020). One example could be the spatial mobility of the creative class[2] (Martin-Brelot *et al.*, 2010).

Planners should focus less on land use and more on incorporating cultural, social, economic and environmental issues (Landry, 2000/2008).

The creative city has often been seen as easily transferable (Kong, 2014), homogenising (Molho *et al.*, 2020) and a 'fast policy' (Peck, 2005). However, the impacts of the policy could be short-lived (Russo and Van Der Borg, 2010; O'Connor, Gu and Kho Lim, 2020), and flagship events cannot do more than divert attention away from the real problems of cities (Mooney, 2004).

The critical critique focuses on gentrification (McGuigan, 1996; Seo, 2002; Evans, 2005). Creative workers and productions depend on specific locations, but at the same time, they are threatened by delocalisation due to the rising valorisation of urban land (Vivant, 2013).

That leads us to another issue: the frequent omittance of the topic of social exclusion in creative cities (Sasaki, 2010). The impacts of the policy could be socially exclusive (Russo and Van Der Borg, 2010). Groups such as the socially excluded, older adults and people experiencing homelessness are not being integrated (Landry and Bianchini, 1995; Landry, 2007; Müller, 2019). We also should not leave out spatial inequalities (Evans, 2005).

Role of International Creative City Networks

Cities are influenced by the increasingly uneven global inter-urban connections (Molho *et al.*, 2020) and seeking a change in their aspirations and identities, however successful in the long term and the extent of their implementation (O'Connor, Gu and Kho Lim, 2020).

[2] Empirical European data show that creatives are less mobile than in the United States due to cultural and institutional barriers. In a search for a location to settle, look for hard factors such as the quality of jobs. Soft factors such as cultural amenities only determine the particular district where to settle (Martin-Brelot *et al.*, 2010).

To meet the challenges of globalisation and ensure cities' success, we must rely on something other than traditional political institutions but on individuals, groups and bottom-up processes. Global public policy networks must include groups from the global South. It is critical in the design and implementation of policies (Reinicke, 1999).

There is a great diversity of institutional frameworks and governance mechanisms in implementing creative city policies. Besides, many public bodies and organisations use these concepts locally and nationally. There are also supranational institutions, such as the UNESCO, European Commission and OECD (Organisation for Economic Co-Operation and Development). Their focus lies in the multidisciplinary approach, management, and governance (Costa *et al.*, 2007).

UNESCO's ''Global Network of Creative Cities," launched in 2004, has quickly spread to developing countries. Now, 350 cities in 7 fields worldwide are registered in the global UNESCO network. There are efforts to strengthen the connections between 'global South' cities (Molho *et al.*, 2020). Ahead of these designations, UNESCO declared the Universal Declaration on Cultural Diversity in 2001. Its purpose is to combat standardisation under globalisation (Sasaki, 2010).

Creative City Policy Travels to the Global South

An increasing number of cities in the global South are introducing the creative city policy (Molho *et al.*, 2020). However, this complex model cannot be re-applied without modification (Bianchini and Parkinson, 1995). All cities are diverse; thus, many formulas address all the city's problems (Molho *et al.*, 2020).

Luckily, not all global South cities accept imported models without changes (for example, Beirut and Istanbul took Dubai as an anti-model) (Centner, 2020). Many cities found alternatives and new approaches to hegemonic models from the West worldwide (Molho *et al.*, 2020).

From a practitioner's or policy outcome-oriented scholar's perspective, 'good' or at least promising solutions must also be transferable from one place to another. And they need to know how this might be done most effectively (Baker and Temenos, 2015).

Guidelines about how global creative policy circulates, vernacularises and is unevenly adopted can offer policy mobility theory. Where and to whom they travel and how they vernacularise depends on the institutions and actors who receive them. It depends on their position and power. Remember that conflicting interests around the globe also influence local policies (Molho *et al.*, 2020).

Policy Mobility Theory

An increasing number of scholars are paying attention to the circulation of urban policies and the concept of 'policy mobilities' (Baker and Temenos, 2015).

There have been numerous attempts to reproduce and implement various entrepreneurial development policies due to intensifying interurban competition (Harvey, 1989; Brenner and

Keil, 2014), increasing globalisation of politics, society and economy (Hall and Hubbard, 1998), and the socio-spatial processes derived from it (Peck and Tickell, 2002; Baker and Temenos, 2015).

Emerging in the early 2010s (Baker and Temenos, 2015; Haupt, 2023), the policy mobility approach was primarily driven by critiques of the previous approaches by human geographers and urban studies scholars (Peck and Theodore, 2010; McCann, 2011; Peck, 2011; Temenos and McCann, 2013). Later, it led to the emergence of urban policy mobilities as a sub-field (McCann, 2011; Baker and Temenos, 2015; Lovell, 2019; Haupt, 2023).

Policy mobility theory emphasises thought patterns and mindsets and the directions of movements that express power relations (Haupt, 2023).

Critical Features of Policy Mobility

Critical features of policy mobility, besides the spread between cities, include international (global) geographical reach (Haupt, 2023), the mobile and changeable character of policies (Peck and Theodore, 2010; McCann, 2011), that are modifiable right from the beginning of the process. Ideas, discourses, or synthesised models can travel in selective and partial forms (Peck and Theodore, 2010; McCann, 2011; Temenos and McCann, 2013).

How ideas/policies might change the places they are spreading to (Stone, 2004; Peck and Theodore, 2010; McCann, 2011; Temenos and McCann, 2013).

Emphasis is more firmly placed on the effects of policy discourse and implementation on social life and practices (Haupt, 2023).

The focus is more on the role of non-state actors, such as NGOs, consultancies, or multinational corporations, and how they influence governmental bodies with their mostly neoliberal policies (Peck and Theodore, 2010; Prince, 2010; McCann, 2011).

Another key feature is the significance of failed policy spread – policy immobility (McLean and Borén, 2015; Lovell, 2019) no longer studied from a positive point of view but to research the power relations and inequalities and drawing attention to failed or harmful policies that can also travel to different places (Lovell, 2019).

Policy mobilities literature has a critical perspective (critical of policy spread and society) (Haupt, 2023).

Urban policy mobilities research has no defined paradigm or definitive approach. Instead, they draw from various epistemological perspectives spanning planning, sociology, geography and political science (Baker and Temenos, 2015).

Critique of Policy Mobilities and Recommendations for Future Research

Early critiques focused on neoliberal policies, orientation toward the global North (Bunnell, 2015), and presentist outlook are being answered (Temenos, Baker and Cook, 2019).

Further critique of policy mobilities scholars addresses the work of scholars who rarely reach out to policymakers and politicians with suggestions on how to improve current practices (Haupt, 2023).

Söderström and Geertman (2013) and Cohen (2015) argue that focusing on Southeast Asian cities has led to the conclusion that we should further focus on understanding ad hoc networks and nonliberal urban practices.

For future studies (Temenos, Baker and Cook, 2019) recommend foregrounding the integration of policy mobility within the socio-spatial fabric of cities and urban life and (a) engaging with other conceptual questions in the field of urban studies, (b) enlarging the collection of studies outside of the Anglo-American area. That would be beneficial in policy mobility studies for differentiating what is general and specific, and (c) conceptualising policies on dualities: local/global, fixed/mobile, territorial/relational—also adding mobilities of knowledge, people, materials and politics.

Shaping a Framework for Creative City Policy Mobility and Its Urban Planning Impacts Across Global Regions

Stevenson (2004) highlights the necessity for new methodologies that combine approaches of anthropology, sociology, and cultural and urban studies that can be applied to evaluation models to measure physical, social and economic changes. Responding to the need for more conceptual and integrative groundwork, this paper proposes a framework for urban planning effects of creative city policy mobility from the global North to the South.

I build my framework on the work of Evans (2005), Temenos, Baker and Cook (2019), and Müller (2015).

The proposed framework involves types of evaluation, who and what moves policy, the three stages of policy mobility, and key features of urban effects of creative city policy.

Types of evaluation

The following types of reporting can evaluate culture's contribution to regeneration (Evans, 2005): (a) project evaluation and (b) programme evaluation.

(a) Project evaluation focuses on the project's process and results. It can use quantitative or qualitative evidence. Data are collected via unstructured interviews, focus groups, questionnaires and participant observations. It is ideal to start evaluating from the beginning of the project, during and after post-completion. The assessment area is not limited (it can be a local regeneration area or national programme). The evaluation may include one or multiple projects (see Programme evaluation below).

(b) Programme evaluation includes multiple projects in one local, national or transnational initiative. It uses Project evaluation techniques and can be measured by standard output criteria, including performance indicators (comparing actual and targeted performance).

Academic discourses often counter overly optimistic official narratives on urban development. Usually, it is not possible to access the necessary data. The studies include more technical quantitative impact assessments (economic/econometric) and area and sectoral case studies of a particular cultural activity like theatre quarter and fashion industry. „In some respects, the lack of 'hard evidence', of access to detailed data, decision-making processes and the basis to measure impacts over time, have limited more 'scientific' analysis, leaving little scope, outside political and policy discussions and micro-level case studies" (Graeme Evans, 2005, 965).

Area of intervention	quarter(s) city region	(Rato, Roldão and Mühlhan, 2009)
Timeframe	short middle long term	(Evans, 2005)
Amount of funding		(Evans, 2005)

Figure 2

Who and What Moves Policy

Mobility of urban planning effects of creative city policy is possible because of the mobility of (a) knowledge, (b) people, (c) materials and (d) politics (Temenos, Baker and Cook, 2019).

(a) Knowledge is transferred when there is a need for detailed policy or a global approach is desired. It can be local or outside expertise.

(b) Diversity among the team of people is beneficial; it includes all types of policy actors and their mobilities, as there remains a need for shared experiences and face-to-face meetings at conferences and study tours. It can be bureaucrats, politicians, activists, lobbyists, service managers, consultants, architects, etc.

(c) Materials are needed to circulate between people. They can travel in physical and virtual spaces through reports, PowerPoints, spreadsheets, maps, and visualisations. They are crucial for the actors to visualise the proposals and make connections to them.

(d) Politics is central to the mobility of policy. It reflects the current political conditions, ideologies and functions of the state. These conditions are globally different, and various policy advocacy and activism levels exist.

Primary recipients of the intervention	the state the region	(Rato, Roldão and Mühlhan, 2009)

	the city the community a particular group of actors the private sector	
The level of participation of the population in the process	bottom-up top-down	(Rato, Roldão and Mühlhan, 2009)
Inclusion of multiple stakeholders	arts and cultural groups heritage associations and communities	(Evans, 2005)
Accessibility of culture and physical infrastructure	for locals for visitors	(Evans, 2005)
Schemes structured to facilitate collaboration between those responsible for regeneration and those responsible for cultural activity	local authorities partnership bodies responsible for regeneration	(Evans, 2005)
Integration into legal documents	strategic plan master plan	(Evans, 2005)

Figure 3

Three Stages of Policy Mobility

Questions accompanying Figure 4 below help us systematically trace North-South policy mobility and help in orientation and approach to urban planning questions in three time frames: (a) transportation, (b) transformation and (c) translation (Müller, 2015).

(a) Transportation happens when the policy is moved from place A to place B (Healey, 2012; McCann and Ward, 2012). It is transported and impacted by diverse people via various materials to different political systems. It does not come packaged but rather as selected elements brought to one place and assembled. It might be of interest to study what parts of policies are immobile.

(b) Transformation is embedding policy into the local socio-material environment. It is usually changed, seldom not at all. Policy changes are due to interaction with existing policies, translations, interpretations, institutional settings and legislation. The carriers also modify elements of policies.

(c) Translation can be similar to policies' original intentions or have different impacts. Responses to its implementation can be studied from the perspectives of the public, private, and state sectors. Translation is not the end of the cycle; the policy can travel to a new place again.

Transportation	Transformation	Translation
Who and what moves and is moved?	What aspects of a policy change?	What actions does the policy create?

When?	For what reasons and through what channels does change happen?	How well is the policy able to align intentions and actions?
Where to and from?	To what extent is change intentional or unintentional?	Through what mechanisms is the policy applied?
How?	What is the role of already existing policies in affecting change?	What is the response to the policy?
Through what channels or events?	What other elements does a policy enrol?	Does the policy itself serve as a model for others?
Who and what does not move?

Key Features of Urban Effects of Creative City Policy

Urban regeneration is usually directed towards transforming physically, socially and economically declining areas. The paramount principles lie in the sustainability of the place, aiming toward long-term improvement. Responding to the call for a more integrative approach, the evaluation also touches on social and economic domains.

People's needs across the globe are met differently. Guidelines can offer Maslow's hierarchy of needs, including physiological and safety, as the base (Maslow, 1943). The sustainable principles should, therefore, include the liveability of the place, people's quality of life, safety, inclusion and heritage conservation. Inclusion of all groups irrespective of income, ethnic profile, religion, skills, gender, disabilities, age, caste, or political orientation. Quality of life depends on mobility and access to public amenities and open spaces, as well as on the living environment, densities, pollution, and health.

Monitoring should also include social and land use diversity and the multifunctionality of places.

We should remember the authenticity and identity of the place and design quality, which does not rely on homogenising principles.

To attract creative individuals and companies, agglomerations should offer spaces for production (both enabling work from home, small-scale businesses and open coworking places for sharing information, knowledge and skills), consumption, commercialisation (shops, markets), socialisation and residence (Vivant, 2013). Government bodies at local and national levels can support innovative clusters (cooperation of private companies and research centres; networking of local producers) and industrial planning (rezoning large areas for cultural consumption and production) through urban policies (Vivant, 2013).

Graeme Evans (2005) noted that no universally applicable set of indicators for a particular intervention exists. Due to its context-specific nature, a pick-and-mix approach is required. Standardised performance indicators and quantitative benchmarks are also not valuable in this context.

Extent of the physical intervention	heavy intervention in forms of renovations, construction of an emblematic building, transport networks renewal of buildings and requalification of quarters	(Rato, Roldão and Mühlhan, 2009)
Reuse of redundant buildings	studios galleries museums venues	(Evans, 2005)
City's creative historical assets	renewal of buildings	(Rato, Roldão and Mühlhan, 2009)
Reuse of land	brownfields	(Evans, 2005)
Places for production	enabling work-from-home small-scale businesses open coworking places for sharing information, knowledge and skills	(Evans, 2005)
Places for consumption	construction of a new emblematic building	(Vivant, 2013)
Places for commercialisation	shops markets	(Vivant, 2013)
Places for socialisation	public spaces festivals, events and public art schemes	(Evans, 2005), (Vivant, 2013)
Places for residence	houses apartments	(Vivant, 2013)
Innovative clusters	for cooperation of private companies and research centres for networking of local producers	(Vivant, 2013)
Clustering	of producers	(Evans, 2005)
Industrial planning	rezoning large areas for cultural consumption and production	(Vivant, 2013)
Complementary infrastructure (investment in land preparation and transport infrastructure)	air, road, rail/ light rail, metro housing hotels upgrading of existing cultural facilities	(Evans, 2005)

Figure 5

Discussion and Conclusion

This research links creative city and urban development studies with policy mobilities. A theoretical framework has been created on the policy mobility of creative cities in urban development. The proposed framework involves types of evaluation, who and what moves policy, the three stages of policy mobility, and key features of urban effects of creative city policy.

A policy can only be packaged and implemented with changes on its way to a new destination. Moving policy loses or gains different directions depending on who moves it, what moves it, and where it is moved.

There is also no universally applicable set of indicators for a particular intervention. Due to its context-specific nature, a pick-and-mix approach when researching a city is required. Standardised performance indicators and quantitative benchmarks are also not valuable in this context.

Academic discourses often counter overly optimistic official narratives on urban development.

Urban policy mobilities research has no defined paradigm or definitive approach. Instead, they draw from various epistemological perspectives spanning planning, sociology, geography and political science (Baker and Temenos, 2015).

The paradigm shifts from focusing solely on the economic benefits of the arts to sustainability (in terms of physical, social and economic well-being) and distributive equity. From short-term to long-term impacts (Evans, 2005). From building flagship projects to incorporating small-scale public art projects with the stress of everyday use, social inclusion, and design quality (Boddy and Parkinson, 2004) to battle gentrification associated with high art venues and large redevelopment projects. Inclusion of local communities, engagement and consultation. Cultural activity should be incorporated as one key indicator of a city’s quality of life (Evans, 2005).

Limitations include restricted access to data. Frequent omittance of the topic of social exclusion in creative cities (Russo and Van Der Borg, 2010; Sasaki, 2010).

Recommendations for future research are further investigating what influences liveability and quality of life. One of the challenges is the threat of an unfavourable environment that needs to respond to current climate challenges or conserve nature. The following recommendation regards the digital revolution's effects on culture and urban planning.

Transit-Oriented Development Approach to Social Sustainability, Doha city as a Case Study

Author Name: Sara Nafi

Affiliation: Qatar University
Architect, PhD candidate in Urban Planning
Email: sn1405549@qu.edu.qa

Abstract
Transit-oriented developments (TODs) are widely used to promote sustainable mobility by encouraging residents to use public transportation and to reduce car dependence (Calthorpe, 1993). Doha, the capital of Qatar, has faced numerous challenges including excessive reliance on private vehicles and lack of integrated last-mile connections. This study points to better integrating TOD models with sustainability indicators, to achieve more sustainable urban development. Quantitative and qualitative methodologies were used, including literature review concentrating on TOD and sustainable urban mobility, SWOT assessment, site analysis, data collection from the Qatar Ministry of Municipality and Environment (MME), consultant companies, and Qatar Railways Company. The study demonstrates the adaptation of TOD approach to non-western country through promoting socio-cultural spaces, heat mitigation strategy, integrated transport system, and more community engagements.

Keywords: Transit-Oriented Development, Sustainable Development, travel behaviour, Doha, Qatar

1. Introduction

An increasing number of communities have adopted the concept of transit-oriented developments (TODs) as a tool to enhance the city's urban fabric and increase the usage of public transport. The aim of TOD is to promote urban development near the transit nodes, integrate the land use and transport system, and improve compact urban development. Consequently, promoting sustainable urban mobility and a livable urban pedestrian area. The assessment of TOD is crucial for reaching the society's needs. It reflects the pedestrian catchment area (PCA) known for the adequate walking distance. TOD concentrates on 10 - 15 minutes walking distance (400 m - 800m) as a strategic area (Al Saeed and Furlan, 2019, Song et al., 2021).
Doha, Qatar capital city, experienced a rapid development and economic growth over the past two eras. It turned out to be an international leading city due to the host of distinctive worldwide events like the forthcoming FIFA 2022 World Cup (Boussaa et al., 2021). Broad infrastructure developments were developed including the operation of the Doha metro network, as part of the Qatar integrated railway scheme. However, the city lacks the integration of land use and transportation system and suffers from heavy cars dependency causing high traffic congestion. The State of Qatar launched the Qatar National Development Framework (QNDF) 2032 as a long and short-term strategy, at the national level for achieving sustainable development. The

QNDF emphasizes the significance of connecting the Doha Metro within the city's urban development by applying the TODs principles (Nafi et al., 2021).

The TOD design strategy is valuable for improving the air quality, creating compact and sustainable urban form, fostering a pedestrian-friendly environment, promoting attractive and livable spaces, and locating the city development form around transit nodes (Renaissance, 2016, Dong, 2021, Ann et al., 2019).

Consequently, this research aims to evaluates the TOD towards sustainable urban mobility in Doha. The paper investigates the land use and transportation system of Al Waab neighbourhood, mainly the area nearby the Sport City metro station. For the study, the analysis area focuses on 5-10 minutes walking distance (400m) a Quarter mile. Al Waab neighbourhood is located between the municipalities of Al Rayyan and Doha in the state of Qatar in zones (54 and 55), approximately 10 km far from the city centre of Doha. The Sports city metro station operates through the Doha Metro Historic line (Gold line) and is located adjacent to Al Waab primary road and Sports City minor road. Al Waab Road is marked by its distinctive curving streetlights and includes a path to Al Shamal Highway, while Sports City Road includes the path to the Aspire Zone (250-hectare sporting complex).

The research also examines the social travel behavioral change toward Doha metro as a sustainable public transport system; and formulate integrated land use and multi-use transportation system strategies for policymakers to attract the usage of sustainable public transport.
Quantitative and qualitative methodologies were used, including interviews and other qualitative data collection from the Qatar Ministry of Municipality and Environment (MME), International consultant corporations in Doha, and Qatar Railways Company. Moreover, and SWOT assessment. The paper proposed a guideline for the policymakers to develop TOD through sustainable urbanism principle and TOD design strategy.

2. Methodology

In this study, a diverse-method was involved including a mixture of quantitative and qualitative analysis as follow (a) a literature review of recent theories about the relevant topic of sustainable urban mobility, transit-oriented development model and assessments; (b) data collection analysis, containing interview and graphic data from the Qatar Ministry of Municipality and Environment (MME), International consultant companies in Doha, and Qatar Railways Company; and (c) Site observation and SWOT analysis. The mentioned research methodology is represented in Figure 1**.**

2.1. Literature Review

The review was done through examining the findings of the selected literature and evaluating these findings by using a non-statistical procedure. This helped in building interpretations and conceptualizations based on the previous studies. In addition to identifying the key elements for TOD in the research area, such as (a) enhancing pedestrian spaces and mixed-use areas; (b) promoting walkability and connectivity; and (c) integrating land use and public transportation system.

2.2. Data collection analysis tools

The study used a qualitative data collection tool, including a visual analysis and SWOT (strengths, weaknesses, opportunities, and threats) assessment to establish a framework to analyze the study area current conditions. Additionally, interviews were obtained with transport planning specialist working in the governmental agencies and international consulting companies. The data were analyzed and managed through Geographical Information System (GIS) software. This tool helped in gathering information on the study area existing situation and collecting the land use data. This contributes to deeply understand the spatial and geographical data of the study area.

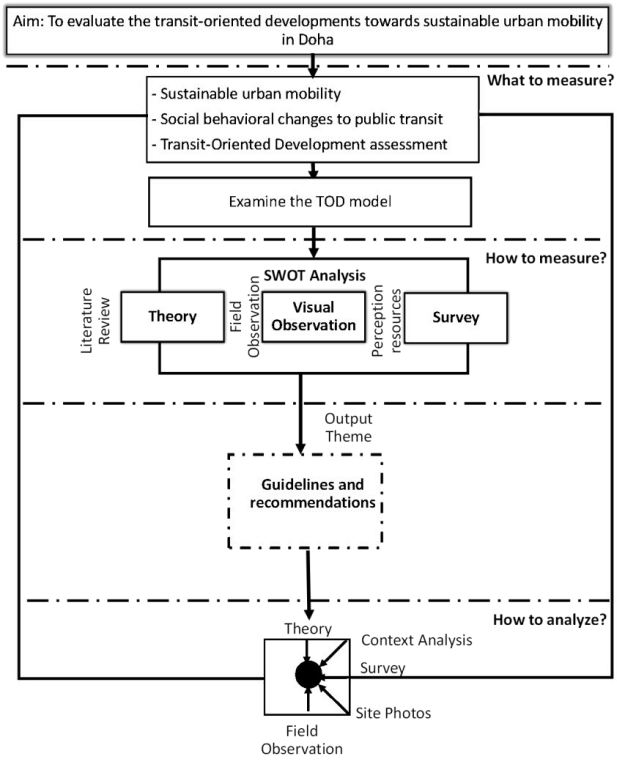

Figure 1: illustration of the research methodology.

3. TODs assessment approaches

TOD usually focuses on an area of 10 minutes walking time (400 m-800 m) as a strategic area when planning the pedestrian catchment area (PCA). (Alawadi et al., 2021, Al-Harami and Furlan, 2020, Dong, 2021). The standard thresholds are 400 m (quarter mile), 500 m (third mile), 600 m (2000 feet), and 800 m (half mile) (Tong et al., 2018).

Using the node-place model, Bertolini (1999) analyzes and examines the interface between the transport and land use systems within station zones. Even though the node-place model does not specify potential development, it is useful for better understanding growth dynamics. (Caset

et al., 2020). Essentially, this model consists of two dimensions: "place" (quality and quantity of land use) and "node" (proportional accessibility of traffic). As a result, if a site is a node for a range of traffic forms, it needs to operate as a diverse land-use pattern. Similarly, intensive use cannot occur in areas where access is inaccessible (Figure 2) (Schulman et al., 2015).

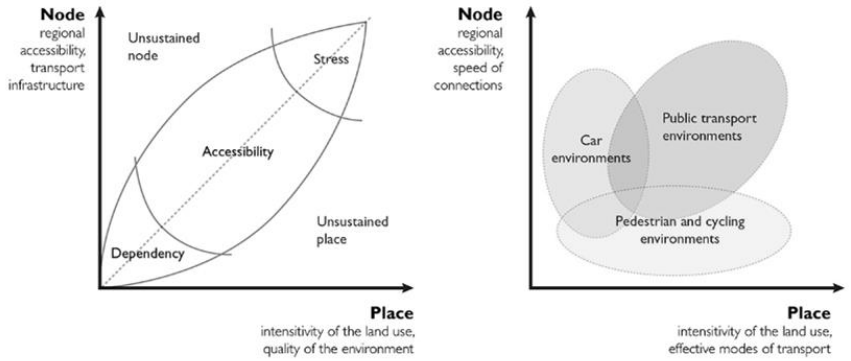

Figure 2: illustration of Bertolini's node-place model (Schulman et al., 2015)

The gap of the TOD features was carried over the outcomes of the political impact of TODs through integrating the essential character like density, compact development, connectivity, integrated land use and public transportation, and amenities (Su et al., 2021, Yildirim and Arefi, 2021). The study process brings several measures to conduct the study and analysis by enforcing various requirements to test the method relating to the TOD (Al Saeed and Furlan, 2019).

4. TODs as a Sustainable urban mobility

Sustainable urban development mainly relates to urban design from the built environment perspective. Urban design can be defined as an "act of designing and forming cities". It is also known as the "art of placemaking" which involves people, space, nature, and activity setting (Alawadi, 2017). Lynch (1981) refer to urban design as "a field handling the built environments form and the link among the physical city and human values.

Various articles have outlined the perception of sustainability, highlighting the social pillar of sustainability. Literature about social sustainability illustrates some assessments and themes. However, due to its complexity, it did not include a specific definition (Bouzguenda et al., 2019). Four main aspects were developed to enhance the social sustainability concerning urban renewal developments including open spaces availability, resources conservation, and enhancing liveability (Figure 3) (Canitez, 2019).

In summary, the sustainable and vibrant cities involve the following: (a) diverse and wealthy urban life and well-designed community spaces; (b) offers a sense of safety and low levels of pollution; (c) generating a positive impact living conditions quality in cities, and (d) facilitating a various social activity (Al-Thawadi and Al-Ghamdi, 2019, Baobeid et al., 2021).Inhabitants feel unsatisfied to live in cities where they are obliged to live in congestion, spend lots of their time at traffic congestion, far to the nature access, and hardly communicates with their neighbours (Al-Thawadi et al., 2020). Interpretation of the literature emphasized that a city to be liveable, it shall offer jobs access that enables a platform for interaction between each other;

and allow self-fulfilment along with providing access to recreation and green open spaces (Al-Thani et al., 2019).

Figure 3: Sustainability in planning and urban renewal.

Generally, TOD for a particular city's requires an integrated transport system encompassing the entire city (Nafi et al., 2021). Consequently, the catchment areas are measured at the urban level instead of the individual level of the transport station, which involves a broad awareness of land use design and the aspects to deliver it. The land-uses shift should be carefully considered as they are mainly affected by the local environmental aspects (Mai et al., 2021, Revoltós Fort et al., 2017).
Nowadays, TOD is known as a well-recognized urban planning model; intended to promote affordability, enhance accommodation quality, promote compact development, and diversify public open spaces (Zhou and Yang, 2021). Once TOD is applied effectively, it could assist in progressing toward the world of vital and sustainable cities (Al Saeed and Furlan, 2019). In addition, TOD improves the creation of wealth for residents, facilitates economic opportunities, and enables societies to react flexibly to possible disruptive incidents like pandemics (Patnala et al., 2020) Figure 4 illustrates the theoretical approach.

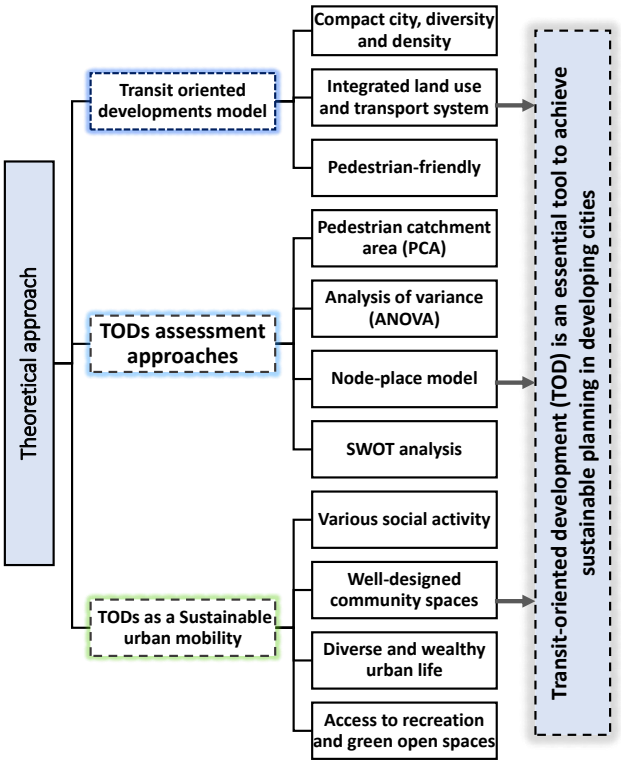

Figure 4: Theoretical approach

Finally, the TOD model is beneficial in promoting sustainable development through (a) lessening the costs and usage of driving; which leads to lowering the air pollution and the usage of energy; (b) raising revenue and economic development; (c) preserving land and green areas; (d) enhancing the neighbourhood diversity and compactness near to transit nodes; and (e) promote accessibility for pedestrian and cyclist which lowering the usage of private car (Furlan et al., 2021, Knowles et al., 2020, Furlan et al., 2019).

5. Qatar's Transport System and Vison

A detailed analysis Qatar has rapidly transformed from a fishing and pearling economy to a powerhouse driven by energy resources over the past two decades. Due to extensive oil and natural gas exploitation since the late 1930s, this shift has shaped the economic landscape but also led to remarkable urbanization. Consequently, Qatar has created a modern cityscape with distinctive architecture that reflects its strategic ambitions for economic diversification, sustainable urban development, and global influence (Burt et al., 2017). Doha, the capital of the country, has gained international prominence by hosting distinctive global events, such as the FIFA 2022 World Cup (Wiedmann et al., 2013, Zaidan and Abulibdeh, 2018). Globalization has resulted in extensive infrastructure development, leading to modern buildings replacing traditional residential structures. The Central Business District of Doha has emerged

as a result of this evolution (Nafi, 2015). Qatar National Development Framework (QNDF) has been developed as a national action plan for managing sustainable urban development.

Emphasizing the importance of transit-oriented developments (TODs), the QNDF aims to integrate the Doha Metro system with city growth (Furlan et al., 2020, Mannan et al., 2019). 'Light Rail Trains' (LRTs) and 'Bus Rapid Transit's (BRTs)' serve the main cores of the city through the Doha Metro network. With this comprehensive plan, users will be able to travel efficiently from origin to destination, promoting public transportation and aligning with Qatar National Vision 2030's sustainable development goals (Rizzo, 2014).

Several major stadium sites are accessible via Doha's metro network, including the Doha Port, Hamad International Airport, and Doha's urban core. In total, there are four metro lines in the city: the Red, Green, Gold, and Blue. The metro line network consists of underground, ground-level, and above-ground railways with a total length of 300 kilometers. Al Wakra in the south and Lusail in the north are served by the Red Line, also called the Coastline. The city center and Hamad International Airport are connected by this line. The network consists of 18 active stations, including West Bay, Katara, and Qatar University. Stations on this line include Lusail QNB and Legtaifiya interchange stations for trams and metros (Al-Janahi et al., 2020). In the direction of Al Mansoura, the Green Line runs for 22 kilometers from west to east. Notable stops on the line include Qatar National Library, Msheireb, Hamad Hospital, and Education City (Revoltós Fort et al., 2017). From Al Aziziya to Ras Bu Aboud, the Gold Line stops at 11 stations including Sports City, Souq Waqif, Qatar National Museum, and Al Aziziya. A 7.5 km semicircular route will connect West Bay and Airport City North along the blue line ("City Line") (Figure 5) (Amerio, 2020).

Figure 5: Scheme of Doha Metro Network (Rail, 2022)

According to Qatar's National Development Framework (QNDF), a well-integrated public transit services will make transportation safer, more efficient, and more convenient. This will reduce the number of cars on the road, helping to reduce traffic congestion and air pollution (The Ministry of Municipality, 2016). Figure 6 illustrates Qatar road hierarchy.

Figure 6: Qatar road hierarchy *(The Ministry of Municipality, 2016)*

6. Results and discussions

A detailed analysis of the site was made to examine the land use and transportation system of the study area. Survey questioner was also conducted to gain a wide idea about the inhabitants' perceptions of their neighborhood. In addition, the existing situation of the site and challenges were examined through SWOT assessment tool.

6.1. Site context

During the site visit, it was observed that the research zone contains diverse land-uses such as residential, commercial, recreation, and educational. The Sports city metro station is located near several popular sites in Qatar, such as the Aspire Zone, Villaggio Mall, Khalifa International Stadium, and Aspire Torch tower (the tallest building in Qatar). Furthermore, the Al Waab neighborhood contains various residential compounds, attached, and detached private villas, and medical developments. The land use data was validated by the Qatar Ministry of Municipality and Environment.

In addition, the study area includes numerous Western schools such as the American School of Doha, Newton International School, and Doha College. Gated communities are common in the Al Waab neighborhood, which generates isolated areas within the city urban fabric, and creates

social segregation which lessens the degree of interaction. Moreover, generating an economic disparity through altering the land values (Figure 7).

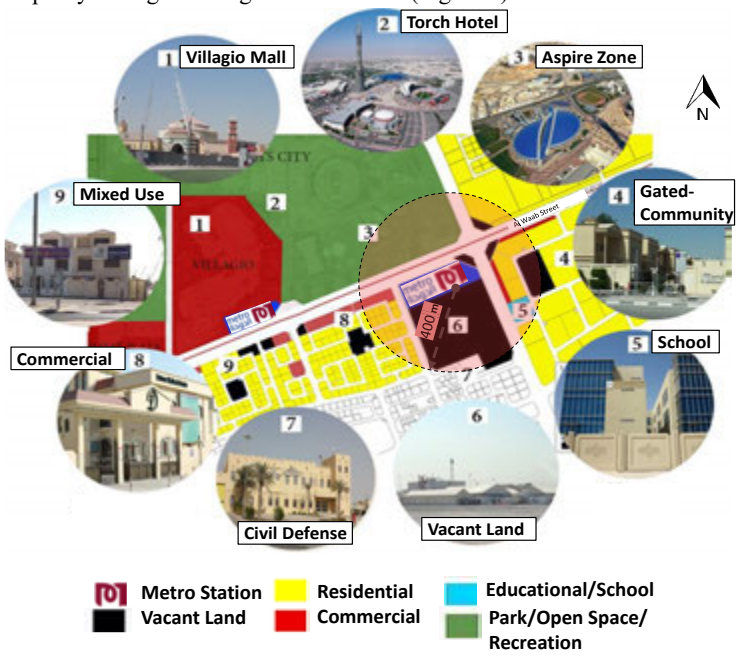

Figure 7: Current land-use map in Al Waab area showing a diverse use.

6.2. Transportation system

The study area consists of various modes of transportation, such as private vehicles, buses, taxis, and the Doha metro. Private vehicles are the frequent mode of transportation in the study area along with buses. An intersecting usage of various transportation systems is not present. Nevertheless, the operation of the Doha Metro has introduced the feeder buses flow at several stations to make it easier to commute. The Sports city metro runs across the Doha Metro Gold line from Doha East-West directions connecting the Airport City North with Salwa Road, Al Waab Street, and Al Rayyan South. The Sports city station includes a key destination for sporting and recreational activities such as the Aspire Zone and Villaggio shopping mall (Figure 9).

The Doha Metro seeks to establish a transport zone through the main city centers and guarantee an effective user's experience. It includes an interchange station between the metro and the tram through Legtaifiya and the Lusail QNB stations. The Green Line (Education Line) passes for 22 km connecting the Al Riffa area from the east to the Al Mansoura area from the west. Finally, the gold line (Historic Line) passes for 14 km connecting the Ras Abu Aboud area to the Al Aziziya area (Al-Harami & Furlan, 2020; Al Saeed & Furlan, 2019).

Figure 8: Current transportation system in the Al Waab area (a) Aspire zone (b) Villaggio mall parking (c) Hayatt plaza sculpture (d) Sport city metro station (e) Al Aziziya metro station.

6.3. SWOT Assessment

SWOT Assessment represents a framework to assess the strengths, weaknesses, opportunities, and threats of the site. It was obtained to get a rich idea of the existing situation of the site and consider the site strengths and opportunities. The assessment examined the weakness and threats of the study area. The weaknesses contain the physical aspects that create the disadvantages of the study area, which reflect as the following: the shortage of mixed uses within a walking distance; traffic congestion due to high traffic flow; lack of integration between the sports city, malls, and residential area; and high noise level. While the threats are the absence of pedestrian and cyclist safety; rents prices for residential and commercial properties have increased due to the existence of the metro; not addressing the transit connectivity and parking management which will attract personal driving.
Furthermore, the results show that the strengths of the study area are the availability of attraction points such as Aspire zone, Villaggio Mall, and Khalifa international stadium; and the accessibility to the sports city and malls attract people to live in the area. Finally, the opportunities are the presence of the metro, which fosters a multimodal transport system leading to less traffic congestion and sustainable solutions. The SWOT assessments summary is shown in Figure 9.

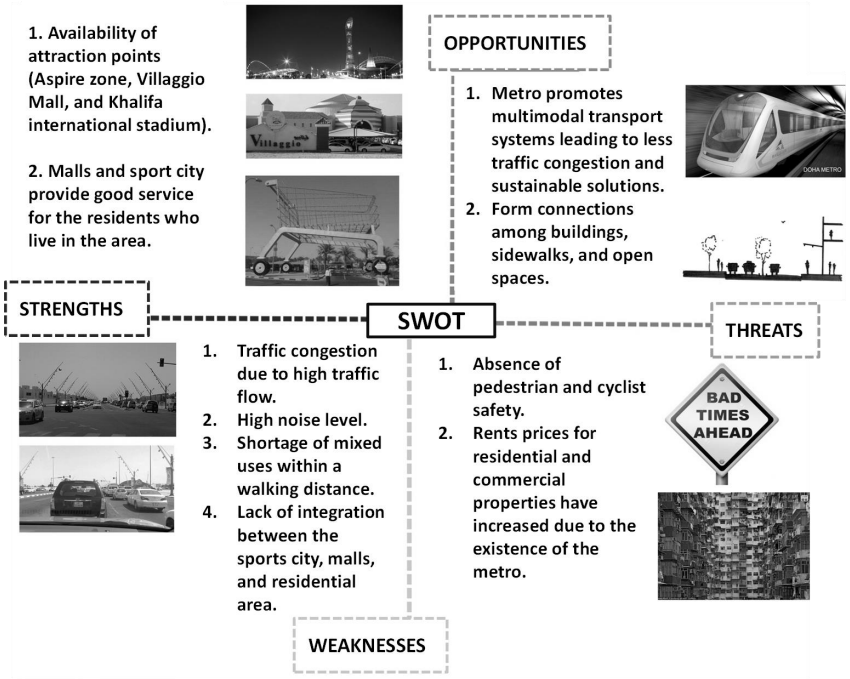

Figure 9: SWOT assessment.

7. TOD Design guidelines and recommendations

A series of TOD design guidelines and recommendations were made to support the stakeholders and policymakers in developing a comprehensive approach of TOD. These guidelines were developed based on the study findings and in relation to the survey outcomes. Mainly through sustainable urbanism and TOD design strategy taking into consideration the Qatar cultural heritage.

7.1. Integrated land uses and social heritage

Literature pointed out that, the TOD model is beneficial in fostering sustainable development through improving the neighbourhood diversity and compactness near transit nodes; and promoting the accessibility for pedestrian and cyclist which lowering the usage of private car (Canitez, 2019). The study area shall include a diverse use along with a social-cultural heritage places that promote the Qatar unique identity and enhance the social interaction in the study are, the proposed spaces are (a) the Barahat which is an open area around the houses that can held some traditional performance and attract public gathering; (b) the Sikka which is a narrow shaded walkable path that create a pedestrian-friendly environments; and (c) the Majlis which considered as a social engagement place where neighbours sit together, socialize, and debate about local events and issues. The neighbourhood will be more liveable when ensuring a balances and mixed distribution of uses where people live, work, learn and leisure. This reduces the travel distance which leading to lessening the private travel demand supporting the public transport, cycling, and walking.

7.2. Public realm and open space scheme

Public realms which contain plazas, souks, parks, squares, and leisure area promotes social cohesion. It also offers a sense of safety and low levels of pollution which generate a positive impact on the living conditions (Al Saeed and Furlan, 2019). As a result, the following has been proposed in the study area to promote TOD and enhance sustainability: (a) create a green corridor in Al Waab Road to connect the Sports City with Aspire Zone; (b) develop a green public realm around the metro station; (c) enhance the street furniture, plaza, and landscaping; and (d) locate the schools near the edge of the commercial zone and the recreational area in a highly visible points around the transit stop. Furthermore, to promote TOD in the study area, public open paces shall contain areas for inhabitants to contribute to community public activities and celebrate their socio-cultural identities. The research area additionally proposes incorporating a public realm with a secure car-free movement adjacent to the metro station.

7.3. Cohesive transport system and pedestrian-friendly design

As reviewed in the literature, the preferred walking distance in the case of TOD is 5 to 10 minutes' walk for 300-800m diameter (Dong, 2021). The neighbourhood within 400m radius shall contain a cohesive transport system with a connected walking and biking networks along with metro and bus stations on the borders. Furthermore, the street system shall be planned in a way that ensure the pedestrian safety, and intersection shall be designed to reduce the distance crossed by the pedestrians. Also, shaded walkways shall be created near the metro station to encourage the individuals to use the public transport.
Through adopting these guidelines, several enhancements will take place in the study area, for example (a) increasing the public transport usage and mobility choices, like the bus, metro, and rail; (b) lessening the traffic congestion which will reduce the pollution and promote sustainable developments; (c) improving access to open spaces, parks, and squares; and (d) promoting the accessibility to retails, recreational area, services, and cultural spaces. Figure 10 illustrates a summary of the reviewed literature.

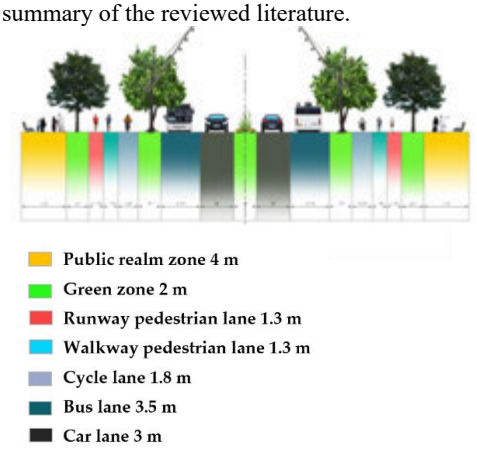

Figure 10: proposed street network for a cohesive transport system and pedestrian-friendly design

8. Conclusion

This paper examined the TOD model implementation for the Al Waab neighborhood in Doha, covering a 400 m radius centered around the Sport City metro station. The social travel behavioral change was explored toward Doha metro as a sustainable system. The study attempts to formulate integrated land use and multi-use transportation system strategies for policymakers to attract people to travel by a green public transport. The findings of this research study also demonstrate the significance of applying the TOD model to promote sustainable urban development and socio-cultural spaces leading to more community engagements. This is achieved through establishing the following guidelines: (1) creating a diverse land-use approach including attractive public areas; (2) promoting the identity of the space surrounding the study area; (3) designing a shaded walkway with cool shading techniques; (4) creating a cohesive transport system and pedestrian-friendly design; and (5) developing a green public realm around the metro station.

The Qatar Rail Development Framework, which includes the Doha Metro and Lusail Tram, serves as a prime example of TOD on a national scale. This framework strategically combines transportation networks with urban development to foster sustainable growth and enhance the quality of life for people. To foster lively and inclusive neighborhoods, it is necessary to strategically design many development and revitalization initiatives centered on metro and tram stations.

Implementing TOD in Qatar presents both obstacles and opportunities. For instance, the region's elevated temperatures and predominant focus on automobiles make it difficult to create pedestrian-friendly environments and efficient public transportation. However, the implementation of strategic planning, creative design, and the acceptance of technology have the potential to revolutionize urban transportation and sustainability.

From Global North to Global South: Exploring Creative City Policy Mobilities and Their Urban Impacts

Author's Name: Ludmila Kolouchova
Affiliation: Faculty of Environmental Sciences, Czech University of Life Sciences Prague

ORCID: https://orcid.org/0009-0006-9548-7908

Abstract
An increasing number of cities of the global South are introducing the creative city policy and pledging to adopt creativity as their main developmental focus to improve the living conditions of their population. Although European cities have long used this policy (Scott, 2014), many have been unsuccessful (Rius-Ulldemolins, Hernàndez I Martí and Torres, 2016). Since developing countries of the Global South are participating in such international models, more research is needed to address a gap in the knowledge on the North-South policy mobility and the urban planning effects of creative city policy in the Global South. This study presents a theoretical framework of creative cities focusing on the urban development of cities in developing countries by rehabilitating cultural creativity, diversity, and social inclusion. The research may provide a valuable knowledge base for international exchange of experience in the planning field.

Keywords: creative city policy, policy mobility, global South, urban planning

Introduction

Creative city policy is a well-established approach to urban development (Costa *et al.*, 2007). This article interconnects research on global urban aspects of creative city policy and policy mobilities. In the past decades, considerable amount of research has focused on creative cities and policy mobilities of the global North[1] (Bunnell, 2015; Molho *et al.*, 2020).

Western cities have long used creative city policies to reposition themselves in the global urban hierarchy and to tackle their problems of rising social inequalities and tensions in the urban context (Scott, 2014). Its roots are in the 1990s, primarily Europe, North America, and Australia (O'Connor, Gu and Kho Lim, 2020).

Nowadays, an increasing number of cities in the global South (Molho *et al.*, 2020) are introducing the creative city policy and pledging to adopt creativity as their main developmental focus. They rely on Western theoretical frameworks to research the cities and use homogenising scripts of creative cities to interpret the cultural policies (Molho *et al.*, 2020; O'Connor, Gu and Kho Lim, 2020). That calls for further investigation due to different socioeconomic and cultural backgrounds. Among others, the relationship between culture and urban development (Russo and Van Der Borg, 2010).

[1] I use the term 'global North and South'. It refers to the regions of Latin America, Asia, Africa, and Oceania. Most countries maintain low incomes and marginalised cultures and politics, although emerging BRIC countries (Brazil, Russia, India, and China) complicate the division. As (Dados and Connell, 2012) state, 'The term Global South functions as more than a metaphor for underdevelopment. It references an entire history of colonialism, neo-imperialism, and differential economic and social change through which large inequalities in living standards, life expectancy, and access to resources are maintained.'

My study aims to prepare a ground for filling a knowledge gap by creating a theoretical framework within which practitioners and academics can approach these questions: How to approach creative city policy mobility from the global North to the South? What are the key features of urban planning effects of creative city policy on recipient cities?

Literature Review

Creative City Policy

Its History and Emergence

The evolution of creative city policies spans the time of the post-industrial crisis, globalisation and the rise of neo-liberal ideologies. In response to these shifts, cities became entrepreneurs in a competitive market striving to attract capital and investors (Pratt, 2011).

This transformation was preceded by the crises of Fordism (Florida 2005, Landry 2008), characterised by mass production technologies predominant in the Western industrialised world until the early 1970s. These changes affected cities such as Detroit, Chicago, the English Midlands, the German Ruhr district, and parts of northern Italy.

The transition from Fordism led to the emergence of more flexible and specialised production models, altering industrial organisation and inter-firm relations. The trend was to liberalise institutional restraints on market competition and weaken the welfare state (Harvey, 1989), (Brenner and Keil, 2014).

These shifts also influenced the spatial patterns of growth (Brenner and Keil, 2014). Industries, like cinema (Storper and Christopherson, 1987), were increasingly clustering in metropolitan areas to improve the efficiency and competitiveness of entrepreneurs and lower production costs. This was possible due to the availability of a specialised and skilled workforce, reduced transaction costs, face-to-face problem-solving, and sharing of skills.

Costa (Costa *et al.*, 2007) suggests five origins for the increasing interest in creativity:

1. 'Creative city' concept developed by, amongst many others Charles Landry (2000), Peter Hall (2000), and Ralph Ebert et al. (1994) in connection with an analysis of 'creative industries' and practical applications via policies
2. Launch of 'Creative Europe' by European research institutions or the project of 'Creative Cities network' by UNESCO in 2004
3. 'Creative class' (Florida, 2002), as a critical driver of competitiveness and urban regeneration processes due to its talent, tolerance and openness
4. 'Creative industries' within the economic analysis originate from the industrial economic tradition, and a similar approach is 'creative economics'. It analyses their organisation in an institutional context, taking their particularities into consideration
5. The importance of creation and artistic creativity, leading to the study of not only the demand side but also the supply (Throsby, 2004)

While the definition of creative cities and creative economies varies (Costa *et al.*, 2007), most authors agree that creative industries include film, music, radio, television, publishing and advertising along with the support infrastructure (organisational or material) (Pratt, 1997). Despite the substantial economic contributions of creative economies, evaluating their impact

can be challenging due to their nature, which has both financial and cultural value (the process of creation is also essential, not only the outcome) (Pratt, 1997; Evans, 2005).

In practice, creative city policies aim to enhance the quality of life for urban inhabitants through targeted interventions in three main areas: (a) economic development, (b) social welfare/inclusion, and (c) urban development (Bianchini and Parkinson, 1995; Rato, Roldão and Mühlhan, 2009). There are benefits in combining all three perspectives (Boddy and Parkinson, 2004; Costa *et al.*, 2007). Figure 1 below gives an overview of the combination of approaches and typical examples of cities.

(a) Economic development is usually the central focus of creative city policies, with the primary objective being the job creation and formulation of industrial and creative strategies.

(b) Social welfare programmes focus on social inclusion or community character.

(c) Urban development plays a central role in shaping the city's physical landscape. It includes renovations and reconstructions to improve the image of the city, even a recreational strategy. These approaches are usually more or less modified and combined (Bianchini and Parkinson, 1995; Rato, Roldão and Mühlhan, 2009).

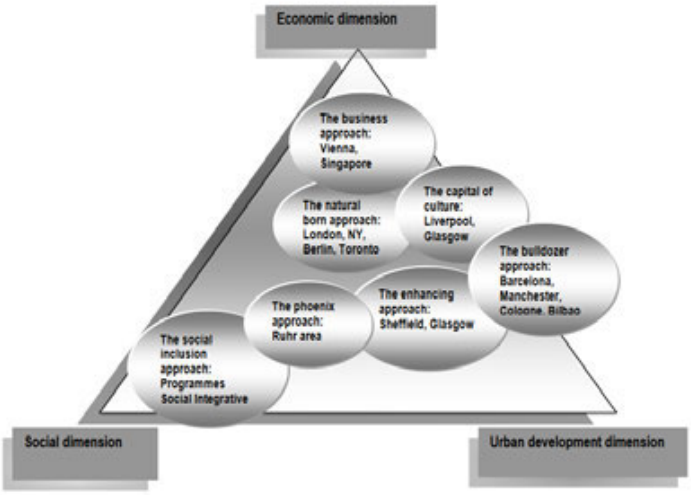

Figure 1 Typology of creative cities (Rato, Roldão and Mühlhan, 2009)

The paradigm shifts to focusing more on sustainability and distributive equity. From short-term to long-term impacts (Evans, 2005). From building flagship projects to incorporating small-scale public art projects with the stress of everyday use, social inclusion, and design quality (Boddy and Parkinson, 2004) to battle gentrification associated with high art venues and large redevelopment projects. Inclusion of local communities, engagement and consultation. Cultural activity should be incorporated as one key indicator of a city's quality of life (Evans, 2005).

Limitations and Contradictions

There are numerous limitations and contradictions to this neo-liberal urban policy. Much of the critique is centred on the fact that researchers predominantly focus on theoretical and empirical research on the global North and the lack of investigation of a broader range of contexts of different countries (Molho *et al.*, 2020). One example could be the spatial mobility of the creative class[2] (Martin-Brelot *et al.*, 2010).

Planners should focus less on land use and more on incorporating cultural, social, economic and environmental issues (Landry, 2000/2008).

The creative city has often been seen as easily transferable (Kong, 2014), homogenising (Molho *et al.*, 2020) and a 'fast policy' (Peck, 2005). However, the impacts of the policy could be short-lived (Russo and Van Der Borg, 2010; O'Connor, Gu and Kho Lim, 2020), and flagship events cannot do more than divert attention away from the real problems of cities (Mooney, 2004).

The central critique focuses on gentrification (McGuigan, 1996; Seo, 2002; Evans, 2005). Creative workers and productions depend on specific locations, but at the same time, they are threatened by delocalisation due to the rising valorisation of urban land (Vivant, 2013).

That leads us to another issue: the frequent omittance of the topic of social exclusion in creative cities (Sasaki, 2010). The impacts of the policy could be socially exclusive (Russo and Van Der Borg, 2010). Groups such as the socially excluded, older adults and people experiencing homelessness are not being integrated (Landry and Bianchini, 1995; Landry, 2007; Müller, 2019). We also should not leave out spatial inequalities (Evans, 2005). Some cities have been unsuccessful in tackling local inequality problems and primary infrastructure access (case of Rio de Janeiro (Claudia Seldin and Gavinho, 2020)) or even enhanced the problems (case of Cape town (Malte Steinbrink and Ley, 2011)).

Role of International Creative City Networks

Cities are influenced by the increasingly uneven global inter-urban connections (Molho *et al.*, 2020) and seeking a change in their aspirations and identities, however successful in the long term and the extent of their implementation (O'Connor, Gu and Kho Lim, 2020).

To meet the challenges of globalisation and ensure cities' success, we must not rely on traditional political institutions but on individuals, groups and bottom-up processes. Global public policy networks must include groups from the global South. It is critical in the design and implementation of policies (Reinicke, 1999).

There is a great diversity of institutional frameworks and governance mechanisms in implementing creative city policies. Besides, many public bodies and organisations use these concepts locally and nationally. There are also supranational institutions, such as the

[2] Empirical European data show that creatives are less mobile than in the United States due to cultural and institutional barriers. In a search for a location to settle, look for hard factors such as the quality of jobs. Soft factors such as cultural amenities only determine the particular district where to settle (Martin-Brelot *et al.*, 2010).

UNESCO, European Commission and OECD (Organisation for Economic Co-Operation and Development). Their focus lies in the multidisciplinary approach, management, and governance (Costa *et al.*, 2007).

UNESCO's ''Global Network of Creative Cities," launched in 2004, has quickly spread to developing countries. Now, 350 cities in 7 fields worldwide are registered in the global UNESCO network. There are efforts to strengthen the connections between 'global South' cities (Molho *et al.*, 2020). Ahead of these designations, UNESCO declared the Universal Declaration on Cultural Diversity in 2001. Its purpose is to combat standardisation under globalisation (Sasaki, 2010).

Creative City Policy Travels to the Global South

An increasing number of cities in the global South are introducing the creative city policy in order to rescale and reinvent themselves (Molho *et al.*, 2020). However, this complex model cannot be re-applied without modification (Bianchini and Parkinson, 1995). All cities are diverse; thus, many formulas address all the city's problems (Molho *et al.*, 2020).

Luckily, not all global South cities accept imported models without changes (for example, Beirut and Istanbul took Dubai as an anti-model) (Centner, 2020). Many cities found alternatives and new approaches to hegemonic models from the West worldwide (Molho *et al.*, 2020).

From a practitioner's or policy outcome-oriented scholar's perspective, 'good' or at least promising solutions must also be transferable from one place to another. And they need to know how this might be done most effectively (Baker and Temenos, 2015).

Guidelines about how global creative policy circulates, vernacularises and is unevenly adopted can offer policy mobility theory. Where and to whom they travel and how they vernacularise depends on the institutions and actors who receive them. It depends on their position and power. Remember that conflicting interests around the globe also influence local policies (Molho *et al.*, 2020).

Policy Mobility Theory

An increasing number of scholars are paying attention to the circulation of urban policies (Baker and Temenos, 2015).

There have been numerous attempts to reproduce and implement various entrepreneurial development policies due to intensifying interurban competition (Harvey, 1989; Brenner and Keil, 2014), increasing globalisation of politics, society and economy (Hall and Hubbard, 1998), and the socio-spatial processes derived from it (Peck and Tickell, 2002; Baker and Temenos, 2015).

Emerging in the early 2010s (Baker and Temenos, 2015; Haupt, 2023), the policy mobility approach was primarily driven by critiques of the previous approaches by human geographers and urban studies scholars (Peck and Theodore, 2010; McCann, 2011; Peck, 2011; Temenos

and McCann, 2013). Later, it led to the emergence of urban policy mobilities as a sub-field (McCann, 2011; Baker and Temenos, 2015; Lovell, 2019; Haupt, 2023).

Policy mobility theory emphasises thought patterns and mindsets and the directions of movements that express power relations (Haupt, 2023).

Key Features of Policy Mobility

Critical features of policy mobility, besides the spread of policy between cities, include international (global) geographical reach (Haupt, 2023), the mobile and changeable character of policies (Peck and Theodore, 2010; McCann, 2011), that are modifiable right from the beginning of the process. Ideas, discourses, or synthesised models can travel in selective and partial forms (Peck and Theodore, 2010; McCann, 2011; Temenos and McCann, 2013).

How ideas/policies might change the places they are spreading to (Stone, 2004; Peck and Theodore, 2010; McCann, 2011; Temenos and McCann, 2013). Emphasis is more firmly placed on the effects of policy discourse and implementation on social life and practices (Haupt, 2023). The focus is more on the role of non-state actors, such as NGOs, consultancies, or multinational corporations, and how they influence governmental bodies with their mostly neoliberal policies (Peck and Theodore, 2010; Prince, 2010; McCann, 2011).

Another key feature is the significance of failed policy spread – policy immobility (McLean and Borén, 2015; Lovell, 2019) no longer studied from a positive point of view but to research the power relations and inequalities and drawing attention to failed or harmful policies that can also travel to different places (Lovell, 2019).

Policy mobilities literature has a critical perspective (critical of policy spread and society) (Haupt, 2023). Urban policy mobilities research has no defined paradigm or definitive approach. Instead, they draw from various epistemological perspectives spanning planning, sociology, geography and political science (Baker and Temenos, 2015).

Critique of Policy Mobilities

Early critiques focused on neoliberal policies, orientation toward the global North (Bunnell, 2015), and presentist outlook are being answered (Temenos, Baker and Cook, 2019).

Further critique of policy mobilities scholars addresses the work of scholars who rarely reach out to policymakers and politicians with suggestions on how to improve current practices (Haupt, 2023).

Söderström and Geertman (2013) and Cohen (2015) argue that focusing on Southeast Asian cities has led to the conclusion that we should further focus on understanding ad hoc networks and nonliberal urban practices.

For future studies Temenos, Baker and Cook (2019) recommend foregrounding the integration of policy mobility within the socio-spatial fabric of cities and urban life and (a) engaging with other conceptual questions in the field of urban studies, (b) enlarging the collection of studies outside of the Anglo-American area. That would be beneficial in policy mobility studies for

differentiating what is general and specific, and (c) conceptualising policies on dualities: local/global, fixed/mobile, territorial/relational—also adding mobilities of knowledge, people, materials and politics.

Shaping a Framework for Creative City Policy Mobility and Its Urban Planning Impacts Across Global Regions

Stevenson (2004) highlights the necessity for new methodologies that combine approaches of anthropology, sociology, and cultural and urban studies that can be applied to evaluation models to measure physical, social and economic changes. Responding to the need for more conceptual and integrative groundwork, this paper creates ground for a novel framework for urban planning effects of creative city policy mobility from the global North to the South.

I ground my framework on the work of Evans (2005), Temenos, Baker and Cook (2019), and Müller (2015). The proposed framework involves types of evaluation, the three stages of policy mobility in detail, and key features of urban effects of creative city policy.

Types of evaluation

The following types of reporting can evaluate culture's contribution to development (Evans, 2005): (a) project evaluation and (b) programme evaluation.

(a) Project evaluation focuses on the project's process and results. It can use quantitative or qualitative evidence. Data are collected via unstructured interviews, focus groups, questionnaires and participant observations. It is ideal to start evaluating from the beginning of the project, during and after post-completion. The assessment area is not limited (it can be a local development area or national programme). The evaluation may include one or multiple projects (see Programme evaluation below).

(b) Programme evaluation includes multiple projects in one local, national or transnational initiative. It uses Project evaluation techniques and can be measured by standard output criteria, including performance indicators (comparing actual and targeted performance).

Academic discourses often counter overly optimistic official narratives on urban development. Unfortunately, it is not possible to access the necessary data. The studies include more technical quantitative impact assessments (economic/econometric) and area and sectoral case studies of a particular cultural activity like theatre quarter and fashion industry. „In some respects, the lack of 'hard evidence', of access to detailed data, decision-making processes and the basis to measure impacts over time, have limited more 'scientific' analysis, leaving little scope, outside political and policy discussions and micro-level case studies" (Graeme Evans, 2005, 965).

Stages of Policy Mobility

Questions accompanying Table 1 below help us systematically trace North-South policy mobility and help in orientation and approach to urban planning questions in three time frames: (a) transportation, (b) transformation and (c) translation (Müller, 2015).

(a) Transportation happens when the policy is moved from place A to place B (Healey, 2012; McCann and Ward, 2012). It is transported and impacted by diverse people via various materials to different political systems. It does not come packaged but rather as selected elements brought to one place and assembled. It is of interest to study what parts of policies are immobile.

(b) Transformation is embedding policy into the local socio-material environment. It is usually changed, seldom not at all. Policy changes are due to interaction with existing policies, translations, interpretations, institutional settings and legislation. The carriers also modify elements of policies.

(c) Translation can be similar to policies' original intentions or have different impacts. Responses to its implementation can be studied from the perspectives of the public, private, and state sectors. Translation is not the end of the cycle; the policy can travel to a new place again.

Transportation	Transformation	Translation
1.1 Who and what moves and is moved?	2.1 What aspects of a policy change?	3.1 What actions does the policy create?
1.2 When?	2.2 For what reasons and through what channels does change happen?	3.2 How well is the policy able to align intentions and actions?
1.3 Where to and from?	2.3 To what extent is change intentional or unintentional?	3.3 Through what mechanisms is the policy applied?
1.4 How?	2.4 What is the role of already existing policies in affecting change?	3.4 What is the response to the policy?
1.5 Through what channels or events?	2.5 What other elements does a policy enrol?	3.5 Does the policy itself serve as a model for others?
1.6 Who and what does not move?		

Table 1 Transportation, transformation and translation of policy (Müller, 2015)

Mobility of urban planning effects of creative city policy is possible because of the mobility of (a) knowledge, (b) people, (c) materials and (d) politics (Temenos, Baker and Cook, 2019).

(a) Knowledge is transferred when there is a need for detailed policy or a global approach is desired. It can be local or outside expertise.

(b) Diversity among the team of people is beneficial; it includes all types of policy actors and their mobilities, as there remains a need for shared experiences and face-to-face meetings at conferences and study tours. It can be bureaucrats, politicians, activists, lobbyists, service managers, consultants, architects, etc.

(c) Materials are needed to circulate between people. They can travel in physical and virtual spaces through reports, PowerPoints, spreadsheets, maps, and visualisations. They are crucial for the actors to visualise the proposals and make connections to them.

(d) Politics is central to the mobility of policy. It reflects the current political conditions, ideologies and functions of the state. These conditions are globally different, and various policy advocacy and activism levels exist.

Where to and how is policy transported is seen in Table 2.

Transportation		
1.3 Where to and from?		
Primary recipients of the intervention	the state the region the city the community a particular group of actors the private sector	(Rato, Roldão and Mühlhan, 2009)
Transportation		
1.4 How?		
The level of participation of the population in the process	bottom-up top-down	(Rato, Roldão and Mühlhan, 2009)
Inclusion of multiple stakeholders	arts and cultural groups heritage associations and communities	(Evans, 2005)
Schemes structured to facilitate collaboration between those responsible for regeneration and those responsible for cultural activity	local authorities partnership bodies responsible for regeneration	(Evans, 2005)
Intended duration of policy	short middle long term	(Evans, 2005)
Integration into legal documents	strategic plan master plan budget	(Evans, 2005)

Table 2 Where to and how is policy transported

Key Features of Urban Development Effects of Creative City Policy

Urban development is usually directed towards transforming physically, socially and economically declining areas. The paramount principles lie in the sustainability of the place, aiming toward long-term improvement. Responding to the call for a more integrative approach, the evaluation also touches on social and economic domains.

People's needs across the globe are met differently. Guidelines can offer Maslow's hierarchy of needs, including physiological and safety, as the base (Maslow, 1943). The sustainable principles should, therefore, include the liveability of the place, people's quality of life, safety, inclusion and heritage conservation. Inclusion of all groups irrespective of income, ethnic profile, religion, skills, gender, disabilities, age, caste, or political orientation. Quality of life

depends on mobility and access to public amenities and open spaces, as well as on the living environment, densities, pollution, and health.

Monitoring should also include social and land use diversity and the multifunctionality of places. We should remember the authenticity and identity of the place and design quality, which does not rely on homogenising principles.

To attract creative individuals and companies, agglomerations should offer spaces for production (both enabling work from home, small-scale businesses and open coworking places for sharing information, knowledge and skills), consumption, commercialisation (shops, markets), socialisation and residence (Vivant, 2013). Government bodies at local and national levels can support innovative clusters (cooperation of private companies and research centres; networking of local producers) and industrial planning (rezoning large areas for cultural consumption and production) through urban policies (Vivant, 2013).

Graeme Evans (2005) noted that no universally applicable set of indicators for a particular intervention exists. Due to its context-specific nature, a pick-and-mix approach is required from Table 3. Standardised performance indicators and quantitative benchmarks are also not valuable in this context.

Area of intervention	quarter(s) city region	(Rato, Roldão and Mühlhan, 2009)
Extent of the physical intervention	reuse of land, brownfields	(Evans, 2005)
	rezoning large areas for cultural consumption and production, Industrial planning	(Vivant, 2013)
	requalification of quarters	(Rato, Roldão and Mühlhan, 2009)
	construction of an emblematic building	(Vivant, 2013)
	renewal/reuse of (historical) buildings	(Evans, 2005)
	upgrading of existing cultural facilities	
Places for consumption + production + commercialization + socialization	art galleries and visual art venues concert and music venues theaters, dance and drama venues cinemas multi-use venues museums libraries	(Duxbury, Garrett-Petts and MacLennan, 2015)

	archives historic buildings and structures historic monuments historic parks and gardens historic landscapes protected natural landscapes archeological sites world/national heritage sites landmarks shops markets public spaces studios festivals, events and public art schemes enabling work-from-home small-scale businesses open coworking places for sharing information, knowledge and skills	(Vivant, 2013) (Montalto *et al.*, 2019) (Evans, 2005), (Vivant, 2013) (Evans, 2005)
Spatial distribution	clusters of producers innovative clusters for cooperation of private companies and research centres innovative clusters for networking of local producers	(Evans, 2005) (Vivant, 2013)

Spatial accessibility of places for consumption, production, commercialization, socialization and complementary infrastructure	for locals for visitors disabled minorities older adults people experiencing homelessness indigenous communities	(Evans, 2005) (Landry and Bianchini, 1995; Landry, 2007; Müller, 2019) (Duxbury, Garrett-Petts and MacLennan, 2015)

Table 3 Key Features of Urban Development Effects of Creative City Policy

Discussion and Conclusion

This research links creative city and urban development studies with policy mobilities. A theoretical framework has been created on the policy mobility of creative cities in urban development. The proposed framework involves types of evaluation, the three stages of policy mobility, and key features of urban effects of creative city policy.

The paradigm of the creative city shifts from focusing solely on the economic benefits of the arts to sustainability (in terms of physical, social and economic well-being) and distributive equity. From short-term to long-term impacts (Evans, 2005). From building flagship projects to incorporating small-scale public art projects with the stress of everyday use, social inclusion, and design quality (Boddy and Parkinson, 2004) to battle gentrification associated with high art venues and large redevelopment projects. Inclusion of local communities, engagement and consultation. Cultural activity should be incorporated as one key indicator of a city's quality of life (Evans, 2005).

A policy can only be packaged and implemented with changes on its way to a new destination. Moving policy loses or gains different directions depending on who moves it, what moves it, and where it is moved (Healey, 2012; McCann and Ward, 2012).

There is also no universally applicable set of indicators for a particular intervention. Due to its context-specific nature, a pick-and-mix approach when researching a city is required. Standardised performance indicators and quantitative benchmarks are also not valuable in this context. Academic discourses often counter overly optimistic official narratives on urban development (Evans, 2005).

Urban policy mobilities research has no defined paradigm or definitive approach. Instead, they draw from various epistemological perspectives spanning planning, sociology, geography and political science (Baker and Temenos, 2015).

Limitations include restricted access to both qualitative and quantitative data. Qualitative data is dependent on subjective opinions of individual actors. Quantitative data can also be difficult to obtain as developing countries are often limiting access or there is absence of data. Countries also use different categories and granularity in the datasets which makes it almost impossible to compare.

Recommendations for future research are further investigating what influences liveability and quality of life of the city, respecting needs of different cultures. Secondly, there is a need to respond to current climate challenges that create an unfavourable living environment. Next recommendation regards the digital revolution's effects on culture and urban planning.

Acknowledgements

I thank the AESOP 2024 LOC for choosing my abstract.

I also thank my supervisor, Professor Karel Maier, for his visionary leadership.

Track 15: Histories

HISTORIES - Knowledge exchanges in urban developments from a historical perspective

Chairs:

- Clément Orillard, Ecole d'Urbanisme de Paris
- Olivier Sykes, University of Liverpool
- Yi Xin, Southeast University of Nanjing
- Asli Ulubas Hamurcu, Istanbul Teknik Üniversitesi

Keywords: *Transnational planning histories, knowledge exchanges, planning models, cross-national fertilisation, technical aid*

This thematic track is dedicated to exploring the intricate history of knowledge exchange among urban experts from various countries along the last waves of globalization. Starting with WWII and continuing to the present day, the landscape of urban development worldwide has been profoundly shaped by the transfer of knowledge, ideas, and urban models. This track focuses mainly on the impact of the third wave of globalization, during the 1980s, 1990s and 2000s, which witnessed a particularly rich and influential cross-pollination of concepts, strategies, and experiences that has left a lasting and transformative impact on urban development practices in numerous nations.

One of the central focal points of this track is the detailed examination and comparison of knowledge exchange processes themselves and their impacts on urban development. The types of exchange include technical aid missions, transnational academic and scientific exchanges, foreign commissions of architectural/planning firms or consultants, etc. This track considers exchanges between countries in Europe, between European countries and other countries in the Global North, and European countries and the Global South and East. Through this exploration, we seek to unravel the multifaceted interplay of ideas, strategies, and shared experiences that continue to shape our ever-evolving urban world.

A special session will focus on exchanges between China and Europe. Within this session, there will be an particular emphasis on urban regeneration practices, a vital facet of urban development that plays a pivotal role in revitalizing and rejuvenating urban areas. By studying the experiences and approaches of these exchanges between Europe and China, we aim to draw valuable insights that can inform and enrich urban regeneration practices on a global scale.

RETAINING INDUSTRIAL HERITAGE PUBLICNESS

The interrelationship of industrial heritage and public space

Abstract

This research aims to explore how to use interrelationship of industrial heritage and public space for making a city with public industrial heritage. In the UK and especially in London, the industrial heritage is gradually becoming a private profitable property rather than being used as historical knowledge for the public. To retain the publicness of industrial heritage, this research uses public spaces as a platform for industrial heritage presentations, examines how the industrial heritage shapes and influences the public space, and in what way the public space reflects and responds to the public value of industrial heritage in the transformation process. The research finds that the interrelationship of industrial heritage and public space can be enhanced and created by intervening on the public space visually, socially and physically. Therefore, three specific strategies of different aspects are proposed to enhance the interrelationship and further to present the publicness of industrial heritage.

Key words: industrial heritage; publicness; public value; public space

0.Introduction

With the pressure of housing and profit rises in the last twenty years and the booming of post-industrial transformation, the abandoned industrial heritage is re-used for stylised high-end housing for urban development. In the UK and especially in London, the industrial heritage is gradually becoming a private profitable property which is purchased by investors and developers because of the location, distinct physical fabric and the high price of land, further transformed into high-level residential and commercial buildings for specific groups. However, as the private value of industrial heritage is continuously magnified, its public values are overlooked. When transformed into residences, the industrial heritage is privately owned and increasingly emphasising its use-value for specific groups, rather than being used as historical knowledge for the public. This makes the industrial heritage lack publicness, private values are over-presented, and public values are under-presented.

This research argues that the industrial heritage needs to retain the publicness in the city rather than utilised as private property. To present public values, the interrelationship of industrial heritage and public space are studied to explore the way of presentation. Thus, two research questions are investigated: how the industrial heritage shapes and influences the public space, and in what way the public space reflects and responds to the public value of industrial heritage in the transformation process (Figure 1).

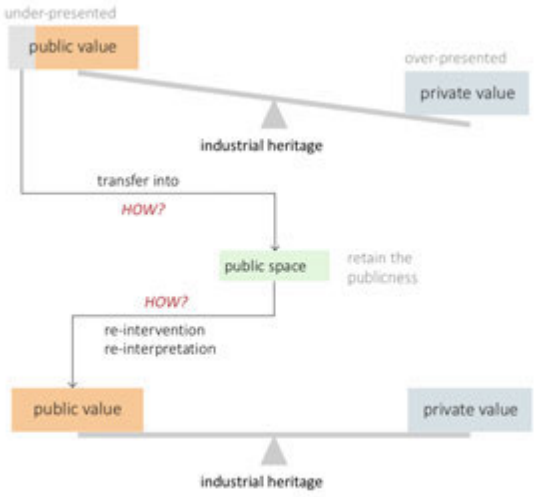

Figure 1. Diagram of research questions

1.Industrial heritage and its public values

1.1 Definition of industrial heritage

In the London context, industrial heritage is usually used as an effective and significant resource for economic growth. With the rapidly increasing of land price, there is a tendency that the industrial heritage is purchased and invested by private developers, the transformation focuses on high-end residences and offices to get maximum profits.

However, the transformation ignores the socio-cultural value of industrial heritage, resulting in the values that should be expressed for the public are under-presented, only reach to specific groups, the true socio-cultural value of industrial heritage may be concealed or even forgotten. For the public, especially the minority with the experience and memory of industrial heritage and the next generation, the value of heritage cannot be felt and loses its inheritance from the past to the future.

From these perspectives, the transformation of industrial heritage indeed should consider the part of definition related to “social activities”, for highlighting its public values and social life and memory related to industrial eras.

1.2 The publicness of industrial heritage

This research argues that the publicness of industrial heritage should be retained and presented for the public. Thus, four elements are selected to figure out what are the “publicness” of industrial heritage and the meanings in the contemporary context.

1.2.1 Physical fabric

The "physical fabric" in this research refers to the "formal appearance" of industrial heritage and its morphological reflection in the urban landscape. ICOMOS（1987）and Historic England (2008) state that the scale and massing, style and form, materials, colours and decoration constitute the appearance of industrial heritage, are "the product of formal design" and the "succession of responses within a particular cultural framework" (Historic England 2008, p. 31). In the larger scale, the physical fabric of industrial heritage treats as an "organic form" (Historic England 2008, p. 31).

It believes that in the “physical fabric”, the industrial heritage shapes the traditional aesthetic value. The architectural design visually reflects the specific architectural and technical significance of the industrial era, the interpretation and preservation of the design over time are overlapped, formed the current industrial heritage landscape, which is the self-development process of industrial heritage. But when it is placed on a city perspective, it is also necessary to consider how to combine with other urban spaces to build a harmonious urban landscape. Specific industrial heritage is mapped as a landmark and it’s meaning is reflected through reinterpretation. This is one of the ways in which industrial heritage can keep up with the times after losing its original function.

1.2.2 History

Lowenthal (1998) made the distinction between “heritage” and “history”, he argues that “history explores and explains pasts grown ever more opaque over time; heritage clarifies pasts so as to infuse them with present purposes” (p. xv). The history itself is what happened in the past, it is the study of the past, did not need to engage with specific groups of people; while heritage is “the celebration of the past” (Lowenthal 1998, p. x).

The theory holds that the history of heritage can be selected and changed according to current purposes. However, heritage is a manifestation of the historical process, as regards the phenomena of heritage development, some of history is interpreted and presented by the authorities, valued and manipulated to benefit them. Therefore, the authorities control history in heritage, the selected parts are in a profitable way to serve some groups. Authorities ignore the history of heritage as it relates to the public because this part of history and its owners cannot contribute to the current development. This makes the historical display of industrial heritage neglect its original value to the public, makes the public gradually forget the original history and heritage. Heritage can cater to the development of the times, inject new functions and serve new groups, but are no longer the public, the heritages is gradually losing the publicness.

1.2.3 Personal memory, collective memory

Memory is related to past experiences. Locke (1971) argues that personal memory is the memory of “particular items [that] personally experienced”, which is physical experience and life, while Benton and Cecil (2010) further treat it as unique “personal mental act”, which is the individuals selective interpretations, related to the people themselves. The minds “encode” the experience as a memory, while the interpretation or intervention in the present is the process of decoding. In common circumstance, it decodes visually through images, objects and sculptures, shows the culturally specific or personal experiences.

Different from personal memory, collective memory refers to groups and their experience as “lived experiences” or “moments from the past”. It is always social and only exists when shared with others. The special nature of group experience creates shared memories and identities; it creates a powerful bond with each other. In the present, the public use collective memory to get identity and sense of themselves, it can occur more powerful resonance than personal memory. The “communal value” of heritage reflects the importance of collective memory. The collective memory of industrial heritage is influenced by the specific physical and social environment of the industrial era, it is reflected in the contemporary resonance of certain people for certain experiences in the past. The resonance is very important for the specific groups, it represents the imprint of experiences and memories. In the social context, these memories further form the every-day urban life and cannot be ignored by the public.

1.3 The presentation of industrial heritage

In the transformation of industrial heritage, how to explain and apply these concepts to the project is very important. In terms of publicness, industrial heritage needs to find a way to show these values to the public to retain the publicness within the privatisation development. This research uses public space as a display platform for industrial heritage, examines the presentation of the values by analysing the relationship between these two aspects.

2. Public space: definitions, dimensions and elements

2.1 The definitions of public space

In the definition of “public space”, “public” refers to the people in general, it points out the nature of “public space”, which can be accessible to or shared by all members of the public; it also provides a place for the use of human contact and interactions related to social. However, the dictionary definitions are not sufficient to systematically describe the public qualities of urban place, in this regard, this section focuses on the publicness in public space.

2.2 Dimensions of publicness

Existing literature agree with the core dimension of publicness and have a high degree of commonality, Varna and Tiesdell (2010) further concludes them into five mega dimensions – “ownership”, “control”, “civility”, “physical configuration” and “animation”. The terms “ownership”, “control” and “civility” refer to whether the space owned and used for the public and how to balance the management of public space for different groups. The “physical configuration” and “animation” are two design-oriented dimensions, the distinction is whether considering the site as a whole to discuss the relationship between other areas (“physical configuration”) or the potential uses and activities inside the site (“animation”).

In the process of industrial heritage, it can be predicted that when the industrial heritage and its public space is privately owned and managed, it is becoming more and more important to discuss the publicness in terms of "physical configuration" and "animation". Therefore, this research focuses on four elements from these two aspects to explore the specific meanings of publicness in the industrial heritage transformation.

2.3 Elements

2.3.1 Morphology

Physical configuration refers to the connection system environment and settings provided by the public space, highlight the “accessibility” and “visual permeability”. The “accessibility” contains the layout and configuration of public space shapes and forms, which can be shown by the morphological changes in the public space. The morphological structure of the public space network defines "streets" and "spaces" through the arrangement of buildings, which can reflect the local development patterns and processes of change. It also constitutes the basic movement patterns of different scales for different groups of people, further determines how easy people can enter and welled-use the public space and the publicness of public space”.

Based on these interpretations, the research defines the morphology of public space in industrial heritage project by two scales, the regional scale and the project itself. In the regional context, industrial heritage is defined for establishing as an important node in the public space system. Its morphology caters to a larger scale public space system, highlight accessibility of different social groups and important social and political position. In contrast, inside the project, the morphology of public space related more to the new building forms and concentrations. The form of public space caters to the new functions of industrial heritage and specific consumers, highlighting the accessibility of specific groups, regardless of the vulnerable groups in the city, contrary to the definition of “public”.

2.3.2 Visual perception

Another concept of physical configuration is “visual perception”. This research argues that visual perception could be used as a tool for visual permeability experiencing and measuring the visual connection to the built environment. The patterns and rhythms of building and its relationship to space help to understand the characteristics of visual perception. The English Heritage (2012) clarifies the important role of views in shaping knowledge and understanding of heritage. For industrial heritage, the view is the historical industrial composite; it represents the specific eras and experiences. The direct visualisation of industrial heritage displays through the official viewing point, which provides the potential restrictions for the proposed developments in surrounding areas to protect the heritage assets and values visually. The document sets up an evaluation viewpoint for heritage but ignores that some groups have no emotion when observed at this point, namely, this has no value for them. Therefore, how to make visual assessment of heritage through public space to meet the needs of specific groups has become a problem that needs to be studied.

Cullen (1971) and Bosselmann (1998) deepen state that scale, massing and building materials interact as relatively static elements with public spaces, this is more largely dependent on the continuous movements, visual and social experiences that occur in the public. From this, the viewpoints cannot be fixed but need to design a series of continuous observation areas in public space to examine the building and pay attention to the feelings in the experience.

Thus, “visual perception” can be explained in two ways: the direct visualisation of the buildings and the visual interaction in the changing environment of movement. Additionally, when observing industrial heritage, perspective recognition should also include the lived experiences that industrial heritage attempts to convey to the public. These experiences are different according to the observers, the history and memory conveyed by the industrial heritage overlap with the social life

in public space, shaped a new visual perception. This perception should not and cannot be assessed by viewing points; they are formed by real social life and exist in the memories and experiences.

2.3.3 Diverse users, activities and events

The animation of the public space refers to supporting a wide range of potential uses and activities, it can be understood in terms of the interpret and use for different social groups, activities and events that the public space can provide to meet the needs of people.

In present, however, some industrial heritage does not show that it should be public. These industrial estates transfer ownership to privately stronger management or business departments for greater benefits, the more powerful departments use industrial heritage for private purposes and serve to the high-end group, the more profiting from it. Each department has the right to use public space according to the benefits it can provide, while some powerless sectors will lose their right to use. From these perspectives, it is important to intervene and negotiate with powerful sectors to make them aware of the needs of public groups for providing more public purposes of industrial heritage.

When it can be used for public purposes, the activities and events could be further considered as a way of engaging with public sectors and presenting the industrial heritage. The activities are particularly relevant to the history of industrial heritage and the memories and experiences of specific groups, through which the public can be made the socio-cultural significance of industrial heritage for the present era, and can present the values of industrial heritage into social interaction in public spaces, thereby keeps it meaningful to every-day urban life.

3. Interrelationship of industrial heritage and public space

Based on these concepts of industrial heritage and public space, this section summarises and proposes theoretical frameworks to explore their interrelationships in the presentation of publicness (Figure 2, 3).

3.1 Interrelationship of elements

From the conceptual discussion in the literature review, the relationship can be summarised as a framework that abstractly shows the relationship of each category. For example, the theory proposes the importance of public life for “visual perception”, for industrial heritage, it is the experiences of history and memory, thus the connection between “visual perception” and “history” and “memory” can be linked. The establishment of this connection is two-direction, and it can be created from two aspects.

Moreover, different elements in the same category can also interact. In the process of transformation, the interpretation of the "history" may affect the "memory" and experience that it conveys to the public, so the presentation of "physical fabric" may be indirectly affected by these factors. This effect varies according to time and space, and external interventions and explanations are considered in the long-term process.

3.2 Add the temporal dimension

Furthermore, the understanding of heritage is not stable and unchanged, the way of use changes through time and space as well. The concepts of temporality in industrial heritage transformation are vital to understanding the changeable process. In this sense, heritage can be interpreted, presented and conserved within any age. In the circumstance, the "process" shows the interpretation in temporal dimension rather than fixed and static intervention. Figure 3 explores the interrelation from the past to present, proposes a reasonable assumption for the future. The appearance of this influence in the process of urban development is subject to time constraints, such as the current intervention in industrial heritage may affect the public space in the future with development and configuration.

Based on this, the empirical analysis will focus on the literature review and Figure 2 to evaluate the relationship between industrial heritage and public space. Figure 3 is used to analyse the specific performance of the interrelationship in the development at different time periods. When there is a contradiction between the practical development process and the theoretical, it will open up the design intervention.

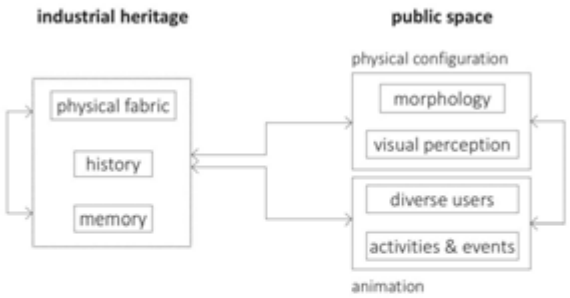

Figure 2. The interrelationship of industrial heritage and public space

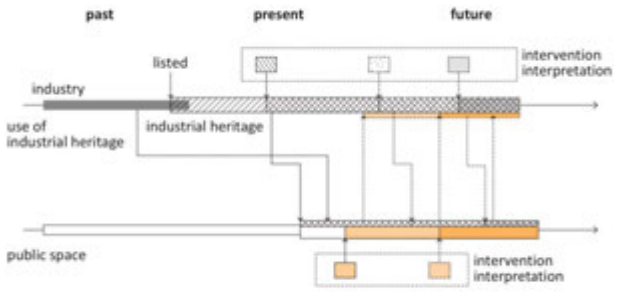

Figure 3. The interrelationship in a temporal dimension

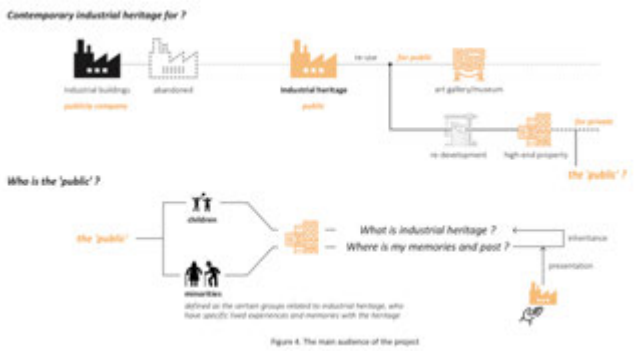
4. Empirical analysis – site intervention and case study

The empirical analysis is divided into four parts. The main audiences of the research will be first addressed. Then the overview of the site (Battersea Power Station) and the case study (Tate Modern) will be introduced to compare the change and use of industrial heritage. Based on the theoretical framework, analysing and comparing the selected elements of public space related to the industrial heritage in two projects. Finally, to conclude the findings from the analysis, two concrete empirical frameworks will be formed and analysed based on the theoretical outcomes, evaluate the condition and degrees of the interrelationship between each element for the design process.

This research focuses on two groups of people – the minority and children – as the representation of the past and the future related to the public industrial heritage. Targeting the high-end property transformation project, the research will further explore how to present the values for these groups to retain the publicness of industrial heritage in the contemporary transformation (Figure 4).



4.1 Overview and relation

Different types of industrial heritage transformation affect the degree of public value presentation. In order to amplify the difference and explore the relationship between transformation project and public space, this research selects Battersea Power Station as the site intervention and the Tate Modern as a case study for analysis and comparison.

These two projects are both in the development Opportunity Area in the central of London, which have the same status in the urban narrative. In terms of difference, the chosen projects show two extremes: a private profitable project and a public welfare project. Therefore, the difference is used as the context and purpose of the analysis to explore the presentation of the industrial heritage public values in the public space (Figure 5).

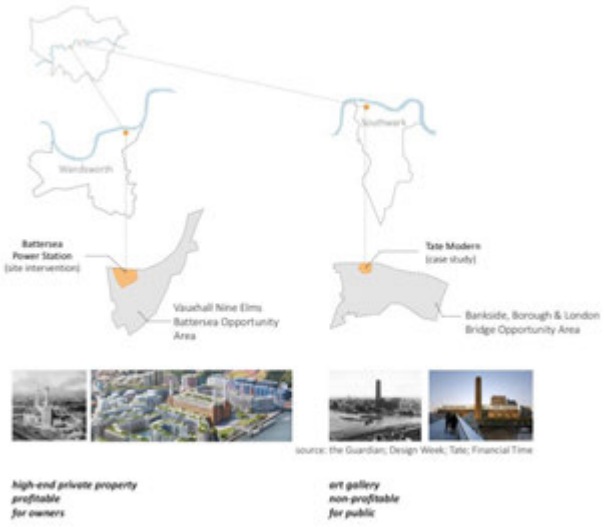


Figure 5. The basic information of site intervention and case study

The Battersea Power Station (BPS) is a regeneration unfinished project located in the centre of London. As a listed British industrial heritage and iconic building in London, BPS is purchased by three overseas investment companies and transforming into the high-end residential and commercial private property from 2011 to 2022. Its private ownership shows that the values of industrial heritage can only be used for a specific type of groups. Differently, as a former power station transformed into a new functional building in 2000, the Tate Modern (TM) is a well-known gallery and the most-visited tourist attraction in London, focusing more on the public sector. With the extension project finished in 2016, TM provides more opportunities and places engaging with the public groups as well as balancing the functions for different users (Figure 6).

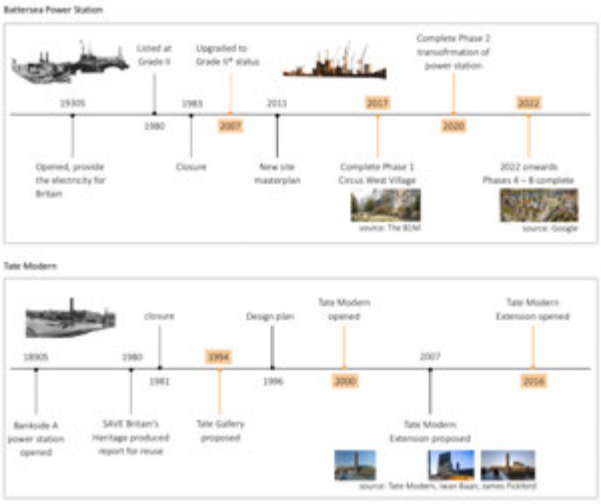

Figure 6. The process of development in Battersea Power Station and Tate Modern

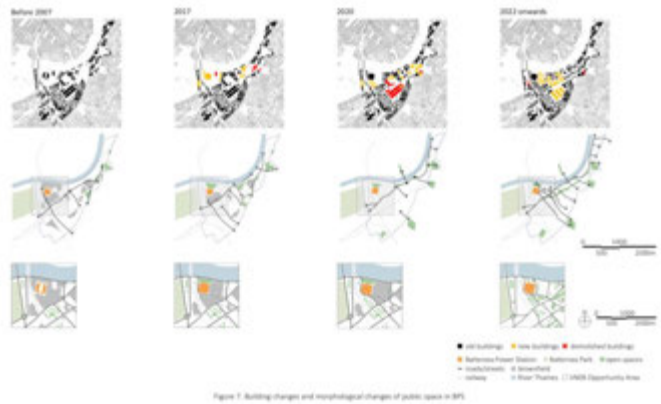
Key time points are selected in different development projects as a context for each project to further detailed analysing the relationship between elements in public space and the intervention of industrial heritage.

4.2 Focused analysis

4.2.1 Morphology

With the development of the VNEB Opportunity Area and the vital position of BPS in the development, the morphology of public space around BPS changed significantly. The brownfields form a systematic public space network, including the linear park and the riverfront trail, cater to the surrounding open spaces. However, the open spaces in BPS are separate from the linear park, shown as the morphology of public space determined by the forms of new buildings (Figure 7).



In contrast, the public spaces in the BBLB Opportunity Area are dispersed. With the development of new projects including the extension, the number of public spaces in TM surrounding areas has increased while no obvious morphological changes (Figure 8).

4.2.2 Visual perception

In terms of view perception, the document Seeing the History in the View provide guidance of heritage view assessment.

It can be seen through the official Viewing Point that the BPS in 2022 will change the skyline of the River Thames. Lower than the four chimneys, the new development buildings will form the backdrop of its urban environment and serve as a foil for the industrial heritage, visually enhance the unique architectural skyline. Meanwhile, the industrial heritage is the new architectural background, is consumed by the new building with its uniqueness and legibility.

Conversely, from the temporal dimension, the view perception of BPS itself is gradually decreasing. With the development of the site, the changing skyline only highlights its chimneys, the heritage building is hidden in the new buildings, the contrast between old and new buildings can only be distinguished through the materials of the buildings (Figure 9). However, the official viewing point is often the optimum locations for heritage observations but is rarely visited by minorities, it cannot be used to obtain visual memory from this location.

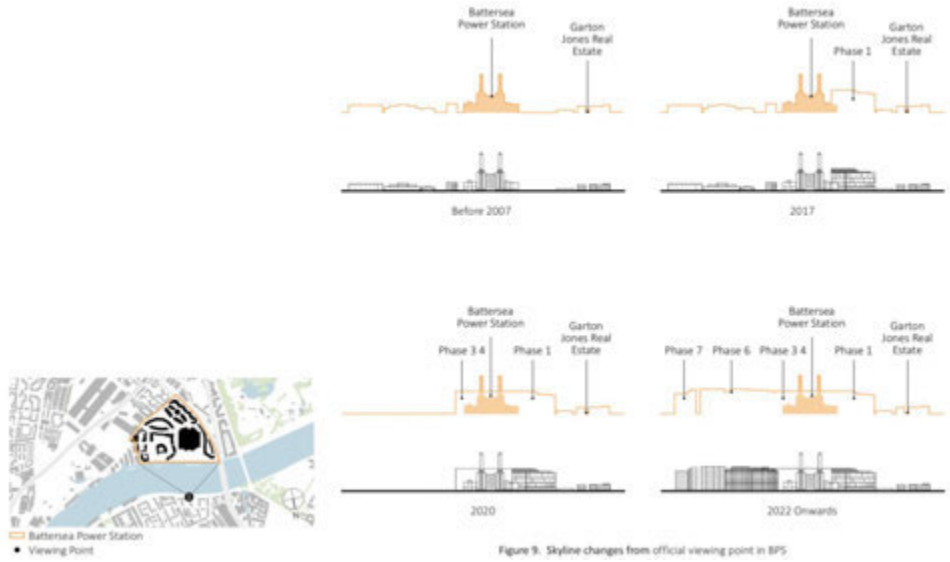


Figure 9. Skyline changes from official viewing point in BPS

Therefore, two political viewing points are also selected in public spaces for minorities, which are in Battersea Park and Chelsea Bridge. It can be clearly seen that the visual perception of the heritage buildings in these two public spaces has reduced obviously. The half or even all the main heritage building are obscured by the new buildings, only use four chimneys as symbols for highlighting the industrial heritage (Figure 10).

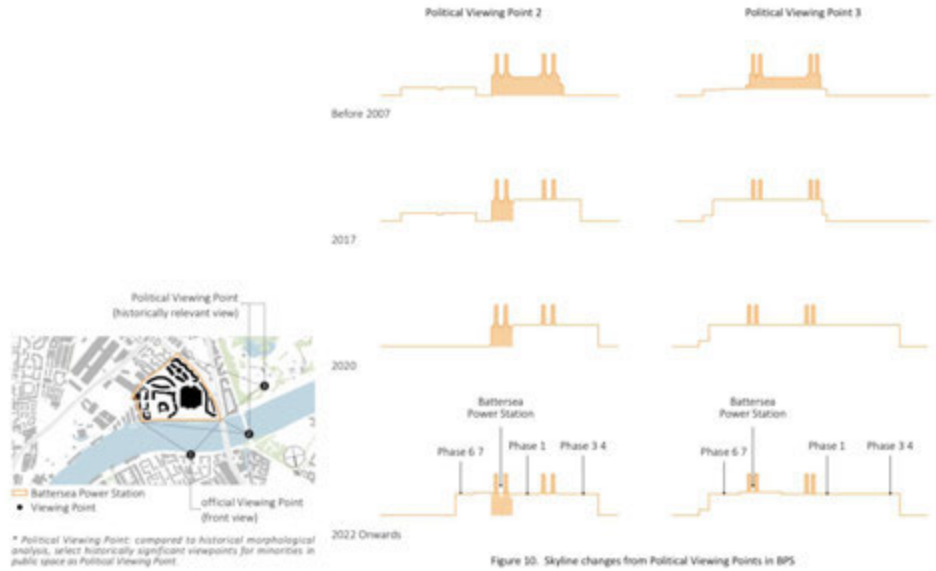

Figure 10. Skyline changes from Political Viewing Points in BPS

The skyline changes in TM are mainly reflected in the extension project and Neo Bankside development after 2016. The new building enhances the public's visual perception both from official Viewing Point and the Political, it contrasted with the main building in volume and height, stands out from the background skyline. For the visual perception from the Political Viewing Point, the new building destroys the original visual perception but to a certain extent, it enhances the recognition of TM in the skyline change (Figure 11).

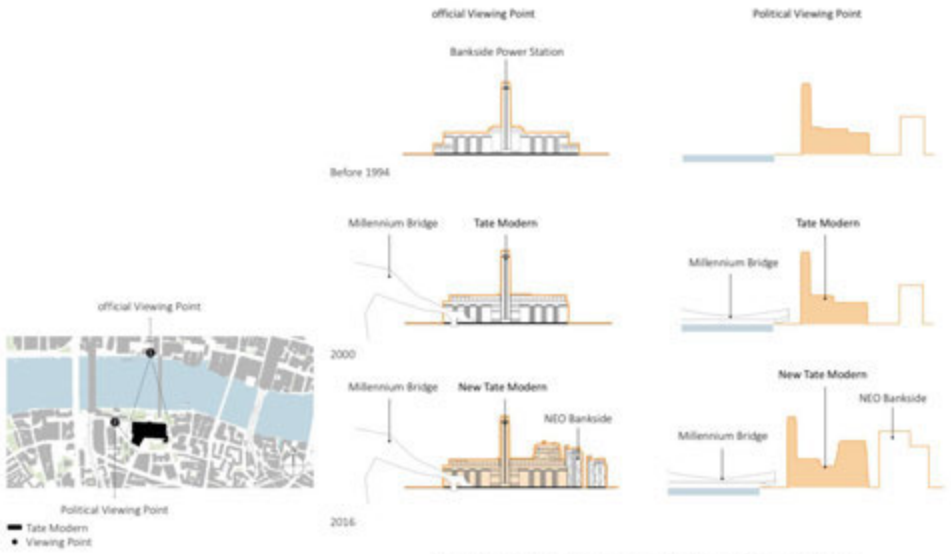

Figure 11. Skyline changes from official Viewing Point and Political Viewing Point in TM

4.2.3 Diverse users

For BPS, the VNEB Opportunity Area development indirectly affects the type of transformation. As a landmark, BPS is positioned as high-end residential and office areas, which will be supported by policies and economically. Meanwhile, such transformation will attract investors and developers with private economic benefits, at this stage, the authority and developers have a common interest. The impact of public groups' economic value is very weak, which leading to these public groups that can use industrial heritage are ignored by the common interests (Figure 12).

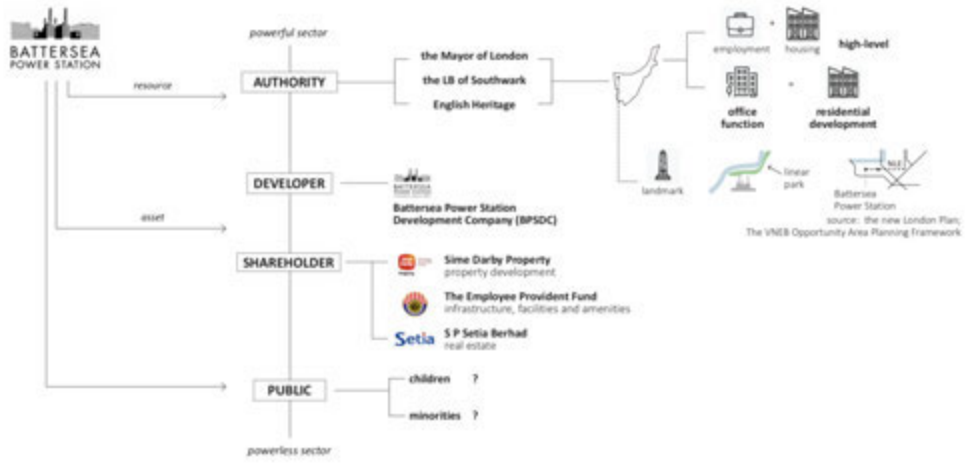

Figure 12. Diverse users in BPS

In comparison, the positioning of TM in the Opportunity Area determines the degree of publicness. As a local attraction, TM is used for the public while serving the tourists. As an NGO, Tate has received policy and economic support developing culture and activities that have made children benefit from it. While for minorities, TM pays more attention to the use of new features rather than provide services for them (Figure 13).

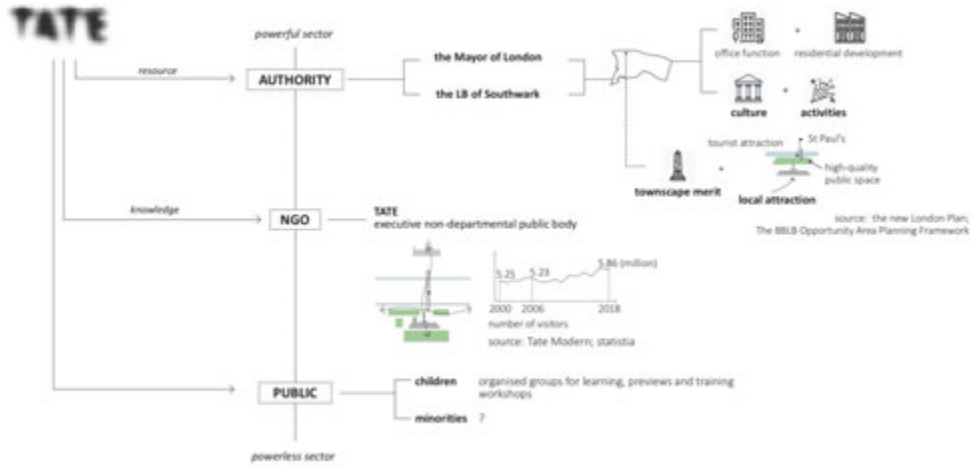

Figure 13. Diverse users in TM

4.2.4 Activities and events

Based on different users, this section further analysed the activities and events of children in the TM public space. Different activities in the north square attract more visitors that come from St Paul's through the Millennium Bridge without any visual obstruction. The riverside also links residential areas in west and east, which provides a linear space for exercising.

In contrast, the southern public space is much quieter. Although it provides places for the public do activities, it is hard to link with TM, the interrelationship between industrial heritage and public space is weak (Figure 14 15).

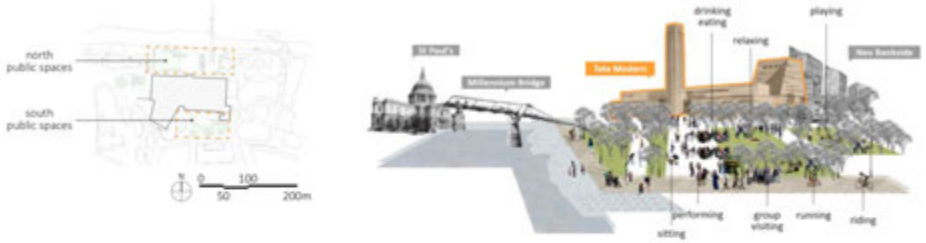

Figure 14. Activities and events of children in TM north public spaces

Figure 15. Activities and events of children in TM south public spaces

Specifically, in the north public space, the bench and chairs provide a place for children relaxing and playing at different times, trees are used as borders separated different spaces for different users. However, due to the visitors, it does not explicitly consider the space dedicated to children.

While in the south public space, the usage is distributed at noon and afternoons. Activities change according to time, basically are resting, chatting and picnics (Figure 16).

Figure 16. Activities and events of children in different times in TM

4.3 Findings of analysis

Through the analysis of industrial heritage and public space, two concrete interrelationship frameworks are summarised for BPS and TM.

As Figure 17 shown, the degree of interrelationship between BPS and its public space is concluded based on the theoretical analysis. However, by analysing the process of development, somehow reality shows conflicts and contradictions between each element.

4.3.1 Memory & history – activities & events – diverse users

The relation between “history” “memory” and “activities and events” should be strong enough to use different activities engaging the public and presenting BPS and industrial revolution and the memory form the public. Represented as an industrial icon in London, the history of BPS constitutes evidence of cultural, social and economic evolution, it documents and interprets public life that contained in urban changes. However, history is not presented in public space through the process of transformation, and the analysis of “diverse users” of BPS also shows the lack of “activities and events” in public life for children and minorities, which can be interpreted through the cut off the connection between these two (line 1 in Figure 17).

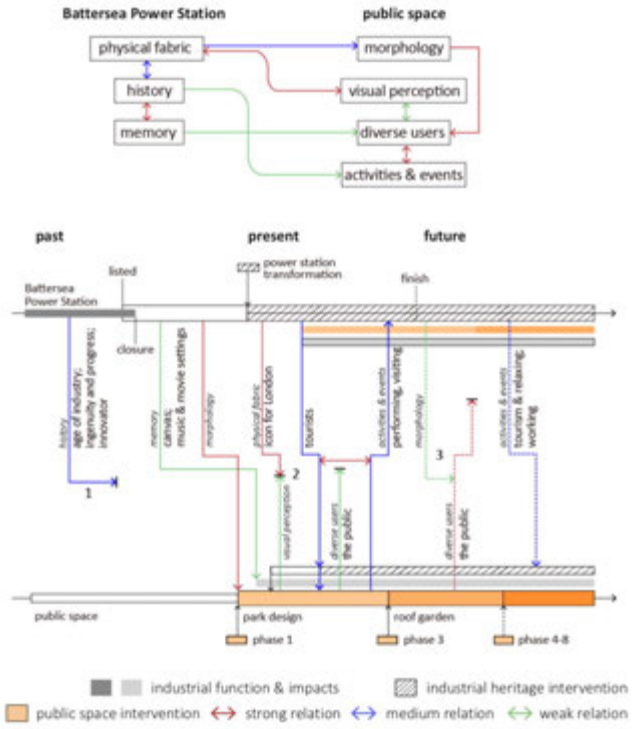

Figure 17. Interrelationship framework of BPS and public space

4.3.2 Physical fabric – visual perception

Similarly, the interrelation of "physical fabric" and "visual perception" is not interrelated with each other through different phases (line 2 in Figure 17). The transformation preserved four chimneys of BPS, which is an iconic symbol in London cityscape, the open space in front of the building indeed reduced obstructions for the visualisation of heritage. Though, in the green space and buildings that developed at different phases, with the regard to the analysis of "visual perception", the visual line obstacles caused by the higher floors, make it impossible for the minorities to obtain visual interaction with the power station from the political viewpoints in public space.

4.3.3 Morphology – diverse users

Based on the morphological analysis and existing information, the "morphology" of the public space after BPS completed will further influence the public's use of BPS (line 3 in Figure 17). It can be seen from the masterplan that the new building will affect the morphological expression of the public space. It cuts off the spatial and visual connection between BPS and the surrounding

area, including the buildings obstacle BPS from the public space, and the public space inside the project does not cater to the public space network and the linear park in the Opportunity Area, makes it difficult for the children and minorities to visually enter and physically use BPS through continuous public space.

In contrast, the interrelationships in TM are more solid and specific. Based on the analysis of "diverse users" and "activities and events", the relationship between industrial heritage and public space can be established through these two aspects. The simultaneous provision of external and internal public spaces increases the maximum use of industrial buildings in public spaces and increases the interaction of the public, especially the children. Meanwhile, the linkage can also be built in the same category (line 1 in Figure 18) by providing "activities and events" that focus on children.

However, for the minorities, the new features of TM did not present the history or memory of Bankside Power Station. The history and memory that TM displays are related to its new function and transformation status without discussing the relationship with minorities, cut off the linkage between TM and minorities in the public space (line 2 Figure 18).

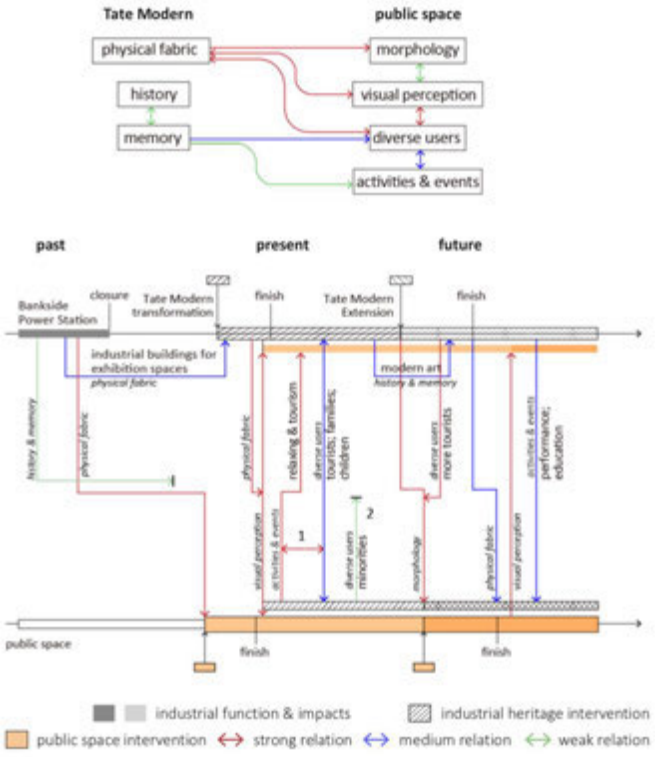

Figure 18. Interrelationship framework of TM and public space

5 Design process

5.1 Types of creating relationship

5.1.1Industrial heritage interventions

The industrial heritage interventions provide physical spaces and indirectly affect the morphology of public space, which can link to the use of the public. The extension project in TM and the other two projects provide more opportunities and options for the children to get involved with the culture and history of industrial heritage indirectly. TM use new building provide more space for events and workshop, while Mining History Centre and the Green Building focus on culture and art, use the building preserve and promote the mining culture and local arts for the next generation (Figure 19).

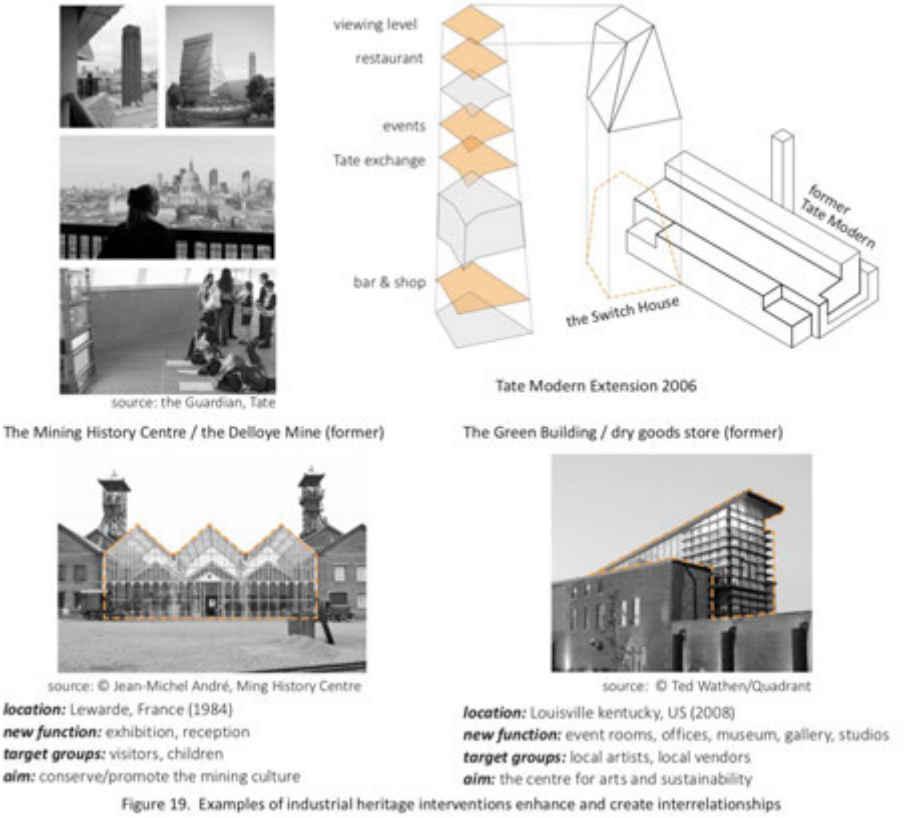

Figure 19. Examples of industrial heritage interventions enhance and create interrelationships

However, it is important to consider the conditions of the surrounding areas. The height and volume of new buildings need to reduce the effects to residential buildings to protect the view corridors of residents.

5.1.2 Public space interventions

Different kinds of detail design make public space play different roles. The publicity display in contrast with the colour of the industrial heritage itself can attract people who are observed in the distance. Temporary exhibitions and events guarantee the public's, it also enables the heritage to integrate with the development, meet the art culture related to its own nature. Furniture is the most direct link between industrial heritage and pedestrians, which should have some practicality and not relevant to its own attributes. The benches and cafes, to a certain extent, can attract pedestrians who do not understand the heritage. It is also a chance to convey information to the public and introduce themselves to people.

These details design and activities in the public space are the most direct display and contact between the industrial heritage and the public. It needs to introduce the past and present to the public with the simplest design methods, which is closely related to its own history and culture. It should serve the public who have a special feeling for it and become the purest historical and cultural space within the entire industrial heritage. (Figure 20).

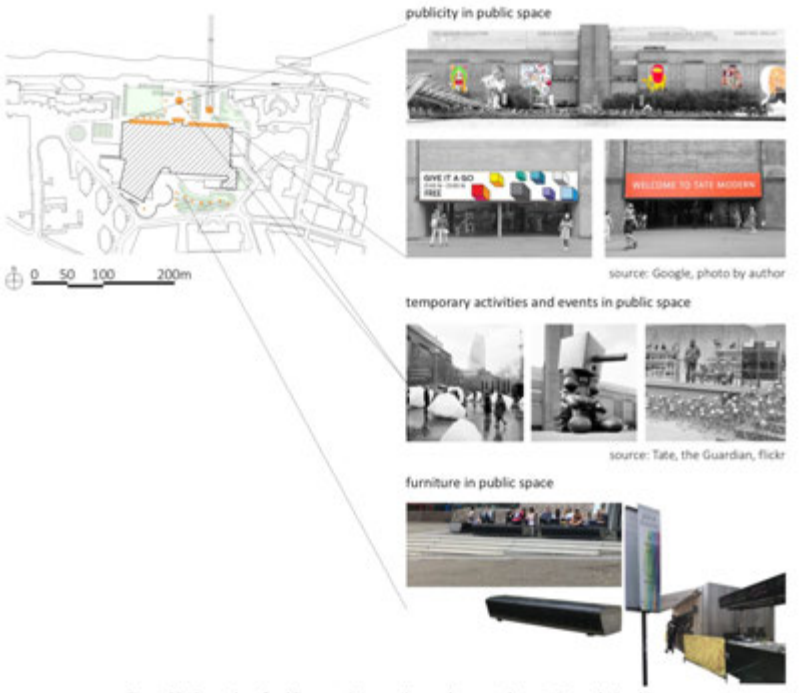

Figure 20. Examples of public space interventions enhance and create interrelationships

5.1.3 External condition influences

In addition, external conditions such as transportation and policies indirectly affect the interrelationships.

The Millennium Bridge and the Thames connect TM to other directions, the Thames cruise routes also link TM to the main tourist attractions on both sides of the river. The status of TM in the Central Activities Zone potentially affects the control of morphological public space and the services of heritage buildings to tourists.

The London View Management Framework emphasizes and protects the important historic buildings through viewings. However, the “assessment point” in this document ignores that some groups have no feelings for the heritage observed at this so-called point, they do not pass through

this point in their daily life, nor do they examine the heritage at this point, this is of no value to some groups. From this and based on the empirical analysis of "view perception", this research believes that the assessment point in the document is detrimental to the evaluation of industrial heritage to a certain extent, it is necessary to explore a new viewpoint that targets specific groups and could reflect public life related to industrial heritage (Figure 21).

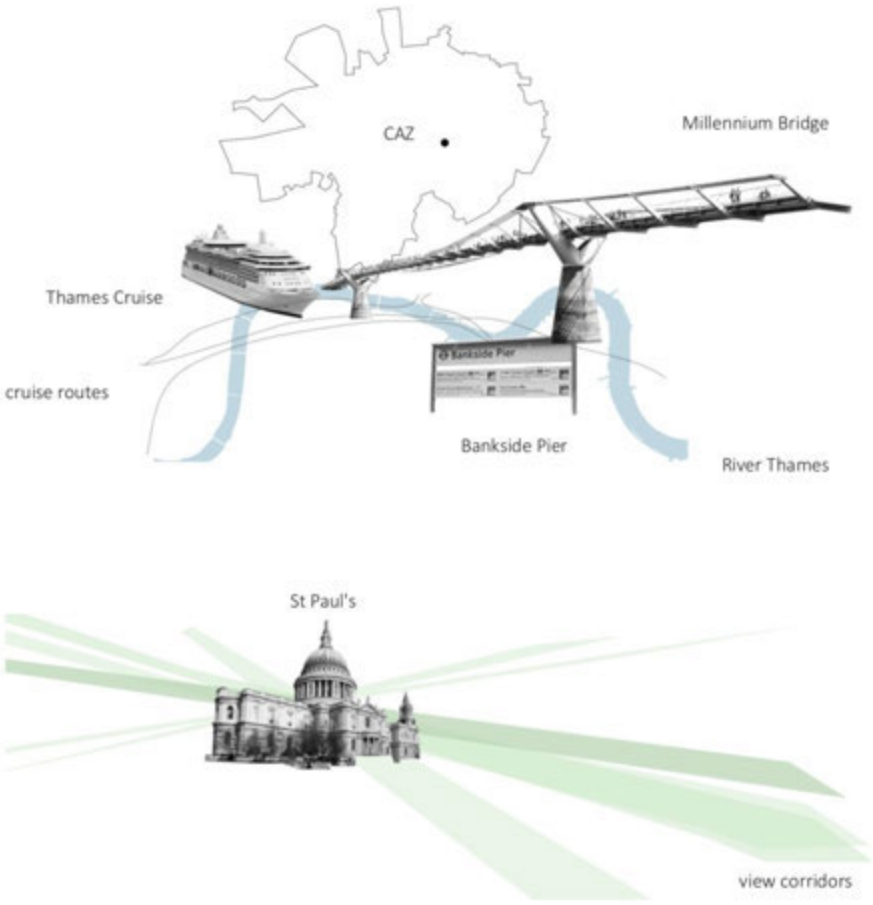

Figure 21. Examples of external condition influences enhance and create interrelationships

5.2 Design brief

Based on the conclusions of BPS analysis, the design begins with a summary of the three interventions in the TM and precedent. The industrial heritage intervention is characterised by

physical morphological changes, including buildings and open spaces, which can enhance the connection related to "morphology" and "physical fabric". Public space interventions enhance the use of public life and different groups by increasing activities and events, it can be summed up to the social dimension. The external condition influence comes from restrictions such as policies and regulations, mainly manifested by the influence of viewing. To conclude, based on the different type of interventions, three directions of strategy are proposed and explored how they enhance and create a relationship between BPS and public space (Figure 22).

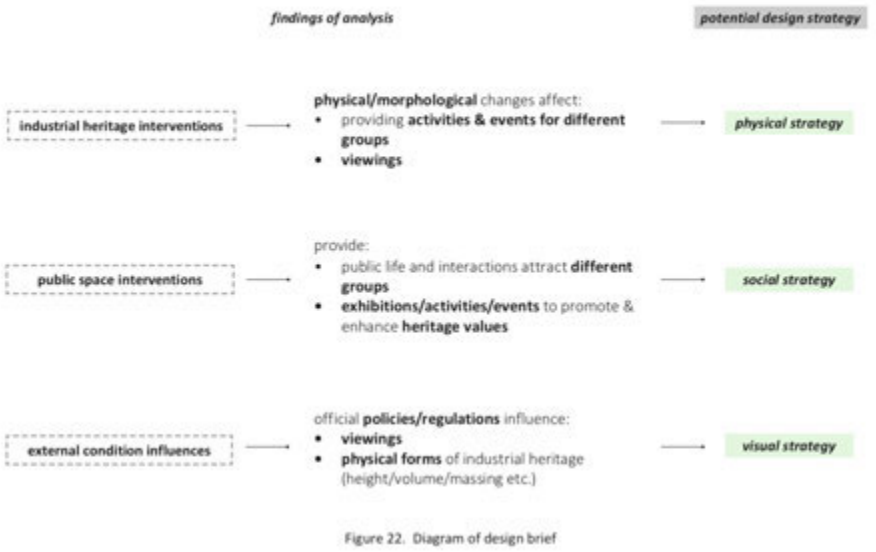

Figure 22. Diagram of design brief

5.3 Visual strategy – defining political viewing system

5.3.1 Process of finding political viewing system

Based on the empirical analysis of "visual perception" and the official document guided in viewing assessment, the strategy tries to apply the conceptual Political Viewing Point in the existing assessment methodology, as an assessment point for evaluating the viewing of industrial heritage for minorities.

For minorities, viewing is not only an intuitive observation but also a reflection of the meaningful public life in public space. Political viewing points are the combination of viewing and public life that it needs to discuss and propose (Figure 23).

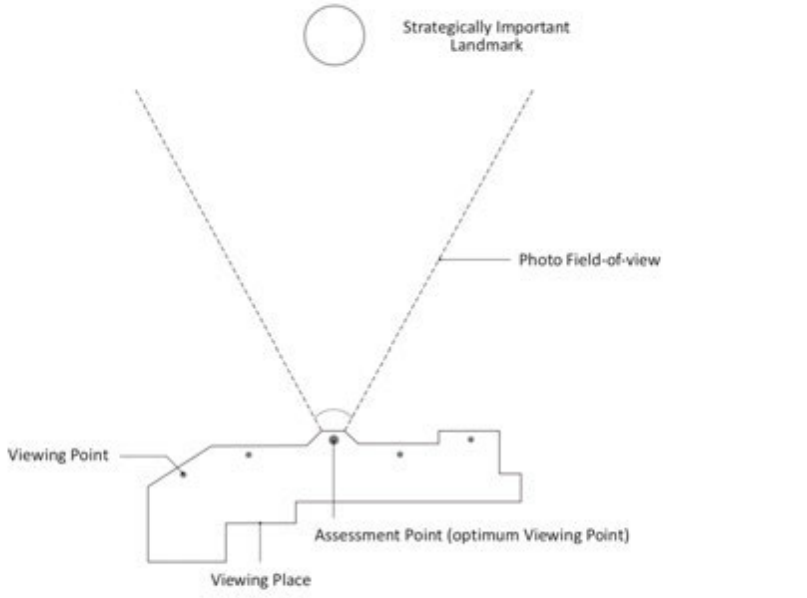

Figure 23. Viewing methodology defined in official document

According to official explanation and empirical analysis, this strategy revises the methodology specifically for an industrial heritage site and the minorities. Compared to the public space historical morphological analysis, the historically significant viewpoints are selected for minorities in public space as "Political Viewing Point". It contains the meaningful public life of minorities related to industrial heritage during viewing, this public space is defined as "Political Viewing Place" (Figure 24).

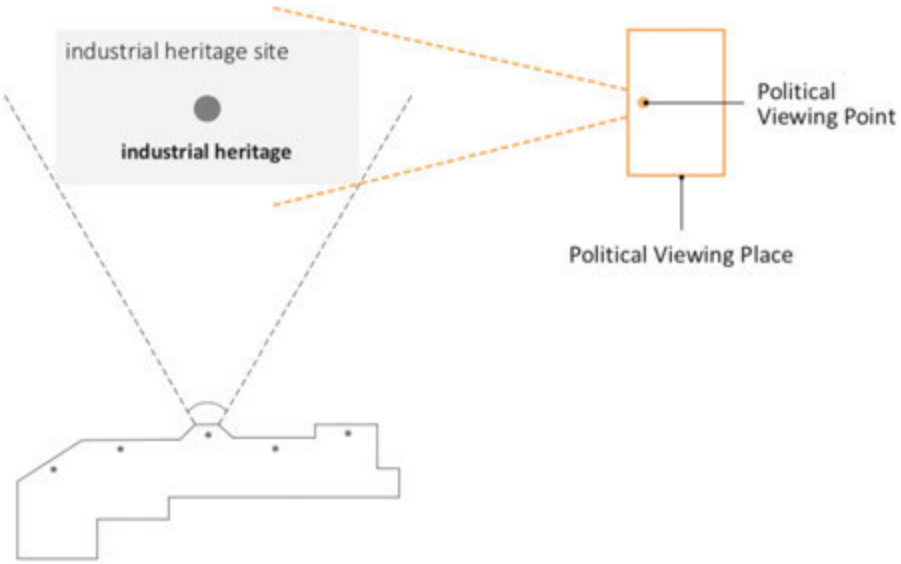

Figure 24. Viewing methodology defined in political viewing system

However, based on the previous page analysis, the political viewpoints cannot treat as the static points such as Assessment Point to express complete social life and vivid memories of minorities, their locations cannot be accurately expressed in the diagram. From this point, the strategy further discusses in another way (Figure 25).

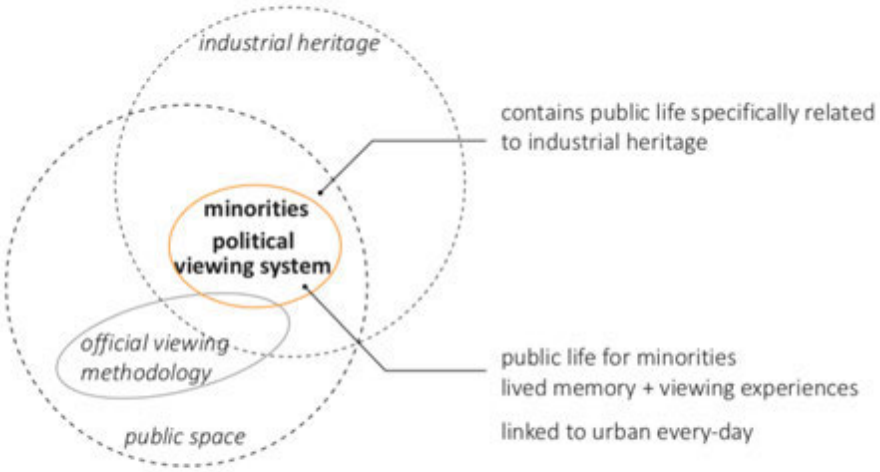

Figure 25. Relationship of official viewing methodology and political viewing system

Figure 26 presents the steps for selecting a political viewing system. It goal is to establish a combination of visual and social experiences for minorities. The Political Viewing Routes replace the previous viewing point, which is represented as a series of points related to life and experience rather than fixed individual viewpoints. The routes at this stage require engaging with minorities to figure out their living experiences in every-day life to achieve accurate and targeted.

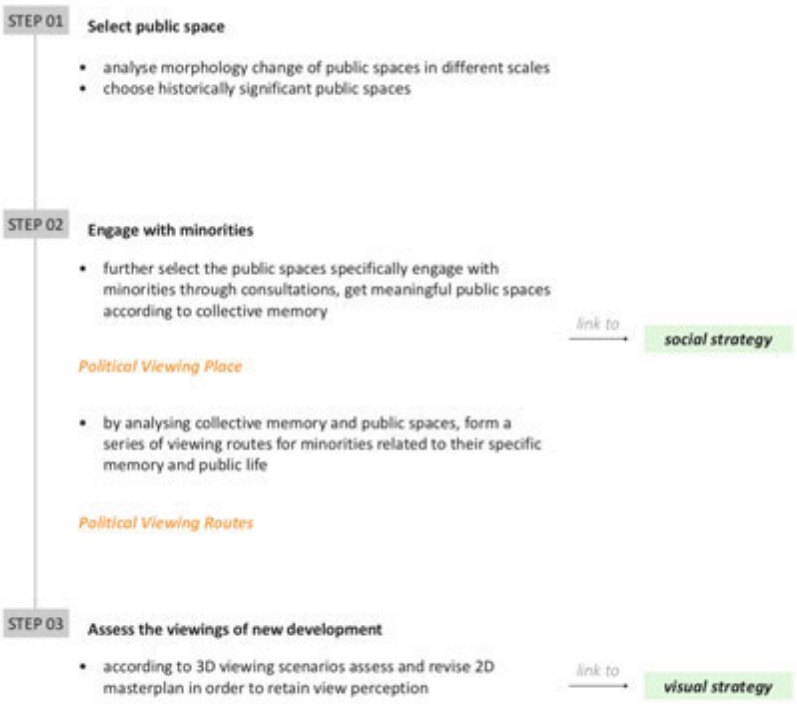

Figure 26. Flowchart of define political viewing system

Regarding with BPS, step 2 can be related to the social strategy that impact on public spaces for minorities, while step 3 is more focusing on the morphology of new development project.

5.4 Social strategy – Battersea Miraculous Journey

The social strategy proposes an event contains three specific events engage with minorities and children, to get the definition of political viewing system in BPS and enhancing the relationship related to activities and events (Figure 27).

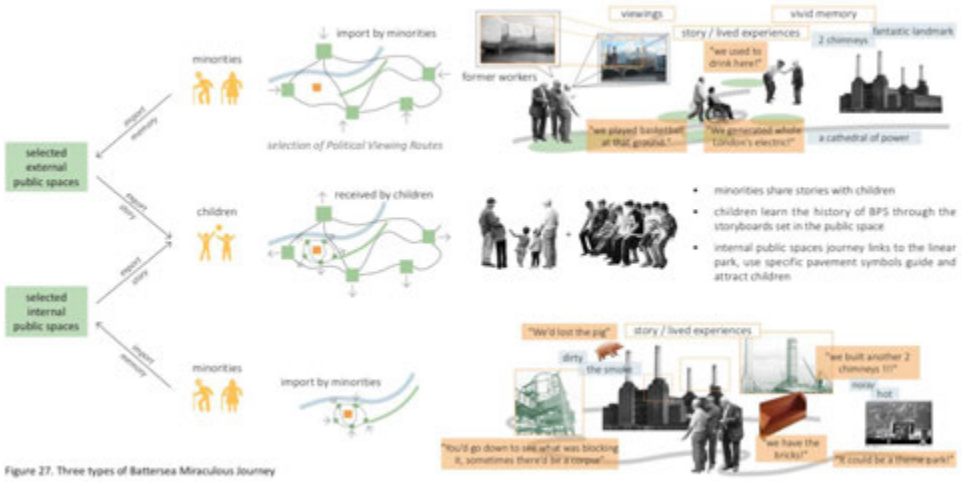

Figure 27. Three types of Battersea Miraculous Journey

The promotion contains three steps. Firstly, finds four potential sectors for supporting and organising the activity. The roles and reasons are as below:

Regarding developers, the event can be a promotional approach that shows how they realise the importance of participating in and promoting public sector activities in the context of private development, expanding their visibility and influence to get more projects and funding, thereby get maximised profits.

Secondly, divided into physical publicity and apps and websites, the event makes posters and booklets at the beginning for propaganda, and posts them on the websites, such as BPS Community Forum and development official website.

Figure 28 shows the timetable of the events for different groups. The experiences and stories that they share during walking tours can be used as data for defining political viewing system. The annual event takes place based on the schools and children, it engages with both minorities and children to share the stories and memories from one generation to another.

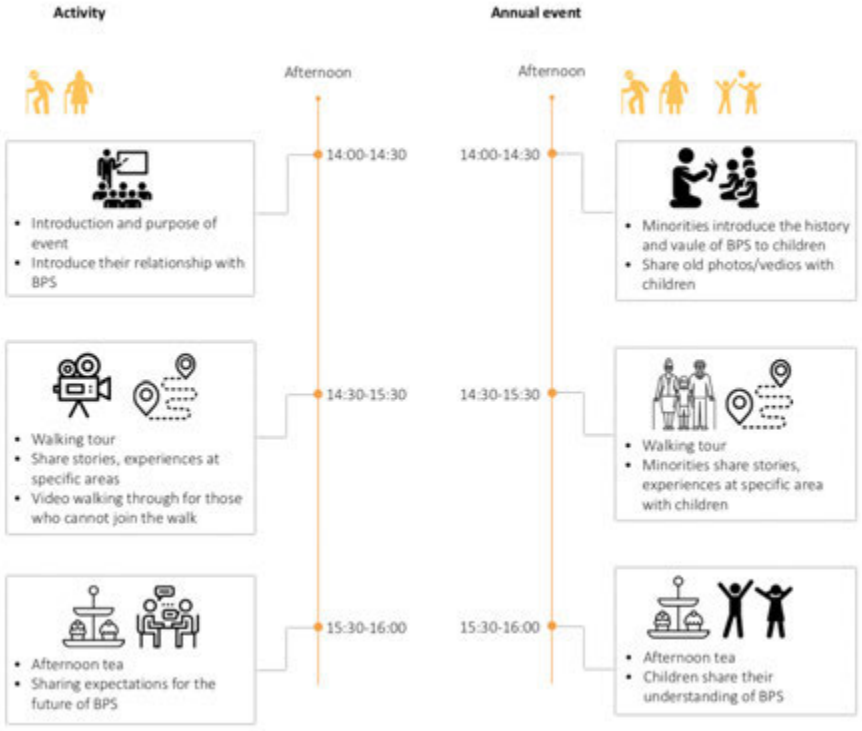

Figure 28. The timetable of Battersea Miraculous Journey Event

5.5 Physical/spatial strategy – testing masterplan

Based on the empirical analysis, the physical strategy proposes new masterplan for BPS, as a way of retaining the viewings in external public space, and the use of children with the public space, which links to the linear park and BPS in the Opportunity Area.

The strategy uses 3D viewing scenarios to assess and revise the 2D masterplan. In the context of the VNEB Opportunity Area Planning Framework, the linear park will provide activities and open space for entertainment and other public life for the children, it is vital that the open space link to BPS get evolve and attract more children (Figure 29. 30. 31).

The second scenario retains the same amount of massing as the existing plan, placing the commercial space underground, and vertically increasing the public life for minority groups and children through the morphological and topographical change of the square and green space. Similar to activities analysis in literature review (see p. 10) and in TM open space (p. 23), the public sector, which is children and minorities can play and rest in this space. At the same time, this space

can also be used as part of the walking tour space in social strategy. Through the display and promotion of billboards, minority groups can communicate with children, including one-way communication in publicity and two-way interaction in activities.

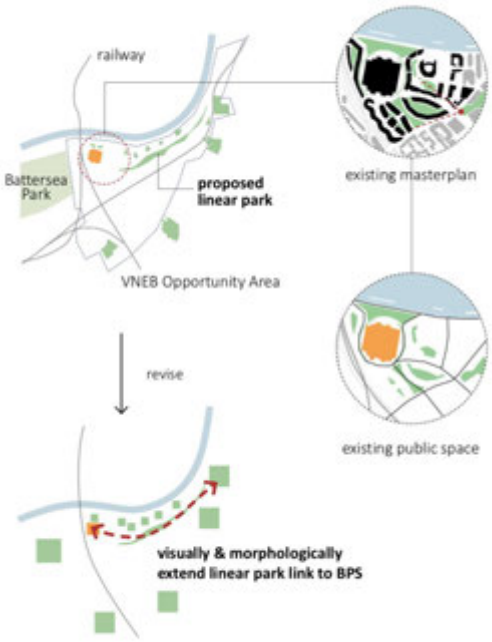

Figure 29. Initial concept of changing masterplan

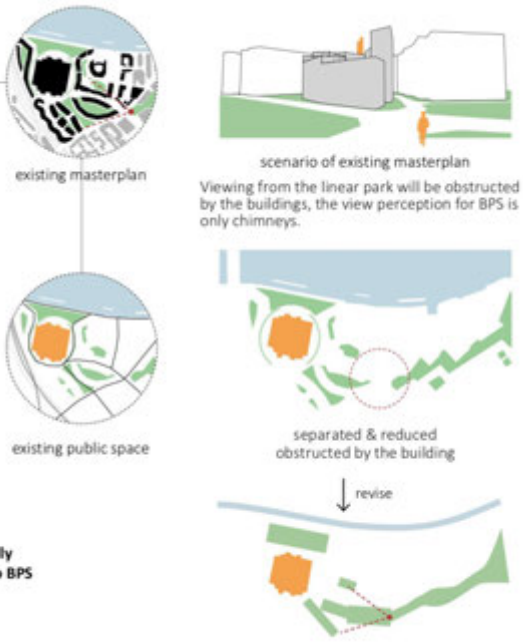

Figure 30. Existing masterplan analysis for changing public space

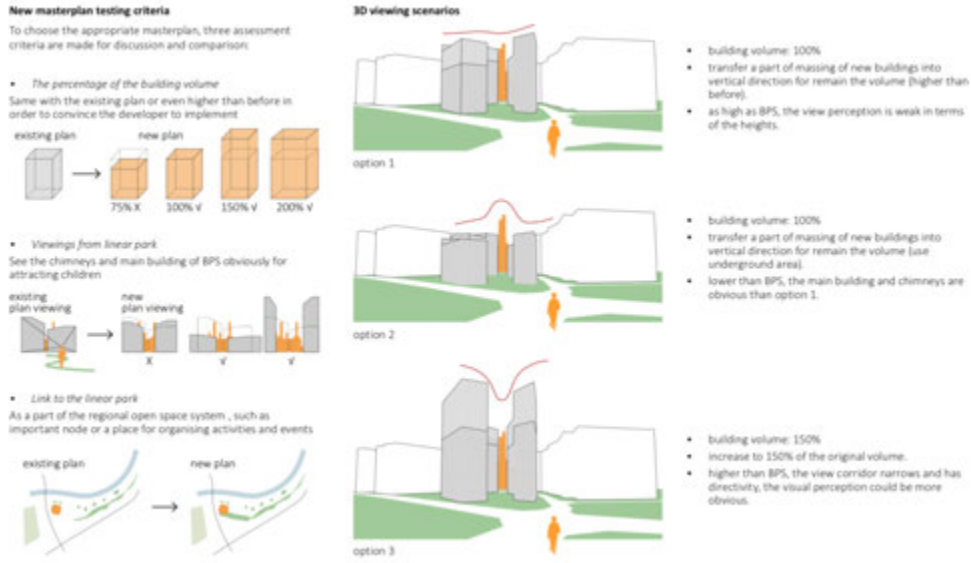

Figure 31. Testing of different viewing scenarios

The evaluation of each plan can be summarised as follows:

Strengths:

The underground commercial can increase continuity and space, it can also increase the types of businesses.

Vertical changes in the public space provide opportunities for interaction between different public groups and stimulate activities.

The sinking square can visually enhance the connection between BPS and public space.

Weakness:

The construction of underground space is inconvenient, and the cost is high.

Strengths:

The underground commercial area is bigger.

Similar to the roof garden, the public space provides the public with activities and green space, the hill can attract people visually to come from the linear park.

The hill can visually enhance the connection between BPS and public space, form a viewing axis.

The cost is lower than the first one.

Weakness:

Large events such as performances or exhibitions will be restricted due to the topography.

The third scenario continues to increase the height of the building, regard case studies as a reference, the increased space is used for residential area and the activities for minorities and children. Activity area includes exhibitions, art gallery and historical pavilions to present the culture of the Industrial Revolution and the history of BPS by photography and paintings.

The evaluation of this plan can be summarised as follows:

Strengths:

Expanding amount of residential areas and indoor activity areas.

Increased space can be used as the platform for industrial heritage presentation for the public.

The viewing level also increases the visual perception of BPS for minorities and children.

Weaknesses:

The plan needs to consider local regulations and policies which control the height of new buildings

In the process of using, it should further explore the tension between residents and minority groups and children.

6. Conclusion

This research focuses on the interrelationship of industrial heritage and public space in order to retain the publicness of industrial heritage specifically for minorities and children, namely, how the industrial heritage shapes and influences the public space, and in what way the public space reflects and responds to the public value of industrial heritage in the transformation process.

Regard to the research aim, the project reviews relevant literature to discuss and analyse the concept "physical fabric", "history" and "memory" of industrial heritage as public values, and further related these concepts to the "morphology", "visual perception" and "activities and events" of public space to study and explore how the concepts of industrial heritage shape and influence in public space, which is concluded into establishing the interrelationship framework of these two aspects. The conclusion can be used as a basis for further specifically evaluated by a case study in order to further understand in what ways that public space demonstration the interrelationships in the practical cases.

The project selects Tate Modern as a case study and Battersea Power Station as the site intervention. Based on the literature review and particularly focuses on the minorities and children in the public, the project focuses on the concrete analysis of elements in public space in the cases and combined with secondary data related to the development of industrial heritage transformation, thus formed the empirical interrelationship framework, including the specific relations and degrees of each element. By analysing the case and precedent studies, the results show that the interrelationship can be enhanced and created by intervening public space in three ways: the visual intervention related to polities and regulations, social intervention including activities and events, and the physical and morphological intervention. These findings answer the research questions to a certain degree.

Based on the findings of the literature review and case study analysis, the design proposal focuses on dealing with the interrelationship framework of BPS, in which shows conflicts and obstructs regard to the development process, and needs to enhance and create the interrelationship visually, socially and physically, the findings help as a reference to come up with three specific strategies for BPS. The visual strategy engages with minorities for a way to enhance and make awareness of the visual perception of industrial heritage on public space. The social strategy gives an opportunity for minorities to introduce history and memory, by interacting with children it also promotes the attractions of industrial heritage to the next generation. The physical strategy is related to regional development planning, the morphological changes of new buildings and public spaces in BPS can enhance and provide more opportunity for industrial heritage presentation for both minorities and children visually and socially.

This research provides a reference for the ways of industrial heritage presentation in private profitable transformation projects. In the context of London, the projects have the same urban narrative, but each project itself also different from BPS, including the local policies and regulations, economic status and development direction of transformation, and the unique socio-cultural values of industrial heritage. Further in the global context, there will be differences in the performance of the elements in this research in different political and development context, but in terms of methodology, the project and research could be the same. As a framework, this research provides a conceptual way to think and examine the relationship between industrial heritage and public space, which meanwhile opens up new research ideas for different projects to explore specific ways in the different context.

For a wider context, such as capitalist cities and developer-driven planning systems, industrial heritage development represents the interests and powers that are controlled by the powerful sector, limit the use and expression. This research and the design strategy redefine industrial heritage from a critical perspective as publicness, representing the equal rights of the public to use it visually, socially and physically. Industrial heritage in capitalist cities needs to highlight its public status, and it needs to explore the publicness expressions of different cultural, social and political contexts, including its targeting groups, the relationship with the urban spaces in different cities in order to maximise its values.

Abstract
As the first steel and coal joint venture in modern China to use advanced machinery and equipment for large-scale production, Hanyeping Company is an important practical case for scientific and technological exchanges between China and Europe. Based on the research on the construction of industrial heritage systems in China and Europe, the paper sorts out the historical development background and actual protection situation of the Company, and analyzes the intrinsic connections and shared values of industrial heritage in time, space, function and cultural dimensions. It is of fundamental guiding significance for the renewal and development of China's industrial cities, and has important reference value for promoting the construction of a systematic and holistic protection and utilization system for world industrial heritage.

Keywords
Self-Strengthening Movement, Technical Import, Linear Industrial Cultural Heritage, Urban Regeneration and Development

Introduction

The 19th century was the period of the emergence of the first industrial revolution, when European countries represented by the United Kingdom began to replace the traditional handicrafts with mechanisation and large-scale production methods, which greatly improved production efficiency. The development of industry led to the migration of a large number of people from the rural districts to the cities, promoting the process of urbanisation in Europe, and realising the country's economic development and social progress. However, at the same time, China was suffering from the failure of the two Opium Wars[1] and the Taiping Rebellion[2], which opened up a number of trading ports, leading to the disintegration of China's natural economy as well as the emergence of the bud of capitalism. In order to cope with these internal and external challenges, the bureaucrats represented by the landlord class, realised that capitalism could be used as a means of developing industry and commerce to maintain the feudal rule of the Qing government, and initiated the Self-Strengthening Movement[3] under the slogan of "learn from the foreigners in order to gain command of them", introducing advanced Western science and technology on a large scale, and setting up a series of modern military

[1] The Opium Wars in the mid-19th century were a critical juncture in modern Chinese history. The first Opium War was fought between China and Great Britain from 1839 to 1842. In the second Opium War, from 1856 to 1860, a weakened China fought both Great Britain and France. China lost both wars.

[2] During the years from the first year of the Xianfeng reign to the third year of the Tongzhi reign of the Qing Dynasty (1851-1864), a peasant uprising war against the feudal rule of the Qing Dynasty and foreign capitalist aggression was initiated by a leading group composed of Hong Xiuquan, Yang Xiuqing, Xiao Chaogui, Wei Changhui, Shi Dakai, and others, starting from Jintian Village in Guangxi.

[3] It was a self-strengthening movement of the late Qing Dynasty from the 1860s to the 1890s, led by the Westernization faction, which utilized Western military equipment, mechanized production, and scientific technology under the slogans of "self-strengthening" and "wealth-seeking" in an attempt to salvage Qing rule.

industries and civilian enterprises, thus promoting the process of China's modernisation. With the construction of the railway, China's demand for iron was increasing day by day, the development of the iron industry has become a pressing task. In 1890, Zhang Zhidong[4] supervised the Lu-han Railway[5] and transferred to the Governor-General of Hubei and Guangdong Province, in Hanyang at the foot of Guishan to establish the Hanyang Iron Works. In 1893, Daye Iron Ore Mine was built as a large-scale open-pit iron ore mine, and began to be mined on a large scale, to provide raw materials for the Hanyang Iron Works. Due to the high phosphorus content of Daye iron ore, the steel produced was easy to be brittle and cracked. In 1896, Sheng Xuanhuai[6] took over the ironworks, and began to mine and refine a large amount of high-quality coal and coke in Pingxiang, Jiangxi Province, to produce compliant rails, which solved the problem of the shortage of raw materials. In 1908, in order to solve the problem of insufficient operating funds, he applied to the Qing government for a merger of the Hanyang Ironworks, Daye Iron Mines, and Pingxiang Coal Mines, to form Hanyeping Coal and Iron Works Co.

As the earliest iron and steel joint venture in China, Hanyeping Company spatially distributed across a number of cities including Wuhan, Daye, Pingxiang, Shanghai and Chongqing, the process involves important production steps such as coal and iron ore mining and iron and steel smelting, and the dissemination of technology involves the introduction of Western science and technology and machine production, and the promotion of advanced industrial production management systems. As a representative of large-scale linear industrial heritage, it has promoted the development of a transport system linking raw materials and products to multiple locations, driven regional economic ties in the central region, and had a profound impact on urban spatial landscapes, production and living patterns. The paper describes the historical development of Hanyeping Company using the methods of metallurgical development history and urban planning history, and analyses the current situation of Hanyeping industrial heritage. Combined with the current experience of industrial heritage protection system in China and Europe, it explores its historical and cultural value, lays the research foundation for the establishment of Hanyeping industrial cultural routes, and provides important reference value for the overall protection research of regional industrial heritage.

1. Historical Development of Hanyeping Company

As an important iron and steel joint venture in China, Hanyeping Company went through three periods of institutional changes: government-run, government-supervised and merchant-managed, merchant-run. With sufficient capital investment and government support, it introduced technological innovations and adjusted its institutional structure to adapt to changes in the global market and promote the development of national capitalism. By analysing the overall historical development of the company, we could better understand the development history and characteristics of modern Chinese industry in the context of the socio-economic environment of the late Qing Dynasty.

[4] A Chinese politician of the late Qing Dynasty and a prominent figure of the Westernization movement. He held various positions including tutor, reader, lecturer, cabinet scholar, governor of Shanxi, governor-general of Guangdong and Guangxi, governor-general of Hubei and Hunan, governor-general of Jiangsu and Zhejiang (acting on multiple occasions but never confirmed), and Grand Secretary of the State Council. He vigorously advocated for the integration of traditional Chinese studies with practical Western knowledge, emphasizing "Chinese learning as the foundation and Western learning for practical application." He placed great emphasis on education and law enforcement, spearheading the modernization of China's police system, which had a significant impact on education and social development in late Qing China. Additionally, he established the Hanyang Ironworks, Daye Iron Mine, Hubei Arsenal, and other enterprises.

[5] The Lugou Bridge and the railway from Zhengzhou to Hankou were the first railways planned for construction by the Qing government of China after the First Sino-Japanese War. They were supervised by the Minister of Beiyang, Shen Xuanhuai, who oversaw the construction of the Luhan Railway. Construction began in 1897, with work starting simultaneously from the north and south ends by the end of 1898. The Yellow River Bridge in Zhengzhou was completed on November 15, 1905. The entire line was completed and opened to traffic on April 1, 1906, with a total length of 1214 kilometers, and it was renamed as the Jinghan Railway.

[6] A representative figure of the Self-Strengthening Movement, he was a renowned politician, entrepreneur, and philanthropist who founded the Beiyang College and Nanyang Public School.

1.1 Government-run Period (1890-1895)

In 1889, Zhang Zhidong planned to set up a factory in Fenghuanggang, Guangzhou under the support of the Qing government's grant, and purchased 2 blast furnaces with a daily output of 200 tonnes as well as machines and equipments for making clinker iron, steel, pressing plate, drawing bar from the Tee Sides Company in Middlesbrough, England[7]. After that, he transferred to Hubei to be the governor of Hubei and Guangdong province to supervise the southern section of Luhan Railway. and to facilitate the regional management, he asked the court to move the ironworks to Hubei. In order to facilitate the regional management, he asked the imperial court to move the ironworks to Hubei, decided to set up a factory in Hanyang area of Wuhan, and shipped the equipment ordered by Guangzhou Ironworks to Hubei instead. To facilitate regional management, he petitioned the court to move the ironworks to Hubei, decided to set up a factory in the Hanyang district of Wuhan and to ship the equipment ordered by the Guangzhou Ironworks to Hubei instead. In 1890, Hubei Iron Bureau was established, which undertook the three major tasks of iron development, coal mining and plant construction, and successively organised 15 batches of 30 people to explore coal and iron in Hubei, Hunan, Sichuan and other places, and hired some foreign mining engineers to explore the iron ore mine in Daye repeatedly, confirmed that Daye iron ore has abundant reserves and can be used as raw materials for smelting.

In 1891, the infrastructure project of Hanyang Iron Works was designed by British engineer Johnson[8] and supervised by Henery Hobson[9]. All materials were imported from Britain and Belgium, building construction and equipment installation were carried out alternately, which took two years and ten months to complete all the construction tasks. Walls were built around the factory, and four main gates were set up, namely, the main gate (facing the Han River), the Xingren Gate (facing the Yangtze River side), the Neode Gate (right side of the main gate), and the Dachang Gate (left side of the main gate). In order to facilitate the entry and exit of materials after construction and production, a pier was first built along the Yangtze River, all of which were made of red sandstone. A large gap was reserved in the middle of the pier, which can be made into a 300-foot-long ramp by steel and timber, and its inclination can be changed according to the rise and fall of the Yangtze River water level. There were large winches, cranes and other equipment on the shore, and a 6-kilometre-long light railway was laid from the bank of the Han River to the factory so that materials could be transported directly to the construction site, and facilities such as an unloading ramp bridge were established. The factory was divided into two types of industrial buildings and civil buildings, with six large factories, four small factories and residential buildings. The six large factories included pig iron plant, clinker plant, Bessemer steel plant (converter steel factory), Martin steelworks (flat furnace steelworks), rail manufacturing works, iron goods manufacturing works, and the four small factories included machine factory, iron foundry, blacksmith factory, fish fillet hook and nail factory. Civilian residences were mainly occupied by technical personnel and were divided into buildings or rooms. The general layout of the ironworks was designed according to the process, means of transport and the actual situation in Hanyang, and the work production lines were designed to avoid crossings and to be short. The building was always planned and comprehensively arranged in terms of energy supply, water supply and drainage, warehousing and transportation, equipment maintenance and administrative management.

[7] A large steelworks stretched from the town of Middlesbrough in North Yorkshire, England, to the town of Redcar along the southern bank of the River Tees. At its peak, there were 91 blast furnaces within a 10-mile radius of the area.

[8] The designer and draftsman of the Hanyang Ironworks.

[9] The Chief Engineer of the Hanyang Ironworks before 1892.

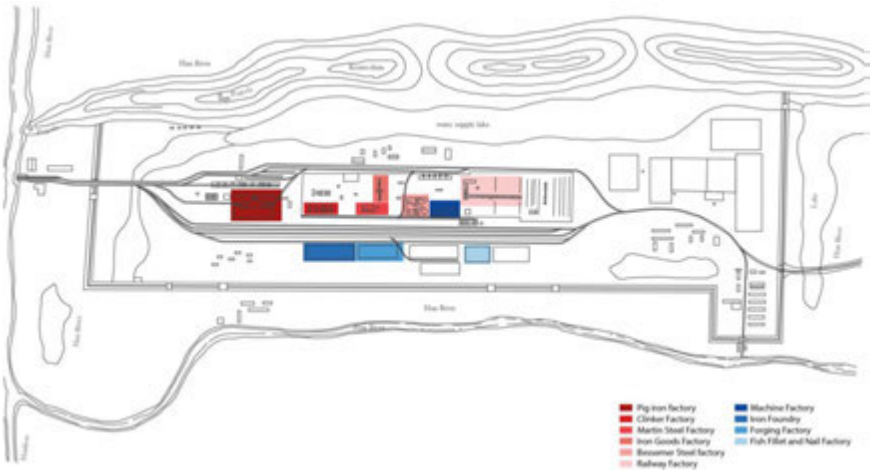

Fig.1: Layout of Hanyang Ironworks

At the same time, with the technical assistance of Belgian and German mining engineers such as Max[10], Gustavus Leinung[11] and Parkinson[12], the exploration and exploitation of the Daye coal and iron ore mines was carried out, while the mining works and the construction of the railway to transport the ore from the Daye mine were actively promoted. The project took one year and four months to complete, with the construction of a large open-pit iron ore mine and the establishment of an iron smelting plant, a depot and accommodation for technicians. A 35-kilometre-long railway from Tieshan to Shihuiyao was equipped with four stations, namely Tieshan, Shenghongqing, Xialu and Shibao, and transport infrastructure such as Shihuiyao Ore Transportation and Loading Terminal was constructed to facilitate the supply of raw materials for the Hanyang Iron Works, such as iron ores.

[11] German, Engineer of the Daye Iron Mine, Chief Engineer of the Pingxiang Coal Mine.
[12] Mine engineer

Fig.2: Location Map of Daye Iron Ore Mine Site

In 1894, Hanyang Iron Works was officially put into operation. No.1 blast furnace, churning and clinker furnaces, steel making and steel rolling were operated at the same time, and soon there were problems such as high phosphorus content in pig iron smelted and insufficient supply of coke, which led to several stoppages of the ironworks, and the operation of the factory under the constraints of the government-run management system resulted in a relatively serious loss.

1.2 Government-supervised and Merchant-managed Period (1896-1907)

In 1896, in order to maintain the production of the ironworks, Zhang Zhidong recommended Sheng Xuanhuai take over the Hanyang Ironworks, adopted investment promotion and undertaking to solve the problem of ironworks losses. Therefore, it entered the period of government-supervised and merchant-managed.

In the same year, Sheng Xuanhuai sent Max and Leinung to Anhui, Henan, Jiangxi and other places to explore coal resources. Two years later chose to open Pingxiang Coal Mine in Pingxiang, Jiangxi Province, and set up the "General Administration of Mines in Pingxiang", to refine a large number of high-quality coal and coke, and to produce compliant steel rails, which solved the shortage of raw materials for the ironworks. Pingxiang coal mine to Anyuan coal mine as the main mine, at the same time in Tianzishan, Zijiakeng, Xiaokeng, Longjiakeng, Wangjiayuan, Tielukeng, Shanzhuling, Zhanggongtang, Gaokeng, Xikeng, Nanmukeng, Bashanchong, Wupixia, Taipingshan and other mines, the construction of 14 earth shafts. The mine is divided into two parts: ground constructions and underground constructions. The ground constructions were divided into three parts: the mining production area, the living service area and the product transhipment and distribution area. The mining production area consisted of modern infrastructure facilities such as power equipment, machine repair equipment, large and small coal washers, coke ovens, machinery plants, power plants, etc., while the living service area consisted of the surveying and mapping office, the construction office, the telegraph and telephone room, the hospital, the mining school, the employees' primary school, the printing press and other living service support facilities. Hanyang Transportation and Marketing Bureau, Changsha Distribution Bureau, and Yuezhou, Zhuzhou and Xiangtan Transfer Bureau were added to the mine to adapt to the multi-channel transport

of iron and steel products, to improve the quality of transport and to drive the economic development along the routes of Hanyang, Daye and Pingxiang. The underground constructions consisted of the large coal chutes, the straight shafts and the flat alleys.

Fig.3: Ground Constructions Map of Pingxiang Coal Mine

Under the management idea of government-supervised and merchant-managed, Sheng Xuanhuai began to raise commercial shares to expand the production scale of the ironworks and reduce production costs, while appointing European engineers such as Gustavus Leinung and Eugène Ruppert[13] to assist the iron and steel industry in realising technological innovation, installing and applying a variety of production equipment for the iron and steel industry, and promoting the systematic innovation of coal and iron enterprises, which helped to establish China's modern company system in China. In 1905, the expansion and renovation project of Hanyang Iron Works was carried out. Due to the problem of matching the Martin furnace with the ore and coal coke, the quality of some of the iron and steel products of the ironworks was not up to the standard, therefore, new machines and equipments were investigated and purchased, and the alkaline Martin furnace was renovated and introduced. Newly built and replaced the equipment and facilities of the steel mill and rolling mill[14], and constructed the wheel plants, cargo completion plants, expanded the machine repair plants, and

[13] Luxembourger, served as the Blast Furnace Engineer at Hanyang Ironworks from 1894 to 1898, and as the Chief Engineer of Hanyang Ironworks from 1905 to 1912.

[14] The ironworks will construct a new No. 3 blast furnace with a daily output of 250 tons of pig iron, dismantle two Bessemer acid converters, and initially replace them with four 30-ton basic Martin furnaces and ten 10-ton small Martin furnaces until seven Martin furnaces are built. Additionally, a new 150-ton mixed iron furnace, two 35-ton electric steel ladle cranes, one 10-ton electric overhead crane, two 50-ton electric traveling cranes, and one vertical steel ingot stripping machine will be installed. The steel rolling mill will include a new 80-ton reheating furnace, one 4-ton electric overhead crane, one fully steam reversible primary rolling mill with a roll diameter of 1016 millimeters and its auxiliary facilities, and one fully steam reversible steel plate rolling mill with a roll diameter of 760 millimeters and its auxiliary facilities.

motor plants. Renovation of the loading and unloading wharf on the river bank, installation of electric loading and unloading devices and a railway line. The railway in the factory area was increased from 6 kilometres to 34 kilometres. The entire expansion and renovation project lasted three years.

During this period, Daye Iron Mine opened up the Shizishan Mining Area in Dedaowan, further expanding the scale of production and increasing the output of iron ore year by year. At the same time, Japan Yawata Iron Works and Sheng Xuanhuai signed the "Coal and Iron Mutual Sale Contract", through the sale of Daye iron ore to the Japanese Iron Works, to raise funds for the Hanyang Iron Works. Although the contract was not in the nature of borrowing, it laid down the mode of capital export from Japan to Hanye Ping Company thereafter.

1.3 Merchant-run Period (1908-1937)

In order to solve the problem of insufficient funds, in 1908, Sheng Xuanhuai petitioned the court to form the Hanyang Iron Works, Daye Iron Mine and Pingxiang Coal Mine into the "Hanyeping Coal and Iron Works Co., Ltd". The company formally entered merchant-run period, with "mining, ironmaking, coal mining" as the main business. According to the joint-stock commercial operation model, it has gained more corporate vitality and gradually improved its economic benefits. Compared with the period of government-supervised and merchant-managed, The company has integrated various factories and mining enterprises, the jurisdiction of the enterprise throughout Hubei, Hunan, Jiangxi, Anhui, Jiangsu, Hebei, Liaoning provinces, to further expand the scale of production, increase the installation of machinery and equipment, and enhance the strength of industrial technology. The rapid development of the company's European engineers into the enterprise's technological innovation and production operations, the company's steel production reached 170,000 tonnes in 1910, the quality of steel broke through the previous technical deficiencies, gained the affirmation of the purchasers and assisted the company in improving the management system and production norms, formulated the Technical Standards and Acceptance Criteria for the production and manufacture of rails, and assisted China in realising the short-lived glory of the coal and iron industry.

With the outbreak of the First World War in 1914, the price of international iron and steel raw materials skyrocketed, and there was a brief boom in Hanyeping, with the production of pig iron, steel, iron ore and coal and coke increasing dramatically, and the company began to purchase some subsidiary enterprises, invested in some joint ventures, and opened a special line of water transport to ensure the company's energy supply and product output.

After the post-war world economic depression, the price of steel plummeted. Due to the severe constraints of Japanese debt contracts, Hanyeping declined rapidly. In 1921, the Republic of China (Beijing) government changed the standard of rails, which caused the company nearly 50,000 tonnes of rails with no sales, and a large number of rails were backlogged, which led to the complete shutdown of Hanyang Iron Works in 1924, and the company couldn't maintain the operation of Pingxiang Coal Mining in 1928, and it was taken over by the Jiangxi Provincial Government. Only one iron ore mine in Daye was left to continue production, and it was reduced to a supply unit of Yawata Iron Works of Japan[15]. This large-scale iron and steel joint venture was basically disintegrated at this point.

[15] Established in 1901, the steelworks located in Kitakyushu City, Fukuoka Prefecture, began operations during the Meiji era in 1903. It was Japan's second steelworks after the Tanaka Factory of the Kamaishi Mining and Smelting Company, which commenced operations in 1887 (Meiji 20) in Kamaishi City, Iwate Prefecture. Prior to World War II, it was Japan's largest steelworks, producing over half of Japan's steel output. In 2015, four assets including the former head office, repair factory, former blacksmith factory (Kitakyushu City, Fukuoka Prefecture), and the Mogagawa water source pump house (Nakama City, Fukuoka Prefecture) were designated as Japan's Meiji Industrial Revolution heritage sites. As part of the "Iron and Steel, Shipbuilding, and Coal Mining Industries" (totaling 23 sites), it was selected as a UNESCO World Heritage Site.

Fig.4: Traffic map between Hanyang, Daye and Pingxiang

2. Status of Hanyeping Industrial Heritage

The development of Hanyeping Company spanned across important industries such as coal mining, iron ore extraction, and steel smelting, exerting profound influence on multiple cities along its route, including Wuhan, Daye, and Pingxiang, from spatial landscapes to production and lifestyle patterns. As a typical representative reflecting the modern industrialization process in China, an analysis of the company's retained industrial heritage and its current status of preservation and utilization is conducted. Furthermore, the relationship between urban development and the conservation and utilization of industrial heritage is explored, delving deeper into its historical significance and cultural connotations, thereby promoting the development of urban clusters in the central region.

2.1 Hanyang Iron Works

From 1927 to 1937, the factory remained abandoned. During the period of the War of Resistance against Japan, all machinery and equipment of the ironworks were relocated to Chongqing, and the factory buildings were entirely destroyed by explosives. It wasn't until 1958, as a continuation of the history of the Hanyang Ironworks, that the Hanyang Steel Works was established on the site of the former Hanyang Gunpowder Factory. Later, the Hanyang Rolling Mill and the Hanyang Steel Works were merged into the Hanyang Steel Works.

The factory is located in the central urban area of Wuhan, bordered to the north by the Han River and to the south by the Beijing-Guangzhou Railway. The division of Qintai Avenue

creates a spatial layout of one factory and two zones[16] within the factory area. In 2000, due to the operation of Wuhan's land reserve system, the northern zone was included in the demolition scope by the government and auctioned off to the real estate developer China Resources. It was swiftly demolished and the land was reorganized.

In 2011, the Hanyang Steel Works was designated as a key construction project in the "12th Five-Year Plan" of Wuhan City. At the same time, the Wuhan Municipal Bureau of Culture established clear protection levels for the cultural relics and buildings within the factory area. With active promotion from the Wuhan municipal government, Wuhan Iron and Steel Group, in conjunction with Vanke Group, initiated the "One Museum, Two Parks" development project[17] for the factory area. During the construction of the Zhang Zhidong and Wuhan Museums by American architect Daniel Libeskind[18], Vanke[19] hoped to acquire further development rights for the factory area by purchasing land. However, the owner of the land use rights, Wuhan Iron and Steel Company[20], firmly opposed this proposal. Due to the lack of capacity and funding to develop the factory area and the government's lack of sustained updates to policies regarding the protection and reuse of the Hanyang Steel Works area, the factory area could only be utilized in an inefficient manner under the game-playing of various stakeholders. Historic buildings with cultural value could only be used as warehouses.

Currently the Zhang Zhidong and Wuhan Museum has been established around the factory, which narrates the life and achievements of Zhang Zhidong as well as his activities and influence in the Wuhan region through narrative design. They utilize a combination of physical artifacts and historical photographs related to the history of the Hanyang Ironworks and Hanyang Manufacturing for exhibition. As a result, an increasing number of people are beginning to pay attention to the significant historical importance of the Hanyang Ironworks in China's modernisation process.

The industrial buildings within the factory area are in relatively good preservation condition and generally follow the layout of the Hanyang Iron Works. The buildings are categorized based on their functions, including production facilities, storage warehouses, office buildings, and dormitories. Most of the buildings were constructed between the 1980s and 1990s. The most distinctive and well-preserved industrial heritage within the factory area is the electric furnace sub-plant converter workshop[21]. It features a red brick facade, reinforced concrete frame structure, single-story layout, with a span of 30 meters, a depth of 90 meters, and a height of 23 meters. The roof is made of prestressed large roof panels supported by truss steel structures. Additionally, there are five historical buildings with modern industrial characteristics, including the electric furnace sub-plant maintenance spare parts room, electric furnace sub-plant smelting workshop, electric furnace sub-plant production workshop, sewage treatment workshop, and industrial oxygen plant workshop. Other remnants such as water towers, chimneys, railways,

[16] The northern section of the plant is dedicated to the rolling mill area, comprising the billet mill workshop, wire mill workshop, universal section mill workshop, special-shaped section mill workshop, and transportation workshop. The southern section of the plant is dedicated to the steelmaking area, including the converter workshop, electric furnace workshop, oxygen-making workshop, and lime workshop, among others.

[17] Zhang Zhidong Museum, Creative Cultural Industry Park, Headquarters Economic Park

[18] A Polish-American architect, artist, professor and set designer. Libeskind founded Studio Daniel Libeskind in 1989 with his wife, Nina, and is its principal design architect.

[19] Vanke Corporation Limited was founded in 1984 and is a leading urban and rural construction and life services provider in China. Its business focuses on the three most dynamic economic circles and key cities in the central and western regions of the country.

[20] Established in 1955, it is the first super-large-scale steel joint venture constructed after the founding of the People's Republic of China. Completed and put into operation on September 13, 1958, it is a centrally administered state-owned key enterprise under the supervision of the State-owned Assets Supervision and Administration Commission of the State Council.

[21] Established in 1965, it was designated as a key project of Wuhan City from 1976 to 1984 and underwent two expansions during this period. Utilizing the three-phase electric arc furnace steelmaking method, it primarily produces high-quality steel. In 2011, including oxygen supply and dust removal pipeline facilities, it was listed in the first batch of industrial heritage sites in Wuhan. In 2017, it was included in the first batch of national industrial heritage sites.

industrial pipelines, and gateways collectively form the historical spatial environment of the Hanyang Steel Works.

Fig.5: Zhang Zhidong and Wuhan Museum
Fig.6: Electric Furnace Sub-plant Converter Workshop

2.2 Daye Iron Mine

During the period of Japanese occupation from 1938 to 1945, the mining area was under Japanese control, and extensive construction was undertaken, resulting in the formation of production and residential zones. It wasn't until after the liberation war that the Daye Iron Mine gradually resumed production and completed infrastructure projects such as water and electricity supply, transportation, industrial plant areas, and worker living quarters for the mine. Roads were constructed from the city to Tieshan, forming the initial grid pattern of roads within Tieshan district.

In the early 21st century, the mineral reserves in the mining area gradually decreased, prompting the government to propose the development of mining culture and tourism industries. In 2006, the Daye Iron Mine Museum was established, featuring multiple exhibitions including mineral displays, ancient mining practices, and modern mining methods, reflecting the entrepreneurial and developmental history of modern mines. In 2007, the Daye Iron Mine Park and the Tonglushan Ancient Copper Mine Site were combined to form the Huangshi National Mine Park. The park's landscape design integrated the reuse of industrial heritage from the Daye Iron Mine, greatly enhancing the public nature of the mining area. In 2012, it was selected "Huangshi Mining and Metallurgical Industrial Heritage" on the UNESCO World Heritage tentative list for China.

Currently, the main industrial relics of the Daye Iron Mine include mining remnants, constructed structures, and mining equipment. The mining remnants constitute the core landscape resources of the Daye Iron Mine, consisting of a 440-meter open-pit mine and underground mines. Constructed structures encompass factory dormitories located in urban areas and buildings in the mining area, such as fortification ruins and ore dressing workshops built by the Japanese. Mining equipment imported from Europe showcases the production process from mining to ore dressing and transportation. Due to the unique production methods in the mining area, the production and residential areas are closely linked, but the lack of spatial boundaries leads to a dispersed spatial layout of industrial heritage, preventing the formation of a systematic and complete spatial form, which is difficult to meet the current needs of urban development.

Fig. 7: Ancient Mining Scene

Fig. 8: Open-pit Mine

2.3 Pingxiang Coal Mine

In 1939, due to wartime reasons, the Pingxiang coal mine was relocated and damaged by the Nationalist Government. It wasn't until 1954 that the Anyuan coal mine resumed operations at the original site and, through renovation and expansion projects, became the largest coal mine among the seven mines under the Pingxiang Mining Bureau. Although the Pingxiang coal mine is still in operation, coal resources are showing a trend of gradual depletion.

During the construction and development of the Pingxiang coal mine, various distinctive architectural heritages were left behind, including production facilities of the coal mine and buildings from the red revolutionary era[22]. Presently, the production facility buildings mainly include mineral offices, dormitories, coal mine passages, coal mining and washing facilities, etc. The buildings from the Red Revolutionary era mainly consist of revolutionary remnants such as the Workers' Club established to lead workers, night schools for guiding workers' learning, consumer cooperatives serving workers' lives, and revolutionary sites like the Autumn Harvest Uprising[23]. In recent years, the Pingxiang coal mine and relevant government departments have been continuously engaged in the conservation of architectural heritage and have collaborated on the development of Anyuan Red Tourism, constructing a scenic area integrating industrial heritage, urban tourism, and the inheritance of the Anyuan spirit. Due to the government's emphasis on the cultural significance of the Red Revolutionary spirit, the investment and effectiveness in the construction of buildings from the Red Revolutionary era have been significantly higher than those of the coal mine production facility buildings, leading to an imbalance between the development of scenic area infrastructure and regional development.

[22] These are buildings primarily used by leaders of the Communist Party of China (such as Mao Zedong, Liu Shaoqi, Li Lisan, etc.) during the period of 1920-1921 to lead workers' production and movements at the Pingxiang Coal Mine, as well as during the guidance of the Red Revolution era.

[23] During the Land Revolution War, the Chinese Communist Party led armed uprisings by peasant self-defense forces, worker patrols, and revolutionary soldiers in the border regions of Hunan and Jiangxi provinces.

Fig. 10: Anyuan Historical and Cultural District

3. Protection and Reflection on Hanyeping Industrial Cultural Route

Based on theoretical literature on the conservation of world industrial heritage and the experiences of the European Industrial Heritage Route, combined with the practical situation of industrial heritage conservation in China, comprehensive protection of Chinese industrial heritage holds significant guiding significance. It has important foundational research value for the establishment of cultural routes for the Hanyeping industrial heritage and the corresponding development of tourism routes.

3.1 World Level

The attention to industrial heritage conservation originated from industrial archaeology in Britain in the 1950s. With the gradual rise of industrial heritage conservation and research in countries such as Germany, France, the United States, and Japan, it has increasingly become a trend in cultural heritage protection. In 1973, the first International Symposium on Industrial Monuments was held at the Ironbridge Gorge Museum in Britain. At the third International Symposium on Industrial Monuments held in Sweden in 1978, the International Committee for the Conservation of Industrial Heritage (TICCIH) was established. Entering the 1990s, with the acceleration of the post-industrial era, the position of industrial heritage in the world cultural heritage became more important. The World Heritage Committee of UNESCO entrusted the International Council on Monuments and Sites (ICOMOS) to conduct studies on various types of industrial heritage, such as "World Heritage Bridges" (1996), "Railways as World Heritage Sites" (1999), and "International Coal Mining Studies" (2002). Of particular note in international activities was the 12th International Conference on the Conservation of Industrial Heritage held in Nizhny Tagil, Russia, from July 10th to 17th, 2003. The conference formulated the "Nizhny Tagil Charter" for the conservation of industrial heritage, which became the most authoritative document on industrial heritage conservation theory and a guide for conservation activities in various countries. In October 2005, at the 15th ICOMOS General Assembly held in Xi'an, China, the theme of "International Day for Monuments and Sites" on April 18, 2006, was designated as "Protecting Industrial Heritage," marking a new stage in international industrial heritage conservation. As of 2024, there are 50 industrial heritage sites listed on the World Heritage List, distributed across 28 countries.

The concept of cultural routes in the field of cultural heritage originated from the "European Heritage Plan" in 1987. In 2005, the "Operational Guidelines for the Implementation of the World Heritage Convention" introduced the concept of cultural routes for the first time, proposing to rediscover shared heritage through tourism, promote cultural interaction, interreligious dialogue, and landscape conservation and development, thereby enhancing cultural cooperation. The emergence of cultural routes reflects the innovation and

breakthroughs in the concept of cultural heritage conservation, where cultural heritage is no longer considered as isolated "heritage points" separate from historical and natural environments. Among them, the European Route of Industrial Heritage, as the only thematic route showcasing industrial and scientific heritage, currently includes over 1,850 industrial heritage sites from 26 countries such as Germany, Belgium, the United Kingdom, France, Poland, Spain, and Italy. It has established a cultural route system composed mainly of 100 important industrial heritage anchor points, 20 regional industrial routes, and 13 European thematic routes, linking industrial heritage sites through natural and artificial geographic factors such as rivers, railways, mines, and industrial areas. With the promotion of international industrial heritage conservation organizations, more countries have formulated policies for the protection and utilization of industrial heritage, clarifying protection objectives, measures, and responsible entities, providing a solid foundation for cooperation and exchange among countries.

3.2 National Level

In 2006, the "China Industrial Heritage Protection Forum" convened by the State Administration of Cultural Heritage, along with the resulting "Wuxi Proposal," marked the formal inclusion of industrial heritage conservation and development into the national policy protection framework. In the same year, in response to the industrial heritage protection work plan, the State Administration of Cultural Heritage issued the "Notice on Strengthening the Protection of Industrial Heritage." From 2017 to 2021, the Ministry of Industry and Information Technology successively announced five batches of national industrial heritage lists, with 11 industrial heritage projects from 13 units selected. In 2018, the "Interim Measures for the Management of National Industrial Heritage" were introduced. In 2022, the "Implementation Plan for Promoting the Development of Industrial Culture" was launched. In 2023, the Ministry of Industry and Information Technology issued the "Management Measures for National Industrial Heritage," implementing General Secretary Xi Jinping's important instructions on the protection and inheritance of historical and cultural heritage, strengthening national industrial heritage management, promoting industrial spirit, developing industrial culture, and enhancing China's industrial soft power and cultural influence.

In recent years, the country has continuously strengthened its emphasis on the protection of industrial heritage, issuing corresponding protection documents and management systems. However, a complete industrial heritage management system has yet to be established, which makes it difficult to provide clear guidance for the planning, construction, and implementation of industrial heritage development and utilization projects. This situation needs to be improved to address the practical contradictions between the cultural value of industrial buildings and the scarcity of land resources.

3.3 Regional Level

In 2007, Huangshi City collaborated with Daye Iron Mine to organize the Mining and Metallurgy Cultural Festival. In 2008, the Zhang Zhidong Memorial and Hanyang Ironworks Museum initiated the commemorative seminar for the 100th anniversary of the founding of "Hanyeping Company" and the protection and utilization of "Hanyang-made" modern industrial heritage. In April 2010, the Chinese Urban Planning Society organized the "Symposium on Urban Industrial Heritage Conservation and Utilization" in Wuhan, resulting in the "Wuhan Proposal on the Conservation and Utilization of Urban Industrial Heritage during the Transition Period." The "Wuhan Master Plan (2010-2020)" explicitly proposed the need to further investigate and excavate industrial factories and blocks reflecting the modern industrial development history of Wuhan, incorporating them into the scope of historical and cultural protection as modern industrial heritage. In 2017, the Pingxiang Municipal Bureau of Culture and Tourism held a conference on the protection and utilization of Pingxiang coal mine

industrial heritage, emphasizing the significant role of industrial heritage in promoting urban transformation and tourism economic development.

In recent years, Wuhan, Daye, and Pingxiang have each introduced corresponding industrial heritage protection policies and management systems. However, due to the dispersed locations and lack of unified protection, utilization, and development policies among the three places, it has not been possible to promote regional connectivity and development. This has resulted in the collaborative form of reshaping the Hanyeping industrial heritage cultural route not yet being realized.

Conclusion

Industrial heritage, as an important component of human cultural heritage, records the trajectory and achievements of past industrial development and serves as a witness to urban history and culture. The Hanyeping cultural route, representing modern industrial heritage in China, introduced advanced Western science, technology, and machine production, spanning multiple cities and involving various smelting processes, thus exerting a significant influence on the economic and urban development of the central region. In the process of its protection and utilization, it is necessary to draw on the rich experience of European cultural routes, combined with the actual situation of industrial heritage conservation in China, to protect and preserve industrial buildings and their historical landscapes through policy guidance, planning recommendations, and design practices based on conservation principles. This transformation of industrial resources into cultural resources enhances cultural cooperation between cities, drives urban regional transformation and development, and provides theoretical references for the protection of industrial heritage in China.

Acknowledgements

I would like to express my heartfelt gratitude to my supervisor, Filippo de Pieri, for his unwavering support and academic guidance throughout the process of researching industrial heritage cases. His expertise and insights have been invaluable in shaping the direction and quality of this work. Additionally, I extend my thanks to Wang Jiayi for her collaborative efforts in providing illustrations for this paper. Working together has greatly enhanced the visual presentation of our research findings.

Research on Sustainable Protection and Inheritance of Overseas Chinese Hometown Cultural Heritage: A Case Study of Xiangshan Ancient City

Abstract
Due to its unique nature, the protection and utilization of overseas Chinese hometown cultural heritage face many practical challenges and ongoing debates. In the past, the protection of overseas Chinese hometown cultural heritage primarily focused on the material aspect and achieved significant short-term results, but it was not sustainable in the long run. Building upon the shortcomings of three previous approaches, a transformation is proposed towards a sustainable mode. Using Xiangshan Ancient City as a case study, this research analyses the sustainable potential and impact of overseas Chinese hometown cultural heritage from both the supply and demand sides. It considers both material and social aspects, covering three dimensions: people, objects, and events. Subsequently, sustainable protection and inheritance strategies are proposed, including 5 aspects.

Keywords: sustainability; overseas Chinese hometown cultural heritage; protection and inheritance; Xiangshan Ancient City

1. Introduction

Overseas Chinese hometown cultural heritage is a special category of Chinese regional cultural heritage, mainly located in the southeast coastal areas (including Guangdong, Fujian, Hainan and Zhejiang). Overseas Chinese hometown cultural heritage not only has unique value at the material space level, but also carries special cultural connotations, endowed with profound humanistic spirit and national sentiment. The overall protection of Chinese historical and cultural heritage began in the early 1980s when the first batch of national historical and cultural cities were recognized, and after four generations, the protection and restriction of the material space level have gradually matured to a certain extent, and a relatively complete system for the protection and utilization of historical cities, towns, villages, and other areas has been formed. Therefore, when heritage protection enters the 4.0 stage in China, the regeneration and sustainable utilization of historical and cultural heritage have to be considered. Focusing on the dimension of overseas Chinese hometown cultural heritage, based on years of research on the protection and utilization of historical and cultural cities in overseas Chinese hometowns, this research takes Xiangshan Ancient City in Zhongshan, Guangdong Province as an example to summarize new ideas for the sustainable protection and inheritance of cultural heritage in overseas Chinese hometowns, with a view to solving practical problems such as unclear property rights, resource mismatch, and inefficient utilization caused by neglecting sustainability in the past practices in overseas Chinese hometowns.

2. The specificity of overseas Chinese hometown cultural heritage and the typicality of Xiangshan Ancient City

2.1. Overseas Chinese culture and overseas Chinese hometown cultural heritage

Overseas Chinese culture is formed in the life process of overseas Chinese in overseas and returned countries, and it is a comprehensive culture that integrates the culture of both their ancestral homeland and their host country [1]. This cultural phenomenon can be regarded as a cultural transformation process [2]. The elements of traditional culture are redefined and shaped

in the new geographical and cultural background, forming a cross-cultural and cross-border cultural construction. Overseas Chinese culture is one of the most important components of the cultural landscape in the southeast coast of China. Protecting and inheriting overseas Chinese culture is of far-reaching significance to maintain cultural diversity, strengthen cultural identity, preserve historical memory, and promote cultural exchanges and social cohesion in overseas Chinese hometowns.

Overseas Chinese hometown cultural heritage carries the connotation of overseas Chinese culture and reflects the social activities, social relations and ideology of overseas Chinese, and is a branch of regional cultural heritage [3]. The immovable overseas Chinese hometown cultural heritage is mainly formed when the overseas Chinese promote the construction of cities and towns, such as overseas Chinese houses, factories, schools, hospitals, parks, etc. The movable overseas Chinese hometown cultural heritage is mainly formed when the overseas Chinese participate in political, economic and cultural activities, as well as in their daily lives, such as the genealogy of the overseas Chinese and the related documents, manuscripts and canonical works, etc. The intangible overseas Chinese hometown cultural heritage includes the lifestyles, religious beliefs, folk customs, and values of overseas Chinese.

From the urban and rural spatial dimension, the overseas Chinese hometown cultural heritage hometown is mainly distributed in historical cities and traditional villages. In recent years, the overseas Chinese hometown areas have paid more attention to rural revitalization, so previous research has focused more on traditional villages in overseas Chinese hometowns, with insufficient attention paid to the study of ancient cities in these areas. As the spatial pattern, industrial structure, land use and population differentiation of the ancient cities are quite different from those of traditional villages, whether the research conclusions can be applied still needs further exploration. In addition, the traditional protection and utilization model limited to material space in the past has shown remarkable results in a certain space and time range, but this effect is limited and unsustainable. This mode relies heavily on government finance and ignores the subjectivity of private forces [4], thus losing the long-term sustainable power of cultural heritage protection and inheritance in overseas Chinese hometowns. In conclusion, this research takes the ancient city in overseas Chinese hometowns as the main research object, and analyses its dynamic protection and inheritance based on the sustainable perspective.

2.2. The Great Xiangshan Cultural Circle and Xiangshan Ancient City

2.2.1. Xiangshan Culture and the Great Xiangshan Cultural Circle

From a geographic perspective, the Xiangshan culture refers to a special regional culture formed in Zhuhai, Zhongshan and Macao, where the history and culture of these three areas have the same roots, forming the Great Xiangshan Cultural Circle. The conceptual connotation of Xiangshan culture is intertwined with but different from "Lingnan culture" and "Pearl River culture", etc. The core and soul of Xiangshan culture is the fusion saltwater and freshwater civilizations. On one hand, centrally reflects the cultural characteristics of the three major ethnic groups in Lingnan culture, namely, Guangdong, Fujian and Hakka. On the other hand, as a typical immigrant society constantly absorbing foreign cultural inputs, multiple cultures collided and exchanged, transformed and upgraded, and demonstrated the cultural spirit of openness and communion. The social and cultural network of the Xiangshan region is intricate but strong and powerful, laying down the tone of the highly open and inclusive Great Xiangshan Cultural Circle.

2.2.2. Typical significance of Xiangshan Ancient City

Xiangshan Ancient City is located in Zhongshan, Guangdong Province, which is the hometown of the great man Dr. Sun Yat-sen and was approved as a National Historical and Cultural City in 2011. In the 22nd year of Shaoxing in the Southern Song Dynasty (1152 AD),

Xiangshan was established as a county, and its original territory included the present-day Zhongshan, Zhuhai, Macao, as well as parts of Panyu District in Guangzhou and Shunde District in Foshan. The scope of Xiangshan Ancient City is from Yixian Lake in the north to Baishi Creek in the south, from Lianfeng Mountain in the east to Shiqi River in the west, a total of 2.42 square kilometers (Fig. 1).

Since ancient times, the Xiangshan region has been one of the most active areas in China in terms of foreign trade and immigration, and it is also one of the most concentrated areas in China in terms of the distribution of overseas Chinese. Since the establishment of Xiangshan County, Xiangshan Ancient City as the birthplace of Xiangshan culture, has always been the political and economic center of Xiangshan region, and also retains a large number of overseas Chinese hometown cultural heritage. Therefore, this research takes Xiangshan Ancient City as a typical case, and analyses the protection and inheritance paths and strategies of overseas Chinese hometown cultural heritage for sustainability.

Fig.1. The scope of Xiangshan Ancient City

3. Realistic dilemmas and sustainable transformation in the protection of overseas Chinese hometown cultural heritage

3.1. Previous coping models

In the actual protection practice, the interests of all parties are often intertwined and complicated, which makes the implementation effect and theoretical research diverge from each other [4], causing a wave of reflection on the heritage protection in recent years. According to the protection route of the overseas Chinese hometown cultural heritage hometown for more than 40 years since China's reform and opening-up, three modes could be summarized (Tab. 1). One is the traditional mode (Mode T), which takes the sample type and static protection as the guide to fix the overseas Chinese hometown cultural heritage in a certain historical period and cultural form; The second is the destruction mode (Mode D), which tends to follow economic interests and carry out low-quality renovation, demolition and construction; The third is the passive mode (Mode P), which maintains the original state but allows its overall decline and the people to live in poverty. There are certain practical problems in the actual implementation of the above three coping modes, which leads to the difficulty in reconciling the contradictions

between the "reformers" and the "fixers" involved in the protection and utilization of the overseas Chinese hometown cultural heritage [5].

Tab.1. Previous three coping modes

Mode	Characteristics	Advantages	Problems
Mode T	specimen-based, static protection	Apply to a small number of original buildings with specimen value, so that they become the original material carriers of cultural memory.	Extreme dependence on local government finances has resulted in a degree of resource mismatch.
Mode D	Low-quality renovation, major demolition	In the short term, it will stimulate local economic development, increase local financial income and slightly improve the quality of the human environment.	Irreversible damage will be caused to heritage resources; a large amount of "antique garbage" may be produced, leading to excessive commercialization.
Mode P	General decline, a mass impoverishment	In the short term, heritage resources can be preserved without burdening local revenues.	Allowing precious heritage resources to decline will result in the disappearance of historical values, the loss of traditional craftsmanship and local cultural memories.

3.2. Realistic dilemmas and sustainable transformation

After more than 40 years of practical exploration on the protection and utilization of overseas Chinese hometown cultural heritage, it is obviously unrealistic to adopt the T model to completely protect and repair, which also imposes a burden on government finance and regional development [6]. In the process of improving the system construction, supervision and control of historical and cultural heritage in China, in recent years, Mode D has also been alerted by all regions, gradually rectified and banned. Therefore, in the current context, the hometown of overseas Chinese is forced to adopt Mode P to passively cope with the large amount of overseas Chinese housing resources. Based on the above background, the author proposes that the sustainable protection and inheritance of overseas Chinese hometown cultural heritage hometown should be considered in the protection 4.0 stage. With the help of the application of new technology and institutional construction, changes should be realistically controlled rather than prevented from evolution, so as to achieve a dynamic balance between cultural inheritance and social needs in the process of protection and utilization, and form a sustainable mode (Mode S), Finally, an innovative model led by the Mode S and driven by Mode T will be formed, and this change in the concept of sustainable heritage protection will also become the key to breaking through the bottleneck and creating value in the future of overseas Chinese hometown cultural heritage protection and inheritance.

4. Exploration of sustainable protection and inheritance practices of overseas Chinese hometown cultural heritage: taking Xiangshan Ancient City as an example

4.1. Paths of sustainable protection and inheritance

According to the above analysis, it can be seen that the effectiveness of the static specimen-type heritage protection mode is extremely limited, while the sustainability-oriented heritage protection and inheritance is continuous, stable and broadly inclusive. In order to solve the practical dilemma, this research takes Xiangshan Ancient City as an example to conduct an empirical study, and analyses the sustainable potentials and sustainable impacts of overseas Chinese hometown cultural heritage from both the supply side and the demand side, respectively, and puts forward the corresponding strategies of sustainable protection and inheritance (Fig. 2).

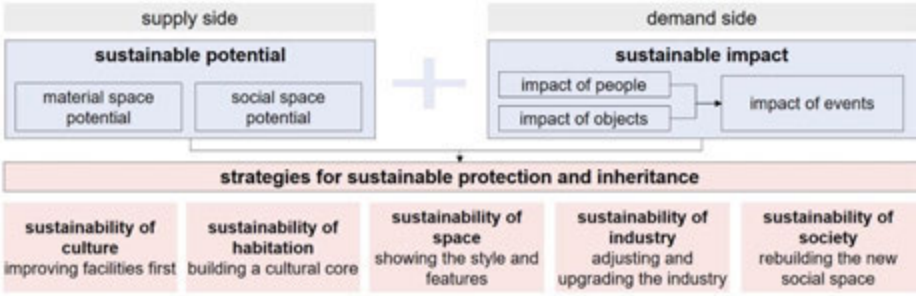

Fig.2. Path of sustainable protection and inheritance of overseas Chinese hometown cultural heritage

4.2. Analysis of sustainable potential

Based on the comprehensive consideration of both material space and human needs, this research analyses the sustainable potential of overseas Chinese hometown cultural heritage from two levels. The potential of material space is "tangible", while the potential of social space is "intangible", which are closely intertwined and intuitively oriented to the sustainable preservation and inheritance strategy of overseas Chinese hometown cultural heritage.

4.2.1. Material space potential

1. The integrity of the city pattern

"Xiangshan County Local Gazetteer" records the construction of rammed earth city walls during the Song Dynasty, which is also the earliest record of the city construction in Xiangshan Ancient City. Based on the street and alley names listed in the *"Zhongshan Gazetteer"* during the Song Dynasty, combined with the length of the city wall recorded in the *"Xiangshan County Local Gazetteer"* (approximately 1425 meters), it is estimated that the location of the Song Dynasty city wall was around the vicinity of today's Renhouli, Shoushanli, and Qixing-Chudi. (Fig. 3).

In the 26th year of the Ming Dynasty (1393 AD), Chen Yu, the defender of Xiangshan County, expanded the city on the basis of the old county seat and built a new brick castle, while the earthen castle built in the Song Dynasty was changed into a military camp. Since then, it had been repaired several times. Compared with the Song Dynasty, the perimeter of the wall during the Ming Dynasty expanded from about 1425 meters to about 2117 meters; west half of the wall location can be calibrated according to the 1933, 1959 Xiangshan County map, the east half of the wall can be identified according to the 1911 Xiangshan County map, presumably the location of the Ming wall in today's Pasha Street, Xiaojiaochang street, Gongjian Alley, Zhian Street, Changtai Street, Fangta Street, and Shanghebo (Fig. 3). There were four gates in total. The south gate was called Fumin Gate, which was located approximately between the intersections of Zhian Street and Changtai Street; the west gate was Dengying Gate, situated roughly between the foot of the Xishan Mountain and the intersection of Minzu Road; the east gate was Qixiu Gate, situated near the post office on Sun Wen Middle Road; and the north gate was Gongchen Gate, located approximately at the Banyan Tree intersection of Taiping Road and Gongchen Road.

Fig.3. Speculation of the location of the city wall

2. The uniqueness of the ancient cityscape

Due to the integration of functions such as trade and education, four closely connected areas (Guanxiang) - east, west, south, and north - gradually formed outside the ancient city, maintaining close ties with the main city. These four Guanxiang areas are vast, covering a much larger area than the main city, thus forming the unique city layout of "small city and large Guanxiang" in Xiangshan Ancient City (Fig. 4).

During the continuous development of Xiangshan Ancient City, the four Guanxiang areas gradually evolved into urban spaces with different functions and characteristics. The West Guanxiang embodies the characteristics of commercial culture, the South Guanxiang represents the clan culture, the East Guanxiang showcases the educational culture, and the North Guanxiang manifests the folk culture. The division of labor and functions among these four Guanxiang areas complements the main city.

Fig.4. The layout of "one main city and four Guanxiang areas"

3. The wisdom of urban planning that harmonizes with nature

The site of the ancient city is located in the north of Wugui Mountain, near the river, which is a natural harbor and can avoid the wind and waves. It is located to the east of Qi River but not close to it, with Yandun Mountain and Lianfeng Mountain to the north, reflecting the practical principles in *"Guanzi"*. The terrain slopes from north to south, with the Jiuqu River

winding past the southern outskirts, creating an overall pattern of "facing the sun and backed by shade.".

In addition to the "Jiuqu River Surrounding the City", the "Seven-Star Peaks Guarding Renshan Mountain" is an even more unique landscape pattern that existed since the inception of the city's construction. According to the "Xiangshan County Gazetteer," the selection of the city's location was based on the formation of the Big Dipper from ancient Chinese astronomical systems, embodying the simple planning ideology of imitating the heavens and following the laws of nature. There were originally 8 mountains within areas, and the landscape pattern was basically intact. Yingshan Mountain, Fushan Mountain, and Phoenix Mountain have been flattened, while Shoushan Mountain and Yingshan Mountain are now the locations of the Radio and Television University. Renshan Mountain is the site of the Sun Yat-sen Memorial Hall, and Yueshan Mountain and Xishan Mountain still serve as mountain parks (Fig. 5).

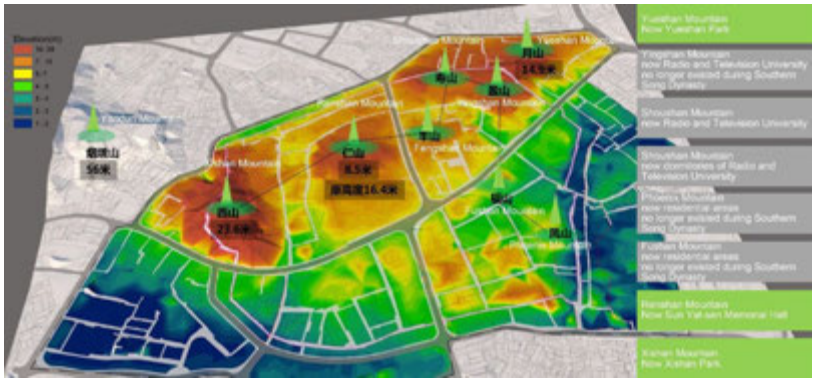

Fig.5. The location of "Seven-Star Peaks Guarding Renshan Mountain"

4. The exemplary nature of modern construction

On April 15, 1925, Xiangshan was renamed Zhongshan in honor of Dr. Sun Yat-sen. Under the convergence of Chinese and Western cultures, Zhongshan has developed a relatively complete urban planning concept, especially during the period when Zhongshan was recognized as a national "model county" in 1929, which supported its large-scale construction and renovation campaign, both economically and politically. Zhongshan's campaign was spearheaded by the plan of "building new roads and constructing the county town", which built the urban skeleton of modern Zhongshan city. As the county town of Zhongshan city, Xiangshan Ancient City has preserved the complete arcade streets and public facilities built during the Republic of China period (Fig. 6), which centrally reflects the construction achievements of the "model county" during the Republic of China era.

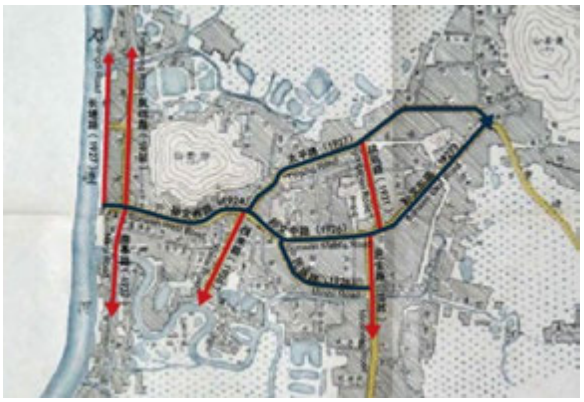

Fig.6. Construction time and location of 10 roads during the Republic of China

5. The exemplary character of the overseas Chinese hometown architecture

Under the combined influence of the traditional culture of the ancestral homeland and the overseas culture of the expatriate countries, the architecture in Xiangshan Ancient City also exhibits a unique fusion of traditional Chinese style and Western and South Asian styles. The proportion of architectures from the Republic of China and before is about 26%, including towers, temples, pawnshops, traditional dwellings (Lingnan houses, bamboo tube houses) from the Qing Dynasty and before, as well as schools, churches, theaters, hospitals, factories, libraries, arcade shops, merchant houses and western-style dwellings from the Republic of China period (Fig. 7).

The architectural styles in overseas Chinese hometowns are diverse, and the most representative architectural styles are Western-style mansions, arcades, etc. The Western-style mansions often appear in the form of multi-story overseas Chinese residences or cottages, with two stories being the most common, and some extending to three or four stories. The arcade buildings are narrow and deep inside, resembling bamboo tubes, and are commonly known as "bamboo tube houses." They often appear in a single plane form, or in combinations of two or more. The facade along the street usually includes Manchu windows, colored glass windows, balcony railings with elaborate patterns, elaborate pediments, etc. The roof often combines a flat roof with a pitched roof.

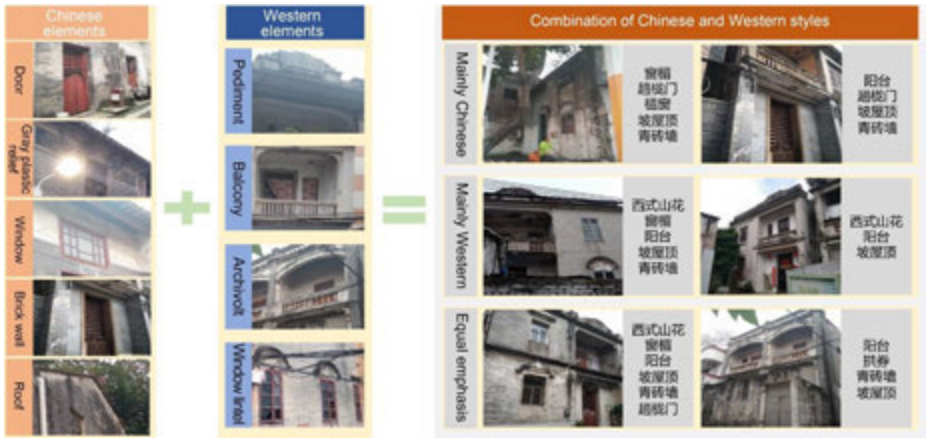

Fig.7. Style and elements of overseas Chinese hometown architecture

4.2.2. Social space potential

1. The leadership of celebrity culture

Since the Ming and Qing dynasties, Xiangshan Ancient City has nurtured many talents due to its special geographical location and cultural and historical environment. A group of modern celebrities in Zhongshan, represented by Dr. Sun Yat-sen, had changed the course of Chinese history and promoted the modernization of China. For example, Zheng Guanying, the earliest theorist, enlightenment thinker, and industrialist with a complete reformist ideology in modern China; Zheng Zaoru, the first Chinese ambassador to a foreign country; Rong Hong, the "father of modern overseas students" in China and the pioneer of Chinese compradors, all of them had a significant impact on Dr. Sun Yat-sen's revolutionary thoughts.

2. The richness of Xiangshan culture

Under the evolution of the vicissitudes of life, the local Lingnan culture has fused with the Central Plains culture from immigrants, the Western culture and the Southeast Asian culture from overseas, developing in harmony and coexistence, thus forming the unique Xiangshan culture. The diverse folk culture, the hybrid overseas Chinese culture integrating Chinese and Western elements, the commercial culture that connects the world, the philanthropic culture of universal love and mutual assistance, and the illustrious celebrity culture are all important components of Xiangshan culture. The modern openness and enlightenment of thoughts have made Xiangshan culture a trendsetter, with characteristics of diversity, inclusiveness, openness, and leadership, and profound modern value.

4.3. Analysis of sustainable impact

The sustainable impact of overseas Chinese hometown cultural heritage is intuitively reflected in the "material" aspect of material space and the "people" aspect of social space. Meanwhile, the spatial composition of "material" and the complex and diverse factors of "people" directly affect the implementation of "events" [7]. Therefore, based on comprehensive consideration of material elements and human needs, this research analyses the most urgent and direct influencing factors for the sustainable protection and inheritance of overseas Chinese cultural heritage from the three perspectives of people, objects, and events.

4.3.1. The impact of people

As more and more attention is being paid to historical and cultural heritage, the overseas Chinese hometowns, especially the majority of areas within and around ancient cities, have gradually become "regularized" and focused on the material space level [8]. Some historical buildings that have been officially recognized have been restored, a large number of old buildings and illegal structures that do not conform to the traditional style have been demolished, and many alleys and lanes have been gradually renovated. This has achieved a certain degree of environmental improvement and enhancement of the overall style of the ancient cities.

In the past, the protection and utilization of overseas Chinese hometown cultural heritage generally focused on the transformation of the material space level, but neglected the governance of the social space level, which also directly led to the gradual loss of the "social autonomy" of the civil power in the process of participating in the protection of overseas Chinese hometown cultural heritage [9]. In the 1980s and 1990s, for example, many overseas Xiangshan groups set up their own social organizations, returned to the ancient city to visit their roots, financed the renovation of their ancestral houses, built public services, and assisted those with the same surname who had difficulties in their lives, but such positive initiatives are now

diminishing. This also indicates that in the past, the bottom-up, self-organized private forces of the overseas Chinese townships in the process of formalizing the protection have been exhausted, the platform for private forces to shine is shrinking dramatically. Due to the lack of capital or formal authority, private forces can only be eliminated in the game with government entities.

4.3.2. The impact of objects

architectural heritage in overseas Chinese hometowns is a very important part of the overseas Chinese hometown cultural heritage. Among them, the protection of Overseas Chinese houses is currently the most tangled in the protection practice. Overseas Chinese houses refer to buildings whose property owners are overseas Chinese, foreign nationals of Chinese origin, returned overseas Chinese, or relatives of overseas Chinese. Although a large number of overseas Chinese houses are privately owned, the property owners, due to their long-term residence overseas, are unable to fully enjoy the right to possess and use these houses [10]. And with the passage of time, it is even impossible to get in touch with the property owner and his or her descendants. Overseas Chinese houses exhibit characteristics such as the separation of property owners from their properties in different countries due to the dispersal of property rights, as well as complex property inheritance. The unclear property rights can also lead to uncertainty in rights, responsibilities, and interests, triggering a series of property issues [11]. Due to the complexity of property rights, the government's efforts in protection work are often hampered. Although these overseas Chinese houses possess distinctive value and characteristics, they often face issues such as long-term vacancy, disrepair over the years, dilapidation, potential collapse hazards, and poor surrounding environments.

According to existing data, the total floor area of overseas Chinese houses within Xiangshan Ancient City reaches 134000 square meters, accounting for approximately 7.7% (Fig. 8). Most of these overseas Chinese houses were built during the Republic of China era and are an important part of the traditional architecture within the ancient city. Approximately 7% of these overseas Chinese houses are classified as protected buildings, about 31% are recommended for protection, and the remaining approximately 62% are traditional-styled architecture. However, due to disrepair over the years, many of these overseas Chinese houses have sustained varying degrees of damage and collapse, posing significant safety hazards. About 38% of them fall into the third and fourth quality categories. The ancient city is rich in overseas Chinese housing resources, but currently, most of the personnel responsible for their protection are elderly and officials, who can only conduct routine maintenance and cleaning of a small number of key houses. The protection and revitalization of overseas Chinese houses is urgent and requires immediate investment in funds, manpower, and intellectual resources.

Fig.8. Distribution of overseas Chinese housing

4.3.3. The impact of events

During the period of China's reform and opening-up, Zhongshan was at the forefront of institutional reform, opening up to the outside world, and attracting investment, etc. Relying on the "three to one complementary" industry, Zhongshan has become a representative of the development of cities in Guangdong and even in the whole country, and has become one of the "Four Little Tigers of Guangdong". As the political, economic and cultural center of Zhongshan, Xiangshan Ancient City has produced famous brands and has a good industrial foundation.

However, at present, the distribution of industries within the ancient city is relatively chaotic, and cannot effectively combine with the historical and cultural space, and the development of industrial integration is insufficient. The development and utilization of overseas Chinese cultural resources failed to form a whole industry chain, branding production and management, such as overseas Chinese architectural resources, overseas Chinese specialties and food, failed to be transformed into differentiated and competitive quality cultural and tourism resources. At the same time, Xiangshan Ancient City also has some common problems faced by other ancient cities, which further lead to the obstruction of industrial development, such as the quality of the human environment needs to be upgraded, the lack of display of core cultural characteristics, the aging population and the lack of vitality in the development of the area.

4.4. Strategies for sustainable protection and inheritance

The above research analyses the sustainable potential and impact of Xiangshan Ancient City from the supply and demand sides. Based on this, this research focuses on sustainability with "people" as the core, considering both material space and social space, and develops a strategy for the sustainable protection and inheritance of overseas Chinese hometown cultural heritage from five dimensions: culture, habitation, space, industry, and society.

4.4.1. Sustainability of culture

With the change of history, Macao has become a special administrative region and Zhuhai has become a special economic zone, therefore, under the new situation, Xiangshan Ancient City should adhere to and inherit the traditional elements of the Xiangshan culture and make it more colorful [12], and to make the Great Xiangshan Cultural Circle more vibrant and powerful.

At the regional level, to build a regional cultural framework of "one core, three centers, one belt, one road and many points" (Fig. 9), and to shape a regionally competitive and unique cultural image. At the ancient city level, the first priority is to maintain the traditional spatial layout (Fig. 9); the second is to clarify the cultural heritage resources of the ancient cities and form a relatively complete system for cultural heritage exhibition and utilization (Fig. 10); and the third is to focus on promoting the protection and utilization of the architectural heritage in overseas Chinese hometowns and continue to promote the protection and restoration of overseas Chinese houses.

Fig.9. Spatial pattern of Xiangshan Ancient City

Fig.10. Display system of cultural symbols throughout the city

4.4.2. Sustainability of habitation

According to the past practice of visiting and researching, the residents in the ancient cities in overseas Chinese hometowns often do not comment on the heritage protection work, and even have a certain degree of resistance, the most critical factor is that the heritage protection and utilization work has not been carried out with the consideration of solving the pain points of people's livelihoods, especially the simultaneous promotion of the infrastructure and the enhancement of the living environment. Take Xiangshan Ancient City as an example, it needs to be upgraded in terms of land structure, population development, facility supply, public space, municipal transportation and living environment.

Therefore, in order to realize the sustainability of Xiangshan Ancient City, the protection work should also take into account the improvement of the living environment, which generally includes six aspects: infrastructure upgrading, improvement of public service facilities, decongestion of non-ancient city functions, governance of backstreets and alleys, classified renovation of buildings, and restoration of landscape environment. Guided by the principle of "comprehensive improvement" and centered on "people" [13], priority should be given to facilities, leaving no weaknesses behind.

4.4.3. Sustainability of space

By locally restoring the ecological and cultural space of the historical Xiangshan Ancient City [14], we aim to promote functional transformation and build an integral system of highlighting the mountains, brightening the water, constructing the city, expanding the lake, and rejuvenating the streets (Fig. 11).

Highlighting the mountains means to protect the circular texture pattern of the Yandun Mountain, restore historical memories, transform the three entrance spaces of Yandun Mountain, restore the park by combining with the Kanggong Temple site, and construct a cultural and creative arts block along the bank of Qijiang River and at the foot of Yandun Mountain.

Brightening the water refers to the restoration of the Jiuqu River, the improvement of the landscape on both sides, and the revitalization of Zhongshan's first electric plant (Diguang Electric Light Plant). We will renovate Yonganfang to form a refined and lively block characterized by water town style.

Constructing the city means to take the ring road of the Ming Dynasty city wall of the Xiangshan Ancient City as the starting point to renovate the seven historical areas along the route.

Expanding the lake means to relocate Guangming Market and move wholesale and logistics functions to other areas. The Yixian Lake will be expanded, and the Hougang Stream will be restored to connect with the Qijiang River and the Yixian Lake, forming a diversified space of water dock.

Revitalizing the streets means proposing plans for facade renovation and business updates, taking the arcade-style streets such as Sunwen West Road and Taiping Road as examples. The goal is to create an external showcase for the historical urban area and foster an open-air living district with the charm of urban life.

Fig.11. Overall style and feature system of Xiangshan Ancient City

4.4.4. Sustainability of industry

There are a large number of vacant public houses and overseas Chinese houses in Xiangshan Ancient City, so on the basis of resource mapping, repair and remediation, further consideration should be given to the revitalization and utilization of these architectural heritage. The promotion of rent through the upgrading of the industry can not only improve the reality of insufficient funds for the protection of heritage, but also help to promote the localization of employment, so that manpower, intelligence and capital will flow back to the local area [15], thus restoring the vitality and attractiveness of the ancient city.

Firstly, promote the reuse of public housing. First of all, for vacant public housing, such as the former municipal party committee building, workers' cultural palace, Sihao Hotel, Hongqi Cinema, Zhongshan Department Store, etc., we will conduct unified planning and introduce new industry forms. In addition, we will promote the construction of demonstration areas for the utilization of public housing, select public housing clusters to collect and store sandwich houses, adjacent houses, etc., and promote the overall renovation and reuse of contiguous public housing. Finally, we will implement the relocation of government-subsidized housing in a distributed manner.

Secondly, improve the current industry type. At present, the overall industry type in Xiangshan Ancient City is relatively low-end, especially the Sunwen West Road, which is the most concentrated historical resources and the most prominent historical value characteristics in the ancient city. At the same time, the vacancy rate of the second and third floors and the rooftop is very high, and the business activity is not enough for most of the arcade streets in the ancient city. In view of the above analysis, the promotion of the industry type of Xiangshan Ancient City should give priority to the development of cultural industry types and time-honored brands, so as to form the complex industry model.

4.4.5. Sustainability of society

The protection and inheritance of overseas Chinese hometown cultural heritage for sustainability emphasizes the construction of overseas Chinese social space, pays attention to the intricate but powerful social network relations in overseas Chinese society, strengthens the emotional connection of overseas Chinese, their descendants and residents to the overseas Chinese region and overseas Chinese hometown cultural heritage, and reconstructs the "new social space".

One of the most prominent cultural features of Xiangshan region is its large number of overseas Chinese and returned overseas Chinese, numerous overseas Chinese-funded enterprises, numerous overseas Chinese donation projects, many pioneers of modern and contemporary overseas Chinese, and a wealth of cultural heritage related to overseas Chinese [16]. From the perspective of social space, to achieve sustainable protection and inheritance of overseas Chinese hometown cultural heritage within Xiangshan Ancient City, there are three core strategies.

Firstly, "gathering overseas Chinese through history" means fully understanding the uniqueness of overseas Chinese culture and deeply grasping its special spiritual connotations and characteristics of the times. Secondly, "using overseas Chinese as a bridge" involves promoting the construction of a network of building owners in overseas Chinese hometowns, leveraging new technologies, methods, and platforms to establish a relatively complete network system for building owners in overseas Chinese hometowns, and resolving the conflict of scattered property rights of architectural heritage. Thirdly, "nurturing overseas Chinese with overseas Chinese" involves organizing activities, strengthening propaganda and exchanges, and consolidating the hearts and strengths of overseas Chinese to attract their investments. This enhances the local identity of overseas Chinese and their descendants towards their hometowns. Meanwhile, it provides residents of overseas Chinese hometowns with a "stage" for social activities to make a contribution [17], bridging the trust gap between residents, between residents and the government, and strengthening their sense of belonging, identity, and cultural confidence towards the ancient city.

5. Conclusions

This research explores the protection and inheritance of overseas Chinese hometown cultural heritage from the perspective of sustainability, considering both material and social dimensions. This shift in approach is a reflection on the practical difficulties faced by the

protection of cultural heritage in the past. It not only enhances and improves the protection system for overseas Chinese hometown cultural heritage, but also represents a historic leap and transformation from traditional protection methods in China. Focusing on practical research in the protection of cultural heritage, although this research cannot be directly translated into relevant theoretical methods, it still provides a certain reference and basis for overseas Chinese hometowns that are currently facing difficulties in practical protection and utilization.

Abstract: Highly condensing the value and characteristics of urban and rural historical and cultural resources in Qinghai is crucial for building a preservation system. This study, focusing on Qinghai, excavates its value themes and summarizes its historical development's core values. Leveraging geography, history, and GIS, it analyzes cultural origins, lineages, and theme condensation. Integrating planning, heritage, and spatiotemporal development, 27 value features are extracted from politics, economy, society, science, culture, and geography. Ultimately, Qinghai's "Four Area" core value is condensed. This study aims to offer insights for recognizing the province's urban and rural cultural value and utilizing cultural heritage.
Keywords: Historical Culture, Historical Culture Protection and Inheritance System, Qinghai Province, Value Condensation

1. Introduction

Excellent traditional Chinese culture is the crystallisation of the wisdom and essence of Chinese civilisation, and is the root and soul of the Chinese nation. The urban and rural historical and cultural heritage of China carries the genes and bloodline of the Chinese nation, contains the great creativity, outstanding wisdom and common memory of the Chinese people, and is a powerful testimony to the continuity, innovation, unity, inclusiveness and peacefulness of Chinese civilisation. In the context of the new era and new journey, the cause of China's urban and rural history and culture protection and inheritance is currently experiencing its most favourable period of development in history, which is also the most critical period.

The systematic protection, utilisation and inheritance of historical and cultural heritage in urban and rural construction is of great significance to the continuation of the historical lineage, the promotion of high-quality development of urban and rural construction, the firming up of cultural self-confidence, the building of a strong socialist cultural country, and the realisation of the great rejuvenation of the Chinese nation in a comprehensive manner by means of Chinese-style modernisation. It is of great importance for Qinghai to explore and construct an urban and rural historical and cultural protection and inheritance system that can fully reflect the characteristics and lineage of Chinese civilisation development. Furthermore, it is vital for the province to research the value system with the province as a unit. This is because it is essential for Qinghai to be able to tell a good Chinese story on the cultural lineage of the whole country.

As a province with a diverse ethnic population, Qinghai has amassed a wealth of historical and cultural legacies, encompassing a multitude of styles and hues, over the centuries. These invaluable resources serve as a vital foundation for the formation of a unified Chinese identity and the safeguarding of the country's ecological integrity. The cultural value of the Qinghai region should be viewed in the context of the complete picture of China, which will be more magnificent and profound. This will have positive value and significance to the understanding of the development pattern of the region, and to the perception of the laws and trends of regional exchanges nowadays and even in the future.[1]

Currently, China's large-scale regional historical and cultural protection is in its nascent stages of development. Currently, the framework for a national urban and rural history and culture protection and inheritance system is being developed, with all provinces and municipalities taking the initiative in this regard. Cities and counties have implemented local responsibility for protection and inheritance work, and a three-level management system for urban and rural history and culture protection and inheritance is gradually being established. Nevertheless, it is necessary to reinforce the integrity of the national-provincial-municipal protection and inheritance system. The province's urban and rural historical and cultural protection and inheritance work lacks sufficient overall coordination and upward and downward linkage. A significant number of urban and rural heritages continue to exist that have not yet been included in the protection list.[2] Furthermore, heritage resources that reflect the historical memories and important cultural values associated with the 100th year of the founding of the Communist Party of China (CPC), the 70th year of the founding of New China, and the 40th year of the Reform and Opening-up period have yet to be fully explored and protected.

This study focuses on Qinghai Province in the context of China's national historical and cultural protection and inheritance system. It employs the principle of "value-based", emphasises multi-level, multi-faceted and continuity, and focuses on the main research line of vein sorting, heritage excavation, value condensation and system construction. The objective is to systematically sort out and excavate the historical stories, cultural values and spiritual connotations of Qinghai. The study analyses the natural and social contexts and the overall dynamic change process of Qinghai's historical and cultural space. It also conducts deeper interpretation and excavation of the historical and cultural connotations and values. Based on the value carrier, a future-oriented, large-scale historical and cultural value system is constructed for the purpose of historical and cultural protection and inheritance in urban and rural areas of Qinghai Province. This system provides ideas for the current cognition of the value of provincial urban and rural historical and cultural characteristics and cultural inheritance and utilisation.

2. Foundations and strategies for building a provincial historical and cultural value system

2.1 Core tasks of provincial historical and cultural preservation and inheritance in the new era

In the context of the new era, the protection and inheritance of historical and cultural resources is of particular importance. The core task is to clarify the three major issues of "what to protect, who to protect, and how to protect", and to focus on the construction of a perfect system of protection objects and a system of management systems.

Firstly, all kinds of historical and cultural heritage should be protected in a systematic and complete manner. A comprehensive census and sorting out will establish a map of the current status of historical and cultural resources in urban and rural areas of the province, as well as the implementation of protection measures. This will result in the formation of a unified database of the province's protection list, ensuring that historical and cultural resources are protected in a comprehensive and effective manner.[3]

Secondly, the revitalisation and utilisation of historical and cultural resources will be strengthened. It is of the utmost importance to conduct in-depth research and analysis of the

historical and cultural values and spiritual connotations inherent in all forms of historical and cultural heritage. This knowledge must be integrated into urban and rural construction, with the objective of promoting the preservation by use of historical and cultural resources. [4]Furthermore, the integration of preservation with use is essential to ensure that historical cultures continue to flourish in the modern
era.

The third and final step is the establishment of a comprehensive management system for the protection and transmission of historical and cultural resources. It is necessary to implement a hierarchical management system, to clarify the responsibilities of governments and authorities at all levels, and to strengthen the coordination capacity at the provincial level and the implementation capacity of cities and counties.[6] This will ensure that the protection work is carried out in an orderly manner.

In addition, five key tasks must be completed in the context of provincial historical and cultural protection and inheritance planning, as shown in Figure 1. These include determining values, types, patterns, themes and standards. By determining the value and characteristics of cultural resources, the foundation for protection and inheritance is established. The types of historical and cultural resources are identified, thereby ensuring the comprehensive coverage of the entire region and its constituent elements. The spatial pattern of protection and inheritance is determined, and The structural requirements for protection are proposed, the theme of display and interpretation is determined in relation to the historical and cultural values and characteristics of the province, and the standards for the work of cities and counties are established in order to ensure that protection and inheritance work is implemented in an appropriate manner.

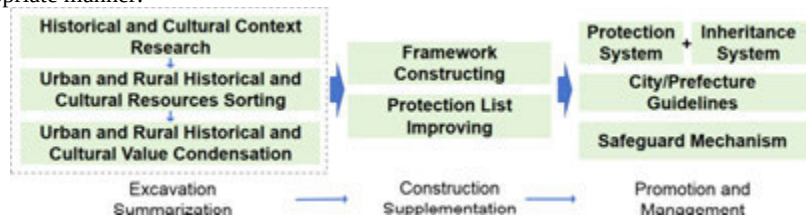

Figure 1 General Framework of Qinghai Urban and Rural Historical and Cultural Protection and Inheritance System

2.2 Provincial Historical and Cultural Value Refinement and System Construction Strategy

The implementation of the requirements set forth by General Secretary Xi Jinping in his "three favourable aspects" directive. In order to fulfil the requirements of "being conducive to highlighting the historical and cultural values of Chinese civilisation, reflecting the spiritual pursuits of the Chinese nation, and presenting a comprehensive and authentic picture of ancient and modern China to the world", it is necessary to distil the value elements and key messages, and condense the core values.

The value system is derived from the overall development of Chinese civilisation, taking into account the historical, cultural, spiritual and contemporary aspects of Chinese civilisation. The research framework of the National System of the Ministry of Housing and Construction was employed, with the five historical stages of 5,000 years of ancient civilisation, 180 years of modern history, 100 years of the founding of the Communist Party of China (CPC), 70 years of

the founding of the New China, and 40 years of reform and opening up serving as the basis for the comprehensive sorting out of the historical and cultural development lineage and the condensation of the core values.

Systematically study the historical and cultural values of urban and rural areas from a multi-dimensional perspective. In the process of constructing the historical and cultural value system, Fernand Braudel's holistic view of history was introduced. This was subsequently deployed by General Secretary Xi Jinping in the report of the 19th CPC National Congress, in which he outlined the overall pattern of "comprehensively advancing the construction of economy, governance, culture, society and ecological civilisation". Similarly, historian Huang Renyu introduced the overall pattern of "promoting economic construction, governance, culture, society and ecological civilisation" in the aforementioned report. The overall pattern can be described as follows. Historian Huang Renyu proposed that history is the need to analyse the whole long period of time. He argued that history is not an isolated event, but rather that there are intrinsic laws and connections. In order to grasp the micro-objects, it is necessary to focus on historical structural changes and long-term development trends. This approach allows one to reveal the laws of history and the concept of big history. Furthermore, the Ministry of Housing and Construction's "national system" research, which established the "five categories" (political, economic, social, scientific, technological and cultural, geographic), and the "fifteen themes" (state power, Institutional civilisation, national rituals, agricultural economy, handicrafts and industrial development, The framework encompasses trade and commercial exchanges, social organisation, ethnic integration, ideology and culture, religious beliefs, literature and art, science and technology, cities and architecture, natural geography and humanities geography. It is designed to facilitate the systematic.

3 Tracing the Historical and Cultural Threads of Qinghai Province

3.1 Overview of Qinghai Province

The province of Qinghai, abbreviated as "Qing", is named after Qinghai Lake, the largest inland saltwater lake in China. The spatial scope of the study is the administrative area of Qinghai Province, which has a total area of 722,300 square kilometres, accounting for one-thirteenth of the country's total area and ranking fourth in the country. Furthermore, the province is endowed with a wealth of natural resources, including petroleum, potash, and lithium, as well as substantial hydroelectric and solar energy reserves. These resources provide a robust foundation for the development of a world-class salt lake industrial zone and a national clean energy industrial hub. Additionally, Qinghai is situated in the northeastern region of the Qinghai-Tibetan Plateau, with a topography that is elevated in the west and low in the east. It is renowned as the "source of rivers" and "Chinese water tower," which has fostered the growth of world-class tourism resources, including the source of the Three Rivers and Qinghai Lake. The natural and humanistic geographic pattern of Qinghai Province is defined by the presence of Qinghai Lake, the Yellow River, Yangtze River, Lancang River, Kunlun Mountain Range, Qilian Mountain Range, Tanggula Mountain Range, a lake, three rivers and three veins. Furthermore, Qinghai is home to a diverse array of ethnic minorities, who live in a region characterised by cultural diversity, unique customs, and the presence of numerous religious traditions.[5] These distinctive geographic and cultural traits serve as a vital link between Tibet, Xinjiang, and the mainland, as shown in Figure 2.

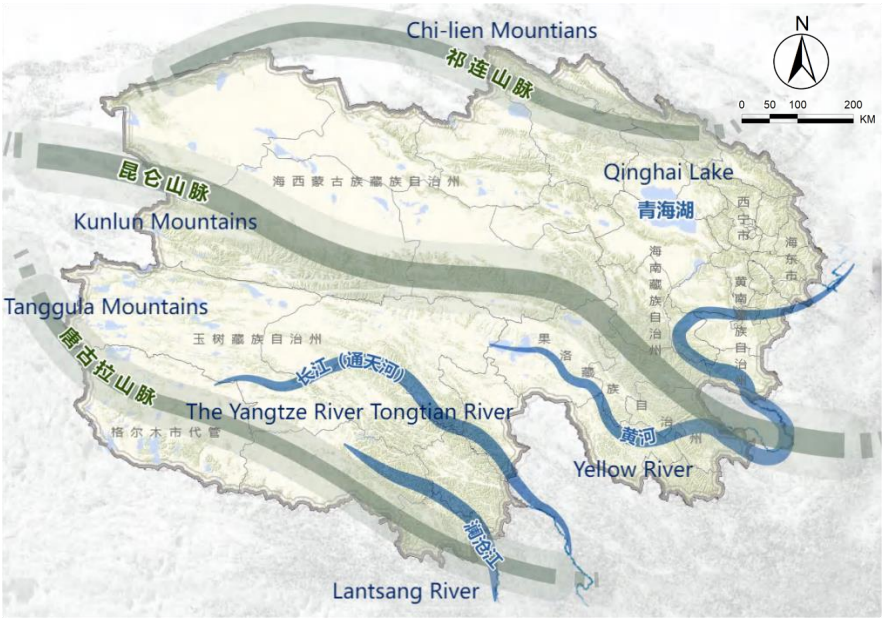

Figure 2 Natural and human geography of Qinghai Province

3.2 Composition and Spatial Distribution Characteristics of Urban and Rural Historical and Cultural Heritage in Qinghai Province

As a province inhabited by a multitude of ethnic groups, Qinghai has amassed a historical and cultural legacy of diverse styles, rich in colour and invaluable in its contribution to the formation of the Chinese nation and the safeguarding of the country's ecological security.[5]

3.2.1 General Situation of Heritage Composition

As of October 2023, Qinghai has one national historical and cultural city, four provincial historical and cultural cities, one Chinese historical and cultural town, nine provincial historical and cultural towns, five Chinese historical and cultural villages, thirty-three provincial historical and cultural villages, eighteen Chinese traditional villages, four historical and cultural districts, and one national scenic spot. Additionally, there are fifty-one national key cultural relics protection units. A total of 466 provincial cultural relics protection units and 6,411 immovable cultural relics have been identified. Additionally, there are 51 national key cultural relics protection units, 466 provincial cultural relics protection units, 6,411 immovable cultural relics, one world natural heritage site, two national industrial heritage sites, and 88 national intangible cultural heritages. These have been the subject of initial protection systems comprising a variety of elements and cultural values, which have effectively safeguarded a significant number of precious urban and rural historical and cultural heritages. The Qinghai region has been at the forefront of exploring and innovating the concept and method of protection and inheritance, particularly in the context of Chinese civilisation exploration, Huangshi culture heritage, the promotion of the "two bombs and one star" spirit, the construction of the plateau beautiful town, and other related fields. This has resulted in the

formation of numerous exemplary cases of protection and inheritance, which have collectively accumulated a wealth of experience.

3.2.2 Spatial Distribution Characteristics of Resources

The distribution of historical and cultural cities, historical and cultural towns, historical and cultural villages, and traditional villages is largely concentrated in the basin and valley areas, particularly in the Huangshui River Basin, where they are particularly dense. The Tongtian River (Yangtze River), the Yellow River, and the Zhaqu (Lancang River) are also located in the river valley basin.

Cultural relics protection units are distributed in the basin and valley area, with a concentration in the Huangshui River Basin, which is particularly rich in such sites, as well as in the Tongtian River (Yangtze River), the Yellow River, and the Zhaqu (Lancang River) along the river valley basin.

The majority of scenic spots are situated in mountain ranges and along rivers, particularly in the vicinity of the Yellow River, which is particularly dense. Other notable locations include the Qilian Mountains and the Kunlun Mountains.

The Silk Road (Qinghai) cultural belt is predominantly located in the river valley and basin areas, with the Huangshuang Basin representing a particularly dense concentration. The Qinghai-Tibet Railway Culture Belt is primarily concentrated in the basin and along the railway line, with the Huangshui Basin exhibiting the highest density. The Tangfan ancient road culture belt is distributed in the basin and valley area, with a particularly dense concentration in the Huangshui Basin. It also extends along the Tongtian River (Yangtze River), the Yellow River, and the Zachu (Lancang River) in the valley area.

Other remains are distributed in the basin, valley and along the belt, with a particular concentration in the Huangshuo Basin. Additionally, the Tongtian River (Yangtze River), the Yellow River, and the Zachu (Lancang River) are located along the valley, along the Qinghai-Tibet Railway, and in other zones, as shown in Figure 3.

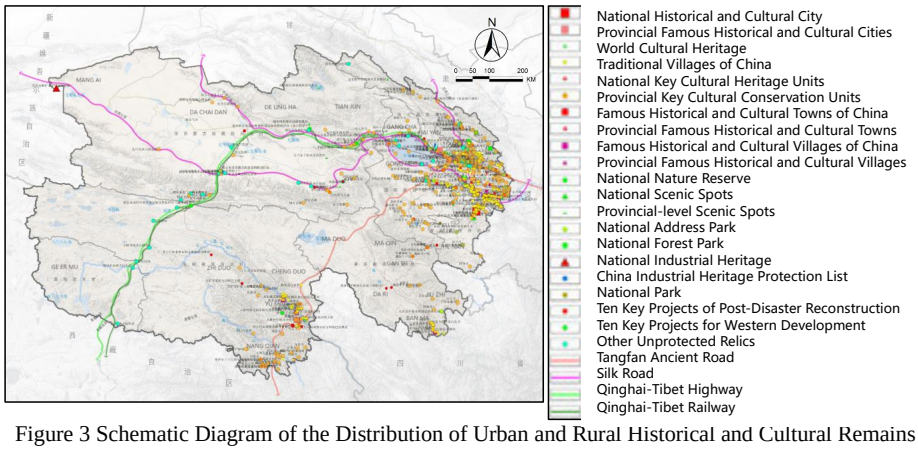

Figure 3 Schematic Diagram of the Distribution of Urban and Rural Historical and Cultural Remains

3.3 The Historical and Cultural Lineage and Phased Characteristics of Qinghai Province

Based on literature and historical materials, the latest archaeological data, historical relics and existing research results, it carries out thematic studies on politics, economy, society, science and technology, culture, geography and other aspects, and systematically sorts out the historical and cultural lineage of Qinghai, as shown in Figure 4 and 5.

3.3.1 From Prehistory to the Han Dynasty: The Emergence of Agriculture and Animal Husbandry in Qiang Region, and the Penetration of Central Plains Culture

From Xia to Shang to Zhou, Qinghai was the "Qiang land of the Xirong clan", and the Qiang people lived by hunting and herding, then turned to agriculture under the influence of Central Plain culture. During the Qin and Han dynasties, the Xiongnu expanded their power and the Qiang people of Qinghai became a force in their attacks on the Han dynasty. When Emperor Wu of the Han Dynasty successfully counterattacked the Xiongnu, the Western Han began to build cities with tunnels in the Huanghe Valley and established Pavilion County, gradually bringing the Huanghe area under the rule of the Central Plains. After the Eastern Han Dynasty, Jincheng and Xiping County (now Xining) were established, and Xining became a major military city, consolidating the western frontier.[5]

At the same time, the Qiang people in the nomadic life, opened to all parts of the traffic road, such as "Huanghuanzhong Road", "Henan Road" and "Qiangzhong Road", these roads to the centre of Qinghai Lake, connecting the four sides, forming a net-like structure. These roads, centred on Qinghai Lake, connected the four directions and formed a net-like structure, providing convenient transportation for Qinghai and the northwestern region. The Qiangzhong Road was particularly unique, as it not only connected the north, west and south, but also led to Zhangye through the Dadubai Valley, making it an important transport route in ancient times.

3.3.2 From the Wei-Jin Period to the Late Tang Dynasty: Frequent Political Changes and Remarkable Cultural Integration

From Wei Jin to the end of the Tang dynasty, Qinghai experienced regime change and cultural fusion. The Xianbei tribes moved in and established the southern Liang state, which was controlled by the northern Wei dynasty, and then established the Shanshan state. The rise of the Tugukhun, a vast territory and close interaction with the central dynasties, had far-reaching effects. After the unification of the Sui Dynasty, Shanshan Prefecture was transformed into Xiping County, and Emperor Yang's personal conquest led to the decline of the Tugukhun. At the beginning of the Tang Dynasty, Li Jing surrendered to the Tugukhun, and the Tang-Fan Road was opened, promoting exchanges between China and foreign countries. The rise of Tubo, the destruction of the Tugukhun, Qinghai has become an important source of horses, tea and horse market prosperity. After the Anshi Rebellion, the Tubo occupied Qinghai, and various ethnic groups integrated into the Tubo, forming a new cultural landscape. The tombs are rich in excavated artefacts, showing the unique charm of Qinghai culture under Tubo rule. At the end of the Tang Dynasty, the internal turmoil of the Tubo brought Qinghai into a new stage of history.

3.3.3 From the Song to Yuan Dynasties: The Process of Political Unification and Deepening Ethnic Integration

During the Northern Song Dynasty, Guosiluo established the Qingtang regime in Qinghai with Tibetans as the main body, integrating Han, Huihe, Dangxiang and other ethnic groups, thus ending a long period of chaos. The rulers attached great importance to the lines of communication between China and the West, and maintained exchanges between the western regions and the central plains. During the reign of Emperor Huizong of Song, the Guosiluo regime was destroyed and the name Xining was adopted. The Song Dynasty followed the Tang system, and the Old Tea Horse Road was further developed, increasing economic and cultural exchanges. In the Yuan Dynasty, the unified situation encouraged ethnic migration and integration. Western Muslims moved to Qinghai, and Islam was introduced and spread there. During this period, the Qinghai region underwent historical changes from local regime to national unity, from ethnic dispersal to integration and development.

3.3.4 From the Ming and Qing dynasties to the Republic of China period, Establishment of the Great Wall Defense and the Transformation of Qinghai Province

During the Ming Dynasty, to ensure the security of the Huangshui area, the Ming army built the Great Wall, which is over 330 kilometres long, and formed a complete defence system with castles, beacon flints and other facilities. At the end of the Ming dynasty, the Heshuit Mongol Ministry entered and ruled Qinghai, promoting the Gelugpa school of Tibetan Buddhism. In the Qing Dynasty, the government introduced the Alliance Flag System, which further strengthened the administration of Qinghai and promoted the economic and cultural development of all ethnic groups. At the same time, the Tea Horse Road flourished during this period, becoming an important trade route between the Chinese and Tibetan regions. During the Republic of China period, Qinghai experienced nearly 40 years of rule by the Ma family warlords, during which time Qinghai was officially established as a province. In 1936, the West Road Army fought hard in Qinghai, and although some of the soldiers were captured and persecuted, their revolutionary spirit lives on, engraving their beliefs on the flower bricks and leaving a deep revolutionary imprint. Rescued by the Party Central Committee and all parties, many of the soldiers eventually survived, and the heroic deeds of the West Road Army soldiers have written a most heroic and tragic chapter in the history of the Chinese revolution.

3.3.5 From the Founding of the People's Republic of China to the Present: Ethnic Unity, Social Harmony, and the Increasing Prominence of Strategic Status

Xining was liberated in 1949 and the Qinghai Provincial People's Government was established in 1950. The Qinghai Provincial Party Committee actively implemented the Party's ethnic policy and promoted comprehensive economic and social development under the guidance of "prudence and steady progress". Under the supervision of the Party Central Committee, Qinghai explored resources, promoted national defence science and technology, and carried out construction, which not only transformed Qinghai's backwardness, but also cultivated the spirit of "Two Roads", "Two Bombs and One Star", "Qaidam" and "Xiaogaoling", which inspired people of all ethnic groups. It is a vivid interpretation of the Party's glorious history in Qinghai during the period of socialist revolution and construction, which inspires and encourages generations of builders and achievers from all walks of life to root themselves in Qinghai and devote themselves to Qinghai.[1]

Qinghai's vast territory and complex climate and geography are the bottlenecks limiting economic development. Reform and opening-up have brought new opportunities to Qinghai. Qinghai's transportation network has been greatly expanded, with highways, railways and aviation facilities becoming more and more perfect, and the Qinghai-Tibet Railway has become

a world-renowned plateau railway. Qinghai has become the transport hub of the Qinghai-Tibet Plateau, laying a solid foundation for economic development.

In recent years, based on the strategic position of "three more important", Qinghai Province has made clear the goal of building "four places" with clean energy industry highland to promote high-quality development. Qinghai has made remarkable achievements in clean energy, big data, agriculture and tourism, and has become a nationally recognised economic highland. These achievements have not only enhanced Qinghai's comprehensive strength, but also contributed to the comprehensive construction of a modern socialist country.

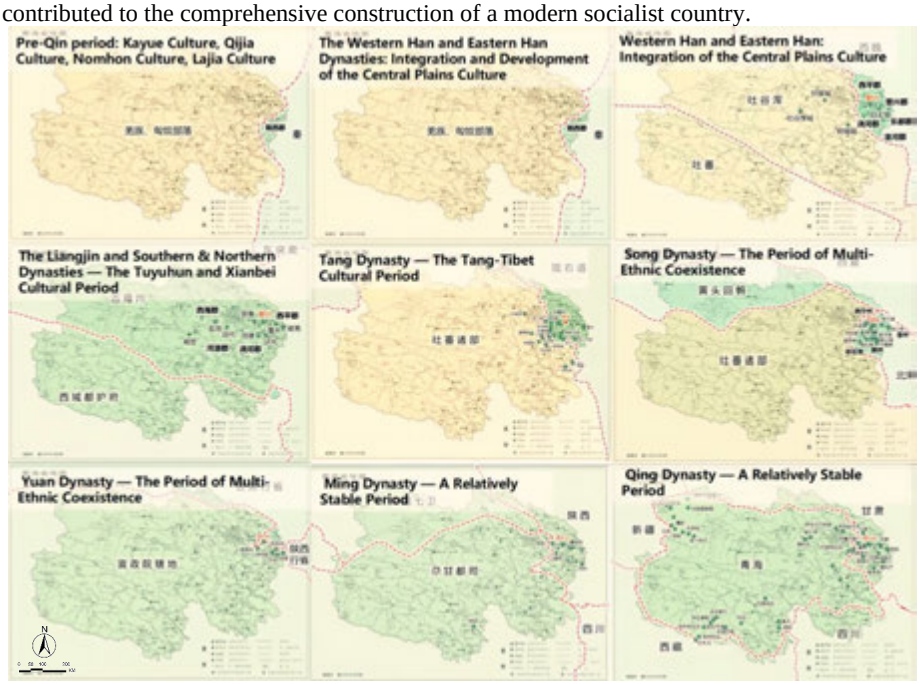

Figure 4 Historical Evolution from Pre-Qin to Qing Dynasties

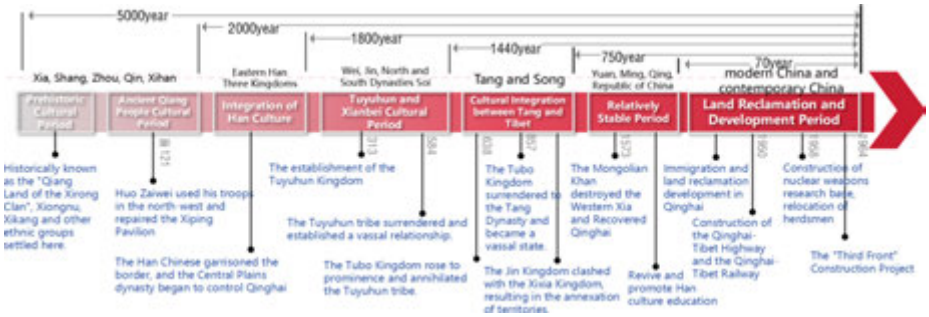

Figure 5 Schematic Diagram of the Distribution of Urban and Rural Historical and Cultural Remains

3.4 The Formation Mechanism of the Historical and Cultural Values in Qinghai

Located at the crossroads of agricultural and nomadic cultures, Qinghai played an important role in the formation and development of the unified multi-ethnic state of ancient China. A number of traditional settlements in Qinghai are important testimonies to the social patterns of multi-ethnic, multi-religious and multi-cultural mixing in Qinghai.

4. Condensation and Framework Construction of Urban and Rural Historical and Cultural Values in Qinghai Province

4.1 Identification and Organisation of the Characteristics of Historical and Cultural Values

From the birth of human civilisation to the new era of scientific and technological innovation selected 24 representative historical events and other five historical veins and spatial and temporal evolution combing, clear Qinghai in the national urban and rural historical and cultural protection and inheritance system, the Yellow River Cultural Corridor, the Silk Road Cultural Corridor, and other national and regional cultural protection system in the positioning, and based on the national and provincial relevant policies and documents, condensed on behalf of the historical and cultural values of Qinghai Province, as shown in Figure 6.

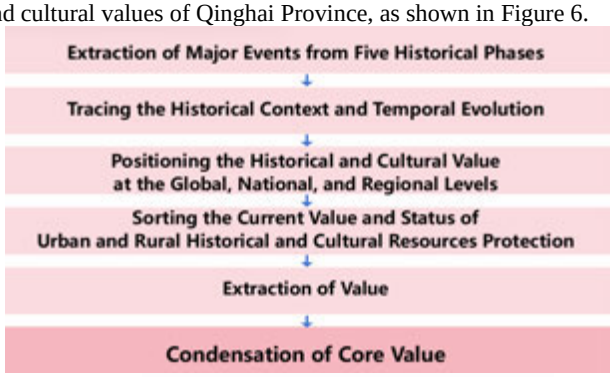

Figure 6 Pathway to Condensing the Values of Qinghai

4.2 Condensing Historical and Cultural Values

The study systematically combed through the five stages of historical development of Anhui Province: 5000 years of ancient civilisation, 180 years of modern times, 100 years of the founding of the Party, 70 years of the founding of New China, and 40 years of reform and opening up, and identified the typical value characteristics of urban and rural history and culture in Anhui Province in terms of five categories: politics, geography, society, economy, science and technology, and five aspects of state power, institutional civilisation, national rituals, agricultural economy, handicrafts, trade and commercial exchanges, social organisations and strata, Chinese nation, ideology and culture. Religious beliefs, literature and art, science and technology, urban architecture, natural geography, human landscape and other fifteen aspects[8][9][10], condensing the typical value characteristics of urban and rural historical and cultural features of Qinghai, and constructing the "5 categories-15 themes-27 characteristics" of Qinghai's historical and cultural value system, as shown in Table 1. The value system of Qinghai's history and culture is constructed with "5 categories-15 themes-27 characteristics", as shown in Table 1.

Table 1 The Historical and Cultural Value System of Qinghai Province

Number	Value categories (5)	Value themes (15)	Value characteristics (27)
1	Political Category	National Governance	1 Prehistoric cultural sites, represented by Lajia Site and Liuwan Site, are significant historical witnesses to the origin of Chinese civilisation in Qinghai. The Hehuang culture in eastern Qinghai is an important symbol of the human civilisation process at the source of the Yellow River and a crucial part of the Yellow River civilisation system.
			2 Qinghai, located at the junction of farming and nomadic cultures, served as an important strategic fulcrum for the Central Plains dynasties to govern the Qinghai-Tibet Plateau, playing a vital role in the formation and development of the unified multi-ethnic country in ancient China.
			3 The Red Army's Second and Fourth Front Armies and the Western Route Army left an epic chapter of battle in Qinghai. The liberation of Qinghai had a profound impact on the liberation of Ningxia, Gansu, and even the peaceful liberation of Xinjiang, Tibet, and other regions.
2		Institutional Civilisation	4 Qinghai is a typical region where the ancient unified country adopted a variety of governance systems such as prefectures and counties, native chieftaincies, chieftaincy households, and alliance banners in multi-ethnic areas.
			5 Qinghai is a typical region where the Central Plains dynasties implemented systems such as garrison farming and garrison institutions in the western region.
3		National Etiquette	6 "Sea Worship" at Qinghai Lake was a national sacrificial system implemented by the Qing Dynasty to enhance national identity and promote ethnic integration among multi-ethnic regions in Qinghai.
4	Economic Category	Agricultural Economy	7 The Hehuang region in eastern Qinghai was an important garrison area of the Central Plains dynasties on the Qinghai-Tibet Plateau and a typical representative of plateau agricultural development in China.
			8 Qinghai's unique geographical environment possesses tremendous advantages for developing animal husbandry. It was one of the main sources of military horses for ancient China's Central Plains and remains one of the four major pastoral areas in China.
5		Development of Handicrafts and Industrial & Information Industries	9 “Qing Embroidery” represented by Tu Nationality Pan Embroidery, Tibetan Embroidery, Danggar Leather Embroidery, Salar Embroidery, Hui Embroidery, and Hehuang Embroidery, along with traditional crafts such as Jiaya Tibetan Carpet Weaving, Tibetan Black Pottery Firing, and

			Traditional Barley Wine Brewing, showcase Qinghai's ethnic-specific, profound, and diversified handicraft system.
			10 Qinghai is the most resource-rich region of salt lakes in the world, with comprehensive development conditions for hydropower, solar energy, and wind energy ranking among the best in the country. It is a crucial salt chemical and clean energy industrial hub for China's modern industrial development.
6		Trade and Commerce Exchange	11 The "Qinghai Route" of the Silk Road and the Tang-Tibet Ancient Road are important passageways connecting the hinterland of the Central Plains to Xinjiang and Tibet. The Riyueshan Market Exchange in the Tang Dynasty and the tea-horse trade during the Song and Ming Dynasties were significant commercial exchange methods between the agricultural areas of the Central Plains and the nomadic areas of the Qinghai-Tibet Plateau.
7	Social Category	Social Organisations and Classes	12 Traditional villages represented by Tibetan Dianda Village, Tu Nationality Guomari Village, Salar Dazhuang Village, and Hui Nationality Hongshuiquan Village are crucial witnesses to Qinghai's multi-ethnic gathering, coexistence of multiple religions, and cultural integration.
			13 After the founding of New China, the Tibetan regions of Qinghai were the first to transition from feudal serfdom to socialism, serving as an important witness to the leapfrog social and economic development of ethnic regions in China.
8		Ethnic Integration	14 Qinghai has been an important region for the integration and development of multiple ethnic groups since ancient times. Modern Qinghai features the harmonious coexistence of Han, Tibetan, Mongolian, Hui, Tu, and Salar ethnic groups, and it has the largest proportion of nationally autonomous areas and the highest percentage of ethnic minority populations in the country.
			15 The Princess Wencheng's route to Tibet and related cultural relics, represented by the Tang-Tibet Ancient Road, Riyueshan, and Beidari Tathagata Grottoes, are crucial witnesses to the long history of exchanges and integration between the Han and Tibetan ethnic groups.
9	Science, Technology, and Culture Category	Ideology and Culture	16 Qinghai is an important place for inheriting and promoting the red genes of the Long March Spirit, the West Road Army Spirit, the "Two Roads" Spirit, and the "Two Bombs and One Satellite" Spirit.
10		Religious Beliefs	17 Qinghai is a significant region for the dissemination and development of Tibetan Buddhism and Islam. Ta'er Monastery, Qutan

			Monastery, Longwu Monastery, and Dongguan Grand Mosque are important witnesses to the harmonious coexistence of multiple religions.
11		Literature and Art	18 Qinghai boasts a rich and diverse multi-ethnic culture, represented by literary works such as "Gesar" and "Camel Spring Legend", performing arts like Flower Songs, Tibetan Opera, and Jianzha Folk Songs, and painting and plastic arts exemplified by Regong Art, Beidari Tathagata Grottoes, and Lebago Cliff Carvings. These are outstanding representatives of ethnic literary and artistic achievements.
12		Science and Technology	19 Qinghai Jinyin Beach is China's first nuclear weapon research and development base, and the cradle of China's atomic energy industry.
			20 The Qinghai-Tibet Railway is the highest and longest plateau railway in the world, achieving numerous "firsts" both domestically and internationally. It is one of the four major projects of China's new era.
			21 Astronomical and medical achievements represented by "Ma Yang Temple Han Calendar Essentials," "Essentials of the Kalachakra Calendar," and Tibetan medical bath therapy are typical representatives of the technological development of ethnic minorities in history.
13		Cities and Architecture	22 Traditional settlements like Tongren Longwu Ancient City, Xunhua Jiezi Town, and Tongren Guomari Village, as well as traditional dwellings like Jianzha Nangla Qianhu Compound and Xunhua Mengda Salar Ancient Residential Groups, are typical representatives of natural adaptive human settlements in China's cold and arid plateau regions, serving as practical examples of traditional wisdom in landscape and cultural construction.
			23 The reconstruction of Yushu is the largest and most effective disaster relief operation and reconstruction project ever undertaken by humans in cold and high-altitude areas, serving as a model for urban construction in the ecologically fragile regions of the Qinghai-Tibet Plateau.
14	Geographic Category	Physical Geography	24 Qinghai is a strategic region for safeguarding national ecological security, undertaking the significant mission of protecting ecological security, the source regions of the Three Rivers, and the "Water Tower of China."
			25 Qinghai is the region with the most concentrated biodiversity in the world's high-altitude areas, serving as the primary habitat for endangered and rare wild animals such as Tibetan antelopes, snow leopards, and Przewalski's gazelles.

15		Human Geography	26 The Kunlun Mountains are considered the "ancestor of all mountains" and the "source of culture" in the collective memory of the Chinese nation. The Qilian Mountains, Bayan Har Mountains, Animaqing Mountains, and Tanggula Mountains are important regional cultural and geographical landmarks.
			27 Qinghai Lake, anciently known as "Xihai," is the largest inland saltwater lake in China, renowned as "the most beautiful lake in China."

5. Core Values and Conclusion

5.1 Core Values of the 'Four Area'

Consolidate the five categories of values of Qinghai Province, condense the core values of Qinghai from the main line of "Four Area", interpret Qinghai based on the special geographical pattern of "one lake, three rivers and three veins", and take on a special mission in the development of Chinese civilisation and the long history of national integration, which is of outstanding significance. It is of outstanding significance to clarify the value and support of Qinghai in the national urban and rural historical and cultural protection and inheritance system.

National ecological safety strategy: "Protecting the ecological environment of Qinghai is 'the most important thing of the country'", and Qinghai has the important task of maintaining ecological security, protecting the source of the Sanjiang River and protecting the "Chinese Water Tower". The mission.

Qinghai is the province with the highest proportion of ethnic minorities, and has a deep history of interaction and exchange among various ethnic groups in western China, which has played an important role in strengthening the sense of community among the Chinese nation.

Where the Red Spirit genealogy is carried forward: Qinghai is an important area for the inheritance and promotion of the Red Spirit, such as the Spirit of the Long March, the Spirit of the Western Road Army, the Spirit of Two Bullets and One Star, the Spirit of the Two Roads, and the Spirit of Yushu Earthquake Rescue and Disaster Relief.

Plateau Habitat Wisdom Inheritance: Qinghai people of all ethnic groups have created regional habitat wisdom adapted to the cold and arid environment of the Qinghai-Tibet Plateau and coexisting harmoniously with nature through long-term production and living practices, forming a rich and varied urban and rural heritage.

5.2 Conclusion

China's original hierarchical classification of historical and cultural heritage protection system has certain limitations, through the provincial level of historical and cultural protection and inheritance planning, can achieve regional coordination, the whole area of the whole elements of the protection of the work of the foundation, has an important practical value. Provincial-level protection and inheritance planning can not achieve the depth of complete excavation and specific positioning of the protection content, the key is to do a good job in coordinating the role of the top and the bottom. This paper combines the methods of geography, history and GIS, analyses the origin of culture, cultural lineage and theme content condensation, and combines

the relevant planning and historical and cultural heritage of time and space evolution characteristics, from the political, economic, social, scientific and technological culture, geography, five aspects of the summary distillation of 27 value characteristics. Finally, the historical and cultural value system of Qinghai with "5 categories - 15 themes-27features" was constructed, and the core values of Qinghai in "Four Area" were integrated and condensed: national ecological security, strategic region, national unity, integration and blending. The core values of Qinghai are integrated and condensed into four areas: national ecological security strategy area; ethnic unity integration and intermingling area; red spirit genealogy promotion area; and plateau habitat wisdom inheritance area. Combined with the exploration of the preparation of Qinghai Province's protection and inheritance planning work, it is intended to provide ideas for the recognition of the value of the historical and cultural characteristics of urban and rural areas at the provincial level and the use of cultural inheritance.

Abstract: In the context of advancing the construction of the Belt and Road, the preservation and perpetuation of the Tang-Tibet Ancient Road holds immense significance in promoting development in the Western region. The Qinghai section, with its abundant cultural heritage, has emerged as the focal point for the cultural preservation. However, the current development and preservation efforts lack a comprehensive analysis and evaluation of heritage resources. This paper takes a cultural ecology perspective as its starting point and conducts a comprehensive survey of existing natural and cultural heritage sites along the Ancient Road. Additionally, it utilizes spatial analysis tools to analyse the accessibility and suitability of the corridor space. Ultimately, this paper constructs a cohesive cultural heritage corridor for the Tang-Tibet Ancient Road.

Keywords: Tang-Tibet Ancient Road, heritage corridor, cultural ecology, linear cultural heritage

1. Introduction

In the era of globalization and modernization, the preservation and transmission of cultural heritage are increasingly receiving extensive attention from the international community. As a carrier of human history and civilization, cultural heritage not only has profound historical, artistic and scientific values, but also serves as a symbol of the spirit of a country. Nevertheless, the development of urbanization has resulted in the continued monolithic and isolated mode of conservation of the majority of cultural heritage[1]. Consequently, the effective safeguarding and transmission of cultural heritage have emerged as a pressing contemporary concern.

Cultural ecosystems are integrated systems in which people and culture, culture and nature, and culture and society are closely linked[2]. It focuses on the relationship between culture and the natural ecology in which it is located and its changes[3]. It emphasizes the organic interaction between humans, culture and the physical environment. The concept of heritage corridors was first proposed by American scholars as a strategic approach to the overall protection of regional historical and cultural heritage and its natural environment[4]. The construction of heritage corridors emphasizes ecological integrity and cultural heritage continuity, connecting natural landscapes with cultural heritage, while integrating recreational, educational, aesthetic and other functions [5]. This integration enables the historical and cultural heritage to be integrated with regional spatial characteristics.

The Tang-Tibet Ancient Road, an ancient route connecting the Central Plains with Tibet, has been witness to numerous significant historical events in Chinese history. As a significant component of the Tang-Tibet Ancient Road, the Qinghai section encompasses a multitude of historical artefacts, ethnic settlements and natural landscapes along the route. Nevertheless, in the context of changing times and external environmental factors, these cultural heritages confront a multitude of challenges and threats.

This paper adopts a cultural ecology perspective to delve deeply into the theory and implementation of heritage corridor construction. It explores the profound cultural significance of the Tang-Tibet Ancient Road and delineates a potential heritage corridor space with the technical assistance of ArcGIS 10.8. Ultimately, it constructs a heritage corridor of the Tang-

Tibet Ancient Road. The objective is to promote the protection and inheritance of heritage resources along the Tang-Tibet Ancient Road.

2. Overview of the Qinghai section of the Tang-Tibet Ancient Road and basic data

2.1 Overview of the study area

The Tang-Tibet Ancient Road stretches for over 3,000 kilometers, traversing five provinces including Shaanxi, Gansu, Qinghai, Sichuan, and Tibet, with the Qinghai segment constituting more than half of its total length. After reviewing a large amount of data to sort out the route of the Tang-Tibet Ancient Road within the territory of ancient Qinghai [6-8], the specific scope of this study encompasses administrative regions such as Minhe Hui Autonomous County, Ledu District, Huzhu Tu Autonomous County, Ping'an District, Xining City, Huangyuan County, Gonghe County, Xinghai County, Maduo County, Chengduo County, Yushu City, as well as Zaduo County(Figure 1).

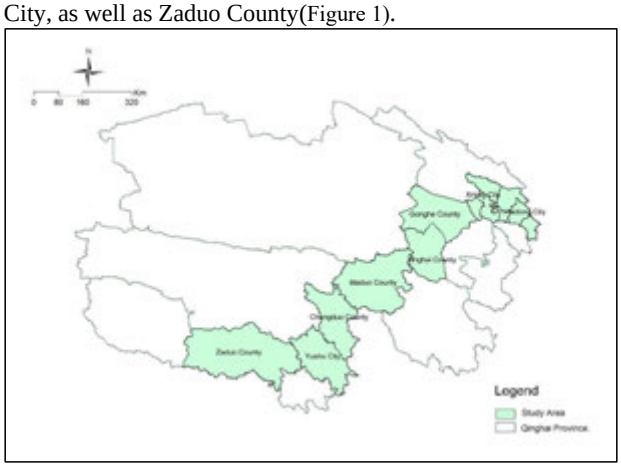

Figure 1 Study Area

The Qinghai section of the Tang-Tibet Ancient Road is an integral and significant component of the route. Its rich natural and cultural heritage serving as an evidence to the grandeur of ancient civilization and the harmonious cultural exchange between Chinese and Tibetan peoples [9]. The Qinghai section of the Tang-Tibet Ancient Road is indelibly marked by the interdependence of its millennia-old cultural heritage and ecological environment.

2.2 Data sources

The data required for the study include: (1) DEM digital elevation data and land use type data of the study area in 2022, obtained from the Geospatial Data Cloud of the Chinese Academy of Sciences (http://www.gscloud.cn); (2) Information on cultural and natural heritage sites, such as cultural relics protection units, traditional villages and scenic spots at all levels, obtained from the cultural and tourism bureaus of prefectures and municipalities in Qinghai; (3) Road traffic and water system data obtained from the Open Street Map platform (https://www.openstreetmap.org/); (4) POI data of public service facilities, such as restaurants, hotels and car parks, obtained from the Baidu Map platform.

3. Research Ideas and Methods

3.1 Research ideas

This paper aims to establish a comprehensive and scientifically sound heritage corridor for the Tang-Tibet Ancient Road. We employ the Analytic Hierarchy Process to quantitatively evaluate and classify the natural and cultural heritage resources. Then, the spatial distribution of heritage resources at all levels was analyzed using GIS kernel density. A comprehensive resistance surface was created to conduct in-depth research on spatial resistance patterns related to corridor construction. A potential Tang Tibetan ancient road heritage corridor network was identified and constructed using cost connectivity tools. Finally, considering environmental sustainability and the preservation of cultural diversity, we propose a heritage corridor protection strategy that integrates macro-strategic considerations with the micro-level requirements of urban development. This strategy aims to foster the overall rejuvenation and enduring prosperity of the Tang-Tibet Ancient Road region.

3.2 Research methodology

The advancement of science and technology has significantly propelled the innovation of heritage resource research methods. Approaches, such as the Analytic Hierarchy Process (AHP), Kernel Density Analysis (KDE), and Minimum Cumulative Resistance model (MCR), have gained widespread adoption among international scholars for conducting in-depth investigations and establishing heritage corridors.

The Analytic Hierarchy Process (AHP), originally introduced by Thomas L. Saaty in the 1970s, is a multi-criteria decision analysis technique that integrates qualitative and quantitative aspects. In the context of heritage assessment, it effectively constructs a hierarchical model of heritage value by establishing a quantitative weighting system through the comparison of varying indicator importance levels[10]. This study incorporates ecological indicators, emphasizing the significance of heritage within the ecological environment and its harmonization with the surrounding landscape to ensure the symbiotic growth of culture and ecology during corridor development. Despite its value, a notable limitation of this method lies in its subjectivity, where expert opinions can influence decision outcomes. To address this concern, 12 experts with relevant backgrounds are engaged in independent evaluations to uphold the objectivity and scientific rigor of the assessment results.

To reveal the spatial heritage distribution pattern and pinpoint heritage concentration zones, scholars globally have increasingly integrated Kernel Density Analysis (KDA) into heritage research. This non-parametric spatial analysis method involves the construction of judgment matrices, computation of weight vectors, and consistency assessments [11]. Within heritage corridor construction, KDA accurately assesses the spatial clustering intensity of heritage sites, aiding in the identification of pivotal corridor nodes and the optimization of spatial layout. The formula is as follows:

$$f_n(x) = \frac{1}{nh}\sum_{i=1}^{n} K\left(\frac{x-x_i}{h}\right) \quad (1)$$

Where n is the number of points included in the threshold range; h is the threshold value; $x-x_i$ denotes the Euclidean distance between two points; K is the kernel function, the larger the value indicating that the distribution of the points of the element is more intense.

In the pursuit of comprehensively establishing the Tang-Tibet Ancient Road Heritage Corridor within the current Qinghai Province landscape, this study adopts the Minimum Cumulative

Resistance model (MCR) proposed by Knaapen in 1992[12] . The MCR model, leveraging diverse resistance factors like topography, rivers, and transportation, determines the path of least resistance for heritage resource dissemination, consequently delineating priority zones for corridor development. The model formula is as follows:

$$MCR = f_{min} \sum_{j=n}^{i=m} (D_{ij} \times R_i) \quad (2)$$

Where Dij denotes the spatial distance of the tourist from environmental element i to heritage site j; R_i denotes the resistance value of the surface suitability of space i; $\sum$ denotes the cumulative resistance that the tourist must overcome to reach the heritage site, and f_{min} is the value of the minimum cumulative resistance.

A multidisciplinary and multi-dimensional approach serves as a critical foundation for constructing the Tang-Tibet Ancient Road heritage corridor. Hierarchical analysis efficiently evaluates heritage site values, kernel density analysis vividly depicts heritage site distributions across all levels, and the MCR model assesses suitable corridor construction areas based on present conditions. Therefore, the integration of diverse disciplines has become imperative for crafting a scientific and comprehensive heritage corridor.

4. Construction of Heritage Corridor of Tang-Tibet Ancient Road (Qinghai Section)

4.1 Comprehensive Heritage Assessment and Grading

4.1.1 Classification and Evaluation of Heritage

Through field research and consultation of pertinent reports, all cultural and natural heritage sites within the study scope were meticulously cataloged, encompassing cultural heritage conservation sites at various levels, renowned towns and villages, industrial heritage sites, amounting to a total of 365 resource points. In accordance with the guidelines outlined in the Convention for the Protection of the World Cultural and Natural Heritage concerning Cultural and Natural Heritage, the evaluation of cultural heritage should encompass its historical, artistic, and scientific significance, while the evaluation of natural heritage should consider its artistic aesthetics and scientific value. In alignment with the criteria for heritage corridor development and the distinctive attributes of the heritage sites along the Tang-Tibet Ancient Road, this study formulates a comprehensive heritage value assessment framework based on five dimensions: Historical Value, Social Value, Artistic Value,Natural Landscape Value, and Economic Value [13-14]. Subsequently, an assessment and grading process for heritage resources is conducted. Given the varying significance of each evaluation criterion and factor in heritage value assessment, this research undergoes multiple evaluations by a panel of 12 scholars and experts to ascertain the relative weight of each factor meticulously.

The evaluation adopts the combination of expert evaluation method, tourist survey method and professional survey method. Relevant experts are invited to evaluate factors such as "relevance to the ancient road" and "tourism development potential". Tourists and residents are invited to evaluate factors such as "visibility" and "emotional recognition by residents". Other quantitative factors such as "historical longevity" and "level of protection" are evaluated through data.

Table 1 Assessment Table of Heritage Value

Evaluation Type	Evaluation Factors	Categorical Indicators	Scoring Criteria	Weight(%)

Historical Value	Historicity	Before the Tang Dynasty (Before 618)	5	40%
		Tang dynasty (618-907)	4	
		Song (960-1129) and Yuan Dynasty (1271-1368)	3	
		Ming (1368-1644) and Qing (1644-1912) Dynasty	2	
		Modern Times (Since 1921)	1	
	Grade of Protection	World-class	5	30%
		National	4	
		Provincial	3	
		municipal	2	
		Unrated	1	
	Relevance to the Ancient Road	Very high	5	30%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
Social Value	Popularity	World-renowned	5	40%
		Nationally renowned	4	
		Provincially renowned	3	
		City and county renowned	2	
		Little known	1	
	Resident Emotional Identification	Very high	5	30%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
	Educational and Research Value	Very high	5	30%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
Evaluation Type	Evaluation Factors	Categorical Indicators	Scoring Criteria	Weight(%)
Artistic Value	Artistic Rarity	Rare in the world	5	50%
		Rare nationwide	4	
		Rare in the province	3	
		Rare in the city	2	
		Common	1	
	Preservation Integrity	Preserved Completely	5	30%
		Partially Damaged	4	
		Majority Damaged	3	
		Heavily Damaged	2	
		Disappeared	1	
	Aesthetic Appreciation	Very high	5	20%
		High	4	
		Relatively high	3	
		Average	2	

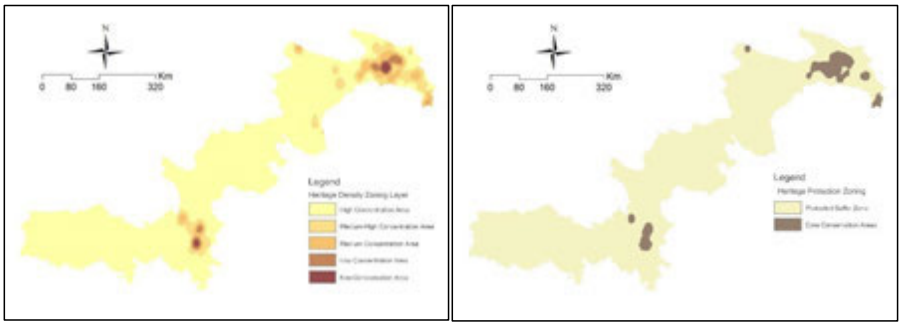
		Relatively low	1	
Natural Landscape Value	Ecological Importance	Very Important	5	35%
		Important	4	
		Moderately Importan	3	
		General importance	2	
		Unimportant	1	
	Grade of Natural Landscape Protection	National Protected Area	5	35%
		Provincial Protected Area	4	
		Municipal/County-level Protected Area	3	
		Proposed Protected Area	2	
		Regular Landscape	1	
	Landscape Coordination	Very high	5	30%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
Economic Value	Economic Contribution	Very high	5	40%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
	Tourism Development Potential	Very high	5	30%
		High	4	
		Relatively high	3	
		Average	2	
		Relatively low	1	
	Transportation Accessibility	Very Convenient	5	30%
		Relatively Convenient	4	
		Moderately Convenient	3	
		Inconvenient	2	
		Highly Inaccessible	1	

According to the heritage value assessment table in Table 1, 365 heritage sites were assessed, and the weighted formula was used to calculate the overall value of each heritage site. A total of 110 heritage sites with a score of 3.50-5.00 were finally identified as Grade I heritage sites; 119 heritage sites with a score of 2.50-3.50 were identified as Grade II heritage sites; and 136 heritage sites with a score of 1.00-2.50 were identified as Grade III heritage sites.

4.1.2 Spatial Classification of Heritage based on Kernel Density Analysis

Based on the evaluation and classification results of heritage sites, the spatial distribution pattern of heritage sites at all levels was explored by the kernel density analysis method. Three kernel density layers were superimposed by the weighted superimposition technique with weights of 3, 2 and 1. The distribution density and importance of different heritage sites were comprehensively evaluated, and the areas of high aggregation, medium-high aggregation, medium aggregation, low aggregation and non-aggregation of heritage sites were identified (Figure 2a). According to the results, areas with a value of more than 326.35 were identified as core conservation areas, mainly located in Xining City, Haidong City and Yushu City. There

have rich natural and cultural heritage and important conservation values, and are important nodes of the heritage corridor. The rest of the area is used as a buffer zone for conservation, where heritage resources are more dispersed, and as a secondary area during the construction of the corridor(Figure 2b).



(a) (b)

Figure 2 (a) Heritage Density Zoning Layer and (b) Heritage Protection Zoning Layer

4.2 Analysis of the Suitability of the Tang-Tibet Ancient Road Heritage Corridor

4.2.1 Construction of Single-Factor Resistance Surface

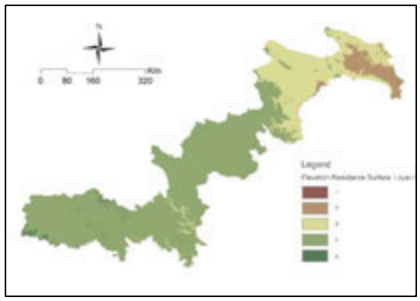
Based on considering the cultural ecological analysis framework comprehensively, the Analytic Hierarchy Process (AHP) method is used to allocate the weights of influencing factors. In Table 2, this study draws on existing research findings to identify and determine 10 key resistance factors in heritage corridors from three dimensions: natural environment, transportation network, and public services. The lower the score, the smaller the resistance, and the more suitable it is for corridor planning [15].

Table 2 Score and weight of resistance factors

Indicator Type	Resistance Factor	Categorical Indicators	Evaluation	Weight
Natural Environment	Elevation	1500	1	0.12
		2750	2	
		4000	3	
		5250	4	
		>5250	5	
	Slope	3	1	0.16
		8	2	
		15	3	
		25	4	
		>25	5	
	Land Use Type	Unused Land	1	0.22
		Developed Land	2	
		Forest and Grassland	3	
		Farmland	4	
		Waters	5	
	Distance from River	300	1	0.10

Transport		300-800	2	
		800-1500	3	
		1500-3000	4	
		>3000	5	
	Distance from Expressway	<500	1	0.8
		500-1500	2	
		1500-3500	3	
		3500-6000	4	
		>6000	5	
	Distance from National Road	<500	1	0.6
		500-1500	2	
		1500-3500	3	
		3500-6000	4	
		>6000	5	
	Distance from Provincial Road	<500	1	0.4
		500-1500	2	
		1500-3500	3	
		3500-6000	4	
		>6000	5	
Public Services	Dining and Accommodation	>900	1	0.10
		488-900	2	
		180-488	3	
		32-177	4	
		<32	5	
	Parking Lot	>1200	1	0.6
		700-1200	2	
		280-700	3	
		48-280	4	
		<48	5	
	Service Area	>52	1	0.4
		30-52	2	
		15-30	3	
		4-15	4	
		<4	5	

At the natural environment level, based on the principle of harmonious coexistence between human activities and the ecological environment, three resistance factors were selected: Elevation, Slope, and Land Use Type[16]. The higher the elevation and the greater the slope, the higher the resistance value, and the resistance value of regional land use type with more convenient human activities is smaller. At the transport network level, the distance to rivers and roads was selected as the key resistance factor [17]. At the level of the public service system, the distribution of service facilities such as dining and accommodation, parking Lots, and service areas were analyzed by the nuclear density tool, and areas with a high-density value can bring a better experience and feeling to tourists [18]. Finally, based on the weight and value of each resistance factor, the single-factor resistance surface of heritage corridor construction is generated (Figure 3).



(a) Elevation

4.2.2 Corridor Suitability Analysis

Using the ArcGIS raster calculator tool, 11 single-factor resistance surfaces were overlaid according to the specified resistance factor weights to construct a comprehensive resistance surface model that comprehensively reflects the resistance distribution in different areas of the study area. Based on this layer, the natural breakpoint method was employed to categorize the comprehensive resistance surface into five distinct classes of suitability zones: High Suitability Area, Moderately High Suitability Area, Medium Suitability Area, Low Suitability Area, and Unsuitable Area [19] (Figure 4). The area centered on Xining City is a high suitability zone, indicating that the heritage in this area has a high suitability and accessibility, and therefore a greater advantage in the construction of the Tang-Tibet Ancient Road heritage corridor. This suitability classification offers valuable guidance for formulating tailored protection and development strategies for different regions, thereby facilitating the scientific preservation and sustainable utilization of the cultural and natural heritage along the Tang-Tibet Ancient Road.

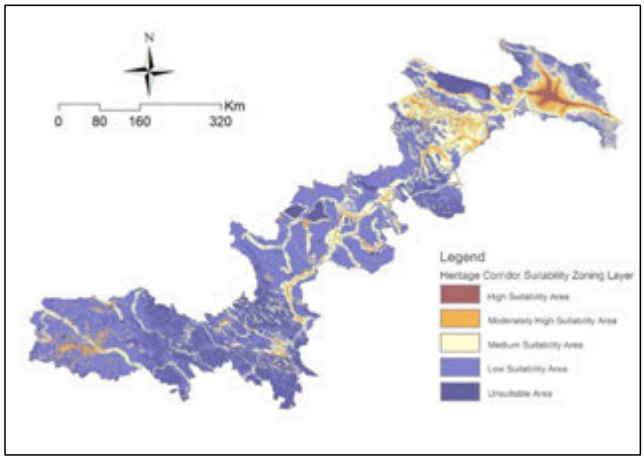

Figure 4 Heritage Corridor Suitability Zoning Surface

4.3 Construction of Tang-Tibet Ancient Road Heritage Corridor

4.3.1 Generation of Potential Heritage Corridors Along the Tang-Tibet Ancient Road

Based on the analysis of the distribution of comprehensive resistance zones in the Tang Tibet Ancient Road Heritage Corridor, using cost connectivity tools, accurately identify and generate the path with the lowest resistance between each heritage point. These paths simulate the direction of the potential corridor of Tang Tibetan ancient road cultural heritage, showing a clear east-west linear direction and densely distributed in the cultural core area (Figure 5). After a rigorous comparison and analysis of the simulation results in relation to the current river and motorway networks, it was found that these infrastructures are mainly built along national and provincial roads. They efficiently connect the region's historical relics and natural landscapes, demonstrating a deep respect for the preservation of cultural heritage and a balanced approach to natural ecology.

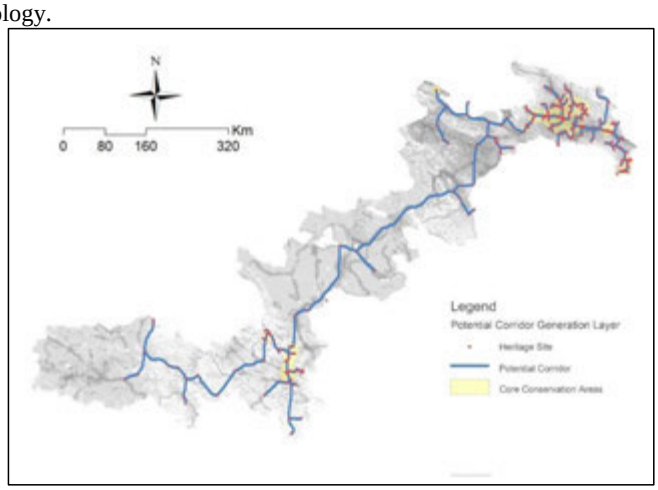

Figure 5 Potential Corridor Generation

Based on the potential of this heritage corridor, a comprehensive Tang-Tibet Ancient Road Heritage Corridor will be established. This corridor will integrate heritage protection, ecological restoration and cultural exhibition, ensuring the sustainable development of the region while safeguarding its rich cultural and natural assets.

4.3.2 Construction of Service Station in Heritage Corridors

The Tang-Tibet Ancient Road heritage corridor's functional integrity is reflected in the protection and display of culture, as well as in the provision of high-quality tourism services. Taking into account the distribution density of heritage and potential corridors, the construction of a corridor service station that integrates tourist rest, cultural exchange, and style display can effectively improve the public service level of heritage corridors. The service station should be situated in areas along the tourist route with a high concentration of tourists, distinctive cultural characteristics, or a limited distribution of heritage resources (Figure 6). The service station of the corridor undertakes the concentration and diffusion of information and functions on the route [19], enhancing the overall coherence of the heritage corridor and further enhancing the overall value and attractiveness of heritage resources in these areas.

4.3.3 Development of specialized tourism routes

Based on the cultural characteristics and protection priorities of the heritage site, construct characteristic tourism routes along the Tang Tibetan ancient road. These routes should include three types: Historic Relic Route, Cultural Experience Route, and Natural Scenery Route [20] (Figure 6).

The route of historical relics is mainly based on core protected areas, which are the areas with the most concentrated heritage and have a large amount of high-value natural and cultural heritage. To enhance the cultural experience of the heritage corridor, rich natural and cultural heritage is linked together through route planning and design while organizing tourists to participate in traditional festivals, handicraft production, and ethnic song and dance performances.

The cultural experience routes are primarily distributed in areas with a relatively low heritage density near the core area. To enhance the coherence and richness of the routes, scientific and technological means can be employed to restore or recreate heritage sites that have been lost or destroyed and integrate them with cultural experience areas such as cultural museums and exhibition spaces.

The main goal of the natural scenery route is to strengthen the connection of each cultural core area. The distribution density of cultural heritage points on this route is relatively low, mainly concentrated in displaying natural heritage and ecological landscapes. By developing and utilizing the natural landscape resources along the route, create a heritage corridor tourism route that simultaneously develops and balances culture and ecology.

4.3.4 Heritage Corridor Interpretation System Construction

The Tang-Tibet Ancient Road embodies a cultural heritage spanning over three thousand years, with its historical value and cultural connotations remaining ever-fresh and enduring. The interpretation system is an effective way to promote and inherit the historical wealth of the Tang Tibetan ancient road heritage corridor. It can effectively convey historical and cultural

information, enrich tourism experiences, promote cultural dissemination and exchange, and achieve the continuity of historical and cultural heritage. Based on the corridor tourist routes and "service stations", the cultural connotation and historical value of the heritage resources in the corridor are conveyed to tourists by means of diversified display methods such as historical images and stories [21].

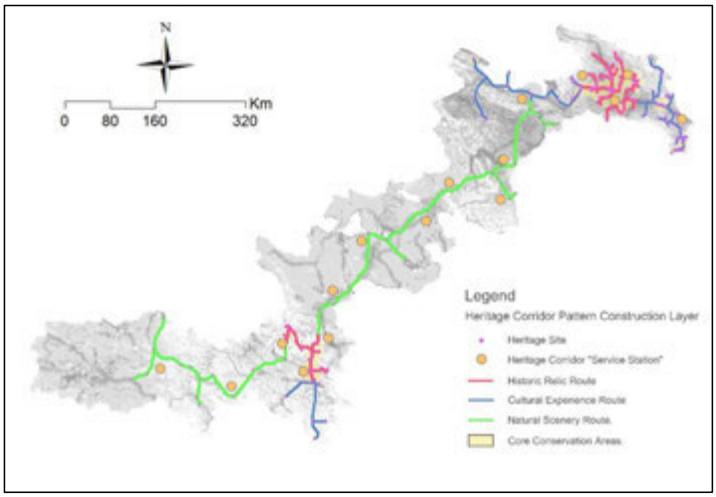

Figure 6 Heritage Corridor Pattern Construction

5. Heritage Corridor Protection Strategy for the Tang-Tibet Ancient Road (Qinghai Section)

To provide a comprehensive and effective protection framework for heritage resources, this paper combines the principles of cultural ecology and focuses on the interconnected elements of "point-line-surface", and puts forward the protection strategy of the Tang-Tibet Ancient Road heritage corridor [20].

5.1 Heritage Resource Hierarchy Protection

Heritage sites represent the core components and main contents of the Tang-Tibet Ancient Road heritage corridor, carrying profound historical and cultural values. The protection of individual heritage sites is the most fundamental practice in the overall protection strategy of the cultural heritage corridor. Grading the protection of different heritage sites according to their importance in the composition of the corridor can ensure the rational allocation of resources and promote the sustainable development of the heritage corridor.

Grade I heritage represents the core and soul of the corridor, carrying rich historical information and deep cultural connotations. It is of vital importance to protect its integrity and originality. Further exploration of its historical, cultural and scientific values should be conducted on the basis of ensuring that its body and surrounding environment will not be damaged. As a significant component of the corridor, the protection and perpetuation of secondary heritage is of paramount importance to the integrity of the entire corridor. It is necessary to fully protect it and strengthen its connection with primary heritage to enhance its status in the corridor system and promote the coordinated development of heritage sites. Tertiary heritage is comparatively less significant, yet its stability is conducive to the comprehensive protection of the corridor.

Therefore, it is necessary to implement certain protection measures to ensure the stability of the aforementioned heritage sites and predict and avoid any potential future threats.

5.2 Overall Protection of Heritage Corridor Routes

The protection strategy for the Tang-Tibet Ancient Road heritage corridor should transition from singular heritage sites to encompass the entire route, emphasizing the dual safeguarding of cultural heritage and the natural environment. Aligning with national and urban development plans, this protection should be integrated into the regional coordinated development framework. Strengthened city cooperation and exchanges are crucial to collectively advance corridor preservation, fostering resource sharing and leveraging complementary strengths. Encouraging community involvement and equitable benefit-sharing can enhance residents' engagement, awareness, and accountability in heritage protection, facilitating a harmonious relationship between economic progress and cultural conservation.

5.3 Protection of Cultural Ecosystems in the Corridor Area

The Tang-Tibet Ancient Road (Qinghai Section) Heritage Corridor traverses 12 districts and counties within Qinghai Province, covering an expansive geographic expanse. The varied natural features of mountains, rivers, grasslands, and forests play a pivotal role in shaping and conserving the corridor's cultural heritage, establishing a distinctive cultural ecosystem. In areas such as Xining and Haidong, which are considered the best for corridor development, priority should be placed on protecting heritage and adjacent ecological environments to maintain the historical and cultural wealth of the region. Simultaneously, the interplay between culture and society is advanced through a range of methods, such as the execution of cultural exhibition events and the augmentation of the area's tourism reception capabilities. In regions with limited suitability for corridor construction, such as Zaduo County and Yushu City, initiatives should prioritize the protection of heritage assets while evaluating and preserving key landscapes and ecosystems. Formulating ecosystem protection strategies can bolster stability and resilience, fostering a harmonious coexistence of cultural heritage and ecology by balancing human activities with the natural environment.

6. Conclusion

The Tang-Tibetan Ancient Road (Qinghai section) spans several cities, counties and natural areas, facing the dual challenges of natural factors such as climate, geology and disasters, as well as social factors including historical changes, urban construction and human forgetting. Therefore, its preservation and inheritance face enormous challenges. This paper analyzes the suitability of heritage corridor construction based on the characteristics of natural ecology and historical and cultural heritage protection in Qinghai. A scientific and complete heritage corridor of Tang-Fan ancient road (Qinghai section) is constructed by using GIS platform to calculate and generate potential corridors, combined with "service stations", characteristic tourist routes and corridor interpretation systems. Eventually, the protection strategy is put forward from the three levels of "point-line-surface", which provides support and guidance for cultural heritage protection and tourism development in the Qinghai area.

Integrating Curation and Retail in Chinese Urban Commercial Revitalization: The transnational exchange of the curatorial concept in Shanghai and Beijing, China

Xiaoyu Shi [a, *]
[a] Department of Urban and Rural Planning, School of Architecture, Tianjin University, Tianjin, China

Abstract: Originally from the Latin for "to care for," curation has evolved from organizing and presenting within museums and galleries, to interactive facilities and immersive experience of audiences in contemporary urban space, where art installations transform streets and commercial complexes into vibrant cultural environments. In this vein, the paper focuses on "CURETAIL," a strategy that integrates curatorial practices into retail to rejuvenate urban commercial areas, and attempts to uncover the knowledge exchange behind. It takes two leading contemporary projects, namely TX Huaihai in Shanghai and The Box Chaowai in Beijing as cases. Contextualized in the historical development of retail commercial space and curation practice globally, the paper investigates the conceptualization of project operators, responsive design strategies and consumers' preferences, identifies the characteristics of CURETAIL and reveals the transnational factors behind.

Key words : Transnational exchanges, CURETAIL, retail commercial space, urban regeneration

Nowadays in China's leading cities, a growing buzz emerges introducing curation and art into commercial spaces, as a way to revitalize old declining buildings and districts. CURETAIL (Curated Retail) is created as an innovative strategy to attract younger generations (Youfang, 2023). It has been applied in key urban regeneration projects like Shanghai's TX Huaihai and Beijing's the Box Chaowai, and successfully transformed traditional malls into iconic retail and pop-culture centers. Against the impacts of online shopping and pandemics, CURETAIL provides consumers with choices that go beyond algorithm-led, fixed recommendations at a time of material abundance, and allows the consumers to have a personal emotional experience. The paper accordingly traces the transnational diffusion and exchange of the curatorial concept and intends to uncover the dynamic reasons behind (Souhu, 2019).

1 The birth of CURETAIL in Chinese cities

Fig.1 Dickson Sezto giving talk at TX Huaihai, 2019 (source: https://www.instagram.com/txhuaihai/)

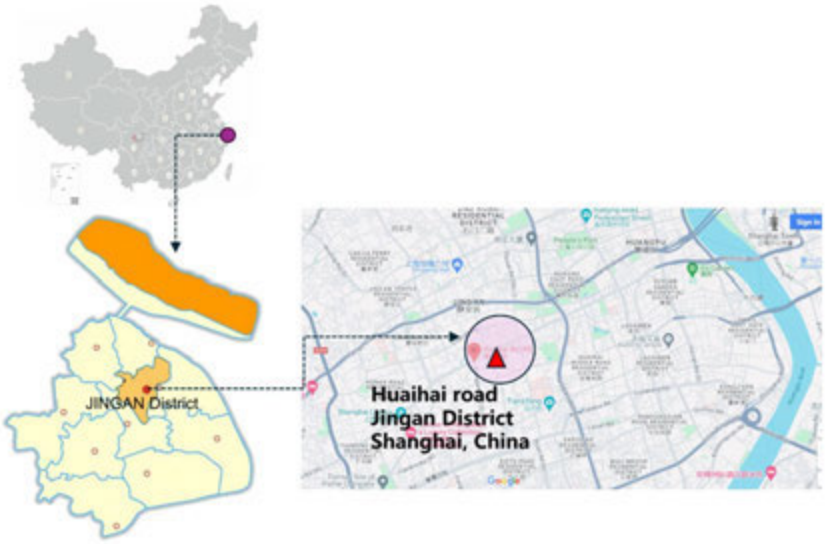

Fig.2 Location of Huaihai Road and TX Huaihai, Shanghai

The CURETAIL concept was proposed by Dickson Sezto (Fig.1), Chairman of URF Yingzhan Group, during the renovation project of the Huaihai Middle Road commercial district in Shanghai. It was first implemented at the Bailian TX Huaihai | Youth Power Center on Huaihai Middle Road (Fig.2). This area, shaded by century-old plane trees and lined with hotels and high-end boutiques, was once recognized as one of Shanghai's most fashionable commercial streets. However, with the rapid development of China's internet economy from

2013 to 2018, physical retail stores, burdened by high rental costs and shrinking sales volumes, were gradually replaced by more convenient and cheaper online stores, forcing many well-known brands on Huaihai Middle Road to close due to financial losses (Souhu, 2019b).

Before Refurbishment, 1990s

After Refurbishment, 2020

Fig. 3 Real scenes of TX Huaihai, Shanghai. (source：https://m.thepaper.cn/wifiKey_detail.jsp?contid=10913161&from=wifiKey)

TX Huaihai was no exception. Formerly home to the First Department Store Huaihai and Isetan (Fig.3), it had been in decline for years and was in desperate need of transformation. On one hand, emerging commercial centers in various districts of Shanghai and internet retail businesses had siphoned off the clientele originally belonging to Huaihai Middle Road. On the other hand, Huaihai Middle Road suffered from typical old-town issues such as insufficient parking and dispersed public transport stops (Karimi, 2023). Sezto's response was to focus on "youth" and "trends." The urban layout of the old district made it difficult to change; middle-class individuals with cars preferred to drive to suburban shopping complexes with better facilities. Elderly people who rely on public transport found it inconvenient, as their physical condition did not support walking several kilometers from the nearest public transport stop to their destination. Only young people, keen on following internet trends and relatively less affluent, would make the effort to travel to places of interest. These potential young customers are known as China's Generation Z. Predominantly university students and young white-collar workers, they are under thirty, mostly unmarried and childless, with some disposable time and a relatively strong purchasing power. On one hand, Generation Z pursues individual interests and emotional experiences, with significant differences among individuals (Zhang and Lee, 2022). On the other hand, due to increasingly frequent and extensive international exchanges, their interests are not limited to domestic cultural IPs but also encompass cultural products from around the world.

Therefore, Dickson Sezto introduced the CURETAIL model, aiming to attract the potential Generation Z consumer group. By consulting with globally renowned trendsetters and incorporating trend culture forums, brands, and events, he transformed the original shopping center into an art gallery, exhibition center, and show venue (Fig.4-6). Considering that the shopping desires of the same consumer group are ultimately limited, it is more effective to rotate exhibitions, pop-ups, parties, and meet-and-greets to meet the varying needs of different consumer groups, ultimately achieving the goal of selling products (Gao et al., 2022). CURETAIL strives to keep the pace of brand scene changes in sync with the speed of young

people's smartphone refresh rates, ensuring that new activities are available in the public spaces every week. The operator continuously attracts new customer sources through these activities, maintaining a steady and sufficient flow of visitors (Zhao et al., 2023).

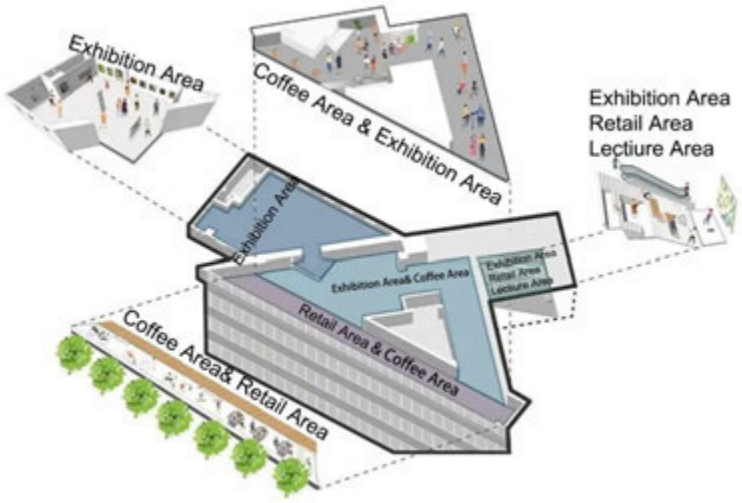

Fig. 5 Functional layout of TX Huaihai

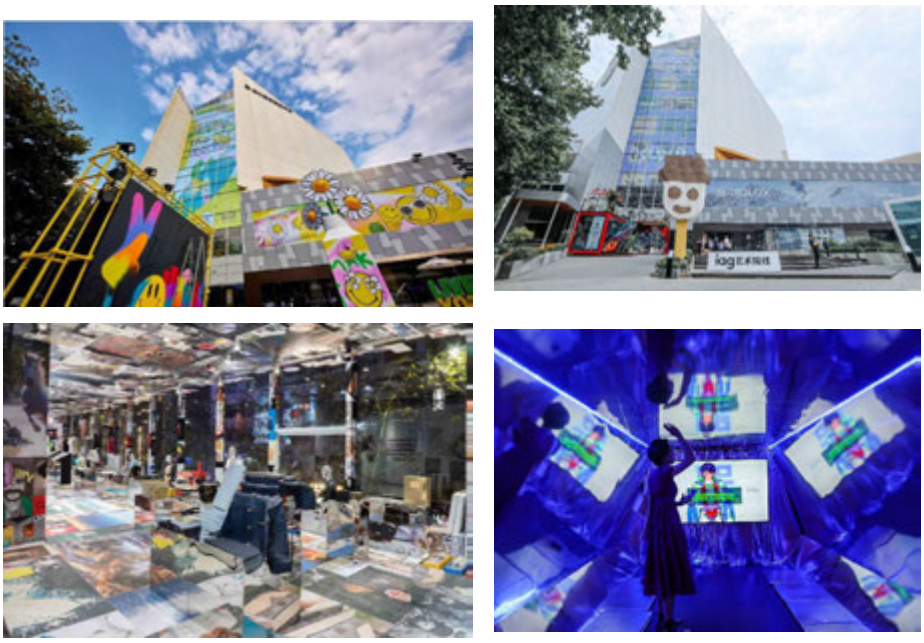

Fig.6 Changing Exhibitions at TX Huaihai, 2019-2020

Dickson Sezto applied the CURETAIL concept once again at The Box | Youth Power Center in Beijing's Chaowai area. Located in one of Beijing's earlier developed regional commercial centers, Chaowai does not have the long history or large scale of other major commercial centers like Xidan, Wangfujing, and Qianmen, nor does it have a diverse range of retail products (Fig.7). Instead, it primarily targets high-income consumers from the Chaoyang district. With the development of Zhongguancun in the Haidian district, the high-income consumer base is gradually shifting northwest, leading to the aging of commercial building facilities in the Chaowai area, which has become increasingly dilapidated (Motomura et al., 2022). Additionally, the area suffers from a severe lack of parking spaces and already has numerous department stores and commercial complexes catering to middle-aged and elderly consumers. To secure a foothold in such a competitive environment, it is essential to develop a new customer base. In 2021, the BaonaoHui, formerly a major electronics marketplace in the Chaowai area, successfully transformed into a retail art experience space themed around home living, thus beginning to attract young people (De Winne et al., 2020). As a result, the CURETAIL concept was chosen for the renovation and redesign of the space at The Box Chaowai (Fig.8).

Fig.7 Location Distribution of Important Business Districts in Beijing

Before refurbishment, 2010s

After refurbishment, 2023

Fig. 8 Real scenes of BOX Chaiwai, Beijing

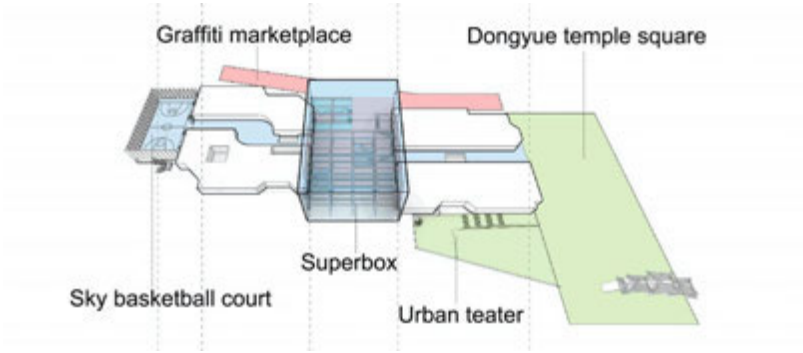

Fig. 9 Functional layout of BOX Chaiwai, Beijing

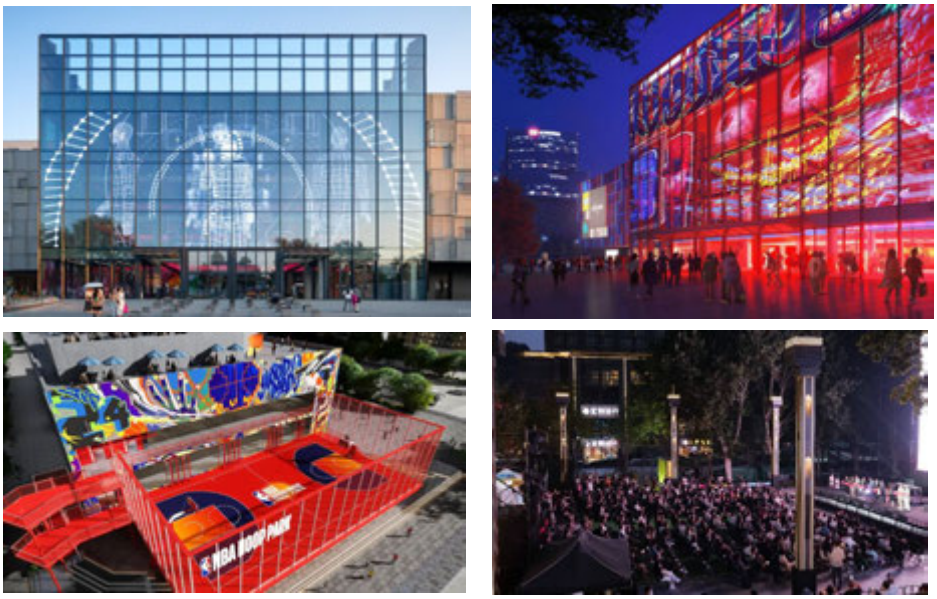

Fig.10 Exhibitions at THE BOX Chaowai, 2022-2023

The main structure of Chaowai THE BOX (Fig.9-10), known as the GLASS BOX Super Trendy Box, retains the original beam and column structure of the KunTai Mall but has been transformed by dismantling and reconfiguring the floor plates into a 360° flexible multi-path space. This space is now used for brand launches, premieres, curated fashion shows, flash retail, and multimedia events. Additionally, it includes numerous functional auxiliary spaces. On the east side, there is an outdoor basketball court and skateboarding area, making it a gathering place for street trend enthusiasts. The south side features Beijing's first graffiti market, while the northwest side has been excavated to create an open-air, immersive "Slope Theater." The west side utilizes the archway of the Dongyue Temple to provide a cultural activity square, offering a variety of spaces for activities and gatherings for young people (Soyinka et al., 2021).

Since its operation began on September 16, 2023, Chaowai THE BOX has seen an average daily foot traffic of about 15,000 people, which increases to 50,000 during weekend exhibitions. The asset value of the enterprise is expected to increase by 20%-30%, with the commercial spaces generating over one billion RMB in annual revenue. Office space rent is expected to grow by 20%-30%, with annual taxes paid amounting to approximately 1.53 billion RMB—an increase of about 1 billion RMB from before the renovation. Additionally, it is projected to create about 3,000 new jobs.

2 The transnational re-shaping of Retail space

When examining CURETAIL within the context of the evolution of retail business, it fundamentally restructures the relationship among "people," "goods," and "spaces" within retail environments (Requena-Ruiz et al., 2023). In the early stages of human society, retail was mostly a small-scale self-producing and self-selling workshop model, with retail spaces

dispersed in narrow fronts and workshops at the back of urban buildings (Fig.11). With the outbreak of the Industrial Revolution in the mid-19th century, the advent of department stores marked the transition of retail spaces indoors, where products moved from being singular and scattered to being centrally displayed and diversified, enhancing the consumer shopping experience significantly. In these department stores, "people" were the main actors in the retail scene, with "goods" and "spaces" playing the roles of objects and backdrops, respectively (Fig.12).

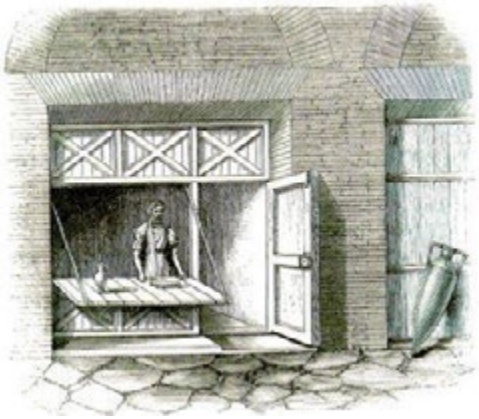

Fig.11 Tabernae in ancient Rome, a plural retail space different from open market

Fig.12 A early 20th century department store in Paris

By the mid-20th century, influenced jointly by the proliferation of automobiles and government housing policies, urban residents massively relocated to the suburbs, and shopping centers made their debut in American suburbs (Fig.13). These centers, composed of department stores and small retail shops, were equipped with large, free parking areas to accommodate consumers who drove there. Beyond "goods," these "spaces" combined indoor and outdoor elements, offering a variety of distinctive public areas that met the social needs of "people," creating an atmosphere conducive to social life and cultural activities.

Fig.13 The Park & Shop in Cleveland Park, Washington, D.C. (1930) is one of the earliest examples of a small center with dedicated on-site parking in front. (source: Neighborhood shopping center - Wikipedia)

Fig.14 The interior of Garden State Plaza megamall in Paramus, New Jersey. (Source: Shopping mall - Wikipedia)

In the 1990s, as urbanization accelerated and land use efficiency improved, the retail "space" moved with "people" back to urban centers, evolving into more intensive and multifunctional urban commercial complexes (Fig.14), serving city dwellers of all ages and incorporating restaurants, cinemas, and entertainment venues to meet diverse free-choice, leisure, and entertainment needs (Liu, 2022). Since the 21st century, as the internal market in cities became saturated, operators of commercial complexes began to strengthen and sustain customer attraction through collaborations with other arts and cultural industries. The CURETAIL analyzed in this paper is one such model.

Under the CURETAIL model, consumer behavior shifts from active to passive, with "goods" being imbued with stories to attract traffic, and "spaces" providing an immersive experience. "Goods" and "spaces" take the leading role, guiding the thoughts and actions of "people" and tying them to consumption. At this point, the exhibitions have become the "social currency" of Bailian TX Huaihai and Chaowai THE BOX, keeping the pace of changing scenes in sync with the rhythm of young

people and using constantly evolving aesthetics to draw them back to once-declining traditional commercial districts.

3 The curate origin of CURETAIL

The term "curate" originates from the occupational meaning of "curator," which itself comes from the Latin word meaning to care or heal, initially used to describe "someone who cares for people's souls," essentially a parish priest (Hu et al., 2022). In the 1660s, the term "curator" began to be associated with the management of art, museums, and libraries. The first recorded curator in history, scientist, inventor, and architect Robert Hooke, in 1667, conducted an experimental project titled "Using a bellows to inflate a dog's lungs to keep it alive." By the 19th century, the term "curator" started to be used for museum curators and independent curators in the modern sense of curation. Subsequently, influenced by the postmodernism trends across various fields in the 20th century, the concepts of "critical curation" and "independent curators" emerged. In 1969, Harald Szeemann, at the Kunsthalle Bern, creatively redefined the relationships between curator, artist, and the exhibition itself in his exhibition "When Attitudes Become Form: Works-Concepts-Processes-Situations-Information." He allowed artists to take over the museum, creating their works on-site, completing most of the exhibits a few weeks before the exhibition opened.

In the 1990s, with the development of internet technology and the advent of the information explosion era, numerous new media platforms enabled everyone to assume the role of a curator in their domain. The concept of "curatorial nature," which encourages exhibition visitors to actively explore the content and meaning of the exhibits, began to enter mainstream vision. As a result, the democratization of curation moved it beyond galleries and museums and into the realm of retail business, emphasizing the interaction between people, the items on display, and the exhibition spaces.

The proponent of CURETAIL is Dickson Sezto, who was born in Hong Kong in the 1970s, a crucial port for international economic and cultural exchanges at the time. Sezto grew up in a bilingual environment where Chinese and English coexisted, deeply identifying with Chinese traditional culture while also being influenced by Western trends and business practices. He graduated in 1992 from Monash University in Australia with a degree in literature, specializing in social statistics and psychological analysis of social phenomena, which honed his skills in statistical analysis and market research, shaping his unique insights and sharp vision as a business executive. Sezto has been dedicated to commercial real estate development, with his most well-known project being the transformation of Shanghai's Xintiandi, an old alleyway, into a landmark international retail and pedestrian area. In 2019, Sezto once again became a focal point in retail business by proposing the CURETAIL model, which led to the creation of the Bailian TX Huaihai | Youth Power Center.

In conceptualizing "CURETAIL as an exhibition-driven business," Sezto drew upon numerous transnational experiences, such as the practices at the Innovation District on Boston's waterfront, the South Lake Union area in Seattle, and the East London Tech City in the UK. These experiences emphasize enhancing the customer experience and creating immersive interactive spaces. Noticing the rapid development of the internet and e-commerce, which has provided consumers with more convenient choices, Sezto realized that shopping is no longer primarily about visiting physical retail spaces. Thus, he focused on creating a rich artistic

atmosphere and a cultural identity aligned with trendy concepts, including virtual and augmented reality displays related to the metaverse, making these the primary attractions of the retail spaces under the CURETAIL model.

4 Conclusion

In general, the CURETAIL includes three main characteristics. Firstly, it emphasizes the open and flexible public spaces. CURETAIL promotes retail spaces that are not confined to indoors but integrate seamlessly with outdoor environments, providing consumers with various options to socialize, enjoy views, or relax over tea. This integration offers more space for activities and ensures a superior experience while walking, viewing, or shopping. Secondly, it frequently updates its exhibitions and displays. The CURETAIL model involves frequent updates of public space arrangements and hosts highly targeted events for different consumer groups. Operators can stay abreast of cultural trends and introduce popular cultural activities, responding dynamically to the changing cultural landscape. Thirdly, it actively collaborates with influential brands and hotspots. Under the CURETAIL model, operators can take advantage of popular influencer spots to forge collaborations with well-known domestic and international brands in specific fields, complementing each other's strengths. Particularly, the "flagship store economy" can be utilized to attract foot traffic and enhance economic benefits.

The formation and successful application of the CURETAIL concept are inseparable from transnational influences. Firstly, global Influence on Interactive Commercial Retail Spaces: Although Dickson Sezto originally conceptualized CURETAIL, similar models of interactive retail spaces have existed worldwide, influenced to varying degrees by the concept of "curated retail." For instance, a subway renovation in East London transformed into the OTHER WORLD gaming experience venue, and in Icheon, South Korea, the NONSPACE café serves as a "cross-cultural space." Secondly, the proponent of CURETAIL Dickson Sezto has transnational background. He grew up in Hong Kong—a melting pot of Eastern and Western cultures. His landmark urban renewal project, Shanghai Xintiandi, was completed in collaboration with Benjamin Wood's architecture firm from the USA and DP Architects from Singapore, incorporating advanced technologies from Germany and elsewhere. During the development of CURETAIL, Sezto frequently consulted with global trendsetters like Hiroshi Fujiwara and Chen Man.

Thirdly, CURETAIL's targeting consumer Generation Z is a transnational generation. The primary target audience for the CURETAIL model is Generation Z, born into the thriving "global village" of the internet age. The advent of the information era has intensified their passion for international trends and cultural shifts, making them particularly sensitive to changes in cultural currents. These factors enable CURETAIL to integrate diverse culture and innovative retail strategies to cater to a globally connected, trend-sensitive consumer base.

Abstract
The city of Delhi, about four centuries old, is a rich example that demonstrates the shades of sustainability. Each of the historical layers were/is comprised of geo-political context wherein the socio-cultural milieu was nurtured: case of Delhi that spans across Hindu, Islamic, Mughals, British to independent India. Delhi was built seven times and the current being the National Capital Region. However, imprints of each one embedded within the city and fairly legible through its fabric, cultural heritage, economies, social connotations' in architectural vocabulary and planning. The paper attempts to highlight the histories from governance perspective and its influence on planning approaches spanning over four centuries. The mapping of planning governed by geo-political through histories for the city of Delhi.
Keywords: Histories, Planning, Urban Governance, Cities of Delhi.

1.0 Introduction:

We must acknowledge that the world is changing but in doing so we must realize that there are still many lessons to be drawn from the past. Whatever design solutions we choose should be conceived in such a manner as to allow evolution and progress to orient us towards the future, rather than retreat into the past for its own sake. Maintaining a sense of historic continuity is essential, especially at a time when our country is striving for cultural identity and survival in the face of standardized values, mass-produced culture and alien influences. The towns, sites and buildings stand out as striking examples of authenticity at a time when new urban development is increasingly impersonal and unimaginative. The preservation of the political power and values of such groups are just as important here, of course as environmental considerations. [Harvey; 1996] In an attempt to find urban development solutions that will not alienate people, it is useful to examine those in history that have accommodated the pressure of technological and social change without alienation. The developed world was once developing, ancient Greece was developed when Rome was developing, Rome was over developed when Byzantine and medieval cities were being established. From all these phases of developing and developed urbanisation there are survivors- towns that exhibit an ability to accommodate the changes of the next generation in an unselfconscious manner. There are patterns of development that on one hand exhibit a seeming indifference to the environment and on the other an environmental quality that transcend time by its neutral rationalism. Our cities should provide visible clues to "where we have been and where are we going" [Ford 1978] or "the excitement of the future should be anchored on the security of the past." [Lynch 1960]. "The sustainability is not a new phenomenon. Historic towns and cities around the world did not have a choice. If they existed for any length of time it was only because they were able to develop and maintain a continually re-balancing relationship among their internal social and economic activities and with their wider natural and agricultural landscape." [Levine 1987] Peter hall [1997] states " The new world will largely depend, as the old world did on human creativity; and creativity flourishes people where they come face to face, only for local milieu will emerge [Willoughby, 1994] or that local culture will be strengthen as Globalises information makes national borders less relevant [Ohmac, 1990; Naisbett, 1994; Sassen, 1994] or that the importance of face to face contact will ensure centres emerge as critical nodes of information oriented production [Winger, 1997].[Sharma.A.K : 2022]

2.0 Planning through Histories

In an attempt to find development solutions that will include people, it is useful to examine those in history that have accommodated the pressure of technological and social change without alienation. The dimensions of urban layout in such cities thus appear to be all important. Space is an asset that permits change to occur progressively and gradually, at low cost and with low expenditure of energy. The historical examples that have enhanced the patterns of change by unselfconsciously adapting themselves to fresh pressure demonstrate a consistency in the shape and size of their irregular grids around which perimeter development has occurred. As the inner city sustains, a city then begins to take its 'inner city' qualities to its suburbs; i.e. in the walled cities, the existing public transport and walking oriented characteristics, mixed land uses with urban design conducive to, face-to-face activity. Hence, it is possible to reach destinations with short distances, without a car, and thus created walk able communities. Interestingly, even today the fastest mode of transportation in historic core cities is walking, rickshaws etc are essentially low carbon in nature. These built environments over a period of time have experienced densification accounting for adaptability and attaining saturation often with the engagement of the local communities. Densification is a cumulative process that takes place over time and it is difficult to define the limits beyond which it may become 'over-developed'. An environment has a limit or capacity up to which it can absorb activities without irreparable form but in historic cities the local communities contribute for the limit to growth i.e. the local communities have an inherent mechanism to stabilise the numbers as a cultural connotation at large.

Delhi has been the administrative capital since its inception dating back to tenth century. Delhi was build many times; interestingly despite the varying political heads the location continued to be same for centuries on. Typically for any city to develop the pillars of sustainability along with governance plays a key role, the role of urban governance influenced the planning decisions with outcome of cities of Delhi each one with a unique identity.
The dimension of city layout thus appears to be all-important. Space is the asset that permits the change to occur progressively and gradually, at low cost and with low expenditure of energy. Those historical examples that have enhanced the pattern by unselfconsciously adapting themselves to fresh pressures demonstrate a consistency in the shape and size of their irregular grids around which perimeter development has occurred. The ground rules for this would appear to be more universal than has hitherto been recognised. Multiplicity of institutions/ agencies, possibilities opened up by new building technologies/ engineering services and a break in the architectural/ planning continuity all have contributed immensely to the physical and perceived economic decline of historic built environments, constrained under blanket bye-laws and regulations which have little relevance to the makeup and historical urbanism of these cities'. Histories are roots for all aspects including planning, as planning is a continuous process over time addressing the needs of the people. People are key for any city therefore when one traces the urban developments from a historical perspective; Knowledge exchanges are insightful. Among the histories of Delhi-seven cities may draw parallel with Rome with 700 years and seven hills.

2.1 Dimensions of historic layers

The historic layers of any city is typically governed across scales from local, regional, national and international as well. Further Globalisation added another dimension of decision making influencing the governance at city level especially mega cities across the globe and Delhi is among the top ten. 2008 crisis large corporate houses investing and for large scale buying of buildings, land, precincts' etc. the land ownership leads to systematic transformations in the city often altering the historic meaning of the city and has significant implications for social equity, local economies and large scale corporate re-development of cities. The re-development meant rebuilding or constructing new buildings that were large, taller, spacious and often luxurious type for offices including apartments. In 2013 to 2014 buying of properties grew by 248% in Amsterdam, 180% in Madrid, 475% in Nanjing, 160.8% for Beijing and in case of Delhi mushrooming of a satellite city: Gurgaon. [Sassen. S: 2015] These mega projects invariably have vast carbon footprint; a typology that is omnipresent in megacities virtually cloning them at the coast of the identity of each of the cities. Cities that were socio-culturally driven were driven by capitalist economy such a paradigm shift from urbanism to gigantic urbanism from public to private: hasn't been healthy for the cities with impacts evident and continuing. Such a dichotomy has made

planning rather complex in more than one ways. Privatisation in 90's resulted in reduction of public buildings with an escalation in corporate ownership's consequently gentrification affecting the social structure,…control of urban land to control of urban governance introducing a universal global typology, a signature of notion of development. However, the paradigm shift also gets translated in other aspects as well i.e. dilution of social classes, role of religion, ethnic diversities etc as the city growing cosmopolitan and in the process the nature of diversity having a paradigm shift as well. The new owners belong to the global culture, irrespective of their birth and origins but are birds of the same flock across the mega cities of the world. [Sharma. A.K: 2022]

3 .0 Historic Cities of Delhi

Delhi, situated on seismically sensitive area is the part of Indo-Gangetic alluvial plain at an elevation ranging from 198m to 220m above the mean sea level. Two major landform systems converge here the Ganga Plain and the Ridge. Physically, Delhi may be divided in to three parts - the plain, the Yamuna flood plain and the ridge. The major part of Delhi is plain area. The Yamuna flood plains are low-lying and sandy and are subject to recurrent floods. The Ridge constitutes the most dominating physiographic feathers in this region. It is an extension of the Aravalli hills of Rajasthan. Climate of Delhi is dry winters humid subtropical climate bordering hot Semi-Arid Climate, extreme temperatures ranging from 2- 48 degrees.
Delhi enjoys a central geographical location in the country; now better known as National Capital Region (NCR). The National Capital Region extends between 28023'17"N & 28053'00"N latitudes and between 76050'24"E & 77020'37"E longitudes. The length is about 51.90 kilometres with breadth around 48.48 kilometres. The area in NCR Delhi is 1483 sq. km. of terrain. Delhi is situated on the bank of the river Yamuna between mountain ranges of the Great Himalayas and Aravallis. The adjoining states are Uttar Pradesh on the eastern side and by Haryana state on northern, southern and western sides.

The time line histories of Delhi may be summarised in broadly three stages as follows:
Stage 1: Seven cities of Delhi- Hindu, Islamic and Moghuls
Stage II: Colonial and Independent India
Stage iii: Satellite cities: Faridabad, Ghaziabad, Gurgaon and Noida: NCR under NCT.

4.0 Seven cities of Delhi

One of the earliest mention of Delhi is by Greek historians who took their accounts from those who accompanied Alexander 327 BC mentions Muttra not Delhi, that depicts unimportance of Delhi then; while one suggestive remark by Arrian's reference from Megasthenes- quotes abandonment of traditional Indraprastha. Further three Chinese pilgrims visited India between 390 AD and 645 AD mention about Muttra however no mention in writings of Delhi. Another reference of Muttra in 1000 AD when Ghazni invaded the country. Thus it may be logical to conclude that Delhi was first occupied around AD 300 and abandoned due to some reasons and rehabilitated in 1052 when Ghazni left. [Risley: 1906]

City Order	City Name	Year Estb.	Founder
I	Lal-Kot	1000	Anangpal
II	Siri	1303	Alau'd-Din Khilji
III	Tughluqabad	1321	Ghiyathu'd-Din Tughluq
IV	Jahanpanah	1327	Muhammad-bin Tughluq
V	Firuzabad	1354	Firuz Shah Tughluq
VI	Purana-Qila	1533	Humayun
VII	Shahjahanabad	1639	Shah Jahan
VIII	New Delhi	1911	Britishers

City Order	City Name	Area Kms2	Dist. from Qutb(Kms)	Real World Coordinates Long.(D:M:S)	Latit.(D:M:S)
I	Lal-Kot	3.40	0.00	77:10:58.799	28:31:51.817
II	Siri	1.70	4.40	77:13:00.306	28:34:21.913
III	Tughluqabad	2.20	7.70	77:15:37.550	28:31:33.227

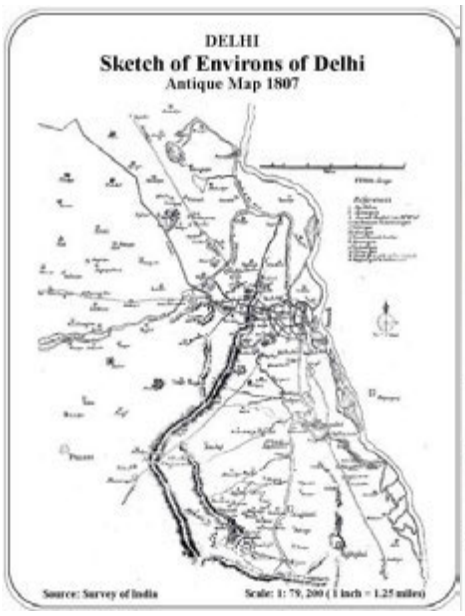
VIII	New Delhi	12.20	10.50	77.12.38.864	28.37.13.452

Table 4.1 establishing dates of cities Table 4.2 Areas & Geographical location of cities [Risley Gordon: 1906]

This first Delhi better known as lalkot established around 1000; evidence in Asoka inscription dated 1164 which stands in Firozshah kotla, also mentions Visala Deva probably the grandfather of Prithviraj Chauhan who built Lalkot as old Delhi. [Risley: 1906] the historicity of this Delhi exists only in texts' and cross references; as the city must have been built in timber and with weathering may have deteriorated over time. Also Delhi was unimportant thus resources may have been limited to none therefore no remains of any kind of Lalkpt. It may logical to conclude that the planning of first Delhi of Lalkot not known except for its existence that was recorded.[ibid]



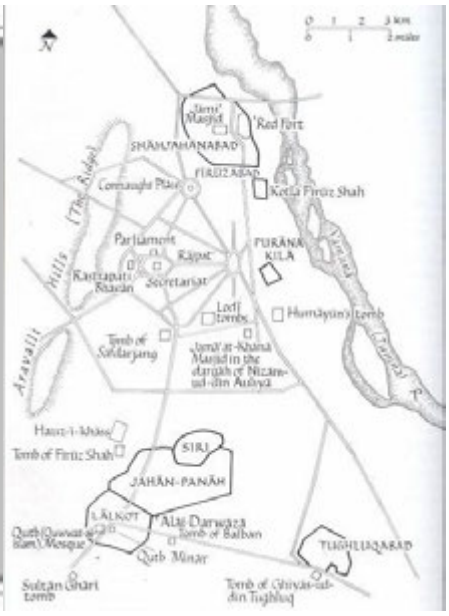


Fig 4.1 Map of Delhi Fig 4. 2 sites of seven Delhi's [Risley Gordon: 1906]

In 1151 AD Chauhan's conquered Delhi, who was defeated by Muhammad Ghori in 1193 AD and Qutub-ud-din Aibak built Qutub minar as a symbol of victory over the Chauhans with existing 27 Hindu temples within the limits. As per Islam personification of Gods' is prohibited thus the structures of existing Hindu temples built in stone with exquisite carvings were retained but with defaced sculpted images of Gods and Goddesses are evident even now. In 1303 AD Alauiddin Khilji constructed the second city Siri occupied by existing village of Shahpurjat and Hauz khaz have had continued existence with parts of remains exist even now. The footprint of second Delhi is legible as precincts' i.e. in Haus Khaz village that has a water body and green spaces that are retained while Shahpurjat the built morphology has transformed to address the need for commercial and office spaces with limited residential. Typically, the stand point of Delhi master plans is that the construction within the laldora: the legal boundary of the village [red thread in Hindi] is to be monitored by the village panchayat the lowest denominator of administration. Next the location of both these villages is extremely strategic as an extension of Lutyens's Delhi and central to the city. Being a village their built morphology is organic in nature which is in stark contrast to the well planned city beyond the laldora. This nature of development offers opportunities i.e. low cost, approvals not a challenge, issues like FAR, building heights, setbacks etc not in place; such a framework offers immense opportunities for one to be creative

exploring scales and urban design issues like element of surprise among others. Hauz Khaz was transformed as fashion hub by individual's entrepreneurs with minimum seed money for the retails'. While Shahpurjat evolved as a hub for retails and office spaces mainly because of low investment required with central location within the city. [ibid]

In 1320 AD Tugluq Shah built rapidly as he lived till 1325 AD he built the third city of Delhi. The city five miles to eastwards around rocky hills largely for security reasons with high sloping walls the remains are still intact. However, the said site did not have any direct access to water which proved prove to be bane and no constriction happened after his death. Conventionally the name of the city followed the name of the king thus Tuqhlakabad the third city. As the king lived for a short duration the city never shaped up also lack of water made it even more difficult. The history of planning neither could get documented nor recorded, whilst the remains of the high sloping walls continue their presence within the Delhi's fabric only. Records states that the minister of the king of Tugluq dynasty built the Khirki mosque [1351-1388] one of the two covered mosques in India; a deviation from the conventional design of mosques'. Thus except for the covered mosque and the sloping walls the planning histories missing but the open spaces including the remains is a bio-diversity park now maintained by Delhi Development Authority cherishes the same name of the dynasty.

1327 AD Muhamad-bin-Tugluq of Tugluq dynasty build a city that accommodated the large population residing on open plains between old Delhi-Lalkot and Siri were insecure and felt the need to build walls resulting in the fourth city: Jahanpanah. In the name of planning histories this city has only remains of the buildings and other structures i.e. tomb of Ghayasudin –Tugluq along with open green spaces that have enjoyed their continued existence. The current master plan Jahapanah forest is acknowledged.

When Firozshah succeeded Tugluq, he constructed the fifth city of Delhi, north east of Siri in 1354 AD towards north and the ridge area. The limits of Firozabad and Shahjahanabad due to close proximity; as it was easier for the inhabitants to pillage the building materials to build. Firozabad had walls only on west side and river edge no walls; thus this city was not a walled city in true sense. Largely it was about access to building materials from the older cities i.e. Siri, Jahanpanah, Tuqhlakabad accessed from three sides road from Qutub Minar, to build the city. The Firozshah kotla fort overlooking the river Yamuna continues its presence in abandoned state. Each of the five cities were built towards the north as river Yamuna the source of water flows from north to the south; thus an attempt to access fresh water moving towards the north was the norm. however, this trend continued till the seventh city only as with the colonial rule and industrial revolution, technologies were in place, when New Delhi-Lutyens' Delhi was built.

After the Moguls conquest Humayun built the Purana Qila in 1534 AD and the walls for the sixth city occupied a part of Firozabad as well. The walls of Tuqhlakabad and Shahjahanabad are in existence while the remains of the rest four cities are legible in the city's fabric. Often Purana Qila is associated with the Indraprastha as the Hindu city that stood in 1450 BC; as described in poem by Homer. In precedence of the previous cities the fort of Purana Qila with a part of moat with water is the only remain of this city. Within the fort too most of the buildings are ruins now.

In 1648 Shah Jahan built the seventh city also known as Shahjahanabad- a living historic city and recognised as heart of Delhi. Following the norm of building towards north continued; however, towards the east was Red fort overlooking the banks of river Yamuna and instead of city walls a moat was constructed similar to previous city of Purana Qila. Shahjahanabad had low walls as it was built later in time line as compared to Tuqhlakabad for that was built on rocky hills with high walls. A water channel was constructed along the main axis that connected the red fort to Fatehpuri [means conquer in Urdu] Mosque. It is believed that a water channel through chandni chowk the central spine of Shahjahanabad the seventh and living city of Delhi, was a part of channel of Firozabad. Most of the cities were built on the same site and in close proximity site partly due to convenience of building materials readily available for centuries. The transition from city walls to moats and bastions were reconstructed as city expanding the bastions rebuilt accounting for the defence mechanisms. Shahjahanabad had fourteen gates they were built over time largely driven by reasons of governance from economic to security.

Fig 4.3 Map of Shahjahanabad 1857-58 [DUAC: 2015]

The city when planned was characterised by organic nature while the gates that facilitated the ease of movement of people which continued for about two hundred years. All the gates were not built since the inception of the city but added as and when required i.e. in 1852 AD Grand Trunk road brought through Chandni chowk. The Grand Trunk road connected Calcutta to Peshawar now in Pakistan that facilitated the British for administration purposes and economic as well. Parallel in 1854 East Indian railways began again by British and in 1852 Lahori gate were built; these transitions culminated with the British rule from 1858 AD. The change of urban governance impacted the fabric however the transition also observed water supply and sewage systems in place. The impact was largely at city level while the individual buildings continued with the prevailing architectural vocabulary.

Zone	I	Delhi gate/ Faiz bazaar

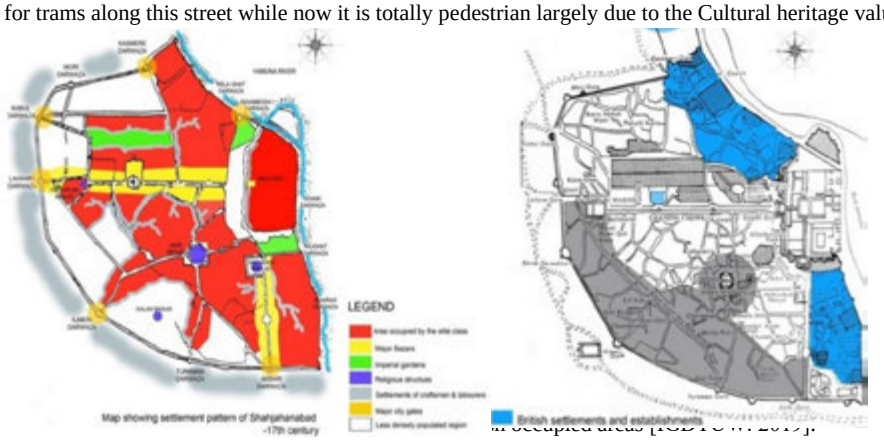
Zone	X	Lahori gate
Zone	XI	Mori gate area
Zone	XII	Kashmiri gate area

Fig 4.4 Zones mapped in Shahjahanabad Tab 4.1 Zones in Shahjahanabad [IGDTUW:2019]

The main east-west axis that connects the Red fort to Fatehpuri masjid was/is significant that transformed with time for the needs of the inhabitants often the decisions were governed by administration. Mughals used it as their main commercial street that had a water channel flowing in the centre. British recognised the relevance of the street and constructed a town hall on this street with large open space in front of it for conjugation and built few churches as well. The colonial rule was responsible for trams along this street while now it is totally pedestrian largely due to the Cultural heritage value.



The Socio-Cultural strength was so strong that even the British could not dilute it. Within the walled city they managed to occupy areas that were lived in by lower class of the society then including the adjacent areas as spill over as shown in Fig 4.8.

Fig 4.5 Trams in Shahjahananbad [Above] [IGDTUW: 2019]

Fig 4.6 Main east-west axis image depicting the open space infront of Town hall in Shahjahananbad [right] [IGDTUW: 2019]

The walled city historically enjoyed the status as administration head and over the years have assumed the status of wholesale market for not only Delhi but for northern India. This economic boom increased the demand for storage spaces for goods and this zone strategically located at the edge and easy access to the market was/ is being used such. Significant is that there have been attempts to shift the wholesale markets outside the walled city and even facilitated through master plans allocating spaces but the social response was not favourable. The socio-economic set up was/is very strong and thus decisions related to governance have continued.

Next the Faiz market better known as Dariyaganj that leads to Delhi gate had development planned based on western norms. One can see the stark contrast as illustrated in the case of Delhi gate and connect with the city expanding beyond the gates. Sharing few examples enumerating the planning approaches of Shahjahanabad and new Delhi along the edge of the walled city where two diverse urban tissues co-exist. First one is that of Delhi gate. Dariyaganj main market street erstwhile Faiz bazaar was once a boulevard between Akbarbadigate of the fort till Delhi gate: 1050 yards long, 30 yards wide with 888 shops built in 1650 it was the main commercial street with central canal shaded on both sides by trees similar in design with haveli's, sarai's, masjids on either sides. In 1800's most of the original fabric levelled by the British to make room for the military. This street is popularly known as the Dariyaganj market now. It's interesting to observe that the part of the walled city continues with residential land use except along the main road that has commercial and retail activities. However, the urban texture on either side of the road is in contrast [refer Fig 4.9] the right side development saw the transformations over the years especially during the late Colonial rule and independent India. On Sundays when the shops are closed this street houses market for old books and was an integral part of the Delhi population for years.

Fig 4.9 Delhi gate zone with current land
current land use [IGDTUW: 2019]

.

Fig 4.10 Time line urbanisation of Delhi gate zone [IGDTUW: 2019]

Ownerships of properties in the walled city typically are multiple ownerships that too is a deterrent for redevelopment thus stabilising the densities. The real estate prices within the walled city are the highest and often accessibility is a challenge as each ward is inhabited by specific community and thus preference is for the clan over the price. All these aspects are typical for the walled city only and not applicable for New Delhi and satellite cities.

The next case example is that is of Turkman gate. This gate was occupied by middle and low class communities and later taken up as an initiative for redevelopment as well. This was largely as an outcome of first master plan that stated that the walled city is a slum area and needs attention. The proposal to rehabilitate them to a different site outside the walled city was apolitical agenda however, the local community protested and eventually the project had to be shelved; something that could happen only in the walled city.

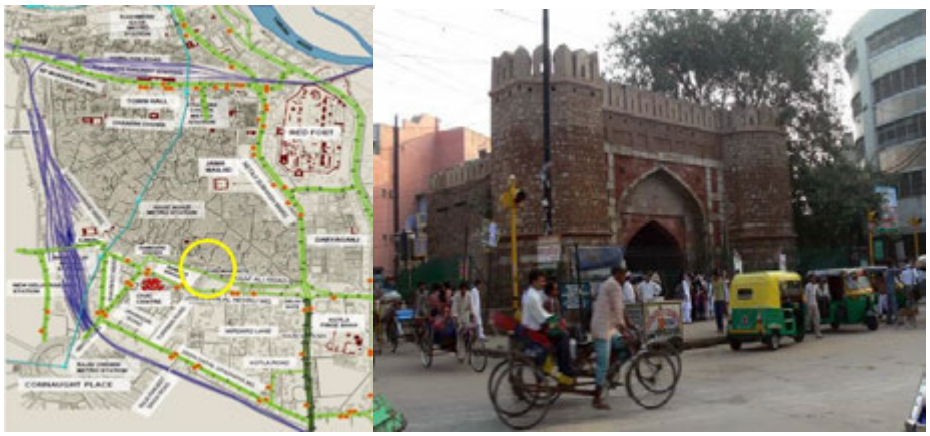


Fig 4.11 & Fig 4.12 location and image of Turkman gate [IGDTUW: 2019]

5.0 Colonial and Independent India

British assumed political power in 1858 and managing the rule from Shahjahanabad proved to be an uphill task with existing city with a planning typology that they were not familier with and to govern decided to have their own establishment as another Delhi : The New Del or Lutyen's Delhi.

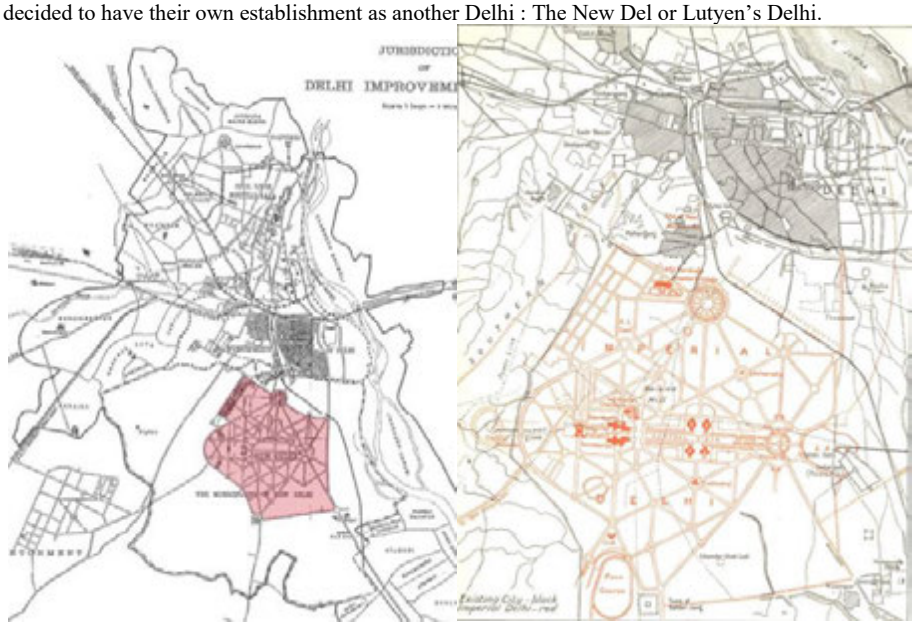

Fig 5.1 & Fig 5.2 Site of Lutyens Delhi and Shahjahanabad [DUAC: 2015]

In 1911 the British Sifted the Capital from Kolkata to Delhi and the birth of Imperial Delhi Community was formed in March 1913 to overseas the construction of the New Capital known as Lutyens's Delhi. In 1916, it was notified as Raisina Municipal Committee under the Punjab Municipal act 1911. In March 1927 this Municipal Committee was redesignated as New Delhi Municipal Committee. [Indian summer:] In 1932 this committee was upgrade as First Class Municipal Committee. MCD act in acted by Parliament in 1957 and Municipal Committee of Delhi election were held in 1958.

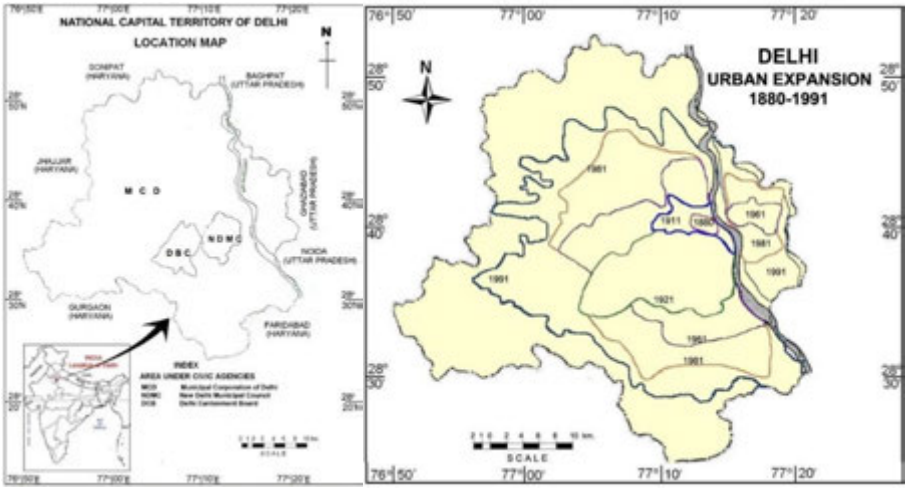

Fig 5.3 Location of Delhi & Fig 5.4 Decadal Expansion of Delhi [Singh.N.C: 2019]

This stage of transition from Colonial rule to independent India and role of Delhi the administration capital. Lutyens' planned the city acknowledging the main axis of the existing cities, river Yamuna and local building materials. Considering the British were to build New Delhi with norms and standards including typologies were rather western i.e. typically the residences in old Delhi were courtyard houses while the bungalows designed had the built in the centre with large open spaces around the built, in total contrast to the traditional typology and so on and so forth. The 'Imperial City' of New Delhi designed on Garden City principles, with a central avenue comprising the President's House and surrounded by government and institutional buildings with residential 'bungalows surrounding the main spine. The plan was conceptually based on the Garden City principles of Ebenezer Howard, with wide tree lined avenues, large plots and bungalows set in them. The main axis was an east-west axis, starting from the Rashtrapati [means President in Hindi] Bhawan atop the Raisina Hill going down to the India Gate; centre of hexagon. The ridge behind the Rashtrapati Bhawan, known as the central ridge, comprises of 864 ha. and most of it has been declared as a 'reserved forest' in the year 1914.

The planning principles were in stark contrast to the compact city, densely populated, mixed land use with low rise high density constructed with locally available materials and vernacular technologies. The statement of avenues, boulevards with bungalow typology was rather an expression of authority and status; something that continues till date. Such a paradigm shift came in for an independent India and the planning of New Delhi was more in sync with the planning vocabulary at global level. The seat of authority is now occupied by first citizen of the nation, the President. The layout of the Rashtrapati Bhawan, North Block and South Block, large bungalow plots and other government buildings with boulevards demonstrates Delhi as a city a grand order, symmetry and unique aesthetic character mainly blended with use of local red sandstone.

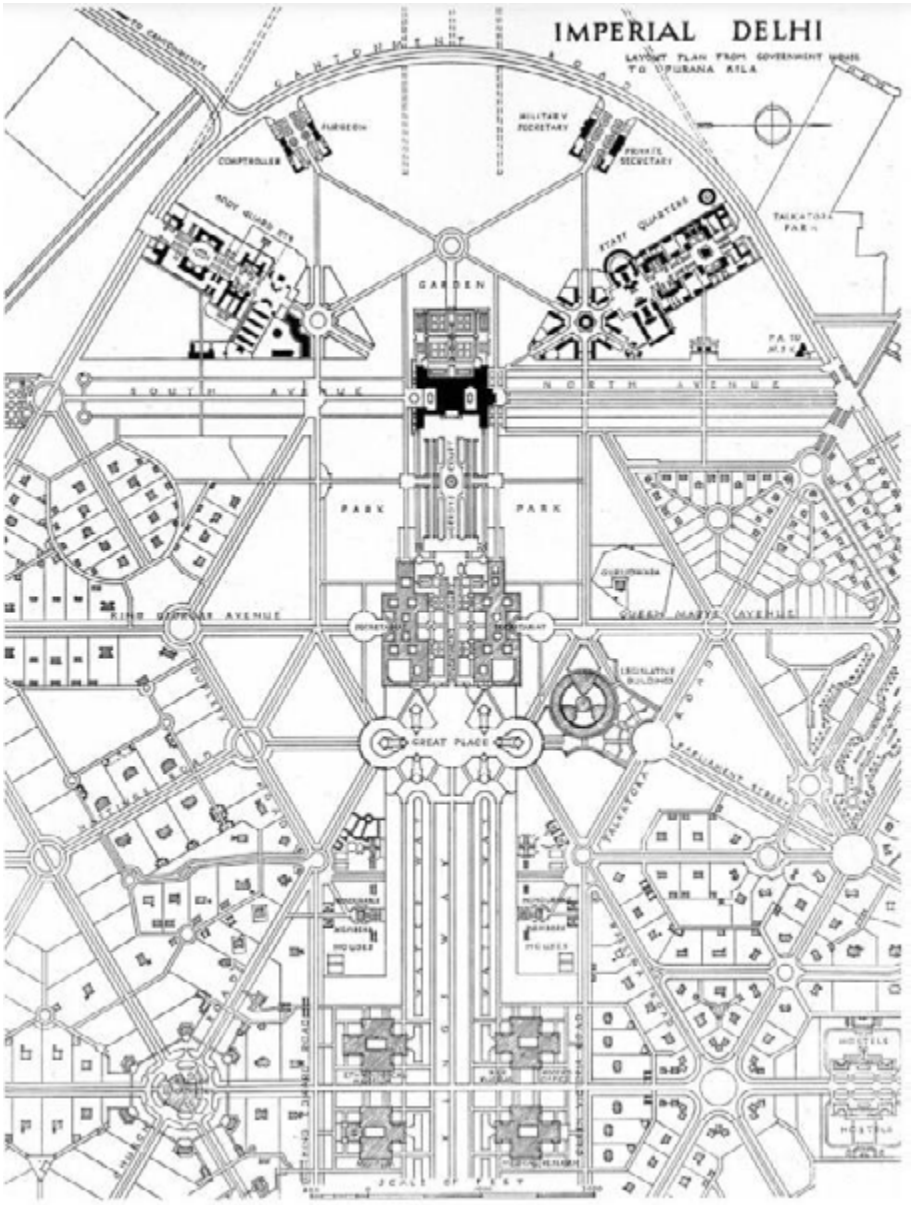

Fig 5.5 Layout Plan of Lutyens' Delhi [DUAC: 2015]

The Delhi master plan 2021 declares Lutyens' Bungalow Zone as heritage zone covering an area of 28.73 sq.km and constitutes approximately 2 percent of the total area of the NCT of Delhi: 1,484 sq.km. The World Monuments Fund has designated Lutyens Bungalow Zone as one of the world's 100 most endangered sites in the year 2002.

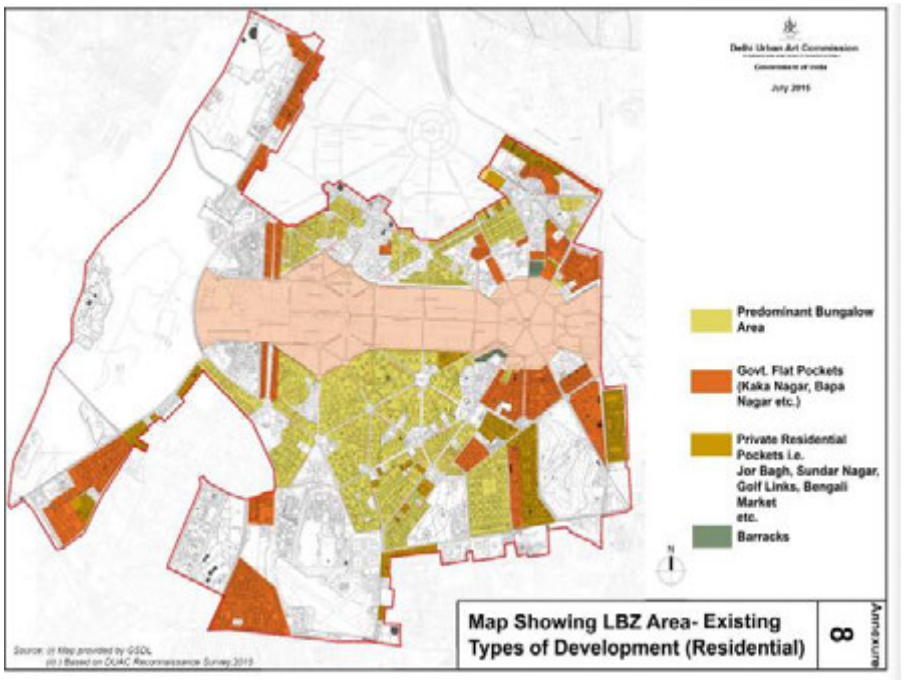

Fig 5.6 Land use of LBZ [DUAC:2015]

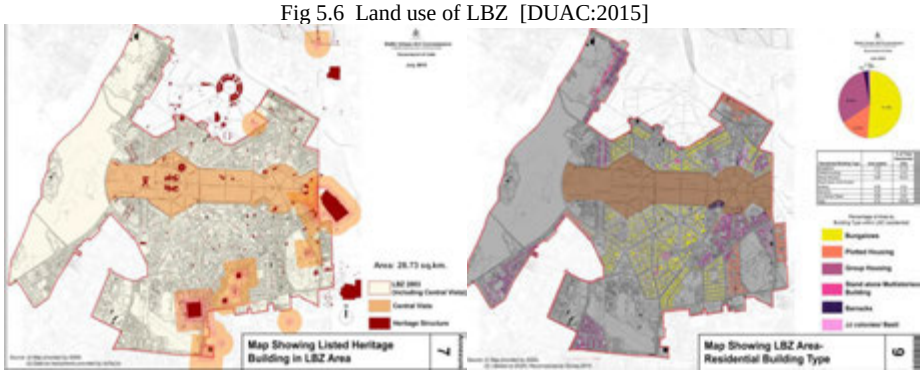

Fig 5.7 Heritage buildings[1] in LBZ Fig 5.8 Land use of LBZ

New Delhi was officially declared as the capital of India after the independence. The State Reorganization Commission 1955 suggested that, 'from the point of view of the law and order, the social life of the people, trade and commerce and common public utility services, old Delhi and New Delhi now constitute one integrated unit and it will be wholly unrealistic to draw a line between the two' [Planning Commission, 2009]. The Government of India accepted the recommendations of State Reorganization Commission, 1955 and Delhi was declared as Union Territory. The Union Territory of Delhi was renamed and now it is formally known as National Capital Territory of Delhi. Key milestones of planning histories of independent Delhi are as follows:

- Original Lutyens's Delhi was planned for an area of 19.12 sq.km, that got revised in 1988 for 25.88 sq.km. in 2003 for 28.73 sq.km and interestingly in 2015 the area was reduced to 23.60 sq.km. Lutyens's Delhi since its inception planned as the administration head continues and

thus the change in areas was to be a part of the prestigious zone. However, with the limitations of building norms coupled with the real estate prices and strategic location propelled such a decision. Although Lutyens's Delhi continued its authoritative position and certain policy decisions encouraged large scale developments initiated both at national level and globalization. One of the earliest local bodies then in place was ASI founded in 1861 by Alexander Cunningham, also the first Director-General. The first systematic research into the subcontinent's history was conducted by the Asiatic Society, which was founded by the British Indologist William Jones on 15 January 1784.

- The independent India among the many challenges with Urban governance and the nations' aspiration to develop was central with this backdrop Delhi was the focus. Therefore, after independence Delhi Development act [1957] was passed by the Parliament. The first master plan for the period 1961-81 was prepared by DDA and notified by the Government of India in 1962. Municipal Corporation of Delhi [1958], National Monuments Authority [2011], ASI [1961]. In 1962 the first Master Plan for Delhi was prepared by DDA, Albert Mayer from Ford Foundation along with Town and Country Planning Organization [TCPO]. The master plans in Delhi were/are formulated based on the provisions of the Delhi Development Act, 1957. Partition of India Pakistan about seventy thousand migrants landed in the city and occupied various pockets In 1985 Enactment of the National Capital Region Planning Board Act was constituted mainly a response to immigration of people to the city and subsequently Zonal Development Plans were prepared in 2001, 2021 and 2041. The first master plan was revised for the extended period up to 2001 by DDA. It was further revised for the standard period for 2001-2021 notified in 2007. Further Delhi fast urbanising was under various local authorities and in an attempt to have uniformity Unified building byelaws were notified by DUAC in 2016.
- The Liberalisation policy in 1991 by the government of India encouraged investors across the globe to setup factories, offices etc and the real estate sector were quick to respond to address the needs of the people i.e. residences, retail etc. Gurgaon shaped up the fastest among the other satellite cities.

6.0 Stage three- Satellite cities: Faridabad, Ghaziabad, Gurgaon and Noida

Delhi after independence being the capital of the nation coupled with its history attracted migration. The earliest mass migration was that due to partition when a large number of people moved to Delhi, both Muslims and Hindus'. The government facilitated them by allocating land parcels to rehabilitate them beyond the limits of Lutyens Delhi. With the city's population growing constantly the need for affordable housing was a challenge. Although the local authorities were at the task to deliver, there was a gap between the demand and supply. Considering Delhi till then was developing and growing on the southern side only but the towns closer to Delhi proved to be a viable option as the land was accessible and affordable. Thus growth of satellite cities of Faridabad and Ghaziabad occurred; parallely the real estate sector was quick to respond to the needs of the society. Proactively the real estate sector along with the local authorities who were struggling with the demand and supply stuck a comfortable balance. Typically the master plans were drawn up for the satellite cities but the nature of development varied. For example, the case of Gurgaon the most recent one; Gurgaon shaped up one of the fastest in Asia. The growing population required transportation thus a plant was set up in collaboration with Japan for affordable cars. Next 20 years later the liberalisation policy gave a boost to Multinationals to invest in India and Gurgaon local authorities were quick to respond to that and facilitated the necessary infrastructure especially internet and with real estate investing the growth began.

It's interesting to note that the neighbouring states looked upon the growth of Delhi as a huge opportunity for the growth of their respective states'. Mainy two states share the edge of Delhi Uttar Pradesh and Haryana; the former towards the east while the rest of the three sides by the latter one. The population growth rate is insightful for the development of the city, with urban land increasing over the years the annual exponential growth rate dipped.

Urban Area and Population of Delhi: 1901-2011

Census Year	Total Urban Area (sq. km.)	Total Urban Population	Percent Urban Population	Annual Exponential Growth Rate	Decennial Growth (percent)
1901	-	214115	52.76	-	-
1911	43.25	237944	57.50	1.1	11.13
1921	168.09	304420	62.32	2.5	27.94
1931	169.44	447442	70.33	3.9	46.98
1941	174.31	695686	75.79	4.4	55.48
1951	201.36	1437134	82.40	7.3	106.58
1961	326.55	2359408	88.75	5.0	64.17
1971	446.26	3647023	89.68	4.4	54.57
1981	540.78	5768200	92.73	4.6	58.16

Table 6.1: Decadal Population of Delhi source: Census of India 2001 & 2011. Economic survey of Delhi 2008-2009, and Town Country Planning Organisation 2007.

Delhi, being the political head there were many job opportunities and thus influx of population occurred and that explains the cosmopolitan nature of the city; quite apt for the capital of the nation as well with 29 states. The rate of migration was substantial and the efforts of the planning authorities could not cope up and with limited resources made it even challenging. The neighbouring states were smart to tab the potential and equipped themselves to address the spill over of the city. i.e. the connecting roads were the spine along which the development occurred. The states have their own respective governance and Delhi had its own. In order to encourage the spill over of Delhi Gurgaon was fast to respond and through the connecting roads from Delhi; in Gurgaon they proposed land use and facilitated, that was in demand in Delhi. This strategic move yielded fruits and Gurgaon was on the move. Gurgaon typically evolved as a city based on the need duly patronized by political will, as revenue generation proved to be an asset for the state to fund their own, other parts of the state. Multinationals chose Gurgaon as the political will facilitated them with all necessary approvals and required infrastructure this gave momentum to the speed of development. The real estate sector patronised by the political will was/is the main driver for decisions of planning in every way. Thus today Gurgaon boosts of Cyber city including high end residential condominiums'. The strong nexus between the real estate and local authorities under pinned by political agenda: the developers were allocated large land parcels and each one planned them based on the section of society they intended to cater. Therefore, the urban fabric of Gurgaon isn't consistent with disparate planning co-existing; sometimes one often comes across sustainably planned and developed such. But stitching the sustainable pockets do not necessarily yield sustainable city. The land prices too vary with the kind of developments by selected real estate developers.

Noida in contrast; part of Uttar Pradesh observed and planned the city with infrastructure especially connectivity to Delhi. However, people never responded to Noida in the same manner like Gurgaon mainly due to political setup that was corrupt and poor to offer security although recent government has improved the situation but India being democratic people are not certain for sustenance of security issue thus the pace of development has been slow. Also the stakes by real estate sector is much lower thus rather affordable for the middle class of Delhi population. Delhi witnessed these trends and need to get these satellite cities under one umbrella and National Capital Territory [NCT] was created; with standard norms for the region governed by the NCT panning board. The present setup of NCT of Delhi came into existence with the passage of the NCT of Delhi act 1991 [by the parliament by way of incursion of Article 239AA though 69th Constitutional Amendment. This NCT Act came into force in 1992 with this New Administrative setup in Delhi a number of organizational and administrative changes have been brought in by the GNCT of Delhi.In the process among the descriptions of Delhi, one of its locations, Kilokhri, that formed a separate 'city' in the thirteenth and fourteenth centuries, now a part of

the Delhi NCT. [najaf haider] Faridabad and Ghaziabad grew gradually mainly due to their locational advantage only as compared to Gurgaon the prices of the flats were much less.

Fig 6.2 Map of Delhi

Fig 6.3 Map of NCT Delhi [Singh: 2019]

Significant to note is that the spill over of Delhi encouraged gentrification in certain pockets within Delhi housed a section of the society and they relocated such in the NCT i.e. Gurgaon houses condominiums that are high end luxurious apartments followed by Noida. While Faridabad houses mostly middle class affordable flats with Ghaziabad to follow. State of Haryana [Gurgaon and Faridabad] offers better security over state of Uttar Pradesh [Noida and Ghaziabad] reflected such in the development and growth of these cities. although the initial development in these satellite cities were largely driven by political and change in land use was inherent again more a response to demand than an outcome of planning at large. Now all of them have master plans in place and the existing Integrated such.

7.0 Planning histories of Delhi

Delhi enjoyed a central position as administration head since its early days. Therefore the planning was driven by political agenda and the political will only. Tracing the timeline the early cities were aspirations of the kings who established the cities to demonstrate their strength and valour; that continued for Islamic, Moghuls, Lutyens' to independent India and NCT.

The remains of the seven cities clearly enumerates that through religious structures' be it temples or Mosques duly patronised. When the transition time was less the existing ones were defaced etc to meet the political agenda. However, they all utilised locally available materials and indigenous technologies and typically, the planning was a strategic site for the kings with social hierarchy translated in the built morphology surrounding the king. The last of the seven cities the Shahjahanabad was taken care by the British for their own vested interest to rule the nation but did make their presence through planning interventions: location and building Town hall with large open space in front [the only large open space in the walled city] including construction of barracks in Redfort area. Also illustrated in the example of Delhi gate shared in the paper.

Lutyens Delhi and the main buildings constructed then are continuing including the Viceroy's lodge as Rashtrapati Bhawan; the residence for the head of nation, the President, while the rest of the buildings serve for government offices including a few institutional buildings. All buildings placed along the Raj path, the central spine of LBZ now the main public open space for Delhi. Ironically in the recent past the currently elected government proposed a major planning intervention in the Central vista in the Raj path spine; again a demonstration of political agenda to leave a mark in the histories of Delhi. However, among the planner it was a bone of contention but in vain as the political will stood tall.

The planning approaches in the satellite cities again demonstrates the negotiations of political agenda through planning strongly underpinned by capitalism. Planning was incidental with decisions i.e. change in land use, preferences for certain real estate developers including the vested interest of the officials of the local politicians and authorities. The compromise filtered down across all hierarchies i.e. plan of a residential condominium had parks designed in the layout and later they were converted into plots and sold at higher price. Another instance when a large plot was bought for institutional land use at a nominal rate and later negotiated for additional land use. Such decisions impact the use of infrastructures and delivery of the same at city level and the impact is evident in the current scenario.
Another significant dimension for legible histories of Delhi is that in the contemporary situation the investment to preserve and conserve the remains of the history are not universal. The Aga khan foundation has invested in buildings and precincts built by the Moghuls i.e. Humayun's Tomb, Nizamuddin area among others while the others are neglected and in a dilapidated state. Thus the layers of histories construct a narrative that is far from the truth.

However the silver lining is that people were/ are and shall continue to be responsible for the cities. In the case of Delhi as well, all the cities are living and thriving with their own sustaining mechanisms to show their resilience to adapt to varying circumstances. Covid impacted many cities of the world and with the best of communication technologies people moved closer to nature but Delhi with poorest AQI has not been abandoned whilst gentrification got cemented.
The people took the onus onto them and are responding to their built environs for being healthy and improved air quality; partly contributed by the local administration too more to woo the voters as democracy is the norm.

8.0 Conclusions

Delhi being one of the top five largest metrapolis in the world and now with India with highest populated nation in the world puts Delhi in a precarious situation. Delhi has deilivered across varying political heads goverened by administration, economic, religion castes', Social-Cultural, to political agenda. Among the various Delhi's till Lutyens's' Delhi's urban tissue is unique whereas the satellite cities rather clones abiding by the norms of notion ofdevelopment defined by the developed nations. As developing nation then; the need to be a part of the global platform the planning standards were implemented. Ironically the nature of development not being in sync with contextual has incresed the footprint and thereby contributing for climate change. This is important as the so called developed nations have saturated with their growth and concious for the concern and with resources and technolgies are in a position to address the issue. This gives one an opportunity to learn from global examples maybe as best practices i.e. systems in place in London Twentieth century society now Pluralist society only transition of name but existence continued that offers Certificate of immunity [COI] including grading for a limited term subject to renewable with the Intent of histories for buildings by STAB- Society for the Protection of Ancient Buildings setup by William Morris and Philip Webb [1877]. In case of Delhi similar intiatives may be in place and extending beyond buildings for precints to cities too. However, initiaves are being looked at for footprint for developments that are sustainable by allocating addtional FAR-floor area ratio for green rated buildings but the norms to be abided by are non contextual thus do not contribute much for the carbon footprint.

Delhi grew and developed for its geographical, political, economic, social aspects the pillars of sustainability strongly underpinned by Cultural heritage. Globalisation facilitated by liberalisation policy encouraged the satellite cities to develop with the global norms of planning.
The current rate of growth is continuing through TOD-transit oriented development that encourages continuous development along the connecting spines i.e. DMIC-Delhi Mumbai Industrial corridor operational now. Urban governance is a challenge especially for a capital city with strong intervention of geo-political agenda. Delhi demonstrates histories of planning typologies and most of them either in place or documented and NCT has the opportunity to relook at and plan the way forward.

Annexure-1 TEN CITIES OF DELHI [Gupta.Narayani, 1987]

1. Lal Kot/Qila Rai Pithora {the Tomars): The broken walls of this can be seen on the road to the Qutub (Aurobindo Marg). Many of the stones and carvings of Prithviraj Chauhan's fort were used to build the arches near the Qutub Minar. The Minar, begun by Iltutmish, has 378 steps.
2. Siri (Alauddin Khilji): Much of this has been later built on, but parts of its wall can be seen near the Asiad Village and near the MadangirRoad-Saket crossing.
3. Tuqhlakabad (Ghiyasuddin Tughlak): Notice the sloping walls {to make them stronger) and the beautiful tomb of Ghiyasuddin (which used to be surrounded by a lake).
4. Jahanpanah (Mohammed Tughlak): Vijay Mandal (between Panchshila Park and Malaviya Nagar) was where Mohammed Tughlak reviewed his troops.
5. Ferozeshah Kotla (Ferozeshah Tughlak}: In this fort, notice the Ashoka Pillar that the Emperor had brought to Delhi and placed here. His own tomb is in the beautiful Hauz Khas complex (see Chapter 13).

6. Sayyid and Lodi Delhi: Most of these monuments are enclosed in the Lodi Gardens (Lady Willingdon Park) which was earlier the village of Khanpur. The Lodis also built Masjid Moth, which is near present-day Uday Park.
7. Purana Qila (Humayun and Sher Shah): The enormous gateway on the Bahadur Shah Zafar Marg, outside Ferozeshah Kotla, belongs to Humayun's city. Sher Shah's mosque in the Qila has beautiful marble and sandstone work. The library is of interest because of Humayun's accidental death there when he tripped and fell on the staircase.
8. Shahjahanabad (Shahjahan): If you approach Delhi Gate from Bahadur Shah Zafar Marg., you will see the city wall stretching to the right towards Ring Road.
9. British Delhi: a) The Ridge. Opposite the main gate of Delhi University is Flagstaff Tower, which the British army occupied in the 1857 siege. Further west is the British Victory Tower.
b) New Delhi. Walk or drive down from India Gate (built in memory of the soldiers killed in World War I) to Rashtrapati Bhavan. Look at the Secretariat buildings and notice how they combine Indian and Western styles of architecture.
10. Modern Delhi: The capital of independent India, a) Diplomatic Enclave, Chanakyapuri. An area set aside for foreign embassies.
b) Buddha Jayanti Park. A beautiful open park, sited on the Ridge.
c) Ashoka Hotel. The earliest of the big hotels necessary for a major capital city.
d) Jawaharlal Nehru Stadium. One of the largest stadiums in Asia, built for the Asian Games of 1982.
e) Birla Mandir.

Abstract
The port city Izmir has a long history, dates back to Hellenistic times. This multi-layered historic city, known as Smyrna, has enduring powerful connections based on trade within Mediterranean regions. The city was a multi-cultural place especially during the 19th and early 20th centuries, covering diverse typologies of cultural assets formed by diverse communities. Throughout the history, fires, earthquakes, and conflicts affected the urban tissue, which are followed by important planning studies. This paper aims to understand cultural heritage based on the historic roots and develop new strategic framework regarding whole cultural layers. Past plans and spatial maps are analysed in detailed and evaluated. The interpretation and presentation strategies are defined to foster mutual understanding and respect, in a broader sense, building peace among communities.
Keywords: Historic port city, interpretation and presentation, cultural heritage, Smyrna, Izmir.

1. Introduction

In the history, the very first settlement named Smyrna was established in Bayraklı district, known as Old Smyrna today in the Bornova Plain, at an area that forms a natural harbour in 3000 BCE in Izmir (Figure 1). Due to Persian attacks, Alexander the Great reestablished the city on the skirts of Pagos Hill, next to the Meles River and Gulf of Izmir around 300 BCE (Doğer, 2020; Ersoy, 2015; Tanrıver, et al., 2016).

Smyrna had an inner harbour and a port during the Hellenistic Period, and agricultural products from the fertile valleys of the Küçük Menderes (Kaystros) and Büyük Menderes (Meandros) rivers in the south and Bakırçay River (Kaikos) in the north were transferred (Doğer, 2020).

Figure 1: Location of Historic Centre of Izmir

Smyrna went under the control of the Seleucids in 281 BCE, then under Roman Rule in the late Hellenistic Period, and later under Eastern Roman Empire until 11th century. Earthquakes, fires, and epidemics threated the city during ancient times. Components of Smyrna Ancient City, namely the Smyrna Acropolis, Theatre, Agora, Harbour Bath, some parts of main roads, and housing area of Altınpark have reached today, while traces of some components such as Stadium, city walls, and urban pattern are still visible.

The settlement captured by Çaka Bey in 1081 (Daş, 2009) and ruled under Turks' control since then. Aydınid Period was followed by the Ottoman Era. With the increment of trade volume at the end of the 16th century, the city expanded towards the cape called *Punta* on the coastline. The European states opened consulates, and the population of Greeks, Jews, Armenians, and Levantines increased, and they formed their own neighbourhoods (Goffman, 1995).

Figure 2: İzmir at the end of the 17th Century (source: Rijksmuseum, Amsterdam as cited in Nizamoğlu, et al., 2022, p.109)

Figure 3: A Gravure form (Cornelis de Bruyn, source: Archive of Konak Municipality, 2021)

Due to the changes in transportation technology, security concerns, and natural processes, a larger quay and developed port trade functions were required. Hence, the inner harbour of the ancient times was filled starting from the 17th century and expanded over a span of 400 years (Figure 2, Figure3). The infilled area was designed as an Ottoman Bazaar, and diverse types of architectural heritage, such as khans, bazaars, churches, mosques, synagogues, İzmir houses, fountains, significant public and cultural buildings were built (Beyru, 2011b).

In the late 19th century, trading activities were expanded to its largest network in the Mediterranean Basin and beyond (Figure 4). New buildings were developed in the urban area. The banks, post offices, stock exchange building, insurance companies, and entertainment enterprises were at the coastal zone so called Kordon, the Ottoman bazaar on the infilled area so called Kemeraltı, and a modernized bazaar at the north of Kemeraltı, namely as Mimar Kemalettin, and residential areas towards the skirts of the castle skirts.

The revival of the commercial life also led to a vibrant city life. Travelers and tourists visited Izmir and noted that diverse communities with different culture and religion lived in their neighbourhoods, which has characteristic architectural styles based on their lifestyles (Yaranga, 2000).

The defeat of the Ottoman Empire in the WWI was followed by Greece occupation in 1919, then the war between Turkish and Greek armies. The great fire 1922 destructed a significant part of the city, many cultural heritage buildings were destroyed (Naimark, 2002; Biondich, 2011; Neyzi, 2008). Afterwards, the population exchange between Turkey and Greece agreed with Treaty of Lausanne in 1923, and entire Greek, Armenian, and a significant part of the Levantines and foreigners left İzmir.

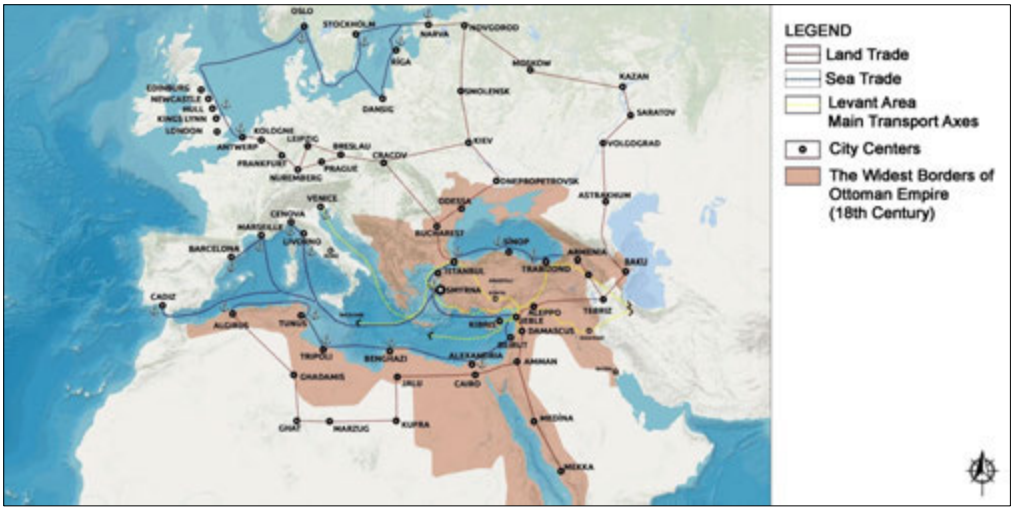

Figure 4: International Trade Routes of Ottoman Empire in the 18th Century (illustrated by authors, Source: Nizamoğlu, et al., 2022, p. 125)

In the Republican Period of today's Türkiye, Izmir still conserves important cultural buildings and urban pattern, which has evolved with cultural layers throughout the history. This settlement still exhibits various layers of civilization including Roman, Byzantium, Ottoman, and Republican Era. Although functions and buildings were altered in times of modernization and globalization, spatial organization and macroform of the urban space has been conserved.

Smyrna, as the historic centre of İzmir, is in the Tentative List within a name "The Historical Port City of Izmir" and studies are conducted for inscription on the UNESCO World Heritage Site. The recent plan, the Historical Port City Site Management Plan (2022-2027) states that interpretation and presentation studies must be conducted for the conserved urban fabric including urban pattern and street forms, also cultural routes to be determined accordingly (Nizamoğlu, et al., 2022). In line with the Site Management Plan, this paper asserts that cultural heritage of the past, which has not sustained today, should be interpreted and presented as a conservation attitude.

The study aims to understand cultural heritage assets based on the historic roots and develop new strategic framework in a way of regarding whole cultural layers of the multicultural urban heritage. The city has a rooted past, yet 19th and 20th centuries are the heydays of cultural diversity. This study aims to expand the question of *how to interpret and present multilayered urban heritage with all aspects, in respect of cultural diversity*. In this regard, plans and maps of 19th and 20th centuries are analysed in detailed, evaluated with comparison of present urban fabric, as well as social and cultural life of those times are indicated. The interpretation and presentation strategies for sustaining cultural diversity are developed in line with the Site Management Plan.

2. Scope, Context, and Methodology

This study focuses on urban heritage of Izmir in Türkiye, mainly the management site of the Historical Port City of Izmir and northern part of the historic city centre, which is beyond the management site. The management site covers 372.40 hectares with diverse conserved areas and listed buildings. The northern part of historic city centre has not survived today with its integrity and authenticity.

The methodology is based on case study, consisting of literature review and illustration of spatial plans and maps via CAD programme. The spatial maps are digitalised by the first author and further illustrated with Adobe programmes. To understand the case, planning history which shaped the urban fabric as a port city in 19th century is analysed to understand previous planning decisions and their impacts on today's urban place. In this sense, spatial maps of 19th century are digitalized on todays' urban pattern. The general macroform of the city is analysed and evaluated, while detailed analyses and evaluation are conducted for the area issued in the Goad Insurance Plans. Afterwards, proposals for interpretation and presentation strategies are developed.

3. Literature

Interpretation and presentation of all layers and aspects of cultural heritage is related to fostering cultural diversity, culture of democracy, and building peace among varied groups of people of the world. International legal framework expands cultural diversity and interpretation and presentation of heritage with diverse layers. In this context, the noted international texts are given in brief.

Universal Declaration on Cultural Diversity of 2001 is one of the earliest binding documents in the context of cultural diversity. The Declaration determines that cultural diversity, which is composed of uniqueness and plurality of the identities of people, is the common heritage of humanity. The Declaration stands on three principles of identity, diversity, and pluralism and states respecting cultural diversity ensures social cohesion and international peace. Cultural heritage in all its forms must be conserved to flourish dialogue among cultures and foster creativity with diversity.

Furthermore, the 2005 Convention on the Protection and Promotion of the Diversity of Cultural Expression by UNESCO defines that cultural diversity is innumerable ways of expression of cultures of groups and societies. The Convention expresses that cultural diversity, which creates rich and varied world, should be preserved for the benefit of all within a framework of democracy, social justice, and mutual respect between peoples and cultures. Hence, cultural diversity is related to culture of peace, strengthening the free flow of ideas, freedom of thought, expression, and information. Including the cultures of minorities and indigenous peoples, recognition of equal dignity of and respect for all cultures are among guiding principles.

The ICOMOS Charter for the Interpretation and Representation of Cultural Heritage Sites (2008) expands objectives and principles on interpretation and presentation strategies and methodologies. Interpretation is defined as “the full range of potential activities intended to heighten public awareness and enhance understanding of cultural heritage site” and covers on-site and directly related off-site installations, trainings, publications, and alike. Presentation refers to “the carefully planned communication of interpretive content through the arrangement of interpretive information, physical access, and interpretive infrastructure at a cultural heritage site”. At that sense, presentation tools can be information panels, displays, guided tours, websites, etc.

The charter defines main principles of interpretation and presentation to enhance public appreciation and understanding of cultural heritage sites. These principles and objectives include encouraging individuals and communities to reflect their own perceptions and develop connections to site, taking into consideration of all groups of people who have contributed to historical and cultural significance of the site and cross-cultural significance of the site, respecting authenticity in designing a heritage program with traditional social functions of the site, cultural practices, and honour of locals and associated communities.

4. Understanding Smyrna with Historic Plans and Maps

Todays’ urban heritage, historic centre of Izmir, was established on the Smyrna Ancient City. The famous historian Strabo (XIV.1.37) described the city as:

> After Smyrna had been razed by the Lydians, its inhabitants continued for about four hundred years to live in villages. Then they were reassembled into a city by Antigonus, and afterwards by Lysimachus, and their city is now the most beautiful of all; a part of it is on a mountain and walled, but the greater part of it is in the plain near the harbor and near the Metroum and near the gymnasium… The River Meles flows near the walls; and, in addition to the rest of the city's equipment, there is also a harbor that can be closed.

The Gulf of Izmir at the west, Pagos Hill at the southeast, and Meles River at the west are the natural edges. The geographical location of the city is suitable for defence, and the port nearby enabled to develop trading activities (Köksal, 2014). The Acropolis on the Pagos Hill, also known as Kadifekale, Theatre, Agora, and Stadium are main monumental structures of the Smyrna Ancient City.

Todays' living heritage place covers Agora, Theatre, Acropolis, Caravan bridge, ancient street, harbour bath, Altınpark residential area, several aqueducts, and some remains of city walls. Although the sketches of Hans Naumann (Konak Municipality archives, as cited in Nizamoğlu, et al., 2022) show a Temple, Harbour Castle, Ephesus and Magnesia gates, they are not visible today (Figure 5).

The multilayered heritage place is still open to new discoveries, there might be new findings as the archaeological studies are conducted. Ibn Battuta (Tanci, 2004) states that the city was largely devasted, especially Acropolis and harbour castle when he came to Izmir in 14th century. After conquered by Ottomans, the harbour castle was demolished in 15th century (Baykara, 1974). The population growth in the Mediterranean during the 16th century, while population of Izmir was mostly composed of Turks and Greeks (Arıkan, 2001).

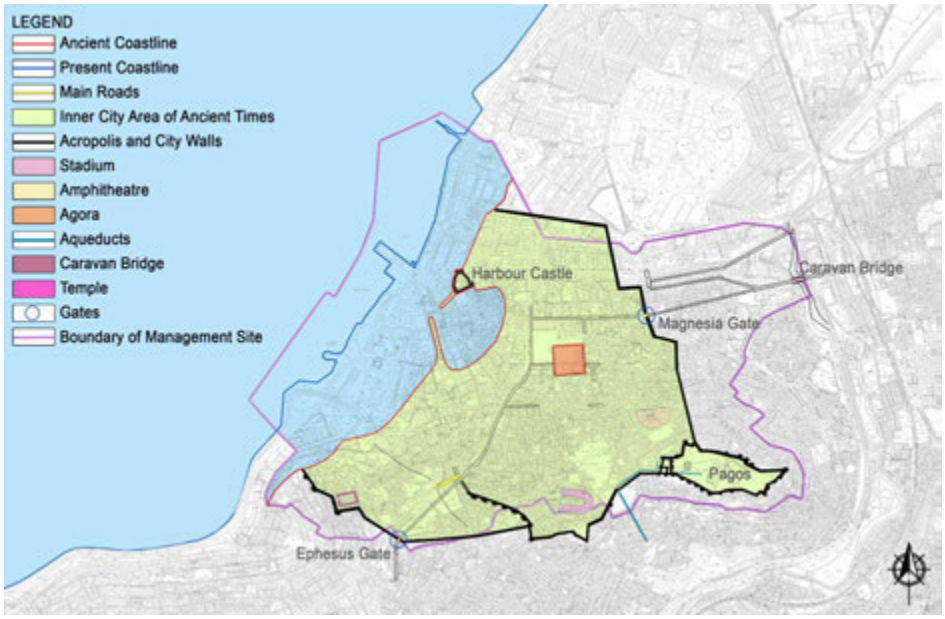

Figure 5: Ancient City Illustration on Present Historic City (illustrated by the authors)

The increment of trade and opening of European consulates also led to increase in population of Greeks, Jewish people, Armenians, Frenchs, Netherlanders, and British people in the 17th century (Goffman, 1995). Turks settled on the slopes of Kadifekale, Jewsih people were around Kemeraltı Bazaar and among Turkish neighbourhood, Levantines were lined up in the part extending from the port to the north along the coast, Greeks were just behind Levantines and Armenian neighbourhood was between Greek and Turkish neighbourhood (Figure 6) (Kıray, 1972).

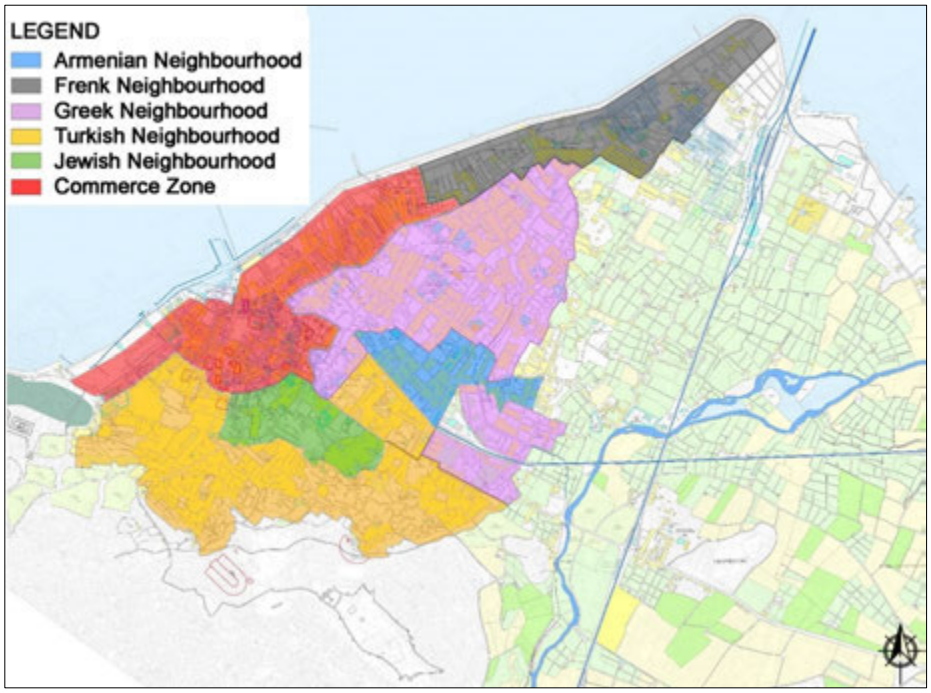

Figure 6: Neighbourhoods in the 19th Century (illustrated by authors, Source: Nizamoğlu, et al., 2022, p. 114)

The city had become an attraction centre for people from diverse religion and nationalities since 17th century. Especially after ahitnames signed between Ottoman and European states, European merchants came frequently to the city and some of them settled (Goffman, 1995).

The inner harbour was filled in 19th century, and several planning studies were carried out for the reconstruction of the city. The overall macroform of the city and components forming urban pattern are investigated throughout plans and maps of the 19th century, which is the heydays colourful and multicultural life of Smyrna.

4.1. Thomas Graves Plan

The Graves Plan, dated 1836-7, shows the city of Smyrna and Vourlah Road and adjacent islands connected by the Gulf of Izmir (Figure 7). The map shows that Smyrna was developed on the remains of the ancient city, oriented to the harbour, and spread to north reaching to the Punta.

Acropolis, and partly Stadium were conserved, while Agora was in a ruined condition, just traces of theatre and temple were noticeable. The site of ancient port is clearly noticeable within the building stocks, close to Governor's House, Barracks, and Parade. The Custom House, breakwater, and port offices shows actively used harbour.

Meles River is crossed by the Caravan Bridge, which is still a main entrance of the historic city. The road reaches to Çorakkapı Mosque and continues to inner part of the city, through partly in the form of Anafartalar street today. The city covers several significant places, such as the Historic Kemeraltı Bazaar (on the infilled area of the ancient port), mosques, churches, hospitals, and cemeteries.

The city had organic pattern with cul-de-sacs and long narrow parcels on the north of the historic bazaar, next to the harbour. In these long narrow parcels, English Consuls, Marina, and cooperage buildings are visible, while English, Sardinian, American and Dutch places are also indicated.

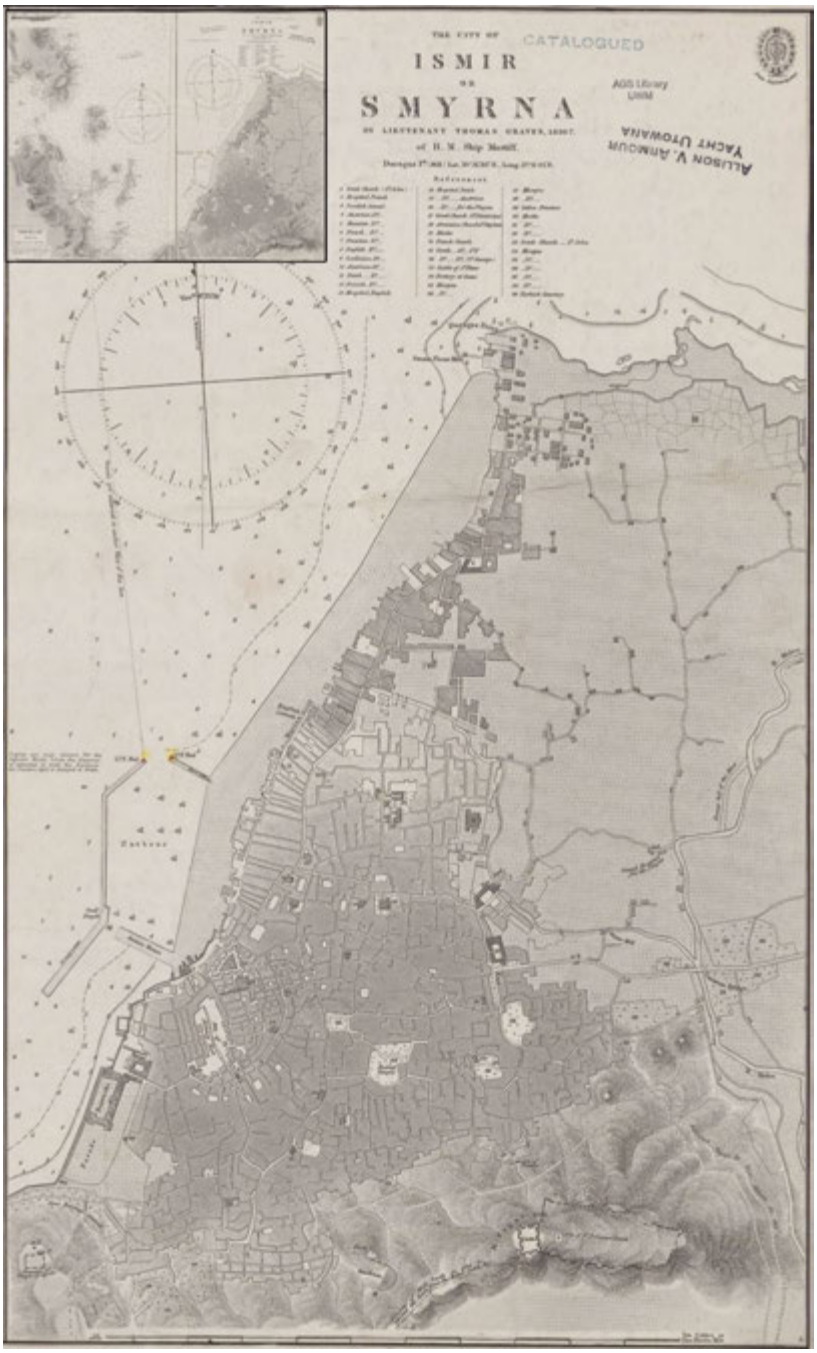

Figure 7: Smyrna Part in Thomas Graves' Plan (1836-7), illustrated by the authors to focus of the City of Smyrna (Source: American Geographical Society, 2021)

4.2. Luigi Storari Map

The two big fire events occurred in 1845 and 1852. The Turkish and Jewish quarters and Kemeraltı Bazaar were highly destructed, while the Armenian Quarter completely disappeared (Beyru, 2011a). Afterwards, the Storari Map was prepared between 1854-1856 to rebuild the city (Figure 8).

The map does not show port and harbour but presents urban layout in detail. It is seen that the city continued its port-oriented development and further extended to the northern side. Punta Region became to develop with building blocks, as quadrangular islands opening to the sea. Long and narrow parcels were extended, behind the quay perpendicular to the sea and new parcels have been formed. Todays' archaeological sites of Agora and Altınpark were used as cemeteries. After the fires, the plan of Armenian Quarter was revised, grid pattern with wider street was introduced instead of traditional organic pattern with narrow streets.

The Storari map also shows that the commercial centre of the city developed, and many khans were built in this period. The bazaar was spread around the inner harbour towards the non-Muslim quarter in the north of the city by the end of the 19th century.

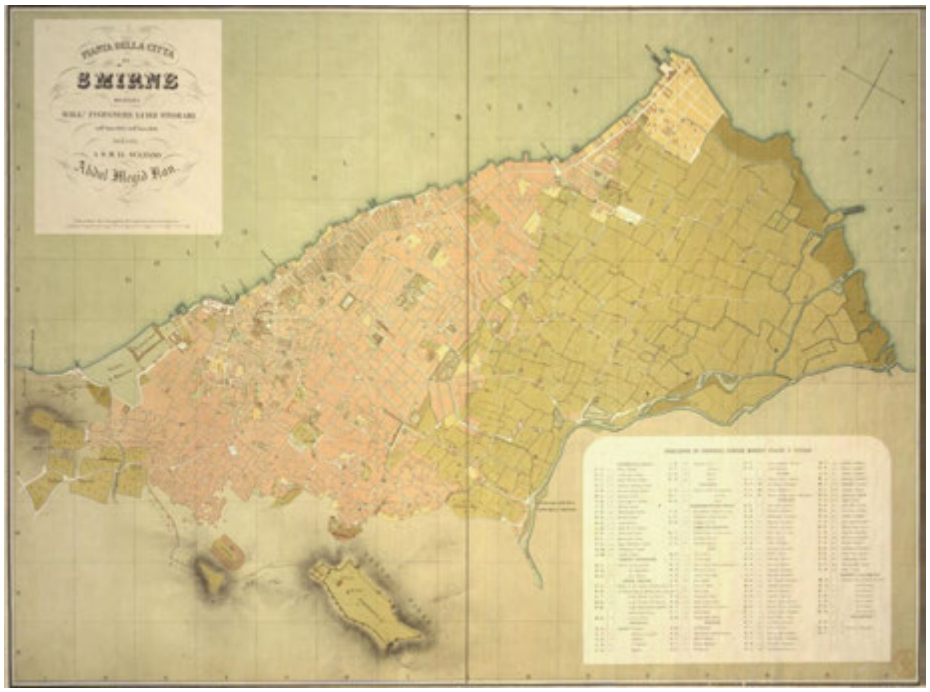

Figure 8: Map of Luigi Storari (1854-56) (Source: Konak Municipality Archive, 2021)

When compared to todays' urban heritage (Figure 9), the hinterland was broader on the southern and eastern part, and the coastal line closer inner to the city. The settled areas in the city were around 429,3 hectares.

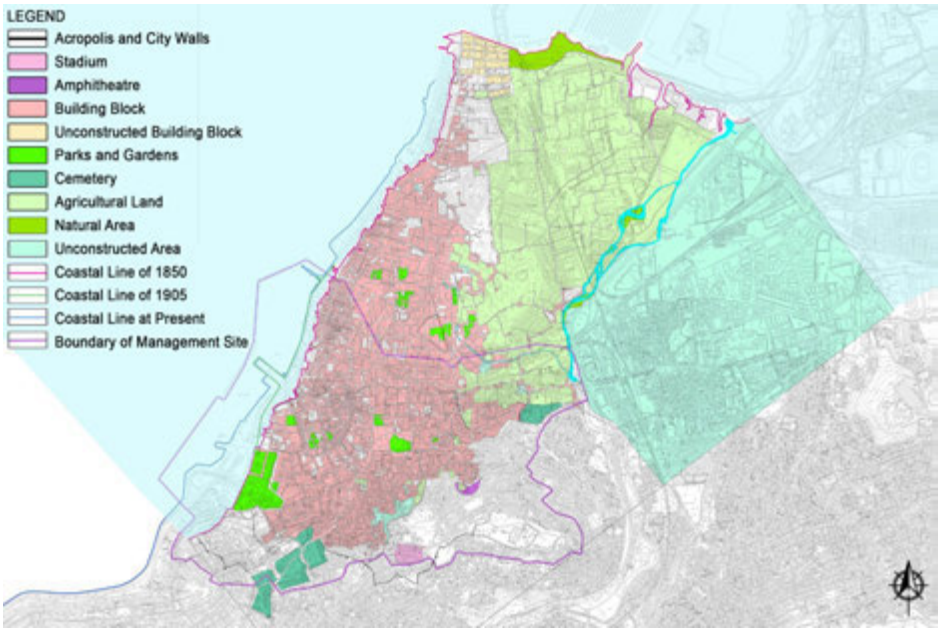

Figure 9: Storari Map on Present Historic City (illustrated by the authors)

4.3. Lamec Saad Plan

Dated 1876, the Saad Plan clearly represents urban layout and main transportation infrastructure at those time (Figure 10). The railway connections were built to export the products grown in the Aegean Region through the port and significantly shaped the urban morphology.

The first railway of the Ottoman period, Aydın-Izmir railway was completed in 1866. In the Plan, Alsancak Station and Basmane Station, railway routes, breakwater and port are seen together for the first time. With Alsancak Station and its facilities, the east of the station was developed as an industrial zone (named as Darağacı today) and the west as a residential area in Punta region. Industrial buildings and density of urbanization increased in this area.

Components of Smyrna Ancient City are also seen in the plan. The acropolis is shown as Ancient Fortresse, traces of Stadium, Theatre, and Temple are indicated, and Agora and Altınpark are shown as cemeteries. The inner harbour is completely filled. Customs of Turks and Europeans were segregated. Today's Governors House is shown as Palas. There were barracks and manoeuvre area, which are not survived today, as also shown in the Graves Map. Near to barracks, there was a prison, which is seen in the first time.

Long narrow parcels between the shore and Frenk Street led to emergence of passageways called "ferhane", distributed across residential areas, storage facilities, and shops erected on either side (Beyru, 2011b). Sanitary Office, Lighthouse Office, Passport Office, Port Captain's Office, Fish Market were located next to lighthouse. Steamboat and Letter Post agencies, foreign consulates, as well as breweries, cafes, and casinos were near to sea.

When compared to todays' urban heritage (Figure 11), the hinterland was broader on the southern and eastern part, and the coastal line were closer to the inner city. Yet, the infilled area became bigger compared to Storari Map. The city in the Saad Plan was around 696 hectares, including both urban and rural settled areas.

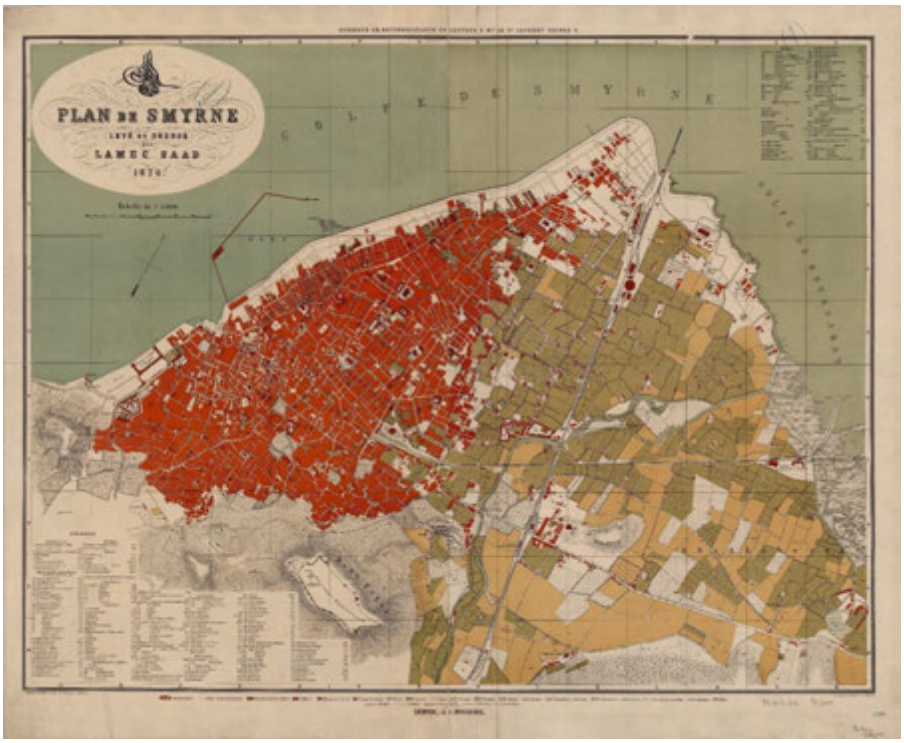

Figure 10: Map of Lamec Saad 1876 (Source: Konak Municipality Archive, 2021)

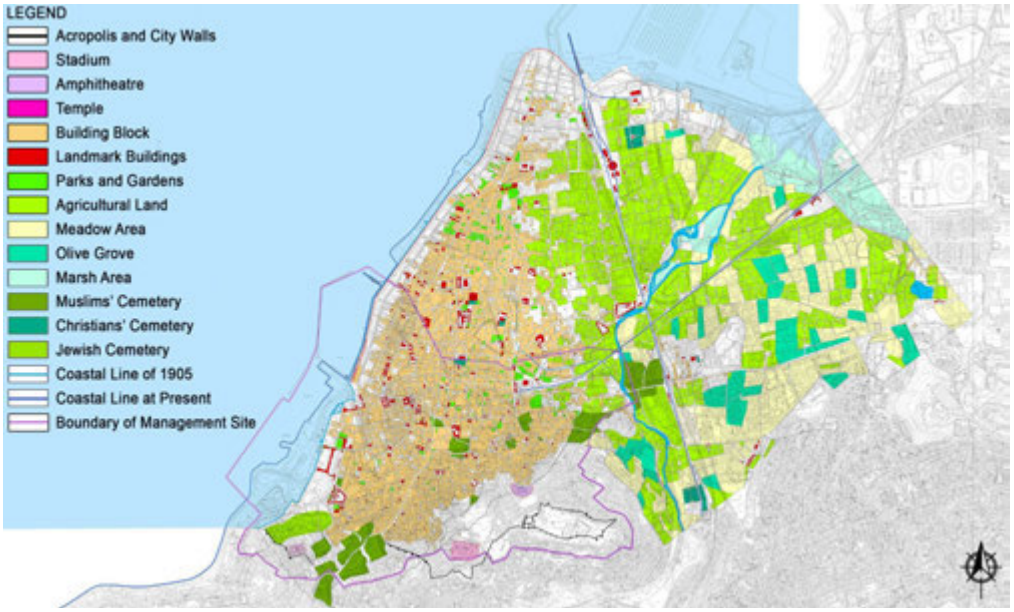

Figure 11: Saad Map on Present Historic City (illustrated by the authors)

4.4. The Goad Insurance Plans

After Lamec Saad Plan, two major fire disasters occurred in the city, which led to preparation of Goad Insurance Plans (Figure 12, Figure 13). The Insurance Plan was prepared by Charles Edward Goad in 1905 focusing on the commercial areas of the city where the need of insurance is high.

The Goad Plans are consisted of 11 detailed maps with scaled 1:3600 and a legend. The maps are significant documents to understand commercial land use of early 20th century. The areas near to port and historic bazaar area were issued in the maps. The area covers 73,5 hectares, 77% of which is in the boundary of management site today. In a way, these areas are valuable for maintenance of port city functions. Also, in the legend several names of owners were indicated. Diversity of these names from different cultures and ethnicities show the cultural diversity in the city at those times.

Figure 12: Index and Legend of the Goad Plans
(Source: Archives of Konak Municipality, 2021)

Figure 13: Insurance Plan of 1905 - Charles Edward Goad Plan (Source: Archives of Konak Municipality, 2021)

4.4.1. Exploring the Goad Insurance Plans

The 1905 Goad Insurance Plans are analysed by matching with today's maps. For the illustration, studies of Rauf Beyru (2011b) and George Poulimenos (2022) are used (Figure 14, Figure 15).

The Insurance Plans covers an area of approximately 73.54 hectares, and 56.80 hectares of which is also in the boundaries of management site today. Commercial uses, production and storage areas, service facilities, houses, and other uses are shown in the maps. Besides, ferhanes and inns are seen as main building typologies in the city. The map indicates that Kemeraltı Region was the administrative and commercial centre of the city in 1905, but the central functions began to spread towards to Punta region.

Figure 14: The Uses of Buildings in the Goad Insurance Maps ((illustrated by the authors)

Figure 15: Legend of the Goad Map

The area distribution of the 1905 map is evaluated (Table 1). The majority of the buildings in number with 34,5% are daily commercial uses, which is followed by housing areas with 21.7%. This also shows the active and vibrant life of the city. Also, inn, bazaar, and ferhane types of buildings covers around 38,8%, and warehouses covers 17,4% of the total area. Hence, commercial buildings are mostly concentrated close to coastal area as the main land use. The Goad Plan illustrates that the city was colourful with commercial buildings, traditional arts, small producers, merchants, as well as residential uses and entertainment and leisure facilities.

Table 1: Distribution of Building Types and Uses in the Goad Insurance Map

Building Types and Uses	Building		Total Area	
	No.	(%)	m^2	(%)
Inn, Bazaar, Ferhane	211	5.7%	201216	38.8%
Warehouses	322	8.7%	90204	17.4%
Housing Areas	806	21.7%	61345	11.8%
Daily Commercial Uses	1278	34.5%	49099	9.5%
Production	394	10.6%	34351	6.6%
Public Buildings	88	2.4%	32794	6.3%
Entertainment and Leisure	279	7.5%	24153	4.7%
Agent, Stock Exchange, Bank, Insurance Companies and Offices	161	4.3%	12301	2.4%
Traditional Arts	80	2.2%	4644	0.9%
Accommodation Facilities	18	0.5%	4625	0.9%
Trade of Other Products	72	1.9%	4321	0.8%
Total	3709	100.0%	519052	100.0%

The commercial buildings such as hotels, cafes, restaurants, clubs were mostly located along the First Kordon, while these types of uses were few in the Kemeraltı Bazaar. These kinds of popular buildings of those times, where people interact with each other, were in associated with the Frenk Neighbourhood, spreading over the ferhanes, shops, passages and commercial streets.

Close to seaside, near to Kemeraltı Bazaar, there were hotels, office uses, banks, stock market structure, agencies and inns used as storage areas, related to the First Kordon Street and Custom Pier. In the Kemeraltı Bazaar, inns and passages were used as commercial buildings and storage areas. The map also shows that the uses such as stores, pharmacies, chapels, flea markets, tailors, shoemakers, candy shops, coal shops, clothing shops and antique shops were intensified. It is also noticed that some streets and bazaars were specialized in certain functions and craftworks, such as Sandıkcılar (means chest makers) street, confectioner street, butchers street, loggers street, glass sellers street, honey sellers, pancakes street, jewelers' bazaar, stoneworkers' bazaar, flea market, fish market, chestnut market.

For the social and economic life, different communities were making living by diverse businesses. For instance, Turks were settled around Kadifekale and near to Kemeraltı Bazaar, and working as tailor, shoemaker, furrier, saddler, herbalist, butcher, turban and cap maker for both women and men, farriers, coppersmiths, jewellers, and alike (Bauden, 2003).

Greeks were the highest population after Turks, from 17th century to middle of 19th century. They were settled neat to commercial district and close to Churches. Greeks works in almost

all sectors, while most of them were engaged in agriculture in the hinterland of Smyrna. They are also work as merchants, boatmen, tailors, bottlers, shoemakers, grocers, tavern keeper, butcher, grocer, greengrocer and tellak (Kütükoğlu, 1992).

Armenians were the smallest population when compared to other communities. Living in the Armenian Quarter, named as Haynots, Armenians were composed of diversified communities, such as Gregorian, Catholic, and Protestants (Hovannisian, 2018). Close to the Caravan Road, Armenians were active in international trade, they were intermediary actors in transfer of Iranian silk carried through caravans and other products to European ports.

Jewish people migrated from Portugal and Spain settled in Izmir. They were both rich and poor Jewish, many of them had their own business (Bauden, 2003), effective in collecting İzmir custom revenues, act as money changer and broker, and served as intermediary for merchants (Frangakis-Syrett, 2006).

Levantine communities are of English, Dutch, Italian, French, Hungarian and Slavic origin. They worked in banking, finance, insurance, and logistics sectors, especially in trade and industrial works. They were active in construction of docks, railway investments, operation of tram and ferry lines, as well as, sustaining communication between local producers and sellers in agriculture sector (Yıldız, 2012).

Levantine's neighbourhood known as Belle-Vue or Bella-Vista was along the Frenk Street (APİKAM, 2020). The narrow and long passages near to coastline were named Frenkhane, which changed into 'ferhane' over time. Residences, shops, and warehouse buildings were lined up on both sides of these ferhanes. Ferhanes also represented western type of consumption (Beyru, 2011b). Levantines constituted clubs, where they followed the printed publications in Europe, which had libraries, arcades, ballrooms, and theatres (APİKAM, 2020).

The inns and ferhanes are analysed further to understand predominant characteristic building typologies in the Goad Insurance Maps (Figure 16, Figure 17). Names of inns and ferhanes in the Goad Plan are determined according to study of Rauf Beyru (2011b) (Table 2, Table 3). Inns are typological buildings used in the commercial life of the city in the past to meet buying, selling, storing, and accommodation needs of people engaged in trade, especially caravan trade (Ersoy, 1988). There are 120 inns, all of which are in Kemeraltı Bazaar and its surroundings on the Goad Map. Most of the inns were in the arc form, adjusting to the Anafartalar street, which was named as Kemeraltı Street in the past. Anafartalar Street, which is the ancient harbour axes at past, gives a unique form to Kemeraltı Bazaar.

36	Küçük Kuzuoğlu Inn	76	Maksudyan Inn	116	Abacıoğlu Inn
37	Yandevi Inn	77	Karantina Inn	117	Arap (Eski Cezayir) Inn
38	Çukur Inn	78	Sadık Bey Inn (Büyük)	118	Evliyazade Inn
39	Anavutoğlu Inn	79	Halima Inn	119	Yusufoğlu Inn
40	Arap Inn	80	Keşişoğlu Inn	120	Ekmekçi Inn

The inns on the first Kordon Street, nearby the Customs Pier, are in different sizes and forms. In the Kemeraltı Bazaar, the inns lined up one after the other from the beginning of Sahur Street (Mezarlık street) (853 Street today) to Kemeraltı Street. They were followed by the inns lined

up on Cezayir Inn Street (855 street today) located just parallel to Kemeraltı Street. These were the widest streets, linearly extending in Kemeraltı Bazaar, facilitated the access of goods between inns and the pier. In similar, the linear Government Street (today Cumhuriyet Boulevard) was also composed of inns around.

Another region where inns form a cluster is near to Osmaniye Street (todays Mimar Kemalettin Street), which is associated to Basmane Station, and Mahmudiye Street (today's Halit Ziya Boulevard). Besides, there were the Fisherman's Market Mosque and bath, Hisar Mosque and Acem Mosque, which were characteristic to the area.

There were 34 Ferhane buildings, 31 of which were located within the boundaries of management site, as shown on the Goad Map. Ferhanes covered a total area of approximately 47,546 m² and around 42,643 m² in the management site. It can be seen that ferhanes had diverse functions such as businesses related to food and beverage, workplaces with alcohol drinks, agencies, stores, and dealers in Frenk Neighbourhood.

5. Evaluation of Historic Plans and Maps

The Graves Plan dated 1837, the Storari Map dated 1852, and the Saad Plan dated 1876 are important documents showing the development tendency of the urban and rural areas, important axes, main land uses, as well as cultural groups living in the city of those times. These plans show the overall urban and rural areas, giving important general view of the historic roots.

The Goad Insurance Plans, dated 1905, presents significant details. The Goad plans show the most significant and vulnerable place of the city, the most vital part of the historic city near to port. This area witnessed to cultural life of heydays of Smyrna, when diverse communities were living side by side, charming intellectual life of the merchants were happening in the 20th century.

When the historic city is analysed throughout the maps, it is seen that settled part increased, building typologies diversified based on daily uses and trading activities, and infilled areas in the gulf changed the coastal line. However, the 1922 fire, also noted as Smyrna Catastrophe and The Great Fire of Smyrna in the history, not only affected built environment but also multicultural life of the city.

The fire affected northern part of commercial area (Figure 18), whole Armenian and Frenk neighbourhoods, significant part of Greek neighbourhood, and some part of Turkish neighbourhood. Spatially, inns, ferhane buildings, public buildings, several religious buildings including churches were destroyed due to the fire. The place of Greek and Armenian neighbourhoods redesigned as urban park, named Kültürpark in the Republican Period. Besides, boulevards were constructed at the north of Kemeraltı Bazaar. The construction of boulevards as main roads not only damaged to the historic pattern but also caused to complete destruction of several inns and partly demolishment of several inns, such as Selvili Inn, Büyük Demir Inn, and Çukur Inn. On the other hand, several inns in Kemeraltı Bazaar, religious buildings, including mosques, synagogues, several churches, as well as street pattern of 1852 and 1905 shaping the urban fabric have conserved today.

Although changes in urban pattern and living population over time, there is still significant conserved urban fabric. This urban fabric is registered as conserved areas diversified as urban conservation area, archaeological conserved area, historic conserved area, and natural conserved areas, also including diversified types of registered buildings based on the national legislative framework. However, interpretation and presentation installations of the historic centre of Izmir is insufficient today. It is not clear for a visitor or local to understand the cultural significance of the historic centre, which is composed of traces of tangible and intangible values from different times, diverse cultures and communities.

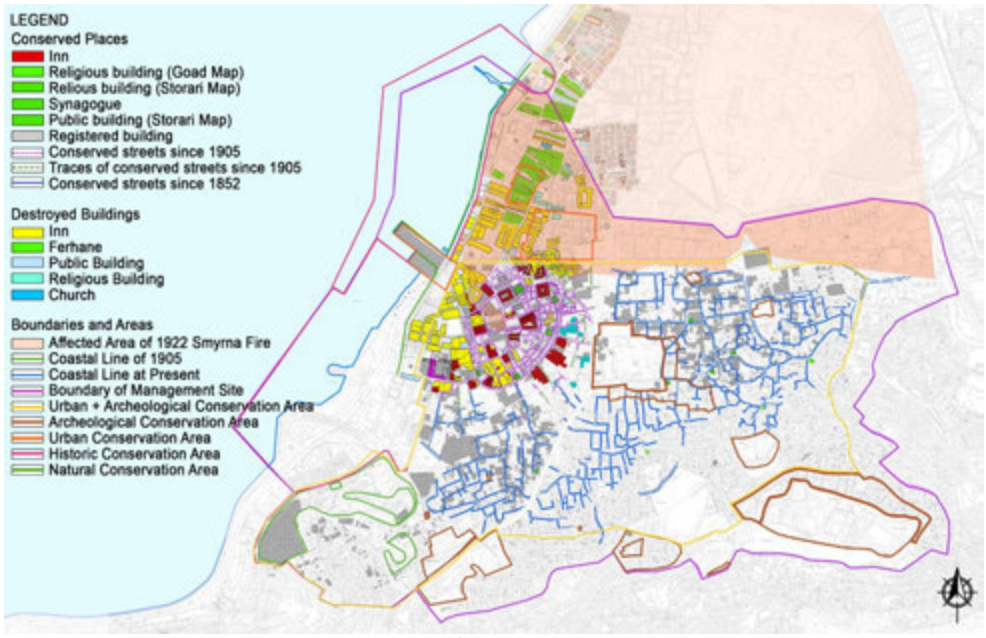

Figure 18: Synthesis of Conserved and Destroyed Places

28

6. Proposals for Interpretation and Presentation

The historic city was compact, covering commercial, administrative, entertainment facilities, as well as housing areas. Although, todays' residential areas are not well integrated with the centre, it is important to associate residential area and central functions to foster a vibrant city.

For interpretation and presentation in the historic centre of Izmir, key principles are determined as follows:

- Interpretation and presentation studies are conducted within the framework of culture of democracy, culture of peace, and cultural expressions to sustain equal dignity and mutual respect of all people and communities.
- Memory of the place is interpreted and presented to foster cultural diversity, plurality, and identity as common heritage of humanity.
- Interpretation and presentation techniques supports inspiration, creativity, and imagination of people.
- The heritage information with all layers, tangible, and intangible aspect would be secured and accessible for all.
- Social inclusion and public participation are to be ensured in interpretation and presentation studies, in overall processes of planning, design, implementation, and monitoring.
- Interpretation and presentation studies are to be related to capacity building activities for people on mutual understanding, mutual respect, and culture of living together in a harmonious way.

Based on these principles, several interpretation and presentation strategies are proposed preliminarily:

- The lost and survived cultural heritage with intangible and tangible aspects is to be interpreted and presented with involvement of the representatives of communities from Levantine, Greeks, Armenians, Jews, and Turks. The overall process of interpretation and presentation should sustain building a strong network among communities.
- As mentioned in the Site Management Plan, an urban design guideline to create specific design language for the historic centre of Izmir is to be prepared. The guideline should determine general principles, such as rules to be flowed in historic environment, modern buildings, and new additions.
- From Hellenistic times until today, place names are to be illustrated on the site. The components of Smyrna Ancient City that are not visible at present, such as ancient breakwater, harbour castle, and Temple, as well as historic places, public squares, and street names from Ottoman period are given through information and way finding panels that will arouse people's curiosity.
- The past maps of the historic centre of Izmir, covering diversified cultural and historic layers, are to be illustrated on visitor information systems.
- The monumental buildings such as Aya Fotini Church, places of memory such as Kültürpark, the uses covering big areas such as inns and ferhanes, famous meeting places such as Sporting Club in the historic city at past are to be interpreted and presented. Standard information signs with QR codes can be designed on buildings. Sculptures and installations on public squares can be designed. For instance, visitor information panels illustrating gravures of historic urban landscape with Kadifekale, harbour, and environs can be designed near to Pasaport Ferry Terminal at Kordon.

- The neighbourhoods and communities that lived in the city in history are shown through information panels with flu boundaries. Main information about people and communities are to be given.
- As mentioned in the Site Management Plan, a digital data system to storage and monitor heritage information is established. Collaboration with other relevant information systems such as data in Centre for Asia Minor Studies, the Bologna University Historical Archive, Rijksmuseum Amsterdam are developed to share and exchange knowledge about the heritage of historic Izmir. The security and accessibility of heritage information are to be ensured.
- A set of workshops, panels, and participatory meetings is to be organized periodically with both people and communities left the city and those still living in the city to determine interpretation and presentation aspects. Besides, institutions, municipalities, academicians, professional chambers, NGOs, and all related stakeholders should be involved the whole processes.
- A set of trainings and informative sessions are to be conducted periodically with people who are associated the historic city centre of Izmir to support mutual understanding, mutual respect and equal dignity of people and communities with diversified cultures.

7. Conclusion

Unfortunately, ethnic groups of people, indigenous people, small communities, people with different gender, religion or migrants facing discrimination today. Rise of nationalist trend causes to conflicts within and among societies. These are significant threat for all and should be dealt with sincere collaborative efforts.

In this regard, over all aim of this study to strengthening collaborative efforts to reintegrate cultural heritage to contribute to cultural interaction, cultural diversity, as well as culture of democracy and dialogue. As a multilayered cultural heritage place, the historic centre of Izmir was multireligious, multicultural, and multilingual. Places and societies are dialectical, inseparable parts of the whole, thus interpretation and presentation strategies must cover tangible and intangible aspects of cultural heritage.

Accordingly, interpretation and presentation strategies are preliminarily defined for the historic centre contribute to relation of societies, places, cultures, and memory. The survived and lost cultural values of the historic centre of Izmir are explored to reintegrate tangible and intangible cultural values of all times in today's living urban heritage. In this regard, the study also aims to contribute to foster importance of the historic roots, improve networks, and maintain sustainable development. This is a way of respecting whole cultural layers of the multicultural urban heritage, and respect for the past and todays' communities.

Constituting interpretation and presentation strategies for this historic city with its evolving roots creating its heritage values is a significant issue. Interpreting and presenting the multicultural heritage, which is formed with synthesis of diverse cultures throughout the history, means remembering and recalling the memories and building futures for all. The living heritage places as the historic centre of Izmir can foster mutual understanding and respect, in a broader sense, contribute to building peace among communities and cultural of living together in harmony.

Rural Heritage Governed as Commons: A Case Study of a Chinese Heritage Village from the Cultural Capital Perspective

Abstract
The concept of commons in economics and management has been positioned within the heritage field to emphasise their characteristics like Common Pool Resources. Rural heritage governed as commons means building a new understanding of its values, which extends beyond consumerism or state identity to embrace the local community, and implicating dynamic governance processes towards a more sustainable, equal and inclusive development in rural areas. Under the framework of 'Resources-Governance Community-Governance Systems' in heritage commons governance and the perspective of transformation of cultural capital, this paper re-examines the two typical eras governance process of a centuries-old village in southwest China. This study first reveals tensions between community heritage versus official heritage and commercial heritage. Secondly, 'governance community' is more complex than common sense, particularly, local government has different hierarchies and departments with multiple targets. Besides, an effective conservation and development planning with appropriate mechanisms is the core of coordinating heritage management system, tourism development system, rural revitalisation campaign system, and community self-governance and social-engagement system. Lastly, two cases show that social power and community have the vitality to cover the shortage of physicalised cultural capital, constituting an alternative path towards common benefits and inclusive development of rural heritage communities.

Keywords
rural heritage; governance; commons; cultural capital; heritage community

1 Introduction

Popularised by Elinor Ostrom's pioneering work on natural resource community-based management systems (Ostrom,1990), the term 'commons' has been traditionally used in economic analysis to define physical resources which are subject to overuse and appropriation dilemmas, as well as property and governance regimes over resources that are owned in common. More recently, a growing recognition has emerged that important types of humanly constructed shared resources, such as information, knowledge, infrastructures, or urban landscapes, could be appreciated and analysed as new forms of commons (Gould, 2017). It has been observed that while much attention is given to natural resource management, the field of heritage studies lacks sufficient discussion on the relationship between heritage and community, and there are only a few accounts that explore this topic. It is possible to apply the principles of commons governance to the cultural heritage field (Lekakis, Shakya and Kostakis, 2018).

Heritage commons are not only an academic issue but an emerging reality in the field of heritage management. Recently, the cultural heritage conservation approach has shifted from 'object-centred' to 'people-centred' methods, the latter emphasises the concept of 'Living heritage' and 'continuity', which means the core community is responsible for the continuous care of the heritage through traditional or established paths (Wijesuriya, 2015). This trend makes it particularly important to view the relationship between rural heritage and its community from the commons governance perspective to create the necessary tools to develop a community-based approach to conservation and management.

Heritage commons highlights the necessity of analysing heritage as shared resources by a community even a country in terms of tangible and intangible dimensions towards public interest and sustainability principles, constituting an alternative path towards safeguarding heritage and communal benefits (Bertacchinni, 2020). Furthermore, it extends the collective action problem to a wider array of social dilemmas involving the conservation of heritage. There is mounting evidence to suggest that this approach can empower user communities, leading to a more democratic distribution of managerial control and fostering reciprocity and social values (Lekakis and Dragouni, 2020).

Ostrom's research (2002) focuses on two main questions related to the commons, which also happened in the heritage field. Firstly, why are heritage resources often exploited, and how can we accurately define their value? Secondly, what circumstances enable heritage resource users and communities to create effective management rules? In this paper, we draw on an analytical framework applied to the case of China, which is informed empirically by our longitudinal fieldwork research on the area, in order to explore how the resources governance process has happened in the rural community from the past to the present and how cultural capital has transformed in a centuries-old heritage community.

The paper is structured as follows: The primary section discusses a general conceptual analysis of the commons and the specificities of heritage commons. The second section comprises an analysis of two key governance eras and the transformations that occurred in Nuodeng's rural heritage in terms of its economic, social, and cultural capital within a theoretical framework. Lastly, the final section delves into the tensions among resources system, communities and governance systems when rural heritage governed as commons, and presents the possibility of commons-based sustainable development strategies through two social and community engagement actions, highlighting some important issues that deserve the attention of future scholars and researchers.

2 Rural Heritage Commons Governance Theoretical Framework

Hardin’s research(1968) on the ‘tragedy of the commons’ brought the commons into the forefront vision of public resources governance problem. Commons, also known as Common Pool Resources (CPRs), according to the classification of public goods by Ostrom (2002), commons are a kind of public goods that are non-exclusive but competitive at the same time. Commons is understood as any natural or manmade resource that is or could be held and used in common to obtain social wealth and organise social production (Berge and van Laerhoven, 2011; De Angelis 2005). It encompasses not only goods and products but is also conceived as a productive force or dynamic process that is necessarily established and maintained by social groups, which control for their accessibility and use on regulated but equal terms (Hardt and Negri, 2012).

In this sense, commons governance is believed to be an effective avenue for protecting resources. Similar to the peasant lands a few centuries ago, cultural heritage can be formally defined as a Common Pool Resource based on the traits that the commons can be used and disposed of by anyone under certain formal or informal rules (Gonzalez, 2014; Dragouni, 2020). The scholars discuss this issue to respond to the three major contradictions in rural cultural heritage management.

- *Heritage commodification or Disneyfication.* Many rural cultural heritage have turned turn into ‘monuments’ for state identity and ‘products’ for tourism consumption under the

obsession for growth push and economic rationalism, and excessive development of heritage tourism demand in villages has threatened the local and traditional community. However, unlike other standard economic goods, which could gain direct income from their real estate value or tourism revenue, cultural heritage as commons may also generate non-market and non-use benefits, given the component of collective use and significance expressed by its recognition (Bertacchini, 2020).

- *Government-led heritagisation.* This type of dilemma entails a conflict over the heritage values between public authorities and communities. Heritage commons is a concept situated in community and identity contrast to treat heritage as a universal global endeavour (Gonzalez, 2015). When a village becomes heritage recognised by the office, too strict conservation approaches may hinder other heritage values that are more likely to express local traditional practices (Bertacchini, 2020).

- *Unequal distribution of benefits and costs among heritage stakeholders.* Both cultural and natural capital have been inherited from the past and will deteriorate or degrade if not maintained (Throsby, 2016). However, a wilder group of stakeholders(i.e., local community, tourists, private business owners) do not directly pay for its preservation and maintenance (Bertacchinni, 2020) while they enjoy the benefit of the common cultural brand. The authority and right to govern heritage resources are rarely aligned with community organisations, even when they are obvious candidates for managing that heritage (Gould, 2017). Heritage governed as commons provides a possibility to help bridge some gaps among various stakeholders in rural heritage, and it is a treasury of the community's imagined identity, part of the aspired and yet utopian democracy of the commons.

Getting back to the core of the commons conceptualisation, the present study references related analytical frameworks inspired by Ostrom (2009), Dellenbaugh et al. (2015), and Lekakis and Dragouni (2020). Ostrom proposed the Social-Ecological Systems Framework (SES) of common resources, which focuses on 'resources system and resources units', 'actors and governance system', and 'governance interaction and output'. In terms of heritage common governance, Dellenbaugh and Lekakis understood the commons through the tripartite constituent elements: the resources, the communities that manage them, and the regulatory framework for the management process, which Lekakis call it 'commoning' to analyse rural heritage governance and reproduction process.

Furthermore, when discussing the public goods character, cultural heritage such as monuments, museums, and historic buildings may be considered as a form of cultural capital that embodies both economic, social and cultural values (Throsby, 2001). Bourdieu (1984) proposed the concept of 'Cultural Capital' to strengthen elitism and the role of culture as a social distinction mechanism, and cultural capital, economic capital and social capital can be transformed and reproduced under certain conditions. Tsongkha and Wang (2021) reveal the three forms of cultural capital in Tibetan heritage villages in China based on Bourdieu's research: one is the physicalised form, as culture is ingrained in the human body and spirit, like local language and place identity, which is inherited through family, community and school education; the second is object form, such as vernacular architecture and manmade tools; the third is institutionalised form, such as village regulations and non-governmental agreements, particularly in acquiring recognised qualifications, identities, and status. By establishing mechanisms conducive to sustainable resource utilization in heritage communities, the accumulation and reproduction of cultural capital can be achieved (Zhu and Min, 2021).

In this study, we conduct a theoretical framework of 'Resources-Governance Community-Governance Systems' to delve into how rural heritage is governed as commons (Fig.1). The governance process promotes the formation and transformation of cultural capital. Under the framework, we consider the following points in the empirical case:

Fig.1 Rural Heritage Commons Governance Theoretical Framework
Source: the authors.

- *Resources:* In this section, we will examine how natural resources turn into economic-social-cultural capital through traditional governance process and how they have changed in heritagisation. Heritage regarded as commons means to explore how resources are maintained sustainably and how immaterial value or public interest is produced and captured not only under a market consumption regime and will of the state, but also for its surrounding communities.

- *Governance Community:* While the main stakeholders of rural heritage communities are commonly understood through a model of government-residents dichotomy, such understanding tends to neglect the variety composition of intra-government and intra-community. These agencies, often with different goals, create a complex heritage common governance network.

- *Governance Systems:* As Gonzalez (2015) said, the construction of heritage as a social object is a complex process involving many objects and subjects. Heritage must be seen as a terrain of struggle where certain forces tend towards disciplining, segmenting and reconstructing the community. it is necessary to consider how stakeholders construct different governance systems to use and maintain the resources and how the governance output influences the reproduction of cultural capital. Rural heritage governed as commons also points to a polycentric governance model.

3 Commons Governance in the Salt-Industry Era and Heritage Era

3.1 The Case Study of Nuodeng Village

This study takes Nuodeng Village, a historic salt industry village in Yunlong County, Yunnan Province, southwest China, as an empirical example. Since cultivation is the economic foundation of most rural heritage communities in China, there is a lack of research on

settlements that rely on other public resources, such as the salt industry settlements. Traditional salt manufacturing villages have developed a human–nature interaction paradigm based on salt wells instead of agriculture, which indicates specific public resource governance characteristics.

The salt industry played a crucial role in the birth, growth, and fall of Nuodeng Village. With a history of more than 1,300 years, the inhabitants have been mining salt well since the Tang Dynasty (618–907 CE), and the industry has contributed to the village's thriving economy and culture. However, societal changes and the popularisation of sea salt during modern times have caused the salt industry to stagnate and the hamlet to collapse. It wasn't until the last 30 years that the village regained its status as an officially designated cultural heritage, and tourism has since become its primary industry. The salt-producing era has left abundant tangible heritage for Nuodeng Village, which still retains the relatively complete rural scape and fabrics (Fig.2), ancient architectural groups of the Ming and Qing dynasties (1368–1911), including more than 20 temples and over 100 vernacular dwellings (Fig.3). Meanwhile, intangible heritage is also preserved in the community (Fig.4), such as the Dragon King Festival, the Confucius Ceremony, salt-making crafts, and the Dongjing Taoist music. Nuodeng Village has been officially designated as the 'National-level Cultural Heritage Sites', 'National Historic and Cultural Village', and 'Chinese Traditional Village' in the last decades. The heritagisation also brings rural gentrification and commercialisation. In the process of tourism development in Nuodeng Village, local residents and migrants join heritage tourism by opening homestays and selling agricultural products.

The authors have been conducting heritage education activities with a social organisation and long-term field investigations in Nuodeng village Since 2014. During the past 10 years, the authors observed the changes in the village continuously and interviewed more than 30 stakeholders in order to obtain firsthand information, including the county government officials from planning, constructing and tourism development departments, indigenous and migrant residents of different ages and jobs, local organisations and elites, enterprises and related academics and technical experts.

3.2 Salt-industry Era: The Formation and Accumulation of Cultural Capital

3.2.1 Resources: Natural Resources in the River Valley

Nuodeng Village's salt brine resources originate from the Bi River, which is a tributary of the Lancang River. About 50 metres below the surface of the Bi River Valley, salt brine from the Ancient Yunnan-Guizhou Sea formed veins of potash due to geological tectonic processes, and these veins erupted out of the surface to produce salt wells. The Bi River Valley is a significant resource system that contains not only brine but also rivers, mountains, forests and land, which

produces additional resources such as the fuelwood needed to boil salt brine and the logs and raw earth for building salt wells and dwellings.

Overall, the brine resource is competitive, non-exclusive, and limited, which is consistent with the qualities of CPR. Individuals acting irrationally by over-exploiting the resource will decrease its availability to other members of the community and the output of the resource. As a result, a governance community is formed through official and local forces, and regulations for the resource's sustainable usage are created.

3.2.2 Governance Community: Production-based, Bloodline-based, and Geography-based Communities

A social network jointed by the salt industry was progressively established, involving salt-producing households, labours that maintaining salt wells and carrying brine, artisans, farmers, footmen transporting salt packages on the ancient roads, merchants in the salt trade, etc. In the Ming Dynasty (1368–1644), the central government established *wujing yanke tijusi* (tax collecting institution on five salt wells) in Nuodeng Village in order to reinforce its authority over the southwest border region, particularly with regard to the salt business. As a result, the officials from the Central Plains moved their entire family to Nuodeng Village and brought Confucian culture to the southwest border. The clan force became a dominant social group in the village after hundred-years of solidification of Confucian values.

During the salt industry era, Nuodeng village saw the steady development of a governance community based on salt production, bloodline and geography. Rural clan statutes managed and restricted the behaviour of the community members.

3.2.3 Governance Systems: Community–Authority Cooperation

Public resources with potential economic value attract more individuals seeking to exploit them. However, due to the limited supply of these resources, it is necessary to establish governance regulations to restrict irrational behaviours and ensure sustainable utilisation of these resources. Hence, the primary objective in establishing a governance system for the commons is to ensure fairness of resource distribution, optimise resource flow without causing harm to the resource system, and facilitate a sustainable exchange with external resources. Furthermore, the formation of a governance system is influenced by the social and cultural environment of the time, including factors such as the level of social productivity, tool-making technology, ethnic customs, and political order. During the salt-industry era, three distinct governance systems were established:

- *Brine Distribution Regulation*

The brine resources were the most significant means of production in Nuodeng Village in the early days. The community distributed all of the brine resources independently and adopted the decentralised family workshop production mode. To avoid over-exploitation, approximately 200 households in the village were divided into 16 ‘stove groups’, each of which possessed 30 barrels of brine (Zhu, 2007). The amount of barrels allocated to each household determines how many days in a month they can produce salt. During the rest of the month, they are not permitted to use the water for salt production. The distribution unit was established based on a lunar month of 30 days, which accounted for the distinct production patterns and measuring techniques of the salt-producing society that differed from the agricultural society.

This spontaneously organised production system operated organically for millennia until the central government implemented a system of salt taxation and established certain zones for selling salt in the Ming and Qing dynasties. However, it primarily adhered to this distribution system and allowed communities to determine their own governance regulations autonomously. For instance, the 'stove manager' was given the authority to administer salt resources with the consent of the government and acted as a representative for the salt-producing households to negotiate with the government. Another example is *longgong*, a group of highly skilled labourers responsible for constructing and repairing wells. Typically, they were hired and remunerated by the government to ensure the welfare of the community. This profession was then passed down from one generation to the next, ensuring the inheritance of these skills. The distribution system as a whole exemplifies the intricate governance relationships between human and the natural world, interpersonal connections, and the individual and the government.

- *The Organisation of Salt-producing Households*

Due to the impact of Confucian culture, the clans held significant importance as community units in salt settlements. The prestige elderly villagers and local elites took the responsibility to establish stove managing association, and set up social norms and regulations to manage public affairs within the community. The association both exhibited the traits of industrial organisations and fostered a strong sense of identity and belonging. Since association members were entitled to the income from production, they had to engage in community discussions, public welfare initiatives, religious activities, and other public matters. Simultaneously, the community also preserved the 'public brine', the profits from which were used towards communal services including building infrastructures and temples, conducting festivals, celebrations and village education, etc. This exemplified the principle of equitable distribution of benefits and expenses in the governance of public resources.

- *Beliefs and Identities*

Community beliefs and identities were strengthened by the compound effect of nature and culture. The Bai minority group had a primitive nature belief, worshipping the mountain rock formations and the water flows where the brine resources come from. The indigenous residents burned incense in the well house every day, and held the Dragon King Festival once a year, in order to pray for the abundance and continuity of the brine. This demonstrated how the resource was kept spiritually intact and demonstrated how the belief in the salt god was in harmony with the natural world. The customs reaffirmed to the villagers the importance of protecting valuable resources while managing public resources sustainably.

Cultural exchanges among the salt well settlements increased after the scale of the salt industry reached a certain level and the economic and cultural level developed accordingly. The Bai culture of the Erhai region, the Buddhist culture of the Indian region, the Confucian culture of the Central Plains, and the Taoist culture merged with the local belief system of Salt Gods to form a distinctive wellsite cultural circle, further strengthening the cultural identity bond within the governance community.

3.2.4 Governance Output: Formation and Accumulation of Rural Cultural Capital

In the heritage community, the formation and accumulation of cultural capital stemmed from the ongoing use and management of salt, a shared resource during the salt industry era. A governance community based on production, bloodline, and geography was formed by salt-

producing households, officials, merchants, horse gangs, etc. Natural resources were converted into economic and social capital through the mechanism of public governance, and eventually accumulated into cultural capital, forming the initial accumulation of rural tangible and intangible heritage resources(Fig.4).

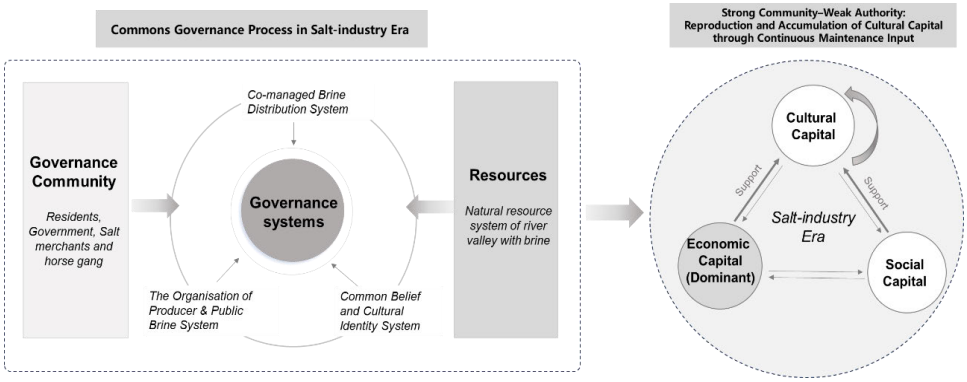

Fig.5 Commons Governance Process in The Salt Industry Era
Source: the authors.

Cultural capital was embodied in three different forms: institutionalised, objectified, and physicalised (Fig.5). The commons governance system that created the cultural capital exhibited a model of community–authority collaborative governance. It reflects the wisdom of sustainable utilisation of public resources in the historic village of Nuodeng, and can still provide insight into the sustainable conservation of heritage resources in the present.

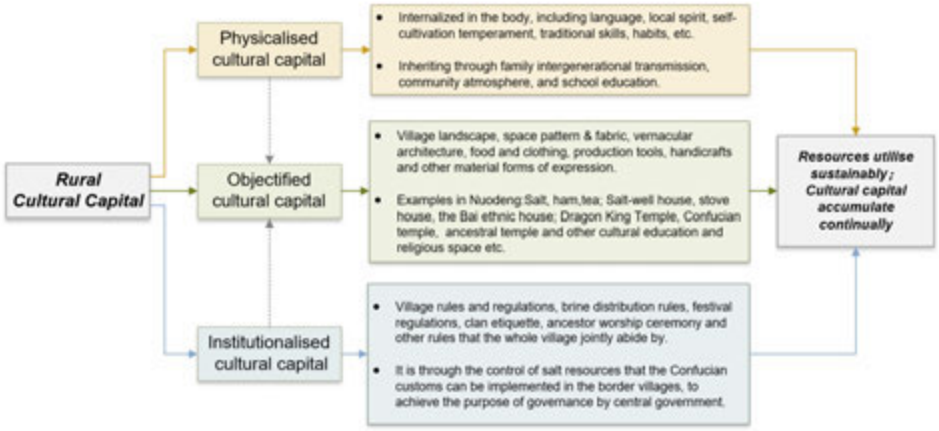

Fig.6 Three Forms of Cultural Capital in the Salt Industry Era of Nuodeng
Source: the authors.

3.3 Heritage Era: The Recession and Transformation of Cultural Capital

3.3.1 Resources: From Natural Resources to Cultural Heritage

Salt production persisted until the 1960s and 1970s, when traditional family-based production gave way to collective production centred on salt factories. However, the traditional system of villagers governing the public commons vanished as a result of the nationalisation of brine rights. The salt factories eventually stopped operations in the 1980s and 1990s due to the advancement of mechanical manufacturing processes and the popularisation of sea salt.

The absence of intentional communal care caused the salt wells to progressively silt up and collapse over the course of the next three decades. Simultaneously, with the rapid growth of urbanisation and globalisation, Nuodeng village, like plenty of other Chinese villages, was facing the issue of aging and hollowing out.

Since the turn of the 21st century, the Chinese government has established and improved national heritage conservation systems, including the World Heritage Sites, 'National Historic and Cultural Cities, Towns, and Villages', and 'National-level Cultural Heritage Sites'. Social projects like the 'Beautiful Countryside', 'Characteristic Small Towns', 'Poverty Alleviation', and 'Rural Revitalisation' have also been implemented at the national level, pushing rural heritage conservation further.

Despite the village's abandonment of salt resource development, local elites have been constantly excavating Nuodeng Village's cultural capital, which attracted the attention of the government and media. With the approval of the Ministry of Construction, Ministry of Culture, and the State Administration of Cultural Heritage, Nuodeng Village was designated as 'National Historic and Cultural Village' in 2006, 'Traditional Village of China' in 2012, and 'National-level Cultural Heritage Site' in 2013.

3.3.2 Governance Community: Hierarchical Local Government and multiple stakeholders

The previous production-based, bloodline-based and geography-based communities have been replaced by hierarchical governance communities with the primary goal of conserving and utilising heritage resources. A variety of actors, including governments and related functional departments at all levels, market forces, communities (e.g. new residents, indigenous residents, and autonomous organisations within the communities), and social forces (e.g. academics from universities, technologists, and social organisations), have replaced the original actors, who were primarily residents and local governments. The primary mode of governance also shifted from community-led and official participation into government-led and community-supported.

Even in the modern and contemporary era, key members of the original governance community, such as cultural elites and prestige people, continue to be involved in the governance of public cultural affairs and preserve cultural heritage. Local elites who work in government will draw greater official attention and obtain resources for the heritage community. For instance, Mr. Y, a cultural elite of the famous local clan, has placed high value on protecting Nuodeng Village's cultural heritage and implemented relatively strict tourism regulations during his time as the county tourism bureau's director. In order to encourage government-community collaboration in heritage conservation and cultural tourism development, he established a leading group within several governmental departments, and also instituted a Heritage Conservation and Tourism Development Association in Nuodeng Village.

3.3.3 Governance Systems: Multi-objective and Absonant Governance Systems

The governance systems evolve along with the change of resources and the composition of the governance community. In the heritage era, four governance systems have emerged in the communities and are nested within each other: a system aimed at conserving the legal heritage, a system aimed at developing cultural tourism, a system aimed at carrying out national political tasks like Poverty Alleviation and Rural Revitalisation, and a governance system of community self-governance and participation of social forces, which is aimed at community development.

- *Heritage management System*

The 'heritageisation' process has given the community's legacy a legal identity and, along with it, the national standards for the preservation of the legal cultural heritage. The various departments within the county government have been collaborating with specialists, academics, and planning institutes to manage heritage sites, including formulating conservation planning, setting up daily monitoring systems, and developing townscape guidelines. Actually, the conservation plan has not truly been implemented because of the disagreement between the departments, leaving the rural scape protection in an empty talk. Furthermore, the management of national heritage properties is frequently standardised, which causes the neglect of local public demands. For instance, the county government has chosen to adapt the national heritage site Salt Bureau in Nuodeng Village into a bookstore and café for the outsiders, with doors opening and closing on a regular basis. This decision has limited the Salt Bureau's original function to serve as a public venue for the elderly's cultural activities.

- *Tourism and Development System*

Gaining national recognition increases institutionalised cultural capital, which indirectly raises the village's popularity in the eyes of the general public. Cultural capital may transfer into economic capital with the momentum of tourism. In order to profit from the cultural brand, local people, both native-born people and recent immigrants, have spontaneously opened hotels and sold regional specialties; on the other hand, the government has partnered with businesses to enact a comprehensive tourism development with administrative will. The county government wants to turn Nuodeng Village into a national scenic spot, so it has given permission for two tourism investment companies to move in. It has also attempted to raise money from higher levels of government and social capital in the name of building tourism facilities. However, the government has encountered challenges in establishing a mechanism for sharing benefits with the local community, and the residents have shown limited interest in participating. As a result, the progress of the development project has been hindered.

- *Rural Revitalisation Campaign System*

The rural areas of China serve as the place for the national large-scale social initiatives, reflecting the government's goal of modernising agricultural practices and rural administration. Within this objective, the central government carries out top-down political initiatives such as Poverty Alleviation and Rural Revitalisation. These state-initiated social engineering often involve a focused allocation of resources and policy direction for a specific duration (Scott, 1998). They possess a significant ability to mobilise local governments due to the evaluation mechanism of government officials. The discourse on how to maintain and utilise cultural heritage as resources has become a means for local government authorities to meet the goals of rural revitalisation. Due to its abundant heritage assets and widespread popularity, Nuodeng

Village is highly likely to attract attention and secure fund from higher authorities when applying for various rural revitalisation projects.

- *Community Autonomy and Social- engagement System*

The initial three governance systems mostly exhibit a government-driven, top-down governance mode, although the formal and informal community self-governance organisations continue to exist in Nuodeng village. In the village, there is an Elderly Association established by local cultural experts apart from the officially-led Heritage Conservation and Tourism Development Association. These associations are primarily composed of highly esteemed elderly individuals who are responsible for organising and executing various ceremonies, including the Dragon King's Festival and ceremonies dedicated to Confucius.

Furthermore, the Women's association led by Ms. H, who holds community respect due to her establishment of the village's first homestay and her lineage as a descendent of the Huang family, plays a significant role. She collaborated with other women to coordinate other smaller celebrations throughout the town. Additionally, she urged the villagers to contribute financially towards the restoration of the San Chong Temple and the repainting of the statue of the Goddess of Mercy. Although the San Chong Temple is an unofficial heritage site, it holds significance as a cultural symbol that is highly valued by community members, who are internally driven to preserve it.

3.3.4 Governance Output: Depletion and Transformation of Cultural Capital

In the salt era, the management of public resources involved the preservation and use of natural resources such as brine, mountains, forests, and fields. On the other hand, in the heritage era, the management of public resources refers to the cultural resources, the physicalised, objectified, and institutionalised cultural capital that was amassed during the salt era, in both tangible and intangible forms. The previous production-based, bloodline-based and geography-based communities have been replaced by hierarchical governance communities with the primary goal of conserving and utilising heritage resources, thus forming a governance mechanism aiming at various objectives.

In contrast to the salt era, which focused on economic capital and later evolved into social and cultural capital, the heritage era centred on the accumulated cultural capital as a core to foster the reproduction of all three types of capital. Indeed, the cultural capital has diminished due to insufficient investment in resources and maintenance, particularly driven by tourism. This has resulted in the conversion of cultural capital into economic capital on a large scale, leading to the commodification and gentrification of rural heritage. As a result, a positive cycle has not been established (Fig.7).

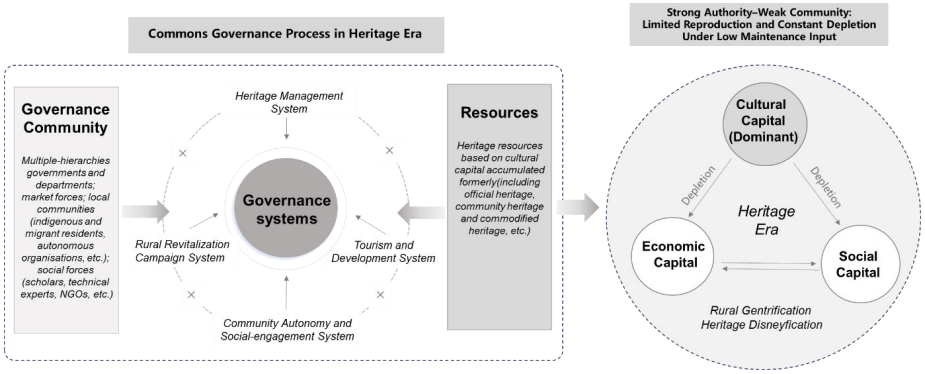

Fig.7 The Governance Process of Heritage Era
Source: the authors.

The implementation of this mechanism has led to the initial transformation and reproduction of the cultural capital in rural heritage communities. However, there are challenges in ensuring sustainable governance. The absence of family education, community education, and school education has caused a significant depletion of physical cultural heritage, of which the core of inheritance is the 'human being'. This also demonstrates that the public management of cultural assets not merely involves the physical artefacts, but also exhibits a multifaceted challenge of governing a social system (Fig. 8).

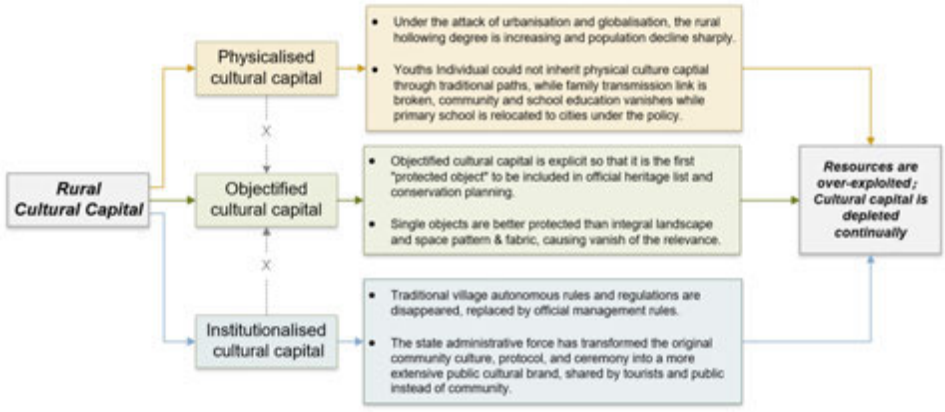

Fig.8 The Change of Cultural Capital in Heritage Era
Source: the authors.

4. Governance Dilemma and Potential Solutions

4.1 Governance Dilemma

4.1.1 Tensions between Community, Official, and Commodified Heritage

The process of heritagisation has resulted in a dual contradiction between community heritage and official heritage in terms of evaluation and administration. While culture is an integral asset for the entire community, the official value-based protection focuses primarily on tangible cultural assets such as buildings and relics. Unfortunately, little attention is given to the preservation and inheritance of intangible cultural heritage, such as social norms, rituals, and ceremonies that used to play a crucial role in rural society. This has resulted in the 'hollowing out' of heritage communities.

At the same time, the official heritage designation highlights the public attribute of heritage and the government's obligation to manage it. As the protection level of heritage increases, the primary responsibility for management and rights for development rests with the county and township governments, limiting the community's initiative to participate in governance. During the field survey, the villagers initially blamed the government for the silted salt wells and decaying buildings, rather than taking responsibility themselves. This passive attitude demonstrated a lack of active participation, and the community's awareness of the need to maintain resources and continue their public use vanished.

Furthermore, the original village full of locality has turned homogenised and gentrified due to the neglect of physical cultural capital. The aborigines of the community, particularly the younger generation, lack a sense of identity and belonging to their hometown cultures and are highly vulnerable to the influence of the 'imaginary countryside style' popularised in social media. New immigrants who have opened upscale lodgings in the countryside that cater to urban tourists have strengthened this imagination. Consequently, numerous recently renovated residences fail to adhere to the townscape preserving regulations, leading to damage to the vernacular architectural style. To some extent, the original 'living community' has evolved into a 'performing community' and a 'commercialised community'.

4.1.2 Management Vacuum Caused by the Expansion of Governance Community

The governance community is comprised of multiple actors who exhibit distinct purposes, resulting in complicated behaviours. Local government departments and technical experts prioritise heritage preservation, while private owners and enterprises focus on economic gains from the cultural brand. The goals of the community's aboriginal people are more multifaceted. On one hand, they have a strong emotional attachment and identity to the community. Particularly, the older generation believes that cultural heritage is of utmost importance and should not be sacrificed for development. However, on the other hand, they also need to earn a living in response to the evolving social and cultural context, attempting to reap the advantages of their cultural legacy by opening accommodations and selling agricultural products.

It is worth noting that in previous studies, the 'local government' is often regarded as a single entity. However, in this particular example, we observe that there are multiple levels and aims of actors inside the government. From a hierarchical perspective, the vertical structure of government involved in heritage governance consists of five levels: national department, provincial department, city-level department, county-level government and corresponding offices, town-level government and village committee. Additionally, there are various

horizontal departments such as planning and construction, culture and tourism, and agriculture and rural affairs, each with distinct requirements for heritage conservation. This results in the challenge of overlapping management for heritage conservation.

County-level government and its corresponding offices take the initial responsibility for local public affairs. The application for national heritage declaration, conservation management, funding allocation, and tourism development are all primarily carried out by the county-level government. The higher-level departments prioritise heritage conservation, but county and sub-county governments have multiple responsibilities and must strike a balance between social stability, economic development, and public services. In order to effectively implement heritage conservation, it is necessary for these governments to incorporate it into their governance tasks. However, this integration can sometimes lead to a distortion of the objectives of heritage conservation.

Contrary to the traditional salt era, the governance community of public resources has now expanded. The previous model of a strong community and weak government has shifted to a strong government and weak community model. This means that the government now has more influence in the heritage commons governance, while the participation of the community and social forces has been hindered. Additionally, the government entity has become more complex with multiple layers, making it difficult to coordinate and work together and finally causing a vacuum in the specific management role.

4.1.3 Lack of Coordination between Four Governance Systems

The primary factor contributing to governance failure in rural heritage communities is the absence of effective coordination across the four governance systems: heritage conservation, tourism development, rural revitalisation, and community autonomy and social engagement. ‘Heritage conservation’ has become a discourse when county-level governments tend to apply for national projects such as cultural tourism and rural revitalisation, since it is more likely to be taken seriously by higher-level government departments. Actually, there is a patchwork of projects and inconsistent use of funds in the name of heritage conservation. The allocation of funds is mostly directed towards infrastructure improvement since the governments prioritise short-term outcomes, thus there is a deficiency in the development of sustainable systems for comprehensive conservation. Although the advancement of cultural tourist services and products has enhanced the local economy, there is now no distribution mechanism for allocating the benefits and costs among the community, which can result in unfairness.

Cultural, social, and economic capital in the bottom-up community autonomous system translates into the ‘prestige’ of local elites, which is crucial for community self-government. But as the cultural elites of the community get older, the younger and middle-aged generations have not been able to acquire enough prestige in the altered governance environment. Additionally, the government’s heavy involvement in the cultural heritage management has resulted in a lack of participation by village associations and social organisations, leaving a void in the community.

More significantly, as Fig.9 illustrates, the cooperative operation of the four governmental systems depends on conservation and development planning and the related mechanism. As regulated by the documents of higher government departments, conservation planning should include the following aspects: a multisectoral synergistic management mechanism; guidelines for the control of townscape; fire safety; improvement of infrastructure and living conditions;

and reasonable use and development of cultural legacy. The conservation and development planning is expect to be the statutory authority for approving new constructions, the guide in tourism development, the source of project in the rural revitalisation movement, and the result of community and social forces' participation. However, the current conservation planning has been stranded because of disagreements within the governance community, which obliquely results in the lack of a dominating department to manage the approval of new constructions, modifications, and additions. A fundamental characteristic of rural governance in China is the project-based governance mode, which also serves as a means of investing funds, attracting government attention, and other aspects of governance. Conservation and development planning should have initially aimed at achieving sustainable development for rural communities and then proceeded to formulate project plans. Nevertheless, in practice, there is a deficiency in addressing pertinent aspects, leading to the heritage community projects that primarily focus on fragmented infrastructure construction. This approach places excessive emphasis on short-term, observable outcomes, which hinders long-term development.

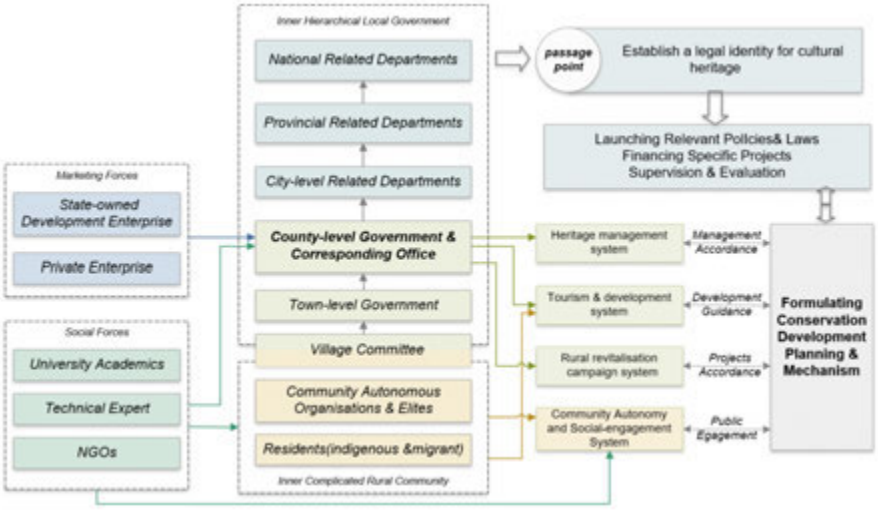

Fig.9 Interactive Analysis of Governance Behaviour in Governance Community

4.2 Reconstruction of Common Governance Exemplified by Two Cases

The government-led governance prioritises the objectified and institutionalised cultural capital, while neglecting the transmission of physical cultural capital of the heritage community, which is the core of living heritage that focuses on the well-being of people. Despite the implementation of a strong government and weak community model in Nuodeng Village, the community's spontaneous participation demonstrates the vitality and potential for rebuilding public governance through tactical resistance.

4.2.1 Revitalisation of the Traditional Dragon King Festival

The Dragon King Festival was a significant celebration in Nuodeng during the salt industry era. People would worship the Dragon King who was responsible for the brine vine to impetrate the abundance of the salt brine since it was the main income for the hamlet. Nevertheless, following

the decline of the salt economy era, the festival was halted for over three decades. The revival of the festival was the outcome of a collaborative effort between the local community and the government.

The government, with the support of the local elites, aimed to establish a festival sightseeing project as part of its heritage tourism initiatives. The community responded favourably to the signal, with the respected elderly villagers leading the way. The organisers consist of the Elderly People's Association, the Dongjing Taoist Music Band, and the Association for Heritage Conservation and Tourism Development of Nuodeng Village. Through interviews with the elderly, the ceremonial details of the festival were documented (Fig.10). The revival of this event fulfilled both the governmental and community's objectives, while also revitalising the cultural ambiance of the community, drawing in tourists, and preserving the salt culture in a more dynamic manner.

Fig.10 The Dragon Festival in Nuodeng Village
Source: the authors.

4.2.2 Heritage Education for Community Held by the NGOs

The Beautiful Nostalgia Social Organisation is a non-governmental organisation (NGO) dedicated to promoting local cultural inheritance and providing cultural heritage education. For almost a decade, it has been actively engaged in heritage education initiatives in Nuodeng Village. The university student volunteers have published *Nuodeng Vernacular Culture Reader* and arranged annual summer camps in the village, where they collaborate with local teenagers to design project-based learning (PBL) projects that aim to investigate and comprehend the community's culture (Fig.11). The curriculum incorporates the content of the natural environment, cultural characteristics, and community evolvement, highlighting the landscape, salt industry traditions, rehabilitation of traditional dwellings, and the design of guided tours.

Starting from the children, a greater number of family members were connected, eventually involving the entire community. Various public cultural events were held, such as creative bazaars, cultural exhibitions, and villagers' tea parties. Furthermore, members of the community actively contributed to the programme through musical performances, material provision, participation in activities, involvement in interviews and discussed the protection of community heritage. These new cultural festivals have garnered significant interest from the local government, social media, and the general public.

By combining heritage education activities with community cultural creation, the community residents' physical cultural capital was effectively enhanced. As a result, the case won the 2022 'Global Awards for World Heritage Education Innovative Cases'. This achievement highlights the potential for social forces to engage in heritage governance actively.

5 Conclusions

In the context of the double failure of the bureaucratic government governance of public resources and the pure market mechanism governance, Ostrom showed empirical studies that people in many communities can successfully implement appropriate governance of certain resource systems through the independent governance and rule-making of communities. We could also find the successful commons governance traditional experience in the traditional salt-industry village in China. However, the community now is facing challenges in protecting and reproducing heritage resources.

This paper proposes a theoretical framework to analyse the process of commons governance and transformation of cultural capital, suggesting that heritage commons can serve as an alternative reality approach in the field of rural heritage management. Governing heritage governed as commons means building a new understanding of its values which extends beyond consumerism or state identity to embrace the local community. Furthermore, 'commons' implicates dynamic governance interaction processes towards more sustainable, equal and inclusive development in heritage communities. It can also facilitate the creation of a shared vision and bridge the gaps in perceptions and behaviours, while it could help to build a common vision and bridge some perceptions and behaviour gaps among the various stakeholders, such as different hierarchical local governments, academics, local residents, market forces, and NGOs, and making. This, in turn, leads to a more democratic decision-making process.

From the cases, we can observe that the introduction of the cultural capital perspective can help better understand how heritage resources, as commons, are formed, accumulated, and transformed. During the era of traditional small-scale natural resource governance, each form of cultural capital was strengthened and the public interest was promoted, thus facilitating sustainable resource utilisation and community development. However, in today's trend of heritagisation and commercialisation, stakeholders focus more on objectified and institutionalised cultural capital, while neglecting the transmission of physicalised cultural capital, which is the core of 'people-centred' dynamic heritage conservation. The community's self-governance and social participation show the possibility of addressing this deficiency.

Currently, there exist four governance systems in the heritage commons of Chinese rural areas—heritage management system, tourism and development system, rural revitalisation campaign system, and community self-governance and social engagement system —that have yet to be coordinated and unified. This is also the cause of the current dysfunction in the governance of public affairs in rural heritage communities. By drawing on traditional governance experiences and establishing a community-led model with multi-level government

coordination, enterprise negotiation and social forces participation, we could achieve a more inclusive, equal and sustainable development in rural heritage communities.

Abstract. Archaeological site parks, as a government led form of site protection and utilization, are reflected in a series of constructive protection practices for the site, involving the site itself and its surrounding areas. In the construction process of the archaeological site parks, not only should the focus be on protecting the site itself, but also on meeting the practical needs of the population. This paper reviews the relevant theories of heritage value and re-examines the important role of value construction in the construction of archaeological site parks in the modern context of aesthetic evolution. It proposes a basic path for value reconstruction based on value selection and creative transformation, and explores the planning strategies and design methods of archaeological site parks through practical cases.

Keywords: constructive protection, value selection, creative transformation, value reconstruction

Introduction

As a constructive form of protection of sites, the *archaeological site park* has gradually developed and improved in the practice of site protection in about 40 years since its emergence in the 80s of the twentieth century in China, along with the rapid construction of the city after the reform and opening up. With the deepening of heritage protection in the past 15 years, the protection form of China's "archaeological site parks" has become more and more mature. As a constructive conservation practice led by the state and the government, under the strong leadership of Authorized Heritage Discourse, although the protection of "parks" is effective, it is always difficult to balance the value selection problems faced in the construction process, which is not only reflected in the contrast between huge investment and meager benefits, but also in the process of aesthetic transformation and cultural value dissolution.

From the perspective of heritage discourse, the AHD（Authorized Heritage Discourse） plays a decisive role in the construction process of archaeological site parks, and top-down intervention can often protect the site in time during the rapid development of the city, but this strong intervention cannot directly revitalize the site, and the result is obvious. In China, although the protection of great sites has achieved fruitful results, there is still a need to face the problem of heritage activation. In 2021, the *14th Five-Year Plan for the Protection and Utilization of Large Ruins* clearly mentions: There are still deep-seated problems in the protection and utilization of *the great sites*①, with a relatively single mode of protection and display utilization. There are not many ways for great sites to come to "live" and their vitality is insufficient.

From the perspective of CHS（Critical Heritage Discourse）, in the process of construction practice of archaeological site parks dominated by AHD, the construction of heritage value is mainly based on the discourse of experts and the government, and insufficient attention is paid to the participation of the public, community and market, which makes the archaeological site parks lack specific objects in operation and use, and it is difficult to establish economic sustainability, resulting in insufficient motivation for cultural dissemination. From the perspective of the practical process of the construction of the archaeological site parks, it is not only necessary to understand the shortcomings of the existing value framework through discourse analysis from the theoretical level, but also to explore the creative transformation methods in the design process as planners and architects, so as to fully respond to the needs of the public and promote the construction of the revitalization mechanism of the archaeological site parks, so as to realize the protection and inheritance of cultural heritage. This is not only an issue for China, but also an important issue for world heritage protection today.

1. The practice of "constructive protection" in parks

1.1 The development of international archaeological site parks

The protection of Italian archaeological sites can be traced back to the Renaissance period in the 15th century, and a relatively complete method of preserving archaeological site parks has been developed during its long process of site protection. The Italian central government promulgated the *Monuments Act* in 1902, confirming that the comprehensive protection of cultural heritage such as historical buildings and archaeological sites is the responsibility of the state (Gianighian G., 2001, p.186). From the late 19th century to the early 20th century, some relics have developed according to the concept of "open-air museums" and have approached the concept of archaeological site parks. In 1998, the Ministry of Cultural Heritage was established, and cultural heritage bureaus were established in various places to assist in the consultation and registration of cultural heritage. In 2012, the Italian Ministry of Cultural Heritage issued *the Guidelines for the Construction and Strengthening of Archaeological Site Parks*, which reflected on and provided suggestions for the interpretation and planning and design methods of Italian archaeological sites and landscapes (Du Qian, Cao Yongkang, 2019, p.83).

In 1943, France promulgated the *Law on the Surrounding Environment of Historic Buildings*, which emphasized the principle of overall protection. Subsequently, in 1960, the *National Parks Law* was promulgated, further expanding the protection of the surrounding environment of archaeological sites, and the concept of "protected areas" was proposed in the 1962 *the French Loi Malraux*. In 1993, *the Landscape Protection and Value Representation Law* was promulgated, which included the surrounding landscapes of the site in the protection scope, laying the foundation for the development of the archaeological site parks. In the process of protecting the site, multiple channels and measures were taken to promote education and promote the use of cultural heritage, in order to mobilize public participation.

The driving force behind the preservation of archaeological sites in the UK mainly stems from the call for the preservation of historical buildings in the 18th century. In 1882, *the Monument Protection Law* was promulgated, and in 1913, *the Comprehensive and Revised Monument Law* was promulgated, which clearly included site protection in urban planning. In the process of protecting the site, the model of national parks is also adopted, in which the government, local residents, and non-governmental organizations jointly participate, and the proportion of personnel is equal, each bearing different responsibilities. Local residents directly participate in the protection of natural heritage and native culture, and are responsible for providing certain economic vitality.

The United States is a pioneer in protecting cultural heritage in the form of national parks, which are the fundamental structure of cultural heritage protection in the United States (Xia Jiechang, Liu Ruiyi, 2023, p.67). In 1832, the United States proposed the concept of national parks; In 1889, the first archaeological national park was established - Big Bend National Park; In 1916, the National Park Administration of the Ministry of the Interior was established and *the Basic Law on National Parks* was promulgated. In 1966, *the National Historical Protection Law* was promulgated to register historical relics in national historical parks. After more than a hundred years of exploration and practice, a relatively complete national park management system has been formed. (Ning Zhaoyong, 2024, p.114) Overall, national parks in the United States are mainly natural landscapes, while also taking into account the protection of historical and cultural heritage. Initially, they were not formed specifically for site protection.

In 1897, Japan promulgated *the Law on the Preservation of Ancient Shrines*, which included ancient temples, shrines, etc. in the scope of protection. In 1919, *the Law on the Preservation of Historical Sites, Scenic Spots, and Natural Monuments* was promulgated to protect the site. In 1966, *the Ancient Capital Preservation Law* was promulgated, and the construction of

①The Great Site： In 2005, *the Measures for the Management of Special Funds for the Protection of Large Ruins* clearly stated that "large ruins mainly include reflecting the various stages of development of ancient Chinese history, involving politics, religion, military, science and technology... and other historical and cultural information, large-scale settlements, city sites, palaces, mausoleums and tombs and other sites, ruins and cultural landscapes with large-scale, significant value and far-reaching influence".

archaeological parks became the norm for the protection of Japanese archaeological sites. In 1996, Japan reformed the system of cultural heritage selection from the top down to a bottom-up registration system, which greatly promoted the participation of local and civil society groups in heritage protection. While protecting the site, great attention is also paid to the protection of the intangible cultural heritage related to the site. Through the "human national treasure" mechanism and a series of reward and subsidy measures, traditional Japanese arts and crafts have been preserved to this day at a high level, which has a good promoting effect on the revitalization and inheritance of the site.

Overall, the construction model of archaeological site parks in European countries is relatively flexible and emphasizes joint management. Communities can play a certain role in the protection and revitalization of archaeological sites. The United States focuses on legislative protection, with federal government leadership and unified management, resulting in high execution and management efficiency, and low public participation in the construction of archaeological site parks. Japan pays more attention to the combination of material and non-material aspects in the construction of archaeological site parks, which can fully grasp the market, transform heritage cultural resources into tourism resources, and activate and inherit heritage culture.

1.2 The Development of China Archaeological Site Parks

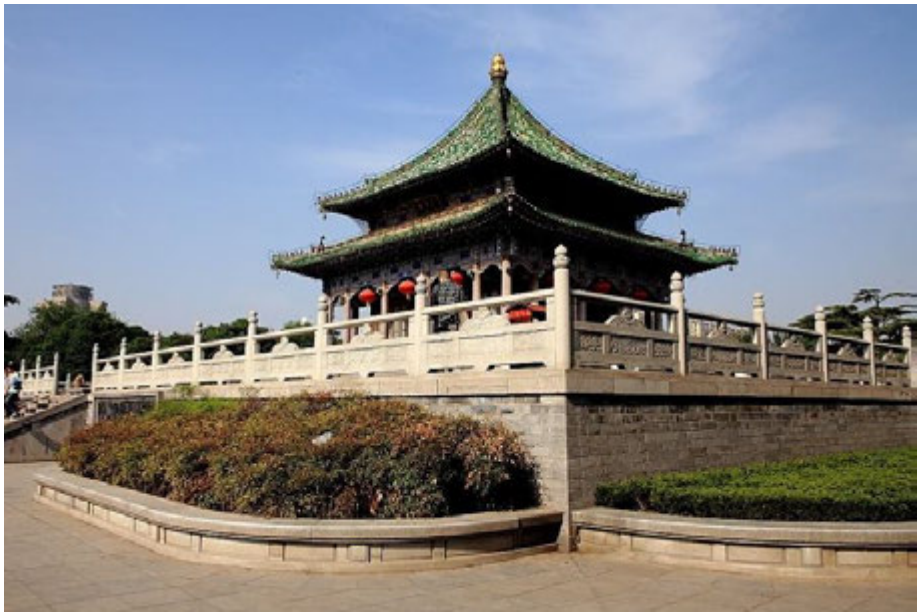

Figure 1. Xingqing Palace Park（https://baike.so.com/doc/5379882-5616132.html）

At the beginning of the founding of the People's Republic of China, some places began to explore the construction of urban parks on archaeological sites. A typical example is the Xingqing Palace Site Park built in Xi'an in the 1950s on the basis of the Xingqing Palace Site, as shown in Figure 1, but there was no clear awareness of the protection of archaeological site parks at that time. It was not until 1983 when the State Council approved the "Master Plan for Urban Construction in Beijing" that it was first proposed to designate the Yuanmingyuan Site as a " Archaeological Site Park ". In 2000, the concept of " Archaeological Site Park " was linked to the management of cultural heritage in the "Yuanmingyuan Archaeological Site Park Plan". Until 2009, *in the Liangzhu Consensus on the Construction of Archaeological Site Parks* formed at Liangzhu Forum, it was clear that "building an archaeological site park" was the way to protect China great sites (Xi Yueting, 2013, p.10). In the same year, the National Cutural Heritage Administration issued the Administrative Measures for National Archaeological Site Parks (for trial implementation), marking the birth of a new management model for the protection of great sites - "National Archaeological Site Park", that is, "a specific public space with important archaeological sites and their surrounding environment as the main body, which has the functions of scientific research, education, recreation, etc., and has nationwide demonstration significance in the protection and display of archaeological sites". (Wang Lu, Liu Kecheng, 2016, p.10). Subsequently, the National Cutural Heritage Administration successively announced a total of 55 national archaeological site parks in 2010, 2013, 2017 and 2022, and 80 of them were included in the project list. From this, it can be seen that the concept of China's archaeological site parks has continuously developed and matured in the process of protecting "great sites".

Since 2009, the National Archaeological Site Park has entered an accelerated development stage as an important carrier for the protection and display of China's major archaeological sites. The "Archaeological Site Park" in China has been continuously developed and improved in practice, gradually becoming an important way of site protection, display, and utilization. With clear requirements for establishment, management methods, and evaluation rules, emphasizing the initiative and purpose of "protection", it is a government led "park protection" model that has emerged with China's rapid urban construction. It is a "constructive protection" that corresponds to "constructive destruction".

From the perspective of the development process of international heritage protection theory and practice, the formation process of archaeological site parks in different countries varies. Due to the early development of heritage protection theory and practice in Europe, the awareness of heritage protection sprouted in the late Renaissance of the 14th century, developed and formed in the early 17th to 19th centuries, and gradually improved after the 19th century. Archaeological site parks also appeared earlier; However, the development of China's heritage protection theory and practice started relatively late, originating from the introduction of Western protection theories by Chinese scholars in the early 20th century, and the full absorption and reference of Japan's heritage protection experience. It was not until the 1990s, with the rapid development of cultural relics protection, that China's heritage protection theory and practice gradually developed.

1.3 International Consensus on the Protection Model of Archaeological Site Parks

Throughout the development of international archaeological site parks, the protection model of archaeological site parks has developed at different stages of the protection process of various countries. Archaeological site parks are widely developed and popularized worldwide due to their outstanding advantages in overall protection, coordinated management, and coordinated development, as well as their wide applicability. In 2015, the International Council on Monuments and Sites (ICOMOS) held its first global conference on archaeological sites parks in Salalah, South Sultanate of Oman, proposing the *Salalah Recommendation*, which stated that "archaeological sites parks" should be a common concept of the International Council on Monuments and Sites. At this point, the global community has generally accepted and adopted this important creation formed in the practice of national cultural heritage protection and utilization(Gao Jing, Zhou Jia, 2023, p.23).

1.4 Reconsideration of Archaeological Site Parks in the Context of Contemporary Heritage Protection

With the development of modern heritage protection theory and people's attention to AHD, in the context of CHS, it is also necessary to reconstruct the concept of archaeological site parks through cognitive reconstruction. Archaeological site parks are not just "parks", they play an important role in cultural dissemination and value recognition. Therefore, in the face of many problems in the construction process of archaeological site parks, it is necessary to first reinterpret two deep-seated issues. Firstly, what is archaeological site parks and why is it a

"park"; Secondly, what has been reconstructed in the practice process of archaeological site parks.

The first question: Firstly, explain the meaning of "site" in archaeological site parks. The author believes that archaeological site parks should first break away from the label of "park". Archaeological site parks, as a form of site protection that has emerged in contemporary urban construction and development, have become very common. The park has shaped the rationality and legality of the protection and preservation of archaeological sites, and is a function that can be better embedded in the city and used by people. Therefore, for the construction and protection of archaeological site parks, "parks" are only a prerequisite, and as the outer shell, "parks" need to be supplemented with more content. The value released by archaeological site parks and the information transmitted need to be truly related to the site. The meaning of a park not only gives legitimacy to the purpose of protecting archaeological sites, but also emphasizes the public welfare and openness of public services. Archaeological site parks require both archaeological sites and the public, and "parks" are an important medium for public participation in the protection and construction of archaeological sites.

The second question: In order to cater to the market, under the current situation of site park construction, where cultural consumption has reduced the cultural significance of sites, archaeological site parks have been transformed into highly recognizable typified products, become popular clock-in places, and are collaged and reconstructed in mass consumption. In the process of individual participation in cultural consumption, the cultural significance of archaeological sites is dissolved. However, if we do not inquire about the cultural significance of the sites themselves, do not see the changes and unchanging cultural values, and the role and influence of culture on the public in this process, archaeological site parks will eventually become "symbols" and lose meaning in consumption.

2. Realize the Reconstruction of Culture Values Through Public Participation

This section expands the discussion of value reconstruction, which attempts to examine from the perspective of CHS and pull away from the existing discourse system.

From the perspective of the development of the international archaeological site parks, as a constructive protection practice for the sites, AHD strongly dominates the construction of the archaeological site parks and plays a fundamental role in the construction process of it, which makes public participation and community participation in a relatively weak state. In the regard, countries have paid a considerable attention to the construction process of archaeological site parks and also protected by legislation, incentives, subsidies and other forms of protection. It can be seen that public participation is an indispensable and significant part of the construction of archaeological site parks. The construction of archaeological site parks needs to coordinate the intricate practical problems through public participation and complete the distribution of rights and interests, and establish a bottom-up participation mechanism to balance the contradiction between urban development and site protection.In this process, public participation is regarded as an important part of the construction of the

archaeological site parks, there will give no cause for much criticism if standing in the perspective of supplementing the integrity of the construction system of it. However, accomplishing the sustainable construction of the archaeological site parks, public participation is not only an important link, but also the ultimate goal of the construction of it.To clarify this point, it has to conduct an in-depth analysis about the role of public participation in the value reconstruction of heritage culture.

Under different national conditions, the construction mechanisms of archaeological site parks are different. But the problems China faces in the construction of archaeological site parks are also faced by other countries. While protecting the archaeological sites, fully responding to the public's needs through the park is an important issue that cannot be avoided in the construction of archaeological site parks. The following is a detailed discussion of the process of construction practice of archaeological sites parks in China, with a view to providing reference and inspiration for common problems faced by the construction of international archaeological site parks.

2.1 Public Participation In the Construction Process of China Archaeological Site Parks

The construction of archaeological site parks can prompt local governments to pay attention to the protection and management of archaeological sites, so that residents where the archaeological sites are located can obtain corresponding benefits from the archaeological site parks, thereby alleviating the contradiction between protection and development faced by archaeological sites (especially great sites) (Sun Hua, etc. 2022, p.04). At present, China's heritage protection has begun to shift from rescue protection to preventive protection, and public participation is also increasingly valued during the construction of archaeological site parks. There are also more and more heritage protection workers and scholars proposing initiatives to improve the vitality of cultural heritage through public participation. There are two stages of public participation in the construction process of archaeological site parks in China, namely the land acquisition, storage and allocation stage at the beginning of park construction and the park construction process and use and operation stage. The former mainly involves the issue of accommodating rural collective land in the face of some large-scale archaeological sites. The land is generally accrued once or in batches through economic compensation, and is mainly completed by the government; the latter is done by the designer during the design process. Public participation is reflected to a certain extent through research and is reflected in the design. When the design is completed and handed over to government operation and management, public participation is mainly reflected in the use of the parks.

2.2 Public Participation that Meets Needs

What the archaeological site "park" coordinates is the balance between historical value and social value, which leads from the issue of site protection to many practical needs. Therefore, it is necessary to conduct a correlation analysis between a series of public's needs and a series of practices in site protection.

In the early stage of the construction of the archaeological site parks, the acquisition and storage of land is mandatory. In principle, the land included in the scope of the archaeological site parks will be owned by the state. The public participation at this stage mainly involved in the process of benefit distribution. The government meets the basic needs of local residents through financial subsidies. The public participation in the archaeological site parks during the construction process and operation stage is post-positioned, supplementary, and relatively passive. The construction process of China's archaeological site parks generally consists of four progressive links: archeology-protection-display-utilization, with a relatively clear paradigm structure (Figure 2). These four stages are all completed by the government and experts. The "utilization link" best reflects the relationship with users. It needs to fully consider the needs of the public and is mostly expressed as an attractive cultural consumption or service, which is a kind of utilization that caters to the market, is popular with the public, and is easier to create economic benefits. It can better meet the public's demand for cultural experience. Compared with "Internet celebrities", it fully caters to the market and the public's cultural consumption psychology. However, the purpose of this kind of utilization is mostly to generate income to make up for the huge financial investment during the initial construction and operation of the parks.

In this way, the construction of archaeological site parks dominated by AHD ultimately serves the issuer of the discourse, and public participation falls into passivity. In summary, both types of public participation reflect the fit with demand. The early stage of the heritage park is in line with the public's basic life security needs, and the middle and later stages of the archaeological site parks construction are in line with the market's cultural consumption needs.

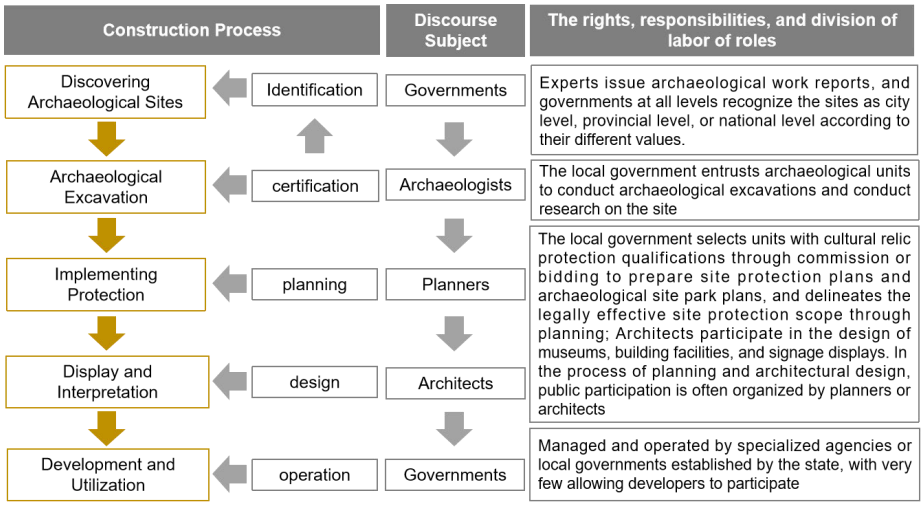

Figure 2. The Discourse Subject in the Construction Practice of Archaeological Site Parks

2.3 The Potential Demand

The construction practice of archaeological site parks meets the existing needs of security and consumption to a certain extent. In addition to this, there is also a potential need—the need for self-realization that creates unique meaning for the individual and is established in the process of dialogue with the site. The individual can fully obtain the freedom of choice to think, welcome, reject, and dispute. rather than being overwhelmed or coerced by authoritative words. Meeting this demand needs to be achieved through public participation in the true sense - in the process of cultural transmission and in the process of dialogue with history, it stimulates individuals to think about their lifestyle. This public participation has a deeper role in promoting a modern translation of the cultural significance of the site.

If you want to get to know the role of this kind of public participation, you first need to fully realize the importance of archaeological site parks in creating or reshaping personal experience and meaning. Secondly, you need to make it clear that this translation is not done by designers, but is completed through the public's experience. What designers do is to realize the dialogue between the public and history through creative transformation, and create a channel for dialogue. Translation is created by individuals, formed from individual experiences, and has meaning for individuals. It needs to be emphasized here that the meaning created by this cultural experience should be rooted in an individual's thinking about lifestyle, rather than arising from a cultural consumption behavior. Translate the cultural significance of the site through individual experience and experience to generate individual meaning and value, making it contemporary, thereby giving the site new commemorative and cultural value. The contemporary translation of heritage culture is not achieved through design; design is just a passage.

2.4 Coping with the Malady of Cultural Consumption

The utilization is limited to the level of "park" form and the level of market demand,which makes essentially no real public participation in the entire process of archaeological site parks construction, only cultural consumption, whether at the beginning of construction or after it is put into operation. Because of the shortcomings of marketing-style cultural communication, the cultural value of archaeological sites is at great risk of being eliminated in the market. The reasons why cultural value is eliminated in the process of market consumption may come from the commercialization of cultural products, the impulse of consumerism or the diversity of consumers. The preventive measures are also multi-faceted. Such as strengthening the guidance and education of cultural consumption, improving the public's understanding and attention to cultural value, strengthening the innovation and quality of cultural products, etc. However, the underlying reason for the dissolution of culture comes from the elimination of the potential needs of the crowd in the process of market operation. In the current era of aesthetic evolution, the marketing of parks by consumerism eager for quick success and quick gains cannot achieve true public participation. At this point, the premise of a value choice has been established.

3. The Value Framework under Discourse

3.1 The Authoritative Discourse Composition of Chinese Archaeological Site Parks

The construction of archaeological site parks under AHD has its existing discourse subject, which expresses the value recognized by authorities.In such a value framework, authoritative discourse generates the first driving force and serves as the starting point and guarantee for the construction of archaeological site parks. Authoritative discourse is often effective in protecting heritage sites. But it cannot play a role in the subsequent operation of the site park, as the operation of the park is directly related to the needs of people's use.For the National Archaeological Site Park, the current main target audience is tourists, while for provincial and municipal level site parks, their main target audience is residents of surrounding communities.In this case, archaeological site parks are important living places for the surrounding communities, different from the construction of scenic areas, because public participation is highly routine and the main purpose of visiting archaeological site parks is not for cultural consumption, but mainly for leisure. At this time, public participation cannot be achieved through the path of scenic areas.It is necessary to examine from a daily critical perspective what kind of creation can attract tourists to stop and become a community monument or symbol to reflect the community spirit or accumulate community memories.

This is also a new perspective that CHS can bring us. The sustainable driving force of archaeological site parks serving the community directly comes from the people's experience and thinking of daily life. The relationship between people and sites is established in daily life and is related to the memory of the community population.This type of public participation and community participation directly points to people's daily lives and specific needs. This bottom-up force is the key to establishing a revitalized and sustainable archaeological site park, which can provide new clues and thinking for the organic development of the site park.

3.2 The Path and Dynamic Cycle of Value Reconstruction under Discourse

The research on cultural capital in heritage value in China is still in its early stages. According to David Throsby's(2010) theory, cultural capital is defined as another asset in addition to the traditional three types of economic capital (material capital, human capital, and natural capital). In addition to the potential full economic value, cultural capital also reflects, stores, and provides cultural value. In his research on the value of industrial heritage, Xu Subin(2024a, p.50) defined the inherent value of industrial heritage as material capital, human capital, natural capital, and cultural capital. The value of cultural capital is reflected in the form of cultural value and economic value. This definition also applies to archaeological sites. Due to the long history and strong cultural significance of archaeological sites, as well as their high degree of damage, their cultural and potential economic value constitute a greater proportion of cultural capital in their inherent value compared to their material capital. The material capital, natural capital, and human capital in the inherent value of archaeological sites are consolidated and strengthened by their cultural significance (Figure 3-a).

According to the "Guidelines for the Protection of Chinese Cultural Relics and Monuments", there are five values: "The value of cultural relics and historical sites includes historical value, artistic value, scientific value, social value and cultural value. Social value includes memory,

emotion, education, and other content, while cultural value includes cultural diversity, the continuation of cultural traditions, and intangible cultural heritage elements.". We can temporarily understand the cultural value in cultural capital as a broad concept, which includes the five types of values mentioned above. In the market environment, the above-mentioned cultural values (five values) also have potential economic value that can be transformed. The potential economic value and cultural value (five values) together constitute cultural capital in the inherent value of archaeological sites. Because the economic value in cultural capital often accompanies the generation of cultural value, economic value is referred to as potential economic value here (Figure 3-b).

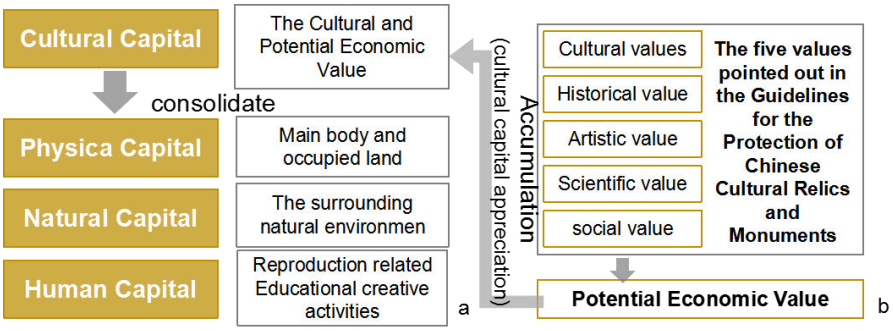

Figure 3. The Intrinsic value of archaeological sites

Authoritative heritage discourse plays an important role in the protection of archaeological sites and the recognition and dissemination of their cultural value. This value is officially recognized, and when heritage departments and governments formulate and implement cultural and funding policies, they participate in heritage manufacturing (Smith, L., Zhang Yu, 2011, p.67). In the process of cultural dissemination and interpretation, the official creates cultural IP, enhances the influence and attractiveness of the site culture through marketing methods, and then converts it into economic benefits through the consumption behavior of tourists. In this process, the national and ethnic level memories carried by the site are interpreted and disseminated through authoritative discourse, in order to achieve the goal of national and ethnic identity.

Under the authorized heritage discourse, the recognized heritage value is reconstructed for the first time by artists and designers through creative transformation, manifested in four levels of cultural industry. They are respectively creative arts, core cultural industries, broad cultural industries, and related industries (Xu Subin, Qingmu Xinfu, 2024b, p.53) (Figure 4-a). From the perspective of the relevant levels of creative value, architecture itself is not the best way to reflect the creative value of heritage. It should reserve sufficient space for the entry of creative art as much as possible, or it should reflect the characteristics of creative art itself, and should have stronger publicness and openness. The creative activities related to heritage in the city are all aimed at building a channel for dialogue with history, but the architecture is more expressed at the spatial or site level. When architects participate, they should first clarify their identity as builders of historical and cultural channels, paying special attention to the

interaction between the building and the surrounding environment, society, culture, and history. Corresponding to the level of creative value, the closer the form of public participation is to creating art, the higher the degree of freedom of participation, and the more number of communities can participate. Therefore, attention should be paid to the importance of artistic creation in the dissemination of site culture and promoting public participation (Figure 4-b).

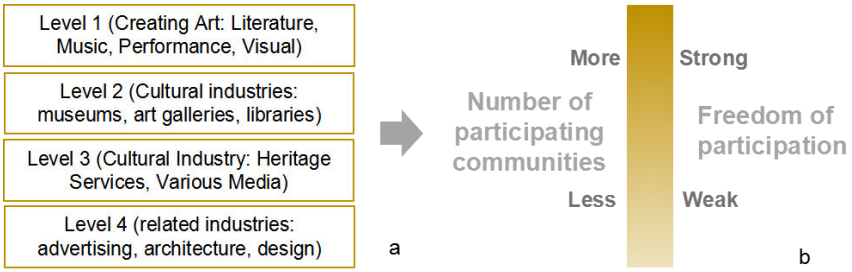

Figure 4. Creative industry hierarchy and public participation level

In the environment of market and cultural consumption, public participation is passive, and the transformed and processed cultural information is transmitted from top to bottom through various creative activities. When the public participates in the services provided by the creative industry, they process, translate, and remember this information through their own experiences. In this process, good ideas often mobilize personal emotional and cognitive initiative, inspire thinking, and trigger resonance. The stronger the individual's emotional and cognitive agency, the deeper the individual's memory, and the stronger their desire to express themselves. In the process of participation, the public actively participates with new understanding, evaluation, advocacy or creation through hands-on experiences, reconstructs the value of heritage, endows the site with new cultural value, and participates in the co construction of archaeological site parks. From this perspective, design should inspire and guide people's attention to history as much as possible, stimulate their interest in history, and involve them in the process of dialogue with history.

In summary, the cultural value of the site is recognized in authoritative discourse, consumed and disseminated in the process of creative transformation, translated in individual experiences, and thus endowed with new cultural value, forming a cycle (Figure 5). In this dynamic cycle, the cultural value of the site continues to accumulate in the social development of aesthetic evolution and the involvement of the public, with potential economic value expanding, cultural capital increasing, cultural industry iterating, and cultural resilience enhancing.

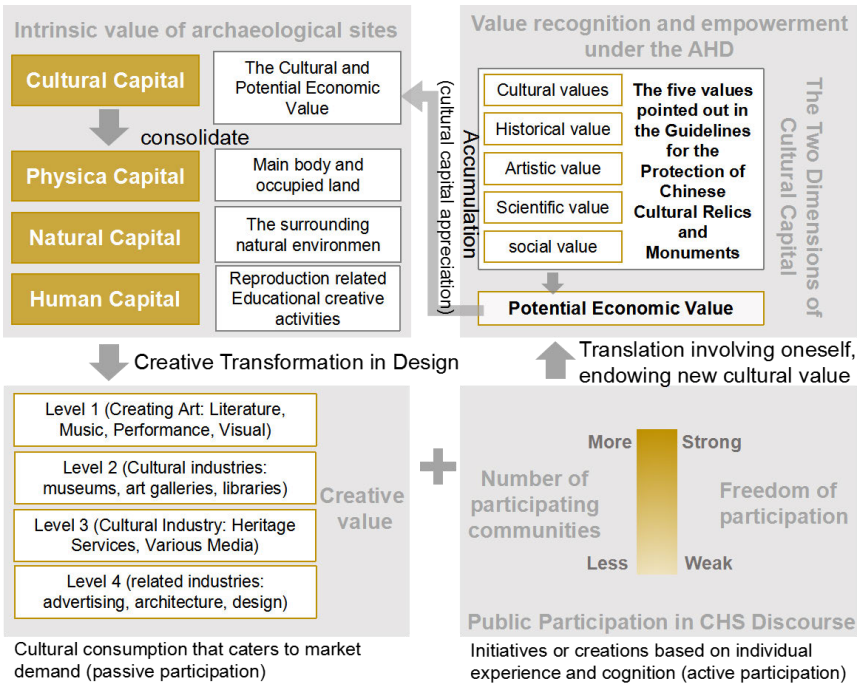

Figure 5. The Path of Cultural Value Reconstruction under Discourse

3.3 Creative transformation with critical color

During the construction process of the archaeological site park, designers need to clearly define their role in every value selection process. As the builders of the channel, the translation of historical and cultural information is completed through every immersive experience of public participation. The channel can take various forms, but its purpose is to allow the public to enter the site that carries historical information for free retrieval. Through public participation in immersive translation, the dialogue with history is completed, awakening the public's thinking about the current way of life, and weaving history and reality.

This is not a simple process, it requires us to deeply and accurately grasp the cultural connotation of the site, uphold the spirit of criticism, and explore potential needs through creative transformation methods. Overlap and reconstruct the self-worth that potential needs can provide with the cultural value of the site, connecting history and the present. Creative transformation should have a color of daily criticism, which often requires a certain amount of time to be accepted by the public, requires time to precipitate, and its form may be unconventional, anti status quo, and needs to be reconstructed in public evaluation, discussion, and controversy. Its transmission of culture is not directly given, but needs to be digested in the form of dialogue. Only cultural cognition or identity reconstructed through personal experience can have strong resilience and vitality. The park is not the end of protection, but the shell of protection and the beginning of involvement.

4. Design for the public

This article takes the design practice of the "Daren Site" Park, a provincial-level cultural relic protection unit in Xi'an, Shaanxi Province, as a case study to respond to the current situation of insufficient construction of provincial and municipal level archaeological site parks in China. It tries to detach from the discourse framework of authoritative heritage as much as possible and focuses on discussing creative transformation design methods based on public experience.

4.1 Audiences of the city

The critical heritage discourse emphasizes public participation in heritage construction. So first of all, the audience should be analyzed at the city level, and the archaeological site parks should be examined in the whole urban group structure to meet the needs of future urban development. Accurately grasp the nature of heritage parks in terms of urban audience and functional structure.

At the urban level, different sites have different audience compositions due to differences in their level and location. According to the classification of sites by country, province, and city/county, the audience scope gradually decreases from the national scope to the city/county scope, and the main proportion of the audience shifts from tourists to surrounding residents. According to the different geographical relationships between the site and the city, the audience of urban type sites, suburban type sites, village type sites, and wilderness type sites (Chen Wenliang, 2010, p.9-10) are also differentiated. The first three types of sites mainly used by urban residents or villagers, while wilderness type sites mainly used by tourists.

Therefore, in the planning of the archaeological site park, it is necessary to combine the actual situation, fully consider the differences in objects, flexibly respond, and formulate different design strategies. In the planning of the Daren Site Park, in the face of the current situation of abandoned site and the huge contrast with the rapid construction of the surrounding area (Figure 6), a temporary urban park implementation plan is adopted. On the premise of fully protecting underground sites, supporting block development and matching urban needs,give consideration to both urban ecological and life, and reserving maximum potential for future archaeological excavations.

4.2 Audiences of the community

Figure 6. Current situation of the site and surrounding areas

At the site level, there may be multiple communities distributed around the site, and the population composition of different communities varies. It is necessary to effectively combine the needs of the population to accurately locate. In the design process, the protection of the site should be taken as the premise, and the relevant content of the site display should be combined with differentiated community needs. Through appropriate travel route design and functional settings, organization and arrangement should be carried out to enrich the content of the archaeological site parks.

In the planning of the Daren Site Park, the core ecological status in the CID urban new area is first clarified through environmental and future potential analysis. Combined with the needs of the surrounding community audience, select appropriate cultural images, and connect the specific needs such as leisure, rehabilitation, education, rest, and gaming for residents, patients, students, and healthcare workers, with cultural images that can fully reflect the culture of the site, such as poetry, books, rituals, and music. Implant historical and cultural nodes that reflect the characteristics of the site and vitality sports nodes that adapt to modern life into the park, and construct a modern urban healthy living green space linked by historical civilization (Figure 7).

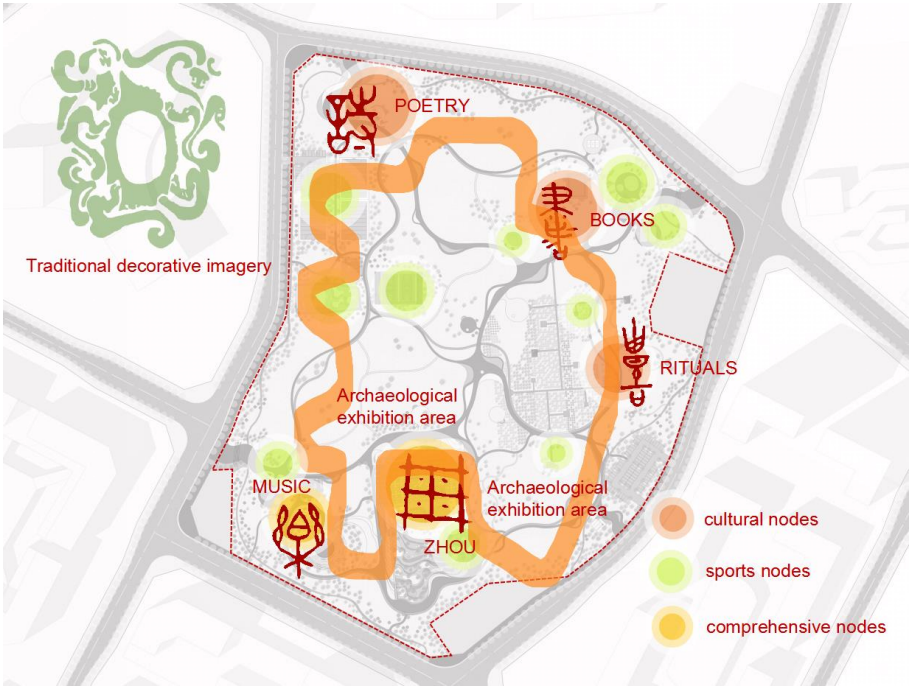

Figure 7. The planning structure diagram of the archaeological site park

4.3 Protection of archaeological sites

Sites protection is a prerequisite for the construction of archaeological site parks. Sites are carriers of historical and cultural heritage. Only by fully ensuring the safety of sites can we continuously explore their cultural value from history and effectively maintain intergenerational fairness.

In the planning of Daren Site Park, in the face of the ash pit, the tombs type site and the shallow burial depth of the site, the planning conforms to the original terrain, and the existing plants in the park are not cleaned on a large scale. Instead, according to the distribution of the site, differentiated disinfection and sterilization, retention, and transplanting are carried out by stages. Shallow root plants are used for greening near the site, and the park road planning adopts a comprehensive strategy of avoiding the site (Figure 8) to minimize surface disturbance and ensure the safety of the site.

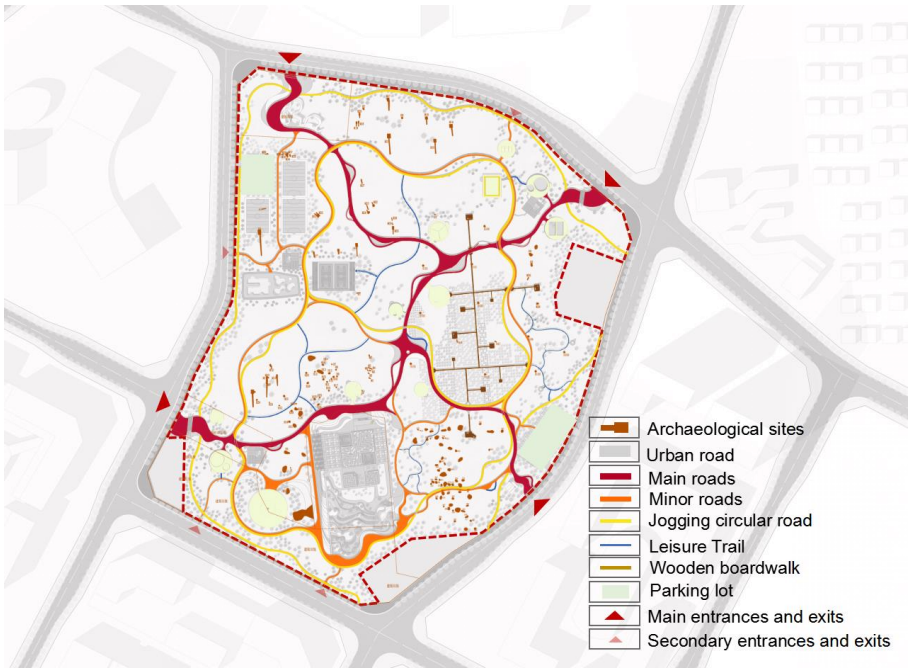

Figure 8.The site park road planning map

4.4 The Passageway of History

The design inside the park is directly related to the public's usage experience. As the creators of historical passages, designers should fully protect the right of the public to participate in the planning and design of archaeological site parks. These rights include the right to know about heritage, the right to approach heritage, the right to understand and interpret heritage, the right to use heritage, and the right to choose their own future lifestyle based on heritage. The protection of power is not only a bottom-up construction of heritage discourse, but also an effective measure to prevent the dissolution of heritage value in cultural consumption. Under the critical heritage discourse, designers should uphold a public oriented attitude and serve the realization of public participation rights.

The focus of the design is on how to enable the public to fully exert their cognitive initiative and complete dialogue with history during the visit of the archaeological site park. The following will explain from four aspects.

4.1.1 Memory in the site

The folk memories in the excavation site of the Pit Square are responded to in the design, interweaving and juxtaposing folk memories with history. Folk memory is a profile of history

and also a dimension of historical channels. The design retains the original deep pit of the site and transforms it into a unique garden at the bottom of the pit, which not only confirms the original brick burning production activities of the villagers, but also serves as a game park for cultural experience in modern cities (Figure 9).

4.4.2 Viewing during Travel: Mirror Maze and Array Ladder

Turn landscape sketches into an interactive device, turn static ornamental into dynamic travel,

Figure 9. The pit Garden

and complete the reading of history through the public immersion experience. The mirror maze and array ladder in the Daren Site Park combine the content of "Zhou Li" culture with the interaction of "technology" to organize exhibits and activities, guide the public to collect historical fragments in dynamic streamlines, and gradually restore the imagination to gradually restore the restoration Historical appearance. (Figure 10)

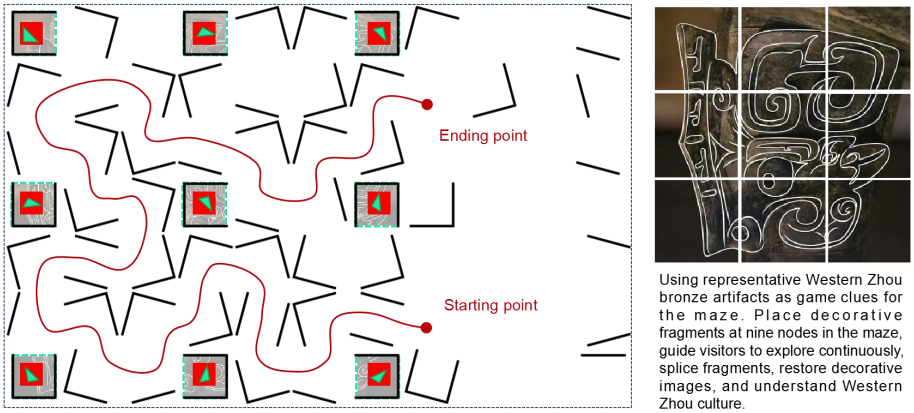

Figure 10-1. The Plane of Huan Yuan

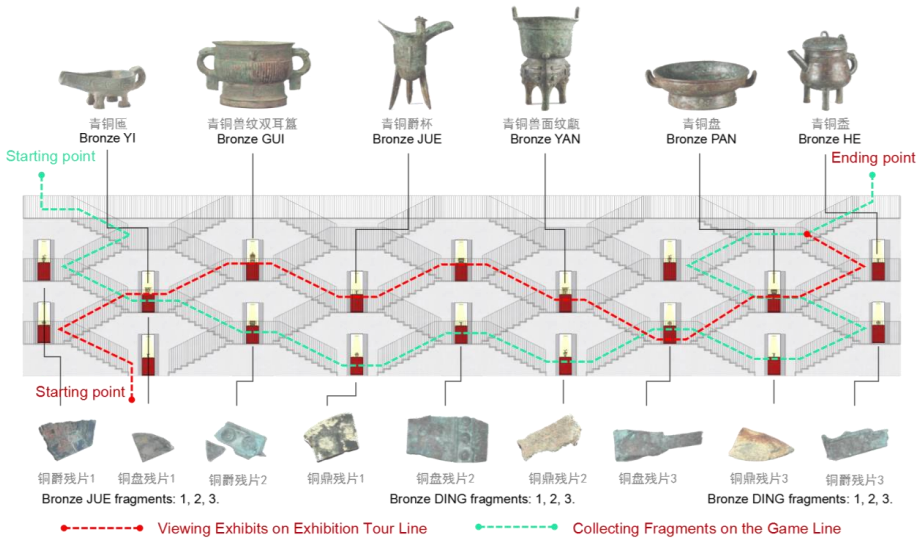

Figure 10-2. The facade of Huan Zhen

4.4.3 Education in the game: Archaeological Sandpit

The response of archaeological site parks to "archaeology" should also be open, the related construction of public archeology should be encouraged. Understanding archaeological activities also helps to deepen understanding of the site and is an important dimension of public participation. Transforming a children's playground sand pit with a single gaming nature into an archaeological sand pit with educational significance in the design, and realizing children's right to participate in heritage in the game.

4.4.4 Guidance in Dialogue: Logo Design

The identification system is an important part of the construction of archaeological site parks, and textual content explanations also need to be designed. History is not a straightforward statement of "I tell you, please listen to me", but rather a narrative of "feel it, experience it". The signage design in the Daren Site Park is presented in a simple form (Figure 11), guiding the public to pay attention to the text content. The text on the signage is presented in the form of dialogue, such as "Take a look!", "Experience it!", "What do you think?", etc.

Figure 11. Signboard in the park

5. Summary

At present, the methods of cultural experience in archaeological site parks are still mostly traditional, and tourists are mostly passively receiving information, which does not consider the possibility of treating tourists as creators and participants. Therefore, tourists should be provided with opportunities to actively participate in the construction and interpretation of cultural content. The name "park" is only the beginning of site protection, and the interior of the park is the place that needs more design.

With the development of cultural relics protection, when archaeological site parks are everywhere, they will eventually become a place for our daily lives. We must interact with the landscape we are in every day and bear its shaping on our body and mind in real-time. Arousing people's reflection on contemporary life is one of the important roles of artistic contemporaneity, enabling each individual's innocence to resist the alienation of grand narratives. (Duan Jianqiang， 2024, p.20) To record the significance of archaeological sites in your life in an individual way is to participate in the contemporary "regeneration" of archaeological sites. The "revitalization" of archaeological sites is the contemporary interpretation of the cultural significance of the sites, and the future of the construction of archaeological site parks is hindered and long. The above are some thoughts of the author on the construction practice of archaeological site parks, which need to be further practiced in future practice. We hope to provide reference and thinking for relevant research on the construction of archaeological site parks.

Are metropolitan-oriented major infrastructure networks adequate and aligned with growing environmental pressures and raising calls for just and sustainable urban regions? Planning activities are increasingly destabilised when not ontologically questioned by the environmental turmoil and its different facets. Large-scale infrastructure systems have long been framed as resource-efficient socio-technical arrangements of service provision. However, their material and energy footprint and the dynamics of growth of resource-intensive practices they have often supported have largely been neglected. Can the LTS (Large Technical Systems)-urbanism and the thermo-industrial nexus it encapsulates be somewhat overcome? Is one such transformation a shared concern or a new form of geographical divide? Recent examples like the road projects assessment in Wales, where a vast number of infrastructure projects have been halted or abandoned due to their contribution to environmental degradations, shed light on possible new infrastructural trajectories, hence transforming planning practices in the face of climate pressures.

At a larger level, the activity of planning of/for urban/regional infrastructures thus seems to be torn between potentially incompatible transitions and objectives, i.e. the quest for sufficiency and resource-sensitive approaches on the one hand and continuously growing, supply-driven, material-intensive and carbon-heavy infrastructural developments on the other one. There is a vivid need to equip reflections on what ecological networks and a redistributive sufficiency-oriented ecological planning of infrastructures can be, which coalesces environmental and justice concerns and considers the level of material and social interdependences between territories.

Concomitantly to these raising issues, and possibly in contradiction with them, continuous advances in digital technologies and Artificial Intelligence (AI) have had enormous impacts on the evolution of socio-spatial systems and on planning practices. How is such a transformation shifting the type of problems addressed by planning (only those subject to digitalisation and quantification) and the type of urban order that it entails? This questions how digitalisation may create the new broad geographical and social divide and pushes to challenge the so-called promise of smart infrastructural systems that are supposed to improve resource efficiency, to

grasp their variegated contributions to tackle or even to contribute to environmental and social transformations.

This track welcomes critical contributions on substantive and processual issues and socio-technical approaches, such as (but not limited to):

- Ecological expertise in planning practices (presence, implications)
- Sufficiency-oriented infrastructure networks
- Urban justice, urban sustainability, and urban networks
- Planning support methods, technologies, systems
- Conflicts around digital technologies in urban planning
- Articulation between digital and ecological perspectives in planning
- Alternative forms of planning for socio-technical systems and their governance (grass-rooted, demand-oriented, resource-sensitive, etc.)
- Infrastructural violence, inequalities of access to networks and planning
- Big geospatial data for planning (open, social, volunteered, sensors, infrastructures, platforms)
- Urban and regional models (multi-dimensional representations, digital twins, Virtual/Augmented reality, simulation, impact assessment, forecasting, what-if, etc.)
- Artificial intelligence in spatial planning and governance
- Innovative technologies for smart urban and territorial systems (in transport, energy, nature, agriculture, tourism, housing, industry, etc.)
- Diffusion of digital technologies in spatial planning and governance research, education, and practice
- Social appropriation of digital technologies in urban and regional systems.

Digital Modelling and Analysis of the Network Structure for Residential Historic Areas in China

Abstract
Residential historic areas in China are crucial for urban fabric and cultural heritage. Given the complexity and dynamic nature of these areas, the conservation and renewal efforts demand precise spatial interpretation and effective methodological approaches. Under the hierarchical framework of typo-morphology, the network structure in discrete geometry is used to recognise the spatial pattern. Then a digital model is constructed, which calculates quantitative morphological indicators and clusters elements. This model enables real-time adjustments and feedback of the morphology and has been packaged as a software application. This study advances the scientific rigour and efficiency of the planning process and promotes it from 'the prediction based on human experience' to 'the precise evaluation based on data analysis'.

Residential Historic Areas; Urban morphology; Network Structures; Digital analysis; Planning strategies

1. Introduction

1.1 Background

Many cities in China have long histories, and as a result, a large number of residential historic areas with different situations have been formed. Residential historic areas (RHAs) in this study mainly refer to a complete block with relatively old age, a certain scale, residential as the main function, and retaining the traditional Chinese low-rise residential and courtyard model (Pang et al. 2023). These historic areas are not only important components of the urban space but also important carriers of traditional culture in the urban area. As the most complex but necessary object in urban renewal, RHAs' conservation and renewal have become increasingly important issues, hence it is crucial to investigate digital modelling approaches and design strategies.

In the current urbanization process in China, planning and design work for urban renewal has already broken away from the simple mode of large-scale demolition and construction with the gradual popularization of the people-oriented design concept. The corresponding work mode has being shifted towards a more refined and focused direction on the traditional urban spatial pattern. In this process, qualitative analysis and decision-making methods make it difficult to form accurate value judgments when facing the complex built environment of RHAs. Therefore, it is necessary to systematically understand the overall spatial structure of historic areas and the characteristics of each micro unit, and based on this, the corresponding design strategies for each spatial element should be developed, so that differentiated conservation and renewal actions can be carried out.

However, residential historic areas in China have often undergone a long historical evolution. The street networks in historical areas have been constantly destroyed and redeveloped due to residents' disorderly construction of their own houses. The scope of each household's residential plot has also been repeatedly redefined with changes in property rights. Because of this historical process, RHAs often have an exceptionally complex structure composed of various spatial patterns. In addition, RHAs are not static objects, but dynamic material carriers that constantly change and develop along with government protection planning and residents'

independent updates. During the regeneration process, minor updates or constructions from a single sector, such as resident's properties or government's policies, may affect the spatial structure of the entire block. These changes have brought about a lot of repetitive analysis and redesign work.

Based on the above issues, we see that the conservation and renewal of RHAs in China should be guided by a detailed understanding of complex spatial structures. This is a process that takes micro units as the operating object, integrates multiple information and analytical results, and repeatedly formulates reasonable design strategies to achieve progressive work. On the one hand, a clear and accurate interpretive pattern is required. This pattern can accurately provide feedbacks to designer and planners with the overall spatial structure of RHAs and the detailed characteristics of each spatial unit in the complex environment. On the other hand, a more efficient and accurate system is also needed to provide the morphological analysis results of spatial units in real time to assist designers in making design decisions.

Therefore, in order to support and enhance the planning and design work of complex and dynamic environments in historic areas, this study intends to expand the existing form interpretion theory and construct a network structure analysis model that is in line with the current spatial relationship of RHAs in China. Subsequently, based on this network structure, the digital modelling of RHAs was achieved through autonomous programming technology, including the corresponding morphological analysis. At the same time, the methodology proposed by this research should be combined with the progressive and diachronic characteristics of the conservation and renewal of RHAs in practice. The real-time morphological analysis results can be provided during the dynamic evolution of the spatial environment, which can guide refined design decision-making work.

1.2 Literature review

1.2.1 Morphological interpretation research of historic areas

The morphological analysis of RHAs is based on the description and interpretation of its material space. After a long period of systematic research on urban morphology and its evolution, European scholars have gradually formed the Historico-geographical School represented by Conzen (Conzen 1960) and the Process Typological School represented by Muratori and Caniggia (Caniggia & Maffei 2001). The two schools of thought mutually confirm and form a complete system of typo-morphology. Subsequent scholars have continuously improved the interpretive patterns of typo-morphology, such as Kropf's multi-level theory, which integrates the views of the two schools of thought (Kropf 2014). Faced with the complex spatial environmental characteristics of RHAs in China, many researchers have begun to apply various interpretive methods involved in typo-morphology to the study of RHAs. Ji and Ding et al. applied the research method based on Nori maps to the old city of Nanjing and verified the similarities and differences between traditional urban space and modern urban space (Ji & Ding 2021). Dong et al.'s research focuses more on the combination of methods and practice. By drawing typological maps of different eras in the conversation and renewal of the Xiaoxihu Historical and Cultural Block, the evolution patterns of the block's spatial structure have been identified. Based on this, the targeted design of each property rights plot can be conducted

(Dong et al. 2019). Xia et al.'s research is more comprehensive. They analysed the typological characteristics of the block at multiple scales, from street texture to courtyard space, and then to detailed craftsmanship, in the conversation and renewal of the Kaiyuan Temple area in the old city of Bin County, Shaanxi Province. These characteristics were used as the main basis for the design of the block restoration (Xia et al. 2015). The current research demonstrates the feasibility and effectiveness of applying an interpretive system from the perspective of typo-morphology to RHAs. This method can incorporate the complex and disordered spatial environment of RHAs into a relatively clear interpretive framework. However, current research has not been able to fully and effectively adapt to the large number of complex special situations in RHAs, and most methods mainly rely on manual work to complete a large amount of information sorting and graphic drawing. This process requires more effective methods to assist.

1.2.2 Technical Analysis Methods for Historic Areas

The interpretation and analysis of the morphology of RHAs is a complex process. Digital models can make up for the limitations of traditional statistics such as low reliability and slow computation in large-scale data processing, and suggest strategies for solving complex problems in morphological research. Ding and Ma interpreted the layout characteristics of traditional residential buildings in Anhui, Jiangsu, and Zhejiang provinces through spatial syntax, and conducted data clustering analysis using SPSS to explore the different usage patterns reflected by different residential spatial structures (Ding&Ma 2020). Dabbour used Depthmap to analyse the connectivity and visibility indicators of pedestrian movement in the old urban area of Damascus, the morphological characteristics of the urban road network in terms of accessibility have been quantitatively described (Dabbour 2021). Huang et al.'s research used 23 indicators from multiple dimensions such as "physical space vitality", "network space vitality", and "emotional level" to define the vitality characteristics of historic areas and evaluated them using the random forest algorithm. The corresponding methods were written in Python. (Huang et al. 2022). Wang et al. introduced deep learning methods in the study of village morphology and used algorithms written in Mathematica to represent images of over 6000 traditional villages in binary, thereby converting their morphological features into feature vectors. Finally, cluster analysis was performed on the feature vectors to reveal the type patterns of traditional village spaces (Wang et al. 2023). Cai et al. proposed a hybrid data-driven approach to support urban morphological quantification and multi-dimensional similarity analysis, using high-dimensional feature vectors (HDFV) extracted by a deep convolutional neural network (Cai et al. 2021). It can be said that whether based on existing analysis platforms or through programming to build corresponding method systems, digital methods have demonstrated accuracy and efficiency that manual statistical and analytical methods cannot achieve. In the early research process of conservation and renewal of historic areas, it has become a mature method to select appropriate digital technology means to achieve efficient and accurate rapid analysis of problems.

2. Construction of network structure of residential historic areas in China

2.1 General hierarchical structure of the residential historic areas

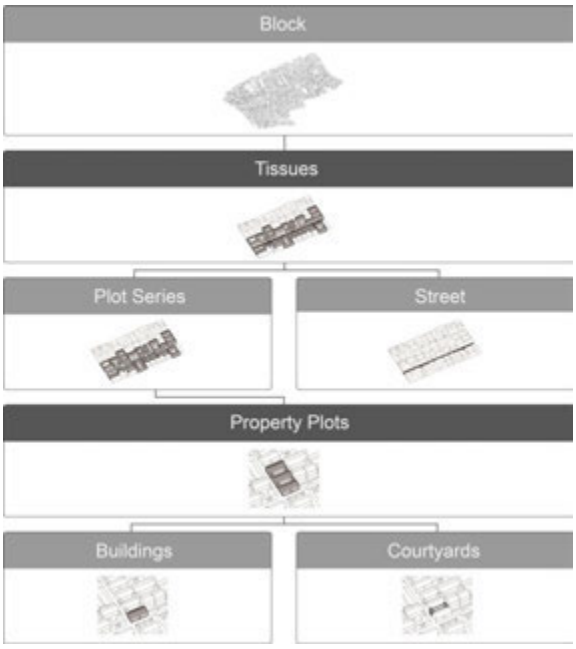

Figure 1. The hierarchical structure of components in residential historic areas in China

The description and analysis of the complex built environment of RHAs is the start point of design work. The scale hierarchy structure in the field of typo-morphology provides a clear descriptive framework for the spatial environment of RHAs, which can connect scattered and multi-class spatial elements into a whole. Based on the combination hierarchy theory of Kropf (Kropf 2014), the interpretive pattern in this study employs the hierarchical structure of 'block-tissues-street and plots series-property plots-buildings and courtyards' to recognize and identify the spatial structure of RHAs (Figure 1). The entire block is often connected by a complete road network, and the plots which are divided based on the evolution of property rights are the basic living units of residents. Therefore, the "simple tissue" composed of each road and its two sides connected in a fishbone shape becomes the basic element of the neighbourhood. Within the plot, traditional Chinese housing often presents a multi-courtyard pattern, with entrances and exits mainly located on the short side of the plot. Therefore, buildings and courtyards become the most basic spatial units. In this hierarchical structure, roads, plots, buildings and courtyards are the three most closely related levels to design, and their spatial characteristics will become the direct focus of this study.

2.2 Spatial complexity of the residential historic areas

Typo-morphology originated in Europe, where many cities often have relatively regular spatial patterns and the boundaries of plots are completely occupied by building facades (Figure 2). So the spatial status can be accurately reflected by a regular hierarchical structure. However, the

RHAs in China are different. On the one hand, due to the limitations of traditional building materials, low-rise brick and wood structure houses often cannot maintain a constant state for a long time. Therefore, most of the residential buildings in the blocks have undergone multiple demolition and reconstruction during their use (Pezzetti 2019). Each reconstruction will make corresponding adjustments based on the property rights and site conditions at that time. This process will not only change the spatial pattern inside the plot but also affect the overall road network spatial structure of the block. On the other hand, in just the past few decades, Chinese residential property rights policy has undergone multiple adjustments, resulting in plots being reclassified multiple times with changes in property rights (Dong et al. 2019). Its morphology has already broken the 'one-way entry, multiple courtyards' pattern which formed during the initial construction (Figure 3). The access and use methods of many plots are far from their actual layout patterns. The above two aspects together contribute to the spatial complexity of RHAs, which contains various special situations that cannot be directly identified using existing hierarchical structure theory.

Figure 2. The spatial patterns of three European cities: Florence (left), Barcelona (middle) and Paris (right).

Based on the spatial relationship between roads, plots, buildings, and courtyards, four special situations of spatial structure within RHAs can be identified: interlocking, overlapping, co-inflection, and a composite condition termed the superposition state integrates these three configurations (Figure 4). Interlocking means that the same plot is connected to multiple roads and belongs to multiple tissues. Co-inflection is reflected at a more subtle level, that is, the same building or the same courtyard belongs to different plots due to the continuous division of property rights (Kropf 2014). Overlapping is relatively common in China's RHAs, that is, the plot is not directly adjacent to any road and must be reached through surrounding plots. (Song et al. 2024). The above three types of special situations often do not appear independently, but often co-occur in the same block or even the same plot. This also leads to the need to establish a more refined spatial relationship description system based on the hierarchical structure so that the morphological characteristics of each subtle element can be accurately reflected.

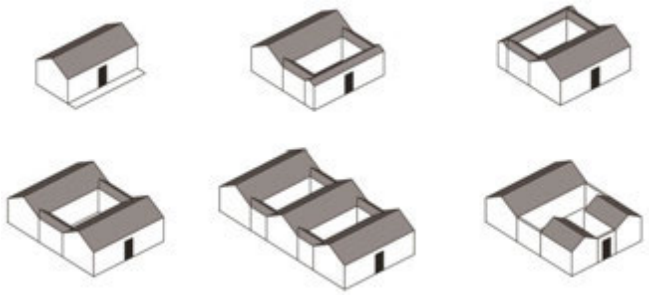

Figure 3. Typical layouts of traditional Chinese residential building groups including buildings and courtyards

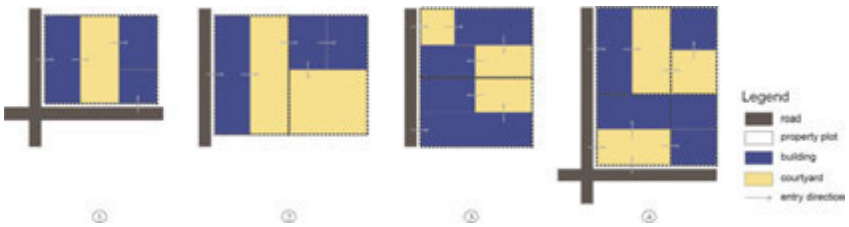

Figure 4. Illustration of 4 special situations of spatial structure within residential historic areas: (1) Interlocking, (2) Overlapping, (3) Co-inflection, (4) The superposition state

2.3 Access Network Structure of Residential Historic Areas

RHAs are generally based on a multi-scale hierarchical structure and contain a large number of complex situations. Faced with this characteristic, this study attempts to introduce graph theory models from the field of discrete geometry into morphological analysis. Under this model, the spatial elements and their connection relationships at multiple levels in RHAs will be abstracted into a network structure diagram composed of 'points' and 'lines'. Multiple quantitative indicators in spatial syntax theory are used to analyse the position of each 'point' (i.e., each spatial element) in the overall network, to clarify the relationship between spatial elements and the overall neighbourhood, as well as the interrelationships between spatial elements.

Firstly, in the road hierarchy, each road is abstracted as a 'point' in graph theory, and the connection between roads is abstracted as the 'line' (Figure 5). The quantitative indicators of road morphology are measured by three values: depth value, connection value, and the proportion of connections with low-depth roads. The depth value refers to the minimum number of spatial conversions required for this road to reach the main roads outside the block. The depth value of the main roads outside the block is defined as 0, and the other roads are calculated progressively in sequence. The connection value refers to the number of other roads connected to this road, which reflects the connecting role that a certain road plays in the entire road network. The proportion of connections with low-depth roads reflects the degree of

commonality of the road relative to other surrounding roads. The calculation method is as follows: the number of roads connected to a certain road is A, the number of roads with lower depth values than this one among these roads is B, and the proportion of low depth value connections is B/A. The above three values can accurately define the position of any road in the road network, they can fully reflect the public and connectivity of a road.

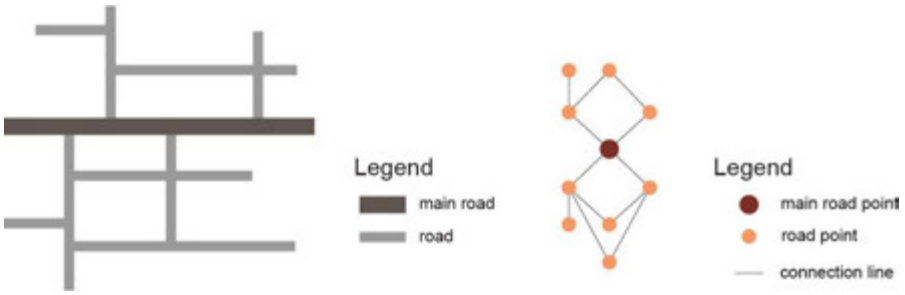

Figure 5. An example of extracting access network structure (right) based on a road-wise morphology instance (left)

In addition, in the plot hierarchy, the plots are abstracted as another set of 'point line' systems attached to the road network. Among them, 'points' represent various plots, and 'lines' represent the connection between plots and roads, as well as the connection between plots (Figure 6). The quantitative indicators of the plot's morphology are measured through external depth values, external connectivity values, internal depth values, and internal connectivity values. The external depth value and external connection value refer to the depth value and connection value of the most public road that the plot can be directly accessed. These two values are derived from the road network and reflect the accessibility and convenience of reaching the plot through the road network. The internal depth value is the minimum number of spatial conversions to reach the plot from the road and reflects the degree of overlap of the plot. In this case, the road is defined as the start point with a depth value of 0. The internal connection value refers to the number of paths that can directly enter the plot, including entering from surrounding roads and surrounding plots. This value is a visual representation of the tightness of the connection between the plot and surrounding spatial elements. The above four values collectively reflect the position of a plot in the street network (i.e. the higher level) and the plot sequence (i.e. this level).

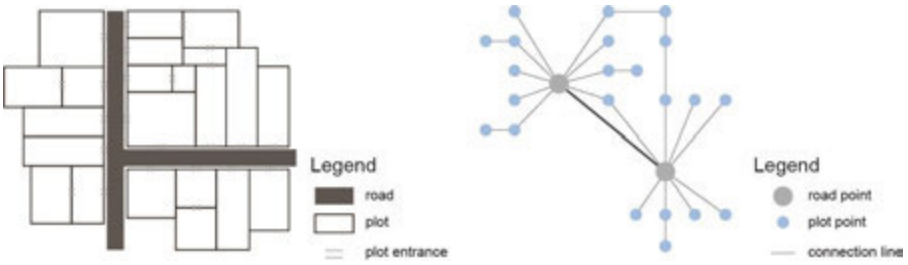

Figure 6. An example of extracting access network structure (right) based on a plot-wise morphology instance (left)

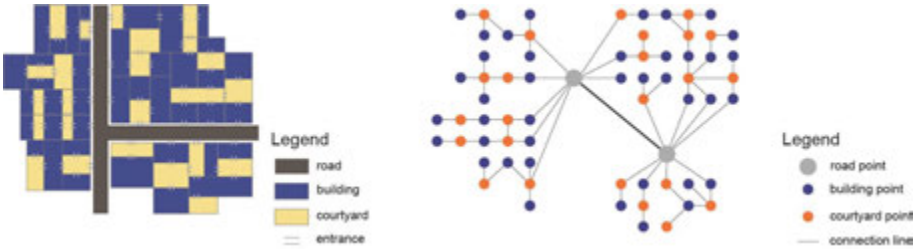

Figure 7. An example of extracting access network structure (right) with a focus on building-courtyard relationship from a morphology instance (left)

Finally, we focus on the hierarchy of buildings and courtyards. Due to the existence of various complex and special situations in RHAs, the access relationship between buildings and courtyards is significantly different from that of property plots. The division of property plots often completely breaks the spatial form of courtyards. Therefore, in order to conduct in-depth research on the position and interrelationships of each building and even each courtyard in the entire block, we need to build an independent 'point-line' network system outside of the property plots. The 'point-line' network system of buildings and courtyards is also attached to the road network. Buildings and courtyards are represented by different 'points', and 'lines' represent the connection relationship between buildings and courtyards and their connection relationship with roads (Figure 7). The quantitative indicators of the form of buildings and courtyards are also measured through external depth values, external connection values, internal depth values, and internal connection values. The calculation method for external depth values and external connection values is the same as the calculation method for plots. The internal depth value is also the minimum number of space transformations to reach the building or courtyard with the road as the starting point of the 0 depth value. The internal connection value refers to the number of paths that can directly reach the building or courtyard, including entering from surrounding roads and from adjacent buildings or courtyards. This value reflects the degree of tightness between the building or courtyard and the surrounding spatial elements. The above four values can also be used to measure the position of the building or courtyard, the most basic spatial element, in the overall network.

After the above process, we have preliminarily constructed an interpretation, representation and evaluation system based on a multi-scale hierarchical structure as the basic framework. In this system, the network structure diagrams have been used to define the connection relationships between spatial elements, the public and connectivity of spatial elements are accurately measured in the network through quantitative indicators. This system can accurately describe the complex spatial conditions of RHAs, and has a clear logical framework and quantifiable measurement methods, making it very suitable for simulation and reproduction through program algorithms.

3. Digital analytical modelling methods and their applications

3.1 Digital analytical model based on the hierarchical structure

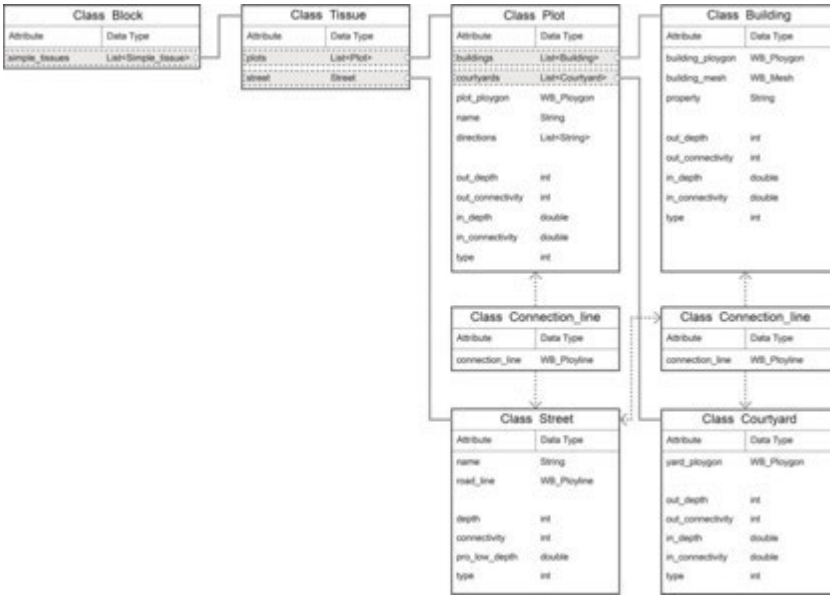

Figure 8. The structure of the digital model

Based on this multi-scale hierarchical network structure, this study constructed a corresponding digital analytical model through Java programming, allowing real-time RHA morphological structure analysis and interactive user interfaces. This model takes the basic class and object structures in the Java language as the main underlying logic, and constructs different classes for spatial elements (i.e., 'points' in the network structure diagram) and connection relationships (i.e., 'lines' in the network structure diagram) at multiple levels. At each level, information on all spatial elements is stored through a dataset containing all objects of that class. The quantitative feature values of each spatial element, the spatial elements of the next level which are contained within them, and their related connection lines are all included in the attributes of each object (Figure 8). At the same time, the various datasets in this digital model are not fixed entities, and the attributes of objects of each class are interconnected. Various datasets can also

be added or reduced at any time. These settings provide an algorithmic basis for the real-time completion of morphological analysis in the progressive conservation and renewal process of RHAs.

In order to have quick feedbacks of the morphological analysis for spatial elements at various levels, we translated the quantifiable feature values and the corresponding calculations from the network structure into mathematical or geometric algorithms, and then we implemented those in our interactive digital analytical model. Whenever the dataset of objects at each level is updated, the program can call the corresponding algorithm to recalculate the quantified values linked in the attributes of each object, thereby the temporal morphological analysis work in the RHAs progressive change process can be completed.

However, the complex quantitative indicators are still not intuitive enough and are difficult to directly guide the design. Hence the clustering algorithms have been introduced into the analysis framework of the program. This study incorporates the K-Means clustering algorithm into the digital model. After each update of the morphological quantification values, spatial elements at each level will be clustered based on the quantification values, the commonality and connectivity of spatial elements in the overall network can be reflected by clear type characteristics. Based on such type characteristics, the planning and design strategies can be referenced from similar cases. It should be noted that the weights of various quantitative indicators of spatial elements in the clustering process are adjustable to match the diverse needs. Users can obtain biased clustering results according to design needs to develop more targeted design strategies.

3.2 Add a front-end interface to form an analytical technology platform

After the construction of the digital model, it is necessary to build a matching front-end interface based on the designer's real-time need to obtain corresponding analysis results according to the updated site status or design adjustments in actual work. The front-end interface is a path for human-computer interaction with digital models. It is mainly used by designers and should be able to reasonably collect users' adjustments to multi-level spatial structures. Within the digital model, this interface should be linked to the backend data structure and algorithms. On the one hand, it should be able to visualize the necessary information in the digital model in real time. On the other hand, it needs to provide real-time feedback to the user's operations in the digital model and update the datasets at all levels.

This interface is based on the overall map of the block, which can visually display the spatial elements on multiple levels within the block, and indicate their type characteristics with colours. It can also display the network structure of points and lines between various spatial elements, allowing users to intuitively identify the entry relationship of the entire block. On the right side of the interface is the data display bar, which can display the overall form analysis results of the block in real-time. This interface has a detailed information query function. Users can click on any spatial element, and its detailed morphological information can be displayed in the data bar on the right (Figure 9). In order to meet the needs of users to obtain multivariate analysis results, the interface also has multiple display modes. Users can view separate analysis maps of spatial

elements at different levels at any time as needed and can adjust the view to three-dimensional for easier observation (Figure 10).

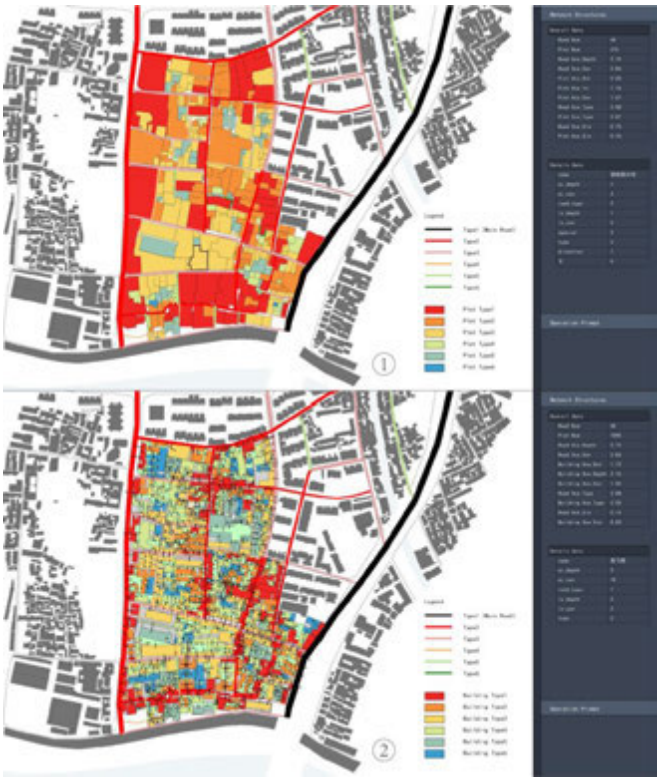

Figure 9. The analysis map and information bar in the user interface, where users can view detailed information of a certain plot (top) or detailed information of a certain building (bottom)

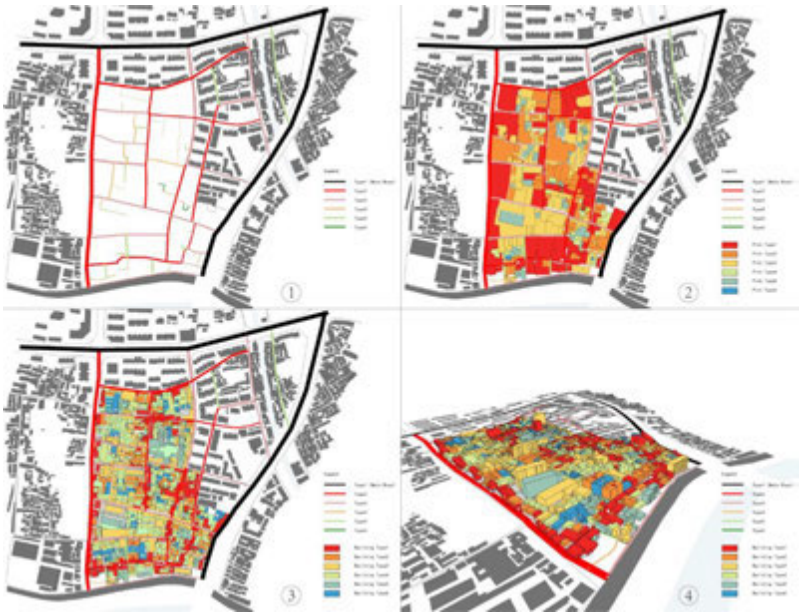

Figure 10. Multiple display modes for analysis map in the user interface, including analysis map of roads (top-left), analysis map of plots (top-right), analysis map of buildings (bottom-left) and 3D analysis map of the buildings (bottom-right)

The diachronic storage, recording, updating, and reanalysis functions are the core requirements in the conservation and renewal of RHAs, and they are also the core functions of our digital model. In the front-end interface, the operation panel is located on the left side of the interface, and users can directly modify spatial relationships at multiple levels on the block map through simple operations (Figure 11). One main mode of operation is to adjust the spatial elements themselves, including adding or removing roads, redefining plots, demolishing buildings, etc. Any operation will directly change the dataset of spatial elements. Another operation mode is to adjust the connection relationship between various spatial elements, users can add or subtract the connection lines between each element at any time to change the network structure of the block (Figure 12). Any modification is operated by the user within the interface based on the autonomous updates of residents in the neighbourhood or the active design of the designer. The digital model can provide new analysis results in real-time based on any modification, thereby providing feedback in real-time during the dynamic and gradual change process of RHAs. At the same time, the model also has the function of information export and storage. Users can export any state of the block and the analysis results in that state in various forms during the adjustment process, including exporting JPG format images of the analysis overall map, exporting Excel lists of various spatial elements and their corresponding morphological analysis results, and exporting dxf files including block topographic maps and corresponding analysis result layers. Through this mechanism, users can store the status of each stage in the design

adjustment process and conduct comparative analysis to find better planning and design strategies.

Figure 11. The complete user interface of the digital analytical model

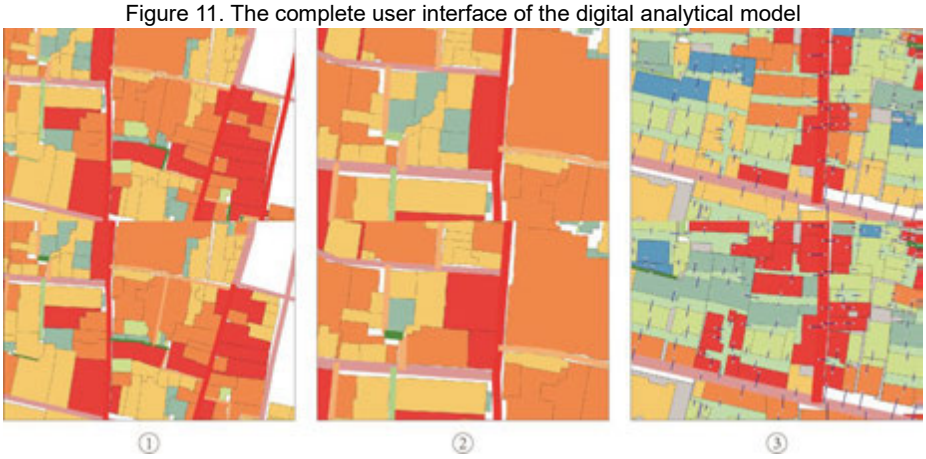

Figure 12. Users can operate data by adding or removing roads (left), redefining plots (middle), and adding or subtracting the connection lines (right) through the digital analytical model.

3.3 Application Trial and Feedback

In order to facilitate the usages for planning designers in practical work, this digital model is packaged into an exe running program through exe4j. Then the relevant files of the program and the running environment are combined into an installation package through Inno setup. This digital model has been developed into an analytical technology platform that can be installed on any computer. The study is based on the actual conservation and renewal work of multiple RHAs (including Xiaoxihu, Diaoyutai, and Hehuatang) in the southern area of Nanjing.

Multiple planning designers were invited to test the value and shortcomings of the analytical technology platform based on the actual workflow.

During the trial process, this analytical platform demonstrates the effectiveness of assisting the planning and design phase of the RHAs' conservation and renewal through digital methods. Users can intuitively obtain detailed morphological analysis results of each spatial element, which serve as the main basis for obtaining design strategies. Quantitative indicators and clear type characteristics are used to guide planning and design work. This technical path makes up for the ambiguity of manual judgment and enhances the scientific nature of the design results. At the same time, the analytical platform has greatly reduced the repetitive analysis work caused by complex and dynamic spatial structures, which effectively improves work efficiency.

However, the designers involved in the trial also pointed out some limitations of the analytical platform. Firstly, in the conservation and renewal design process of RHAs, diachronicity is a very important concept. Although the current analytical platform takes into account the storage and export of analysis results at each stage, it does not form a historical operation path in the platform that can be rolled back, viewed and called at any time, so it cannot fully match the actual work needs. Meanwhile, current platforms can only provide morphological analysis of complex spatial environments from the perspective of network structure. In practical work, various constraints and problems should be considered in the conservation and renewal of historic areas. The platforms have not yet been able to overlay and analyse more information. Finally, this platform can essentially only complete morphological analysis work, it mainly targets the pre-design analysis and strategy acquisition stage. Therefore, the process from design strategy to actual design scheme generation still needs to be manually completed by designers, and technical methods have not yet penetrated the entire process from analysis to design.

4. Conclusion

In the field of planning and architecture, morphological design often relies on morphological analysis (Han 2013). Morphological analysis can reveal the objective laws of the spatial environment and provide early guidance for morphological design. This study applies data-driven techniques to the conservation and renewal of residential historic areas in China. A hierarchical network structure model is used to recognize the complex and dynamic multi-level spatial environment of the block, and accurate morphological analysis results are obtained in real-time to assist design decision-making. This research reflects the great potential of integrating digital methods in the planning and design process in complex spatial environments and involving multiple information, such as in RHAs in China. Digital methods can comprehensively analyse complex problems from a more quantitative and rational perspective, and provide accurate results in real-time. This research brings not only advancements in technical methods but also changes in working models. In this way, we can improve the planning process from 'the prediction based on human experience' to 'the precise evaluation based on data analysis'.

Abstract

The concept of “humanity-oriented transportation” primarily stems from the negative impacts of "car-oriented transportation," prompting a shift in thinking towards emphasizing a more humane approach to traffic planning to ensure public safety. This involves prioritizing pedestrian and bicycle traffic on roads, increasing pedestrian activity space, and reducing the impact of motor vehicles on road users. This prompted the present study to explore the utilization of Shepard density interpolation method to establish traffic density fields and to introduce topological optimization models to investigate how to reasonably reduce vehicular space within the acceptable range of overall service levels on urban roads, thereby releasing more space for pedestrian activities. By combining adaptive refinement strategy, this allows for more accurate estimation of traffic density, facilitating effective allocation of both vehicular and pedestrian spaces.

Keywords: Humanity-Oriented Transportation, Topology Optimization, Shepard interpolation, Adaptive Refinement Strategy

1. Introduction

The Athens Charter mentions that "transportation" plays a crucial role in connecting residence, work, and leisure. Since World War II, the rapid development of motorized vehicles, mainly cars, has occurred worldwide, starting with European cities, followed by the United States, and later by Asian cities. However, virtually all cities worldwide have been affected. With increased mobility and accessibility, users have multiplied, but so have traffic congestion, conflicts, and accidents between vehicles and users.

The efficiency and convenience brought by car-based transportation come with negative

consequences such as increased traffic conflicts, decreased quality of life, and ecological imbalances. European cities, first captivated by cars, began reflecting in the 1960s on how to break free from the grip of vehicle traffic and return to a humanity-oriented urban environment from a "car- oriented" urban model.

European cities recognize earnestly that "cities cannot continue to be dominated by vehicles. It is impossible and inappropriate for cities to accommodate unlimited traffic and activities by vehicles. People should find ways to reclaim cities, making them humanity-oriented again." Thus, initiatives like the "Vision Zero" were launched, aiming for zero fatalities in traffic accidents. So, some practical actions come out which includes:

(1) Car-Free Movements and Car-Free City Centers: The "International Car-Free Day" originated in France. On September 22, 1998, a group of French youths first chanted the slogan "In Town, Without My Car!" hoping to reclaim their cities from vehicles for a cleaner environment. This movement quickly gained attention and response from neighboring countries. By February 2000, the French-originated car-free day was integrated into the European Union's environmental policies. The first European Car-Free Day took place on September 22 of the same year with 760 European cities jointly organizing car-free day activities, marking a significant milestone. Furthermore, in addition to hosting car-free days in 1999, all participating cities actively identified car-free zones within their city centers as part of action plans to promote old city areas as pedestrian zones.

(2) Bicycle Culture: While pedestrian zones ensure that only a portion of the city remains unaffected by vehicles, the entire city still experiences significant daily transportation needs. Therefore, "bicycles" have once again become a mode of transportation for urban residents in advanced countries like Europe. In the Netherlands, known as the world's cycling country, 70% of urban streets have a speed limit of 30 kilometers per hour, making streets safer for cyclists and pedestrians alike[1].

The US media CNN once described Taiwan's traffic chaos as a "living hell" in its reports. For example, narrow roads filled with motorcycles and cars, obstructed by lampposts and transformer boxes, and storefronts crowded with plants or signs, forcing pedestrians to often walk on the roadway or shuttle between congested lanes and sometimes blocked sidewalks. Additionally, pedestrians must beware of numerous small motorcycles weaving through traffic. When crossing the street, caution is advised as many drivers do not respect pedestrians' right of way or traffic regulations [2].

Furthermore, in Taiwan, in the past five years, there have been over three million traffic accidents annually, resulting in nearly three thousand deaths each year, with over four hundred of them being pedestrian fatalities, accounting for 13% of the mortality rate. In the past decade, nearly fifteen thousand pedestrians have been injured in traffic accidents while walking, leading to long-term impacts on their lives and significant costs to families and society. According to statistics from 2022, those aged 65 and above account for 69% of pedestrian fatalities[3].

In light of this, the Taiwanese government is striving towards the ultimate goal of zero traffic accidents, gradually shifting from the concept of "vehicles" dominating road spaces to a mode of thinking where "humanity" take center stage in urban spaces and transportation systems, emphasizing the humanization of urban spaces and transportation systems and considering both the safety of the public and the environmental burden.

Defining "humanity-oriented transportation" as a system that is oriented towards people, pursuing a transportation system necessary for sustainable and better human life. In a narrow

sense, it can be defined as a transportation system primarily based on "human-powered" modes such as walking or cycling, which are low-pollution and environmentally friendly. However, in a broader sense, regardless of the development of motor vehicles or other mass transit vehicles, or the construction of roads, all should be oriented towards people, meaning they should align with the "values of sustainable and better human life," avoiding harm to people and hindering the ways people achieve a better life.

Its four main contents are:

(1) Maximizing the use of green transportation: Transitioning from past reliance on motor vehicles to prioritizing human-powered modes such as walking and cycling as the main "green transportation."

(2) Natural energy as the primary source of mobility: Transportation development in the new century should aim to achieve comprehensive goals such as health, safety, efficiency, environmental protection, and sustainability, considering the use of natural energy for energy consumption and mobility maintenance.

(3) Target system emphasizes humanization: Adjusting the functional structure of road systems, changing the configuration of road space, coordinating overall greening efforts, reducing the impact of through traffic, lowering the speed of traffic in the area, ensuring traffic safety, and increasing pedestrian activity space.

(4) Construction methods focus on localization and community: Designing an urban living space where residents can achieve various travel purposes by walking, which could potentially change the history of transportation development. Under this design concept, various transportation projects will no longer prioritize car travel but instead focus on walking, cycling, and public transportation. Mixed land use and pedestrian-oriented road systems will be developed based on the scale of community space [4,5].

Current efforts in Taiwan towards humanity-oriented transportation include the establishment of pedestrian lanes, the delineation of marked pedestrian paths, the installation of pedestrian-specific traffic lights and pedestrian refuge islands, the removal of motorcycles from sidewalks, and the reconfiguration of lanes [6,7]. Research directions mostly explore how to adjust vehicular spaces[6-12], seeming to lack rational studies on reducing vehicular spaces. Therefore, this study initiates a preliminary investigation into the rationality of reducing vehicular spaces.

2.Concept of Methodology

The inspiration for this study stems from combining topological optimization with Shepard interpolation method and adaptive refinement strategy, applied to the rigidity assessment of material structures [13,14]. The aim is to minimize material usage while maintaining a certain level of rigidity strength to support loads. Extending this argument to the allocation of traffic lanes, the goal is to reduce the maximum amount of road space while still maintaining an acceptable overall service level.

2.1. Definition and Classification of Traffic Service Levels

In Taiwan, the primary purpose of analyzing urban arterial roads is to estimate average travel speeds to assess the overall traffic function service level of an arterial road. Another purpose is

to assess the traffic operation at intersections that affect the continuity of traffic flow on arterial roads, to help determine which sections need improvement or how to improve them. The division standards for transportation service levels (Table 1) are analyzed.

Table 1. The division standards for urban and suburban arterial road service levels[15].

Level of Service	Average Speed /Speed-limit ($\bar{V}/V_L$)
A	$\bar{V}/V_L \geq 0.8$
B	$0.6 \leq \bar{V}/V_L < 0.8$
C	$0.5 \leq \bar{V}/V_L < 0.6$
D	$0.4 \leq \bar{V}/V_L < 0.5$
E	$0.2 \leq \bar{V}/V_L < 0.4$
F	$\bar{V}/V_L < 0.2$

Here, we define the overall service level and its acceptable range.

(1) Overall service level: Consideration of the individual service levels of each road (main roads, secondary roads, local highways) within the study area (urban areas).

(2) Acceptable range of overall service level: Within the study area, allocation of proportions between service levels based on different road hierarchies (main roads, secondary roads, local highways).

2.2. Construction of Traffic Density Field

2.2.1. Defining the Design Variable Points:

In Fig 1, assume we have n design variable points $x_i = (X_i, Y_i)$, where X_i, Y_i define the ith point location in a Cartesian coordinate system, with the volume values $q_i (i = 1,2, \dots, n)$.

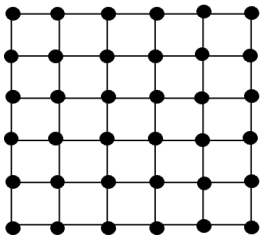

Fig 1. Design variable points are defined in the study area.

2.2.2. Adaptive Refinement Strategy

There are two conditions for adding nodes. One is that the node is located on the boundary of the study area, and the other is that within each unit area set, different speed limits exist on road segments. The estimated volume values of the added nodes (empty circles) are the average volume values between the surrounding nodes (solid circles) (Fig 2).

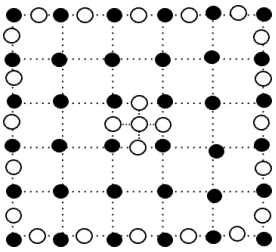

Fig 2. Newly-added nodes by adaptive refinement strategy.

2.2.3. Shepard Interpolation Method

Before using the Shepard interpolation method, it is necessary to define the influence region that affects the calculation of volume value at point x, for example, a circular area with a radius of R_C. The volume value at the interpolation point is then related to the design variables within its influence region (Fig 3).

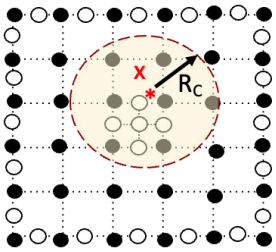

Fig 3. Only design variable points within the influence region R_C. contribute to the volume value of point x

Within the study area, at regular intervals, using the Shepard interpolation method to calculate the volume value:

$$q(x) = \sum_{i \in S_x} \Theta_i(x) q_i \tag{1}$$

where $\Theta_i(x)$ is a Shepard-family interpolation function expressed by

$$\Theta_i(x) = \frac{d(x-x_i)}{\sum_{j \in S_x} d(x-x_j)} \quad (i \in S_x) \tag{2}$$

with $d(x - x_i) = \|x - x_i\|^{-2}$ $(i = 1,2, \dots, n)$ being the Euclidean distance between the points x and x_i and the set S_x denoting the design variable points located within the influence domain of point.

2.3. Topology Optimization

The size of road space will affect the volume value (or flow rate) and average speed of lanes, thereby leading to either a decrease or increase in the level of road service. The premise of implementing humanity-oriented transportation is to first reduce the road space, minimizing road capacity while still meeting the overall level of road service. This involves adjusting the proportion of service levels according to different road hierarchies (main roads, secondary roads, local roads), and the allocation of service level proportions can be adjusted appropriately according to different regions. Therefore, the topology optimization can be expressed as

$$\text{Minimize } C_{Mi} + C_{Sj} + C_{Lk}$$
$$Subject\ to \begin{cases} SL_{\alpha M} * r_1 + SL_{\beta M} * (1 - r_1) \\ SL_{\alpha S} * r_2 + SL_{\beta S} * (1 - r_2) \\ SL_{\alpha L} * r_3 + SL_{\beta L} * (1 - r_3) \end{cases} \quad (4)$$

where C_{Mi} $(i = 1,2, \dots, n)$, C_{Sj} $(j = 1,2, \dots, m)$ and C_{Lk} $(k = 1,2, \dots, o)$ are the capacity of main roads, secondary roads and local roads, respectively. The capacity is calculating by [16]

$$C = F * N * 1000 + (W - P) * 200 \quad (5)$$

where F is the road type correction coefficient, N is the number of express lanes, W is the width of slow lanes, and P is the width of parking spaces. SL_{α}, SL_{β} are different levels of service, with subscripts M, S, L representing main roads, secondary roads, and local roads respectively. r_1, r_2, r_3 are the proportions allocated between different levels of service.

3. Discussion and Conclusion

This study utilizes the Shepard interpolation method, supplemented by adaptive adjustment strategy, to establish a traffic density field. Through topological optimization analysis, it evaluates whether the overall traffic service level remains within an acceptable range to determine the rationality of reducing vehicular space. Since this study focuses on the overall service level rather than the traditional individual segment service level, it assesses traffic flow smoothly. Therefore, even if congestion occurs on certain road segments, other segments may remain unimpeded, resulting in smoother overall traffic.

Thus, through the methodology proposed in this study, it aims to re-examine spatial configurations and adjustments before implementing humanity-oriented transportation. This approach seeks to simultaneously meet the needs of pedestrian and vehicular spaces, contributing modestly to emissions reduction and sustainable development, thus addressing climate change.

Abstract
Urban development in today's rapidly evolving landscape demands the integration of Artificial Intelligence (AI) to foster sustainable growth amidst vast spatial data. AI applications offer invaluable insights, revolutionizing decision-making processes by uncovering patterns, trends, and relationships. This paper explores the transformative potential of AI in urban development decision-making, highlighting trends, challenges, and future perspectives. Through advanced analytics and reporting tools, AI enables targeted interventions for environmental sustainability, resource optimization, and equitable social development. We delve into emerging trends such as Urban AI and synthetic data, examining their role in reshaping urban governance and planning. By addressing challenges and embracing innovative solutions, AI paves the way for sustainable, resilient, and inclusive urban futures.

Introduction
In today's rapidly evolving landscape of urban development, the integration of Artificial Intelligence (AI) has become imperative for fostering sustainable regional growth amidst the deluge of spatial data. AI applications stand poised to revolutionize decision-making processes by offering invaluable insights that inform strategic actions and guide initiatives towards sustainable outcomes. Through advanced data analytics and reporting tools, organizations can sift through vast datasets, uncovering intricate patterns, trends, and relationships that lay the groundwork for informed development strategies.

Consider, for instance, the role of AI in pinpointing critical areas for intervention within urban environments. By analyzing diverse datasets, AI applications can identify opportunities to enhance environmental sustainability and optimize resource utilization. Whether it's reducing energy consumption, curbing waste generation, or preserving biodiversity hotspots, AI-driven insights enable targeted interventions that align with broader sustainability objectives.

AI holds the potential to revolutionize how stakeholders engage with communities and address social and economic disparities. Through the analysis of demographic data, municipalities, cities, and regions can gain a nuanced understanding of the needs and aspirations of their residents. Armed with these insights, decision-makers can craft tailored programs and policies aimed at fostering social cohesion, environmental stewardship, and economic prosperity within communities. From equitable access to services to inclusive urban planning initiatives, AI-enabled decision-making fosters holistic approaches to sustainable spatial development.

AI facilitates dynamic, data-driven approaches to urban governance, enabling real-time monitoring and adaptive decision-making. By harnessing the power of predictive analytics, cities can anticipate emerging challenges and proactively devise strategies to mitigate risks and capitalize on opportunities. This forward-thinking approach not only enhances the resilience of urban systems but also fosters a culture of innovation and continuous improvement in sustainable development practices.

As we navigate the complexities of urbanization and strive to build more inclusive and resilient cities, the role of AI in sustainable regional development cannot be overstated. By harnessing

the power of data-driven insights, AI empowers decision-makers to navigate complex challenges, seize opportunities, and chart a course towards a more sustainable and equitable future. In the following sections, we delve deeper into the transformative potential of AI in urban development decision-making, exploring emerging trends and envisioning future pathways towards sustainable spatial development (Luusua et al., 2023; Cugurullo, 2020; Pellegrin et al., 2021).

The aim of the paper is to contribute valuable insights to the ongoing discourse on the evolving landscape of urban planning and governance, highlighting the game-changing role of AI in driving innovation and progress in urban development decision-making.

2. Trends and challenges of AI in urban development

As we embark on an exploration of the dynamic landscape of AI integration in urban development decision-making, it becomes crucial to examine both the evolving trends and the complex challenges that accompany this transformative process. In this section, we delve into the emerging trends that underscore the increasing role of AI in shaping urban development strategies, alongside the multifaceted challenges that must be navigated to harness its full potential. From leveraging AI-driven analytics to address urban challenges to grappling with issues of data quality, algorithmic bias, and community trust, understanding these trends and challenges is essential for steering urban development initiatives towards a more sustainable and equitable future. Let's delve deeper into this intricate intersection of technology and urban governance, exploring the trends driving AI adoption and the challenges that must be overcome to realize its transformative promise.

2.1. Urban AI

"Urban AI" represents the convergence of AI and the concept of "Smart Cities," where algorithms are trained on urban datasets to develop solutions tailored for urban environments. This concept is closely intertwined with the notion of "Big Urban Data," highlighting the significance of large-scale urban datasets in informing AI-driven solutions.

During a global exploration, two primary branches of Urban AI emerged:

1. Ontology: This branch focuses on transforming urban data into actionable knowledge about the urban environment, infrastructure, and usage patterns.
2. Robotics: This branch involves developing robots capable of navigating urban environments and performing predefined tasks. This includes autonomous vehicles, delivery drones, and cleaning robots, with Urban AI playing a crucial role in the software components of these robots. This encompasses environmental recognition, decision-making processes, and human-machine interactions (Hubert Beroche).

Urban AI refers to any system that incorporates data derived from the urban environment and processes it using algorithms. The resulting insights have practical applications within the socio-spatial fabric of the city.

Three key features distinguish Urban AI:

- Complexity of the City. Urban environments are multifaceted, with intricate interactions among people, infrastructure, and natural systems.
- Policy Contexts. Urban AI operates within specific policy contexts, influenced by local governance, regulations, and cultural nuances.
- Hybridity. Urban AI blends diverse data sources, technologies, and stakeholder interests.

Urban AI not only revolutionizes travel practices but also contributes to the creation of digital twins of cities, fundamentally altering our understanding of urban dynamics and decision-making processes. Adaptive and autonomous algorithms, powered by AI, play a pivotal role in shaping our travel experiences, influencing the routes we take via car, air, rail, or foot. Moreover, accommodation services guided by AI recommendations enrich our travel experiences, ensuring personalized and seamless journeys.

It facilitates the creation of digital replicas of cities, known as digital twins, which amalgamate data from diverse sources to provide comprehensive insights into urban infrastructure, dynamics, and human behavior. By integrating previously disparate datasets, Urban AI empowers decision-makers and urban planners to gain a holistic understanding of urban environments, facilitating more informed and strategic planning processes.

Urban AI transcends traditional boundaries, transforming how we interact with our environment and society. From optimizing travel routes to enhancing decision-making processes through digital twins, Urban AI emerges as a powerful tool for shaping the future of urban development and governance. As cities continue to evolve, Urban AI will play an increasingly integral role in fostering sustainable, resilient, and inclusive urban environments (Luusua et al., 2023; "AI: Revolutionizing Urban Planning and Smart City Development," n.d.).

Urban AI has made significant strides in enhancing cities and improving urban living. Here are some successful examples:

- **New York City's Community-Centric Planning.** New York City utilizes AI to gauge public sentiment on development projects. By fostering community-centric planning, they ensure that urban development aligns with the needs and preferences of residents1.
- **Tokyo's Optimized Public Transportation.** Tokyo leverages AI-driven commuter data analysis to optimize its public transportation system. This approach eases congestion, enhances commutes, and ensures efficient mobility for millions of residents and visitors1.
- **Copenhagen's Eco-Friendly Urban Design.** Copenhagen uses data analytics and AI to track progress toward its goal of carbon neutrality by 2025. This informs eco-friendly urban design decisions, contributing to a sustainable and livable city (AI: Revolutionizing Urban Planning and Smart City Development, n.d.).

These examples demonstrate how AI can revolutionize urban planning, transportation, and environmental sustainability. As cities continue to evolve, urban AI will play an increasingly pivotal role in shaping our urban landscapes.

But implementing Urban AI in the context of smart cities presents several challenges. Let's explore them:

1. **Technical Challenges:**

1.1. **Standardization and Interoperability**. The integration of diverse technologies in urban AI often leads to fragmentation, hindering seamless communication and compatibility between systems. To address this challenge, standardized interfaces and data models are essential. Establishing common standards ensures interoperability, enabling different AI systems to communicate effectively and share data seamlessly. By adopting standardized protocols, urban AI solutions can integrate more efficiently, fostering collaboration and synergy among diverse stakeholders.

1.2. **Data Handling and Storage.** Urban AI generates vast and complex datasets from various sources, including sensors, social media, and administrative records. Efficient data handling, storage, and processing become critical to extract meaningful insights and derive actionable intelligence. Scalable and robust data infrastructure is essential to manage the volume, velocity, and variety of urban data effectively. Implementing advanced data management techniques, such as distributed storage and parallel processing, can enhance the efficiency and scalability of urban AI systems, enabling timely analysis and decision-making.

1.3. **Scalability.** As cities continue to grow and evolve, the scalability of AI systems becomes crucial. Ensuring that AI solutions can handle increased data volume, user demands, and computational complexity is a significant challenge. Scalability issues can arise in various aspects of urban AI, including data processing, machine learning algorithms, and infrastructure capacity. Adopting scalable architectures, leveraging cloud computing resources, and implementing parallel processing techniques are key strategies to address scalability challenges and support the sustainable growth of urban AI applications.

1.4. **Mitigating Network Congestion.** Urban AI relies on real-time data exchange and communication between devices, sensors, and systems. Managing network congestion and ensuring timely data flow are ongoing challenges in urban environments with dense populations and high data traffic. Traffic optimization techniques, prioritization algorithms, and adaptive routing protocols can help

mitigate network congestion and ensure reliable data transmission in urban AI systems. Additionally, investing in robust network infrastructure and bandwidth expansion initiatives can improve the resilience and performance of urban AI networks, enhancing their ability to handle peak loads and unexpected surges in data traffic.

1.5. **Privacy and Security Concerns.** Balancing data accessibility with privacy protection is a fundamental challenge in urban AI deployments. Urban AI systems must safeguard sensitive information, such as personal data and location-based data, while providing valuable services to residents and stakeholders. Addressing privacy and security concerns requires comprehensive data governance frameworks, encryption protocols, and access control mechanisms. Implementing privacy-enhancing technologies, such as differential privacy and federated learning, can help preserve individual privacy rights while enabling data sharing and analysis for urban development purposes. Moreover, raising awareness among citizens about data privacy risks and rights is essential to foster trust and transparency in urban AI initiatives. By prioritizing privacy and security considerations, urban AI systems can uphold ethical standards and ensure responsible data stewardship in urban development decision-making processes.

2. Financial and Legal Obstacles:

2.1. **Funding Complexity.** Implementing large-scale urban AI projects demands significant financial investment, ranging from infrastructure development to talent acquisition and ongoing maintenance costs. Securing funding and allocating resources for these projects can be challenging, particularly in the face of competing priorities and budget constraints. Municipalities, government agencies, and private sector stakeholders must collaborate effectively to mobilize resources and secure sustainable funding sources for urban AI initiatives. Innovative financing mechanisms, public-private partnerships, and grant programs can help address funding complexities and ensure the long-term viability of urban AI projects.

2.2. **Regulatory Complexities**. Navigating the complex landscape of regulations, compliance requirements, and legal frameworks is another obstacle in the adoption of urban AI technologies. Legal considerations related to data privacy, cybersecurity, intellectual property rights, and liability pose significant challenges for urban AI deployments. Urban AI initiatives must comply with various regulations, such as the General Data Protection Regulation (GDPR) in Europe or the California Consumer Privacy Act (CCPA) in the United States, which mandate stringent data protection measures and transparency requirements. Moreover, emerging regulatory frameworks specific to AI technologies, such as AI ethics guidelines and algorithmic accountability standards, further add to the regulatory complexities that urban AI projects must navigate. Collaborative efforts between policymakers, industry stakeholders, and legal experts are essential to develop clear guidelines and frameworks that balance innovation with regulatory compliance in the urban AI space.

2.3. **Ethical Dilemmas.** Urban AI decisions have profound implications for human lives, communities, and society as a whole. Ensuring ethical practices and transparency in urban AI deployments is paramount to build trust and mitigate potential harms. Ethical dilemmas may arise from algorithmic biases, discriminatory outcomes, and unintended consequences of AI-driven decisions. For example, AI algorithms used in predictive policing or resource allocation may inadvertently reinforce existing inequalities or perpetuate social injustices. Urban AI initiatives must adopt ethical principles, such as fairness, transparency, accountability, and inclusivity, to guide decision-making processes and mitigate ethical risks. Stakeholder engagement, public consultation, and ethical impact assessments are essential tools to identify and address ethical dilemmas in urban AI projects. By upholding ethical standards and promoting responsible AI practices, urban AI initiatives can foster societal trust and contribute to positive social outcomes in urban development contexts.

3. Human Involvement:

3.1. **Active Participation.** In the realm of urban AI, where projects intersect with the intricacies of the human-built environment, the active involvement of people is paramount at every stage of development and implementation. From conceptualization to deployment and beyond, incorporating the perspectives, insights, and feedback of diverse stakeholders is essential for ensuring the success and sustainability of urban AI initiatives. Active participation from community members, urban residents, local businesses, and other relevant stakeholders enriches the decision-making process, bringing valuable local knowledge and contextual understanding to the table. By engaging with those who will be directly affected by urban AI projects, planners and developers can gain deeper insights into the needs, preferences, and concerns of the communities they serve. Involving people in urban AI projects fosters a sense of ownership and empowerment, cultivating a shared vision for the future of the city. Collaborative decision-making processes that prioritize inclusivity and transparency build trust and foster positive relationships between stakeholders and project implementers. Active participation enables ongoing monitoring and evaluation of urban AI initiatives, allowing for course corrections and adjustments based on real-time feedback and evolving community needs. By maintaining open channels of communication and fostering a culture of continuous engagement, urban AI projects can adapt and evolve in response to changing circumstances and emerging challenges.

The active participation of people is not just a nicety but a necessity in the realm of urban AI. By embracing inclusivity, transparency, and collaboration, urban AI projects can harness the collective intelligence and creativity of diverse communities, ultimately leading to more equitable, resilient, and sustainable urban futures (Sampath Lonka, 2023; A Guide to Urban Artificial Intelligence, 2023; Smart Cities: Navigating Urban Frontiers with AI and IoT, 2023).

In autumn 2022, the collaboration between the Paris-based think tank Urban AI and Cornell Tech's Jacobs Urban Tech Hub marked the inception of "The Future of Urban AI" project. Their shared goal was to delve into the evolving landscape of Urban Artificial Intelligence (AI) and its profound implications for urban life. The project aimed to deepen understanding of how AI technologies can shape the trajectory of cities, particularly as they undergo rapid transformation due to technological advancements and societal shifts.

The project unfolded through a series of engaging webinars, each focusing on a specific aspect of Urban AI. These sessions featured thought leaders and experts from various domains, shedding light on critical topics such as participatory planning, trustworthy cartography, self-repairing cities, software-defined sensing, anticipatory government, reimagining offices, and decolonizing smart cities. Each webinar provided valuable insights into the applications, challenges, and potential of AI in urban contexts, fostering informed discussions and sparking innovative ideas.

Central to the project's ethos was the aim to build a diverse and inclusive community of experts, comprising researchers, public servants, startups, and subject matter specialists. This global network collaborated at the intersection of cities and technology, working on multidisciplinary projects to assess the impacts of AI on urban life and vice versa. Through shared knowledge, expertise, and experiences, the community aimed to shape the future of AI-driven urban innovation, prioritizing resilience, inclusivity, and forward-thinking approaches.

The project prioritized accessibility and inclusivity, holding all webinars on Zoom and making them open to anyone interested in the intersection of AI and urban development. This approach fostered global dialogues, encouraging knowledge exchange and collective insights from participants across diverse backgrounds and geographies. By facilitating broad participation, the project aimed to democratize access to cutting-edge discussions and empower individuals to contribute to shaping the future of urban AI.

Building on the success of its inaugural season, "The Future of Urban AI" project entered its second season, delving even deeper into the realms of urban AI. Drawing on insights from Cornell Tech's Future of Urban Tech Horizon Scan, the project remained at the forefront of AI-

driven urban innovation, exploring emerging trends, opportunities, and challenges. Through ongoing exploration and collaboration, the project remained committed to driving positive change in urban environments, ensuring they evolve in a sustainable, inclusive, and future-ready manner.

"The Future of Urban AI" project exemplifies a collaborative effort to harness the potential of AI in shaping cities for the better. By fostering knowledge exchange, community building, and ongoing exploration, the project seeks to create resilient, inclusive, and forward-thinking urban environments powered by AI technologies. For more information and registration details, interested individuals can visit the Urban Tech Hub's event page, contributing to the collective effort of shaping the future of urban AI (Urban AI x Cornell Tech, 2023; The Future of Urban AI: Towards Participatory Planning, n.d.; Leading the way in artificial intelligence research, n.d).

2.2. Synthetic data

Synthetic data refers to information that is artificially generated rather than produced by real-world events. Today exist a lot of different definitions of synthetic data. For example, world leader in artificial intelligence computing NVIDIA (NVIDIA, n.d.; NVIDIA. What Is Synthetic Data?, n.d) define it as annotated information that computer simulations or algorithms generate as an alternative to real-world data. Put another way, synthetic data is created in digital worlds rather than collected from or measured in the real world.

It may be artificial, but synthetic data reflects real-world data, mathematically or statistically. Research demonstrates it can be as good or even better for training an AI model than data based on actual objects, events or people.

On the other hand, Indian multinational information technology services and consulting company HCLTech (HCL Technologies, 2019) shows that synthetic data is a type of data which is generated based on the characteristic of different variables, understanding of the probability distribution of the expected data, and the relationship between the different variables.

They defined, that there are three types of synthetic data, i.e., fully synthetic, partially synthetic, and hybrid synthetic. Fully synthetic data: The data is fully generated from scratch, based on assumptions around the probability density function of the data, the correlation among the variables, and constraints/rules on the variance of data. Partially synthetic data: If there are some variables which are sensitive for disclosure in a large data set, such variables can be replaced by synthetic data. Imputations are applied to mask the data and make it untraceable. E.g.: Personally identifiable information (PII)

Hybrid synthetic data: A limited volume of original data or data prepared by domain experts are used as inputs for generating hybrid data. The underlying distribution of original data is studied and the nearest neighbor of each data point is created, while ensuring the relationship and integrity between other variables in the dataset. This ensures that the generated synthetic data closely resembles the original data.

In a June 2021 report on synthetic data, Gartner predicted by 2030 most of the data used in AI will be artificially generated by rules, statistical models, simulations or other techniques (HCL Technologies, 2019).

“The fact is you won’t be able to build high-quality, high-value AI models without synthetic data,” the report said (NVIDIA.What Is Synthetic Data?, n.d.).

In IDC was defined, that companies offering synthetic data solutions are mostly doing so within their existing product offering for computer vision AI software and are largely not offering it as a standalone solution.

"Synthetic data will be a tool used for positive benefit in computer vision AI software applications. It will permit not only the creation of models with sparse data sets but also help with the elimination of bias in models to better reflect real-world edge cases," said Peter Haas, research director, Computer Vision AI Software at IDC. "Synthetic data can provide a path to learning from sparse examples in certain domains, such as medicine, where some rare conditions may only have a few examples in the literature; this will be a game-changing technology." (IDC. The Fundamentals of Synthetic Data for Computer Vision Applications, n.d).

Synthetic data plays a crucial role in enhancing urban planning models. Let’s explore how it contributes:

1. **Testing and Simulation.** Synthetic data allows urban planners to create prediction models and simulate various scenarios using artificial intelligence (AI) and data analytics techniques.
   These models can:
   - Forecast the city's future growth and development.
   - Evaluate the potential effects of various planning choices.
   - Efficiently allocate resources.
2. **Privacy Protection.** In cases where real-world data cannot be released due to privacy concerns (e.g., individual mobility data), synthetic data provides an alternative. It enables testing and analysis without compromising confidentiality.
3. **Resource-Efficient Mapping.** Mapping street trees, for example, is labor-intensive. Researchers have used Google Street View images and machine learning techniques to quantify green canopy in cities at the pixel level. This open-source algorithm allows cities worldwide to plan and increase greenery efficiently.
4. **Addressing Data Gaps.** Urban planning often grapples with incomplete or insufficient data, particularly in rapidly evolving urban environments where traditional data collection methods may struggle to keep pace. Synthetic data fills these data gaps by generating realistic and representative data that complement existing datasets. Whether it's demographic information, transportation patterns, land use dynamics, or environmental factors, synthetic data provides planners with the necessary insights to gain a comprehensive understanding of the urban landscape. By augmenting real-world data with synthetic data, planners can overcome limitations in data availability and ensure that their analyses are robust and comprehensive.
5. **Fine-Grained Exposure Assessment.** When measuring residents' exposure to pollutants, synthetic data can provide finer spatial and temporal resolution. By considering not only home addresses but also commute and work/school locations, it enhances exposure assessment.
6. **Inclusive Decision-Making.** Synthetic data enables urban planners to explore scenarios and make informed decisions. It bridges the gap between theoretical models and real-world applications, ensuring more inclusive and effective planning. Synthetic data empowers urban planners to test hypotheses, protect privacy, and optimize resource allocation, ultimately improving the quality of urban planning models (Duarte, F., & deSouza, P., 2020; Grover, N., 2023; Weiler, C., 2020).
7. **3D Urban Models.** Urban designers can generate synthetic 3D urban models from open city data. Environmental Analysis: These models are used for environmental analysis, such as assessing sunlight exposure, wind patterns, and energy efficiency. Integration with Urban Design Tools: By integrating synthetic data into existing urban design tools (e.g., QGIS), planners can make informed decisions (Chen, K., & Norford, L., 2016).

Synthetic data offers a powerful tool for enhancing urban planning workflows, addressing data gaps, and ensuring effective decision-making in a rapidly changing urban landscape.

The future of synthetic data in urban development is brimming with potential, offering innovative solutions to complex challenges and driving positive change in cities worldwide. City Digital Twins (CDTs), representing digital replicas of urban environments, stand to benefit significantly from synthetic data, addressing issues surrounding privacy, data availability, and predictive simulations. As cities grow more intricate, CDTs powered by synthetic data promise more accurate predictions and informed decision-making, empowering planners to tackle urban challenges effectively and allocate resources optimally. Agile data workflows are essential for urban planning, and synthetic data seamlessly integrates into these processes, enabling real-time testing, scenario simulation, and resource optimization. Moreover, synthetic data provides privacy-preserving solutions, essential in an era of tightening data regulations, ensuring that urban development initiatives respect individual privacy rights. By leveraging synthetic data for predictive simulations and policy interventions, cities can craft effective strategies tailored to community needs while fostering trust and transparency. Embracing

synthetic data is not just about innovation; it's about driving positive changes, building smarter, citizen-centric cities that thrive in a data-driven future.

3. Discussion

The transformative potential of AI in urban development decision-making is undeniable, yet its implementation poses both opportunities and challenges that warrant further discussion. One key aspect of the discussion revolves around the ethical implications of AI adoption in urban governance and planning. While AI holds the promise of enhancing efficiency, transparency, and inclusivity in decision-making processes, it also raises concerns about algorithmic biases, discrimination, and privacy infringement. Addressing these ethical dilemmas requires a multidisciplinary approach, involving policymakers, technologists, ethicists, and community representatives in designing AI systems that prioritize fairness, accountability, and transparency. By embedding ethical principles into the design, deployment, and monitoring of AI applications, cities can mitigate potential risks and ensure that AI-driven urban development initiatives uphold societal values and respect individual rights.

The game-changing role of AI in urban development lies in its capacity to revolutionize community engagement and participatory approaches. As cities embrace AI technologies to optimize resource allocation, enhance service delivery, and improve infrastructure management, it is essential to involve residents and stakeholders in decision-making processes. Engaging communities in co-designing AI solutions, soliciting feedback on urban plans, and fostering dialogue around AI-driven initiatives fosters trust, ownership, and social acceptance. By prioritizing community engagement, cities can leverage the collective intelligence and creativity of diverse stakeholders, ensuring that AI-driven urban development reflects the needs, preferences, and aspirations of the people it serves.

The discussion should explore the capacity-building efforts needed to ensure that urban stakeholders, including policymakers, planners, and residents, possess the requisite skills and knowledge to harness the full potential of AI. Investing in education, training, and capacity-building programs can empower individuals and organizations to leverage AI tools effectively, interpret data insights responsibly, and make informed decisions that advance sustainable urban development goals. By democratizing access to AI literacy and skills development opportunities, cities can foster a culture of innovation, collaboration, and continuous learning, driving positive change in urban governance and planning practices.

Interdisciplinary collaboration and knowledge sharing play a crucial role in advancing AI-driven urban development agendas. As AI technologies continue to evolve rapidly, collaboration between academia, industry, government, and civil society becomes paramount in driving innovation, scaling solutions, and addressing complex urban challenges. By fostering cross-sector partnerships, sharing best practices, and facilitating knowledge exchange forums, cities can harness collective expertise and resources to accelerate the adoption of AI in urban governance and planning. Embracing a collaborative approach enables cities to tap into diverse perspectives, leverage complementary strengths, and co-create solutions that are contextually relevant and impactful. As cities continue to evolve, embracing AI as a tool for positive change requires a collective commitment to ethical principles, social equity, and responsible innovation, ensuring that AI-driven urban development initiatives benefit society as a whole.

Conclusion

The paper delves into the game-changing role of Artificial Intelligence in urban development decision-making, highlighting emerging trends, challenges, and future perspectives. Through the integration of AI applications, cities can harness data-driven insights to revolutionize decision-making processes, fostering sustainable growth and resilience amidst the complexities of urbanization. From optimizing resource allocation to enhancing environmental sustainability, AI empowers decision-makers to navigate complex challenges and seize opportunities for inclusive and equitable urban development.

The exploration of trends such as Urban AI and synthetic data underscores the transformative potential of AI in reshaping urban governance and planning. Urban AI, characterized by its ability to process vast urban datasets and develop tailored solutions for urban environments, promises to revolutionize how cities are planned, managed, and experienced. Synthetic data

offers a powerful tool for addressing data gaps, enabling predictive simulations, and ensuring privacy-preserving solutions in urban planning workflows. The adoption of AI in urban development is not without its challenges. Technical complexities, regulatory frameworks, and ethical considerations must be navigated to realize the full potential of AI in driving positive change in cities. By addressing these challenges and embracing innovative solutions, cities can harness the power of AI to foster sustainable, resilient, and inclusive urban futures.

Looking ahead, the future of AI in urban development is brimming with potential, offering opportunities for innovation, collaboration, and community engagement. As cities continue to evolve and face new challenges, the integration of AI presents a pathway towards smarter, more responsive, and citizen-centric urban environments. By leveraging AI technologies and fostering partnerships between stakeholders, cities can chart a course towards a more sustainable, equitable, and resilient urban future.

Abstract
Citywalk, a popular trend on social media platforms, is transforming people's preference for walking in cities. Despite its growing influence on street and place-making efforts, the relationship between Citywalk preference and built environment remains undisclosed, let alone their concerted efforts for informing more complex urban planning. In this research, a comprehensive evaluation system is proposed based on space analysis of built environment indicators and data of Citywalk from Xiaohongshu, to reconstruct a new urban perception model and recommend route selections for urban renewal practices. We take Shanghai's historical area as the representative example and find the results well correspond to real pedestrian preferences in LBS data, which suggests this measurement is a potential valuable guidance for urban planning in the future.

Key Words
Citywalk, social media data, spatial analysis, route selection

1 Introduction

Citywalk means "roaming around the city" on foot, referring to a popular way of exploring old buildings, browsing boutique shops, sipping a cup of coffee, or indulging in authentic local snacks. (Borucka J., 2019, p.158-163). In China, the emergence of social media platforms in the digital age has led to the evolution of Citywalk into a popular leisure activity among a diverse range of groups, particularly young people. It encourages individuals to engage in outdoor activities, benefiting health and attracting tourist economy to urban areas (Kordi. A.O. et al., 2023, p.34). Besides, Citywalk represents an opportunity for tour guides and travel service providers to offer a more tailored, professional service to meet with ever-changing market demands. As a popular trend in social media, Citywalk is transforming people's behaviour of exploring cities, with popular walking tours furthermore influencing city image and place-making efforts.

Despite many other social media factors preference found in existing researches to influence people's urban perception and behaviour in addition to Citywalk, the relationship between Citywalk indicators and built environment characters remains undisclosed.

In this vein, this study focuses on 'route' as the fundamental premise, proposing a walking tour evaluation system to assess the correlation between Citywalk preference and existing built environment, reconstructing a synthetical urban perception model, and employing new methodologies to measure these public involvement data for informing more effective urban planning practices. The framework of our study is implemented through a practical case study, in response to the emerging Citywalk trend on Xiaohongshu, a popular social

media platform, with the aim to provide an expanded measurement for informing data-driven urban planning based on social media analytics.

2 Literature Review

Media data has become a crucial indicator of human activities correlating with the built environment vitality despite traditional methods and basic indicators for urban space evaluation. Data accessible on media platforms were frequently employed to discern urban spatial structures imbued with vitality (Chen et al., 2019, p. 102005), and to reveal a series of potential attractions (Jankowski et al., 2010, p. 833–852). For instance, Zhang et al. (2022) measured virtual visiting preference based on data from TikTok filming locations. Salazar-Miranda et al. (2022) focused on street activity measurement around slow-traffic zones using Twitter comments as indicators. Similarly, existing basic environment indicators are also available to evaluate both physical and social features of streets, such as accessibility, quality, walkability and vitality, influencing subjective feelings (Ma, 2024, p. 104797). Li et al. (2022) and Jiang (2022) have provided insights into the association between street vitality and the built environment, utilising urban data such as Location-Based Services (LBS), road networks, building and street data, street view images and Points of Interest (POI). However they overlook the assessment of a street's latest internet-famous properties. Fortunately, advanced technology has opened up the possibility of quantitative research on social-economic analysis, such as interaction between media data and environmental elements. Improved computation methods could hold practical significance on urban regeneration efforts, including street renewal, urban planning and vitality prediction. For example, an application proposed by Li et al. (2022) and Huang et al. (2021) measured the city image perception through social media analytics and proposed instructions for planning practice. Garay Tamajón and Cànoves Valiente (2017) also utilised various data on social media platforms to explore the formation mechanism of people’s city image.

Furthermore, emerging social media trends are shaping pedestrians’ travel preferences, offering an expanded metric for evaluating urban regeneration practices. Specifically, Ye et al. (2023) observed the alterations in Twitter usage leading to the mobility fluctuations during pandemic era in New York City. Liu et al. (2023) discovered that young women's choice of shopping destinations is more influenced by word-of-mouth marketing on social media platforms. In China, Citywalk has been a pop trend that influences many people’s route preference (Liang, 2023, p.72). To finds motivations for planning and design efforts in specific sites, which helps to address the urban renewal position, Ma et al. (2021) utilised the correlation analysis between visual elements and human perception to support city regeneration decisions. In addition, online opinions from residents about city streets also serve as crucial references for street planning improvements (Wang et al., 2022, p.215–230), such as internet investigations of underground pedestrian networks as valuable guidance for city’s infrastructure construction (Chan et al., 2022, p. 104678).

In this context, based on the established muti-sourced data-driven planning system, we chose Citywalk preference as the fundamental premise, applying a systematic framework of methodologies to comprehensively uncover Citywalk’s internet-famous nature as well

as its role within the urban environment, instead of relying on limited manual intuition or isolated data units.

3 Citywalk and Current Situation

Citywalk originated from international media like Twitter, but are currently trending across multiple Chinese social media platforms such as Xiaohongshu and Weibo. This research selected Xiaohongshu, a popular Chinese social media platform, as the channel to obtain relevant data of Citywalk issue in Shanghai. The feasibility demonstrated by previous researches and empirical evidence. Gu et al. (2023) and Zhou et al. (2021) verified that the data crawled from Xiaohongshu notes is correlated with citizens' recreational activities in urban spaces, which affirms its significance in exploring the connection between virtual media space and real physical space. In addition, the data from Xiaohongshu features characteristics of large quantity, time sensitivity, public participation, wide transmissibility, accurate location, etc. Prevailing in its individual convenience for publishing, sharing and recommendation, Xiaohongshu gathers high-quality Citywalk notes, providing representative and operable data for this study.

To improve comprehension of the social media influence on mechanism of route selection, we diagrammed the operation of Citywalk notes on Xiaohongshu platform (refer to **Fig. 1**). Firstly, users browse Citywalk contents using keywords, freely filtering by the hottest, latest, most relevant, most recent, or the notes published by specific users. Secondly, by clicking into any note, users can access routes including their names, mapping locations, itineraries, surrounding internet-famous sites and recommendation reasons, with which travellers can select destinations and travel routes efficiently. Besides, the number of likes, favourites, and comments of the note can additionally help the viewers with insights into the popularity of their travel decisions. Concluded from recommendations on Xiaohongshu, Citywalk primarily takes place on the main streets within the Inner Ring of Shanghai, spanning a comprehensive range of topics including popular commercial activities, public spaces hosting temporary events, and historic districts with pleasant street views.

Fig. 1 The Interface of notes on Xiaohongshu

4 Methodology

4.1 Road as the primary measurement object

This study selects road as the primary measurement object for gathering statistical data on Xiaohongshu and other built environment indicators. When constructing models, we also incorporate roads to analyse correlations and make predictions based on the collected data. The specific methods are as follows.

1) In contrast to activities in huge plots and buildings inside, Citywalk mainly takes place on city streets. However, this does not result in negating the significance of buildings adjacent to or bordering plots, as they will significantly impact the perception of street walking.

2) Besides, considering point data such as Points of Interest (POI), we associate their information with the nearest roads. This is because POIs can significantly influence people's behaviour on the street, particularly when citizens are inclined to follow instructions from social media platforms.

3) The acquisition of street view images provides great help in analysing the built environment of the road itself, including various indicators such as greenery, sky view, pedestrian space, motorisation and diversity.

4) Each road is assigned a unique name, corresponding to the same name used on the social media platform. This allows us to align media data with each road accurately for mapping.

This approach ensures that roads are associated with integrated numerical and spatial data while preserving their spatial connectivity for further applications such as network analysis and route selection.

4.2 Comprehensive evaluation system

To make this comprehensive system more clear, the study divides the paradigm into two main functional modules and four interconnected steps. These parts integrate various data analysis methods based on numerical and spatial aspects, such as Network Analysis and Proximity Analysis within Geographic Information System (GIS), as well as Spearman Correlation and Stepwise regression. Once this synthetic evaluation model is established, it enables quantification of interactions among multiple data sources and facilitates tenable predictions for street utilisation in the future, which is helpful for vitality analysis and urban renewal route selection (see **Fig. 2**).

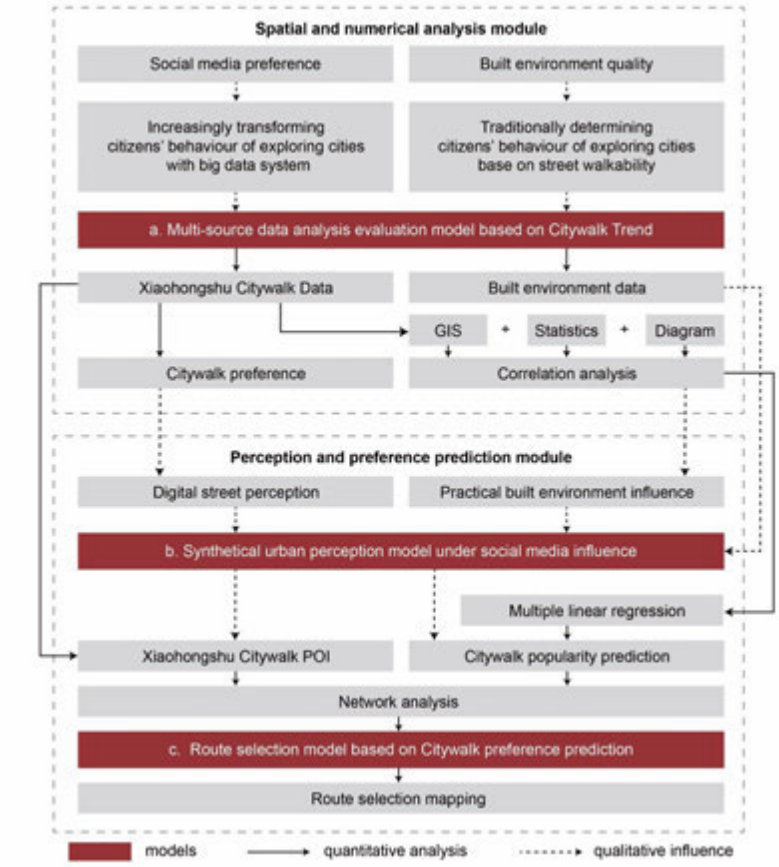

Fig. 2 Research framework and comprehensive evaluation system

4.3 Study area

To effectively establish the data analysis model, this study selects top-typical roads from the crawled data on Xiaohongshu platform as research objects (specific details are in analytical framework *step 1*). We mapped these roads onto the road network, revealing that social media platforms tend to recommend areas with numerous attractions for pedestrians. For instance, roads proximate to tourist attractions and historical districts are more apt to be suggested compared to those situated within residential communities. Therefore, the inner ring of Shanghai (refer to **Fig. 3**) is more suitable for conducting correlation analysis and predicting Citywalk patterns, following the selected Hengfu historical area in introduction.

Fig. 3 Most popular Citywalk roads are circled in the Shanghai Inner Ring.

4.4 Analytical framework

Step 1 Data acquisition and preparation

To thoroughly validate the quantifiable relationship between Citywalk preference and built environment, this study adapts three categories of data based on key indicators from existing research. Firstly, popularity data related to Citywalk destinations on social media platforms is employed to inform Citywalk preferences. Secondly, built environment data including transportation stops, street accessibility, Points of Interest (POIs), adjacent Floor-Area Ratio (FAR), and building density is integrated for route preference correlation analysis in different Citywalk themes among 'shopping districts', 'tourist attractions' and 'historical streets'. Lastly, street view image data containing information on greenery, sky view, pedestrian space, motorisation diversity and other factors is also included as street quality measurements, which can influence Citywalk preference.

The quantifiable indicators and quantification methods are presented in **Table. 1** below. Given that roads are the final measurement units, we adopt the proximity principle to attach the data to each road segment. This involves directly adding average numerical data to road attributes and converting spatial data into area density for calculation.

Data Categories	Indicators	Quantification method

Citywalk preference	Citywalk point vitality Citywalk road vitality	Points | average value Numerical attributes | average value
Built environment	Living facilities Tourist attractions Shopping places Restaurants Metro Stations Bus stops	Points | density (numbers/m²)
	FAR Building density	Polygons | average value
Street view image	motorisation ratio sidewalk ratio Building ratio Greenery Sky view Urban furniture Colour diversity Façade permeability	Numerical attributes | average value(0~100%)
Accessibility	500m_accessibility 300m_accessibility Full_accessibility	Numerical attributes | value
Vitality	Location Based Services (LBS)	Grids | qualitative mapping

Table. 1 Citywalk preference data and built environment data.

For data acquisition, we utilise all publicly accessible open data online, which is also readily available in other regions worldwide if using the similar technique framework of this study. The following are the resources we utilised in Shanghai for example, along with the detailed data processing methods.

1) To quantify Citywalk preference, the data obtained from the Xiaohongshu platform (a widely used social media app, particularly among individual users in China) is classified into three categories: texts, number of likes, and release time (refer to **Table. 2**).

Texts(i)	Number of likes	Release time
从[**武康路**]步行到[**徐家汇**]，今天成功打卡[**武康大楼**]……	6667	2023.11.1
…	…	…

Table. 2 Each text includes many places of interest with preference data.

Considering Citywalk is a time-sensitive activity and may change over time, this study only takes data from November 2023 to December 2023 as an example， And we convert it into a quantifiable indicator, as shown in the following formula:

$$Activity_{j-place} = \sum_{i=1}^{i} \frac{likes_{i,j}}{time_{i,j}} \quad (1)$$

Here, $Activity_j$ represents the vitality of each place with its unique name code such as [武康路]. $likes_{i,j}$ and $time_{i,j}$ represent the *likes* number and *duration time* of each i text containing each j place in this stratified framework.

Since the locations mentioned in the texts include both roads and points of interest, we compute the average value of the vitality-related data surrounding the measurement roads, using GIS buffer with the following formula:

$$Redu_{z-road} = \sum_{j=1}^{n} \frac{Activity_{j-place,z}}{n} \quad (2)$$

As roads are linear features, this study utilizes a spatial buffer consisting of circles at both ends of each road segment and a band area along its length to gather road-related data. Here, $Activity_{j-place,z}$ represents the places within this buffer, and n represents the total number of places nearby (refer to **Fig. 4**). Therefore, each road is able to obtain an average activity $Redu_{z-road}$ from places around. Considering pedestrian's walking habit, we apply the distance of 500 metres (5-7min walking) from *15-Min Pedestrian Neighbourhood* theory in China's urban planning.

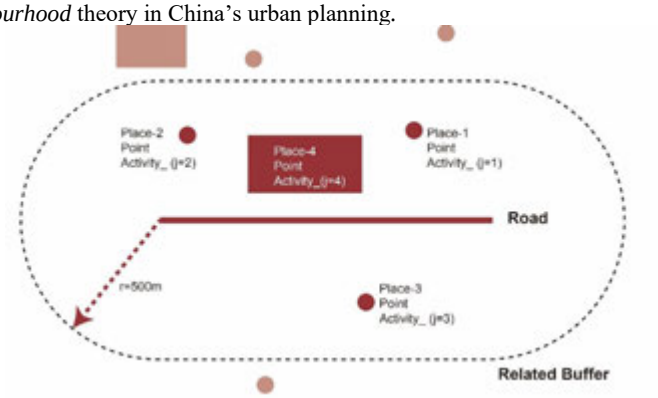

Fig. 4 Buffer is employed to collect Citywalk preference data for each road.

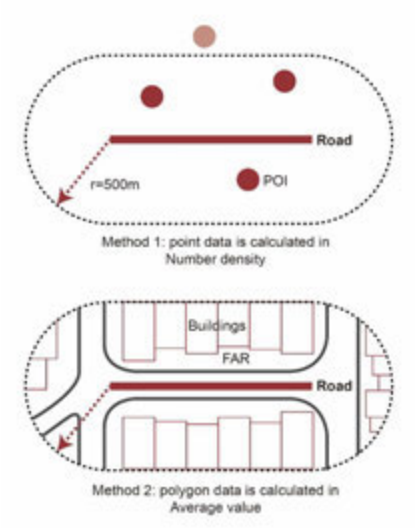
2) To pithily measure the various built environment indicators, we mainly acquire POI data and basic urban 3D spatial information from Amap (a popular mapping APP in China), utilising GIS for subsequent processing. Similarly, the data of each indicator is linked within different buffers of each road, whose radius vary according to the service distance stipulation in planning policy documents and pedestrian perception of the built environment. The two different computing methods and distance radius are shown below (**Fig. 5, Table .3**).



Indicators	Radius(metres)
Living facilities	200
Tourist attractions	600
Shopping places	300
Restaurants	300
Metro Stations	500
Bus stops	300
FAR	50
Building density	50

Fig. 5 Two different computing method;
Table. 3 Different buffer radius according to planning stipulation and urban perception

These two methods mainly focus on numerical computation while the spatial influential factors are embodied in distance radius specified in **Table. 3**. The detailed calculation formulas are as follows:

$$Density_{i-point,\ z} = \frac{N_{i,z}}{Area_z};\ AveValue_{i-area,\ z} = \frac{\sum_i (Value_i \times Area_i)}{Area_z} \quad (3), (4)$$

Here, $Area_z$ represents the buffer area of road z. In method 1, $N_{i,z}$ is the total number of each kind of point data within this buffer. In method 2, $Value_i$ represents either the FAR of including plots or the total floor area of intersecting buildings, while $Area_i$ only represents to the part of buildings and plots in the buffer area. Despite that the average value may be lower than the practical data due to the indicator area being smaller than that of the buffer, it still provides a quantifiable measurement of the FAR and building density along the road.

3) To incorporate factors directly from the street itself, this study supplements street view image to provide indicators of human-scale perception. These measurements primarily concentrate on the visual proportion of different categories of graphic elements. The specific diagram and indicators are shown in **Fig. 6** and **Table. 4**. Given the linear features of street, average computing method is similarly employed for each road.

Fig. 6 Semantic segmentation

Indicators	Practical meaning
motorisation ratio	Proportion of motor vehicle lanes, reflecting motorisation
sidewalk ratio	Proportion of sidewalks, reflecting walking environment
Building ratio	Proportion of building objects, reflecting building density
Greenery	Street greening degree, reflecting environment quality
Sky view	Sky visibility, reflecting street openness or width
Urban furniture	Urban Infrastructure construction degree
Colour diversity	Colour richness, which reflects visual richness
Façade permeability	Proportion of transparent doors and windows on façade

Table. 4 Each text includes many places of interest with preference data.

Using this quantifiable measurement with Citywalk preference and built environment data, we can establish the statistical table with each selected road as the fundamental data preparation for next computation.

Step 2 Correlation analysis

In the first analysis module, we primarily address the qualitative correlation between the Citywalk preference and miscellaneous built environment indicators. Since there is no direct computation on practical meaning of the data, normalisation is employed to simplify small or large values into range [0,1] for improved calculation. The normalisation is indicated in the following fumula:

$$Value_{indicator-normalised} = \frac{Value_i - \min(Value_i)}{\max(Value_i) - \min(Value_i)} \quad (5)$$

Meanwhile, to enhance precision, we excluded abnormal high $Redu_{z-road}$ values which may be more influenced by recommendation algorithm of Xiaohongshu platform, together with those low values that include only one or two Citywalk places.

Step 3 Synthetical urban perception model

To convincingly establish prediction and route selection models from human-scale perspective, we employ a new synthetical urban perception model to address digital influence like Citywalk preference or internet-famous phenomenon on social platforms. Extended from the research framework on spatial perception based on psychological processes, this urban perception model integrates digital street perception from media platforms and practical built environment feelings (refer to **Fig. 7**), reflecting on the various indicators selected above. In addition, the potential causation from objective feelings to subjective behaviour generates a more complex issue, for which we utilise another relatively quantifiable regression method in step 4 to explain.

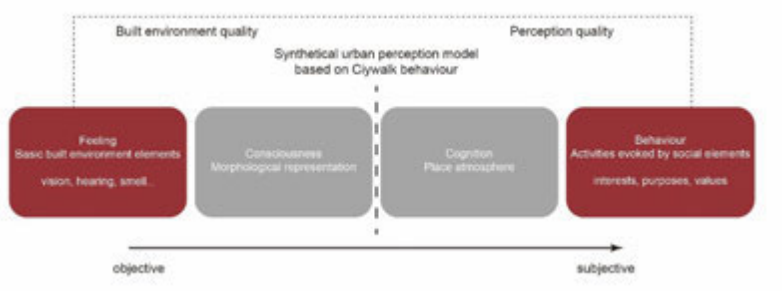


Fig. 7 Synthetical urban perception model based on Citywalk

Step 4 Regression and prediction model

To quantitatively address the relationship between built environment and Citywalk preference, this study apply multiple regression analysis, constructing an objective expression to estimate the popularity of future Citywalk routes upon the built environment data (refer to **Fig. 8**). Through this regression, other roads without current Citywalk preference may realise their potential to become lively in the next social media trend.

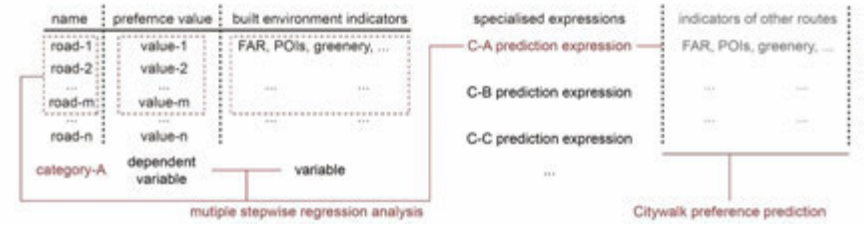

Fig. 8 Regression analysis and preference prediction of different route categories

To improve the precision of regression, we classified the selected road into three main groups through text analysis in module 1 and subsequently implemented three pertinent prediction from 'shopping districts' to 'tourist attractions' to 'historical streets', which allows for more nuanced insights into the relationship between the built environment and different Citywalk preference.

Step 5 Route selection

Route selection model is established based on regression analysis, integrating popular Citywalk destinations identified during data preparation as penetration points. Additionally, subjective manual adjustments are supplemented to connect road segments into cohesive routes in the final part.

Considering the diverse characteristics of Shanghai's political districts, we chose four central areas, with built environments similar to those of the popular Citywalk sample roads selected in data preparation, ensuring that the selected roads are not excessively repeated (refer to **Fig. 9**). Subsequently, network analysis in GIS is applied with popular Citywalk places as penetration points and three categories of Citywalk preference predictions to ascertain road throughput (shown in **Fig. 10**).

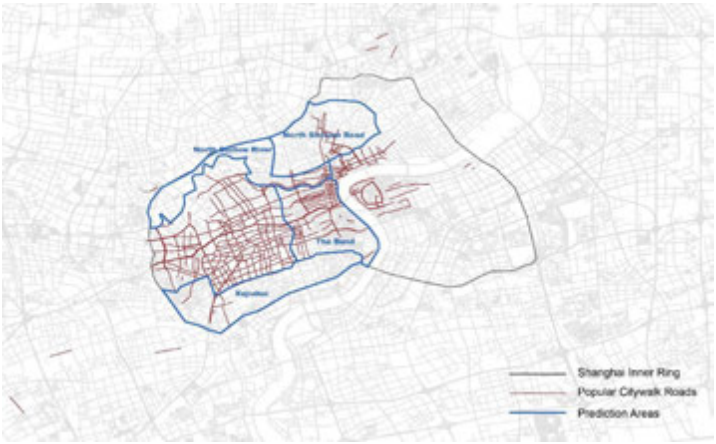

Fig. 9 Four prediction areas in contrast to popular Citywalk sample roads.

Fig. 10 Route selection framework using GIS and manual adjustment.

5 Results

In this present study, after cleaning the relevant data from Xiaohongshu platform, a total of 822 outstanding Citywalk road segments were included in the research. Following text analysis of all preferred Citywalk places, we categorized them into three groups with different themes - 'shopping districts', 'tourist attractions' and 'historical streets'. Category

'shopping districts' comprised 362 roads, featuring texts related to special shops, exquisite stores and restaurants. Category 'tourist attractions' included 350 roads, containing more texts of tourist destinations and scenic spots. Category 'historical streets' consist of 361 roads, representing streets with texts focusing on historical buildings and sites. All categories of road segments are attached with the computed built environment data, including both direct and normalised values (details refer to **Appendix Table. 1**).

5.1 Indicators Correlation analysis

Centred on the calculated Citywalk preference value as the dependent variable, we separately listed the Spearman's rank correlation for three categories of road datasets (refer to **Table. 5**). Despite the key computational indexes R^2 remaining around 0.3~0.4, which are tenable to reveal socially interactive relationships, the outcomes potentially indicate the comparative advantage of certain indicators such as Tourist attractions, Shopping places, Restaurants and Metro Stations.

Indicators (normalised)	C-shopping districts Preference R^2	C- tourist attractions Preference R^2	C- historical streets Preference R^2
Living facilities	0.142(0.007***)	0.165(0.002***)	0.153(0.004***)
Tourist attractions	0.351(0.000***)	0.313(0.000***)	0.404(0.000***)
Shopping places	0.262(0.000***)	0.259(0.000***)	0.284(0.000***)
Restaurants	0.235(0.000***)	0.209(0.000***)	0.275(0.000***)
Metro Stations	0.302(0.000***)	0.292(0.000***)	0.283(0.000***)
Bus stops	0.118(0.024**)	0.113(0.035**)	0.191(0.000***)
FAR	-0.084(0.112)	-0.079(0.141)	-0.053(0.316)
Building density	0.045(0.389)	0.088(0.101)	0.041(0.433)
motorisation ratio	-0.098(0.062*)	-0.03(0.577)	-0.042(0.425)
sidewalk ratio	0.22(0.000***)	0.292(0.000***)	0.256(0.000***)
Building ratio	-0.07(0.183)	-0.108(0.044**)	-0.126(0.017**)
Greenery	0.148(0.005***)	0.172(0.001***)	0.169(0.001***)
Sky view	-0.265(0.000***)	-0.255(0.000***)	-0.285(0.000***)
Urban furniture	-0.086(0.103)	-0.158(0.003***)	-0.147(0.005***)
Colour diversity	-0.063(0.233)	-0.074(0.171)	-0.085(0.109)
Façade permeability	0.256(0.000***)	0.318(0.000***)	0.32(0.000***)
500m_accessibility	-0.032(0.539)	-0.05(0.355)	-0.038(0.478)
300m_accessibility	-0.037(0.482)	-0.048(0.369)	-0.051(0.334)
Full_accessibility	-0.018(0.732)	-0.017(0.748)	-0.01(0.857)

Table. 5 Spearman analysis of Citywalk preference and built environment indicators.

Conclusively based on the results, Citywalk preference is partly correlated with street elements. Individuals are more likely to walk on streets with greater amenities, wider sidewalks, and more permeable façades. This further validates our findings regarding the complexity of citizens' urban perception and Citywalk preference, which are synthetically influenced by physical feelings of built environment indicators in addition to recommendations from social media platforms such as Xiaohongshu.

5.2 Regression analysis

To make predictions of Citywalk preference under different themes for the unselected roads, we employed three distinctive stepwise regression expressions, extracting the original data computed in module 1, which is imbued with practical meanings. The final prediction results should be absolute values, thus it is also essential for other indicators to be realistic values throughout the calculation process. After eliminating the irrelevant indicators through stepwise multiple regression analysis, we obtained three expressions with indexes R^2 around 0.4~0.5 (refer to **Table. 6,** the number is computed without normalisation). In the context of social-economic analysis, it attains a convincing level, particularly for predictions of potential Citywalk roads derived from computed outcomes rather than relying solely on planners' empirical intuition.

-	C-shopping districts		C- tourist attractions		C- historical streets	
Indicators (without normalisation)	Unstandardized Coefficients	R^2	Unstandardized Coefficients	R^2	Unstandardized Coefficients	R^2

Table. 6 Stepwise multiple regression analysis results from three categories of roads

5.3 Route selection

According to preference predictions computed by expressions with the given built environment indicators of each roads in the four selected regions, we subsequently employed network analysis in GIS to generate complete potential Citywalk routes.
By utilising high score Citywalk places as penetration points (shown in **Fig. 11** as red points) and Citywalk preference values of roads, we delineated suggested routes in each prediction area following a few manual adjustments (refer to **Fig. 11**), which anticipated

prospective Citywalk behaviour in next social media trends. To further validate the potential vitality of the final selected routes, we compared the data with the layer of Shanghai's daytime average Location-Based Services (LBS) data (depicted by points in **Fig. 12**). The strongly correlated results indicate that the roads outlined in red from the diagrams could indeed provide quantitative recommendations of urban renewal streets for urban planning endeavours in the future.

6 Conclusion and Disscusion

This study focuses on Citywalk, a spontaneous urban exploration behaviour significantly influenced by social media, and constructs a comprehensive framework for route research, encompassing the entire process from exploration to application.

By examining particular behaviour pattern, this research responds to the changing patterns of urban experiences and interaction modes in social media era. Additionally, the quantitative relationship between Citywalk preference and built environment elements is unveiled in our experiment, which is often neglected in previous studies. As a supplement, this study develops a walking targeted comprehensive urban perception model under the influence of social media. To validate our findings in practice, we ultimately employ a prediction model to identify potential Citywalk routes for future urban renewal endeavours.

In terms of theoretical contributions, the study extends the boundaries of existing theories of urban perception and behavioural analysis. The findings deepened understanding of the relationship between urban behaviour and built environment elements, and enriches the understanding of urban walking behaviour. From a practical perspective, this study incorporates multi-source data into the analysis, providing a new data-driven paradigm for public participation in urban planning. Meanwhile, the prediction model offers decision-making reference for urban pedestrian system renewal, providing new possibilities into digitally-driven urban planning practices.

From a technical perspective, taking Shanghai as a significant exploration case allows for the development of an analysis paradigm that can be broadly applicable to other cities globally, by collecting the local data and making route selections tailored to each city's

unique characteristics. However, we claim the limitations of the insufficiency of the quantitative indicators of online social media data, since incorporating more city samples and diversified social media platform resources may raise the coherent influence of superfluous varieties of data on the analysis and modelling, resulting in lower correlation index R^2. Additionally, extended comprehensive analysis of geographic covariance and more precise extraction of human perceptions and evaluations from social media information that we didn't pay enough attention to may enhance the accuracy of the model as well.

Abstract

The development of the concept of growth as the mainstream has led to the neglect of the shrinkage phenomenon in China. However, identifying shrinkage areas is significant for regional coordinated development and urban-rural integration. There are few studies on shrinking areas from the perspective of the spatial networks and the characteristics of towns in the urban-rural spatial networks. The study identifies shrinking towns based on traditional demographic data in the Shanghai metropolitan area, then uses massive mobile phone positioning data to build urban-rural and rural-rural population flow networks to analyze the characteristics of shrinking towns and put forward planning strategies. This study explores shrinking towns from a new perspective of spatial networks and provides references for implementing shrinking area management policies.

Keywords: Urban–rural integration; Shrinking area; Mobility network; Shanghai metropolitan area

1. Introduction

In 2019, the National Development and Reform Commission of China issued the "Key Construction Tasks of New Urbanization in 2019", which proposed for the first time "shrinking small and medium-sized cities" and required "slimming down and strengthening", guiding the concentration of population and public resources to urban areas. The task indicated that the country began to attach importance to urban shrinkage. At the same time, many studies have shown that with the implementation of China's regional integration, urban-rural integration and other policies, under the siphoning effect of central cities at all levels, many integrated development areas such as urban agglomerations and metropolitan areas in China have different degrees and types of shrinkage. Currently, most Chinese scholars pay attention to the urban shrinkage caused by long-term dependence on resource-based industries in northeast China and pay less attention to the shrinkage phenomenon in economically developed regions, such as the Yangtze River Delta and the Pearl River Delta. However, some scholars have found that in the Yangtze River Delta, the central urban areas of Shanghai, some counties and small towns of Taizhou, Yancheng, Nantong, Jiaxing, Wuxi and other cities have shown shrinkage phenomenon (Cheng et al.,

2021; Wu, Long and Yang, 2015; Lu, Xu and Zhou, 2023). Therefore, for China, the logic of urbanization dominated by the traditional growth model in long-term planning practice may no longer be applicable. China's urban development has ushered in a post-growth era.

At present, the identification of shrinking areas is mainly based on population statistics. However, no consensus has been reached on the measurement standards due to the differences in the development background and urban statistical calibre of cities in different countries. At the same time, Martinez-Fernandez (2013, p. 303-308) proposed that from the perspective of global urban networks and mobile spatial networks, shrinking cities may also be represented by the gradual weakening or even interruption of the connection with global mobility space. However, there are few relevant studies on this theoretical speculation. Compared with urban networks, there are fewer studies on the characteristics of town networks or urban-rural networks. Therefore, this study hopes to explore the characteristics of shrinking areas in metropolitan areas from the perspective of regional spatial network correlation and the agglomeration ability of town population elements.

Compared with Western countries, population loss is not significant in Chinese cities due to the continuous urbanization process. Meanwhile, urban shrinkage is not only the function of cities themselves but also the result of regional correlation and spatial correlation. Therefore, looking at shrinking cities from the phenomenon and process of element flow can more effectively judge their future trend of change. The "spatial mismatch" of elements and resources is avoided, and the development elements also have the possibility and feasibility of artificial regulation to optimize the allocation of regional resources further and promote regional coordination and urban-rural integrated development.

This study takes all towns in the Shanghai metropolitan area as the research object. The area is a relatively developed area in China with frequent connections to various economic activities and has apparent characteristics of network connections. Firstly, the traditional demographic data is used to calculate the population change of each town and make a preliminary judgment of the shrinking towns. Secondly, by using massive mobile phone data, weighted degree centrality and connection strength, the urban-rural and rural-rural population mobility networks in the Shanghai metropolitan area are constructed, the spatial network characteristics of each shrinking town are extracted, and the spatial connection relationship with different cities and towns is explored. By comparing the spatial location and connection of nodes and the function, the research evaluates the characteristic types of shrinking towns from the perspective of the network, analyzes their main influencing factors, and puts forward optimization strategies. This paper attempts to analyze the characteristics of shrinking areas from a new perspective of population flow networks and provides a new experience for promoting China's coordinated regional development, urban-rural integration and implementing shrinking area management policies.

2. literature review

Although there have been abundant research results on shrinking cities, involving many

disciplines such as economics, geography and urban and rural planning, there is no consensus on the population base, changing years and total scale of shrinking cities due to the differences in the development background and urban statistical standards of different countries. The definition of a shrinking city mainly involves population, economy and time. Even though the definition of the Shrinking City International Research Network(SCIRN) has a high degree of acceptance, there are still many ambiguities, such as the inconsistency of the "city" scope, which makes it impossible to determine a clear statistical range. At the same time, the decrease in population is the concept of a period. If the change in population in a specific period is measured in another period, the conclusion may not be consistent (Wu and Qi, 2021). Although the discussion on shrinking cities in China is on the rise, due to the focus on the "reference" of shrinking cities and its theoretical analysis framework in other countries, the discussion on "Chinazation" is relatively lacking. At present, the concept of shrinking focuses on describing phenomena and ignores the relationship between element and function development (Sun, 2022). Therefore, the current definition of "shrinking city" based on a variety of factors is diversified, and it is difficult to determine a unified judgment standard for shrinking city.

At present, the identification methods of shrinking cities are mainly based on static data analysis and the need for dynamic analysis from the perspective of network connection and essential feature analysis based on the outflow of development factors. The current identification of shrinking cities is mostly from the population perspective, combining statistical and spatial data to build a multidimensional index system. Meanwhile, with the progress of technology, the model simulation method has gradually emerged (Liu, 2016). The measurement and identification units are mainly prefecture-level cities, and the identification studies of counties and towns as the units are gradually increasing.

At the same time, some scholars have proposed that from the perspective of the global urban network and mobile space network, shrinking cities may also be represented by the gradual weakening or even interruption of connections with global mobile space (especially knowledge flow and information flow) (Martinez-Fernandez, 2013, p. 303-308). Inequality is increasing between cities and regions integrated into global networks and those that are not (Allen and Storper, 2003). Shunned by the global network, shrinking cities will enter the black hole of globalization proposed by Castell (1989), so shrinking cities can also be considered in terms of their association with the urban element network, areas with weak or broken connections to the rest of the region can be explored to identify cities with shrinking trends.

Currently, relevant studies on shrinking cities still focus on describing the phenomena. However, with the continuous advancement of economic globalization and regional integration, the traditional "place economy" based on comparative advantages of resource endowment has been gradually replaced by the "mobile economy" centred on capital, technology, market and innovation, and flow space has become the mainstream of The Times (Shen and Gu, 2009). At present, some scholars in economics use total factor productivity combined with econometric methods as the basis for judging contraction or growth (Yang,

Wang and Tao, 2022). Wu and Yao (2021) utilized a unique dataset on intercity investment flows in mainland China to verify that centrality in the investment network is significantly positively correlated with urban population changes. They explored the relationship between shrinking cities and the loss of external investments. Sun (2022) proposed that urban shrinkage is a market behaviour in which the development elements mainly represented by population make "re-location" due to the relative or absolute decline of urban "agglomeration ability of regional development elements" in regional correlation. Population outflow is only a phenomenon, and urban shrinkage can be resolved from the perspective of element flow. With the proposal of the theory of flow space, the research on spatial network has been deepened, and the progress of information technology enables the big data generated by mobile phone signaling and Internet App to identify the flow of various elements. The algorithm is relatively mature and has been widely used in the research reflecting the spatial structure of urban agglomerations and metropolitan areas (Wang et al., 2022). It makes the measurement method of element flow mature gradually and provides the possibility to analyze the contraction area from the perspective of element flow.

3. Methodology and data

3.1 Research area and data source

The Shanghai metropolitan area, located in eastern China, is a vital component of the Yangtze River Delta. In 2022, the governments of Shanghai, Jiangsu Province, and Zhejiang Province issued the "Spatial Coordination Plan for the Shanghai Metropolitan Area," aiming to deepen the implementation of the national strategy for integrated development of the Yangtze River Delta. The planned scope includes the administrative regions of "1+8" cities such as Shanghai, Wuxi, Changzhou, Suzhou, Nantong, Ningbo, Huzhou, Jiaxing, and Zhoushan. The Shanghai metropolitan area exhibits diverse population agglomerations. As the leading area with the most concentrated functions in the Yangtze River Delta urban agglomeration, it experiences a highly concentrated and rapidly developing economy. It features multiple interconnected centres with closely associated networked relationships and demand for close cooperation, driving the coordinated development of various regions. Therefore, urban-rural integration development is also essential to the Shanghai metropolitan area. This study takes the Shanghai metropolitan area as the research area, dividing nine cities into 913 street (town) level administrative divisions. According to the "Statistical Compilation Rules for Administrative Division Codes and Urban-Rural Division Codes" (index no. 410A03-1201-201708-0006) from the National Bureau of Statistics in China, the urban-rural attributes of each street (town) level administrative division are classified based on the first digit of their urban-rural classification code: 1 represents urban, and 2 represents rural. A total of 428 urban streets and 484 rural towns were identified, with all towns within the Shanghai metropolitan area being the subjects of this study, as shown in **Figure 1**.

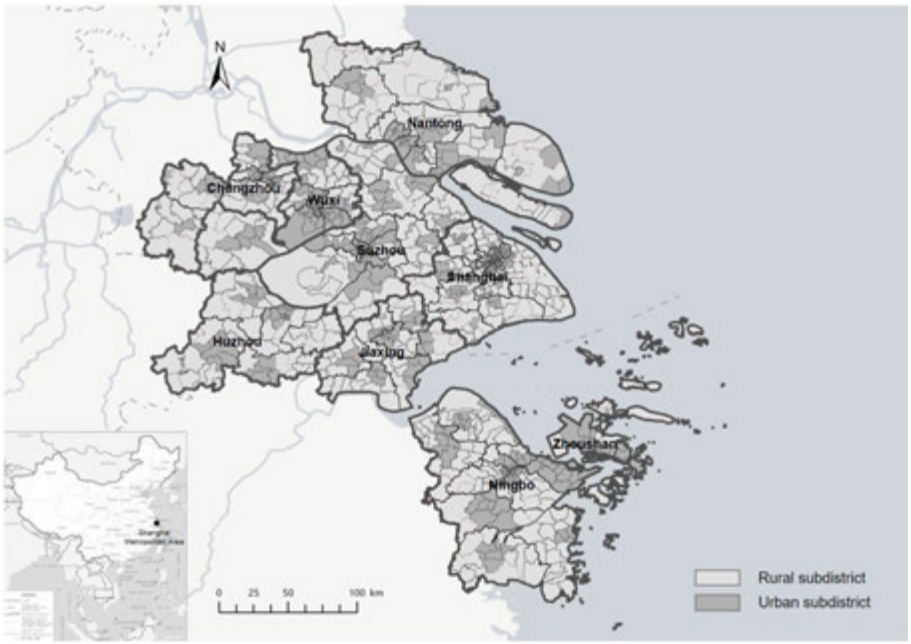

Figure 1. Location and urban-rural classification layouts of Shanghai Metropolitan Area

This study primarily employed statistical data and Baidu LBS (Location-Based Service) data. The population statistics data were sourced from the sixth national census of China in 2010 and the seventh national census in 2020, representing the resident population of each street and town. The LBS data consisted of Origin-Destination (OD) travel data for working days in September 2021. It utilized station grids to locate user travel, determining residential and workplace locations by statistically analyzing users' most extended daytime and nighttime stays. This encompassed home-based work trips, home-based other trips, and non-home-based trips. The population flow statistics for this study included all trip purposes.

3.2 Research approach and methodology

3.2.1 Research approach

In contrast to traditional studies that investigate the characteristics of shrinking areas solely based on statistical data, this study aims to explore the features of shrinking areas within the metropolitan area from the perspective of regional spatial network correlations and the clustering capacity of town population element. Therefore, this paper, departing from the traditional criterion of population quantity changes, first identifies shrinking areas with significant population decrease characteristics by calculating population growth rates. Secondly, based on big data on population mobility, population flow networks within the

Shanghai metropolitan area are constructed, examining the characteristics of shrinking towns in the network from both urban-rural and rural-rural population flow network perspectives. This can respectively characterize the connections between shrinking towns and urban streets or surrounding towns and, to some extent, reflect the clustering capacity of shrinking towns for population development elements in a relatively timely manner. This holds significant implications for the urban-rural integration and coordinated development within the Shanghai metropolitan area.

3.2.2 Identification of shrinking areas

Although the phenomenon of population shrinkage has garnered attention from numerous scholars, there still needs to be a consensus in the academic community regarding methods for identifying population shrinkage. Nonetheless, negative population growth remains a crucial criterion. The continuous development of urbanization in China has led to a sustained decrease in rural population. The Yangtze River Delta region, where the Shanghai metropolitan area is located, is an economically developed area in China with a high capacity for population aggregation. Its urbanization development process differs somewhat from the overall process in China. Therefore, considering the influence of the urbanization process, this study adopts the methodology referenced from relevant research (Wang and Xue, 2016; Cheng, Zhang and Liu, 2021). Firstly, the average annual population growth rate of towns in the Yangtze River Delta region (comprising three provinces and one municipality) from 2010 to 2020 is calculated. Then, the average annual population growth rate of each town within the Shanghai metropolitan area is calculated over the same ten-year period, subtracting the average annual population growth rate of townships in the Yangtze River Delta region from it, with an adjustment of -1.4%. This adjustment accounts for the difference in the urbanization process. The resulting relative population growth rate of towns, after excluding the influence of urbanization in the Yangtze River Delta, is used to define towns with a negative relative population growth rate as population shrinkage areas.

3.2.3 Analysis of population flow networks

Based on Baidu LBS data, this study calculates the total volume of bidirectional purposeful trips between streets and towns as the strength of network connections. Subsequently, an undirected weighted network is constructed. Network centrality is then analyzed, with methods referenced from relevant research (Xie, Zhen and Xi, 2022). To mitigate the impact of significant differences in the area between streets and towns, network centrality is calculated as the sum of the network connection strengths between each street or town and other streets or towns, normalized by the unit area of each street or town. Exploratory spatial data analysis is conducted using GIS platforms, employing natural break methods to visualize the spatial distribution characteristics of network centrality and network connection strengths. The network connection strengths and weighted centrality are calculated and ranked for the 484 towns at both urban-rural and rural-rural levels, with visual representations to explore the characteristics of each town within the urban-rural network.

4. Results and discussion

4.1 Characteristics of shrinking areas based on population changes

Based on the calculation of the relative population growth rates of towns after excluding the influence of urbanization in the Yangtze River Delta, there are a total of 85 shrinking towns with negative population growth in the Shanghai metropolitan area. These shrinking towns are visualized in GIS, as shown in **Figure 2**. Among the nine cities, Shanghai and Nantong have

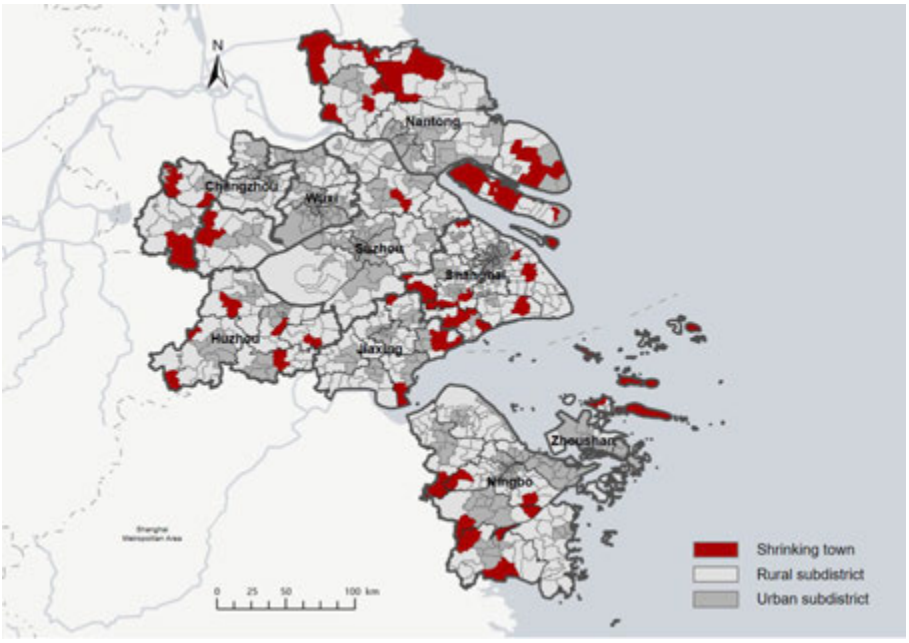

Figure 2. Location and urban-rural classification layouts of Shanghai Metropolitan Area

the highest number of shrinking townships, with 23 and 20, respectively. Suzhou and Wuxi have fewer shrinking towns, with 1 and 2, respectively. Among the other five cities, Zhoushan has 12 shrinking towns, Ningbo has 10, Huzhou has 8, Jiaxing has 5, and Changzhou has 4.

From the overall spatial distribution characteristics, the towns in the Shanghai metropolitan area exhibit localized shrinkage phenomena, which are relatively concentrated or extended. They are primarily concentrated in the peripheral areas of the metropolitan area and at the boundaries between cities. For instance, the shrinking towns in Nantong, Ningbo, and Changzhou are mainly located in the peripheral border areas of the cities, where town development is significantly influenced by geographical location. Meanwhile, the shrinking towns in Jiaxing and Shanghai are mainly situated at the boundaries between the two cities, where the population is notably affected by the central urban area's suction effect. Some shrinking towns in Zhoushan and Shanghai are located on coastal islands and bear more ecological protection tasks, which also have specific impacts on population changes.

4.2 Characteristics of population flow network

4.2.1 Characteristics of urban-rural population flow network

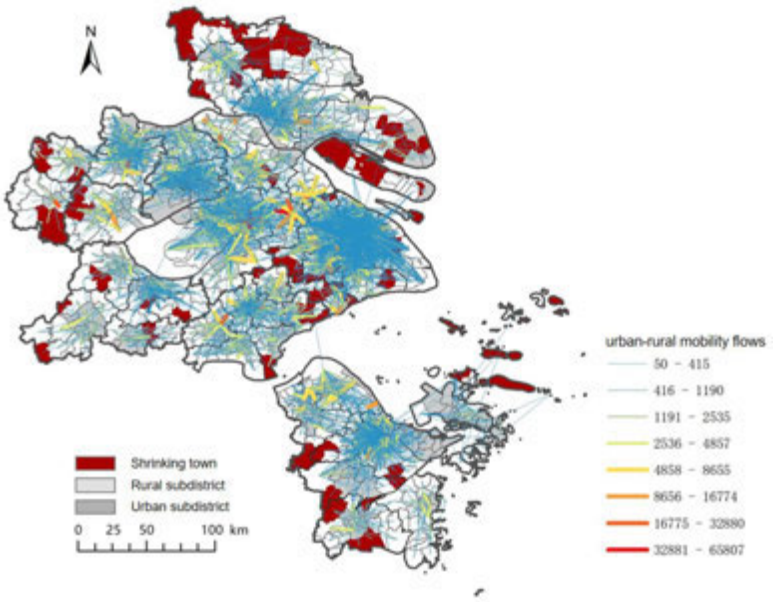
Through analysis of the urban-rural population flow network, using the natural break method in the GIS platform, the connectivity strength and weighted centrality of each town are classified, visually analyzed, and ranked, and relevant information about the shrinking towns mentioned earlier is filtered out.

The spatial characteristics of urban-rural population connectivity strength in the Shanghai metropolitan area are illustrated in **Figure 3(a)**. Overall, Shanghai and Suzhou exhibit relatively frequent urban-rural population connections, with higher connectivity strength within each county (district) and fewer connections across districts or cities. Only some areas have surpassed the constraints of administrative barriers, such as the central urban area of Shanghai with its internal towns and the border towns between Suzhou and Shanghai. However, these connections have limited flow distances, which are associated with the geographical locations of towns and the strong suction effect of Shanghai's central urban area. This indicates significant room for improvement in the urban-rural integration and development of the Shanghai metropolitan area.

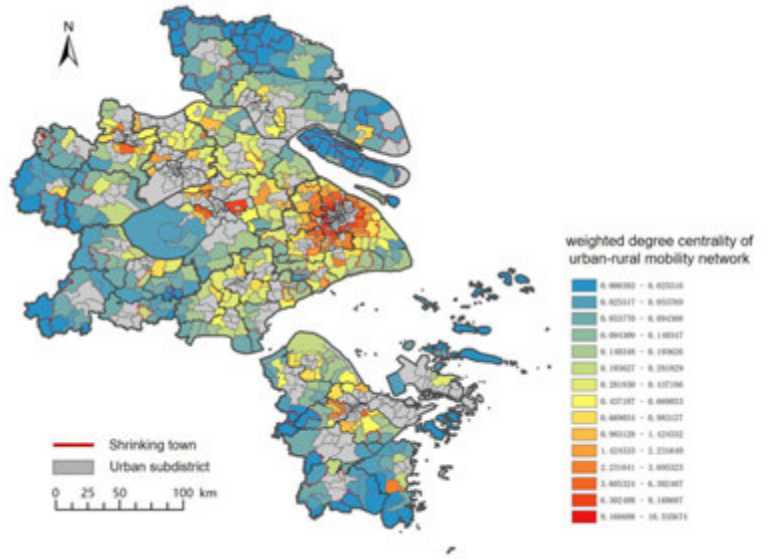
From the perspective of shrinking towns, most of them have low connectivity strength with

urban streets. Only some shrinking towns in Shanghai and Suzhou have strong connections

with urban areas. Examples include Jinqiao Town and Chuansha New Town in Pudong



(a)



(b)

Figure 3. Characteristics of urban - rural population flow network in shrinking towns of Shanghai metropolitan area: (a) intensity of urban - rural population connection, (b) weighted degree centrality of urban-rural mobility network

District of Shanghai and Chedun Town in Songjiang District. These towns have experienced significant population relocation due to the development of large-scale service projects or industrial parks, leading to a substantial decrease in population. However, their economic development remains robust, indicating that they are not in a state of shrinkage. This underscores the limitations of using population decline alone as a criterion for identifying shrinking areas. Additionally, the weak connections between most shrinking towns and cities indicate their marginal status in the process of urban-rural integration and metropolitan area coordinated development.

The centrality distribution characteristics of the urban-rural population flow network are shown in **Figure 3(b)**. Overall, the towns with higher centrality levels within the Shanghai metropolitan area are mainly distributed around the urban areas, closely related to geographical location. For example, there are a large number of medium to high-level towns in Shanghai, distributed in concentric circles around the central urban area. Compared to other cities, Suzhou and Jiaxing, which are adjacent to Shanghai, have more medium to high-level towns, indicating a higher degree of integration between urban and rural areas.

From the perspective of shrinking towns, extracting the centrality rankings of each shrinking town reveals that half of the shrinking towns are ranked at the bottom of all towns in terms of centrality level. Examples include all shrinking towns in the Chongming District of Shanghai, most shrinking towns in Nantong, and the most shrinking towns in Zhoushan, generally located in the peripheral areas of the Shanghai metropolitan area or have implemented related ecological conservation measures.Shrinking towns located between Shanghai and Jiaxing generally have higher centrality levels than other towns, reflecting the driving role of the central urban area of Shanghai on the surrounding towns.

Comparing the centrality levels of shrinking towns within each city, towns like Jinqiao, Chedun, and Chuansha in Shanghai, Guli in Suzhou, Lintuo in Jiaxing, Daochang and Qianyuan in Huzhou, and Putuoshan in Zhoushan, are significantly higher than other shrinking towns in the same city. Investigations into the specific development situations of each town indicate that significant factors influencing development include the development of tourism industry brought by large scenic spots, industrial development brought by industrial parks, and geographical advantages adjacent to central urban areas, all of which contribute to the frequent population flow between urban and rural areas.

Overall, most of the shrinking towns identified based on population changes are positioned relatively low in terms of both connectivity strength and centrality within the urban-rural population flow network compared to all towns. They exhibit a notable "depression" phenomenon in the network, indicating lower frequencies of urban-rural population flow, which is unfavorable for urban-rural integration and regional coordinated development. However, the central urban area of Shanghai gradually exhibits a diffusion trend starting from the aggregation of population elements, influencing nearby cities and towns, thus maintaining a certain level of population flow and aggregation capacity at the urban periphery where shrinking towns are located. At the same time, a small number of shrinking towns still hold

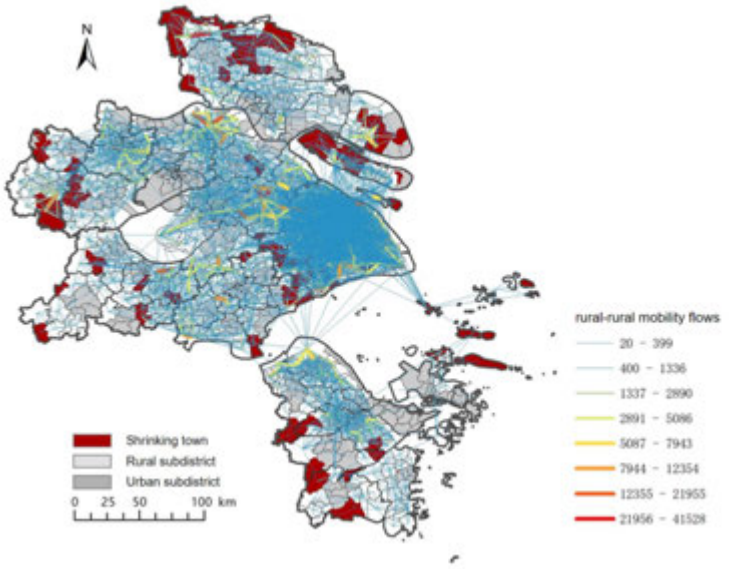
relatively high positions in the network, mainly influenced by factors such as town construction and geographical location, demonstrating higher population aggregation capacity. This also indicates the limitations of identifying shrinking areas based solely on population statistics standards.

4.2.2 Characteristics of the rural-rural population flow network

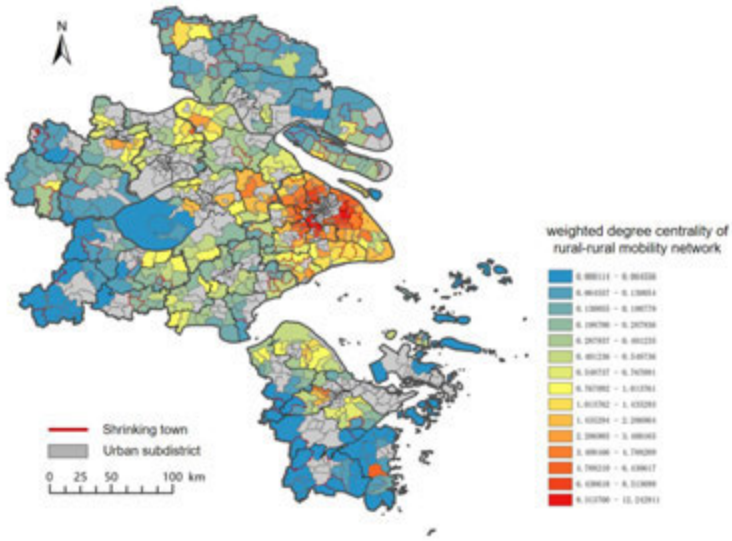
Following the same analytical process as the urban-rural population flow network, the spatial characteristics of rural-rural population connectivity strength within the Shanghai metropolitan area are illustrated in **Figure 4(a)**. Regions with higher rural-rural connectivity strength remain concentrated in Shanghai and Suzhou. While population movement predominantly occurs within each district or county, there is also a notable amount of inter-district flow, with administrative barriers exerting less restriction compared to urban-rural population movement, and longer distances of population flow.

Regarding shrinking towns, certain ones in Shanghai, Nantong, and Changzhou exhibit stronger population connections with other towns. Examples include Fengcheng Town in Shanghai, Tianmu Lake Town in Changzhou, and Huiping Town in Nantong. Fengcheng Town houses an economical park, Tianmu Lake Town incorporates the Tianmu Lake tourist resort, and Huiping Town serves as a significant centre for industry and agriculture. These towns have experienced population relocation due to ecological conservation or industrial park construction, but their industrial development has also stimulated surrounding areas, strengthening population connections between towns. For the majority of shrinking towns, the population connectivity strength with other towns is lower. Examples include shrinking towns in Ningbo, Zhoushan, and Huzhou, as well as shrinking towns at the border between Jiaxing and Shanghai. These towns are primarily influenced by geographical location, and the lower inter-town population connectivity strength within their respective cities indicates limited economic activity between towns.

The centrality distribution characteristics of the rural-rural population flow network are depicted in **Figure 4(b)**. Towns with higher centrality levels are primarily located in Shanghai and Suzhou, with notable centrality levels also observed in the eastern parts of Wuxi and Changzhou, as well as in Jiaxing and the northern parts of Ningbo. This clearly illustrates the frequent population activity radiating from Shanghai, influencing surrounding towns.



(a)



(b)

Figure 4. Characteristics of rural - rural population flow network in shrinking towns of Shanghai metropolitan area: (a) intensity of rural - rural population connection, (b) weighted degree centrality of rural-rural mobility network

Extracting relevant information on centrality from shrinking towns and ranking them, there are 26 shrinking towns ranked beyond the 400th position, compared to 45 in the urban-rural

population flow network, indicating that shrinking towns, on the whole, experience more frequent population movement than urban streets when compared to other towns. There are a total of 58 shrinking towns ranked beyond the 300th position, indicating that, overall, shrinking towns still occupy lower positions in centrality within the rural-rural population flow network, exerting some inhibitory effect on regional coordination.

Among these, shrinking towns located in the peripheral areas of Ningbo, Changzhou, Huzhou, Wuxi, and Zhoushan all exhibit the lowest centrality levels, indicating lower population aggregation capacity. Shrinking towns situated at city boundaries, such as those between Shanghai and Jiaxing, Shanghai and Suzhou, and Jiaxing and Huzhou, have relatively higher centrality levels, reflecting the radiating influence of central cities like Shanghai and Suzhou.Furthermore, compared to the centrality in the urban-rural population flow network, the centrality levels of shrinking towns in Nantong and Chongming District of Shanghai are relatively higher in the rural-rural population flow network, suggesting lesser functional connections with urban streets but more significant potential for coordinated development with surrounding towns.

Overall, most shrinking towns exhibit weak population aggregation capacity, low centrality, and connectivity strength within the rural-rural population flow network. This is likely to negatively impact the coordinated development of surrounding towns and hinder the smooth flow of population elements within the region. Simultaneously, some towns hold lower positions in urban-rural networks, yet they experience a specific elevation in their positions within the rural-rural network. This indicates their clustered development with surrounding towns. Shrinking towns located in cities like Shanghai demonstrate higher network characteristics, which correlate closely with their industrial development and geographical location.

4.3 Classification and influencing factors of shrinking towns

Above, Based on population changes, shrinking towns in the Shanghai metropolitan area were identified and characterized from both urban-rural and rural-rural population flow network perspectives, providing a dynamic reflection of their population aggregation capacity. Overall, combining with the analysis content of the three parts, the shrinking towns can be roughly divided into four types, and have different influencing factors.

The first type of shrinking towns, both in the urban-rural and rural-rural population flow networks, exhibit high levels of connectivity, with frequent population interactions with urban streets and other towns, showcasing strong population aggregation capabilities. These towns are predominantly located in Shanghai, such as Chuansha New Town, Jinqiao Town, Chedun Town, Tinglin Town, Caojing Town, and Dushangang Town in Jiaxing. The primary influencing factors for these towns include: 1. Prime Geographical Location: Benefiting from their strategic geographical positioning and the radiating influence of the central urban area of Shanghai, these towns maintain active population interactions and functional connections with surrounding areas. 2. Development of Tourism Areas or Economic Industrial Parks: The

presence of developed tourism areas or economic industrial parks in these towns drives frequent population movements and functional connections. For instance, Chuansha New Town's Disneyland, despite causing population relocations, has spurred rapid economic growth, while Jinqiao Town's proximity to the Shanghai Zhangjiang Hi-Tech Park has facilitated functional connections in the surrounding areas. Although these types of shrinking towns may experience a decline in permanent population numbers, they still possess significant population aggregation capabilities and hold potential for development.

The second type of shrinking towns exhibit high levels of connectivity in the urban-rural population flow network but lower levels in the rural-rural population flow network. Examples include Guli Town in Suzhou, Qianyuan Town in Huzhou, and Putuoshan Town in Zhoushan. These towns have close functional connections with urban streets but interact less with surrounding towns. The primary influencing factors for these towns include: 1. Proximity to Urban Streets: Being adjacent to urban areas and within the radiating range of cities, these towns have close population connections with urban areas, such as Qianyuan Town. 2. National Scenic Spots: Some of these towns are renowned for their national scenic spots, such as Guli Town, a famous ancient town in Suzhou, and Putuoshan Town, which attracts a large number of tourists due to the Putuoshan scenic area. As a result, these towns have close transportation links with urban areas. These types of towns maintain a stable level of economic development due to their inherent resource endowments. Changes in the permanent population numbers may not accurately reflect their current situation.

The third type of shrinking towns exhibit lower levels of connectivity in the urban-rural population flow network but relatively higher levels in the rural-rural population flow network, with frequent population interactions with surrounding towns. Examples include Luxiang Town, Langxia Town, Fengcheng Town, and Jianshe Town in Shanghai, as well as Tianmu Lake Town in Changzhou. The main influencing factors for these towns with high connectivity to surrounding towns include: 1. Service Function for Surrounding Areas: Some towns serve as functional hubs for surrounding areas, such as Fengcheng Town's bus station acting as a transportation hub for the surrounding region, providing service functions for external connectivity. 2. Interlinked Industrial Development: Towns like Luxiang Town, with its carpet industry, Langxia Town, with mushroom cultivation, and Tianmu Lake Town, primarily focused on tourism engage in synergistic cooperation and development with surrounding towns. These shrinking towns possess a certain development foundation and collaborate with neighbouring towns in a cluster-based development model. However, they may also experience population loss due to insufficient developmental momentum.

The fourth type of shrinking towns exhibits low levels of connectivity in both the urban-rural and rural-rural population flow networks, a characteristic shared by most shrinking towns. These towns demonstrate a noticeable "depression" phenomenon in the regional spatial network, with insufficient population aggregation capabilities hindering the smooth flow of population elements within the region. The primary influencing factors include: 1. Geographical Location: Most of these towns are situated on the periphery of the metropolitan

area, experiencing significant population outflow due to the suction effect of central cities. Additionally, transportation conditions in some areas, such as the reliance on waterways for transportation in towns in Zhoushan, are also hindering population mobility, heavily influenced by external conditions. 2. Lack of Key Industries: The absence of critical industries and lagging economic development result in labor outflow and a lack of inherent population aggregation capabilities. 3. Implementation of Ecological Protection Policies: The implementation of ecological protection policies restricts regional development, leading to population outflow. Overall, these types of towns lack vitality in regional development and have limited functional connections with surrounding areas. Under the processes of urbanization and development of central cities, they may continue to shrink in the future.

4.4 Development advice for shrinking towns

Based on the overall characteristics and types of shrinking towns, and in conjunction with the existing planning in the Shanghai metropolitan area, this study proposes the following recommendations:

1. Attention to Shrinking Areas in Metropolitan Area Coordination: Given the current development context, shrinking areas should be given attention in the coordinated development of metropolitan areas. Current domestic planning primarily focuses on the development of central areas, overlooking regions with relatively lower overall development levels. These areas often create structural "depressions" in the regional coordination network, hindering the free flow of various elements within the region and adversely affecting urban-rural integration. Furthermore, while using population quantity as a criterion for identifying shrinking areas has its limitations, it can preliminarily screen out areas with shrinking trends. Thus, a deeper assessment of shrinking areas should integrate the aggregation capacity of development elements.

2. Breaking Administrative Boundary Constraints: Fragmented administrative boundaries pose obstacles to coordinated planning by impeding the free flow of elements. Most population movements, whether urban-rural or rural-rural, predominantly occur within cities or even within districts and counties. The fragmentation of administrative jurisdictions poses certain obstacles to coordinated planning. Currently, local governments provide corresponding public service facilities based on administrative boundaries, resulting in weak and poorly connected public service facilities in border areas, hindering the cross-border flow of population elements.

3. Development Strategies for Shrinking Towns: Effective strategies should be formulated to drive regional coordinated development based on the characteristics represented by the aggregation capacity of the shrinking towns. Different response strategies should be adopted for each type of shrinking town:

- For the first type of shrinking town, which still retains high aggregation capacity, exclusionary strategies should be implemented. Despite a decrease in population, these towns still possess significant development potential.
- For the second type, existing advantages such as location should be prioritized to promote complementary urban-rural functions, drive the flow of urban-rural elements, fully utilize existing regional advantages, and achieve differentiated urban-rural development.
- The third type, characterized by solid linkage with surrounding towns, should initially adopt cluster development models to achieve functional complementarity with surrounding towns. Leveraging their own industrial advantages, active promotion of cluster development should be pursued, along with strengthening transportation links and industrial cooperation with urban areas to promote urban-rural integration.
- For the fourth type, which is more common, efforts should focus on strengthening infrastructure such as transportation to enhance connections with surrounding areas. Towns under ecological policy protection can consider developing tourism or agriculture under permitted conditions. Towns without pillar industries should actively seek coordinated development with surrounding areas. Aging or severely hollowed-out towns could consider moderate village integration and relocation in line with current development trends.

5. Conclusions

Under the national development strategy of fostering urban agglomeration and metropolitan areas, coordinated development and urban-rural integration have always been topics of concern. This research, based on traditional population data analysis, initially identifies shrinking areas. Leveraging big data technology and network analysis methods, constructing urban-rural and inter-town population flow networks within the Shanghai metropolitan area to deeply analyze the network characteristics of shrinking towns, revealing the following main findings:

1. Based on the traditional population data analysis, the towns in the Shanghai metropolitan area show a phenomenon of local contraction of relatively clustered or extended branches, mainly concentrated in the peripheral areas of the metropolitan area and the border areas between cities. Cities with a large number of shrinking towns include Nantong, Shangha, Zhoushan, Ningbo, etc.

2. Most of the shrinking towns identified based on population change are at a lower level in the rural-urban population flow network. A few shrinking towns still have a higher level in the network under the radiation of Shanghai and other central cities, which are mainly affected by town construction and, geographical location and other factors, and have a higher population gathering ability.

3. Most of the shrinking towns have weak population gathering ability in the rural-rural population flow network, which will adversely affect the coordinated development of surrounding towns and hinder the smooth flow of population elements within the region.

Some towns have a lower status in the urban-rural network. However, their position in the rural-rural network has been improved to a certain extent, indicating the different development modes from the surrounding towns.

4. Based on the characteristics of the network, the shrinking towns can be divided into four types according to different energy levels, and the influencing factors of the four types of shrinking towns are different. The towns with higher energy levels in the urban-rural and rural-rural population flow network should be considered excluded from the shrinking towns, which are mainly concentrated in Shanghai. Different development strategies should be adopted for the other three types of towns. In general, the shrinking towns from the perspective of the network are mainly concentrated in Nantong, Zhoushan, and Ningbo. Due to its strong radiation effect, the inner towns of Shanghai still have a high factor agglomeration ability.

Through the refined analysis of population flow at the street and town scale, this study finds the limitations of judging shrinking areas by population change as the standard and analyzes shrinking areas from the perspective of regional correlation, which can essentially judge their future development trend. In addition, the theory to view shrinking areas from the perspective of urban network and mobile spatial network is preliminatively verified. Most shrinking areas are indeed weakened or even interrupted in the network connection with surrounding areas. By identifying the shrinking areas from the perspective of element flow and differentiating the types simultaneously, we can better judge their development direction and formulate strategies through human manipulation, which will also provide a clearer optimization direction for the coordinated development and urban-rural integration of the Shanghai metropolitan area.

At the same time, this study still has some things that could be improved due to the limitations of time, data and other factors. First, the purpose of LBS data has yet to be fully mined to distinguish the differential characteristics of commuter and non-commuter flow. Secondly, an in-depth coupling analysis of the related factors, such as traffic conditions and economic industries, needs to be conducted. These are the directions that need further research in the future.

Biographical notes

Dr. Fabio Bayro Kaiser is a research associate at the Institute of Urban Design, Faculty of Architecture, RWTH Aachen University, Germany. His research focuses on understanding urban transformations through spatial analysis, while his teaching focuses on urban design and planning. Previously, he worked as a research associate at the Faculty of Spatial Planning, TU Dortmund, Germany, and was a partner in the architecture and planning office M.Kaiser in Tarija, Bolivia.

Prof. Christa Reicher is head of the Chair for Urban Design, the UNESCO Chair for Cultural Heritage and Urbanism, and the Institute for Urban Design and European Urbanism at the Faculty of Architecture, RWTH Aachen University, Aachen, Germany. Previously, she was Professor of Urban Design and Land Use Planning at the Faculty of Spatial Planning at the TU Dortmund University and Professor of Urban Design at the Bochum University of Applied Sciences. Christa Reicher founded the architecture and urban planning firm RHA REICHER HAASE in Aachen and Dortmund.

Esther Padberg is a research assistant at the Institute of Urban Design, Faculty of Architecture, RWTH Aachen University, Germany. Her research at the Institute of Urban Design focuses on the development and active shaping of the M.Sc. Transforming City Regions programme, in which she is currently enrolled. Previously, she completed her Bachelor's degree in Applied Geography with a focus on urban planning and geohazards at RWTH Aachen University. She is currently working on her Master's thesis with a focus on large housing estates.

Sebastian Beisel is a research assistant at the Institute of Urban Design, Faculty of Architecture, RWTH Aachen University, Germany. His research focuses on the further development of the Master's programme Transforming City Regions as well as the exploration of data-driven methods in urban design. Sebastian holds a Bachelor's degree in Architecture and a degree in International Business. He is currently pursuing a Master's degree where his research focuses on improving housing affordability and optimising resource use in the built environment.

Abstract
This paper examines the implementation of a co-design approach in planning education, focusing on the M.Sc. Transforming City Regions (TCR) programme at RWTH Aachen University. Through workshops and interviews with focus groups, it explores how diverse students' expectations are aligned with institutional teaching and learning objectives and how interdisciplinary knowledge is effectively integrated into the curriculum. It describes and analyses the outcomes of these workshops and offers empirical insights that shed light on the future trajectory of interdisciplinary planning education and the challenges it faces. On this basis, the paper argues that fostering collaboration and feedback responsiveness facilitates continuous improvement in preparing students for the challenges of contemporary urban transformations.

Keywords
Transforming City Regions; Collaborative; Interdisciplinary; Integrative Urban Planning; European Education Pathways

1. Introduction

Contemporary urban development has reached an unprecedented scale and speed, posing profound global environmental and social challenges. Housing shortages, inadequate service provision, strained social infrastructure, and increased vulnerability to natural hazards and climate change are now pressing issues city regions face. Beyond the urban fabric, accelerated urbanisation contributes to biodiversity loss, land degradation and the need to transition away from fossil fuels worldwide. Balancing the demands of urban growth with environmental and social sustainability is, therefore, a critical imperative, requiring innovative and integrated urban planning and design approaches and pedagogies for the city regions of the future.

These challenges are also evident in the European context, as urbanisation continuously reshapes the European territory. On the one hand, the territory is undergoing significant changes from the dense urban cores of major metropolises to the sprawling suburbs and rural-urban fringes. On the other hand, the European dimension adds evolving layers of complexity as cities across the continent grapple with unique historical, cultural, and institutional contexts. This transformation requires a nuanced understanding of urban dynamics and sustainable development strategies tailored to Europe's diverse landscapes and communities.

In response to such social and spatial challenges, higher education institutions have a key role to play in educating capable young professionals who bring fresh ideas and approaches to address new challenges. As urbanisation accelerates and cities evolve, there is a growing need for skilled urban planners and designers who can navigate complex urban landscapes while integrating sustainability principles into their work. It is imperative that educational programmes equip students with the knowledge, skills, and interdisciplinary perspectives needed to address the multifaceted issues of contemporary urban development.

Against this background, the Institute for Urban Design and European Urbanism, part of the Faculty of Architecture at RWTH Aachen University (RWTH), introduced the master's degree Transforming City Regions (TCR) in October 2019 (TCR 2024). TCR is an innovative degree that consistently integrates different disciplines and planning methodologies to address European regions' complex challenges. Its core premise is rooted in the recognition of the growing territorial complexity and the interplay of structural and substantive priorities with foundations from different disciplines, underlying the need for integrative and conceptual thinking. Emphasising a project-based educational model, TCR not only provides graduates with up-to-date and in-depth knowledge, but also equips them with the tools and methods essential for tackling pressing issues in Europe's developing city regions.

Since its inception and launch, TCR has been committed to the continuous improvement of its teaching content, with a particular focus on internationalisation, interdisciplinarity, and sustainability. In pursuing this commitment, TCR has integrated key principles of RWTH's mission statement on teaching and learning. This approach emphasises, among other things, the recognition of students' diverse backgrounds and needs, the stimulation of research-led and practice-oriented teaching, and the promotion of student and staff mobility (RWTH 2023). In addition, TCR has joined the European Education Pathways exchange programme through the ENHANCE Alliance. This alliance comprises ten leading European universities that are pioneering a common curriculum for various pilot study programmes (ENHANCE 2023). This strategic involvement underlines TCR's commitment to promoting collaborative educational initiatives at an international level.

However, aligning students' expectations from diverse backgrounds with institutional teaching and learning objectives and integrating interdisciplinary knowledge into a well-defined curriculum framework is a multifaceted challenge. Therefore, this paper proposes a co-design approach to update and develop urban planning and design education curricula continuously. The co-design approach consists of three types of workshop formats. Firstly, feedback workshops were held with alumni and enrolled students to gather their experiences with specific and general teaching and learning objectives and the associated module workload. Secondly, semi-structured interviews were conducted with graduates to understand and compare their expectations before starting their studies with their achievements after graduation, i.e. learning outcomes. Thirdly, workshops were convened with the core teaching group to refine the specific and general learning and teaching objectives, revise the description of the graduate profile, and improve the links between modules. This paper describes and analyses the outcomes of these workshops and offers empirical insights that shed light on the future trajectory of interdisciplinary urban planning education and the challenges it faces.

2. Transforming City Regions

2.1 Curriculum framework

TCR’s curriculum framework comprises core courses, compulsory electives courses, and a range of electives courses. This provides a comprehensive curriculum covering theoretical, practical, methodological, and empirical aspects—facilitated by an interdisciplinary and international faculty (Fig. 1).

The core courses of the programme focus on the fundamental dynamics of contemporary cities, the processes that shape their form and structure, and the design tools necessary for urban transformation. These courses, taught by a multidisciplinary teaching staff, provide students with the essential knowledge, tools, and methodologies to address the challenges of evolving European territories. The core curriculum, which emphasises awareness of different spatial aspects such as social, economic, and environmental factors, ensures that graduates are equipped with a solid foundation to understand and address complex urban issues with sensitivity to their multifaceted nature.

The programme offers compulsory elective courses designed to foster integrative and conceptual thinking in response to the increasing territorial complexity and the different priorities within the different structural and content-related areas. These courses cover a wide range of methodological, procedural, morphological, landscape architectural, ecological, legal,

and economic aspects. By exploring these diverse areas, students are encouraged to make connections between disciplines and develop a holistic understanding of urban challenges. Taught by experienced faculty members, these courses provide students with the flexibility to tailor their education to their interests and career goals while ensuring a comprehensive understanding of urban transformation processes.

In addition to the compulsory core and elective modules, the programme offers a range of elective courses supported by a multidisciplinary teaching staff. Like the compulsory elective, the elective courses also cover a wide range of aspects. By focusing on specific topics of interest, students have the opportunity to deepen their knowledge and skills in areas relevant to their career aspirations. These electives provide students with the flexibility to explore specialised areas of study while benefiting from the expertise of faculty members with diverse backgrounds and expertise. Through these courses, students can further refine their understanding of urban transformation processes and develop the necessary skills to effectively address contemporary urban challenges.

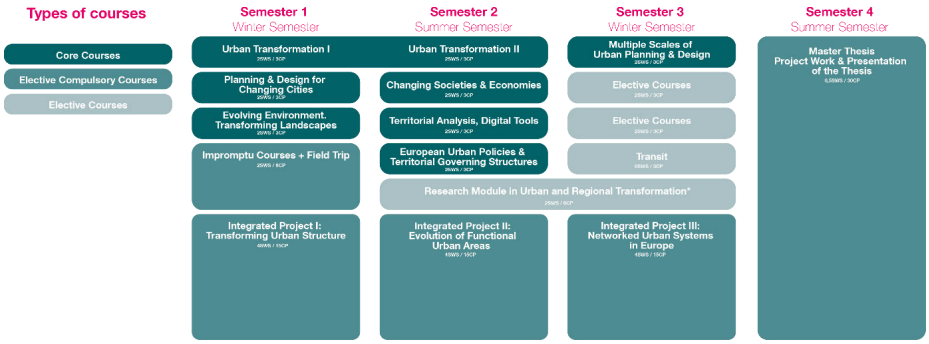

Fig. 1: RWTH's M.Sc.Transforming City Regions curriculum framework. Source: (Authors, 2024).

TCR adopts a multi-faceted approach to teaching, including lectures, tutorials, seminars and projects. Lectures provide specialist knowledge and methods on a weekly basis, while projects offer supervised opportunities to deepen understanding through practical design and planning tasks. Seminars, whether weekly or as compact events, explore complex issues and provide additional factual and methodological knowledge, encouraging critical thinking and discourse. At the heart of the curriculum are projects that integrate various subject areas with a focus on design and planning, allowing students to apply theoretical concepts to real-world scenarios. Assessment methods include written and oral examinations, term papers and presentations of urban design and planning concepts, ensuring that students not only acquire theoretical and methodological knowledge but also develop the presentation skills necessary to communicate visions for urban transformations to a broader audience.

2.2 Learning outcomes

Through TCR's curriculum framework, graduates acquire a robust set of skills, including analytical, conceptual and design skills (Fig. 2). They gain in-depth multidisciplinary knowledge that enables them to understand and manage complex urban problems and systems with a scientific and solution-oriented attitude. Equipped with advanced methodological tools and techniques, they are able to analyse changing urban and regional structures, conceptualise

scenarios for future change, and formulate strategies for sustainability and resilience. Graduates also excel at selecting, analysing, and interpreting spatial data, preparing them to tackle challenges at different scales in interdisciplinary teams. Their ability to communicate urban concepts, ideas and policies to a wider audience ensures that their solutions can be effectively communicated and implemented.

The analytical skills of graduates are sharpened through interdisciplinary training. They learn to describe, analyse, and interpret relationships and interdependencies within European territorial challenges. Equipped with analytical methods from different disciplines, they navigate complex spatial problems with a scientific and solution-oriented attitude. This training fosters practical decision-making skills that are applicable in all professional settings, including the private sector, public institutions, and civil society organisations. Graduates are also instilled with a sense of social responsibility, ensuring that their analytical skills are applied ethically, considering social, cultural, and environmental factors.

The conceptual skills are refined through the exploration of dynamic territorial processes and the conceptualisation of future scenarios. Real-world case studies provide a platform for the application of design and planning methods, considering different spatial aspects such as social, economic, and environmental factors. Graduates gain an in-depth understanding of European policies and governance structures, enabling them to interpret social and economic processes in urban and rural spaces. They can conceptualise strategies for sustainability, resilience, and risk mitigation, ensuring alignment with the evolving needs of European territories.

Moreover, the TCR curriculum emphasises the development of design skills in its graduates. They acquire skills in selecting, analysing, and interpreting spatial data, preparing them to tackle challenges at different scales in multidisciplinary teams. With responsibility for specific tasks, they solve complex spatial problems and present solutions effectively to the public. The final semester, dedicated to the final thesis, offers students the opportunity to showcase their individual skills through integrative projects, whether theoretical-conceptual or design-oriented. Throughout the programme, TCR highlights the importance of design and technical knowledge grounded in social, cultural, and environmental responsibility, ensuring that graduates are equipped to contribute meaningfully to the transformation of urban regions.

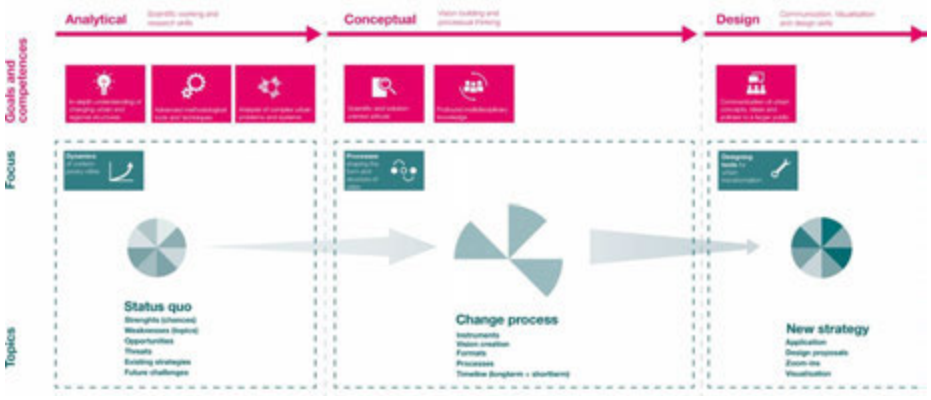

Fig. 2: RWTH's M.Sc. Transforming City Regions academic approach. Source: (Authors, 2024).

2.3 International and multidisciplinary setting

TCR welcomes students from a wide range of academic backgrounds concerned with spatial issues, including disciplines such as urban design, urban planning, architecture, spatial planning, landscape planning, geography, sociology, and cultural studies, among others. Taught entirely in English, the programme attracts students from all over the world, ensuring a rich cultural and disciplinary mix among its participants. Accordingly, the international and multidisciplinary nature of the programme is its main characteristic. On the one hand, this contributes to RWTH's internationalisation strategy and fosters an environment where interdisciplinary teamwork is highly valued and encouraged. On the other hand, it provides an environment that is personally and professionally enriching for students. In combination, TCR offers students valuable opportunities to work with peers from different cultural and academic backgrounds, broadening their perspectives and preparing them to tackle the complex challenges of urban change on a global scale (Fig. 3).

Fig. 3: RWTH's M.Sc. Transforming City Regions student composition. Source: (Authors, 2024).

3. Co-designing future planning education

The relevance of internationalisation and multidisciplinary environments in planning education has become increasingly important in addressing the complex challenges of contemporary urban development. As cities around the world grapple with issues such as housing shortages, environmental degradation, and social vulnerability, there is a growing need for innovative approaches and integrated pedagogies in urban planning and design education. One of the key challenges, however, is to match the expectations of students from diverse backgrounds with institutional teaching and learning objectives, on the one hand, while integrating interdisciplinary knowledge into a coherent curriculum framework, on the other hand. This multifaceted challenge raises a two-fold question. Firstly, of how diverse students' expectations can be aligned with institutional teaching and learning objectives. Secondly, of how interdisciplinary knowledge can be effectively integrated into a well-defined curriculum framework. To address this, the paper proposes a co-design approach involving workshops with alumni, enrolled students, and faculty to continuously refine and develop curricula for urban planning and design education.

3.1 The process

The co-design of a curriculum framework is a collaborative effort in which educators, students, administrators, and sometimes community members work together to build a comprehensive educational structure. This process begins by embracing the diverse perspectives and needs of all stakeholders and creating an environment where every voice is considered. In the context of higher education, it ensures not only a well-rounded curriculum framework but also one that is culturally sensitive and responsive to the community it serves. Through open dialogue and collective effort, the framework becomes a product of shared knowledge, bringing together the expertise and insights of multiple contributors. This approach encourages innovation and adaptability, as the latest educational trends, technological advances, and diverse pedagogical methodologies can be integrated.

Moreover, co-design fosters a sense of ownership and commitment among participants, making them active contributors to the educational landscape. This process cultivates a shared responsibility for the success of the curriculum and fosters a sense of unity and common purpose among stakeholders. Ultimately, co-designing a curriculum framework means taking a progressive and inclusive approach, which is essential for creating an educational roadmap that is versatile, relevant, and responsive to the diverse needs of learners and society.

This section provides a comprehensive overview of the TCR timeline, the co-design workshops, and the key role of each milestone in shaping the curriculum framework. It details the sequence of events and workshops, highlighting their essential contributions at two levels. Firstly, these collaborative workshops facilitated discussion between teachers, students, and administrators, encouraging diverse perspectives and innovative ideas. Secondly, each workshop and milestone provided valuable insights that guided the development of the framework, resulting in a synthesis of collective knowledge. Overall, the section highlights how the iterative process of workshops and milestones significantly influenced the overall design, resulting in a comprehensive curriculum that is finely tuned to meet diverse educational needs with cultural responsiveness and adaptability (Fig. 4).

The timeline of the TCR is marked by four key moments: the establishment of the Chair and Institute of Urban Design at RWTH in October 2018, the official launch of TCR in October 2019, the first feedback workshop in March 2022, and finally the integration of the TCR into the UNESCO Chair of Cultural Heritage and Urbanism in March 2023. Figure 5 illustrates the timeline of the TCR and maps three key workshops that were held with different focus groups to capture their perspectives. The first workshop with the first graduates took place in March 2022, followed by the second with enrolled students from all semesters in February 2023, and, lastly, the third with alumni and enrolled students in November 2024. The results helped to reflect on teaching and learning outcomes in a workshop with lecturers in April 2024.

These workshops provided valuable insights into the programme's effectiveness and highlighted areas for improvement. Feedback from enrolled students and alumni informed ongoing discussions on curriculum development, pedagogical approaches, and the integration of international perspectives. In particular, the integration of the TCR into the UNESCO Chair of Cultural Heritage and Urbanism emphasised the need to revise the curriculum framework, integrate the Sustainable Development Goals (SDGs), and strengthen internationalisation in line with UNESCO and RWTH guidelines.

3.2 Alumni perspectives

The first feedback workshop, held in the winter term of 2022 with the first graduating class of TCR, aimed to assess the first impressions of alumni and identify critical issues early on. It provided an opportunity for alumni to reflect on their experiences during the programme and give feedback on various aspects, from the application process to postgraduate concerns. The timing of the workshop allowed alumni to assess the effectiveness of the programme in preparing them for life after graduation and to apply their learning experiences retrospectively.

During the feedback session, the alumni were divided into several themes, including pre-study expectations, courses and workload during the programme, and postgraduate issues. Special attention was given to the Integrated Projects, a key component of the programme, which were heavily weighted with 15 ECTS credits. Alumni were encouraged to record their feedback anonymously on a visual collaborative web platform and to discuss their opinions further during

the session. The workshop began by addressing the alumni's expectations before the start of the programme, followed by evaluations of the application process, the organisation and content of the courses during their studies, and their personal experiences. In addition, alumni were invited to discuss important issues for their life after graduation, and to give free feedback on all areas of the programme.

Initial findings from the workshop identified several areas for improvement. Alumni expressed concerns about the clarity of programme requirements, particularly for students from different disciplines. The level of stress during the programme, especially in relation to the Integrated Projects, was highlighted, as well as the desire for more support for academic work, the preparation of the Master's thesis and design skills. The lack of thematic coordination between courses, particularly in Integrated Projects, was criticised, as was the perceived overemphasis on urban design. Suggestions were also made to improve the programme's relevance to practice, such as increased collaboration with professionals and courses on potential careers. These findings led to short-term actions, including the establishment of a student support forum, the provision of resources and expanded collaborations, with plans for long-term improvements, including a review of the Integrated Projects strategy. A further workshop was planned to validate these findings from the perspective of subsequent classes.

3.3 Students' perspectives

The second workshop, held in February 2023, invited all students enrolled in TCR at that time. Building on the findings of the first workshop, the second workshop aimed to validate and further develop them, focusing on course weighting, course content and post-graduation perspectives. This workshop was informed by internal reflections on the content and structural orientation of the programme. Concrete questions, including true/false and multiple choice, were used to explore different topics, with an open discussion at the end to allow students to raise points of their choice. The interactive platform used allowed students to actively participate in discussions during the workshop and to anonymously share their opinions afterwards (Fig. 6). In total, about 30 people participated in at least one of the two activities.

The results of the second workshop echoed some of the findings of the first. Students expressed a desire for a stronger focus on scientific work and a clearer relationship between courses. They also emphasised the need for more electives to provide opportunities for specialisation and suggested collaboration with specific faculties of interest. In addition, students expressed a desire for more practical relevance in the programme through field trips and a focus on developing software skills. Career prospects were also discussed, with students identifying professions such as urban sociologist, urban designer, AI designer, smart city product manager or consultant, researcher, or architect. Many emphasised the importance of scientific work and software skills for their professional future, especially for those planning to work in Germany. General comments reiterated concerns about the application process for the programme, the workload for few ECTS, and the desire for more individual work.

The results of the second workshop largely confirmed those of the first, and led to ongoing internal reflection and action. These include a redistribution of ECTS and thematic emphases, particularly regarding the redesign of Integrated Projects and a greater emphasis on academic work. Tools are being developed to address criticisms of the pre- and post-study periods, with the aim of providing guidance and support. However, not all students' wishes can be met, such as the offer of a compulsory module in building and planning law for those interested in German design and planning practice. Nevertheless, there is a commitment to increase collaboration

within the university to provide students with greater flexibility in their elective and transit modules to ensure that the programme remains sustainable and adaptable to student needs.

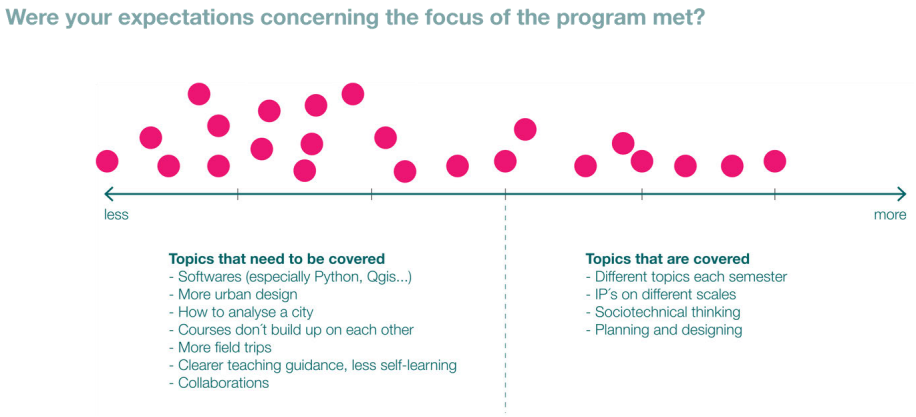

Fig. 6: TCR students' expectations mapped anonymously. Source: (Authors, 2024).

3.4 Mapping expectations and achievements

The third student workshop, offered as part of an impromptu course, gave students the opportunity to conduct semi-structured interviews with TCR alumni. The aim of the course was to illustrate the diverse backgrounds of TCR alumni and to compare their situations before and after their studies, i.e. mapping expectations and achievements. Through the semi-structured interviews, students gained valuable insights into the different experiences of alumni, allowing them to formulate questions related to their own study interests. In addition, participants learned about innovative visualisation and interviewing techniques and had the opportunity to network with TCR alumni, gaining valuable insights into their experiences and career paths.

Questions in the interviews focused mainly on expectations before starting the TCR programme and achievements after completing it. The results were ultimately used to create personas that anonymously represented the alumni (Fig. 7). These personas indicated the alumni's undergraduate background, whether their expectations were met and what they were able to achieve after completing the programme. These personas were then published on the Transforming City Regions website, giving potential applicants an insight into the diverse backgrounds of successful alumni, and helping them to understand the content of the programme through these personas. This initiative not only provided valuable information for prospective students, but also served as a platform for alumni to share their experiences and insights.

The findings from the interviews provided valuable feedback on the programme from an alumni perspective. Interestingly, ratings of expectations were generally lower than ratings of achievements, suggesting that TCR exceeded expected outcomes or needed to be better explained in advance (Fig. 8). Multidisciplinarity was consistently cited as an important achievement, indicating the programme's success in promoting a diversity of skills and perspectives among its graduates. However, practice orientation was rated the lowest overall, highlighting an area for potential improvement. In addition, TCR alumni emphasised the importance of programmes that provided hard skills, although this category was not rated

highly. Perceptions of research orientation varied among alumni, with those working in research-oriented positions rating the programme's skills more highly. This diversity of perspectives demonstrates the programme's ability to enable students to find their own areas of interest and develop their skills, regardless of their undergraduate background.

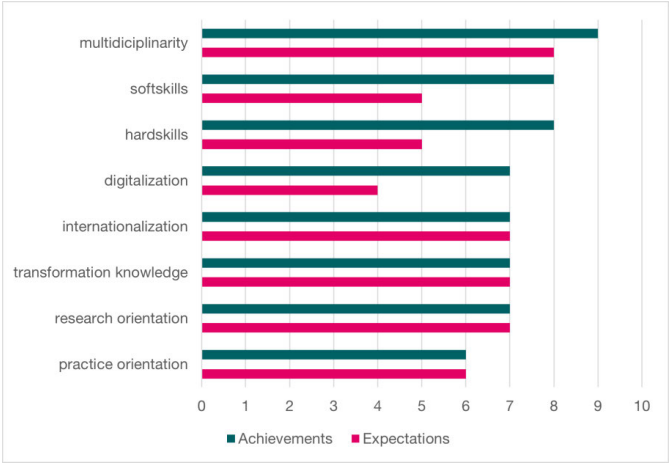

Fig. 8: Mapping expectations and achievements. Source: (Authors 2023).

3.5. Lectures' perspectives

The workshop with lectures was designed to address the alignment between the learning outcomes of individual courses and the overarching objectives of the programme. Core lecturers attended and were tasked with presenting their courses and discussing any issues they were facing. In addition, the results of student workshops were presented to provide insights into the challenges faced by students. Thematic consolidation of courses was a key focus, with examples given of courses that had already been coordinated to support student work. There was unanimous agreement that projects should be supported by core courses, highlighting the importance of coherence in the curriculum.

The workshop explored the challenges posed by the interdisciplinary nature of the programme, which brings together students from different thematic and cultural backgrounds. While students benefit from learning from each other, it becomes difficult to assess them on the same level and to set consistent requirements. Discussion centred on how to bring students to a common level that can be assessed consistently, particularly in areas such as design skills where student levels vary widely. A key outcome was the need for the programme application to be clearer about the requirements that applicants need to meet. This isn't to restrict the interdisciplinary nature of the course, but to give students a clearer understanding of the programme in advance, so that they can acquire the necessary skills before they start their studies. The workshop suggested the introduction of a self-assessment tool for applicants to reflect on their suitability, enabling them to understand what skills are needed for the programme.

The workshop emphasised the importance of regular meetings between lecturers to focus on the main objectives of the programme and to engage in thematic discussions. This ongoing dialogue would help to ensure that courses are aligned with the programme's objectives and that students receive consistent support and guidance. By addressing the challenges of interdisciplinary learning and providing clearer expectations for applicants, the programme can better equip students with the skills they need to succeed and foster a more cohesive learning environment.

4. Discussion

Contemporary urban development presents unprecedented challenges, including housing shortages, environmental degradation, and social vulnerability, and requires a responsive and adaptable planning education to address the complexities of urbanisation. To achieve this, future planning education should focus on multidisciplinarity and internationalisation. The TCR programme at RWTH Aachen University exemplifies this approach, integrating different disciplines and methodologies to address the complex challenges of European urban regions. Accordingly, the core premise of the programme is the recognition of the growing territorial complexity and the interplay between structural and substantive priorities—emphasising the need for integrative and conceptual thinking. Furthermore, TCR recognises the critical need to reconcile urban growth with environmental and social sustainability and aims to equip students with the skills and knowledge needed to effectively address contemporary social and spatial issues. Through a project-based educational model, TCR provides graduates with up-to-date knowledge and essential tools to address pressing issues in Europe's developing urban regions.

However, aligning the expectations of students from diverse backgrounds with institutional teaching objectives, while integrating interdisciplinary knowledge into a well-defined curriculum, is a multifaceted challenge. TCR addresses this challenge through a co-design approach. Through feedback workshops with alumni and enrolled students, as well as interviews with graduates, the programme continuously refines its curriculum. This collaborative effort ensures that the curriculum remains relevant and responsive to the evolving needs of both students and the urban planning profession.

The co-design approach outlined in section 3 emphasises iteration and inclusivity. By involving different focus groups in the curriculum development process, TCR creates an environment where every voice is considered. This process encourages innovation, adaptability, and cultural sensitivity, resulting in a curriculum framework that reflects the collective knowledge and insights of multiple contributors. Through open dialogue and collaborative effort, TCR ensures that its educational roadmap remains diverse, relevant, and responsive to the diverse needs of learners and society.

Alumni, students, and lecturers provide valuable perspectives on the effectiveness of the TCR programme. Alumni highlighted concerns about programme clarity, workload, and thematic coordination, while students emphasised the need for a stronger focus on scientific work and practical relevance. Lecturers discussed the challenges of assessing students' interdisciplinary learning and suggested clearer programme expectations for applicants. Despite different perspectives, all agree on the importance of continuous improvement and alignment with the programme's objectives. The mapping of expectations and achievements, as discussed in section 3.4, provides insights into the effectiveness of the programme from the alumni perspective. While TCR has generally exceeded expectations, areas for improvement include practical relevance and clarity of programme requirements. These findings will inform ongoing curriculum development efforts to ensure that TCR remains responsive to student needs and industry demands. By addressing these shortcomings and continuing to engage various focus groups in the curriculum development process, TCR can further enhance its educational offering and make a meaningful contribution to the community it serves.

While the co-design approach offers valuable insights and improvements for educational planning, it also has several challenges and limitations. Resource constraints, lack of perspectives from practice, and the need for more time to assess programme quality and graduate market readiness are some of the shortcomings highlighted. Balancing expectations for a more scientific or practical education with the complexity of integrating interdisciplinary knowledge is another challenge. In addition, the high expectations of students and the time required to implement improvements can slow progress. Despite these challenges, TCR remains committed to addressing them and ensuring the continuous improvement of its educational offerings. By effectively utilising available resources, seeking input from industry experts, and transparently managing student expectations, TCR can mitigate these limitations and further strengthen its position as a leader in interdisciplinary urban planning education. Through ongoing collaboration and a commitment to innovation, TCR can continue to adapt and evolve, preparing students to navigate the complexities of contemporary urban development and make a positive contribution to the future of urban regions worldwide.

5. Conclusion

In addressing the main research question, the paper explored how the expectations of students from diverse backgrounds can be aligned with institutional teaching and learning objectives and

how interdisciplinary knowledge can be effectively integrated into a well-defined curriculum framework. Through a series of workshops and interviews, we found that a co-design approach involving focus groups such as alumni, enrolled students, and faculty is essential to achieve this alignment. By actively involving these groups in curriculum development, we ensure that educational programmes such as TCR at RWTH Aachen University meet the needs of a diverse student body while maintaining a coherent and comprehensive curriculum. The workshops showed that clarifying programme requirements, improving thematic coordination, and providing adequate support are crucial steps in aligning expectations and effectively integrating interdisciplinary knowledge. This collaborative effort not only ensures that students from diverse backgrounds are adequately prepared for the challenges of contemporary urban development, but also fosters a sense of ownership and commitment among groups, making them active contributors to the educational landscape.

The findings of Chapter 3 on the co-design process have significant implications for the challenges outlined in Chapter 1. As contemporary urban development faces unprecedented challenges, there is a growing need for innovative approaches and integrated pedagogies in urban planning and design education. The co-design approach outlined in this paper offers a promising solution to these challenges by fostering collaboration and responsiveness to stakeholder feedback. By continuously refining and developing curricula through workshops and stakeholder engagement, educational programmes can better prepare students to address the complexities of urban development and contribute meaningfully to the future of city regions. These findings highlight the importance of ongoing dialogue and collaboration between educators, students, and practitioners in shaping the future of planning education. By adopting a co-design approach, educational institutions can adapt to emerging trends and challenges in urban development and ensure that graduates are equipped with the skills and knowledge needed to effectively address real-world issues.

The co-design approach discussed in this paper represents the first step in a larger effort to improve planning education at RWTH Aachen University and beyond. Collaboration with other universities and involvement in initiatives such as the ENHANCE University Alliance (ENHANCE 2023) and the UNESCO Chair in Cultural Heritage and Urbanism (UCCU 2024) are seen as potential game changers—enriching the educational experience and ensuring its relevance to contemporary urban challenges. By embracing this approach and actively engaging with focus groups, educational institutions can foster innovation, adaptability, and cultural sensitivity in urban planning education, ultimately preparing students to navigate the complexities of urban development and make a positive impact on the future of city regions worldwide. This collaborative, inclusive and iterative approach to curriculum development is critical to addressing the multifaceted challenges of contemporary urban development and ensuring that planning education remains responsive and relevant in an ever-changing world.

Burcu Soygüzeloğlu holds a BSc in City and Regional Planning from METU, Ankara. Recently, she received her MSc degree in Urban Design at ITU, Istanbul, with her thesis titled “Discovering the Public Use Potentials of City Walls and Their Surroundings: The Case of Istanbul Theodosian Walls” in 2023. She is currently pursuing her PhD studies in the Department of City and Regional Planning at the same university, and has been working as a research assistant at Department of City and Regional Planning at GTU, Kocaeli since 2020. Her research interests revolve around daily life practices, urban morphology, sustainable urban mobility, spatial perception and behaviour.

**Fatih Terzi, Istanbul Technical University

Prof. Dr. Fatih Terzi, is a faculty member in the department of urban and regional planning at Istanbul Technical University. The area of interest focuses on sustainable urban development, climate responsive design, and eco-smart cities. Fatih Terzi paid a visit to Clemson University, SC, USA, in 2004; the Center for Advanced Spatial Analysis Center (CASA), University College London, in 2008; and the Technology and Community Research Center of the Technical University Berlin in 2017 as a guest researcher. TERZİ, has worked as a researcher in projects supported by the European Union, COST, TUBITAK, and the Development Agency related to sustainable urban development, ecological planning, risk reduction, and quality of life issues. Most recently, he worked as a team co-leader in the "Medium-Term Development Planning and Financing in Five Turkish Metropolitan Cities (Kayseri Muğla Mardin, Malatya, Kahramanmaraş) under the World Bank's "Sustainable Cities Program" being carried out by PWC, funded by the European Union under the leadership of Ilbank.

Abstract

Key hubs like transfer centers facilitate intra-urban travel and accessibility in large cities. Understanding urban activity patterns around these hubs is vital for improving urban planning and infrastructure, thus enhancing livability. However, traditional research methods often fall short in capturing dynamic urban activities, whereas social media data provides rich insights into geographical locations, activity types, and movement patterns. This study uses location-based services from social media to analyze urban activity patterns around Marmaray stations on the Anatolian side of Istanbul. Analyzing Foursquare venue data within a 500-meter radius of 29 stations, Kernel density and K-means cluster analyses revealed four distinct activity clusters. These findings suggest varied urban activities at each station and help refine urban planning and transportation strategies.

Keywords: Activity patterns, Foursquare, Istanbul, location-based social network data, Marmaray stations

1. Introduction

The expansion of public transportation systems in large cities is a crucial strategy to alleviate traffic congestion and promote sustainable urban development. Public transportation hubs, transfer centers, and stations play a pivotal role in facilitating intra-urban journeys and offering accessibility to the activity spaces in their immediate surroundings. However, a better understanding of human mobility and activity patterns around these stations is needed to enhance urban planning, transportation infrastructure, and overall urban livability (Lang et al., 2020). The necessity arises because traditional research on individual activity-travel patterns over extended time periods has relied on labor-intensive surveys and questionnaires (Vilhelmson, 1999). While these methods have provided valuable insights, they are often costly and limited in covering a large number of individuals (Zhou et al., 2018). Additionally, there are data-related constraints in the analysis of urban space and dynamics, such as currency, availability, accessibility, representativeness, objectivity, and diversity of the data.

On the other hand, the proliferation of location-based services in social media applications, which has ushered in an era where people willingly share their activity-related choices, such as check-ins on various platforms like Facebook, Foursquare, and X (formerly Twitter), has emerged as an alternative data source. This has led to the accumulation of a high volume of user-generated data, offering valuable insights into human movement and activity patterns. This data source not only contains specific geographic information but also provides insights into how different types of activities are chosen for various purposes, activity categories, and movement patterns.
In recent studies (Hasan et al., 2013; Zhou and Zhang, 2016; Üsküplü et al., 2020; Ebrahimpour et al., 2020; Mohammadbagherzadeh & Terzi, 2022), location-based data has gained increasing interest due to its rich information, linking each geographical record to a venue category that explains the reasons behind the activities. Consequently, this has opened doors to novel applications, from recommendation systems for physical locations to travel route optimization. Beyond these applications, the data has the potential to revolutionize fields such as travel demand modeling, urban planning, epidemiology, security, and health monitoring (Ling-Yin et al., 2012).

In this context, this research investigates the activity patterns around the stations of the Marmaray mass rapid transit railway system on the Anatolian side of Istanbul, one of the important public transportation lines, by exploring the potential of using data from location-based social networks, specifically venue data from Foursquare. The research aims to answer two key questions:

• What are the differences among Marmaray stations in Istanbul in terms of the distribution of activity spaces?

• What characteristics can be observed through venue data in the surroundings of these stations?

2. Exploring urban spatial dynamics through location-based social networks

This chapter presents the theoretical background for the research, which extends to the activity spaces and activity patterns in urban spatial dynamics, location-based social networks, and their innovative perspectives on the analysis of spatial dynamics within urban research.

2.1. Activity spaces as spatial components of urban dynamics

Activity space is an important component in urban dynamics since it traces its origins to the conceptualization of social space and the analysis of urban time-space patterns in behavior. Activity spaces, defined by Horton and Reynolds (1971) as "the subset of urban locations with which an individual interacts due to their activities," encompass both the physical locations and the subjective experiences within these spaces, reflecting a blend of objective spatial structure and individual urban interactions (Golledge and Stimson, 1997). The concept of activity space has evolved from behavioral geography over time and has been defined with various terminologies in different contexts, such as "activity system" (Chapin, 1968), "awareness space" (Brown and Moore, 1970), and "action space" (Horton and Reynolds, 1971). Activity space is a multidimensional concept with spatial, temporal, and cognitive dimensions (Wang et al., 2012). These dimensions are evident in the diverse ways individuals use urban space, influenced by factors such as mobility and access.

To understand the multidimensional structure of activity spaces, the use of the concept in urban research has also varied, with methodologies including the standard deviational ellipse (SDE), network-based approaches, kernel density estimations, minimum convex-hull polygons (MCP), and other methods (Patterson and Farber, 2015). Each of these approaches offers a different perspective on understanding activity spaces, but within this research, it is important to elaborate more on kernel density estimation (KDE). Each of these approaches offers a different perspective on understanding activity spaces, but within this research, it is important to put more elaboration on kernel density estimation (KDE), as a data smoothing technique, which plays a significant role in examining activity spaces by interpolating point data to create a continuous surface (Bailey and Gatrell, 1995). Since it offers insights into the intensity and distribution of activities within urban spaces with its this feature, it has been used in different research studies (Kwan, 2000; Axhausen, 2002; Kamruzzaman et al., 2011).

Furthermore, the advancements in Geographic Information Systems (GIS) and the availability of extensive geographical data have opened up new opportunities for researchers to digitally define activity spaces. This potential has expanded beyond mobile phone data to encompass crowdsourced information like social media and Points of Interest (POI) data (Yuan et al., 2012). These sources, including social media, POI data, websites, and various online platforms relying on voluntary data sharing, have primarily been utilized for modeling aspects of urban activity patterns, mobility, land usage, location preferences, as well as for conducting semantic and perceptual studies related to spatial analysis (Niu and Silva, 2023). In this context, exploring these new sources of data and methodologies is considered important for gaining a deeper understanding of activity spaces and providing insights into the dynamics of the urban environment.

2.2. Digital footprints for urban spatial dynamics: Location-based social networks

User-generated content has emerged as a critical source for investigating interactions with urban spaces and explaining how people engage with their environment in daily life. This phenomenon demands new theoretical perspectives, as suggested by Cope (2015), to gain a deeper understanding of these interactions. The integration of digital services into daily urban life, noted by Dunkel (2015), offers a valuable lens for exploring the various components and socio-spatial dynamics of urban environments. The advancement of GPS technology has introduced a novel dimension to urban analysis by linking user-generated content with specific geographic locations within the urban landscape. This process encompasses recording, sharing, reviewing, and recommending spaces and functions, significantly enhancing the comprehension of city dynamics (Arribas-Bel, 2014). Within this context, location-based services and social networks represent a convergence of internet-connected devices, location-based technologies, and GIS (Brimicombe, 2002). Social networks, as virtual social structures, are formed through connections such as friendships, shared interests, and collective knowledge among users. These networks enable users to express thoughts, opinions, activities, and interests.

The integration of location-based data into social networks, creating location-based social networks (LBSNs), bridges the gap between online interactions and real-world environments. This integration allows tracking users' interests and behaviors through their location information within these networks (Zheng, 2011). Moreover, LBSNs facilitate the sharing of location-specific data within an existing social network and the creation of new networks where users connect based on physical location. Consequently, LBSNs gather extensive databases containing variables such as text, images, and quantitative data. The database structure, formed by users' location history and the shared archive of geo-tagged content, is instrumental in understanding users' preferences, behaviors, and activities (Marti et al., 2019).

The functionalities and content of each social network vary, but commonalities exist in how they establish networks of contacts and allow users to register with a profile, create, share, or interact with content. Bernabeu-Bautista et al. (2021) categorize current social networks into five types: contact-focused networks like Facebook or LinkedIn, microblogging networks such as X or Tumblr, multimedia sharing networks including Instagram, Flickr, Pinterest, or YouTube, specialized networks like Airbnb, Google Places, Foursquare, or Sina Weibo, and instant messaging services such as Telegram or WhatsApp. Each category serves distinct user interactions and needs. According to Bernabeu-Bautista et al. (2021), the suitability of these networks for urban studies hinges on four key characteristics: precise geolocation of data, accessibility and privacy of the data, the ability of data variables to reflect urban and social activity, and predominant use on mobile devices. These aspects enable the analysis of user behaviors, interactions, mobility, and activity patterns within urban spaces in real-time and dynamic contexts. Choosing the right social network for urban research depends on the study's goals and the required data format, be it text, images, opinions, or quantitative data. In this way, LBSNs have demonstrated extensive potential in urban research. For instance, Lee, Wakamiya, and Sumiya (2013) utilized social media data to discern behavioral patterns and types of spaces within cities. This data, emerging as a by-product of everyday life, contrasts with planned surveys, providing a free and widely accessible resource for urban research, especially valuable in locations with limited official data (Arribas-Bel, 2014). However, the computational exploration of this data often lacks a well-established theoretical or philosophical framework, indicating a need for urban research to establish its own methodological framework to develop a more comprehensive understanding of urban dynamics.

Focusing on geo-tagged data obtained from different LBSN platforms and methods, various studies have utilized it to examine urban dynamics through activity and mobility patterns (Table 1). Liu et al. (2014) focused on intra-urban trip patterns and spatial interactions using Weibo's check-in data, employing a gravity model and particle swarm optimization (PSO) to analyze the data. This approach allowed for an understanding of movement patterns within urban environments. Hasan et al. (2013) suggested that social media users tend to visit different places with decreasing regularity following Zipf's law and analyzed Foursquare check-in data posted on Twitter. In a subsequent study, Hasan et al. (2014) shifted their focus to user-specific activity patterns using geo-tagged tweets from Twitter by applying Latent Dirichlet Allocation (LDA), a method that helped identify patterns based on the content of tweets.

Zhou and Zhang (2016) also explored activity intensities in a temporal context by combining data from Twitter and Foursquare. They analyzed geo-tagged tweets with related Foursquare categories, using hotspot and spatial clustering analyses to study the temporal dynamics of urban activities. Zhou and Xu (2017) extended this approach to the spatio-temporal evolution of natural (heavy precipitation) and specific social events in New York City, employing density-based spatial clustering (DBSCAN), KDE, and sentiment analysis on various features of Twitter data to understand the city dynamics.

Cui et al. (2018) focused on the temporality of frequently visited places by integrating Weibo check-in data with survey data. They used a distance-based clustering algorithm to understand how frequently certain locations were visited and the patterns associated with these visits. Yang et al. (2019) studied human mobility and activity patterns at the group level using geo-tagged Weibo messages. Their approach involved multiple spatial distribution analyses, providing insights into group behaviors in urban spaces. Üsküplü et al. (2020) analyzed activity patterns in parts of historical districts in Istanbul using Foursquare data, specifically POI and check-in data. They applied hotspot and spatial clustering analyses to understand the activities within these culturally significant areas.

Ebrahimpour et al. (2020) focused on socio-geographic human mobility patterns using geo-located Weibo data. They utilized KDE and DBSCAN to analyze the spatial and social aspects of human mobility. Mohammadbagherzadeh and Terzi (2022) conducted a study on activity patterns around metro stations in Istanbul using Foursquare's POI data through KDE and K-means cluster analysis. Since their case area involves the Marmaray stations on the European side of the city, it is considered an important example in terms of both the case, methodology, and the results for comparison among the Marmaray stations on both sides. Lastly, Niu and Silva (2023) employed hotspot analysis on geo-tagged tweets from Twitter to explore spatial, temporal, and demographic patterns of urban activities, offering a comprehensive view of how different demographic groups interact with urban spaces.

In conclusion, this comprehensive exploration of urban research through LBSNs emphasizes the common use of density-based clustering methods for analyzing urban activity and mobility patterns. The studies reviewed in this chapter demonstrate a diverse context of approaches using geo-tagged data from various LBSNs, which has been instrumental in revealing complex patterns of urban life. The different applications of LBSNs in urban studies underscore their potential in shaping our understanding of urban environments and make them an invaluable tool in the realm of urban research.

Table 1. Studies of activity and mobility patterns inference from geo-tagged social media

Studies	Research focus	Data source	Data used	Method/ Algorithm
Liu et al. (2014)	Intra-urban trip patterns and spatial interactions	Weibo	Check-in data	Gravity model and PSO
Hasan et al. (2013)	Activity and mobility patterns	Foursquare and Twitter	Foursquare check-in data posted in Twitter	KDE and statistical distribution analysis
Hasan et al. (2014)	User-specific activity patterns	Twitter	Geo-tagged tweets	LDA
Zhou and Zhang (2016)	Activity intensities in temporal context	Twitter and Foursquare	Geo-tagged tweets and their category links to Foursquare	Hotspot and spatial clustering analyses
Zhou and Xu (2017)	Spatio-temporal evolution of natural and social events	Twitter	Various features pf Twitter data	DBSCAN, KDE, sentiment analysis
Cui et al. (2018)	Temporality of frequently visited places	Weibo and survey	Check-in and survey data	DBSCAN
Yang et al. (2019)	Human mobility and activity patterns at group level	Weibo	Geo-tagged Weibo messages	Multiple spatial distribution analyses
Üsküplü et al. (2020)	Activity patterns of historical districts	Foursquare	POI and check-in data	Hotspot and spatial clustering analyses
Ebrahimpour et al. (2020)	Socio-geographic human mobility patterns	Weibo	Geo-located Weibo data	KDE and DBSCAN
Mohammadbagherzadeh and Terzi (2022)	Activity patterns around metro stations	Foursquare	POI data	KDE and K-means cluster analysis
Niu and Silva (2023)	Spatial, temporal, and demographic patterns of urban activities	Twitter	Geo-tagged tweets	Hotspot analysis

3. The case area: Marmaray stations

Istanbul, with a population exceeding 15 million according to TUIK (2022), is Turkey's largest city, covering an area of 5,461 square kilometers. These characteristics make Istanbul the most densely populated city in Turkey, with around 20% of the nation's population residing within its boundaries. The city is divided into two parts by the Bosphorus, with one side in Europe and the other in Anatolia. Throughout Istanbul's history, infrastructure and transportation projects have played a significant role in the city's expansion and have influenced its spatial and social aspects.

In this context, the Marmaray mass rapid transit railway system, one of the mega-infrastructure projects, enhances accessibility to activity spaces in its immediate vicinity. It has a total of 43 stations, spanning from Halkalı to Sirkeci on the European side (14 stations) and from Üsküdar to Gebze on the Anatolian side (29 stations). By focusing on the stations on the Anatolian side and the different types of venues around them, this research aims to gain insights into how social media data can provide evidence of urban spatial dynamics in response to transportation infrastructure (Figure 1).

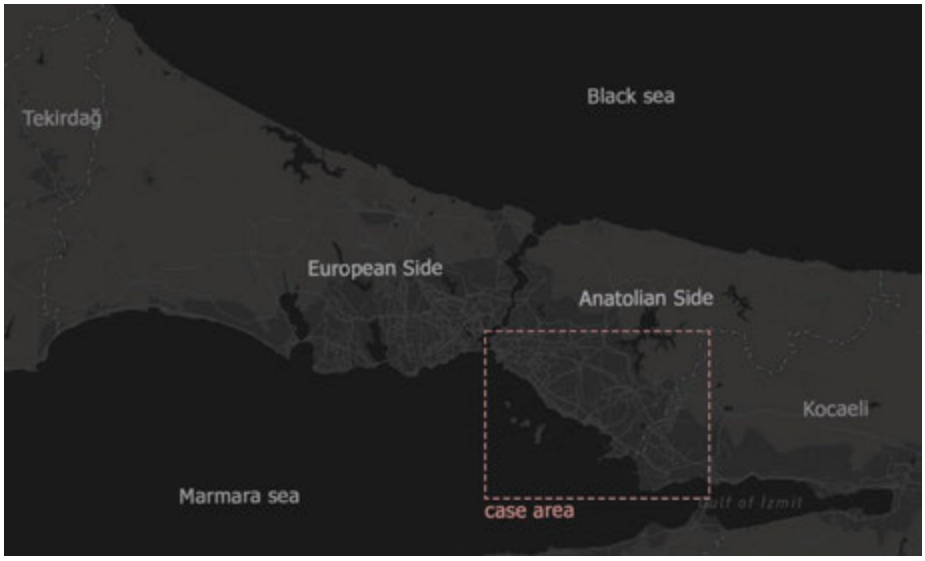

Figure 1. Location of the case area in Istanbul

4. Data and Methodology

This research focuses on integrating geo-tagged social media data, specifically venue data from Foursquare, to develop insights into the spatial dynamics around Marmaray stations through activity spaces and patterns. Accordingly, the methodology of this research comprises three sequential phases with two main analyses (Figure 2):

- Data Collection: Retrieving the data through the use of Social Network's Application Programming Interface (API) for the analyses.

- Kernel Density Estimation: Revealing the spatial distribution of venues/activity spaces' density.
- K-means Cluster Analysis: Evaluating the clustered characteristics of the stations

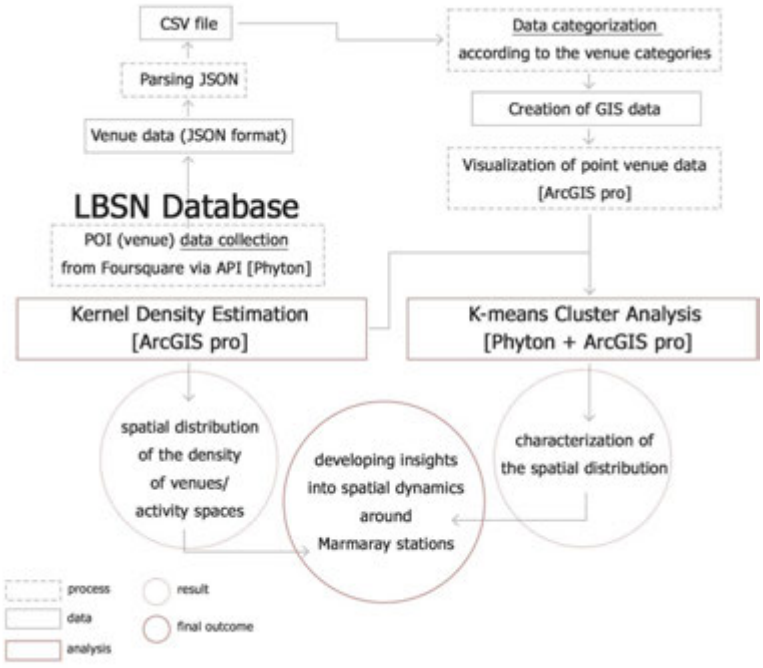

Figure 2: Flowchart of the research design

4.1. Data Collection

As part of this research, venue data from Foursquare—a location-based social network—was employed due to its easily manageable content, inclusion of geographical information, and public accessibility for researchers. To gather venue data within a 500-meter radius of 29 Marmaray stations, a search query was executed through an API, which is an interface that enables users to integrate with data from various social media platforms, using the Python programming language.

Since the Foursquare Public Search API allows a maximum of 50 venues per a single search, the search radius was progressively expanded from 50 to 500 meters in increments of 50 meters. Consequently, the search was conducted ten times for each category. The Foursquare categories searched include: Arts and Entertainment, Dining and Drinking, Landmarks and Outdoors, Retail, Sports and Recreation, Business and Professional Services, Community and Government, Health and Medicine, and Travel and Transportation. The resultant dataset includes venue points with details such as venue ID, venue name, location (latitude and

longitude), category name/id, and sub-category name/id. Duplicated venue points within the overlapping search radii were removed based on their venue IDs, resulting in a total of 4,566 unique venues. The dataset, encompassing nine categories as shown in Table 2, was converted from JSON format into a CSV file for data analysis in ArcGIS.

Table 2. Distribution of the searched categories

Venue Categories	# of venues	% of venues
Arts and Entertainment	344	7.53 %
Dining and Drinking	1939	42.46 %
Landmarks and Outdoors	315	6.90 %
Retail	1686	36.92 %
Sports and Recreation	192	4.21 %
Business and Professional Services	76	1.66 %
Community and Government	6	0.13 %
Health and Medicine	7	0.15 %
Travel and Transportation	1	0.02 %
ALL	4566	

4.2. Data Analysis

In the data analysis process, two main analyses were conducted: Kernel density estimation and K-means cluster analysis, respectively.

4.2.1. Kernel Density Estimation

As mentioned earlier in the literature review chapter regarding its application in urban research, KDE is a widely used method in spatial analysis. It is employed to create a continuous density surface that visualizes the spatial clustering of point or line features in a two-dimensional space (Wilson and Gerard, 2019). To generate a smooth curve within the venue dataset obtained from Foursquare and identify the most significant densities in ArcGIS Pro, several steps were taken. First, the categories "Community and Government, Health and Medicine, Travel and Transportation" were excluded due to their limited venue data. The point venue data from the remaining six categories were mapped in ArcGIS Pro, as illustrated in Figure 3, with the Marmaray line divided into four sections to provide a more detailed view of distribution. Subsequently, KDE was applied to all venues and separately to venues within these six categories (Figure 5).

4.2.1. K-means Cluster Analysis

The K-means algorithm is well-known for its ability to cluster data into n groups, each with approximately equal variance, while minimizing a measure called inertia or the sum of squares within each cluster (Jain et al., 1999). In this direction, to categorize and comprehend the types of activities and their distribution across different stations, the Python library Scikit-learn was

used for K-means cluster analysis. Within the scope of this research, the results of the elbow method, using inertia, were more suitable, with the optimum cluster value (k) being determined as four (Figure 4). The clusters were then visualized in ArcGIS Pro (Figure 6), and the results were evaluated further.

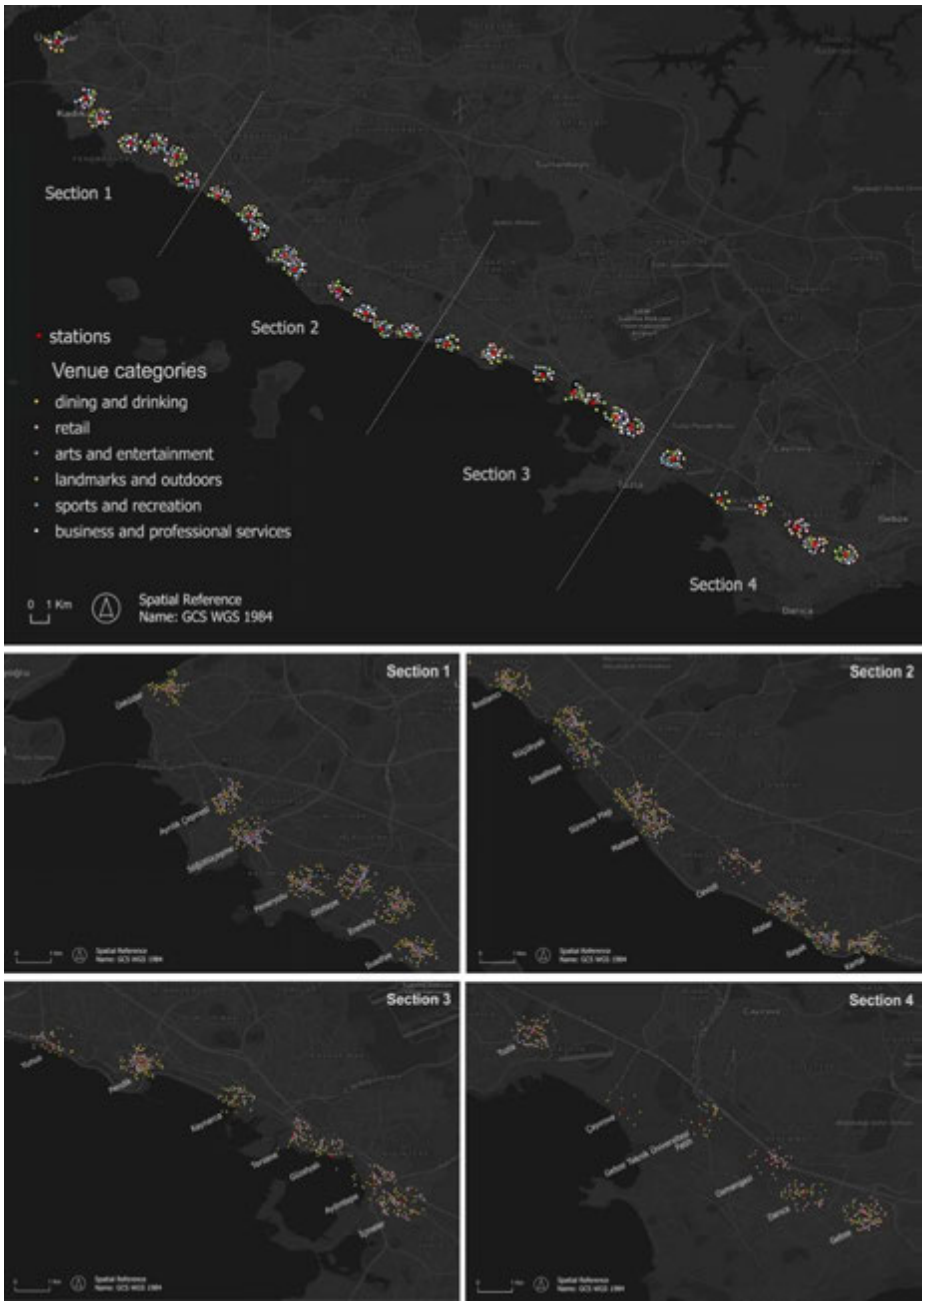

Figure 3. Visualization of point venue data

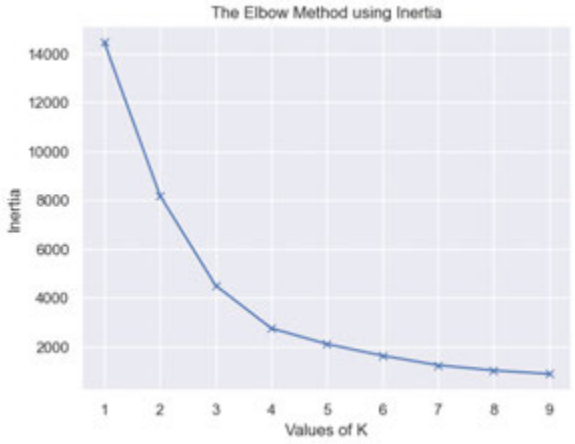

Figure 4. Optimum cluster value (k) according to Elbow Method

5. Results and Discussion

In this chapter, the results and the further discussion are presented in two parts: distribution, and clustered characteristics of activity spaces around Marmaray stations, as parallel to the data analysis.

5.1. Distribution of activity spaces/venues around Marmaray stations

The results indicate significant venue densities around several stations, including Ayrılık Çeşmesi-Söğütlüçeşme in Kadıköy, Göztepe-Erenköy, Küçükyalı-İdealtepe, Süreyya Plajı-Maltepe, and Başak-Kartal. Conversely, venues around Gebze Teknik Üniversitesi/Fatih and Çayırova do not form any significant densities.

Arts and recreation venues create notable densities along the stations Ayrılık Çeşmesi, Söğütlüçeşme, Feneryolu, Göztepe, Erenköy, Suadiye, and Başak-Kartal. Dining and drinking venues show remarkable densities from Göztepe to Maltepe, with the highest concentration at Maltepe. Subsequently, high densities are observed at Ayrılık Çeşmesi and Başak-Kartal. Landmarks and outdoor venues form significant densities at Küçükyalı-Maltepe, Başak-Kartal, and Göztepe-Suadiye. Retail venues show the highest densities at Göztepe-Suadiye, followed by Pendik and İdealtepe-Maltepe. Sports and recreation venues form significant densities at Atalar-Kartal, İdealtepe-Maltepe, and Feneryolu-Suadiye. Lastly, business and professional service venues create significant densities at Güzelyalı-İçmeler and in the areas around Söğütlüçeşme-Göztepe, Kartal, and İdealtepe (Figure 5).

Considering the density distribution of venues along the entire Marmaray line on the Anatolian side, retail venues, while forming significant densities at certain stations, are relatively more evenly spread across all stations. Additionally, a noticeable decrease in dining, drinking, and sports and recreation venues beyond the Pendik station highlights a distinct shift in venue density, giving Pendik and similarly Tuzla stations a unique character compared to other stations. When these results are compared with the existing study by Mohammadbagherzadeh and Terzi (2022), despite differences in venue categories and analysis processes, similar

concentrations of retail venues at stations like Göztepe and Suadiye show high density of shop and service venues found around the Sirkeci station. Furthermore, the European side exhibits strong densities of outdoor and entertainment venues at stations like Sirkeci, Bakırköy, and Ataköy, reflecting a pattern similar to that of the Anatolian side's clusters around stations like Küçükyalı-Maltepe and Göztepe-Suadiye. These similarities in findings underscore the need for a more comprehensive evaluation of all the stations along the entire Marmaray line, including the European side.

5.2. Clustered characteristics of activity spaces/venues around Marmaray stations

The K-means cluster analysis of activity spaces around Marmaray stations, as shown in Figure 6, has categorized the stations into four distinct clusters, each demonstrating unique characteristics in terms of venue distribution. The statistical distribution of venue categories for each cluster is also presented in a boxplot (Figure 7).

Cluster 0, comprising five stations (Cevizli, Pendik, Tersane, Aydıntepe, and Osmangazi), which constitute approximately 17% of all stations, has predominantly a retail-based character, with a considerable number of dining and drinking venues. These stations likely serve as local commercial hubs.

Although their characters are different, clusters 1 and 3 are the closest clusters to each other in terms of the number of stations they have. Cluster 1, with 13 stations (Söğütlüçeşme, Feneryolu, Göztepe, Erenköy, Küçükyalı, Maltepe, Başak, Kaynarca, Güzelyalı, İçmeler, Tuzla, Darıca, and Gebze), accounts for approximately 45% of all stations. In this cluster, retail and dining and drinking venues show a balanced distribution. Cluster 2, with only one station, Çayırova, features limited dining and drinking, landmarks and outdoors, sports and recreation, and lacks arts and entertainment as well as business and professional services. This cluster represents unique characteristics, possibly indicative of a less developed area in terms of urban functions.

Cluster 3 includes 10 stations (Üsküdar, Ayrılık Çeşmesi, Suadiye, Bostancı, İdealtepe, Süreyya Plajı, Atalar, Kartal, Yunus, and Gebze Teknik Üniversitesi/Fatih), making up approximately 35% of all stations. This cluster is predominantly characterized by dining and drinking venues, followed by retail, indicating vibrant commercial and social life. Overall, arts and recreation, landmarks and outdoors, sports and recreation, and business and professional services venues do not have significantly impact cluster formation and show a relatively balanced distribution, except for cluster 2 as an outlier. Therefore, the clusters are primarily characterized by retail, and dining and drinking venues.

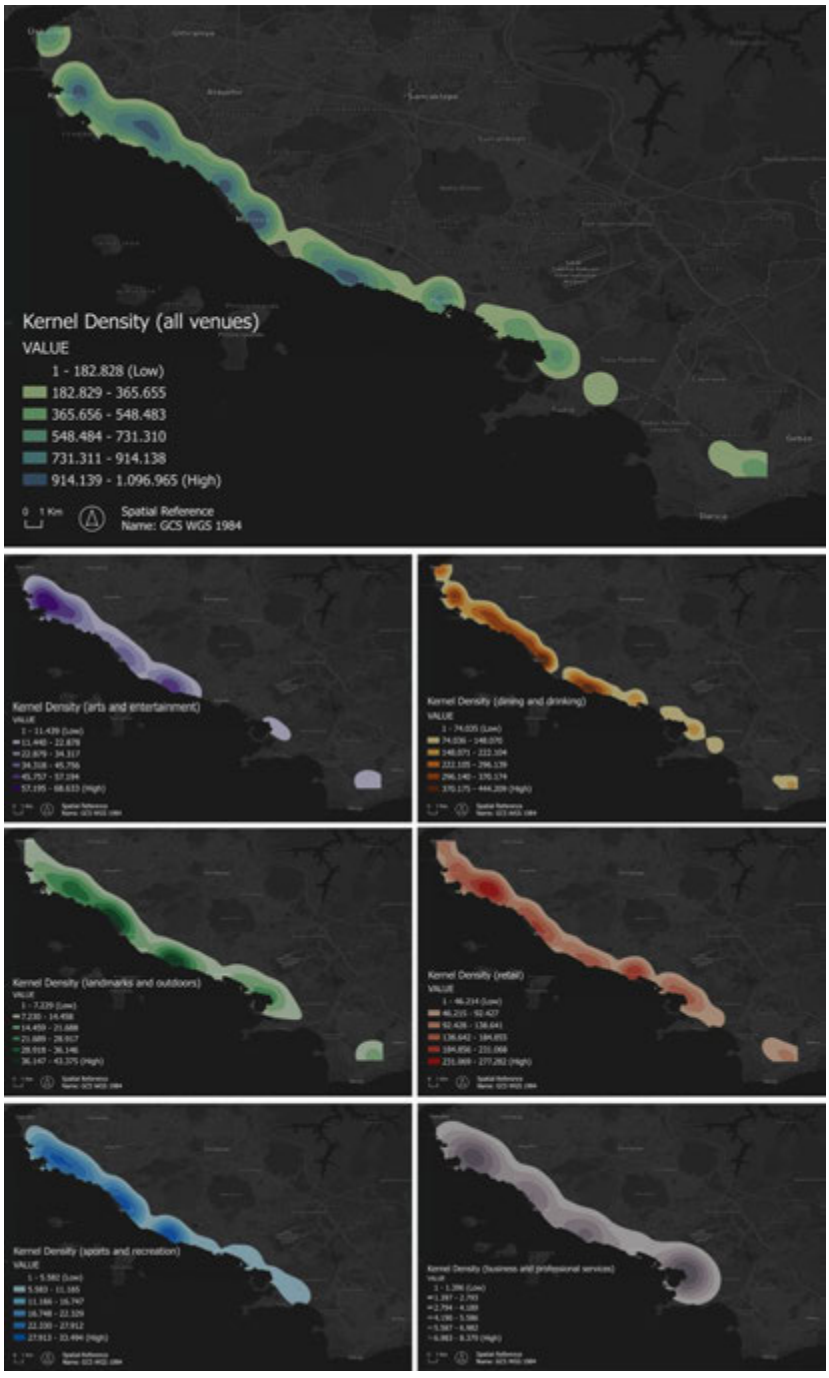

Figure 5. Distribution of the activity spaces around the stations

Figure 6. Clustered characteristics of activity spaces around the stations

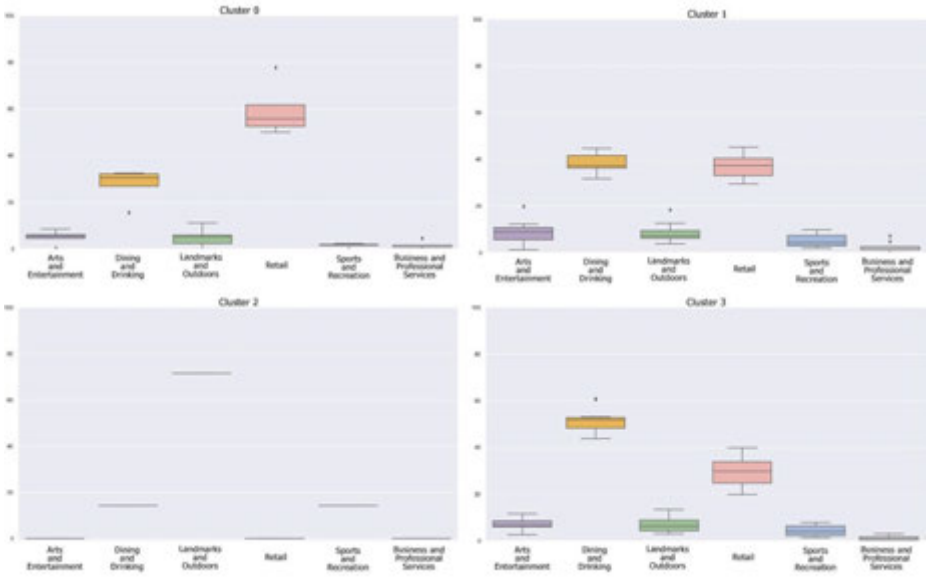

Figure 7. Distribution of categories for each cluster

6. Conclusion

The expansion of public transportation in large cities, particularly the role of transportation hubs like the Marmaray stations in Istanbul, is critical for sustainable urban development and reducing traffic congestion. These hubs are central to accessing nearby activity spaces, yet there is a knowledge gap in understanding their relationship with human mobility and activity patterns through different data and methodologies. This study addresses this gap by using Foursquare venue data to analyze the spatial distribution of activities around these stations.

The findings reveal significant densities of various venues around specific Marmaray stations, with notable clusterings in the characterization of these densities. For instance, cluster 0, including stations like Cevizli and Pendik, predominantly features retail activities. Cluster 1, with stations such as Söğütlüçeşme and Göztepe, exhibits a balanced mix of retail and dining venues. On the other hand, cluster 3, including stations like Üsküdar and Bostancı, is marked by a strong presence of dining and drinking venues and indicates areas with vibrant commercial and social life. These examples demonstrate how clusters differ in their urban function characteristics and the valuable insights offered by LBSN data into urban research more broadly (Dunkel, 2015). This data allows for precise estimation of geographic densities at both global and local scales and facilitates geographic clustering to identify areas with similar characteristics.

However, while the data used in this research was publicly accessible, challenges such as access to, reliability, and management of LBSN data can pose significant limitations. Particularly in this research, findings highlight the need for a more comprehensive evaluation of all stations on the Marmaray line, including those on the European side. Moreover, the study currently focuses only on the spatial dynamics formed by activity spaces. Future studies could extend to include social, perceptual, and/or temporal dimensions to thoroughly discuss urban dynamics, considering the potential of LBSNs in these dimensions. These points as limitations of the current research can also provide clues and direction for future studies.

Track 17: Risks

RISKS - Planning for adaptive capacity: disasters, uncertainty, long-term problems, preparedness and responsiveness

Keywords: *crises, long-term transformations, urban and territorial planning, uncertainty, public policy evaluation, pandemic, flooding, water management*

A crisis or an accumulation of crises? Which crisis(es)? For a long time now, the word has seemed empty, tired of being used to justify a widening gap between promises of development on the one hand and the stark reality that nothing is going according to plan. There is always a trigger for crises, a primary cause deemed paramount that causes events to fall (Walter Benjamin). It is a war that triggers an oil crisis, a speculative bubble that bursts, a virus that spreads, a storm that breaches a dyke and causes flooding… a shock that can be localised or global, with significant consequences in a circumscribed area or worldwide. However, this explanation of the root cause overlooks the regular waves of transformation that herald the rise of perils. The more perceptible signals of climate disruption and resource depletion are all warnings. The crisis, intended to be brutal and sharp, is then stretched out into a slow slump that feeds the comments of declinist experts and essayists.

Are we still in crisis? Or are we in the midst of a long and profound transformation that affects every aspect of our ordinary lives: our social ties, our relationship to the body and gender, and our historical, economic and geopolitical reading? So much for the social fact; our relationship to the planet, to territories, to ecosystems, to biodiversity and to life itself, for what concerns our relationship to the Earth.

This task invites contributions on the topic of Risk, namely on planning for adaptive capacity. For instance, proposals can deal with topics like the conditions and limits of planning, uncertainty in collective decisions and radical uncertainty, emergent crises like the recent pandemic, environmental disasters like flooding, etc.

Propositions are welcomed that shed light on theoretical principles, methodological approaches and empirical work. They can address, for instance, questions like: Given that we now face long-term transformations, how can we organise and pool our capacities to mitigate the consequences of our daily lives and adapt our practices? How can we even retain the ability to define common objectives instead of being tossed about like corks on the water? How can we express and prioritise, organise and adapt our systems (economic, institutional or social) to cope

with the disaster, the evil that is coming (Pierre-Henri Castel), without abandoning the conditions of fulfilment, solidarity, freedom and transparency that forged our present. How can we express the problems that are already there or will be there in the future, perceptible in the long term and the context of diplomatic, economic and health uncertainties and threats? How can we finally take action on the ground? How can we define planning that will be useful in times of storm, i.e. capable of identifying our capacity to adapt? What diagnoses can we make, and what lessons can we learn? What tools can we use to overcome the uncertainties? Finally, is there a dimension required to carry out this planning?

Resilience building of tourism villages confronting COVID-19 in China's Metropolitan Hinterland: Evidence from Shanghai Metropolitan Area

Abstract
Most villages in the world are facing the test of transformation and revitalization in the process of globalization and urbanization. China's "rural revitalization" strategy has allowed rural tourism to flourish, but it has been greatly impacted by COVID-19. How to enhance resilience in response to public health events has become a topic worthy of in-depth study. Therefore, our study takes Guzhu Village in the suburbs of Shanghai, a tourist village that has overcome the epidemic and gained resilience, as the main case. Our research provides a theoretical framework for enhancing rural resilience on a global scale, aims to contribute to the revitalization and recovery of rural tourism during or after crisis events and provides an empirical approach to rural industry transformation, upgrading and sustainable development.

Key words
Resilience, socio-ecological system, tourism village, COVID-19, Shanghai Metropolitan Area

1 Introduction

As globalisation deepens, the relationship between rural and urban areas is becoming increasingly close, and more and more factors of production are flowing from rural to urban areas, thus aggravating the problem of rural population loss and economic decline(Woods and M., 2007,p.485-507). As a matter of fact, the decline of the countryside has become a global problem, and the transformation and revitalisation of the countryside cannot be delayed(Carr and Kefalas, 2010,p.30-34). Since the 1950s, the countryside in developed countries such as the UK and the US has undergone significant changes and reconstruction in the context of urbanisation and counter-urbanisation, showing a shift from productivism to post-productivism(Wilson, 2001,p.77-102). For China, over the past four decades, it has experienced rapid industrialisation, urbanisation and modernisation, and the rural territories have been more and more significantly affected by urban development, and the traditional countryside, with its single agricultural function as the main mode of production, has undergone unprecedented changes(Tu and Long, 2017,p.1169-1184). Especially in the developed areas of China's eastern seaboard and the villages around big cities, the transformation of farmers' lifestyles has been driven by the transformation of production methods, and industries such as cultural tourism, recreational and healthcare experience, farmhouse, and B & B (bed and breakfast) have been incubated and rapidly developed in this context. These villages also experienced greater disruption and negative impacts during the COVID-19 period due to the increased integration of rural livelihood activities into the market economy(Hickey and Toit, 2007,p.).

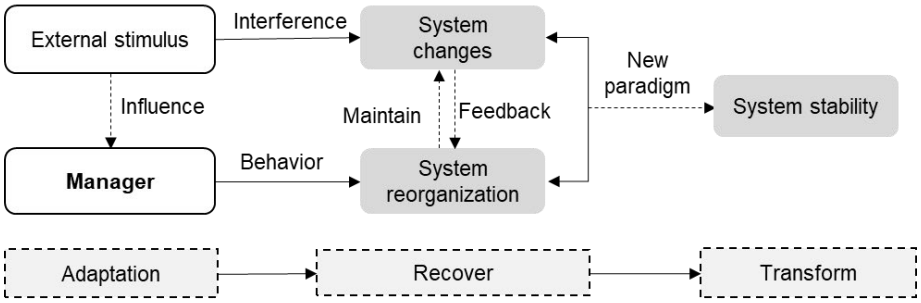
The COVID-19 outbreak made us realise that any localised public health event can spread rapidly across the globe with the movement of people and goods, with serious impacts on national economies, social security and individual health. Shanghai, China, as one of the most representative metropolises in China, has direct or indirect socio-economic links with the hinterland countryside, and the role of urban-rural relations is the strongest(Gu et al., 2019,p.102041).During COVID-19, in order to safeguard the lives of the city residents, the epidemic prevention system set up in Shanghai cut off to a greater extent the links with the neighbouring areas, including the rural areas that received the radiation from Shanghai, and their economies were affected in a comprehensive manner(Bartik et al.). In addition, due to the sensitivity and vulnerability of the tourism industry, its defences against such public crises were relatively weak and it was hit harder than other industries(Gssling et al., 2021,p.). The spatial isolation between Shanghai and the countryside has caused the rural tourism industry to be hit hard, and the B&B industry, which relies on tourism for its survival, has been hit by a cliff, with a large number of rural B&Bs going out of business or even closing down. However, some tourism-based villages survived the impact of COVID-19 and transformed into more resilience-based sustainable development strategies under the catalyst of COVID-19, which triggered more in-depth research and discussion on the rural tourism model and the mechanism of rural resilience(Wang et al., 2024,p.400-421).

Our study focuses on the rural areas in the hinterland of the Shanghai metropolis, and selects Guzhu Village, a tourist-oriented village that survived the epidemic and has the ability to recover, as a case study. We explore how the tourism industry in the rural areas of the Shanghai hinterland experienced and adapted to the economic shock caused by COVID-19, and in the process constructed a resilience mechanism for the rural socio-ecological system. Field surveys, questionnaires and semi-structured interviews are used to answer the question of the resilience construction mechanism and the role of the subject in Guzhu Village after the epidemic impact.

2 Literature Review

2.1 Rural Resilience In Socio-ecological System

Resilience is the ability to retain basic functions in a destructive state and to return to a state of equilibrium after the destruction. resilience undergoes the stage of 'engineering resilience - ecological resilience - evolutionary resilience'. "The recovery path of evolutionary resilience is derived from the evolutionary trajectory of socio-ecological systems (SESs), which are coupled systems of human social systems and natural ecosystems. It is generally believed that the evolutionary trajectory of socio-ecological system has two cycles and four stages(Holling, 1986,p.). Among them, the growth phase (R) and the conservation phase (K) constitute the first slow, cumulative cycle of positive looping, and the collapse and release phase (Ω) and the reorganisation phase (α) constitute the second unpredictable cycle(Gunderson and Holling, 2003,p.). In the study of socio-ecological system, adaptation, recovery and change are three attributes that characterise the evolutionary trajectory of socio-ecological system. Among them, adaptation can be understood as the behavioural activities of managers in human societies, whose decisions and behaviours consciously or unconsciously affect the resilience of the socio-ecological system, and change is the introduction of new components and ways of making a living based on restoration, which defines and creates a new stable state (Figures.1) . Therefore, the essence of socio-ecological system resilience evolution resilience construction is the capacity building of the evolutionary process and circular mechanism of the socio-ecological system.



Figures.1 Building socio-ecological system resilience

Source: Author's own drawing

Rural areas are more vulnerable to shocks and have a weaker resilience than regional and urban areas because they lack the necessary financial and human resources to plan and respond to emergencies(Ge et al., 2022,p.14533). The concept of rural resilience emphasises that rural areas are adaptive, resilient and transformative, moving from decline to regeneration as they interact with their internal and external environments(Huang et al., 2018,p.47-55). Rural areas that interact more frequently with the market economy and have more social and environmental capital are generally considered to have stronger resilience. The village is a component of socio-ecological systems (SESs), in which humans, natural resources and the environment interact at multiple spatial and temporal scales, and the socio-ecological system plays an important role in providing material and non-material support for villagers' production and life(Cheng et al., 2022,p.645-661). Rural resilience played an important role in the COVID-19 shock, and despite the spatial isolation of rural areas in China as a result of the restrictive measures implemented during COVID-19, there are still parts of the countryside that have the governance system, social effectiveness, physical and technological infrastructure, and economic flexibility to organise the flow of local commodities to meet emergency needs(Hu and Zhang, 2022,p.). Most academic studies on the impact of COVID-19 on rural China view resilience as a cross-sectional state, and few studies have explored the process and trajectory of resilience in terms of its formative elements and constructive mechanisms, which require a certain amount of time to follow up. Compared with large-scale tracking surveys, micro-case studies of tourism villages can better illustrate the process and operational mechanisms of resilience. Therefore, it is necessary to study the resilience of the socio-ecological system in the villages that recovered quickly and operated normally after the impact of the epidemic, as to provide theoretical support for the construction of rural resilience in the post-COVID-19 era.

2.2 Social Capital In Rural Governance

Unlike traditional management, governance refers to the process by which public management organisations, whether official or non-governmental, coordinate and cooperate in defining norms and rules for the conduct of public affairs on the basis of common goals(Modelski and George, 1993,p.311-545). Traditional top-down rural governance is no longer suitable for the existing multifunctional rural environment, and flexible multi-participant collaborative models provide adaptive capacity to manage complex rural socio-ecological systems by increasing the economic capital of the system and strengthening industrial linkages. Adaptive governance provides better opportunities for decision-making structures, long-term social welfare and sustainable economic development(Rivera-Arriaga et al., 2021,p.105518). In China, the

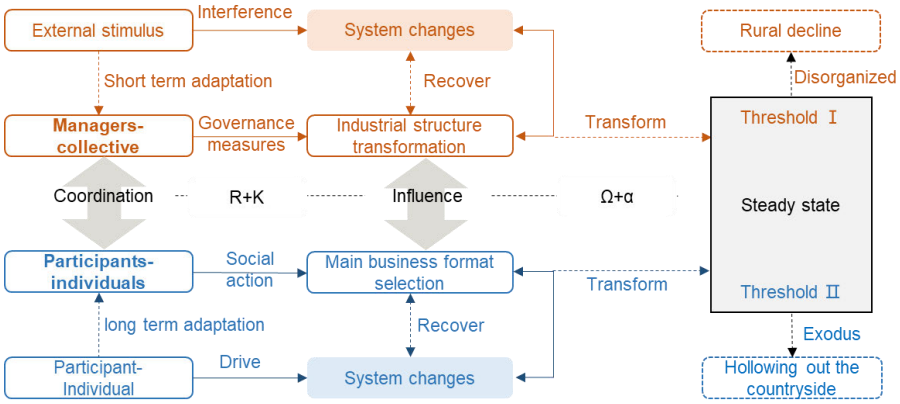
governance system is characterised by a combination of political centralisation and economic regional decentralisation. As rural revitalisation is regarded as a national policy, local governments with the intervention of state power have the right to directly lead, encourage farmers to organise themselves, and promote the participation of enterprises in projects. With the progress of modernisation and the extension of state power to the countryside, grassroots governance in Chinese villages has been transformed from folk clan power to a long-term political-administrative model of governance(Yin and Rui, 2023,p.8882), resulting in the formation of a particularly informal administrative body, the village committee. As local (grassroots) administrators, they can not only ensure the implementation of the work of the state in the countryside, but also promote the stability of the order of the socio-ecological system in the countryside(Ye et al., 2019,p.). In the process of transformational development of villages, village council administrators may have less authority and influence over their residents, but they play a key role in adversity in the face of risky shocks(Liu and Yang, 2019,p.5553).

Due to the characteristics of China's countryside, such as low population mobility and small regional scale, the formation of an acquaintance society is not conducive to the vertical decentralisation of state power for administrative organisations to solve rural governance problems(Hu, 2020,p.012077). Social capital, as an important type of informal system, serves as a lubricant between institutions and the public, and can reduce the transaction and implementation costs for the government to promote and implement policies and regulations(Evans, 1996,p.). At the same time, because villagers have the same identity perceptions, values and emotional perceptions, they interact with each other to participate in public events, and reciprocity or constraints are formed between participants and administrators in order to reduce costs and difficulties, which can improve rural environmental governance(Wang and Li, 2018,p.46-55). Positive and responsive attitudes in this process can effectively improve the relationship between participants and managers to better conduct public affairs and accumulate social capital in the process(Coles and Buckle, 2004,p.6-15). The role of social capital in the socio-economy is accentuated by the lag in the development of formal institutions in the countryside. Social trust provides a structural basis for the formation of social networks and the occurrence of social participation that provides mutual benefits, a process that is conducive to the implementation of public policies and the accumulation of social capital(Wang et al., 2021,p.11883), which provides social, economic, and human resources to withstand a variety of natural disasters, and is an important contributor to the construction of rural resilience(Vesely et al., 2017,p.93-110). The specificity of Chinese rural social capital provides different perspectives for the study of rural resilience, and has outstanding theoretical value and practical significance in enhancing the resilience of rural areas to cope with internal and external perturbations, and thus resolving the impacts and crises of the internal and external environments(Ge et al., 2022,p.14533). Previous studies have mainly focused on the direct causal relationship between rural social capital and resilience and how to use social capital to build resilience, but under the cycle of rural social system, the construction of rural resilience is actually a synergistic effect of multiple elements. Therefore, the interaction and synergistic paths of different elements in the process of building rural socio-ecological system resilience deserve further research and exploration.

2.3 Research Framework

Based on the above discussion, we propose an analytical framework for rural socio-ecological systemresilience(Figures.2). In order to better adapt to the rural governance and social capital context, we add the participant dimension to the original manager dimension, and analyse them as the action subjects of rural governance and rural social capital respectively, to reveal the process of constructing RESILIENCE for the two dimensions of rural subjects under the micro

perspective. Among them, synergy is reflected in the fact that the adaptive governance and participation model of rural socio-ecological system can enhance social capital accumulation. Local managers use the interactive bridge of social capital to connect villagers for the exchange of information and resources, gluing together village functions and social networks, and helping to develop measures and approaches to promote environmental governance and improve resistance to public disaster events. The accumulation of social capital can promote villagers' participation in grassroots governance, and good social network relationships can enhance social trust among villagers. Positive social participation can improve the relationship between participants and grassroots managers, promote the development of new ideas, create the necessary flexibility for ecosystem interactions, and deepen the understanding of socio-ecological system resilience.



Figures.2 Research Framework

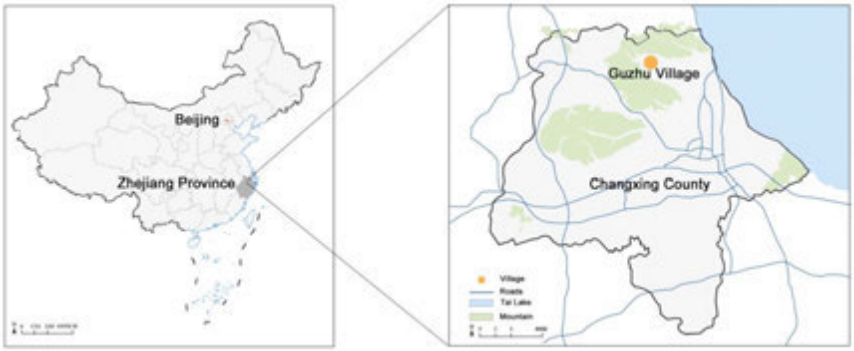
3 Research Design

3.1 Study Site And Representativeness

Guzhu Village is located in Changxing County, Huzhou City, northern Zhejiang Province, China (Figures.3). Although the variety of village resilience models that survived COVID-19 makes it seem impossible to generalise, our case village represents a metropolitan hinterland tourism-based village, which should be applicable to many rural socio-ecological system resilience constructs for the following reasons:

Firstly, the selected villages are representative of rural tourism, with a relatively well-established farmhouse tourism cluster before COVID-19, and a good base of rural governance and social capital. This is also more relevant to the village's location in Zhejiang Province, which is located in the eastern coastal region of China, in the Yangtze River Delta economic frontier circle. after 2002, rural tourism in Zhejiang Province entered a period of rapid development. Guzhu Village is one of the largest rural tourism clusters in the Yangtze River Delta region, and the farmhouse tourism industry has been evergreened for 20 years. Secondly, Guzhu Village farmhouse is spontaneously formed, due to the village's geographical location and convenient traffic. The straight line distance between Guzhu Village and the urban area of

Shanghai is about 160 km, the straight line distance between Guzhu Village and the urban area of Hangzhou, the capital city of the province, is about 100 km, and the straight line distance between Guzhu Village and large and medium-sized cities, such as Nanjing, Suzhou, and Wuxi, is not more than 150 km. Guzhu Village has developed rapidly to form an industrial cluster by virtue of its characteristic industries and transport advantages, and in the process, the government has maintained benign interactions with the operation owners, owners and customers, and owners among owners. In the process, the government and business owners, owners and customers, as well as the owners maintain a positive interaction, showing a more ideal sustainable state of the village.



Figures.3 The geographical location of Guzhu Village

Source: Author's own drawing

3.2 Research Methods

Our research team conducted a field survey of Guzhu Village in 2023, mainly using field surveys, questionnaires, in-depth interviews, and other research methods, distributing research questionnaires to local villagers and tourists, and conducting semi-structured interviews with the main participants in the local farmhouse tourism industry. The research questionnaire was conducted from the dimensions of basic crowd information, family livelihood, spatial environment, rural governance, rural tourism pension, rural resilience, social perception and before and after the epidemic. Interviews were conducted from both groups of managers and participants. The interview process also observed the impact of rural planning on living, production and ecological space.

4 The Evolution Of Farmhouse Tourism Before And After The Epidemic

4.1 Pre-Epidemic: The Growth And The Conservation

Guzhu Village's initial leading industry was the textile industry, where villagers used unused farm buildings for weaving, which not only required 24/7 production, but also earned extremely low processing fees. With the small scale and low income, the farmers lacked the freedom of decision and choice. 1993, a retired Chinese medicine practitioner, Wu Ruian, established the first rehabilitation and convalescent centre for the elderly in Guzhu Village - the "Shenxing Rehabilitation and Nursing Home", which attracted a large number of elderly people from Shanghai to recuperate here. Due to the increase in traffic and the shortage of rooms, villagers in the neighbourhood began to rent out their own farmhouses for the elderly to use. The villagers

realised the business opportunities and in 2000, the first local villager-run farmhouse, Wang Ta Zhuang, was born. As the entry threshold for farmhouses is not high, and farmhouses are relatively easy to run compared to 24-hour looms, local residents have since followed suit, and the development of farmhouses has gradually become a trend.

After 2005, the number and size of Guzhu Village farmhouses grew dramatically. By 2014, the 325 B&Bs in Guzhu Village had received 2.5 million visitors in a year, 80 percent of whom came from Shanghai, making it a well-known "Shanghai Village". After 2015, after a period of growth in the number of dramatically increased, the market competition has become more intense, monotonous, crude farmhouse business model has gradually failed to meet market demand. As the farmhouse tourism industry enters a stable development stage, the production resources of the socio-ecological system are gradually locked, and the system matures with the inevitable rigidity, and the flexibility and resilience of the system will gradually decrease. Specific manifestations include product quality and economic service level failing to keep up, serious homogenisation, lack of public support services, and the need to improve the hygienic environment. Many farmhouse operators began to seek business philosophy innovation and quality enhancement, township government, village committees and other managers combined with the comprehensive improvement of the overall environment to carry out comprehensive renovation and upgrading of the farmhouse in the business environment and quality of service and other aspects of the overall transformation. They rely on farmhouse industry associations to establish and improve industry standards and boost the transformation and upgrading of farmhouses to boutique B&B.

'With regard to the rectification and upgrading of farmhouses, we have carried out the following work: strengthening the rectification of farmhouse food safety, fire safety and security safety. Concentrate on farmhouse environmental hygiene and improve public supporting facilities. Standardise the level of farmhouse services and improve the quality of farmhouse space. Establish farmhouse long-term management mechanism, etc. (Township government staff)'

4.2 Post-epidemic: The Release And Reorganisation

Guzhu Village farmhouse was at the bottleneck stage of industrial development from scale expansion to quality upgrading, and despite the manager's governance measures, little was achieved. Because renovation and upgrading meant a phased closure of the business, which greatly affected the owners' income, the emergence of COVID-19 turned things around. In fact, the impact of the epidemic on Guzhu Village was so great that in order to safeguard people's lives and property, the township government in which Guzhu Village is located activated a comprehensive emergency response plan as soon as the outbreak occurred, made the decision to shut down the entire industry immediately, and summoned all the village cadres, members of the industry association, and volunteers to take measures to prevent the epidemic.

During 2020-2022, in order to properly deal with the problem of migrant workers staying in the village during the epidemic and to improve the scenic quality and supporting facilities for rural tourism, the village committee's rural planning and spatial environment improvement introduced projects such as the Twelve Square of the Tang Dynasty and the Great Tang Nocturnal Street, and called on the stranded workers to form an engineering and construction team to push forward scenic area renovation (Figures. 4). The manager's governance measures address the problem of epidemic impact while providing new components for village change, laying a hardware foundation for resumption of work and production after the epidemic, further

enhancing the village's ability to resist external impacts, and establishing a long-term plan for the village's sustainable development.

'The next relevant planning, will continue in the village public space layout Lu Yu study, Huaxi Valley camp, the new visitor centre, style station, etc., and some tea culture supporting facilities for commercial business to do supporting space, including for some of the young people to Guzhu, the original market has been relatively complete, the subsequent supporting facilities are actually geared to the needs of other age groups. (Cultural Tourism Corporation staff)'

Figures.4 Guzhu Village Leisure Tourist Attractions

Source: On-site shooting and Internet

The construction and renovation of the rural scenic spot project has also led to the renovation and upgrading of 156 rural farmhouses and the construction of beautiful courtyards in three districts. The business owners did not stay in the vicious circle of homogeneous competition, and used the gap time of the epidemic to participate in the village collective skills training, for example, to carry out e-commerce operations, and to carry out the construction of beautiful courtyards and environmental improvement with the help of village committees and associations and organisations (Figures.5).

Figures.5 Skills training, beautiful courtyard construction, and farmhouse upgrades during the epidemic in Guzhu Village (from left to right)

Source: Information provided by the village committee

The cycle of the village socio-ecological system shifts from collapse to restructuring, and turning crisis into opportunity requires a great deal of preparation. In the case of Guzhu Village, the post-epidemic reorganisation was undoubtedly a success, thanks to the adaptive decisions and actions of managers and participants in the face of shocks, as well as to the participation of

the entire population through effective village planning, which prepared them for innovation and transformation in the face of uncertainty during a period of change.

5 Managers And Participants Of Rural Resilience Building

5.1 Adaptive Governance For Managers

5.1.1 The Main Body Of Governance Supports The Development Of The Industry

Although China has adopted a market-oriented development path, the allocation and supply of resources is manipulated by the government, and the Guzhu Village farmhouse tourism industry, although it has formed industrial clusters in which many operators and enterprises have joined, is essentially a village collective type of rural tourism. The village collective type of rural tourism mainly refers to the village to form the appropriate management organisation, the top-down implementation of unified marketing, management, training and supervision mode, the village tourism entities actively participate in it, abide by the rules and regulations of the village, enjoy the rights and interests therein. The support of the local government provided a favourable social environment for rural development, which played an effective macro-control role during the epidemic. The top-down vertical governance system in the implementation of the village collective rural tourism model can better discipline the behaviour of the villagers, integrate resources, and promote industrial transformation and upgrading. This governance model is also recognised by the villagers, with more than 75 percent of villagers believing that the "government" is the main body that supports the development of the tourism industry in Guzhu Village farmhouse.

'During the entire epidemic, the government does not allow crowds to gather, and do not allow mahjong, then we mobilise people to do volunteers, to skills competitions, to promote the construction of beautiful courtyard. At the same time, our government introduced support and encouragement policies, in fact, is to assist in equipping strategic materials, masks can not be bought, temperature guns can not be bought, disinfectant can not be purchased, whoever is doing a good job will be given priority to configure, to improve the overall owner's motivation. (Village Council staff)'

5.1.2 Association Organisation Drive The Implementation Of Decisions

Although the vertical governance body lays the policy foundation for rural industrial development, the implementation and practice of decision-making requires the collaboration and co-operation of many parties to ensure the positive cycle of the socio-ecological system, which is reflected in the existence of the farmhouse association organisation. As the members of the association are spontaneously selected by villagers, they have a foundation of social trust. They have established a social network with the villagers' owners and have a certain sense of identity and reverence. The association managers are willing to take the initiative to undertake the tasks assigned by the organisation, and the participants are also willing to respond positively. Although the association does not have administrative functions and management functions, but the village committee grants the association organisation certain power to maximise the interests of business owners, that is, to win the support of the masses, but also to carry out their work better. While the association promotes the implementation of decisions, it also seeks benefits for the participants, who are themselves farmhouse owners, understand the real needs of the participating groups at different stages, and have a certain degree of voice.

'For farmhouse scenic spot renovation and upgrading, many villagers are also reluctant at first. Then the village cadres, party members, association directors, villagers' representatives take the lead in the first demolition of the first change. For a part of the farmhouse owners who have ideas and concepts and urgently want to renovate and upgrade, we fully support them in terms of design, construction, funding, etc., to create samples, and driven by the samples, the villagers slowly began to renovate and upgrade on their own initiative (Association organisation staff)'

5.2 Social Capital Accumulation Of Participants

5.2.1 Family Business Promotes Social Trust And Reciprocity

The villagers of Guzhu Village are both managers and participants in the construction of the village's socio-ecological system resilience, and more often than not, they play a role in the system and accumulate social capital as participants. In addition, there are also hotel chains and fleet operators, who together with the majority of villagers constitute the group of participants. The family business model created by the participants, mainly farmhouse owners, lays the foundation for the creation of social trust and plays a crucial role in business transactions and daily life. Although this business model is small in scale, low in management, and weak in branding and competitive market influence, the bound social trust has not hindered innovation and adaptation, but on the contrary, has higher risk resistance and lower operating costs, and the flexible business model improves the resilience of system.

Farmhouse owners are getting younger, with an average age of 39.4, and are able to keep up with the times and develop diversified industrial businesses. Although most of the villagers are engaged in commercial services, they still choose to take care of their farmland privately and hire their relatives to do farming, accounting for 79.8 percent, which makes the villagers' incomes more diversified and affluent, and enables them to have enough economic basis to resist external shocks. This kind of family business model is restricted by the geographical location of the village, and is generally composed of villagers from the same village, who rely on the formation of an "acquaintance society" to attract new customers, which prevents the formation of "low-price competition" to a certain extent. The case of Guzhu Village proves the virtuous cycle of the family business model, and also serves as the basis of resilience building to ensure the stable operation of the system.

'In the operation process will also encounter some bottlenecks, for example, now more and more farmhouse well, competition is also more and more. But we are not afraid of competition, because we correspond to different consumer groups in different places, good relations between peers. Sometimes there are things in the family can not receive, other families have a lot of farmhouse ah, can be recommended to other people's homes. (Rural farmhouse operators)'

5.2.2'affectionate'aterelationships strengthen social networks

The patron-client relationship in general business transactions is an interaction based on the goods being traded, where both parties clarify their respective responsibilities and rights, and establish a good relationship of trust and co-operation in order to achieve common business goals. However, in Guzhu Village, after many years of receiving tourists, there is a high degree of integration between urban and rural civilisations, and a high degree of trust has been built up between the owners and the tourists, which goes beyond the relationship between the host and the hosted, and the social network formed as a result of this relationship is more close and intimate. This 'affectionate' relationship is also an important motivation for the transformation

of Guzhu Village into a B&B. On the one hand, the owners will listen to the suggestions of tourists to optimise their products and services, and on the other hand, the accumulation of social capital will increase economic efficiency.

'Having run a B&B for many years, I have kept in mind the points of need of our guests and have made it a point to refer to most of our regular customers. Also, because of this kinship, because of this trust, customers will lend us their savings interest-free to help us with remodelling and upgrading or investing in potential projects in the village. As far as I know, more than 60 percent of the operators in the whole B&B industry get part of their renovation funds from tourists. (Village boutique B&B operators)'

6 Conclusion

China's rural transformation has a different background from that of Western countries, and through the case of Guzhu Village, we can see the evolutionary trajectory and cyclical process of rural socio-ecological system resilience, which forms a better inspiration and paradigm for the construction of resilience in rural areas. Through the incident of COVID-19, our research has deeply explored the construction process and operation mechanism of rural socio-ecological system resilience, and formed the following conclusions.

First, farmhouse tourism provided new possibilities for economic activities in Guzhu Village, triggering an explosive growth of farmhouses. However, the outbreak of COVID-19 revealed the vulnerability of village tourism, and the stagnation of the industrial economy accelerated the collapse of the village socio-ecological system, which in turn catalysed the transformation and upgrading of the village. Second, managers effectively enhance rural resilience. adaptive governance by managers vertically integrates resources from different levels of government to support the operation of the rural socio-ecological system. Horizontal collaborative governance promotes the implementation of decision-making and assists clusters in adapting to external shocks and promoting system change. In addition, participants guarantee system stability. The family business model derived from the villagers as participants is the economic foundation of the farmhouse tourism industry, and the basis for the construction of socio-ecological system resilience, and the "affectionate" patron-client relationship constructs a two-way multi-node social network connection, realising social capital. The "affectionate" patron-client relationship constructs a two-way multi-nodal social network connection, realises the transformation of social capital into economic capital, and enables the system to have a stronger adaptive capacity.

Our case study reveals the construction process and mechanism of rural socio-ecological system resilience under the COVID-19 shock, but inevitably there are certain limitations, as there are many types of villages in China, and villages in the hinterland of the metropolis respond to the shock of public events such as epidemics in different ways, and the mechanism of their resilience needs to be revealed by more extensive research. In future research, we will explore the resilience patterns of villages in other regions.

Abstract

Smart cities are rapidly emerging globally, with data resources being crucial in their development. Currently in China, data in smart cities is largely acquired through tracking and monitoring by sensors and control rooms. Moreover, challenges in managing, transforming, and sharing heterogeneous data result in smart cities facing the issue of "data islands." Furthermore, urban issues and development complexity call for more grassroots collective intelligence. Addressing the above-mentioned challenges, this paper proposes a new approach from the perspective of platform urbanism. It suggests constructing a "platform data ecosystem" for smart city development, contemplating how to enhance data acquisition diversity and human-centric nature, optimise data resource management, and facilitate diverse open data utilisation.

Keywords

Platform urbanism, Smart cities, Data, Human-centric, Collective intelligence

1. **Introduction**

With the advent of the Fourth Industrial Revolution, commonly referred to as Industry 4.0, urban development has been transitioning from informatization towards intelligence (Liu, 2019). The emergence of Smart Cities signifies a paradigm shift towards a more systematic, interconnected, and efficient urban development model, embedding cities into extensive networks of digital and technological infrastructure through the advancement of Information and Communication Technologies (ICT), Internet of Things (IoT), pervasive technologies, Augmented Reality (AR), and Artificial Intelligence (AI). The integration of Smart Cities with various infrastructures such as IoT, sensors, Wi-Fi, among others, has given rise to what is termed as the "digitisation city," aiming to gradually construct urban spaces through the capture and analysis of data. However, as highlighted by Barns (2018), the current mechanistic approach to data collection often leads to a proliferation of disparate data services and assets rather than broadly applicable socio-technical solutions. Similarly, Shelton, Zook and Wiig (2015) argue for the necessity of more location-based and experiential explanations to capture urban dynamics. Currently, data sharing practises and circulation increasingly gather and organise through "urban data platforms," representing a new data-driven governance model characterised by various types of open data services covering the entire process of collection, management, and application.

According to the 17th to the 52nd "Statistical Report on the Development of the Internet in China" by the China Internet Network Information Centre (CNNIC), from 2006 to 2023, the usage trends of the internet have shifted from activities such us online music, streaming, news, search engines, and online gaming towards online shopping, travel booking, ride-hailing, online government services, social media, and public services. Particularly after the widespread establishment of WiFi in 2016, the increase in the number of internet users and robust market demand has fuelled a boom in platform development. Major digital platforms have gradually penetrated all aspects of urban living, transportation, consumption, and governance in China(Caprotti, Chang and Joss, 2022). The scale of China's platform economy has grown significantly, continuously changing urban experiences around the "sharing" and "real-time" organisational logic, and related platform research has also flourished. Meanwhile, the rapid development of digital platforms in China, through the generation of vast amounts of data, and the enhancement of communication and transmission capabilities, has become intricately linked with the development of Smart Cities（Caprotti and Liu, 2020）. Platforms are increasingly

becoming essential for experiencing, regulating, and governing cities, and are critical for the transformation of China's smart cities from informatization and intelligence to intelligent based on new economic development models, new life and work models, and new spatial interaction models.

Amid this trend, the discourse on Platform Urbanism has emerged (Barns, 2014), encompassing discussions on open data, diverse participation, urban economy, urban governance, urban life, and space, aiming to seek more inclusive and sustainable smart city development solutions (Richardson, 2020; Odenaal, 2022). Platform urbanism emphasises bottom-up data creation, promoting diverse, open data management and application as an essential aspect of smart city development in the new era. This paper first reviews the origin of platform urbanism and its relationship with Smart Cities, integrating the discussion of platform urbanism into the framework of smart cities. Subsequently, it summarises the data collection and management challenges faced by China's smart city development, identifying platforms as a new opportunity for data governance in the new era of smart city development in China. The paper proposes a "platform data ecosystem," discussing the role of platform data in smart city development in three aspects: platform database construction, management, and application, providing insights for China's smart city development in the new era.

2. Smart Cities and Platform Urbanism

2.1 The Origins of Platform Urbanism Research

The study of platform urbanism originated from reflections on smart cities, initially proposed by Barns (2014) during the American Association of Geographers Annual Meeting. She suggested rethinking the top-down model in smart cities, advocating for smart citizenship and urban participation, emphasising that "creating data" means "creating cities" and promoting bottom-up urbanism. Additionally, a crucial feature of platform urbanism is viewing data as a resource for urban management and economic development.

2.2 The Relationship Between Smart Cities and Platform Urbanism

As a new concept, the discussion of platform urbanism is rooted in the lineage of smart cities (Caprotti, Chang and Joss, 2022). While there is overlap in content between the two, there are key distinctions: smart cities typically focus on governance entities with clear geographical boundaries, led by governments and supported by enterprises providing digital systems and technologies to upgrade infrastructure. They aim to enhance urban operational efficiency, competitiveness, and long-term public governance services, supporting long-term planning. Smart cities primarily extract data through intelligent technologies, such as digital sensors and control rooms, to track and monitor people and things. In contrast, platform urbanism, although rooted in urban environments, exhibits geographical flexibility, operating across different countries and borders. Platform providers act as intermediaries between producers and consumers, embedding themselves in the daily operational environment of cities and involving users in city operations. Moreover, they support urban governance through real-time data and voluntarily uploaded data (Caprotti and Liu, 2020) (See Table 1).

Despite the varying emphases in different dimensions, platform urbanism can still be seen as an extension and expansion of smart cities. By combining digitalisation with smart cities and leveraging characteristics such as boundarylessness, daily operation, real-time interaction, flexibility, and participation, platforms strive to transform cities into vast ecosystems. They

serve as intermediaries in coordinating cities, enriching the application scenarios of smart cities, and enabling residents to participate more actively in the construction of smart cities in a more daily manner, thus further realising the human-centred, sustainable, and coordinated development concept of smart cities.

Table 1. Key Differences Between Smart Cities and Platform Urbanism

2.3 Data Challenges in China's Smart City Development

Comparison Aspect	Smart Cities	Platform Urbanism
Core Focus	Bounded city, defined by geographical boundaries and governed by administrative entities	Unbounded city, characterised by geographical flexibility
Participants	Government: The government is the main driver of smart cities, serving public governance, enhancing urban efficiency and competitiveness; Enterprises: Enterprises sell digital systems and technologies to the government.	Platform Providers: They provide an attractive digital interface between producers and consumers that can layer, embed, and apply to multiple urban environments. They operate the urban platform through local providers and user participation; Platform Users: They obtain information and consumer services in real-time on integrated platforms and participate in social interactions and public affairs.
Timeframe	Long-term: The investment in smart cities is related to government strategic cycles, such as upgrading long-term infrastructure and administrative management systems, providing support for long-term planning.	Instantaneous: The focus is on daily and instantaneous services and interactions based on short timeframes.
Materiality	Digital sensors, control room	The daily operating environment of urban functions: such as Airbnb houses, food delivery factories, express delivery vehicles
Primary Technology	Smart City Technologies: The Interaction of Digital Infrastructure and Municipal Management	Digital technology and data analysis technology: analysis of real-time data in specific platforms
Digital Resource Characteristics	Extractive data, usually obtained through tracking and detection	Interactive data, voluntarily uploaded by the public

China's smart city construction is booming, and its advanced development stage is believed to involve building digital twin cities—a cyber-space with a mapping relationship to the physical urban space, emphasising real-time interaction between the two (Wu et al., 2022). Real-world urban dynamics are fed into the virtual city in real-time to analyse urban issues on cloud platforms and manage cities in real-time. The key is real-time data collection, storage, computation, and analysis of urban spaces. Through the diverse and multi-temporal data in cyberspace or digital space, the physical city can be analysed in real-time to achieve intelligent management and provide decision-making suggestions for urban governance and future

development.

However, achieving this vision still faces barriers such as limited data acquisition channels, low real-time precision in data collection, low data sharing rates, and non-intelligent data analysis. Firstly, the sources and channels of data acquisition for smart cities in China are relatively limited, primarily relying on extractive data obtained through tracking and detection technologies, lacking diverse and heterogeneous data management, conversion, and sharing data. Additionally, the storage and management of data have not reached an organised state of openness and sharing. Various entities such as government agencies, platforms, and enterprises in urban areas generate vast amounts of data. The challenges of managing, transforming, and sharing diverse and heterogeneous data interchangeably have led to the current dilemma of smart cities facing both a "data explosion" and "data isolation." It is imperative to establish unified management and regulations to facilitate data sharing and security across departments. Moreover, smart data analysis has not yet achieved the desired level of intelligence. The continuous emergence of new technologies, such as the Internet of Things, cloud computing, and artificial intelligence, undoubtedly drives the development of intelligent data analysis. However, addressing the complexity of urban issues and development requires more collective intelligence from the bottom up, as solely relying on technological development may risk deviating from the essence of public life and the city. Therefore, the intelligent level of data analysis requires greater collective intelligence from the grassroots.

3. The "Platform Data Ecosystem": Platform Data Collection, Management, and Application

This paper proposes a "platform data ecosystem" to leverage platforms' broad user base and diverse data content for smart city development. The ecosystem encompasses platform database construction, management, and application strategies.

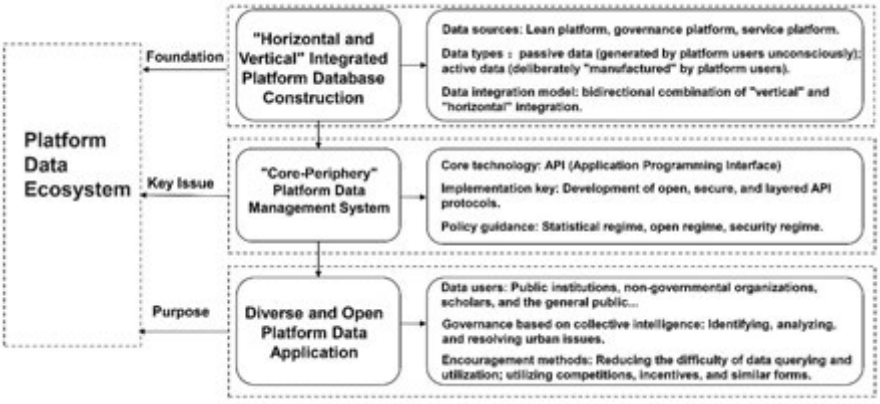

Figure 1. Framework for “Platform Data Ecosystem”

3.1 Platform Types and Data in China

Urban data primarily comes from three sources: remote sensing, infrastructure sensing, and social sensing (Xu, 2023). Among them, remote sensing and infrastructure sensing are relatively "traditional" observation methods in smart cities, while "social sensing" has emerged as a new data source with the development of various platforms. It includes economic data with geographic coordinates, mobility data, emotional data, life data, and resident feedback data on

urban issues.

Based on the platform typology proposed by Caprotti and Liu (2020), this study categorises the commonly seen platforms closely related to cities in China into two types: lean platforms and governance and service platforms. Then, it summarises the characteristics of representative platforms in China and the primary data types they generate (Sun and Wang, 2021; Zhou, Liu and Sun, 2023) (Table 2). These data have been widely used in various aspects, such as urban traffic research, spatial pattern research, urban vitality research, and urban image research, becoming essential resources for smart city governance and efficient urban operation.

Table 2. Common Urban-Related Platform Types and Their Data in China

Platform Type			Platform Characteristics	Platform Examples	Primary Data Types
Lean platform	Commercial/retail platform		Producer/distributor and consumer links. The platform provides an interface for manufacturers and consumers through which goods can be sold and ordered.	Taobao	Economic data
				Ele.me, Meituan	Rider trajectory data
				DianPing	Store scores, location, user's text, image reviews
	Sharing Platform	Transportation platform	Platform operators charge rent or service fees for providing the right to use goods or services. At the same time, through the platform, they can also access goods and services provided by individuals rather than directly owned by the platform operators.	Map platforms: Baidu Maps, Amap, Tencent Maps...	POI, travel trajectory, heat
				Taxi-hailing platforms: Didi Chuxing, Xiangdao Chuxing, Huaxiaozhu Taxi...	Travel trajectory
				Shared bikes/electric bikes; hello bike; Qingju bike...	Travel trajectory, travel location
		Accommodation platform		Wood Bird B&B; Shell Rental	Geographical coordinates, rent, transaction volume, transaction amount
		Office platform		Wework China; Fast Office	Geographical coordinates, rent, transaction volume, transaction amount

Social media platform	Real-time information sharing and dissemination interaction are achieved through broadcast-style information release, which is not limited to text, but also supports pictures, videos, etc.	Weibo, Xiaohongshu, WeChat, Douyin	Check-in information, user text, images, videos, user interaction data
Governance platform	Information and data about the city are aggregated in the platform and analysed through algorithms	city brain	Real-time access to urban transportation, environmental and other data
		pinstreet	Urban problem data with geographical coordinates as reported by users
Service Platform	The government provides services and determines platform functions, usually with a public welfare nature.	Guangzhou E-Government Platform, Zhejiang Li Office, Jiangsu Service Office, Medical Health	Data related to medical, education, municipal administration, etc.

The data generated by the platforms mentioned above can be categorized into two main types: passive and active data.

Passive Data: Obtained without the observed subjects' awareness or knowledge. Platforms can leverage the public as distributed "sensors" in cities (Odendall, 2022), gathering bottom-up, citizen-participatory, and real-time data such as mobile signalling data, map street view data, and traffic trajectory data (Van der Graaf and Ballon, 2019)

Active Data: Data that platform users consciously and voluntarily create. This includes spatial images, text, and emotional data voluntarily created by citizens. For example, text, photos, and videos voluntarily uploaded and reposted by users on social media platforms; evaluations of merchants and scenic spots on consumer platforms—all reflect the public's perception and feedback on cities. Furthermore, another type of "new government data" generated with the construction of urban platforms in recent years also deserves attention. This includes various urban incidents reported by urban management law enforcement officers and community volunteers, and residents' opinions on urban experiences, traffic experiences, neighbourhood renovations, and street quality collected by platforms such as "Lu Jian pinstreet." (Wang, et al., 2020)

Platform users have become a creative infrastructure through platforms, actively participating in shaping, altering, and sharing data content. These data are crucial for experiencing and understanding cities, supplementing bottom-up data sources in China's smart cities, enhancing

the human-centric nature of smart city data sources, and serving as an essential resource for smart city governance and management in the new era.

3.2 "Horizontal and Vertical" Integrated Platform Database Construction

Platform urbanism aims to establish a "horizontal and vertical" integrated platform database. Vertical integration refers to coupling socio-technical elements across physical and digital infrastructure layers to achieve data capture, storage, and utilisation. Horizontal integration refers to extending data collection to different urban fields of human activities and integrating data from different sources and activities into a platform to accumulate cross-domain data (including economic data, mobility data, and public sentiment data) to predict urban issues and provide solutions (Lee et al., 2020). For example, the "Park&Ride" mobile service in the Connecting Digital Cities (CDC) project of the European EIT ICT Laboratory involves data from users (such as mobility trajectories and social networks), data describing the environment (such as weather conditions), and data generated by public authorities (such as public transportation and traffic flow). The Park&Ride service includes a back-end system (Park&Ride Server) responsible for data collection and connected to the CDC platform. The platform processes data integration from various heterogeneous real-time data sources, including standardised RESTful Application Programming Interfaces (APIs) and crowdsourced data sources, and develops wrappers to adapt to different data types, data models, refresh rates, and storage methods. Different modules, such as "Disruption Checker," "Parking Service," and "Route Optimiser," predict traffic congestion, provide parking recommendations, and suggest optimal routes. In this case, the "Park&Ride" mobile service uses vertically acquired data and platform data as the foundational data for traffic services to improve urban traffic efficiency.

This provides new insights for obtaining smart city data in China. On one hand, the development of smart cities in China needs to improve data infrastructure to enhance vertical data integration and improve the "infrastructure-sensor-data storage" vertical data collection process. On the other hand, it is also essential to recognise the new data brought by platform users to enrich the bottom-up data sources in smart cities. The platform itself should serve as an intermediary for integrating and storing both horizontal and vertical data to build a horizontally and vertically integrated platform database, laying the foundation for data management and application in the "platform data ecosystem."

3.3 "Core-Periphery" Platform Data Management Approach

At the management level, platform urbanism describes an interoperable system containing a set of stable core components or services, associated with highly variable external components, thus forming a "core-periphery" data management system that lays the foundation for managing massive platform data. The establishment of API technologies and urban open data policies and regulations are key to the orderly operation of this management system.

Technically, the key to establishing the "core-periphery" relationship through API technology lies in several aspects. Firstly, APIs create an open and programmable environment, allowing developers to build new applications or services on existing platform foundations to expand data scope. Secondly, APIs can set rules to control the collection, use, and sharing of data, and manage third-party access to the platform via keys or tokens, including the accessible data and conditions. Thirdly, APIs ensure security through access control and data transmission limitations, ensuring that only requests that meet specific conditions are processed (Barns, 2020). Thus, API regulations form the fundamental basis for platform data governance.

Reasonable rule formulation is conducive to enhancing the quantity and quality of data, protecting user privacy and data security, and increasing openness and sharing.

Moreover, at the management level, the introduction of policies and regulations related to urban data aggregation, governance, and updates is crucial. This helps break down data barriers, guide the management of authoritative public data sets, and effectively direct open data publishers and users. For example, the INSPIRE (Infrastructure for Spatial Information in the European Community) directive in Europe focuses on environmental, land use, natural conditions, and basic services data, aiming to establish a European spatial information infrastructure. The directive requires member states to ensure the interoperability of geographic spatial data and services, which are made available through open data portals (Živković and Đorđević, 2016).

Currently, data held by the Chinese government and various platform data are often heterogeneous, existing in different formats, and are voluminous. Ensuring the smooth transmission, effective integration, and real-time storage of data from different entities, with different attributes and formats, is a key focus for the new development of smart cities in China. Thus, the Chinese government should establish and improve the legal system for open urban data. Firstly, statistical systems should standardise the minimum spatial statistical unit system, establish spatial metrics for data, and provide data pre-processing to integrate diverse heterogeneous data. Secondly, open systems should be established by the government to define the norms for data opening, guide enterprises and industry associations to legally open data, and promote the multi-dimensional opening and integration of public and non-public data. Thirdly, safety systems should combine public data security requirements, providing secure encryption, logging, and other data management functions for the opening entities, and establish a transparent security management system.

3.4 Diverse and Open Platform Data Application Strategy

One of the goals of establishing the "platform data ecosystem" is to allow and encourage third parties to create value by accessing and using data, which helps promote innovation and transparency. It allows public institutions, non-governmental organisations, scholars, and citizens to access and use the data, directly participating in discussions on urban issues (Pflughoeft and Schneider, 2020). This aggregation of collective intelligence is crucial for identifying, analysing, and solving complex urban problems and helps promote smarter urban governance (Alizadeh, Sarkar and Burgoyne, 2019).

To achieve this goal, it is necessary, firstly, to reduce the difficulty of data querying, reading, and utilisation. This can be accomplished by supporting non-specialist users' access to and utilisation of data through standardisation, visualisation, and other methods. This facilitates citizens in finding urban data related to issues of their concern, enhances citizen interaction with platform data, and leverages public wisdom in identifying urban issues. For instance, Lyon's VLKO (Lyon City Map Observatory) platform is a research and development collaboration project between Lyon's Territorial Development Department, think tank Cité Publique, and the Altercarto Association. VLKO provides geographic information system software for data combination and visualisation, supporting non-professional users in accessing and understanding complex datasets, and organises grassroots workshops to help participants identify interesting issues through related datasets. Additionally, using open-source software encourages users to explore and analyse geospatial data (Slobodova and Becker, 2020).

The second step is to use the platform as a bridge between the public and public institutions.

Competitions, bonuses, and other incentives encourage skilled citizens, academic institutions, and groups to propose solutions to urban problems, and bottom-up solutions are evaluated and improved through voting and discussion to enhance effective data collaboration. For instance, the Apps for Development concept was proposed by former Chief Technology Officer of Washington, D.C., Vivek Kundra. He asked iStrategyLabs to design an open data catalogue useful for citizens, developers, and public institutions. This platform provides a large amount of urban data through competitions, encouraging citizens to develop applications based on this data to solve urban problems. Participants propose innovative solutions based on open data, and the best programmes are selected through evaluation and public voting and awarded prizes.

4. Discussion and Conclusion

Platform urbanism provides a unique socio-technical opportunity for the development of smart cities, and platform data offers a richer, more diverse, and deeper contextual perspective for understanding urban areas. This paper, from the perspective of platform urbanism, explores how to enhance the diversity and human-centric nature of data acquisition in smart cities through active and passive data related to cities on platforms. It advocates improving the openness of digital resources, using the power of the public to help identify and solve problems, and leveraging collective knowledge to achieve smarter, more open, and more innovative urban governance. This paper innovatively proposes a governance framework for the "platform data ecosystem" tailored to the development of smart cities in China, incorporating the integration of platform databases horizontally and vertically, the "core-periphery" management of platform data, and the diversified application of platform data. It calls upon urban planners and managers to adopt new ways of thinking to address emerging challenges, emphasising the role of "platform data" and leveraging platform-related technologies to achieve synchronised planning between digital virtual cities and real cities. This aims to explore new models of intelligent spatial planning and realise new goals for the construction of digital twin cities.

Despite the many advantages of platform data, its inherent limitations in acquisition methods may lead to potential observational biases, including selection bias (Slobodova and Becker, 2020) and information bias (Tripepi et al., 2010). The former means that the observed sample not representing the overall picture of the target population, while the latter refers to errors generated during data collection or measurement. For instance, many studies show that datasets produced by social media platforms are not random samples of the population, excluding a large number of digital disadvantaged groups. Furthermore, platform users, as a type of "sensor," cannot be "deployed" and have the right to choose when and where to upload or not upload specific content. This self-selection may cause information bias. Thus, paying attention to urban data biases, especially those related to human behaviour in active data, and establishing a framework and path for understanding and correcting biases are future focuses of the "platform data ecosystem."

Abstract: In recent years, the acceleration of urbanization and the occurrence of intense rainfall

have led to urban waterlogging, resulting in property damage and threats to human life. The development of flood resilient infrastructure systems is therefore crucial. However, achieving this goal can be challenging in high-density urban areas due to land resource constraints. This study proposes a framework based on local human wisdom that can withstand, absorb and recover from floods in a timely manner to enhance flood resilience in the urban design process. In this study, we analyzed the hydrological characteristics of Zhengzhou City and constructed a rainfall and flood security pattern using GIS and hydrological models. Corresponding blue-green solutions were determined for different topographic conditions. Finally, a macro-scale rainfall and flood mitigation program was designed and its effectiveness was evaluated using the Storm Water Management Model (SWMM). The results show that the Blue-Green program created 40,000 cubic meters of rainwater storage, resulting in significant economic benefits for the community. This approach can improve the flood resilience of inland cities, particularly in response to heavy rainfall and river flooding.

Keywords: urban waterlogging; topographic conditions; flood resilience; Blue-Green solutions; SWMM

1.Introduction

With increasing urbanization and impervious underlying surface, the risk of urban waterlogging has increased significantly (N. Q. Zhou & Zhao, 2013). The frequent occurrence of extreme weather events and the rising threat and impact of climate variability on cities have made urban waterlogging a major concern in many highly urbanizing areas (Hammond, Chen, Djordjević, Butler, & Mark, 2013; Liu et al., 2023). Urban waterlogging disasters cause huge economic loss and pose a serious threat to people's lives. For example, Beijing was hit by a torrential rainstorm in 2012, resulting in 79 deaths, affected 1.602 million people and resulted in loss of more than US$ 1.64 billion (T. Xu et al., 2021); in 2014, Shenzhen suffered the strongest rainstorm since 2008, with economic loss of more than US$ 11 million (Q. Zhang, Wu, Zhang, Dalla Fontana, & Tarolli, 2020). Urban waterlogging has now become a serious obstacle to sustainable urban development and has attracted widespread attention worldwide (da Silva, Alencar, & de Almeida, 2022; Ward et al., 2017). To address this growing challenge, improving urban resilience and enhancing urban waterlogging risk management has become a new topic in many research fields (Liu et al., 2023; Sharifi & Yamagata, 2014).

The development of flood-resistant infrastructure systems is critical. However, achieving this goal in high-density urban areas can be challenging. On the one hand, traditional urban water control infrastructure, such as retention ponds or pumping stations, take up a lot of land and result in a waste of money. They are usually designed with one function in mind: to store rainwater when it rains, or to drain excess rainwater, but they are not designed for dry days (Cheng, Qin, Fu, & He, 2020). On the other hand, land resource constraints could make it difficult to build infrastructure in high-density urban areas. Therefore, in densely populated urban areas, there is a contradiction between the space required for waterlogging management and the scarcity of space (Q. Zhang et al., 2020). In recent studies, scientists have proposed many new ways to reduce urban waterlogging. The relative concepts include Sustainable Drainage System, Sponge City Construction, Water Sensitive Urban Design, and Low Impact Development (Nguyen, Ngo, Guo, & Wang, 2020; M. Wang et al., 2023; Mo Wang et al., 2023; H.

Zhou, Li, Zhao, & Ding, 2021). These theories and techniques suggest that the problem of urban waterlogging management can be partially solved through adaptive initiatives using nature-based solutions (C. Xu, Jia, Xu, Long, & Jia, 2019). However, relying solely on flood prevention to mitigate disasters will make cities more vulnerable (Liao, Le, & Nguyen, 2016).

Taking the heavy rainstorm that occurred in Zhengzhou City on 20 July 2021 as an example. This study first analyzed the hydrological characteristics of Zhengzhou City and constructed the rainfall and flood security pattern using GIS and hydrological models. On this basis, the corresponding Blue-Green solutions was determined for different topographic conditions. Finally, macro-scale rainfall and flood mitigation scenarios were developed and their effectiveness was evaluated using the SWMM. In order to promote urban flood resilience in high-density urban areas, this paper proposes a Blue-Green solutions for improving flood resilience in the urban design process, based on a framework that relies on local human ingenuity and is able to resist, absorb and recover from floods in a timely manner. This is an example of a flood adaptation paradigm and offers lessons for modern cities. This study provides a theoretical and practical reference for the government and urban planners for urban waterlogging prevention and management.

2. Study area

Zhengzhou is the capital of Henan Province, China, with a population of 12.74 million at the end of 2021 and a total urban area of 7,567 square kilometers. The general topographical trend of Zhengzhou is high in the southwest and low in the northeast, with a temperate continental monsoon climate (Fig.1). There are 124 rivers of various sizes within the Zhengzhou Municipality, spanning the two major river basins of the Yellow River and the Huaihe River. The average annual rainfall is 632.4 millimeters, and the average annual number of rainy days is 78. Rainfall is concentrated from June to August each year, with the heaviest rainfall occurring in August. On 20 July 2021, in less than an hour, Zhengzhou was hit by an extreme 1,000-year storm event in which 201.09 mm of rain, exceeding the historical extreme of meteorological observation records in mainland China, left large areas of the city under up to almost a meter of water (Fig.2). The heavy rainstorms affected 13,664,300 people, with direct economic losses of up to US$12.255 billion, and 398 people were killed or missing in Henan Province as a result of the disaster.

3. Data and methods

3.1. Data source and pre-processing

The data used in this study include historical hydrological data, rainfall data, topographic data, and data from the Third National Land Survey in the study area. The data resources are summarized in Table 1.

Table 1

The data and variables used in this study.

Category	Data	Data resource	Abbreviation	Unit
Historical hydrological	Rainfall intensity (2000-2020)	http://ha.cma.gov.cn/	RI-2020	mm/d
	Rainstorm intensity formula (2021)	http://ha.cma.gov.cn/	q	L/s·ha
	Runoff coefficient	http://ha.cma.gov.cn/	y	R/P

	Catchment area	https://www.zhengzhou.gov.cn/	F	m^2
Rainfall data	Rainfall intensity (2021)	http://ha.cma.gov.cn/	RI-2021	mm/d
	Rainfall duration (20 July 2021)	http://ha.cma.gov.cn/	T	min
Topographic data	DEM 30m	https://www.usgs.gov/	DEM	-
Third National Land Survey data	Land use	-	-	-
	Land cover	-	-	-

Enter the relevant data using Arcgis 10.8 to establish a typical rainfall scenario ensemble, record the historical maximum rainfall of the storm at the site as $Pmax/d$, and calculate the required carrying rainfall for the storage cluster Zr

$$Q = qyF \quad (1)$$

$$Z = QT \quad (2)$$

$$Zr = 1.2Z \quad (3)$$

Where Q is the design flow rate of the stormwater system, q is the local storm intensity, y is the local runoff coefficient, and F is the local catchment area; Z is the volume of the storage group, and T is the rainfall duration of the storm.

In Arcgis 10. 8, enter the historical rainfall and water level data of the site, and record the starting time of the field rainfall as T1, the average water level of the regional river network at the time of T1 as W1, the time when the water level of the river network reaches the peak of the field rainfall as T2, and the corresponding peak of the water level at the time of T2 as W2, and the rainfall process from T1 to T2 is defined as the rainfall and water rise period of a field, and in the 24h before the time of T1, the average rainfall intensity should be less than 1mm/d; the maximum rainfall P≥250mm/d in a single day during the T1-T2 period.

3.2. framework of the Blue-Green solutions

The process has been formalized as the Blue-Green Solutions and is implemented through the following five steps: (1) Delineate important mountain and river corridors as ecological protection zones and protect their ecological protection function. The specific way is to accurately identify the extent of the floodway within the corridor, and put forward control requirements -- the road across the ecological corridor should be in the form of a bridge or other does not block the corridor, and leave sufficient safety protection distance on both sides of the floodway and other measures; (2) Include existing gullies into ecological protection. The specific way is to identify the existing gullies that have flood function, delineate the protection line and propose the control requirements - the ecological space within the gullies should be protected from obstruction, filling and construction. The gully within the growth boundary of the town could be landscaped with public recreational demands while ensuring flood safety; (3) Delineate safety groups and calculate water catchment. The safety group is delimited by considering the catchment zoning, the river and the urban growth boundary. Then, the detention space requirements for excess storm water in each safety group under extreme storm conditions are calculated; (4) Implement specific Blue-Green Solutions according to different site

conditions; (5) Attractive development areas are created based on blue-green spaces. The specific way is to landscape the above blue-green spaces and develop them into country parks, riverside green spaces, rain gardens and so on. In normal times, these blue-green systems are superimposed with functions such as pedestrian system, interaction space, agriculture and forestry survival, while in extreme weather conditions, they become important distributed flood storage areas and disaster prevention systems.

3.3. Hydrological Model Selection

There are a variety of ways to assess the effectiveness of the implementation of the Blue-Green Solutions, the most direct and accurate method is using models. A plethora of models have been devised to forecast the consequences of flooding and the efficacy of water systems. Examples of such models include MIKE, Infoworks ICM, and SWAT (Luo & Zhang, 2022; Mignot & Dewals, 2022; Wang, Li, Yu, & Zhang, 2021; Wu et al., 2017). However, it should be noted that the majority of these models are commercially available and are unable to simulate the hydrodynamics of 1D drainage networks and 2D surface flows simultaneously. Consequently, there is a necessity for the development of a comprehensive, accurate, simple, and visual open-source urban flood model for computation (Tan et al., 2024). SWMM is an open-source computational model based on rainfall runoff dynamics developed by the U.S. Environmental Protection Agency (EPA) and is widely used to simulate the quantity and quality of urban runoff (Shahed Behrouz, Sample, & Nayeb Yazdi, 2023). The model is based on physical processes, such as surface runoff, infiltration, surface ponding and flow paths, and can therefore simulate storm runoff volumes (Luan et al., 2017). In comparison to other models, SWMM exhibits superior simulation efficacy and has been extensively employed by scholars engaged in the assessment and forecasting of storm-flood surface runoff processes (Gironás, Roesner, Rossman, & Davis, 2010; Luan et al., 2017; Tan et al., 2024).

In this study, the selected software was SWMM version 5.1, which was employed to describe the dynamic process of rainfall runoff. The construction of SWMM in the study area was based on the urban planning map and the stormwater network layout map. The required basic data, including topographic data, drainage network data, elevation data, and land use type, were analyzed and processed using AutoCAD 2021 and ArcGIS 10.8 software.

4. Results

The topography-based Blue-Green Solutions is applied in Zhengzhou City. The team selected three sites, representing three different topographic and natural conditions, each covering approximately 10 square kilometers in a watershed with high potential flood risk in the center of Zhengzhou City, as demonstration areas to showcase the improved design approach of the Blue-Green Solutions. The final validation was carried out by SWMM to calculate the increased water storage space under the Blue-Green Solutions.

4.1 Trench Ring + Dry Pond mode

This approach has been specifically designed for settlements situated on terraces or sloping plains upstream from the main urban center (Fig.3). The topographical characteristics of these areas typically include steep slopes with gradients greater than 8 degrees and the presence of naturally occurring lowlands, which can be scattered or concentrated. The primary objectives of this mode are twofold: firstly, to ensure the flood safety of the settlement itself and secondly, to prevent the exacerbation of the flood control and drainage burdens on the main city during periods of excessive rainfall. The strategic implementation entails the excavation of trenches

around the perimeter of the town's development boundary, thereby creating a trench ring for each group of settlements. The trenches serve to intercept and manage upstream catchment waters in an effective manner. Concurrently, the delineation of boundaries for flood storage areas, termed dry ponds, is based on the existing natural lowlands. Subsequently, these boundaries are incorporated into the land use plan, with a stipulation that prohibits any urban construction within these designated areas. This ensures the preservation of these critical flood mitigation features.

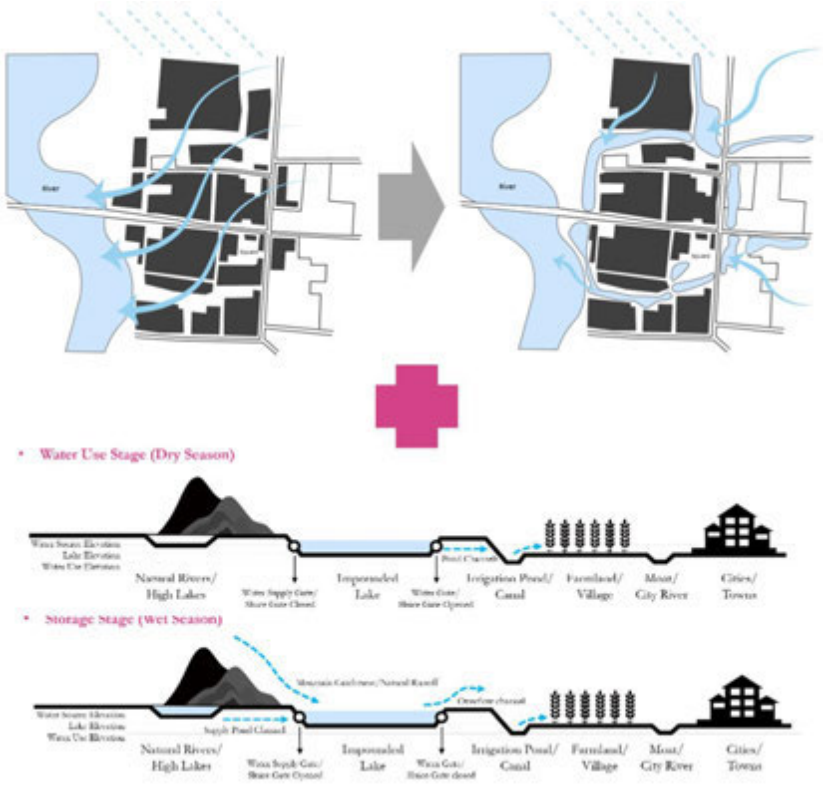

Fig. 3. Trench Ring + Dry Pond mode.

4.2 Connected Ponds + Sponging Infrastructure mode

This mode is particularly suited to main cities located within the plains, which are characterized by a more gentle topography with slopes ranging from approximately 3‰ to 8‰ and a sparse river network (Fig.4). The objective is to address the challenge of urban flooding due to heavy rainfall by providing storage or diversion for such floodwaters. The strategic approach involves the construction of a continuous system of dry ponds, which are interconnected and strategically positioned along natural lowlands and catchment pathways. In areas of the old city where open spaces are scarce, the creation of large, low-lying wet green spaces or natural lands is recommended. Such green spaces are then enhanced through the

integration of grey infrastructure and urban renewal initiatives, such as the renovation of rain gardens in parks and courtyard spaces, and the implementation of eco-roofs and vertical greening on existing buildings. These measures not only contribute to flood resilience but also promote biodiversity and enhance the aesthetic appeal of the urban environment.

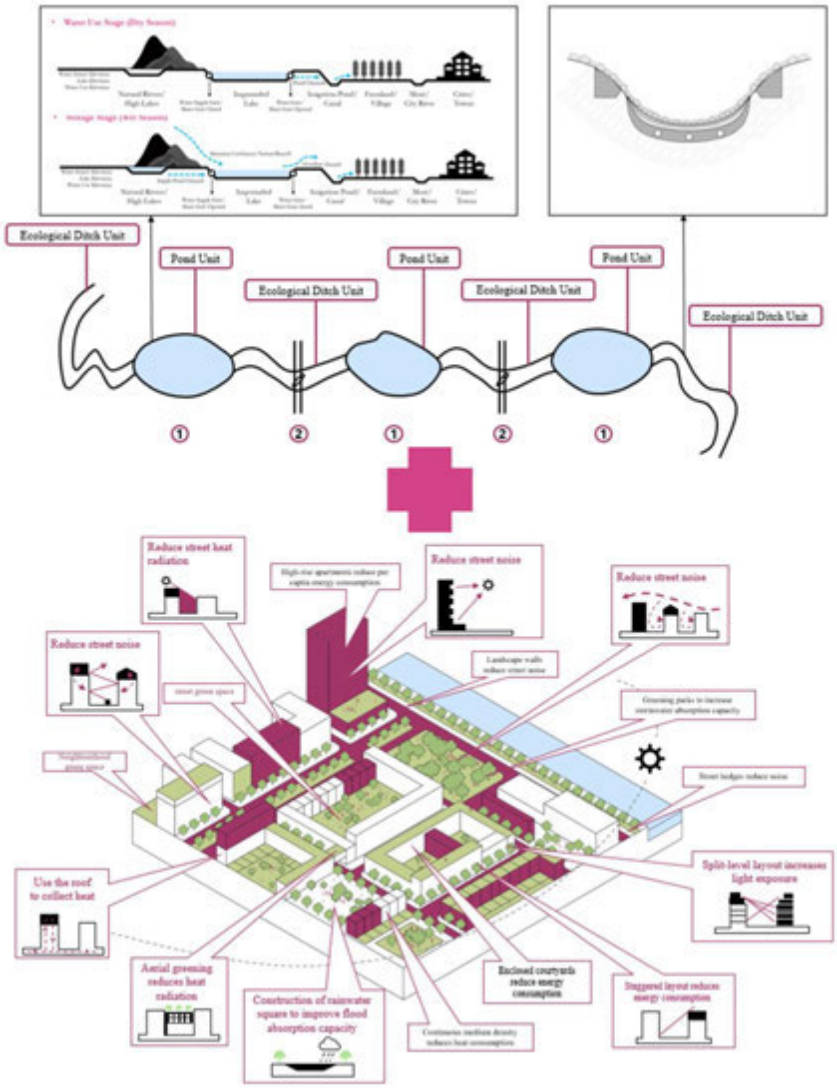

Fig. 4. Connected Ponds + Sponging Infrastructure mode.

4.3 Blue-Green Network + Elevated Groups Mode

This mode is designed for settlements in the low-lying plains downstream of the main city, where the topography is generally flat with a gradient of less than 1‰ and an abundance of

rivers and ponds. The settlements' objectives are multifaceted (Fig.5). They include the storage or diversion of urban flooding resulting from heavy rainfall and the facilitation of the rapid drainage of rainwater through the utilization of blue-green spaces. The strategic response entails the preservation of the site's existing hydrological features and the creation of a landscape comprising ponds, farmland, and streams, thereby forming residential clusters that are surrounded and buffered by blue-green spaces. In order to mitigate the risk of flooding in each cluster, it is proposed that the earth excavated from these areas be strategically used to elevate the road networks and the sites themselves. This elevation provides a crucial buffer, ideally exceeding 3 meters above the surrounding areas, offering protection against potential floodwaters and ensuring the continued habitability and safety of the settlements.

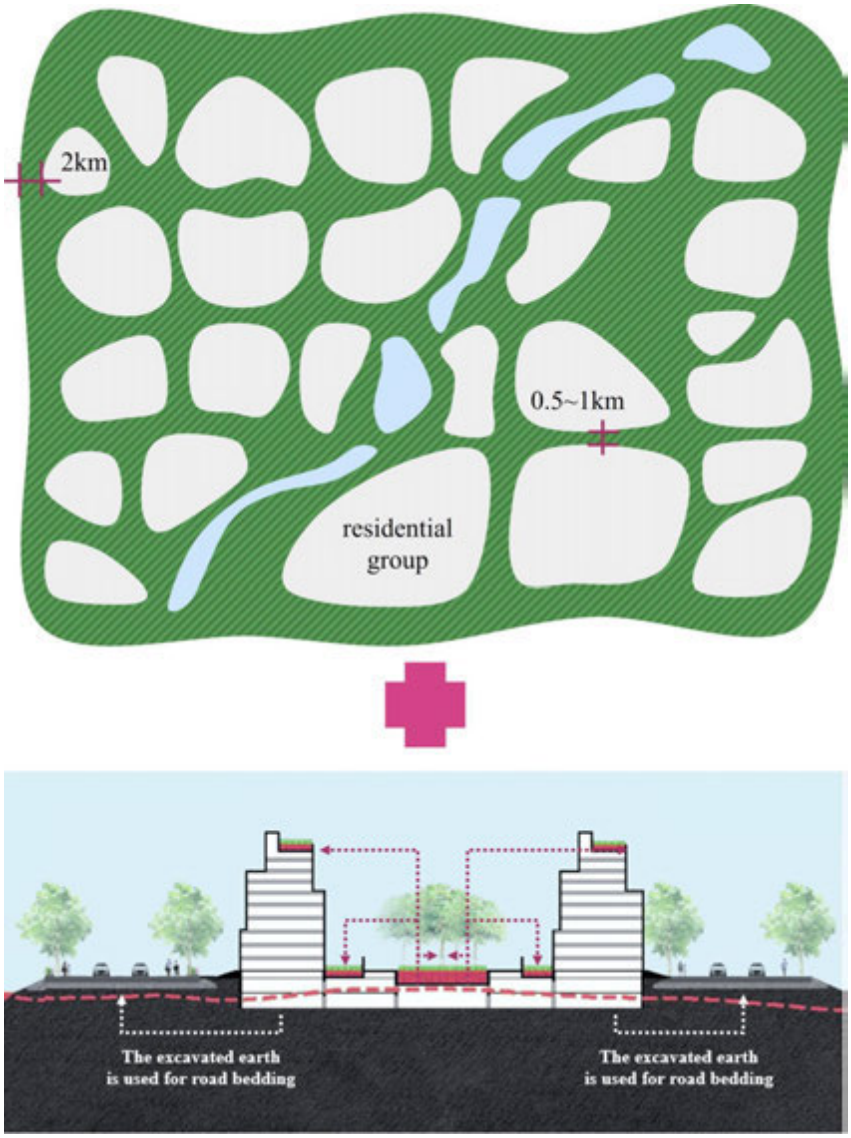

Fig. 5. Blue-Green Network + Elevated Groups Mode.

4.4 SWMM calculates the increased water storage space

In this study, the rainfall data of 20 July 2021 in Zhengzhou City was used to simulate the water storage capacity of the blue-green system under extreme rainfall conditions. A total of three sites were selected as the simulation area (Fig.6), of which Site 1 used the Trench Ring + Dry Pond mode, Site 2 used the Connected Ponds + Sponging Infrastructure mode, and Site 3 used the Blue-Green Network + Elevated Groups mode.

Under the conditions of 1-in-1,000-year rainfall in Zhengzhou City, Site 1 used the Trench

Ring + Dry Pond mode to increase the water storage space by 3918.6 cubic meters compared to the previous one (Fig.7), Site 2 used the Connected Ponds + Sponging Infrastructure mode to increase the water storage space by 2,450.6 cubic meters compared to the previous one (Fig. 8), and Site 3 used the Blue-Green Network + Elevated Groups mode to increase the water storage space by 3,932.9 cubic meters compared to the previous one (Fig. 9). In total, up to 40,000 cubic meters of water storage can be added in Zhengzhou using the three modes above, reflecting the effectiveness of the Blue-Green solutions.

5. Discussion and conclusion

The results of the study underscore the critical role of topography in controlling urban waterlogging, especially in the context of high-density urban areas such as Zhengzhou City. The application of Blue-Green Solutions tailored to the city's diverse topographic conditions has shown significant potential to improve flood resilience and reduce economic losses associated with extreme rainfall events (Lu, Sun, & Steffen, 2023). At the same time, the study provides some spatial recommendations for policy makers and urban planners to improve resilience.

The Trench Ring + Dry Pond mode, designed for hilly or sloping areas, effectively intercepts and manages upstream catchment waters, thereby safeguarding settlements and alleviating the drainage burden on the main city. This approach aligns with the principles of

Sustainable Drainage Systems (SuDS), which emphasize the importance of source control and the use of natural features to manage water runoff (Nguyen et al., 2020). In contrast, the Connected Ponds + Sponging Infrastructure mode addresses the challenges of urban flooding in plain areas with gentle slopes. The creation of interconnected dry ponds and the integration of grey infrastructure with urban green spaces not only contribute to flood resilience but also promote biodiversity and urban aesthetics (Lu et al., 2023). This multifunctional approach reflects the concept of Sponge City Construction, which seeks to mimic natural water absorption and retention through urban design (M. Wang et al., 2023). The Blue-Green Network + Elevated Groups Mode, tailored for low-lying plains, preserves existing hydrological features and creates a landscape that buffers residential clusters against floodwaters. This strategy resonates with the Water Sensitive Urban Design (WSUD) principles, which advocate for the integration of water management into urban planning to enhance the city's adaptability to climate variability (Hammond et al., 2013).

The use of SWMM for validating the effectiveness of the Blue-Green solutions is a testament to the model's robustness and its widespread application in urban hydrology. SWMM's ability to simulate the dynamic process of rainfall runoff makes it a valuable tool for assessing the hydrological performance of urban water management strategies (Luan et al., 2017). The study's results, which indicate an increase of up to 40,000 cubic meters of water storage through the implementation of Blue-Green solutions, highlight the economic and environmental benefits of these approaches. The savings realized are more than three times that of traditional solutions, suggesting a strong case for the adoption of nature-based solutions in urban waterlogging management. However, the study also acknowledges the challenges of implementing these solutions in high-density urban areas, where land resource constraints can limit the space available for waterlogging management (H. Zhang, Zhang, Fang, & Yang, 2022). This underscores the need for innovative and space-efficient solutions, as well as the importance of policy support and community engagement in realizing the full potential of Blue-Green infrastructure (Xiao et al., 2023).

In conclusion, the study provides a comprehensive framework for improving flood resilience in urban areas through the application of Blue-Green solutions. The findings offer valuable insights for urban planners and policymakers, emphasizing the importance of considering local topographic conditions and the integration of nature-based solutions into urban design. By doing so, cities can become more resilient to the impacts of climate change and extreme weather events, ensuring the safety and sustainability of urban environments.

Abstract
In recent years, extreme weather, geological disasters, infectious diseases and other emergencies have put forward higher requirements for the normal functioning of cities. Large cities with high population density and high construction intensity are facing the dual pressure of disaster emergency support and economic production guarantee. As the carrier of most traffic activities, the public transportation system has the characteristics of closed space, high crowd density and high mobility of personnel, thus is easy to become a high-risk and disaster-stricken area in sudden disasters. This paper analyzes the development trend of individual transportation and public transportation, taking into account the characteristics of the two travel modes, the travel characteristics of large cities, the impact of sudden disasters on public travel, and the value orientation of policy strategies. This paper proposes that ensuring the sustainability of public transportation capacity is an inevitable choice in the face of travel demand, ensuring the safety and controllability of public transportation is the basis for resuming work and production after sudden disasters, and the value orientation of public transportation plays an important role in restoring normal urban life after disasters. At the same time, combined with the existing public transportation system and the attempt of new public transport products, the possible directions for the strengthening and development of public transport in the future are proposed.

Keywords
security and resilience, public transport, individual transportation, travel needs

Full text
Emergency events such as extreme climate, geological disasters, and infectious diseases have brought severe blows and security threats to large cities with high density of people. Public transportation space, as the carrier where most transportation activities take place, has the characteristics of closed space, high crowd density, and high mobility of people. It can easily become a high-risk area and disaster-stricken area in sudden disasters. Taking the COVID-19 epidemic as an example, as the prevention and control stages change, the public transportation systems in China's major cities have successively gone through the stage of high-risk transmission without measures, the stage of suspension of operations under the isolation policy, and the prosecution and resumption stage. Taking the "7.20 Incident" in Zhengzhou as an example, due to problems such as the quality of transportation facilities and traffic scheduling, Metro Line 5 was besieged and became a severely affected area. However, whether it is the normal life needs of residents from the perspective of individual travel, or the needs for efficient urban operation from the perspective of economic efficiency, they all have a high dependence on the public transportation system as the blood vessel of the city. On the one hand, large cities have high population density, complex population sources, and large commuting needs, which make it necessary to further develop public transportation. On the other hand, large cities have a relatively complete public transportation construction foundation and strong intelligent prosecution equipment layout capabilities, making it feasible to further develop public transportation. This paper will discuss this in detail from aspects of necessity, feasibility, and importance.

1. Necessity: The sustainability of public transportation capacity makes it an inevitable choice when facing travel needs

1.1 Characteristics of public transportation and individual transportation

Public transportation refers to transportation services open to the public, of which buses and rail transit are the main parts. Public transportation provides low-cost, high-quality services by integrating similar travel needs in a centralized form. After the preliminary construction of site facilities and network planning is completed, the public transportation system can carry most of the passenger traffic in the central areas of large cities with smaller maintenance costs and lower negative environmental impacts.
Individual transportation refers to a form of transportation in which the vehicle is owned by an individual. It usually has the characteristics of low transportation volume, convenience, flexibility, and good privacy. The early purchase of equipment requires individual residents to have certain financial strength, and in daily operation, the per capita occupation of urban traffic space is large.

Comparing the performance characteristics of public transportation and individual transportation (Figure 1), from the perspective of citizens' travel, the overall cost of public transportation is lower and the service distance is longer. However, buses and rail transit adopt a fixed-station model. Although the station network coverage in large cities is wide and the departure interval is short, there are still station blind spots and a certain waiting process. It is not as good as individual transportation in terms of getting on the bus nearby and getting on the bus immediately. From the perspective of overall urban transportation operations, public transportation has a large volume, a wide range of services, and a small occupation of road space. At the same time, it is more environmentally friendly than private cars and is an efficient mode of transportation to ensure basic urban transportation activities.

运量较高　　运速较高　　运距较远　　占地较少

Figure 1 Comparison of the characteristics of public transportation and individual transportation (left side is from the perspective of passengers, right side is from the perspective of urban transportation system)

Public transportation carries most (especially low-cost) long-distance travel needs and is an indispensable part of the urban transportation system (Figure 2). In addition to limited coverage distance, low-cost options in individual transportation are strongly affected by external factors such as weather. They are more likely to turn to public transportation in extreme weather conditions. This part of the travel demand is also a potential service target of public transportation. The travel efficiency of private cars, which are the most maneuverable among individual transportation, is severely limited by urban road space resources. At present, China's big cities are facing severe road traffic pressure and vehicle parking pressure. Considering that existing roads in big cities are difficult to expand on a large scale in a short period of time, and

the city's motor vehicle capacity is nearly saturated, further promoting the development of private cars will not have positive benefits. Another important component of individual transportation, electric vehicles, as a transitional method between walking and car travel, have the advantages of low price, high mobility, long distance and fast running speed. However, parking and charging are also inconvenient, making it a compromise choice for many low- and middle-income people with frequent travel needs. From the perspective of overall management of the urban transportation system, the chaotic parking of electric vehicles, serious interference with road traffic capacity at intersections, and low driving safety have caused certain damage to the urban traffic environment in terms of road resources and traffic order. The incompleteness of relevant regulations and the complexity of mixed traffic in road planning have put urban electric vehicles in a gray area that is difficult to manage, resulting in the reality that they gain their own convenience at the expense of other modes of transportation. To a certain extent, the large number of citizens choosing electric vehicles is due to the imperfection and incomplete coverage of the public transportation system. We should realize that this seemingly convenient individual transportation mode is not feasible for popularization in large cities with huge motor traffic and tight road resources, nor is it sustainable for carrying major commuting trips.

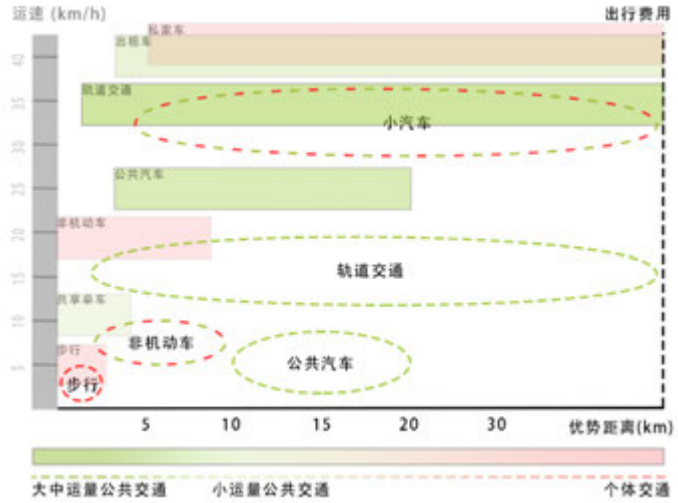

Figure 2 Passengers' willingness to choose travel mode

1.2 Travel demand characteristics of big cities

Big cities integrate the flow of more people within a larger geographical space. Its transportation system faces longer transportation routes, denser commuter crowds, higher traffic intensity, and more complex and diverse circulation options. Under the highly intensive development, the strong attraction of public services and commercial office functions in central urban areas is accompanied by extremely high land rents and housing prices. This makes the phenomena of job-housing separation, commuting peaks, and tidal traffic particularly significant. In addition, the siphon effect of big cities across the country continues to attract young talents and low-level migrant workers from other provinces and cities. These migrant populations do not have strong economic strength but have long-term willingness to settle, making them more dependent on public transportation for daily commuting. Generally speaking, the travel demand in big cities is characterized by long commuting routes, large instantaneous passenger flows, and heavy reliance on large-capacity, intensive and efficient transportation systems. However, the high per capita road area occupied by individual traffic makes it difficult for the city's limited road

space to withstand the traffic flow during peak commuting periods. This part of the daily peak passenger flow must be shared by public transportation with large or medium capacity, especially rail transit using underground space. At the same time, compared with individual transportation that is limited by road space resources, public transportation with adjustable departure frequency and vehicle grouping is also more flexible and can better adapt to the imbalance of daily traffic flow.

In addition, price-sensitive people account for an important part of the complex population structure of big cities. They have a certain spirit of hardworking and are also the main group of urban commuters. Their requirements for the convenience and efficiency of the travel environment are much higher than comfort, thus having a strong dependence on public transportation. Their commuting and employment provide important basic services for the normal operation of the entire city. The guarantee of their travel needs is also a part that cannot be ignored in the urban transportation system.

To sum up, most travel needs in big cities must and can only rely on public transportation to a large extent. The inefficient mode of individual transportation lacks sustainable carrying capacity in terms of road space resources, public economic strength, and natural ecological environment, making it difficult to promote and develop it as the main form of urban transportation.

2. Feasibility: The safety and controllability of public transportation make it the basic guarantee for resuming work and production after sudden disasters

2.1 Traffic characteristics in different periods of sudden disasters

After a disaster breaks out, it goes through different periods such as the disaster emergency period, the post-disaster rescue period, and the post-disaster recovery period. Each stage puts forward different functional requirements for the urban transportation system (Figure 3). Overall, the disaster emergency period truly reflects the ultimate carrying capacity and risk resistance of the transportation system. The long period of rescue and reconstruction after the disaster has had a great impact on citizens' living habits and travel needs.

Figure 3 Characteristics of traffic elements at each stage of sudden disasters

Passengers' choice of transportation mode is comprehensively affected by multiple factors such as travel purpose, transportation conditions, and personal purchasing power (Figure 4).

Take Wuhan, where the COVID-19 epidemic first broke out, as an example. As the first place and hardest-hit area of the epidemic, the initial stage of the lockdown was a disaster emergency period, which coincided with the Spring Festival holiday, thus there were no problems with the supply of basic daily necessities in the short term. Under the circumstances at that time, the needs of ordinary citizens for commuting, daily consumption and entertainment travel disappeared. The main purpose of travel became emergency medical treatment for fever patients and commuting for work for medical staff. Coupled with the complete shutdown of the public transportation system, patients and medical workers are highly dependent on individual transportation for travel. Facts have proven that the coverage of private cars and the accessible distances for bicycles or walking in the city are extremely limited, which resulted in a difficult commuting situation for a large number of medical staff in the early stages of the city's lockdown, some of whom had to cycle across the river to work. In big cities, there is a certain

mismatch between the coverage of individual transportation and the people with basic commuting needs. The actual traffic situation during this emergency period truly reflects that under the current economic structure and population structure, individual transportation does not have the supply guarantee for emergency needs, not to mention the transportation demand that has increased dramatically in intensity and complexity after the resumption of work and production.

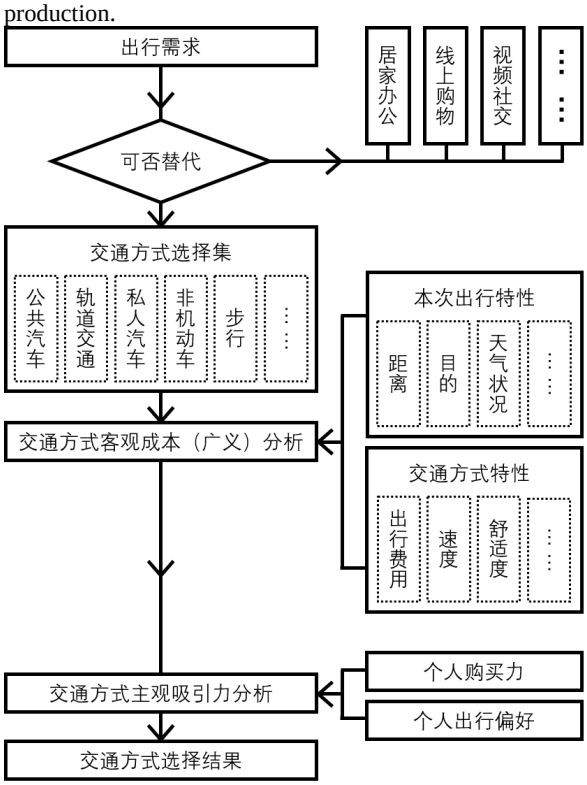

Figure 4 Passenger transportation mode selection flow chart

When severely infected people were basically treated, the number of infections peaked, and the scale of the epidemic was basically controlled, Wuhan launched a two-month home-based prevention and control measure, that is, entering the post-disaster rescue period. This stage lasts for a long time, and the various needs of daily life gradually emerged. The citizens' first principle for the transportation system has changed from "accessible at any cost" in the early emergency period to "accessible and sustainable". Medical treatment for patients with mild symptoms, medical treatment for other diseases, and purchasing basic daily necessities have become the main travel purposes. At the same time, due to the systematic development of anti-epidemic work, a large number of party members, community workers, and sanitation workers were required to commute to work. At this stage, the government uses the surplus road space resources and bus transportation capacity to provide customized buses for hospitals and other units in need to ensure the effective progress of anti-epidemic work. At the same time, the community collected residents' material needs and medical needs in a unified manner, and provided services such as collective procurement and special medical vehicles. At this stage, citizens’ travel mode choice set has been significantly reduced, and the substitutability of each

mode has been greatly reduced. At the same time, the purpose of travel determined whether the right to travel can be obtained. The interruption of low-price public transportation and the competition for travel rights increased objective costs (in a broad sense). Purchasing power became the main basis for determining travel mode. The traffic control measures at this stage have greatly affected citizens' long-term living habits and travel concepts. Network technologies such as home office, online shopping, video social networking, and material distribution systems transform the spatial flow of people into the flow of information and goods. Small-capacity door-to-door public transportation methods such as customized buses and community buses have improved safety and convenience compared with traditional buses. Limited by travel policies and individual transportation capacity, citizens' willingness to seek medical treatment and purchase goods nearby rather than at long distances increased significantly. The flow of people gathered in large hospitals and shopping malls had been divided into various residential areas. This travel habit of weakening intensity, shrinking distance, and reducing mix has also continued in the post-epidemic period after the isolation.

	公共交通	**个体交通**
使用者	公众	工具所有者
	开放	私密
运量	大	小
	人员流动、集聚	人员固定
范围	固定站点	门到门
优点	低费用	安全性
缺点	受灾风险	覆盖人群有限

Figure 5 Characteristics of public transportation and individual transportation during the post-disaster reconstruction period

After the unblocking of Wuhan, public transportation resumed normal operations, but a temperature measurement and code verification process was added at each station to ensure safety in a visible way and at the same time make the transmission path traceable. At this time, the travel mode choice set regained its diversity, but the characteristics of each transportation mode had changed (Figure 5). For example, the addition steps of temperature measurement and code verification had changed the operating efficiency of the public transportation system. The proportion of safety factors in citizens' travel preferences had increased, while the proportions of efficiency and cost had decreased. The purchasing power of citizens had partly declined due to the impact of the national economy, but the sense of depression after not spending for a long time and the concept of life safety first had weakened their price sensitivity and increased their willingness to consume.

2.2 Public transportation safety controllability during the post-disaster recovery period

Although public transportation does have dangerous factors such as dense crowds, it can be effectively dealt with by formulating complete emergency plans, monitoring operating conditions in real time, and accurately dispatching emergency resources. On the other hand, in the context of the demand for normal social and economic operation, it is meaningless to cut off the contact gathering of large flows of people by strengthening individual transportation to completely eliminate the risk of collective disasters. Transforming and improving safety based on the existing public transportation system, rather than turning to the development of "absolutely safe" individual transportation, has absolute advantages in both scientific and economic efficiency.

3. Importance: The value orientation of public transportation plays an important role in supporting the normal life of urban operations in the context of disaster response

The post-disaster reconstruction period means that the city's economic and cultural activities should gradually return to normal operations. As an important part of normal urban life, public transportation has also been a key component of the city's intensive development. Adhering to the development of public transportation systems in large cities has both scientific significance and positive value orientation.

3.1 Establish confidence in preventable and controllable reconstruction

We can all feel the psychological and emotional impact of policy guidance at all stages of disaster response. The positive significance of targeted support, targeted donations, and official media reports from other provinces and cities is largely reflected in the attitude and psychological stimulation of people in disaster areas. Psychological care and confidence building are of great significance in the aftermath of disasters. The enhanced development of public transportation in the context of disaster response is not only an implementation of actions to restore normal life, but also reflects the preventable and controllable value orientation, providing citizens with positive and stable beliefs for resuming work and production.

3.2 Demonstrate concern for public welfare and people's livelihood

As a public welfare urban infrastructure, public transportation is an important part of people's livelihood projects. Its low price and strong transportation capacity provide travel guarantee for many low- and middle-income groups. Among various types of disasters, low-income groups are more severely affected by economic impacts, as they are more price sensitive and more dependent on public transportation. Strengthening the development of public transportation is also a practical concern for people with limited purchasing power and difficulty in paying for individual transportation.

3.3 Continue the environmentally friendly decontamination concept

Strengthening the development of public transportation has always been an important strategy for large cities. Existing urban problems such as road congestion, exhaust pollution, noise pollution, and traffic accidents are mostly caused by inadequate public transportation and oversaturation of individual transportation. From a long-term perspective, a slow-travel-friendly environment based on walking and cycling must also rely on a strong public transportation background. True decentralization, environmental optimization, and future health cannot exist without a strong public transportation system.

On the one hand, the starting point of avoiding the risk of clustered disasters is highly consistent with the original efforts in the city to ease travel, avoid crowded places, and stagger peak hours. Flexible working, home working and other methods can be continued.On the other hand, in limited spaces, the dispersion of people should be based on the optimization of the public

transportation environment, ensuring safe distances and personal space, and achieving intensive and efficient evacuation. It is not feasible to turn to extensive and unsustainable individual transportation, otherwise it will only cause extreme deterioration of the urban traffic environment for the so-called "absolute safety" and bring about more severe environmental safety problems.

4. Possible directions to strengthen the development of public transportation

Strengthening the development of public transportation is essentially to improve the efficiency and quality of citizens' travel. From the overall perspective of urban development, certain intervention and regulation should be carried out on citizens' travel decisions (Figure 6). Optimizing their travel modes from the root (such as shortening daily travel routes through improving basic living facilities, etc.) and optimizing the citizens' travel environment in the process (such as building a slow traffic system to encourage green travel, etc.) will have a good effect on the overall transportation and will also provide a better background environment for urban public transportation.

出行阶段	调控焦点	干预手段
出行产生	交通发生源	土地控制
		现代网络通信技术（线下活动转线上）
出行分布	交通吸引源	土地控制
		优化生活基础配套（就近解决）
出行方式	低容量运载方式	激励政策（费用补贴/增收）
		优化高容量环境
空间路线	拥挤空间	实时路况信息
		硬性路障
时间路线	高峰时段	错时调峰

Figure 6 Regulation methods for citizens' travel decisions

4.1 System improvement and environmental optimization

Controlling the upper limit of the number of passengers in public transportation spaces and ensuring a relatively sufficient personal safety distance have put forward requirements for the waiting and riding environment of public transportation stations. Improving the coverage of the existing line network and improving the smoothness of the connection between rail transit and ground transportation can also effectively disperse the concentrated passenger flow and improve the quality of citizens' travel.

4.2 Personalized services for small and medium-sized transport volumes

Some cities in China, such as Beijing, Jinan, and Kunming, have tried to promote customized buses and temporary routes. This point-to-point transportation mode with small and medium-sized transportation volume and multi-vehicle dispatching serves people with the same or similar needs, avoiding excessive agglomeration of people. This model also relies on the information collection and integration of the Internet platform and the real-time information

exchange system to give full play to the intensive and efficient performance of public transportation through a static reservation mode and a timely response mode, while making up for the blind spots of existing public transportation.As of April 2023, the cumulative number of registered customized bus users in Beijing has reached 90000, and 173 customized bus lines have been opened, with a daily departure volume of 191 buses.

Compared with the traditional single operation model of fixed lines and unified vehicles, small and medium-volume public transportation that adopts a demand response model based on user demand data has the characteristics of high quality, efficiency, comfort and accuracy. It can integrate personalized and differentiated travel services and high-quality bus experience while ensuring efficiency.

4.3 Marketization of operation management

Compared with the traditional urban bus operation model monopolized by state-owned enterprises and subsidized by local governments, market-oriented attempts may be better able to provide personalized and precise services in line with the diverse travel needs of passengers. While adhering to the attribute of public transportation as the basic guarantee of urban public services, two or three public transportation enterprises can be established through area division and other methods. Use social capital and market rules to seek the optimal model based on passenger needs, encourage new public travel products, and achieve diversification of public transportation.

5. Summary

In summary, in the context of sudden disasters such as extreme climate, geological disasters, and infectious diseases, public transportation is fully capable of providing safety guarantees that are no less than the city's overall prevention and control level. Strengthening Developing public transportation is the only and wise choice for my country's big cities, taking into account the high dependence of the normal operation of large cities on public transportation, the sustainability of public transportation from a long-term perspective, the decentralization concept of public transportation under policy guidance, the existing relatively complete bus network system, as well as the trial of diversified bus products.

Abstract
In 2022, China experienced its first population decline in decades, leading to an increasingly common phenomenon of urban and rural shrinkage. Small towns, under the dual pressures of the suction effect from larger cities and rural revitalization policies, face elevated development risks. This paper proposes pathways to enhance the resilience of the social-ecological system of shrinking small towns through the territorial spatial planning. These pathways include enhancing buffering capacity both within and beyond urban development boundaries, strengthening self-organisation at all levels, and improving learning capacity through dynamic assessment and adjustment. The aim is to proactively mitigate the risks faced by shrinking small towns, improve residents' quality of life, and offer insights for China's high-quality urbanization development and governance.

Keywords: shrinkage, small town, social-ecological system, resilience, territorial spatial planning

Full text

1. Introduction

Globalization has led to a reconfiguration of population distribution, increasingly resulting in the phenomenon of shrinkage (MARTINEZ-FERNANDEZ, C. et al., 2012), which is drawing scholarly attention at various scales. Scholars suggest that small towns, with weaker development conditions compared to larger cities, face more complex challenges due to shrinkage (Mayer, H. and Knox, P., 2010)(Atkinson, R., 2019)(Caselli, B., Ventura, P. and Zazzi, M., 2020)(Rogatka, K., Kowalski, M. and Starczewski, T., 2023).

China, a vast developing country, has a large number of small towns. Despite regional variations in development levels and potential (Liu, Z., Qi, W. and Liu, S., 2021), small towns generally have lower administrative levels and simpler functional structures compared to larger cities,

making them more vulnerable to internal and external risks. These towns also have smaller populations, economies, and land scales, which diminish their developmental momentum and attractiveness, increasing their risk of shrinkage (Chen, C., Luo, Z. and He, H., 2016). This is not only an issue in underdeveloped areas; even in developed regions such as the Yangtze River Delta and the Pearl River Delta, small towns are experiencing shrinkage (Lang, W., Deng, J. and Li, X., 2020)(Shan, J., Liu, Y. and Kong, X., 2020). Many shrinking small towns are long plagued by social, economic, and environmental risks, necessitating a shift in planning paradigms to address these risks. Since 2019, China's emphasis on new urbanization has repeatedly highlighted the need for "slimming and strengthening" shrinking small towns. As China's urbanization progresses from an intermediate to an advanced stage, the high-quality development of small towns is crucial for the healthy advancement of China's urbanization process.

Internationally, the issues of shrinking towns are increasingly recognized not merely as demographic or economic problems but require a comprehensive approach from a complex social-ecological perspective (Jin, H. et al., 2021)(Haase, A. et al., 2021)(Dona, W, G, T, C., Mohan, G. and Fukushi, K., 2022). As the concept of "resilience" has expanded from ecology to urban and rural planning, "resilient planning" has become a global focus (Folke, C., 2006). In 1999, the Resilience Alliance, an international research organisation from multiple disciplines, was established to conduct interdisciplinary research on the resilience of social-ecological systems worldwide, achieving significant results (Resilience Alliance, 1999). Planning concepts based on the resilience of social-ecological systems are crucial for addressing the challenges faced by China's shrinking small towns. Therefore, it is necessary to develop territorial spatial planning approaches for these towns that enhance social-ecological system resilience, promoting regional high-quality development through scientific planning methods.

2. The Significance of Enhancing the Resilience of Social-Ecological Systems in Shrinking Small Towns

Shrinking small towns face significant risks, with some experiencing various crises in economic, ecological, and social aspects. Addressing the sustainable development of shrinking small towns is an urgent issue. To promote harmonious development between humans and nature, many scholars have begun to understand human-environment relations from a resilience perspective, leading to the emergence of the concept of resilience in social-ecological systems that integrates natural, economic, social, institutional, and cultural characteristics. The Resilience Alliance defines the resilience of social-ecological systems as the capacity of the social subsystem, the ecological subsystem, and their interactions to absorb disturbances, reorganize, and fundamentally maintain the same structure, identity, and feedback mechanisms under change (Walker, B., Gunderson, L. and Quinlan, A., 2010). International experiences show that shrinkage does not necessarily lead to decline but can also present an opportunity to optimize urban system functions (Fitton, J. et al., 2021)(Wirth, P. et al., 2016). High resilience in social-ecological systems is typically recognized by three characteristics: achieving positive outcomes despite high risks, maintaining capabilities under threatening conditions, and

recovering from shocks and stresses (Kerner, D. and Thomas, J., 2014). Resilience in social-ecological systems emphasizes transformation and innovative potential, including attributes of buffering capacity, self-organisation, and learning ability (Speranza, I, C., Wiesmann, U. and Rist, S., 2014). (Figure 1)

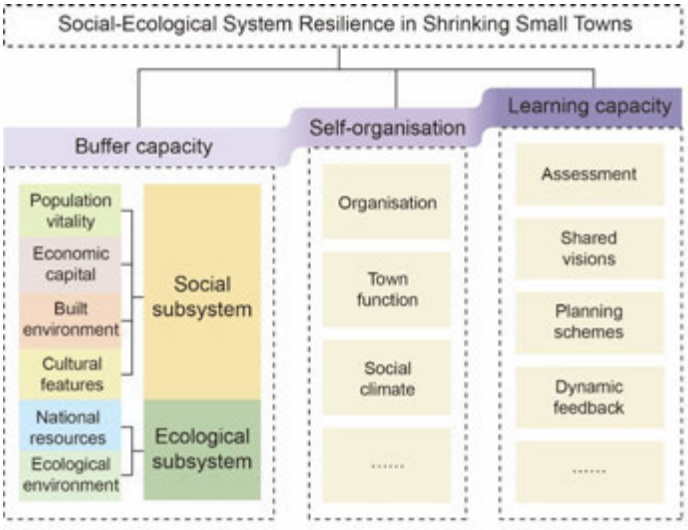

Figure 1: Attributes of the Social-Ecological System Resilience in Shrinking Small Towns

(1) Enhancing Buffer Capacity is Essential for Managing Complex Risks and Responding to Crises

Buffer capacity is the ability of social-ecological systems to withstand, absorb, and maintain their functions and structures when faced with risks (Carpenter, S., Walker, B. and Anderies, M, J., 2001), which is essentially their stability against shocks. Shrinking small towns, with their smaller scale and simpler functions, have relatively lower capacities to resist internal and external risks. Additionally, the increasing severity of climate change brings potential threats such as meteorological disasters, crop reductions, infrastructure damage, and outbreaks of infectious diseases (Haines, A. et al., 2006). On one hand, shrinking small towns need to uphold the functions of maintaining regional food and ecological security; on the other, they must seek stability and development amidst various crises. Modifying elements such as the infrastructure, landscape, land use, aesthetics, and policies of small towns can enhance the buffer capacity of their social-ecological systems (Pickett, A, T, S. et al., 2013). This enhancement improves the towns' ability to react, adjust, and adapt to shocks and disturbances from both internal and external factors, preventing their fragile social-ecological systems from facing significant crises when tackling risk challenges.

(2) Enhancing Self-Organisation is a Key Approach to Improving the Quality of Shrinking Small Towns

Self-organisation refers to the forms, processes, and outcomes through which social structures and human behaviors allow social-ecological systems to function (Obrist, B., Pfeiffer, C. and Henley, R., 2010). The shrinkage of small towns may bring a series of negative impacts, yet there is a continuous increase in residents' demands for quality of life. Residents of shrinking small towns require more comprehensive town functions and better ecological environments. Although generally shrinking small towns have an average level of socio-economic development, the decrease in population frees up some resources and environmental capacity, offering opportunities for ecological restoration and enhancing the overall quality of the town. Enhancing the self-organisation of social-ecological system resilience emphasizes trust and effective interaction between decision-makers and users, requiring the integration of resources from various departments related to the development and construction of small towns. It is also necessary to consider the basic conditions of ecological resources, as well as the economic base of the town and the needs of its residents. This approach coordinates the relationship between human society and the natural environment, promoting the improvement of town services and the protection and rational use of natural resources. This leads to the enhancement of the well-being and quality of life for residents of shrinking small towns.

(3) Enhancing Learning Capacity is a Practical Necessity for Territorial Spatial Planning and Governance

The capacity for learning implies the transformation of knowledge into action through adaptive planning and management measures, thereby improving the performance of social-ecological systems (Armitage, D., Marschke, M. and Plummer, R., 2002). In the adaptive renewal cycle, the development stages of small towns can be divided into four repeating phases: periods of exponential change, periods of growing stasis and rigidity, periods of readjustments and collapse and periods of re-organisation and renewal (Folke, C., 2006). Traditional growth-oriented planning primarily focuses on the first two periods, often neglecting the last two periods, yet these are equally important for system development (Figure 2). The method to address shrinkage involves enhancing the learning capacity within the dynamics of shrinkage through continuous improvement via assessment alerts, planning regulations, and dynamic feedback, achieving balance and development to prevent the system from collapsing. Integrating the concept of enhancing resilience of social-ecological systems throughout the entire process of territorial spatial planning and management can promote the scientific formulation of assessment, planning, and governance strategies for shrinking small towns at various stages.

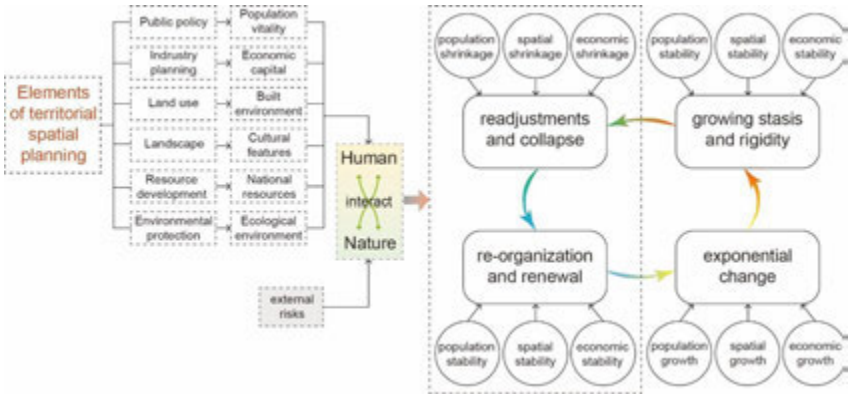

Figure 2: Relationship between Territorial Spatial Planning Elements and Enhancement of Social-Ecological Systems Resilience in Shrinking Small Towns

3. Pathways to Enhancing the Resilience of Social-Ecological Systems in Shrinking Small Towns from the Perspective of Territorial Spatial Planning

When the buffer capacity of a social-ecological system is stable, self-organisation is promoted, and learning ability continues to develop, the resilience of the social-ecological system is enhanced. The means to enhance the resilience of social-ecological systems in shrinking towns include introducing new technologies and industries, strengthening skills training, adjusting town sizes, enhancing cooperation between governments and enterprises, enhancing public participation, and providing external assistance when necessary (He, Y, S. et al., 2017)(Martínez-Fernández, C. et al., 2012)(Rosenman, E. and Walker, S., 2015)(Joo, Y. and Seo, K, B., 2018)(Leetmaa, K. et al., 2013)(Bernt, M. et al., 2013).

With the ongoing application of the results from China's third National Land Survey, the formulation of county-level and township territorial spatial planning will become a focus in the coming period. Therefore, scientific territorial spatial planning is a necessary means to enhance the resilience of social-ecological systems in China's shrinking small towns. Territorial spatial planning can comprehensively enhance the resilience of social-ecological systems in China's shrinking small towns through three pathways: enhancing buffer capacity, strengthening self-organisation, and developing learning capacity.

3.1 Differentiating Buffer Capacity Enhancement Within and Beyond Urban Development Boundaries

Territorial spatial planning emphasizes comprehensive control over all elements and areas. This approach involves differentiated management of spaces within the urban development boundaries and ecological and agricultural spaces beyond these boundaries. At the same time, it aims to enhance the capacity of the social-ecological system to cope with both internal and external risks. This is precisely where the comprehensive enhancement of buffer capacity for

shrinking small towns is targeted.

Within the urban development boundaries, the focus is on enhancing the ability to cope with risks to the social subsystem. This requires considering the current situation of population loss and demographic imbalance. Key areas of focus include talent policies, industrial development, land use, and landscape. Firstly, innovative mechanisms for attracting talent and strengthening vocational training should be implemented to boost the demographic vitality of shrinking small towns. Secondly, based on existing resource endowments, guide the diversified development of industries in these towns while also stimulating income growth for residents. Additionally, create an attractive built environment. Determine the appropriate scale of land use based on reasonable population projections. Towns with weaker development potential could trade surplus land quotas to other regions with greater development needs, alleviating fiscal debt while preventing inefficient land expansion. Inefficient and underutilized lands should be repurposed for service facilities and green spaces. Land degraded by industrial activities should be designated as ecological restoration areas to achieve improved urban functions, manage environmental pollution, improve living conditions, and enhance regional vitality. Moreover, special planning for towns with cultural characteristics should be carried out to fully exploit tourism resources and develop the tourism industry. Towns with weaker capabilities may apply for policy support and external capital to enhance the social capital of shrinking small towns and effectively cope with risks.

Beyond the urban development boundaries, the basic principle should be to protect the ecological environment and food security, enhancing the ecological subsystem's capacity to handle risks. In terms of natural resource management, pay attention to the development and control of non-construction land. Strictly implement controls for ecological corridors, water source protection areas, and other designated zones to protect the ecosystem services of shrinking small towns. Additionally, financial revenue can be increased through ecological compensation policies. For the natural resources of shrinking small towns, utilize excellent ecological and agricultural resources to cultivate cultural, educational, and scientific research functions, and develop ecological research and eco-tourism. In terms of ecological protection, promote the scale operation of agricultural land, improve the land inheritance mechanism, and prevent the abandonment of arable land. Enhance agricultural output while improving the livelihoods of farmers. Intensive and large-scale production and living modes also facilitate centralized municipal facility construction, reducing energy consumption and environmental pollution. High-quality natural resources and a good ecological environment form the ecological capital of shrinking small towns provide necessary support in times of risk.

Additionally, for towns particularly vulnerable to specific risks, special planning should be formulated, such as for managing mining subsidence areas and watershed ecological restoration. These plans should focus on addressing the most urgent risks faced by the towns and filling the gaps in their buffer capacity.

3.2 Strengthening Self-Organisation in Territorial Spatial Planning and Governance at All Levels

It is necessary to establish a well-defined organisational structure that ensures the smooth operation of small towns and fosters a harmonious social atmosphere. In China, county-level territorial spatial planning constitutes the "overall arrangement and comprehensive deployment" of land use, while township territorial spatial planning deals with the "specific arrangements" of land use purposes. Township planning plays a crucial role in transmitting and implementing the content of provincial and city-county level spatial planning to the township level, and in controlling and guiding rural planning. It is key to the new urbanization and high-quality rural development.

Thus, township-level territorial spatial planning plays a vital role in strengthening self-organisation. During the formulation, implementation, and management of territorial spatial planning, it is essential to coordinate governments at the city-county, township, and village levels and different departments such as environment, security, finance, industry, and agriculture. Encouraging local enterprises and residents of small towns to participate in decision-making is crucial to fully understand the challenges and development needs of different stakeholders.

Firstly, in implementing county-level territorial spatial planning, it is important to maintain the overall pattern of land use. Ensuring that ecological protection red lines and permanent basic farmland are inviolable maximizes the ecological and agricultural functions of shrinking small towns. At the comprehensive planning stage, township construction guidance according to county-level spatial planning should be studied. Based on the unique characteristics of different towns, cultivate distinctive industrial features and development directions to avoid homogeneous competition. Given the limited allocation of land quotas in shrinking small towns, territorial spatial planning should prioritize the allocation of construction quotas to industrial development land and public facilities. During the detailed planning stage, smart provision of functional spaces and facilities should be ensured, utilizing limited resources to improve the industrial and public service functions of small towns.

Additionally, in linking rural planning, township territorial spatial planning should guide the development directions of the villages it governs. The migration of rural populations to towns is an important process in urbanization, and the villages under shrinking small towns may also be undergoing shrinkage. In shrinking small towns with development potential, focus on cultivating industries, allocating service facilities, and guiding rural labour to converge in small towns. Lastly, cultural construction should be strengthened. Promoting local historical and cultural heritage through tangible and intangible carriers fosters cultural identity and belonging among small town residents, enhancing their participation in local development. By optimizing the town operation model through top-down transmission by decision-making bodies and bottom-up feedback from town users, the self-organisation of shrinking small towns can be strengthened.

3.3 Developing Learning Capacity through Dynamic Assessment and Adjustment

Having the learning capacity means that shrinking small towns can continually acquire

development experiences from other towns and integrate their own past experiences into current actions. Learning capacity includes aspects such as alerts, shared visions, planning schemes, and dynamic feedback. The concept of "smart cities," widely adopted globally and increasingly combined with artificial intelligence in recent years, greatly aids in enhancing the learning capacity of shrinking small towns.

In the knowledge identification stage, it is crucial to scan and obtain knowledge valuable for enhancing the resilience of shrinking small towns, including the visions of town users, historical data, and current data. Therefore, it is necessary to learn the collection and analysis technologies for integrated data, such as through government transparency platforms and social media to gather users' opinions on town development. After establishing a database for small towns, data analysis and simulation can be performed using computer deep learning techniques and other methods. Under the goal of enhancing social-ecological resilience, deduce key elements such as population and economic changes, land scale, and facility siting to form learning outcomes, which is territorial spatial planning. After evaluation and public participation, planning schemes can be transformed into statutory planning and practical actions. Statutory planning and planning actions become a knowledge-sharing process within the shrinking small town's social-ecological system, thus continuously updating users' visions for the town.

Territorial spatial planning is a dynamically evolving planning and management process, so it is essential to regularly check whether the learning outcomes effectively serve the goals. That is, during the assessment of territorial spatial planning, determine whether the implementation of the plan effectively supports the enhancement of resilience. Develop different indicators for different types of towns and continuously collect data on the effectiveness and issues in resilience enhancement through a normalized monitoring system. Timely transform new data into knowledge, iteratively update decision-making simulation algorithms, thus providing a basis for dynamic adjustments in planning. Also, scientifically arrange the sequence of tasks based on the supply and demand relationships revealed by the assessment results, gradually realizing users' visions. This increases the attractiveness of small towns, mitigates the desire of residents to move out, and attracts rural populations, enabling shrinking small towns to achieve sustainable development.

4. Conclusion

Due to factors such as industry, location, and policy, a number of small towns in China have experienced a continuous population decline. These small towns play a crucial role in linking urban and rural development. Scholars widely recognize that growth is not the only option for small towns. The concept of resilience in social-ecological systems, through a dynamic adaptive cycle, has emerged as an approach to address the challenges faced by shrinking small towns. In the phase of widespread county and township level territorial spatial planning in China, in-depth research on planning for shrinking small towns guided by the enhancement of social-ecological system resilience is of great significance. This paper suggests enhancing the resilience of the social-ecological systems in shrinking small towns from the perspective of territorial spatial planning. It proposes planning response pathways in terms of enhancing buffer

capacity, strengthening self-organisation, and developing learning capacity. The aim is to improve the linkage role of shrinking small towns in the regional urban system and to promote healthy regional development.

Abstract: Urban residential areas are an important unit of urban disaster prevention and reduction, which affects the goals, strategies and countermeasures of urban disaster prevention and reduction. The characteristics of current research on evaluating residents' disaster prevention capabilities are not applicable to urban planning research and practice. Based on the concept of comprehensive disaster prevention, this paper establishes a theoretical formula for assessing vulnerability and constructs six evaluation indicators that affect the disaster prevention capacity of residential areas. The weight of factors is determined by Delphi method and establish an evaluation model. Evaluate the disaster prevention capacity of residential areas using the standard evaluation guideline method. It provide guidance for evaluating the disaster prevention capacity of urban residential areas in China and formulating disaster prevention countermeasures.

Key words: the residential area, disaster prevention capability assessment, vulnerability, assessment model, Standard Assessment Guide Method

As a composite unit of humanities and space, urban residential area is composed of social groups living in a specific area. These groups have common interests, social interaction and corresponding service system (Jacobs,1961). In the process of urban development, residential function has always been one of the important functions it undertakes. With the development of society, large-scale, high-density and high volume rate have become the mainstream architectural trends in modern urban residential areas. The agglomeration of buildings and population leads to more security risks in residential land (Zhao Yiting et al. 2013, Meng Fanliang et al. 2011). However, the planning and construction of residential areas in China generally lack disaster prevention and safety considerations. At the same time, the occurrence of disasters is often sudden, and it is easy to cause secondary disasters, resulting in

serious loss of life and property. Therefore, it is of great practical significance to study the problem of disaster prevention and mitigation in urban residential areas, and to put forward the improvement scheme of physical space and the guiding measures of public policy, so as to reduce the loss of urban disasters and improve the safety and resilience of cities. Through these measures, we can effectively deal with various disaster risks, ensure the safety of life and property of urban residents, and also help promote sustainable urban development (Sun Shiwen, 2021).

Currently, there are more studies on disaster risk assessment in China, while relatively less attention is paid to the assessment of disaster prevention capacity. In terms of residential disaster prevention research, more attention is paid to single-system disaster prevention and safety, while relatively little research is done on comprehensive disaster prevention in residential areas. In addition, many scholars have conducted a large number of studies on disaster prevention planning in residential areas, but there is a relative lack of studies on the evaluation of disaster prevention capacity. In summary, a relatively complete research technical route on the evaluation of disaster prevention capacity of residential areas has been initially formed: the route is based on disaster prevention theory and aims to construct a comprehensive set of evaluation criteria and subdivide the evaluation elements. Next, the disaster prevention capacity of the study area is systematically assessed through quantitative evaluation methods. Finally, based on the assessment results, effective disaster prevention countermeasures are formulated to enhance the disaster prevention capacity of the residential area. For example, from 2009 to 2016, Liu Peng (2017) studied the risk assessment model of residential communities, and proposed 16 kinds of community hazard factor assessment indicators. The risks of Shanghai communities through demographic and economic data were assessed, and the risk maps of Shanghai communities were drawn. The identifying risk types, vulnerable areas, important infrastructure, safe places, countermeasures, and suggestions were proposed. A security risk assessment method for old urban communities based on Bow-tie model (BT) and Bayesian network (BN) was proposed by Gu Tiantian (2023). It was inferred that the personal unsafe behavior, the vulnerability of community infrastructure and the risk of surrounding facilities in Y community of Shenzhen City were high-risk factors. This study evaluated the security risk level of Y community in Shenzhen City. Lian Dajun et al (2017) built a community disaster reduction capability index assessment system with 30 secondary indicators from six aspects: disaster risk assessment capabilities, rescue and support capabilities, engineering defense capabilities, economic base support capabilities, disaster management capabilities, and residents' cognitive capabilities. The entropy grey target model and the approaching degree classification were used to classify and assess the disaster reduction capability of the community, and the disaster prevention capability of the residential area in Suzhou was calculated with the help of GIS spatial overlay analysis technology. In his study, Kong Feng (2019) pointed out that the problems of disaster prevention, mitigation and relief in urban and rural communities are reflected in the obvious regional differences in infrastructure, the prominent problem of coordination of disaster

mitigation resources, the weak applicability and practicability of disaster prevention and mitigation plans in urban and rural communities, as well as the weak awareness and ability of residents to mitigate disasters. Wu Dafang et al (2015) evaluated the fire protection capability of buildings in city villages in Guangzhou. A fire risk evaluation indicator system was constructed based on the fire resistance rating and purpose of the house, the layout of fire hydrants and the setting of fire passages. The analytic hierarchy process, Kriging spatial interpolation, and buffer analysis were applied to obtain the building fire prevention capability evaluation model. The weak links were found to improve the fire prevention capability of the city village. By analyzing and summarizing the potential of enhancing community resilience in disaster prevention and mitigation planning and the impact of improving community resilience on the implementation efficiency of disaster prevention and mitigation planning, Ma Chao et al (2020) proposed to enhance community resilience through four methods. Obviously, in the process of assessing the disaster prevention capacity of residential areas, there are differences in the understanding and knowledge of experts and scholars in various academic fields about disaster prevention in residential areas, which mainly stems from their different research focuses, thus leading to inconsistencies in disaster prevention strategies and goal setting. Therefore, in order to assess the disaster prevention capacity of residential areas as comprehensively and accurately as possible, researchers have adopted diversified evaluation indicators and complex quantitative evaluation techniques, and ultimately come up with a variety of different disaster prevention countermeasures and measure recommendations, with a view to better improving the level of disaster prevention and the ability to cope with disasters in residential areas.

From the perspective of urban planning, this paper focuses on the theory and evaluation index of disaster prevention in urban planning system. Therefore, in terms of evaluation objectives, evaluation indicators and evaluation methods, this paper is significantly different from the existing research. This study focuses on the evaluation of disaster prevention capacity of residential areas by scholars and planners in the field of planning. This study takes the disaster prevention and mitigation of residential areas as the research object, and constructs the theory of urban disaster prevention planning from the concept of urban comprehensive disaster prevention. By establishing the theoretical formula of the vulnerability of the bearing body and coordinating with the planning elements of the residential area, six evaluation indexes affecting the disaster prevention ability of the residential area are constructed. Delphi method is used to determine the weight of factors, and the evaluation model is established. The standard assessment guide method is used to assess the disaster prevention capacity of residential areas. The conclusions of the study have important support for the assessment of disaster prevention capacity and the formulation of disaster prevention countermeasures in urban residential areas in China.

1.Basic thoughts and planning elements of disaster prevention in residential areas

1.1 Basic thoughts of disaster prevention in residential areas

Based on the basic concept of urban disaster prevention, 'a variety of preventive measures for the loss of life and property of urban residents and various types of engineering facilities in order to resist and mitigate all kinds of natural and man-made disasters and the secondary disasters caused by them' (He Lei, 2016), as well as the basic components and formation mechanisms of disasters, this idea is based on the fundamental composition and formation mechanisms of disasters understanding of disasters and aims to protect the safety and property of urban residents and ensure the sustainable development of the city. The idea of disaster prevention can be summarized as follows:

(1) Reducing the exposure of the disaster-bearing body: in order to reduce the probability of a disaster occurring, it is necessary to fundamentally change the environment or conditions of the disaster-forming mechanism in order to reduce the scope of action of the disaster force and separate it from the coverage of the disaster-bearing body so that the disaster is not likely to occur.

(2) Reducing the vulnerability of the disaster-bearing body: in order to reduce the impact of the disaster, it is necessary to change the state of the physical spatial components in order to reduce the vulnerability of the disaster-bearing body, and consequently to reduce the probability of the occurrence of an extreme disaster state.

(3) Improvement of emergency evacuation capacity: In order to reduce the casualties caused by disasters, the emergency evacuation system should be improved according to the occurrence of disasters in order to reduce the casualties. Residential areas are considered to be densely populated 'target areas'[1] where the exposure of disaster carriers is generally stable. Disaster preparedness strategies focus on emergency actions aimed at reducing vulnerability and casualties in the aftermath of a disaster. Self-help and mutual aid by community residents before, during and after a disaster, as well as the timely evacuation and relocation of people to safe areas, can significantly reduce casualties. Therefore, the construction of a sound evacuation and rescue system is an important material foundation. Based on this concept, this paper starts from building an evacuation and rescue system to establish a model of the disaster prevention capacity of residential areas.

[1] refers to the weak areas in the built-up areas of cities that are affected by disasters, have disaster losses, and require emergency rescue.

1.2 Planning element screening

According to the current national standard 'Code for Urban Residential Area Planning and Design', the planning elements of residential areas can be divided into four aspects, namely land use and construction, housing, public service facilities and roads. By carefully combing the planning elements in the national standard 'Urban Residential Area Planning and Design Code', combined with the micro-mechanism of disasters and urban space, the elements closely related to community safety in residential area planning can be determined.(1) In terms of land use and construction, it includes factors such as floor area ratio, building density and population density related to the prediction of the size of the affected population and the spatial layout of the affected buildings after the disaster. These factors are of great significance for post-disaster reconstruction and population evacuation.(2) public service facilities, including facilities such as education, health care, culture, sports, business services, community services, administrative management and public parking lots (garages). These facilities play an important role in emergency services during disasters[2]. (3) Road system, including factors such as road density and road width. Good road planning is essential for emergency evacuation and rescue operations. The goal of disaster prevention in residential areas is to reduce material and property losses and casualties. Therefore, in the combing of the elements of residential area safety planning, it is necessary to comprehensively consider the details and interrelationships of the above factors:

1. Reduce material and property losses and reduce the vulnerability of residential areas.

The factors affecting the vulnerability of disaster carriers can be considered at three levels: (1) the disaster resistance and building quality standards of physical space, which are closely related to the degree of disaster damage; (2) demographic characteristics, including factors such as population distribution and population density, which affect the degree to which people are affected by disasters; and (3) the ability of physical space to recover from damage, which is linked to the local level of economic development and the ability to prevent and mitigate disasters. capacity is associated. However, the characteristics of different population groups affected by disasters are often neglected. Population distribution and population density are closely related to the spatial distribution of buildings, building density, and floor area ratio. In general, the level of economic development and disaster prevention and mitigation capacity are consistent with the development trend of emergency shelter buildings: the higher the level of economic development, the higher the emphasis on safety; the higher the disaster prevention and mitigation capacity, the more balanced the layout of evacuation and emergency shelter sites and the higher the level of service. Therefore,

[2] refers to places and facilities such as medical and sanitation, water storage, material storage and distribution, and fixed refuge necessary for emergency rescue, emergency evacuation, and post-disaster life.

vulnerability has an inverse relationship with building quality and shelter layout, and a positive relationship with building density, building volume ratio, and proximity of spatial distribution. The logical relationship of vulnerability is as follows:

$$\mathrm{V} = \frac{De \cdot Fr}{Qa \cdot \mathrm{Sl}} \cdot \mathrm{Lo} \qquad (1)$$

Among them:
V: vulnerability
De: building density
Fr: floor area ratio
Qa: building quality
Sl: shelter layout

Lo: proximity of building space distribution. According to the distance to the disaster-prone area, the Lo value is between 0 and 1. The Lo value is 1 of the disaster-prone area, and the Lo value is 0 of the area far away from the disaster-prone area, and the value of the rest takes the difference based on the distance to disaster-prone area.

The vulnerability theory of disaster bearing body reveals the following viewpoints: when determining the location of residential area (keeping Lo value unchanged), the area with low plot ratio, low building density, high building quality and reasonable layout of shelter has low vulnerability, that is, less material and property loss. Therefore, the planning elements of residential areas need to meet the following requirements: the overall spatial structure adopts the layout mode of low building density and low floor area ratio. At the same time, the construction quality must be strictly controlled to meet the standards of disaster prevention and resistance.

2. Reduce casualties, including emergency evacuation, emergency rescue and emergency resettlement.

(1) Refuge population evacuation: During a disaster, the number of evacuated people is directly related to the quality of the buildings, the density of the buildings and the plot ratio of the residential area. The quality of a building determines whether or not it is damaged during a disaster: if a certain type of building is completely destroyed, then everyone living in that type of building should be evacuated. According to the ‘Code for design of disasters mitigation emergency congregate shelter’ (GB51143-2015), the size of the emergency evacuation population should take into account the urban resident population and the mobile population. In the area around crowded public places, the size of the emergency evacuation population should be no less than 80% of the annual maximum daily flow. For permanent refugees, the size should not be less than 20% of the permanent population, and the following requirements need to be met: a) the area where the area of buildings (structures) with low

disaster resistance exceeding 60% shall not be less than 45% of the permanent population; b) areas where the area of buildings (structures) with low disaster resistance exceeding 40% should not be less than 35% of the permanent population; c) areas where the area of buildings (structures) with low disaster resistance exceeding 20% should not be less than 25% of the permanent population.

(2) Refuge channel evacuation: Evacuation of evacuation routes is an important measure to ensure effective evacuation of refugees before they enter an evacuation area. The accessibility and capacity of evacuation roads are therefore critical to the efficiency and capacity of evacuation. In community planning, the design of refuge roads is directly related to the layout of the road network, the organization of roads and land, and the width of roads. According to the 'Code for design of disasters mitigation emergency congregate shelter' (GB51143-2015), under the conditions of calculation of the building collapse model on both sides, the width of the main evacuation road should be no less than 7 meters, the width of the secondary evacuation road should be no less than 4 meters, and the width of the general evacuation road should be no less than 3 meters. In addition, there should be convenient transportation access between buildings and evacuation shelters. In order to increase the density of the road network, a square grid-like road network layout is usually adopted, which can improve the connectivity of roads in the community and enhance the efficiency and capacity of evacuation.

(3) Shelter evacuations: During a disaster, buildings and open spaces used to accommodate refugees may include educational facilities such as schools, sports facilities such as stadiums, other large public buildings, squares, and green spaces (especially public green spaces), and these places should have a certain effective refuge area. These functional facilities should not only meet the normal needs of normal use, but also assume the function of sheltering and evacuating refugees in the event of a disaster. Therefore, when planning and laying out these places, it is necessary to take into account their ease of use during a disaster, and their capacity should not only meet the needs of daily use, but also be able to cope with the evacuation needs fixed in the service area. Therefore, the total capacity of such public facilities and green spaces should be designed and checked against evacuation needs.

(4) Emergency rescue channel: The emergency relief channel is the main channel connecting the residential area with the outside world and is used to connect various services in the residential area such as medical and health services, community services, administration and commercial services. It provides a transmission channel for basic living materials such as medical aid, community organization, special people aid, disabled people aid, food and drinking water. According to the 'Code for design of disasters mitigation emergency congregate shelter' (GB51143-2015), the width of the emergency relief channel should be 15 meters, taking into account the model of building collapse on both sides.

(5) Emergency service facilities: they mainly include the functions of medical and health services, commercial services, community services and administration in public service facilities. Medical and health facilities assume the important responsibilities of emergency rescue and rescue of the injured during disasters; service facilities in residential areas are important institutions for vulnerable groups to take refuge during disasters; administrative facilities are the organizational centers for refuge, rescue and emergency services in residential areas; and commercial service facilities are the places for storing and distributing emergency food and drinking water. Therefore, in addition to meeting the day-to-day needs of a residential area, there is a need to assess its configurability for emergency use during a disaster.

(6) Emergency support infrastructure: Emergency protection infrastructure is the municipal public facilities that directly provide emergency water, electricity, road and communication services during disasters. To ensure their reliability in times of disaster, they should be designed and constructed in a disaster-proof manner to enhance their ability to withstand disaster damage. In addition, redundancy and multi-source planning need to be considered to ensure continuity of supply during disasters. Therefore, municipal planning should be reviewed with special attention to the security of water, electricity and information supply during disasters.

(7) Disaster prevention engineering facilities: Disaster prevention engineering facilities are important municipal infrastructures, such as flood walls, levees, and rainwater regulating basins, which are part of municipal infrastructures in a broad sense as disaster prevention engineering facilities to ensure community safety. However, such facilities are usually seldom seen in residential areas because these disaster prevention engineering facilities are usually municipal public investment projects with limited relevance to residential areas. In contrast, people's air defense engineering facilities are more widely distributed in residential areas. When planning and laying out these facilities, they not only need to comply with the requirements of the Civil Air Defense Law and relevant national standards, but also assume responsibility for disaster prevention in residential areas. Therefore, when planning and constructing disaster prevention engineering facilities, comprehensive consideration needs to be given to the rational distribution of different types of facilities to ensure the overall disaster prevention capability of the community.

The above elements are summarized in Figure 1.

Figure 1 Influencing factors of the disaster prevention capability model of residential areas

‘Disaster prevention’ objects	System of planning elements	Segmentation of planning elements	Layout element
Material	Land use and	Residential	Building density

property	construction	building	Building floor area ratio
		Building quality	--

2 Weights of element in the assessment of disaster prevention capability in residential areas

2.1 Major issues identification

The basic idea of model construction is shown in Figure 2. The expert scoring method is used. Each expert's opinion passes the consistency test of the pairwise comparison matrix, and qualitative issues are transferred into quantitative calculations.

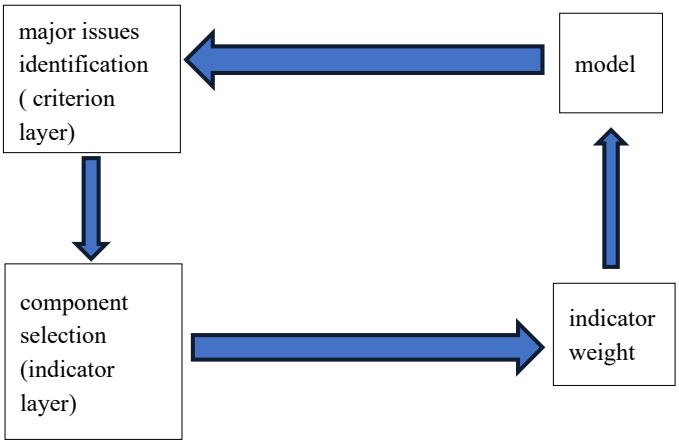

Figure 2 Model building work flow
Source: it is made by the author

The basic goal of disaster prevention in residential areas is to reduce material losses and casualties. Reducing the material loss, that is, reducing the loss rate of buildings and structures when damaged by disasters, is the foundation of disaster prevention in residential areas; reducing casualties, that is, improving the capability of personnel emergency evacuation and rescue, is the focus of disaster prevention in residential areas. Therefore, take the personnel emergency evacuation and rescue in residential areas as the major research issues, and the research is conducted around the relevant elements of the evacuation and rescue system in residential areas. The elements that are not closely related to it, such as the scale of residential buildings (building density, building floor area ratio) are eliminated.

2.2 Component selection

With reference to the research conclusions of the influencing elements of the disaster prevention capability model of the residential area, the main components that affect the disaster prevention capability are as follows:

(1) Building quality: whether the building quality meets the standard determines whether the building is damaged during the disaster, which affects the loss of material property, the number of casualties, further impacting the number of emergency personnel resettlement. Especially public buildings that undertake important functions, such as hospitals, fire stations, stadiums, police offices, schools, etc., have higher building quality requirements to ensure normal functions during disasters.

(2) The road traffic: once the damage to the building is inevitable, the road traffic is responsible for emergency evacuation and rescue of affected people. The density of the road network of road traffic, the width of the main evacuation road and the main rescue road should meet the requirements of safety and capacity.

(4) Evacuation shelters: affected people enter the evacuation shelters through the road traffic. The accessibility, safety and effective area of evacuation shelters should meet specific requirements. The location, their spatial layout with residential buildings, and building capacity (floor area ratio, density) and other indicators of public service facilities, green space, open space, etc. that can be used as evacuation shelters should meet certain requirements.

(5) Emergency service facilities: the affected people are separated from the disaster site. After being placed in a relatively safe area, they need the most basic living materials such as medical treatment, food, and drinking water. Therefore, medical and health, commercial facilities, community services, and administrative management in public service facilities should bear the emergency needs at this time.

(6) Emergency support infrastructure: the water supply, electricity supply, and communication in the municipal infrastructure directly serve for emergency support during disasters, and play an important role in post-disaster restoration, resettlement and reconstruction. If the infrastructure can be restored as soon as possible after the disaster, not only can the confidence in reconstruction be established, but also the lives of the people in the disaster area can be restored to normal order in the shortest time.

2.3 Determination of element weight

The Delphi method is used to determine the weight. Based on a total of 111 people including design professionals, experts, government management practitioners tested scoring (original data is omitted), their mean value, variance, and mode are analyzed, as shown in Figure 3 below.

Figure 3 Summary of opinions from the expert questionnaire

(1) Design professionals (31 people)					
	Building quality	Road traffic	Emergency shelter	Emergency service facility	Emergency support infrastructure
Mean value	27.1	21.6	16.7	15.4	19.2
Variance	119.1	31.2	22.9	14.3	23.6
Mode	20	20	15	15	20
(2) Experts (10 people)					

Mean value	27.3	21.6	19.3	14.7	17.1
Variance	72.6	29.9	13.9	14.9	22.2
Mode	20	15	20	15	20
(3) Government management practitioners（70 people）					
Mean value	25.2	19.5	17.5	16.4	21.4
Variance	107.9	23.2	20.2	17.2	26.7
Mode	20	20	15	15	20

T test is used to test whether the mean values of the three types of people's opinions are significantly different. Assume that there is no difference between the scores of the three types of personnel, that is, the mean values are the same. The EXCEL is adopted to perform calculations to obtain the conclusions shown in Figure 4 below. After checking the value figure of the T distribution, it can be seen that the t values among the three groups in Figure 4 are all less than the threshold value, indicating that the hypothesis test can be accepted at the 95% level, that is, the mean values of the three groups are the same. Therefore, the three groups of people have basically the same judgment on the problem, and the components and weight are relatively stable. The average of the three groups can be used as the final weight of the Delphi method, see Figure 5.

Figure 4 T-value analysis results of the significance test of the difference in the mean values of the three groups

T value	Building quality	Road traffic	Emergency shelter	Emergency service facility	Emergency support infrastructure	T test value (n) (95% level)
t_{12}	-0.0048	0	-0.3284	0.1267	0.2361	1.69(39)
t_{13}	0.0941	0.2956	-0.2067	-0.2894	-0.4148	1.66（99）
t_{23}	0.0585	0.2519	0.26742	-0.2899	-0.4744	1.67（68）

Note: t_{12} in the figure *represents the T-test value between the first group of design professionals and the second group of experts. t_{13} in the* figure *represents the T-test value between the first group of design professionals and the third group of government management practitioners. t_{23} in the* figure *represents the T-test value between the second group of experts and the third group of government management practitioners.*

Figure 5 Final weights of expert scoring method

Mean value	Building quality	Traffic	Emergency shelter	Emergency service facility	Emergency infrastructure
Mean	27.1	21.6	16.7	15.4	19.2

value 1					
Mean value 2	27.3	21.6	19.3	14.7	17.1
Mean value 3	25.2	19.5	17.5	16.4	21.4
Grand mean	26.5	20.9	17.8	15.5	19.3

2.4 Element weight subdivision

The weight of subdivision elements can be obtained in the same way, see Figure 6 below.

Figure 6 Element subdivision and weight analysis

Basic elements	Element characteristics	Element subdivision	Control variable	Value standard
Building quality (0.265)	--	--	Building quality (Qa)	The value is set as 3 for higher than the standard; the value is set as 1 for reaching the standard; the value is set as 0 for being substandard
Road traffic (0.209)	Road network density (0.4)	Relationship between traffic and land use	Overall spatial structure (SS)	The value is set as 3 with higher road network density; the value is set as 1 with middle road network density; the value is set as 0 with large road network
	Road width (0.6)	Route selection and surrounding building restrictions	Road width (RW) (0.4)	The value is set as 3 for higher than the standard; the value is set as 1 for reaching the standard; the value is set as 0 for being substandard
			Land function along the road (RL) (0.15)	The value is set as 3 for small flow traffic, 1 for general flow traffic, and 0 for high flow traffic
			Building setbacks along the road	The setbacks is set as 3 for more than 15 meters,

			(RB) (0.3)	as 1 for more than 5 meters, and as 0 for less than 5 meters.
			Building quality along the road (RQ) (0.15)	The value is set as 3 when it is beyond the standard; the value is set as 1 when it is satisfy the standard; the value is set as 0 when it is substandard
Evacuation shelter (0.178)	Accessibility (0.3)	Public facilities layout	Time for taking refuge (ST)	The value is set as 3 for satisfying requirements. The value is set as 1 for not satisfying requirements.
	Effective area (0.3)	Building capacity	Capacity for taking refuge (SC)	The value is set as 3 for satisfying requirements. The value is set as 0 for not satisfying requirements
	Safety (0.4)	Location	Safety of location (SL)	The value is set as 3 for satisfying requirements. The value is set as 0 for not satisfying requirements
Emergency service facilities (0.155)	Medical and health (0.4)	Location and capacity of medical institutions	Medical institution capacity (EH) (0.6)	The value is set as 3 for satisfying requirements. If there is an emergency plan but it does not meet the capacity requirements, set it as 1; if there is no emergency preparation, set it as 0
	Food (0.3)	Location and capacity of commercial facility	Commercial facility capacity (EC) (0.4)	The value is set as 3 for satisfying requirements. If there is a reserve of emergency supplies but the quantity does not meet the requirements, set it as 1; if there is no

	Drinking water (0.3)	;Location and capacity commercial facility		reserve, set it as 0
Emergency support infrastructure （0.193）	Electricity supply (0.3)	Electricity supply system	Safety measures for electricity supply system planning (IP) (0.3)	The value is set as 3 for those with disaster relief safety considerations, 0 for those without such considerations
	Water supply (0.4)	Water supply system	Safety measures for water supply system planning (IW) (0.4)	The value is set as 3 for those with disaster relief safety considerations, 0 for those without such considerations
	Communication (0.3)	Communication system	Safety measures for communication system planning (IC) (0.3)	The value is set as 3 for those with disaster relief safety considerations, 0 for those without such considerations

Source: it is made by the author

Based on the above analysis, a disaster prevention capability model can be obtained, as shown in formula 2.

$$\text{Disaster prevention capability} = 0.26Qa + 0.12SS + 0.05RW + 0.02RL + 0.04RB + 0.02RQ + 0.05ST + 0.05SC + 0.07SL + 0.08EH + 0.06EC + 0.05IP + 0.08IW + 0.05IC \quad (2)$$

3. Assessment method and practice of disaster prevention capability in residential area

3.1 Assessment method of disaster prevention capability

Standard Assessment Guideline Method is used for disaster prevention capability assessment. Figure 6 shows the value standard. The items in Figure 6 are scored one by one by trained professionals who are proficient in the principle of scoring. For example, the scores can be divided into three levels of 0, 1, and 3, and scores are based on the degree of compliance described in the item: 3 means higher than the standard or disaster relief considerations, 1 means that the standard is met, 0 means that the standard is not met or there is no disaster relief consideration. Generally, the more levels are designed, the higher the

requirements for scoring personnel, the greater the risk of error. The score is divided into three levels for easy operation. According to the disaster prevention capability model constructed above, see Formula 2, and the scoring rules, the residential areas are scored. Based on the pre-set assessment criteria, the highest score of the ideal plan can be calculated. In Figure 6, take the highest score for the 14 selected elements as 3, so the full score for disaster prevention capability is 3. The scores are compared with the highest score after disaster prevention capability assessment in the study area, and the level of disaster prevention capability in residential area can be roughly assessed. For example, it can be set: (1) 80% or more, that is, disaster relief capability with a score of 2.4 points or more is at the excellent level and have good disaster prevention capabilities; (2) between 50% and 80%, that is, the disaster prevention capability with a score of 1.5 to 2.4 belongs is at the middle level and has a specific disaster prevention capability; (3) between 30% and 50%, that is, the disaster prevention capability with a score of 0.9 to 1.5 is at the poor level and has a certain disaster prevention capability; (4) less than 30%, that is, the disaster prevention capability with a score less than 0.9 is at the worst level, that is, it does not have the disaster prevention capability.

Usually, in order to improve the credibility of the assessment method, two rounds of assessment are performed. In the first round, two people are selected to assess the disaster prevention capabilities of the same residential area, the assessment is conducted independently. Afterwards, the assessment results are compared and analyzed to find out the difference in scoring, and discuss and correct them. After the first round, the assessment staff reaches an agreement on the assessment standards. The second round is a formal capability assessment, which also adopts the method of double assessment and mutual check. According to experience (He Lei, Dai Shenzhi and Song Yan, 2011), without correction, when the same part of the two scores exceeds 70%, the assessment is considered to be very effective and the assessment results are highly reliable.

This method is suitable for the assessment of disaster prevention capability of mature residential areas and the residential areas that have not yet been implemented and in the planning stage. The variables in the formula are estimated and scored according to the evaluation criteria, and the disaster prevention capabilities, strengths and weaknesses of the assessment objects can be basically known.

3.2 Assessment practice of disaster prevention capabilities in residential areas

The model formula of disaster prevention capability, formula (2), shows that the 14 elements that affect disaster prevention capability are ranked as follows according to the impact weight: building quality (0.26), spatial structure (0.12), medical institution capacity (0.08), emergency water supply (0.08), location safety of evacuation shelter (0.07), emergency commercial facility capacity (0.06), road width (0.05), accessibility of evacuation shelter (0.05), evacuation shelter capacity (0.05), communication system (0.05), electricity

supply system (0.05), buildings setbacks along the road (0.04), land function along the road (0.02), and building quality along the road (0.02). The disaster prevention capabilities can be changed through changing the status of influential factors with larger weights. The following are the main methods to improve disaster prevention capabilities:

(1) Improving the building quality can greatly improve disaster prevention capabilities. The disaster resistance level standard of the building is proposed based on the prediction of the disaster level and disaster scale of the residential area, and the design, construction and maintenance of the building are carried out based on this standard. The overall safety of the residential area is closely related to the safety of each building. Improving the building quality can also effectively reduce the need for emergency refuge and ease the contradiction between supply and demand for refuge systems in residential areas.

(2) The spatial structure of residential areas can improve the efficiency of disaster prevention and evacuation of residents in residential areas. Increase the density of the road network, promote small-scale spaces and a pedestrian environment, improve the closed access control system with only one entrance and exit, connect groups and residential communities with each other, and improve the connection and space sharing between different areas in the community.

(3) The location and capacity of medical institutions is an important force to ensure emergency medical assistance during disasters. The allocation capacity of residential hospitals, health centers, and medical points should be checked according to the emergency medical assistance needs during disasters.

(4) Emergency water supply is the most important infrastructure to sustain life. From the two aspects of drinking water storage and emergency water supply, the safety of emergency water supply is comprehensively improved in terms of location safety, facility reliability, and emergency response capabilities.

(5) The safety of evacuation and refuge location is the basic prerequisite for ensuring evacuation safety. Choose buildings with strong earthquake resistance for evacuation shelters; choose areas with high terrain that are not flooded or buildings with reliable structures; choose places with convenient transportation that are free from bad geological disasters and far away from dangerous sources.

(6) The capacity of emergency commercial facilities includes the storage of important materials such as food and drinking water, which are the most important materials for sustaining life and living after disasters. For residential areas with a certain scale, there should be a stock of materials that can meet the basic needs of residents within 1-3 days after the disaster.

The methods corresponding to the above 6 variables are the main methods, accounting for 61% of the total impact. The remaining 8 variables, due to their smaller weights, are of limited importance compared with the 6 variables, so the variables with smaller weights are ignored.

4. Conclusion

As the most basic component unit of a city, residential area is the 'target area' affected by disasters, the basic unit of disaster prevention and mitigation, and the cell and cornerstone of urban safety and disaster prevention. In the urban disaster prevention planning system ('disaster avoidance -- disaster reduction -- disaster relief '), the residential area, as a micro unit, takes the reduction of material property losses and casualties as the disaster prevention goal, and the reduction of vulnerability and the improvement of disaster relief and emergency response capability as the overall disaster prevention requirements. On this basis, the safety plan elements in residential area are sorted and analyzed, and this paper puts forward that six elements such as the building quality, spatial structure, location and capacity of medical institutions, emergency water supply, safety of evacuation shelter, and emergency commercial facilities greatly affect the disaster prevention capability in residential area, and are the main influencing factors to improve the disaster prevention capability in residential areas. In the planning and design of disaster prevention and mitigation in residential areas, the above six elements are prioritized as strategic measures for planning and improvement, which can effectively improve the disaster prevention capabilities in residential areas.

Meanwhile, a complete research idea for the assessment of disaster prevention capabilities in residential areas is constructed, namely 'basic disaster prevention ideas--disaster prevention goals--element indicators--element weights--assessment methods'. The element indicators are systematic, and the assessment method is simple and easy to operate. It not only contributes to the research on the disaster prevention capability assessment of residential areas in China, but also facilitates the guidance of planning practice. The deficiencies are that the expert scoring method is used to determine the element weight, which is subjective; meanwhile, the disaster prevention capability assessment model has not yet been applied in practice. These aspects will be further study in this paper.

Identification and Planning of Potential Ventilation Corridors: A Case Study of Wuhu, China

Po-Yu Yang
Affiliation: Southeast University
Email: pyang@seu.edu.cn

Abstract
Ventilation corridors have a significant effect on the improvement of urban climate adaptation as well as the improvement of habitat quality. In the context of climate change leading to the frequent occurrence of extremely high temperatures, it is necessary to research urban ventilation corridors to optimise the urban wind environment and thermal comfort. In the past, wind speed measurement and computational fluid dynamics methods have had limitations in their application to large-scale urban spaces. In this study, with Wuhu City as a case study, a geographic information system (GIS)-based method was adopted to design an urban ventilation corridor suitability assessment framework for identifying potential ventilation corridors, which can support the identification and planning of ventilation corridors in large-scale urban planning and design.

Keywords: Urban Wind Environment; Ventilation Corridors; Compensation Space; Urban Heat Island (UHI)

1. Introduction

The world is currently experiencing significant changes characterized mainly by warming. Climate change is one of the most important challenges facing the global community in the 21st century, as it is causing problems such as sea level rise and the frequency of extreme weather events, which in turn are leading to a series of meteorological disasters and will continue to have significant impacts on natural and human systems (IPCC, 2021) The greenhouse gas (GHG) emissions lead to thermal changes in the built-up area. The deterioration of the thermal environment in built-up areas due to greenhouse gas emissions, the heat island effect, and the transformation of green spaces into impervious surfaces have also become one of the major concerns for global sustainable development, and how to cool cities has become a hot topic of research worldwide (Mirabi & Davies, 2022).

The heat island effect is closely related to urbanisation (Su et al., 2012). The problems of insufficient green space, over-concentration of population, and a large number of artificial heat sources all make cities heat islands. China is one of the significant regions in the global urbanisation process; in the rapid urbanisation process, the increase of urban population density and development intensity has led to a rise in the intensity of capacity release within the city. At the same time, the continuous expansion of the area of the urban construction area and the transformation of the land use type have led to a weakening of the ability of the city to communicate with the surrounding natural environment, especially in the urban construction area of the wind blockage by the building complex, the hardening of the urban underlay, industrial waste gas and traffic exhaust emissions, etc., all of which have led to the heat island effect. In particular, the blockage of wind by buildings in urban construction areas, the

hardening of the urban subsurface, and the emission of industrial and traffic exhaust have all had a negative effect on the urban atmospheric environment.
In the context of climate change, the heat island effect has become one of the major concerns of urban planners and designers today. The great potential of ventilation corridors in mitigating the urban heat island effect has been proven to be an effective urban cooling method in planning studies in Japan and Germany (Barlag & Kuttler, 1990; Kagiya & Yasunobu Ashie, 2009).

Ventilation corridors are an essential part of the urban wind environment, and urban canopy ventilation is considered to have great potential for improving urban heat islands. Many regions have incorporated them into their urban planning. To improve thermal comfort in cities, the 2016 Climate Change Adaptation Action Plan for Cities (CCAAPC) of China proposes the creation of urban ventilation corridors to improve the ventilation benefits within cities. Cities such as Shanghai, Beijing, Wuhan, and Nanjing have proposed "ventilation corridor planning" in their urban planning, intending to improve the urban ventilation environment through the study and planning practice of ventilation corridors.

Identifying spaces with ventilation potential is a prerequisite for ventilation corridor planning. To provide a reliable urban ventilation corridor planning method, this study uses Wuhu City as an experimental case to calculate the ventilation potential within the study area. The purpose of this study is to propose a quantitatively calculable method for identifying urban ventilation corridors, to estimate the suitability of ventilation corridors through heat island identification and built environment morphology analysis, and to provide a reference basis for ventilation corridor system planning.

2. Literature Review

The term "urban ventilation corridor" is derived from the German word "Ventilationsbahn", which refers to the channel constructed to improve the air mobility of the city, alleviate the heat island effect, improve the comfort of human beings, introduce fresh, cold and humid air into the urban area, which is an integral part of the urban wind environment. Urban natural ventilation comes from the local circulation system formed by the wind pressure difference and heat pressure difference. Kress carried out studies on air circulation in regional areas and pointed out that the urban ventilation system mainly consists of effective space (Wirkungsraum), compensation space (Ausgleichsraum) and ventilation paths (Luftleitbahn) (Kress, 1979). Ausgleichsraum refers to areas of the city where the wind environment urgently needs improvement, such as high-intensity built-up areas, densely populated areas, etc., and usually also areas with an intense heat island effect. Compensation space refers to areas that provide a source of fresh air, generate cool air, and promote air circulation, usually including broad blue-green spaces such as lakes and urban green spaces. Air-guided channels are air transfer paths that connect the compensation space to the action space. Based on the characteristics of the air flow, these passages can be divided into three categories: ventilation corridors (Ventilationsbahn), fresh air passages (Frischluftbahn), and cold air passages (Kaltluftbahn). Figure 1 demonstrates the relationship between the compensation space, effective space, and ventilation path.

The most commonly used technical approaches in the study of urban ventilation corridor analysis methods are wind speed analysis and computational fluid dynamics (CFD) methods (Ramponi et al., 2015) K. Niachou et al. conducted in wind speed measurements of street

canyons in Athens, Greece, to analyse the influence of urban morphology on airflow, environmental thermal effects (Niachou et al., 2008). The wind speed was measured in the street canyons of Athens, Greece. Because in situ measurements are time- and resource-intensive for data collection and are susceptible to unstable meteorological conditions (Schatzmann & Leitl, 2011), wind tunnels have been introduced to simulate urban wind environments. Previous studies have validated the correlation between building density and mean wind speed using wind tunnel test results (Kubota et al., 2008). The method can scale down the urban space and simulate the airflow in the laboratory by emulating the wind environment's characteristics such as wind speed, direction, and air pressure. This technique is simple, controllable, less susceptible to external environmental disturbances, and capable of continuous observation. However, it is more dependent on equipment and funding (He et al., 2022). Either field measurements or wind tunnel tests require costly experiments, limiting the method's practicality. With the advancement of computer science and technology, the computational fluid dynamics (CFD) method has been widely used in the simulation study of urban wind environments due to its advantages of lower cost, high accuracy, and speed (Ling Chen et al., 2017; Peng et al., 2017). Although CFD methods can simulate wind flow conditions in a small area with a high degree of refinement, they have a high demand for computational resources, and the modelling of CFD methods is too complex for many large-scale urban applications. In recent years, some scholars have used geographic information system (GIS)-based spatial morphology analysis methods to analyse building morphology and assess the urban wind environment using indicators such as surface roughness and building density for the identification of ventilation corridors (Hsieh & Huang, 2016; Peng et al., 2017; Liu et al., 2022).

Considering the limitations of wind speed analysis and CFD methods in large-scale urban space and the advantages of GIS-based wind environment analysis methods in large-scale spatial computation, this study will use GIS-based methods to assess wind environments and identify ventilation corridors at a large scale.

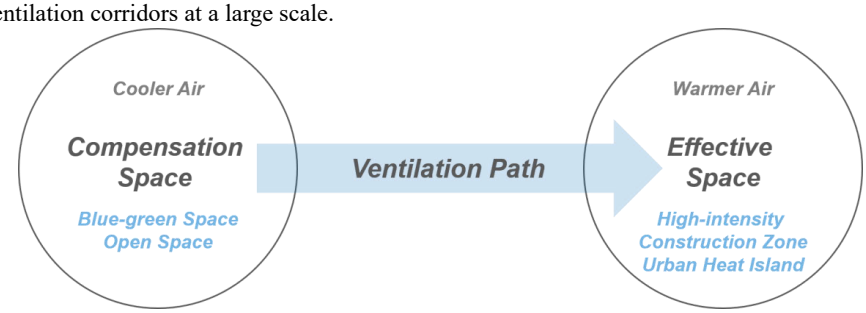

Figure 1. Relationship between compensation space, effective space and ventilation path

3. Materials and Methods

3.1 Study Area

Wuhu City is located in Anhui Province, China, on the lower reaches of the Yangtze River. The study area of this study is located along the Yangtze River in Wuhu City, north of the Qingyi River, about 30 kilometres along the river, with a total area of about 82 square kilometres. The year-round dominant wind direction in the study area is easterly, with an annual maximum wind speed of 18 m/s and an annual average wind speed of 2.8 m/s.

In summer, Wuhu City is controlled by the subtropical high pressure in the western Pacific Ocean, and there is more high-temperature and high-humidity weather. In the summer of 2022, the number of high-temperature warnings (≥35°C) in the area reached 41 days, in which there is a large slice of the high-temperature slice in the northern industrial agglomeration of the study area with a noticeable heat island effect. In terms of cold island areas, more cold island areas are distributed in the study area, including the Yangtze River, mountains, lakes, etc., forming more compensation space. Figure 2 shows the study area of this paper, a wind rose map with wind frequency statistics for different months of the year in the region, and urban heat islands identified by land surface temperature retrieval based on the August 2022 Landsat 9 OLI/TIRS data.

Given the high-temperature problems in the area, it is necessary to evaluate the wind environment in the area, identify and construct potential urban ventilation corridors, harmonise the characteristics of the urban climate environment, and improve the urban air circulation system.

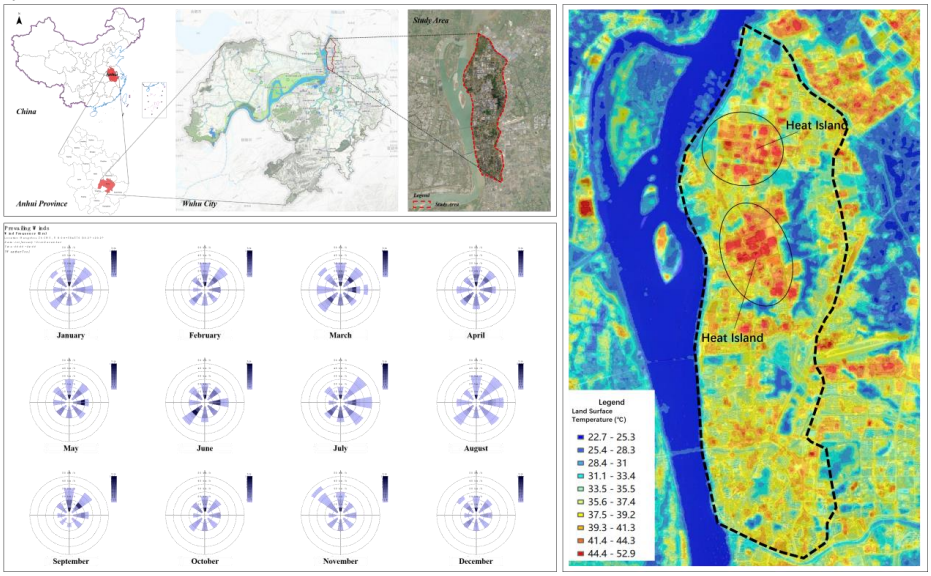

Figure 2. Study area boundaries, wind rose diagram, and land surface temperature

3.2 Data

Data were obtained from various sources, as shown in Table 1. All the data used in this study were calculated with the CGCS2000 coordinate system as recommended by the national government.

Table 1. Data sources and descriptions

Data	Data Source	Year
Landsat 9 OLI/TIRS data	United States Geological Survey (USGS) (https://earthexplorer.usgs.gov)	2022

Land use data (land use type)	Wuhu City Planning and Natural Resources Bureau	2022
Building data (footprint, height)	Wuhu City Planning and Natural Resources Bureau	2022
Road network data	Wuhu City Planning and Natural Resources Bureau	2022

3.3 Methods

This study aims to construct a wind environment assessment method based on a GIS multi-factor overlay to support the identification of ventilation corridors. The framework of the methodology used in this study is shown in Figure 3.

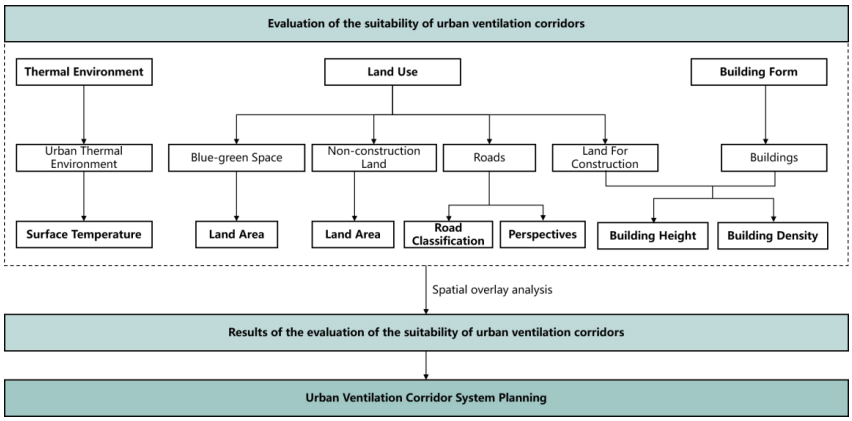

Figure 3. The framework assesses the wind environment and identifies urban ventilation corridors.

This study established a ventilation suitability evaluation method based on spatial superposition analysis, mainly considering the thermal environment, land use, and building form.

3.3.1 Thermal Environment

Land Surface Temperature (LST), a key parameter in the determination of urban heat islands, is the temperature of the Earth's surface as measured by thermal radiation and is one of the most important physical parameters examined in the modelling of land surface processes (Stewart & Kremer, 2022). This study used Landsat 9 OLI/TIRS data to retrieve the surface temperature to evaluate the urban thermal environment. In the analysis process, data from August 2022 were used, severe weather events such as rainy days were excluded, and the steps shown in Figure 4 were followed to calculate land surface temperatures within the study area using the atmospheric correction method and to identify heat island areas in the region.

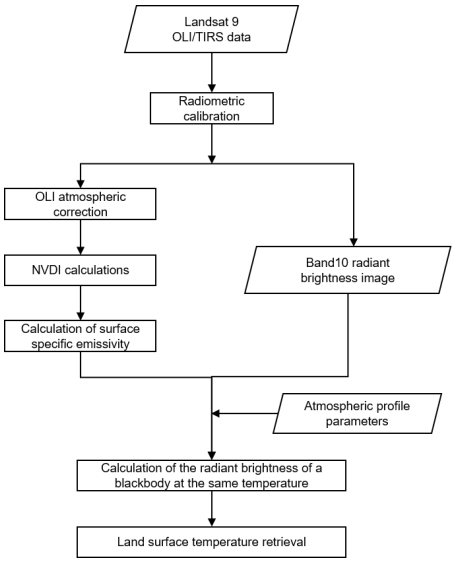

Fig. 4. Workflow of satellite image processing for land surface temperature

3.3.2 Land Use

The form of land use has an essential impact on the urban heat island effect, with different land use types having a heating or cooling effect on air temperature, affecting air movement (Hsieh & Huang, 2016). For example, blue-green space and non-built-up land use have a significant cooling effect and can serve as compensation space for urban ventilation systems; built-up land use acts as a heating effect on air temperature, while roads provide space for air circulation and has the potential to reduce temperature.

In this study, the land use types were divided into four types: blue-green space land, non-construction land, construction land, and roads, where blue-green space land, non-construction land, and construction land were assigned values based on the land area of the parcel, as well as the grade of the road and the angle to the dominant wind direction, which were used to calculate the suitability of the ventilation corridor.

3.3.3 Building Form

Building form affects urban ventilation mainly through building height and windward surface density (Yuan et al., 2014). Buildings are resistant to wind, and the higher the average building height and density in a plot, the more excellent the resistance to airflow. In this study, the average building height and windward surface density in each plot were calculated using building data as an indicator to evaluate the impact of building form on the wind environment.

3.3.4 Overlay Analysis

In this study, the data of three types of thermal environment, land use, and building form, were pre-processed, unified spatial reference coordinate system, resolution, rasterised and graded according to the ventilation potential for suitability evaluation, and the assignment rules are shown in Table 2. Among them, the very strong/strong suitability zone is an important wind

promotion element in the region and has the potential to become an important compensation space and ventilation corridor in the region; the very weak/weak suitability zone is an area with more serious thermal and air pollution problems, and it is a role space that needs to be considered for the construction of ventilation corridors in the future. After completing the assignment, the weighted overlay tool in ArcGIS Pro is used to performe the calculation. Finally, the evaluation results of the suitability of the ventilation corridor in the study area are obtained.

Table 2. Criteria for evaluating the suitability of ventilation corridors

Factor		Value	Suitability scale	Ventilation corridor suitability
Thermal environment (land surface temperature) (℃)		25-38	1	Excellent suitability
		38-40	3	Strong suitability
		40-42	5	Medium suitability
		42-44	7	Weak suitability
		>44	9	Very weak suitability
Blue-green space (waters, green spaces) (ha)		0-30	5	Medium suitability
		30-50	3	Strong suitability
		>50	1	Excellent suitability
Non-construction land (ha)		0-10	7	Weak suitability
		10-30	5	Medium suitability
		>30	3	Strong suitability
Land for construction (building height) (floors)		1-2	3	Strong suitability
		2-5	5	Medium suitability
		5-10	7	Weak suitability
		>10	9	Very weak suitability
Road (angle to prevailing wind direction) (°)	**Expressway**	0°-30°	1	Excellent suitability
		30°-60°	3	Strong suitability
		60°-90°	5	Medium suitability
	Main road	0°-30°	3	Strong suitability
		30°-60°	5	Medium suitability
		60°-90°	7	Weak suitability
	Secondary roads, branch roads	0°-30°	5	Medium suitability
		30°-60°	7	Weak suitability
		60°-90°	9	Very weak suitability

4. Results

The optimisation strategy of the ventilation corridor system in this plan mainly consists of compensation space and ventilation corridors, and the locations of the compensation space and ventilation corridors are determined using the results of the suitability evaluation in combination with the surrounding environment of the study area. The large agricultural and forestry land on the east side of the study area and the Yangtze River on the west side can be regarded as a considerable compensation space outside this ventilation corridor system, where cooler air can be blown by the prevailing easterly winds from the agricultural and forestry land on the east side to the action space within the study area, thus mitigating the impacts of the urban heat island and air pollution and evacuating the warmer air to the Yangtze River to improve the thermal environment in the study area.

The optimised ventilation corridors align with the prevailing wind direction in Wuhu City. This plan also grades the ventilation corridors and proposes the control requirements for urban construction in the areas around the ventilation corridors and recommendations for the width of the ventilation corridors. Figure 5 shows the ten ventilation corridors of the optimised ventilation system. In the first-level ventilation corridor, building height and density in the upwind direction of the city should be controlled as much as possible, and high-rise buildings should be appropriately dispersed to reduce building density and surface roughness. Appropriately increase the construction of open space in the upwind direction, maintain openness, create various forms of open space, appropriately increase the water area, and reasonably create ecological barges. Within the secondary ventilation corridor, the urban road system should be optimised as much as possible, keeping the road direction and the dominant wind direction all the time, improving the regularity of the road network and the number of straight lines to the road network. Improve the road section and design the combination of arterial roads and walking paths; both sides should be set up with a large width of the dense forest belt, planting sparse, low plants, which is conducive to air circulation—appropriate construction of green berms on both sides of the water system to improve airflow rate. Tables 3 and 4 show the compensation space and ventilation corridor in the Optimised ventilation system, respectively.

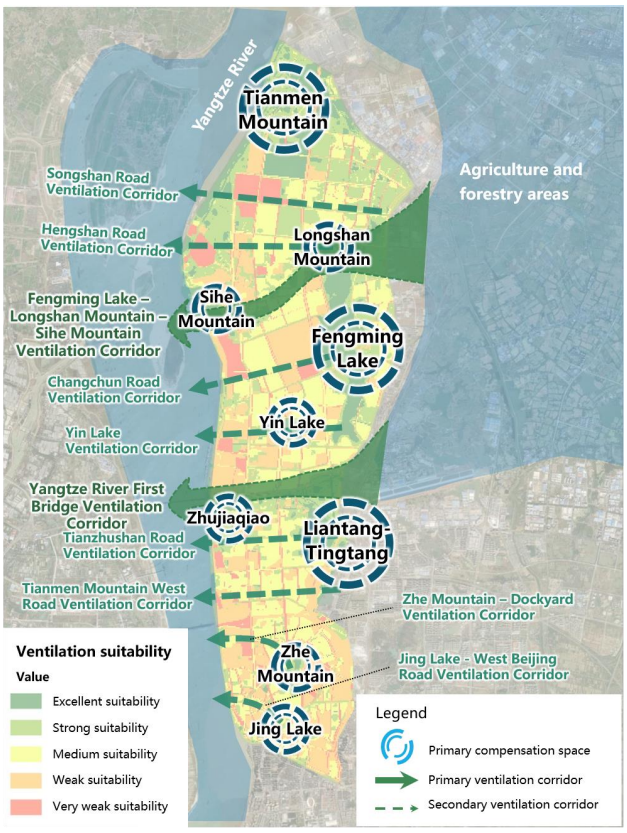

Figure 5. Optimised ventilation system.

Table 3. Compensation space in the optimised ventilation system

Type	Name
Compensation space outside the study area	Yangtze River
	Agriculture and forestry areas
Primary compensation space	Tianmen Mountain
	Fengming Lake
	Longshan mountain
	Sihe Mountain
	Yin Lake

	Liantang-Tingtang
	Zhujiaqiaowei Water Ecological Park
	Zhe Mountain
	Jing Lake

Table 4. Ventilation corridor in the optimised ventilation system

Type	Name	Function	Widths	Guidance for urban construction
Primary ventilation corridor	Fengming Lake – Longshan Mountain – Sihe Mountain Ventilation Corridor	Primary airways improve the quality of the urban atmosphere at the macro-overall level by integrating wind-promoting factors, including large-scale ecological resources such as lakes, forests, and farmland within and near the city, to lower the city's temperature and generate more cool winds for the city.	≥200m	Within the urban primary wind channel, building height and density in the upwind direction of the city should be controlled as far as possible, and high-rise buildings should be dispersed appropriately to reduce the density of buildings and reduce the roughness of the ground surface. Appropriately increase the construction of open space in the upwind direction, maintain openness, create various forms of open space, appropriately increase the water area, and reasonably create ecological barges.
	Yangtze River First Bridge Ventilation Corridor		≥200m	
Secondary ventilation corridor	Songshan Road Ventilation Corridor	The secondary wind channel mainly relies on roads and rivers parallel to or with a small angle to the dominant wind direction as a carrier to establish a secondary wind corridor with compensation space and action space to alleviate thermal and air pollution in local urban areas.	≥50m	Within urban secondary wind corridors, the urban road system should be optimised as much as possible to keep the road aligned with the dominant wind direction all the way and to improve the regularity of the road network and the number of straight lines to the road network. Improve the road cross-section and design roads combining arterial roads and footpaths, which should be flanked by dense forest belts of larger widths and planted with sparse, low-growing plants
	Hengshan Road Ventilation Corridor		≥50m	
	Changchun Road Ventilation Corridor		≥50m	
	Yin Lake Ventilation Corridor		≥50m	

	Tianzhushan Road Ventilation Corridor		≥30m	that are conducive to air circulation. Appropriate green space berms are constructed on both sides of the water system to improve air movement.
	Tianmen Mountain West Road Ventilation Corridor		≥50m	
	Zhe Mountain – Dockyard Ventilation Corridor		≥30m	
	Zhe Mountain – Dockyard Ventilation Corridor		≥30m	

5. Discussion and Conclusion

Ventilation plays an essential role in mitigating the heat island effect and improving air quality, and the evaluation of ventilation potential is a prerequisite for the identification of ventilation corridors. In this paper, by comprehensively considering various factors closely related to urban ventilation, we propose a framework for evaluating urban ventilation corridors based on GIS spatial overlay analysis, which is used to identify areas with ventilation potentials in a large-scale urban space. Based on the evaluation results, we propose a strategy to optimise the urban ventilation corridor system and clarify the ventilation corridors and compensatory spatial layout of the study area, which is inspiring for the study of urban ventilation corridors.

The method adopted in this paper can quickly quantitatively evaluate the ventilation potential of a city using only remote sensing data, land use, and building datasets and optimise the urban ventilation system accordingly. Compared with traditional techniques such as wind speed analysis and CFD, this method shows significant advantages in terms of efficiency and cost. It is well-suited for urban planning and design in large-scale spaces. In addition, we have also applied this method in the conceptual planning project along the Yangtze River in Wuhu City, and we hope that it can provide a convenient and intuitive scientific basis for urban planning decision-makers to promote more effective planning and decision-making.

Nevertheless, many factors affect the urban wind environment, and this study mainly analyses the thermal environment, land use, and building form for computational convenience. However, different types of construction land use have different impacts on the thermal environment, and various land use types should be further differentiated in future studies; meanwhile, the relationship between the orientation and frontal area density of the building form and the prevailing wind direction, as well as the frontal area density of the building, may also have different impacts on the ventilation efficiency. In future research, it is necessary to refine the specifics of the evaluation indicators to achieve a more refined analysis and improve the accuracy of this method.

Abstract:
Public and private actors who develop mobility innovations in practice often rely on control and reduce strategies when facing uncertainty. Different strategies to deal with uncertainty have been proposed in theory that are more adaptive and robust, such as joint-fact finding and other collaborative governance approaches. Question is how to stimulate actors to use these approaches in practice. This paper has evaluated the effectiveness of an intervention on mindset and synergy, to test the idea that stimulating behavioural conditions can lead to more collaborative responses to uncertainty. This intervention was evaluated in a control and intervention session of a serious game that simulates a multi-actor decision-making process of negotiating about mobility innovations for a sustainable mobility plan. Both sessions were compared in terms of negotiation process and outcome, and strategies to deal with uncertainty. We found that in both sessions actors used collaborative strategies to deal with uncertainty, but in the control session participants were also applying control strategies for their own organization to reduce uncertainty, because of the inhibiting conditions on mindset and synergy. We conclude that combing a psychological perspective with governance approaches for uncertainty is a promising way to experiment with interventions to deal with uncertainty.

Key words: Uncertainty; Risk; Serious Game; Intervention; Decision-making

1. Introduction

In the context of a transition and implementing corresponding socio-technical innovations, public and private actors must collaborate (Ansell & Gash, 2007), especially in the field of transport (Lyons & Davidson, 2016; Martens & van Weelden, 2013). Making choices under uncertainty collaboratively is part of establishing a transition towards a sustainable society (Köhler et al., 2019). Where transition research is 'relatively strong in explaining past transitions and case studies, it seems less strong in designing (practical) interventions' (Zolfagharian et al., 2019, p. 11). Such interventions are necessary though, as actors struggle with finding appropriate responses towards uncertainty, and tend to rely on control strategies via traditional project management approaches, thereby ignoring the unpredictable and unknowable nature of innovations and transitions (Akse et al., 2023) .

In the literature, a broader set of go-alone and concerted strategies for dealing with different types of uncertainty has been proposed (Dewulf & Biesbroek, 2018), ranging from improving information exchange between actors, joint fact-finding, to stimulating trusting relations. The question is how to stimulate actors to use these approaches in practice. Different methodologies have been developed in other domains to stimulate collaboration and moving forward *despite* uncertainty, ranging from psychological interventions regarding judgement and uncertainty (Mussweiler & Posten, 2012) to analytical modelling approaches for constructing adaptive policy pathways (Marchau et al., 2019). Although such methodologies are promising in itself as a way to reflect on the role of uncertainty for individuals and organizations, there is a large challenge to connect these methodologies with actual decision-making practices and find conditions that help implementing them. In other words, there is a gap to apply promising approaches in a behavioural setting that does right to the complexity of an uncertain decision-making processes.

Therefore, we built a non-digital serious game that simulates a decision-making process in a transport context, with the aim of testing a multi-layered intervention. Serious games offer great opportunities to test and play with interventions in a controlled environment (Lukosch et al., 2018; Vervoort et al., 2022). In literature, a serious game is often treated as an intervention with the aim of education and learning (Stanitsas et al., 2019). It can be a form of decision-making support so that organizations can learn about a complex environment (Mayer et al., 2016; Meijer, 2012), or be part of an intervention in the design of the decision-making process without actively intervening in the behaviour of actors (Bekius et al., 2021). In this research, we take a hybrid approach, where we use a serious game as a scientific tool to experiment with an intervention that primes participants in changing their decision-making behaviour throughout the game. The research question this paper wants to answer is: How do conditions regarding mindset and synergy-thinking stimulate or inhibit decision-making practices under uncertainty in a serious game?

2. Theoretical Framework

2.1 Actor behaviour under uncertainty

Multi-actor decision-making for innovations involves two types of uncertainty (Mayer, 2009): system uncertainty, related to the unknown physical and technical state of the system that includes an innovation, and governance uncertainty, related to the social-political issues as a result of the interactions between multiple actors who have diverging and conflicting interests. Uncertainty is not just a characteristic of a system, independent of actors' interpretation of it. However, many studies do consider uncertainty in this way (Jensen & Wu, 2016; Lyons & Marsden, 2019). The consequence of conceptualizing uncertainty in that way is that both actors and scientists look for ways to reduce uncertainty, by getting a better understanding of the

system through gaining more knowledge about that system. Uncertainty is thereby outsourced and externalized by the decision-maker, without reflecting on underlying mechanisms, causes and values and assumptions that support behavioural responses to uncertainty in the form of double-loop or triple-loop learning (Argyris & Schön, 1978; Tosey et al., 2011).

This paper separates therefore an actors' *experience* of uncertainty in the decision-making process and response to it by specific strategies of dealing with uncertainty (Akse et al., 2023). Separating these concepts enables us to pinpoint specific behavioural conditions that stimulate or inhibit specific behavioural responses to uncertainty. In other words, it opens the opportunity for a more intervention-type of thinking in complex decision-making processes, which does right to the *human* aspect of uncertainty and its interpretation by actors in the field. In the design and playing of the serious game, we have developed an intervention that builds on two behavioural building blocks: mindset and synergy. We will theoretically work out these two concepts below.

2.2 Intervention for uncertainty management

2.2.1 Mindset

Mindset plays a crucial role in how individuals and groups perceive and manage uncertainty. The interplay between mindset and uncertainty can significantly impact emotional responses and actions, for example, in the context of information processing, approach to problem-solving, willingness to collaborate, or decision-making (Dweck, 2006).

People with an open mindset, in situations of uncertainty, are more likely to embrace challenges as opportunities (Baas et al., 2011; Silvia et al., 2009). This mindset fosters a more explorative and resilient approach to uncertainty, where the focus is on what can be learned or how one can adapt rather than on the potential for failure. People with an open mindset typically view uncertainty as a puzzle to be solved, which can lead to innovative problem-solving and creative thinking (McCrae, 1987; Williams, 2004). They are more likely to engage with complexity and seek out new information to navigate uncertain situations effectively and collaboratively (Grant & Berry, 2011).

Important to realize, an open mindset is not inherently a stable personality trait; rather, it can be viewed as a dynamic state that can be actively developed and stimulated through various practices and experiences. This view aligns with the broader understanding that many aspects of our personality and behaviour can be influenced by intentional actions and environmental factors (Steg & Vlek, 2009).

Two key approaches to stimulating and cultivating an open mindset are framing and inducing a promotion focus. Framing refers to the way information is presented or structured. The frame that surrounds a set of facts can alter perceptions by highlighting specific aspects, thereby influencing how people interpret, feel about, and react to information (Tversky & Kahneman, 1974).

For instance, framing information in terms of potential gains vs. losses leads to a promotion focus vs. a prevention focus. Promotion vs. prevention focus is known to lead to different thoughts, emotions, and behaviour (Higgins, 1998). The concept of framing is extensively used in psychology, marketing, politics, and media to guide opinion and behaviours in a specific direction (Levin et al., 1998). In the current study, we induced an open mindset and a promotion focus by how we framed the title of the game as well as the role description.

2.2.2 Synergy

In addition, cooperative and synergetic approaches towards dealing with uncertainty can be found in multiple fields of literature. Actor network theory (ANT) (Latour, 2007) points at the synergies that actors can develop, by finding shared solutions for in principle unshared problems. In the interaction with the other, actors can experimentally define how they complement each other's perspective and codevelop solutions that fit those perspectives. This is described in a more normative sense in the works on network management in decision-making processes (De Bruijn & Ten Heuvelhof, 2018; Koppenjan & Klijn, 2004). Moreover, contract design and management literature suggests practical incentivization of synergies via the usage of cooperative approaches (Roumboutsos & Pantelias, 2014), for example through revenue and risk sharing. When uncertainty is coming from actor interactions with possible conflicting goals, experimental cooperation is an enabling condition for trust building and solution finding so that different goals can be part of a shared solution. Adaptive co-management and trust building are thereby key in conditions of uncertainty (Armitage et al., 2009). Collaborative multi-actor approaches emphasize synergetic thinking as a way to deal with uncertainty of innovations, as these synergies can compensate for large uncertainties. Also, actors can embrace synergies as an instrument for designing future systems. In the current study, we induced synergy thinking by how the game was introduced to the players and by adding bonus effects between different innovations.

3. Game Description

To assess the effect of a multi-layered intervention on the decision-making behaviour under uncertainty, we developed a negotiation game in which a government, a public transport company and a start-up must negotiate in multiple rounds to develop a sustainable plan for a city region. The game includes a fictive but realistic setting of dilemmas and dependencies between multiple stakeholders about deciding which innovations will be part of the plan, and under which conditions. The game is open, in a sense that players have a lot of freedom to define these conditions in line with their need to accommodate and prepare for uncertainties that are inherently part of the innovation options and negotiation process. We played the game in an intervention and a control session, to compare how different conditions leads to different decision-making behaviour and outcomes. The intervention on mindset affected the players individually, and the intervention on synergies affected the relationship between the players and the different innovation options. An overview of the game is displayed in Figure 1. We will go into more detail about the scientific set-up and interventions of the game in Section 3.2.

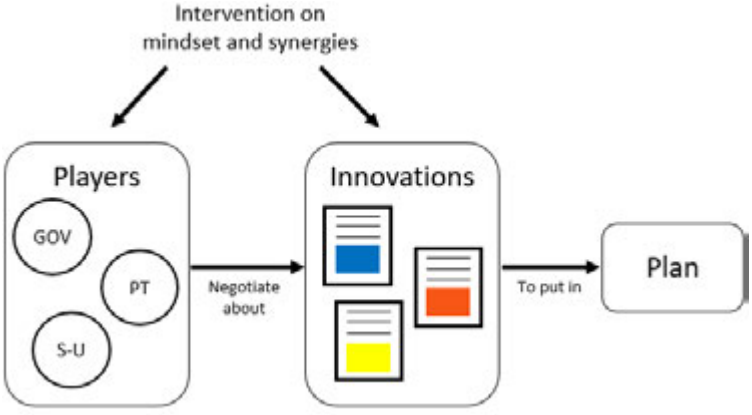

Figure 1: Overview of game, including the intervention. GOV = Government, PT = Public Transport Company, S-U = Start-up

3.1 Outline of game

The game is played in-person in a room, where the local public transport company and start-up have been called by the government to present their innovation options that could be part of the sustainable mobility plan of the government. Eventually, the practical aim of the game is to draft and negotiate a sustainable mobility plan for a city region that works towards zero emission in 2040. Previous research has described several elements that are useful for setting up a game that incorporates uncertainty. For example, Avendano-Uribe et al. (2022) have developed a serious game that allows a local community to play with uncertainty to build resilience. Uncertainty elements built in the game include role-playing cards, different scenarios, disaster dice and conflicting variables. Similarly, Schueller et al. (2020) let participants play a game to assess how uncertainty impacts the processing of information during natural disasters. Leclercq et al. (2023) developed a game-based learning workshop using role-playing activities and increasing self-awareness and reflection on participants' attitude towards uncertainty. van Schaik (2023) played two board games that include multiple roles and measures, aiming to ask participants to identify uncertainties. Other studies use digital tools, in the form of virtual reality (Hajahmadi & Marfia, 2023), or use a co-design approach to develop a game that helps make decisions under uncertainty for an ecological water system (Powell et al., 2021).

The building blocks for our game are the following:

- The transport planning context consists of a city region of about 150.000 inhabitants and is expected to grow by 20% by 2040. There are local diesel trains and buses, and intercity train station.
- Each player has multiple options in its portfolio to put into the sustainable mobility plan. These options have an expected estimated range of investment costs, realization time, emission effect and passenger revenue.
- An independent Assessment Agency provides feedback to the players by presenting the effect of the draft mobility plan regarding emission effect and passenger revenue.

A game session has the following structure:

1. Introduction of the city region, and division of roles between the players. Two participants play one role, and they read their role description and look into their budget and portfolio regarding mobility innovations. The government can pick from land-use measures such as a station renovation, densification, or bus-lanes. The public transport company has more incremental innovation measures in its portfolio such as a data-dashboard, electric buses, or on-demand transport. The start-up had more radical innovations in its portfolio, like mobility hubs, autonomous vehicles, and a drone delivery service system. A summary of the roles is given in Table 1.
2. The first negotiation round starts, and players talk about their measures and preferences
3. After a short individual reflection, players start a second round of negotiation and develop a draft plan with innovation options.
4. The independent Assessment Agency calculates the effect of the draft mobility plan. These numbers are not dependent on the players' plan and are used to put pressure on players to make a more ambitious plan. Also, three scenarios are presented to the players to stress-test their draft plan against.
5. In a final negotiation round, players can change their draft plan based on the calculations and stress-test against the three scenarios. Then, they deliver a final plan and then the game is over.

6. Individual filling in of a post-game survey and plenary de-brief regarding what went well, what could have been better and the role of uncertainty in the game.

Table 1: Players of the game

	Government	Public transport company	Start-up
Budget	50	10	5
Playing card typology	Land-use measures and station upgrade	Improving incrementally the existing public transport system	More radical innovations
Range of effect	Possibly large effect, but also high costs	Smaller effects, but lower range difference	Larger effects, but higher range difference

Uncertainty comes into the game in two ways. Firstly, the measures in the portfolio of players do not show exact estimates of the effects of each measure. Moreover, it is unknown what the total number of selected innovations does to the overall emission reduction of the mobility system. These elements refer to system uncertainty in the game. Secondly, in the negotiation rounds players do not know what options are available with other players, or how to value the estimates that other players present to them. Can they indeed rely on the numbers and narratives presented, or is the innovation overhyped? Players have the freedom to use and interpret the numbers to what they think is wise. This means they can also be overly optimistic or just lie to other players. These elements refer to governance uncertainty.

3.2 Scientific set-up of intervention

We developed two versions of the game in the form of a between-subjects design, where a control session is compared with an intervention session. The multi-layered intervention focuses on changing relevant conditions for actors (Rauws, 2017), priming them towards different decision-making behaviours. The conditions in the control session are not neutral, meaning that the difference between both sessions is just the intervention. Rather, we designed the two groups in such a way that the control session worked under inhibiting conditions for collaborative and adaptive decision-making behaviour, and the intervention session worked under stimulating conditions for collaborative and adaptive decision-making behaviour, based on theoretical insights on mindset and synergies as set out in Section 2.2. The intervention consists of two elements: (1) priming a different uncertainty mindset of promotion-focus that stimulates collaboration and (2) emphasizing synergies and design thinking between different types of innovations. An overview of how these concepts have been operationalized for the two different sessions is displayed in Table 2. A different mindset was induced by the title of the game and the given role description to players. A different synergy effect was induced by describing the aim of the game and the innovation bonuses on the playing cards.

Table 2: Operationalization of conditions in control and intervention session

	Operationalization	Control Session	Intervention Session
Mindset	Name of the game	"A safe journey to the future"	"Design the future together"
	Role description (example of government)	Pay attention: • You don't have experience with the start-up • You do not feel much support from the local alderman • You want to reduce the risks as much as possible for your organization	Pay attention: • You have successfully worked together with the start-up • You do feel much support from the local alderman • You would like to explore together to come a robust and sustainable plan
Synergy	Introducing the aim of the game	• Distribute the investment costs • With a focus on an optimum of costs and revenues	• Realize as much benefits as possible • With a focus on the other and a sustainable future
	Playing cards (example of public transport company)		
An important element in the game flow is the so-called 'stress-testing' of the draft plan by players, which involves an examination of how it would perform in different possible futures (Marchau et al., 2019). When a plan is seen to perform less well, it may prompt either a rethink of the plan or consideration whether implementation should be delayed until clearer indications how society is changing, or whether implementation should proceed with the option to scale back if change is unfavourable. Stress-testing is based on the idea of dynamic or adaptive robustness, by making adaption key in the plan formulation (Moallemi et al., 2020). Through monitoring and mid-course corrections, actors keep the system headed towards the original goals while the future unfolds. In the context of our game, we let players stress-test their draft plan against three different scenarios:

- Scenario 1: The 15-minute city has become a prominent paradigm to plan the urban system by
- Scenario 2: Current trends of higher individualized mobility and increasing travel distances by car continue
- Scenario 3: There are lower entry barriers for companies to enter the mobility market, so that there is more competition and flexibility in transport market

The purpose of the stress-testing element in the game is to trigger participants to reflect about the robustness of their plan, and whether the interventions on mindset and synergy influence

participants in the form of choosing for adaptive actions as a response to the three different scenarios.

3.3 Data gathering and analysis

We have played the control and intervention session with a mix of professionals having a background as a practitioner or scientist in the field of transport, mobility, and planning. Each role was played by a team of two persons, so that players had the opportunity to discuss and reflect within their team. To test the game, we piloted the control version of the game in three sessions with master students who had a background in geography and planning. Different authors of the paper facilitated the control and intervention session, but used the same game, session-specified presentation, and a facilitator script.

Research data has been gathered both on a content and process level. Content-wise, the sustainable plan itself has been compared in terms of cohesion. Through observations and transcribing the conversations between players, uncertainty management strategies have been retrieved and compared between the control session and the intervention session. A post-game survey asked questions about the level of uncertainty that players experienced, and the extent to which they collaborated well with other players.

4. Results

4.1 Overall impression

In both the control and intervention session, participants struggled with the uncertainties in the game in the form of unknown estimated effects of the innovations and uncertainties related to interaction with other players. In the de-briefs, participants mentioned about system uncertainty that they 'found it hard to compare two measures with each other, even when there is no different range of effects. How can I negotiate based on that, while I am not entirely sure myself?'. Participants mentioned about governance uncertainty for example that 'especially in the beginning, I was not sure what the government wanted. And I could not see all the cards, for example the parking option was a bit hidden'. Participants appreciated some elements in the game as very realistic, such as the promises made by companies about sustainable effects and the role of the Independent Assessment Agency who presented cost-benefit calculations and emission effects. Because the government had significantly more budget than the other players, they also had a strong say in both mediating and selecting innovations as part of the mobility plan, just as in practice. Some players missed an element to make a balance between long-term and short-term effects of innovations, but this can also be related to the real-life uncertainties of innovations in practice. When comparing the test sessions with planning students with the sessions with work professionals, it was striking to see that the students were highly focused on cost-effectiveness of innovations, calculations, and the division of investments between players. Participants with work experience in control and intervention session, however, acted more vision-led based on the possibilities of innovations, supported by their experience with such innovations in the work-field.

4.2 Control session versus intervention session

We will now analyse the effect of the intervention by comparing the game sessions of the control session with the intervention session, according to two categories: negotiation process and outcome, and strategies to deal with uncertainty.

4.2.1 Negotiation process and outcome

After reading their role and deciding on the strategy to go for, both the governments in the control session and the intervention session started with explaining their goals for the city. In
