Nowadays, World Cities Report 2020 by United Nations Human Settlements Programme (UN-Habitat) estimates that by 2050, approximately 6.4 billion people will live in cities and that demand for water will increase by 55% compared to current estimates. Moreover, given that half of the world's population lives within three kilometres of a surface freshwater body, and over 40 per cent reside in coastal areas, these populations would be at risk from sea level rise and extreme weather events associated with climate change (Barragan and De Andrés, 2015; Voskamp et al. 2021). It is estimated that the combined threat of rising sea levels and storm surge in coastal cities could result in the loss of more than one trillion dollars each year by 2050 (Hallegatte, et al, 2013).

Over time, water in the territory has shaped the landscape, directing the choice of a city's foundation site and the development processes that followed. Indeed, throughout the city's history, different evolutionary phases have followed, characterised by different relationships between the urban system and the water body. Matos Silva in 2016 mentioned both Saraiva's text (*O rio como paisagem: gestão de corredores fluviais no quadro do ordenamento do território*) from 1999, in which the author identifies four main evolutionary phases; and Brown et al.'s text (*Transitioning to Water Sensitive Cities: Historical, Current and Future Transition States*) from 2008 in which the author, similarly, identifies six different phases of water management over time. The first phase, coinciding for both authors, defined by Saraiva as 'harmony' and by Brown as 'water supply city,' corresponds to pre-industrialisation in which human activities were adapted to the natural water cycle. From 1800, with the beginning of the modern age, until the second half of the 1900s, Saraiva (1999) identifies the beginning of a period defined as 'domination' in which the water body was transformed and adapted to human needs. Brown et al (2008), more precisely, identify within the same period two phases, the 'sewer city' and the 'drained city.' A period in which urban transformations were guided by theories that favoured a strict separation between the city and water, whereby the first large water containment and channelling infrastructures were built: dirty water was channelled outside the city limits, large areas were reclaimed, canals, pipelines and river and sea embankments were built (Matos Silva, 2016). The third period, defined by Saraiva as a phase of 'degradation', coincides with the economic boom after the end of the Second World War and was characterised by massive exploitation of the water resource, in which the ecological damage caused in favour of economic progress became evident. The fourth period beginning in the 1980s is defined by the increased awareness of the environmental, ecological, cultural, social, economic and symbolic value of water. Brown et al (2008) identify the 'waterways city' phase from the late 1960s, with the beginning of heightened environmental awareness. During this period, legislative plans and programmes for the regulation of water as a resource and for its protection began to be drawn up. The last period theorised by Brown et al (2008) coinciding with the beginning of the 21st century is defined as 'water cycle city' and by Saraiva in 1999, as 'sustainability.' For the authors, the concept of 'water cycle city' encompasses a multifunctional, integrated and adaptive management of the entire water cycle, taking into account the precautionary principle instigated by the ongoing climate change projections (Matos Silva, 2016).

While the two authors mentioned above dealt in their study with the paradigm shift, which occurred over time, in the relationship between the urban system and the water body from a river perspective, Miriam García García (2019) outlines similar, and temporally coinciding,

processes in the approach to the marine limit. As the author highlights the progressive increase in population, and consequently economic development, along the coastline has over time brought the construction of massive defence infrastructures and the artificiality of the margins (García García, 2019).

Since the late 1990s, with the first report of the International Panel Climate Change (IPCC), the concept of adaptation to climate change has been introduced into the scientific debate (Matos Silva, 2016). Therefore, the political and social models and techniques we have been working with need to be reformulated, for as García García (2019) states, the reinvention of the coast requires a dynamic vision based on detailed observation of the natural phenomena occurring on it. Therefore, nowadays aware that disturbances of the natural water cycle within the urban environment (such as soil sealing, channelling of watercourses, delimitation of sea banks, among others) significantly increase the negative externalities of extreme events (Ciupa et al, 2020) nature-based projects are beginning to be considered alongside hard infrastructure.

The form of the Portuguese coastline

The form of water in the city is particularly evident in the multiple relationships, spatial and temporal, that occur in the shore space, a zone of transition and tension between the anthropic system, the city, and the natural system, the sea. The reconfiguration of the interface, of the space between land and sea, through the introduction of the rigid infrastructure, the seashore street, throughout the 20th century in the Portuguese coastal landscape, changed the relationship between the city and the water (fig. 2).

Fig. 2: Portugal Coastline. Author's editions, 2022

Along the Portuguese coastline, urban settlements, located near the water line, are characterised by the presence of a linear public urban space in which the city's social and economic activities take place. Urban space that is defined on one side by the buildings' façade, mainly designated for tourist use, and on the other by the natural element, the beach. Indeed, the rise of the tourism sector and the demand for seasonal tourism, which arose after the end of World War II, and the development of the automobile as a mass commodity in the 1960-70s, induced major transformations in the urban development of coastal cities. In cases where the construction of the seashore street is older, the old fishing buildings, built adjacent to the seashore street, were demolished and replaced by tourist structures, positioned parallel to the water line to obtain a

larger built-up area facing the seascape. In more recent cases, the seashore street has served as a driver of the urban agglomeration development, to which tourist-oriented buildings have been built alongside the urban layout (fig. 3).

Fig. 3: Quarteira: Topography, Urban Layout, Built-up area. Author's editions, 2022.

Quarteira's seashore street case

On the 943 km of coastline, it is estimated that the areas affected by extreme tidal flooding and SLR will be 903.1 km2 in 2050, impacting 59.530 buildings and 145.550 residents; this value will increase to 1146 km2 (river delta areas are included in the estimate), with 82.000 buildings and 224.830 residents in 2100 (regarding the relative contemporary mean sea level on the Portuguese coast, reference is made to Cascais tide gauge data) (Antunes et al, 2019) (fig. 4).

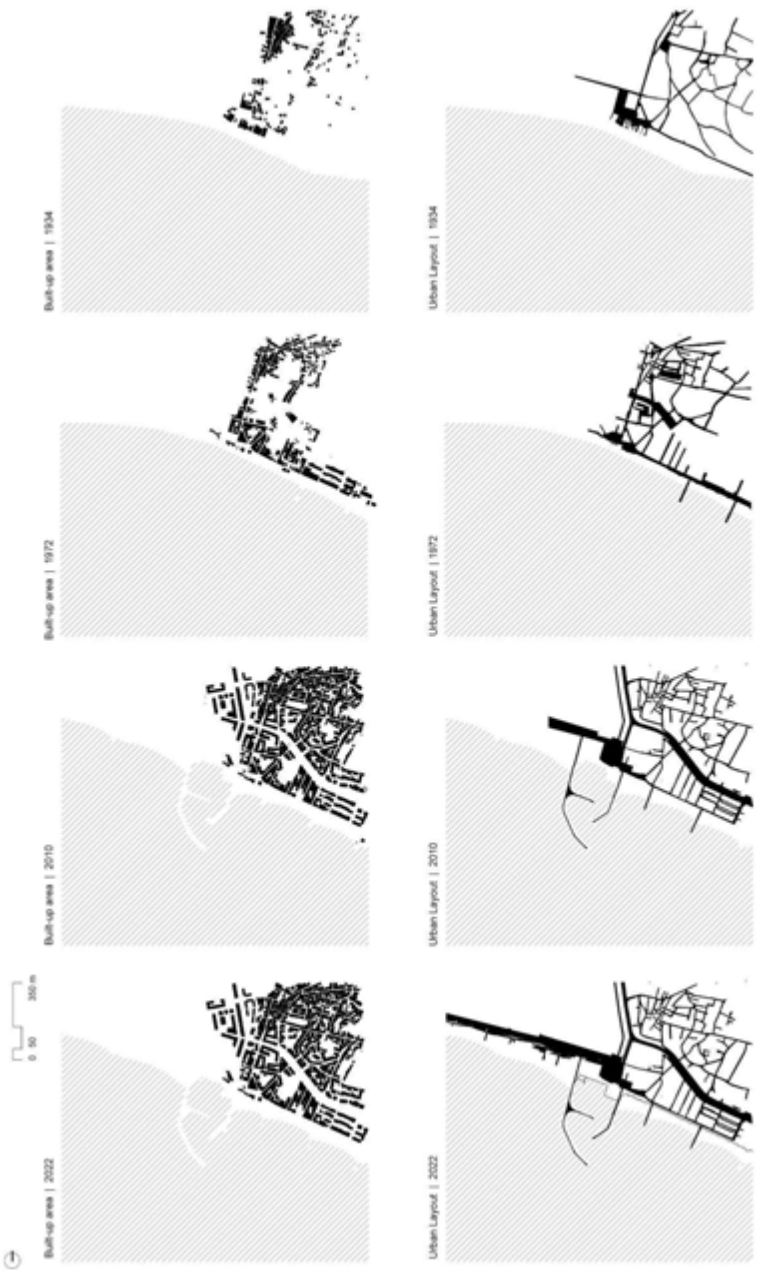

Fig. 4: Quarteira: Urban Evolution. Author's editions, 2022.

Research case study is the coastal city of Quarteira, situated in the Algarve region of southern Portugal, where approximately 24.421 people live during the year, a number that triples during

the summer period (INE, Instituto Nacional de Estatística) due to the tourism. Until before the emergence of mass tourism, Quarteira was a fishing town built far from the shoreline. The urban transformation of the coastal town of Quarteira began in the early 1950s, the construction of the street parallel to the sea, on the edge of the sandy beach, and the construction of the marina at the mouth of the Ribeira de Quarteira (Lobo, 2018); introduced a change in the relationship between the urban agglomeration and the sea. The seashore street stretches for about 3 kilometres with an average width of about 60 metres, and is situated at a height of between 4 and 5 metres above mean sea level, and is today, due to the effects of the rise in mean sea level, vulnerable to flooding and erosion. According to Teixeira, coastal erosion, caused by the prevailing wave motion from west to east, has increased with the construction of the breakwaters of the Vilamoura marina and also with the more recent construction of the defence infrastructure of the fishing harbour in 1999. Indeed, over the past three decades, several coastal protection structures have been built along the Quarteira coastline (Braz Teixeira, 2004) (fig. 5).

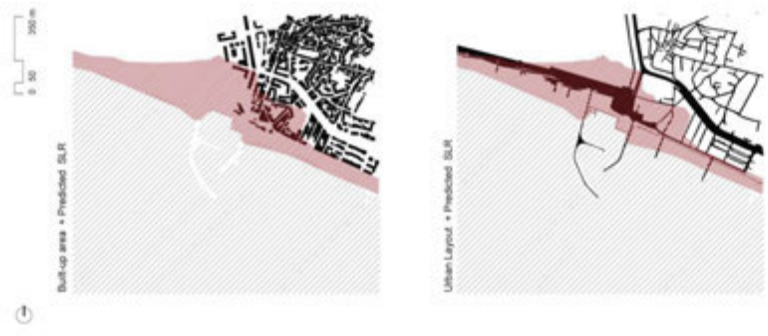

Fig. 5: Quarteira: Built-up area and Urban Layout + SLR. Author's editions, 2022.

Portugal's coastal protection policy, as of 2013, is no longer based on the construction of rigid protection structures. Indeed, since 2013, the majority of interventions are allocated to the maintenance of existing hard structures (Pranzini et al, 2013). In 2019, the Algarve Intermunicipal Climate Change Adaptation Plan, PIAAC-AMAL (*Plano Intermunicipal de Adaptação às Alterações Climáticas do Algarve*), was drafted, framed within the main objectives of the European Climate Change Adaptation Strategy (EEA) and the National Climate Change Adaptation Strategy (*Estratégia Nacional de Adaptação às Alterações Climáticas 2020*) (ENAAC 2020; PIAAC-AMAL, 2019), with the aim of supporting the protection, redevelopment and enhancement of the coastal strip. For Quarteira's urban waterfront, the PIAAC-AMAL, provides scenarios of shoreline retreat in the urban coastal front and suggests continuing to artificially feed the beach over the next decade, and subsequently proposes the construction of a dike-in-dune, while addressing the need to remove and relocate the first built line of the waterfront from 2040 (Dias and Santos, 2019). Moreover, the Algarve PROT (*Plano Regional de Ordenamento do Território*) territorial management regional plan establishes a ban on urban occupation in protected areas to ensure the continuity of ecological corridors connecting the coast and the interior (fig. 6).

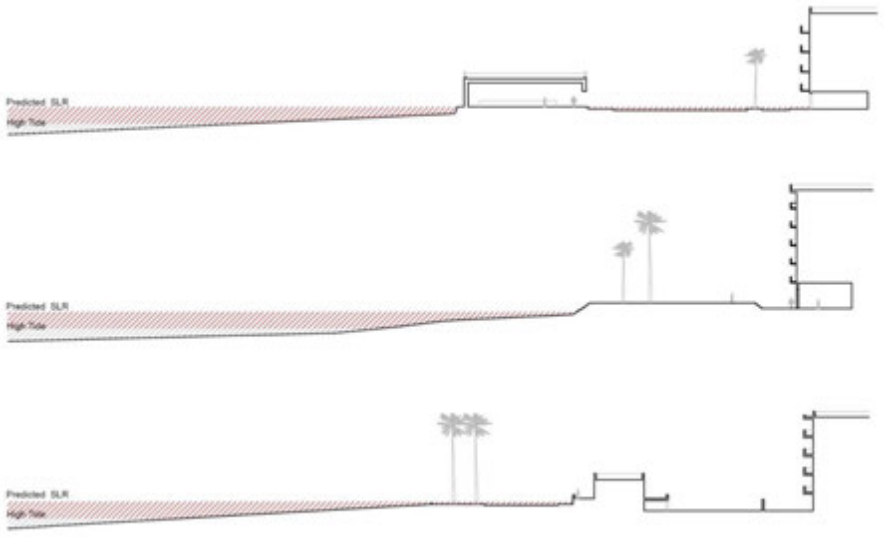

Fig. 6: Quarteira: Urban Sections + Sea Level Rise Scenario. Data estimated by IDL.Instituto Dom Luiz, Faculdade de Ciências da Universidade de Lisboa. Sea level rise scenarios available at: https://smart.campus.ciencias.ulisboa.pt/portal/apps/MapSeries/index.html?appid=ebee609293804c49abd52ccfb07f4762. Author's editions, 2022.

In 2016, the *Passeio das Dunas*, designed by João Nunes, *PROAP: Landscape Architecture and Design Studio*, was inaugurated, an urban public space designed with the intention of connecting Quarteira with Vilamoura and with the objective of protecting the urban agglomeration from the effects of the rise in the average sea level.

Passeio das Dunas, (seafront promenade), extends for approximately 675 m occupying an area of 52.329,54 square metres (fig. 7).

Fig. 7: Quarteira: Plan, Section and Image of *Proap: Landscape Architecture and Design Studio Project*. Author's editions, 2022.

João Nunes' project was based on the possibility of artificially creating natural conditions for the dune system to settle and develop, as in the natural process, recovering the existing dunes and vegetation. The project planned to work with natural dynamics, such as the movement of the dunes, through the creation of a thickness with blurred boundaries, allowing the continuous transformation of the space over time.

If in the competition phase the *Passeio das Dunas* was conceived as non-linear forms and paths related to working with living and evolving ecological systems such as green and blue

infrastructure, in the realisation phase the same forms were realised through rigid systems that delimited the space with rigid elements that prevented its continuous transformation. Results are sand dunes within which there is a rigid structure that holds the vegetation firm, bordered by a concrete walking surface as in the case of the seashore street to the east of the port.

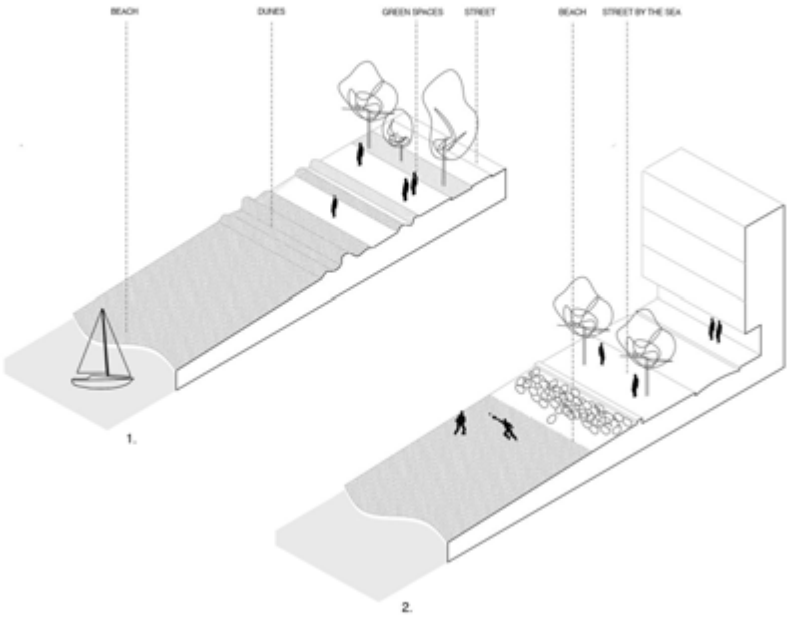

Fig. 8: Quarteira. Author's editions, 2022.

We observe in *Passeio das Dunas* project, João Nunes's design purpose to recognise the transformative process that the marine environment entails and thus propose in the project a dune landscape in continuous transformation.

The alteration of Joao Nunes' project has resulted in the construction of an infrastructure that will have the same problems over time as the fixed infrastructure, indeed, like the seashore streets, it will become a ruin over time due to the effects of extreme weather phenomena: such as erosion and floodings phenomenon.

Water: a territorial project

Water, as a structuring element of places, may guide the design of the form of the city (Proença et al, 2021). As Conceição (1997) affirms, water can structure places through functional, conceptual, symbolic, and geometric relations. Although water is an element with no intrinsic form, it forces us to question and discuss its presence in architectural and urban projects. Examples where the design of public space has taken into account the natural element of water include the Living Breakwaters project, which envisages risk reduction by improving physical resilience along Staten Island's south shore through the use of hard infrastructure, the

breakwaters, and green and blue infrastructure. As is the Climate Ready Boston project, to make the East Boston and Charlestown coastal area resilient through the use of green infrastructure - vegetation - as a protective and adaptive system that accommodates rising mean sea level. As Figueira (2020) argues, the river and the sea are primordial elements in determining urban design, whether during a flood or a high tide, in both cases water is the regulating element (Figueira, 2020, p.33).

Drawing the transformation of the Landscape: a constructed nature

Nowadays, due to the increasing effects of sea level rise, such as erosion and flooding phenomena, there is a political and administrative demand to establish urban adaptation plans and projects for vulnerable areas. As with all environmental frontiers, the shore is an ecosystem with a dynamic and fragile equilibrium, therefore water-related challenges - such as storm surge protection - are often addressed in a separate way through limited procedures and plans. Landscape plans, of European character and national implementation, also identify lines of urban vulnerability, for example, the lack of resilience and doubtful reliability of water defence, collection and transmission systems in the face of extreme climatic events.

To wonder nowadays, to discuss, which is the construction with nature and which is the constructed nature becomes not only an academic exercise but a political act of recognition of the elements that exist in the Landscape and with which to operate compositionally in the architectural and urban process. World Cities Report 2020 by United Nations Human Settlements Programme (UN-Habitat), indeed reports that when nature-based solutions are incorporated into design and management, urban areas can benefit from multiple ecosystem services, including carbon sequestration, local climate regulation, stormwater capture and water and air purification. Landscape architecture, urban design, spatial planning and architecture, must be concerned with consciously shaping the environment (Oudes et al, 2020).

Conclusion

In conclusion, we consider it essential to highlight how the theme of water, in its different conjugations, allows the exercise of recognising the physical characteristics of the territory. Therefore, we can state that climate change, specifically the effects of extreme weather phenomena and rising mean sea level, becomes a pretext, a *conditio sine qua non*, to rethink the elements on the territory, not as belonging to different systems, but as subjects of transformation. We believe that recognising the role of water not only as an integral and constituent part of the landscape, but as a subject enables the drafting of adaptation plans and projects coherent with the the form of the place.

We feel it is important to summarise the main theoretical outcomes derived from the formal comparison of the two projects and the debate on the design choices undertaken, knowing that they are the first step in the development of new research on urban design transformation and adaptation paradigms:

1. Designing under uncertainty, resulting nowadays for the effects of climate change on the urban fabric, to decrease urban vulnerability requires a deep and precise knowledge of the urban landscape, from the macroscale of the territorial planning to the microscale of urban drawing;
2. Comparing different project, design and planning, visions and scales of spatial approach enables the understanding of contemporary criticalities that can be observed in the spaces, object of study, at the margins between the city and the sea;

3. Understanding that in the space between the city and the sea, the implementation of blue-green infrastructural solutions, achieved through working with nature, provides a greater palette of solutions for urban adaptation.

In conclusion, we consider that only by understanding the physical characteristics of two different approaches to public space by the coastline, - one based on the design of rigid layouts with fixed linear infrastructure systems and the other (on non-linear forms and layouts related to the use of living and evolving ecological systems such as green and blue infrastructure - can efficient designs be outlined.

The theoretical reflection carried out so far about the case of Quarteira, composed of two fixed linear infrastructure systems - the seashore streets - and a dune park, the *Passeio das Dunas* (which, as mentioned, was planned to be constituted through ecological system), demonstrates the need for a paradigm shift in the design approach to the transformation and adaptation of coastal cities. Although the *Passeio das Dunas* was not constructed as designed, we consider that it remains an initial starting point for a long theoretical discussion and one of the possible paths on the future formal definition of the vulnerable public space, between the city and the sea, of the effects of climate change.

Abstract

Public spaces embody the intricate interplay of power dynamics influenced by governmental, societal, and economic factors, shaping spaces to reflect idealized lifestyles guided by urban management, societal norms, and capitalist economies. However, the emergence of playful actions disrupts these norms, offering fresh perspectives on power structures and public spaces. Activities characterized by playfulness, illuminated by play theory, advocate for innovative approaches to public space design, exploring play's transformative role in nurturing social connections and enriching urban life while reshaping social interactions and landscapes.

Focused on Şeyh Said Square and nearby parks adjacent to the Diyarbakır walls in Turkey, this study employs field research, observations, and surveys. Renowned for its vibrant culture and diverse societal representations, this locale fosters unique connections among users, authorities, and urban designers. Playful actions serve as a catalyst for challenging established power dynamics and fostering greater participation in the design and use of public spaces. Acknowledging play as fundamental in urban design, the research explores alternative narratives, emphasizing social engagement and public space utilization. Through a comprehensive and participatory methodology, it highlights play's significance in promoting participation and shaping urban design.

Keywords: play theory, power dynamics, social interaction, participation, urban design.

Introduction

Public spaces in urban environments are vital for social interaction and community engagement. These areas have evolved into dynamic arenas where power dynamics, conversations, and collective activities converge, deeply influencing the fabric of society (Lefebvre, 1991; Sennett, 2018). As essential components of an open society, public spaces serve as venues for socialization, counterbalancing divisive societal forces. Although they may not directly resolve social and economic challenges, these spaces are fundamental to the effective functioning of democratic societies (Madanipour, 2010).

Play theory offers a unique lens through which to view public spaces, revealing the underlying power dynamics and social interactions that shape them. Embracing play enables individuals to overcome power barriers, establish new social connections, and redefine the essence of public spaces (Stevens, 2007). Beyond mere entertainment, play serves as a mechanism for reclaiming, designing, and transforming existing spaces and urban landscapes (Shaftoe, 2008).

This study aims to apply play theory to specific public spaces, including Şeyh Said Square and the parks surrounding the Diyarbakır Walls in the Sur district of Diyarbakır province. This region, recognized for its rich historical and cultural significance, has long been a site of power struggles and political activity due to its strategic location and historical importance.

The Sur district encompasses remnants from nearly 30 civilizations, including churches, mosques, and bazaars, creating a rich cultural mosaic with a profound historical narrative (Diyarbakır Cultural Inventory, 2011). With its architectural marvels and narrow alleyways, Diyarbakır's historic Sur district reflects the complex interactions among diverse civilizations over time (Aslan, 2013). During bustling commerce and vibrant markets, these areas continue to serve as centres for communal life and social interaction, preserving their traditional charm and cultural heritage (İnce, 2011).

Despite its rich history and diversity, Sur faces challenges from homogenizing urbanization and rent-driven economies. Migration, urban transformation, and urban destruction have gradually eroded the unique character and identity of Sur’s public spaces. However, these challenges also present opportunities for revitalization and renewal through playful urban interventions.

Playful activities, emerging in response to entrenched power structures, offer a dynamic and inclusive approach to urban life. Play serves as a form of participation, allowing residents to engage with and shape their surroundings. This study aims to explore play activities within public spaces and investigate residents' expectations for these communal areas. By understanding user preferences, the research seeks to enhance community engagement and empowerment in urban design through play. Additionally, the study examines the complex power dynamics inherent in urban design, aiming to dismantle traditional hierarchies and promote a more collaborative approach to urban development.

2. Theoretical Framework: Play, Power Relations, and Public Space

Understanding the intricate relationship between power dynamics and the use of public spaces is crucial for navigating the complexities of urban life. These spaces are influenced by a range of factors, including political, military, economic, and social forces, all of which are

interconnected within broader national and international contexts (Mitchell, 2003). Because of power dynamics, public spaces have evolved to become increasingly impersonal and transient, often serving functional or symbolic roles. These ongoing transformations underscore the dynamic nature of public spaces, which are continually shaped by diverse societal, national, and international factors impacting their liveability, sustainability, and user-oriented design in urban environments (Madanipour, 2010).

This section explores the nuanced power dynamics within public spaces, examining how historical contexts, regulatory frameworks, and theoretical perspectives influence the urban social fabric. It also considers the role of play theory, highlighting its impact on public spaces and its potential to influence power relations by promoting inclusive social interactions and challenging traditional hierarchies. By applying this perspective, the study aims to foster a more equitable and engaged urban community.

2.1. Understanding Power Relations in Public Space Use

Public spaces within urban areas are crucial in defining a city's character and identity. These spaces—including parks, plazas, sidewalks, and other communal areas—are managed by authorities to ensure they fulfil their intended functions effectively. Initially, rules governing public spaces were established for practical reasons such as maintaining order, safety, and cleanliness (Carmona, 2010). Over time, these rules have evolved into complex systems of regulations resembling localized legal frameworks. Each public space has its own set of rules tailored to its specific context, reflecting the unique dynamics and priorities of the surrounding community. These regulations shape social behaviour and interactions within public spaces, creating a sense of order and predictability. However, what began as temporary or exceptional rules often become normalized and entrenched in everyday life. Public spaces thus transcend their physical attributes to become symbolic arenas where societal norms and values are expressed and enforced. Understanding the evolution and implications of these regulations is crucial for policymakers, urban planners, and residents as they strive to create inclusive and vibrant public spaces that meet diverse community needs (Stavrides, 2019). Examining these power dynamics is essential for exploring how interventions can reshape public spaces.

In the early 20th century, urban designers and architects did not directly challenge the existing system but sought to impose order on the chaos of modern life and urbanization (Gilloch, 2001). Their focus was on standardizing everyday life and practicality, with less emphasis on entertainment in city planning. Le Corbusier, a prominent figure of this approach, argued that many existing cities could not meet the demands of modern life due to rapid urban development and industrialization. He viewed urbanization as a natural progression and emphasized the need for ideal planning to foster progress. Le Corbusier envisioned cities characterized by organized transportation, clean environments, and strong ethical values, placing importance on working conditions and the layout of business areas. In contrast, Jane Jacobs criticized Le Corbusier's projects, arguing that they prioritized cars over people and promoted functional separation of urban areas, limiting social interaction. Jacobs advocated for diverse, interactive urban spaces such as vibrant streets and sidewalks, which she believed were essential for fostering human connections and enhancing city liveability (Jacobs, 2009). Examining these historical perspectives reveals the evolving relationship between urban design, societal norms, and power dynamics.

Michel Foucault's concept of disciplinary society provides a profound exploration of power dynamics, extending beyond mere coercion to emphasize the systematic organization and

control of individuals. In a disciplinary society, power operates through various mechanisms of discipline—such as surveillance, normalization, and examination—that are embedded within social institutions and practices. These mechanisms regulate behaviour and shape spatial organization. For Foucault, discipline is not just a coercive force but an art of distribution that actively influences individuals' actions within a societal framework (Foucault, 1995). The spatial aspect of this disciplinary order is crucial, as power intervenes to regulate the physical distribution of individuals, turning discipline into a tangible influence on spatial organization (Foucault, 1995). In public spaces, disciplinary power is evident in design and surveillance measures that control behaviour, impacting social interactions and shaping usage patterns (Zukin, 1995). Analysing power dynamics in public spaces provides insight into how disciplinary mechanisms manifest and influence social interactions within urban environments.

In public spaces, power dynamics work to establish order, standardization, and an ideal societal vision. Drawing on Foucault's concept of biopower, which encompasses control over life itself (Foucault, 1978; Foucault, 2003), public spaces become arenas where structures, relations, and practices shape political subjects. These spaces are not merely passive backdrops but are imbued with power mechanisms that regulate and organize human behaviour. Biopower reveals how political subjects are constituted and deployed through regulation and surveillance of various life aspects, including time and bodies (Cisney & Morar, 2016). This lens highlights how the management of public spaces involves asserting authority over populations, shaping behaviours, interactions, and collective dynamics (Agamben, 1998). The regulation and surveillance in public spaces extend beyond individual bodies to broader population dynamics, reflecting a biopolitical approach to community life (Negri, 2016). Thus, the design and management of public spaces are intertwined with power dynamics aimed at creating standardized, organized environments conducive to an ideal societal vision (Boano & Talocci, 2014). Exploring these dynamics opens opportunities to apply play theory, paving the way for innovative approaches to challenge and reshape entrenched power structures.

2.2. Utilizing Play Theory to Reshape Power Dynamics in Public Space

Play theory can be applied to public spaces to empower communities and transform power dynamics. It involves the actions of individuals, their use of space, and their engagement, either individually or collectively. Play theory holds the potential to rejuvenate existing power structures and foster new social connections. In everyday life, people often unconsciously replicate societal norms and behaviours through playful interactions, creating their own set of rules, rhythms, and social orders within the context of play (Lefebvre, 1991). To fully comprehend play theory in public space design, it is necessary to explore the concept of play itself and its impact on power relations within public spaces.

Play is frequently perceived as a creative and productive activity that fosters innovative potential. However, it is not confined to just children; rather, it is a voluntary engagement that individuals undertake throughout their lives in various spaces and times. The foundational work on play comes from the Dutch historian Johan Huizinga, who introduced his work "Homo Ludens" in 1938. Huizinga explores the historical significance of play, asserting that it played a crucial role in the emergence of culture. He conceptualizes human beings as "Homo Ludens" or playing humans, suggesting that actions performed in social life serve to produce the essential needs and requirements of life. Huizinga characterizes early human societies' life-sustaining activities, such as building shelters, hunting, and gathering, as acts of play. As human beings started creating their reality, they initially shaped everything in rhythm, arrangement,

and repetition. In essence, reality emerges as a product of playful social interactions (Huizinga, 1995).

Agamben provides a profound insight into the concept of play, defining it as the act of liberating things, actions, or events from the confines of the sacred realm, thereby enabling individuals to interact with them without the constraints imposed by sacred conventions. The contemporary manifestations of the sacred are diverse and complex, encompassing phenomena such as militarized security institutions, military urbanism, and the capitalist process of dispossession. Agamben's concept of profanation involves returning sacred objects or spaces to the free use of humanity, thereby subverting the control imposed by governmental mechanisms and neoliberal ideologies. Play, through its transformative power, empowers citizens to reshape urban environments, while profanation disrupts dominant narratives by reclaiming sacred spaces for common use (Boano & Talocci, 2014). By encompassing all human activities that transcend the limitations imposed by the sacred, play serves as a potent tool for challenging established norms and practices dictated by sacred tradition. Particularly evident in children's play is the transformative nature of ordinary objects, as items like cars, toy guns, or even electric stoves assume new roles and meanings through imaginative exploration. Through play, children freely navigate social conventions and expectations, unleashing their creativity and expressing their unique perspectives (Agamben, 2007).

Play activities in public spaces emerge as a means to challenge the stability and rationality of modern life. Shaped by the intricate social and cultural norms of the city, these activities do not always occur spontaneously but possess creative potential, offering new perspectives on the world. French sociologist Pierre Bourdieu conceptualizes play activities as a form of habitus, constituting a set of beliefs, values, and practices evolving through daily experiences. Play becomes a tool for personal and social transformation, enabling individuals to surpass their customary ways of thinking and behaving (Bourdieu 2000).

According to Sennett (1974), the playful theatricality of roles and masks in urban encounters goes beyond traditional responsibilities, reshaping the rules of social participation. Play in public spaces prompts individuals to discover new needs and develop fresh forms of social life and space, offering a lived critique of instrumental rationality and challenging conventional definitions of function. Playful behaviour, marked by sudden, unplanned, and unpredictable social encounters, takes on a spontaneous and creative dimension. Each urban period introduces new roles and potentials, inducing corresponding changes in laws, etiquette, and the overall transformation of the city (Stevens, 2007).

Public spaces, whether among friends or strangers, serve as environments where individuals engage in various modes, acting as both spectators and performers. Participation in these areas fosters a shared understanding that others, like oneself, possess a rich repertoire of social behaviours, reinforcing the joyful and pleasurable aspects of social interaction (Lennard & Lennard, 1984). This learning extends beyond public space, influencing structured relationships and other environments. The organization of people's activities in and around public spaces contributes to its theatrical quality by providing a wide range of potential actors and framing their interactions (Stevens, 2007). In these dynamic environments, individuals, whether friends or strangers, collectively realize that they share a broad spectrum of social behaviours through play, leading to the creation of new spaces (Lennard & Lennard, 1984). These evolving interactions weave into Sur's Story, illustrating how historical events and urban realities shape and are shaped by the dynamic nature of public spaces.

3. Contextual Background: Sur's Story: A Tapestry of Historical Events and Urban Realities

Understanding the historical narrative and demographic shifts of Sur is essential for contextualizing the complex interplay of power dynamics and urban development in the region. Before delving into the study area, it is crucial to explore the events that have shaped Sur's rich historical legacy and ongoing socio-political changes, as public spaces derive significance from these structural, demographic, and political contexts.

Sur, originally a diverse settlement embracing various ethnic and religious groups, has undergone profound transformations over time. Historical events such as the mass deportation of non-Muslim populations in 1915 and the suppression of Kurdish uprisings in 1925 have significantly influenced the city's collective identity (Gambetti, 2009). However, the most impactful event reshaping Sur's demography was the conflict between Turkish state forces and the PKK (Kurdistan Workers' Party) in the 1990s. This conflict led to the forced migration of numerous residents from rural areas to Sur, further altering the city's demographic landscape and contributing to its evolving identity (Ayata & Yükseker, 2005; Çelik, 2005).

The intense clashes between state forces and Kurdish fighters from 2015 to 2016 represent another critical chapter in Sur's history. The Kurdish issue and demands for rights, longstanding since Turkey's establishment, gained prominence in 2013 with peace negotiations, only to end abruptly in 2015. Subsequently, conflicts erupted as Kurdish militants declared self-governance and autonomy, resulting in widespread violence and destruction, particularly in Sur. The aftermath of these conflicts witnessed urban transformation projects, leading to the demolition of buildings within the Sur region and significant changes to the cityscape (Kibar, 2017).

The urban transformation has sparked debates about preserving Sur's historical and cultural heritage, particularly as new developments often clash with the city's historical fabric. Criticisms have been raised regarding the construction of concrete structures and widened roads, which deviate from the old ambiance and contribute to the displacement of residents, turning parts of Sur into ghost towns (Eşin, 2018).

These intricate social and urban transformations underscore the complex interplay of political, economic, and ideological factors shaping Sur's urban landscape. As Sur continues to evolve, research into its past and present becomes indispensable for understanding urban spaces and broader societal dynamics. When examining these events within the city walls, it becomes imperative to reconsider the roles of decision-makers and power dynamics within the city and how these dynamics will be influenced by the unfolding events.

4. Study Areas: Şeyh Said Square and parks around Diyarbakır Walls

This study focuses on Şeyh Said Square and the surrounding parks near the Diyarbakır Walls, areas of profound historical and cultural significance. These locations offer valuable insights into the dynamics of power and playful interactions within public spaces.

Diyarbakır's city centre, with origins dating back to approximately the 6th millennium BC, flourished under the protection of the Diyarbakır Walls. The walls, constructed during the Roman era, include both inner and outer fortifications, symbolizing Diyarbakır's enduring heritage. Designated as a UNESCO World Cultural Heritage site in 2015, the walls extend over 5.5 kilometres. They feature bastions that rise 10 to 12 meters high and possess a thickness of

3 to 4 meters, significantly contributing to Diyarbakır's distinctive urban landscape (Diyarbakır Cultural Inventory, 2011). The parks that surround these walls further enhance the study area, offering additional context regarding the region's historical and social fabric.

Şeyh Said Square, formerly known as Dağkapı Square, was renamed in 2014 in honour of Şeyh Said, a notable Kurdish figure who was executed by the Turkish government in 1925. In 2019, the Turkish government appointed trustees to the Kurdish-majority area and declared a state of emergency (Kibar,2017). Despite the ongoing uncertainty regarding the square's official name, the local community continues to refer to it as Şeyh Said Square, underscoring its enduring significance and the lasting legacy of Şeyh Said.

The square has undergone significant transformations over time. The most notable changes began in the 1930s, when the demolition of the Sur walls was carried out to improve airflow and reduce heat. This demolition led to the reconfiguration of the square and the surrounding roads (Gambetti, 2009). These modifications were part of a broader effort during the early Republican era to establish a uniform and modern society, as reflected in the development of contemporary urban spaces (Bozdoğan, 2002). At that time, the area surrounding Dağkapı Square was developed with a focus on military infrastructure, shaping its initial landscape (Gambetti, 2009). Today, Şeyh Said Square functions as a bustling transit hub, as shown in the function map (Figure 1). It is surrounded by large, dynamic traffic roads, medical facilities, hotels, restaurants, retail shops, and remnants of its military history.

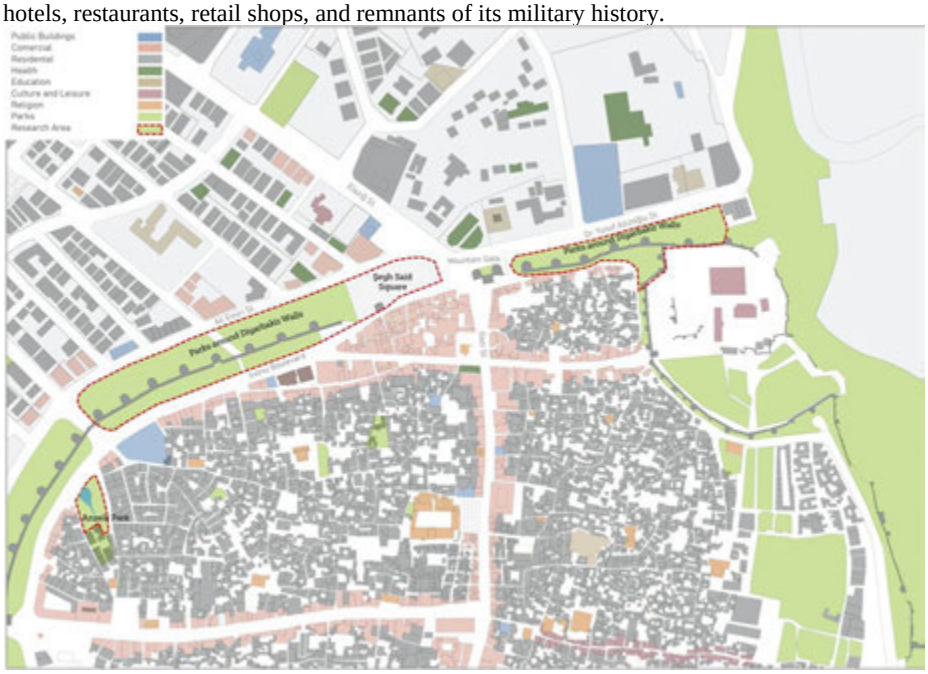

Figure 1. Map of research areas: Şeyh Said Square and Parks around Diyarbakır Walls

5. Methodology

This research employs two primary methodologies: observational study and structured questionnaire survey. Together, these approaches aim to provide a comprehensive

understanding of public space utilization, socio-cultural influences, and individual perceptions within Diyarbakır.

Observational research was conducted to investigate the use of public spaces in Şeyh Said Square and the neighbouring parks beside the historic Diyarbakır Walls. Observations were carried out primarily in the afternoon, between 16:00 and 17:00, during March and April to capture peak activity periods under favourable weather conditions. Following principles from urban ethnography (Whyte, 1980), the observations focused on documenting interactions between individuals and their physical environment, particularly playful activities, and social behaviours. This included monitoring movement patterns, social interactions, and prevalent activities within the selected public spaces. Data were recorded through detailed notetaking and photography to capture insights into space utilization and the nature of activities.

A structured questionnaire survey was utilized to gather quantitative data from 227 residents of Diyarbakır. The questionnaire was carefully designed to capture participants' descriptions and perceptions of public spaces, as well as their engagement with playful elements. According to Taherdoost (2022), questionnaires are essential for collecting standardized and comparable data, ensuring a rigorous approach to data collection. The questionnaire followed a structured format, with sequential questions designed to guide participants through the survey systematically. This approach aligns with the methodological principles outlined by Burgess (2001), from defining the research objectives to analysing the collected data. By adhering to these methodological standards, the study aims to offer a thorough analysis of the perceptions and activities of individuals within Diyarbakır's public spaces.

6. Case Study: Şeyh Said Square and Parks around Diyarbakır Walls

Şeyh Said Square predominantly hosts similar types of activities, reflecting its role as a communal space. In the afternoon, people often gather to socialize, sitting on small stools while enjoying cups of tea (Figure 2). It is a popular spot for chatting with friends, watching people go by, and soaking in the atmosphere. The square features two open-air tea houses on opposite corners, which are mostly frequented by older men. Nearby, children aged 7 to 15 play football, turning parts of the square into a playful area (Figure 3). They are quite agile and can organize games in any available space better than adults.

Figure 2. Tea drinkers on small stools

Figure 3. Children playing football.

The square is primarily used by pedestrians, with people moving at varying rhythms and speeds. As observed in Figure 4, the fountain pools are typically empty, and some benches are occupied

by individuals waiting for friends. In the centre of the square, a clock tower stands above a closed market. Most of the market stalls are vacant, except for one music studio. The lower market area is transient, particularly for young people visiting the studio. Beyond the clock tower, the square is mostly empty, with some scattered seating. Figure 5 illustrates the evening ambiance as clothing stalls begin to appear around the square, sometimes even within it, displayed on hanger racks. While informal sellers can occasionally change, this gives a basic identity of the square during the afternoon and evening times.

Figure 4. People sitting on benches and walking

Figure 5. laid out on hanger racks.

In the parks around the city walls, you'll find mobile liver kebab carts positioned near the entrance gates (Figure 6). Although some people complain about the smoke and smell from these carts, many still choose to sit on stools and enjoy the liver kebabs. Picnicking used to be more common, but it has decreased due to past conflicts and changes in the area. Outside of tourist activities like taking photos of the walls, the connection between people and the city walls tends to be more passive.

Anzele Park, as shown in Figure 7, offers a playful approach within a historical context. Located near the Diyarbakır Walls, but separated by a busy road with heavy traffic, the park features a vibrant and playful environment. The pool area next to the old historical fountain serves as a space for children to learn swimming. Currently frequented by residents who have remained despite urban transformation, the park functions as a vibrant public space where activities such as swimming, watching children, chatting, and enjoying tea take place.

Figure 6. Mobile liver kebab carts

Figure 7. Children are swimming.

Şeyh Said Square primarily functions as a waiting and transition space, with occasional events like festivals managed exclusively by governmental organizations. Similarly, parks in non-tourist areas often serve as brief waiting spots but lack significant user engagement despite their inherent potential. Anzele Park stands out with its numerous playful dynamics, whereas other parks around Diyarbakır generally exhibit less vibrancy.

The connection between the city walls and their users remains largely passive. Even though these walls provide shaded areas crucial for the hot climate, people use the parks infrequently. Activities such as eating liver kebabs or drinking tea around the Sur area contribute to the unique character of these spaces. However, due to urban transformation projects and migration, parks experience minimal user participation. Promoting more playful activities could potentially alter this dynamic, enhancing user empowerment and fostering greater involvement in the design process. To further understand these dynamics and the underlying reasons for limited engagement, the subsequent analysis of the questionnaire data provides valuable insights into user perceptions and preferences regarding public spaces in Diyarbakır.

7. Analysing Public Space Perceptions and Urban Design Participation: Insights from Şeyh Said Square and Diyarbakır Walls

To understand users' perceptions of play activities and public space, as well as their participation, the results of the questionnaire were analysed. Responses were gathered from a diverse pool of 217 participants, providing perspectives and preferences regarding public spaces, particularly Şeyh Said Square and parks in the Sur surroundings. Among the respondents, 54% identified as male, 45% as female, and 0.50% as other. Regarding age demographics, the participants were distributed as follows: 2.80% were under 18, 20.20% were aged 18-24, 30% were aged 25-34, 27.20% were aged 35-44, 15% were aged 45-54, and 5.20% were 55 and above. In terms of educational attainment, most respondents held a bachelor’s degree (70.00%), followed by those with a master’s degree (18%), individuals with a high school diploma or lower (9.00%), and a small proportion with a doctoral degree (2.80%). These responses were not only from the residents of the Sur District but also included participants from other neighbourhoods, reflecting the area's appeal beyond its immediate vicinity. The aim was to gain insights into participants' perceptions of public spaces, understand how these spaces are utilized, and explore views on play activities within these environments.

The representation of public spaces plays a crucial role in defining their function and impact on the community, as it shapes how individuals perceive and interact with these environments

(Lefebvre, 1991). Participants offered varied definitions of public space, with a majority emphasizing its pivotal role as accessible areas for diverse segments of society to converge and interact. As illustrated in Figure 8, public spaces are regarded as common areas for social interaction and fostering a sense of community, with an emphasis on the importance of civil participation. Conversely, a smaller segment of participants considers public spaces as dynamic environments meant to break away from daily routines and encourage spontaneous, unpredictable interactions. This limited acceptance suggests that people may be less open to encountering new and diverse experiences within these spaces, reflecting a reluctance to embrace risk and novelty. This hesitation aligns with Stevens' observations on the difficulties of integrating playful and unpredictable elements into public spaces (Stevens, 2007).

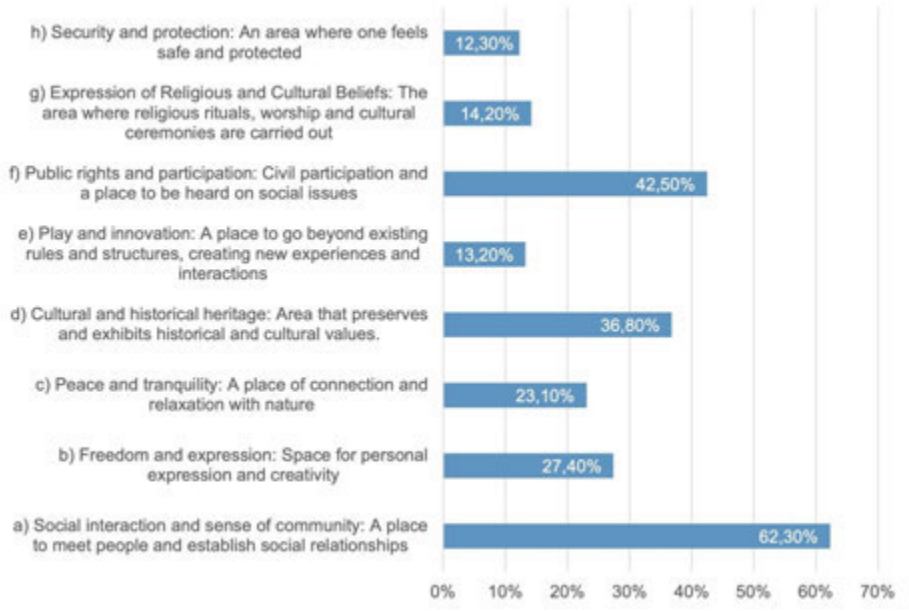

Figure 8." Which of the following do public spaces represent to you?" (np:227)

The survey results reveal a broad spectrum of activities that people associate with play in public spaces, highlighting varying preferences and perceptions. Figure 9 illustrates that socializing and meeting with friends is the most favoured activity, reflecting the importance of public spaces as venues for social interaction and community engagement (Shaftoe, 2008; Whyte, 1980). This underscores the role of play these spaces in facilitating informal social gatherings and connections. Children's games, while significant, are viewed as a more traditional aspect of play, illustrating a common perception that play is primarily for younger individuals (Huizinga, 1955). This perspective is supported by the popularity of sports and games, which are seen as organized and regulated forms of play in modern contexts. Additionally, creative, or artistic activities and social and political activities also receive notable support, indicating that respondents view play in public spaces as encompassing opportunities for creative expression and civic engagement. This reflects a broader and more inclusive understanding of play, highlighting the evolving nature of these activities beyond traditional recreational pursuits (Huizinga, 1955).

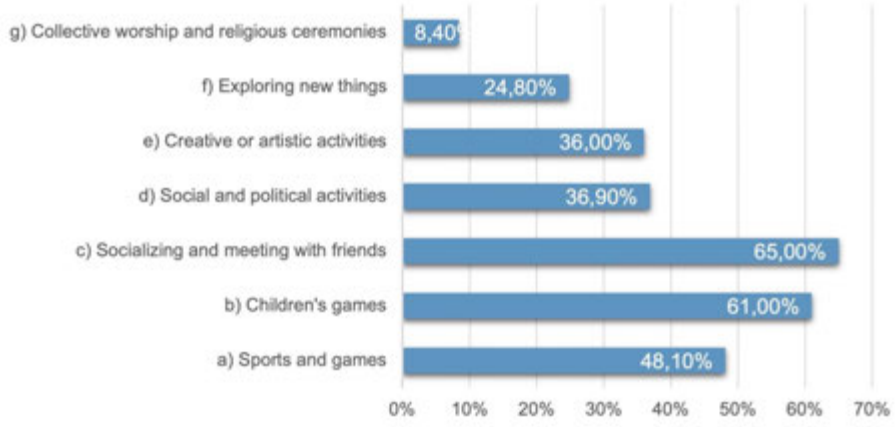

Figure 9." What types of activities do you consider as play in public spaces?" (np:227)

The range of activities that people currently engage in or plan to pursue at Şeyh Said Square underscores its multifaceted role within the community. According to Figure 10, sitting, resting, and chatting are the most common activities, highlighting the square's function as a space for relaxation and informal social interaction. This underscores the need for comfortable and inviting areas that foster leisure and social connections. Additionally, there is significant interest in participating in events that enhance the square's aesthetic appeal, such as art installations and festivals, indicating a desire for a visually and culturally enriched environment. Activities related to social, political, or environmental causes, such as protests and rallies, also play a notable role, underscoring the square's importance as a venue for civic engagement and community activism. Cultural activities, including street performances and outdoor theatres, as well as support for local businesses through markets and fairs, are also valued, reflecting a preference for diverse public programming. In contrast, outdoor sports, yoga sessions, and fitness classes are less emphasized, suggesting these activities are not central to the square's current usage.

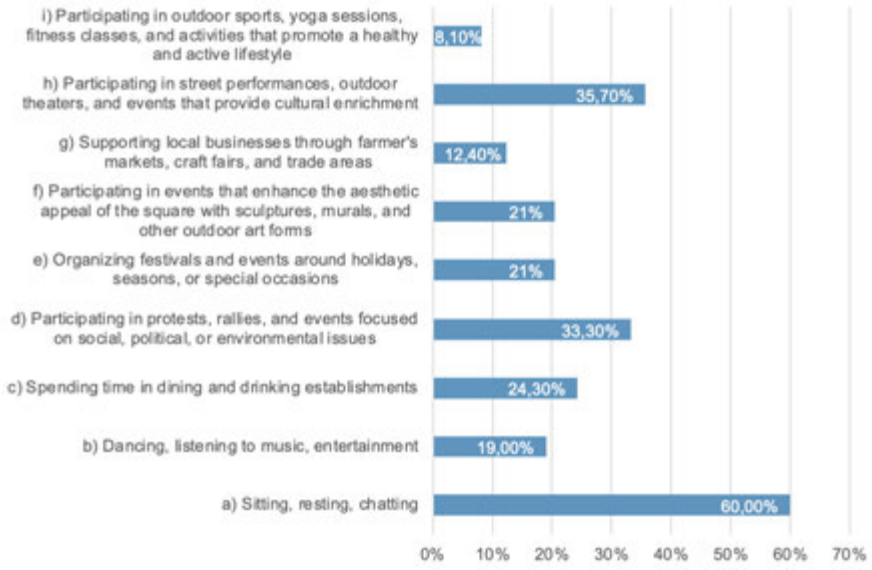

Figure 10. "What activities currently or intend to engage in at Şeyh Said Square?" (np:227)

The survey explores the participation of various stakeholders in the design process and their respective roles. Most respondents believe that users should be directly involved in the design of public spaces, reflecting a strong desire for public engagement and input in shaping their environments (Shaftoe, 2008). This perspective suggests that incorporating user feedback can lead to more responsive and inclusive designs that better meet the community's needs and preferences. Figure 11 highlights the decision-making responsibilities, with architects, urban planners, and environmental experts seen as the most crucial contributors to public space planning. This underscores the value of professional expertise in creating well-designed and functional spaces (Lefaivre & Döll, 2007). Local governments also play a significant role, emphasizing the importance of municipal involvement in managing and maintaining public spaces. Moreover, there is substantial support for involving users, non-governmental organizations, and local communities, indicating a recognition of the importance of diverse perspectives and grassroots input in the decision-making process (Boano & Talocci, 2014).

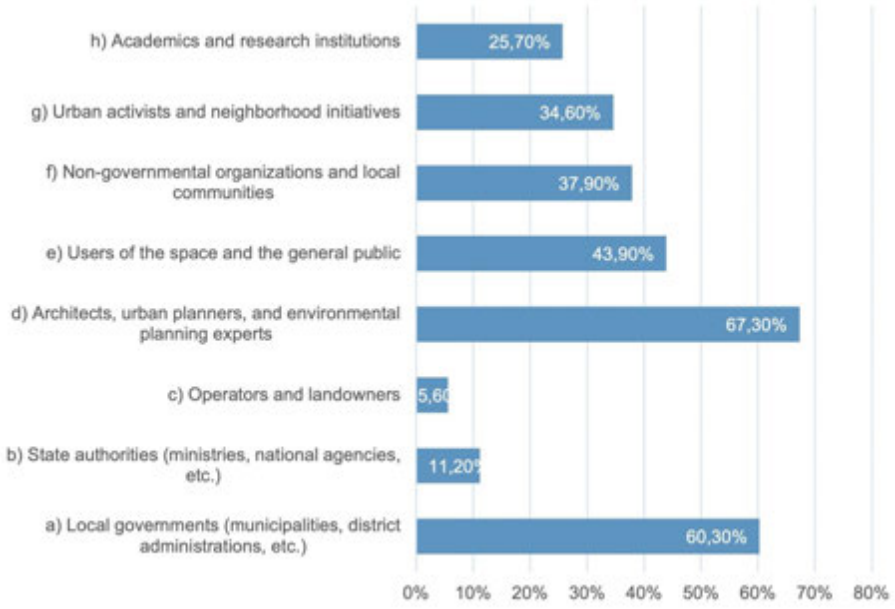

Figure 11. " Preferred Decision-Makers in Public Space Planning and Management?" (np:227)

The findings underscore the multifaceted nature of public spaces and emphasize the importance of incorporating diverse perspectives and user engagement in their design. These insights will serve as a foundational basis for future initiatives aimed at enhancing public spaces in Şeyh Said Square, parks in the Sur surroundings, and beyond, ultimately fostering social cohesion, cultural vibrancy, and community well-being. This emphasis on participation and play highlights the importance of giving users the power to shape their environments and make decisions that reflect their needs and preferences. It is imperative to recognize that participation and play are not only integral components of vibrant public spaces but also mechanisms for empowering individuals and communities to actively engage in the process of urban design and decision-making.

8. Discussion: Playful Participation in Urban Design to Play with Power Relations: Towards Inclusive Public Spaces

Observing the events shaping the history of the Sur district reveals that life within Şeyh Said Square and its surrounding parks is significantly influenced by power dynamics, particularly urban transformations driven by state interventions and economic factors. Social life, characterized by group activities and male-dominated gender dynamics, also plays a major role in these power dynamics. Despite these challenges, a closer examination of how people navigate their everyday lives reveals new ways of utilizing the space. In these instances, playful engagements have the potential to shift power dynamics, granting individuals greater autonomy within the spatial realm. Playful interventions can disrupt dominant narratives, subvert spatial hierarchies, and create opportunities for collective empowerment and expression (Boano & Talocci, 2014). In urban public settings, play often arises in response to the uncertainties and

tensions inherent in everyday life. Play within public spaces promotes interactive engagement and heightened awareness of others participating in the same activity (Stevens, 2007). This participation and its benefits produce new powers and spaces. Play serves as a communication network, actively engaging people within these dynamics (Sennett, 2018).

Understanding the diverse needs, preferences, and behaviours within the community is essential (Madanipour, 1996). Play theory suggests that the introduction of playful elements into public spaces can facilitate new forms of usage by encouraging risk-taking and spontaneous behaviours (Stevens, 2007). In Şeyh Said Square and the surrounding parks, functions such as eating and drinking areas are identified with the area and contribute to the spatial distinctiveness of these locations. The music workshop situated in the unused covered bazaar beneath the public space could potentially spill over into the square, adding to its vibrancy with playful activities. Additionally, the questionnaire responses indicate a broad and diverse perception of play among the participants, highlighting the multifaceted nature of playful interactions within these spaces. Specifically, play facilitates social interaction and integration with nature, bringing new possibilities for rhythms of behaviour and new communication systems (Lefebvre, 2004).

The interplay between the city walls and local activities can make play activities unique to a specific place. In play theory, adopting a historical perspective is crucial for evaluating a location based on its history. The embedded stories and memories within the urban fabric enrich our understanding of the place's identity (Boano & Talocci, 2014). The city walls of Diyarbakır, often seen merely as a backdrop, reveal deeper historical significance upon closer examination. Locals refer to the city walls as the 'body,' a term that holds substantial meaning and plays a distinct role in everyday life. Historically, street fighters would challenge each other in the areas near the walls, which were referred to as the "body," and social gatherings would often take place in these spaces (Diken, 2002). This term embodies a form of spatial ownership and identity, where play functions as a mediator in this ownership process (Boano & Talocci, 2014).

The character of playful activities is significantly influenced by the surrounding urban structures and the overall urbanization of the area. One major factor that restricts the playfulness of this space is the high density of vehicular traffic and the designated use of these areas for vehicles only (Shaftoe, 2008). Roads around Şeyh Said Square and nearby parks are heavily trafficked, and the rise of automobile-dependent transportation has further diminished opportunities for outdoor interaction. Consequently, public spaces have been reduced to main roads and isolated gardens. Modern design principles for public spaces should focus on human-centred planning. This approach should foster environments that promote social interaction, spontaneous play, and community engagement, while also integrating elements of nature to enhance liveliness and strengthen the connection between people and their surroundings (Gehl, 2011; Gómez-Baggethun et al., 2013; Beatley, 2011).

Participatory design workshops, interactive installations, and collaborative activities that invite residents to contribute their ideas and wishes are essential for creating playful public spaces (Boano & Talocci, 2014). Actively involving the community in the design and planning of these areas ensures that they reflect the desires and aspirations of their users. This participatory approach leads to urban environments that are more inclusive, user-friendly, and vibrant—a concept that aligns with play theory, which emphasizes the interactive and participatory dimensions of play within societal norms (Bateson, 1987). Findings from the questionnaire reveal a strong desire among people for greater involvement in the public space design process, indicating a wish to have more control over their surroundings. Residents of Sur, in particular,

have expressed a desire to engage in discussions about the city with designers, supported by contributions from local administration. This call for empowerment reflects a broader aspiration for community-driven urban development, where residents actively shape the environments, they inhabit.

The insights presented in Table 1 highlight the importance of integrating playful interventions, active participation, and historical exploration into urban design. Such approaches contribute to the creation of inclusive, vibrant, and nature-oriented public spaces.

Table 1: Insights into Urban Design Approaches through Play Theory

Urban Design Approach	Key Insights	References
Empowerment to Users	Playful interventions can disrupt dominant narratives and challenge the sacredness of, thus dismantling power dynamics embedded within urban spaces.	(Stevens, 2007), (Shaftoe, 2008), (Whyte, 1980)
Creating New Actions	Playful design encourages the creation of new actions and interactions within public spaces, fostering a sense of ownership and empowerment among individuals in reshaping their environments.	(Stevens, 2007), (Shaftoe, 2008), (Whyte, 1980)
Active Participation	Actively involving the community in playful design processes empowers individuals by giving them a voice in shaping their surroundings, leading to more inclusive and user-centric urban spaces.	(Boano & Talocci, 2014), (Shaftoe, 2008), (Carmona, 2010)
Historical and Cultural Exploration	Exploring the history and culture of public spaces through a playful lens enriches the understanding of place identity and encourages meaningful interactions between users and their urban environment.	(Huizinga, 1995), (Boano & Talocci, 2014), (Jacobs, 1961)
Connectivity and Accessibility	The proliferation of playful spaces is facilitated by the interconnectedness of public spaces	(Shaftoe, 2008), (Whyte, 1980)
Varied and Stimulating Environments	Public spaces gain meaning through the functions and life surrounding them.	Lefaivre & Döll (2007); Whyte,(1980)
Lively and Nature-oriented	Incorporating nature elements and promoting vibrant activities enhances the vitality and connection to the environment in public spaces.	(Gómez-Baggethun et al., 2013), (Beatley, 2011), (Francis, 1987)

9. Conclusion

Active participation in the design and planning of public spaces is pivotal in shaping environments that foster inclusive and empowering experiences. By involving the community in these processes, public spaces can be transformed into dynamic arenas where individuals not only participate but also shape their surroundings according to their needs and aspirations. This approach challenges existing power dynamics inherent in urban transformations and state interventions, offering an opportunity to democratize spatial experiences. Through playful interventions, individuals gain agency within the spatial realm, disrupting dominant narratives

and subverting spatial hierarchies (Boano & Talocci, 2014). Promoting interactive engagement and heightened awareness of others, play creates opportunities for collective empowerment and expression, ultimately sharing power equally and fairly among users (Sennett, 1977). Prioritizing human-centric design principles and facilitating active community involvement in creating public spaces are essential steps toward building vibrant, inclusive, and socially connected urban environments where the transformative potential of play can be fully realized (Shaftoe, 2008).

In examining Şeyh Said Square and the neighboring parks in Sur, an ongoing urban change is evident, affecting residents, often without their realization. However, through observing playful activities and engaging with people about their desires, these places can become lively through active involvement. Even when power dynamics are influenced by the conservative values of the state, economy, or society, play always introduces a new way of exerting influence. According to Agamben, play empowers citizens by involving them in the design process and allowing them to reshape their environment based on their aspirations and everyday needs. The act of play is explored as a means of opening up the fence and unlocking new uses and modes of politics within urban design processes (Boano & Talocci, 2014). Play theory offers a framework for understanding the aesthetic and political dimensions of urban design. Designers can challenge established norms and power structures, opening possibilities for alternative forms of social and spatial organization (Sennett, 1970; 1972).

Concluding the exploration of the importance of play by delving into Nietzsche's philosophy, his character Zarathustra famously declares, "*I will believe in only one god, a god who dances!*" (Nietzsche, 1995). In Nietzsche's philosophy, dance symbolizes the affirmation of bodily pleasures and the celebration of life. Rejecting dogmatic truth claims, Nietzsche advocates for a philosophy that embraces the richness of life and celebrates free thought. He emphasizes activities like dance and music that transcend intellectual constraints, offering avenues for self-expression and empowerment. Thus, the prevalence of play activities in space signals a community actively engaged in shaping their existence, embodying Nietzsche's vision of personal autonomy and creativity (Hinman, 1975). In conclusion, integrating play theory into the collaborative design process empowers individuals to actively shape the evolution of public spaces, fostering a spirit of playfulness, encouraging social interaction, and deepening the sense of place (Whyte, 1980; Shaftoe, 2008). Embracing play as a vital force in urban design leads toward establishing lively and adaptable cities that reflect the rich tapestry of experiences inherent in diverse communities.

Abstract
This study aims to explore the preferences of different user groups for urban (public) spaces and their selective behaviours within them. The study centres on the Kadıköy Historical City Centre (KHCC) in Istanbul, Türkiye. A public online survey was conducted with 473 participants representing residents, workers, and visitors. Survey data were analysed using mixed methods techniques, including descriptive statistics, discourse analysis, and mapping. It was found that there were notable differences in terms of urban space preferences among locals and visitors, and that the place attachment different user groups developed with the space were diversified and differentiated. The study underscores the need for inclusive urban spaces that cater to the needs and demands of all user groups, given the transformation of KHCC.
Keywords: urban (public) space; user preferences; place attachment

Abstract
This study aims to explore the preferences of different user groups for urban (public) spaces and their selective behaviours within them. The study centres on the Kadıköy Historical City Centre (KHCC) in Istanbul, Türkiye. A public online survey was conducted with 473 participants representing residents, workers, and visitors. Survey data were analysed using mixed methods techniques, including descriptive statistics, discourse analysis, and mapping. It was found that there were notable differences in terms of urban space preferences among locals and visitors, and that the place attachment different user groups developed with the space were diversified and differentiated. The study underscores the need for inclusive urban spaces that cater to the needs and demands of all user groups, given the transformation of KHCC.
Keywords: urban (public) space; user preferences; place attachment

1. Introduction: Urban Users and Place Attachment

Different user groups perceive urban (public) spaces and interact with them in unique ways. This experience is shaped by intricate connections between cultural, economic, environmental, geographical, political, social, and technological factors. These encounters shape the attachment individuals develop to these spaces, which is rooted in both direct and indirect physical and social engagements in their daily routines.

Different from place identity and sense of place, place attachment specifically refers to "the cognitive-emotional bond to a meaningful setting […] observed across cultures, place types, and eras" (Scannell and Gifford, 2017, p. 256). It is "an emotion experienced toward a given place, knowledge and beliefs about the place, and behaviour and activities in the place" (Altman and Low, 1992, in Wohl and Blit Cohen, 2024, p. 2). Therefore, it has three main dimensions: personal, psychological, and spatial (Scannell and Gifford, 2010). The personal dimension refers to the individual and collective meanings that people ascribe to a place, whereas the psychological dimension includes feelings, thoughts, and behaviours that are a result of the attachment process. The spatial dimension, on the other hand, stresses the physical and social qualities of a place, like its uniqueness, interpersonal connections, and the built and natural environments.

According to Lewicka (2011), the majority of place attachment research takes neighbourhoods as the place type, whereas the other types are either neglected or have little body of research. Therefore, there is a high need for research in different place types and in different socio-geographical locations to better understand how place attachment is developed and can be sustained so as to instrumentalise it for the betterment of societies and future cities. Especially in the case of deteriorating city centres, place attachment can be used as a mediator for the revitalisation of vivid city life.

In this context, this study aims to explore the preferences of different user groups for urban (public) spaces, as well as their selective behaviours within these spaces, by analysing and comparing the place attachment these groups develop with them. The study centres on the

Kadıköy Historical City Centre (KHCC) in Istanbul, Türkiye, as it accommodates multiple user groups from different socio-cultural and socio-economic backgrounds and has been one of the most important sub-centres of the Istanbul Metropolitan Region since the 19th century. A public online survey was conducted with different user groups (residents, employees, and visitors). A total of 473 participants took part in this study. Survey results were analysed by means of mixed methods techniques, including descriptive statistics, discourse analysis, and mapping.

2. Case Study Area: Kadıköy Historical City Centre (KHCC), Istanbul, Türkiye

Kadıköy Historical City Centre (KHCC) is located on the Anatolian Side of Istanbul Metropolitan Region (see Figure 1). It is one of the oldest settlements dating to 675 B.C. (T.C. Kadıköy Kaymakamlığı, n.d.). Until 1882, it was known for its summerhouses and excursion spots, as well as its agricultural lands, vineyards and Turkish gardens (Ayvazoğlu, 2011; Ekdal, 1997; Kütükçü, 2014) (see Figure 2). Starting with the very first systematized urbanization movements at this time, these places began leaving their spaces to a densely concentrated commercial activity – a city centre – on the coastline and to residential areas in the inner sides of the area (Ulubaş Hamurcu and Terzi, 2021). Beginning with the 20th century, KHCC hosted a vast variety of ethnic and religious groups including Armenians, Bulgarians, Greeks, Jews, Levantines, Roman Catholics and Protestants, and Turks (Kütükçü, 2014). The most dramatic change in KHCC dates to the mid-1900s (Ulubaş Hamurcu and Terzi, 2021). Along with the modernism movement, the existing housing stock was merely replaced by apartment blocks. Following the incidents in 1955 and 1964, the social conjuncture of the area changed drastically (Kavukçuoğlu, 2010).

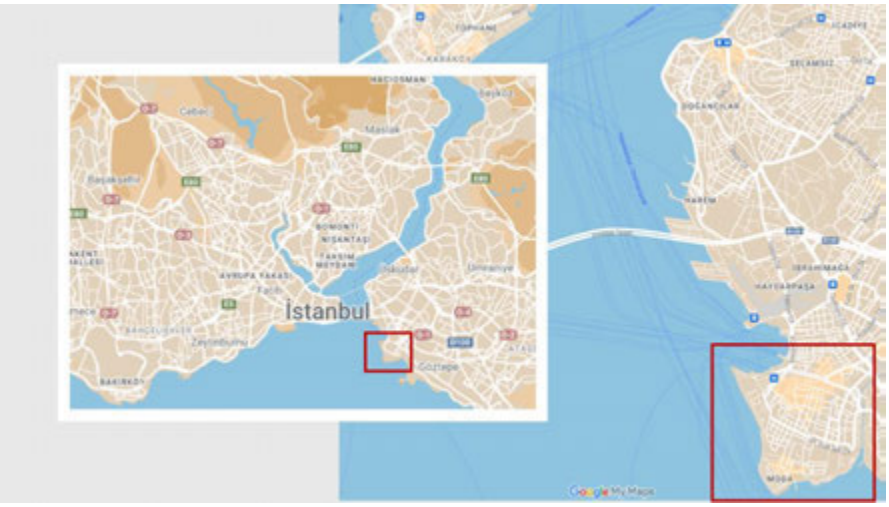

Figure.1 Location of KHCC (prepared by the authors)

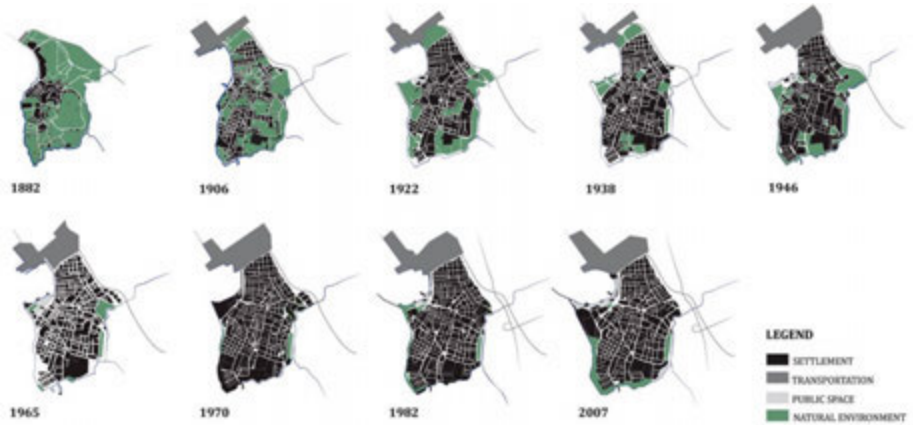

Figure.2 Urban pattern change in KHCC between 1882 and 2007 (Ulubaş Hamurcu and Terzi, 2021, p. 14)

Large-scale urban transportation projects at the beginning of the 2000s resulted in KHCC becoming an important transfer centre for daily mobility and an attraction point for local and foreign visitors (ÇEKÜL, 2014). Along with the renewal projects, it also started housing young white-collar workers, (exchange) students, and professionals from different sectors.

Today, KHCC hosts a variety of users from different economic, educational and social backgrounds (Ulubaş Hamurcu and Terzi, 2021). The diversity and vibrancy brought about by these developments have changed KHCC's appeal, affecting a sense of belonging and attachment among its residents and frequent visitors. This place attachment is further influenced by user preferences that dictate the amenities and social spaces they frequently use within KHCC, shaping their daily interactions and experiences.

3. Data and Methodology

A public online survey was conducted with different user groups (residents, employees, and visitors) before the breakout of the COVID-19 pandemic, between April 29, 2019, and December 18, 2019. A total number of 498 participants was reached. Nevertheless, 25 answers were excluded due to misuses and misunderstandings faced in the answers which resulted in a total of 473 participants.

Among these, 71% are visitors, 22% live and 7% work in the area. A detailed analysis revealed that 55% of participants come to KHCC for leisure activities, 10% for transportation, 5% for shopping, and 3% for other purposes. It was also discovered that 3% of the participants both live and work here.

Participants were asked to: (1) list the first three things that come to their mind when Kadıköy is mentioned; (2) choose among the list of regions of KHCC which they think they mostly use; (3) list where they specifically spend most of their time in KHCC; (4) and choose among the listed publicly owned places which they think they know. By asking these, it was aimed to understand how the participants related themselves to the existing physical environment (in this case, KHCC) and what type of meaning they attribute to it.

Thus, survey data were analysed using mixed methods techniques, including descriptive statistics, discourse analysis, and mapping. Descriptive statistics are used to frame the user profiles of different sub-groups whereas discourse analysis is used to reveal the level of place attachment to KHCC in relevant sub-groups. Mapping is done for visualising the selective behaviours of sub-groups within these spaces. The results are given space based on the representativeness of the sub-groups within the sample one-by-one.

4. Findings and Discussion: User Profiles and Preferences of Urban (Public) Spaces of KHCC

In this section, the results of the study are delivered based on the representativeness of the sub-groups within the sample one-by-one and a thorough discussion is held.

4.1. Visitors

A vast majority of the participants are visitors. A total of 323 attendees come to KHCC for transfer (= 43 people), shopping (= 20 people) and leisure purposes (= 260 people). Among these 69% are women and 31% are men. The general profile of the visitors might be categorised under two: (1) 18-24-year-old university students and (2) full-time workers with at least bachelor's degrees. 84% are single, 15% married and 1% have another marital status. 61% are tenants of which 66% live with full rent, 32% share their accommodation and 2% sub-rent it. 71% know their neighbours. Most of them use rail transit and ferries to come to KHCC.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the physical attributes of the site. These can be listed as Moda (*a neighbourhood*), Boğa (*a bull statue in the middle of a roundabout*), Rıhtım (*coastline where the jetties are located*), Moda Sahil (*coastline where the open public green spaces are located*), ferry, Fenerbahçe, and beer. Among the frequently used words listed, only two have direct emotional connotations, which are 'crowded' and 'fun' whereas 'Fenerbahçe' as a football club also has emotional connotations (see Figure 3).

Figure.3 Three things about KHCC – Visitors (prepared by the authors using Word Clouds)

Visitors state that they spend most of their time in Moda. Following Moda, they spend time in Bahariye, Caferağa, Çarşı (*bazaar*), and Moda Sahil. These regions are closely located to each other creating an axis which begins with Çarşı (*the commercial centre*) till Moda Sahil (see Figure 4 – left).

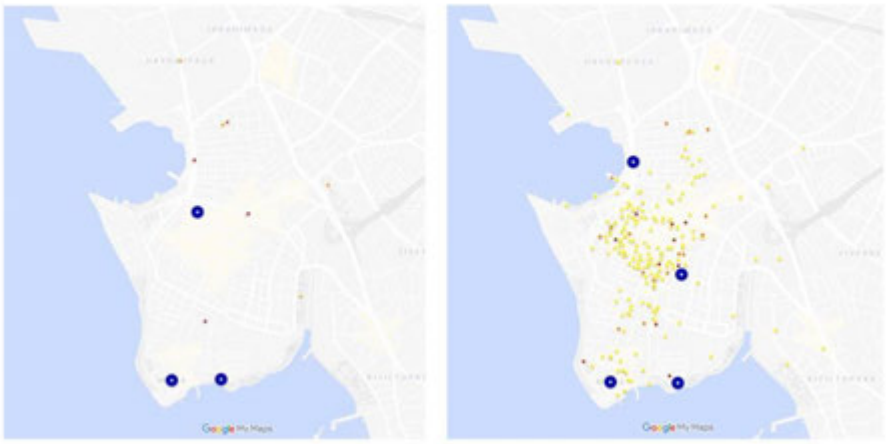

Figure.4 Top districts accommodated by visitors (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Again, Moda, Moda Sahil, Bahariye, Rıhtım and Çarşı (Bazaar) come to the forefront. In addition to these districts, they also go to Starbucks, Moda Aile Çay Bahçesi (*tea garden*), Akmar (*a building where second-hand bookstores are located*), Asuman (*chocolatier*) and cafes (see Figure 4 – right).

On behalf of publicly owned spaces, Nazım Hikmet Kültür Merkezi, Süreyya Operası and Barış Manço Evi are well known, whereas the rest of the spaces have equal significance. These publicly owned spaces also exist on the same axis beginning with the Çarşı to Moda Sahil.

4.1.1. Visits for leisure time activities

55% of the participants (=260 people) come to KHCC for leisure time activities. Among these 68% are women and 32% are men. The profile of the visitors with leisure purposes is similar to the general profile of the visitors which is 18-24-year-old university students and full-time workers with at least bachelor's degrees. 85% are single, 14% are married and 1% have another marital status. 65% are tenants of which 66% live with full rent, 31% share their accommodation and 3% sub-rent it. 69% know their neighbours. Most of them use the ferry to come to KHCC along with wide ranging ways of transport including minibus, rail transit, car, metrobus, bus, bicycle and walking. A small group uses taxis to come to KHCC.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the physical attributes of the site. These can be listed as Rıhtım, ferry, Moda, Boğa, Moda Sahil, beer and Fenerbahçe. In terms of emotional connotations, 'crowded' and 'fun' comes to the forefront, whereas 'Fenerbahçe' as a football club also has emotional connotations (see Figure 5).

Figure.5 Three things about KHCC – Visits for leisure time activities (prepared by the authors using Word Clouds)

Visitors with leisure purposes state that they spend most of their time in Çarşı, Moda and Moda Sahil. Haydarpaşa and Rasimpaşa are the least preferred regions by them (see Figure 6 – left).

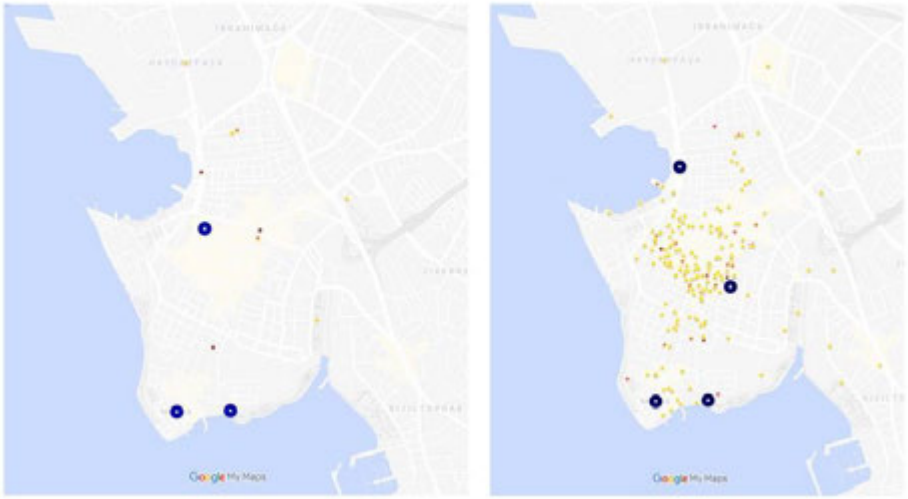

Figure.6 Top districts accommodated by visitors with leisure purposes (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Bahariye, Moda, Bazaar, Moda Sahil, and Rıhtım come to the forefront. In addition to these districts, they also go to Starbucks, Asuman, Akmar, Barlar Sokağı (*a street where bars and pubs are dominantly located*), Moda Aile Çay Bahçesi, and IDEA Kadıköy (*public working space and initiative*) (see Figure 6 – right).

On behalf of publicly owned spaces, Barış Manço Evi, Süreyya Operası and Barış Manço Kültür Merkezi are well known, whereas the rest of the spaces have equal significance. As aforementioned, these publicly owned spaces are located near these most used and preferred places and regions.

4.1.2. Visits for transfer

10% of the participants (=43 people) come to KHCC for transfer purposes. Among these 72% are women and 28% are men. The profile of the visitors with transfer purposes is similar to the general profile of the visitors which is 18-24-year-old university students and full-time workers with at least bachelor's degrees. 76% are single and 24% are married. 54% are tenants of which 70% live with full rent and 32% share their accommodation. 77% know their neighbours. Most of them use ferries to come to KHCC. This is followed by rail transit, minibus, metrobus, bus, taxi, and on foot. A small group also uses bicycles to come to KHCC.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the physical attributes of the site. These can be listed as Moda, Boğa, Rıhtım, ferry, Haydarpaşa, bars, beer, shopping and İskele (*jetty*). Among the frequently used words listed, only two have emotional connotations, which are 'crowded' and 'fun' (see Figure 7).

Figure.7 Three things about KHCC – Visits for transfer (prepared by the authors using Word Clouds)

Visitors with transfer purposes state that they spend most of their time in Moda, Moda Sahil and Çarşı whereas Haydarpaşa is the least preferred region by them (see Figure 8 – left).

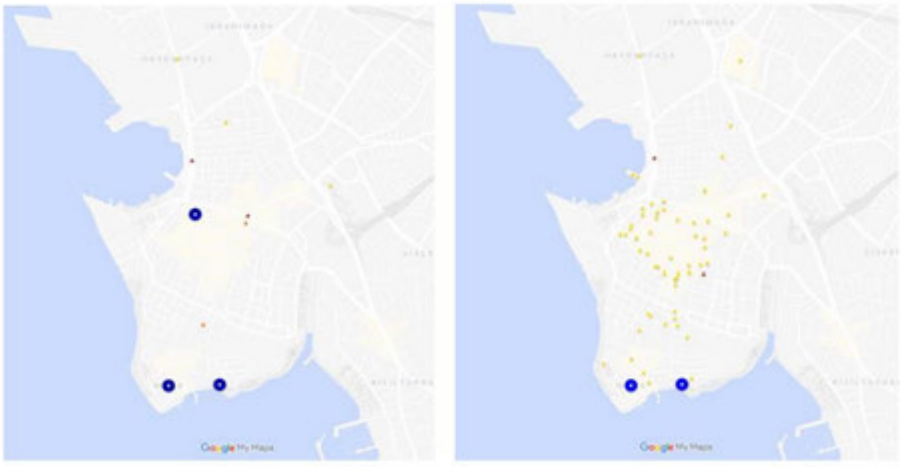

Figure.8 Top districts accommodated by visitors with transfer purposes (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Again, Moda and Moda Sahil come to the forefront. In addition to these districts, they also go to Starbucks, Rıhtım, Akmar, and cafes (see Figure 8 – right).

On behalf of publicly owned spaces, Nazım Hikmet Kültür Merkezi, Süreyya Operası and Barış Manço Evi are well known. Surprisingly, though Tarih Edebiyat Sanat Kütüphanesi (TESAK) is located on the coastline right behind the Beşiktaş-Adalar jetty and IDO terminal, and next to the first-final stop of Moda tram and Kadıköy-Bostancı minibus terminal, and at the back of bus stops, it is the least known by the visitors with transfer purposes.

4.1.3. Visits for shopping

5% of the participants (=20 people) come to KHCC for shopping purposes. Among these 70% are women and 30% are men. The profile of the visitors with shopping purposes is similar to the general profile of the visitors which is 18-24-year-old university students and full-time workers with at least bachelor's degrees. 76% are single and 24% are married. 30% are tenants of which 50% live with full rent and 50% share their accommodation. 85% know their neighbours. Most of them use bus, minibus, rail transit, ferries, and car to come to KHCC. A small group also uses taxis and metrobus to come to KHCC.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the physical attributes of the site. These can be listed as Moda, Boğa, shopping, ferry, sea, Bazaar, Haydarpaşa, Rexx, beer, fish and cafes. Among the frequently used words listed, 'crowded', 'culture', 'arts', and 'ease' come to the forefront with emotional connotations (see Figure 9).

Figure.9 Three things about KHCC – Visits for shopping (prepared by the authors using Word Clouds)

Visitors with shopping purposes state that they spend most of their time in Moda and Çarşı whereas Haydarpaşa is the least preferred region by them (see Figure 10 – left).

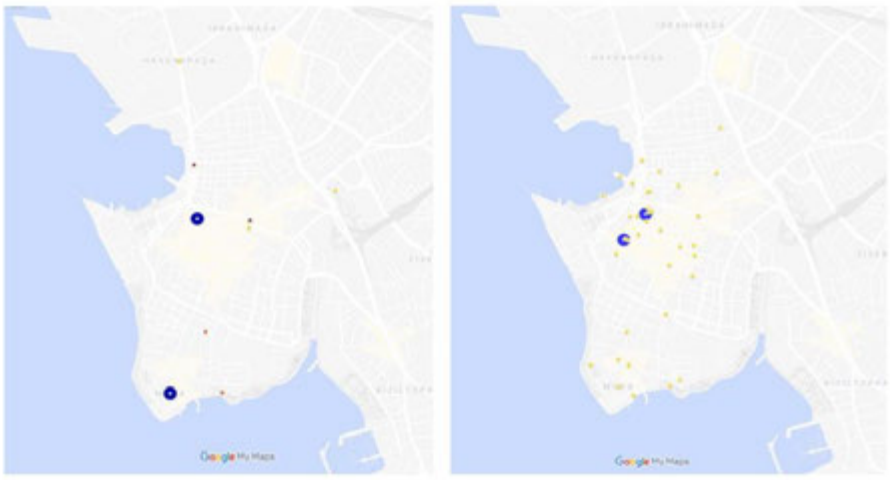

Figure.10 Top districts accommodated by visitors with shopping purposes (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Boğa, Bazaar, Moda and Moda Sahil come to the forefront. In addition to these districts, they also go to Starbucks, Mephisto (*bookstore*), Baylan (*patisserie*), Rexx (*bar*) and second-hand bookstores (see Figure 10 – right).

On behalf of publicly owned spaces, Yeldeğirmeni Don Kişot Evi, Karikatür Evi, Yeldeğirmeni Sanat and Tarih Edebiyat ve Sanat Kütüphanesi (TESAK) are the least known whereas the rest of the spaces have equal significance.

4.2. Locals

Locals consists of residents, workers, and people who both live and work in KHCC.

4.2.1. Residents

22% of the participants (=105 people) live in KHCC. Among these 54% are women and 46% are men. The general profile of the residents is 25-45-year-old full-time workers with at least bachelor's degrees. 62% are single, 35% are married and 3% have another marital status. 63% are tenants of which 79% live with full rent and 21% share their accommodation. 77% know their neighbours.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the emotional connotations of the site. These can be listed as 'home', 'ease', 'crowded', and 'fun'. These are followed by 'freedom', 'civilization', 'safety', 'friends', 'arts', 'life', 'history', and 'social environment'. Among the frequently used words listed, only a few refer to the physical environment. These are Bazaar, Boğa, Moda, and Moda Sahil. Sea, ferry, Yeldeğirmeni and Haydarpaşa are also among frequently referred physical attributes of KHCC (see Figure 11).

Figure.11 Three things about KHCC – Residents (prepared by the authors using Word Clouds)

Residents state that they spend most of their time in Moda, Moda Sahil and Bahariye whereas Haydarpaşa is the least preferred region by them. Yeldeğirmeni and Caferağa are also among the frequently preferred regions of KHCC (see Figure 12 – left).

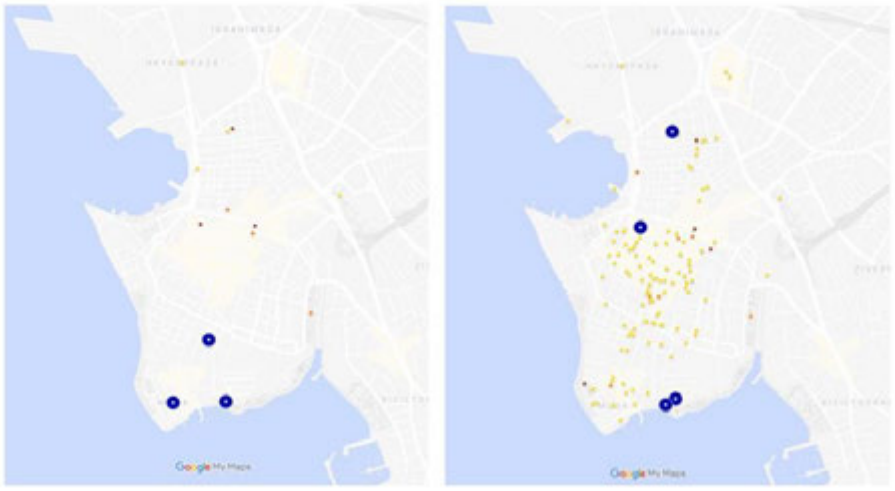

Figure.12 Top districts accommodated by residents (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Again, Moda and Moda Sahil come to the forefront. In addition to these districts, they also go to Yeldeğirmeni, Çarşı, and Bahariye. It is also observed that they visit Moda Aile Çay Bahçesi, IDEA Kadıköy, Küff (*pub*), and Nazım Hikmet Kültür Merkezi (see Figure 12 – right).

On behalf of publicly owned spaces, Nazım Hikmet Kültür Merkezi, Süreyya Operası and Barış Manço Evi are well known by residents. The rest are also known by the residents of KHCC.

4.2.2. Workers

7% of the participants (=33 people) work in KHCC. Among these 30% are women and 70% are men. The general profile of the workers is 25-45-year-old full-time workers with at least bachelor's degrees. 61% are single, 33% are married and 6% have another marital status. 58% are tenants of which 89% live with full rent and 11% share their accommodation. 79% know their neighbours. Only a small group uses taxis to come to KHCC whereas the rest of ways of transport are preferred by a general audience. However, metrobus is not preferred by any of the participants, who are workers, for coming to KHCC.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the emotional connotations of the site. These can be listed as 'ease', 'crowded', and 'home'. These are followed by 'civilisation', 'noise', 'fun', 'night life', 'freedom', and 'Fenerbahçe'. Among the frequently used words listed, only a few refer to the physical environment. These are Moda Sahil, Moda, Boğa, Rıhtım, ferry, beer, theatres, and Yeldeğirmeni. Work and Fenerbahçe can be also included in both categories (see Figure 13).

Figure.13 Three things about KHCC – Workers (prepared by the authors using Word Clouds)

Workers state that they spend most of their time in Moda and Bahariye whereas Haydarpaşa is the least preferred region (see Figure 14 – left).

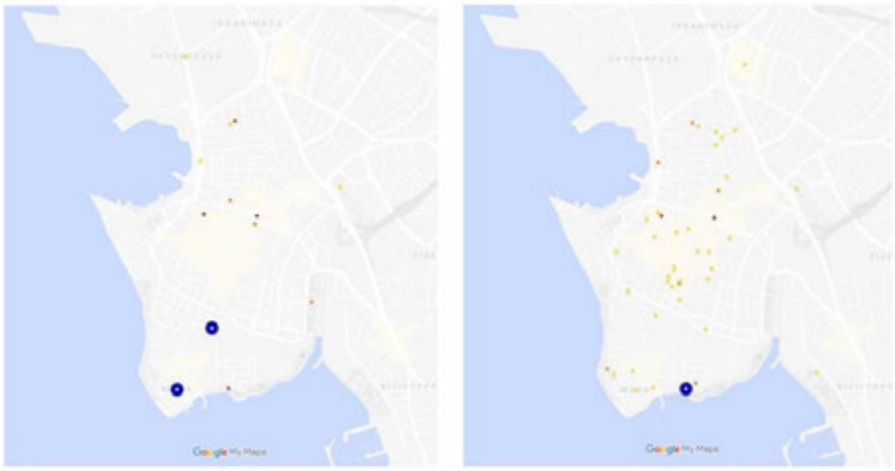

Figure.14 Top districts accommodated by workers (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Again, Moda Sahil come to the forefront. In addition to Moda Sahil, workers also go to Bahariye, Moda Aile Çay Bahçesi, IDEA Kadıköy, and Rıhtım (see Figure 14 – right).

On behalf of publicly owned spaces, Barış Manço Kültür Merkezi, Süreyya Operası and Barış Manço Evi are well known. The rest are also known by the workers of KHCC.

4.2.3. Both

3% of the participants (=13 people) both live and work in KHCC. Among these 23% are women and 77% are men. The general profile of the workers is 25-45-year-old full-time, freelance and multiple job workers with at least bachelor's degrees. 46% are single, 39% are married and 15% have another marital status. 85% are tenants of which 29% live with full rent and 18% share their accommodation. 77% know their neighbours.

The answers given to the question about the three things that come to one's mind when Kadıköy is mentioned are cumulated around the emotional connotations of the site. These can be listed as 'noise', 'ease', 'home', and 'crowded'. Among the frequently used words listed, only Moda Sahil comes to the forefront on behalf of physical attributes of the site. Different than that of other user profiles, this group also refer to a list of words which consists of the following: 'neighbourhood', 'neighbourhood culture', 'streets', 'my youth', 'my life', and 'motherland' (see Figure 15).

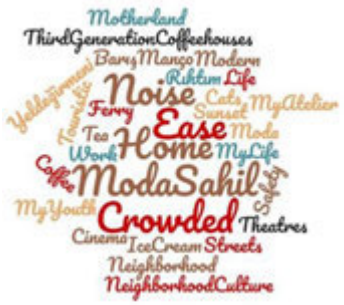

Figure.15 Three things about KHCC – Both (prepared by the authors using Word Clouds)

Participants who both live and work in KHCC state that they spend most of their time in Moda and Bahariye. Rasimpaşa, Altıyol/Boğa and Rıhtım are the least preferred regions (see Figure 16 – left).

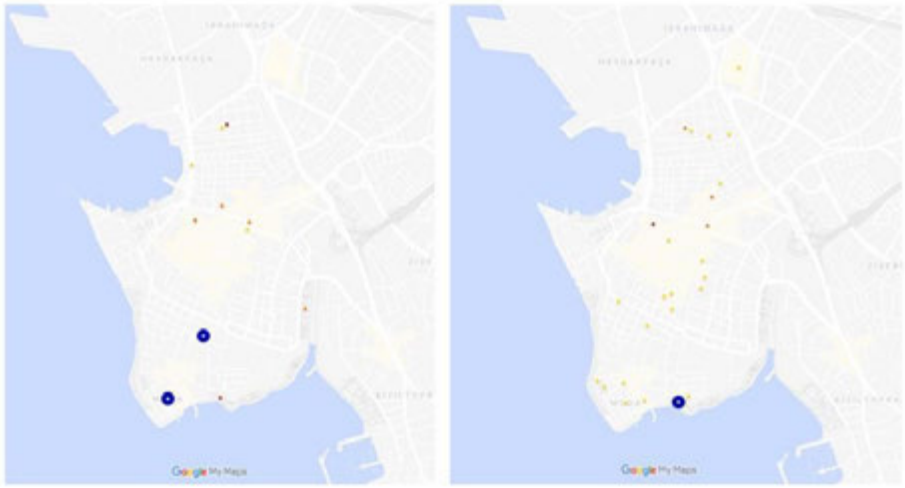

Figure.16 Top districts accommodated by both residents and workers (left); Frequently visited places (right) (prepared by the authors)

Participants are also allowed to give detailed answers to the places where they go frequently. Again, Moda Sahil and Bahariye come to the forefront. In addition to these places, they also go to Yeldeğirmeni and Çarşı (see Figure 16 – right).

On behalf of publicly owned spaces, IDEA Kadıköy, Süreyya Operası and Barış Manço Evi are well known. The rest are also known by the participants who both live and work in KHCC.

4.3. Discussion

Based on the discourse analysis, two major groups of participants are revealed. These are visitors and locals. Both groups stand on the opposite sides of the spectrum as they have different types of place attachment with KHCC. It is obvious that the emotional and social ties of locals with the place were very strong, and the meaning they attribute to the urban space was determined considering these premises, whereas visitors mostly referred to the physical elements of the urban space when describing the KHCC (see Figure 17). On behalf of locals, it is also observed that participants who are both residents and workers in KHCC have a different place attachment when compared to other sub-groups of locals as they also emphasize on a group of words which are ‘neighbourhood’, ‘neighbourhood culture’, ‘streets’, ‘my youth’, ‘my life’, and ‘motherland’. Not only this but also their mentioning only a few physical aspects of KHCC strengthens this premise. This is not surprising as the more the time spent the stronger the place attachment is (Lomas et al., 2024).

Figure.17 Comparison of the physical and emotional connotations by visitors and locals (prepared by the authors)

It was also found that there were notable differences in terms of urban space preferences among locals and visitors (see Figure 18). When a detailed analysis was made by visitor purposes to KHCC, it was determined that there were subdivisions in terms of their spatial preferences, revealing that the different sub-regions of KHCC were intensively used and preferred by different user groups. In other words, different user groups are clustered in different regions of this urban space, interact with different parts of it, and have different spatial experiences. In detail, visitors with shopping purposes reveal a dispersed pattern across the area without any significant clustering, whereas visitors with transfer purposes prefer similar regions with visitors who come to KHCC with leisure purposes showing clustered patterns around Çarşı, Bahariye, Altıyol/Boğa, Moda and Moda Sahil (see Figure 18a). On behalf of locals, workers show a similar behaviour with visitors with shopping purposes as they display a dispersed pattern across the area, whereas residents permeate like an oil stain between Çarşı, Altıyol/Boğa and Bahariye (see Figure 18b). Participants who are both living and working in KHCC are, on the other hand, mobile on a North-South axis between Yeldeğirmeni and Moda Sahil creating sub-clusters. Nevertheless, there are certain regions where all user groups come together. These are Moda and Moda Sahil where the coastline with green areas exists and act as the main common public space for all types of users.

(light colours=leisure, medium colours=shopping, dark colours=transfer)

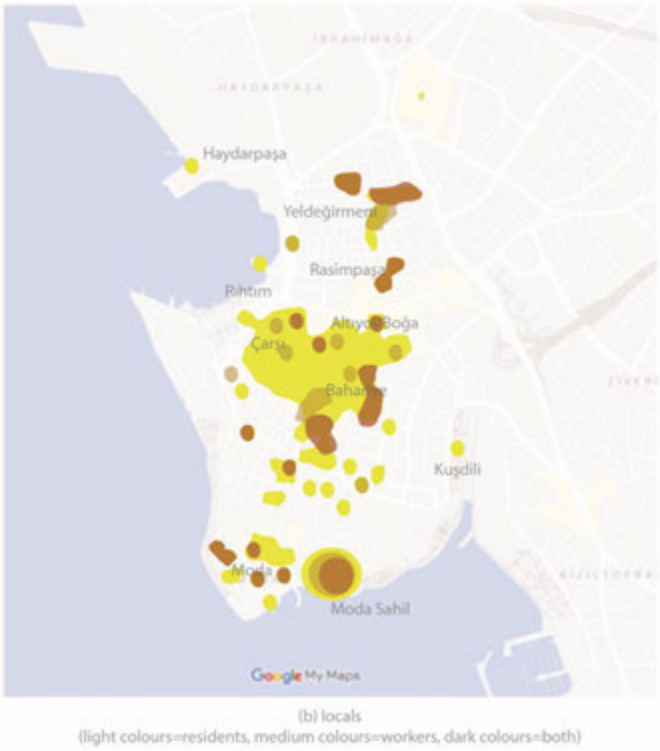

Figure.18 Comparison of the spatial preferences by visitors (a) and locals (b) (prepared by the authors)

5. Conclusion

Considering the transformation that KHCC is currently undergoing, it stands out that there is a high need to design and plan urban (public) spaces that are inclusive of all user groups and respond to their needs and demands. As there is a major differentiation between two different user groups (visitors and locals), the sustainability of the city centre and mixed-use areas depends on how these needs and demands can be faced and how much the place attachment would be developed and made stronger. These findings are also expected to contribute to the international urban planning discourse, emphasizing the importance of socio-cultural diversities in shaping the future of urban spaces and placemaking.

Prof. Dr. Aslı Ulubaş Hamurcu which is defended in September 2021 under the supervision of Prof. Dr. Fatih Terzi. These results were not given space in the Ph.D. thesis, thereby, the authors ensure that the submission is original and has not been previously published.

Ethical Approvals, As this research includes human research participants, ethics approvals from the Istanbul Technical University Social and Human Sciences Human Studies Ethics Committee are taken (Date: November 2, 2018, Number: 99). In place of informed written consent, the web-based survey included two mandatory checkboxes to start the survey and to participate in the research: (1) participants confirm that they are over 18 years old; and (2) they accept voluntary participation in the survey on the condition that they can leave it at any time before submitting their answers if they do not want to continue it. In addition to these, detailed information about how and where this data will be used was included above these checkboxes.

How social media influences rural spatial practice and place identity: A case study of Fuling Village

Yiting Jiang[1]

[1]School of Architecture, Southeast University, Nanjing, China

Abstract: Social media have opened up new growth opportunities for the development of tourism in traditional villages. It can not only attract the attention and sustainable development of villages, but also make villages dependent on the outside world's imagination of "tradition" and "the gaze of the other" in spatial remodeling. In this paper, we take Fuling Village as a case, and explore the spatial practice and changes in villagers' local identities triggered by social media in the context of rural tourism. It is found that (1) the village is changing from a local space to an fluid space under the shaping of social media.(2) Social and power relations in the social media space influence there modeling of local space, forming the "production of virtual space".(3) The development of rural tourism affects the community and rebuilds place identity. The development of traditional villages needs to pay more attention to refining and transforming local characteristics, preserving originality and promoting individuals' place identity in order to achieve sustainable development.

Keywords: Place, identity, tourism development, social media, traditional village

1. Introduction

In the context of global digitization, rural China has ushered in new development opportunities, with an increasing number leveraging social media to develop the tourism industry, aiming to drive economic growth(Liu et al., 2024, Su, 2011). Compared to the past when villages were inward-looking, closed-off, and primarily locally significant spaces, they are now not only shifting towards fluid spaces but also becoming objects of spatial production catering to virtual imagination through tourism development, showcasing cultural interactions with "others."(Jay, 1993, Poole, 2005). With the flourishing development of the tourism industry sparked by social media, there has been infiltration into rural areas, triggering the capitalization transformation of traditional spaces, even to the extent of the entertainment-oriented utilization of spaces of faith. This has led to a contestation among diverse entities for space and the weakening and reconstruction of spatial and place meaning(Guo, 2020). At the same time, with the rise of cultural heritage tourism and rural tourism, traditional villages like Fuling Village located along the southeast coast of China are actively engaging in tourism practices and community development construction, leveraging their unique natural and cultural resources. Similar to many traditional ancient villages in China, in their process of modernization, the intervention of external forces inevitably changes the original economic, cultural, and social relationships. The originally relatively

stable local significance is continuously deconstructed and reconstructed. This not only leads to drastic changes in the architectural landscape of the villages but also creates confusion among local residents about the "why" of tradition display and concerns about the loss of indigenous cultural heritage.

The theoretical study of place originated in the 1970s, slightly later than the study of space. In the context of modernity, space was initially rationalized as abstract geometry. However, with deeper reflection, the concept of place gained attention. Particularly, human geographers represented by Yi-Fu Tuan emphasized that the process of endowing space with meaning gives rise to place (Relph, 1976, Tuan, 1977, Wright, 1947, Tuan, 1971). After cultural accumulation and identity formation, a sense of place is established(Crang, 2013). The essence of sense of place lies in the transformation of spatial meanings into new places and the generation of identity. In this process, spatial practices are essential. Without human spatial practices, a place is merely space(Relph, 1976). However, imposing violence or authority on spatial practices can disconnect individuals from their sense of place, leading to the destruction of the meaning and identity of place(Tuan, 2013). In urban design, place identity primarily revolves around the physical appearance and how people perceive it, with less focus on the extent of the bond between people and place or the depth of its significance. Studies in environmental psychology often link place attachment to individuals' sense of self and community identity, as well as their sense of uniqueness(Ujang and Zakariya, 2015).

Tourism has promoted rural geographical imagination and spatial construction, influencing place meanings and identities. Social media has intensified this change. With its extensive marketing capabilities, social media has increased the attention to rural tourism and promoted the development of rural tourism industry(Senyao and Ha, 2020, Harb et al., 2019)。Due to binary definitions(Dymitrow and Brauer, 2018), urban people often view rural areas with curiosity, which is why content with "rural" titles on social media often receives higher click rates. Current research focuses on the motivations behind tourists' viewing and sharing behaviors on social media (Munar and Jacobsen, 2014)， the influence on tourists' expectations and decisions(Narangajavana et al., 2017, Palazzo et al., 2021, Liu et al., 2024), and the impact on tourists' social networks(Meek et al., 2019). However, most studies overlook the importance of social identity. In this process, virtual spaces and real-life spaces are connected through social media, reshaping social and power relations(Senyao and Ha, 2020). The groups of social actors become more complex, not only affecting spatial practices and changing the lifestyle and livelihood (Su et al., 2019) of local villagers but also influencing their sense of place(Guo, 2020). Due to the neglect of local subjects, there is a lack of theoretical and principled guidance in spatial practices, thus further analysis and strengthening of the guidance and control of local spatial practices are necessary. Therefore, this study focuses on three aspects of spatial creation in Fuling Village's tourism development process under the influence of social media as the research object. It specifically analyzes the changes in spatial practices and social identity, posing the following questions: 1) Under the background of tourism development mediated by social media, what kind of changes have three types of public spaces in Fuling Village experienced? What factors have led to these changes? 2) What perceptions and local identities have the changes in public space practices in Fuling Village brought to the villagers? What does this reflect in terms of substantive issues? 3) As a microcosm, what insights does the case of

Fuling Village offer for understanding new development models for villages in the context of rural revitalization in China? How can the significant gap between spatial practices relying on virtual imagination and the obscured real history be bridged? Additionally, how can the misinterpretation of tradition and the pandering to sensationalism be avoided in tourism development? Research and answers to these questions can deepen people's understanding of rural spatial practices and place identity theoretically. In practice, they can provide reference for practical activities in Fuling Village and similar regions.

2. Methods of case study

2.1 Context of the study area

Fuling Village is located in the coastal region of the Xinghua Bay in Fujian Province, China. The site of village is near the Wuhou Mountain and leading to the Taiwan Strait. Fuling Village and Wuhou Mountain are well-known scenic spots along the coast of Putian (Figure 1). The village has a history of around 1000 years and was officially listed in the fourth batch of traditional villages by the Fujian Provincial People's Government in 2021. Currently, the village comprises 232 households with a permanent population of 1580 people, predominantly consisting of three major family surnames: Chen, Xiao, and Xu. Before the 1950s, the village was primarily governed by clan autonomy. After the establishment of the People's Republic of China, the clan system was replaced, but local elders and other respected individuals still oversee the village's political, religious, and daily management affairs. Following the reform and opening-up policies, the closed pattern of the village has been disrupted, with a large number of villagers going out for work or business. Since the beginning of the 21st century, there has been a gradual increase in folk activities, such as the Wuhou Mountain religious and scenic tourism experiences. Traditional ceremonies like the Lantern Festival celebration have started to revive. Since 2010, Fuling Village has primarily experienced a phase of spatial practices characterized by simultaneous tourism development and community reconstruction. Especially in 2019, the village established a tourism development company with a focus on using social media as a means to attract tourists, highlighting the cultural theme of "福" (fortune) to generate additional income for the village and stimulate industrial development.

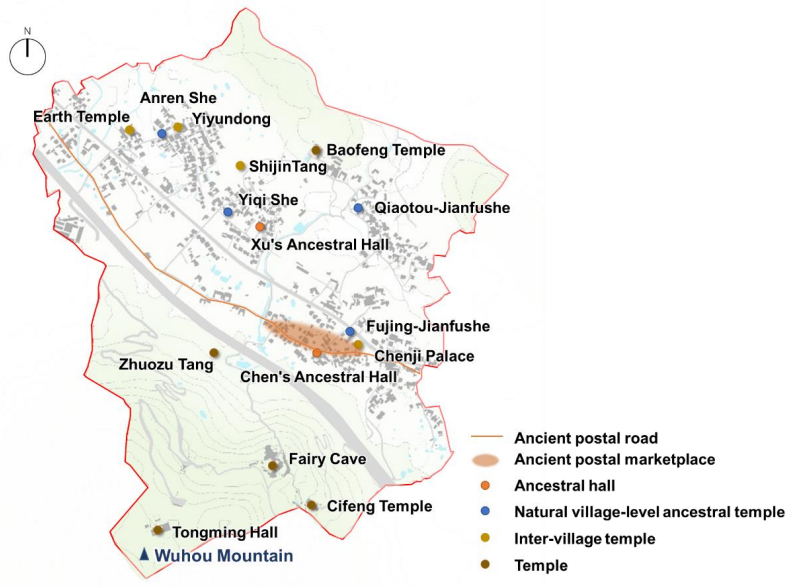

Figure 1. Distribution of public spaces in villages

The selection of Fuling Village and its public space transformation focuses on three case studies: "Religious Belief Space," "Family Ancestral Hall," and "Post Road Marketplace." This choice is based on several reasons. Firstly, Fuling Village, as a traditional coastal village in China, mainly relies on tourism development, making it an ideal place to observe spatial practices influenced by tourism. It heavily relies on social media and social communication to promote its local characteristics, making it a typical destination for technology-mediated tourism. Secondly, the three public spaces in Fuling Village exhibit differences in type and scale. They have clear functional boundaries within the old village and collectively constitute the core public spaces of the village. These spaces have undergone morphological and functional changes under the influence of social media and tourism development, fundamentally altering the usage and perception of daily social life by villagers, leading to changes in local connotations. The interpretation of traditional culture is flattened, and the spiritual foundation based on place identity is shaken. The balance between development and preservation requires urgent consideration and resolution. Thirdly, the spatial practices in Fuling Village are not unique, especially in the context of rural revitalization in China. The challenges it presents have implications and warnings for other regions.

2.2 Data collection and processing

In this research, participant observation and semi-structured interviews were mainly undertaken to study the causes and processes of rural change and the place identity of various villagers in the process.

The research process is mainly divided into two stages: data collection and data analysis. The survey consists of two stages. In February 2023, a village survey was conducted to collect basic data and conduct preliminary investigations. Researchers visited all religious buildings, residential houses, ancestral halls,

and government offices in Fuling Village to gain a preliminary understanding of the overall environment, culture, population, spatial layout, and tourism development situation of the Fuling community. After obtaining basic information about Fuling Village, participatory observation and in-depth interviews were conducted. Researchers entered the case study site multiple times to observe interactions among villagers, tourists, and administrators, as well as changes in lifestyle, recording observations in diary format. In-depth interviews were conducted with 19 respondents as listed in the table below, covering their perceptions of material and cultural changes within the village and their evaluation of village tourism development. In addition, a supplementary questionnaire survey was conducted, targeting individuals who work outside the village but still maintain household registration in the village (and are still involved in village public affairs), with 105 valid questionnaires collected. Subsequently, data analysis and validation were performed. In August 2023, a return visit to the village was made to supplement research and revisit, to understand the situation of tourism development construction and community development. In addition, historical information was supplemented and verified through multiple local chronicles, genealogies, and other historical records.

3. Findings

3.1 Social Media Landscape in Fuling Village

Historically, the development of Fuling Village into a popular tourist destination on social media is closely intertwined with people's use and understanding of social media. The village own several religious destinations, famous for special mountainous coastal landscape and efficacious gods, which attract disciples and tourists. People initially used the photography and video features of social media to document and share the local scenery and activities, aiming to connect people both inside and outside the village. Since the 1980s, many villagers have migrated elsewhere, yet due to difficulties in obtaining urban residency or basic services, they still retain rural household registrations. As a result, they need to participate in certain village collective affairs, necessitating them to stay in touch through mobile phones. Consequently, many important village matters are now disseminated through social media platforms like WeChat. Subsequently, with the rise of short video platforms like Douyin (Tiktok in China), some villagers have uploaded these unique village scenes to platforms with wider audiences, garnering significant attention. Moreover, proud villagers often share the distinctive features of their hometown on social media, leading to an initial understanding of the village's original intentions from outsiders.

After the central government implemented the rural revitalization strategy, government of Fuling village try to show the local scenery online in order to resonate or trigger curiosity with consumers. In 2019, the village was designated as a pilot village for rural revitalization in Fujian Province and established a tourism company in the same year, officially initiating tourism development. It mainly attracted investment through the social capital of villagers and enhanced the village's visibility in Putian City and surrounding areas through marketing and promotion on the Douyin platform. In 2021, Wuhou Mountain was rated as a 2A-level scenic spot, and the village was included in the list of traditional villages in Fujian Province, receiving some special funds, which accelerated its construction.

It does get a lot of attention, according to the search results on the Douyin platform. Douyin (TikTok) is a music and creative short video social networking app. By April 2019, TikTok has gained 200% market-share in a two-year growth period(Lee and Nass, 2005). The app had 51 million ratings on iPhone app store, 19.31million ratings on Google Play, and over 5 hundred million downloads (2024 May).

On Douyin, searchers using keywords such as "Fuling Village, Putian City," and "Fuling Village, Wuhou Mountain" saw a rapid increase in video creation and views in 2021 (Figure 2). The most viewed video had approximately 27 thousand plays. Promotion focused on keywords like "internet celebrity," "check-in spot," "Spring Festival," "night scenery," and "dream prayer holy land," constructing local cultural landscapes and guiding people to understand and imagine the geographical features of Fuling. Local features such as Xianv Cave, Lover's Bridge, and Rainbow Path were amplified and became symbols of promotion, attracting numerous comments and attention, and enhancing on-site experiential perception. Internet users and the village formed a relationship of mutual gaze through the internet, with Douyin serving as a theater for tourism promotion and display.

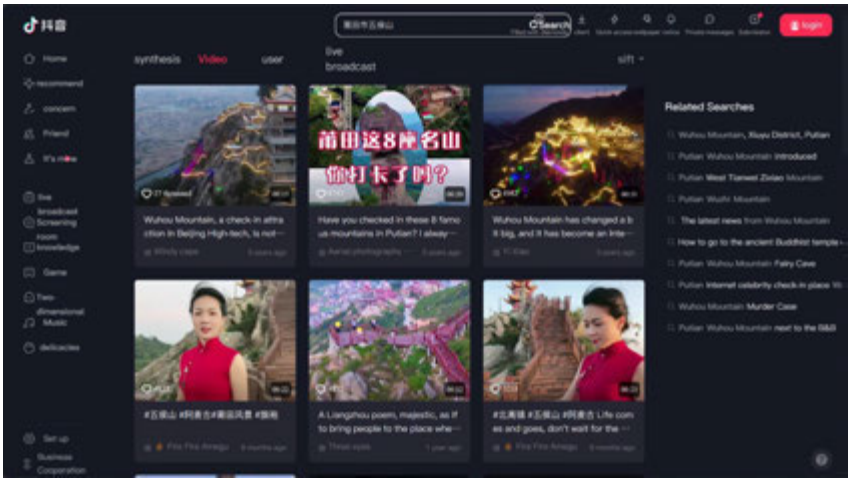

Figure 2. The search results for "Wuhou Mountain in Putian City" on Douyin

3.2 Influence of Social Media on Spatial Practices

3.2.1 Religious belief spaces and tourist attractions

Since the Northern Song Dynasty, ancestors have been building temples in Fuling Village. Due to its unique geographical location in the plain area, Wuhou Mountain serves as a natural "landmark" for the safe passage of boats in and out of Xinghua Bay in Putian and Fujian. In ancient times, people believed that the gods could conquer the forces of nature, and the safe sailing of ships was believed to be blessed by the gods. Over time, this place became a gathering place for guardian gods of fishing boats heading out to sea. During the Northern Song Dynasty, the statesman Cai Xiang supervised the

construction of the "Two-Pavilion Temple" on Wuhou Mountain to enshrine the Jade Emperor. In the early Song Dynasty, a clever girl named Chen Mingzhu in the village ascended to heaven as a fairy after reaching enlightenment here. Later, people built the Fairy Cave and the Ruizhu Palace in her honor. It is believed that the gods here help those in need and bless the villagers, so prayers are constantly answered. The village still preserves nine religious belief spaces, including the Tongming Hall, Qingyun Pavilion, Qingyun Cave and Fairy Cave.

For generations of Fuling villagers, their daily lives are closely intertwined with the religious belief spaces on the mountain, forming an inseparable emotional bond with themselves. Villagers participate in various religious activities throughout the year, over a dozen festivals and ceremonies annually. To facilitate these ceremonies, villagers even invite deities down from the mountain for daily worship, seeking blessings for the villagers. In the construction of their homeland, religious beliefs connect villagers and believers from all directions through various activities, fostering significant emotional ties to the space. In the villagers' perception, religious beliefs symbolize the rich culture and long history of their village, affirming it as a "blessed land" and strengthening collective consciousness. It is evident that religious beliefs shape the worldview and environmental perception of local villagers.

Since 2018, the village has been actively developing rural tourism. The abundant religious belief spaces have become the primary resource for tourism development and are now "spaces under scrutiny." The tourism company, managed and operated by villagers elected for their high social status and economic strength, collaborates with the temple board to discuss development plans. This new organization, as a driver of tourism practices, has initiated a reinterpretation and reconstruction of Fuling Village. These transformations are based on the spatial imagination of potential tourists analyzed by the tourism organization. They observe the "Internet-famous tourist villages" on social media and believe that the social construction of tourists' visual and psychological perceptions, as well as their aesthetic appreciation of the Jade Emperor culture and the Fairy Maiden Cave, should be based on freshness and unique experiences. Therefore, facilities that can become focal points for sightseeing must be redesigned to serve as tourist attractions. Under this concept, religious spaces have encountered modernization erosion, and the tourism development company has expanded and transformed the original spaces. For example, the Golden Dragon, symbolizing the "distinguished status of the Jade Emperor"; the Lover's Bridge, originating from "many people come here to make wishes for love, and the construction of ropes symbolizes climbing together through the trials of love."(Figure 3)

(a)  (b) 
Figure 3. New facilities for religious spaces，(a) "Lover's Bridge," and (b) "Golden Dragon"

It can be seen the fundamentally different logics in spatial connotation between original religious spaces and the tourist attractions in Fuling Village. Although the villagers who built the temples and the members of the tourism development company mainly come from within the village, the subjects with different behavioral purposes have significant differences in the concept of spatial practice. The religious beliefs originated from worship of nature and deities, leading villagers to form a natural-space territorial view in spatial practice, resulting in strong local cognition. However, spatial practices under tourism influence take tourists' spatial imagination and psychological needs as starting points, demanding novelty and popularity, thus creating a large number of symbolic expressions.

3.2.2 Ancestral temples and ritual performance spaces

The four natural villages in Fuling Village are all family lineage clans primarily based on surnames. In ancient China, the lineage was an important organization and responsible for the regulation of rural populations(Chen, 2016). In folk tradition, the ancestral hall is an important public space where clan members engage in daily recreational activities, discussions, ceremonies, and social mobilization(Dean, 2010). Traditional ancestral hall spaces not only host public affairs but also serve as places to maintain emotional connections among villagers of different surnames. The most frequent and fundamental activity is after a day of farming, villagers gather in front of the ancestral hall to chat, share stories, and then light incense inside the hall before returning home. This has been the daily routine for villagers for centuries. Additionally, various clan affairs must be consulted with the ancestral hall's deities, leading to periodic ceremonies. Through these ceremonies, blood ties are emphasized, creating tighter connections among clan members. Within the ancestral hall space, people share emotions, making it a crucial space for local emotional communication. After the establishment of the People's Republic of China and especially during the reform and opening up period, the clan system dissolved. The village's lifestyle was disrupted, clan-based production and life disintegrated, and with the outflow of population, clan ceremonies decreased or ceased altogether, weakening collective consciousness and local spirit.

With the increase in income among some villagers, local spirit and traditional culture have seen a resurgence. Clan culture has been revitalized, and since 2010, villagers have begun rebuilding their

communities. Concurrently, the ancestral halls of various clans have been renovated to restore and promote clan activities. Building upon this foundation, village management proposed integrating the development of rural tourism by packaging major ceremonies such as ancestral worship activities with festivals like Lantern Festival (Figure 4). These events are organized and performed, coupled with promotion on social media platforms like WeChat and TikTok, resulting in widespread sharing among both locals and outsiders, once again boosting attention and visits.

(a) (b)

Figure 4. (a)Chen's Ancestral Hall, (b) Clan rituals

Source: *Chinese Traditional Village Archives Survey Form - Fuling Village*

The transformation of the functional role of ancestral halls fundamentally reflects a shift from utilitarian space to symbolic space. The rebuilding of ceremonies and spaces is diminishing the practical significance for the original users. Meanwhile, tourists, as the target audience for tourism development, are gaining prominence. Although clan ceremonies emphasize identity and belonging to some extent, arousing villagers' attachment to their land, the ambiguous modernity of their multifaceted objectives and villagers' doubts about their own identity are evident. Ultimately, this process represents a form of spatial disciplining in the locality.

3.2.3 Postal marketplace and the "Rainbow Blessing Path"

Besides religious spaces, the primary public activity space in the village is the marketplace developed from the postal station. Ancient Post Road was established by ancient Chinese authorities to meet various governmental, military, and economic requirements, including the dissemination of decrees and official communications, administrative transactions, and the transportation of goods between central and local regions. To ensure the swift delivery of official documents, post stations were strategically placed along the route, equipped with amenities like post buckets, relay horses, and resting facilities for travelers(Kauz, 2005, Wang et al., 2020). The branch line of the Fuxing Post Road system, which was established during the Tang Dynasty (Fuzhou to Xinghua region), passed through Fuling Village. A post station was established at Puochoujing in Fuling Village to accommodate the increasing number of travelers, gradually forming a marketplace. Named Puochou Pu, the post station evolved from a public service facility to a retail business space with the increase in exchanges, offering tea houses, grocery stores, etc., thus forming a small-scale market. Over the nearly one thousand years of existence of the

post road, the prosperity of the post stations continued, where people communicated and cared for each other. Despite being strangers, it became a warm space.

As the 20th century brought the construction of inter-village connecting roads and county highways, and in the early 21st century, the completion of highways passing through villages, car travel became the main mode of transportation for people. As the width of the post roads mainly suited pedestrian and horse-drawn carriage traffic, they were designated as village-level internal roads, resulting in fewer travelers and a decline in vitality. Consequently, street-front shops gradually closed down, and the marketplace lost its vibrant public activities, gradually fading away.

With the rise of tourism development in Wuhou Mountain, village administrators noticed that the tourism industry lacked a long supply chain, with most tourists staying only in the temples for sightseeing experiences, without contributing to the overall development of the villages at the foot of the mountain, thus limiting further consumption. Therefore, a plan was devised to construct the "Rainbow Blessing Path" to connect the foot of the mountain with the village, promoting it as a significant experiential facility in tourism videos. It emphasized guiding people to experience the village on foot rather than leaving directly by car. However, due to the lack of vitality in the village and insufficient tourism experiences and service facilities, it failed to attract tourists to come and experience it, leaving only the "rainbow" waiting quietly (Figure 5).

(a) (b)

Figure 5. (a) Ancient Post Road, (b) "Rainbow" road

Due to the outflow of population and the reduction in community public life, the frequency of use of public spaces has sharply decreased. The original "Post Road," as the main space for village life, remains an emotionally significant "place" for them. Many elderly villagers recalled in interviews the lively and warm atmosphere of life on the "Post Road," saying, "In the days when travel to distant places could only be done on foot, the mutual help between strangers is something we cannot experience today," expressing regret for the loss of close connections between people. Meanwhile, the "Rainbow Path" has become the choice for villagers commuting to work in the fields and for accessing external roads by car.

From the case of the "Rainbow Blessing Path," it can be seen that the post station, as a service facility, is an important source of spatial vitality. It forms a fluid social network through social

interactions, creating emotionally special "places" and fluid "communities." However, after modern facilities disrupt the foundation of the village community, attempts to transplant, imitate, and reconstruct spaces without resonating with the villagers or attracting tourists. This is fundamentally because tourism producers overlook changes in relational connections, leading to differences in social culture and place identity.

4. Discussion and conclusion

4.1Discussions

Social and cultural identity is a socio-psychological phenomenon formed through the spatial-temporal process(Hidalgo and HernÁNdez, 2001), constituting an important spiritual essence for national and local development. The social community of traditional villages, on one hand, sustains organization and perpetuates collective and national momentum, while on the other hand, it is rooted in its subject—the people(Castells, 1997).

From the case of Fuling Village, it can be observed that in traditional societies, local socio-cultural values construct and maintain villagers' unique cultural identity through local religious beliefs, customs, social organization, and ways of life. In traditional spatial practices, people devoutly believe in the protection of religion, deities, and clans, relying on the identity conferred by structural frameworks. Villagers form a negotiated "natural identity" through interaction with nature and society, based on accumulated a priori rules that lead to stable, consistent understandings and beliefs. However, in recent years, the external focus brought about by tourism has led to the inclusion of new actors in spatial practices: tourism development enterprises and their imagined network tourists. Due to the differing interventions of various actors and their divergent understandings and practices of space and place, the roots of identity have undergone changes. Developers aim to gain profits, while tourists seek experiences and exploration. Social media amplifies the audience's curiosity, leading to the rapid production of symbols and differential identification in the crowded network image competition. For the new spatial villagers, they find themselves in an awkward situation where they cannot fully identify, yet they cannot maintain their original identity through reminiscence and reproduction. This case reflects that modern public spatial practices are transitioning villages from sacred spaces to secular spaces, and natural identities are shifting towards mechanical identities collectively constructed by subjects with different backgrounds and cognitions. Local meanings and attachments are in a state of flux.

It can be seen that complexities exists in giving places their identities under the tourism backdrop. Holding on to one’s place meanings may become increasingly challenging as the gap widens between the meaning and the physical characteristics of the setting(Fitchen, 2019). The loss of place meanings and attachment result in the inability to continue to feel, to practice and to recall experiences(Ujang and Zakariya, 2015). Therefore, in the context of fluidity, the future spatial practices of rural areas require respecting local natural identities, orderly developing diverse mechanical identities, avoiding nihilism, and better promoting the healthy development of local socio-cultural through multi-party negotiation.

4.2 Conclusions

The transformation of Fuling Village reflects the powerful impact of modernization intrusion on traditional spaces. While tourism development brings possibilities of economic growth to ordinary rural areas, the new ideologies it brings about lead to the transformation of traditional values and customs. This subjects them to the rapid influx of information, making it difficult to extricate themselves. In the longer term, this may prove to be short-lived and bring about even more severe challenges.

Public spaces play a significant role in the formation of place identity and attachment, but their creation and governance have always been a complex process. In tourism-oriented community development, particular caution should be exercised. Traditional consumption and tourism rely on meaningful places, so it is still necessary to understand and construct what constitutes a place within the new system. This involves identifying social and cultural differences and commonalities among different stakeholders, and re-evaluating space and locality.

It can be observed that the development of the internet society has once again changed the way people travel. People share and obtain information through the internet, forming virtual communities and online identities. This not only affects users' perceptions but also influences specific places and their indigenous inhabitants through their spatial practices. As early as the 20th century, Joshua Meyrowitz proposed that the emergence of new media directly led to the fragmentation, reorganization, and transformation of social situations, affecting people's definition of contexts(Meyrowitz, 1986). In China, there are still many places similar to Fuling Village that are becoming tourist spaces under the focus of mobile networks. The spatial practice case of Fuling Village can provide reference for other places, reminding people that locality is not only a physical space and region, but more importantly, the associations and meanings generated by interactions among subjects. Perhaps in practice, tourism development can expand digital utilization methods, such as reflecting local culture and heritage through digital platforms, to strengthen interaction and negotiation among subjects, and explore the possibility of place identity on the basis of building communities.

Abstract
Exploring and continuing the spiritual connotation of community public space is of great significance to shaping the place identity. "*Pu-Jing*", the grass-roots organisation system of Quanzhou during the Ming and Qing dynasties in China, created the "*Pu-Jing"* community, a governance unit that combined official administration and folk beliefs, and had a profound impact on the community public space system. The purpose of this study is to interpret the spatial characteristics and cultural connotations of public space in *Pu-Jing* community by analysing the spatial carriers and social factors. The research examines the compositions of the community public space, explores their spatial structure, and then summarised the formation logic and building ideas of the public space. The study reveals a public space system with the *Jing* Temple as the core, the streets and alleys as the link, and the belief realm as the unit was formed in *Pu-Jing* community under the combined effect of official management and civil autonomy, creating a stable sense of spatial domain for the residents' ritual and daily activities. The wisdom of place-making implied in the public space of *Pu-Jing* community provide inspiration for contemporary community governance.

Keywords: Community public space; spatial characteristics; place identity

1. Introduction

1.1 Theoretical background

With the emphasis on reviving the spirit and sensibilities of urban construction (Alexander, 1987), there is a growing realisation that shaping identity is key to truly revitalizing a place (Xia, 2020). Only when we learn from existing experiences and promote the conservation of urban spiritual significance can urban structures become life structures, allowing urban identity to emerge naturally (Zhao and Jiang, 2022).

In communities, individuals feel emotionally connected to the community by sharing similar cultural experiences and values with it (Durkheim, 1984), gradually forming a cultural identity with the community (Tajfel and Turner, 1986; McMillan and Chavis, 1986). Thus, community identity becomes a close psychological experience linking individuals and the community. For each individual in the community, mutual promotion of belongingness and identity helps satisfy their need for external dependence to some extent (Wu and Qin, 2022), thereby enhancing their sense of happiness. For the community, reinforcing members' cultural identity contributes to community cohesion and promotes its stability and development. Therefore, community identity becomes the core content of community construction.

As the accumulation of history, culture, traditions and values within a community, community context becomes the common cultural foundation of its members. Consequently, it becomes an important factor in forming a sense of community identity and constitutes the characteristics of the community. Inheriting community context can

help community members feel the continuity of its history and the perpetuation of its culture, thereby establishing their own historical connection and sense of identity with the community.

Public space, as venues for daily activities, interactions and various collective events among community members, is regarded as the core place of community life. Within urban community public spaces, buildings and structures with historical significance, as well as venues for traditional festivals and celebrations, serve as tangible witnesses to historical activities and events, conveying the collective memory of the community and embodying its collective spirit. Community public spaces not only serve as important carriers of community context but also as crucial places for its inheritance and development. Therefore, exploring the historical context and spiritual significance of community public spaces is essential for shaping the cultural identity of the community.

1.2 Overview of the study area

"*Pu-Jing*"(铺境), the grass-roots organisation system of Quanzhou in the Ming and Qing dynasties, created the “*Pu-Jing”* community, a governance unit that combined official administration and folk beliefs. Formed under a specific social background and urban governance, the *Pu-Jing* community responds to the most essential characteristics of the community, and is a special form of traditional Chinese community evolution.

Located in the southeastern coastal region of China, Quanzhou has been an important port city in southern China since the 9th century AD. During the Song and Yuan Dynasties, it was China's world centre of maritime commerce. Maritime trade and fishing life made Mazu, the goddess of the sea, one of the most revered deities of the people of Quanzhou. The geographical advantage facilitated the spread and exchange of different religions such as Buddhism, Taoism, and Islam in the Quanzhou area, making it a region of diverse religious beliefs. People integrated their life needs with religious beliefs, leading to the development of a thriving folk belief system, which has had a far-reaching impact on the Quanzhou community.

After the prosperity of the Song and Yuan dynasties, Quanzhou's economy declined and its status as a regional centre fell away due to the strict restrictions and controls on trading activities overseas and the frequent occurrence of wars during the Ming and Qing dynasties, but the folk beliefs remained vibrant. In the context of the maritime prohibition and external defense, the government's control over the grassroots society was greatly consolidated, which directly led to the creation of the *Pu-Jing* system (Lin, 2007).

The *Pu-Jing* system is "a comprehensive urban social spatial classification system implemented in Quanzhou during the Ming and Qing dynasties" (Wang, 2003). The concept of "*Pu*" (铺) points to urban governance and refers to an administrative spatial unit promoted by the authorities (Chen, 2009, pp. 103). According to the "Political Records", there is a strict population control system implemented within the *Pu* unit[1].The affairs of household management, taxation, public security and education in it are subject to official management (ibid.). "*Jing*" (境) is the next level of the "*Pu*". It refers to local beliefs, which denotes the jurisdiction of a temple, as well as the scope

of the "parade around the realm" when the folk welcome deities (Wang, 2022). The people of a *Jing* unit share a common belief in the sacred. According to the Qianlong edition of Jinjiang County Annals, the city of Quanzhou in the Qing Dynasty was divided into 36 *Pu* units and 72 *Jing* units. The assemblage of the *Pu* and *Jing* units is to some extent equivalent to today's neighborhoods.

The people of Quanzhou, based on their spiritual needs, have integrated belief systems carried by the "*Jing*" into the official framework of control organised by the "*Pu*". With the harmonisation of the two, a governance unit combining official administration and folk beliefs was formed in Quanzhou. The local significance of the *Pu-Jing* community was gradually strengthened by its role as a spiritual support for the people. Even today, the people of Quanzhou still attach great importance to the concept of “*Pu-Jing*”. One can still hear Quanzhou residents narrate stories about their origins from a particular *Pu* or *Jing* unit, and which deity they believe in. When overseas Chinese write letters to their home countries and when Taiwan compatriots return to their hometowns to recognise their ancestors, they use a certain “*Pu*” and “*Jing*” as their address (Chen and Lin, 1990, pp. 2).

The local characteristics of Quanzhou's *Pu-Jing* community are prominently reflected in the public spaces consisting of facilities that support the belief system and daily life. Based on this, this study starts from the perspective of community public spaces to investigate their spatial features and social significance, explore how they contribute to shaping a sense of belonging, and summarise their spiritual connotations, hoping to provide insights into the continuity of cultural context in contemporary urban development.

2. Methodology

This paper takes the public space of the *Pu-Jing* community as the study object, focusing on its physical characteristics and cultural connotations. The study is based on the “Map of Quanzhou City”, which was surveyed and mapped by the Quanzhou Public Works Bureau in 1922. This historical map was calibrated based on the historical nodes of the current satellite map on the GIS platform. And then we overlay the calibrated “Map of *Pu-Jing* in Quanzhou City” (Chen and Lin, 1990) on the “Map of Quanzhou City” to identify the 31 *Pu* units and the *Jing* temples in the 79 *Jing* units within the ancient city of Quanzhou. The exact boundaries of the *Jing* units cannot be examined at present, but its coverage can be roughly inferred from the accounts of its internal streets and alleys documented by Chen and Lin (ibid.).

Based on the above materials, we extracted the data of the public space elements of the *Pu-Jing* community, and analyzed the spatial characteristics with digital methods. The *Jing* temples, streets and the boundaries of the *Pu* and *Jing* were redrawn by using ArcGIS. The distribution of *Jing* temples was identified by Kernel Density, and the local integration of streets was identified by Space Syntax. Local integration is used to indirectly account for the accessibility of a space to other spaces within a given spatial radius. On this basis, the location characteristics and service coverage of *Jing* temples, the relationship between streets and *Jing* temples, and the urban public space system could be explored. Further, the building ideas of public space were discussed.

3. Spatial composition and structure of the public space in *Pu-Jing* community

The analysis shows that the public spaces of Quanzhou's *Pu-Jing* community comprise three constituent elements: the unit, the core and the link.

3.1 Unit: *Pu* and *Jing* realms related to spiritual beliefs

“*Pu*” and “*Jing*” are the two hierarchical organisational units of Quanzhou's *Pu-Jing* system, each with its specific physical spatial domain. The demarcation of their domains adopts a unique local method, where psychological factors play a significant role.

As a management unit, the delineation of the "*Pu*" took into account both administrative management and mental identity. According to the "Map of *Pu-Jing* in Quanzhou City", the boundaries of the “*Pu*” were not strictly divided along the streets and lanes, but were irregularly shaped (Figure 1). This is a psychological boundary formed through the construction of locality based on psychological identity(Cai, 2022), which is constructed based on the common worship of deities and ritual ceremonies among the residents within the boundary, and forms the foundation of the local identity network (Chen, Guan and Lin, 2011). The scales of these *Pu* units vary. By comparing the scope of the *Pu* units with the urban construction area, it can be observed that the its demarcation is related to the distribution of the population's residence in the ancient

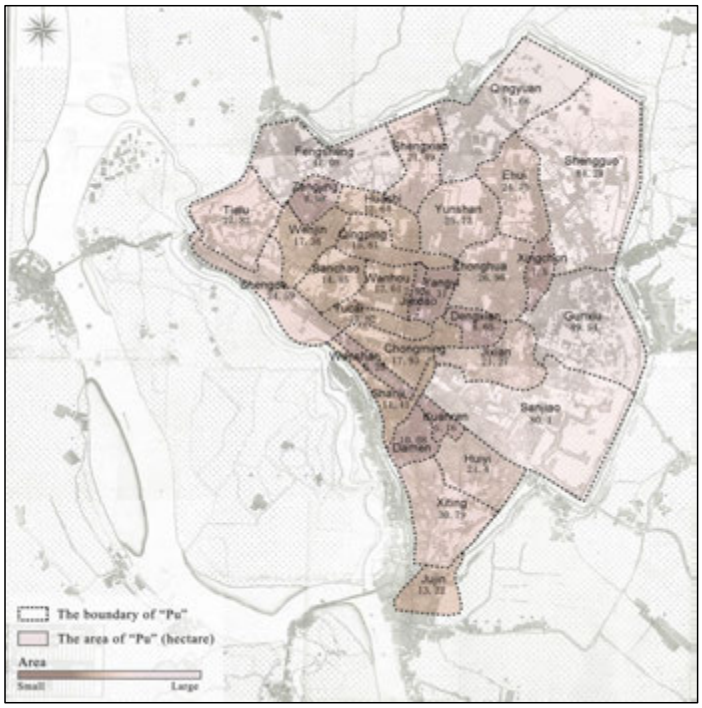

Figure 1 The boundary and area of *Pu* units.
Source: Drawn by the authors based on the “Map of Quanzhou City”. Quanzhou Public Works Bureau, 1922.

city of Quanzhou. In areas where the residential areas are dense, the scale of the *Pu* units is often smaller, with the smallest being about 3 hectares, while in the areas close to the edges of the city walls, the size of the *Pu* units is larger, with the largest reaching up to 80 hectares. The number of *Jing* units divided within different *Pu* units also varies. Within a single *Pu* unit, there are usually 2-5 *Jing* units, with the most having up to 9.

As a belief unit, the realm of the *Jing* is recognised through a twice-yearly ceremony of stabilizing boundary (Wu, 1985, pp.98). Like the *Pu* unit, the scope of the Jing unit is also usually related to the built-up area scale in order to ensure a balanced population size within the realm. Taking *Sanjiao Pu* as an example, the scale of its nine *Jing* units ranges from 1.69 hectares to 12.43 hectares. The built-up areas and distribution of people in *Yichun Jing* and *Wenxing Jing* are relatively centralised, so they are smaller in scope; the sites in *Longgong Jing* and *Fengchi Jing* are fragmented, so their scope is larger. On this basis, the residents further define the boundaries of the *Jing* units through the ritual activity of "parading the *Jing*'s realm". The activities include the rituals of " greeting the deity" and "seeing off the deity". Usually, the residents of the *Jing* unit carry the Main Deity of the *Pu* or *Jing* along the streets to patrol the area under their jurisdiction in order to strengthen the boundaries of the realm. However, when the members of one *Jing* realm invades the territory of a *Jing* realm belonging to an opposing power during a ritual parade, it can result in conflict between the two *Jing* units (ibid.). Boundaries formed by consensus among different *Jing* units ensure harmonious coexistence. The immaterial elements of religious rituals, together with the physical space, define the realm of the *Jing* units, shaping in the consciousness of the inhabitants an organisational unit that is closely related to their own experience of spiritual life.

From the perspective of the entire city, the scale of a *Jing* unit generally remains within a certain range. Nearly 90% of the *Pu* areas have an average *Jing* scale ranging from 3 to 12 hectares. Compared to the ideal community scale today, which covers a range within a 300m walking distance (8-18 hectares), this is slightly smaller. It seems to have achieved a belief unit scale suitable for the social environment of that time and place.

3.2 Core: *Jing* temples as a place of spiritual cohesion

3.2.1 Functions of the *Jing* temples

In the system where *Jing* serves as the belief unit, each *Jing* unit is equipped with a *Jing* temple, which undertakes daily worship, large-scale rituals, and grassroots management functions. The founding years of these *Jing* temples span a wide range, from the Tang Dynasty to the Ming and Qing Dynasties. With the establishment of the *Pu-Jing* system, they have continued to exist as the spatial carriers of the system, and undergone changes to adapt to social needs under the amalgamation of official governance and folk beliefs.

Each *Jing* temple enshrines the respective protective deities of each belief unit, and the variety of deities worshipped reflects the coordination between folk spontaneity and official authority. The number of deities that are mainly worshipped amounts to more than 30. With the exception of Buddhist and Taoist deities such as Guanyin, Guandi, Mazu, Erlangshen, and Xuantian Emperor, which are included in the national

sacrificial system, the folk deities worshipped in the *Jing* temples are generally those closely related to local history, culture and legends. One type is deities highly associated with life services, such as the theater deity "Xianggongye," the medical deity "Baosheng Dadi," and the childbirth protector "Pingtian Shengmu". The other type is local protective deities established based on the worship of historical figures.

The identification of these ritual deities was often the result of dual interaction between the folk and the authorities. On the one hand, the official authorities of the Ming and Qing dynasties continuously absorbed symbols deemed practical from the folk, such as eminent scholars, righteous individuals, and heroes, and exalted them as deities to establish role models for governance and personal conduct (Wang, 2017, pp. 248-249). On the other hand, the people needed to obtain official recognition for the deities they worshipped in order to keep their own deities from being abolished by the authorities. This is often done by giving the local deity the name of an officially recognised historical figure with the same surname, thus transforming the community's protective deity into a famous historical figure.

Besides daily worship, the *Jing* temple also undertakes more solemn festival ceremonies, and gradually becomes an important venue for the city's periodic celebrations. In the aforementioned custom of "parading the *Jing*'s realm", the *Jing* temple is the key node for the entire event, serving as both the starting point and the end point. City-wide "*Pudu*"[2] activities are also held alternately in the *Jing* temples of various units (Wang, 2017, pp. 292-295). Additionally, due to the diversity of deity worship, Quanzhou hosts deity birthday celebrations every month, with such events spanning over 100 days within a year (Chen and Lin, 1990, pp. 98-101). These activities all rely on the *Jing* temples to be carried out.

Due to official administrative intervention, the *Jing* temple also undertake the function of "*Yuesuo*" (covenant house)[3]. According to records in the "Political Treatise," the formulation and implementation of township covenants often rely on existing temple spaces. The purpose is to utilise the religious and public attributes of temples and the deterrent effect of local deities to strengthen the moral education role of the township covenants, and thus to guide the grass-roots administrative affairs. In the ancient city of Quanzhou, the *Jing* temple called "*Yuesou*" in *Qingyuan Pu* used to be the place where township covenants were made and local civil disputes were dealt with (Wang, 2017 pp. 284). The *Jing* temple such as *Fengsheng* Temple and *Shangdi* Temple also have relevant records as the covenant house.

The *Jing* temple, as a public building for folkloric enshrinement of deities and rituals for blessings, has become a core place where the urban governance system integrates with the local belief system, with the superimposition of official control and supervision functions.

3.2.2 Distribution of the *Jing* temples

Within the *Jing* realm, the *Jing* temple are often located closely adjacent to residential buildings, establishing a tight relationship with them (Figure 2). Influenced by the high-density built environment of the ancient city, most of the *Jing* temples are of the single-hall type, with a narrow internal space, where the deity statue and the offering table are located at the entrance, which can only provide space for the basic

worship activities. In contrast, the *Jing* temples in the urban fringe present larger and more complex architectural styles, such as *Tongtian* Temple with three halls and three openings, *Fumei* Temple with two halls and three openings, and *Xiling* Temple, which consists of a combination of two single-hall temples side-by-side.

Figure 3 Photographs of the *Jing* temple and its relationship with the surrounding area. Source: Quanzhou Culture and Tourism. (2023). *Explore the lesser-known Jing Temples in the south of the city.* Available at: https://mp.weixin.qq.com/s/pb44AgMzeS440H089IWZbw (Accessed: 6 May 2024).

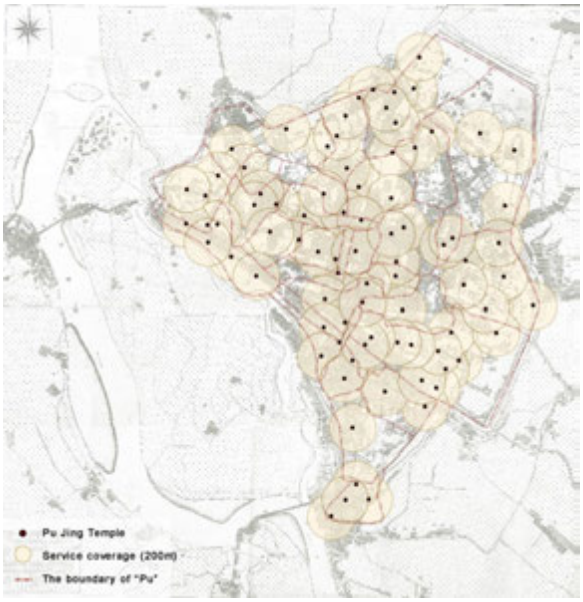

Figure 2 The service range of the *Jing* temples
Source: Drawn by the authors based on the "Map of Quanzhou City". Quanzhou Public Works Bureau, 1922.

At the urban level, *Jing* temples are widely distributed throughout the entire city. The service range of the *Jing* temples essentially covers residential areas within the city if measured at a radius of 200m (Figure 3). The *Jing* temples, as

community-level public buildings serving the basic units of the city, have achieved a grid-like distribution as if following today's standards for the layout of public service facilities.

3.3 Link: Streets and alleys connecting the individual and collective spaces

3.3.1 Roles of the streets and alleys

As transportation passages for people, streets and alleys form the basic skeleton of the community's public space. The distribution of *Jing* temples is based on this historically established and stable spatial foundation. Streets and alleys, as important venues for the daily life of Quanzhou residents, are closely related to their collective life. Residents gather here to exchange information, host community gatherings, and participate in festive events. The streets and alleys reflect the life trajectory and psychological experience of residents. The values of comity, filial piety and positive enterprising embodied in the historical alleys such as Comity Alley, Filial Piety Alley, and Taikui Alley, reflect the deep historical memories and cultural spirit of residents. Due to the prosperity of folk beliefs, the streets and alleys not only assume administrative and daily life service function, but also become important places for religious activities.

Firstly, the streets and alleys link up the *Jing* temples, serving as the essential passageways for pilgrimage, prayers and religious ceremonies, connecting the daily life of the residents with their spiritual beliefs. The streets and alleys link the public spaces in front of the *Jing* temples, the public spaces shared by several families and the public spaces in front of each house. They connect the individual lives with public social activities.

Secondly, streets and alleys serve as routes for ceremonial activities and the important places for local residents to worship deities. During the rituals such as “greeting the celestial troops” in the spring, “offering incense” in the summer, and “seeing off the celestial troops” in the winter, the residents of the *Jing* units carry the Main Deity of *Pu* or *Jing* along the alleys, and the deities will be enshrined by each family.

Thirdly, the alleys serve as stages for performances during religious festivals and celebrations. In the first month of the lunar calendar, the “makeup people” would parade along the alleys and make a variety of folklore performances such as Lantern Show, Parade floats and Gaojia Opera. The alleys around the *Jing* temples are usually responsible for more public activities. The stage of *Tongjing* Temple in *Ciji Pu* is erected above alley and water system. Residents built a stage out of wooden boards that were usually kept in the *Tongjing* Temple, and then they could gather in the alley in front of it to watch the play (Wang et al., 2022). The alleys closely connect the religious activities with community life and become a space that bridge the gap between people and the deities.

The *Pu-Jing* system in Quanzhou integrates the administrative, religious, and daily living functions, with the streets and alleys playing a role in connecting and coordinating these functions. While not directly stemming from the *Pu-Jing* system, the streets and alleys build an important support system for it.

3.3.2 The relationship between the streets and *Jing* temples

The analysis results show that the majority of temples have high accessibility relative to their surrounding areas. By examining the distribution of *Jing* temples and the local integration of streets and alleys, it is observed that the areas with a high concentration of *Jing* temples coincide with the areas where the local integration of streets and alleys is higher (Figure 4). It can be seen that from the perspective of the entire city, temples are mostly distributed in areas with high road accessibility within a small range, and their main service area is within a certain range around them.

Figure 4 The distribution of Jing temples and the local integration of streets and alleys. Source: the authors.

Furthermore, the temples are closely associated with the streets, resulting in three types of "temple-street" layout forms. (1) The *Jing* temple is located on the corner of street. This is the most common layout form (Figure 5(a)). (2) The Jing temple is located on the T-shaped junction. Accessibility of the *Jing* temple is greatly enhanced by the location of transportation node and focal point (Figure 5(b)). (3) The Jing temple is located on one side of the street. Compared with other forms, the *Jing* temple is more difficult to be noticed, but the combination of *Jing* temple and public space can increase the publicness of the *Jing* temple (Figure 5(c)). The public space system linked by streets and alleys further emphasises the centrality of the *Jing* temple.

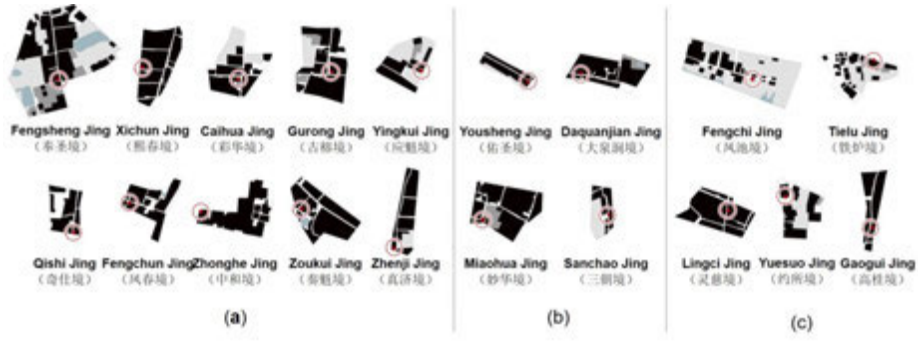

Figure 5 Three types of "temple- street" layout forms. Source: the authors.

4. Characteristics of public space in typical community - *Sanjiao Pu*

"*Sanjiao Pu*" is a typical representative of the *Pu-Jing* community in Quanzhou, which is large in scale and rich in elements. The area of *Sanjiao Pu* is 80.10 hectares, surrounded by the city centre to the west and the suburbs to the east. It enshrines the deities of Confucianism, Taoism and Buddhism, and includes the Confucian Temple, Guandi Temple and Tongfo Temple. Historically, it was a sacred place where the beliefs of the deities were gathered, and it was also the centre of official administration. The *Sanjiao Pu* is divided into nine *Jing* units: *Wenxing Jing*, *Houcheng Jing*, *Baiyuan Jing*, *Longgong Jing*, *Guangxiao Jing*, *Yichun Jing*, *Yuxiao Jing*, *Shangdi Jing*, *Fengchi Jing* (Figure 6).

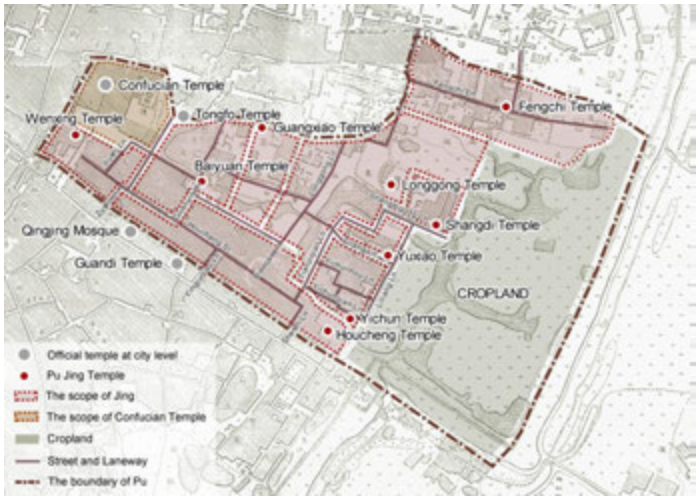

Figure 6 The Pu-Jing system in "Sanjiao Pu".
Source: Drawn by the authors based on the “Map of Quanzhou City”. Quanzhou Public Works Bureau, 1922.

The *Sanjiao Pu* exhibits a structural characteristic in its public space organisation, forming a spatial pattern centred around the *Jing* temple, connected by streets and alleys, and organised into units based on folk beliefs. As stable spatial elements in the history of urban development, the alleys such as *Longgong* Alley, *Shangdigong* Alley, and Comity Alley, have constructed the spatial framework of the community and partly serving as boundaries of the *Jing* realm. Each of the nine *Jing* units has a *Jing* temple with the same name as it. The *Jing* temple serves as a core and is located on the main alleys, serving as a spatial and visual focal point. For example, *Shangdi* Temple is located along the alley and orients to the main alley, which strengthens its recognizability and accessibility; *Yuxiao* Temple is located on the corner of the alley, facing Comity Alley, greatly improving the degree of perceptibility; *Yichun* Temple faces the water, which forms a good fengshui node. At the same time, the Jing temples are closely related to residential buildings, and their volumes harmonise with each other. For example, the *Shangdi* Temple has a street frontage of only four meters, but a depth of sixteen meters, with very little interval to the left and right, and is close to the buildings behind it.

What’s more, the public space system becomes an important spatial carrier for social activities and cultural connotation. In the term of social activities, the *Sanjiao Pu* are responsible for the *Pudu* activities and Deities’ Birthday ceremonies like other *Pu-Jing* communities in Quanzhou. The *Pudu* activities are held at different *Jing* temples on the first day (*Baiyuan Jing*, *Longgong Jing*), second day(*Houcheng Jing*) and nineteenth day(*Fengchi Jing*, *Yichun Jing*) of the seventh month of the lunar calendar every year (Wang, 2017, pp. 292-295). And the activities such as the street-based “parading the *Jing*’s realm” strengthen the sense of community. *Fengchi Jing* even had disputes with the others during the activity of “parading the realm”. This conflict based on the different beliefs of each Jing units, usually arises when the residents of one Jing unit intrude into the other *Jing* unit during the parading along the streets and alleys. This shows that, the belief system of the *Jing* unit and its “spiritual boundaries” are inviolable in the residents' mindset.

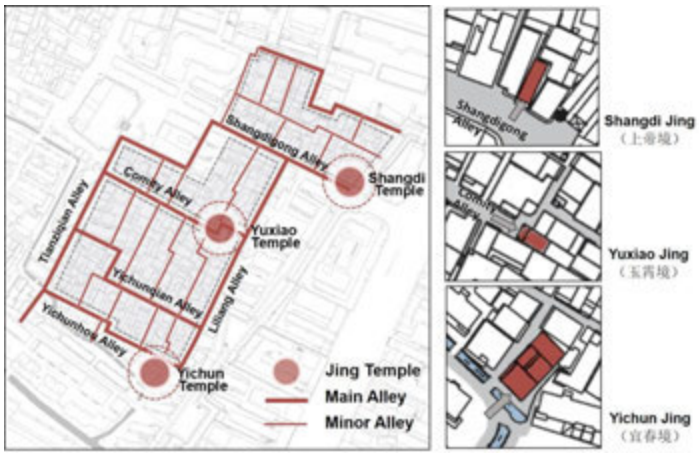

Figure 7 The public space system in "Sanjiao Pu".
Source: the authors.

In the term of cultural connotation, as the spatial carrier of community spirit, the alleys reflect historical memories and collective spirit that further strengthen the sense of community attachment. In the *Sanjiao Pu*, the names “*Shangdigong* Alley”, “*Longgong* Alley” and “*Fengchi* Alley” were all named by the name of *Jing* temples, which reflects the influence of the deities in the *Pu-Jing* communities. The name “*Houcheng Jing*” is derived from “*Houcheng* Street”, which emphasises the meaning of loyalty and honesty, and has greatly influenced the family rules of the residents in this area. The name “Comity Alley” originated from a story about comity. In the early years, when the residents of the Comity Alley built new houses, they would take the initiative to set back a bit of space, so that a public space was formed at the entrance of each house. All of these form the spiritual core of the community.

5. Discussion and Conclusion

Through the analysis of the public space composition and the spatial structure of the *Pu-Jing* community in the old city of Quanzhou, it is found that a well-defined and structurally stable public space system was developed in the *Pu-Jing* communities

during the Ming and Qing dynasties. Through even coverage and relatively high accessibility, a systematic distribution of *Jing* temples has been realised. The public space system with the *Jing* Temple as the core, the streets and alleys as the link, and the belief realm as the unit was formed throughout the city. This grid-based public service system supports traditional beliefs and grassroots governance systems.

Through this public space system, we can further understand the space formation logic and building wisdom reflected in it. On the one hand, the public space has gradually developed a specific structure and a stable pattern, which supports folk beliefs and grass-roots management to be carried out in a long-term and orderly manner. The pattern of public space of Quanzhou's *Pu-Jing* community has the following three main elements. (1) Units of appropriate scope: Folk belief units are further subdivided within the framework established by the authorities. Their scale is determined by population size and the level of social development and their boundaries are delineated by both material and psychological factors, which fosters the formation of a sense of community spatial domain. (2) Universally recognised core: Within each unit, there are *Jing* temples where collective beliefs and public affairs activities are held, serving as a place of spiritual cohesion among residents. Their intentional placement enhances their recognizability and accessibility. The main body of these *Jing* temples (sometimes combined with surrounding areas) typically forms the most influential public space within the community. (3) Stable connecting structure: Relying on the basic organisational elements of the community, streets and alleys connect individual private dwellings to the public centre. Through this spatial pattern, favorable conditions are created for the continuation of social activities and a strong link is established between the secular and spiritual activities of people and specific places. The public space of *Pu-Jing* community has long played an important role in maintaining neighborhood relations and supporting social activities, and thus serves as a vital connection between individuals and their surroundings, allowing the residents to gain a sense of belonging.

On the other hand, the public space system reflects the ability of the civil society to develop autonomously in response to and in coordination with the official management and its relentless pursuit for spiritual meaning-making. The social relations constructed by the bond of common beliefs are fully reflected in the public space system. Folk belief activities, daily life, and administrative affairs are accommodated and integrated within this public space system. The construction process of communities under the *Pu-Jing* system transcends the guidance and management of the authorities, reflecting the practical embodiment of residents' adaptation of daily living spaces to their mental needs. The public and government departments have established a relationship of mutual recognition and influence that works together at the social and spatial levels thereby contributing to the shaping and development of the community. In a stable faith-based social and spatial structure, people perpetuate spiritual activities deep in their memories, and the constant consolidation of their beliefs also allows for the conservation and continuation of the community's collective memory. Today, folk festivals and belief rituals are still active in Quanzhou, and the public space system remains strong and continues to play a promoting role in community identity. The community public space system has become an important carrier of the historical and cultural values and spiritual connotations of the *Pu-Jing* community.

The *Pu-Jing* community has explored a certain degree of autonomous development under official control, and realised the shaping of sense of place. The wisdom of place-making implied in the public space of *Pu-Jing* community provide inspiration for contemporary community governance. The social structure and activities supported by the public space of the *Pu-Jing* community are the core social characteristics of this distinctive community form. This is precisely what modern communities lack— in contemporary community building, the serious homogenisation and economic orientation gradually erode the cultural and social relationships within the community. As a critical entry point for community governance, the planning of public space has become an important means of creating a sense of belonging to the community. When planning public spaces, it's crucial to preserve and perpetuate stable spatial patterns that have been formed over a long period of time to maintain social relationships. We should strive to preserve indigenous populations and their social networks as much as possible while pursuing development, so that the original spirit of the community can be continued over time.

Funding: This research is supported by the National Natural Science Foundation of China, grant number [52078116] and the Postgraduate Research & Practice Innovation Program of Jiangsu Province, China, grant number [KYCX23_0314].

Conflicts of Interest: The authors declare no conflict of interest.

Notes

1. According to the "Political Records", one headman is appointed for each "*Pu*", along with one assistant headman, one constable, and one deputy constable. The headman and the constable respectively manage the "*Pu*" records, and constabulary records. The "*Pu*" records are mainly related to public security and labor duties, specifying the daily duties of watchmen and miscellaneous laborers. The constabulary records mainly address local emergencies, recording the number of watchmen each household under each "*Pu*" should provide.
2. In Quanzhou, the term "普度" (*Pudu*) refers to a traditional Buddhist ritual known as the Ghost Festival or the Hungry Ghost Festival, which is part of Chinese folk religion and also observed in the Buddhist tradition. The purpose of this festival is to release the suffering of the deceased, particularly those who have become "hungry ghosts" due to unfulfilled desires or neglect by their descendants. By the end of the Ming and the beginning of the Qing dynasty, it had developed into a city-wide "rotation" system. Each communities takes turns hosting the *Pudu* festival on specific dates, usually from the fifth to eighth lunar month.
3. The "covenant house" is the place where the grassroots society promotes and formulates the "township covenant" to restrain the townspeople. The "township covenant" combines indoctrination and administrative attributes, and is an extension of the administrative management system at the grassroots level (Kang & Wang, 2022).

Corresponding author at: No.2 Sipailou, Nanjing, Jiangsu Province, 210096

Abstract

In the digital era, public spaces are not only significant venues for daily recreational experiences in the physical world but also the focus of online social platforms. This study, using Guochuang Park in Nanjing, China, as a case study, to explore how online social activities influence the production of virtual spaces on social media platforms and the vitality and landscape of physical public spaces. The research indicates that users on the platform establish new social relationships and virtual spaces through online social activities. Additionally, platform activities can inject vitality into physical spaces but may also lead to some social and spatial issues. Consequently, this study advocates for urban planning to accommodate digital activities while preserving the significance of physical spaces.

Key words

Social Media Platform, Online Social Activities, Public Space Vitality, Production of Space, Local Culture

1.Introduction

With the increasing integration of digital platforms into urban life, numerous urban experiences are being mediated through digital technologies, enhancing the complexity of place experiences and activities. According to a new survey report released by Meltwater and We Are Social, the global social media user population has surpassed 5 billion, accounting for 62.3 percent of the world's population (CNMO Mobile China, 2024). Meanwhile, as indicated by the 52nd Statistical Report on Internet Development in China, as of June 2023, China's internet users have reached 1.076 billion, with 1.03 billion being social media users (CNNIC, 2023). Social media has unprecedentedly permeated into our daily lives, influencing people's perception of the real world and altering public demands (Hyun et al., 2018; Van der Hoeven, 2019). It has become a medium for the public to understand localities and cultures, playing a significant role in exploring, selecting, and experiencing cities. At the same time, people's activities on social media cannot be separated from urban spaces. From text to images and videos, urban spaces are acquired, edited, disseminated, and constructed on the internet by social media platform users, forming a "media landscape" characterised by visual symbols.

More and more scholars are paying attention to the role of social media in urban studies, for example, using social media data with coordinates to analyse the vitality of urban space, urban sentiment, public landscape preferences, and so on (Sun, Shao and Chan, 2020; Dorostkar and Najarsadeghi, 2022; Ma, Yang and Jiao, 2021; Tieskens et al., 2018) Most of the studies seem to treat the text and images in social media as simple "information" or data sources. However, from the perspective of the sociology of media space, social media platforms are not only online information spaces in the physical sense, but also complex social spaces built on the multiple values and social meanings of different groups of people. As Rose (2014) suggested, it is important to regard the

social networks constructed through images, short texts, comments, and ‘likes’ as integral components in the construction of urban places and social relationships. Social media platforms encompass various entities such as capital, influencers, and regular users, whose activities reconstruct social relationships and shape new virtual images (Huang et al., 2021). Online social activities, as a means of publicly conveying visual, textual, or physical representations of urban areas (Bronsvoort and Uitermark, 2022), promote the overlap and interweaving between offline physical spaces and online virtual spaces (Zhou, Lu and Wang, 2023). The "media landscape" based on mass aesthetics is gradually becoming a fundamental element of urban space, guiding its development.

In the digital age, public spaces are not only important venues for people's daily leisure experiences in physical spaces but also the focus of social platforms. As vital social spaces in cities, the functions of public communication and cultural dissemination have been continually amplified and diffused on social media platforms. Therefore, it is necessary to study the influence of social media on urban public spaces in the digital age. Consequently, this paper will take Nanjing GuoChuang Park (hereafter referred to as "GuoChuang Park") as an example, employing a combined quantitative and qualitative research approach to explore the construction and mechanism of public spaces on social media and provide new insights into how social media produces and shapes places.

2. Data and method

2.1 Case background

Located in the Qinhuai District of Nanjing City, Guochuang Park occupies a prime geographical location and serves as a significant public space for both citizens and tourists to visit, relax, and engage in activities within the old city area. Previously, Guochuang Park was the headquarters of the Jiangnan Mint Bureau during the Qing Dynasty and later the Nanjing Second Machine Tool Factory during the Republic of China era. Later, it underwent industrial upgrading and was renovated with market capital. The park officially opened to the public in 2012, largely preserving its original spatial layout, including large-scale production equipment, ancient trees, and some industrial buildings. It also established the Jiangnan Modern Industrial Heritage Park, which effectively showcases the style and characteristics of Chinese industrial architecture. Following the regeneration of Guochuang Park, its internal functions initially focused on office spaces, accommodating fashion and art-related enterprises, software development, design decoration, and other cultural and creative industries. In recent years, with the successive opening of cafes, flower shops, art merchandise stores, and the hosting of public events, the park has gained popularity on social media platforms such as RED, Weibo, and Douyin (Chinese TikTok). It has gradually become a trendy destination for young people to visit and capture moments, making it a popular “Wanghong area(refers to a popular area or district where people visit to take photos

and share them on social media)".

Dubbed as the "Chinese Instagram," RED was founded in 2013. As of 2023, its user base has exceeded 350 million, with approximately 100 million daily active users and 260 million monthly active users. Targeting high-spending urban white-collar workers, post-90s, and post-00s young generations, the platform has a remarkably high female user ratio of 87 percent and a 51 percent proportion of high online spending users. It serves as an interactive platform primarily focused on sharing lifestyles and consumption experiences, representing one of China's iconic social media platforms. Compared to other social media platforms, RED emphasises platform "tones" more. This study aims to use RED as an example to explore the image and production process of Guochuang Park on social media platforms, as well as the influence of platform discourse on material space culture, landscapes, and more.

2.2 Data collection

2.2.1 Interviews and Field Surveys

This study conducted in-depth interviews with relevant participants. Initially, ten influencers (with over 1000 followers) and ten regular users (with fewer than 1000 followers) who had captured content at Guochuang Park were invited to participate. This study aimed to understand their processes and motivations behind capturing images and videos, writing captions, commenting, and liking posts. Acknowledging that the majority of regular users on RED are "silent content consumers," whose online posting and commenting behaviors may not fully reflect the audience's attitudes and behaviors (Turri, Smith and Kemp, 2013), the author conducted offline interviews with visitors to Guochuang Park. Among them, platform users attracted to Guochuang Park by RED were selected, and their reasons for visiting Guochuang Park, purposes, and actual experiences were enquired. A total of 6 visitors attracted to Guochuang Park by RED were interviewed. Then, interviews were held with staff responsible for RED's operation and brand promotion to gain insights into the platform's business model and its collaboration patterns with influencers.

2.2.2 Social Media Data Collection and Preprocessing

(1) Data Collection

In this study, a custom Python programme was used to collect data from RED by searching for the keywords "Nanjing Guochuang Park" and "Guochuang Park". A total of 400 image-text notes were comprehensively collected. After filtering out irrelevant or non-primary content related to Guochuang Park, 314 notes remained for analysis. The collected data was then cleaned to remove emojis and irrelevant characters from the note descriptions. The final dataset is presented in Table 1. Metrics such as likes, bookmarks, comments, and shares collectively reflect the popularity of the notes. Note

descriptions consist of textual content describing the user's cognition and experiential information about Guochuang Park, while images represent the visual representations of Guochuang Park by platform users.

Table 1: Sample Data of Note Content

Users Name	Note Title	Number of collections	Number of likes	Number of Comments	Number of Shares	Upload Time
W***Nao	Exploring stores in Nanjing	This supermarket makes You never want to leave	10114	12308	424	6878	2022-10-04 20:25:41
Note Description			Note Tags			Note Images
This new store in Guochuang Park is truly eye-catching, with a distinctive storefront design that makes you stop in your tracks. Inside, they sell a wide variety of imported beverages, alcoholic drinks, snacks, instant noodles, beef... it's so dazzling! The entire store exudes an American retro vibe, it's really amazing! The photos come out beautifully.			#Note inspiration; #Nanjing travel; #Nanjing photography; #Nanjing store exploration; #Discovering a great Nanjing store; #Weekend store exploration; #Nanjing dining and entertainment; #Nanjing vintage store; #Nanjing internet-famous supermarket			Saved in a folder

(2) Text Data Preprocessing:

All note descriptions undergoing preprocessing were imported into the semantic analysis software ROST CM6. Initially, the segmentation function in the functional analysis module was utilised to divide the entire text into vocabulary units. Following this, any special place names or internet buzzwords unrecognised by the software were manually added to the custom segmentation word list, such as "Guochuang Park," "Daka（take photos and upload them to social media）," and "Tandian(visiting or exploring various stores, usually to discover new products, experiences, or places)," The segmented files underwent frequency analysis, where synonymous words, such as "good for photography" and "good photo spots,"were merged, and meaningless words were removed.

(3) Image Data Preprocessing:

Out of the 314 notes obtained, a total of 2852 images were collected. Using custom Python code, the local images were converted into the Base64 format. Next, the images were automatically imported into analysis using the Tencent Cloud image tagging API interface. The output results were then saved in Excel format, identifying 2793 images with an impressive recognition rate of 98 percent. The obtained data (Table 2) retained the top three-level tag

classifications (category1-3) and their confidence levels (confidence: values ranging from 0 to 100, where higher values indicate greater confidence). Subsequently, tags with similar meanings in this study were standardised, such as merging "flowers" and "floral arrangements" into "flowers", "food" and "diet" into "food". The processed data served as the foundation for analyzing the virtual landscape construction of Guochuang Park.

Table 2: Top Five Examples of Image Recognition Labels

3. Online Social Activities and the Production of Virtual Space in Guochuang Park District

Online social activities have led to the formation of social relationships and societal significance within virtual spaces. The images and text used by users for interaction on social media platforms serve not only as carriers of encoded information but also as contributors to the creation of virtual spaces through user interaction. This chapter begins by analyzing the actors, processes, and motivations of social media activities based on research and interview findings. It then reveals the landscape representation of Guochuang Park on RED through semantic and frequency analyses. Finally, it draws on spatial production theory to explore the production of virtual space.

3.1 Actors, Motivations, and Processes of Activities in Social Media

Based on interviews with influencers, regular users, and platform operators, this study examines the processes and motivations of activities on social media platforms from three perspectives（Figure 1）.

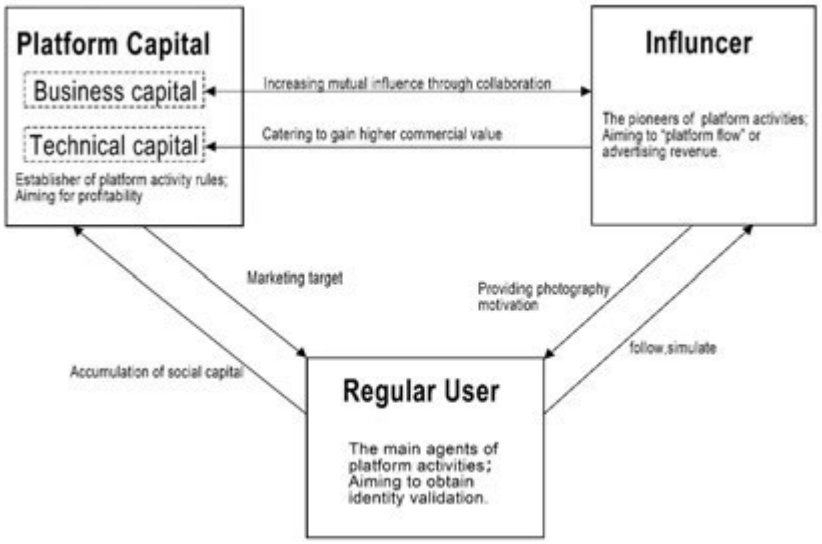

Figure 1. Actors and motivations of social media activity.

3.1.1 Influencers - Pioneers of Platform Activities

Among the 10 influencers interviewed, 4 disclosed that their posts were commissioned advertisements for businesses within Guochuang Park. They stated that before shooting, they would receive specific requirements, and they need to capture images and write captions accordingly, which would then be subject to review and approval before fee settlement. For instance, a promotion for a grocery store required influencers to capture scenes containing crucial marketing elements such as storefronts and brand logos, with the published content needed to incorporate keywords like "American-style" and "retro."

Additionally, the other 6 influencers posted content related to Guochuang Park aiming to "create better content to attract platform flow." As the primary market of RED comprises women and high-end consumers who pursue fashion, influencers tend to select spaces with the potential to create elegant, delicate, and upscale symbolic experiences, using professional cameras and techniques to photograph and produce images. They amplify these aspects through eye-catching titles and exaggerated descriptions to foster identification among regular users. One influencer with 28,000 followers on RED commented:

The backgrounds here are perfect for photography. I brought several sets of clothes to capture photos in different styles for my daily creative content, and the high-end background here naturally attracts attention on RED.

Based on the statistical findings, among the 54 blog posts with popularity levels exceeding 1000 (the sum of likes, comments, saves, and shares), 49 were contributed by influencers, while 5 were from regular users. From this, it can be inferred that influencers with larger online followings occupy significant impact on shaping the discourse during social platform activities and the construction of virtual landscapes.

3.1.2 Platform Users - Followers in Platform Activities

Upon viewing the images and text shared by influencers on RED, regular users are motivated to physically visit the location to obtain embodied experiences. Among the 10 regular users interviewed, all of whom had posted content related to Guochuang Park on RED, 7 indicated that they had "liked" and "saved" photos from influencers for guidance on angles, composition, and poses when taking photos at Guochuang Park. They search for specific angles to capture photos, upload them to RED, and obtain identity recognition through likes, comments, shares, and other interactions, thereby constructing a virtual social circle. One respondent commented:

I refer to photos from other influencers, imitating their poses and backgrounds to take better-looking pictures.

3.1.3 Platform Capital - Establisher of Platform Activity Rules

Based on interviews with official operators and brand promoters of RED, it is evident that RED, as a platform targeting women and high-end consumption, aims to establish a new capital circulation system through commercial spatial strategies. For instance, it aims to generate advertising revenue in industries such as tourism and shopping. The platform releases "influencer recruitment" information through features such us "Dandelion Plaza" or Multi-Channel Network (MCN) agencies, which include details about advertising products, fan requirements, and shooting needs. This facilitates direct interaction between commercial and tourism capitals with influencers. Capital intervention prompts influencers' sharing to be oriented towards capital diffusion, and the purpose is for the audience to see and accept marketing information hidden beneath experience sharing. Furthermore, the platform indirectly influences the activities of both influencers and regular users through "platform flow" (Push mechanism formed by algorithms, the more "platform flow" the more likely to be popular), encouraging users to align with the platform's high-end and sophisticated ideals to the greatest extent possible. Under the “platform flow” mechanism, individuals choose for "premium," "Instagrammable," and "Korean-style" photos as backgrounds to cater to the platform's aesthetics, seeking more exposure and interaction.

3.2 The landscape of Guochuang Park presented by text and images on RED

3.2.1 Landscape Presented by Text

The visualisation results of word frequency are illustrated in Figure 2. Further, verbs, nouns, and adjectives were sorted by frequency, and the top 10 were extracted and summarised in Table 3. Verbs and nouns reflect the social behavioural characteristics of RED users in Guochuang Park, including users' activities and the main purposes of visiting Guochuang Park. Adjectives reflect RED users' subjective perceptions of Guochuang Park. According to the sample results, "taking photos" is the most common activity RED users engage in at Guochuang Park, followed by "strolling," "eating," "Daka (take photos and upload them to social media)," "Tandian (visiting or exploring various stores, usually to discover new products, experiences, or places)," "buy," "city walk," "exhibition viewing," etc. Apart from "Guochuang Park" itself, "Café " "supermarket," "restaurant," and "flower shop" are the main destination points mentioned in the samples, followed by "buyer's store," "factory," "exhibition," "boutique," "museum," etc. RED users consider Guochuang Park to be very photogenic, portraying it as a space characterised by "retro," "American style," "artistic," "niche," "Korean style," "atmospheric," "Wanghongable (a specific place that is highly visible and talked about on social media)," "valuable," and "creative."

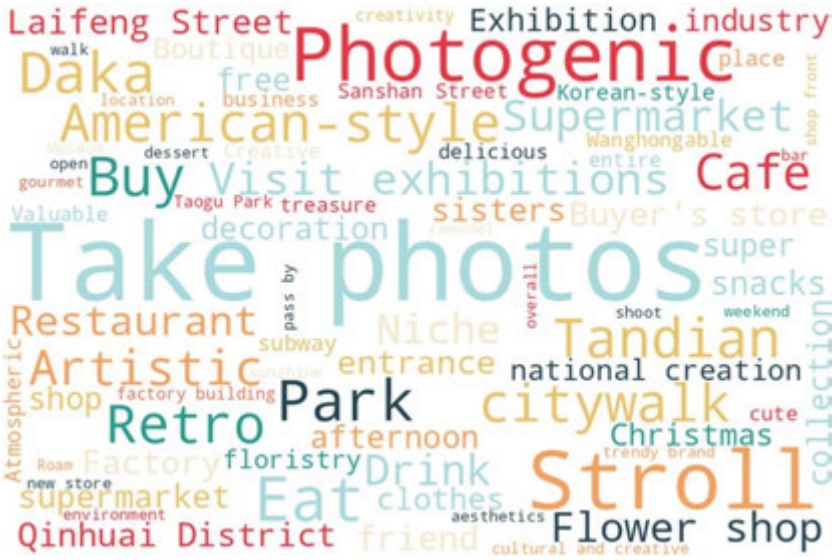

Figure 2. High-frequency word cloud.

Table 3: Frequency Statistics Results

Verb	Frequency	Noun	Frequency	Adjective	Frequency
Take photos	398	Park	99	Photogenic	176
Stroll	207	Café	73	Retro	87
Eat	115	Supermarket	57	American-style	84
“Daka”	98	Flower shop	49	Artistic	72
“Tandian”	90	Restaurant	48	Niche	50

Buy	89	Buyer's store	46	Korean-style	31
citywalk	85	Factory	45	Atmospheric	30
Visit exhibitions	60	Exhibition	40	"Wanghongable"	29
Drink	53	Boutique	32	Valuable	29
Roam	16	Museum	21	Creative	26

3.1.1 Landscape Presented by Image

According to the tag results obtained from sample image recognition, the "person" tag appeared most frequently, occurring 1212 times, accounting for over 40 percent of the total. Among them, 952 instances were in the first-level tags, 155 in the second-level tags, and 105 in the third-level tags. Following closely are scenes such as streets, art, food, flowers, and architectural exteriors, comprising the top 5 percent, as shown in Table 4.

Table 4: Image tag word frequency statistics results

Category Label	Frequency_ category1	Frequency_ category2	Frequency_ category3	Sum
People	952	155	105	1212
Street	25	408	103	536
Art	168	189	138	495
Food	187	108	86	381
Flower	122	138	84	344
Architectural facade	94	108	123	325
Cloth	52	110	128	290
Furniture	79	97	92	268
City	60	81	71	212
Retail	75	69	24	168
Tree	48	48	40	136
Transportation	45	56	27	128
Market	28	39	53	120
Christmas Decoration	38	26	23	87
Restaurant	27	27	30	84

In summary, under the intervention of platform capital and users' pursuit of “platform flow”, Guochuang Park on RED has been constructed as a place predominantly featuring various high-end trendy shops such as cafes, restaurants, and flower shops. It is characterised by its retro, artistic, and niche ambience, suitable for photography, exploring shops, and leisurely city walks, catering to a bourgeois consumption experience.

3.3 Production of Virtual Space in Social Media

Lefebvre's theory of spatial production (Lefebvre, 1991) proposes a triad of space to answer how space is produced: (1) Spatial Practise: the perceived environment involving the concrete shaping and Practises of spatial production and reproduction; (2) Representations of Space: the imagined space controlled and dominated by the will of power and capital, representing the spatial projection of capitalist ideology and imagination; (3) Representational Space: the social relations that emerge from the interaction between users and the environment (Xia, 2019). The theoretical focus on the sociality of space corresponds to the essence of social media platforms—which is the social construction of various social subjects. Therefore, the author will draw on Lefebvre's theory of spatial production to explore the mechanism of constructing virtual landscapes in social media through the three dimensions of "Spatial Practise," "Representations of Space," and "Representational Space."（Figure 3）

3.3.1 Spatial Practise: Concrete Operations and Practises in Constructing Social Media Landscapes

Platform users (including influencers and regular users) are the direct producers of social media landscapes. They select shooting locations in physical spaces, establish local connections, and create media products through text, images, videos, etc., essentially practising place, space, and body. Firstly, based on the audience characteristics of RED, users tend to choose spaces that may create symbolic experiences of delicacy and fashion. Throughout the process of image production and text embellishment, they continuously magnify these aspects, providing imaginative spaces for the audience through mental maps and role symbols (Speake, Kennedy and Love, 2023), thus inducing group identification.

3.3.2 Representations of Space: Capital Intervention and Interference

Platform capital mainly affects the spatial Practises of influencers and regular users in two ways: through direct commercial capital and through platform technical capital—the "platform flow" generated by algorithms—to amplify the imbalance in power relations. Under the influence of advertisements and "platform flow", influencers' activities on the platform are both restricted by commercial cooperation contracts and require catering to platform algorithm to enhance their commercial value (Kaymas and Yakin, 2021). The collaboration between platforms and influencers indirectly influences the decisions and behaviors of regular users. In this process, platform capital amplifies the imbalance in power relations (Söderström and Mermet, 2020) and cleverly reconstructs the spatial Practises and representations of image landscapes in the virtual world by controlling the code and data in virtual network spaces to circumvent regulation in the real world.

3.3.3 Representational Space: Social relationships shaped by platform users

Platform users are also audiences in virtual spaces. After viewing media landscapes on screens, they may visit the places presented in the media in the real world, or explore based on pre-constructed spatial imagination maps, and may discover differences between media landscapes and real landscapes in the process. Moreover, users may imitate others' perspectives in photography for check-ins or engage in new creations, continuously shaping the reproduced space in social media through daily activities. Additionally, through interactions, users form virtual social networks, where metrics such as "followers," "likes," "saves," "comments," etc., seem to visualise the accumulation process of social capital in virtual spaces and construct social relationships within virtual spaces(Speake, Love, and Kennedy, 2023).

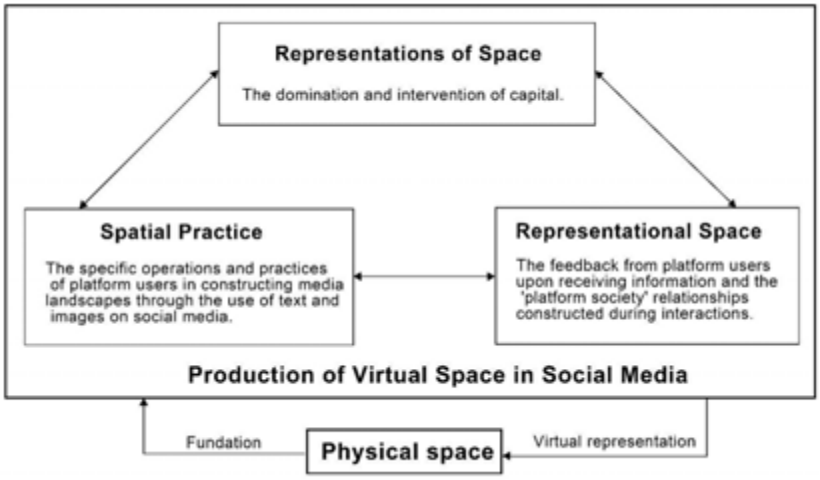

Figure 3. Production of virtual space in social media platforms

4. The Vitality and Landscape of National Innovation Park Blocks Under the Influence of Online Social Activities

4.1. The Conversion of Online-Offline Vitality

Spaces with physical environments can be accessed and experienced both offline and through social media platform, with their popularity online being translated into vitality offline. The positioning of Guochuang Park as "creative" and "artistic" aligns perfectly with the style of RED, and the exposure from RED undoubtedly brings more popularity to Guochuang Park. Influencers and other ordinary platform users seek specific angles to capture photos and upload them on the RED platform, where they gain identity recognition and construct virtual social circles through likes, comments, shares, and other interactions. In this process, platform users utilise the street backgrounds of Guochuang Park to enhance their image in the "platform society" (Walters and Smith,

2024), continuously attracting others and thereby increasing the vitality of public spaces. For instance, one interviewed blogger stated:

Many people tagged their friends in my posts, inviting them to come to Guochuang Park for photos.

Among the 10 randomly interviewed visitors to Guochuang Park, 6 were attracted through RED, 2 through other social media platforms (such as TikTok, WeChat, etc.), and the remaining 2 through other channels. Among the 6 visitors attracted by RED, 4 respondents roughly followed the "play map" from RED's posts, while the other 2 mentioned they just wandered around. Additionally, one respondent mentioned discovering Guochuang Park through RED and finding it different from what was seen online, finding the industrial culture here very appealing:

I came across Guochuang Park on RED. Today, I had no classes, so I came over. Before coming, I didn't know it was an industrial site, but after arriving, I found it more interesting than what I has saw online. I even took a photo in front of the building with the slogan "The helmsman relies on the wind."

Moreover, RED indirectly increases the vitality of physical spaces by enhancing the platform's influence through official offline events. For example, in the "Strolling in the Park Is Serious Business" event initiated by RED in March 2023, four shops in Guochuang Park collaborated with RED, namely, "Some No Some Art Store," "glue," "ETE Supermarket," and "bamboo today cafe." Participants were required to post a note on strolling in parks in Nanjing with the hashtag "#Strolling in the Park Is Serious Business" to receive a free picnic mat from the above-mentioned stores. Many residents and tourists participated in this activity, and Guochuang Park also became their destination for participating in the event. One of the respondents who participated in this activity said:

I saw this event on RED and found that there are several picnic mat pickup points in Guochuang Park. I wanted to check in before, and now I can also get a picnic mat for free.

4.2 The Transformation of Landscape through "Behavior-Space"

UGC on RED, driven by algorithms, influences people's aesthetics and lifestyles. We have ample reason to believe that digital platforms can also have material consequences (Bronsvoort and Uitermark, 2022). Through a series of online-offline activities brought by RED and the interaction among platform users, an increasing number of images capturing the "best angles" are uploaded to social platforms. In the process of mechanical photography, space seems to become a sort of circulating "commodity." Taking photos at "popular spots" is a typical behavior among RED users in Guochuang Park. People seem to be controlled by space and its underlying rules, consciously or

unconsciously engaging in the same behavior, partially losing subjectivity (Li and Wang, 2024). Users seek to obtain "identity inspired by object images" subconsciously and produce the same images continuously, using the symbolic image of a place as proof of a successful visitation (Spierings and Van Houtum, 2008). Subsequently, re-uploading images creates a continuous, repetitive, and widespread dissemination, thus eliciting an aesthetic resonance effect.

The culture and space of Guochuang Park District seem to cater more to the needs of social media dissemination, flattening into backgrounds for photography. Other cultural and creative industry parks, such us Dongxinhe Creative Park in Hangzhou, DEMOHOOD in Ningbo, and N150 Creative Park in Jinan also appear to be shaping images of "niche," "artistic," and "creative" spaces. They promote themselves as trendy popular spots by introducing formats such as cafes, upscale restaurants, galleries, and boutiques to enhance the vitality of the parks. The “Balcony Bowkonts” and the wall-climbing Santa Claus, which started to trend on Wukang Road, and the Rose Waterfall, which has become popular on Summer Palace Road in Nanjing, can also be found in the National Creative Park. Different "creative industry parks" and "Wanghong districts（district which is very popular on social media）" learn from each other, imitating each other's landscape construction methods and development models, resulting in similar evolutionary trends in the presentation of material space landscape, structure, and function, and the unique personality of space is diminishing.

Furthermore, driven by social media, local culture constantly caters to globalised consumerism, often turning spaces into "consumption spaces" with "local culture" as selling points. Dominant cultures oriented towards platform capital and economic development may potentially infringe upon local cultures. For instance, "ETE American-style Supermarket" promotes itself on RED as an "American style" hot spot for photography, while the streets where Glue clothing store and Today shop café are located are also advertised by influencers as "Korean streets." Under the discourse construction of RED, the industrial historical culture in Guochuang Park is marginalised or even dissolved, and external culture and online culture gradually dominate the discourse, creating industrial historical districts as symbolic space landscapes that meet the mass demand for "photo taking." Such uniform constructions may lead to the loss of sustainable development charm in the districts.

5. Conclusion

As our urban imagination increasingly builds upon digital platforms, studying their roles in contemporary cities becomes increasingly significant. In today's society, where social media pervades all aspects of life, Guochuang Park serves not only as an industrial relic but also as a hub for original artistic endeavours, a hotspot for creative industry development, an emerging tourist destination, and a popular spot for photography. Throughout its development, it continually breaks its geographical boundaries, promoting itself in cyberspace, expanding its local influence, and

establishing new local meanings. In this context, researching the virtual construction of Guochuang Park on social media and its impact on physical space is meaningful.

This paper utilises UGC on social media platforms to analyse the activities of platform users in both social media and urban spaces. It argues that pursuing commercial value and obtaining identity recognition are the primary purposes of influencers and regular users respectively. They use physical spaces as the background for photography, engaging in interactions on social platforms, forging new social relationships, and driving the production of virtual spaces. However, their activities are influenced by platform commercial capital, often resulting in virtual space production that aligns with platform commercialisation strategies. While activities on social media platforms can inject vitality into physical spaces, the "platform flow" mechanism and capital may homogenise behavior, flattening space into mere photographic backgrounds, and eroding local culture under the invasion of external culture.

Social media platforms are mobilising user capital, potentially altering users' behaviors, spatial usage patterns, aesthetics, and design standards (Chang and Spierings, 2023). In this process, the construction of platform discourse seems to generate new spatial production modes. Spatial production in social media involves capital using virtual space as a tool to reshape power relations in the real world, aiming for capital diffusion (Senyao and Ha, 2020), which may impact gentrification, community change, spatial aesthetics, local culture, spatial justice, among other aspects (Törnberg and Uitermark, 2022; Duignan et al., 2021; Polson, 2024). The representational power of electronic media cannot be overlooked. It is essential to explore how different types of social media dynamics emerge from urban spaces and feedback into urban changes in future research.

Faced with the strong influence of the silicon-based civilisation, public spaces in various Chinese cities are undergoing extensive updates in social interconnection functions. Therefore, it is necessary to prioritise the needs of digitalisation for physical public spaces in the planning process, integrating online and offline activities into urban scenes to enhance spatial vitality. However, urban spaces should not become mere consumer products on the internet; instead, they should evolve into "carbon-silicon hybrid spaces" that are in line with the development of the times and play a long-term positive and active role in local development and social relations.

Furthermore, effective guidance and control measures should be taken to guide and supervise platform capital, preventing excessive capital in the construction of social media platform discourse, which may lead to the passive dissolution and alienation of locality. It is crucial to prevent material spaces from becoming subservient to digital spaces.

Enhancing suburban life with Victor Gruen

Giulio Giovannoni
Department of Architecture, University of Florence, 50100, Florence, Italy
Email: giulio.giovannoni@unifi.it

Abstract
The essay deals with the theme of the prejudices that prevent us from designing vibrant suburban spaces and argues that we should rediscover Victor Gruen's lesson in doing so. The first part analyzes the consequences determined by the advent of the car and the urban explosion on public spaces. The second section of the essay develops a critical reflection on the way we look at suburban collective spaces and proposes a change of perspective. The concluding section of the essay contains some specific proposals, of a planning and normative kind, to improve the quality of collective suburban spaces.

Keywords: urban explosion; public places; collective spaces; non-places; Victor Gruen

1. The urban explosion and its effects on public places

The urban growth caused by industrialization and urbanization and therefore the subsequent crisis of the historical mobility networks has led to the inevitable abandonment of the traditional way of conceiving and designing public spaces. Much literature has been written on the functional separation brought about by the emergence of the principles promoted by the Modern Movement and urban planning based on zoning and on functional separation. This literature, with its often nostalgic accents, has not been followed by a similar discussion of the implications that the transformations described above have had on the relationship between public space and transport infrastructure and consequently on the character of new suburban public spaces. In fact, the separation of large traffic flows from urban centers entailed the almost complete decoupling of transport infrastructures and urban public spaces. The urban crisis took place at staggered times based on the level of industrialization and motorization of different countries and cities. In large American cities, such as Boston, Chicago and New York, it manifested itself as early as the turn of the 19th and 20th centuries.
The solutions adopted in the different countries were diverse. In the United States the removal of large traffic flows from the Central Business Districts was going to damage huge economic interests, so it was tried to safeguard the accessibility of these through the creation of true urban highways. These entailed huge public works and massive demolitions inside city centers. The case of the Central Artery, built in Boston in the 1950s as the John F. Fitzgerald Expressway, is one of the most emblematic. Funded with $100 million worth of bonds, it involved the destruction of large parts of the city's most central neighborhoods and was met with enormous opposition by residents and businesses that were being harmed (Tsipis, 2001). In the mid-1970s, due to its devastating effects on urban livability, plans were already being made for its undergrounding. At the beginning of the 1980s the first plans were drafted and after seventeen years of work, in 2007, the new underground freeway was inaugurated. This further titanic work of engineering had cost, at current values, the gigantic sum of 24 billion dollars (Moskowitz, 2012). Despite these huge investments, however, the attempt to safeguard the economic and financial interests of the Central Business Districts was doomed to failure. Demographic, financial, commodity and mobility flows would have shifted inexorably to suburban areas, triggering ruinous trajectories of decline and of social and material degradation in the downtown areas. In some cases, these central spaces, once thriving business districts, would never again experience a real recovery process.

In Italy, these phenomena began much later. The rate of motorization began to grow exponentially in the late 1950s. This, in turn, determined a real crisis in the now obsolete historical mobility network. Already in the mid-1960s, the first experiments in pedestrianizing some parts of the historic centers began. At the same time, large-scale programs for the construction of new infrastructures and for functional decentralization were conceived. These projects adopted different planning models. To remain in the Florentine area, the Detti Plan, adopted in 1962, proposed a model of decentralization organized along a major axis connecting Florence to Prato and hosting the main commercial and directional facilities. However, compared to the rapidity with which the 'suburban flight' reconfigured the economic and social geography of large American cities, in Italy the decentralization process took place in a much slower and incomplete manner, reaching a degree of completion only in the last thirty years.

In fact, until a few decades ago the regional system was still urban-centric. Each portion of the urbanized countryside gravitated towards a historic center where all services (commercial, directional, etc.) were located. Today, such a hierarchy has definitely collapsed and historic centers are just nodes, often peripheral, of wider regional systems whose barycenter is in the periphery. The main commercial, service, and directional functions, both public and private, have moved towards the edge of urban areas, close to major arterial routes. New social spaces have arisen in peripheries as well: from outlets to sports facilities, from multi-theaters to gas stations, from entertainment centers to parking lots. These same historic centers are used in very similar ways to shopping malls: you get the car, find parking in a multi-story garage, and plunge into a crowd of consumers. In terms of regional hierarchies we have shifted from a polycentric system to a centrality that is dispersed throughout the entire urbanized territory.

Although suburban studies made considerable progress in recent years, most scholars and politicians are still bound to a pre-modernist idea of the city. They go on conceiving the city and the country as two totally distinct worlds. Metaphors alluding to urban walls (urban boundaries, green walls, etc.) are largely used to symbolically or physically mark boundaries that only exist in our minds. Wachsmuth (2014) pointed out that these conceptions have strong ideological connotations. In most suburban peripheries such boundaries are simply impossible even to imagine. Aside from the fact that a sharp distinction between city and country never existed in the past (Bruegmann, 2005), the problem with this way of conceptualizing the territory is that it obstructs our capacity to solve real problems and to seize the many opportunities that contemporary suburban landscapes offer (Sieverts, 2003; Ingersoll, 2006). New social spaces are assimilated into the non-places of an alienated existence. The corollary of such an absurd postulate is that nobody takes up the task of controlling and guiding the production of these spaces in order to maximize the benefits to society. This is paradoxical even in historical terms: the shopping mall was invented in 1940s by a socialist utopian, Victor Gruen, in order to create a place for public life in the suburbs; in his visionary Broadacre City, Frank Lloyd Wright conceived gas stations as community centers. A paradigm shift is a prerequisite for better-balanced development: the shift consists of recognizing that the periphery has become the center.

2. The rhetoric of 'non-places': a way of looking that obstructs our view.

The concept of non-places, introduced by Marc Augé in his 1994 book of the same name, is often used to describe most of the spaces that characterize the contemporary city. This use is widespread among architects and urban planners, who often qualify as 'non-places' spaces ranging from shopping centres to airports, car parks, service stations, public housing districts, and the suburbs in general. I believe that the concept of the non-place is an ideological device that is both useless and harmful. Its uselessness derives from its inadequacy to describe any

social-spatial system. In fact, by qualifying a space as a non-place, a generic negative connotation is attributed to it and, in fact, its deeper understanding is precluded. The harmfulness of this concept is a direct consequence of its futility. By preventing us from understanding the complexity of the social dynamics that take place in space, the concept of non-place ends up by greatly limiting the design capacity of architects, urban planners, and politicians. This is particularly regrettable, since the spaces considered non-places by dominant urban thinking correspond to much of the contemporary city and its suburbs. Therefore, it stands to reason that the frequent use of this concept would manifest a widespread attitude that is unscientific, ideological and nostalgic to the study and planning of the contemporary city and suburban areas.

What Augé defines as non-places constitute the main social structure of the contemporary city. This social framework has been little studied by academics, and neglected by architects, urban planners and politicians, who have only in a handful of cases been able to plan and design it in a way that is appropriate to its economic and social function. I argue that by challenging Augé's concept of non-places, and proffering a theory that instead elevates and promotes these important spaces, it would be possible to manage and organize them appropriately as well as explore their full potential through architectural and urban design.

For Augé, non-places are the product of what he defines with the neologism 'supermodernity' (surmodernité), that is, the current condition characterized by three main figures of excess: overabundance of events, spatial overabundance, and the individualization of points of reference. For Augé, supermodernity, that is to say the present era characterized by excesses, essentially produces non-places, i.e. spaces without history, identity and social relations[1]. The concept of non-place is defined by Augé in opposition to that of anthropological place. Of variable size, the anthropological place is such insofar as it is an entity invested with meaning. It is also concerned with identity, as a place of birth and of self-identification; relational, as the object of a shared identity as well as support of social relations; and historical, as it is stable over time and it is possible to find in it points of reference that are considered as fixed and immutable. On the contrary "a space which cannot be defined as relational, or historical, or concerned with identity will be a non-place" (Augé, 1995, p. 77-78).

Although the title of Augé's book speaks of the 'anthropology of supermodernity', his definition of non-places – and his repeated classification of their features – is not presented as a research hypothesis to be verified through accurate anthropological work but is a kind of 'ideal type'.[2] It is interesting, therefore, to consider the concept of non-place in light of Max Weber's definition of ideal type: "It is a conceptual construct (Gedankenbild) which is neither historical reality nor even the "true" reality. It is even less fitted to serve as a schema under which a real situation or action is to be subsumed as one instance. It has the significance of a purely ideal limiting concept with which the real situation or action is compared and surveyed for the explication of certain of its significant components." (Weber, 1949, p. 93)

If we assume that Augé's non-place falls into the category of the ideal type described by Weber, what is missing from the work of the French anthropologist is the comparison of this

[1] "[N]on-places are the real measure of our time; one that could be quantified – with the aid of a few conversions between area, volume and distance – by totalling all the air, rail and motorway routes, the mobile cabins called 'means of transport' (aircraft, trains and road vehicles), the airports and railway stations, hotel chains, leisure parks, large retail outlets, and finally the complex skein of cable and wireless networks that mobilize extraterrestrial space for the purposes of a communication so peculiar that it often puts the individual in contact only with another image of himself". Augé (1995, pp. 51-52).

[2] This is somehow recognized by Augé himself when he states: "Place and non-place are rather like opposed polarities: the first is never completely erased, the second never totally completed; they are like palimpsests on which the scrambled game of identity and relations is ceaselessly rewritten" (ibid. p. 79).

concept with the empirical reality of which Weber speaks in the above definition. Spaces that are identified as non-places are never described and studied by him except in a generic, abstract and atopic way. This is the case when he speaks of shopping centres, which he claims are experienced "through gestures, with an abstract, unmediated commerce; [and that are] a world thus surrendered to solitary individuality, to the fleeting, the temporary and ephemeral" (Augé, 1995, p. 78). Similarly, he imagines a hypothetical user of non-places as a "foreigner lost in a country he does not know (a 'passing stranger') [who] can feel at home there only in the anonymity of motorways, service stations, big stores or hotel chains" (p. 106). Also following this model are his descriptions of airports and stations, perhaps the spaces that are closest to the ideal type conceived by Augé.

Now, as we have seen, the non-place is defined as the negation and opposite of the place. The latter is such only if it is historical, identitarian and relational. Even this definition is questionable to say the least. In fact, by prioritizing the characteristics of history and identity, the concept of place thus refers to a narrow and potentially perverse conception of the relationship between space and community, one in which those whose histories and identities are not rooted in the place where they live – who make up a considerable and growing share of the population of every contemporary city – might in theory have no right to claim to belong to that community or territory. In my opinion, the notion of place defined by Augé risks interpretation in this narrow and exclusionary sense.

Being representative of the current era, non-places describe what Henri Lefebvre would have defined, albeit in different words, as the production of abstract space in contemporary capitalist society. Behind the concept of non-place, in fact, there is on the one hand a general criticism of urbanization, and on the other, a yearning for the pre-industrial city. In fact, Augé's book is dominated by a clear nostalgic accent, which can also be discerned in works by many of the great critics of contemporary urbanization, including Lefebvre. It is important to give due attention to the persistent longing for the old city, as it continues to have profound effects on the way space is being produced today.

The notion of non-place developed by Augé in 1992 is part of a broader narrative characterized by nostalgia for the city of the past and by phobia of the contemporary city. Nostalgia for the city and countryside of the previous era has shaped the planning debates in Europe and the United States since their originations (e.g. Secchi, 1984, Boyer 1983). I will focus in particular on Lefebvre, an author who had a strong influence on the urban debate and policies in Europe since the early 1960s. In the Anglo-Saxon context, the scholar who most contributed to what we could call 'suburbs-phobia' is certainly Jane Jacobs (1961). Lefebvre's critique of contemporary urbanization is based on the Marxist concepts of work and product, use value and exchange value. While use value is related to the utility of a good, exchange value refers to its selling price. For Lefebvre, contemporary urban growth has abandoned the traditional urban model in favour of abstract urbanization. Whereas the city of the past was a work (oeuvre) and was socially experienced according to its use value, contemporary urbanization is conceived as a product to be exchanged on the market as any other good. The shift from the traditional city to urbanization, determined by the advent of industrialization, causes the disappearance of community relations typical of pre-industrial societies: in fact, contrasting with today's model, in the past the city was considered a work of art to be used and enjoyed without any consideration for profit.

> *This city is itself oeuvre, a feature which contrasts with the irreversible tendency towards money and commerce, towards exchange and products.*

> *Indeed the oeuvre is use value and the product is exchange value. The eminent use of the city, that is, of its streets and squares, edifices and monuments, is la Fête (a celebration which consumes unproductively, without other advantage but pleasure and prestige and enormous riches in money and objects).* (Lefebvre, 1996, p. 66)

In addition to being poorly supported in terms of historical research, this way of representing the old city is quite idealized. In contrast, the representations of the periphery provided by Lefebvre are strongly dystopian. Also, they have more than one point in common with Augé's descriptions of non-places.[3]

It is not difficult to take a contrasting viewpoint and see how, in many cases, the monumental splendour of historical cities had opposite meanings to the positive ones attributed to them by Lefebvre. For example, many of the old monuments were nothing more than the architectural and urban codification of a deeply hierarchical, unjust and authoritarian social and political order. Not to mention the baroque monumentality of Haussmann's Paris, that was produced by policies of social and spatial purification of the centre of Paris, to the detriment of the lower classes. Correspondingly, it is possible to find numerous positive representations of contemporary mobility as a symbol of freedom and emancipation, both at class and gender levels.

Such a perspective on the contemporary city is deeply rooted in the urban debate in the West, and has significant effects on the way we understand and govern it. In the United States, the condemnation and demonization of sprawl and suburbs commonly perpetuated by scholars (e.g. Davis, 1990; Duany, Plater-Zyberk and Speck, 2001; Silverstone, ed., 1996) and policy-makers prevented them from grasping the complexity and diversity that certainly characterizes the American suburbs, in terms of social and ethnic composition, built environment and lifestyles. Only a small number of more recent studies have attempted to account for this complexity (Nicolaides and Wiese, eds., 2006; Archer , Sandul and Solomonson, eds., 2015).

In Italy and Europe, the myth of the city of the past is even more deeply rooted. In the German context, Thomas Sieverts (2003) argues that the myth of the compact city of the past prevents us from correctly understanding and designing peripheries, i.e. the living space of most people. For this reason, he focuses his attention on the analysis and design of the Zwischenstadt, or in-between city, that is, that hybrid mixture of city and countryside which is one of the main features of most suburban areas. On a similar slant, Rem Koolhaas speaks of the historical centres of the past as symbolically strong apparatuses that are now completely inadequate to support articulated and complex urban systems. And yet, their cultural and symbolic weight prevents the 'new city' from being understood and designed for what it is (1994, pp. 1248-9):

> *Identity centralizes; it insists on an essence, a point. Its tragedy is given in simple geometric terms. As the sphere of influence expands, the area*

[3] "Urban reality, simultaneously amplified and exploded, thus loses the features it inherited from the previous period: organic totality, belonging, an uplifting image, a sense of space that was measured and dominated by monumental splendor. It was populated with signs of the urban within the dissolution of urbanity; it became stipulative, repressive, marked by signals, summary codes for circulation (routes), and signage. It was sometimes read as a rough draft, sometimes as an authoritarian message. It was imperious. But none of these descriptive terms completely describes the historical process of implosion-explosion (a metaphor borrowed from nuclear physics) that occurred: the tremendous concentration (of people, activities, wealth, goods, objects, instruments, means, and thought) of urban reality and the immense explosion, the projection of numerous, disjunct fragments (peripheries, suburbs, vacation homes, satellite towns) into space." (Lefebvre H., 2003, p. 14).

> *characterized by the center becomes larger and larger, hopelessly diluting both the strength and the authority of the core; inevitably the distance between center and circumference increases to the breaking point. In this perspective, the recent, belated discovery of the periphery as a zone of potential value —a kind of pre-historical condition that might finally be worthy of architectural attention— is only a disguised insistence on the priority of and dependency on the center: without center, no periphery; the interest of the first presumably compensates for the emptiness of the latter. Conceptually orphaned, the condition of the periphery is made worse by the fact that its mother is still alive, stealing the show, emphasizing its offspring's inadequacies. The last vibes emanating from the exhausted center preclude the reading of the periphery as a critical mass. Not only is the center by definition too small to perform its assigned obligations, it is also no longer the real center but an overblown mirage on its way to implosion; yet its illusory presence denies the rest of the city its legitimacy.*

In fact, consolidated representations of historical cities and of contemporary suburbs strongly inhibit our ability to interpret and design peripheries. Augé's book certainly belongs to this type of polarized utopian/dystopian representation, and is widely used by architects and planners to describe the contemporary city in opposition to the city of the past. My thesis is that the so-called non-places (i.e. mobility infrastructures, shopping centres, multiplexes, service stations, etc.) that the French scholar speaks about and that are strictly connected to the new mobility networks play the role of 'squares' – understood as the traditional places of urban sociality – of the contemporary city. However, while the debate on the dialectics between the centre and the periphery is now quite consolidated, that on the relationship between traditional public spaces/mobility infrastructures and the new social spaces on the periphery is much less developed.

2. Learning from Victor Gruen: designing 'non-places' as the social infrastructures of the suburbs.

Our inability to understand the role and potential that so-called 'non-places' assume in contemporary society determines a more general incapacity to grasp the demand for sociality that exists in the periphery. What is it that obstructs our gaze and inhibits our planning? According to Sieverts, the persistence of the 'myth' of the old town is responsible. From Europe to the United States, suburbs and suburban areas are generally ostracized, because they do not fit with the traditional and stereotypical image of the city. To be seen in this way, a city must correspond to the urban canons of density, of mixed-use, of a certain relationship between solids and voids. These canons, codified in Jane Jacobs's urban theory and easily found in European and North American cities before the First World War, prevent us from considering as a 'place' whatever does not conform to them. From this perspective, only the square and the street possess full dignity as public spaces. Koolhaas, as we have seen, maintains that the centre, with its symbolic weight, continues to orphan the periphery and prevent us from appreciating its real importance and relative weight in contemporary urban systems. However, his analysis, just like Sieverts's, limits itself to providing an overview of the periphery as a whole without considering its social spaces. This consolidated view of traditional public spaces as the only legitimate social spaces of our cities has strong negative implications for the ways in which contemporary spaces are regulated at a functional, infrastructural and performance level, and designed at an architectural and social level.

Despite the recognized importance of shopping centres in contemporary society these spaces continue to be considered by many the enemies of the retail trade, the ‘bad giants’ who close the shops of the town centre. Polemicists of the 'small shops closing syndrome' do not acknowledge the facts that the majority of the population has been living in the suburbs for some time now, and that many lack the resources to go shopping in the city centre. However, in the United States, this rhetoric has been swept away by the advent of electronic commerce and by the subsequent phenomenon of 'dead malls'. Now that shopping centres are disappearing, their loss is also being lamented. These spaces, after all, have enjoyed considerable importance in the social and cultural history of tens of millions of Americans (Kurutz, 2017). The rapid evolution of e-commerce could quickly make Italian and European shopping centres obsolete as well. The fact remains that these centres have been and still are exclusively regulated as consumption spaces. For example, the legislation in force in Tuscany, drawn up on the basis of the national framework legislation, sets out the number of parking spaces that must be provided in relation to the selling surface. It also limits the number of large shopping centres that can be built. However, it does not give any guidance about the range of public and private functions that should be realized, the accessibility that should be provided for the various modes of transport (cycling, walking, driving, public transit), the necessity of creating some spaces of an exclusively public nature and that of providing adequate urban furnishings (such as seating areas and the like). For this reason we should rediscover today Victor Gruen’s lesson, get rid of our prejudices on the suburban world and on their collective, most often privately owned, facilities. The Austrian-American architect, known as the inventor of the American mall, conceived his commercial suburban outlets as vibrant collective spaces, comfortably usable with their abundant seating, careful and meticulous landscaping, and ample space for collective and social activities (Gruen and Smith, 1960; Hardwick, 2004). Although privately owned and albeit not embedded in the urban fabric of the historic city, Gruen’s commercial centers were real community centers and hosted concerts, festivals, county fairs, political events: they were much better than the anonymous and gloomy non-places imagined by Marc Augé.

Similar considerations, taking into account the difference in scale and the smaller radius of influence, can be made in relation to the planning of petrol stations. Although most of the petrol stations are exclusively technical facilities, some of them may well become, as recent research has demonstrated, small centres for the local community (Giovannoni, 2017). Urban planning and fuel distribution plans should acknowledge this reality and rework their regulations to recognize the difference between facilities providing simple petrol pumps and car washes, and the integrated service stations that could have a wider role in serving local communities. For the latter, functional hybridization with complementary social and commercial activities should be encouraged, and better accessibility from the surrounding residential areas should be ensured.

This reconceptualization should involve a much more varied set of 'types' of new public spaces, which would include outlet villages, airports, multiplex cinemas, service stations, large car parks and sports facilities. Outlet villages could be thought of as gates that connect the highway network along which they are located with the surrounding regions. By integrating commercial functions with tourist and social services, the economic and social benefits of these large magnets could be distributed over wider regions. The airports, usually conceived as negative elements that reduce the real estate values of the surrounding areas, could be transformed into generators of positive externalities, as places of attraction in which

to dine at night while observing the air traffic, to visit exhibitions and commercial spaces, to avail of personal services, and to participate in political and social events.

The transformations I have described above are in part already underway. However, they are almost exclusively led by big economic actors, without any capacity for control and direction by national and local political and administrative bodies. As I have tried to demonstrate, it will only be possible to develop an adequate regulatory framework and reach design potentials once the annihilating and obscuring rhetoric of the non-place has been overcome. This would involve deconstructing the consolidated and dominant narratives on this subject and basing our knowledge of these spaces on accurate socio-anthropological work that would allow us to grasp and appreciate their social relevance and functionality.

Abstract

In the last two decades, global cities are addressing climate challenges, by transforming their infrastructural spaces through Climate-adaptive Nature-based regeneration, also aiming to cope with local ecological, social and economic asymmetries. Inside a prevailing technical and performance-based approaches, to date design research around Climate-adaptive Nature-based regeneration of urban infrastructure is limited, failing to impact on current transformations and to be implemented beyond larger cities. Taking advantage from a 'research by design' methodology, the research aims to leverage design potential for climate-adaptive green regeneration of infrastructural spaces and mainstream this approach in current practices. With this purpose, an operational Framework is defined, giving both conceptual and operational insight for Climate-adaptive Nature-based Streetscapes that will be tested inside a Southern Europe urban context in the future.

1.Introduction[1]

In the last two decades, cities are addressing simultaneously climate change and its challenges, by transforming their infrastructural spaces through Nature-based regeneration, also aiming to cope with local asymmetries. Within these diverse actions and programs put in place, abandoned, underused or in use infrastructural spaces are transformed into new urban commons and experimental prototypes where cities are testing planning/design strategies and actions to be replicated and upscaled, enhancing spatial quality, liveability and wellbeing for all. Built around a specific idea of society and life standards, infrastructural spaces often reflect the values of society, giving or taking space and time off from social encounters and interaction, regardless of the impact on society at the different scales. Furthermore, on the smaller scale of public and collective spaces, the direct influence between the spatial configuration of these spaces on human activities, pointed out already by sociologists (Debord, 1957), anthropologists (Jacobs, 1961), and architects (Gehl, 2011) still constitutes a means to express a need for the upcoming transitions. In fact, the physical, social, infrastructural, and cultural complexity of grey infrastructures, from local streets to interregional highways, contributes to proactively transforming abandoned, underused or mono-functional pathways into livable and shared public spaces. In this way, by also including Nature-based solutions, they contribute to the urge for climate-adaptability.
By integrating Nature-based solutions, pedestrian-friendly and multi-modal mobility features, accessible public spaces and program through innovative and regenerative design processes into existing mono-functional infrastructural spaces, these spaces are turned into vibrant and multi-purpose streetscapes, providing economic, social and ecological benefits. The green regeneration of infrastructural spaces had been proven to be crucial to support and enact sustainable scenarios and foster environmental consciousness inside the urban environment. In essence, the integration of ecological principles into the social urban fabric underscores the interconnectedness of environmental sustainability and societal well-being, with streetscapes serving as tangible manifestations of this symbiotic relationship. The street, in its various shapes and configurations, (re) claims its central role in the urban morphology (Gregotti, 1989) and acts as a spatial collector of unregulated social practices, and as an urban attractor of time, space and mixité of uses (Andaloro, 2022). New urban natures and aesthetics had emerged, especially from the hermeneutical circle between EU and US, impacting both on our perception of what a climate-adaptive green streetscape is and the way we design it. From the New York City Greenstreet's program (1996) - today part of the City's Green Infrastructure (NY Environmental Protection, 2022)- green regeneration urban initiatives have evolved and multiplied, embracing new challenges, i.e., climate change. Boston, one of the pioneering cities in adaptation to climate change, from its report Climate Ready (2016) has continued its efforts to adapt that resulted also in the elaboration of the Urban Forest Plan (City of Boston, 2022). Los Angeles program for Urban Streets Forest (UFEC, 2021) addresses heat and pluvial flooding extremes from an equity perspective, selecting and re-designing infrastructural spaces that cross low-income, disadvantaged communities where disinvestments are chronic. At the same time, many European countries have developed adaptation plans and projects for cities to prepare to adapt to the worsening of climate changes through Nature-based solutions and Green Infrastructures and, at the same time, contribute to the decarbonisation of the built environment, coherently with the UN directives (United Nation, 2015b). Among the first ones, Danish National Adaptation Plan (NAP), developed after 2008 climate extremes (2008), the Dutch Delta Programme (2010), which informs and leads the national regeneration plan for all the different delta areas, and the Swedish National Adaptation Strategy (NAS) (2019), which also includes concern over the (negative) impacts of extreme weather events on public health, the economy, and the environment. (Sida, 2011). Moreover, and following the Paris Agreement (2015a), several municipalities across the continent have elaborated a Municipal Pact for Climate Action, developing strategic actions at a smaller scale to cope and/or adapt to climate changes. In addition, new geographies

[1] This paper is the result of a shared reflection of the authors, which have together contributed to the drafting version of the paper, under the supervision of Prof. I.Macaione. Theoretical backgrouns', '5.2 Vief kwartier, a new neighboorhood in the change', '6. Discussion' are attributed to B.Andaloro.

for climate-adaptive nature-based regeneration of streetscapes are emerging. Melbourne, thanks to its Urban Forest Strategy (2012) and its operational plans at the neighborhood scale, had started redesigning its streets and public spaces increasing canopy to adapt and mitigate climate change (City of Melbourne, 2012). The Green Riyadh project (2019) is one of the most ambitious urban forestation plans developed in an arid city, which foresees 6,400 kms of streets and roads shaded by trees and the longest urban green corridor worldwide (Royal Commission for Riyadh City, 2024). Bogota, thanks to its Climate Action Plan (2021), is leading adaptation in the Global South through the implementation of Nature-based Solutions in the urban fabric and simultaneously addressing green inequalities (Bogota Climate Action Plan, 20xx). Nature-based solutions, thanks to pioneering cities pilot projects, are mainstreamed in big cities' streetscape worldwide by providing replicable and up-scalable examples. But a deeper understanding of this ongoing phenomena is lacking from a design perspective, both on a theoretical and operational level.

2.Literature review and research questions

In the last two decades green regeneration of infrastructural spaces had arouse interest also inside the design disciplines, questioning how nature-based design of streetscape can contribute to shape more sustainable scenarios (Im 2019; Rehan 2019). Johansson (2024) discuss the importance of implementing sustainable streetscape at the local scale through the design of Nature-based Solutions. Green regeneration of urban infrastructures via NbS implementation provides many benefits, i.e., economic, social and ecological while also improving space quality and supporting cities in climate change adaptation. The ubiquitous and multi-scalar nature of infrastructural systems provide opportunities, through green regeneration, to balance green open space unequal distribution, working on the quality of spaces where people spent more time daily; but also leverage issue and challenges, as underline by Raffa (2023) concerning climate-resilient nature-based regeneration of streetscapes at the neighborhood scale. In order to explore the present state of the art concerning the entanglements between green regeneration, climate adaptation and Nature-based solutions in terms of spatial quality and from a design perspective, a literature review has been conducted through Scopus and Google Scholar database and also through open-source international organization report and city's authorities plans and planning reports. Compared to other disciplinary fields, the contribution to the topic of design disciplines is quite reduced; among scientific contribution co-authored by multi-disciplinary research team, design disciplines are among the least recurrent. These resulted also in the low spatial quality of spatial visualizations that accompanied experimental works, which are more focused on the implementation of Nature-based solutions and the evaluation of their performance than their spatial implications. The majority of the selected papers develop design guidelines through analytical-comparative approach (Steenberg et. al., 2008; Klaasen 2007) among case studies or through experimental design (Nijhuis & Bobbink, 2012) in specific cities and/or streets typology; or combining both methods. Cabanek et al. (2022) elaborate a Biophilic Design Framework for streets' green regeneration via Nature-based Solutions and apply it to four prototypical streets sections between EU, US and Australia. Klemm et al. (2017) elaborate design guidelines for urban green infrastructure for climate adaptation, working at the city, park and neighborhood street level through a mixed method analysis that integrates micrometeorology and landscape architecture procedures. Furchtlener et al. (2022), inside a landscape design led multi-disciplinary research, provide qualitative-quantitative guidelines for turning Wien streets sustainable and integrating them into the city's green infrastructure, coping with climate change and ecological challenges. Tamminga et al. (2020), arguing that convivial green streets could be source for climate adaptation, extract from ten European case studies Nature-based solutions and devices at the interface between the streets and building. These were implemented in specific street sections, generalized according to the adopted typological criteria and translated into simple visualization to support future community engagement activities. Another consistent group regards experimental design studies, process and outputs, that beside being specific, have a general value. Lotfata et al. (2023), by research through design methodology (Cortesao & Lenzholzer, 2022), developed a conceptual study to test the feasibility of nature-based solutions into different street sections inside an informal neighborhood in Cairo. Moscatelli et al. (2023) through design-driven research explore the interconnection between neighborhood streetscape green regeneration, energy transition and climate change through Nature-based solutions design in arid climate. Hagen et al. (2021), inside an interdisciplinary project and

through a Living Lab approach, introduce processes and actions for the co-design of greener and climate-adaptive regeneration of streetscapes in a dense neighborhood in Wien. Through a collaborative process replicable design solutions were elaborated, and tactical urbanism action take place as a means for raise awareness among neighbors.

Parallelly to our main objective of the literature review other considerations arose that had informed the present research. (i) Geographical asymmetries. Beside specific urban contexts that are at the forefront in tackling contemporary challenges - which are recognizing the urban relevance of infrastructural spaces to reinforce urban green infrastructure and the city's adaptive capacity- US a Northern and Central Europe are leading in the design research and urban experiments for the regeneration of infrastructural spaces into vibrant and adaptive streetscapes through NbSs implementation. Design research and implementation is to date limited in Southern Europe and in Mediterranean urban areas. Studies that deal with these geographical, climatic and socio-cultural contexts are lacking, although its urban areas are already starting experiencing the strong effects of climate change extremes and stresses. (ii) Urban environments' size. Large urban areas are pioneering the implementation of climate-adaptive Nature-based regeneration, worldwide. Medium and small size cities and urban environments, due to structural gaps, seem to be aside from this global tendency of regenerating infrastructural spaces into climate-adaptive nature-based streetscapes, not taking advantage from its potentials. Both these asymmetries are evident inside Italy, between North and South part of the country and among major and medium/small urban areas.

From the literature review, a three-folded problem appears. First, the possibilities derived from infrastructural spaces' nature-based regeneration is quite underestimated in current design strategies and actions which address urban climate adaptation and green infrastructure. Beside the asymmetrical conditions between pioneering cities and medium and small urban settlements there is a spread lack of consciousness about infrastructural spaces' transformation and their ecological, social and economic opportunities. Secondly, the role of design research for infrastructural space climate-adaptive nature-based regeneration is poorly explored in the current practices, which are still functionalist and sectoral. The hypothesis this research support is that the transdisciplinary dimension of architecture and design-related disciplines could contribute to deal with the complexity the topic requires and provide effective solutions that could innovate current approaches and practices and, at the same time, improve space quality and urban spaces' livability. There is a lack of knowledge concerning design principles and procedures to operationalize regenerative potentials of infrastructural spaces's climate-adaptive nature-based regenerations.

Thirdly, concerning the design, although the research has limited impacts in innovating current practices, it can guide and influence the practice, in a learning loop of knowledge. Understanding proper design procedures and tools is essential to mainstream climate-adaptive nature-based regeneration of infrastructural spaces, especially inside those geographical contexts and urban environments where is mostly lacking. There is the need to bridge design research and real-life outputs, through experimental design study as a bridging point between design research and urban effective transformation. Design as a form of transformational knowledge employs also methods and tools that can contribute to raise awareness, understanding and make shared choices among stakeholders.

Inside this problematic framework, the following research questions emerged: (i) How to leverage, from a design perspective, green regeneration for infrastructural spaces, turning them into climate-adaptive nature-based streetscapes? (ii) Which design procedures and tools can be displayed to enact, at a neighborhood level, streetscapes' potential to support also middle and small cities adaptation while reinforcing their green infrastructure? (iii) How this could work inside a Mediterranean, and in particular, Southern Italian (urban) context?

3. Theoretical background

Aiming at exploring climate-adaptive and nature-based approaches for streetscapes through a design-oriented research, it is relevant to position the research with the key concepts it is built on. The large overlapping of meanings and (design) approaches related to concepts such as climate, nature-based solutions, streetscapes, and adaptation, often related to a particular appropriation by a specific knowledge field, can in fact easily cause misinterpretation of these phenomena, their potentialities and vulnerabilities.

While we know from the recent regulations that climate acts and programmes are required to the municipalities, in order to alleviate the central governmental burden and to ensure a targeted approach to local specificities (as for example the Mayor Act), it is useful to point out the meanings and the implications of 'adaptation', especially on the physical space.
The idea of 'adaptation' to climate change is strictly interconnected to the process of 'mitigation', which constitutes an alternative approach to the climate issues, especially for specific sectors of production and consumerism (Klein at al, 2007). Mitigation is, in fact, defined as "an anthropogenic intervention to reduce the sources or enhance the sinks of greenhouse gases" (IPCC, 2001, 990), developed in order to implement policies for the progressive reduction of greenhouse gas emissions, which should not exceed 2°, as agreed in the Paris Agreement (2015a). While mitigation acts mostly on the causes of climate change, adaptation influences and focuses on its effects, through the definition of preventive or reactive actions (Manigrasso, 2019). The IPPC defines adaptation as an "adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities" (IPPC, 2001, 982). This difference helps understanding the impact of these phenomena, which are more a-spatial in the case of the mitigation acts, as they refer to broader systems, such as production, or energy consumptions. Furthermore, adaptation actions can be earlier applied and shaped to the territories, at their different scales, so as to answer specific (local) needs. Additionally, the definition includes that "various types of adaptation can be distinguished, including anticipatory and reactive adaptation, private and public adaptation, and autonomous and planned adaptation" (IPPC, 2001, 982). In this addition we can notice the predisposition to an uncertain and indefinite contest, as a new state of art in the near future. This clarification therefore plays a crucial role in understanding the role of the spatial design, which is confronted with an unpredictable and uncertain reality, in which the possibility of change (at different scales and relative to different elements), becomes a new invariant element of the contemporary. The core of adaptation to support different types of policies and (governmental, social, cultural, spatial) tools, has contributed to the large diffusion of the term among the different knowledge fields, which has resulted in several different interpretation. Despite this, we can recognise a common shift in the paradigm: instead of acting (or designing) against the climate, we need to acting (or designing) with the climate.
In this respect, despite a ten-year development, as from the 'Urban Adaptation in Europe' (2024), the most recent EEA report, it has been highlighted how adaptation must (still) span all sectors and governance levels, addressing current and future climate risks. Additionally, the report underscores the need for concrete targets to measure progress, as only a small fraction of indicators in local adaptation plans are presently linked to specific goals. However, in the broad context presented by the EEA report, it is pointed out the growing focus on the adoption of nature-based solutions (NbS), which feature prominently in 91% of local adaptation plans there considered.
The spread of the culture of Nature-based solutions among different knowledge and research fields has recently contributed to focus on greenery as a crucial element of the spatial project. Firstly defined in 2008 (World Bank), in the frame of a research on the management of natural systems by benefitting both nature and society, NbSs have also contributed to the definition of a different approach about Nature: not against it, but rather with it (European Commission, 2021b). Lately, the attention for Nature-based solutions has also risen from different field, engaging different aspects and leaving considerable space for ambiguities and uncertainties derived by the inter-disciplinarity of this issue (European commission et al., 2020). Some of the definitions include "actions ad- dress environmental, social and economic challenges simultaneously by maximizing the benefits provided by nature (…) inspired by, supported by, or copied from nature" as from the EU initial document (European Commission, 2015c); or "actions to protect, sustainably manage, and restore natural or modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits", as by International Union for Conservation of Nature (IUCN, 2020); finally as "concept of nature-based solutions embodies new ways to approach socio-ecological adaptation and resilience, with equal reliance upon social, environmental and economic domains" (European Commission, 2021a). The heterogenity of the fields here involved, as stated by IUCN (2020), contributes to claim a more structured way to identify NbS as, for example, through eight criteria, such as (a) address societal challenges, (b) landscape scale of intervention, (c) biodiversity gain, (d) economic viability, (e) governance capability, (f) equitably balance trade-offs, (g) adaptive management, and (h) mainstreamed within an appropriate jurisdictional context. The impact of these solutions on the built and natural environment is broad and

can also lead to a multi-functionality of NbS, or to their capacity to simultaneously address multiple societal challenges (Raymond et al., 2017; European Commission, 2021a; Sowińska-Świerkosz et al., 2021).
In addition to the multi-purpose aspect of involving NbS into a regeneration project, it is also crucial to consider the possible overlapping in the definition between NbSs and green (and blue) infrastructure (Albert, et al, 2019), as both terms refer to a not better specified infrastructure, which takes into account green elements as their main core. Nonetheless, as stated by IUCN (2020), the presence of blue-green elements as part of engineered solutions is a key criterion of Nature-based Solutions. The difference between Nature-based solutions and Green Infrastructure can lead to different interpretation. According to the definition provided by the European Commission (2013), which refers to Green (urban) Infrastructures as different kinds of natural and semi-natural assets that are strategically planned as a network of interlinked elements, they would enhance and synergize benefits provided by nature, in contrast to monofunctionally planned "grey" infrastructure (Hansen et al., 2014; Karsten, 2019). Finally, the Environmental and Energy Study Institute (EESI, 2019) attempts to define a difference among the terms by considering NbS as "solutions often result in environmental, economic, and social co-benefits" which "includes both green and natural infrastructure", and Green Infrastructures as "Projects that combine gray infrastructure with nature-based solutions to create hybrid systems that improve resilience to climate impacts, while also often resulting in environmental, economic, and social co-benefits".
The combination of Green Infrastructures and Nature-based solution contributes thus to exploring climate-adaptation in the physical space of collective (grey) infrastructures, investigating their (multi-purpose) potential in urban regeneration. In order to do so, the research focuses on the concept of streetscapes, meant as "the natural and built fabric of the street, defined as the design quality of the street and its visual effect" (Rehan, 2013), including horizontal and vertical surfaces which define its edges, as well as the facilities related. By considering the entire three-dimensionality of the streets, and by considering it not only as an infrastructural device, rather as a social, environmental, cultural, and also economic element of the built environment, it is possible to exploit its potential in boosting climate-adaptive nature-based design approaches for urban regeneration. The relationship between streets and public spaces and climate-adaptive approaches is also being explored in the last decade through the elaboration of (design) tool to help supporting a multi-disciplinary research or design approach. Among them, Raymond et al. (2017) shows that streets scale nature-based intervention addresses climate mitigation and adaptation to a much greater extent than building scale interventions. Moreover, Furchtlehner et al. (2022) questions how streets can be re-thought as green living spaces and provide recommendations for future-proof and sustainable streetscapes.
In conclusion, exploiting Nature-based solutions as learning devices for informing climate-adaptive and nature-based streetscapes, supports a design-based methodology able to deal with the urgent transitions of the physical space, thus also providing benefits on social, environmental and economic aspects.

4. Methodology

To deal with the uncertainty of the future, in the attempt to enrich design and research processes with new and unpredictive knowledge, requires defining a positioning between research and design. As for the field of Architecture (at its different scale, from building, to landscape, to urban studies), design constitutes both a means of exploration of theoretical questions, and of testing of practical matters. Moreover, while considering (re)new(ed) complex environmental challenges for the future, it is also important to support and focus on a reflexive approach with multiple feedback loops (Beck, 1994), as well as thriving for an answer which can no longer be certain (Rittel, 1973). Looking at the definition of research and design methodology through time, and looking at the categories defined by Frayling (1993), Hauberg (2011) and Schreurs (2005; Bruns, 2010), we have identified a three-phases methodology, divided into: (1) Research about (into) design, which examines models from which it derives its rules and procedures. This phase, as also intended by Findeli (2004) documents objects, phenomena and history of design, contributing to a scientific discipline studying design (Godin & Zahedi, 2014); (2) Research by or through design, a more explorative phase in which design (in its different forms and meanings) is shaped, in order to produce a new level of shared knowledge. For those who follows a RtD approach, this means to relate to material-based research, development works and

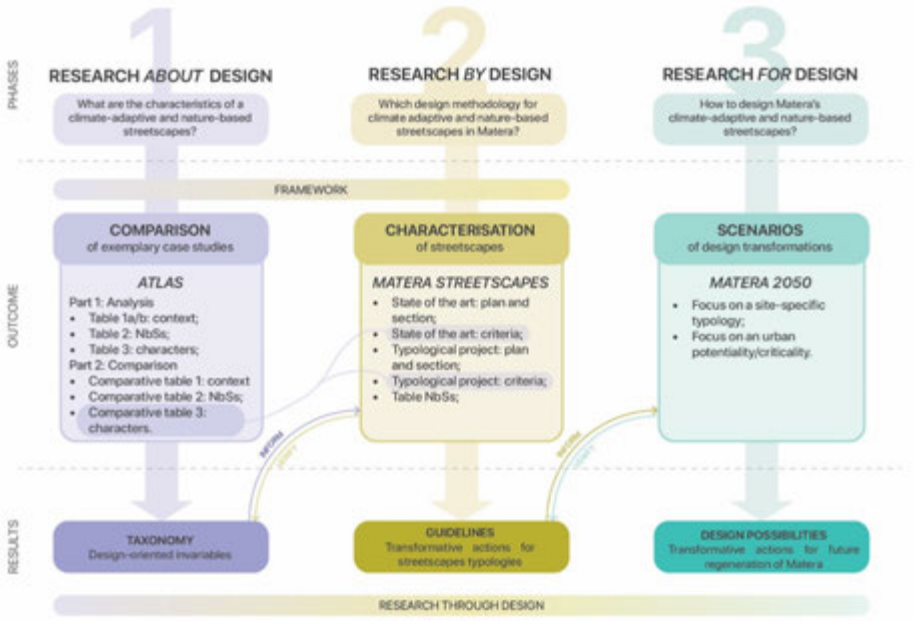
action research, through practical experiments in laboratories. These would result in reports (Hauberg, 2011), with the intended goal of societal change (Binder et al, 2006; Swann, 2002; Zimmerman et al., 2010). Also, RtD supports a (artifact) design process based on trial and error, to better tackle complex design problems (Toeters, et al., 2013). On the other side, in Research-by-design "concordance is sought between the methods of research and a form-giving, experimental design practice" (Hauberg, 2011): the approach produces knowledge through the design's tool and methods, in a direct relationship between analysing and proposing solutions. (3) Research for design, which explores a development phase, whose end product is an artefact, where the thinking is embodied in the artefact and the goal is not primarily communicable knowledge in the sense of verbal communication (Roggema, 2016)

Based on this structure, the research here discussed[2] is structured into these three phases, each one exploring a section of the research question, and informing and verifying the others in a continuous feedback loop. The first phase of 'Research about Design' aims at investigating the invariant characteristics of a climate-adaptive and nature-based streetscapes, aiming at desining a taxonomy of invariable design features.

The second phase of 'Research by Design' takes into account the lessons learned by the first phase, as to resonate on the possibility of defining a characterisation of streetscapes for the city of Matera, which will later be the application case of the research. In this phase, design and research will be highly interconnected to produce knowledge through the act of designing itself. As stated by De Jong (1992), this phase aims to generate desirable, perhaps unexpected, urban perspectives in place of probable, but less desirable, urban developments. By combination of the first and second phase, a Framework for Climate-adaptive Nature-based Regenerative Streetscapes is then defined, giving both conceptual and operational insight for designing for streescapes. Finally, the Guidelines will then inform and be verified by resulting from the final third phase of 'Research for Design', which will explore urban transformation scenarios for the future of Matera through a design-driven approach.

In the following paragraph, the paper will discuss in more details the first phase of the methodology, through ongoing insights of the research, focusing on its role in contributing to the definition of the design Framework.

[2] The paper refers also to the researches conducted in the frames of (1) Urban Green Shape (2021-2023) "Axis IV-Education and Research for recovery – REACT-EU", Action IV.6 "Actions for research contracts on innovation and green topics", funded by PON R&I and FSE REACT EU, carried out by Alessandro Raffa, Scientific Resp.Prof. Ina Macaione (NatureCityLAB_DiCEM, Unibas) and (2) project Tech4You Technologies for climate change adaptation and quality of life improvement, 4.3.1 Azione 1, Fellow Researcher grant "Mitigation and Adaptation to Climate Change in Urban Areas: Green and Blue Infrastructures for the Resilient City", carried out by Bianca Andaloro, Scientific Resp. Prof. Ina Macaione (NatureCityLAB_DiCEM, Unibas).



4.1 Research about design, and the structure of the Framework

Within the first phase of 'Research about Design' we explore the complexity of the concepts which have defined the research question, investigating how practitioners, architecture firm and municipalities have tackled climate-adaptive nature-based design. Specifically, we explore how they have embedded NbSs into their projects though an Atlas of exemplary case studies, which showcases transformation processes. Although still in the making, the Atlas counts about sixty projects, designed and/or built in the last twenty years between Europe and United States[3] which contribute to the elaboration of the Framework for Climate-adaptive Nature-based Regenerative Streetscapes. The Framework, which explores both conceptual and operational approaches, aims to understand how to de-structure and de-compose nature-based, climate-adaptive projects, in order to extract and define applicable design principles and procedures. Its design-oriented nature contributes then to support a multi-scalar research process which could later be applied both for deductive and inductive approaches.
The Framework supports then a critical reflection on similar climate-adaptive and Nature-based regenerative projects: it is devised as a comprehensive design tool for architectural designers keen on exploring the spatial potentials offered by Nature-based Solutions (NbSs), and it aims to furnish multidisciplinary insights into the broad implications of these relatively recent solutions, evaluating the emergence of new typological and morphological categories in architectural composition. Therefore, the Framework integrates both qualitative and quantitative information and data to describe and analyse the projects chosen upon selection (Macaione, 2024). For the variety of information gathered and elaborated, the Framework can also relate to different stages of project development, involving realized, unrealized, and ongoing projects, thus providing nuanced but relevant interpretations. Moreover, it facilitates the examination of projects at different scales, from urban to building, encompassing public spaces and infrastructural elements.

[3] The projects considered by the research are mainly designed, developed and/or built from the years 2000, so as to show a declared interest towards the climatic issues. They all relate to the transformation of grey infrastructures at the different scales, analysing a multitude of typologies and the related transformation scenarios suggested by architecture and landscape recognized studios.

In addition to an initial section, related to the selection criteria of the projects involved, the Framework can be divided into two sections: Section1 is about the analyse of the selected case studies; section 2 is about the comparison of the analysed case studies.
Therefore, the first section ('Analyse') relates to the first level of understanding and de-composition of the cases and is divided into[4]:

- Part 1 delves into the contextual analysis of the projects, focusing on climatic, social, economic, and infrastructural aspects.
- Part 2 scrutinizes the specific climate-adaptive strategies and Nature-based solutions implemented in the projects, assessing their role in the design process and their impact on the site's social, environmental, and economic dimensions.
- Part 3 elucidates the intrinsic characteristics of each project, considering aspects such as time, space, and scale.

This initial phase of analysis leads then to the second section, 'Comparison', in which the projects are progressively put in relation with each others. In order to do so, a three-part comparison is developed:

- Part (a) compares contextual information about the projects, in order to point out initial insight about the relationship between geographical and climatic placement, as shown in Table 1 and 2;
- Part (b) shows the frequency and the details of the Nature-based solutions recognizable in the project involved. This would contribute to understand, in relation with the previous comparison, which solutions are …
- Part (c) aims to deeply explore the implication of the design invariants both in the process and in the projects, as to understand the common elements that fuel climate-adaptive and nature-based projects for streetscape.

5. Comparing case studies

The Catalogue of projects which feeds and inform the Framework includes projects related to different scales and in specific geographies, which explore the theme of urban regeneration through climate-adaptive and nature-based solutions. By collecting and analysing these exemplary case studies, we aims identifying design principles and procedures that facilitate the integration of climate resilience considerations into streetscapes' regenerative processes through Nature-based Solutions (NbSs). While the following paragraphs will contribute with more detailed information about two cases chosen from two different geographical areas, and the related analysis, the Tables 1 and 2 provide a first insight on the comparison of forty projects. Chosen between the US and Northern Europe, these projects highlight their potential in dealing with climate hazards, mainly with heath stress and flooding[5] in different types of grey infrastructures[6], regardless of the climatic types[7], or morphology[8].
The majority of these projects are also related to the development of research and development (R&D) processes conduced together with professionals, municipalities, community-based organisations, research centers and universities, which have often lead to the publication of operational documents, design-oriented guidelines and report, aiming to inform a wide public, including also planners and designers. The general approach of these documents is more technical and performance-oriented and, in the majority of cases, are less focused of streetscape spatial implications. Against this backdrop, two experiences, by using logics and tools proper of the 'designerly way of knowing' can contribute also to inform possible design modes of inquiry and procedures for enacting climate-adaptive and nature-based streetscapes. The case studies which will be deepen in the following paragraphs are framed inside these

[4] Regarding the two case studies discussed in this paper, the related tables of Section 1 'Analyse' can be found among the Annexes.
[5] As from the tables, six cases are related to only one climatic hazard, twenty cases to two climatic hazards, eleven to three climatic hazards, and three to four climatic hazards.
[6] As from the tables, fifteen cases refer to the Linear type, six cases refer to the Network type, four cases refer to the Radial type, and fourteen cases refer to the Grid type.
[7] As from the tables, two cases refer to the type A (tropical), three cases refer to the type B (arid), thirty-one cases refer to the type C (temperate), four cases refer to the type D (continental), according to the Koppen classification.
[8] As from the tables, six cases refer to the Costal type of city, twelve cases refer to the Delta type of city, fifteen cases refer to the River type of city, zero cases refer to the Mountain type of city, seven cases refer to the Flatland type of city.

experimental design guidelines, which had been developed in collaboration with two globally-relevant design firms.
The first experience regards Los Angeles streets' network has been developed by an interdisciplinary consortium, the Urban Forest Equity Collective (UFEC), which has landscape firm STOSS Landscape Urbanism among its consultants. The efforts of UFEC resulted into *LA Urban Forest Equity Street Guidebook* (UFEC, 2021) and other documents which address specific LA neighborhoods. Streets are envisioned as space of possibility to tackle climate change and the structural asymmetric distribution of green spaces which affects especially the most vulnerable neighborhood. Recognizing that each street, neighborhood, and community in Los Angeles embodies a unique set of social, economic, environmental, ecological, and infrastructural dynamics, the guidebook built up a multilevel and multi temporal model able to provide a straightforward and adaptable framework for prioritizing interventions and devising a street-space reforestation strategy which encompass both the neighborhood and the city scale. Central Alameda is then a pilot-project which tries to implement site-specific, climate-adaptive NbS and actions into underused, degraded streets spaces. Through a community design process, STOSS Landscape Urbanism, together with a multidisciplinary consortium, tries to operationalize the Urban Forest Equity strategy the city of Los Angeles has been developing.

The second one is *New Space For Living. Design guideline for public space (Felixx, 2021),* by the landscape firm FELIXX for the City of Groningen (the Netherlands), where the urban infrastructural system is decomposed through a typological approach. Nature-based solutions are implemented also with a spatial quality purpose according streets's context-specific conditions and constrains and visualized through sections. Climate-adaptive nature-based regenerative efforts is evaluated according to a set of parameters (mobility, safety, accessibility, health, social, economy, experience, ecology, climate adaptation and identity), before and after the foreseen implementation (visualised through scenario-based sections) also through a design approach based on phases. In the last part of the guidelines envisioned streets solutions are recombined and tested inside three Groningen's neighborhoods to tackle urban complexity with a site-specific approach. Within this context, Vief kwartier, is a development plan designed in collaboration between the Municipality of Groningen and renown architectural and landscape firms. As part of a broader urban project over the Europark area, the architects aim to transform a wide semi-abandoned parking lot area into a new, sustainable and climate-adaptive neighborhood, which implements a multiplicity of NbS into its streets and public spaces.

5.1 Central Alameda District: Central Avenue & 42nd Place, Los Angeles, CA

Over the past decades, the City of Los Angeles has undertaken a series of green urban regeneration initiatives that look at street spaces as opportunities to address the challenge of climate change, particularly urban heat, through an approach inspired by the concepts of equity and resilience. As part of the LA County 2045 Climate Action Plan (LA County, 2023), the City's Green New Deal. Sustainable City Plan (LA County, 2019) and the LA Countywide Sustainable Plan (LA County, 2019b) but also actions urged by local communities, the city has become a laboratory for green and climate adaptive urban regeneration of streetscapes. With the objectives of adapt to climate change, in particular heat stress, and simultaneously cope with the chronic asymmetries in green spaces distribution [9] which particularly affects the most vulnerable neighborhoods, the city has undertaken a process to explore design and planning opportunities coming from the interconnection between climate adaptation, equity and Nature-based regeneration and provide replicable and up-scalable solutions. With this objective was established the Urban Forest Equity Collective (UFEC), a consortium of designers and planners, forestry experts, researchers, Los Angeles City staff and community-based organization to create holistic, integrative and multifunctional strategies to support urban forest equity, adapt to climate change and improve space quality. Inside the LA Urban Forest Equity Street Guidebook (Shandas , 2022), streetscapes, and their multi-scalar ecological, social and economic entanglements with surrounding neighborhoods and communities, are envisioned as spaces of possibilities to pursue a more equitable, climate-adaptive and resilient urban environment through the implementation of NbS. This strategic document also tries to answer the question on how to operationalize urban forest and to assure an impactful and lasting implementation at a neighborhood scale. The UEFC worked on a framework that provided practical tools to prioritize and plan for the increased presence of green spaces and NbS in urban areas, and offer decision making support, community engagement strategies and visions for LA neighborhoods, demonstrating a powerful and achievable vision for a greener future. This framework adopts a three-tiers approach (Shandas, 2022): the green spaces and tree canopy implementation in the streetscape is described across three levels of intervention which have different intensity, i.e., low [10], medium, and high. Through these tiers, it becomes possible to assess the necessary investments, constraints, and opportunities to address historical inequalities in green spaces distribution. Recognizing that each street, neighborhood, and community in Los Angeles embodies a unique set of social, economic, environmental, ecological, and infrastructural dynamics, this multilevel model provides a straightforward and adaptable framework for devising a street-space reforestation strategy on a neighborhood and urban scale. In order to select pilot neighborhood and prioritize interventions a set of quantitative-qualitative parameters has been defined and organized in four steps which address both vulnerabilities and opportunities: (i) Step 1: Physical and economic needs (i.e. lack of tree canopy, high distribution of impervious surfaces, below average household income); (ii) Step 2: Environmental exposure (i.e. upper 50% for days projected over 90F, for PM2.5 and Diesel PM); (iii) Step 3: Socio-demographic conditions (i.e. poverty, level of education, population density, non-white and non-English speakers distribution, housing conditions, and areas previously redlined); (iv) Step 4: Feasibility and community readiness (i.e. partner activity, area utilization, presence of sites, community interest)

[9] Historical disparities in urban forest distribution that, in conjunction with present and future climate change patterns, can expose Los Angeles communities, in particular those that are already vulnerable, to increasing risks. Past race-based urban policies and planning, i.e. redlining, and structural disinvestments has resulted in urban forest unequal distribution across the city, affecting in particular low-income and black communities. Their impossibility to access to 'ecosystem services' provided by green spaces will exacerbate their vulnerabilities in the context of a changing climate, i.e. extreme urban heat, degraded air quality and heightened levels of flooding.
[10] In the case of level 1 (low complexity), community engagement and involvement of local associations in reforestation activities can be pursued.

(Shandas, 2022). After this investigation, Central Alameda (Gilliam et al., 2024) and Sylmar (Gibson et al., 2024) neighborhood had been selected and specific streetscapes pilot-projects had been identified in it. In the Central Alameda neighborhood, Central Avenue & 42nd Place and other streetscapes have been selected as test beds to apply the three-tier approach and implement NbS. STOSS Landscape Urbanism integrated community inputs throughout the design process (Gilliam et al., 2024). This collaborative approach involved multiple iterations of discussion, enabling the refinement of ideas and concepts. As a result, the design evolved through several rounds of feedback and led to the creation of diagrams and sections (Gilliam et al., 2024). This iterative process not only ensured that the final design resonated with the needs and aspirations of the community but also enriched the project with diverse perspectives, ultimately yielding a more comprehensive and inclusive outcome.

5.2 Vief kwartier, a new neighbourhood in the change

In the frame of a broad development project carried out in the last ten years by the Municipality of Groningen for the Europapark area (Gementee Groningen, 2024), the site 'Vief kwartier' is one of the nine plots destined to be redesigned and transformed. The area is relatively close to the city center of the capital of the Groningen region, and known for the FC Groningen's Euroborg football stadium. It is well connected to the national highway (N7, N37), and a few public transport stops can be found. Moreover, 'Vief kwartier' takes its name from the former Helpman Centrale gas power station and its five towering chimneys. Although it was demolished in 1998, the foundations of the gas power station are still in the area, willing to be involved in the future development plan. The project of the 'Vief kwartier', of which only the Masterplan has been released so far, presents the transformation of the whole area, now used as a parking lot. The project, promoted by the Dutch-based real estate companyABC Vastgoed and designed by a consortium comprising EFFEKT, vector-I, and Felixx landscape architects, embarks on the ambitious endeavor of developing a mixed-use, energy positive and climate-adaptive neighborhood. Moreover, it is based on the "New Space – Design Guideline Liveability of Public Space" developed in 2021 by the Dutch architectural firm Felixx and the Municipality of Groningen, for the transformation of public spaces, thus promoting five quality of life values, among which public space, sports and health, connection, and mobility, mixed-use and sustainability (Felixx et al., 2021). This research work, developed also in collaboration with the University of Amsterdam, points out several transformation scenarios for the different typologies of public spaces, and more specifically, of streets (Figure 4).
In order to build on the former foundations of the gas station (5.000-plus existing concrete piles and blockwork), the new 315 residential units will be entirely constructed using lightweight hybrid timber system, aiming for a energy positive design able to sequester carbon and integrate spatial devices able to harvest rainfalls and mitigate flooding. Four different plots are defined with different typologies and heights, creating a higher external edge and a progressive smaller terraced skyline toward the park. In the four block, the project envisions also courtyards for natural light and cross-ventilation (Table 4). The approved preliminary Masterplan introduces different nature-based solutions and nature-inclusive areas in the district, such as green avenues, and green shades (especially on the edge of the site), but also natural parks and playgrounds in the middle of the site, defining a core place for collective social activities for the surrounding communities. In addition, the project envisions smaller poket-parks where to engage in social activities.
The ongoing development of the Vief kwartier shows the Interest of the Municipality of Groningen to develop a system of spatial transformations which will take into strong consideration the natural components of the urban landscape, thus allowing green and blue infrastructure to settle. Furthermore, as foreseen in the "New Space – Design Guideline Liveability of Public Space", the transformation is envisioned to happen during different periods of time, allowing the neighborhood and the city to adapt to the changes.

6. Discussion

In the last part of the Analyse section[11] the two case studies are compared according to the main design principles: (i) Multi-scalarity, (ii) Multi-temporality, (iii) Multi-Functionality, (iv) Replicability and up-Scaling; (v) Multi-stakeholder collaboration [12]. These design principles had been previously deduced from the intersection between literature review's findings and from a wider comparison among the research's taxonomy of case studies . Both projects show how the integration of climate adaptation into urban green regeneration requires an holistic, integrative approach grounded on multi-disciplinary collaboration. Both projects address (i) Multi-scalarity (City, Neighborhood and Building) and, in particular, in Vief kwartier NbS are also embedded into the buildings. (ii) Multi-temporality is addressed differently in the two projects and in particular, in Central Alameda street project temporality shapes also an implementation logic. (iii) Multi-functionality is also strategic: in the US case study multi-functionality is explored on a street level while in the EU project through the integration between built and unbuilt space. (iv) Replicability and up-Scaling is addressed in both projects. Central Avenue & 42nd Place and its neighborhood is envisioned as a pilot project with an urban and metropolitan relevance. In the Dutch case, instead, Vief kwartier is a pilot project of a broader development project for the whole Europark area. (v) Multi-stakeholder collaboration is operationalized in both cases through a consortium that integrates public and private institutions, researchers, no-profit and community-based organizations and urban designers. Both projects show the synthetic dimension of the design process, through which bridging together different disciplines, objectives and aspirations, supporting adaptation and improving space quality, public health and resilience.
By combining the analyses of the design cases and of some recent design catalogues, and guidelines for the development of public, collective and open-air spaces in the urban fabric (World Bank, 2021; Felix et al., 2021), some design features are recurrent and support the contemporary search for flexibility in use, time and space. First, what seems the most relevant feature, is the necessity of a vision of transformation which guides the development of the project through all its phases, thus emphasizing the need for the project to focus on the quality of living space. Then, the aforementioned introduction of green matters among the architectural ones, for example, not only shows their recurrence, but claims for a deeper understanding of their role in spatial design. Furthermore, it is possible to notice that the developed process supporting the project has a strong component of multi-scalarity, providing solutions which work at the intersection of urban, neighbourhood and building scales. Finally, the regeneration of grey infrastructures into liveable, sustainable and climate-adaptive public streetscapes underlines the necessity and the possibilities envisioned by phase-based planning, ensuring the feasibility and economic viability of the project, allowing the ecosystems involved to integrate in a renewed balance.
As emerged by the analysis of case studies, the emphasis posed to the multi-functionality of NbS, in most cases, is today dominant and preventing form a space-based reflection that could improve spatial quality, together with economic, ecologic, and social benefits.

7. Conclusions

In a renewed approach on the relationship between Architecture, Nature and Climate Change, pioneering cities worldwide are experimenting on grey and mono-functional infrastructural spaces, turning them into climate-adaptative Nature-based streetscapes to date, this trend reveals also asymmetries in the geography and size of cities.
Through the climate-adaptive Nature-based regeneration of infrastructural systems, new ecologies and aesthetics are emerging, but their spatial implications are currently under-investigated. Despite the emerging role of infrastructural spaces green regeneration to tackle climate challenge the role of design, both as a mode of research and practice, is underestimated and poorly-explored in this specific field, both in literature and practice. In addition, a strong disconnection between design research and practice

[11] The corresponding Tables can be consulted as Annexes of this paper. Specifically, here we refer to Table 3..
[12] Multi-scalarity, or the capability to a project to integrate design approaches which intertwine different scales; Multi-temporality: or the capability of the project to adapt and change over time, in relation to different moments of days, season and years, or scenarios; Multi-functionality, or the capability of the project to support different activities and functions in the private, public and collective spaces; Replicability and up-scaling, or the capability of the project to be applied, scaled up or down in analogous (climatic) condition; Multi-stakeholder collaboration, or the peculiarity of the project to be developed by a multidisciplinary group of direct, indirect, public, and private actors which represent diverse needs (Macaione et al., 2024).

still exists. More research is needed to go beyond current sectoral, technical and performance-based approaches and to leverage the potential of urban and architectural design inside this emerging field. A design-based approach can help to address the streetscape's climate-adaptive nature-based regenerative design in a more complex, integrative, and holistic manner. In order to overcome present limitations, the research, through the elaboration of the Framework for Climate-adaptive Nature-based Regenerative Streetscapes, aims to leverage the spatial dimension for streetscape's transformation and pursues operative outcomes. Future advances inside the ongoing research will involve completing the Framework by identifying design procedures and operational guidelines. Operational principles and procedures previously deducted, will be tested inside a medium size city and its neighbourhoods in the Mediterranean region, according to the third phase of the research methodology,
Once completed, the Framework would support the realisation of a design-oriented guidebook, providing a design methodology capable of tackling urgent inter-disciplinary spatial issues through the many facets of design, providing operational tools for future-proof resilient streetscapes, also for cities that are to date not tacking advantage from this opportunity.

Aknowledgments
This work was supported by two ongoing research: (i) Urban Green Shape (2022-2025), funded by PON R&I and FSE-REACT-EU. PON "Research & Innovation" 2014-2020, Asse IV "Istruzione e ricerca per il recupero" – Azione IV.4 – "Dottorati e contratti di ricerca su tematiche dell'innovazione" e Azione IV.6 – "Contratti di ricerca su tematiche Green" and FSE-REACT-EU; Research Contract number 38-G-14879-1, CUP C49J2104334000, carried out by Alessandro Raffa, Scientific Res. Prof. Ina Macaione; the investigation has been also nurtured by the research carried by out by A. Raffa as Fulbright Visiting Scholar at University of Florida, College of Design, Construction and Planning and FIBER-Florida Institute for Built Environment Resilience (August-February 2024); (ii) Next Generation UE - PNRR Tech4You Project funds assigned to Basilicata University (PP4.3.1 - Green Shapes for the Urban Regeneration Processes, Environmental, Social, Cultural and Tourism Sustainability, Scientific referent: Professor Mariavaleria Mininni) - Technologies for climate change adaptation and quality of life improvement", field of intervention "1. New approaches and design paradigms to insertion and development of "green shapes" in the cities, to raise the architectural and urban quality, the environmental, social and cultural benefits", Code ECS00000009 – CUP C43C22000400006.

Annexes

		Central Alameda District/ Central Avenue & 42nd Place	**Vief kwartier**
Design firm		STOSS, LA Urban Forest Equity Collective	Felixx, EFFEKT, vector-I
City		Los Angeles, US	Groningen, the Netherlands
Type of city		Flatland	Flatland
Year and status		2021-ongoing	2022-2023
Type of grey infrastructure		Linear/Grid	Urban grid
Extension of grey infrastructure		2.18 square miles	0,24 square miles
Shape of grey infrastructure		Linear/Grid	Grid
Climate type		BSh Semiarid Low Latitude	Cfb Temperate, no dry season, hot summer
Climate hazard	H	X	
	F	X	X
	D	X	X
	W		
Implementation phases		• LA Urban Forest Equity Collective was created; • Phase 1: • Los Angeles Urban Forest Equity (LAUFE) Streets Assessment Report (2021); • LAUFE Streets Guidebook (2021); • Phase 2: • LAUFE Design Guidebook (2024) • LAUFE Neighborhood Strategy (2024) • LAUFE Neighborhood Strategy Central Alameda (2024) • Urban Forest Equity Community Action Toolkit (2024)	• ABC Vastgoed (Dutch-based real estate company) acquired the site from the municipality of Groningen • ABC Vastgoed comprises a consortium of international designers: architects EFFEKT Architects, vector-i (local), Felixx landscape architects (landscape); • Approval of Felixx's "New Space - Design Guideline Liveability of Public Space, Groningen" (2021); • ABC Vastgoed and Municipality of Groningen sign a cooperation agreement for the development of Vief kwartier at the event Let's Gro(2023) • Feasibility studio approved

Table 3: Table 1A compares the U.S. and EU projects from a contextual point of view, giving a first insight on the typology of (grey) infrastructure which the project aims to transform, and the main climate issues of the related areas (elaborated by A.Raffa and B.Andaloro).

	Central Alameda District/ Central Avenue & 42nd Place	Vief kwarter
Vulnerabilities	Climate LA hardest-hit neighborhoods; Difficulties in managing flooding; Ecological Lack of tree canopy and green open spaces; Degraded green spaces; Lack of biodiversity and proliferation of invasive species; Low quality of natural resources, i.e. soil and water and noise pollution Infrastructure Mobility Car-centric mobility infrastructure; Lack of slow mobility; Lack of multimodality; Grey infrastructure Underutilized vehicular lane; Abundance of parking areas; Abundance of Impervious surfaces (more than 60%); Obsolescent water management gray infrastructure Utilities Overhead utilities limit sizes of existing trees Commons Lack of public space for social interactions; Lack of of public spaces, also green, for passive and active recreation; Lack of urban furnishing; Structural lack of investments on urban spaces, also as a result of 'redlining' Housing & Public Health Poverty; Low level of education; Cultural and linguistic divide; Cost burden renters and households; Household income lower than city average Lack of home internet and digital divide; Unhealthy habits of neighbors	Climate Difficulties in harvesting rainwater Difficulties in managing flooding Difficulties in saving energy Ecological The area destined for the new neighbourhood was a former industrial area In the proximity of the area there are small, disconnected green spaces; In the surrounding are there is the Helperpark; Lack of biodiversity ; The area is closed to a canal; The soil consists of a relatively poor quality of terrain with soft banks, grassland, shrubs and trees. Infrastructure Mobility Car-driven area; The area is in the proximity of a national highway (N7; N37); The area is served with train and bus stations; In the surroundings of the area there are a few disconnected bike lanes. Grey infrastructure The site is a parking lot; The area is paved with spontaneous grass and asphalt; The site is surrounded by a dense grid of driveways; Proximity of a medium-size connecting roadway; Commons The plot hosted the former plot of Helpman Centrale power station ('Vief piepen'), demolished n 1998; The site is currently used as parking spot for FC Groningen's Euroborg football stadium; The site contains the original power factory's foundations; The surrounding area has few services The surrounding area is manly residential; In the proximity is the FC Groningen Euroborg football stadium. Housing & Public Health Groningen's population is rapidly increasing; Groningen is suffering from a housing shortage;
Climate-related hazardous events	Flooding Climate change is heightening the likelihood of inland and coastal flooding through rising sea levels and increased occurrences of intense rainfall. Heat Rising average temperatures are leading to more frequent occurrences of dangerously hot days and heatwaves. Over the next three decades, Los Angeles is projected to endure 21 days with	Flooding 1) High emissions scenario: sea levels rises by up to 1.2 m by 2100, and possibly up to 2 m if the Antarctic ice sheet melts faster. 2) Lower emissions scenario: the rise could be between 26-73 cm by the end of the century. Temperature Increases Future projections suggest a further increase in temperature, ranging from 1.4 to 5°C higher by the end of

	temperatures exceeding 93ºF. Extreme heat stands as the primary climate hazard in the city, resulting in a considerable number of climate-related fatalities and hospitalizations. Additionally, the urban heat island effect is amplifying urban temperatures significantly. Extreme Weather Events The combined effects of climate change are amplifying the severity and frequency of extreme weather events, with drought, wildfires, and flooding emerging as particularly acute challenges. Projections suggest an intensification of these risks in the coming years	the century compared to the reference period (1995-2014). Extreme Weather Events The Netherlands is expected to experience more frequent and intense heatwaves, regardless of the emission scenario. By 2050, the number of tropical days (above 30°C) could increase significantly, with a possibility of temperatures reaching 40°C annually by the end of the century in a high emissions scenario. Additionally, the country is likely to face more extreme storms and an increased risk of drought, particularly in spring and summer.
Climate-related planning frameworks	LA Heat Action Plan (ongoing, expected 2024) LA County 2045 Climate Action Plan (2023); Green New Deal (2019); Complete Streets Design Guide for LA (2015) LA Countywide Sustainable Plan (2019); Stormwater Capture Master Plan (2015)	Europapark plan (2013; 2015; 2019, Gronigen Gementee); New Space - Design Guideline Liveability of Public Space, Groningen (Felixx, 2021);

Table 4: Table 1B analyses the two projects from a contextual, more specific point of view, pointing out the climatic, ecological, social, economic vulnerabilities from a spatial perspective, as well as climate related risks and the associated policy and planning framework (elaborated by A.Raffa and B.Andaloro).

Central Alameda District/ Central Avenue & 42nd Place				
Climate-adaptive spatial regeneration strategies	• Reinforce ecological connectivity; • Preserve existing vegetation and increase tree canopy; • Increase biodiversity, by introducing native species and make diverse habitat for other species; • Enhance quality for air and water; • Increase Multimodality and make space for safe, accessible and inclusive slow mobility (i.e. pedestrians and cyclist) across scale; • Stimulate local economies and investments in the surrounding areas; • Integrate bleu-green infrastructure for flood management with existing grey infrastructure;			
Nature-based Solutions			**Spatial actions**	**Spatial devices**
Typologies	**Benefits**	**Techniques**		
Open Green spaces	Climate: Reduce Heat Stress; Reduce Pluvial Flooding risk; Carbon Storage and sequestration; Ecological: Increase Biodiversity; Enhance soil and water quality; Social: Improve interaction; Improve physical, emotional and mental health; Provide opportunities for active recreation and tourism; provide educational opportunities;	Pocket Park	Distribute	Room
		Natural Playgrounds	Re-Connect	Room
Green Corridors	Climate: Reduce Heat Stress; Reduce Pluvial Flooding risk; Carbon Storage and sequestration; Ecological: Enhance ecological connectivity; increase Biodiversity; enhance soil, water and air quality; reduce noise pollution; Social: improve interaction; improve physical, emotional and mental health; provide opportunities for active recreation; Economic: Increase value; Create green jobs; Reduce healthcare costs; Reduce energy consumption;	Street Tree Canopy	Cover	Diaphragm
		Green Avenues	Connect	Threshold
		Urban Green Corridor	Connect	Pathway
Bioretention Areas	Climate: Reduce Pluvial Flooding risk; Carbon Storage and sequestration; Ecological: Enhance ecological connectivity; increase Biodiversity; enhance water quality; Social: improve interaction; improve physical, emotional and mental health; provide opportunities for active recreation; Economic: stimulate local economies and job creation;	Bioswale and Rain Garden	Gather	Threshold
		Permeable pavements	Clad	Surface

Table 5: Table 2 analyzes the Central Alameda District/Central Avenue &42nd Place project from a contextual point of view, giving a first insight on the typologyf (gray) infrastructure which the project aims to transform, and the main climate issues of the related areas (elaborated by A.Raffa).

Vief kwartier				
Climate-adaptive spatial regeneration strategies	• Promote five quality of life values: public space, sport and health, connection and mobility, mixed-use and sustainability; • Boost the importance of public open pedestrianised spaces to improve healthy lifestyles; • Increase availability of public spaces in different meteorological conditions for flood mitigation; • Renaturation of collective spaces; • Promote an innovative timber-hybrid mixed-use development; • Carbon-neutral and energy-positive scheme in existing and new construction; • Minimise carbon emissions; • (Rain)water management, through rainfall harvest;			
	Nature-based Solutions		**Spatial**	**Spatial**
Typologies	**Benefits obtained or expected**	**Technologies**	**actions**	**devices**
Building solutions	Climate: Delay in drainage of rainwater; Pluvial flood regulation; heath regulation; Ecological: Biodiversity increase (i.e.: sensory plants); Seasonal plants; Creation of new habitats for little animals; Noise reduction; Dust absorption; reduce air pollution. Social: Social engagement; social interaction; direct human contact with nature; Economic: Job opportunities for maintenance; (optional) savings for water consumption;	Extensive green roof Ground-based facade	Overlay Overlay	Surface Envelope
Open green spaces	Climate: Management of rainfall; Recycle of rainfall; Water storage; Heath stress reduction; air purifying; cooling effect; Ecological: Biodiversity increase and support; Seasonal plants/landscape; Creation of new habitats for little animals; Food production; removal of pollutants from air, water and soil; Social: Recreational use of garden; community engagement; social inclusion; human direct contact with nature; sensory skills improvement; physical activities encouraged Economic: Create training opportunities; Create Green jobs opportunities.	Climate-proof residential gardens Pocket parks Natural playgrounds	Connect Connect Connect	Filter Horizontal surface Room
Green corridors	Climate: Pluvial flood regulation; water pollution regulaton; heath stress reduction. Ecological: Encourage animal settlement; increase biodiversity in the area; Air quality improvement; carbon storage sequestration; UV ray reduction; Noise buffer. Social: Encourage social encounters and interaction; Shading; Enhancing street quality; Enhancing street identity. Economical: Create training opportunities; Create Green jobs opportunities.	Street tree canopy Green avenues	Connect Edge	Pathway Pathway

Table 6: Table 2 analyses the Vief kwartier project from a contextual point of view, giving a first insight on the typology of (grey) infrastructure which the project aims to transform, and the main climate issues of the related areas (elaborated by B. Andaloro).

	Central Alameda District/ Central Avenue & 42nd Place	Vief kwartier
Multi-scalarity	City • The project is part of a larger development project for equitable urban forest implementation both at a urban and neighborhoods scale; Neighborhood • The project regenerate streets spaces and has been developed at the neighborhood scale, engaging communities, local activities and residents; • Nature-based solutions are embedded into space, according to the local context characteristics; Buildings • the project do not work directly on surrounding buildings but it aims also to improve wellbeing for all, especially for the most vulnerable;	City • The project is part of a larger development project concerning the whole area of Europaparkhas both an infrastructural and proximity scale Neighbourhood • The project is developed at the neighbourhood scale, engaging communities, local activities and residents. • Open-air public spaces are designed as part of the neighbourhood and support community engagement. • Different nature-based and nature-inclusive solutions are embedded into the space, with different scales of deepening. Buildings • The area is divided into four blocks of buildings, the design of which has not been released yet (2024) • Nature-based and/or green solutions are embedded into buildings
Multi-temporality	• The development of the project is at a conceptual phase; • The project will be implemented through a three-tiers framework - according to the different intensity of forseen interventions - that has been defined by the Los Angeles Urban Forest Equity Streets Guidebook (2021);	• The development of the project is following administrative phases, and is now into the deepening of design phase • The project has a vibrant environment with retail, workplace, leisure and community facilities which create activity 18 hours a day, seven days a week in the neighbourhood • Proximity parks, poketparks and green areas are open during day and night
Multi-functionality	• Multi-functionality is promoted in the area, also introducing different type of mobility for pedestrian and bikers; • Nature-based solutions implementation will transform existing streetscape into a multi-functional and diverse space; • Streetscape are re-designed in order to multiplicate public space and activities, also in connection with existing facilities and amenities	• The neighbourhood aims to welcome a variety of uses for the open-air spaces; • Multi-functionality is promoted in the area, also introducing different type of mobility for pedestrian and bikers; • The neighbourhood will have mixed-uses in the buildings which will host residential unts (around 315), together with retail, workplace, leisure and community facilities • Green areas and corridors welcome interaction between species;
Replicability and up-scaling	• The project is one of the two pilot for the implementation of Los Angeles Urban Forest Equity Street Guidebook (2021) at a neighborhood scale and, once completed, to be tested and monitored • As a pilot project, it aims to be replicable and up-scalable, impacting on LA streetscape nature-based regeneration • Nature-based Devices and Solutions adopted address recurrent issues and can pe replicate in similar circumstances	• The project adopts “New Space - Design Guideline Liveability of Public Space, Groningen” (Felixx, 2021) for the (replicable) design of public open-air spaces; • Open-air spaces refer to specific typologies of nature-based devices which can be replicable in similar circumstances; • The built environment envisioned at this stage seems to be made of buildings with modular structure and nature-inclusive solutions integrated into them.
Multi-stakeholders collaboration	• The Urban Forest Equity Collective (UFEC) is a consortium of urban designers and greening experts, City of Los Angeles staff, community-based organizations, researchers, and consultants; • City of Los Angeles: LA Office for Forest Management; LA Bureau of Street Services & Sanitation and Environment; Department of Public works, Water and Power, Recreation & Parks; LA Center for Urban Natural resources Sustainability • University: LA Laskin Center for Innovation (UCLA); University of California Division of Agricolture and Natural Resources; University of Southern California Urban Tree Initiatives; • Organizations: Tree People, City Plants, North East Trees, South LA Tree Coalition; California Climate Action Corps; • Landscape architectural firm: STOSS Lanscape Urbanism • Consultancy for Climate Adaptation planning & analytics: CAPA Strategies	• Municipality of Groningen • The ABC team comprises a consortium of international designers that includes Copenhagen-based international practice, Groningen-based local architectural firm and Rotterdam-based Felixx landscape architects. The design team is supported by advisers and consultants, including integrated design for construction, for sustainability, Spark for mobility, Bouw 21 for realisation and Re:Invest for the co-working design. • Architectural firm(s): EFFEKT Architects, vector-I (local) • Landscape architectural firm(s): Felixx • Consultancy agency for construction: BREED ID • Consultancy agency for sustainability: Traject • Consultancy agency for mobility: Spark • Consultancy agency for building realisation: Bouw 21 • Consultancy agency for co-working design: Re:Invest

	• The project is grounded on community-informed design

Table 7: Table 3 explicates and compares the intrinsic design features of the two projects, specifically in relation to the notions of time, space, and scale (elaborated by A. Raffa and B. Andaloro).

Urban parks through people's new lens: Opportunities behind COVID-19 for public spaces' policies in Costa Rica.

Abstract
The lockdown and restrictions during the last COVID-19 health crisis confronted the population with an unprecedented situation for urban life. Green areas, mainly large urban parks, become highly valued spaces during and even after the pandemic. This work shows the visitation patterns of users from three large urban parks within the Greater Metropolitan Area of Costa Rica (GAM). The research is based on 8575 in situ surveys carried out between January and August 2023; our team also conducted an exploratory study between 2018 and 2019 (pre-pandemic), which was resumed to compare some aspects before and after the pandemic. The findings allow to explore challenges in public policies to improve access and enjoyment of urban recreational spaces in Costa Rica, replicable in other parts of the world.

Keywords: COVID-19, post-pandemic, Costa Rica, public policies, urban parks.

1. Introduction

Public spaces played a crucial worldwide role during COVID-19; they contributed to meeting social needs and physical activities and positively affected users' health (Lin et al., 2023). However, each country approached its restriction measures during the lockdown differently. In Costa Rica, access to many public open spaces such as beaches, National Parks, squares and urban parks was limited or denied. The access to large urban parks within the Greater Metropolitan Area (GAM) was strongly reduced during 2020 and 2021; sometimes, there was no access at all; others, a visitation schedule was enforced for weekdays, and no visitation was allowed during the weekends.

This study focused on the three large urban parks within the GAM: La Sabana, La Paz and El Este; it aims to analyse users' visitation patterns and place appreciation one year after the government lifted COVID-19 restrictions. Urban residents might have a reappraisal of green

local spaces in the early stages of the pandemic (Alizadehtazi et al., 2020). This research intends to understand if urban park users perceive those places as more valuable today than before the lockdown and to reflect if any change in planning policies must be implemented to embrace that fresh lens.

This research is mainly based on 8575 *in situ* surveys carried out between January and August 2023 in the largest urban parks of the GAM: La Sabana, La Paz, and Parque del Este. The sample included teenagers from 14 years old, adults and people over 65. Additionally, between 2018 and 2019, just months before the spread of COVID-19, our team conducted an exploratory study in the same urban parks to examine visitation patterns and user perceptions with a sample of 491 individuals. In the 2023 survey, we repeated the same questions as the previous study and added specific enquiries regarding visitation and perceptions before and after the pandemic. Therefore, this paper analyses participants' new perspectives while considering views from the same places before the outbreak.

The findings suggest that COVID-19 was a game changer in people's visitation patterns and appreciation of large urban parks within the GAM. The results show that 50% of participants state that they visit the park more often today than before the outbreak; that behaviour was even higher in teenagers, with 56% assured of having increased their visitation frequency. Individuals over 65 years were the group that missed the urban parks the most; 88% mentioned that they missed open spaces or they were looking forward to them being opened. These findings contribute to understanding the effect of COVID-19 in Latin American public spaces.

Although more research is needed, some examples show an increase in visitation patterns in local parks in Brazil after the lockdown (Freires et al., 2022) or a decrease in Puerto Rican parks by 2021 (Luengo-Duque and Crespo, 2022). In Costa Rica, despite the self-reported increase of visitation post-pandemic, planning policies in urban parks face challenges; private cars are the dominant mode of transport to get there, and there are safety concerns, infrastructure, and accessibility issues. Public policies should focus on promoting more accessible and secure urban spaces aiming to ensure a better quality of life for its residents. This paper aims to address public policy challenges according to new post-pandemic visitation patterns.

2. COVID-19 and spatial inequalities

The spread of the COVID-19 pandemic brought crucial challenges to contemporary planning policies. The cities were scenarios of several restrictions in public spaces; each country applied them differently, but common elements such as lockdown, social distance, and limited use of public transport were implemented worldwide. Furthermore, COVID-19 unveiled and aggravated many inequalities related to urbanisation practices; the impact of the lockdown affected disparately for those without access to outdoor spaces and who had a garden or any open space to relax or exercise (Orford, Fan and Hubbard, 2023). The purpose of public policies during the pandemic was focused on stopping the spread; however, suspending routine activities brought devastating effects on mental health (Castillo, 2023).

Beyond the income inequalities, the pandemic also intensified discrimination towards marginalised and stigmatised groups, such as the LGBTQ+ community (Kneale and Bécares, 2020) and older people (Buffel *et al.*, 2023). People over 60 were unreasonably affected by COVID-19; Buffel et al. (2023) highlight that according to the WHO Europe, they represented 95% of deaths in Europe; nonetheless, despite the number of fatalities in residential care (half of them) and older people been identified as the most vulnerable during pandemic, there is a limited amount of public policies to address this population issues. Furthermore, the access to

urban green space reveals spatial inequalities among different age ranges.Buffel et al. (2023) suggest that those circumstances have rarely been transferred to public policies; therefore, 'Age-friendly recovery planning' (p.1472) is required to involve older people in 'designing smart, liveable and resilient cities of the future' (p.1473).

2.1 Planning policies adopted during the COVID-19 pandemic

Measures undertaken to reduce COVID-19 transmission aimed at diminishing crowding; for instance, enhancing online services, reducing face-to-face services and promoting active transport means such as walkability and bike sharing (AbouKorin, Han and Mahran, 2021). However, urban morphology also had a role in the disease spread; AbouKorin, Han and Mahran (2021) carried out research in England, Germany and Italy; they found different infection rates in cities with radial, grid and linear forms; in this respect, radial and grid forms were related to with higher infection rates, mainly because those morphologies allow to concentrate higher densities. Those findings shed light on the planning challenges to keep cities efficiently connected but also resilient to face health emergencies.

Temporary solutions were adopted during the COVID-19 pandemic; many actions were approached through Tactical Urbanism, which allows small-scale interventions with low cost and quick implementation (Vázquez and Berardo, 2023). According to Sáez Reale and Azpiroz de Achával (2022), Tactical Urbanism proved to be a valuable tool during the lockdown; then, when the countries started to lift COVID-19 restrictions, those interventions allowed the create new public spaces in sectors formerly dedicated to cars; also promoted sustainable and safe mobility by expanding footpaths, pedestrianising streets and creating new bike lines.

Within the Latin American region, like many countries worldwide, there were many transformations in public spaces; for instance, in Argentina, they focused on three main strategies: urban mobility, green spaces and open street markets; there was a change in mobility by creating temporary pedestrian areas through the closure of perimeter streets high traffic areas (Vázquez and Berardo, 2023). The expansion of gastronomic public space through platforms dedicated to tables and chairs, commonly known as 'parklets' or 'gastronomic decks' was another tactical intervention with a significant impact on Argentina, as they represent a cost-effective way to reclaim space from cars (Sáez Reale and Azpiroz de Achával, 2022).

Some planning concepts that somehow existed before the pandemic emerged and were further developed, such as 'superblocks', aimed at reducing traffic by closing some streets and dedicating more space to active travel; also, the '15-minute city' (Moreno, 2024), which seeks dwellers can access their essential living needs in less than 15 minutes. Those initiatives search to promote the planning pyramid in favour of public transportation, walking, and cycling (Gesto Rodríguez, 2021)

2.2 Responses post-pandemic

Post-pandemic debates in planning encompass inequality, community participation, green spaces, mobility, and proximity. Shatkin, Mishra and Khristine Alvarez (2023)suggest that post-pandemic informality discourses are framed in three main approaches: the first is 'revanchist' which is based on stigmatisation of informal settlements, often through urban exclusion; the second is 'incrementalist' which is focused on the most immediate contagion threats, and finally a 'reformist' approach which addresses structural causes that foster informality and inequality.

Urban parks play a crucial role in reducing part of spatial inequalities and ensuring equitable access to recreation; however, citizen participation is the first stage in equitable park planning; people want to incorporate their vision in what they wish parks to be, proximity and access are

essential but also quality and sense of belonging (McCormick, 2020). Citizen-led interventions provide balance to city management, and it helps to encourage the use of neighbourhood parks and squares, avoiding long travel distances (GIZ Ecuador, 2020; Bueno Carvajal, 2022). Kyriakidis et al. (2023) found in Athens that the lack of engagement provokes dissatisfaction, and people might feel unfamiliar with the intervention; nevertheless, quick participation interactions through electronic devices such as mobiles (apps) allow people to discuss their community and perceive themselves as empowered.

Some approaches suggest it is not necessary radical city transformations; however, tools for better mediation between citizens and their built environment are required; CAF (2021) recommends four types of public spaces: parks, vegetable gardens, markets and leisure spaces. Furthermore, it is necessary to rethink streets and public spaces for the post-pandemic city; thus, they should prioritise public transit, walking and cycling, more outdoor space, improving the city's environmental conditions, and giving people more space (Barbarossa, 2020). In places such as Italy, the planning policies redefining urban streets for leisure and cultural uses were actions to promote intermodality, traffic data monitoring, tactical urbanism, new parking rules, and an increase in non-polluting means of transport, among others (Barbarossa, 2020).

Lessons that the COVID-19 pandemic left behind suggest the local government should have more quantitative and qualitative information about their parks that help to make medium and long-term decisions about the use and management of public spaces, considering safety and future risks (GIZ Ecuador, 2020); however, this type of information is still limited in places such as Costa Rica (Cruz Zuniga, Centeno Mora and Barrantes Chaves, 2023). Municipalities are the closest institution for citizen participation; therefore, updated data allow them to intervene more quickly than a centralised response through national institutions; local government could encourage a neighbourhood governance model for the organisation of residential communities, recognising their power to transform their local spaces (Fan, Orford and Hubbard, 2023).

3. Costa Rican Context

As in many Latin American countries, the pandemic surprised health authorities and those in charge of public policies. Costa Rica's Minister of Health was trained in epidemiology and led the lockdown policies; however, the main goal was to stop the spread. It was not considered how the adopted measures could affect citizens' right to recreation, leisure, and healthy coexistence.

Even before the pandemic, Costa Rica had a real shortage of spaces dedicated to recreation and sports. The national body in charge of the issue, ICODER (Costa Rican Institute of Sports and Recreation), have had a low budget and many restrictions on its actions. Therefore, the lack of urban planning policies to create green spaces in Costa Rican cities has resulted in historical shortcomings (Cruz Zúñiga, 2002; ProDUS, 2007; Araya-Vega and Quirós-Solano, 2024). For instance, in 2002, Cruz Zúñiga (2002) found sectors of GAM Costa Rica with an average of 2.27 m2/inhabitant of green and recreational areas, against a standard established 12 m2/inhabitant; this flaw has not improved recently; Araya-Vega and Quirós-Solano (2024) found GAM's districts with figures from 1,23 m2/inhabitant to 8,97 m2/inhabitant.

On the other hand, looking back at how the pandemic was experienced in Costa Rica, the focus of attention throughout the first two years was stopping the contagion. Free movement measures were strongly restricted, especially during 2020, mainly focused on all people who could be

fatal victims of the disease, including older adults. During 2020, the parks under study were closed on weekends due to non-compliance with sanitary measures (Peña Nassar, 2021); some areas, such as children's playgrounds, were closed due to being considered places with high human contact. Over the weeks with the highest contagious peaks, these parks were only open for few hours in the mornings (from 5 am to 10 am) to strictly allow outdoor activities and individual sports. The closure of open spaces meant a considerable impact on older people (Barrantes-Chaves, Centeno-Mora and Cruz-Zúñiga, 2023); the Costa Rican population is ageing rapidly (Costa Rica's global fertility rate is ultra-low, 1.31 per woman) (INEC, 2022) and older people choose these spaces for social gatherings and sharing with their peers.

During the lockdown, there was a decrease in traffic on roads, including the park's surroundings. According to previous studies (Barrantes-Chaves, Centeno-Mora and Cruz-Zúñiga, 2023), there has been a strong dependence on private vehicles to visit GAM's urban parks, both before and after the pandemic. In those places, especially on weekends, spaces for private parking are not enough and illegal parking occurs in the park's surroundings, mainly in La Sabana, contributing to the dense local traffic. The economic losses due to heavy traffic within GAM have been estimated at 3.8% of the Gross Domestic Product (GDP) (PEN, 2018).

According to the National Time Use Survey (INEC, 2023), the time per week that Costa Ricans spend in recreational activities has decreased from 2017 to 2022; however, men still prevail as those who dedicate more time to activities such as playing sports or training, while women prefer passive leisure activities. The study infers that before the pandemic, it was more common for both men and women to practice passive leisure activities. However, in 2022 (the last year of the pandemic), these activities reflected a slight shift towards more active routines (it rose on average 1.4% in women and 0.33% in men).

4. Methods

For this study, three main stages were considered. The first involved a thorough exploration and understanding of the different dynamics of the three parks evaluated; the second addressed a literature review on public policies related to public park management; and the last was the fieldwork conducted in the parks. Each of these stages is detailed below.

4.1 Description of the parks considered in this study

The parks considered in this research were all located in San José, the Costa Rican capital, and can be classified as urban parks. Figure 1 presents the location of the three analysed parks: La Sabana, La Paz and El Este, whereas

Table ***1*** summarises their main characteristics relevant to this work.

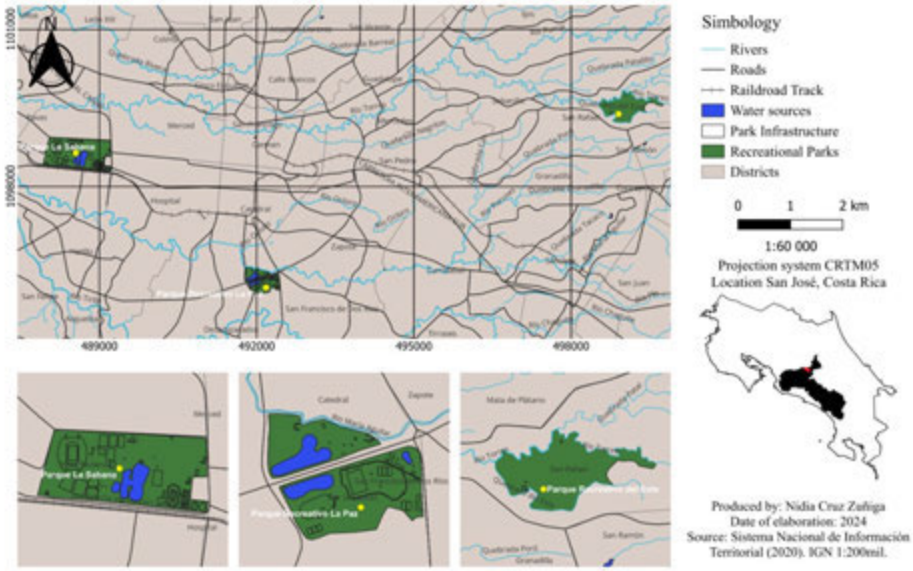

Figure 1. Location of the analysed parks.

Table 1. Main characteristics of each public park

Characteristic	Park		
Park name	Parque Metropolitano de la Sabana	Parque de La Paz	Parque del Este
Location	Canton: San José, District: Mata Redonda	Canton: San José, District: San Sebastián	Canton: Montes de Oca, District: San Rafael
Year of inauguration	1873	1989	1982
Extension (hectares)	72	53	24
Administrative entity	Costa Rican Institute of Sports and Recreation	Costa Rican Institute of Sports and Recreation	Municipality of Montes de Oca
Entry fee	No	No	Yes, approx. US$ 2.0
Opening hours	24/7	24/7	8 am-4 pm
Approx. distance from the centre of San José	3 km	4 km	6 km

4.2 Literature review

A systematic literature review was performed to identify the main published studies worldwide, with more emphasis on Latin America and the Caribbean, about the usage of public parks in the pre-COVID and post-COVID eras.

A protocol was established according to the selection criteria, search terms, and databases. The search was conducted across the academic databases such as Scopus, Web of Science, and Google Scholar, using keywords such as "COVID-19", "public parks", "park usage," "urban parks" and "policy", in English and Spanish. Boolean operators (AND, OR) were employed to refine the search.

Studies were included if they provided empirical data on park usage during or after the COVID-19 pandemic and were published in English or Spanish from 2019 onwards. Exclusion criteria included non-peer-reviewed articles and studies that did not focus on empirical data regarding park usage. After the initial search, titles and abstracts were screened for relevance. Selected articles underwent a full-text review and considered for this article.

4.3 Data collection and analysis

For data collection in this research, 8 575 in situ surveys were conducted across the analysed parks from January to August 2023. The sample included teenagers from the age of 14, adults, and seniors over 65. The surveys were administered by research assistants from the University of Costa Rica, who were previously trained for this task.

Our team undertook a preliminary exploratory study in the same urban parks in a previous publication (Cruz Zuniga, Centeno Mora and Barrantes Chaves, 2023) between 2018 and 2019. This initial research, conducted just months before the COVID-19 pandemic began, aimed to assess visitation patterns and user perceptions with a sample of 491 individuals. It is important to note that during the pandemic, these parks were partially closed following government directives, significantly impacting the usual visitation patterns and park usage. In the new 2023 in situ survey, we not only repeated the questions from the previous study but also introduced specific enquiries designed to understand changes in park visitation and user perceptions before and after the pandemic. This approach allowed a comparison of how perceptions have shifted due to the pandemic and to consider the effects of the partial park closures mandated by the government. To facilitate the processing of field data, an electronic form was created on the Typeforms digital platform, allowing surveyors to enter the information into the platform directly.

Additionally, as a complement to the surveys of 2023, visitation counts were conducted in the parks. For this purpose, in the case of Parque La Sabana and Parque de La Paz, the entire perimeter of the parks was divided into various entry and exit points, and the project assistants were trained to carry out visitation counts, being instructed on how to proceed to avoid duplicating counts. In the case of Parque del Este, being a park with a single entry and exit point where an entrance fee is charged, the counts were conducted only at the park's entrance. These counts were carried out for 5 to 10 hours, repeated over several days of the week, to identify visitation patterns; in total, 38430 people were counted. The data analysis was conducted using Excel (descriptive analysis) and RStudio (descriptive and inferential analysis).

5. Results.

Understanding visitation patterns in large urban parks is essential for developing inclusive planning policies; these findings explore the frequency of visits, transportation means to reach the park, self-reported visitation after the COVID-19 pandemic, and changes in visitation according to data from 2019 and 2023.

5.1 Characterisation of visitors

Visitation patterns of large urban parks within the GAM in Costa Rica have nuances according to age or sex. The age range of the sample is shown in Table 2; it was noticed that users at both ends of the distribution represent the smaller number of participants; which is consistent with the visual counts that were made to triangulate the data and choose the sample size. The figures show that less than 10% of visitors are older people, and a slightly higher number are teenagers.

Table 2. Age range of participants by park (Survey 2023).

	Age range							
Park's name	Under 18 (14-18)	18-30	31-40	41-50	51-64	65 or older	N/A	Grand Total
La Paz	71	632	515	385	329	120	1	2053
El Este	141	945	729	343	207	43		2408
La Sabana	159	1456	1116	815	434	134		4114
Grand Total	371	3033	2360	1543	970	297	1	**8575**

The sex distribution of participants is shown in Table 3; women's participation was around 47%, and men 53% of the sample. Once again, the data closely aligns with the counts; during the counts, 44% of visitors observed were women, and 56% were men. As shown in the Costa Rican National Time Use Survey (INEC, 2023), women spend less time in recreational activities than men; the report shows that women dedicate to sports 4:32 hours a week while men spend 5:12 hours; also, in active leisure women spend 5:10 hours, in contrast with men who use 6:49 hours a week. In this regard, it is expected to find more men than women in both counts and survey applications.

Table 3. Sample by sex and park (Survey 2023)

	Sex			
Park's name	Women	Men	Prefer not to say	Grand Total
La Paz	949	1094	10	2053
El Este	1231	1171	6	2408
La Sabana	1809	2268	37	4114
Grand Total	3989	4533	53	**8575**

The educational level of participants (see Table 4) shows that people with lower qualifications are the minority in the sample. As will be shown, most park users respond that their main transportation means to reach the park is by car. This situation exacerbates inequalities in access to quality public spaces within the GAM (Barrantes-Chaves, Centeno-Mora, and Cruz-Zúñiga, 2023). Therefore, the limited participation of people with a lower educational level could be explained by the challenges they have to face to get there.

Table 4. Educational level of participants (Survey 2023).

	Women	**Men**	**Prefer not to say**
Primary	9%	7%	8%
High school	36%	39%	45%
University (incomplete)	33%	34%	25%
University (complete)	23%	21%	23%
Grand Total	100%	100%	100%

5.2 Visitation Patterns

Participants were asked how they perceived their visitation frequency compared to pre-pandemic times. Figure 2 shows that around 50% of people of all range ages reported that they visit the park more often; this finding concurs with the rise in park visitation after the COVID-19 pandemic in some places from Latin America (Freires *et al.*, 2022). Furthermore, the high increase in teenage frequency visitation (56%) is important because they are not always on the target of planning policies; these data could help local authorities to encourage youth's participation in community park designs. Also, it is essential to highlight that less than 9% of people over 18 years old perceive a reduction in their visitation routine.

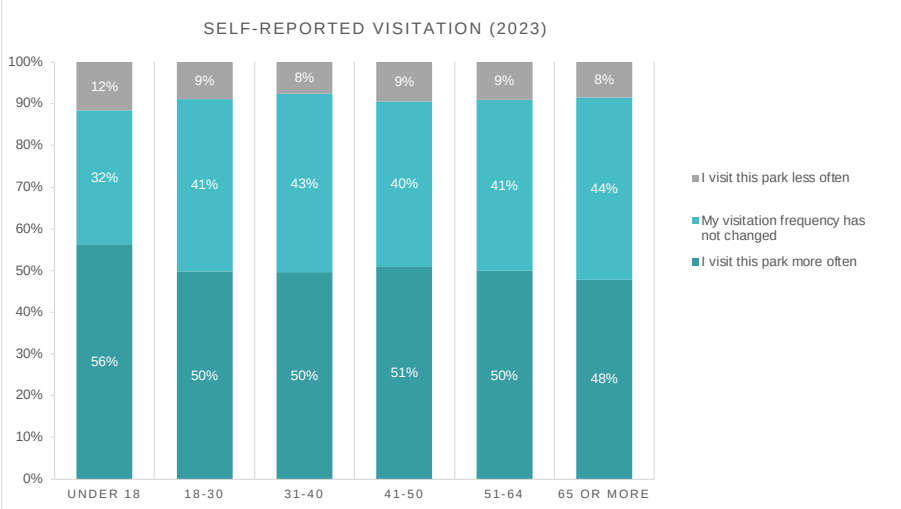

Figure 2. Self-reported visitation after COVID-19 pandemic

Figure 3 shows the visitation frequency in accordance with age. It is noticeable that the visitation frequency of older people (65 years or older) was the highest, with almost half of that age sample visiting the park more than once a week and 16% once a week; research in Atlanta has demonstrated that older people heavy use large scale parks after pandemic due to concerns about contagion and to keep social distance (Liu *et al.*, 2024). This tendency appeared to increase with age, as individuals aged between 51 and 64 also reported more frequent park visits. Other studies have shown the importance of public and open spaces, such as parks, for the well-being of the older population (Xie *et al.*, 2018). Finally, the age group with the lowest visitation frequency is those between 18 and 30; only 31% state that they go to the park at least once a week.

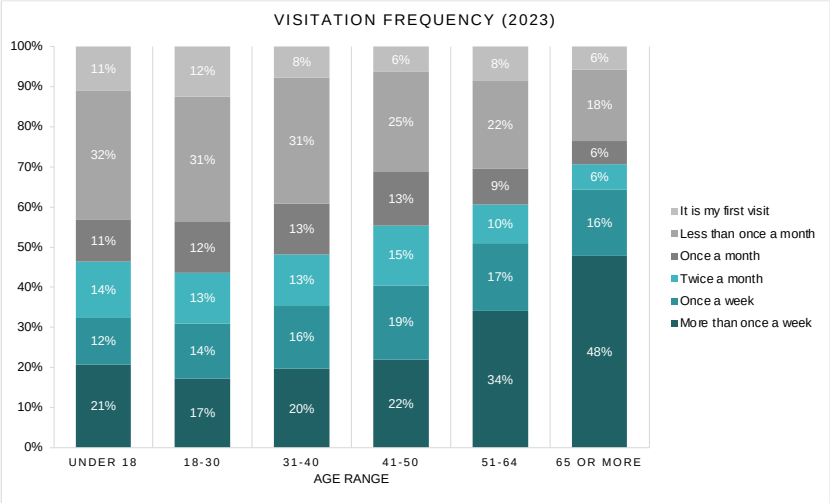

Figure 3. Visitation frequency

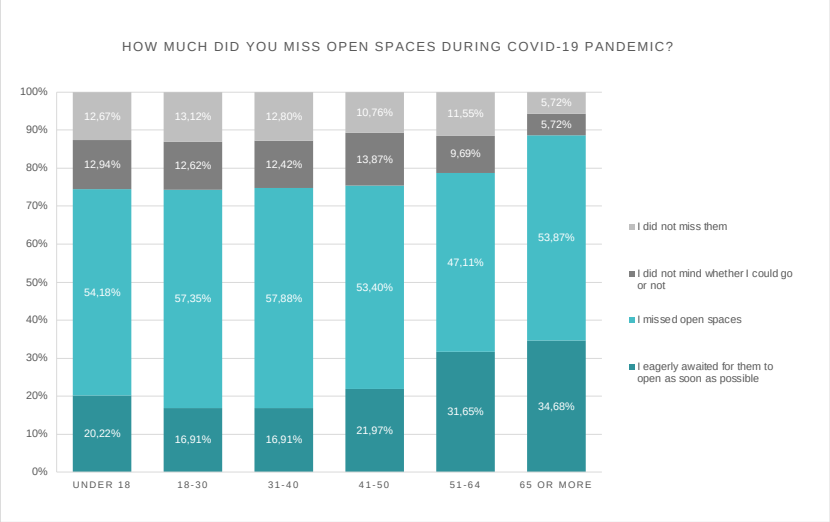

Figure 4. Reports about how people missed the parks during the lockdown.

Users from GAM's parks in San José, as worldwide, had to follow sanitary measures during the pandemic; therefore, all three parks were closed or partially closed during the lockdown. Participants were asked about how much they missed those large open spaces during the COVID-19 lockdown (see Figure 4); the responses show that more than 75% of the sample (N=6484) missed those places or eagerly awaited for them to be open, even those users who reported lower visitation rates admitted to feeling the need to visit these places. The age group that missed parks the most were again those over 65; more than 88% missed or enormously

missed those places. It is noticeable that the eagerness to return to open spaces was highest among the oldest population (over 65) at 34.68% and decreased with age, except for teenagers. Conversely, indifference towards accessing open spaces decreased with age, peaking at 12,94% in the youngest population. The trend of not missing open spaces at all, decreased with age (except for teenagers), with the group between 18-30 expressing the highest indifference (13.12%). These trends suggest a strong affinity for open spaces in older individuals.

Table 5 presents the park visitation for each gender. The visitation patterns show that men generally visit parks more frequently than women; the highest disparity is seen in the "More than once a week" category, suggesting men have a greater tendency for frequent visits. Therefore, 39% of men answered that they visit the park once a week or more, and 36% of women visited those sites under the same conditions. First-time visitors are more likely to be women, perhaps indicating different motivations or opportunities for initial visits between genders. Overall, men's more significant total visit numbers could reflect higher engagement or opportunities to attend the location surveyed.

Table 5. Park visitation variation with gender

Visit frequency	Women	Men	Prefer not to say
More than once a week	21%	23%	21%
Once a week	15%	16%	15%
Twice a month	11%	14%	32%
Once a month	11%	13%	8%
Less than once a month	31%	27%	19%
It is my first visit	11%	8%	6%
	100% (N=3889)	100% (N=4533)	100% (N=53)

As mentioned in the methods section, our team undertook an exploratory study in early 2019 (pre-pandemic) to understand the visitation patterns in those parks from the GAM. As the research used the same survey tool for the post-COVID-19 investigation (2023), it was possible to make an association. Figure 5 displays a comparison between 2019 and 2023; by analysing women and men visitation frequency, it is noticeable that in both samples, 20% of men attend 'more than once a week' to those parks, with a short increase post-pandemic in contrast, women increase their frequency (more than once a week) from 13% in 2019 to 21% in 2023. However, it is worth mentioning that both genders cover a higher range of people who visit the park 'less than once a month'; this figure was lower in 2019. These findings suggest that users of those parks might come more often than before the pandemic, which aligns with the self-reported visitation shown in Figure 2.

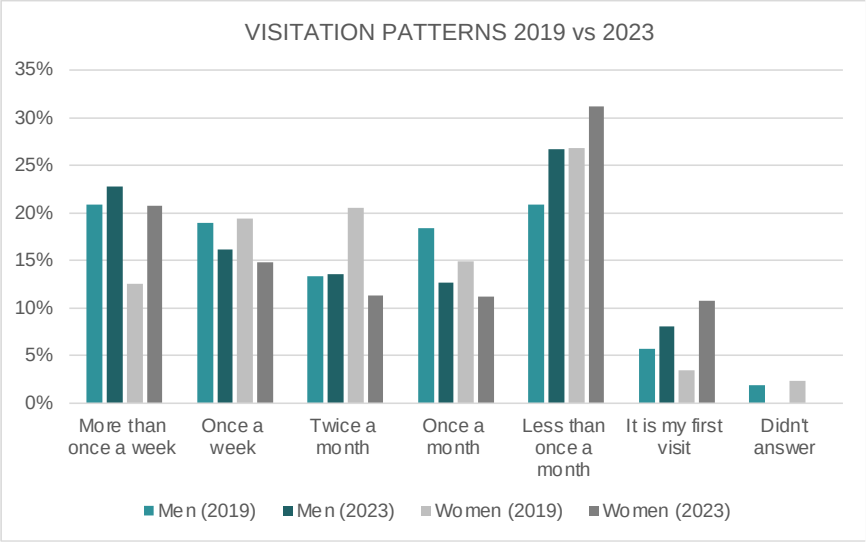

Figure 5. Visitation patterns before and after COVID-19 pandemic

Users from those parks come mainly by car (see Figure 6); despite being urban areas with bus stops nearby, public transport is one of the less popular options to get there. Costa Rica has severe issues with mobility; 34% of the population commutes by bus and 33% by car; 90% of the High Capacity Network does not meet the National Transportation Plan's parameters regarding the number of lanes (PEN, 2018). This means that even a short trip can take a long time. In this regard, more than 40% of large park users prefer to come by car; however, 37% of visitors over 65 come by walking, which is the highest percentage among all age ranges. Less than 25% of park users reach those places by public transport. These findings suggest that large urban parks in Costa Rica's capital might not be easily accessible to people with lower incomes who are not able to afford private transport.

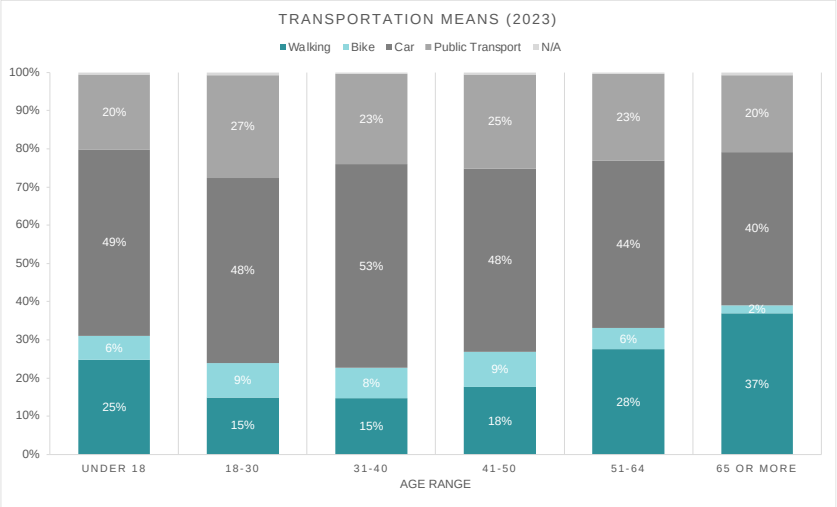

Figure 6. Transportation means after COVID-19 pandemic

By comparing transportation means between 2019 and 2023 (see figure 7), the COVID-19 pandemic seems to have not any incidence in transportation means to reach the parks; in fact, there was a reduction in the use of active ways of transportation such as walking and biking in almost all cases, except for walking in men. In this regard, despite people missing parks and there being an increase in visitation, the mobility conditions have not changed, and public transport has not improved; this situation could lead in the short or middle term to go back to the visitation patterns pre-pandemic as there is not urban policies that foster better macro mobility to urban parks.

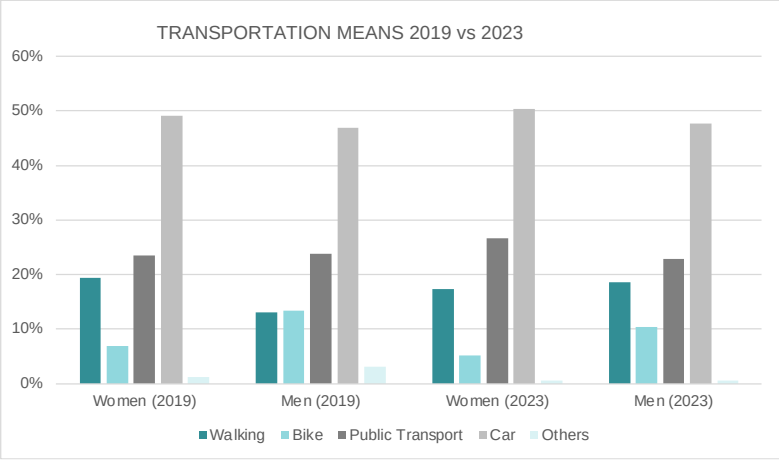

Figure 7. Transportation means before and after the COVID-19 pandemic

6. Discussion

The COVID-19 pandemic brought many lessons to urban planners. The spatial inequalities exacerbated by the pandemic reveal how disparities impact public health in general. Despite park visitation drop during the pandemic in different contexts (Dawwas and Dyson, 2021; Wu *et al.*, 2023), this work reveals that around 50% of visitors reported an increase in their visitation to GAM's parks after the COVID-19 pandemic, which concurs with others context in Latin America (Freires *et al.*, 2022). This research joins a body of literature that demonstrates that after the COVID-19 pandemic, there is a stronger appreciation of parks' contribution to everyday life and recreation (Soares and Brasil, 2020; Wu et al., 2023).

The pandemic has notably changed some behaviours; although an increase in visitation to parks was detected, it remains to be seen if new people's appreciation and preferences will return to pre-pandemic times (Wu *et al.*, 2023). In this regard, authorities in charge of public policies must take advantage of the opportunity to hold that enthusiasm and facilitate better conditions for enjoying those public spaces; for instance, lessons about how flexibility can help to face short to medium-term disruptions (BID, 2022). This new awareness about the importance of green spaces for mental and physical health (Wu *et al.*, 2023) can be approached through new perspectives such as 'Nature-Based Solutions' (NbS) that can offer new possibilities for the public, encompassing integrality, multifunctionality, governance and action orientation (Hernández-García, 2020).

There are also many structural challenges to ensure higher visitation of women in parks; in Costa Rica, women spend less time for leisure than men (INEC, 2023). Although there is still a long way to ensure that men and women equally share responsibilities in domestic and caregiving tasks, some affirmative actions can be taken to facilitate women's access to recreational spaces, such as more versatile infrastructure to meet different needs, and better safety conditions; for instance, minimise blind areas and implement a complete structure with complementary services (Zhang et al., 2022).

This research also shows that older people more frequently visit the GAM's parks; they are willing to come by walking, but their use of public transport is very limited. In this regard, Buffel et al. (2023) recommend an 'age-friendly recovery plan' post-COVID-19, which allows a rethink of which type of urban infrastructure meets older people's needs to support vulnerable populations in order to keep alive informal networks that protect everyday life. Buffel et al. (2023) suggest six principles to secure 'age-friendliness': protect the most vulnerable, mainly when spatial inequality is present, fight against ageism, inclusive post-pandemic city, promote community-based services and infrastructure as well as green areas, develop local partnerships and finally include older people in co-design cities.

The possibility of installing temporary markets would allow nearby communities to interact, sell their products and improve coexistence, which helps the local economy and activation of public spaces, avoiding longer travel times, lower prices from direct producer-to-consumer sales, and natural and fresh products that help maintain a healthy immune system (BID, 2022). Mobility could be the most critical challenge to face; the current transportation system prioritises private vehicles, thus exacerbating inequalities in access to recreational sites.

7. Conclusions

The findings of this work highlight how public policies need to be improved to ensure better access to recreation for Costa Rican citizens. Open spaces were highly valued during the COVID-19 pandemic, and they are necessary and convenient to create a pleasant environment

in the city. The situation experienced during the pandemic left lessons learned about how regional parks are seen with a new lens.

COVID-19 was a game changer in people's visitation frequency in GAM's large urban parks; around 50% of the sample reported increasing their visitation frequency after the COVID-19 pandemic. However, their means of travel have remained the same compared to pre-pandemic times; cars are still dominating the way to get there. Therefore, this momentum could be threatened by growing traffic issues and the need for an efficient public transport system. Biking is not a popular means of transportation; poor infrastructure and heavy traffic make it dangerous. Central and local governments must commit to providing bike lines and pacified streets.

Older people manifested a higher attachment to GAM's large urban parks; it was the age group which missed the most those places during the lockdown; currently, they are the most frequent visitors, and the proportion of senior citizens arriving by walking at the parks is much higher than other age groups. Like many countries worldwide, demographic trends in Costa Rica reveal that the population pyramid has transformed. The proportion of older people has increased; currently, it is 9,6% of the Costa Rican population. The global fertility rate is 1.31 children per woman, considered ultra-low (INEC, 2022), making it necessary to design friendly cities for older adults. Planning policies to encourage better cities for this population are limited; some initiatives are focused on persons with disabilities who are not necessarily older people; for instance, since 1996, Costa Rica has had a law (# 7600) which aims to provide tools for persons from all age with disabilities to achieve their maximum development, social participation, exercise of rights and duties; that includes universal physical accessibility. Costa Rican planning codes could include guidelines to improve the condition of pavements, footpaths, signage, panic buttons, information points, complementary services, and enhance the quality of the walk by planting trees along streets (reducing outdoor temperature). On the other hand, teenagers were the group that reported a higher increase in visitation; thus, the growing interest of teenagers in green spaces and the engagement of older adults might be an invaluable opportunity to promote intergenerational encounters.

Women's visitation frequency was slightly lower than men's, and visual counts showed a higher number of men than women coming to the parks;. However, both genders have similar trends in transportation means to reach the parks; men lightly use more active means such as walking and biking. Affirmative actions could help provide safer pathways for women that could encourage them to try healthier travel methods.

Less than 10% of the sample were people with low educational attainment, which shows how unequal the enjoyment of recreational spaces, even those freely accessible. The poor quality of public transportation and extended times might discourage those people who do not own private vehicles. Outdoor markets stimulate the visitation of people from different economic backgrounds, not only by providing the opportunity to sell products but also by reducing intermediaries and offering fairer prices. As demonstrated in other initiatives worldwide, these spaces might activate public spaces and provide natural surveillance that contributes to the area's security and vitality.

Finally, community participation has been proven to engage people in their familiar environment successfully; therefore, planning policies have to be able to capture citizens' views fairly; data is crucial, not only for authorities but also for citizens to make informed decisions. Planning policies can be addressed to meet people's needs and new visitation patterns after COVID-19. For example, how can we promote a richer intergenerational exchange by taking advantage of teenagers' increase in visitation? Which activities would keep the interest of older

people in those spaces? How can we promote new ways of commuting and reduce access inequalities? How can we provide safer walking and biking routes for women? Public spaces are volatile places (Jacobs,1961); therefore, new users' attitudes also bring new opportunities that must be noticed.

Abstract

In the contemporary context of a profound crisis of public spaces in general, and the Portuguese context in particular, questions of intensive 'touristification', fast gentrification, and concentrated immigration are reshaping the use and values of traditional urban spaces. The introduction of new public actors, new communities, and associated different social practices, often lead to feelings of estrangement of the public space, as well as to the emergence of different intermittent uses of public space. In this context we aim to discover different formal and social conditions of space especially within 'off-map' places whose use and value are currently being rediscovered and/or shifted.

In this article, we propose a new approach to public space as a threefold notion based on: (1) the idea of Pocket spaces, (2) Foucault's heterotopia and (3) intermittent occupation. We analyse fifteen different potential heterotopic pocket spaces from a threefold perspective composed by the (1) morphological qualities of pocket spaces, (2) the socio-spatio-temporal relationships of Foucault's heterotopia and (3) the social use based on the capacity of the space to accommodate different uses and practices.

We argue that, due to its complexity and ability to embrace contradictions and conflicts, heterotopic pocket spaces can be used as a valuable concept for describing, analysing, and creating speculative designs for a more democratic city, embracing and re-signifying possible estrangement of the public space in the contemporary, everchanging context.

Keywords: *heterotopia, urban pocket spaces, intermittent occupancy, public space*

Heterotopic Pocket Spaces

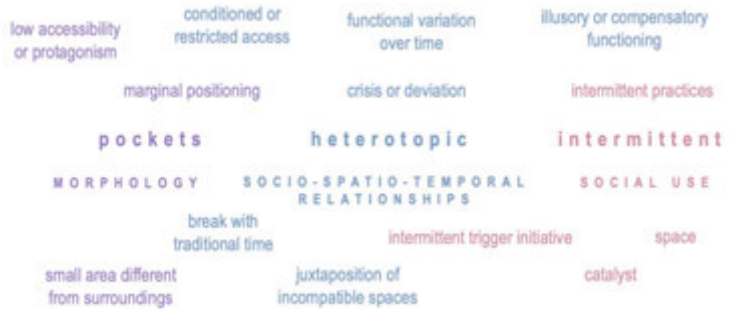
Complexity of contemporary public space is challenging to describe, and it cannot be approached from a one-dimensional only point of view, formal, social, or relational - it requires a comprehensive reading strategy.
While urban morphology can quite clearly describe qualities of the formal dimension of traditional public spaces, the permanently evolving social dimension is more challenging to address. Questions such as of touristification, immigration and social discrepancies are being exposed and becoming evident in the nowadays occupation of public spaces. Negotiation of spatial occupation occurs on various levels and is commonly visible in traditionally recognised and mapped public places. These encounters, as a representation of permanent spatial negotiations between different actors, are bringing certain theatrical qualities to the use of the city as we observe each other from a distance. One finds oneself exposed.

Differently, less known out-of-touristic-map and untraditionally generated public spatial pockets, are emerging in different, less described, and unexpected locations hosting spontaneous community-orientated uses. These emerging spaces are relevant for social cohesion and well-functioning society in terms of interpersonal dynamics and/or collective efforts (Qi, Mazumdar and Vasconcelos, 2024). These spaces can function as "third places" of "great good places" between home and work, the core of a

community's social vitality as designated by (Oldenburg, 1999). Moreover they can work as “fourth place” as defined by (Simões Aelbrecht, 2016), lively and inclusive public spaces, characterised by its social openness beyond social comfort and their capacity to bring strangers together.

Taking into consideration the need for a comprehensive spatial reading and based on empirical observation of 15 public spaces in Lisbon, we propose a descriptive matrix for the description of emerging public spaces. We address these out-of-touristic-map pockets, as heterotopic pocket spaces and define them from a threefold perspective:

1. morphology (based on the definition of pocket spaces)
2. socio-spatio-temporal relationships (based on Foucault’s heterotopic principles)
3. social use (based on their capacity to accommodate intermittent practices)



Definition of Pocket Spaces

“Pocket is a kind of small bag which forms part of a piece of clothing, and which is used for carrying small things such as money or a handkerchief.”; however, the definition goes on, and includes an idea of “a pocket of something” and as “a small area where something is happening, or a small area which has a particular quality, and which is different from the other areas around it.”. [1]

In literature, science fiction and fantasy, the pocket spaces can mean small, hidden, or magical dimensions or realms. These are often used in stories to represent secret or additional storage areas, hidden worlds, or alternate realities that exist alongside the main world. One of the most illustrative examples of pocket space as realm of infinite possibilities is Borges’ Aleph: “the only place on earth where all places are […] all lamps, all sources of light are in it.” (Borges, 1971) In his “The Poetics of Space", Gaston Bachelard delves into the intimate spaces of our lives such as those: “…of a hut, of a nest, or of nooks and corners in which he would like to hide away, like an animal in its hole…” (Bachelard, 1994), which metaphorically can be extended to the idea of pockets considering it as a small, personal world carrying our private thoughts and treasures. Junichiro Tanizaki’s "In Praise of Shadows" (Tanizaki, 1977) apart from primarily dealing with Japanese aesthetics and the beauty of shadows, implicitly discusses the significance of small, contained spaces and how they contribute to our experience of the world. This can be interpreted to include the idea of a pocket as a miniature, intimate space of its own.

[1] Examples given by Collins English Dictionary: “He survived the earthquake after spending 3 days in an air pocket.” And “The army controls the city apart from a few pockets of resistance.” https://www.collinsdictionary.com/dictionary/english/pocket consulted on 11th of May 2024

Regarding the application of pocket spaces in urban design practice, Kimmel describes them as social thresholds and negotiation space. She gives an example of small wire-separated areas of Refugee Cricket Project (East Croydon, London) designed by Muf architecture+art, a London-based practice[2]. These small areas primarily intended for young refugees allowed anyone from the neighbourhood to come, watch the cricket game and engage with the teams. It was unpolished, low cost and temporary, public space that was a threshold between communities. Another quality of pocket spaces is that they are negotiation spaces, where different actors negotiate presence and movement. The author recognizes these negotiation spaces in skating areas of parks where small size skating platforms are pocket spaces and surrounding area are thresholds between semi-private skating area and public space. (Kimmel, 2021 pp.119-120).

Thus, pocket spaces refer to different concepts depending on the context they are applied at. In urban planning and architecture, pocket spaces refer to small areas within a city or urban environment, like pocket parks or public squares. They provide green space, relaxation areas, or pedestrian-friendly environments within a dense urban setting. In the "Architecture of threshold spaces: a critique of the ideologies of hyperconnectivity and segregation in the socio-political context" (Kimmel, 2021) describes pocket spaces "as an architecturally defined place of social interactions in public space, such as an 'open urban room' where people linger[3]" (2021, p.116, par.1) and they are commonly localized at the margins of main paths in less accessible areas[4].

Foucault's Heterotopia and Socio-spatio-temporal Relationships

The understanding of heterotopia necessarily implies the understanding of utopia. The prefix "hetero" designates "different", while the prefix "u", from the Greek "ou" means "not", or, also from the Greek "eu", which means "good"; in other words: utopias are unreal places (good, as opposed to dystopias), heterotopias are "other", different places (*Des Espaces Autres*). The word "utopia" is used for the first time in 1516, as the title of the influential book by Sir Thomas Moore, which describes a perfect society, in opposition to the English court of the time. The word "heterotopia" is first used by Michel Foucault four hundred and fifty-one years later. In fact, before naming heterotopias as such, Foucault presented the concept under the name of "localized utopias"[5] which, despite being a contradiction, is very suggestive: "real places situated outside all other spaces destined to efface, to neutralize, to compensate or purify the spaces they oppose."[6]. The concept of heterotopia, was introduced by Foucault on a lecture in 1966 and, having gained significant protagonism, published in several versions and various translations[7].

The notion of Heterotopia has inspired diverse interpretations of complex and conflicting contemporary public spaces. In her chapter "The many mirrors of Foucault and their architectural reflections" Boyer (2008) criticizes architects for, given the fascination with the concept developed by Foucault, reducing heterotopic space to "any autonomous fragment set in opposition to the compositional totalization of the city" (p. 64, par.4). There are several works that overpass this reductionism by introducing the intrinsic quality of 'otherness' in understanding public space. In their analysis of urban margins Wallace and

[2] "Muf base their project designs on concepts around the resolution of social conflicts. They primarily work for people in social minorities so that they can be present in, and use public space, interacting with other communities."

[3] Laurence Kimmel uses the example of Yokohama Ferry Terminal

[4] Public space of the Oslo Opera House

[5] "The many mirrors of Foucault and their architectural reflections" Boyer, 2016; from Heterotopia and the City, Public Space in post-civil society" first published in 2008 by Routledge

[6] Ibidem

[7] Here we use the translation of Lieven De Cauter and Michiel Dehaene, from "Heterotopia and the City, Public Space in a post-civil society" by the same authors, first published in 2008 by Routledge

Stalcup, (2022) use heterotopy to grasp the visibility of adjacent spaces and how individuals perform when they are visible, revealing how they comprehend themselves in relation to others. Soja, (1996) employs the heterotopy in his definition of "Thirdspace" and deconstructing traditional spatial dialectic between real and imagined space. Based on the reading of Foucault's heterotopia, Tekinalp and Şentürer, (2024) created seven-step view lens for analysis of public space regarding presence of different identities that coexist with others.

Instead of reducing heterotopic spaces to fragments, in this work, we propose to start precisely from the opposite, that is, from the idea of "compositional totality of the city". We evoke heterotopia as quality that instead of discretising space into parts, puts into a relationship diversities and oppositions of the city as a whole. Starting from compositional totality of a city we define heterotopic pocket spaces by looking not only at the pocket itself but the socio-spatio-temporal fabric in which the pocket is tailored.

In his text, Foucault introduces six principles:

1st Principle of Crisis or Deviation

Heterotopias often house individuals experiencing crises or those considered deviant. In earlier societies, these spaces might be reserved for rites of passage, such as puberty, marriage, or pregnancy. In contemporary times, they tend to house those who deviate from the established (societal) norms, like prisons or psychiatric hospitals. Nowadays, there is a cultural obligatoriness for inclusion that almost cancels any possibility for deviation, as deviation ought to be accepted. In urban-architectural practices the principle of so-called crisis or deviation are nowadays evident in the contexts of queer spaces (Doan, 2007) or those of people that are houseless and occupy public spaces by temporarily shelters. In the case of Lisbon, in the garden António Feijó, next to the Church of Nossa Senhora dos Anjos, houseless people are not necessarily unemployed but have chosen provisional shelters as answers to high cost of living space rents.

Fig. 2. Marvila 8
https://www.8marvila.com/gallery

2nd Principle of Functional Variation Over Time

The function of heterotopias can evolve with time and cultural shifts. For instance, cemeteries were historically central to communities, and thus placed at city centres, but later moved to city outskirts due to changing conception of health and death. This principle indicates that the meaning and role of heterotopias is deeply rooted on their context. In the contemporary urban-architectural practice this principle is being widely explored. Such an example is Marvila 8 project, situated in Lisbon, which is an on-going ephemeral initiative that transformed 22.000 m2 of the old Abel Pereira da Fonseca wine warehouses, a city landmark, retaining their original space delineations created by the wine cellars. The "8" symbolizes the space's reuse, as Marvila 8 has refurbished the distinctive façade and embraced a reuse philosophy, repurposing over half of the rubble, wood, iron, and sheet metal, including the warehouse counters.

3rd Principle of Juxtaposition of Incompatible Spaces

Heterotopias can contain or juxtapose various spaces that wouldn't normally coexist. A theatre stage can depict multiple locations within a single play, while a garden can symbolize a microcosm of the world and represent an ideal of Eden. This principle reveals how heterotopias can bring together contrasting spaces within one setting. This juxtaposition nowadays seems less invasive as limits between categories such as for example those between sacred and profane blur (see an example of Kruisherenhotel Maastricht in Netherlands).

Fig. 3. Kroon Gallery & Kruisheren Hotel Maastricht
https://maastrichtgalleryweekend.nl/author/johan/

4th Principle of Heterochronism (Link to Time)

Some heterotopias are linked to different concepts of time. Cemeteries represent a kind of timelessness, whereas museums and libraries are heterotopias where time accumulates through historical artifacts and records. This principle highlights how these spaces can create a very singular relationship with time, either as static or constantly evolving. As an outcome, heterotopic spaces also culminate in a rupture with current or traditional time.

5th Principle of Conditioned or Restricted Access (Opening and Closing)

Heterotopias often have specific systems for access and control. They can be restricted with barriers or require rituals and permissions for entry, like prisons or religious sites. This principle acknowledges that access to heterotopias is often regulated, creating a sense of separation from everyday spaces.
https://maastrichtgalleryweekend.nl/author/johan/

6th Principle of Function as Illusion or Compensation

Heterotopias can serve to create a space of illusion or compensation. As illusions, they can reflect the illusory nature of societal norms (like brothels, which offer an alternative to mainstream society). As spaces of compensation, they can offer a more ordered or idealized environment compared to the real world (like utopian colonies or carefully planned gardens, such as Persian). This principle suggests that heterotopias function as a critique or provide an alternative to conventional societal structures.

Intermittent Practices as Heterotopic Pocket Uses

Apart from the ideas of pocket spaces and heterotopias we introduce the notion of intermittent practices which are the validation of existence of heterotopic pocket spaces. We observed the use of these public spaces through the lens of "**Intermittent Practices**"[8], as defined by Allegri and Ochoa (2021) that refer to temporary and flexible activities or uses of urban spaces that deviate from traditional, permanent arrangements. These practices are characterised by their adaptability and responsiveness to changing urban needs and conditions and emphasise values of temporariness and sharing, reflecting broader socio-economic, political, and technological shifts. These new and unconventional dynamics are emerging in various forms: housing models (co-living, co-housing, temporary accommodation); work arrangements (co-working, remote work); shared mobility (bike-sharing, car-sharing); shared goods and services (creative commerce, Netflix, Spotify); spontaneous cultural events; and innovative uses of spaces (parties in abandoned buildings, urban agriculture in vacant lots) (ibid.).

In Search for Heterotopic Pocket Spaces

Taking into consideration the morphological characteristics of pocket spaces and relational aspects of heterotopic spaces proposed by Foucault we examined fifteen different spaces of the Metropolitan area

[8] https://intermittentcity.fa.ulisboa.pt consulted on May 17, 2024

of Lisbon. We considered the properties descriptive of pocket spaces such as: marginal positioning, low accessibility, and small area in comparison to surrounding urban tissue and the 6 principles of Foucault's heterotopias. In these fifteen different spaces, we further analysed the existence or absence of intermittent practices and the triggers that initiated them.

In the table we observe a set of diverse open public spaces that are recognized and mapped by Ochoa and Allegri as places for intermittent practices. These places host different functions (social, economic, cultural, etc.) that occur in different intervals (yearly, weekly, daily, irregularly) and are initiated by different actors (municipality, small entrepreneurs, community groups, squatters citizens, etc.).

1 intermittent city's* heterotopic pocket spaces

11 potential heterotopic pocket spaces

pocket spaces

heterotopia

intermittent city*

Heterotopic Pocket Space + Intermittent Practices

In the first example, the beach in jardim do Torel, Lisbon, the use or intermittent practice takes place one month per year, namely in August, and occurs in this public garden and viewpoint. Since 2014, a part of the garden is transformed into a beac sand and sun umbrellas brought in, and the 18th cer tank is filled with water enjoyed by the public.

Fig. 5. from https://intermittentcity.fa.ulisboa.pt/praia-do-torel/

This heterotopic pocket space is situated in the centre of Lisbon, yet it is of low accessibility and has controlled opening and closing times. To access this beach in the garden one must go through different spatial transitions, such as sinuous streets, or an overwhelming staircase that goes through a yard of a primary school. Apart that, this garden is 'different', or 'other' as explained by Foucault[9]; since, like all gardens, the meaning of their existence and creation comes from a need for the representing the paradise on earth, of nature in the city (natural environment vs. built environment). The principles of juxtaposition of incompatible spaces and illusory or compensatory functioning are especially interesting here. On the first one, the desire of having a beach in the middle of the city, literally (since the viewpoint-garden of Torel allows for a panoramic view of the city), is in itself quite incompatible with the garden's situation in the city, usually, (in the case of Lisbon, Barcelona, etc.) when there are beaches near the city, they are located at its borders, never, geometrically or geographically in the middle, as is the case in this occupation.

This garden is already both a pocket space and a heterotopy, however, what enhances these characteristics, and truly turns it into a heterotopic pocket space is its intermittent occupancy, the desire of intermittently turning it into a beach.

Heterotopic Pocket Space - Intermittent Practices

Heterotopic pocket spaces where intermittent practices don't occur, are only *potential* heterotopic pocket spaces, left-over, marginal space. Like heterotopic pocket spaces, their morphology is linked to the fact that these spaces are rather small spaces, and different from their surroundings: this relates to their shape, scale, and dimensions. This aspect is linked with Foucault's principle of restricted or conditioned access since the access of these heterotopic pocket spaces is what segregates (restricts and conditions) them from their surroundings – not exactly in Foucault's visualization of restriction, the one that demands a permission (ritualistic, religious, legal) – rather in urban-architectural terms, in the way our bodies are influenced

Fig. 4. author's photograph

[9] *Des Espaces Autres* (Foucault, 1984)

by built space, the morphology of the access of these spaces is what restricts and conditions them (Hillier *et al.*, 1984, p. ix)[10].

The morphology of potential pocket spaces also contemplates the morphology of their access, as we understand this as being a crucial part of them: namely, because, by differing in scale, dimension and sometimes in shape, they evoke the principle of restricted or conditioned access, the perception of being in some *other* space. Thus, their morphology is indissociable from the built space that contains them: they do not have a specific shape (they rather vary in shape) and do not correspond to any typology.

Use, or rather, lack of use, is the major characteristic of *potential* heterotopic pocket spaces, and is what ultimately differentiates them from heterotopic pocket spaces. Unlike the latter, characterised, as seen previously, by an occupation, these are rests[11], remaining, located in the back façades of buildings, commonly occupied by parked cars and garbage cans[12], this is, they haven't yet been occupied by people, they are exempt of activity.

Final Considerations

The search for an explanation regarding these by us called heterotopic pocket spaces, originally came from an empirical observation of neglected, marginal spaces. A link with Foucault's heterotopia was very helpful, since it exemplified how space can function as a tool for embracing contradictions and conflicts rising from the contemporary crisis of public space (neglected space vs. over-exposed and 'touristified' space). However, heterotopic pocket spaces are not merely conditioned by morphology (pocket spaces' qualities) nor socio-spatio-temporal relations (heterotopia's qualities), they need a social use, without which they cannot be considered as such. The social use (occupation: appropriation, subversion) is ultimately the clue for differentiation between heterotopic pocket spaces and *potential* heterotopic pocket spaces. The study carried by Intermittent City is very relevant, since it shows how people perceive and therefore project themselves in the space (often, but not always pocket spaces) they inhabit, giving a hint of what they think is missing in their city (Foucault's principles). This analysis clarifies how use (occupancy, appropriation, subversion) is crucial for understanding the concept of [intermittently occupied] heterotopic pocket spaces, since without it, this activation of neglected and marginal spaces, doesn't occur.

Finally, we argue that this result (combining these three different frameworks: morphological, socio-spatio-temporal, and social use) provides a comprehensive tool for operating in towns and cities suffering from excessive tourism, fast gentrification, and loss of character – such as in the Metropolitan area of Lisbon, Portugal.

Keywords: Urban Design, Walkability, Urban Heat Island (UHI)

Abstract
This study examines the relationship between urban design, walkability, and climate change, with a particular focus on the necessity for public spaces that can accommodate rising temperatures and heat waves. Using Bergamo, Italy, as a case study, the research combines GIS-based spatial analysis with stakeholder interviews to assess the impact of urban heat islands on pedestrian mobility. The findings indicate that effective urban design must balance the practical needs of mobility with the social benefits of public spaces. The paper advocates for the implementation of adaptive design strategies that enhance walkability, promote social interaction, and mitigate heat-related barriers. These strategies are expected to support the health and well-being of urban residents, particularly those who are most vulnerable.

Introduction
The future of urban areas appears to be contingent upon the implementation of sustainable and active transportation strategies. However, the effects of climate change are intensifying, particularly in relation to rising temperatures and heat waves (IPCC, 2023). Consequently, novel approaches are required to promote a soft mobility paradigm that considers the implications of climate change, while designing 'spaces for mobility'. Cities and their vitality are pivotal to societal well-being. Nevertheless, it is essential to ascertain whether these urban areas are accessible and available to all members of society. There are major differences in the mobility requirements and various degrees of social relationship needs of different street users, and public space planning must necessarily take these into account.
Henri Lefebvre identified the practice of the use of the city, describing pairs of opposing and complementary needs. These included security and openness, certainty and adventure, work organisation and fun, predictability and the unexpected, unity and difference, isolation and encounter, and independence and communication. He posited that humans need to see, hear, touch, taste, and fuse all these perceptions into a World (Lefevbre, 2013). For 75% of the European citizens (Eurostat, 2022) the concept of the World encompasses a specific urban form – cities, towns, suburbs. These needs are distributed in different ways among people and evolve over time, both in the short term (from morning to night) and in the long term (across different age groups). The importance of public space, and particularly of the sidewalk, has been widely documented in the literature. In her 1961 work, The Dead and Life of Great American Cities, Jane Jacobs identified three primary functions for this section of the street. Firstly, it serves as a form of self-surveillance, protecting residents and non-residents alike. Secondly, it provides a space dedicated to the formation of networks based on trust. Thirdly, it facilitates the assimilation of younger individuals into the urban social context (Jacobs, 1992). It is important to note that the three roles are not contingent upon mobility, even though the sidewalk was

originally designed for that purpose. The three roles that Jacobs describes are primarily social in nature, with the public walkability space serving as a conduit for interaction. It is important to recognise that urban life is not solely about the movement between spaces; it is also about the act of staying in spaces. As Cerdà observed, urban life is constituted by two fundamental elements that include all of the functions and activities that comprise human life. The human being rests and the human being moves (Cerdà, 1867).

The term 'walkability' is open to interpretation. To identify a clear definition, Ann Forsyth (2015) conducted a literature review. The outcomes can be condensed into three categories:

- Walkability is defined as a condition that favours or enables walking. This definition emphasises elements such as movement, the compactness of the urban fabric, safety, security, and the attractiveness of the pedestrian route. It is the simplest definition of walkability.
- Walkability is defined as the perceived outcome of walking. It encompasses a number of factors, including livability, sociability, sustainability, and physical exercise. It places emphasis on the secondary outcomes that pedestrians obtain in addition to the main objective of moving from one point to another.
- Walkability is defined as a proxy for the evaluation of urban environments. The conversion of pedestrian mobility into numerical values provides a means of comparing different environments or, in the case of the same environment, highlighting the results of a design intervention. In essence, it is the measurement of pedestrian mobility.

The absence of a unified accepted definition can potentially make the phenomenon challenging to comprehend and, subsequently, slow its advancement. Nevertheless, there are some similarities between the three categories. Firstly, the environment that a pedestrian must traverse and secondly, the distance to the destination. The configuration of the city, and in particular the area allocated to pedestrians, is of paramount importance. Whether it is the absence of obstacles that impede walking, the provision of adequate lighting to enhance perceived security, or even the simplicity of creating spaces conducive to social interaction, the manner in which the pedestrian aspect of the city is conceived and designed aligns with numerous of these definitions. The second factor to be considered is the distance. It is evident that pedestrians are unable to traverse distances that can be covered by other forms of transportation at fixed times. In such instances, the use of motorised or public transport is unavoidable. Nevertheless, urban compactness can positively influence the security and sociability of places. A denser city tends to offer a greater number of accessible locations and services that can be reached on foot. Consequently, an increase in the number of pedestrians will result in more opportunities for social interaction and a perception of enhanced security.

The concept of pedestrian public space can then be seen from two distinct perspectives. Firstly, it is the pathway that allows pedestrians to traverse between two points, thereby ensuring the walkability of the space. Secondly, it is a social space where public life takes shape and 'things happen' (Gehl, 2010). Mobility space, therefore, is also a part of the public city system and should fulfil both the roles of becoming a quality space and facilitating the movement of people.

Once the space of walkability has been defined, it is necessary to frame the people who move in this space. The World Health Organization (WHO) define the pedestrian as '*any person who is travelling by walking for at least part of his or her journey. In addition to the ordinary form of walking, a pedestrian may be using various modifications and aids to walking such as wheelchairs, motorized scooters, walkers, canes, skateboards, and roller blades. The person may carry items of varying quantities, held in hands, strapped on the back, placed on the head, balanced on shoulders, or pushed/pulled along. A person is also considered a pedestrian when running, jogging, hiking, or when sitting or lying down in the roadway.*' (WHO, 2013, p. 3). While this definition is comprehensive, the difficulty in identifying the characteristics of

pedestrians is considerable. The utilisation of public space is contingent upon the characteristics of the pedestrian in question. Individuals with temporary or permanent mobility impairments, the elderly, parents with children, pregnant women, and so forth, may necessitate different requirements than those that the city can provide.
The mobility behaviour of a pedestrian is influenced by internal or external factors. Internal factors include the state of health (e.g. temporary injuries), the time and objective of the journey, whether they are alone or in company, the possibility that the individual is carrying material burdens (e.g. a package) or immaterial burdens (e.g. sadness or depression), the age, etc. The external factors include physical elements – such as pavement and street width, number of people, climate, etc. – and subjective qualities of the walking environment: imageability, enclosure, human scale, complexity, etc. (Singh, 2016). The walking speed of moving pedestrians varies considerably, with a range of between 1 km/h and 5 km/h (GDCI, 2016). This fact alone should highlight the extreme differences within the usually generalized category of pedestrians.

The objective of this contribution is to propose a rethinking of the design process and organisation of public mobility space, with a particular focus on those aspects related to walkability. This is achieved by emphasising the role and impact of heat waves, a highly topical subject given climate change, in shaping the design principles of public space, which is defined here as an open and accessible space for city users. This is done trying to promote walkability, in particular for the more vulnerable people. To do so, it is necessary to apply methodologies based on complex and diverse analyses to investigate and define the main spatial critical points. These must be the basis for the definition of subsequent mitigating actions aimed at removing urban barriers to walkability, in particular the effects of heat waves and the urban heat island, so as to intercept different aspects including the personal perception of the inhabitants.
The next paragraph introduces the topic of heat waves and the urban heat island, emphasising their barrier effect on walkability in urban public space. The case study is then presented, namely the Redona district of Bergamo, a medium-sized city in northern Italy. The methodologies and materials used are then illustrated, dividing them into quantitative and qualitative. The same division is applicable to the data analysis and comments section, where both positive and negative findings regarding the effect of heat on walkability are highlighted.

Heat, public spaces and walkability
The walking practice can be reduced or limited by the design of the streets and by various public spaces' barriers, which are connected both to the space-time context and to the characteristics of the people walking. The environmental conditions can act as a limiting factor to walkability, as the utilisation of public space varies throughout the day and across different seasons. This is due to the influence of varying temperatures on human behaviour. Among the various effects that climate change is causing on human beings' daily lives, the rise in temperatures is of particular concern, with the greatest impact being felt in urban areas. Heat can be then conceptualised as a form of hidden barrier. In Italy, the average global temperature in 2020 was 1.44 °C higher than in the 1961-1990 reference period. Furthermore, the ten hottest years recorded are all positioned after 2005 (ISPRA, 2021). The projections indicate a rise in average temperatures between 1.6 °C in the case of drastic reductions in emissions and 5.1 °C in a scenario of constant emissions, over a reference period between 1990 and 2100. Additionally, the number of heat waves days is projected to increase from 10 in 1990 to a range between 75 and 250, respectively, in a scenario of strong emission reductions or constant emissions (UNFCCC, 2018). From 1960 to 2020, temperatures in urban areas increased by approximately 3 °C, with cities such as Milan, Turin, Bologna, Florence and Genoa experiencing the greatest rises (IIPH, 2022). The effects of heat waves are worsening when it

is combined with the urban heat island (UHI) effect. This is the phenomenon whereby temperatures in urban areas are higher than in rural areas (Oke, 1982). The UHI phenomenon is the result of the accumulation of heat during the initial hours of the day, followed by its subsequent release, which leads to a sharp increase in urban temperatures. This situation is potentially dangerous for people, especially those in vulnerable categories. It is not possible to generalise the impact of the UHI and heat waves on human beings. The personal thermal comfort varies based on environmental factors such as temperatures, humidity, wind, atmospheric pressure, and direct sun exposure (Yang et al., 2015). However, there are general studies about heat effects. The results of the EuroHEAT project showed that people living in areas with moderate climates are more susceptible to heat waves. Italy was identified as one of the European countries with the highest rates of morbidity and mortality associated with high temperatures, with an increase of 20.3% in mortality observed on days with average temperatures approximately 3 °C higher than the historical seasonal distribution (CCM, 2019). For example, in the city of Bologna, a 1 °C increase in temperature above 24 °C is associated with a 2% increase in mortality (IIPH, 2022). It is well documented that several physical diseases are closely linked to heat. One of the immediate effects of heat stress is dehydration, which is caused by sweating and a failure to replenish fluids (CCM, 2019). This phenomenon is particularly detrimental to individuals with a diminished capacity to perceive dehydration, such as children and the elderly. The latter are particularly susceptible to the phenomenon due to causes such as reduced perception of thirst, impaired kidney function or cognitive impairment (ASUGI, 2020). Heat-related lipothymia is a transient alteration in blood pressure balance that can manifest in a variety of ways, ranging from mild dizziness to complete loss of consciousness. (CCM, 2019). Finally, heatstroke represents one of the most serious consequences of heat exposure and, if not treated promptly, can result in death. The condition is caused by an impairment of the body's ability to thermoregulate due to a temperature that is too high. Once more, it is important to note that there are several symptoms associated with heatstroke, which can manifest in a number of ways. These include, but are not limited to, weakness, nausea, pulmonary oedema and shock. The potential for confusion regarding symptoms is a further complicating factor. For instance, the elderly may experience temporary temperature rises due to medication (CCM, 2019). In urban areas, where green spaces are scarce, the risk of mortality from elevated temperatures is elevated by 5% (UNEP, 2021). In addition to the direct effects on the human body, high temperatures are also linked to mental and psychological health problems. These include increases in suicide, anxiety, and stress, as well as decreases in personal happiness and well-being (IIPH, 2022).

Case study

To identify relationships between temperature and walkability, this paper uses as a case study a district in the city of Bergamo, a medium-sized city in northern Italy, located 50 km from Milan at the confluence of the Brembana and Seriana valleys. Over the past decade, the population of Bergamo has grown from 115.000 in 2011 to 120.000 in 2022. As is the case with the rest of Italy, Bergamo is also characterised by a progressive ageing of its residents. In 2022, the over-65s constituted 25% of the total population (ISTAT, 2024). The city was founded by the Romans and is situated on a hill. From this centre, fortified during the sixteenth century by the Venetian Republic – the walls of which are today UNESCO heritage – roads were developed, and boroughs grew up around them. Therefore, the ancient Bergamo is characterised by a hand form. At the beginning of the 20th century, the area between the boroughs was developed, resulting in an increase in population density within the city (Pagani, 2000). Following the Second World War, as was the case in many Italian cities, the urban form underwent a significant expansion, resulting in the creation of entirely new neighbourhoods or the expansion of the periphery with the establishment of small settlements, known as 'Corpi

Santi'. This rapid expansion from one side enabled the city to meet housing demands, yet on the other side resulted in a detachment from historical and cultural values, as well as from forms of mobility other than the car.

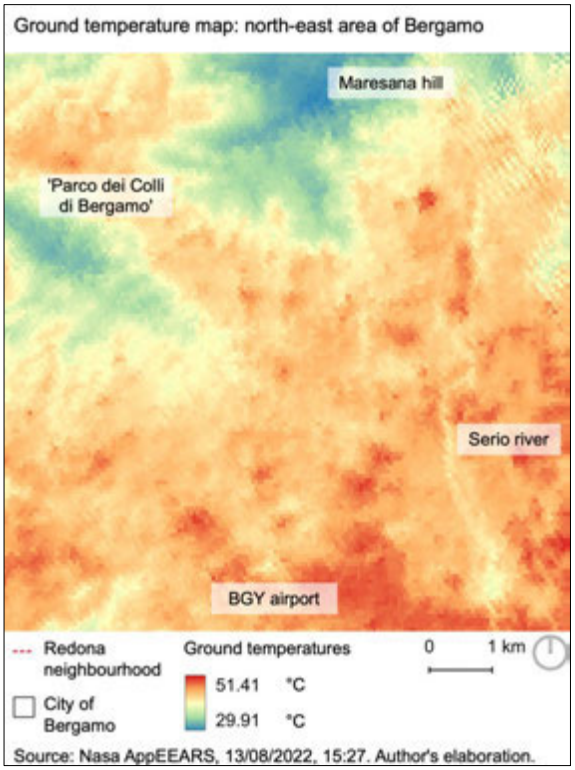
The Redona neighbourhood, which serves as a case study for this examination, was established as a 'Corpo Santo' on a road that connects Bergamo to the Seriana Valley. The district's population has increased since 1995, reaching a total of 7.041 in 2021. The proportion of the population aged 65 and above is approximately 25%, which is comparable to the citywide figure (retidiquartiere.it, 2024). During the period of urban densification, the district underwent a profound transformation, with the construction of both residential buildings and factories (which are now largely unused). The Redona neighbourhood was selected as a case study due to three key characteristics: i) it is a highly dynamic area in terms of past, ongoing, and planned urban regeneration processes. ii) It encompasses a diverse range of building types (tower blocks, single-family houses, commercial complexes, brownfields, etc.) and green features (parks, agricultural areas, nature reserves, etc.). iii) It serves as an infrastructural node for rail and road transport, both on a local and provincial scale.

Methodology ad materials

The methodology adopted for the analysis of spatial aspects is based on a combination of quantitative and qualitative approaches. The quantitative analysis is comprised of a series of investigations into the spatial aspects of the problem, primarily conducted through the use of geographic information systems (GIS). In contrast, the qualitative analysis is based on a series of semi-structured interviews with local stakeholders, which aim to gain an understanding of the perception and awareness levels regarding the problem.

The data used in the quantitative analysis was gathered from three main sources: the Regional Topographic Database (DBT) of the Lombardy Region, which was updated to January 2022. The DBT is an official geographical database of digital spatial information representing and describing the topographical objects of the territory and is the basic cartography. The data set contains information on a range of geographical features, including roads, railways, buildings, natural and artificial watercourses, altimetry, quarries and landfills, vegetation cover, and so forth. However, some geometries about recent interventions were absent. Consequently, data from Open Street Maps (OSM) were employed. The dataset was obtained from Geofabrik and updated to September 2022. To validate the data and collect new data not available from the first two sources, multiple surveys were conducted on the field in the second half of 2022. The data not officially available include the width of pavements, the type and colour of surface materials, the facilities of public transport stops and pedestrian crossings, and permanent and temporary point obstacles. The data was used to conduct four sets of analyses. The preliminary analysis included green spaces, mobility and the built environment, shop windows and abandoned businesses, neighbourhood-scale demographics, the dynamics of motorised traffic, and building heights. The pedestrian accessibility analysis considered pavement width, punctual obstacles (permanent or temporary), surface materials, facilities at pedestrian crossings and public transport stops. The pedestrian mobility analysis included walkable catchment areas from public transport stops and theoretical pedestrian flows. The UHI analysis employs data from the preceding three groups, namely building heights, public surface materials, and the location of green areas, trees, and bodies of water. These elements are among the factors that influence the urban heat island effect (Map B). Furthermore, a city-scale heat analysis was conducted utilising data from NASA-AppEars, which enables the clear delineation of urban areas (BGY airport) and rural/natural areas (natural park 'Parco dei Colli

di Bergamo', Maresana hill, Serio river) based on the temperature differences illustrated by the map (Map A).
The surface materials have particular importance when analysing the UHI because of the Albedo index. This index has a range from 0, representing a perfectly black surface that absorbs all solar radiation, to 1, representing a completely white surface that reflects all solar radiation (Moretti et al., 2021). The properties of the material itself and the colour influence the Albedo index. A low index indicates a high capacity to absorb solar radiation, which has a negative impact on the urban heat island, as is the case with asphalt (Albedo 0.10). The calculation of the Albedo index is complex and varies based on the methodology and instruments used during the survey. However, for comparative purposes, other materials with different albedo indices include marble (0.80), limestone (0.70), concrete and granite (0.50), and basalt (0.40) (Moretti et al., 2021).



Map A: ground temperatures using Nasa AppEEARS data and G.I.S. elaboration.

Qualitative analysis was conducted through four semi-structured interviews between December 2022 and January 2023. Nine people were interviewed, both as individual stakeholders and as representatives of the respective association. The objective of the dialogue

with local stakeholders was to confirm and integrate the information gathered during the initial phase of the analysis. All interviews were conducted in person, with an average duration of one hour. The associations interviewed were selected with the objective of achieving the greatest possible representation of citizens and thus of different users of public space. The first group, *Associazione Genitori Costruire Integrazione ONLUS*, is a non-profit organisation of social utility that was established in 2006 by a group of parents with children with impairments. Its objective is to create projects that will enable young people with disabilities to participate in a community and enjoy quality leisure time. The *Comitato per Redona* was established in 2001 by a group of citizens who were opposed to the municipality of Bergamo's proposal to construct a new sports hall within a local park. Their efforts were successful in preventing the implementation of this project. The *Gruppo Aquiloni* is an organisation that provides disabled young people with the opportunity to engage in leisure activities in the form of excursions, theatre, painting workshops, and so forth. The *Banca del Tempo Scambiotemporedona* is an association for social promotion founded in 2010. Its objective is to offer the residents of the area a form of service exchange that does not involve the use of money, using time as the unit of measurement. The interviews were structured by introducing the research themes (walkability, urban barriers, UHI, etc.) and leaving the interviewees free to highlight the specificities of the neighbourhood in relation to these themes. For some interviews, additional tools were used, such as paper maps – on which it was possible to write and draw – or digital maps.

Data analysis and comments

The combination of the three elements selected for analysis of the UHI effect – surface materials, building height, and green elements – has identified certain heat-susceptible areas.

The majority of the car parking areas in the neighborhood (1 on map B) are covered by asphalt, with the southern side lacking protection from the buildings' shade and generally devoid of trees. Parking areas are among the most straightforward areas to intervene in order to mitigate the heat absorption capacity. This can be achieved by improving the shade effect and changing the pavements, thereby increasing the albedo index. The main local road, via Corridoni, presents two different conditions. The northern side (2.1 on map B) is characterised by a greater presence of tall buildings and trees, which, despite the use of asphalt as a main surface material, can offer mitigating effects. In contrast, the southern side (2.2 on map B) presents an opposite situation, with a general lack of shade due to the absence of tall buildings and trees, and an abundance of asphalt. The Plorzano highway and adjacent roads can also be divided into two sections. In the southern part (3.1 on map B), pedestrian transit is rare and in certain portions forbidden. In the northern sector (3.2 on map B), this road system serves as a connection route between districts. The former Reggiani factory provides shade in a portion of the pedestrian path, but the total absence of trees and green areas, the presence of a large car park, and the use of asphalt as the sole pavement material make the stretch highly susceptible to the effects of the UHI.

However, an overall assessment of the neighbourhood indicates that the UHI effect is adequately counteracted in almost all areas. Despite the neighbourhood being strongly composed of asphalt elements (more than 87%), the large amount of greenery, whether in the form of trees or public parks within the urban area or agricultural areas surrounding the neighbourhood, offers the possibility of cooling. Furthermore, the new urban interventions are based on materials with a high Albedo index.

The results of the interviews can be classified according to the following categories: urban barriers, car traffic, and heat effects. The first category is not pertinent to the scope of this contribution. The second category, similar to the first, generates problems that are not directly related to the subject matter of this work. Nevertheless, the interviews yielded some insights

that could inform strategies to address the issue of heat. In particular, rush hours are identified as the most challenging for walkability, due to the difficulty in breathing and the accumulation of heat on asphalt and the emission of heat from car engines. The final category, heat effects, reveals that the most significant challenge in discussing heat is the bench situation in Redona. The area in question is deficient in seating facilities, which are both a source of respite and a venue for social interaction. While there are benches situated around the district, these are often combined with bus shelters. Furthermore, there are few seating areas within parks, with the notable exception of Turani Park. The park benches have recently been replaced with new ones, and their position has also been changed. Consequently, a series of problems directly related to heat have emerged. The benches were previously constructed from wood but have since been replaced with iron ones. The combination of the new position and the lack of shade results in the benches becoming uncomfortably warm, rendering them unusable for several hours, particularly during the summer months. Additionally, the benches were placed at a considerable distance from one another, which has the effect of reducing the spontaneity and complexity of social interaction. It is not uncommon for elderly individuals to visit the park with a folding chair or stool from their own homes.

Map B: triggering and mitigating elements of the UHI in Redona Neighborhood.

A discontinuity in the quality of pedestrian public space can be identified when the results of quantitative and qualitative analysis are considered. Such deficiencies can often be rectified through the implementation of relatively minor alterations. The creation of continuous and protected walkability spaces within street areas is possible through the implementation of NBSs, depaving interventions, street space redesign, green areas, and pedestrian resting points. However, there is a need to integrate mobility road design and road functions within planning tools. This can be achieved by linking mobility management and planning management, which

are often administered by different offices within the Italian context. This would facilitate the enhancement of not only the mobility role that roads fulfil but also the social function of public space that the footpath has lost.

Conclusions

To comprehend the impediments to walkability resulting from urban barriers, particularly the effects of the UHI, it is essential to adopt an analytical approach that integrates the spatial configuration of cities, the citizens' perception of streets, and the impact of heat waves in an urban context. The reduction of walkability represents a barrier to the opportunity to utilise public spaces, particularly for the most vulnerable population groups. An integrated project offers the potential to establish minimum conditions that would ensure the widest possible use of the road and pavement. This would facilitate the right to the city and the ability to walk to the widest possible number of citizens, while also enabling public space to fulfil its social function.

In the name of Peace, Sanitise!

Author's Name: Kundani Makakavhule
Affiliation: University of Pretoria
Email: kundani.makakavhule@up.ac.za

Sanitised space is a concept that is quickly gaining momentum in the disciplines of urban planning and architecture. It refers to the process in which urban space is 'cleansed' from all things that make it dirty, undesirable, and differentiated. The process can be achieved through the use of soft power or it can also be achieved through hard power. Through the use of semi-structured interviews with municipal officials, this paper seeks to showcase the various efforts by the capital city of Tshwane, South Africa to sanitise space in the name of peace. With the use of examples from public parks, the paper argues that although the sanitisation of space is done in the name of public interest, peace, it often conflicts with the public experience.

Key words

Sanitisation, Public Space, Safety and security, Peace, Symbolic violence

Introduction

Public spaces are regarded as quintessential for any settlement; they provide opportunities for interaction, recreation, leisure, public expression and greening, amongst other benefits. They are also spaces in which historic events have occurred, in different eras and contexts. For instance, The George Floyd protests demonstrations against police brutality and riots in the United States in 2020, The Soweto Student Uprising in South Africa in 1976 to change the medium of instruction from Afrikaans to English, The Arab Spring in Tunisia in 2010, The annual Rio Carnivals in Brazil and the Holi in India, amongst many others. As such, public spaces are spaces in which communities come together to demonstrate solidarity, to celebrate and to rebel against matters of public interest. Public spaces thus play an important role in transforming society and contributing to civic culture, values and peace. However, what happens when public spaces are not of good quality? threatened by crime, are a breeding ground for social ills, housing undesirable members of society and are underutilised? How does urban planning and urban management institution respond or ought to respond, in the name of peace?

This paper focuses on public spaces in the Capital City of Tshwane, South Africa. It investigates different public open spaces and the way in which peace in public space ideas, perceptions, and management practices are conceptualised in the City of Tshwane from those in decision-making positions. It also explores these conceptions in relation to the inter-conflicts between society and the municipality in the production of peaceful public spaces. Moreover, it also interrogates the intra-conflicts between municipal officials themselves. This is done in an attempt to uncover the various processes of sanitising public spaces in the city and contestations embedded in the realisation of peaceful public spaces. The paper employs the concept of conceived space by Lefebvre's (1991). It will draw links between the said concept and the concept of sanitisation, so as to make a contribution to the current literature on the topic. This paper offers new insights to the ongoing conversation of sanitising space through soft and hard power by municipalities.

The Historical Overview of Urban Public Spaces in South Africa: A History of Sanitisation

Many South African cities have a shortage of quality public space, and much of our public space is considered unsafe, due to perceived and real crime, under management and under resourced spaces (Landman,2017). According to the South African Urban Reference Safety Group (2020), this is due to the historic spatial injustices of colonialism and apartheid, which left a legacy of inadequate public space in disadvantaged areas like townships and informal settlements (Makakavhule, 2022). Venter (2020) , also argue that the legacies of Apartheid and how it distributed resources and infrastructure such as public spaces continues to shape the levels of access and perceptions of public spaces to date.

This section focuses on the overview of urban public spaces in South Africa during the apartheid era. It seeks to demonstrate how urban public space were perceived and conceived, and attempts to lay a foundation for understanding public spaces today. The Reservation of Separate Amenities Act of 1953 is crucial to mention in this section. The Act was put in place to regulate public spaces and spaces meant to cultivate civic culture. It was used to expand existing segregation practices that came before it, for example, the Urban Areas Act of 1923, which sought to segregate and restrict the presence of blacks in urban areas. However, the Reservation of Separate Amenities Act later extended to include restrictions and the segregation of particular races in public and private premises, such as public parks, restaurant, squares, public transport, hotels and cafes (Donaldson; 1996; Sidogi, 2020; Swilling et al. 1991). Therefore, the Act allowed the provincial and municipal authorities to regulate public access and use. The Act also regulated private spaces by preventing “indecent acts” as defined under the Immorality Act of 1927. In 1960, the Act was amended to include beaches, in the quest to control all spaces of potential multiracial contact (Goitom, 2015). According to Lemon (1991: 51), the Act was deployed to “minimise racial contact and thereby, it was argued to minimise friction.” The Reservation of Separate Amenities Act had to be paired with other pieces of legislation that would support it so as to contribute to the realisation of the Apartheid dream. For example, it was paired with the Prohibition of Mixed Marriages Act of 1949 to engrave a sense of “otherness” which could discourage interaction amongst different racial groups.

Upon reflection, such controls represented stiff forms of sanitisation whereby groups in society were regulated to portray a certain image as conceived by those in power and decision-making positions. Urban public spaces were discursively represented using rhetorical strategies, which imagined urban space through the eyes of the beholders, whether that beholder was the cartographer, the planner, the politician or the municipal official. In other words, black people were not to be visible in public spaces because they did not represent the urban image that the apartheid government sought to establish and maintain. As such, public spaces were reserved for interactions between white people, representing apartheid beliefs. Therefore, the uses and users of urban public spaces physically represented and communicated apartheid ideology.

The local authorities in white neighbourhoods would also control society and enforce legislation through signage that served to remind both blacks and whites of the rules and regulations of public and private spaces. Therefore, town planners, architects, and designers would work to design, provide and regulate public spaces as instructed by the state. Accordingly, they would communicate apartheid rationale and ideology through policies and by-laws. Evidently, harsh punishment was inflicted on those who broke the law either by making use of spaces that they were not supposed to, or through their associations with other racial groups. People would face brutal police violence or even prosecution for such violations.

The Reservation of Separate Amenities Act was fortunately repealed in the year 1991. Thereafter, all citizens of the country could use the same public spaces and meet and integrate as they so wished. However, even with this development, urban public space planning in South Africa continues to represent efforts by the state to sanitise space and dominate it for ideological reasons. This experience of space throughout history has had implications on how public space is perceived, and how urban managers, in the name of creating and maintaining peace, plan and govern these spaces.

Conceived Space and Sanitised Space In Post-Apartheid South Africa

Lefebvre's framework – which is also the most popular - is his unitary theory or 'spatial triad' (Ghulyan, 2019; Nkooe, 2015). Lefebvre's triad introduced the concepts of perceived (spatial practices), conceived (representations of space), and lived space (representational space) which he regards as the premise for the production of space (Lefebvre, 1991: 33, 38-39). These spaces can be thought of as (1) the routine and spatial activities that can be perceived in the world (perceived space); (2) the conceptions of space which order our notion of what is possible (conceived space); and (3) the spaces that are produced by the body in everyday practice (lived space).

A discussion of the conceived space is discussed as the crucial element central to the conceptual thinking of this paper. Conceived space refers to the mental and conceptual space encompassing normative standards and ideologies (Lefebvre, 1991). It is identified as a set of representations of space that are rendered and produced by technical planners, designers, architects, technocratic, sub-dividers, and bureaucrats that have legitimised power to (re) produce space (Ng, Tang, Lee and Leung, 2010). Conceived space produces the images, sketches, and visions of the urban space. These are influenced by state institutions and are devised in plans, maps, and schemes to order society. Everyday human spatial practices and processes in this space are either legitimised or contested against a set of ideologies. This done through the use of surveillance, plans, policy, zoning laws, and by-laws which are often conceptualised in an effort to uphold normative ideas (Lefebvre, 1991; Zhang, 2006).

The state is then able to control planners, architects, and geographers and instruct them on how to represent certain locations and order their social and spatial practices according to its own socio-cultural or economic posture. This is important to note because of the role that the apartheid state played in the conceived space of South Africa. As such, Eden (2004), Lefebvre (1991), Mwathunga (2014) and Nkooe (2015) argue that conceived space is not neutral or passive, but rather, it is instrumental in seeking order and control, sometimes through extreme measures of violence.

Reflecting on the nature of perceived space as discussed earlier, one can argue that it is the manifestation or embodiment of conceived space. This is because what is conceived is physically produced and therefore, perceived. This close association of the concepts can make the triad somewhat confusing. Therefore, an example is used to clarify. In the context of urban public space, perceived space is the physical composition of a space. This includes the benches, pavement, lighting, fences and gates, and all other objects which can facilitate or hinder certain activities within that space. The by-laws and rules and regulations of the space form part of the conceived space. These can also facilitate or hinder certain activities within that space. In this context, what these two spaces have in common is the fact that they offer an objective view of how public spaces should work for all, through their attempts at creating a homogenised social life. Adversely, this often results in unintended consequences where, instead of homogenisation, resistance manifests in the name of informality and disorder. Thus, conceived

space is seen to undermine the realities of everyday citizens, their conditions, and circumstances through how it imposes its ideologies and normative ideals.

Sanitisation of space on the other hand seeks to create spatial relations that encourage behaviours that are repeatable, predictable and compatible with the dominant social roles and rules of engagement (Stavrides, 2015). More recently, we have witnessed these efforts of normalisation through the use of surveillance cameras, biometrics, and other forms of technology that shape human behaviour and sanitise public space in the name of peace and security.

Drawing the link between sanitised space, and conceived allows for a focused interrogation on urban planning actions in urban spaces. For example, Dorman's (2016) article on the regulation and control of urban life in Zimbabwe highlights how processes of urban control and sanitisation are represented by policies that seek to dictate the behaviour of urban people. These policies lie in the hands of planners and politicians alike, whom according to Healey (1997) and Harvey (2006), are engulfed with scientific and technical knowledge which often overrides their human convictions. In this regard, urban planners and architects exist as decision-makers who disregard their emotions in the work that they do. Healey (1997) echoes are verified in the Zimbabwean case of Operation 'Murambatsvina' (translated as one who rejects filth). This was a programme used to enforce by-laws and eradicate informality and illegal activities in the city of Harare and surrounding urban areas. This operation was legitimised in the name of 'planning' and seen as an effort to rebrand the image of Harare and spruce up its reputation as a world class city by ensuring that it is 'clean, well laid out and comparing favourably with cities anywhere in the world' (City of Harare 2005 as referenced in Dorman, 2016). The case of Zimbabwe is one, amongst many other cases, that describes how space can be sanitised in the name of the planning, order, and organisation that exists in the conceived space.

The city of New Delhi is also a good example of how cities sanitise their urban spaces in order to appear more modernised, beautiful, and appealing to tourism and business investments. New Dehli's hosting of the commonwealth games in 2010 is a direct example of this. The city had a campaign to remove beggars, vendors, and the homeless off the streets whilst also deploying police men and women to roam the streets so as to discourage the troubling population from being visible in the public spaces (Cook and Whowell, 2011). The city argued that it was creating a safe, peaceful and conducive environment for tourisms to enjoy and experience New Delhi. However, it was taking away the character of the city and disseminating the injustices suffered by those of lower classes who were regarded as 'undesired'.

In Italy, decades after the Second World War, the processes of urban expansion represented the clean-up of Italian city centres. The process was undertaken by removing the poor from the urban centres after which they were moved to mono-functional high density neighbourhoods on the periphery of the historical city centres. These areas were homogenous, segregated and far from all city amenities (Chiodelli, 2013). To date, the city centres in Italy are inhabited by the upper class who are afforded access to entertainment, other conveniences, and an active social life. On the other hand, the peripheries are still inhabited by the poor who are hidden away and excluded from city life.

The deployment of the concept of sanitised space alongside the concepts of space provided by Lefebvre provide an opportunity to zoom in and out of the complexities, continuities, and discontinuities of the urban public space controls and orderings in The City of Tshwane. In addition, it can also reveal the contradictions and paradoxes that exist between the societal and municipal perceptions and meanings of peace in urban public spaces.

Methodology

The paper draws its findings from multiple case studies on different types of public spaces, in different parts of the city of Tshwane. The data was collected over the period of 2016-2021 as part of a larger project on understanding the nature of public spaces in the Capital city. The paper will draw examples from different public spaces which are part of the larger project. The paper is specifically concerned with the municipal official's perceptions of peace in public spaces, how they create, restore and maintain peace, as such, the paper will refer to the qualitative face to face interviews and focus group data that was collected in this regard. As expected, professionals working in public spaces come from different disciplines. Therefore, town planners, landscape architects, environmentalists and horticulturalists were interviewed and given pseudonyms to protect their identity. The paper will also refer to some of the official municipal documents that give information about how the city conceptualises its public spaces, its vision and mechanisms of management and governance. The rationale behind the selection of these specific documents was their accessibility not only to professionals, but also the general public. The officials interviewed and the documents reviewed are summarised in Tables 1 and 2 respectively.

The data for this paper was analysed thematically. Municipal responses and information contained in municipal documents were analysed to draw emerging themes and sub-themes as it pertains to the topic. This was also triangulated with observations conducted at the different sites, where pictures were taken and activities were documented.

Findings:

Global Competition and Its Influence on Sanitising Public Space

Municipal officials seem to be facing structural pressures to produce peaceful and safe public spaces in the midst of existing and ever increasing global and capitalist pressures. According to Castells (1996), there are tensions that exist between globalisation, global competition, and local identity which affect planners and designers in their everyday quest to produce meaningful spaces. Mamdeli (2019) also argues that city officials are increasingly emphasising new versions of public spaces to generate and globally disseminate the promotional images that make their cities competitive. This is done in the name of attracting investment either through the tourism industry or private business and property investments. However, scholars

such as Allmendinger (2001) and Qian (2017) carry the assumption that these efforts of global competition are rationalised sanitisation, at the expenses of existing socio-cultural ideas and needs in public space.

In line with the above, interviewed officials indicate that they face pressure within their everyday working environment because of the need to provide locally contextualised public spaces whilst also chasing global titles in the name of performing according to global and capitalist standards. According to Lefebvre (1991), the conceived space maintains the hegemony of the ruling class by prioritising exchange value over use value, thereby producing abstract space. Unfortunately, the results of such prioritisation can easily lead to measures of sanitisation and over regulation. Furthermore, these global and capitalist aspirations shared by municipal officials have implications on what is produced in the material space, and how the material space is perceived and therefore managed as demonstrated by the responses below:

> In my experience, all those informal things taking place now in Jubilee Square, like the soccer and informal trading repeal the investors and kill the beauty of the environment as well. It does not look good for us, like we are not doing our job. We need to remove all those things if we want to attract investors there.
>
> (Jim: Parks and Horticulture, 2019)
>
> When you see other cities like Paris and Buenos Aires, they have nice looking public spaces … we went to Argentina for a tour as the division, and we want to bring back the things we saw there.
>
> (Mike: Parks and Horticulture, 2019)

The rationale shared by the officials above perpetuates the marginalisation of those who are already marginalised, for example, the homeless community, street vendors, and the poor. The ever growing anxiety over homelessness, trading and other "informalities" in the public parks of the City of Tshwane, is, therefore, related to the rationalities of beauty, investment, and competition as discussed by the officials. Moreover, it presents dilemmas in cities filled with a rich diversity of inhabitants with different spatial needs, wants, and desires, and which may conflict with the desires of the elitist few. According to Marais and Nel (2019), planners and designers find themselves in a space where rules, plans, and frameworks regarding urban space need to be drafted amidst such relativity.

With this in mind, it is apparent that processes of sanitising space in post-apartheid South Africa and, particularly, in the City of Tshwane should be analysed beyond the questions of inclusion or exclusion, black or white, the haves and the have nots, and move towards more empirical examinations of the powers, interests, institutions and ideas which govern and ultimately influence decisions of sanitisation. With such interrogation, the understanding of the drivers of privatisation, regulation, and sanitisation of space become more meaningful. This interrogation may also be useful in understanding certain imposed public space identities and their implications on broader global city pursuits. It is within this dichotomy between the city's aspirations and meeting the needs of the public that professionals need to navigate. However, as a result of this, we continue to witness an increase sanitising processes under the legitimised pursuit of global competitive public spaces and cities.

Polarised State Responses: Planning Contradictions and Forms of Domination

Neighbourhood socio-economic statuses have influenced the ways in which municipal officials respond to, and act on, certain matters. This is also seen in how law enforcement agencies handle informality. There are certain unspoken assumptions about certain neighbourhoods that

lead to officials treating communities differently. In the context of this paper, the planning contradictions in sanitisation processes are seen in the different treatment of the same activities in public spaces. For example, Jubilee Square's, located in a diverse predominantly black neighbourhood, showed an obvious presence of unanticipated trading, whilst Magnolia Dell, located in a predominantly wealthy white neighbourhood has the same. However, the views and acceptability of the two activities differ. In Jubilee Square, trading activities were frowned upon by the officials whilst the same activity was approached with empathy in Magnolia Dell Park. According to Ghertner (2011), the state responds differently to the rich and the poor. In rich areas, informal activities are dealt with in terms of legalisation, whereas in poor areas their response is violence. Such contradictions allude to the fact that municipalities respond to poverty and not necessarily informality. In light of this, the City of Tshwane officials lamented over the 'invasion' of street traders in Jubilee Square, and how they are destroying the image of the city and emphasising the need for their removal:

> On the streets and in parks of Sunnyside, they should be removed because we haven't allowed it, we haven't designed for it and even our policies don't allow it.
>
> (Rendi: Environmental Management, 2018)
>
> I would say remove them, simply because their presence there also influences littering and influences all sorts of other trading that you don't want to subject your kids or people who use the parks to. People are kind of naïve about what's going on around the park, and trading can conceal a lot of things. It's just better to remove them.
>
> (Leslie: Environmental Management, 2018)

The officials in this regard hold the power of producing a space according to their image. Ultimately, they pave the way for law enforcement to handle the issue on the ground and in many instances, through violence and public disgrace (Pezzano, 2016). The urban poor who attempt to salvage a living in the city outside the 'formal' market find themselves having to contend with hostile officials who are bent on sanitising the city (Bayat, 2004; Graham and Healey, 2007; Lindell, 2010; Steck et al., 2013).

Interestingly, although informal traders are also present in Magnolia Dell Park, officials did not indicate their disapproval of them there. Surprisingly, they communicated with empathy regarding the trading in the area. Jubilee Square traders predominantly serve the Sunnyside community with their goods and services. However, Magnolia Dell Park traders serve the tourists who visit the park. One can argue that the market being served has implications on the official's perception of the activity. This substantiates Campbell and Marshall's (2002) ideas which suggest that there is no single public and therefore, no unified public peace. Although trading was unwanted and clearly stipulated on the rules and regulations board when entering Magnolia Dell Park, the officials had different sentiments regarding the practice, as one official noted:

> So... the trading in Magnolia Dell Park is something we need to take into consideration...because they are trying to make a living and it probably activates that space a little more. The tourists can also see something different.
>
> (Longtom, Environmental Management, 2019)

It is comforting to hear a humanistic sentiment from the official regarding this particular activity. However, it was saddening that this sentiment was only directed to this specific space. Planning contradictions can be detrimental when officials refuse to acknowledge practices in a

just manner. However, in light of this, one may argue that such a response also indicates that there is a paradigm shift towards consideration of unanticipated activities in urban areas.

The unanticipated trading activity that occurs in public parks seems to be increasing in the City of Tshwane despite all the attempts to combat it. According to officials, they have been dealing with this phenomenon for quite some time. They discussed the different ways in which they have attempted to get rid of the traders in public parks or at least find a way to regulate them, even in different political administrations as is evident by the respondent below:

> What happened is that, with the previous administration, they realized that they needed to formalise the informal traders in order to regulate them. So, they built an area, a place here in the city. It is municipal structures and then we just rent [the structures] out to the public.
>
> (Motho: Environmental Management, 2018)

The statement above alludes to a particular method that the city has used in effort to clean up and sanitise public spaces. Moreover, it indicates that such a planning rationale exists alongside the political rationale because planning and politics are working together in the city to ensure the realisation of a globally competitive city that has been envisioned. Moreover, one cannot simply ignore the environmental degradation and health hazards prominent in the informal sector, as discussed by the respondents below:

> To me, the trading in Jubilee square is kind of unhygienic. They cook the food in the trailer or the tent, then they throw out the used oil just next to the trailer. Health inspectors must come and see what they are doing and even where they get their water from. I don't think the trading would pass the health test.
>
> (Leslie: Environmental Management, 2018)
>
> Some of these kiosks are on a trailer there at Jubilee, and they need to pull it on a bakkie or a car to move it, so now they move into the parks and they damage our irrigation and sprinklers.
>
> (Colt: Parks and Horticulture, 2019)

As noted from the quotes above, there are valid concerns pertaining to the use of public parks for unanticipated trading and these concerns are justified. Accordingly, the officials' responses towards this phenomenon can be regarded as well-meaning. However, the approaches that are suggested perpetuate the sanitizing tendencies. The notion of creating safe and clean spaces in urban planning should be sensitive to function and quality of life, not merely aesthetic, and image. Mandeli (2019) argues that public spaces should progress beyond ruthless functionalism and aesthetic concerns in the global south. In moving forward, there is a need for planners to be well aware of how people on the ground survive, how livelihoods are stitched together in public spaces and in what ways planning can positively reinforce the positives of these phenomena. It is imperative to study the practice from those practicing it and to refrain from seeing the task of sanitising informality as an elite project that is reserved for technical experts.

In Space but Out of Place: Homelessness as a Complex Sanitisation Motivation

Homelessness remains a persistent social issue throughout the world. This is also the case in the City of Tshwane (Brand, De Beer, De Villiers and Van Marle, 2013; Kriel, Tembe, and Mashava, 2017.) The officials in the city of Tshwane were very eager to discuss the homeless community, how they make use of public space, and their general sentiments towards the rising phenomenon. It was clear that all officials were aware of the significant presence of homeless

people in parks in the city. The general consensus was that homeless people should not be there and that they were out of place as echoed by the officials below:

> These vagrants have such a big impact on our parks, we are on the break of doing a redesign of Springbok Park which is a monument. Because people won't use it anymore. They don't feel safe in the park because of these vagrants, we don't want Jubilee Square and Magnolia to also end up like that.
>
> (Colt: Parks and Horticulture, 2019)
>
> When people visit the park, we don't want them to think "someone will break into my car whilst I am here". Vagrants are just a threat
>
> (Mike: Parks and Horticulture, 2019)

Contrary to the above quotes, scholars such as Baron (2015) argue that this threat in South Africa is merely a perception constructed by the dominant groups and cultures in society and that it does not mimic reality. Furthermore, it is used as justification for the privatisation of space of bourgeois cleanliness. However, in a country like South Africa, one may argue strongly against such a proposition. Crime rates in South Africa have continued to rise steadily since 1994. In 2020, South Africa was rated as the third highest in terms of the crime rate in the world (Crime Index, 2020) following Venezuela and Papua New Guinea. Moreover, scholars in the domain of public spaces and sustainable neighbourhoods in South Africa have also written extensively on the impact that crime has on the use of public spaces (Breetzke, 2010; Kruger et al, 2017; Landman, 2017, 2019; Mavuso, 2016).

Accordingly, it was not surprising that the officials would view the homeless community as predominantly made up of criminals and, therefore, consider them not welcome to share spaces with mainstream society. Their views on homelessness and its prevalence in public spaces was not only shaped by their professional ideas of aesthetics and order, but also because of the overall perception of the homeless community as shared by society. According to Kriel et al (2017), most people who are homeless are treated with suspicion, alarm, annoyance, and fear in the public spaces that they occupy. This is rooted in the stigmatisation of poverty. The urban poor who have homes to live in, are "out of sight" and, therefore, "out of mind". However, the homeless are unfortunately often in plain view and therefore, subjected to this harsh stigmatisation justifying sanitisation processes.

During focus group discussions, officials often referred to themselves as civil servants who work to please their customers. Moreover, they discussed how they need to ensure the safety and peace for the communities they serve. An official in particular mentioned that they received pressure from various communities regarding the removal of homeless people in parks, and as a way to maintain the peace, they need to respond:

> Communities come to our office, requesting that we take care of the vagrant problem in their parks. That puts us in a very difficult position because we get complaints from the public all the time. For example, Rietondale community has approached us. Look at the state of the park, how can you allow the vagrants, it's not safe for them to stay there, it is not hygienic for them to stay there, how can you allow it. It is not a question that we are allowing it, we can do nothing about it because we don't have shelters for these people.
>
> (Shane: Parks and Horticulture, 2019)

As alluded to in the quote above, communities have certain expectations of their public spaces, and officials are seen as the people who should deliver on these expectations. Officials lament on how communities expect them to regulate the homeless community's presence in public spaces. However, according to them, this is the task of the Metropolitan Police Office. Officials argue that it is their duty to draft by-laws and institutionalise them. However, it is the task of the metro police to enforce those by-laws. This lamentation is not surprising because scholars such as du Toit (2010) have argued that local governments tend to see homelessness as an issue outside their jurisdiction because it can be ascribed to individuals' lack of affordable housing or their individual moral failure and, therefore, should be the responsibility of law enforcement:

> Come on, we do not have the power to arrest these people or even give them fines to get them out of the parks. That is what the metro police are supposed to do. I will see them in the park, like all the time in Jubilee, but I will just pass like any other person.
>
> (Longtom: Environmental Management, 2019)

According to the City of Tshwane Metropolitan Municipality By-Laws Pertaining to Public Amenities (under the section of loitering and prohibited action), "it is illegal for anybody to be homeless and perform actions like begging or being on the streets without a home to return to" (Environment and Recreation Management, 2014 as quoted in Kriel et al, 2017: 433.) The by-law statement above can be regarded as problematic because of how it explicitly discriminates against the homeless.

The criminalisation of homelessness, informal trading, loitering, and unauthorised gathering (Landman, 2019; Middelmann, 2020; Nkooe, 2015) depict the attempts that were made to cleanse the public spaces from disorder, to create and maintain peace. For instance, the regulations on loitering, as per the City of Tshwane Metropolitan Municipality By-Laws related to public amenities (City of Tshwane Metropolitan Municipality, 2010) state that no loitering or lingering by the general public is permitted in public spaces. In this regard, loitering becomes an activity that infringes on the desired public space order as conceived of by local authorities.

With the above in mind, the control of public spaces in the city, as represented by the by-laws, prove to be a violation of the homeless community's democratic right to enjoy state provided public spaces (Lefebvre,1991). Moreover, it can be regarded as an attempt to sanitise space and display an image of "public space neatness" whilst institutionally hiding the brutality of rigid urban space controls. However, one can also argue that the concerns regarding the presence of homeless people in public spaces and their use of the spaces are not completely unwarranted. Unfortunately, the homeless community is not made up of a homogenous group of people with the same socialisation, aspirations, and view of life. Thus, they cannot be discussed as such (De Beer, 2013). The officials are aware of this, and also indicate that this makes their task to design, develop, maintain and regulate peace in public spaces that much more difficult. For example, the officials argue that they need to navigate between protecting the rights of all urban citizens whilst also maintaining safe public space, to attract and maintain investments and to decrease the deterioration and vandalism of public infrastructure as echoed by the following respondents:

> Yes, they have the right to use those spaces, it would be nice if they could use it like all other people. But they don't only use it exercising the democratic right, some of them actually have got this urge to break something. You can use it; we can't complain if you use it. We complain if you break it.
>
> (Jammy: Parks and Horticulture, 2019)

> In Jubilee we've got the outdoor gym and the homeless people come and steal everything that they can take for scrap metal so we can't keep advocating for them when they are destroying everything.
>
> (Jim: Parks and Horticulture, 2019).

From the quotes above, it is clear that the officials are not against the use of space by the homeless, therefore, not maliciously advocating for their exclusion. They are merely against the vandalism that they have witnessed. Bergamaschi et al (2014), mentions that once a person has lived on the streets their former identity disappears and they form a new identity based on their situation and as such, many act and engage in activities that they normally would not, for example, the unwarranted vandalism as explained by the officials above. From the focus group discussions, it was made clear that the harsh by-laws pertaining to the homelessness phenomenon in public spaces came into being as a result of such activities. The officials were also adamant that the locking up of public abolition facilities in parks in the city was a decision taken because of the criminal activities that would take place, as well as the homeless people who would sleep in them as one official noted:

> I don't know how to handle the question on access to toilets, it is very difficult. You find that parks that have toilets end up being a very scary park. Because homeless people will hide in the toilets, you go there and they ambush you because you don't know what happens in the toilet. So we are trying to manage, that but unfortunately it is creating problems but we still don't know how to handle it.
>
> (Rendi; Environmental Management, 2018)

The decision made by officials to lock up toilets in the public parks deals with the issue of crime, safety and illegal occupancy which are highly prioritised matters. Unfortunately, the trade-off is that society's experience of public life and comfort becomes constrained. Officials also indicate that the other alternatives could be the introduction of a payment system where individuals could pay a certain amount to use the facilities. However, the question that kept recurring was "what about those who cannot afford?" One participant mentioned that:

> Public toilets are a problem in the city, not only in the public spaces you are researching. The city is now stinking because of this. So every night we have people that go around all corners spraying chemicals. It's costing the city a lot of money. We are saying build more toilets and have a lady at the entrance charging R1.00. But then again, how can you charge a homeless person R1.00 to use a toilet when he has nothing.
>
> (Oupa: Integrated Development Planning, 2019).

The concern raised above by the official is a valid one. Moreover, the introduction of payment fees to enter and use the toilet has direct exclusion implications for the less privileged. However, it is clear that the first priority in public spaces is safety and restrictions which function to protect society. In light of this, officials recognise that there is more that still needs to be done to ensure safe public spaces for both the homeless and other members of society. Their approach leans towards soft governance measures that can be interpreted as over-regulation of the public space. According to Carmona (2010), public space can be placed into two broad classifications in contemporary society, either being over-managed or under-managed. In this situation, the officials either under-manage by insisting that there is nothing that they can do in a situation and, therefore, the spaces are left neglected and invaded. On the other hand, they over-manage by proposing measures that result in exclusion, access control, and sanitisation. The homeless community in the City of Tshwane continue to be at the mercy

of the officials, their urban policies, by-laws and law enforcement agencies. Whether it is in the name of preserving the image of the city, sanitising space, protecting civil society or attracting businesses, the homeless communities' right to the city and their place in the production of democratic public space remains contested amongst an array of competing interests.

Conclusion:

This paper explored the ways in which public space ideas, perceptions, and desires are conceptualised in the City of Tshwane from the perspectives of technical practitioners and those in decision making positions. It explored the thinking and rationale behind the plans and policies that we see in the pursuit of peace in public space and the contestations thereof.

Using the concepts of sanitisation and conceived space, the paper revealed that the officials involved in public spaces in the City of Tshwane do not work in isolation, nor are they immune to the social, political, economic and global factors, which inevitably influence their decisions. Officials find themselves having to constantly construct and deconstruct their identity as 'technical professional' and 'civil servant' in rationalising what is order, peace and safety in public spaces. The paper locates the conflicts and contestations between global competition, planning contradictions, forms of domination and fixation on universal standards as phenomenon's perpetuating the continuity of sanitised spaces in the city. Lastly, the paper discussed the complex problem of handling homelessness in public spaces and how sanitisation practices are seen as legitimate, in processes of maintain peace in communities. The justifications of such rationalities lie in the conceived space which is supported by the measurable variables of health, public safety, security, sanitation, and environmental protection as emphasised in the physical design and legal controls of public spaces. However, the unintended consequences of such practices result in the control and suppression of minorities, the creation of societal divisions, and the perpetuation of classism. The concept of peace and how it is pursued by municipal officials in public space presents conflicts when interrogated in terms of whose peace and with what sacrifices.

Abstract:

This paper discusses the oldest and most important port city in the Kingdom of Saudi Arabia focusing on the impact of modernity on development that occurred in the architectural and urban spaces in contemporary passenger ports in the city and their historical comparators. Contemporary passenger ports in the city are supposed to reflect the identity and spatial, cultural, and social heritage of the port cities in the Kingdom. The passengers' experience and view of the culture and identity of these port cities is discussed within the context of the non-place theory (Auge, 2010). This paper will present a comparative study method based on literature review and personal interviews of cruise visitors' experiences, evidenced and measured through different taxonomies (envelops). The study particularly focuses on the forms of architectural building space and the users understanding and interpretation of these spaces created during the arrival, visiting and departure process, resulting in a critique and dialogue between past rituals, culture, and future aspirations.

Key words:

Port cities - Culture – Hospitality spaces – Passenger experience - Maritime architecture- Jeddah.

1. Introduction

This paper focuses on contemporary passenger ports in Jeddah, Saudi Arabia and their handling mass tourists and pilgrims and reveals and considers the types of practices taking place in architectural spaces in contemporary passenger ports in the city. The paper compares these with the past to propose what ports could look like in future within the context of the 2030 Vision of the Kingdom. The paper explores the influence of modernity in the development and evolution of architectural space and contemporary passenger ports in the historical port city of Jeddah, looking at these architectural spaces thorough the theoretical lenses of place and non-place to understand the effect on the passengers' experiences.

Through study of the concept of "non-place" and how modernity affected forming bonds of familiarity between the traveller and place in contemporary ports, the paper raises questions of how to create an identity for each user who can then develop an intention to return, based on their experience. This paper presents findings based on the concept of 'then' versus 'now', incorporating a comparative study between an historical literature review and personal contemporary interviews that charts the evolution and development of hospitality in Jeddah. This is designed to identify developments and changes to spaces of hospitality over time with a particular focus on the forms of building and architectural building space, unpacking the users understanding and interpretation of these spaces.

Non-place theory provides a theoretical framework for understanding why we perceive places as we do, proposing that anthropologically formed spaces began to recede after the rise of modernity and supermodernity, which led to the loss of identity, history, and social relations and the emergence of the banal non-places, often associated with spaces of transit and movement. (Auge, 2010) argued that non-placeness boils down to self-similar, unremarkable places where some sort of process based, spatial patterning process occurs. The non-place is designed for a specific purpose, such as an airport, train, or bus station. In addition, the familiarity with the typology of experience between the user and the place, regardless of where the users are going, it's important to recognise and understand the various specific criteria shaping experience in these spaces. Sequencing and ritual filter the users through processes, places, and systems that are not of their choice. The user is an integral part of the rituals of arrival, transit and departure that nowhere involves a personal relationship with its users. There are several reasons why theories of place and non-place are essential to this study. Contemporary passenger ports are both a characterization and visualisation of non-place, creating a kind of architectural spatial identity in port cites. Understanding and taking a theory and applying or testing it in place and space creates a connection between the theoretical approach to enable development of design frameworks; finding the boundaries of possibilities of the future ports that makes the conditions of place and non-place connect better through design.

1.1 Background

The Red Sea ports form a link between East and West trade, the oldest and most important of which is the Islamic Port of Jeddah in the city of Jeddah. Historically Jeddah port was famous for its hospitality and reception for pilgrims, Umrah pilgrims and visitors (Mawani, 2021). It was a major centre for the Hejaz trade and a safety crossing for travellers since ancient times, and it played a major role in reflecting the spatial, cultural and social identity of the city of Jeddah as well as being known as the Gate of Mecca and the Gate of Holy Mosques.

Jeddah was included in this study as a case study for several reasons. Jeddah city is the oldest and the largest port city in the kingdom, the poet Taher Zamakhshari, called Jeddah 'Bride of the Red Sea' (Zamakshari, 1987) and it was later known by this name and also locally called Al Balad. The unique and strong architectural identity of the historic city supported a strong hospitality culture. In 2014, the Historical Jeddah in Jeddah city was classified and included in the UNESCO List of World Heritage Sites, confirming its cultural heritage and global significance (UNESCO, 2014).

Vision 2030 stated that the Kingdom of Saudi Arabia is committed to strengthening its distinctive heritage and historical identity in all spheres, particularly in tourism, and it desires to encapsulate this identity in all areas of development through vision's projects and programmes (2030, 2017).

Tourism in the Kingdom has improved significantly since the launch of Vision 2030. According to the Ministry of Tourism statement, the total number of tourists for all purposes only in the first half of the year 2023 reached 53.6 million, including 14.6 million international tourists and 39 million local tourists in the Kingdom. The Kingdom ranked first in the G20 for the growth of international tourists. KSA Vision 2030, focusing on strategic goals and programs through approved implementation plans guided by pre-defined goals and key performance indicators(arabiya, 2023, Tourism, 2024).

Among the most important of these programs, which represent a direct relationship within the current study, is the Public Investment Fund and Quality-of-Life Program to develop the tourism sector in the Kingdom and to contribute to strengthening the Kingdom's position as a global tourist destination. Infrastructure and real estate development, development of significant projects and formation of international strategic partnerships have resulted accordingly (Vision, 2017a, Vision, 2017b, 2030, 2017).

The Public Investment Fund was launched as one of the programs to achieve Vision 2030, which works to achieve the goals of the vision by working on a targeted mechanism that contributes to the launch of new sectors and companies. The Fund launched the Saudi Cruise Company in line with the Fund's 2021-2025 strategy, which focuses on unleashing the capabilities of promising non-oil sectors, enhancing the Kingdom's efforts to become a tourist destination on the map of international tourist cruises, and developing the tourism sector in line with the Kingdom's (2030, 2017).

On the 29th July, 2021 Saudi Cruise Company established with the launch of the Kingdom's Vision 2030, and it is responsible for the development of this sector. Saudi Ports Authority (Mawani) and the Saudi Cruise Company inaugurated the first terminal for cruise ships at Jeddah Islamic Port (Mawani.gov.sa., 2021, Mawani, 2021). The size of the cruises arriving into the port has been increasing since then, targeted to reach one million tourists by the end of 2025. Through this collaboration between government and industry to develop the area, the tourism and cruise sectors have seen significant growth recently.

Contemporary Jeddah Port is going through significant development to accommodate cruise liners and their passengers as an outcome of this. During the year 2023, Cruise Saudi received more than 170.5 thousand cruise tourists representing 120 different nationalities on 65 trips aboard 16 ships belonging to 11 international cruise companies (CruiseSaudi, 2024, newspaper, 2024)

2. Methodology:

This study uses a mixed qualitative methods approach which began with a literature review, focusing on historical Jeddah as a port and the visitors' experiences of Jeddah city. Additionally, reviewing appropriate literature sources allowed conceptualisation of the spatiality of the port such. This included *Non-place*, (Auge, 2010), *The image of the city* (Lynch, 1977) and *Space and Place theory* (Tuan, 1979). Subsequently a series of semi structured interviews were undertaken with stakeholders and users of the port, which generated a series of outcomes including interview transcripts and the drawing of mind maps. This material was then developed into word clouds to identify focus key themes (Figure 1).

The literature review and the semi-structured interviews that chart the evolution and development of hospitality experience in port city in Jeddah, identify developments and changes to spaces of hospitality with a particular focus on the forms of building and urban space that have been created over time.

Qualitative data was considered one of the best methodological approaches in this study, which is used to identify multiple ways for analysing a group of people's behaviour and ethics. Furthermore, it facilitates the necessity for a detailed understanding of people, their behaviours, and their perspectives. Linda Groat had argued that providing qualitative research into user needs, cultural context, spatial experiences, and socio-environmental dynamics can contribute to the enhancement of design processes (Groat, 2013).

The research is designed to focuses on a deeper understanding, interpretation, and contextualization of data, so that researchers can identify nuances, patterns, and relationships that may not be easily quantifiable. Based on Creswell and Poth, (Creswell and Poth, 2016) this can only be accomplished by participating in their lives and visiting their homes, workplaces, and excursions. Moreover, to be able to evaluate how people interact with each other and their stories in society, which can sometimes be challenging to comprehend due to its complexity, it conveys the information in a flexible literary style that can provide insight into the contexts and settings in the study of a particular problem or issue; also, emphasis is on developing theories that have not been adequately narrated.

Figure 1 : An extract of words from the transcriptions of the interviews was used to generate a word cloud the by the Author.

3. Discussion of 'envelopes'

This paper develops and frames conceptual the idea of 'envelopes' of historical, contemporary (and future) hospitality. These envelopes divided into multiple themes, each focused on a particular area of research. In the beginning, the history and legacy review addressed a series of three different envelopes that observed spatial, cultural, and visual aspects during that period of time, then compared them with current experiences through narrative stories in the interviews. Aids in unpacking each theme of envelopes were based on a number of taxonomies; rituals, hospitality and customs within the cultural envelope, landmarks, architectural façade and ornamentation within the visual envelope, and proximity (or distance) of inhabitation and relationship to climate within the spatial envelope (Figure2).

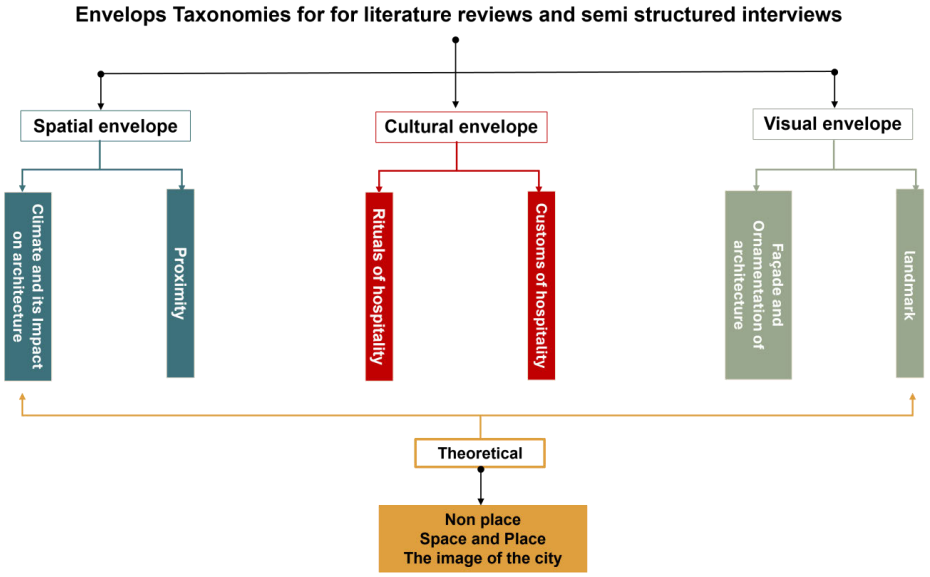

Figure 2 : General methodology diagram by the Author.

3.1 Spatial envelope:

3.1.1 Climate and its Impact on architecture:

The location of the city of Jeddah in the middle of the Red Sea has played an important part in its prosperity and expansion in urbanisation, as it was considered the connecting point between production centres and international and local consumption areas until it became one of the most important ports in Hejaz. Moreover, the architectural and cultural character of Jeddah is primarily influenced by its geographical location. This region is affected by high levels of humidity most days of the year and this usually rises at the end of summer (late August to early October), when the sea temperature is at its highest (Najib, 1987). Summer is generally characterized by higher humidity levels than winter (Division, 2005).

According to (Al Jaziri, 1962) the city of Jeddah witnesses' changes in the winds during the day, referred to as sea breezes. The north-westerly and western winds are the ideal winds due to the cooling effect they have during the summer (Al-Lyaly, 1990). All of these factors significantly affected the urban planning of Jeddah and the architectural design of exterior and interior of buildings' spaces to achieve the greatest benefit from good ventilation and coolness during the summer period, considering it to be the longest season during the year by 50% (Figures 3-5).

Figure 3, :Layout of Old Jeddah map (Abu-Ghazzeh, 1994).

Figure 4: Old Jeddah showing the wall, and the Sea edges. (Abu-Ghazzeh, 1994)

Figure 5 : The contemporary city of Jeddah made of gridiron patterns with the Old City at the centre. by (Mahbub

Historic iterations of urban space in old Jeddah worked with environmental forces in a more direct way, where the sea breezes had value in regard to the city design and the architecture. The city was designed and built in such a way that, with respect to the waterfront, sea breezes were captured to maximised their cooling climatic benefit. Thus, Jeddah in the past served as a port city, where the sea meets human settlements, directly connecting nature with culture via its urban plan and architecture. Although the city of Jeddah is situated in a semi-desert coastal area, which directly influences its atmosphere, its residents were more aware of their surrounding environment. Their structural system for the city was designed to attract cold north and northwest winds during the summer months.

This climatic relationship has significantly changed. Contemorary iterations of urban space and architecture in Jeddah relies on air conditioning and climatic control systems, which separate the inhabitants and tourists from engaging with the true nature of the area. This shapes the tourist's experience. Interview responses indicate that the process of passengers arriving in the city via Jeddah Islamic Port goes through several stages, all of which depend on temperature controlled environments all the time, starting from disembarking from the air-conditioned ship, all the way to their destination. Essentially, it means that the value of these temporal climatic effects of the coastline are now about their removal, rather than their celebration.

3.2 Spatial envelope:

Proximity:

History of Shuaiba Port and the Origin of Jeddah Port: Until 646 AD, Al-Shuaiba, nicknamed the Port of the Ship Cemetery, was the port of Makkah until people complained about the damage to ships from this port due to the large number of coral reefs located near Cape Black, located about 50 km south of Jeddah, near the confluence of Wadi Fatima in the sea. From this point on, Jeddah was adopted as a port city and outpost for Mecca in 646 AD, where it began to grow because it was taken as the main entrance to the city of Mecca during the Hajj and Umrah seasons, supplemented by trade movement (Shuaib, 2020).

In the tenth century AD 901, the city of Jeddah became a prosperous port and was described as the treasury of Mecca, Yemen and Egypt due to the abundance trade movement. The port of Jeddah continued to grow as it received ships loaded from Aden. These ships unloaded their cargo and then transported goods by private ships in the Red Sea to other ports such as the port of Al-Tur and Eila, due to the significant number of coral reefs north of the Red Sea, which large ships could not cross due to their large size. In the fifteenth century, it became one of the most important ports in the Red Sea due to the arrival of Indo-Sino ships. As a result, Jeddah became a prosperous international port. In 1514 Hussain Al-Kurdi built the port of Jeddah, including several residences and two large yards for storing goods coming by sea from ships.

In 1805, the explorer, Viscount Valentia, visited the port of Jeddah to discover whether European ships could dispense with the Red Sea. He described the port of Jeddah as having many coral reefs that extend nearly four miles from the shore and reach the deepest of which is 22 meters, valid for entering large ships, and ships can only enter with the guidance of sailors. The traveller Tamisier described the port berths during his visit to Jeddah in 1834 as several longitudinal beams completely covered by wooden panels made of teak. During a visit by Russian officer Dolchin in 1898, the port was so strong and robust that it was even suitable for warships. The port of Jeddah has been distinguished since ancient times by its natural immunity represented by the coral reefs, which made it difficult for ships to enter the port, and it was impossible to enter the port after the afternoon without a guide. Therefore, ships do not enter or exit it except during the day (Al-Amayreh, 2007, Al-Ghamdi, 2021).

The port had several facilities, such as customs and commercial stores. Over time, it went through several stages of restoration and rebuilding due to climatic conditions and events including water torrents that flowed into the Red Sea and the high humidity due to its proximity to the sea. Port facilities were the focus of the rulers' attention during the Ottoman era because of the high economic income they generated. He renovated warehouses due to damage to commercial funds in 1872 to build new stores. In 1883, the General Secretariat of Customs submitted a request to build dilapidated warehouses within the customs administration in Jeddah.

By the mid-1950s, Jeddah had become an established international port (Figures 6-9). Punt was considered the first port for pilgrims, and visitors to enter the city of Jeddah until it was built in 1867. It consists of three vital facilities, which are "Al-Iskala", "Al-Karantina" and "Al-Hajjaj Customs". The Karantina section was the medical examination for pilgrims and visitors to ensure they were free of contagious diseases. This building stopped working in the mid-fifties to transport all facilities to the Jeddah Islamic Port (Al-Thaqafi, 2015).

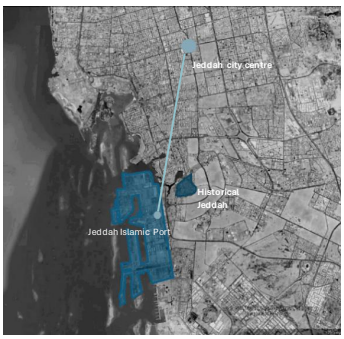

Figure 11: Current map of Jeddah that illustrate the tow points of proximity between the port and the central Jeddah. Google Map edited by the author.

Historically the proximity and location of the port connected it to the city's heart, according to many travellers' narratives and pictures. Thus created a kind of connection between the city's edges and the city itself, including its landmark, its identity, its streets, its paths, and its districts. As a result of the proximity in space and the move from the edge to the heart of the city, it achieved one of the most important elements of the Sense of Place theory by Yi-Fu Tuan (Tuan, 1979). Emphasising creating an impact on the place on human interaction and attachment, creating memories of this experience that lead to connection to the place.

This historical reading and experience of arrival in Jeddah significantly differs from contemporary readings of transit spaces captured by Auge's concept of non-places. The factors shaping diametrically different character of contemporary spaces of arrival underpin this research. Why are contemporary spaces of arrival now non-places that do not motivate their users to build social interactions? These non-places are characterized by forcing users to move within specific parameters to experience in these spaces, which leads to feeling of anonymity and separation from his surroundings and other individuals (Auge, 2010).

A factor raised by interviewees mentioned the time and distance it takes to get from the ship to the station and then to the destination itself, which goes through several stages using modern transportation methods. This can cause a delay in the customer's immersion in the experience of the port city and can occasionally lead to disorientation. Historically, there was a similar time taken in transportation phases between sea and land, but the differences were in the speed of immersion in the experience and the distance between the port station and the city centre. Auge's (Auge, 2010) described this as evidence of modernity's influence on spaces and the reason for the loss of identities of users and spaces as well. Even though some of these specific parameters were present at that time, the surrounding environment and proximity to the heart of the city mitigated the feeling of them. We conclude from the above that there are similarities and differences regarding proximity. The contrast is that things used to be compact, and now they're extensive. While the similarity included in rituals of moving through the experience, regardless of the difference in the visitor's immersion in the experience (Figures 10-11).

3.2 Cultural envelope History

Rituals, and customs of hospitality:

Local residents have long used the port as a major source of income and trade from the Red Sea in the form of ships coming from the Mediterranean Sea carrying ivory, feathers and sandalwood and serving pilgrims (Figure 8). Consequently, residents of Jeddah speak different languages due to their close contact with non-Arab merchants, visitors, and pilgrims. As a custom Jeddah was converted into a 'factory' of hospitality where all its residents worked in serving the pilgrims in order to provide the service, and to make a living from their service, as houses turned into caravanserais. Jeddah's historic homes are designed to be accommodate pilgrims until they leave the Holy Land and after they return to continue the sea journey that returns them to their homelands.

Historically the Arabs custom of hospitality is three days of hospitality of course. It is possible for the guest to stay for a longer period of time than this, but the guest has the right to full hospitality during this period.. Hospitality is known as Hafawa, which is the highest form of generosity, welcome, and attention to the guest in the Arabic language, evident in their daily practices, their poems, and stories told. As the first commercial gate and been the main sea crossing serving the holy sites of the Kingdom of Saudi Arabia, Jeddah city has served as an applied example of Hafawa.

Those passing through Jeddah had several options and rituals of hospitality if they wished to stay. They could stay in Khan or Ahwash, which hosted visitors, or they could stay in residents' homes called Almabet, a ritual familiar to Jeddah residents. Almabet consists of a room located on the upper floors of the houses to provide privacy for the visitor and the people of the house, as was narrated by the traveller Tamizier 1834, where he said (we were accommodated in a beautiful house with a location overlooking all the roofs of the houses adjacent to it). Walls are usually built of wood to allow the maximum amount of air to pass through, as is the house of Noor Wali, in which the dorm rooms are located on the third floor Figure 13.

Where the first area is located in the northwest corner of the floor, its area is 7.55 square meters by 3.74 square metres. This room is divided into two parts by an ornate wooden partition consisting of three bent wooden columns linked to each other at the end by three arrayed arches. The architect constructed the north and west walls of the room out of wood rather than excavated stone to allow an air current to arrive and relieve the loads on the foundations. The room in the northeast corner has a large facade and measures five meters in width of Roushan Figure 12,13.

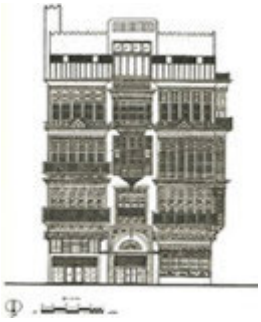

Figure 12: Elevation of Noor Wali home one pf the hospitality home_in Jeddah. Architecture in the Ottoman era. prepared by Nibur Architecture in the city of Jeddah in the Ottoman era, by Dr. Abdullah Al-Thaqafi

Figure 13: Plan of Almabeet in third floor at Noor Wali home one of the hospitality home_in Jeddah . Architecture in the Ottoman era. prepared by Nibur Architecture in the city of Jeddah in the Ottoman era, by Dr. Abdullah Al-Thaqafi

As narrated by the traveller Tamizier in 1834, when he said: “We were accommodated in a beautiful house with a location overlooking all the rooftops of the houses adjacent to it’’ (Al-Thaqafi, 2015). As well as Philby describes his journey and hospitality in the city of Jeddah In his book, The Heart of the Arabian Peninsula. Philby entered the door of that big house that welcomed them from its balcony and went up two floors to welcome and meet them on the stairs of a person whose rank is no less than the ruler of the city, who is Sharif Mohsen. Sharif Mohsen grabbed Philby's hand and then led him into his private reception room, in which he sat next to him on the porch furnished with pillows next to the window, and he gestured with his hand to my companions to sit in the corners of the room and then asked us for coffee (Philby, 1922-2009).

From the above, we can observe the strength of social construction, which is reflected in the rituals, customs, traditions, and societal norms of Jeddah. The culture of Jeddah city as a port city has a distinctive heritage and identity, which is unique among port cities along the Red Sea. The city of Jeddah is known by many names, including the port of Mecca, since it is its sea gate. Residents have a reputation for their custom of receiving pilgrims and visitors from the port as soon as the ship docks there. Hospitality persists through rituals that provide for the guest, including food and drink, and a place to stay in their homes until they leave. Consequently, these values, rituals, and customs contribute to a visitor's sense of identity and belonging to a particular place. Thence, promoting emotional connections between visitors and destination establish meaningful social interactions spaces. Performing these rituals and customs created a sense of familiarity and physical experience for the visitor, which was chronicled and recorded by foreign travellers in their writings.

At the present time, it is clear that the Kingdom is keen to emphasize the rituals and customs of hospitality in the tourism sector as a mechanism that contributes to attracting tourists. Several interviewees indicate that Historic Jeddah is a top-selling tourist destination because of its historical and cultural significance. Many of them agreed that capturing the cultural and heritage identity of the city of Jeddah, plays a vital role in tourism experience. According to some of them, tourists expressed a desire to return to Jeddah for a longer period of time, as well as to visit the historic city again.

3.3 Visual envelope History

Facade and landmark of architecture form impact on the visitor experience:

The taxonomy of facades of architectural forms and landmark is presented in this envelope. It frames the concept of "imageability" in the city of Jeddah as well as the importance of the architectural characteristics of the city in influencing the tourist's experience. This highlights the most significant architectural visual elements, including facades and ornamentation that created visual interest and variety in the built environment, and which were praised by foreign tourists.

Historical Jeddah has a distinctive architectural character and facades that includes iconic elements of the city's most important fortification system, the wall that is visible from the city's entrance as a first-land mark. Built in 1509 AD, the wall features five sides and three main gates serving as entrances and exits to the city: Bab al-Madina in the north, Bab Mecca in the east, and Bab al-Bahr, also known as Bab al-Bunt, in the west, facing the sea(Ismail, 1997).

Jeddah's architects had consistently focused on building facades and ornamentation incorporated and illustrated into the Rawashin and Mashrabiyas as geometric and plants motifs. Architects design the building facades and add the ornamented Rawashin in order to provide beauty to the rest of the parts of the city, reflect its identity, and give a cohesive sense of the city Figures 14,15. Rawashin and Mashrabiyas are the most important architectural statements that distinguished the facades of the city of Jeddah.

Figure 14: The façade of Rawashin in old Jeddah residential houses.(AL-LYALY, 1990)

Figure 15: The façade of Rawashin in old Jeddah residential houses at present time.(2022)

These architectural huge windows serve not only aesthetics but also satisfy the public's taste and provide privacy for the users. Jeddah had numerous visits by foreign travellers and Arab historians because of its status, geographical location, and openness to the whole world, who in turn provided a description of their visual experience of the city of Jeddah and what its buildings looked like and the places of hospitality in which they were hosted. As the first traveller to visit Jeddah at the beginning of 1806, he described the houses as beautiful, gigantic, beautifully decorated, and with large and numerous windows (Roshawn) overlooking the north and south.

Based on writings by the traveller Burkhardt, he described the buildings of Jeddah as well-built, built of square-shaped stones, most of which come from the Red Sea coast (Mangabi, Coral stone), and each house has two floors. Most have windows with wooden covers, and some have arched doors.

Tamisier observed that Jeddah's houses were constructed from rock blocks with a characteristic white colour, which were transported from the sea specifically for this purpose, and their windows were decorated with wooden panels. These houses were well ventilated, spacious, and clean. According to French traveller Charles Didier, the houses of Jeddah and their architectural style are very beautiful, and he described them as a rare style in the countries of the Islamic world. In addition, he mentioned that their architectural design depends on the continuity of the inside with the outside while preserving the privacy of those inside the building due to the design of the windows, which are covered by finely crafted wooden brocades (Ismail, 1997) (Figures 16,17).

Figure 16: On one of the facades of the northern wall of Jeddah, one can see the houses of the city of Jeddah, including the home of Sharif Muhanna(Bakr, 2014).

Figure 17: The waterfront of Jeddah's old port, Al-Bunt, one of Jeddah's landmarks.(Bakr, 2015)

In light of the above, many travellers agreed during their visits to Jeddah, at different times, on the extent of the cohesion and sequence of the visual experience of the image of the city of Jeddah. Jeddah's architectural language, which extends from it's the port as a major landmark to its building facades and landmark, significantly influences visitors' experiences in the city. This demonstrates the strength of the city's architectural and spatial character, as evidenced by the facades and landmark of its architectural forms. Through its architectural facades and ornamentation, the city not only reflects the identity of its residents, but it also fosters a sense of belonging among visitors. This visual communication significantly enhances the imageability and memorability of the visitor experience. Additionally, visitors used it as a landmark to signify their arrival at their destination.

Landmarks are the brand of the city, while architectural facades are a language of cultural exchange that reflects the identity of the coastal city. Although they are two symbiotic factors that contribute mainly to attracting tourists, they differ in the way they are read and received visually by the visitor and tourist (Lynch, 1977). This attributed to the difference in scale between each of them, where landmarks are often looked at from a distance and seen as a whole or as a shape, while the facade is viewed as the building envelope within urban space.

At present, industrial interfaces for logistics services in ports have become part of the features and landmarks of the modern port city, while passenger ports function as transit points in most parts of the world. Several interviews indicated that port stations must be smoothly and quickly operated to achieve the principle of comfort for the traveller and to save time. This idea of efficiency and smoothness, demonstrates the quality of performance and operation of these spaces, which is the prevailing principle around the world that determines the quality of these spaces. According to some, that the purpose of this place is purely operational, allowing passages through to reach their destinations without remembering the experience through these spaces.

Consequently, the way passenger ports are understood today reflects the experience of non-place, where among its characteristics is the emphasis on speed of movement and passage through environments (Auge, 2010). The current understanding of the role and function of passenger ports is as frictionless landmark. Facades (in the port) act as dislocated symbols that reflect the city port City identity and culture in the passenger experience. This is differs from historic understanding of the port where it was considered to be one of the distinctive landmarks of its residents and played a significant role in leaving a stamp on the tourist's first visual impression, its buildings also representing and embodying the language of cultural exchange for its visitors.

4. Conclusion:

In conclusion, this study discusses passenger ports, including the ways that they are viewed, received, and understood by the user. This is not only from a historical and contemporary perspective, but also from a social perspective, an environmental perspective, a cultural perspective, and a visual perspective. The development of the research methodology is designed to help understand and communicate the vision of the port as a place of diverse opportunities in many ways, beyond those perspectives defined by a framework of operational efficiency or a gateway to transit. The study examines the impact of non-place, sense of place, and imageability on users' perceptions of port spaces. As a method is intended to promote a more complete understanding of passenger port spaces by reintroducing ideas that can eliminate placelessness in public spaces in the future and stimulate the evocation of history in a meaningful manner. This work examines and discusses potential trajectories for designing and realising passenger port spaces, aiming to frame, speculate and unpack possible rather than the probable futures for those spaces.

Keywords: *Diversity, Equity, Cultural Integration, Coexistence, multiculturalism, Community Engagement, Minority Groups, Welcoming and Accessible Cities, reception systems, Open Space, Social and Economic Inclusion*

There is a growing awareness of the significance of diversity and the tensions it may generate in societies, with major cities leading the way in facing this challenge. Inclusivity is now a fundamental principle in urban planning theories and practices, marked by a renewed commitment to advocating for cities that are fair, multicultural, welcoming, and open to all. Among other topics, issues such as migration, multiculturalism, minority groups, gender, religion, identities, accessibility, and the quality of essential services and spaces, as well as urban inequalities, urban poverty, and the emergence of diverse lifestyles (or the possibility of embracing new ones), are all central to the contemporary discourse. How can planners deal with these challenges? What kind of planning frameworks and approaches can better support inclusivity?

This track aims to thoroughly explore the multifaceted concept of inclusion in urban planning, with a particular focus on the idea of the open city—a city capable of embracing diversity, multiculturalism, experimentation, and fairness while acknowledging the diverse challenges planners must address in upholding these values. It is designed to encompass a wide range of contributions, including theoretical reflections, ethical perspectives, urban policies, urban design strategies, discussions on regulation and the law, interesting case studies, analyses from the field, best practices, and other pertinent urban planning viewpoints that can enhance the contemporary discourse. Therefore, the track welcomes diverse contributions, encompassing the formulation of policies and planning interventions, examinations of current socio-spatial dynamics, and broader reflections on the issue at hand.

The track aims to facilitate a dynamic exchange of ideas and experiences and welcomes abstracts addressing, but not limited to, the following themes:

- Diversity and Equity: How can urban planning promote equity and accommodate the diverse needs of urban populations?
- Cultural Integration and Coexistence: What strategies can cities employ to foster cultural integration and multiculturalism?
- Community Engagement and Minority Groups: How can planners ensure that residents can be heard and included in relevant decision-making processes?

- Welcoming and Accessible Cities: What initiatives can cities, along with other public and private actors, implement to create welcoming environments for newcomers, individuals with disabilities, etc.?
- Open Space and Social Interaction: How can open spaces and the built environment be designed to promote interaction and exchange among diverse people?
- Social and Economic Inclusion: What policies and practices can bridge the gap in access to resources, education, employment opportunities, and (small) entrepreneurship?

Research on the Psychological Health Impacts for Children in Urban Built Environments

Abstract:

In recent years, the incidence of psychological and behavioral problems in children has increased, making it a critical intervention target within the framework of the Healthy China Action. The development of children's psychological health is influenced by a myriad of factors, with psychological biases potentially accumulating over time and evolving into psychological health issues such as depression and autism. Various disciplinary fields address the development of children's psychological health through genetic factors, family dynamics, social surroundings, and material space. Among these, urban and rural planning disciplines optimize the material spatial environment through planning design and indicator regulation, mitigating or reducing biases in children's psychological development and thus preventing or ameliorating the psychological health risks they face. Existing studies indicate a substantial correlation between factors of the urban built environment and residents' psychological health, exerting long-term, sustained, widespread, and subtle effects on psychological well-being with the potential for optimization and improvement. Moreover, owing to their social vulnerability, health susceptibility, and highly malleable biological characteristics, children's psychological health is particularly susceptible to the influence of urban built environments. The developmental trajectory of children's psychological health possesses unique characteristics, and their utilization and experience of urban space differ from that of adults. Some studies have noted that certain material spatial elements relevant to adult psychological health may not hold the same significance among children and adolescents. Therefore, in urban planning research addressing the psychological health needs of children, the following questions merit further elucidation: (1) What constitutes the specific connotation of children's psychological health, and what comprises psychological health at different age stages? (2) What are the characteristics of the effects of urban built environments on children's psychological health? (3) What potential impact pathways exist during this process? This article aims to explore the impact of the urban built environment on children's psychological health across these three dimensions. Comprehensive interdisciplinary research seeks to clarify the concepts, processes, and compositions of children's psychological health, along with the psychological health characteristics of children across all age groups; extract and identify elements and characteristic indicators of the urban built environment, analyzing their impact pathways from various perspectives on the psychological health benefits for children.
Keywords: Children's Psychological Health; Urban Built Environment; Interdisciplinary Research

1. Introduction

The healthy development of children is crucial for determining a nation's future potential. With the advancement of modernization, improvements in living environments, and enhancements in medical care, there has been a significant improvement in children's health levels. However, simultaneously, there has been a rising occurrence of and public concern about psychological health issues in children.

Existing research suggests a significant correlation between urban built environment elements and residents' psychological health. These influences are long-term, continuous, extensive, and subtle, with the potential for optimization and improvement. Additionally, due to their social vulnerability, susceptibility to health risks, and highly malleable biological characteristics, children are particularly susceptible to the influences of urban built

environments (Evans, W, G. and Ferguson, T, K., 2011). The developmental process of children's psychological health is unique, as children utilize and experience urban spaces differently from adults. Some studies have also found that certain material spatial elements relevant to adult psychological health are not significant among children and adolescents (Foster, S. et al., 2015). Interventions in children's psychological health development across various disciplinary fields, including genetic factors, family atmosphere, social environment, and material space, are crucial (Culbertson, L, J., Newman, E, J. and Willis, J, D., 2003). Urban and rural planning disciplines aim to alleviate or reduce biases in children's psychological development through planning design and indicator regulation to optimize material spatial environments. Consequently, this helps prevent or ameliorate the psychological health risks faced by children.

Therefore, in the context of urban planning research focusing on children's psychological health, further clarification is required on the following issues: (1) What are the specific connotations of children's psychological health and the psychological health characteristics at different age stages? (2) What is the relationship between urban built environments and children's psychological health? (3) What are the pathways through which urban built environments affect children's psychological health? These will provide insights for the construction of child-friendly cities.

2. The composition and age characteristics of children's psychological health

The meaning of psychological health has become increasingly enriched with the development of medical, psychological, and social psychological service systems, extending gradually from individual mental aspects to various facets including cognition, language, emotion, and social adaptation (Bhugra, D., Till, A. and Sartorius, N., 2013). Research on children's psychological health focuses on the developmental processes of psychological behavior based on brain development and the associated issues arising from biases (Shvaleva, M, N. et al., 2018). Children's psychological health emphasizes the changing processes of psychological and behavioral development, exhibiting stage-specific characteristics at different age stages while demonstrating a continuity of mutual influence and connection throughout the overall developmental process. The age range of children can be divided into four stages: infancy, preschool, school-age, and adolescence (Clay, T. and Fox, G., 2008).

(1) Cognitive Ability

Cognition generally refers to the process of knowing or cognitive activities, which is a higher psychological activity that reflects the characteristics, states, and interrelations of objective things in the brain, and reveals the significance and effects of things on individuals (Chernikova, V, I., 2014). Cognitive development is closely related to changes in brain morphology and the development of brain function. Cognitive abilities mainly include aspects such as perception, memory, attention, and thinking (Flavell, H, J., 1992).

(2) Emotions and Feelings

Emotion is the attitude experience generated by whether objective things meet human needs, reflecting the relationship between objective things and human needs (Rodríguez, L., Ramos, F. and Wang, Y., 2012). Feelings are attitude experiences related to whether advanced social needs are satisfied, gradually formed in the practice of social interaction, such as feelings of friendship, morality, beauty, and rationality (Keung, H., 2013). This is a unique emotional state of human beings. Emotions and feelings play an important role in the lives and overall psychological development of children and adolescents, influencing their cognition, behavior, social relationships, and personality formation and development (Suveg, C., Southam-Gerow, A, M. and Goodman, L, K., 2007).

(3) Personality and Socialization

In the process of growth and development, influenced by various factors, each individual gradually forms a unique personality. At the same time, as social beings, humans inevitably form various relationships with others and gradually develop sociality. The development of sociality is crucial for children, as well as for groups and society (Mukhina, V., 1982).

2.2 Age Characteristics of Children's Psychological Health

(1) Infancy (0-3 years old)

During infancy, children's brains develop rapidly, marking a key period of cognitive, motor, and language development, as well as the initial stage of personality formation (Bornstein, H, M. and Shriver, K, E., 2015). Scholars widely agree that psychological development during infancy is the result of interactions between individuals and their environment (Sale, A., Berardi, N. and Maffei, L., 2014).

(2) Preschool Period (3-6 years old)

As children acquire language skills, they begin to engage in representational thinking. However, thinking at this stage tends to be rigid and irreversible (Ulu, E. and Kiraz, A., 2014). Children's emotional experiences become quite rich during this period, gradually developing higher-level emotions such as trust, sympathy, aesthetic sense, and morality. Moreover, they begin to develop self-awareness and can begin to regulate their activities and behaviors (Brown, T. and Jernigan, L, T., 2012).

(3) School Age (6-12 years old)

Psychological development in school-age children, including attention, thinking, and emotions, is more stable compared to preschoolers and adolescents (Collins, A, W., 2001). Their memory and imagination abilities undergo significant development, and they exhibit various forms of human emotions. The stability and regulation ability of their emotions gradually strengthen (Ferdinand, K, N. et al., 2018).

(4) Adolescence (12-18 years old)

During adolescence, thinking becomes more comprehensive and profound. Adolescents exhibit psychological characteristics that retain traces of childhood while also showing the emergence of various adult behaviors (Brizio, A. et al., 2015). Their sense of morality, rationality, and aesthetics undergo significant development. Their interpersonal relationships become more complex, and they engage in meaningful social activities (McLaughlin, A, K., Garrad, C, M. and Somerville, H, L., 2015).

In summary, infancy is a critical period for psychological development, with infants exhibiting significant plasticity. The preschool period prepares children for school before formal education begins. School age represents a significant transition period in psychological development. Adolescents' psychological characteristics become richer and more stable.

3. Factors influencing children's psychological health

Psychological health refers to a state of complete psychological well-being, encompassing both positive and negative aspects (Bhugra, D., Till, A. and Sartorius, N., 2013). Research on psychological health has been conducted across various disciplines, including psychology, medicine, sports science, education, sociology, geography, and urban planning (Fusar-Poli, P. et al., 2020). Numerous studies have shown that psychological health is influenced by a diverse array of factors, which can be classified medically into biological factors and

psychosocial factors (Singh-Manoux, A., Macleod, J. and Davey, S., 2003).

Children's psychological health emphasizes the changing processes of psychological and behavioral development, exhibiting stage-specific characteristics at different age stages while demonstrating a continuity of mutual influence and connection throughout the overall developmental process. Similarly, the influencing factors follow medical classifications and can focus on intrinsic genetic and individual factors as well as external environmental factors. External environmental factors can be further categorized into social determinants, family environment factors, and material environment factors. The pathways of influence can be direct or indirect through behavioral means.

3.1 Endogenous influences

Genetic and individual factors are endogenous influences on children's psychological health, determining the potential for children's psychological health development. At the same time, the development and changes of these potentials are also subject to various external environmental constraints and interventions. The prenatal cortisol levels and telomere lengths of parents with adverse childhood experiences can affect their offspring through genetic or environmental pathways, thereby increasing the risk of psychological problems in children such as negative emotions, depressive symptoms, and defiant behaviors. However, the impact of genetic factors during childhood is much lower than that of external environmental factors (Gene–environment interactions in psychopathology throughout early childhood: a systematic review, 2015)(Vendlinski, K, M. et al., 2014), and the degree of influence diminishes with age(Franić, S. et al., 2010). In terms of individual factors, temperament traits, personality characteristics, cognitive abilities, self-awareness, and other aspects all influence children's psychological health. The family environment is an important external environmental factor that contributes to children's psychological health (Aronen, T, E., 1991)(Ferguson, T, K. et al., 2012)(Hank, K. and Steinbach, A., 2018).

3.2 Exogenous influences

With the rapid development of society, external environmental factors have gradually increased their impact on children's psychological health, making family environment, social environment, and material environment hot topics in this field. The influence of family environment on children's psychological health is profound. Factors such as family economic status, family atmosphere, family structure, parenting styles, and parental education level all have varying degrees of influence on children's psychological health (Bornstein, H, M., 2013)(Veronese, G. et al., 2014)(Manor-Binyamini, I. and Naamneh, G., 2019). In terms of social influences, socioeconomic background, cultural differences, medical services, personal social interactions, neighborhood cohesion, and school life all impact children's psychological health (Perna, L. et al., 2010)(Immelt, S., 2006)(Ferguson, T, K. et al., 2013). Social psychological stress exposure is one of the most significant factors affecting adolescent depression (Twenge, M, J., 2020).

Material environment has a significant impact on children's psychological health (Jevtić, M. and Bouland, C., 2019). The impact of climate change on children's psychological health includes direct effects on emotions, stress, and happiness, as well as indirect effects such as trauma, post-traumatic stress disorder, depression, and cognitive development disorders resulting from secondary disasters (Karaliūnienė, R. et al., 2022)(Cianconi, P., Betrò, S. and Janiri, L., 2020)(Xu, Z. et al., 2012). Studies in regions such as Northern Europe and North America have found seasonal variations in the incidence of psychological health problems in children, such as anxiety disorders, obsessive-compulsive disorders, attention deficit hyperactivity disorder, and severe depression (Nillni, I, Y. et al., 2009)(Kovalenko, P. et al.,

2000)(Copeland, N, J. et al., 2022). Children are particularly susceptible, and exposure to environmental factors such as air pollution, noise, electromagnetic radiation, and radiation can disrupt the normal development of children's psychological behavior. Due to children's faster respiratory rates and lower activity spaces, various air pollutants such as vehicle exhaust, cooking fumes, and odors from garbage are more likely to trigger emotional responses in children, and even cause respiratory system damage, leading to lung inflammation and poisoning (Song, J. et al., 2018). Different types of noise pollution from traffic, construction, and neighborhoods can affect the activity and function of children's nervous systems, leading to psychological health risks such as depression and anxiety (Schubert, M. et al., 2019). Children have larger pupils than adults, and facilities such as nighttime lighting or overly bright signs and illuminated buildings with high contrasts in environmental light are more likely to inhibit children's melatonin secretion, affecting their circadian rhythm regulation (Navara, J, K. and Nelson, J, R., 2007). Exhaust deposition and meltwater containing de-icing agents can cause heavy metal or chloride pollution in soil and surface water, affecting children's intellectual and immune function development (Brockmeyer, S. and D'Angiulli, A., 2016).

3.3 The influence of children's behavior on psychological health

Children's behavior is the outward expression of their lifestyle and habits, serving as an intermediary factor for various psychological influences. Children's activity behavior includes physical activity, sedentary behavior, and sleep (Karwowska-Struczyk, M., 1998).

Physical activity refers to any activity that involves energy expenditure through skeletal muscle contraction, including exercise training, daily chores, commuting, and other leisure activities, which may occur in urban outdoor environments. The social-ecological model suggests that the main influencing factors of children's physical activity behavior include: a. Individual factors such as motivation, skills, attitudes, knowledge, and perception; b. Interpersonal relationship factors such as family, peers, teachers, and social support; c. Institutional or organizational factors such as school regulations, attention from relevant departments, and health services; d. Community factors such as public green spaces, recreational facilities, and road traffic, as well as neighborhood effects; e. Public policy factors such as laws and regulations, education policies, financial support, and public health strategies (Gao, W. et al., 2022).

Outdoor physical activity is closely related to children's psychological health and promotes the cultivation of willpower, cognitive abilities, optimistic emotions, and good interpersonal relationships. Physical activity affects children's psychological health through three pathways: biological factors, individual psychological factors, and social psychological factors (Biddle, H, J, S. et al., 2019). Biologically, physical activity can improve sleep and alleviate childhood depression by increasing hippocampal volume (Vancampfort, D. et al., 2018). Psychologically, physical activity can improve self-esteem and self-efficacy mechanisms to alleviate childhood depressive symptoms (Ahn, S. and Fedewa, L, A., 2011). Socially, physical activity enhances children's social connections, increases social support, and reduces anxiety (Gorham, S, L. et al., 2019).

4. The factors and pathways of urban built environment impact on children's psychological health

In the process of urban planning, the elements of urban built environment intertwine with the factors affecting residents' psychological health, mutually influencing each other. Numerous studies have confirmed that the urban built environment has long-term, sustained, extensive, and subtle effects on residents' psychological health, with the possibility of optimization and

improvement (Núñez-González, S. et al., 2020)(Gascón, M. et al., 2015)(Gong, Y. et al., 2016)(Clark, C. et al., 2007). Building on this foundation, scholars have further focused on the child population, conducting research on the impact of community built environment, external building environment, urban green-blue spaces, and equity of facilities on children's psychological health (Villanueva, K. et al., 2016)(The influence of the neighborhood physical environment on early child health and development: A review and call for research., 2015)(Alderton, A. et al., 2019)(Hitch, L. et al., 2023). Buttazzoni constructed a research framework for urban planning and children's psychological health from the perspective of neuro-urbanism (Buttazzoni, A., Doherty, S. and Minaker, L., 2021), which has significant reference value.

4.1 Influencing factors

Research on urban planning for children's psychological health is closely related to the concept of child-friendly cities, which align with the 12 characteristics outlined by the United Nations Children's Fund (UNICEF) (Vliet, v, W. and Karsten, L., 2015). The urban planning elements influencing children's psychological health are highly similar to the healthy environment and services that children should enjoy, including green-blue spaces, land use, road layout, space site, and service facilities.

(1) Green-blue spaces

Green spaces such as water bodies, parks, and walking trails have various beneficial effects on improving children's physical and mental health and rarely induce negative behaviors. The proportion of green spaces and their accessibility determine children's opportunities to interact with nature. Insufficient green space indicators reduce children's contact with nature, diminish their environmental perception and activity levels, leading to phenomena such as nature deficit and psychological and behavioral problems (Vanaken, G. and Danckaerts, M., 2018). Microscopic spatial visual indicators such as green view ratio, color richness index, sky openness index, and transparency affect children's sense of security, comfort, and pleasure (Dadvand, P. et al., 2014). Excessively monotonous and desolate green spaces are detrimental to the formation of children's attention and imagination and may even lead to emotional depression and disorders (Engemann, K. et al., 2019).

(2) Land use

Land use indirectly affects children's psychological health by influencing their physical activity. Moderate physical activity helps alleviate children's emotional problems and promote cognitive development. The intensity of community land development affects children's physical activity levels. Building height is positively correlated with children's physical activity levels (Li, L. and Hin, ., 2009). Overall building density is negatively correlated with children's physical activity (Durand, P, C. et al., 2011). Mixed land-use environments in communities promote children's physical activity (Masoumi, E, H., 2017). Additionally, the building layout and spatial form of high-rise communities alter the microclimate environment, affecting children's immune, nervous, and skin systems to varying degrees (Vanos, K, J., 2015).

(3) Traffic layout

The richness of social activities and interfaces, population density, and pedestrian accessibility on streets affect children's activity preferences (Villanueva, K. et al., (no date)). The safety of intersections, parking forms, and pedestrian facilities influence parental supervision and significantly determine children's physical activity decisions (Carver, A., Timperio, A. and Crawford, D., 2008). Behavioral activities are crucial intermediary factors

in streets' impact on children's psychological health and affect children's perception and nervous system development (Tappe, A, K. et al., 2013).

(4) Space site

In recreational spaces within urban public areas, factors such as zoning functional complexity, composition of gaming elements, and size of connection areas influence children's choices of social behaviors (Dong, N., Chen, J. and Zhang, S., 2017). The accessibility of sports facilities and the cleanliness and attractiveness of activity environments affect children's physical activity, thereby influencing their psychological health development (Xiao, Z. and Li, H., 2012).

(5) Service facilities

Service facilities are closely related to children's health risks. The service scope and accessibility of medical facilities affect the emergency response time for children's accidents and the availability of medication for children in need of psychological healing (Savagea, R., Helfer, B. and Lash, M., 1997). The types and accessibility of retail and food facilities affect the variety of food children can access and the balance of nutritional intake. Low-income communities are more prone to "food deserts," increasing health risks such as childhood overweight and obesity (Ploeg, V, M., 2010), affecting children's personality and social development. The accessibility and visibility of tobacco and alcohol retail facilities affect children's exposure probability and increase tobacco smoke exposure, affecting children's neurological and respiratory health (Marsh, L. et al., 2021), thus influencing the formation and development of perception.

4.2 Influencing pathways

Urban built environments primarily affect children's psychological health through two pathways: direct effects on senses and indirect effects through spatial or service changes. The former directly impacts children's psychological health under environmental stressors (such as environmental colors, housing congestion, neighborhood safety, etc.). The latter involves changes in social interactions, physical activity, and environmental perception resulting in psychological behavioral changes such as a sense of belonging, security, or discomfort (Franklin, M. et al., 2020). Additionally, indirect impact mechanisms are not limited to the above processes and can produce multiple or multidirectional potential influences, such as physiological health mapping and coexistence of promotion and inhibition. For example, research has found that when children are in environments with low street connectivity or school accessibility, they tend to choose active commuting modes such as walking or cycling (Pabayo, R. and Gauvin, L., 2007). Such commuting modes can increase their psychological well-being and reduce psychological stress. From the perspectives of neurobiology, social psychology, and behavioral science, green spaces have been found to improve children's psychological health levels by reducing exposure to harmful factors, enhancing recovery capabilities, and strengthening self-capabilities (Vanaken, G. and Danckaerts, M., 2018). However, the specific results are influenced by children's socioeconomic backgrounds.

5. Research Prospects

In the fields of medicine, psychology, education, sociology, architecture, landscape architecture, and urban planning, both domestically and internationally, research has been conducted on the factors influencing children's mental health, including genetic and individual factors, family factors, social environment, and physical environment. This research has accumulated certain methodologies and findings, highlighting the specificity of children's mental health development. It's recognized that children's use and experience of urban spaces

differ from those of adults. Additionally, some studies have found that certain physical spatial elements related to adult mental health are not significant among children and adolescents. Therefore, it's necessary to conduct research on the impact of built environments on mental health specifically targeting children, this unique population.

The practice and research of building child-friendly cities mainly propose planning and design methods from the perspective of urban public spaces, residential areas, and streets, with a greater focus on children's physiological and behavioral needs and safety risks. Although some scholars have conducted research on children's psychological development, much of it focuses on special groups of children and specific mental health issues. Moreover, the translation and application of relevant research results into planning intervention paths in the practice of building child-friendly cities still require further exploration. Therefore, it's particularly important to conduct research on the mechanisms and planning intervention paths of the impact of built environments on mental health at the scale of school districts, which is most relevant to the daily lives of school-age children.

In the field of urban planning, many studies are limited to cross-sectional data due to data constraints, although the medical field often uses correlation analysis methods based on cross-sectional and panel data in research on factors affecting mental health. The mechanisms through which built environment elements in urban school districts affect children's mental health are complex. Cross-sectional data-based correlation studies cannot control for potential variables, thus reducing the accuracy of mechanism analysis and making it difficult to determine causality. Therefore, integrating longitudinal tracking experiments and analysis methods from other disciplines such as medicine and psychology and incorporating a time dimension through the comprehensive use of panel data to quantitatively explore the relationship between urban school district built environments and children's mental health holds significant scientific value.

Study on the Comparison of Development Efficiency between Inner and Outer Urban Circles and the Balanced Development Strategy of Marginal Areas : Analysis based on the county scale of Chongqing

Mengyao Zhang [1]*, Pan Hu [1]
[1] School of Architecture, Southeast University, Nanjing, China
*zmy4633@163.com

Abstract. The article takes 38 counties in Chongqing as the research object, conducts social and economic development data statistics and spatial analysis, and divides them into the core, inner circle and outer circle counties based on the theory of 'core-periphery' and the circle structure characteristics of municipal areas. The data envelopment analysis (DEA), exploratory spatial data analysis (ESDA) and geographically weighted regression (GWR) models are introduced to conduct a comparative analysis of the characteristics of the spatial patterns and factors affecting the development efficiency of the inner and outer circle counties in the municipal area, and to explore the differences in the development of the inner and outer circle counties, as well as the main development problems and strategies.

Keywords: urban circles; development disparities; peripheral areas; balanced development; ESDA

1. Introduction

The interaction between regional development differences at the geographic spatial level and unbalanced regional development policies has accelerated the emergence of the 'core-periphery' structure in regional space (Yang *et al*., 2023). In this regard, many scholars use qualitative, quantitative and other methods to carry out the regional unbalanced development research to demonstrate. Some studies have found that the 'core-periphery' feature is not only reflected in the regional economic differences but also manifested in the social elements such as the cultural divide (Savini *et al*., 2016). When identifying the core or peripheral areas of the region, the regional economic, demographic, political and knowledge levels should be considered and reflected in regional policymaking (Eder, 2019). Meanwhile, the spatial variation trend and distribution characteristics of socio-economic development inequality have also been increasingly concerned (Wei, 2015). Some studies have used the Theil Index (Wei *et al*., 2020), Reilly's Law of Retail Gravitation model (Rana, Routray and Younas, 2020) and Cluster Analysis (Shi, 2023) to reveal the internal development differences of the region and their dynamic evolutionary processes and spatial pattern. Research based on the Multi-dimensional Equality Development Index (MEDI), including economic vitality, innovation capacity, social convenience and inclusiveness, found that the

pattern of spatial inequality in China has shifted from 'coastal-inland inequality' to 'core-periphery inequality' (Yang *et al*., 2023). There is a prevalence of 'core-periphery' spatial development structure in provinces and large cities in China, the phenomenon is mainly produced by the combined effect of natural geographical spatial differentiation, socio-economic spatial organisation and regional spatial connection (Wang and Fan, 2019), and the significant 'core-periphery' structure can exacerbate provincial spatial polarisation and reduce local mobility (Wei *et al*., 2020). Multi-dimensional and multi-scale studies have been carried out on the 'core-periphery' structure within the region. Some scholars have focused on the temporal and spatial variation characteristics of the 'core-periphery' structure in the economic development process of counties within the Yellow River Basin, and used regression models to explore the driving mechanism of the evolution of the 'core-periphery' structure of counties on provincial boundary (Zhang *et al*.,2023). On the inter-provincial scale, the spatio-temporal pattern and formation mechanism of regional economic differences in the inter-provincial fringe areas were discussed (Xia *et al*., 2014; Yu *et al*., 2012). At the provincial and city scales, research often focuses on a typical provincial or municipal unit, specifically analysing the process of change, stage characteristics and internal mechanisms of districts from core to fringe (Yang *et al*., 2023), as well as analysing the spatial pattern of inequality in the provincial area through Spatial auto-correlation Models (Wei and Ye, 2009; Wei *et al*., 2020; Li, Ding and Liu, 2012), and applying multi-level regression model to explore the influencing factors for the formation of the provincial 'core-periphery' structure (Li, Miao and Ye, 2016), and using Geographically Weighted Regression (GWR) to explore the spatial heterogeneity of the factors affecting inequality in the provinces (Wei and Ye, 2009; Cao and Xu, 2018).

Research on the 'core-periphery' structure within regions has been ongoing and has produced rich results, but most of the existing studies have focused on inequality within developed regions in eastern China (Wei and Ye, 2004, 2009; Wei *et al*., 2020; Liao and Wei, 2012, 2015; Zhang, Tong and Liang, 2018), and there are less analyses of county economic differences in less developed western provinces (Zhou and Li, 2021). Therefore, a multidimensional division of analysing the development differences in typical western regions, tailoring regional development strategies according to the degree of marginalisation of the region, and helping marginalised regions to break through geographical constraints to form agglomeration advantages, which have strategic value for accurately improving the level of regional coordinated development (Eder, 2019). Chongqing is a typical city with a 'core-periphery' structure (Wang and Fan, 2019), although counties have made remarkable achievements in economic and social development in recent years, the development level of counties in the non-central urban area is lagging behind, and not only is there a clear gap with the top one hundred counties in the country, but also has no competitive advantage in the ranking of the top one hundred counties in the west. There is significant spatial dependence in the economic and social development of counties in the long term, that is, the economic growth of a district is significantly positively affected by the economic growth of

neighbouring counties. For Chongqing, this trend is even more pronounced, with significant positive spatial correlation in the economic growth of counties, significantly forming a high economic growth agglomeration area mainly consisting of the nine districts in Chongqing's central urban area, as well as a low economic growth agglomeration area mainly located in southeastern Chongqing and northeastern Chongqing. According to 'the Outline of the Fourteenth Five Year Plan and Vision for the 2035 Plan for the National Economic and Social Development of Chongqing Municipality', the ratio of per capita GDP between the 'one region' and the 'two clusters'[1] was 1.84:1 by 2020. Chongqing has markedly regional uneven development characteristics, forming an economic spatial pattern with the 'one region' as the core and the 'two clusters' as the periphery.

Given this, this paper selects Chongqing as the research area, takes counties as the research unit, and divides them into three levels: core, inner circle and outer circle. Analyse the development efficiency of counties in Chongqing, as well as their spatial distribution characteristics and agglomeration patterns. Furthermore, it uses stepwise linear regression and geographically weighted regression models to quantitatively analyse the factors influencing the development efficiency of the counties and explores the spatial heterogeneity of their influencing effects. On this basis, a balanced development strategy for marginal counties is proposed, to provide a theoretical basis for the coordinated development among various circles in the city, and to enhance the overall inclusiveness of the city.

2. Overview of the Study Area, Data and Methods

2.1 Overview of the Study Area

Located in southwestern China, Chongqing is an important growth pole in the western region of China. It covers an area of 82,400 square kilometres and currently has 38 districts and counties under its jurisdiction, including 26 municipal districts, 8 counties and 4 autonomous counties. According to the Fourteenth Five-Year Development Programme of Chongqing, the economic spatial layout of Chongqing has a significant development pattern of circle structure. At the municipal scale, promoting the

[1] 'One Region' and 'Two Clusters': 'One Region' refers to the main urban metropolitan area of Chongqing, which includes nine counties in the central urban area and other twelve counties. Nine central urban counties including Yuzhong, Dadukou, Jiangbei, Shapingba, Jiulongpo, Nanan, Beibei, Yubei, and Banan. Other twelve counties including Fuling, Changshou, Jiangjin, Hechuan, Yongchuan, Nanchuan, Qijiang, Dazu, Bishan, Tongliang, Tongnan and Rongchang, with a permanent population of over 21.22 million in 2022. 'Two Clusters' refers to the town cluster of Three Gorges Reservoir Area in northeast Chongqing and the town cluster of Wuling Mountain Area in southeast Chongqing. The town cluster of Three Gorges Reservoir Area in northeastern Chongqing includes eleven counties, including Wanzhou, Liangping, Kaizhou, Chengkou, Fengdu, Dianjiang, Zhongxian, Yunyang, Fengjie, Wushan and Wuxi, with a permanent population of over 8.04 million in 2022. The town cluster of Wuling Mountain Area in southeast Chongqing includes six counties (autonomous counties), including Qianjiang, Wulong, Shizhu, Xiushan, Youyang, and Pengshui, with a permanent population of over 2.86 million in 2022.

coordinated development of 'one region' and 'two clusters', forming two basic circles, including the main urban metropolitan area and the peripheral counties. At the scale of the main urban metropolitan area, a pattern of gradual development is formed with the 9 central urban districts as the core to drive the tiered development of the new districts of the main urban area.

According to Friedmann's 'core-periphery' theory (Friedmann, 1966), there is a dominant 'core' in the regional development process, where production factors such as capital, technology, labour and production activities are concentrated. From the current development situation of Chongqing, the central urban area composed of nine districts constitutes the core circle. The various elements of the surrounding counties continue to flow out under the siphoning effect of the central urban area, which is gradually being at an unfavourable position in the process of economic development, forming the 'periphery'. According to the Fourteenth Five-Year Development Plan of Chongqing, the counties in the main urban new area are in the main circle of influence of the central urban area, and most of them border directly with one or more administrative districts in the central urban area, and are directly driven by the central urban area, and undertake the spillover of the functions and the industry of the central urban area. With the characteristics of 'the periphery near the core', they are divided into inner-circle counties. The town clusters in the Three Gorges Reservoir Area in the northeast of Chongqing and the Wuling Mountain Area in the southeast of Chongqing, which are developed relatively independently of the central urban area, have a certain spatial distance from the central urban area, do not border one or more administrative districts in the central urban area, and are subject to the limited radiation by the central urban area, and are gradually marginalised in the process of development to form a group of their own. The counties and districts contained in the 'two clusters' are classified as outer-circle counties.

Fig.1. Spatial distribution map of core, inner circle, and outer circle counties in Chongqing

2.2 Data

There is a substantial interactive correlation between the level of regional basic public services and the quality of economic and social development (Fang, 2012; Rana, Bhatti and e Saqib, 2017). Basic public service is one of the core factors directly or indirectly determining the state of economic and social development of a region (Holtz-Eakin and Schwartz, 1995), which plays an important role in promoting economic growth and significantly improving the social equity level (Liu, 2012). At the same time, the level of regional economic development also significantly affects the development of basic public services (Wang *et al*., 2023). Therefore, based on the empirical analysis of the interaction between basic public services and county economic development in Chongqing (Xiong, Yu and Wang, 2019), it is feasible and effective to use the financial expenditure and allocation efficiency of basic public service facilities as an indicator to measure the level of regional development in this paper.

This paper takes 38 districts and counties in Chongqing as the research object. The basic data of all the indexes come from the 2019-2023 Chongqing Municipal Statistical Yearbook, China County Statistical Yearbook (County and Municipal Volume), and 2022 Statistical Bulletin of the districts.

In terms of the selection of indicators for calculating efficiency, based on comparability and accessibility, this paper mainly selects three per capita indicators as input variables, including education expenditure, health expenditure, and social security and employment expenditure. In setting the output variables, the effectiveness of education, health care and social welfare services are taken into account. Adopting a series of representative indicators, including the ratio of students per full-time teacher in general secondary schools, and the ratio of students per full-time teacher in primary schools, which are used to assess the efficiency of the allocation of education resources. Four indicators have also been introduced, including the number of beds in medical and health care institutions per thousand people, the number of medical and health technicians per thousand people, the number of beds in adoptive social service institutions per thousand people and the number of industrial activity units per thousand people, to comprehensively reflect the coverage and effectiveness of public health services and welfare services. Together, these output indicators build a three-dimensional, multifaceted evaluation system to accurately measure the efficiency of financial expenditure and allocation of basic public services.

Table 1
Input and Output Variables for the financial expenditure and allocation of Basic Public Services

Input Variables	Output Variables
Education Expenditure	Number of full-time teachers in general secondary

	schools / Number of students in general secondary schools
	Number of full-time teachers in primary schools / Number of pupils in primary schools
Health Expenditure	Number of beds in medical and health care institutions per thousand people
	Number of medical and health technicians per thousand people
Social Security and Employment Expenditures	Number of beds in adoptive social services institutions per thousand people
	Number of industrial activity units per thousand people

2.3 Methodology

2.3.1 Data Envelopment Analysis (DEA)

DEA is a non-parametric method for efficiency evaluation that can be applied to Decision-Making Units (DMU) with multiple inputs and multiple outputs. This paper adopted the DEA-BCC model in STATA software to measure the efficiency of financial expenditure and allocation of basic public services in each district and county of Chongqing, and used it as a quantitative value to measure the level of regional economic and social development. The model formula is as follows (Charnes, Cooper, and Rhodes, 1978; Liu *et al*., 2020):

$$(BC^2)\begin{cases} \min \theta \\ s.t.\sum_{j=1}^{n}\lambda_j x_{jm} + s_i^- = \theta x_0, i = 1,2,...,m \\ \sum_{j=1}^{n}\lambda_j y_{js} - s_r^+ = y_0, r = 1,2,...,s \\ \sum_{j=1}^{n}\lambda_j = 1, \lambda_j \geq 0 \\ s_i^- \geq 0 \\ s_r^+ \geq 0 \end{cases}$$

Where: $\theta(0<\theta\leq 1)$ is the combined efficiency of decision-making units; n is the number of decision-making units; λ_j is the weighting variable; x_{jm} represents the inputs of the m^{th} indicator of the j^{th} unit, and y_{js} represents the outputs of the s^{th} indicator of the j^{th} unit. s_i^- and s_r^+ are slack variables for the m input variables and s output variables, respectively.

2.3.2 Stepwise Regression Model

Stepwise regression equations were created using the Statistical Package for the Social Sciences (SPSS) to extractive analyse the key factors in the independent variables. Using the optimal model R^2 to explain the coefficients of the model, which represents the overall significance. The standardised coefficients explain the positive and negative correlation with efficiency. Using the sig. to explain the significance of the independent variable on efficiency. The factors that are the main drivers of district and county development efficiency were analysed in this paper, where the various development indicators were the independent variables and the efficiency values were the dependent variables. The model formula is as follows (Paudel and Thapa, 2004):

$$\gamma = b_0 + b_1 x_1 + b_2 x_2 + ... + b_n x_n$$

Where： y is the efficiency value of the dependent variable, b_0 is the intercept, b_1， b_2,..., b_n are the coefficients of the explanatory variables x_1, x_2,...,x_n respectively.

2.3.3 Exploratory Spatial Data Analysis (ESDA)

This paper applied ESDA to measure the spatial correlation of counties in Chongqing. Used the description and visualisation of district and county distribution patterns to detect spatial clustering and spatial anomalies. Took Global Moran's *I* index to analyse the global spatial auto-correlation characteristics of the distribution of counties, and clarified the spatial clustering relationships of the analysed units, that is, high-high clustering, low-low clustering, low-high outliers, high-low outliers or insignificant features. Used hotspot analysis tools to analyse local areas where spatial （1） ıg of high or low development efficiency units were clustered in space. The m nula is as follows (Liu, Hu and Li, 2014):

$$I_i = \frac{n}{\sum_{i=1}^{n}\left(x_i - \bar{x}\right)^2} \frac{\sum_{i=1}^{n}\sum_{j=1}^{n} W_{ij}\left(x_i - \bar{x}\right)}{\sum_{i=1}^{n}\sum_{j=1}^{n} W_{ij}} \qquad (2)$$

$$Z(I_i) = \frac{I_i - E(I_i)}{\sqrt{VAR(I_i)}}$$

Where: I_i represents the overall trend in spatial correlation across the study area; x_i represents the development efficiency at location *i*. W_{ij} is the spatial weight value between elements *i* and *j*, and the neighbourhood matrix is used here. The neighbourhood matrix defines a binary symmetric spatial weight matrix W_{ij} to express the spatial neighbourhood of *n* positions, when *i* and *j* are neighbouring, the element of spatial weight matrix W_{ij}=1, otherwise W_{ij}=0. The value of Moran's *I* is generally in the range of [-1,1], I>0 indicates a positive correlation, and the closer the value tends to be to 1, which indicates that the spatial agglomeration of the research units with the same level of economic development is more significant; I<0 indicates a negative correlation, and the closer the value is to -1, which indicates that the spatial agglomeration of the research units with the different level of economic development is more significant. I=0

means that the regional units are independent of each other, spatially uncorrelated, and randomly distributed.

2.3.4 Geographically Weighted Regression (GWR)

GWR is a spatial regression model based on the idea of local smoothness. Embedding the geographic location of the data in the regression equation can effectively estimate the data with spatial auto-correlation as well as reflect the spatial non-stationarity of the parameters in different regions, which makes the spatial location of the different parameters change, and the results are more in line with reality. This paper used it to study the spatial heterogeneity of the factors affecting the development efficiency of counties in Chongqing. The model formula is as follows (Wei and Ye, 2009):

$$y_i = \beta_0(u_i, v_i) + \sum_{k=1}^{p} \beta_k(u_i, v_i) x_{ik} + \varepsilon_i$$

Where: y_i is the value of the dependent variable of sampling point i; β_0 is the intercept, (u_i, v_i) is the coordinate of sampling point i, β_0 (u_i, v_i) is the constant term of sampling point i; β_k (u_i, v_i) is the coefficient of the k^{th} independent variable of sampling point i; x_{ik} is the k^{th} independent variable of sampling point i; ε_i is the random error term.

3. Result

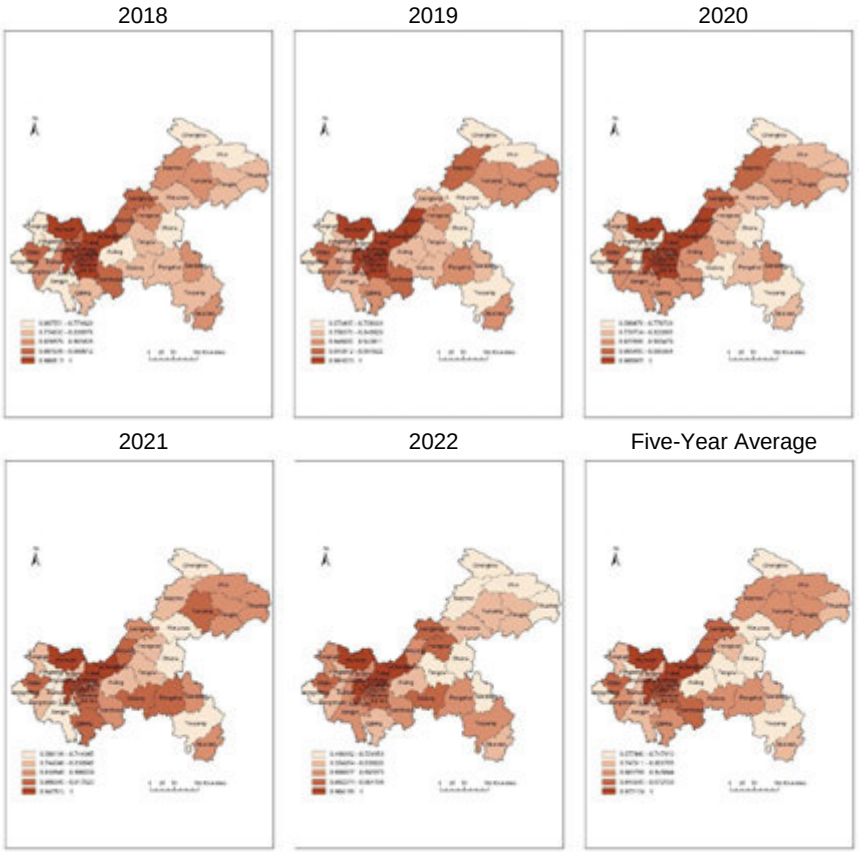
3.1 Spatial Patterns of Development Efficiency

3.1.1 Spatial Distribution Patterns

The spatial distribution of development efficiency in Chongqing's districts and counties were markedly geographically differentiated. The overall development efficiency in the western, northeastern, and southeastern of Chongqing was low. During the study period, areas with less development efficiency had shifted, with the least efficient zones formed in 2018 in western Chongqing, consisting of Tongnan, Tongliang, Rongchang, and Jiangjin districts, which gradually shifted to the least efficient zones in northeastern Chongqing, consisting of Chengkou, Wuxi, Wushan, and Kaizhou counties, and the lowest in southeastern Chongqing, consisting of Shizhu, Fengdu, and Qianjiang counties. From the perspective of circle division, the low-value areas of development efficiency were shifted from the inner circle to the outer circle, and in 2022, there were as many as seven low-value areas of development efficiency in the outer circle of Chongqing, accounting for more than 40 percent of the total.

An analysis of the average development efficiency of the districts and counties in Chongqing found that Yubei, Yuzhong, Shapingba, Nanan and Jiulongpo districts in the central urban area, as well as Hechuan and Changshou districts, which are directly neighbouring the central urban area, had better development efficiency. While Fengdu,

Chengkou and Wanzhou districts in the northeastern part of Chongqing, Shizhu and Youyang counties in the southeastern part of Chongqing, Rongchang and Tongliang



districts in the western part of Chongqing and Fuling districts in the central part of Chongqing had poorer development efficiency, of which Chengkou, Wanzhou, Shizhu, Youyang, and Rongchang district are all located in the municipal boundary area. From the point of view of circle division, the development efficiency of the core circle of Chongqing had been higher, with a stronger radiating and driving role. The number of counties with low development efficiency in the outer circle was significantly higher than that in the inner circle. This showed that the inner circle of counties are being radiated and driven by the central urban area, and the overall level of economic and social development presented a good trend, while the outer circle counties are relatively disadvantaged in terms of spatial distance, subject to the location of the marginalisation of the city, the urbanisation process and the construction of basic public facilities had lagged behind for a long time, the level of economic and social development was relatively low, in the process of economic development, they were in a crisis of being continuous marginalised.

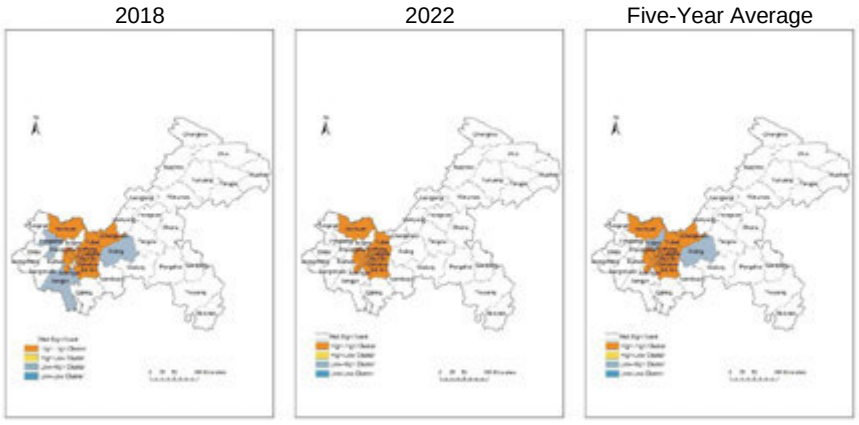
Fig.2. Spatial distribution characteristics of development efficiency of counties in Chongqing during the period 2018-2023.

Further using the global spatial auto-correlation tool（Global Moran's *I*）in ArcGIS *10.2* to analyse the spatial pattern of the development efficiency of Chongqing counties. The Global Moran's *I* index of the development efficiency of counties in Chongqing in each year of the study period was *0.3340*, *0.1528*, *0.2813*, *0.1086*, *0.4577*, and the *Z*-value of the normal statistic was *5.29*, *2.65*, *4.55*, *1.99*, *7.08*, respectively. The Global Moran's *I* index of the spatial distribution of the average development efficiency of Chongqing counties during the study period was *0.3265*, and the *Z*-value of the normal statistic was *5.19*. The index values were all positive and passed the test of significance at the level of *0.05*, indicating that the distribution of development efficiency of Chongqing counties had always had obvious global spatial auto-correlation characteristics. Despite fluctuations, counties with comparable development efficiency had always been highly agglomerated in space, and reached the highest value in 2022. At the same time, there had always been a significant difference in development efficiency between inner-circle counties and core-circle counties, but the gap was gradually decreasing.

Comparison of the results of the spatial clustering and outlier at the beginning and end of the study period showed that， in 2018, the central urban area (except Beibei district), Changshou district, and Hechuan district were high-high clusters, while Tongliang district, Jiangjin district, and Fuling district were low-high anomalies. In 2022, the central urban area (except Beibei district) and Hechuan district were high-high clusters, and the other areas were not significant. This indicated that: 1) counties exhibiting high-high clustering of development efficiency were always concentrated and contiguous, but the scale was shrinking. 2) Tongliang, Jiangjin and Fuling districts had gradually reached almost the same level of development efficiency as their neighbouring counties at the end of the study period.

From the analysis of the average development efficiency of the counties in Chongqing, the central urban area (except Beibei district), Changshou and Hechuan district were high-high clusters, and had formed a trend of taking the central urban area as the core to drive the continuous development of surrounding counties in the north. Beibei and Fuling district were low-high anomalies, forming two major 'depressions' around the central urban area, and facing the risk of marginalisation around the core circle.

Fig.3. Spatial clustering and outliers of development efficiency of counties in Chongqing at the beginning and end of the study period.

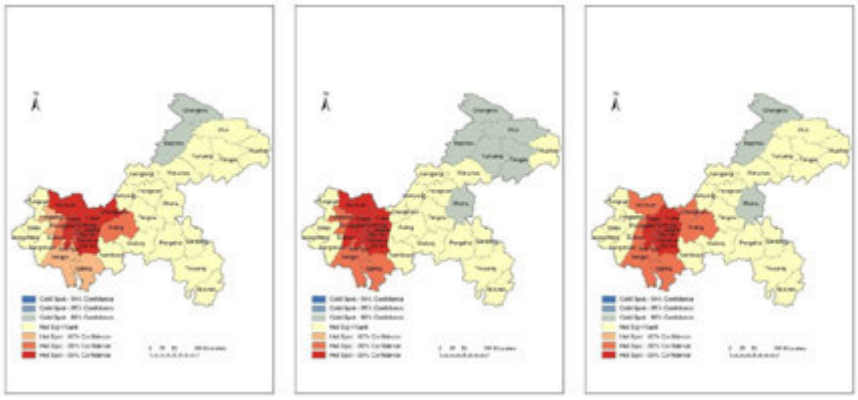


3.1.2 Spatial Agglomeration Patterns

Using the hotspot analysis tool to carry out local spatial auto-correlation analysis, the results showed that in 2018, the high value of the development efficiency of the counties in Chongqing was mainly concentrated in the hot spot area composed of the central urban area, Hechuan and Changshou district, and the Tongliang, Bishan, Jiangjin, Qijiang as well as Fuling district immediately adjacent to the central urban area had become secondary hot spots. The low value of the development efficiency was mainly concentrated in the cold spot area composed of the Chengkou and Kaizhou districts. By 2022, the high value of development efficiency of counties in Chongqing was mainly concentrated in the hotspot area composed of the central urban area, Hechuan, and Bishan districts. The hotspot area was basically unchanged, and was still centred on the nine districts of the central urban area, and its surrounding counties, Chanshou district, had insufficient development efficiency, and became non-significant, while Bishan district, with significant improvement in its development efficiency, integrated into the hotspot area, and Tongliang, Jiangjin, and Qijiang district, which were adjacent to the central urban area, form a sub-hotspot area. The Fuling district was non-significant. The scope of the low value of development efficiency of counties in Chongqing further expanded, adding Wuxi, Yunyang, Fengjie and Shizhu county based on Chengkou and Kaizhou district, forming a large-scale cold spot area in the northeast of Chongqing. In terms of circle division, the development efficiency of the core circle had always been

at the high values, the secondary hotspot area composed of counties and districts in the inner circle had shrunk. The cold spot area composed of some counties and districts in the outer circle had significantly expanded, and the number of counties with low values of development efficiency had increased significantly. This indicates the emergence of a 'periphery of the core' character of the inner circle districts, and the marginalization of counties and districts in the outer circle was becoming increasingly serious.

Analysing the spatial clustering characteristics of the average development efficiency of each district and county in Chongqing during the study period, it was found that the hotspot areas were mainly the nine districts in the central urban area and their direct neighbouring counties, of which only Nanchuan district was insignificant. Chengkou and Kaizhou district in northeastern Chongqing, and Shizhu county in southeastern Chongqing constituted the cold spot areas. The distribution pattern of circles was



significant, with the nine districts in the central urban area as the core circle with high development efficiency, the inner circle counties directly neighbouring the nine districts in the central urban area with high development efficiency, while other outer circle counties had low development efficiency.

2018 2022 Five-Year Average

Fig.4. Spatial agglomeration characteristics of development efficiency of counties in Chongqing at the beginning and end of the study period.

By calculating the average development efficiency of the core circle, inner circle and outer circle counties each year, it was found that the core circle had always maintained a significantly high level of development efficiency, and the fluctuations of the development efficiency had tended to be stable. The overall development efficiency of the inner circle and outer circle was generally on a downward trend, and the development efficiency of the inner circle is always higher than that of the outer circle. In 2022, the development efficiency of both the inner and outer circles decreased

considerably, with the outer circle experiencing a significantly larger decrease than the inner circle, while the core circle showed a slight increase. This suggested that the vulnerability of the peripheral counties was higher when dealing with major risk challenges, with the inner counties being more resilient to risk than the outer counties.

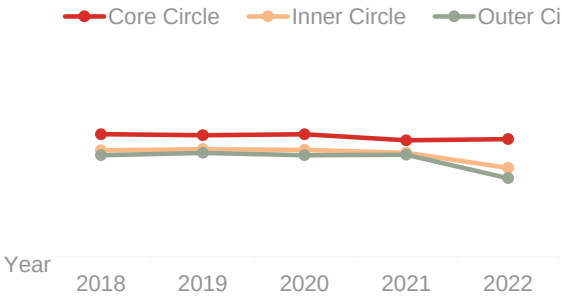


Fig.5. Changes in the overall development efficiency of counties in the core circle, inner circle, and outer circle of Chongqing during the period 2018-2023.

3.2 Analysis of Influencing Factors

3.2.1 Independent Variable Selection

Existing studies have shown that the development efficiency of cities and towns in China is affected by various factors, including economy, population, land, industry, and income (Sun Wang and Sun, 2013; Li *et al*., 2019; Yin, Wang and Duan, 2021; You, Jiang and Li, 2022; Luo, Cai and Wen, 2022). Therefore, this paper selects 20 indicators as independent variables from five dimensions: economic development level, population agglomeration capacity, built-up area development conditions, industry agglomeration capacity and residents' income level. Taking the efficiency value of financial expenditure and allocation of basic public services as the dependent variable to explore the factors affecting the differences in the development efficiency of counties.

Table 2
Development indicators and variables classification of counties in Chongqing

Development Indicators	Variables Classification
Level of Economic Development	• Gross regional product (10,000 yuan). • Gross regional product per capita (yuan). • Average land output value (10,000 yuan/square kilometer). • Per capita tax revenue (10,000 yuan). • General public budget revenue at district and county level (yuan).
Population Agglomeration	• Permanent population (10,000 people). • Population density (person/hectare).

Capacity	• Share of county population in total city population (%).
Development Conditions of Built-Up Areas	• Built-up area (square kilometers). • Built-up population density (10,000 people/square kilometer). • Land urbanisation rate (%). • Population urbanisation rate (%).
Industrial Aggregation Capacity	• Total industrial output value (100 million yuan). • Number of industrial enterprises above designated size. • Share of industrial output value in the city's secondary industry output value(%).
Level of Residents' Income	• Per capita investment in social fixed assets (yuan). • Per capita disposable income of rural permanent residents (yuan). • Per capita disposable income of urban permanent residents (yuan). • Per capita savings deposit balance of residents (yuan).

3.2.2 Stepwise Regression Analysis of Influencing Factors

The variables were processed in SPSS *20.0* using the stepwise regression model. The calculation results showed that three explanatory variables passed the significance test and covariance diagnosis, that is, the influencing factors of the development efficiency of counties in Chongqing were mainly related to the per capita tax revenue, the urbanisation rate of the population and the per capita balance of residents' savings deposits, which were respectively related to economic development level, development conditions of built-up areas and residents' income levels. All three indicators had a positive impact on the development efficiency of counties. In terms of the intensity of the effect, the balance of per capita residents' savings deposits > per capita tax revenue > population urbanisation rate, indicated that the level of residents' income had the strongest impact on the development efficiency of counties.

Table 3
Stepwise regression modelling results

Variable	Standard Coefficient	Sig.
Population Urbanisation Rate	0.486	0.027
Per Capita Tax Revenue	0.571	0.006
Per Capita Residential Savings Balance	0.509	0.027
R^2	0.363	

3.2.3 Analysis of Spatial Heterogeneity of Influencing Factors

To explore the spatial differences in the effects of the above three significant influencing factors, the GWR model was used to further analyse the spatial heterogeneity in the intensity of the effects of the influences. The results of the GWR model showed that:

(1) Tax revenue per capita.

The per capita tax revenue was positively correlated with the development efficiency of counties, that is, the higher the per capita tax revenue, the higher the development efficiency of the counties. The regression coefficient of per capita tax revenue showed the distribution characteristic of gradually increasing from west to east, and the regression coefficient fluctuated a lot, which indicated that its influence effect on the development efficiency of counties in Chongqing had strong spatial heterogeneity. In terms of inner and outer circles, the regression coefficients of the factors in the outer circle of the eastern area were larger, that is, the per capita tax factor had a more significant impact on the development efficiency of the counties located in the periphery. The per capita tax reflected the industrial tax contribution capacity and economic development level of counties, the higher the per capita tax, the stronger the industrial development, the stronger the tax contribution capacity and the relatively higher the development efficiency of counties. In the long-term development of outer-circle counties, they had been constrained by the unbalanced development strategy at the policy level. At the same time, their development emerged with a lot of problems, including weak industrial foundations, unclear advantageous industries, imperfect industrial systems, as well as limited location conditions, insufficient construction of production factors, slow improvement of the investment environment and so on. The cumulative cycle of all kinds of problems, emerged from the lack of development impetus, which had influenced the improvement of the economic development level of the outer-circle counties.

(2) Population urbanisation rate

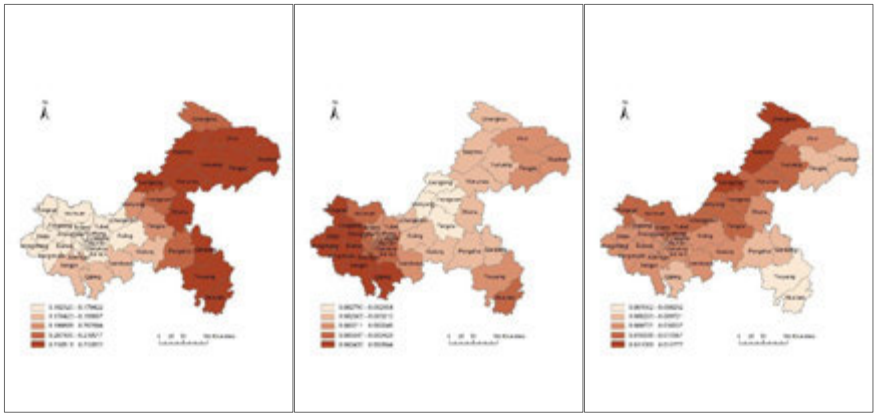
The population urbanisation rate had a positive impact on the development efficiency of counties. The regression coefficient of the population urbanisation rate showed a spatial distribution characteristic of gradually decreasing and then gradually increasing from west to east, and the spatial heterogeneity was relatively obvious. From the perspective of inner and outer circle division, the regression coefficients of inner circle counties in the west were larger, that is, the population urbanisation rate had a greater impact on the development efficiency of counties located on the edge of the core in the west. The population urbanisation rate reflected the changes in the urban and rural population structure and the development level of built-up areas in the counties. Counties located at the edge of the core were subject to the obvious siphoning effect of the core circle counties, and the phenomenon of the population moving to the central urban area in pursuit of higher levels of public services and higher quality employment opportunities was obvious, while the level of their urban construction was insufficient, making it difficult to attract the transfer of surplus rural labour to the cities, and the

development elements were insufficiently concentrated, resulting in the overall development efficiency of the counties being relatively low.

(3) Per capita residential savings deposit balance

There is a positive correlation between per capita savings deposit balance and development efficiency of district and county. The regression coefficients of per capita savings deposit balance showed a spatial distribution characteristic of decreasing from north to south. In terms of inner and outer circles, the regression coefficients of the factor were larger in the outer circle counties in the northeast area that were located in municipal border areas, which meant that the development efficiency of these counties was closely related to the per capita savings deposits balance. The per capita savings deposits balance reflected the level of residents' income. Chengkou, Kaizhou, and Liangping districts had poor local production conditions, and limited sources of income for residents, mainly relying on agricultural production and migrant work, the income level was low, making the overall development efficiency of the counties relatively low.

Fig.6. Spatial heterogeneity of influencing factors of tax revenue per capita, population urbanisation rate, per capita residential savings deposit balance.



4. Strategy

The classical theory of urban geography holds that the core and the periphery are interdependent, jointly constructing a complete spatial system, the development process of which has evolved from unrelated, isolated development to unbalanced development, and from unbalanced to interrelated balanced development (Lu *et al.*,2016). Based on the efficiency differences between the inner circle counties and outer circle counties in Chongqing, the city is in the stage of unbalanced development. To optimise the

economic spatial pattern of Chongqing, and to promote the formation of an interlinked balanced development pattern in counties of each circle, combined with the differences in the influencing factors of the development efficiency of each district and county, the following suggestions are put forward for the development of the inner circle counties and the outer circle counties, respectively.

4.1 Inner-Circle Counties

The factors affecting the development efficiency of inner circle counties are mainly the population urbanisation rate in the indicators of built-up area development condition. As a result, raising the urbanisation level of built-up areas, enhancing the attractiveness of counties, and promoting population concentration and development are the keys to raising the development efficiency of inner-circle counties.

On the one hand, inner circle counties need to comprehensively improve their soft and hard capabilities based on the diverse needs of various types of populations. At the hardware level, through the phased promotion of urban construction and renewal, the quality of the spatial environment in built-up areas should be optimised, and good housing, transport and other living conditions should be provided; and the efficiency, quality and satisfaction of public services should be upgraded in key areas, such as education, medical care and housing, so as to create conditions to attract the outgoing population back to the county. Second, reforms and innovations in the population system, community governance, and employment policies at the software level should be implemented to jointly promote the citizenship of the agricultural transfer population and the inward migrant population. By deepening the reform of the household registration system and relaxing the restrictions on urban settlement, it will guide the rural population and the migrant population from outside to gather in counties in an orderly manner. At the same time, to enhance community governance capacity, improve the quality of residents through organising community education, cultural and sports activities, and so on., and promote greater interaction among residents, to foster social integration among different groups of citizens. As well as implementing a proactive employment policy, optimising the environment for innovation and entrepreneurship, creating more high-quality jobs within counties, supporting the expansion of employment, and promoting high-quality development of the population.

On the other hand, take the initiative to collaborate with the integration of the Chongqing metropolitan area and strengthen the joint development with the core circle, thus effectively curbing the continuous loss of population in inner circle counties. Narrow the gap with the central urban area by upgrading public services and establishing a mechanism for the common construction and sharing of public service facilities, to achieve the sharing and accessibility of public resources. Strengthening transport and information links with the central urban area, so that residents of the counties can more conveniently enjoy high-quality resources as well as employment opportunities in the central urban area, and attracting the population of the central urban

area with the unique ecological and cultural resources of the counties, and promoting the reverse flow of population. Enhance industrial collaboration between inner-circle districts and the central urban area, forming industrial linkage effects, create more local employment opportunities, reduce the out-migration of residents due to employment, and at the same time, attract industrial spillover and talent overflow from the central urban area, to jointly improve the development efficiency of inner-circle counties.

4.2 Outer-Circle Counties

The development efficiency of outer-circle counties is mainly affected by the per capita tax revenue in the indicator of the level of economic development, while some outer-circle counties are also affected by the per capita residents' savings balance in the indicator of the level of residents' income. It can be found that promoting economic growth and increasing residents' income is the core driving force to enhance the development efficiency of Chongqing outer-circle counties.

On the one hand, the outer circle counties should focus on optimising their development environment and gathering internal forces for development. Firstly, according to the comparative advantages of their resources, they should guide the transformation and upgrading of traditional industries and cultivate competitive leading industries. At the same time, increases financial expenditure on innovation, stimulates the vitality of scientific and technological innovation, actively cultivates emerging industries, forms a diversified, high-value-added industrial system, improves product value-added and labour productivity, and drives tax growth. Secondly, optimize the allocation of public services and infrastructure, improve the investment and living environment, attract talent, technology and capital pouring in, and in the spatial planning of each level, strengthen the layout of the outer circle counties of transportation, information and other infrastructure, promote the interconnection of counties of each circle, shorten the spatial and temporal distance between the outer circle and the core circle, and improve the flow efficiency of resources between counties to support the Economic growth.

On the other hand, make full use of the positive edge effect of interaction and borrow development momentum. Firstly, based on regional synergy policy, using the radiation-driven role of the core circle and the inner circle to undertake the transfer of industries and technological overflow, and take the initiative to buttress its advantageous industries, develop supporting industries, and form an upstream and downstream linkage, division and collaboration of the industrial system. Secondly, given the weak economic foundation of the outer circle counties, which are at a disadvantage in regional competition, it is possible to establish a cooperation mechanism, build a group development mode, focus on cultivating group-level growth poles, and promote in-depth cooperation between counties in the form of co-built industrial parks, tourism zones, and logistic hubs, to form a secondary interrelated development mode in the outer circled districts and enhance the overall competitiveness.

5. Conclusion

Under the guidance of the 'core-periphery' theory, interpret policy documents and identify the uneven development of counties at the level of the regional development strategy of Chongqing, and divide them into three circles, including the core, the periphery of the core, and the periphery. Using the DEA model to measure the development efficiency of counties, and analyze the spatial distribution characteristics of the development efficiency of counties in Chongqing through the spatial auto-correlation method, identify the hot spots, cold spots and outliers of the development efficiency at the end of the study period, and analyze the spatial variations of the development efficiency of counties in different circles. A total of 20 variables in 5 dimensions, including economic development level, population agglomeration capacity, built-up area development conditions, industrial agglomeration capacity and living standard of residents, are selected to study the spatial heterogeneity of factors affecting the development efficiency of the counties of Chongqing and the effect level of the factors by applying the stepwise regression model and the GWR model, and to discuss the development strategies of the counties in different circles of Chongqing. The main findings are as follows:

（1）During the study period, the development efficiency of counties in the core circle of Chongqing has remained consistently high value, and the development efficiency of counties in the inner circle as a whole has continued to be higher than that of counties in the outer circle. Some inner-circle counties
have large differences in development efficiency with core-circle districts and counties in the process of development, and face the risk of marginalisation around the core circle. The area of low development efficiency in outer-circle counties is expanding significantly, and the characteristics of marginalisation are increasing.

（2）Tax per capita, population urbanisation rate and per capita savings deposit balance are the main factors influencing the development efficiency of counties in Chongqing, and their effects are spatially heterogeneous and positively correlated with the development efficiency. The development efficiency of counties in the inner circle is mainly affected by the population urbanisation rate, especially in Tongnan, Tongliang, Dazu, Bishan, Rongchang, Yongchuan, Jiangjin and Qijiang. The development efficiency of outer circle counties is mainly affected by per capita tax revenue, with the outer circle counties represented by Liangping, Kaizhou and Chengkou simultaneously significantly affected by per capita residential savings balances.

（3）Inner-circle counties need to optimise urban space and public services to retain population, and realise population agglomeration through population management, community governance and employment policy innovation. Also, strengthen collaboration with the core circle, share resources, smooth traffic and information, and cooperate with industrial development to mitigate the impact of siphoning and curb the outflow of population, as well as to stimulate economic vitality and efficiency through

the convergence of human capital. The outer circle should focus on building a competitive industrial system to accelerate economic growth, improve infrastructure, optimise the investment environment, participate in the division of labour under the framework of regional coordination, undertake industrial transfers, and develop complementary industries; deepen cooperation between counties to form a development model of clusters, cultivate growth poles, and drive economic growth in the region.

Maintain Temporal Dynamics

What temporal characteristic needs to be preserved within the historic marketplaces of Palermo to encourage sustained interactions?

Abstract:
Immigration to Europe significantly increased in the 21st century, which challenges the integration of these immigrants. Palermo, is a significant destination for immigrants where tensions unfold between immigrants and locals. Many newcomers are economic immigrants seeking informal opportunities to secure their income in historical marketplaces where dynamic characteristics unfold. The aim is to identify the temporal characteristics that shall be retained within the historic marketplaces of Palermo, which encourage sustained interactions. The study uses Doreen Massey's theoretical framework on temporalities (2005) and Gehl's methods through an observational study (2013) in Ballaró and Vucciria markets. The results of the analysis demonstrate two market space typologies which encourage sustained interactions. Furthermore, five key spatial and social factors are defined as necessary to retain within historic marketplaces.

Keywords: immigration, sustained interaction, immigrant-local coexistence, marketplaces, temporality, social and economic inclusion

Special thanks is given to my supervisor, Camilla Pezzica, for her continuous enthusiasm and support on the paper.

1. Introduction

Over the past decade, immigration to Europe increased by 18% between 2020 and 2021 (Eurostat, 2023). This surge in the population is due to localised wars and considerable loss of habitats (Sassen, 2016; Montgomery, 2016). Italy is a significant destination for immigrants from Northern Africa, East Asia, and Europe (Comune di Palermo, 2021). However, the rise in illegal smuggling networks into Italy is host to many human rights issues. On the one hand, numbers rose due to criminal actions and environmental catastrophes in Northern Africa (Carney, 2021). On the other hand, the increasing number of people being trafficked to Lampedusa and Sicily is uncertain and dangerous (De Bruycker, 2013). The concern amongst many researchers is neutral on those committing to the journey as minimal resources are shared between them.

Across many Southern Italian cities, the distribution of immigrants is a concern as newcomers are undemocratically assigned a much greater percentage of residences compared to Northern Italy. Even if there are economic benefits for cities to accept immigrants, as they take on low-paying work that locals reject (Cole and Booth, 2007), their social integration is problematic. In Sicilian cities, the concern is the tensions between immigrants and locals that unfold due to cultural differences (Gutekunst et al., 2016). Palermo is a critical mediator between Lampedusa and Northern Italy. Over the 19th and 20th centuries, the middle and upper classes moved to the outskirts. Meanwhile, criminal forces surged in the historic centre (Schneider and Schneider, 2003), resulting in its physical degradation (Lo Piccolo, 1996). Consequently, the centre became a major attraction for immigrants to settle and form informal economic networks.

Liveability, access to employment, and socio-economic mobility are all human rights that economic immigrants seeking financial prosperity deserve. In informal economies, the illegalities and tensions between them and locals are unfolding due to the unresolved socioeconomic inequalities that immigrants face. The informal economies within the historic centre are crucial survival opportunities for immigrants, illustrating the significance of its study (Akiyode, 2017). Many economic immigrants trial informal vending on unauthorised lands such as residential and servicing streets (Lo Piccolo and Leone, 2018) and historic marketplaces on secondary commercial streets. Secondary streets are significant when discussing the tension between residents and immigrants as they are well-connected

to primary streets. Furthermore, these streets provide higher commercial prospects, which attract residents.

Previous research highlighted the urgency for revitalising the historic centre due to its physical degradation. These strategies outlined the historic marketplaces as a primary area to take action on (Wulff, 2020). Relevance to this focus includes the increasing number of low-income immigrants reliant on informal vending and the marketplaces' historical significance within the city. Therefore, the strategies infer the need to study the characteristics of historical marketplaces to suggest how to approach their continually dilapidating civic and built infrastructure.

The increasing number of immigrants and their informal practices present challenges in revitalising the city centre. Their socioeconomic characteristics can be defined by their propensity to change spatially, revealing the social characteristics of their practices (Kamalipour and Dovey, 2020). Therefore, the research focuses on studying the dynamism of historic marketplaces that demonstrate opportunities to ease tensions between immigrants and locals. As a theoretical framework, temporality is applicable and is defined through the incomplete nature of space (Massey, 2005). Temporality can be seen as both spatial and social processes. The former is viewed as the spatial morphology of space, and the latter is observed through encounters. Therefore, the research aims to define the temporal characteristics of historic marketplaces that shall be retained within historic marketplaces due to their physical degradation.

The research hypothesises that identifying temporal characteristics that shall be retained within the historic marketplaces of Palermo can gain benefits to the vibrancy and dynamism of the city.

The study's objective is to show which temporal characteristics can aid policymakers in developing alternative proposals for the revitalisation of the historic centre. Furthermore, the research provides a chance for a socio-spatial perspective which can support arguments on retaining the marketplaces' multicultural assets (Cole and Booth, 2016; Napoli and Bonafede, 2021) – such as the benefit to both immigrant and local citizens whose tension unfolds within them. Finally, this study is relevant to other Sicilian and Southern Italian streets of cities where informal vending activities are dominant. This can shed light on cities' informal, self-initiated employment structures that shall not and cannot be erased (Lefebvre, 1996).

An empirical visual assessment study is applied to study the temporal characteristics of marketplaces in Ballaró and Vucciria markets. Culturally diverse groups are investigated due to the difficulty in differentiating between the number of immigrants and residents (without implying bias). The theoretical framework investigates temporality through Massey's definition (2005). Three key concepts of her work can be applied in the historic marketplaces of Palermo to answer the following three research questions:

1. To what extent are the spatial characteristics of historic marketplaces temporal, measuring their spatial characteristics (through the theory of space as a process, constantly under construction)?

2. What spatial characteristics of marketplaces can be defined as everyday, and what can be seen as sustained by observing social actors (through the theory of space as a multiplicity of coexistence)?

3. What social characteristics of marketplaces are everyday and sustained measuring social interactions (through the theory of space as a product of interrelations)?

To answer the research questions, Section 2 introduces temporality as a theoretical framework by first discussing Doreen Massey's (2005) and Henri Lefebvre's (1996) definitions. Section 2 introduces the relevance of this research's empirical, observational methodology - using Doren Massey's theoretical framework (2005). Gehl's and Sverre's research methods (2013). Section 4 research question by

research question presents the observational study's findings, and Section 5 discusses and concludes the relevant temporal characteristics of historic marketplaces that shall be retained.

2. Theoretical Background: Temporality's role in historic marketplaces

The temporal was introduced through the philosophical conceptualisation of sharing spaces (Foucault, 1980, p.70). As societies develop over time, new occupations and, in turn, spatial pluralities are formed. The historical understanding of space understood the temporal as the layering of urban forms. However, spatial pluralism opened diverse discussions on the temporal by analysing time and breaking it down into smaller intervals (Bergson, 1911, p.131; Deleuze, 1980). Here, Deleuze's conception of continuous multiplicity is implemented, where the small intervals are seen as infinite and indivisible. Based on this definition, temporality can be examined through the morphological changes within the city. Two theorists' works are relevant in the context of historic marketplaces' multiculturalism, describing temporalities through simultaneity: Henri Lefebvre and Doreen Massey (1996, p.19; 2005, p.48).

Lefebvre's *right to the city* captures the incompleteness and ever-changing nature of the city (1986). He states that citizens shall practice this over spatial use. He sees temporality as an openness that shall be allowed and located among the homogeneous forms that connect the spatial and the social (1996, pp.105-106). According to his views, the marketplace is a mediation (1996, p.107) since it is neither a fragment nor a homogeneous part of the city. When marketplaces are closed, they become spatially fragmented (divided into unused spatial segments) and homogeneous (for instance, used for residents to retreat for the night). Therefore, the temporal can be seen as a mediation that serves everyday life. Lefebvre believed such mediation between the two is not accidental but the condition of the urban form.

In comparison, Massey's understanding of spatial justice considered the differences between spatial occupations that require negotiation and constraints. Her emphasis highlights the proximity of social actors occupying spaces (2005, p.93) which derive from Giddens's understanding of exclusion based on distances (1984, p.192). This results in space's dynamic and plural characteristics. She described the *simultaneous* characteristic of space as a critical principle that is constantly present in temporal sequences (2005, p.23). Instead of seeing as fragmented elements, she considers space as always incomplete, which becomes temporal through social relations. These relations unfold negotiations across its spatial occupation to acknowledge its plurality (Massey, 2005, pp.9-13). Plurality illustrates that space constantly changes as social processes inform spatial alterations, which then alter social relations. (Massey, 2005, p.71). Based on Massey's understanding, temporalities are located where social relations occur.

Applying this concept to marketplaces suggests that Massey's concept is relevant. Marketplaces are understood as the collection of individual market spaces, open for alteration through the spatial occupation of merchants and visitors. These two groups enact new social relations through interactions. A temporality is created when a new spatial use occurs that makes a market space open for change (for instance, expanding a vending area). Based on Massey's theoretical understanding, temporality can be defined according to three conditions of space: process, constantly under construction, multiplicity of coexistence, and product of interrelations. These concepts need to be studied to reveal the marketplaces' temporal characteristics.

Firstly, by seeing space as a process, constantly under construction, allows marketplaces to be perceived as open-ended (Massey, 2005, p.107), which defines them as both spatially and socially temporal. Consequently, the characteristics of marketplaces can be divided into a continuous and indefinite number of events (Massey, 2005, p.23). These events are a sequence of spatial changes, and, as such, the market spaces' dislocation (removal and displacement of spatial characteristics) can be understood as a process that defines them within an open system (Bergson et al., 1911, p.43). For instance, a user might infer spatial change that impacts another spatial condition and; therefore, impose alterations elsewhere. This understanding shows that marketplaces and their market spaces can be observed through their spatial changes, locating their frequency and occurrences.

Secondly, investigating space as a multiplicity of coexistence acknowledges its simultaneity and spatial plurality (Massey, 2005, p.9). The social processes that change them can be seen as minor co-constitutions that are temporal in character (Massey, 2005). Once a social relation (interaction) ends, the spatial differs from the temporal. This concept demonstrates that the temporal influences the spatial; therefore, the spatial constantly changes (Massey, 2005.p.18). While the temporal can be reduced to an event, the spatial cannot. For instance, a vendor might change the market space that a pedestrian uses for commuting. This example presents that a singular event (a vendor altering its market space) can be described as temporal. At the same time, the marketplace (seen as the spatial) has plurality, which is defined by social actors. This concept suggests the significance of studying market spaces according to the location of social actors (users).

Thirdly, space as a product of interrelations can be viewed as a negotiation that informs temporal changes (Massey, 2005, p.9). These social alterations occur at the edges of market spaces' different spatial elements and can be described as social relations. These social relations (interactions) are negotiations that require a mutual opening of borders spatially and socially (Massey, pp.56-66). This understanding implies that an encounter requires two participants to acknowledge each other's presence and form a relationship temporally. This social condition is significant because, if mutual recognition is not provided (for instance, one social actor observes another social actor), there is no encounter and; therefore, no spatial change. Alternatively, the spatial change can cause tensions between social actors. This concept highlights the need to study social relations in marketplaces, revealing spatial changes.

2.2. Interactions as Social Temporalities: differentiating everyday and sustained encounters

The concept of social relations as drivers of spatial changes derives from public life studies (Jacobs, 1961; Gehl, 2010) to ensure the vibrancy of the street. These studies demonstrate the significance of examining spatial conditions that influence the number of social actors and interactions between them. Encounters can be defined as everyday or sustained, depending on their nature (Jacobs, 1961; Mayblin et al., 2016, p.213).

In some cases, everyday interactions can be seen as a pleasant exchange (for instance, asking a stranger for directions). However, these encounters can also be considered inconvenient or cause discomfort (for example, bumping into someone on the street). These are often established within unfamiliar contexts (Loukaitou-Sideris and Ehrenfeucht, 2009) and seen as the initial contact. Consequently, these encounters are not timebound, and; thus, they can be defined as temporal interactions (Maybin et al., 2016; Massey, 2005). In contrast, sustained interactions are decided by individuals before the encounter. These can be considered sustained upon contacting them for the second time, which can occur in a familiar context.

Therefore, the difference between the encounters infers that there is significance in observing the spatial characteristics that promote sustained interactions. As everyday interactions occur more frequently, these affect the spatial alterations within marketplaces. Consequently, accidental interactions, and the context in which they occur, must be observed to study sustained encounters. Furthermore, their situational characteristics present the need to uncover what spatial characteristics contribute to both everyday and sustained interactions within the historic marketplaces of Palermo.

3. Methodology

The historical marketplaces must be observed to present the temporal characteristics that shall be preserved in Palermo. An empirical study visually and qualitatively assesses the historic marketplaces (Ewing and Clemente, 2013). Although other marketplaces were considered, Vucciria and Ballaró markets are studied as these have a high ratio of informal vending and are well-connected to formalised high streets that attract many residents.

The historic centre is divided into four quarters by Via Roma and Via Vittoria Emanuale. Ballaró market sits in Palazzo Reale, between two major pedestrian routes (Via Vittorio Emanuele and Via Maqueda) and is located near other tourist attractions (Palermo Cathedral and Norman Palace). However, the networks towards those areas are in poor condition and; consequently, the marketplace is mainly accessed from Via Maqueda. In comparison, Vucciria market is in Castellamare, which is close to the city port, a major pedestrian route called Via Vittorio Emanuele, and a significant vehicle road (Via Roma). This indicates that Ballaró and Vucciria are comparably accessible with slightly greater attraction towards Ballaró market (see Figure 1).

Figure 1. Ballaró and Vucciria markets presenting similar connectivity to primary street networks and touristic attractions.

A centrally located 50-metre stretch of the main street of both marketplaces is observed, providing the basis for the comparison (Via Ballaró and Via Maccherronai, respectively). This central location enables the assessment of similar flows and interactions between the two marketplaces. Massey's theoretical framework on temporality (as presented in section 2.1) (2005) is applied to understand the marketplaces' temporalities through both their spatial and social temporalities. The framework is divided into a three-stage analysis of spatial temporalities (spatial changes), social actors (users), and social relations (encounters). Using Gehl and Svarre's visual assessment methodological framework (2013), data is collected and analysed qualitatively to define the spatial and social factors that contribute to sustained interactions. All data is collated under similar conditions and during the end of tourist seasons. Consequently, it could be anticipated that the number of observations tallied would likely drop during other seasons over the course of the year.

The spatial alterations are observed in historic marketplaces by applying the concept of *space as a process, constantly under construction*. Both Vucciria and Ballaró marketplaces have a continuous row of market spaces. Their common spatial characteristics include: a storage unit or shop within the built fabric (serving space) and a unit where the products are sold (exchange space). The space between exchange spaces can be defined as the transition space where the commute occurs. Each market space has an associated transition space based on the centre of the street.

Massey interprets the temporal as being open-ended. Based on this understanding, the edges between serving, exchange, and transition spaces can be seen as the drivers of spatial alteration. Social processes

generate these by adding, removing, or dislocating their elements. The aim is to define where the highest alteration occurs and which spatial characteristic drives spatial changes (Lynn, 2004, p.44). For instance, it can be observed that the edges between transition and exchange spaces are constantly changing if many people and interactions are occurring within them. Therefore, these must be mapped according to the location of these changes (Gehl, 2010). Based on this, seven different spatial temporalities can be defined within the historic marketplaces in Palermo (see Figure 2):

1. Serving space
2. The edge between serving and transition spaces
3. The edge between serving and exchange spaces
4. Exchange space
5. The edge between exchange spaces
6. The edge between exchange and transition spaces
7. Transition space

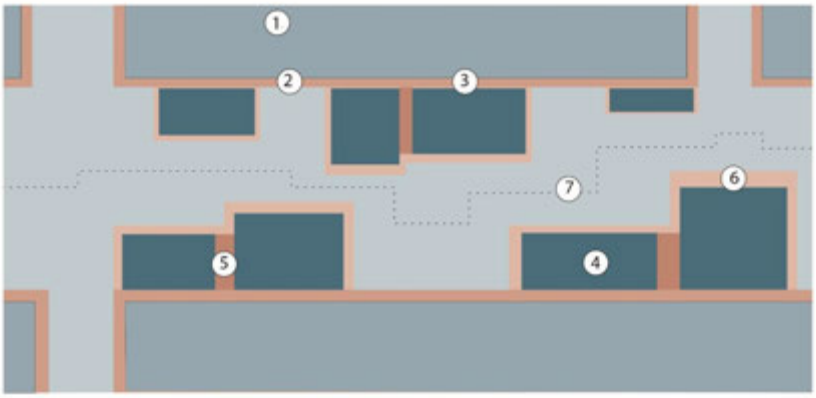

Figure 2: The Spatial Temporalities within historic marketplaces of Palermo

The study conducts a morphological mapping exercise using Gehl's soft and active edge methods. These methods can help quantify the spatial temporalities of Palermo's historic marketplaces. Firstly, soft edges are defined based on the transition between built fabric and public space. In this context, all spatial characteristics can be seen as soft edges as they constantly change. This concept can be applied to this research by examining the market space's size and frontage length. Secondly, active edges are defined based on the frontages' activity related to when a market space is open or closed. This approach can be applied to market spaces by examining opening days and hours. Therefore, spatial changes are mapped according to social actors' location.

Both marketplaces are observed at incremental intervals (hourly, daily and weekly) to establish the time in which spatial changes occur. The aim is to establish the time within which spatial temporalities are not changing and, therefore, are static (Tang and Long, 2019). This approach can be used to justify marketplaces' open-ended nature and define spatial factors that alter within them.

Applying the concept of *space as a multiplicity of co-existence*, spatial plurality can be observed in transition, exchange, and serving spaces (where people are present). For instance, a pedestrian might commute to the same area within the transition space where a market vendor wants to extend their exchange space. This demonstrates both users' need to negotiate over space, forming a temporality within which spatial alterations occur. Consequently, the users that inform these spatial changes must be identified according to their location and length of spatial occupation, using the spatial factors defined in section 3.1.1 (Pratt, 1992).

Social actors' location and length of spatial occupation can be mapped using Gehl's behavioural method. This approach can be applied to this study (Gehl and Svarre, 2013, pp.84-85) by observing pedestrian and stationary activities. Pedestrian transitions are movements between different spatial characteristics. In contrast, stationary activities are static, where users remain within spatial characteristics. Users' location is measured twice at three different times of the day (9 a.m., 12 p.m. and 3 p.m.) The aim is to define the number of people, differentiating market vendors, visitors, pedestrians, and stationary users. This will aid in differentiating everyday and sustained spatial characteristics of the marketplaces. Furthermore, it can help to define social actors within marketplaces which inform spatial changes, using the spatial factors established in section 3.1.

Using the concept of *space as a product of interrelations*, social relations can be seen through interactions based on the location of social actors. As the focus is on examining encounters between spatially different conditions, these are only observed based on the edges between transition, exchange, and serving spaces. Everyday and sustained interactions are differentiated between these edges to determine how these affect the spatial and social alterations (as presented in sections 3.1.1. and 3.1.2). For instance, market vendors often develop encounters with visitors at their counter space, where successful commerce can reinforce the exchange space's expansion. However, an encounter between two users of the transition space does not form spatial alterations in the marketplaces (as they do not withhold agency over trading spaces). Based on this, the study examines four edges where everyday and sustained interactions occur (see Figure 2).

Using Gehl's and Svarre's behavioural mapping method (2013, pp.84-85), encounters are observed based on the users' location in serving, exchange and transition spaces. Using this, the frequency and duration of encounters can be measured to distinguish between sustained and everyday encounters. An interaction lasting longer than five minutes is considered a sustained encounter. The study aims to define spatial and social characteristics (as presented in sections 3.1.1 and 3.1.2) that contribute to sustained encounters.

4. Results: Market space typologies that encourage sustained interactions

4.1.Space as a 'process, constantly under construction'

The study aims to define the extent to which the marketplaces are temporal. Firstly, the analysis presents differences between marketplaces using the seven identified spatial characteristics (serving, exchange, transition spaces and the edges between them). This can aid in defining the alteration rate within market space elements. Secondly, these observations are reasoned by highlighting the differences between market spaces. This analysis enables the identification of dependencies between the observed parameters (opening hours, opening days, frontage length, and area) that aid in defining spatial factors that alter the spatial characteristics of marketplaces.

Firstly, comparing Ballaró and Vucciria markets, the transition space demonstrated a highest alteration rate (minute-based changes), and exchange and serving spaces exhibited hourly and daily changes, respectively. The defined edges illustrate characteristics similar to how the transition, exchange, and serving spaces alter. For instance, the edge between the transition and serving space would present spatial change on a minute basis that matches the transition space. The minute-based alteration rates indicate that the changes in the transition space and associated edges result from direct social relations (interactions). In contrast, the daily and hourly changes of other spatial characteristics result from indirect social relations. These indirect encounters can be interpreted as deriving from more complex social relations between social actors based on market vendors' socio-economic position. For instance, one would enter the market space's serving space following a sustained encounter with the vendor. However, it is assumed that once market vendors become friendly with each other, and have performed multiple previous sustained encounters, they would be willing to allow each other to occupy the area of their exchange space when required. Therefore, minute-based changes need to be recorded through observation of the social actors and direct social relations (interactions). However, the hourly and daily

changes can be observed through the indirect social relations manifested in other market spaces' spatial occupations. These can only occur directly with neighbouring market spaces.

Secondly, the spatial factors that impact changes can be identified upon comparing the market spaces to each other. The hourly and daily spatial alterations are displayed through visual diagrams which investigate four spatial factors which were identified in section 3 (opening days and hours, area, and frontage length). The diagrams indicate that the market spaces with shorter opening hours and days are less likely to change (see Figure 2), whereas market spaces with longer frontages are more likely to occupy other spaces. This factor is more relevant in Vucciria market. The area of market spaces did not reveal any relevance to these factors (see Appendix 7.3.1 and 7.4.1).

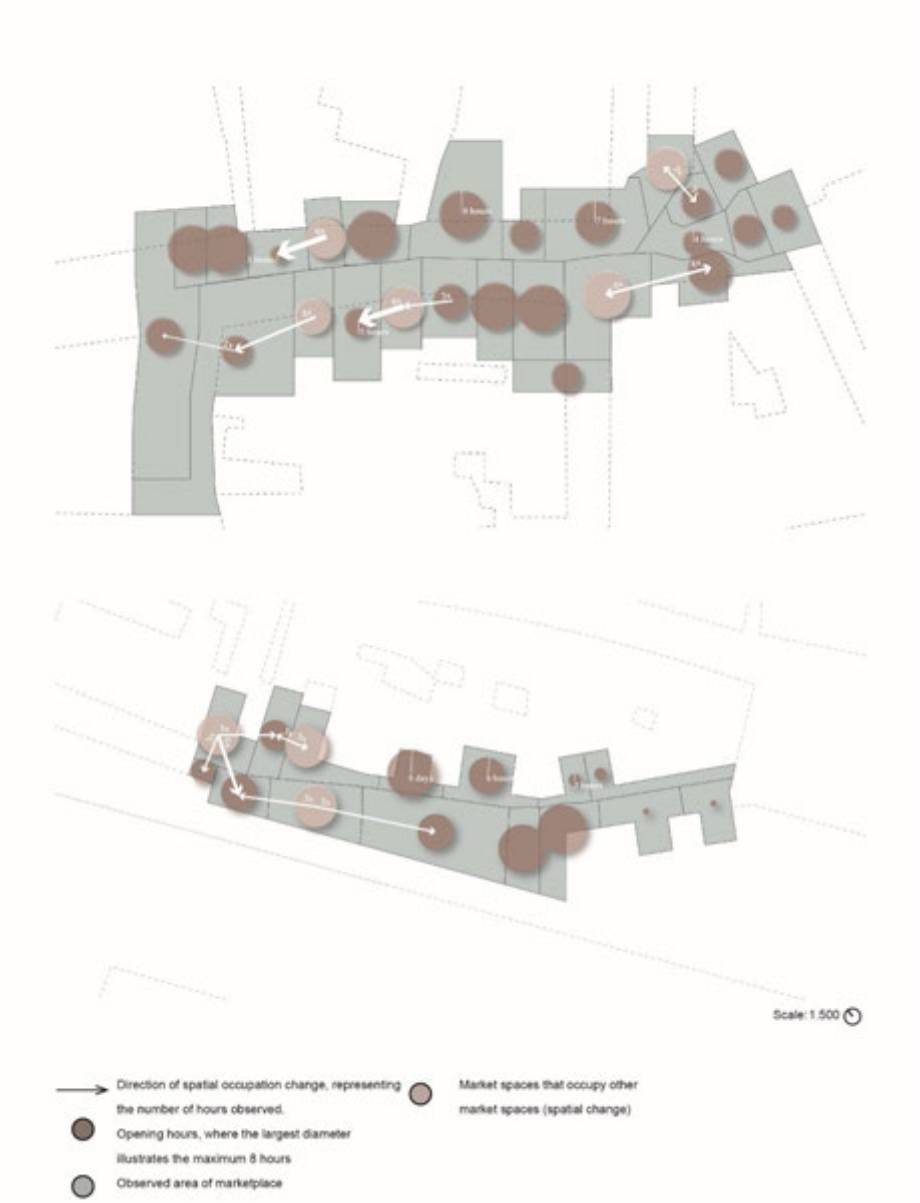

Figure 3: The number of open hours on a day indicated by the diameter size in relation to the direction of spatial occupations of neighbouring market spaces in Ballaró market.

Overall, both indirect and direct social alterations drive the spatial changes in market spaces. Differences were indicated between market spaces that are reflected in the frontage length, opening hours, and opening days. The correlations suggest that the alteration rate can be identified through these spatial factors.

4.2.Space as a ‘multiplicity of coexistence’

The study aims to define if the spatial characteristics of marketplaces can be seen as everyday or sustained. The analysis is based on seeing stationary and pedestrian activities as sustained and everyday spatial characteristics, respectively. Firstly, the number of social actors (pedestrian and stationary) and their roles (as vendors or visitors) are observed between the two marketplaces. Secondly, a comparison is made between the market spaces to understand the relationship between the number and role of social actors. Thirdly, the spatial factors (identified in section 4.1) are observed with regards to social actors to grasp the nature of their relationships qualitatively.

Firstly, comparing Ballaró and Vuccira markets, the analysis shows a similar number of market vendors. Furthermore, similar tendencies can be seen between the two marketplaces when comparing the observation times according to the number of pedestrian and stationary activities. Both Ballaró and Vucciria markets are host to high stationary and pedestrian activities at 12 p.m. However, Ballaró exhibits an average increase of more than 1.5 pedestrian users, with an average of 152 users in comparison to 90 in Vucciria market at 12 p.m. This exhibits a significant difference between the number of visitors between the two marketplaces, showing relevance at all observed times. Similar patterns can be noticed when assessing the spatial distribution of social actors. In the case of stationary users, the difference in distribution is insignificant (see Figure 5). Regarding pedestrian users, both Ballaró and Vucciria markets indicate the highest population of people in the transition spaces (see Figure 4). However, the comparison demonstrates a significant difference in pedestrian users, with an average of 100 users in Ballaró and 51 in Vucciria. Furthermore, serving and exchange spaces exhibit a similar number of everyday and stationary users, similar to the number of stationary users in the transition space for both marketplaces (see Appendix 7.3.2 and 7.4.2). This indicates that transition space generates a significant number of everyday users. However, none of the spatial characteristics can exclusively be defined as everyday. Therefore, the analysis infers that both everyday and sustained conditions are present within all spatial characteristics.

Figure 4: The average distribution of pedestrian users across spatial temporalities in Ballaró and Vucciria markets, showing significance to transition space.

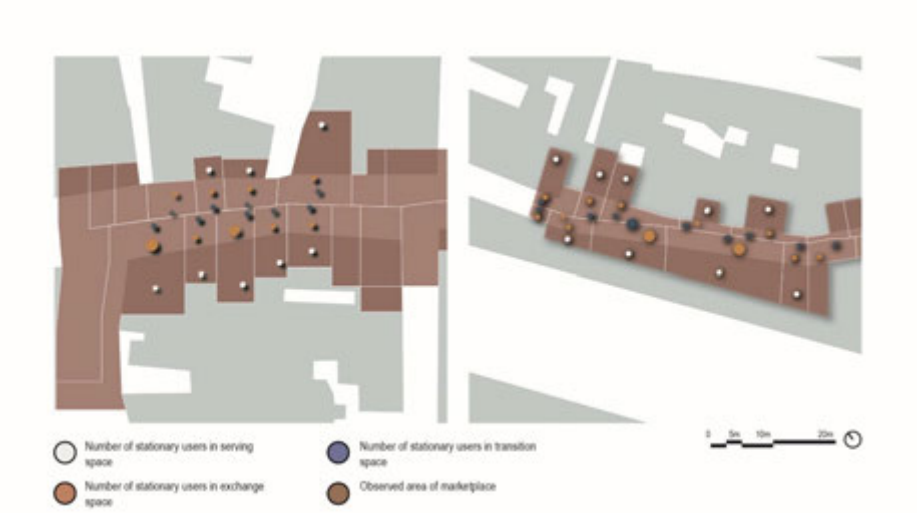

Figure 5: The average distribution of stationary users across spatial temporalities in Ballaró and Vucciria markets, showing significance to transition space.

Secondly, the market spaces are compared to understand the reason all spatial characteristics can be described in everyday and sustained conditions. This study can aid in defining the relationship between pedestrian, stationary, and market vendors. The observed relationship between the number of market vendors and pedestrian activities shows minimal positive correlation (see Figure 35). However, there is a positive connection between the number of people attracted to stationary activities and the number of market vendors. The analysis demonstrates that market vendors play a significant role in generating more sustained encounters. This positive correlation can be interpreted as the market vendors initiating encounters with visitors, encouraging them to become stationary users within market spaces.

When examining the relationship between pedestrian and stationary activities, differences were shown between the two marketplaces and between market spaces according to the measurement time. On the one hand, in Ballaró market, there is a higher density of stationary activities, where pedestrian movement is greater. On the other hand, Vucciria market suggests that the higher number of stationary users is not located in the areas with the highest number of pedestrian users. Both indicate that there is a positive correlation between stationary and pedestrian users. However, the case of Vucciria illustrates that, even if a significant number of pedestrian movement is needed, pedestrian users are widely distributed across all market spaces. This result can be interpreted as Ballaró market driving large pedestrian traffic, certain areas of marketplaces exhibit a high concentration of pedestrian users. Such areas are where a higher number of sustained activities occur in market spaces.

Thirdly, to understand what spatial factors explain the difference between the two types of market spaces, the results of section 4.1 are examined. Based on the comparison, a positive relationship is seen between the opening hours, the area of transition space, the overall market space, and pedestrian movement. The market spaces with shorter opening hours indicate a higher rate of pedestrian activities in both marketplaces. These trends can be interpreted from two differing perspectives: the market spaces might open for shorter periods to generate substantial income more quickly; or market vendors focus more on engaging visitors to make them stop.

However, when looking at the area of transition spaces and overall market spaces, a similar difference can be identified between the two marketplaces, as illustrated previously. In the case of Ballaró market,

the larger market spaces and transition spaces exhibit a larger pedestrian flow. In comparison, in the Vucciria market, those market spaces present the largest pedestrian flow, which indicate an average size. This difference is not apparent when comparing the two marketplaces' spatial factors and stationary activities. Both marketplaces show that stationary activities are indicative of a positive relationship between the area of transition space, the overall area, and the frontage length of market spaces. Consequently, the larger the area and the longer the frontage of the market space, the more stationary users can be accommodated.

Overall, it is possible to see that transition, exchange, and serving spaces all exhibit everyday and sustained spatial characteristics. The positive correlation between stationary and pedestrian activities was examined to understand this condition. This demonstrated how Ballaró and Vucciria market requires a high and average frequency of pedestrian activities, respectively, when the number of stationary activities is high. A similar pattern was indicated when looking at the relationship between the two types of activities and spatial factors. However, the two marketplaces did not differ when examining stationary activities. The results show that the differences are based on pedestrian activities instead of stationary ones. One potential interpretation is that the degradation of the city centre's physical civic infrastructure makes market spaces more accessible to economic immigrants. The dilapidation can be seen as relevant to the ratio of tourists and visitors that should be considered regarding the number and type of users.

Therefore, it can be concluded that seeing marketplaces as a multiplicity of coexistence is relevant to understand their ability to generate everyday and sustained spatial usage. Furthermore, a positive correlation was qualitatively observed between pedestrian and stationary activities. The differences between the two marketplaces suggest the importance of considering the ratio of tourists and visitors relative to the physical degradation of the marketplaces.

4.3.Space as a ‘product of interrelations’

The study aims to define the social factors that are positively related to sustained encounters. Firstly, encounters are examined to compare marketplaces, differentiating their length of time (everyday and sustained). Secondly, market spaces are compared to observe the relationship between the two types of interactions. Thirdly, these differences are observed in relation to the results of sections 4.1 and 4.2.

Firstly, comparing Vucciria and Ballaró markets, the number of sustained and everyday interactions present similar trends according to the time of the day. The largest number of everyday and sustained encounters are exhibited at 12 p.m. This shows similarities to the observations in section 4.2. However, differences are indicated in the overall number of encounters, as Ballaró market hosts twice the number interactions across the day compared to Vucciria market. Similarly, the same patterns can be observed between the two marketplaces in accordance with the location of interactions. In Ballaró market, most encounters happen between exchange and transition spaces (see Figure 6). Furthermore, everyday interactions are observed more frequently in Ballaró market than sustained interactions. In comparison, in Vucciria, interactions are equally distributed (see Figure 7). Moreover, the two types of encounters are equally spread across transition, exchange, and serving spaces in Vucciria.

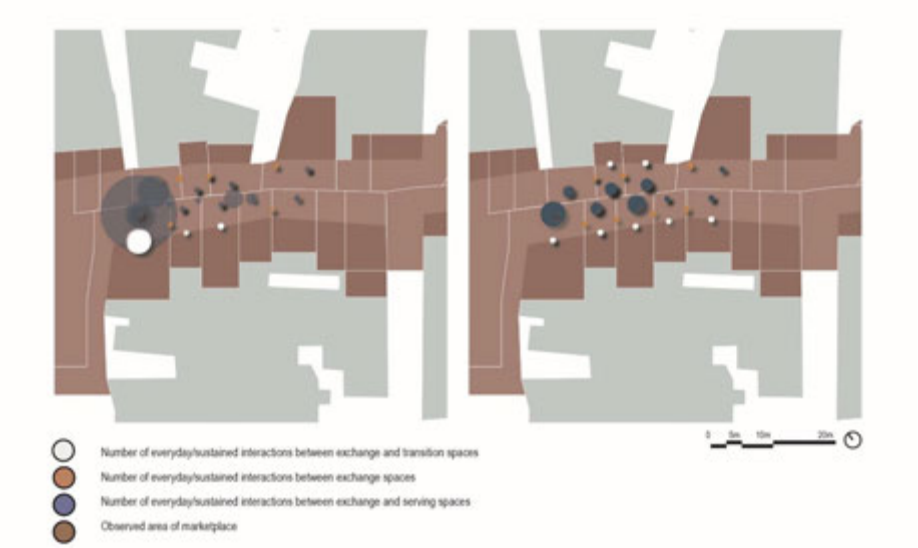

Figure 6. The spatial distribution of everyday (left image) and sustained (right image) interactions in Ballaró market, showing similarities between a higher proportion of encounters between transition and exchange spaces.

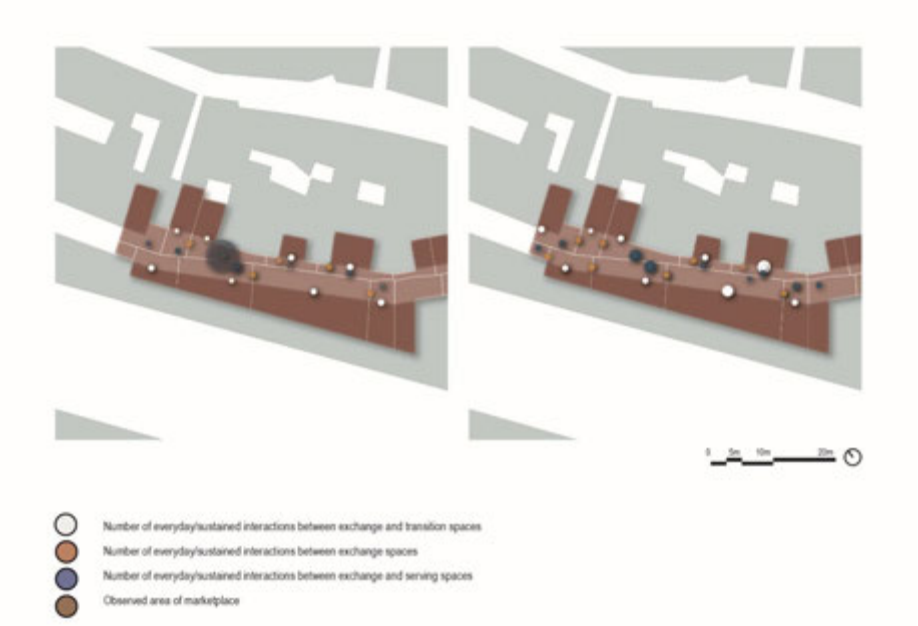

Figure 7. The spatial distribution of everyday and sustained interactions in Vucciria market, showing an equal distribution of interactions across all spatial characteristics.

Secondly, the market spaces are compared to understand the differences in the spatial distribution between the two marketplaces. Looking at the relationship between everyday and sustained interactions, both marketplaces suggest a higher number of sustained interactions in areas with a high number of everyday interactions. However, there are differences in where they occur. In the first case, there are market spaces that are host to the highest ratio of everyday encounters between exchange and transition spaces (as displayed in Figures 6 and 7). When relating these market spaces to sustained interactions, many are held between transition and exchange spaces. However, these market spaces demonstrate a larger proportion of everyday interactions between exchange and serving spaces. In the second case, market spaces show an average number of everyday encounters between exchange and transition spaces. However, these present the highest number of sustained interactions in the same area. Furthermore, these exhibit a higher proportion of sustained encounters between exchange and serving spaces. The analysis indicates that everyday interactions can be a catalyst in forming more everyday encounters within the marketplace. More crucially, there are two different scenarios when a high number of sustained interactions are observed. The spatial factors (illustrated in section 4.1) and social actors (presented in section 4.2) must be examined to understand the reason for these differences.

Thirdly, different positive correlations are presented when comparing spatial and social factors to sustained and everyday interactions. Opening hours, size, and pedestrian users positively connect to everyday encounters. As illustrated in section 4.2, pedestrian activities positively relate to larger opening hours and areas. Looking at the relationship between everyday and pedestrian users, everyday encounters are reproduced if there is a high pedestrian flow. Ballaró market was particularly susceptible to this, being host to the highest number of everyday encounters at these times. When examining sustained interactions, relevance is given to the size, frontage length, and number of stationary activities. As shown in section 4.2, stationary activities positively relate to frontage length and size of market spaces. A positive correlation exists in the relationship between stationary users and sustained interactions. The results show that sustained encounters are spread more widely within the market spaces in both the Vucciria and Ballaró markets. In contrast, everyday interactions are concentrated in certain areas of the marketplace. This pattern indicates that the spatial distribution between the two types of encounters generates two spatially different market spaces where a high number of sustained interactions occur.

In the first scenario, market spaces demonstrate a high number of everyday and an average number of sustained interactions between the transition and exchange space. Furthermore, there is a high number of sustained and everyday encounters between the exchange and serving spaces. As there is a high pedestrian flow, this exhibits shorter opening hours and an average size of market spaces. In this case, everyday interactions generate sustained encounters between the exchange and transition spaces. Furthermore, everyday interactions benefit the generation of sustained ones, mainly between the exchange and serving spaces.

In the second case, market spaces demonstrate an average number of everyday interactions (compared to the first) and a high number of sustained encounters between the transition and exchange spaces. Furthermore, between the exchange and serving spaces, a low number of everyday and an average number of sustained interactions are indicated. In the case that there is an average pedestrian flow, these market spaces are often bigger and can be open slightly longer. In this case, everyday interactions in the transition space generate sustained encounters, mainly between the transition and exchange spaces.

Therefore, the two scenarios infer that the hypothesis must be correct, and there can be beneficial spatial and social constructs where everyday interactions aid in developing sustained ones. It must be understood that Ballaró market is host to more market spaces than Vucciria market. However, Vucciria market holds more examples of the second market space typology. It must be noted that both market space typologies are present in the two marketplaces. The difference is in the user number, and the number of market spaces demonstrated. Consequently, the spread of market spaces needs to be considered regarding the condition and affordability of buildings for immigrants.

5. Discussion and Conclusion: Temporal characteristics that encourage sustained interactions

5.1.Key findings

To study the temporal characteristics which shall be retained within Palermo's historical marketplaces (Ballaró and Vucciria).. Temporalities are studied through Massey's framework (2005) in three analyses, using Gehl and Svarre's empirical and observational methods (2013). Firstly, the extent to which marketplaces are temporal is discussed, identifying spatial factors that alter them. Secondly, marketplaces are studied through social actors that enable distinguishing everyday and sustained spatial characteristics. Finally, everyday and sustained interactions are observed in relation to the identified spatial and social factors.

The research concludes that five key spatial and social characteristics contribute to sustained interactions: the area of market space, the length of frontage, the area of transition space, opening hours, and the number of vendors. These temporal factors manifest in two market space typologies that show beneficial social and spatial constructs where sustained socio-spatial constructs occur. The result infers that marketplaces' spatial and social characteristics should be maintained and encouraged when considering how to regenerate Palermo's historic centre. To accommodate the differences in temporal factors, economic accessibility, physical degradation (civic and built), affordability, tourist appeal, and social integration must be considered. In contrast, the regeneration will not address those socio-economic realities that immigrants inevitably face.

5.2.Contextual factors

Firstly, based on the analysis of spatial factors, the differences between marketplaces showed relevance to land value that influence spatial changes. When comparing the immigration rate and sales value of Palermo's neighbourhoods, both marketplaces are located in the areas with the lowest values (Napoli and Bonafede, 2022, pp.1281-1282). Ballaró market has an immigration rate of 20%, whilst Vucciria market has an immigration rate of 17% (Napoli and Bonafede, 2022, p.1275). Additionally, Ballaró market, on average, has a lower sale value per unit than Vucciria market. These indicators suggest there is a higher association with illegalities and black economies within these areas. The higher immigration and lower sales value in the neighbourhood of Ballaró market suggest that criminal forces have become more prevalent. Therefore, criminal forces can impact immigrants' accessibility to marketplaces, their socioeconomic status and where spatial changes occur.

On the one hand, if forceful incentives continue to be implemented, informal practices would significantly decrease in the historic centre. Such incentives already include the documentation of supply chains, formal registration of business transferral, taxation after commercial activities, and rented property (Comune di Palermo, 1995; ibid, 2021). Consequently, these would continue to reduce the survival activities of immigrant workers. On the other hand, if the dominant actions of criminal forces continue, these will keep altering the temporal practices within the marketplaces. The lack of governance can strengthen black economies, posing challenges to economic growth due to untraceable and untaxable supply chains. Furthermore, these can expose highly unattractive illegalities (such as vandalism and violence) to locals and tourists, reducing marketplaces' attractiveness.
Bottom-up incentives (such as SOS Ballaró and Associazione Mercato Storico di Ballarò) implemented strategies to promote the self-management of marketplaces (Wulff, 2018). These strategies benefited immigrants by indicating the necessity of engaging with local communities and authorities to maintain the spatial dynamism of the marketplace. However, as there is an increasing number of economic migrants and a lack of formal employment, these initiatives need to be considered by local governmental bodies. The self-management of the marketplaces must be encouraged by a regeneration policy involving the participation of locals and market vendors. Furthermore, these need to consider criminal forces that may irresponsibly expand them. Such self-management can be applied by reviewing the existing social infrastructure provision for immigrants (including skill-building and social security).

Secondly, based on the analysis of social actors, there is a difference between Ballaró and Vucciria markets regarding the number of pedestrian users caused by their touristic appeal and physical civic degradation. As presented in Chapter 3, Vucciria is less accessible through pedestrian networks and further away from primary tourist hubs than Ballaró market. These differences can be indicated by comparing these observations to the sales and rental value of high streets (Napoli and Barbaro, 2022, pp.1281-1282). The highest unit sales value can be seen around Vittorio Emanuele and the second section of Maqueda (see Figure 8). These areas are near the key tourist attractions and Politeama, where high-value shops are located. In contrast, the lowest unit values are in the first section of Via Maqueda, which significantly dropped between 2017 and 2020. This decrease in sales value is suggested in both sections of Via Roma, but their unit sales value is closer to the value of Via Maqueda's first section.

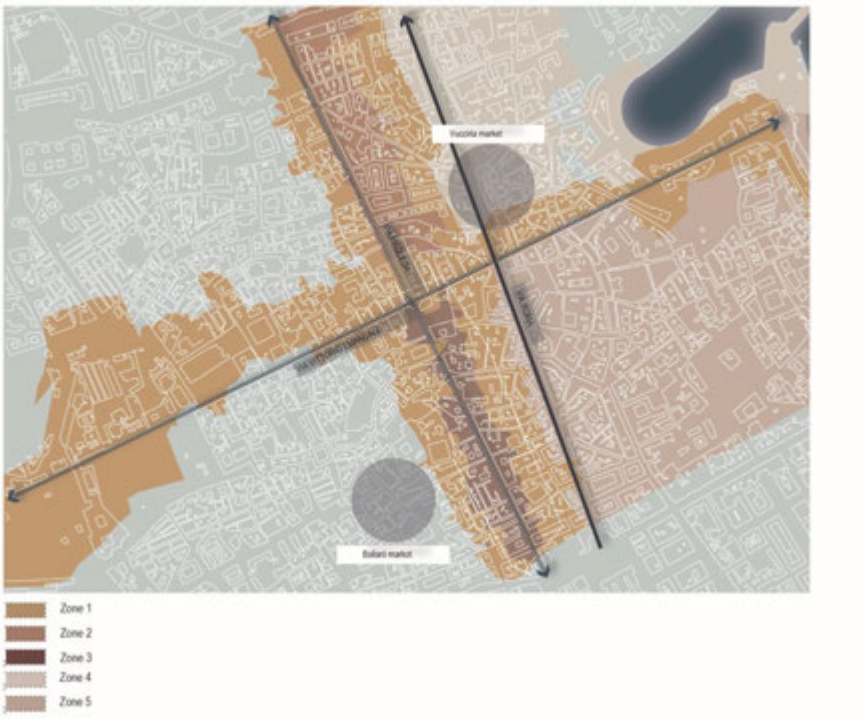

Figure 8. Sales and rental value differences between high streets, figure adapted from Napoli and Barbaro (2022, pp.1281-1282).

A significant difference can be seen between Vittorio Emanuele and the first section of Via Maqueda when looking at the rental value of high street shops. This difference indicates that the marketplaces' location has likely devalued over time, with a more substantial drop in the Ballaró market. The decreasing value can be interpreted as an accessibility issue in Via Vittorio Emanuele, reducing the number of tourists visiting the marketplace. Instead, many users access it from Via Maqueda's first section. Furthermore, the value decrease can also be understood as being due to the higher rate of immigrants within these neighbourhoods (Napoli and Bonafede, 2022, p.1275). However, Ballaró market's proximity to the highest sales value area attracts more tourists than the Vucciria market. Therefore, the analysis shows that regeneration plans must consider the physical civic condition of marketplaces to improve their accessibility and visibility, considering their differences in land value. However, upgrades to physical civic infrastructure must also be proposed with the understanding that

it will raise the property and land values of the areas. Consequently, these market spaces will become less accessible for immigrants to settle and form informal practices.

Finally, the two market typologies derive from the different spatial distributions of everyday and sustained interactions. In Ballaró market, there are more market spaces where a high number of sustained encounters occur in the transition space. In comparison, in Vucciria, these are within the exchange and serving spaces. Therefore, the physical condition (regarding affordability) and social integration (in relation to tourism) need to be considered for future proposed development strategies. On the one hand, in the first scenario, the strengthening of transition spaces can be challenging due to the constrained area between exchange spaces. However, these can be addressed more quickly and allow the continuous running of market spaces. On the other hand, the second scenario, where the exchange and serving spaces require improvements, demonstrates accessibility constraints by large vehicles, restrictions due to the historical setting, and the displacement of market vendors. Furthermore, those market spaces that perform well in generating sustained encounters are dilapidating the most. This negative correlation suggests that accessing these buildings and developing a higher-performing business is only a temporary solution for vendors. This is due to the building's lack of maintenance and the inhabitance of squatters, reducing safety and hygienic conditions.

Therefore, both scenarios indicate that there are difficulties in regenerating marketplaces, and there is a need for affordable incentives for economic immigrants. Contrastingly, the regeneration will result in the dispersal of immigrants into various city segments instead of allowing them to remain within the historic centre. Furthermore, both marketplaces presented a high tourist appeal and opening hours and days that responded to their need. This approach, and the lack of safety around marketplaces, demonstrates why residents avoid entering marketplaces within and beyond tourist periods. Consequently, regeneration strategies must encourage the expansion of the marketplace's opening period to attract more residents and develop better connections between them and immigrants.

5.3.Outlook

The current research findings conclude that the identified temporal characteristics shall be retained within the marketplaces should be considered regarding the broader regeneration of the historic centre. The devaluing of the area attracts many immigrants and causes tensions between them and the residents. Such conditions are influenced by the increasing number of immigrants, the difficulty of their social integration, criminal forces' control over the marketplaces, and the physical degradation of buildings and civic infrastructure. Therefore, to accommodate for sustained encounters within the historical marketplaces, five key requirements must be granted and achieved: social infrastructure provision, self-management of the marketplaces, upgrading physical civic infrastructure to improve the accessibility of marketplaces, affordability of market spaces for market vendors, and extending usage time to attract various social groups.
However, it must be noted that the validity of the results is restrained to the analysed case studies, and the conclusions are essentially qualitative, as the data used to conduct the analysis are not quantitative. The empirical research is, based on observations, beneficial to studying the socio-spatial conditions of these secondary streets where informal economies dominate. Further studies on the historical marketplaces of Palermo and other marketplaces within Sicily and Southern Italy would better this study. Collating additional spatial and social data from wider street networks, using digital scanning methods and observational studies, would be beneficial. Moreover, the study could be expanded to observe different types of streets where informal economies are dominant to give suggestions on how these findings relate to other informal practices.

Similarly to Palermo, many other Sicilian and Southern Italian cities demonstrate similar patterns. To consider the regeneration of decaying historic centres, the study shows that it is crucial to preserve informal economies due to their indispensable ability to ensure marginalised groups' liveability. Therefore, maintaining the temporal characteristics of historic marketplaces plays a significant role in resolving tensions between culturally diverse groups.

6. Data statement

The research has undergone ethical approval, by the Welsh School of Architecture's Research Ethics Committee (SREC reference: 23021).

The submitted paper is adapted from the dissertation submitted as part of Masters of Architecture programme at the Welsh School of Architecture.

Equity in essential services accessibility among the elderly: a comparison of community resilience during and after the COVID-19 pandemic

Email: zhangxiaohe@tongji.edu.cn

Abstract
The COVID-19 has caused heavy damage across the globe. Lockdown measures implemented during the pandemic have affected residents' normal daily lives. During the stay-at-home orders, the elderly faced greater challenges in accessing essential services due to their physical limitations. Reducing inequities in access to essential service facilities is crucial for enhancing community resilience. In this research, three indexes were developed to measure community resilience in accessing essential services. Specifically, we have considered the differences in walking ability between the elderly and healthy adults, as well as the unique needs of the elderly. The Lorenz curve and the Gini coefficient were employed to measure spatial equity. Shanghai was selected as our case study. We utilized datasets from 2020 and 2023 to compare changes in equity during and after the COVID-19 pandemic. The results indicate that the Diversity Index exhibits the highest equity, followed by the Demand Accessibility Index, while the equity of the Per Capita Quantity Index is the lowest. The distribution of essential service facilities post-pandemic is moving in a direction unfavourable to the needs of the elderly. These findings provide valuable scientific insights for policymakers to strengthen community resilience and reduce inequities in essential facility access.

Keywords
equity; the elderly; essential services; accessibility; community resilience

1. Introduction

The COVID-19 has been a serious global pandemic in the past four years, claiming millions of lives and causing significant damage worldwide. During the most severe periods of the pandemic, many countries implemented various restrictions on travel and activities(Abdullah et al., 2020), collectively known as 'lockdowns'. These measures included school closures, remote work, limitations on public gatherings, curfews, the suspension of international flights, and the enforcement of social distancing guidelines, etc.

During the lockdown, only essential services remain open, and residents are permitted to leave their homes only to collect essential items, such as food and medicine.

* Corresponding author

Lockdowns are considered the most effective means of controlling the spread of the virus(Kabiraj et al., 2020), but they also inevitably result in the decline of urban functions and disrupt citizens' normal daily lives. Additionally, the lockdowns have exacerbated many inequities, with vulnerable groups facing greater difficulties such as accessing essential services and working from home, etc. Various viruses may continue to emerge in the future, we need to learn from past lockdown periods and focus on reducing the inequities they cause, thereby enhancing community resilience in the face of infectious diseases.

Recent studies have highlighted that the vulnerability of the population and the built environment are two key factors affecting the resilience of communities impacted by COVID-19(Xu et al., 2021). In this paper, our main focus is on the equity of community resilience concerning residents' accessibility to essential service facilities, particularly for senior citizens. We have found that the elderly suffered more unfairness due to the COVID-19. They are at a higher risk of contracting the virus and developing severe symptoms(Sasson, 2021). Due to limitations in physical condition and mobility, they encounter more difficulties in accessing essential services, especially for those who are not living with their children. Moreover, they have unique needs for essential services, such as a higher demand for healthcare resources. Therefore, we aim to explore whether the elderly experience more inequalities in accessing essential service facilities compared to the general population.

Additionally, with the economic downturn post-pandemic, we have observed changes in the distribution of many facilities, including service facilities and shops. Many facilities in urban areas have closed down or relocated to the suburbs. The redistribution of facilities inevitably affects people's access to essential services. Hence, it is also essential to examine whether the equity of essential service facility distribution after the pandemic is improving or deteriorating.

While some previous studies have focused on the accessibility of essential services(Corso et al., 2000, Manning, 2010, Mayer, 1979), most have only considered spatial accessibility in normal daily life. In fact, there are several differences in accessing essential services during the pandemic. Firstly, public transportation may be suspended or routes adjusted, leading most people to rely on walking to access essential services. Secondly, people's needs for facilities differ from usual during the pandemic. Outings are primarily for obtaining essential services to sustain life, such as for groceries and seeking medical care. Additionally, the needs of the elderly for essential services differ from those of the general population. Thirdly, due to social distancing requirements, essential service facilities often have capacity restrictions or require advance appointments during a pandemic. Therefore, the per capita quantity of facilities is also an aspect that needs to be measured.

Based on these considerations, we created three indexes. Using Shanghai as a case, we calculated these three indexes separately for the general population and the elderly.

Subsequently, we utilized Lorenz curves and Gini coefficients to assess the equity performance of these three indexes. Finally, we compared the data from 2020 and 2023 to illustrate how these three indexes changed in terms of equity performance during and after the pandemic.

The significance of this study lies in examining whether elderly individuals faced inequities in accessing essential service facilities. It explores changes in equity during and after the pandemic and provides recommendations to policymakers, thereby contributing to enhancing community resilience and reducing inequities in essential facility access.

This paper is organized into sections. Section 2 reviews relevant work involving community resilience and equity. Section 3 briefly introduces our study area and data. Section 4 describes the methodology. Section 5 presents the results and discussions. Section 6 concludes the main findings and discusses future research.

2. Literature review

2.1 Community resilience

Resilience was initially introduced in ecology by Holling(Holling and S, 1973), which originally meant "a measure of a system's ability to absorb shocks while still maintaining its previous resistance". Since then, the concept of resilience has been gradually applied to various fields including engineering, environmental sciences, business, disaster management, and urban studies(Hollnagel et al., 2006, Manyena, 2006, Masnavi et al., 2019).

Affected by the COVID-19, improving urban resilience and community resilience has received widespread attention(Yip et al., 2021, Fransen et al., 2022, Bento and Couto, 2021). Cities, especially as dense centres of the mobile population, are more prone to pandemics than rural areas. Intercity and intra-city transporting systems and dense transactions pose more threats to urban areas and make them more vulnerable to pandemics (Mollalo et al., 2020).

Many studies conclude that the pandemic has taught policymakers valuable lessons for planning more resilient communities(Elcheroth and Drury, 2020). The mainstream view is that resilience relies on qualities that enable a community to prepare for, respond to, recover from, and improve after hazards(Zautra et al., 2008). Resilient communities can absorb the impacts of the pandemic more effectively and recover rapidly.

According to previous research(Suleimany et al., 2022), community resilience to pandemics includes institutional, social, economic, built environment and infrastructural, and demographic dimensions. Among these dimensions, built environment and infrastructural resilience reflects the physical infrastructural capacity of a city(Keenan, 2020, Programme, 2021), and it is the most relevant dimension for urban planning.

In terms of built environment and infrastructure resilience, previous researchers have mainly focused on critical infrastructure networks, such as electricity, transportation, and communications, with the goal of quickly recovering from disasters, such as earthquakes and floods(Bruneau et al., 2003, Barker et al., 2013). However, community resilience during the pandemic differs from that during disasters. Infrastructure has not been physically damaged during lockdown(Chang et al., 2022); rather, urban functions have weakened due to limited activities. Therefore, the primary criterion of this dimension of community resilience is the availability of services, including various services such as health and hygiene services, retail, and commercial services, etc.

Therefore, we can explore community resilience from another perspective. Firstly, it's important to understand which essential services people need the most during lockdown. Many studies have highlighted the importance of accessibility to services such as education, healthcare, food, and cultural amenities for a community's vitality and cohesion(Contreras et al., 2017, Dempsey et al., 2011, Talen, 2003). Those services are important in normal times, but the situation is different during the pandemic lockdown. In this paper, we focus on the essential services that need to be obtained by reaching a physical facility. The distribution of these essential facilities is a key determinant of community resilience (Valinejad et al., 2022).

In this paper, these essential services are divided into four categories: food and daily necessities services, health care services, express delivery services, and financial services. These categories were selected based on a comprehensive review of existing research(Foli and Ohemeng, 2022, Figliozzi and Unnikrishnan, 2021, Giebel et al., 2022) and consideration of people's basic living needs during lockdown. Food and daily necessities services are crucial for maintaining physical fitness and daily life. Health care services enable people to receive treatment when sick. Express delivery services also play an essential role, especially with the increasing reliance on e-shopping. During lockdown, e-shopping can reduce people's travel and minimize the risk of cross-infection. Therefore, the distribution of delivery terminals is critical to ensure that people can collect their purchased goods even if the number of couriers is reduced during lockdown. Financial services are also essential as obtaining the aforementioned services usually requires payment. However, other needs such as education and recreation were not included in our research as we focused only on basic needs for maintaining life.

Based on the classification of essential service facilities in China and residents' frequency and preferences in accessing these facilities, these four types of essential services are further subdivided into eight facilities. These include four kinds of facilities related to food and daily necessities services: supermarkets, convenience stores, food markets, and greengroceries. Two kinds of facilities related to health care services: hospitals and pharmacies. One facility related to express delivery services: delivery terminals, and one facility related to financial services: bank ATMs.

Many scholars have conducted research on essential services during the pandemic, but their focus varies. For example, some studies have focused on food access, including

food security(Béné et al., 2021, Laborde et al., 2020), food purchase behaviour(Ellison et al., 2021), and food supply chain(Rejeb et al., 2022), while less attention has been given to the spatial distribution and accessibility of food stores. Additionally, although there have been some studies on the accessibility of certain types of services(Logan and Guikema, 2020, Mayaud et al., 2019, Feng et al., 2017), research on equity in these essential service facilities is still insufficient, especially for vulnerable groups such as the elderly. Therefore, this study aims to fill these research gaps.

2.2 Equity

Litman(Litman, 2002) presented two categories of equity: horizontal equity and vertical equity. Horizontal equity concerns the distribution of impacts between individuals and groups considered equal in abilities and needs, whereas vertical equity concerns the distribution of impacts between individuals and groups that differ in abilities and needs.

Undoubtedly, vulnerable groups face more inequity from the impact of the pandemic, as evidenced by the fact that adults over 65 years of age represent 80% of hospitalizations due to the COVID-19 and have a 23-fold greater risk of death than those under 65(Mueller et al., 2020). Therefore, the elderly are more affected by the pandemic(Sam, 2020). Elderly people are typically less inclined to cover long distances on foot(Somenahalli and Shipton, 2013). Therefore, specific considerations to improve services should adopt an equity-focused approach to address the pandemic needs of vulnerable groups (Sam, 2020).

This is why we emphasize vertical equity. Vertical equity means essential services are accessible to populations with the greatest potential need. Vertical equity in the distribution of resources plays a crucial role in coping with pandemics(Suleimany et al., 2022). Under these considerations, it is imperative to investigate whether the elderly have equal access to essential service facilities.

3. Study area and data

3.1 Study Area

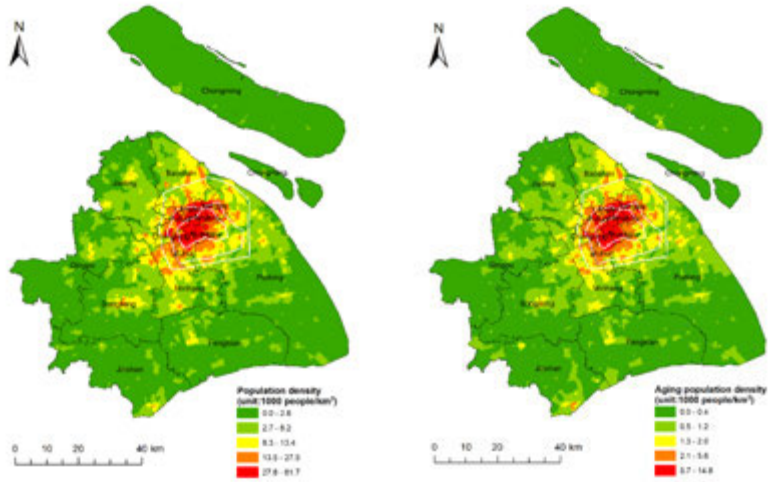
Shanghai, located in the east of China, is the most rapidly urbanizing and developed megacity in the country, encompassing a total area of 6340.5 square kilometres and a population of 24.87 million in 2020(Bureau, 2021). Shanghai is divided into 16 districts (Fig.1). There are three Ring Roads in Shanghai: the Inner Ring Road, the Middle Ring Road and the Outer Ring Road. The area within the Outer Ring Road is defined as the urban area, including the city centre, several sub-centres, and other densely populated areas. Meanwhile, the area outside the Outer Ring Road consists mainly of suburbs, including some new towns and rural areas. Fig.2 shows the distribution of total population density and elderly population (aged 65+) density in Shanghai. It can be observed that the population density is higher in the urban areas and some suburban new towns, while it is lower in other areas.

Fig.1. Study area

Furthermore, Shanghai has entered an aging society. Table 1 shows the total population and aging rate in Shanghai from 2010 to 2022, indicating a continuous deepening of aging in Shanghai. Considering the vast elderly population, Shanghai was chosen as the case city for our research. Investigating the equitable distribution of essential service facilities and offering insights into community resilience within such a megacity holds significant importance.

Table 1 The total population and aging rate in Shanghai from 2010 to 2022

	2010	2020	2021	2022
Total population(million)	23.01	24.87	24.89	24.75
Aging rate (60 years and above) (%)	15.1	23.4	24.0	25.0
Aging rate (65 years and above) (%)	10.1	16.3	17.4	18.7



(a) (b)

Fig.2. (a) Population density distribution in Shanghai, (b) Population density distribution of the elderly over 65 years old in Shanghai (The values are presented as quantile ranges)

3.2 Data

Population data was sourced from the WorldPop-Constrained-individual-countries-2020-UN-adjusted dataset (https://www.worldpop.org/), published in 2020. Moreover, population data for individuals aged 65+ were extracted to represent the elderly population for comparison with the overall population in this study. The selection of the age threshold of 65+ is mainly based on previous research, which suggests that individuals in this age group are more susceptible to health issues(Molarius and Janson, 2002). Additionally, it is a common age threshold in many studies related to aging(Pickering et al., 2001).

The digital geographic data, including eight types of essential service facilities, was obtained from Points of Interest (POI) sourced from Gaode Maps. We acquired Shanghai POI data for 2020 and 2023 to compare facility distribution during and after the pandemic. This data has been converted into WGS1984 coordinates for consistency and compatibility in our analysis.

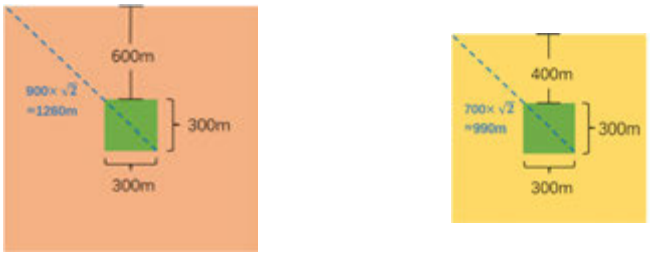
4. Methodology

We divided the entire study area into 300m × 300m grids, which served as our basic research units. We set two types of buffer zones for the grids: one for the general population and another for the elderly. Considering the weaker walking ability of the elderly, the buffer zone for them is smaller than that for the general population. We developed three indicators, calculated separately for different buffer zone sizes to compare the results for the elderly and the general population. Since each grid produces calculation results, we visualize these results on the map. Finally, we use the Gini

coefficient and Lorenz curves to reveal the equity of these three indicators. The following will introduce the specific methods and details of each step.

4.1 The walking buffer area for the elderly and the general population

Due to reduced physical strength in the elderly, their acceptable walking range is smaller than that of the general population. We assume that the maximum acceptable walking time is 15 minutes (Guzman et al., 2021). Given a walking speed of 1.4 m/s for the general population (Bohannon, 1997) and 1.1 m/s for the elderly(Duim et al., 2017), the corresponding walking distances for 15 minutes are 1260 meters and 990 meters, respectively. To establish buffer zones, we determine the maximum walking distance of vertices at the edge of each grid (Fig.3). For the general population, the buffer zone distance is set at 600 meters (Fig.3(a)), while for the elderly, it is 400 meters (Fig.3(b)). Within these buffer ranges, we assume that all essential service facilities are reachable. The following three indexes for measuring the ability to access essential service facilities are calculated within these two buffer ranges, respectively.



(a) (b)

Fig.3. Buffer area for each grid: (a) for general population, (b)for the elderly.

4.2 Demand Accessibility Index

The first index is the Demand Accessibility Index(DAI). It's important to consider that people have different needs and preferences for service facilities. To capture these differences, we conducted an online questionnaire survey in March 2020 to characterize the travel demands and frequencies of different groups in Shanghai during the lockdown. The survey included 1540 respondents, of which 9.4% were over 65 years old. Respondents were asked about the purposes of essential travel, their purchasing preferences for food and daily necessities (shopping at physical stores or online), their preferred shopping locations (supermarkets, convenience stores, wet markets, greengroceries), as well as the frequency of their outings per week.

Based on our previous survey findings, significant differences exist in the demands and preferences between the elderly and the general population. When it comes to purchasing food, senior citizens tend to favour affordable and fresh options, leading them to prefer wet markets over supermarkets and convenience stores. Additionally, due to a higher likelihood of experiencing health issues, the elderly have a greater demand for access to hospitals and pharmacies.

Moreover, with the rapid development of express delivery and smartphone payment services in China, young people show a preference for online shopping and cashless transactions. In contrast, elderly individuals often stick to traditional shopping methods in physical stores and prefer cash payments due to their limited proficiency with internet usage and smartphones. Consequently, senior citizens exhibit lower demand for express delivery services and a higher demand for bank ATMs.

In this study, we utilized weighted values to compute the DAI (see Table 2). The assignment of these weights, totalling 1, draws from our survey data and is supplemented by insights obtained from existing literature(Weng et al., 2019, Lian and Yen, 2014). The computation process for the DAI of a grid involves multiplying the count of each essential service facility within the buffer zone of each grid by its corresponding weight and subsequently aggregating these values.

Table 2 Weights in the calculation of DAI

		Weight (for general population)	Weight (for the elderly)
Food and daily necessities services	Supermarket	0.15	0.08
	Convenience store	0.13	0.04
	Wet market	0.1	0.18
	Greengrocery	0.12	0.12
Health care services	Hospital	0.1	0.2
	Pharmacy	0.1	0.2
Express delivery services	Delivery terminal	0.25	0.06
Financial services	ATM	0.05	0.12

4.3 Diversity Index

As Jacobs(Jacobs, 2016) commented, a fine-grained mixing of diverse uses creates vibrant and successful neighbourhoods. Shannon information entropy is the most widely used tool for quantifying diversity in land use distribution (Christian et al., 2011). In this study, Shannon entropy is applied to measure the Diversity Index(DI) of essential service facilities within each buffer zone, calculated using the following formula:

$$H(X) = -\sum_{x \in X} p(x) lnp(x) \quad (1)$$

where $H(X)$ represents the diversity of essential service facilities within the buffer zone of each grid. X denotes the number of essential service facility types. This study mainly includes eight facility types: supermarkets, convenience stores, food markets, greengroceries, hospitals, pharmacies, delivery terminals, and ATMs. $p(x)$ denotes the proportion of the xth type of facility in each buffer zone.

4.4 Per Capita Quantity Index

The two aforementioned indexes do not involve population quantity, whereas the Per Capita Quantity Index(PCQI) correlates with population size. As previously mentioned, given the constraints on social distancing during the lockdown, the capacity of each service facility is also limited, thus necessitating the measurement of the number of facilities per capita.

The calculation method for this index involves dividing the number of essential service facilities in the buffer zone of each grid by the grid population. Naturally, this calculation is also performed separately for all residents and the elderly population.

4.5 Min-Max Normalization of the data

As each index is measured in a different unit, we adopt a minimum-maximum normalization approach to convert the data into dimensionless values ranging between 0 and 1. Given that higher index values indicate greater community resilience, we perform minimum-maximum normalization using the following equations:

$$z' = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (2)$$

where z' represents the normalized value between 0 and 1, x is the original value, x_{max} is the maximum for a specific index, and x_{min} is the minimum value for a specific index.

4.6 Equity assessment

To assess equity, we employ Lorenz curves, which enable us to visualize and quantify the fairness of the three indexes across residents in various grids. Originally used in economics to depict income or wealth inequality, the Lorenz curve illustrates the relationship between population (%) and wealth (%) (Lorenz, 1905). Now it has been applied to various fields to demonstrate the equity of resources among population(Delbosc and Currie, 2011, Rezaei and Nouri, 2015, Melkamu and Bannor, 2015).

In our study, the Lorenz curve was utilized to illustrate the relationship between the indexes and the population. Subsequently, the Gini coefficient will be computed to quantify spatial equity. The Gini coefficient is calculated using the following formula(Delbosc and Currie, 2011):

$$G = 1 - \sum_{k=1}^{n} (P_k - P_{k-1})(R_k + R_{k-1}) \quad (3)$$

where P_k is the cumulative percentage of grid population, and $R_k$is the cumulative percentage of the index. The Gini coefficient ranges from 0 to 1, where 0 means complete equity and 1 denotes complete inequity. A lower Gini coefficient indicates a more equal distribution of that index. A study suggested that a Gini value under 0.2 denotes satisfactory equity, whereas a value between 0.2 and 0.5 indicates medium inequity and a value above 0.5 is considered high inequity(Delbosc and Currie, 2011). In some studies, 0.4 is considered as a warning threshold of inequity(Wen et al., 2016).

5. Results and discussions

5.1 Community resilience in accessing essential service facilities

5.1.1 The results of DAI

Fig.4 shows the DAI value for all residents and the elderly. Overall, only the regions within the Inner Ring Road have a higher DAI. In the urban area, the Demand Accessibility Index for all residents is usually higher than that for the elderly. In 2020, high values of DAI were primarily concentrated in the core areas of the city, while in 2023, the distribution of high values within the urban area exhibited a trend of dispersion, with some sub-centres of the city also showing high DAI values. Additionally, in some suburban new towns, the DAI values in 2023 were higher than those in 2020. These findings indicate a trend of decentralization and dispersion in the distribution of POIs after the pandemic.

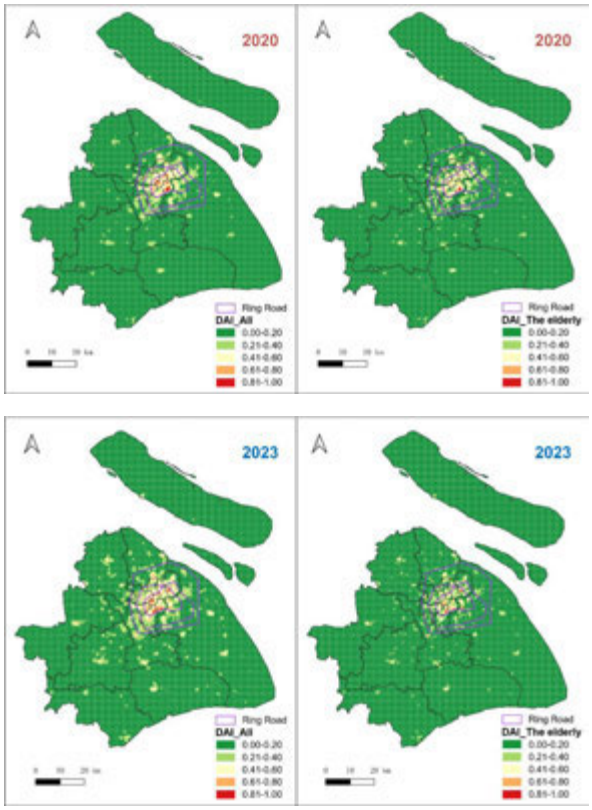


Fig.4. Demand Accessibility Index distribution.

5.1.2 The results of DI

The DI depicts the variety of essential service facility types within the buffer zone of each grid. A higher DI indicates a greater diversity of facilities. As shown in Fig.5, the

distribution of DI appears relatively balanced. Apart from the high values observed in urban areas, many suburban regions also exhibit high DIs, sometimes even comparable to those in the city centre. In comparing all residents with the elderly, the DI for all residents tends to be higher, suggesting that larger buffer areas also mean a richer variety of essential service facilities.

Fig.5. Diversity Index distribution.

5.1.3 The results of PCQI

PCQI is calculated by dividing the number of facilities in each buffer by the population of the grid. Therefore, although the number of POIs in the urban area is large, considering the large population, we can find that the PCQI value in the urban area is not high(Fig.6). Conversely, in many suburban areas, this value is relatively high. Moreover, the PCQI value for the elderly is higher than that for all residents.

Due to the reduction of many POIs in the urban area and the increasing trend of POIs in the suburbs after the pandemic, the PCQI value in some suburban areas in 2023 have

increased compared to 2020, while the PCQI value in some urban areas have decreased compared to 2020.

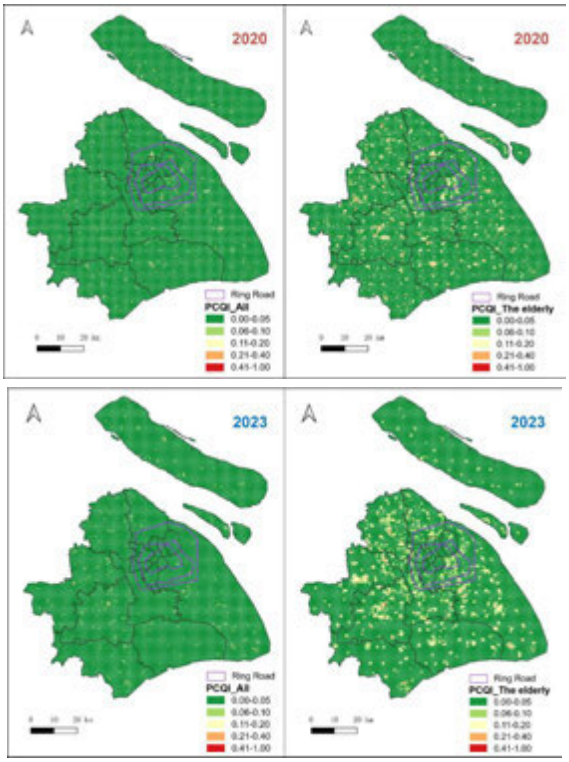

Fig.6. Per Capita Quantity Index distribution.

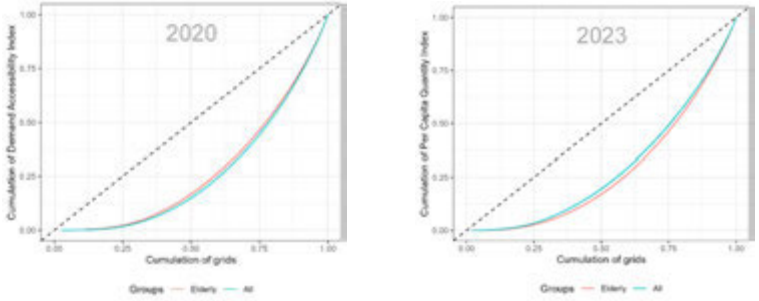
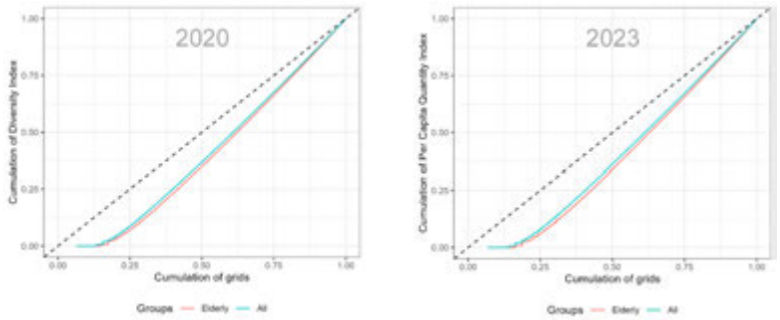
5.2 Spatial equity of essential service facilities' distribution

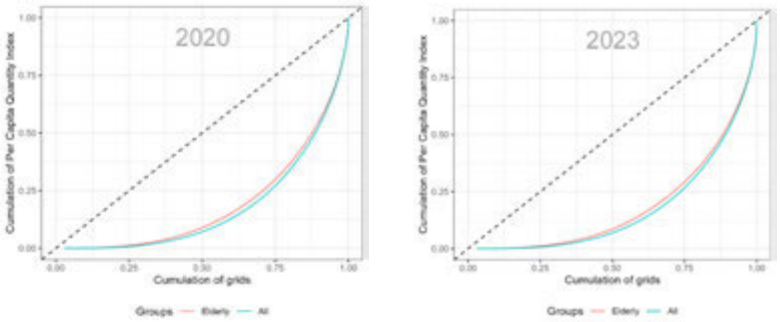
The Lorenz curves for the three indexes were drawn to show the equity of essential service facilities' distribution, and is divided into for all residents and for the elderly (Fig.7). The dash line represents perfect equity. If the curve is closer to this dash line, it means better equity. The Gini coefficients are shown in Table 3.



(a)



(b)



(c)

Fig.7. The Lorenz curves for the three indexes: (a) for DAI, (b) for DI, (c) for PCQI

The results are summarized as follows:

Firstly, The Gini coefficients of PCQI is often the largest of the three indexes, reflecting the most pronounced inequity exhibited by that index. The Gini coefficients of DI is often the smallest among the three indexes, reflecting a relatively balanced distribution of these facilities in terms of diversity. We can see that the Gini coefficients of DAI and PCQI all exceeded 0.4, which is the warning line of inequity.

Table 3 Gini coefficients

	Gini coefficients -DAI		Gini coefficients -DI		Gini coefficients -PCQI	
	All	The elderly	All	The elderly	All	The elderly
2020	0.478	0.456	0.200	0.224	0.649	0.622
2023	0.419	0.451	0.209	0.236	0.657	0.632

Then, let's focus on the differences between all individuals and the elderly in these three indexes. The Gini coefficients of DAI values in 2023 are smaller than those in 2020, respectively. This indicates an improvement in equity in DAI after the pandemic. This phenomenon is mainly attributed to the decentralization of POIs, with many

suburban areas having a richer array of POIs than before the pandemic. However, in 2020, the equity performance of DAI for the elderly was better than that for the general population, while in 2023, the situation reversed, implying a weakening of facility distribution catering to the needs of the elderly after the pandemic.

As for DI, the Gini coefficients in 2023 are a little bit larger than those in 2020, indicating a slight decrease in the equity of facility diversity after the pandemic. Whether during or after the pandemic, this index reflects better equity for the general population compared to the elderly.

For the PCQI, the Gini coefficients in 2023 are also larger than those in 2020, indicating a decrease in the equity of per capita facility quantity after the pandemic. However, when considering the comparison between the elderly and the general population, the equity is better for the elderly.

This outcome indicates a fundamental difference between the three indexes: Shanghai is a diverse and highly commercialized city, so the types of essential service facilities are relatively balanced. However, due to the different population densities between the urban and suburbs, there is a great inequity in terms of per capita quantity of essential service facilities. Among the three indexes, particular attention needs to be paid to the DAI. During the pandemic, the equity of DAI for the elderly was better than for the general population, while the opposite is true after the pandemic. This suggests that the distribution of essential service facilities post-pandemic is moving in a direction unfavourable to the needs of the elderly. This is something that the government should pay attention to, especially in areas with high elderly population density, ensuring that essential service facility distribution meets the needs of the elderly.

6. Conclusions

Strengthening community resilience in cities is urgently needed in this post-COVID era. Reducing the inequity in access to essential service facilities is considered an effective way to improve community resilience dealing with pandemics and to improve the livelihoods of all populations.

In this research, we created three indexes to measure community resilience in accessing essential services. We classified the essential services and their corresponding facilities, taking into account the varying walking capacity and needs of the elderly when measuring accessibility. The Lorenz curve and the Gini coefficient were used to assess the spatial equity of the three indexes, which represents an innovative application of interdisciplinary methods.

The results of our study suggest that the equity level is different among the three indexes. The Diversity Index exhibits the highest equity, followed by the Demand Accessibility Index, while the equity of the Per Capita Quantity Index is the lowest. These findings

underscore the importance of prioritizing fairness in terms of per capita facilities and addressing the diverse demands of different groups.

Several issues need to be addressed in future studies. Firstly, in terms of equity, this paper only considers the elderly as a vulnerable group. However, there are many other vulnerable groups, such as low-income individuals, people with chronic illnesses, and homeless individuals. Future research should also consider these groups to provide a more comprehensive understanding of equity in access to essential services. Secondly, capacity restrictions in public places during the lockdown were not fully addressed in this paper. While the per capita quantity of essential service facilities was considered, the paper did not further limit the number of people allowed to enter these facilities. In the future, this approach can be combined with epidemiological research to conduct accessibility studies based on the maximum number of people allowed to enter each type of essential service facility, which could provide valuable insights for controlling the spread of the pandemic and assisting policymakers in resource allocation decisions.

TRACK 09: Planning for Fair, Plural, and Welcoming Cities

Study on Youth Friendly Urban Renewal Strategies from an Inclusive Perspective

Zihao Chen[1], Yifan Yu[2]

[1]College of Architecture and Urban Planning, Tongji University, 395578527@qq.com
[2]College of Architecture and Urban Planning, Tongji University, yuyifan@tongji.edu.cn

Abstract: With the acceleration of global urbanisation, urban renewal has gradually received attention as a key means to improve urban quality of life and optimise spatial resource allocation. However, the traditional urban renewal model focuses more on land use, construction land development intensity, and other aspects, ignoring the needs of different groups of people. According to data released by the National Bureau of Statistics in 2021, the domestic youth population in China is about 448 million, accounting for about one-third of the total population. This group is an important component of cities and a key part of the city's future development. Currently, youth in urban life face problems such as the lack of urban identity, undersupply of services, and poor quality of living space. Therefore, this study takes an inclusive perspective as the entry point, taking Expo A area of Pudong New Area in Shanghai, China, as an example. Firstly, a literature review, questionnaire survey, and other methods were used to investigate the full needs of young people for public spaces. The research results found that the needs of young people for urban public spaces are mainly reflected in diversity, comfort, and publicness, which mainly reflect their needs for cultural, fitness, social and other public spaces. Afterwards, targeted and actionable youth-friendly city renewal strategies are proposed in terms of spatial optimisation, facility configuration, and business upgrading in order to enhance the sense of security, belonging, and experience of young people. It is not only beneficial for solving various challenges faced by youth in urban renewal, but it also provides feasible solutions for the sustainable development of cities and provides new ideas and methods for future urban planning and urban renewal.

Keywords: Urban Renewal; Youth; Inclusive; Public Space

1. Introduction

In contemporary society, urban renewal has become a key issue in the global urbanisation process. With the rapid changes in economy, society, and technology, urban environments need to constantly adapt to new challenges and demands. Especially for young people, they play an increasingly important role in the cultural, economic, and social activities of cities. However, the traditional urban renewal model focuses more on land use, construction land development intensity, and other aspects, ignoring the needs of different groups of people. According to data released by the National Bureau of Statistics in 2021, the domestic youth population in China is about 448 million, accounting for about one-third of the total population. This group is not only an important component of cities but also a key force for their future development. The proportion of young people in cities, their vitality, innovation ability, and other aspects provide strong support for the sustainable development of cities.

According to the definition of the United Nations Human Settlements Programme, youth-friendly cities refer to cities that carefully consider the needs and rights of young people in policy formulation, planning, and service provision and support their comprehensive development. These types of cities typically have the following characteristics: providing affordable housing, abundant education and employment opportunities, broad social and cultural participation channels, and a safe and healthy living environment. Youth-friendly cities also emphasise the participation of young people in urban decision-making processes, ensuring that their voices are heard in urban development. However, young people often face various challenges in enjoying urban life, such as a low sense of urban identity, insufficient service supply, and poor quality of living space. These issues prompt us to examine urban renewal strategies from a more inclusive perspective, provide a better environment for young people, and ensure that their needs and rights are fully considered.

This study focuses on the exploration of youth-friendly city renewal strategies from an inclusive perspective. Specifically, the study will analyse how existing urban renewal strategies affect young people and explore how innovation in policies and practices can promote the comprehensive friendliness of urban environments and the comprehensive development of youth. This includes evaluating the effectiveness of existing policies, identifying existing issues, and proposing improvement strategies. Through this approach, research not only hopes to provide practical suggestions for urban planners and policymakers but also contributes new perspectives and knowledge to theoretical research. In summary, the purpose of this study is to enhance the construction of youth-friendly cities through urban renewal strategies. This research is not only innovative in theory but also has guiding significance for practice. It is expected to contribute to promoting the sustainable development of global cities.

2. Research on Youth Friendly Cities

The youth-friendly city value the special needs and potential of young people and promote their comprehensive development through a series of methods. In the context of rapid globalisation and urbanization, understanding and implementing strategies for youth-friendly cities has become an important issue in urban planning and policymaking and is conducive to enhancing

the vitality of cities (Della Spina, L., 2019). This article provides an overview of the progress, international cases, and future research directions related to youth-friendly cities.

2.1 Research Progress

Regional competitiveness has become a key factor in achieving sustainable development goals in various research contexts (Cogswell, C., 2018). Sustainable competitiveness is described as determining the productivity level of a region, and young people are the key group to enhance regional core competitiveness. From the practice of urban areas in Europe and America, it can be seen that in the process of forming youth-friendly cities, local governments pay more attention to the needs of young people (Hailu Demeke, Y., 2022), provide diverse ways of participation for young people (Rojas, 2022), accommodate youth culture and activity venues that are conducive to enhancing youth value (Carmona, 2019), provide comfortable transportation environments, and provide facilities preferred by young people (Rigolon, 2018). At the same time, some scholars believe that due to the different geographical locations and economic and cultural characteristics of different regions, the number of people attracted varies, leading to different demands and causing differences in spatial supply, transportation organization, and public facility supply in urban areas (Latham, A, 2019). Understanding the perspectives of different groups of people and finding ways to involve them in urban development is an important process of urban renewal (Konsti Laakso, 2018). Through inclusive urban renewal methods, meet the needs of young people and increase the fair utilisation of urban space (Cole, 2017).

2.2 International Cases

Different countries and cities have demonstrated diverse practices in implementing youth-friendly strategies. For example, D-Street Lawn is a temporary preparation project for the massive expansion of the Boston Convention and Exhibition Center (BCEC) by the Massachusetts Convention Center Authority (MCCA). Before the renovation, D Street was a desolate and underutilised space composed of vacant land, ageing industrial buildings, and parking lots. The Sasaki design team and representatives from the surrounding community and MCCA conceived and constructed a flexible and vibrant temporary urban space - the D Street Lawn as the leading public space for D Street. The ultimate goal of D Street Lawn is to create a vibrant and innovative urban area to support the future expansion of BCEC and the vitality of surrounding communities.

For example, D-Street Lawn is a temporary preparation project for the massive expansion of the Boston Convention and Exhibition Center (BCEC) by the Massachusetts Convention Center Authority (MCCA). Before the renovation, D Street was a desolate and underutilised space composed of vacant land, ageing industrial buildings, and parking lots. The Sasaki design team and representatives from the surrounding community and MCCA conceived and constructed a flexible and vibrant temporary urban space - the D Street Lawn as the leading public space for D Street. The ultimate goal of D Street Lawn is to create

a vibrant and innovative urban area to support the future expansion of BCEC and the vitality of surrounding communities(Figure 1).

Figure 1. Young people engage in activities during the day (life) and at night (right) on the D Street（Source:https://www.douban.com/note/700740078/?_i=5934836XNBK1vY）

Nagoya Juya Datong Park takes outdoor sports loved by young people as the starting point, upgrades the park into an urban outdoor centre, and creates a commercial complex that integrates outdoor camping, dining, indoor camping, and product exhibition and sales functions. Young people can see the application scenarios of products displayed here and experience various themed activities in the venue, including outdoor sports, picnics, camping, reading, rest, and other activities that embrace green nature. These cases provide practical experience in successfully implementing youth-friendly city renewal plans.

3. Youth-friendly Urban Renewal Strategy

3.1 Research Area

The research base is located in the northern part of Zhoujiadu Street in Pudong New Area, between the two core areas of Huangpu Riverside: the Bund Lujiazui North Bund core area and Expo Qiantan Xuhui Riverside. Formerly the A-zone of the 2010 Shanghai World Expo Park. The research base starts from the Huangpu River in the north, extends to Xueye Road in the south, faces Shangnan Road in the west, and ends at Bailianjing in the east, covering an area of 85.54 hectares. The base has high-quality riverside resources, high-level cultural facilities, high-density corporate headquarters, and a high-level youth group.

3.2 Demand for Young and Middle-Aged People in The Area

Taking Expo Area A in Pudong New Area, Shanghai, China, as an example, literature review and questionnaire surveys were first used to fully investigate the needs of young people for urban public spaces. During our on-site investigation, we found that the needs of young people for urban public spaces are mainly reflected in diversity, comfort, and publicness, which mainly reflect their needs for cultural, fitness, and social spaces(Figure 2).

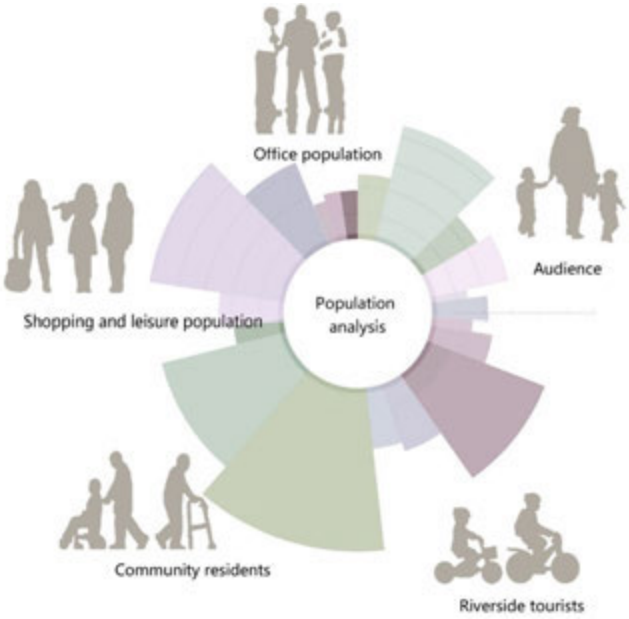

Figure 2. Analysis of the proportion of youth activity groups (Source: author's elaboration)

3.3 Current Problems

Based on current research findings, most of the public core spaces within the base have problems with closed interfaces, low quality, and lack of design. The youth group stays in the public spaces for a relatively short period of time, mostly through pedestrian flow. At the same time, we have found that the space and functions of the business functional areas lack urbanity, and are not attractive to diverse pedestrian flows and activities(Figure 3).

Figure 3. Existing problems in the current situation of the base (Source: author's elaboration)

3.4 Planning Concept

3.4.1 For Public Buildings

Urban-level public facilities, World Expo cultural landmark buildings, with high venue awareness. Local external services are at the bottom level but lack display and scale effects. The main building and celebration square has a huge volume, easily creating a sense of emptiness. The comfort and environmental quality of the surrounding areas of the building need to be improved. It has the potential to initiate cultural activities continuously, and the nearly 10000 spectators attracted by large-scale events have brought evacuation "pressure" but have not played a "resource" role. Expand the influence of landmark buildings, tap into the spillover effects of localised functions, drive surrounding cultural and entertainment, youth gatherings, and catering consumption, and provide diversity in travel and stay. Optimise environmental quality, fully use the venue, and provide tourists and residents with a rich and comfortable venue experience.

Urban-level public facilities, World Expo cultural landmark buildings with a huge scale, unique design, and eye-catching colours. The service functions and spatial interfaces are closed, and there is a lack of dialogue with the surrounding urban spaces. Fully utilise the influence of landmark buildings to strengthen the World Expo's cultural characteristics and visual guidance functions. Collaborate with Meiben Center, Expo Source, and Green Valley to drive vitality in the surrounding space. Enhance the public nature of the street interface by opening up rooftop gardens and entrance squares. Expand the localisation influence of World Expo culture, extract cultural symbols, and create a cultural atmosphere for the surrounding World Expo.

The office building embodies the design concept of "small neighbourhoods and dense road networks". The environmental atmosphere is serious and dull, with homogeneous groups having a single mode of travel and activity. According to the regulations, the bottom layer is open, introducing cultural, leisure, sports, and catering functions to soften the urban interface. Enhance the fun and comfort of outdoor environments, embed unique street furniture and facilities, create relaxed and fun social and sports spaces, and attract young people.

3.4.2 For Open Spaces

A continuous negative interface has formed along Expo Avenue, lacking open space and access channels. The high-quality cycling road along the waterfront cuts through the air, lacking theme venues and necessary leisure service facilities for staying. Transform the "end space" into a "destination", open the southern interface of the riverside green space, increase the places and channels for entering the waterfront shoreline, and promote the integration of waterfront space into daily life in the urban hinterland. Utilise cultural and ecological functional nodes (Meiben Center + Wharf + Bailianjing) to create a POI with distinct functionality and theme, as well as enhance venue awareness and activity attractiveness.

Create daily leisure spaces for office workers and surrounding community residents in Area A.

Connect the development of Snow Wilderness Road Reserve with distinctive functions and environmental quality and build a belt space between Area A and Zhoujiadu Community.

Various ecological green spaces and street squares have abundant spatial resources. Based on system sorting and functional linkage, we have the conditions to shape a high-quality urban environment. Integrate open spaces at all levels and types to inject activity content and build a series of activity venues. Focus on creating the theme of "youth" and the characteristics of "sports". Collaborate with Meiben Center, Zhonghua Art Palace, Green Valley, and other social organisations to plan a series of themed activities to enhance social attention and local attractiveness. Combining the pedestrian space system to build a comfortable and diverse age-friendly open space network, providing local residents with leisure and fitness resources, and supporting the vitality of Area A with daily life activities.

3.4.3 Targeting the Travel Environment

Two high-grade urban transportation arteries have a certain barrier effect on the internal connections of the base but also provide broad pedestrian space. There is a dense flow of people and vehicles on Shangnan Road. On one side of Area A, there is a lack of vibrant places and urban interfaces. Expo Avenue has a wide view and a closed interface, but its riverside advantages have not been fully reflected. The vegetation on the street is beautiful, but the service functions along the street are insufficient.

Guozhan Road runs through Area A, with wide red lines and good greenery. The spatial scale and directional sense of the section near Expo Avenue are out of balance. There is no urban interface on the north side of Xueye Road, and the residential area on the south side is closed, resulting in a poor slow driving experience and a lack of sense of place. The belt area is a key space for two-way functional connection and vitality infiltration, and enhancing interface vitality is crucial.

The subway line along the base has a sufficient flow of office workers during peak hours in the morning and evening, as well as weekend leisure passengers. During large-scale events at Meiben Center, there is a phenomenon of crowds and queuing after the event. The bus stops within the base are mainly distributed on Shangnan Road and Expo Avenue, and there is a pendulum tidal flow of people during morning and evening peak hours. Pay attention to the passenger flow structure and activity characteristics of Meiben Center and World Expo Source, connect the open space of Meiben Center - China Art Palace, and explore opportunities for surrounding services and cultural entertainment spaces for performing arts activities. Improve the quality of public transportation surrounding the environment and the guidance system and strengthen the cultural characteristics of the World Expo. Introduce pedestrian flow and vitality to the east through themes and venues.

The Meiben Center and the Chinese Art Museum lack social parking spaces. The enterprise office building is divided into underground parking lots. Some branches park motor vehicles along the road. The possibility of opening social parking spaces in office buildings. Key

services will be provided for large-scale cultural activities at the Meiben Center, with the establishment of an intelligent indicator system that dynamically guides the flow of vehicles and people during performances.

There are non-motorized vehicle parking areas on Shangnan Road and Gaoke West Road, with no markings on other roads. The current situation is that shared bicycles and non-motorized vehicles are frequently used during peak commuting hours, and the parking methods, locations, and scale need to be organised. Considering the relationship between non-motorized vehicle parking, road walkability, and street interface openness, designate parking areas based on the entrance and exit of the building's underground garage. Strengthen patrols, standardise parking, and control the quantity.

Overall, walking accessibility is good, but comfort and quality need to be improved. The public and continuity of the road interface are insufficient and lacking attractiveness. Sidewalk materials and road facilities' quality need to be improved. The system aims to enhance the public and service-oriented nature of the Road, with a focus on supplementing youth-friendly facilities along Yuntai Road and Gaoke West Road. Focus on building trendy culture and leisure sports characteristics along the horizontal road. Improve the continuity and openness of street interfaces.

3.5 Planning and Design

The planning and design intention is to inject momentum into development, lock in potential human flow, mobilise resource endowment and flow economy, and create a youth development demonstration block. Explore the potential of open spaces and urban interfaces at all levels and types and create sports-themed and vibrant neighbourhoods that meet the needs of young people. Strengthen the World Expo's cultural memory and urban intention and create a district with distinctive World Expo cultural characteristics. By optimising the layout of building clusters, organising slow traffic systems, and opening spaces, we aim to promote the development of youth-friendly urban renewal(Figure 4).

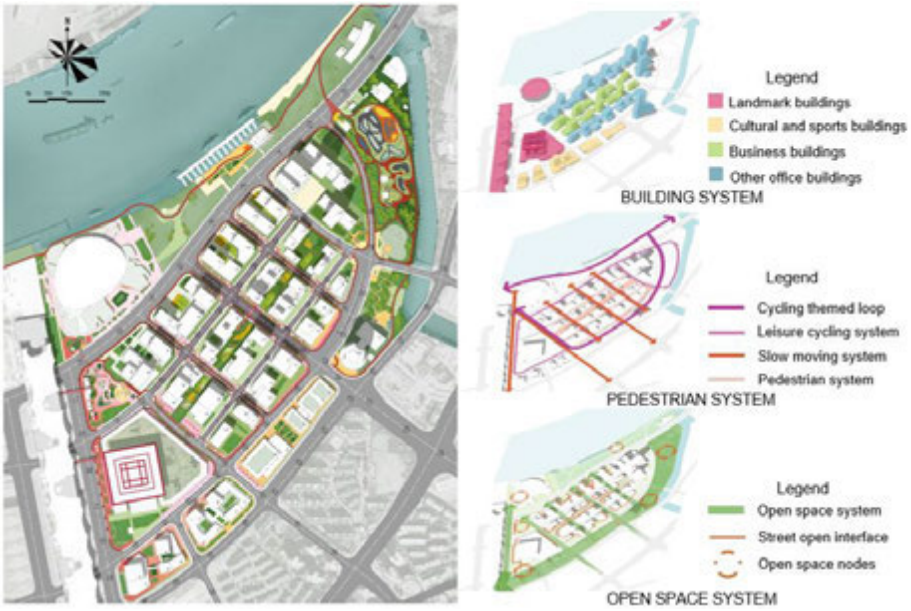

Figure 4. Space system structure (Source: author's elaboration)

In the specific planning and design, method of integrating real-life scenarios, the entrance square of the Meiben Center public building will be moderately opened, with one street square and crossing facilities set up. The celebration square will be equipped with interesting and movable facilities to improve the sense of scale and comfort(Figure 5).

Figure 5. Current situation of Meiben Center (left) and integration of real-life scenes (right) (Source: author's elaboration)

Improve the details of outdoor space and optimize the quality and fun of the neighbourhood environment. The central axis green space is equipped with rich communication and leisure facilities to promote communication and interaction among diverse groups of people. Embed outdoor art exhibitions and smart interactive installations to continue the cultural heritage of the World Expo. Utilise sound, light, electricity, and intelligent means to increase the richness

and fun of street activities, promote full-service functions, and maintain the sustained vitality of the venue. Green valley office area will add youth interactive devices and provide venues for youth activities (Figure 6).

Figure 6. Green valley current situation (left) and realistic integration (right)
(Source: author's elaboration)

4 . Discussion

The study of youth-friendly cities provides effective strategies for urban planners to support youth development, helping to build a more inclusive and dynamic urban environment. This study focuses on exploring the renewal strategy of youth-friendly cities from an inclusive perspective and takes the Expo A area of Shanghai, China, as an example to plan and design, exploring the role of innovative planning schemes in the construction of youth-friendly cities. In addition to the construction of public spaces, transportation environment, and facility supply mentioned in this article, government departments around the world have also generally paid attention to the construction of youth-friendly cities in recent years and have begun to promote policies and practices for urban development. Through continuous practical innovation and improvement, the needs of young people can be better met, and their positive role in urban society can be promoted.

Dispersed Urban Spatial Structure and Increased Urban Greenness Could Reduce Intra-City Health inequalities in England

Yinghui Jia[1], Lan Wang[1], Jiankun Lou[1]
1 College of Architecture and Urban Planning, Tongji University, Shanghai, China
Email: 2210289@tongji.edu.cn

Abstract
The persistence of socioeconomic health inequalities has garnered substantial attention, and a few researchers have explored the impact of neighborhood greenness on mitigating it. However, it remains unclear whether comprehensive planning can address this issue. In this study, we evaluated intra-city health inequality in 105 cities in England and examined the impact of urban spatial structure (measured by dispersion) on it, with adjustment for city size, population density, urban greenness, development level, income gap, and aging. Results revealed that the dispersion of urban population (β=-0.179, p=0.043) and urban greenness (β=-0.147, p=0.087) exhibited significant negative relationships with intra-city health inequalities, while the income gap showed a significantly positive relationship (β =0.5002, p<0.001). These findings underscore the critical role of city comprehensive planning in mitigating health inequalities.

Keywords: urban inequality, city comprehensive planning, urban spatial structure, health and well-being

Introduction

Health inequalities across socioeconomic groups has been increasingly acknowledged in the past decades (Kakwani, Wagstaff and van Doorslaer, 1997; Kawachi, 2002; Kröger, Pakpahan and Hoffmann, 2015). Researchers and politicians have focused on decomposing the drivers of health inequalities and identifying strategies to reduce this inequality (Erreygers and Kessels, 2013; Tan, Wang and Cheng, 2016). Apart from the individual level socioeconomic status such as income, education and employment, researchers have gradually discovered a new perspective in reducing health inequalities at the population level: urban built environment. Starting from the noteworthy Lancet article published in 2008 (Mitchell and Popham, 2008), the effect of greenness in lowering the health gap between the more well-off and less well-off groups of people has come into the view of public health researchers. Subsequent studies further investigated the effect of other neighborhood-level built environment indicators. For example, Mitchell *et al.* (2015) found that the recreational areas are also vital for delimiting the inequality in mental well-being. However, none of the existing studies have revealed the effect of the city level comprehensive planning on health inequalities.

The potential environmental and health effect of urban spatial structure – an important system in comprehensive planning –has received great attention in recent years. Urban spatial structure is defined as the spatial distribution of urban population or economic activities. Following Anas, Arnott and Small (1998), it includes two dimensions: centralisation – dispersion (whether and to what extent population and economic activities are clustered in urban centres), and monocentricity – polycentricity (whether and to what extent an urban system is organised

around a single urban core or a number of proximate and functionally integrated subcentres). Several studies have shown that a more dispersed urban development might exaggerate health risks by elevating the air pollution concentration (McCarty and Kaza, 2015; Cárdenas Rodríguez, Dupont-Courtade and Oueslati, 2016; Fan *et al.*, 2018; Liu *et al.*, 2018; Gao, Yang and Liang, 2020) and greenhouse gas emission (Muñiz and Sánchez, 2018; Hong, Hui and Lin, 2022). The size and accessibility of health resources, such as green space (Han *et al.*, 2023) and urban amenities (Wang, 2021), are also shown to be influenced by urban spatial structures. Additionally, polycentricity might shorten commute distance (Hu, Sun and Wang, 2018), and has an impact on daily activity (Horton and Reynolds, 1971), thus has the potential to influence physical activity.

Although studies have shown that urban spatial structure might influence health, and compared the different urban spatial structure across different cities (Schneider and Woodcock, 2008; Liu and Wang, 2016; Li and Liu, 2018) or along a time span (Garcia-López, 2012; Y. Li, 2020), the potential of urban spatial structure to affect socioeconomic inequality in health within cities has, as far as we aware, received no attention.

In this study, we aim to explore the effect of urban spatial structure on the intra-city health inequalities across areas with varying socioeconomic statuses, so as to inform urban planning strategies and facilitate the eradication of inequality. We postulated that socioeconomic inequalities in health will be less pronounced in cities with a more dispersed and polycentric urban spatial structure. This hypothesis is based on the notion that the relationship between socioeconomic disparities and health inequalities is potentially influenced by urban spatial structure. We know that one crucial pathway of health inequalities is the limited accessibility of health-related material conditions (such as health amenities, shelters and other health resources) for individuals with low socioeconomic status. Consequently, a higher level of intra-city health inequalities indicates a greater disparity in accessing these material conditions among areas with diverse socioeconomic backgrounds. By influencing the distribution of these conditions, urban spatial structure may play a significant role in contributing to the observed inequality. For instance, a centralised city is likely to exhibit larger inequality, as the highly-centralised centre may be equipped with a wide range of high-level amenities, while the sparsely populated outliers may lack sufficient resources and a conducive walking environment. Conversely, a dispersed urban spatial structure is more likely to provide public amenities that are easily accessible. Polycentricity is expected to reduce inequality for the same reasons.

These ideas prompted us to investigate the effect of urban spatial structure on intra-city health inequalities. Here, by utilizing local-scale health and socioeconomic data, we examined this issue within the context of England. The results of this study have significant implications for health-focused urban planning and associated policies, contributing to the advancement of SDG3 (good health and well-being) and SDG10 (reduced inequalities).

Data and Methods

Study design

We compared the income-related health inequalities at the intra-city level, and investigated the effect of urban spatial structure on it, with adjustment for city size, population density, urban greenness, development level, income gap and aging.

Data and variables

We obtained the all-ages standardised mortality ratio (SMR) for deaths from all circulatory diseases from the Office for Health Improvement and Disparities (OHID) by the Office for National Statistics (ONS), which were deaths registered in the calendar years 2016 to 2020 from circulatory disease – classified by underlying cause of death recorded as ICD codes I00 to I99 – for persons of all ages. We selected this indicator because circulatory disease is a leading cause of death, while mortality is a direct measure of health care need, indicating the overall circulatory disease burden on the population and reflecting both the incidence of disease and the ability to treat it.

Data for population income was obtained from the Office for National Statistics (ONS). The total annual household income – the sum of the gross income of every member of the household plus any income from benefits such as the Working Families Tax Credit – was selected as the indicator. This indicator was produced for the financial year ending 2018.

These two indicators were captured at the Middle Layer Super Output Area (MSOA) scale and used to assess health inequalities. Middle Layer Super Output Areas (MSOAs) are a geographic unit designed to improve the reporting of small area statistics in England and Wales. They are built from groups of Lower Layer Super Output Areas, typically 4 to 6, and designed to have a population of between 5,000 and 15,000. There are 6,791 MSOAs in England.

The intra-city health inequalities in our study was calculated as the disparity in standardised mortality ratio across different income levels, with MSOA as the basic geographical unit. To derive it, we first defined the area of the city. Following *Rural and Urban Statistics in England: Guidance Notes*, settlements with populations of over 10,000 are urban. Therefore, leveraging the global urban boundaries (GUB) (Li *et al.*, 2020) and Landscan population dataset, we derived the cities to further calculate intra-city health inequalities. Moreover, to avoid any bias caused by small sample size in calculating the gradient across MSOAs within a city, we only included cities that overlapped with 10 or more MSOAs. 106 cities were identified as a result. Then, we manually excluded the Great London due to its significant disparity from other English cities, leaving 105 geographical units in our further analysis. We adopted the concentration index, which is frequently used in quantifying the health inequalities across socioeconomic gradients, to derive the intra-city income-related health inequalities. The formula is listed below.

$$\mathrm{C} = \frac{2}{\mu} cov(h_i, R_i) = \frac{1}{n} \sum_{1}^{n} \frac{h_i}{\bar{h}} (2R_i - 1) \quad (1)$$

where h_i is the health outcome of MSOA i, while R_i is the rank of income of MSOA i. $\bar{h}$ is the average health status of this city, and n is the number of MSOA included in this city. After being balanced using the average health status and number of MSOA, this indicator is comparable across different cities. Moreover, since the health outcome in our study is mortality, which is negative, we use the absolute value of the concentration index to reflect health inequalities for further analyses. The value is limited to the interval [−1, +1], with −1 indicating an extreme pro-poor distribution of health and +1 an extreme pro-rich distribution of health.

In terms of the independent variables, we involved city size, population density, urban spatial

structure, urban greenness, development level, income gap and aging in consideration. City size was proxied by urban land and urban population. Urban land area was directly derived from the global urban boundaries (GUB) dataset. Urban population is the total population located on the urban land, derived from the LandScan population dataset. Population density was calculated as the division of the former two indicators.

Dispersion was selected as the indicator of urban spatial structure following previous studies. Following the approach of (Lee and Gordon, 2007), we define the degree of dispersion as the share of the population in a city's non-centre areas ($POP_{total} - POP_{cnter}$) to its total population (POP_{total}).

$$DISP = \frac{POP_{total} - POP_{cnter}}{POP_{total}} \quad (2)$$

By definition, the value of DISP ranges from 0 to 1. A higher value of DISP indicates that a city's population distribution is more dispersed.

Our measurement of dispersion draws upon the identification of centres. Following Lee (2007) and X. Liu and Wang (2016), we adopt a relative minimum cut-off approach. By setting a minimum density cut-off at the level of its 95-percentile population density with LandScan grids, we identified the top 5% most densely populated areas for each city. With equation (2), we calculated the percentage of inhabitants that reside outside of the densest urban areas.

Since most of the English cities (90 out of 105) are small cities with inhabitants less than 300,000, it is by large not necessary to involve multiple centres within a city. Therefore, we didn't calculate the indicator polycentricity and only used dispersion as the proxy of urban spatial structure.

Furthermore, by combining the Moderate Resolution Imaging Spectroradiometer (MODIS) data product, we derived the average NDVI of each city as a proxy for greenness. Following previous studies (Kummu, Taka and Guillaume, 2018), we got the gridded GDP per capita and calculated its mean value at the city scale to represent the development level. We obtained the rate of aging over 60 years old using additional datasets from the Office for National Statistics. In addition, we involved the Gini index to measure the degree of inequality of income, with a higher value indicates more inequality. The data source is summarised in Table 1. The descriptive statistics of variables are presented in Table 2.

Table.1 Details of the original data

	Spatial resolution	Time	Source
Urban area	vector	2018	Li *et al.* (2020)
Income	MSOA	2018	The Office for National Statistics (ONS)
standardised mortality ratio for deaths from circulatory diseases	MSOA	2016-2020	the Office for Health Improvement and Disparities (OHID) by the Office for National Statistics (ONS)
Population density	~1km	2017	LandScan population dataset
NDVI	250m	2016	the Moderate Resolution Imaging Spectroradiometer (MODIS)
GDP per capita	~10km	2015	Kummu, Taka and Guillaume (2018)

the rate of aging over 60 years old	MSOA	2018	the Office for National Statistics

Table.2 Descriptive analysis of variables

	mean	sd	min	max
Absolute value of concentration index	0.09	0.03	0.02	0.14
Urban land area (km2)	65.66	111.80	8.68	639.05
Urban population (×e5)	1.95	3.45	0.13	21.95
Population density (×e3/km2)	3.40	0.63	1.90	5.36
Dispersion (%)	90.60	4.88	79.92	100
NDVI (×e-3)	0.51	0.06	0.29	0.68
GDP per capita (×e4)	2.90	0.30	2.36	3.41
Gini index of income	0.09	0.02	0.05	0.14
Proportion of aging above 60 years (%)	24.69	3.53	18.70	37.09

Methods

We pre-examined the association between urban spatial structure and other environmental variables with the intra-city health inequalities using Pearson correlation analysis. Then, we adopted a multivariable regression model to reveal their effects with socioeconomic and demographic variables under control. Urban land area was excluded from the regression due to multicollinearity.

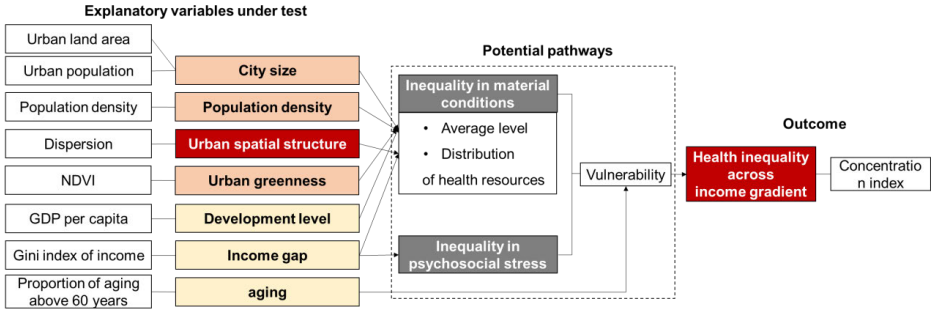

Fig.1 Analytical framework of this study

Results

Income-related health inequalities widely exists across England. We found that geographical areas with higher income presented lower mortality ratio (β=-0.621, $p<0.001$). Intra-city health inequalities range from 0.02 in Cannock to 0.14 in Blackburn (Fig.2), with an average value of 0.09. No significant variance was found between cities of different hierarchies (p-value = 0.388, Fig.3).

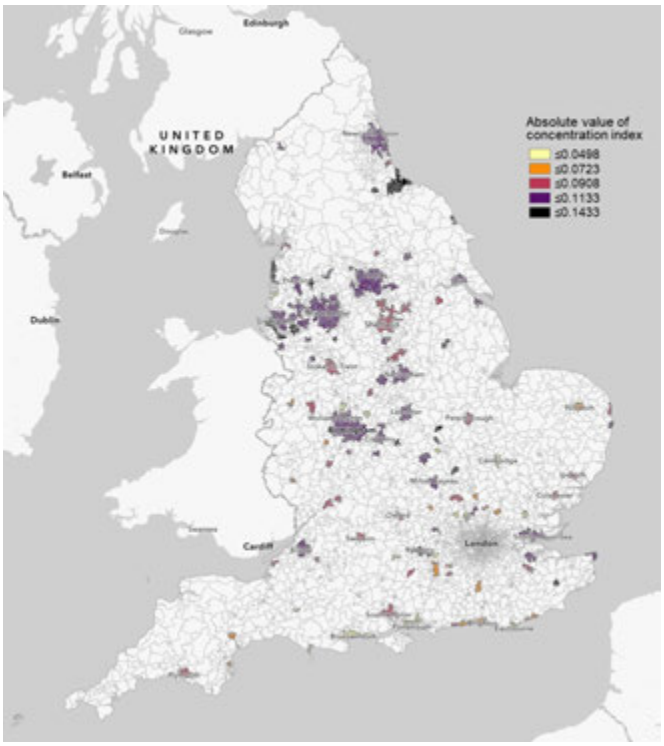

Fig.2 Distribution of intra-city health inequalities in England

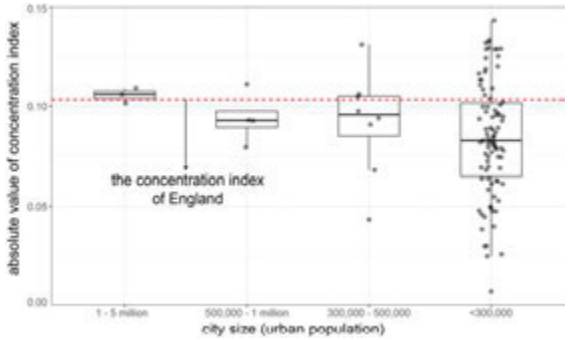

Fig.3 Distribution of intra-city health inequalities across city hierarchies
Note: The division of city size follows World Urbanization Prospects (2018)

In the binary correlation analysis, we found that cities with a more dispersed urban population (β=-0.2507, p=0.010) and a higher NDVI value (β=-0.1663, p=0.090) present lower intra-city health inequality, while cities with more inhabitants present higher levels (β=0.1842, p=0.060). This suggests that the disparity in health outcomes across areas of different socioeconomic statuses might be reduced if a city is greener and less concentrated, while it might be exaggerated when a city is larger.

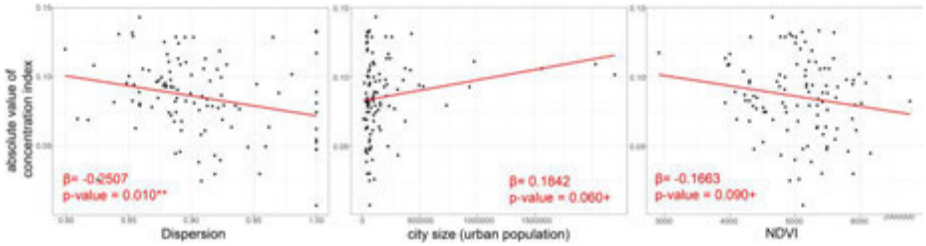

Fig.4 Relationship between environmental factors and intra-city health inequalities

Regression results revealed that the intra-city health inequalities could be explained by urban environment features (F-statistic=7.307, p<0.0001). We identified that the dispersion of urban population (β=-0.179, p=0.043) and greenness (β=-0.147, p=0.087) were in significant negative relationships with intra-city health inequalities. It indicates that cities with more dispersed population distribution and more green areas would exhibit lower levels of intra-city health inequality. Moreover, the disparity in income was also in a super significant positive relationship with income-related health inequalities (β=0.5002, p<0.001), which means that the larger the income gap, the larger the health gap.

Table. 3 Result of the multivariable regression

	Standardised coefficient	Std. Error	t value	Pr (>|t|)

F-statistic		7.307 (p-value<0.0001***)		

Discussion

Our study has demonstrated that, consistent with our hypothesis, intra-city health inequality is lower in cities with a more dispersed urban spatial structure and a greener urban environment. To our knowledge, this is the first study to identify city-scale urban planning factors that contribute to the reduction of intra-city health inequalities.

Our most significant finding is the elucidation of the impact of the urban spatial structure on reducing intra-city health inequalities. This may be attributed to the arrangement of physical conditions (urban amenities) at the city level. From an economic perspective, urban amenities are typically located in densely populated areas due to cost-effectiveness, while sparsely populated areas would have lower accessibility. Therefore, a dispersed urban spatial structure may prevent the concentration of urban amenities in densely populated urban centres, thereby reducing discrepancies in walkability – predicted based on the surrounding urban amenities

(Jones *et al.*, 2021) and significantly influences cardiovascular disease (Zhang *et al.*, 2023) – across different urban areas, leading to lower health inequality. Moreover, the more accessible healthcare resources in a dispersed city is conductive to lowering the inequality in the ability to treat cardiovascular disease. These possible mechanisms, from both the incidence and treatment perspectives, might explain the reduced health inequalities between rich and poor urban areas in dispersed cities.

It is important to note that the analysis regarding the distribution of urban amenities above is based on an assumption that the ability to pay is equally distributed spatially. However, in reality, amenities, especially those with commercial attributes, tend to cater to the rich. This means that even if a poor neighborhood is highly densified, amenities such as healthcare may not be accessible in this area. Conversely, a sparsely populated wealthy neighborhood may have access to highly qualified serves. In the context of England, we observed that the densely populated areas are mainly areas of income deprivation, especially in the Northern part of England. This implies that poor and densely populated neighborhoods might not have the advantage of amenities and may also suffer from overcrowding and poor living conditions. This possibly even exaggerates the health inequalities between rich and poor areas.

Our result also revealed that the average greenness in a city could reduce the intra-city health inequalities. It is not surprising as previous study has demonstrated its effect in mitigating health inequalities at the neighborhood level (Mitchell and Popham, 2008; Mitchell *et al.*, 2015). Here, we extend this finding to the city level, with similar mechanisms including promoting physical activity and alleviating stress (Mitchell & Popham, 2008), both of which are key risk factors for cardiovascular diseases.

Limitations of this study should also be acknowledged. First, the measurement of urban spatial structure is restricted. The population-based method used in our study is a straightforward way to derive morphological urban spatial structure, and is suitable for large scale research without efficient local data. However, during data processing, we found that although this method works well for Chinese cities and US metropolitans (Arribas-Bel and Sanz-Gracia, 2014; Liu and Wang, 2016; Li and Liu, 2018, 2018), its performance in England is not ideal. Due to the relatively small size for most England cities, we can hardly set a minimum threshold for selecting urban centres. For example, previous studies used 3 km^2 as a minimum size for urban centres. When we apply this criterion to England, most of the cities do not have a centre at all. Therefore, we simply used 1 km^2 (a grid in Landscan data) for the inclusion of city centre. But we can hardly tell whether the selected densely populated urban areas are true "centres". Further research is needed to apply other methods to re-test the effect of urban spatial structure.

Second, our data were cross-sectional. We had no means of knowing the migration of urban residents throughout their lives. Therefore, we could not know their living environment and their access to urban amenities and greenness in their earlier life, which also have profound effect on the mortality from cardiovascular diseases (Zhang *et al.*, 2023).

Third, the geographical unit used to measure the inequality in health may also influence the results due to modifiable areal unit problem (MAUP). Therefore, the robustness of our results needs further testing by utilizing available data from other geographic units to calculate health inequalities within cities.

In conclusion, the evidence suggests that built environment interventions at the city level –

which operate upstream and are easily reversible – could be effective in reducing health inequalities across areas with different socioeconomic statuses within cities. Such levels of health inequality are lower in cities with a more decentralised urban spatial structure and higher levels of greening. The implications are clear: while the promotion of compact cities has been prevalent, our findings do not support further over-concentration of the population in existing urban centres, especially when these dense urban centres exacerbate health disparities between the poorest and least poor by worsening the living conditions of poorer urban residents. Additionally, increasing greenness is emphasised as a spatial intervention strategy to effectively mitigate health inequalities. Together, these findings highlight the role of city comprehensive planning in the fight to reduce health inequalities.

Exploring colour planning strategies for children's outdoor playgrounds in communities: An analysis of children's diverse preferences in Shanghai, China

Yajun Wen, Yifan Yu
Affiliation: College of Architecture and Urban Planning, Tongji University, Shanghai 200092, China
Email: wenyajuna@tongji.edu.cn, yuyifan@tongji.edu.cn

Abstract
Children's understanding of the world is largely shaped by their visual perception of their surroundings, with colour playing an integral role. Colour not only creates a visual impact but also has a profound influence on children's emotions, cognition, and behavior. This study explored colour planning strategies for children's outdoor playgrounds in communities, specifically focusing on children's colour preferences. We collected data through a questionnaire survey conducted in Shanghai, China, and employed the chi-square test and single-factor logistic regression to analyze the correlations between colour preferences and individual attributes of children, including gender, age, and community type, which we hypothesized could influence the diversity of children's color preferences. It is found that there exist significant differences in children's colour preferences across various ages and community types. Based on the children's colour preferences and preferences differences, we proposed several strategies for colour planning of children's outdoor playgrounds in the communities. Through these strategies, it aims to enhance the scientificity and universality of colour planning. Overall, this research contributes to the field by providing evidence-based recommendations for colour planning in children's outdoor playgrounds, ultimately contributing to the creation of more inclusive and vibrant child-friendly communities.

Keywords: colour planning, colour preference, children's playground, child-friendly community

1. Introduction

In the process of children's understanding of the world, the primary and most crucial aspect is their perception of the surrounding environment through vision (Proverbio et al., 2004). Within this developmental process, the significance of colour cannot be understated. It possesses the capacity not only to elicit visual impact but also to influence children's emotions, cognition, and behaviour (Jiang et al., 2020). Consequently, reasonable colour planning within the built environment, holds the potential to cultivate a more harmonious, healthful, and conducive environment for children's growth. Conversely, an unsuitable colour environment may inadvertently induce stress and impede the healthy development of children. The community, as the fundamental unit of city, serves not only as the immediate locus of children's daily activities but also constitutes a pivotal point for the realisation of a child-friendly urban environment. In recent years, prompted by the Child-friendly City Initiative (CFCI), there has been a noticeable surge in attention towards the design of children's outdoor playgrounds. Nevertheless, research on colour within the framework of constructing child-friendly communities remains comparatively underdeveloped, marked by a deficiency in quantitative evidence-based studies and systematic planning methodologies. Traditional approaches to colour planning and design predominantly rely on colour coordination skills and planner experience, often neglecting children's colour preferences and the underlying principles. By accumulating and analysing factual evidence, that is, children's colour preferences and laws of

preferences, evidence-based research that replaces empirical means with scientific means can provide an important supplement to planning and design. Consequently, this article takes Shanghai as an example and proposes colour planning and design strategies for children's outdoor playgrounds in communities based on the investigation of children's colour preferences and rules of preferences.

2. Literature Review of Children's colour Preference

In the realm of colour psychology, colour preference, a predilection of an individual or group towards specific hues over others, stands as a pivotal aspect within the broader domain of colour research. This aspect has perennially captivated the scholarly pursuits of various disciplines, including psychologists, urban planners, and artists. Studying colour preferences provides us with a way to understand how perceptual experiences map to cognitive and affective judgements (Ou et al., 2004).

Research on children's colour preferences encompasses three primary dimensions. Firstly, investigations of children's abstract colour preferences. For instance, as early as 1924, Garth (1924) explored the colour preferences of 1,000 white children, revealing an inclination towards blue that heightened with educational attainment, whereas with a decreasing preference for red. Similarly, Xu, Xu, and Guo (2022) corroborated that children aged 3-6 exhibit a predilection for colours with higher brightness, such as red, blue, and yellow. Moreover, as children get older, discernible gender differences emerge, with boys gravitating towards blue and girls towards pink, while red maintains favourability across genders. The second dimension pertains to the investigation of colour preference and perception concerning various objects, including food colour (Walsh et al., 1990), furniture colour (Jiang et al., 2020), and indoor colour (Ghayouri and Ayat, 2020), among others. The third dimension involves examining group disparities in colour preference, with a particular focus on gender and age differences. Sex-based distinctions in children's colour preferences have historically engendered debate. Some studies have identified notable disparities in colour preferences between boys and girls. For instance, Mohebbi (2014) surveyed children aged 7-9 in Islamic countries, revealing significant differences between genders in preferences for blue, green, pink, and black. Conversely, certain studies have indicated the absence of significant gender-based differences in preschool-aged children's colour preferences (Mousavi Samimi and Sadraei Tabatabaei, 2022). Nonetheless, on the whole, a preponderance of research supports the existence of gender differences in children's colour preferences (Child, Hansen and Hornbeck, 1968; Khaki and Mahdavi, 2021). In contrast to the contentious discourse surrounding gender differences, there is a consensus regarding the age differences in children's colour preferences. For example, Baniani (2022) observed marked differences in colour preferences among Japanese primary and middle school students, with primary school students exhibiting a preference for gold. Additionally, there exists a body of research exploring cultural disparities in children's colour preferences.

To sum up, in order to explore evidence-based colour planning for child-friendly community environments based on children's colour preferences, this study intends to address the following two research questions:

(1)What are children's colour preferences for children's outdoor playgrounds in communities?

(2)Are there differences in children's colour preferences for outdoor playgrounds in communities?

Drawing upon existing literature, this study formulates research hypotheses to address the second research question, focusing on gender and age disparities in colour preferences. Moreover, extant studies have evidenced significant variations in city colour preferences among residents inhabiting different housing types (Wen, Himeno and Chung, 2023), with Shanghai exhibiting several distinctive housing typologies. Hence, this investigation posits the following three research hypotheses:

(1) There exist significant differences in children's colour preferences for outdoor playgrounds across genders;

(2) There exist significant differences in children's colour preferences for outdoor playgrounds across ages;

(3) There exist significant differences in children's colour preferences for outdoor playgrounds across various community types.

3. Survey of Children's Colour Preferences

The content of the survey

Colour is the perceptual interpretation of light wavelengths through the visual apparatus of the eyes, processed by the brain, and influenced by life experiences. The diverse colours can broadly be categorised into two groups: achromatic and chromatic. Achromatic colours, characterised by a saturation level of 0, include typical black, white, and grey. In the common perception of the Chinese people, the colour spectrum is traditionally delineated into red, orange, yellow, green, cyan, blue, and purple—commonly referred to as the rainbow colours. Among these, red, yellow, and orange are considered warm hues, while blue, green, and purple are classified as cool hues.

Therefore, the questionnaire item concerning colour preference for outdoor playgrounds within communities is formulated as follows: "What colour do you most would like for the outdoor playgrounds in your community?" Respondents are provided with a single-choice selection from the following options: A. Warm colour, B. Cool colour, C. Black, white, and grey, D. Multicoloured (a mix of warm and cool tones), E. Other. Additionally, demographic details such as gender, age, and housing type of the participants were captured in the questionnaire.

3.1 Selection of survey area and analysis

Housing type is one of the variables of this study, so the area shown in Figure 1 was carefully selected as the investigation area. This area is located in the south-central part of Hongkou District, Shanghai, covering an area of about 1.5 square kilometres and is a 15-minute living circle. Encompassing three prevalent housing typologies emblematic of Shanghai, namely traditional lane blocks predating 1949, post-1949 public housing, and commercial and affordable housing constructed since the 1990s [33], this locale offers a diverse representation of urban residential architecture. Among them, traditional lane housings generally occupy a small area, exhibiting high building density, and dense road networks; public housing residences exhibit obvious grading characteristics, with large land use, low building density and low road network; The newer commercial and affordable housing developments encompass a range of sizes, with high-rise structures characterised by lower density, ample green spaces, and open areas.

There are abundant children's education facilities in the survey area, including one nursery, four kindergartens, four primary schools and three middle schools. Notably, Primary School No. 1

and Kindergarten No. 3 are predominantly surrounded by traditional lane housing, while Primary School No. 2 and Kindergarten No. 4 are situated in high-rise commercial housing. Conversely, Primary School No. 3 and Kindergarten Nos. 1 and 2 are primarily surrounded by multi-storey public housings.

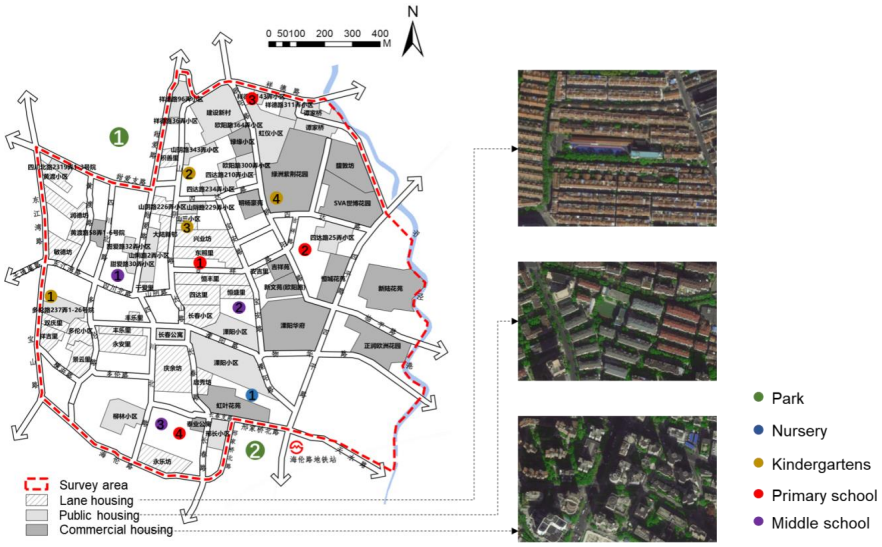

Figure 1. Survey area

3.2 Survey procedures and participants

In October 2023, a questionnaire survey was conducted within the designated area. Employing an offline random sampling approach, the survey targeted children aged below 18 years. Over one month, a total of 210 questionnaires were gathered, out of which 204 were deemed valid, yielding an effective rate of 97.1%. The demographic composition of the participants is illustrated in Figure 2. Specifically, the participants comprised 107 male children (52.45%) and 97 female children (47.55%). The age range spanned from 1 to 17 years, with an average age of 10 years. As per the United Nations Convention on the Rights of the Child, individuals under 18 years are classified as children. In line with the eight-stage theory of personality development proposed by psychologist E.H. Erikson, and the insights from famous Chinese psychologist Zhixian Zhu, the ages of the surveyed children were categorised into four groups: 0-3 years old (1.47%), 4-6 years old (10.78%), 7-12 years old (63.73%), and 13-17 years old (24.02%). Additionally, the distribution of housing types among the 204 participants was relatively even, with 64 children residing in lane housing, and 70 children each inhabiting public housing and commercial housing, respectively.

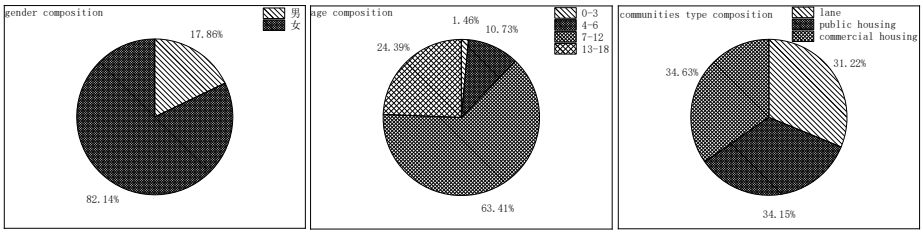

Figure 2. The composition of participants

3.3 Results

Figure 3 depicts the descriptive statistical outcomes of children's colour preferences for outdoor playgrounds in communities, presented as frequencies. Broadly, warm colours emerge as the most favoured choice among children, constituting 40.6% of responses, closely followed by a blend of cold and warm hues, representing 39.2% of preferences. Conversely, the least selected outdoor colour schemes are achromatic options, that are black, white, and grey.

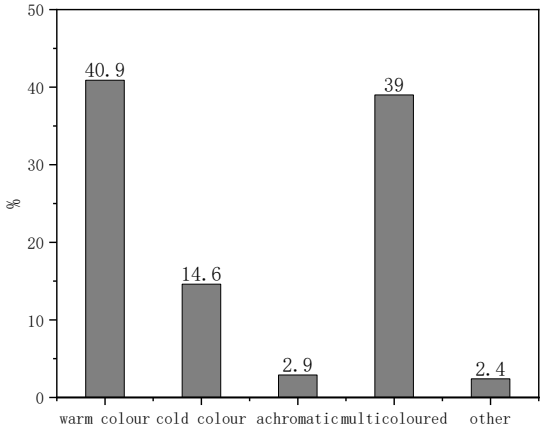

Figure 3. Preferred colour of children

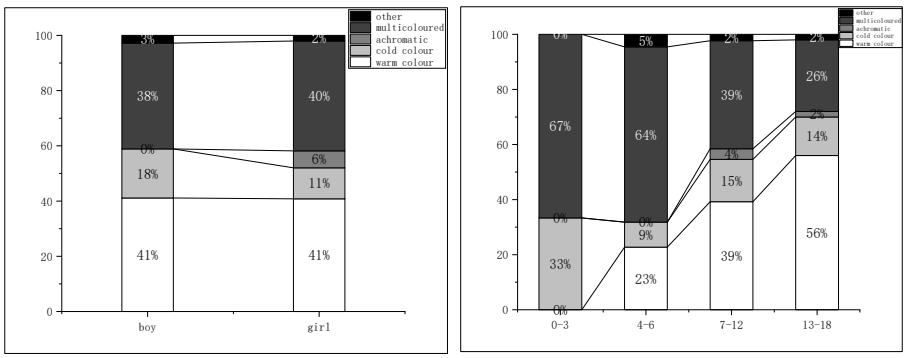
Figures 4 illustrates the colour preferences of children across various genders, age groups, and housing types. Analysis reveals discernible patterns: boys exhibit a greater inclination towards cool colours compared to girls, while girls manifest a heightened preference for achromatic hues in contrast to boys. Regarding colour preferences among children residing in diverse community types, those inhabiting lane communities demonstrate a penchant for vibrant, multicoloured schemes, whereas children in public housing communities preferred warm colour palettes for outdoor playgrounds. Conversely, children in commercial housing communities were more likely to choose cool colours relative to other housing types.



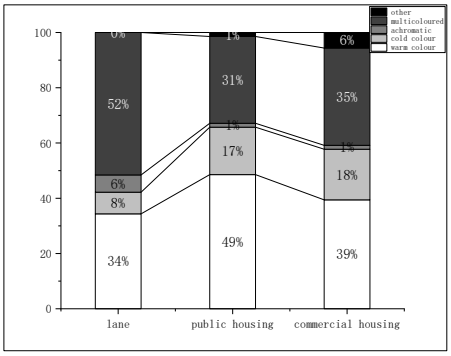


Figure 4. Colour preferences of children across various genders, ages, and housing types

In order to evaluate the statistical significance of gender and housing type differences in children's colour preferences for outdoor playgrounds, this study employed the chi-square test, a widely utilised hypothesis testing method. The chi-square test assesses the extent of deviation between observed and expected values in a statistical sample. The magnitude of this deviation determines the chi-square value, with larger values indicating greater discrepancies and smaller values indicating lesser discrepancies (Wen, Himeno and Chung, 2023). Furthermore, since age is a numerical variable while colour preference is categorical, the chi-square test is suitable for analysing variables when both are categorical. Therefore, to examine the relationship between age and colour preference, this study utilised a single-factor regression model.

The above tests were all performed through IBM SPSS 26. The test results are summarised in Table 1. According to Table 1, the p-value for age (0.043) and housing type (0.043) are both below the significance threshold of 0.05, indicating that the age difference and housing type differences in children's colour preference are significant at the 95% confidence level. That is, children's age and housing type are significantly related to children's colour preference for outdoor playgrounds in communities. Conversely, the p-value associated with gender (0.084) exceeds the 0.05 threshold. Thus, the analysis suggests that gender differences in children's colour preferences for outdoor playgrounds within communities are not statistically significant at the 95% confidence level.

Table 1. Results of significance test

	Value	df	Asymptotic significance	Exact significance
Gender	8.214	4	0.084	0.072
Age	22.346	4	0.000 (significance)	-
Housing type	16.256	8	0.039	0.043

In summary, the findings of this study support the establishment of research hypotheses 1 and 3. Specifically, the results indicate significant age and community-type differences in children's colour preferences for outdoor playgrounds within communities. Conversely, hypothesis 2 is not supported, as there are no statistically significant differences observed in children's colour preferences for outdoor playgrounds across genders.

4. Colour Planning Strategies for Children's Outdoor Playgrounds

Children often exhibit a strong inclination to congregate with peers of the same age group, each age group possessing distinct physiological, psychological, and behavioural needs.

Consequently, many outdoor playgrounds now incorporate activity zones tailored to accommodate children of varying age ranges. However, it is observed that the colour series employed across these activity areas often remain uniform, failing to account for the diverse colour preferences observed among children of different ages. Based on the research findings presented in this article, which underscore significant age-related disparities in children's colour preferences, it is imperative to reconsider the colour schemes utilised in community children's activity venues. Specifically, colour delineations should be integrated alongside age and activity type categorisations. For instance, vibrant and diverse colour palettes are recommended for play areas catering to younger children, whereas a more restrained colour palette may be suitable for play areas targeting older children. By aligning colour choices with the preferences of each age group, community activity venues can better cater to the diverse needs and preferences of children across various developmental stages.

Moreover, given the significant disparities in children's colour preferences for outdoor playgrounds across different community types, this study advocates for tailored colour design strategies for each community archetype. Specifically, lane and public housing communities represent the predominant housing typologies in Shanghai, characterised by high building density and limited space availability. In such high-density urban settings, the scarcity of land resources poses challenges for the incorporation of children's playgrounds. Thus, the study proposes the utilisation of existing spaces, such as idle areas or underutilised spaces within the lane and public housing communities, to augment open space provisions for children. Furthermore, fragmented spaces like stairwells can be repurposed to enhance the availability of recreational areas. Notably, colour can serve as an effective tool for delineating boundaries within these communities. Lane communities are encouraged to employ vibrant and diverse colour combinations, while public housing communities should predominantly utilise warm hues to foster a child-friendly community ambiance. Conversely, commercial housing communities typically offer ample green spaces and open areas, albeit with a more introverted spatial layout. Building upon this foundation, these communities should strive to provide a higher quality colour environment conducive to children's well-being. For instance, outdoor playground floors can be painted according to children's colour preferences, while activity facilities should be adorned with colours tailored to the cognitive and preference profiles of children within the corresponding age groups. By aligning colour design with the unique characteristics and needs of each community type, a more enriching and child-friendly environment can be cultivated within urban neighbourhoods.

5. Conclusion

Children grow up in the urban environment, and the urban environment, especially the community environment, plays a decisive role in their growth. If the community environment is planned in a way that meets the needs of children, such a community environment will not only help children grow up but will also become a beautiful home for future generations. From the perspective of children, this study investigated children's colour preferences for outdoor playgrounds in communities and found the following results: (1) For the colours of outdoor playgrounds in communities, children least like achromatic colours, that is, black, white and grey (2) Children's colour preferences exhibit significant age differences. Specifically, as children's age increases, their preference for warm colours also increases, while their preference for colourful colours decreases; (3) Residential type is related to children's colour preference for the outdoor playgrounds in the community. Children living in lane communities preferred colourful colours than children in other community types, and are less willing to choose cool colours. Children in public housing communities are more willing to choose warm colours for outdoor playgrounds in the communities.

In light of these findings, this article proposes colour planning strategies informed by children's colour preferences and preference trends. By integrating these insights into community renewal initiatives, urban planners and designers can craft children's outdoor playgrounds that are visually captivating, culturally resonant, and emotionally enriching. By prioritising children's colour preferences, community activity spaces can be transformed into vibrant and welcoming settings that enhance the overall experience and well-being of children within the community.

Enhancing Social Interaction in Urban Spaces: The Role of Vertical Greening Systems in High-Density Areas

Xiaojie SHEN[1], **Feng YANG**[1]
[1]College of Architecture and Urban Planning (CAUP), Tongji University, Shanghai, China
2110280@tongji.edu.cn ; yangfeng@tongji.edu

Abstract: The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research, while intensifying urbanization presents growing challenges to the development of the nature in urban areas. The Vertical Greening System (VGS), an innovative approach that conserves land, emerges as a creative solution. However, its potential in enhancing social interactions remains under-explored. To bridge this gap, experiments were conducted to assess the impact of VGS on improving spatial quality, enhancing space attractiveness, and increasing pedestrians' willingness to walk, stay, and engage in social interactions. Results indicate that VGS serve as important visual attractors ang significantly enhances the visual attractiveness of urban spaces, leading to improved perceptions of environmental quality. This enhancement positively affects the affective experience of pedestrians, creating a more inviting atmosphere conducive to walk, stay, and socialize. Eye-tracking data shows that green elements serve as important visual attractors, suggesting that their strategic placement in urban design is critical to promoting social interaction.

Keywords: Vertical greening system, Environmental perception, Affective experiences, Social interaction.

1 Introduction

Continues urbanization has shaped oppressive streetscapes, leading to increased urban population and pressures of city life. The perceived overcrowding and increasing exposure to environmental stressors can significantly diminish individuals' evaluations of the built environment and their willingness to engage in outdoor activities. This, in turn, adversely affects both physical and mental health and reduces opportunities for social interaction, which are crucial for societal health(Zijlema et al., 2024, Luo and Jiang, 2022, Eizenberg and Jabareen, 2017).

The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research. Nature environments not only provide necessary relief from urban stress but also serve as catalysts for social interaction by offering welcoming and livelihood communal spaces for gatherings and recreational activities(Hartig et al., 2014, Kaźmierczak, 2013).

However, intensifying urbanization presents significant challenges to the development and maintenance of natural environments within urban areas, leading to their decline and uneven distribution across cityscapes. Additionally, changes in lifestyle and the accelerated pace of modern life increasingly restrict the time people spend in nature. As Fuller and Gaston (2009) noted, interactions between urban residents and nature are increasingly mediated by informal green spaces, such as streetscape greening and pocket gardens, rather than traditional, large green networks.

In this context, the Vertical Greening System (VGS) emerges as an innovative solution that conservatively uses land while integrating accessible green infrastructure within high-density areas. Several empirical and experimental studies have highlighted the psychophysiological benefits of VGS in urban settings(Chan et al., 2021, Elsadek et al., 2019). Also, the potential of VGS to enhance the attractiveness of urban spaces, increase footfall, and promote social

interactions has garnered increasing attention(Goel et al., 2022), while it remains under-researched and requires further scientific validation.

To address the existing knowledge gap, this study utilized a virtual reality (VR) experiment to evaluate the effects of various streetscape scenes, featuring different coverages of VGS, on individuals' environmental perception, affective experiences, and behaviours. The primary research questions explored were: 1) How does VGS in high-density open spaces affect perceived environmental quality and visual attraction? 2) How does VGS influences pedestrians' affective experiences in urban settings? 3) Does vertical greening enhance pedestrians' willingness to walk, stay, and participate in social activities within these environments?

2 Methods

2.1 Experiment design

A total of 5 streetscape VR scenes were created, each featuring the same building form but varying coverages of VGS, as detailed in Table 1. Each scene comprised 6 panoramic photographs rendered from different positions along the street model to comprehensively depict the street's characteristics. Each photograph was displayed for one minute and shown twice in VR experiment, as shown in Fig.1. Finally, rendered sequence frame images were used to create five 40-second streetscape video segments for post-experiment surveys.

Table 1. Characteristics of streetscape scenes in the 5 experimental groups(G) and 5 videos(V).

Experiment groups	G1/V1	G2/V2	G3/V3	G4/V4	G5/V5
Coverages of VGS in VR scenes (%)[1]	0	8	16	32	48

[1] The coverage of VG in streetscape scenes was quantified by calculating the percentage of the façade covered by VGS relative to the total façade area of the street block.

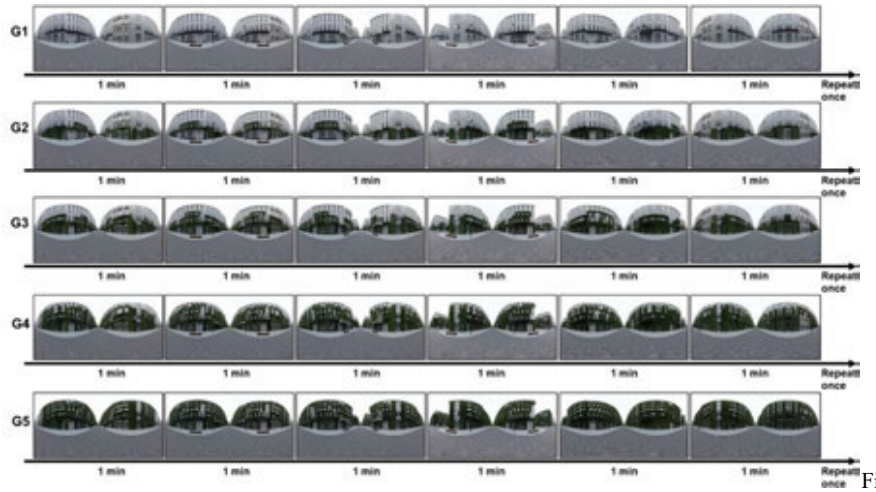

Fig.1. VR experimental stimulation design.

2.2 Participants

We recruited 30 healthy adults from Tongji University to participate in the study. Eligibility criteria required participants to be aged between 18 and 35. Individuals who had consumed tobacco, alcohol, drugs, or caffeinated beverages within 24 hours prior to the experiment, or who had engaged in intensive exercise within 6 hours of the experiment, were excluded. The study received approval from the Science and Ethics Committee of Tongji University, and all participants provided written informed consent before participating.

Prior to the experiment, we collected data on participants' socio-demographic background, chronic mental stress levels, nature connectedness, noise sensitivity, and other relevant covariates through a questionnaire. Participants were then approximately assigned to one of five experimental groups based on their survey responses, allowing for a rough control of these covariates across the groups. The descriptive statistics of their background information are presented in Table 2, and there were no statistically significant differences between 5 VR experiment groups.

Table 2. Descriptive statistics of the participants' background information.

Measures		**Participants Mean (± SD) or Number (percent, %)**					
		G1	**G2**	**G3**	**G4**	**G5**	**V1 to V5**
Gender	Male	4	3	3	3	3	16
	Female	2	3	3	2	3	14
Education	Bachelor	3	2	4	3	4	16
	Master	1	3	2	2	2	11
	Doctorate	2	1	0	0	0	3
Place of upbringing	Central urban district	4	3	2	3	2	15
	Suburbs or townships	2	2	4	2	4	14
	Rural area	0	1	0	0	0	1
Nature connectedness[1]		4.9 (±0.8)	5 (±1.31)	5.3 (±0.84)	5.4 (±0.67)	5.5 (±0.54)	5.27 (±0.85)
Noise sensitivity[2]		92.5 (±6.8)	88.5 (±18)	91.5 (±11)	78.6 (±12.8)	99.3 (±14)	91 (±14)
Chronic mental stress levels[3]		17.5 (±5)	14.2 (±6)	13.7 (±4.8)	12.2 (±7.7)	15.0 (±8.4)	15 (±6)

[1] **Nature connectedness**, describes a psychological state where individuals deeply care for and feel connected to nature, reflecting their innate biophilic tendencies(Capaldi et al., 2014). It serves as an indicator of the extent to which these tendencies are fostered or suppressed(Nisbet and Zelenski, 2013). Research shows that nature connectedness affects, moderates, and mediates the impact of nature exposure on mental health(Liu et al., 2022). In this study, we used 6-iterm and 7-point Nature-Relatedness Scale to measure an individuals' nature connectedness(Gong et al., 2024).

[2] **Noise sensitivity**, which refers to an individual's susceptibility and degree of reaction to everyday noises, was evaluated using the Weinstein Noise Sensitivity Scale (WNSS) in this study(Weinstein, 1978).

[3] **Chronic mental stress levels**, which have been shown to influence the mental effects of nature exposure on individuals(Shanahan et al., 2015), were assessed using the Perceived Stress Scale (PSS-10) in this study(Cohen et al., 1983).

2.3 Procedure

As illustrated in Figure 2, the experiment comprises three phases: preparation, testing, and post-testing.

In the preparation period, participants signed written informed consent and were equipped with the VR devices and biomonitoring sensors. Participants were then asked to close eyes and rest for 3 minutes while electro-dermal activity (EDA) data recording commenced. Subsequently, participants completed a self-reported scale to establish psychological baselines.

During the testing period, participants were divided into five groups and randomly assigned to one of five VR scenes. Initially, they were exposed to traffic noise for 5 minutes and completed a self-reported scale. This was followed by a 12-minute viewing of a VR scene along with the collection of eye-tracking data, after which they filled out the same self-reported scale again. Upon completion, all devices were deactivated and removed, and participants rated their level of discomfort during the VR test using a 5-point Likert scale (1 = very slightly or not at all, 5 = extremely).

After VR testing, participants were required to complete post-test surveys. They viewed five videos through an online link and immediately assessed perceived oppressiveness, environmental quality, visual preference, affective experience, and their willingness to engage in various outdoor activities in such environment. The videos were presented in a random order to prevent any sequence effects.

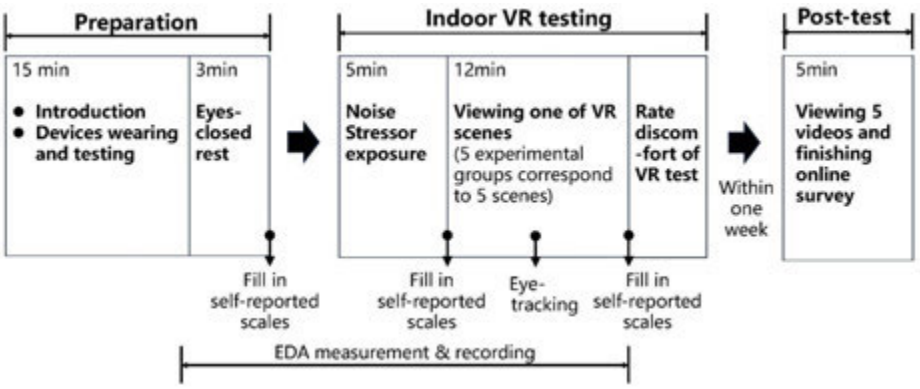

Fig.2. Experimental procedure.

2.4 Measures

2.3.1 Perceived oppressiveness and perceived environmental quality

Perceived oppressiveness (PO) is the subjective experience of feeling overwhelmed or dominated by a physical environment, negatively related to urban environmental quality(Asgarzadeh et al., 2012). Perceived environmental quality (PEQ) involves the subjective evaluation of a physical environment, encompassing an individual's multisensory perception of various environmental attributes. Both PO and PEQ have been identified as mediators in the relationship between an individual's environmental exposure and their psychophysiological responses and behaviours (Luo and Jiang, 2022).

We assessed participants' PO and PEQ in response to online videos by asking, "Do you feel oppressiveness?" and "How would you rate the visual quality/ safety level/ economic level of the street environment depicted in the video?", respectively. An 11-point VAS, ranging from 0 (very low) to 10 (very high), was utilized for these evaluations.

2.3.1 Visual attractiveness

Self-reported visual preferences for online streetscape videos and eye-tracking data collected during VR testing were used to assess the visual attractiveness of the scenes. After viewing the five streetscape videos, participants were asked to rank the videos on a 5-point scale from 1 to 5, where 1 indicates the least liked and 5 indicates the most liked, with scores increasing progressively based on preference. Additionally, eye-tracking data was utilized to analyse visual attention and identify hotspots within the visual stimuli.

2.3.3 Affective experience: psychological and physiological

As detailed in Table 3, the Self-Assessment Manikin (SAM) was employed to assess individuals' affective states through 9-point valence (from 1-unpleasant to 9-pleasant). In addition, individuals' physiological responses were measured using Skin Conductance Level (SCL), which represents individuals' arousal and stress level.

Table 3. Psychological and physiological measures.

Psychological and physiological measures		Description	Relationship with the stress level
SAM	Valence	Affective states	-
EDA	SCL (μS)	Arousal and stress level	Positive

2.3.4 Measures of outdoor behaviours

To measure individuals' outdoor behavioural intent, we asked participants, "How willing are you to visit, walk, stay, or engage in social activities in the street depicted in the online video?" We utilized an 11-point Visual Analog Scale (VAS) for responses, ranging from 0 (not at all willing) to 10 (very willing).

2.5 Statistical analysis

Environmental perception data, including self-reported Perceived Oppressiveness (PO), Perceived Environmental Quality (PEQ), visual preference, and behavioural intent, were collected via a within-subject online survey. Differences in environmental perception and intent data across the five online videos were compared using one-way repeated measures ANOVA for normally distributed data and the Friedman test for non-normally distributed data.

The affective psychophysiological data collected from a between-subject VR experiment design were analysed using one-way ANOVA for normally distributed data and the Kruskal-Wallis H test for non-normally distributed data to compare differences across five VR groups. Additionally, two-way ANOVA models with post-hoc pairwise comparisons were conducted to examine per-minute Skin Conductance Level (SCL) responses to the five VR scenes.

All data were presented as means, and for all comparisons, a p-value of less than 0.05 was considered statistically significant.

3 Results and discussion

3.1 Perceived oppressiveness (PO) and perceived environmental quality (PEQ)

As shown in Figure 3, the post-hoc tests indicated that the PO of V1, which had no VGS coverage, was significantly higher compared to V2 and V3. Conversely, the Perceived Environmental Quality (PEQ) of V1 was significantly lower than that of V2, V3, V4, and V5. This suggests that VGS can significantly enhance people's perceptions of street quality and reduce the oppressiveness of high-density streetscapes. However, it is important to note that when VGS coverage is excessively high, as in V4 and V5, the beneficial effects of reducing perceived oppressiveness in high-density streetscapes may diminish. As shown in Figure 4, the relationship between VGS coverage and PO is depicted by a U-shaped curve. Conversely, the relationship between VGS coverage and PEQ is represented by an inverted U-shaped curve.

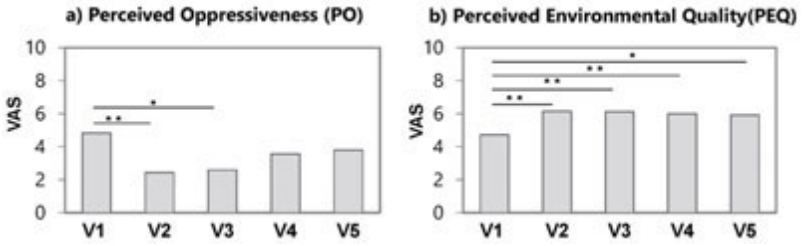

Fig.3. Participants' PO and PEQ across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

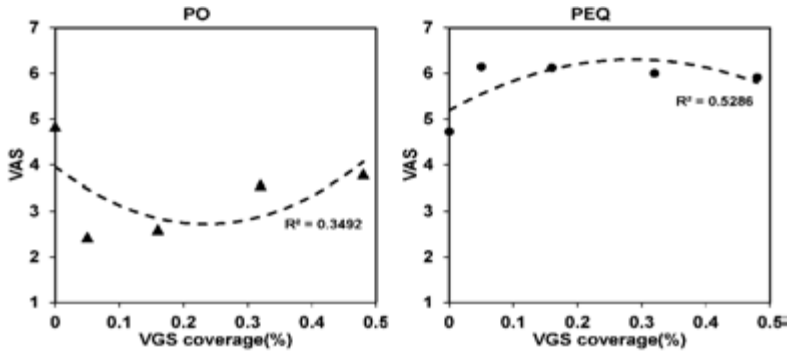

Fig.4. Patterns between VGS coverage and participants' PO & PEQ.

3.2 Visual attractiveness: visual preference and eye-catching factors

As shown in Figure 5, the coverage-response curve between VGS coverage and individuals' visual preference is depicted by an inverted U-shaped curve. Significant differences were observed in participants' visual preferences across five online streetscape videos with varying levels of VGS coverage. Specifically, preferences for V1, which had no VGS coverage, were lower compared to those with VGS coverage in V2, V3, V4, and V5. Statistically significant differences were noted between V1 and V2, V3, and V4. V3, which had the highest visual

preference scores, also showing a statistically significant difference from V5, which had the second-lowest scores.

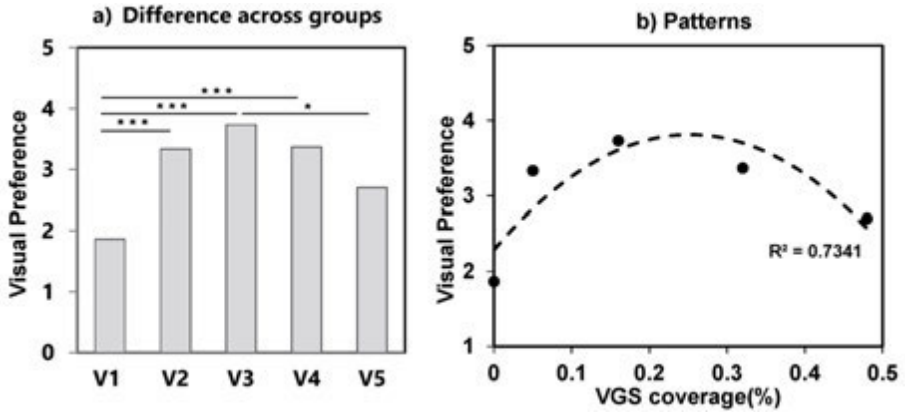

Fig.5. Participants' visual preference across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

After VR testing, eye-tracking hotspots were generated for five VR scene groups, namely, G1 to G5. As illustrated in Figure 6, participants in groups G1 (with no VGS) and G5 (with very high VGS coverage) tended to look straight ahead. They reported feeling oppressed by facades either devoid of greenery or heavily covered in greenery, mentioning that looking forward allowed them to see more sky. Conversely, in groups G2, G3, and G4—where vertical greening coverage was moderate—participants often turned their heads to appreciate the street facades, especially in G2 and G3, which had higher visual preference scores. This suggests that moderate VGS coverage can significantly enhance the visual appeal and of street facades.

G1 G2 G3 G4 G5

Fig.6. Participants' eye-catching factors across 5 VR scenes.

3.3 Affective experience

In this study, we utilized traffic noise to simulate the mental stress commonly experienced by pedestrians in high-density urban areas, where exposure to environmental stressors like heat and noise is prevalent. We specifically investigated how streetscapes with varying levels of VGS coverage influence the affective experiences of pedestrians after these stressor exposures.

Changes in psychological data (*Δ*Valence) and physiological data (*Δ*SCL) before and after experiencing VR scenes were used to assess the effects of VGS on the affective states of stressed participants. *Δ*valence and *Δ*SCL were calculated using equations (1) and (2) respectively and are summarized in Table 4.

Table 4. Measures of the effects of VGS on participants' affective state

Measures	Calculation

*Δ*Valence	(1) *Δ*Valence = Valence $_{\text{scene experience}}$ - Valence $_{\text{noise experience}}$ "+" represents affective improvement
*Δ*SCL (μS)	(2) *Δ*SCL = SCL $_{\text{scene experience}}$ - SCL $_{\text{noise experience}}$ "+" represents arousal and stress Increasing

3.3.1 Physiological data

Our analyses using paired t-tests and Wilcoxon signed-rank tests indicate a significant increase in participants' physiological stress levels following noise exposure. Additionally, ANOVA results reveal no statistically significant differences in physiological data among the five groups after exposure to the stressor. Participants' mean *Δ*SCL across five groups during are displayed in Figure 7and Figure 8. As Figure 7 indicates, statistically significant differences in ΔSCL across VR scenes begin to manifest after 6 minutes of exposure. Consequently, as illustrated in Figure 8, we compared the average ΔSCL after 6 minutes. The post-hoc tests reveal that the ΔSCL of G1 was significantly higher than those of G2, G3, and G4. The relationship between VGS coverage and ΔSCL is characterized by a U-shaped curve, suggesting that moderate VGS coverage can significantly enhance pedestrians' affective states.

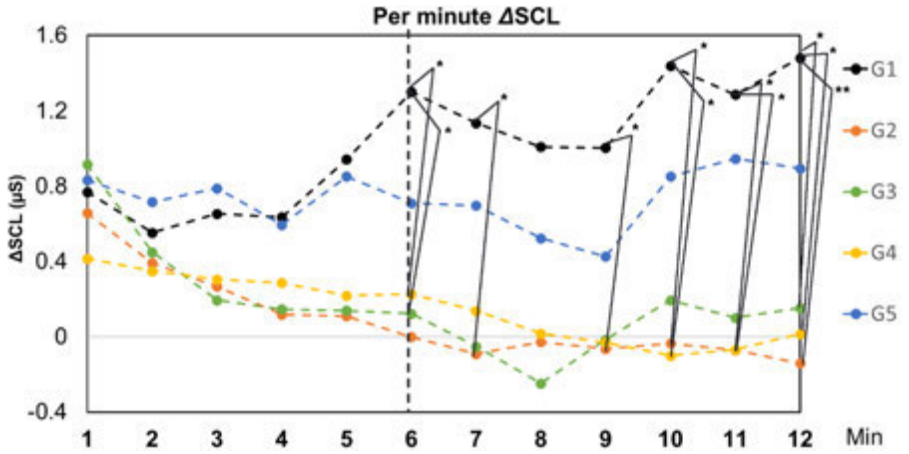

Fig.7. Pairwise comparisons of the estimated marginal means of per minute *Δ*SCL during VR scenes experiencing. *p < 0.05, **p < 0.01, ***p < 0.001.

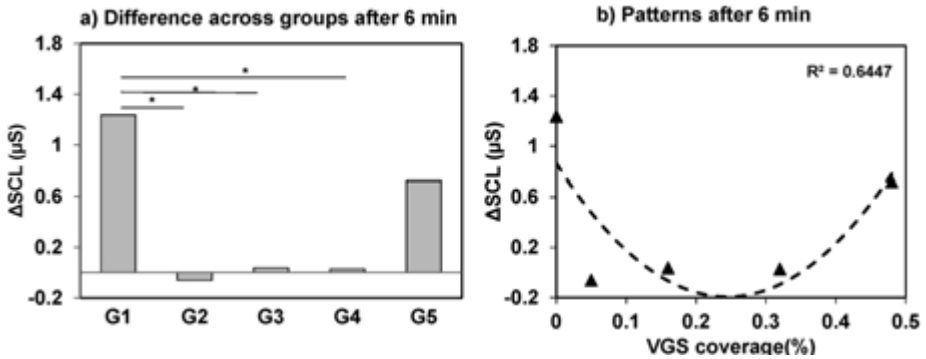

Fig.8. Patterns between the VGS coverage and participants' physiological response, *p < 0.05, **p < 0.01, ***p < 0.001.

3.3.2 Psychological data

As shown in Figure 9, although there were no statistically significant differences of psychological data. comparison between scenes still reflected important trends. The relationship between VGS coverage and Δvalence is characterized by an inverted U-shaped curve.

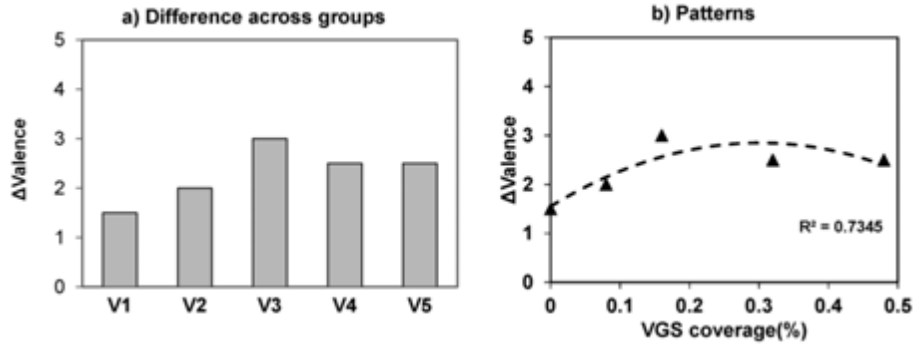

Fig.9. Participants' psychological effect across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

3.4 Outdoor behavioural intent

As depicted in Figures 10 and 11, individuals' willingness to visit, walk, and stay in V1 was significantly lower compared to V2, V3, and V4. Furthermore, the willingness to socialize in G1 was significantly lower than in V2 and V3. The relationship between VGS coverage and individuals' outdoor behavioural intent is characterized by an inverted U-shaped curve, indicating that both very low and very high levels of VGS coverage may decrease the desire to engage in outdoor activities, with moderate levels proving more conducive to positive behavioural intentions.

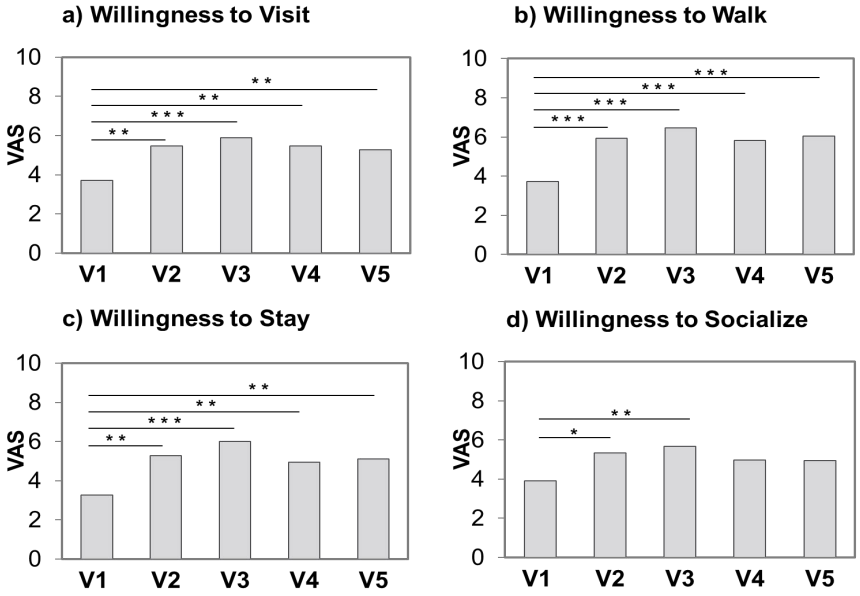

Fig.10. Participants' outdoor behavioural intent across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

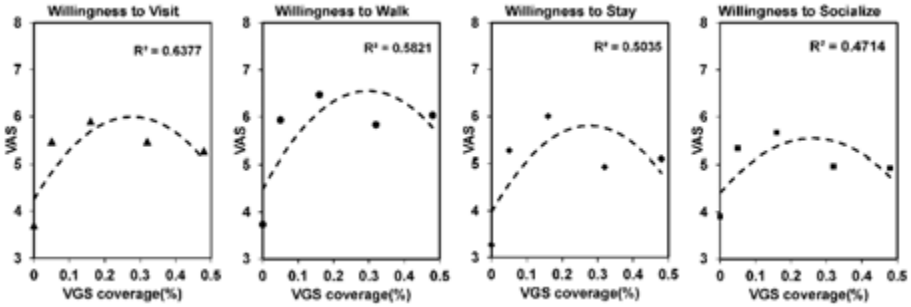

Fig.11. Patterns between the VGS coverage and participants' outdoor behavioural intent.

4. Conclusion

This study investigated the potential of VGS to enhance the attractiveness of urban spaces and promote social interactions. Results indicate that VGS serve as important visual attractors ang significantly enhances the visual attractiveness of high-density urban spaces, leading to improved perceptions of environmental quality. This enhancement positively affects the affective experience of pedestrians, creating a more inviting atmosphere conducive to walk, stay, and socialize. The relationships between VGS coverage and individuals' visual preference, perceived environmental quality and their outdoor behavioural intent are characterized by an inverted U-shaped curve, The relationship between VGS coverage and individuals'; the relationships between VGS coverage and individuals' perceived oppressiveness and stress level ware characterized by an inverted U-shaped curve. Eye-tracking data shows that green elements

serve as important visual attractors, suggesting that their strategic placement in urban design is critical to promoting social interaction.

Can care help conceptualise place futures? Exploring the potential of care as an analytical framework for understanding place qualities

Abstract
This paper explores how the concept of care can structure an analytical framework for understanding place qualities. Care is burgeoning as a major concept within the humanities and social sciences. Given its growing application in planning, it is timely to reflect on what the care concept contributes to understanding places and their possible futures. Following a review of the scholarly literature, this paper proposes an analytical framework based around five characteristics of care: (1) objects of care; (2) caring actors; (3) care practices, (4) care motivations; (5) care relations. The final part of the paper reflects on the potential of the care concept for imagining possible place futures.

Keywords
Care; place; futures; analytical framework

Full text

1. Introduction**:**

The future of the places we engage with – whether, to live, work, visit or use more indirectly concerns us on both personal and professional levels. A plethora of challenges: uncertainties brought by changes in climate, economy and social patterns destabilise long term planning goals. At the same time, planning efforts are asked to meet the needs of a diverse range of stakeholders. In this challenging planning climate, there is a clear need to reflect on and discuss how to cultivate place futures. A range of existing scholarship seeks to address this question, proposing an impressive range of methods and approaches to deliver sustainable futures. However, such efforts are plagued by the fact that the goals and underlying assumptions of how to realise place futures are not clear but at times undermine and contradict each other.

In this paper I use the term place futures to describe in a broad way all the things a place may come to be – whether by design or as a gradual unfolding of incremental, everyday practices. It is a deliberate choice in order to remain unaligned with the conceptual baggage carried by more established terms such as local development or place making. In writing about place futures, I recognise that the motivation for taking action in a place is often explicitly connected to realising a particular future. However, I also recognise that futures of places unfold without (or despite) deliberate interventions, motivated rather by a sense of connection to or concern about a place (Healey 2023). Finally, I use the term place futures to shift the focus from a particular end goal to provide space for seeing that sometimes futures aren't about change, but can equally be about maintaining and sustaining. After all, even a state of sustainability needs maintenance (Ringel, 2021).

It is also necessary to elucidate my perspective on what constitutes a place. Although theoretical definitions of place abound, in this paper I borrow the term 'place qualities' from Healey (2018) to refer to the constituent features of places. This is a relational understanding that casts places as 'loosely-structured assemblages of people and other species, material objects and meanings, action arenas, physical forms and flows, possibilities and memories, emotional attachments and moral values, connected to other times and spaces through complex and multiple webs of relations' (Healey, 2018, p. 67). This paper is not about any one specific place, but rather explores how the concept of care can contribute to how we understand places and conceptualise their possible futures.

Before examining what contribution care might make to how we conceptualise place futures, it is first necessary to review current approaches to cultivating place futures in theory and practice. To this end, the first section of this paper reviews some of the major strategies and approaches to delivering sustainable place futures and classifies the major assumptions on which they are founded. Drawing from the need to broaden our gaze and nuance our understanding beyond these assumptions, the second part of the paper reviews care literature to consider the utility of the care concept to planning. Drawing from this literature, I use five characteristics of care to structure an analytical framework for understanding place qualities. The final part of the paper reflects on the potential of the proposed framework and concludes with some broader thoughts about how care can help to conceptualise other possible place futures.

2. Categorising approaches to place futures

There are two core assumptions that underly approaches to place futures in planning theory and in practice. The first is the assumption that specific futures for places can be created or made. These approaches are characterised by goal-directed action, such as the socio-economic regeneration of a place through the construction of a new museum, or an improvement in social cohesion through a city branding initiative. By contrast, the second assumption rejects the notion of achieving predefined goals, arguing instead that places unfold or emerge over time. These two broad areas of literature are explored below.

2.1 Making futures

There is a plethora of terms that are used in the literature to describe approaches based on the idea of making or creating the future. This making perspective is founded on what Dupre (2019, p. 103) calls a 'determined before-after temporality'. That is, action in the place is taken with a predetermined idea of what the future should be after the intervention. This is not surprising, given the long history of planning to realise desired ends through socio-spatial interventions (Allmendinger, 2017).

One common term that describes structured approaches to realising place futures is place-making. Although poorly defined (Dupre, 2019; Courage, 2021a), place-making is generally recognised as an interdisciplinary field that has particular prominence within the fields of spatial and strategic planning and design, often within an urban development context. Examples of the types of activities structured place-making projects employ include the creation of a sense of place or belonging through the development of place images; physical interventions in space;

and creative initiatives (Dupre, 2019; Courage, 2021b). The wide range of activities that fall under place-making in the literature reflects a lack of consensus over what place-making is and may involve (Strydom, Puren and Drewes, 2018). Much of the regeneration literature also falls into this category, with focus ranging from waterfronts (Jones, 2017) to heritage assets (Wincott, Ravenscroft and Gilchrist, 2020).

Another common term is place branding. Likewise poorly defined (Kavaratzis and Ashworth, 2010; Vuignier, 2017), place branding can be broadly understood as an approach to spatial governance (Van Assche, Beunen and Oliveira, 2020). Place branding initatives differ in scope, from projects that emphasise city uniqueness and value using built heritage resources (Guzijan, 2018) to strategies for recovering after natural disaster (Gotham and Irvin, 2018).

Another common approach to achieving predefined place futures is culture-led development. This body of scholarship seeks to use cultural resources to attain various kinds of local development. It ranges for instance from investments in "capital C" cultural institutions such as museums (Heidenreich and Plaza, 2015), efforts to attract the "creative class" (Florida, 2003) and mobilisation of heritage assets for socio-economic development (Della Lucia and Segre, 2017; Kähkönen and Lähdesmaki, 2019).

The structure of these projects, by whichever term, also differ. Some are more formalised, with an emphasis on common processes (Alwaer and Cooper, 2019), whilst others focus on informal initiatives such as DIY urbanism (Krishnamurthy, 2018). Initiatives may be both individual and collective in nature (Dupre, 2019; Mengi, 2020), and are at times understood as a democratic process (Strydom, Puren and Drewes, 2018). In general, place-making initiatives are following a participative trend where inclusion and participation of the local community is important, and much literature is dedicated to community centric, collaborative processes (Strydom, Puren and Drewes, 2018; Mengi, 2020; Courage, 2021a). This at times includes an emhasis on everyday elements of place-making (Dyck, 2005; Platt, 2021; Vitiello and Willcocks, 2021). The same is true in place branding, where scholars see the need for inclusive, bottom-up processes (Colomb and Kalandides, 2010; Insch and Florek, 2010; Trueman *et al.*, 2010; Brown, 2018; Lucarelli, 2018a; Warnaby, Koeck and Medway, 2018). The importance of local participation is likewise recognised in culture-led development (Sacco and Crociata, 2013).

Whilst the pursuit of a desired future state unites the otherwise diverse body of literature above, the actual goals of these approaches differ widely. Goals of place-making include the improvement of public spaces and community life (Krishnamurthy, 2018); social and spatial justice (Borrup, 2021; Courage, 2021a); environmental sustainability (McKeown, 2021); and economic development and growth (Lima and Jones, 2021). Place branding likewise shares a strong goal orientation (Guzijan, 2018) for economic development (Campelo, 2017), spatial development and physical place making (Therkelsen, Halkier and Jensen, 2010; Oliveira, Van Assche and Beunen, 2021). Place branding efforts may also aim at social inclusion (Eisenschitz, 2018) and community cohesion (Stoica *et al.*, 2021).

Although these approaches clearly aim to improve the future of places in social, economic and ecological ways, there have been a number of criticisms levelled at such initiatives. Place branding in particular has been critiqued as contributing to a neo-liberal transformation of society (Friedmann, 2016; Eisenschitz, 2018; Lucarelli, 2018b) that needs to address issues of power and inclusion (Vuignier, 2017; Kavaratzis, Giovanardi and Lichrou, 2018; Medway, Warnaby and Byrom, 2021). The metrics focus of place branding may also lead it to be a reductive process (Medway et al 2021) that leads to a greater homogenisation of places (Lichrou, Kavaratzis and Giovanardi, 2018).

More generally there is critique of the very idea that places can be "made". These critics argue that places are never new constructions, but rather evolutions of what they were before. The next section reviews literature advocating this perspective.

2.2 Emerging futures

Although the majority of literature falls into the category of goal-oriented approaches outlined above, there is a sizable body of literature that advocates for a different approach to place futures. Rather than setting out with any particular future in mind, or a goal to change the place in some measurable way, scholars in this body of literature argue that place futures emerge in an unplanned way.

To understand this perspective it is useful to review Rauws, de Roo and Zhang's (2016) critique of goal-based planning and its underlying conception of reality. They (2016, p. 244) identify two paradigms of planning: a 'command and control' factual reality where 'planners are…viewed as creators of place…based on facts and predictions', and a communicative planning approach where reality is agreed and consenusal. Both paradigms are critiqued for understanding reality as a 'fixed product in time' (Rauws, de Roo and Zhang, 2016, p. 244). In their view, such an understanding limits the capacity of planning to respond to uncertain and complex planning contexts, and remains in opposition to more emergent, adaptive and autonomous behaviours (Rauws, de Roo and Zhang, 2016, p. 244). To move beyond this linear perspective in planning, they propose that planners need to 'explore alternative views on reality and different ways of guiding spatial transformations' which recognise processes of emergence and employ a relational understanding of space and time (Rauws, de Roo and Zhang, 2016, p. 244).

One alternative perspective is a non-linear planning reality in which direct causal relationships between variables of change are lacking, and where change occurs through the interaction of a system and subsystems and their contextual environment (de Roo, 2012, pp. 142; 151). This perspective emphasises the role of time, where, in contrast to the static perspectives underlying goal-oriented planning, present 'a world in flow, full of discontinuous change' (de Roo, 2012, p. 135). This alternative notion of reality underlies post-structuralist planning perspectives that focus on 'processes of becoming'; poststructuralist planners are interested in processes of change rather than predefined end goals (Boonstra and Rauws, 2021, p. 7). Indeed, in what Boelens and de Roo (2016, p. 43) identify as a 'planning of undefined becoming', the ultimate goal is not known beforehand. Rather 'uncertainty prevails', and futures 'co-evolve' through the reciprocal interaction of actors and their surroundings, and is shaped by specific historical-spatial contexts (Boelens and de Roo, 2016, pp. 43; 48). A core feature of this perspective is the view that meaning is multiple and relational – this means that 'even notions of a good, just or sustainable society, are never closed but always open' (Boelens and de Roo, 2016, p. 44).

Such a post-structuralist perspective has been applied in a place-making context by Dovey (2010). Writing against a concept of place as 'static', or subject to deliberate place-making efforts, Dovey (2010, p. 3) argues that places should instead be understood as being in 'states of becoming'. Platt and Medway (2022, p. 105) likewise critique the idea of 'interventionist' place-making, employing a post-structuralist perspective to emphasise the 'ongoing, always emerging, and never finished presence of the urban placemaking'. This illustrates a different underlying assumption about how place futures come to be – they unfold from the 'middle' and are always in process, rather than having clear before and after states driven by predefined goals.

2.3 Differing positions: navigating approaches to place futures

The exploration of literature above shows that there are different assumptions when it comes to understanding how place futures come to be. Whilst they fall into two broad categories (structured and emergent), there is a further complication: the goals and methods of attaining place futures also differ. To further complicate matters, a tendency for disciplinary silos makes full sharing of knowledge difficult. Many scholars point to this problem, arguing that the 'intent and outcomes' of placemaking may be 'wholly different and in opposition' (Courage, 2021b, pp. 4–5). That such differences can undermine the best efforts of practitioners involved in cultivating place futures is clear in the following statement from Legge (2021, p. 391):

> 'I have never met anyone involved in city-making who does not want to make good cities that support happy and healthy citizens. Of course, we all do this through a different lens.The planner focusses on systems of land use and connectivity, the transport engineer believes that making it fast and easy to get around makes a good city; the architect via beautiful buildings, the social planner through equitable access to services and amenity, the landscape architect will use nature as their tool. Our professional expertise is our strength, but it can also be our limitation – if all we have is a hammer, then all we see are nails (Maslow, 1966)...It is often the differences in professional priorities and in the range of scales involved in place planning that create the most significant barriers to successful placemaking.'

In short, there is a lack of agreement about how (and if) particular place futures should be cultivated. To address this challenge, and building on the metaphor in above, I argue that a different pair of glasses is required; a lens that will help us see the qualities of places more holistically. We need different conceptual glasses in order to ask different questions: what matters in places, and to whom? What motivates action in places? How might we arrive at a more nuanced understanding of the relationships between place qualities, and learn to see beyond boundaries and foci conditioned by fields of expertise and norms of practice? The next section of the paper explores the potential of the concept of care to provide such a lens.

3. Possibilities of care

Care is burgeoning as a major concept within the humanities and social sciences. Developed originally from feminist scholarship within traditional care contexts, care is increasingly being mobilised as a concept for thinking and analysing in contexts including science-technology studies (Puig de la Bellacasa, 2017), heritage studies (Veldpaus and Szemző, 2021) and planning (Davoudi, 2023). Within these contexts the uses of care are diverse, ranging from speculative thinking to identifying practices of care. Given its growing application in planning and fields relevant to place futures more broadly, it is timely to reflect on what the care concept contributes to understanding places and their possible futures.

The next section of this paper reviews current understandings of care in the literature. Drawing from this scholarship, I use care to develop an analytical framework for identifying place qualities. This lays the foundation for a reflection on what other parts of the care concept may be helpful in conceptualising possible place futures.

3.1 Current understandings of care

A review of the care literature indicates that it is a rapidly emerging field. Although common agreement about the scope and meaning of the concept is lacking, it is possible to identify three broad themes: care as a conceptual model, care as practice, and care as a way to foreground relationality. These categories are not mutually exclusive, but often intersect.

3.1.1 Care as a conceptual model

One major way the care concept is utilised in the literature is as a conceptual model. Literature using care in this way spans fields as diverse as nursing (Cloyes, 2002) to the green humanities (Bernau, 2023). The review identified three major uses of care as a conceptual model.

3.1.1.1 Care as a model for thought/action

Care here is used to reframe or rethink through already recognised issues and challenges. This includes, for instance, reframing heritage conservation as a practice of care in order to broaden understandings of the outcomes of conservation (Veldpaus and Szemző, 2021), and exploring expressions of care in hedgerows in order to think though landscape maintenance practices in times of ecological crisis (Bernau, 2023).

3.1.1.2 Speculative care

Used speculatively, care provides a way to imagine alternatives to the current status quo. A widely cited perspective is articulated by Puig de la Bellacasa (2017) who uses care speculatively to question how we might live 'as well-as-possible' in more-than-human worlds. Speculative perspectives arise in critique of certain existing conditions, such as Jacobs and Wiens's (2023, p. 12) interest in the possibilities of care for creating possibilities to live 'in refusal of systems that perpetuate social and ecological injustices'.

3.1.1.3 Care as a critical lens

Care is also employed as a critical lens for analysing contemporary problems. Examples include efforts to further understanding of the problems facing urbanisation (Gabauer *et al.*, 2021), for addressing fast paced societal change (Dyck, 2005) or considering the skillsets required for transitioning to low carbon futures (Carr, 2023).

3.1.2 Care as practice

Care is also referred to in the literature as a set of practices. This is often not separate from drawing on a conceptual understanding of care, and in most instances complements it. The types of care practices that are included in the literature differ widely. They include the more traditional domains of care work in health and dependency contexts within domestic and institutional settings (Tronto, 1998; Cloyes, 2002; Dyck, 2005; José, 2016). More recently however care is being taken up to embrace a wider range of acts of taking care – of humans (Dombroski *et al.*, 2023), more-than-humans (van Dooren, 2014; McConnell, 2023) and their wider environments (Till, 2012; Veldpaus and Szemző, 2021; Woodhead, 2023). It is worth noting that these categories of what is looked after are often blurred, and care for one area is often seen as bringing benefits for others (Bartel, Hine and Morgan, 2020).

One area that emerges from the literature is an understanding of maintenance and repair as forms of caring practice. These concepts appear for instance in the widely cited definition of care by Tronto and Fischer as 'a species activity that includes everything that we do to maintain,

continue, and repair our world' (Fischer and Tronto, 1990 in Tronto, 1998, p. 17). Maintenance is a practice of keeping something the way it is – necessary for instance in the context of growing things such as hedges (Bernau, 2023) or to arrest decay, such as in the context of cultural heritage preservation (Veldpaus and Szemző, 2021). Although maintenance is often discussed in the same context as repair, the concepts are ultimately different. Carr (2023) points to the different temporalities of the two practices, seeing maintenance as anticipatory action required to prevent something happening in the future. Repair on the other hand is retrospective, seeking to restore order following breakdown (Carr, 2023, p. 226). It is important to note that decisions about how and what is maintained are informed by underlying values – for instance, "mow and blow" landscape maintenance may value crop yield over socio-ecological relations (Jacobs and Wiens, 2023, p. 9), or prioritising tidy hedgerows through mechanical trimming may harm biodiversity (Bernau, 2023).

3.1.3 Care and relationality

A key feature of the care concept is its focus on relationality. Evident in the care literature is the notion that all care is relational – care is not an action that occurs on its own but rather always in relation to others – care is always interdependent, it is "care-with" (Tronto, 2013). Whilst much of the care scholarship focusing on relationality has drawn attention to more-than-human relationships (Puig de la Bellacasa, 2017; Dombroski *et al.*, 2023; Jacobs and Wiens, 2023; McConnell, 2023), other scholars seek to recenter human intentionality in regards to care (Huijbens, 2023).

3.1.4 Normative and non-normative trends

Care is often employed to make a normative argument. Some of this literature emphasises the politico-ethical obligation to care (van Dooren, 2014; Puig de la Bellacasa, 2017; Jacobs and Wiens, 2023). Others use care to critique neoliberal practices (Gabauer *et al.*, 2021; Kopitz, 2022) drawing particularly from Tronto's (2017) argument for care as an alternative ontology to neoliberalism. Although acknowledging the body of care literature in this vein, this paper does not take such a normative position.

3.1.5 Care in planning

It is clear that care is becoming an important concept in a planning context. Although not explicitly theorised, Healey (2018: 67) uses the care concept to discuss a relational approach to place governance. This understanding lays the foundation for explicating that people care about different qualities of place, necessary for a place-based politics and improved place governance. Healey (2023) further utilises care in her analysis of citizen-led planning initiatives for local development in Wooler, England. Here again, care is not explicitly theorised, but rather functions to illustrate how collective care about place and its current challenges mobilsed action in the form of self-organisation and citizen-led initatives. It becomes clear that care shows where different community actors have a shared interest or concen (they "care about" an issue) and that this becomes mobilsed in action ("care for"). The caring efforts are in some way about shaping the future of the place, aiming at different forms of local development through grassroots activity.

Other uses of care in the planning scholarship emerges out of dissatisfaction with neoliberal planning contexts and desires to imagine different possible futures. Davoudi (2023) introduces care as an ethical, relational and political concept that he uses to discuss a prefigurative planning approach. A critique of the underlying assumptions of the neoliberal system underlies his

argument, seeing prefigurative planning as a way to negate given assumptions and imagine alternatives to the status quo. Although not fully defined, Davoudi points to relations of (un)care as underlying prefigurative planning in everyday spatial practices.

Gabauer et al (2021) also employ the concept of care to examine the production of urban space through (un)caring practices and relationships. In doing so, they position care as practice, relation and ethics. In particular, they point to the need to recognise contexts of uncare produced by the neoliberal paradigm, and argue for the potential of care as an analytical scope for understanding the urbanising world. Like Davoudi (2023) and Healey (2023), they point to the importance of paying attention to everyday urban life. Furthermore, they go beyond care as a frame for analysis but see it as having potential to alter 'social conditions' (Gabauer *et al.*, 2021, p. 7)

I stand alongside these scholars in seeing the potential of care to further our undertanding of places as complex assemblages of everyday life, shaped by the relations between people and their environments. However, unlike Davoudi (2023) and Gabauer et al (2021) I refrain from presenting a critique of current planning contexts. Instead, I stand back in order to provide a broader perspective on the different approaches to cultivating place futures. Furthermore, I draw from major trends in the care literature to propose an analytical framework for understanding place qualities, which has potential to support thinking about possible place futures. The next section of the paper introduces this analytical framework of care, before briefly reflecting on the broader utility of care in thinking through place futures.

4. An analytical framework of care

To explore how planning might benefit from the care concept, the next section of the paper proposes an analytical framework built from five characteristics of care: (1) objects of care; (2) caring actors; (3) care practices, (4) care motivations; and (5) care relations. Taken together, these characteristics have the potential to structure a more holistic understanding of place qualities.

In presenting this framework, I build on the efforts of scholars such as Tronto (2017) to unpack the care concept. Tronto (2017) identifies five phases of care, which explains the shift from caring *about* something (a noticing of needs) to caring *for* something (practices of delivering and receiving care). Tronto's (2017) understanding of care is also caring *with*, in relations with others. The framework articulated below approaches care in a different way. Instead of identifying phases of care, the proposed framework functions as a tool for mapping the qualities of a place, and their interrelationships, in a broad way. Such a holistic understanding is a prerequisite for conceptualising possible place futures, and has potential to extend the lenses through which we currently conceptualise place futures.

It should be noted that this framework is intended to be applied to places in particular. As Tronto (2017, p. 33) notes, care 'is always contextual and, as a result, non-essentialist…focusing on care requires much attention to the precise details of the situation'. Accordingly, this framework has greatest utility when applied to places in specific moments in time and space.

4.1 Care characteristics for analysing place qualities

(1) Objects of care

The first characteristic of care that has utility in structuring analysis of place qualities is the recognition that there are different objects of care. By object of care, I mean that for which care is given. It is evident from the care literature that a wide range of people, non-humans, material objects, and physical environments can be objects of care. Furthermore, the selection of what is worthy of care is underpinned by socio-cultural and professional values (Healey, 2018; Harrison, 2020; Bernau, 2023). Identifying that for which care is given is applied in a heritage studies context by Veldpaus and Szemző (2021) to question which histories, stories and aspects of the historic environment are preserved through the practice of heritage conservation. I propose that such a technique has utility more broadly in identifying the widest possible spectrum of place qualities that receive care, including people, material things, activities, intangible qualities, and the physical environment.

In particular, broadening what we identify as objects of care can provide a way to break out of specific lenses shaped by fields of expertise that condition what is seen as valuable in places and worthy of carrying into the future. Given the implication of values in determining objects of care, such a broadening also widens our understanding of the values at stake in cultivating place futures.

(2) Caring actors

The second characteristic of care useful to this analytical lens is the recognition that the capacity to care about and for qualities of place is not restricted to experts (be they planners, place branders, heritage managers or other professional actors) but rather open to anyone who engages with place, including the full range of civil society. Although most of the time it is actors who are explicitly involved in efforts to realise place futures (for example city planners and self-organised citizen groups) that receive analytical attention, the growing body of evidence for the importance of everyday practices shows that even actors who are not part of deliberate efforts to realise place futures nonetheless play a role in the way place futures unfold (Carr, 2023). Furthermore, a focus on caring actors opens up the possibility to consider the role that more-than-human actors play in unfolding place futures (Puig de la Bellacasa, 2017; Dombroski *et al.*, 2023).

(3) Care practices

It is clear from the literature that there are different ways to care about place futures. Practices of care range widely, from looking after elderly people to trimming hedgerows (Tronto, 1998; Bernau, 2023). It is also evident from the first part of the paper that different fields of expertise endorse different practices for realising place futures. Incorporating an analysis of care practices into the framework provides a way to identify these practices and see where they may be conflictual or complementary. Furthermore, examining care practices shows that care is not universally “good” or “good for all” (Puig de la Bellacasa, 2017), and that care for one thing might be at the expense of another (van Dooren, 2014). Like care objects, care practices are motivated by different values, and through their implementation give rise to different possible futures.

(4) Care motivation

In order to nuance our understanding of place qualities it is necessary to examine the motivations behind why care is given, and ask what end does giving care seek to achieve? Like objects of care, care motivation is related to values. However, where objects of care is mainly care *about* something, care motivation is what shifts it into care *for* by motivating a practice or action of care. Such an interrogation can enrich our understanding of places by allowing us to identify where different actors care for the same object, but for different reasons. As such it has potential in identifying value conflicts in place.

(5) Care relations.

An important contribution that care can bring to understanding place qualities is its focus on relationality. Many scholars point to the fact that there is a interdependence of care not only between human actors, but also the objects they care for (Tronto, 2017; Gabauer *et al.*, 2021; Davoudi, 2023; Jacobs and Wiens, 2023). This is particularly important in nuancing our understanding of the factors that shape the selection of objects of care and how actors work together (or not) to care for them. Furthermore, knowing and thinking are themselves 'inconceivable without a multitude of relations that also make possible the worlds we think with' (Puig de la Bellacasa, 2012, p. 2). Recognising the wider relations – such as norms of professional practice - that condition our approach to place futures can help us to identify and reflect upon the types of place futures that are considered desirable and possible.

5. Discussion: what do we gain when we use care?

The notion of using care to structure analysis is not new. Indeed other scholars also use care to understand the complexities of place (Healey 2023; Gabauer et al 2021). However, the framework proposed above differs in that it provides a structured approach that is explicitly derived from characterisitcs of the care concept present in previous scholarly work. In this way it contributes to development of the care concept in a planning context.

In addition, the proposed framework has potential to address the problem identified in the first part of this paper: that a lack of shared understandings and different goals, assumptions and practices can oppose and undermine efforts to cultivate place futures. In this sense I follow from Dyck (2005, pp. 235–6) in recognising the potential of care in 'chipping away at sub-disciplinary borders' and realising 'analyses that can bring together the economic, political, social and cultural in understanding the rapid changes of contemporary society'. Employing care as set out in the analytical framework above can facilitate a structured and nuanced identification of place qualities and the values and relationships underlying their care. As such care provides the possibility to broaden our understanding of which qualities of place are important in the realisation of place futures beyond approaches conditioned by specific fields of expertise and norms of practice.

In addition to its utility in structuring an understanding of place qualities, the care concept has further potential in conceptualising the kinds of place futures that are possible or permissible. Harrison (2020) recognises that different practices realise specific futures. The first part of the paper identified two broad approaches to cultivating place futures – structured, goal oriented approaches and post-structrualist emergent ones. Care can help us to think through other possibilities. For instance, maintenance is commonly identified as a practice of care (Bernau, 2023; Carr, 2023; Dombroski *et al.*, 2023). Focussing on maintenance can help shift the point of focus in efforts to cultivate place futures. Rather than striving to achieve particular goals, or

manage emerging transitions, care can help us to see where change is less of a driving factor; sometimes what is needed is a maintenance of what already is.

6. Conclusion

This paper has explored the utility of the care concept in a planning context through proposing an analytical framework structured by five characteristics of care. A brief reflection on other qualities the care concept may help us see, such as place futures centered around maintenance rather than change suggests further potential for the development of the concept in a planning context. Further work is required to test the proposed analytical framework and explore further benefits of applying care in conceptualising place futures.

Enhancing Social Interaction in Urban Spaces: The Role of Vertical Greening Systems in High-Density Areas

Xiaojie SHEN*[1], Feng YANG[1]
[1]College of Architecture and Urban Planning (CAUP), Tongji University, Shanghai, China
2110280@tongji.edu.cn ; yangfeng@tongji.edu

Abstract: The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research, while intensifying urbanization presents growing challenges to the development of the nature in urban areas. The Vertical Greening System (VGS), an innovative approach that conserves land, emerges as a creative solution. However, its potential in enhancing social interactions remains under-explored. To bridge this gap, experiments were conducted to assess the impact of VGS on improving spatial quality, enhancing space attractiveness, and increasing pedestrians' willingness to walk, stay, and engage in social interactions. Results indicate that VGS serve as important visual attractors and significantly enhances the visual attractiveness of urban spaces, leading to improved perceptions of environmental quality. This enhancement positively affects the affective experience of pedestrians, creating a more inviting atmosphere conducive to walk, stay, and socialize. Eye-tracking data shows that green elements serve as important visual attractors, suggesting that their strategic placement in urban design is critical to promoting social interaction.

Keywords: Vertical greening system, Environmental perception, Affective experience, Social interaction.

1 Introduction

Continues urbanization has shaped oppressive streetscapes, leading to increased urban population and pressures of city life. The perceived overcrowding and increasing exposure to environmental stressors can significantly diminish individuals' evaluations of the built environment and their willingness to engage in outdoor activities. This, in turn, adversely affects both physical and mental health and reduces opportunities for social interaction, which are crucial for societal health(Zijlema et al., 2024, Luo and Jiang, 2022, Eizenberg and Jabareen, 2017).

The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research. Nature environments not only provide necessary relief from urban stress but also serve as catalysts for social interaction by offering welcoming and livelihood communal spaces for gatherings and recreational activities(Hartig et al., 2014, Kaźmierczak, 2013).

However, intensifying urbanization presents significant challenges to the development and maintenance of natural environments within urban areas, leading to their decline and uneven distribution across cityscapes. Additionally, changes in lifestyle and the accelerated pace of modern life increasingly restrict the time people spend in nature. As Fuller and Gaston (2009) noted, interactions between urban residents and nature are increasingly mediated by informal green spaces, such as streetscape greening and pocket gardens, rather than traditional, large green networks.

In this context, the Vertical Greening System (VGS) emerges as an innovative solution that conservatively uses land while integrating accessible green infrastructure within high-density areas. Several empirical and experimental studies have highlighted the psychophysiological benefits of VGS in urban settings(Chan et al., 2021, Elsadek et al., 2019). Also, the potential of VGS to enhance the attractiveness of urban spaces, increase footfall, and promote social

interactions has garnered increasing attention(Goel et al., 2022), while it remains under-researched and requires further scientific validation.

To address the existing knowledge gap, this study utilized a virtual reality (VR) experiment to evaluate the effects of various streetscape scenes, featuring different coverages of VGS, on individuals' environmental perception, affective experiences, and behaviours. The primary research questions explored were: 1) How does VGS in high-density open spaces affect perceived environmental quality and visual attraction? 2) How does VGS influences pedestrians' affective experiences in urban settings? 3) Does vertical greening enhance pedestrians' willingness to walk, stay, and participate in social activities within these environments?

2 Methods

2.1 Experiment design

A total of 5 streetscape VR scenes were created, each featuring the same building form but varying coverages of VGS, as detailed in Table 1. Each scene comprised 6 panoramic photographs rendered from different positions along the street model to comprehensively depict the street's characteristics. Each photograph was displayed for one minute and shown twice in VR experiment, as shown in Fig.1. Finally, rendered sequence frame images were used to create five 40-second streetscape video segments for post-experiment surveys.

Table 1. Characteristics of streetscape scenes in the 5 experimental groups(G) and 5 videos(V).

Experiment groups	G1/V1	G2/V2	G3/V3	G4/V4	G5/V5
Coverages of VGS in VR scenes (%)[1]	0	8	16	32	48

[1] The coverage of VG in streetscape scenes was quantified by calculating the percentage of the façade covered by VGS relative to the total façade area of the street block.

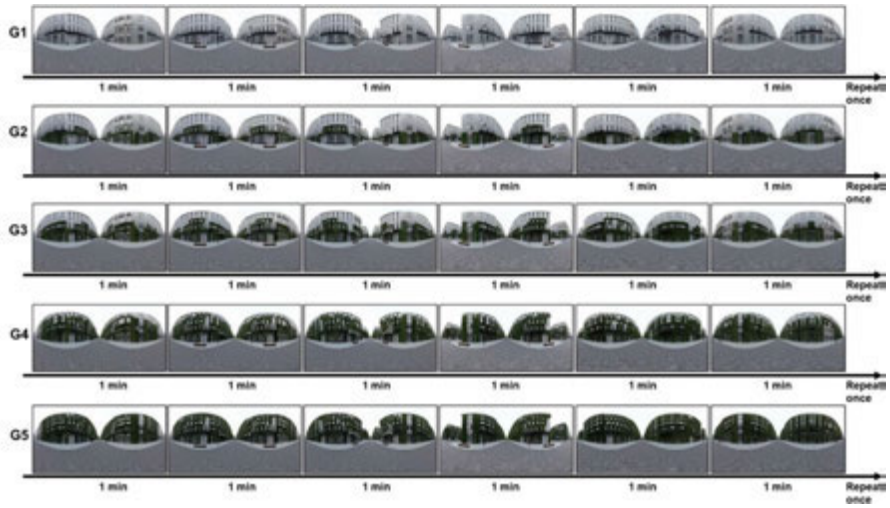

Fig.1. VR experimental stimulation design.

2.2 Participants

We recruited 30 healthy adults from Tongji University to participate in the study. Eligibility criteria required participants to be aged between 18 and 35. Individuals who had consumed tobacco, alcohol, drugs, or caffeinated beverages within 24 hours prior to the experiment, or who had engaged in intensive exercise within 6 hours of the experiment, were excluded. The study received approval from the Science and Ethics Committee of Tongji University, and all participants provided written informed consent before participating.

Prior to the experiment, we collected data on participants' socio-demographic background, chronic mental stress levels, nature connectedness, noise sensitivity, and other relevant covariates through a questionnaire. Participants were then approximately assigned to one of five experimental groups based on their survey responses, allowing for a rough control of these covariates across the groups. The descriptive statistics of their background information are presented in Table 2, and there were no statistically significant differences between 5 VR experiment groups.

Table 2. Descriptive statistics of the participants' background information.

Measures		Participants Mean (± SD) or Number (percent, %)

	Suburbs or townships	2	2	4	2	4	14
	Rural area	0	1	0	0	0	1
Nature connectedness[1]		4.9 (±0.8)	5 (±1.31)	5.3 (±0.84)	5.4 (±0.67)	5.5 (±0.54)	5.27 (±0.85)
Noise sensitivity[2]		92.5 (±6.8)	88.5 (±18)	91.5 (±11)	78.6 (±12.8)	99.3 (±14)	91 (±14)
Chronic mental stress levels[3]		17.5 (±5)	14.2 (±6)	13.7 (±4.8)	12.2 (±7.7)	15.0 (±8.4)	15 (±6)

[1] *Nature connectedness*, describes a psychological state where individuals deeply care for and feel connected to nature, reflecting their innate biophilic tendencies(Capaldi et al., 2014). It serves as an indicator of the extent to which these tendencies are fostered or suppressed(Nisbet and Zelenski, 2013). Research shows that nature connectedness affects, moderates, and mediates the impact of nature exposure on mental health(Liu et al., 2022). In this study, we used 6-iterm and 7-point Nature-Relatedness Scale to measure an individuals' nature connectedness(Gong et al., 2024).

[2] *Noise sensitivity*, which refers to an individual's susceptibility and degree of reaction to everyday noises, was evaluated using the Weinstein Noise Sensitivity Scale (WNSS) in this study(Weinstein, 1978).

[3] *Chronic mental stress levels*, which have been shown to influence the mental effects of nature exposure on individuals(Shanahan et al., 2015), were assessed using the Perceived Stress Scale (PSS-10) in this study(Cohen et al., 1983).

2.3 Procedure

As illustrated in Figure 2, the experiment comprises three phases: preparation, testing, and post-testing.

In the preparation period, participants signed written informed consent and were equipped with the VR devices and biomonitoring sensors. Participants were then asked to close eyes and rest for 3 minutes while electro-dermal activity (EDA) data recording commenced. Subsequently, participants completed a self-reported scale to establish psychological baselines.

During the testing period, participants were divided into five groups and randomly assigned to one of five VR scenes. Initially, they were exposed to traffic noise for 5 minutes and completed a self-reported scale. This was followed by a 12-minute viewing of a VR scene along with the collection of eye-tracking data, after which they filled out the same self-reported scale again. Upon completion, all devices were deactivated and removed, and participants rated their level of discomfort during the VR test using a 5-point Likert scale (1 = very slightly or not at all, 5 = extremely).

After VR testing, participants were required to complete post-test surveys. They viewed five videos through an online link and immediately assessed perceived oppressiveness, environmental quality, visual preference, affective experience, and their willingness to engage in various outdoor activities in such environment. The videos were presented in a random order to prevent any sequence effects.

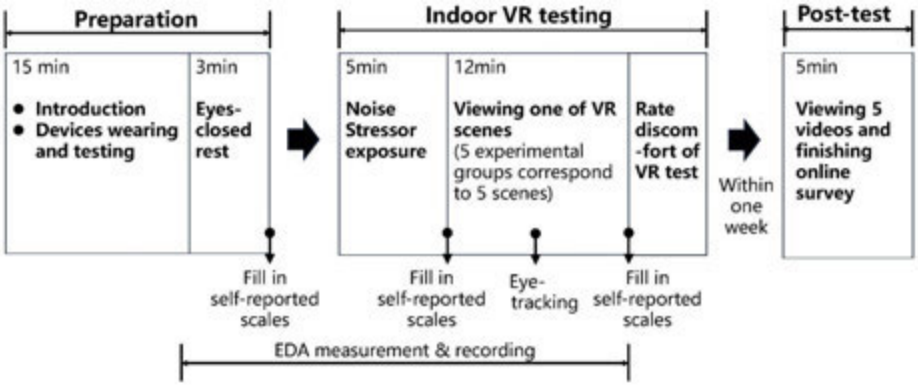

Fig.2. Experimental procedure.

2.4 Measures

2.3.1 Perceived oppressiveness and perceived environmental quality

Perceived oppressiveness (PO) is the subjective experience of feeling overwhelmed or dominated by a physical environment, negatively related to urban environmental quality(Asgarzadeh et al., 2012). Perceived environmental quality (PEQ) involves the subjective evaluation of a physical environment, encompassing an individual's multisensory perception of various environmental attributes. Both PO and PEQ have been identified as mediators in the relationship between an individual's environmental exposure and their psychophysiological responses and behaviours (Luo and Jiang, 2022).

We assessed participants' PO and PEQ in response to online videos by asking, 'Do you feel oppressiveness?' and 'How would you rate the visual quality/ safety level/ economic level of

the street environment depicted in the video?', respectively. An 11-point VAS, ranging from 0 (very low) to 10 (very high), was utilized for these evaluations.

2.3.1 Visual attractiveness

Self-reported visual preferences for online streetscape videos and eye-tracking data collected during VR testing were used to assess the visual attractiveness of the scenes. After viewing the five streetscape videos, participants were asked to rank the videos on a 5-point scale from 1 to 5, where 1 indicates the least liked and 5 indicates the most liked, with scores increasing progressively based on preference. Additionally, eye-tracking data was utilized to analyse visual attention and identify hotspots within the visual stimuli.

2.3.3 Affective experience: psychological and physiological

As detailed in Table 3, the Self-Assessment Manikin (SAM) was employed to assess individuals' affective states through 9-point valence (from 1-unpleasant to 9-pleasant). In addition, individuals' physiological responses were measured using Skin Conductance Level (SCL), which represents individuals' arousal and stress level.

Table 3. Psychological and physiological measures.

Psychological and physiological measures		Description	Relationship with the stress level
SAM	Valence	Affective states	-
EDA	SCL (μS)	Arousal and stress level	Positive

2.3.4 Measures of outdoor behaviours

To measure individuals' outdoor behavioural intent, we asked participants, 'How willing are you to visit, walk, stay, or engage in social activities in the street depicted in the online video?' We utilized an 11-point Visual Analog Scale (VAS) for responses, ranging from 0 (not at all willing) to 10 (very willing).

2.5 Statistical analysis

Environmental perception data, including self-reported Perceived Oppressiveness (PO), Perceived Environmental Quality (PEQ), visual preference, and behavioural intent, were collected via a within-subject online survey. Differences in environmental perception and intent data across the five online videos were compared using one-way repeated measures ANOVA for normally distributed data and the Friedman test for non-normally distributed data.

The affective psychophysiological data collected from a between-subject VR experiment design were analysed using one-way ANOVA for normally distributed data and the Kruskal-Wallis H test for non-normally distributed data to compare differences across five VR groups. Additionally, two-way ANOVA models with post-hoc pairwise comparisons were conducted to examine per-minute Skin Conductance Level (SCL) responses to the five VR scenes.

All data were presented as means, and for all comparisons, a p-value of less than 0.05 was considered statistically significant.

3 Results and discussion

3.1 Perceived oppressiveness (PO) and perceived environmental quality (PEQ)

As shown in Figure 3, the post-hoc tests indicated that the PO of V1, which had no VGS coverage, was significantly higher compared to V2 and V3. Conversely, the Perceived Environmental Quality (PEQ) of V1 was significantly lower than that of V2, V3, V4, and V5. This suggests that VGS can significantly enhance people's perceptions of street quality and reduce the oppressiveness of high-density streetscapes. However, it is important to note that when VGS coverage is excessively high, as in V4 and V5, the beneficial effects of reducing perceived oppressiveness in high-density streetscapes may diminish. As shown in Figure 4, the relationship between VGS coverage and PO is depicted by a U-shaped curve. Conversely, the relationship between VGS coverage and PEQ is represented by an inverted U-shaped curve.

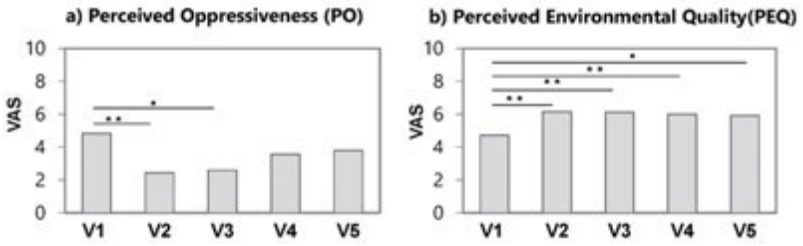

Fig.3. Participants' PO and PEQ across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

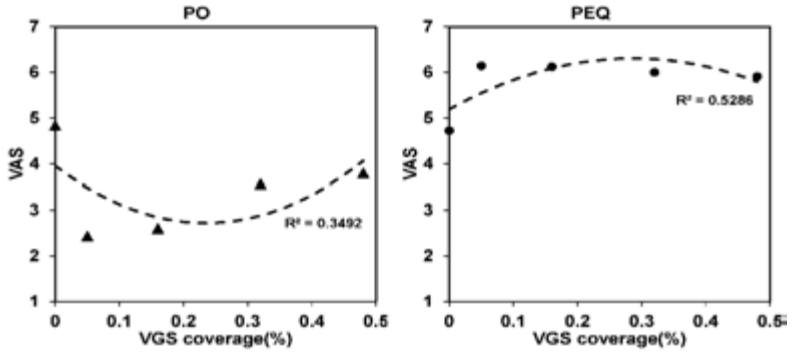

Fig.4. Patterns between VGS coverage and participants' PO & PEQ.

3.2 Visual attractiveness: visual preference and eye-catching factors

As shown in Figure 5, the coverage-response curve between VGS coverage and individuals' visual preference is depicted by an inverted U-shaped curve. Significant differences were observed in participants' visual preferences across five online streetscape videos with varying levels of VGS coverage. Specifically, preferences for V1, which had no VGS coverage, were lower compared to those with VGS coverage in V2, V3, V4, and V5. Statistically significant differences were noted between V1 and V2, V3, and V4. V3, which had the highest visual preference scores, also showing a statistically significant difference from V5, which had the second-lowest scores.

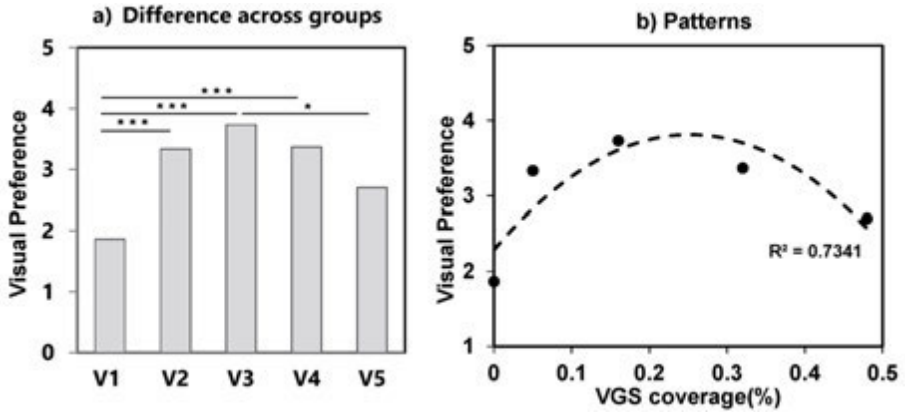

Fig.5. Participants' visual preference across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

After VR testing, eye-tracking hotspots were generated for five VR scene groups, namely, G1 to G5. As illustrated in Figure 6, participants in groups G1 (with no VGS) and G5 (with very high VGS coverage) tended to look straight ahead. They reported feeling oppressed by facades either devoid of greenery or heavily covered in greenery, mentioning that looking forward allowed them to see more sky. Conversely, in groups G2, G3, and G4—where vertical greening coverage was moderate—participants often turned their heads to appreciate the street facades, especially in G2 and G3, which had higher visual preference scores. This suggests that moderate VGS coverage can significantly enhance the visual appeal and of street facades.

G1 G2 G3 G4 G5

Fig.6. Participants' eye-catching factors across 5 VR scenes.

3.3 Affective experience

In this study, we utilized traffic noise to simulate the mental stress commonly experienced by pedestrians in high-density urban areas, where exposure to environmental stressors like heat and noise is prevalent. We specifically investigated how streetscapes with varying levels of VGS coverage influence the affective experiences of pedestrians after these stressor exposures.

Changes in psychological data (*Δ*Valence) and physiological data (*Δ*SCL) before and after experiencing VR scenes were used to assess the effects of VGS on the affective states of stressed participants. *Δ*valence and *Δ*SCL were calculated using equations (1) and (2) respectively and are summarized in Table 4.

Table 4. Measures of the effects of VGS on participants' affective state

Measures	Calculation
*Δ*Valence	(1) *Δ*Valence = Valence $_{\text{scene experience}}$ - Valence $_{\text{noise experience}}$ '+' represents affective improvement
*Δ*SCL (μS)	(2) *Δ*SCL = SCL $_{\text{scene experience}}$ - SCL $_{\text{noise experience}}$

'+' represents arousal and stress Increasing

3.3.1 Physiological data

Our analyses using paired t-tests and Wilcoxon signed-rank tests indicate a significant increase in participants' physiological stress levels following noise exposure. Additionally, ANOVA results reveal no statistically significant differences in physiological data among the five groups after exposure to the stressor. Participants' mean ΔSCL across five groups during are displayed in Figure 7and Figure 8. As Figure 7 indicates, statistically significant differences in ΔSCL across VR scenes begin to manifest after 6 minutes of exposure. Consequently, as illustrated in Figure 8, we compared the average ΔSCL after 6 minutes. The post-hoc tests reveal that the ΔSCL of G1 was significantly higher than those of G2, G3, and G4. The relationship between VGS coverage and ΔSCL is characterized by a U-shaped curve, suggesting that moderate VGS coverage can significantly enhance pedestrians' affective states.

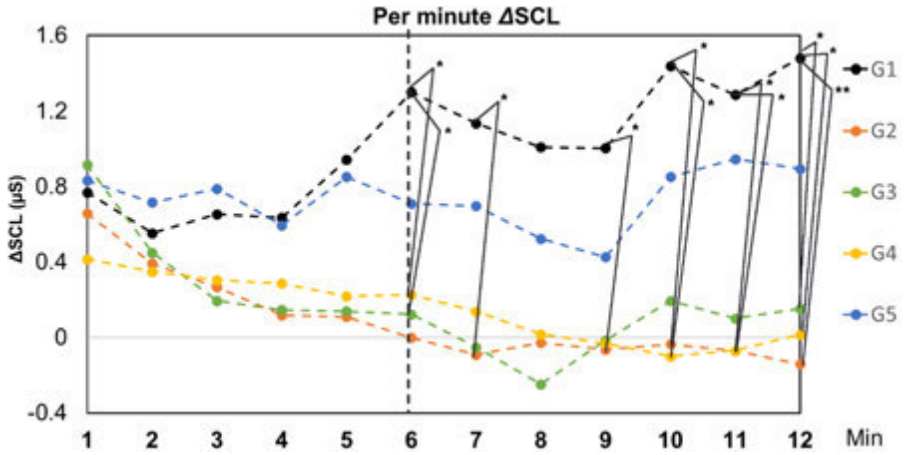

Fig.7. Pairwise comparisons of the estimated marginal means of per minute ΔSCL during VR scenes experiencing. *p < 0.05, **p < 0.01, ***p < 0.001.

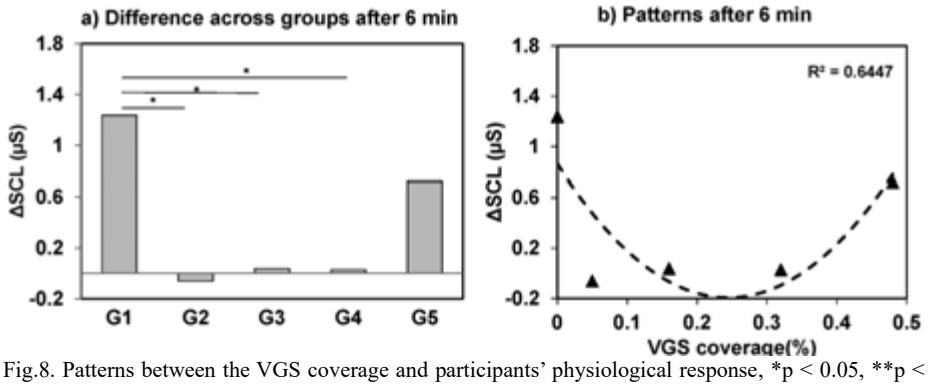

Fig.8. Patterns between the VGS coverage and participants' physiological response, *p < 0.05, **p < 0.01, ***p < 0.001.

3.3.2 Psychological data

As shown in Figure 9, although there were no statistically significant differences of psychological data. comparison between scenes still reflected important trends. The relationship between VGS coverage and Δvalence is characterized by an inverted U-shaped curve.

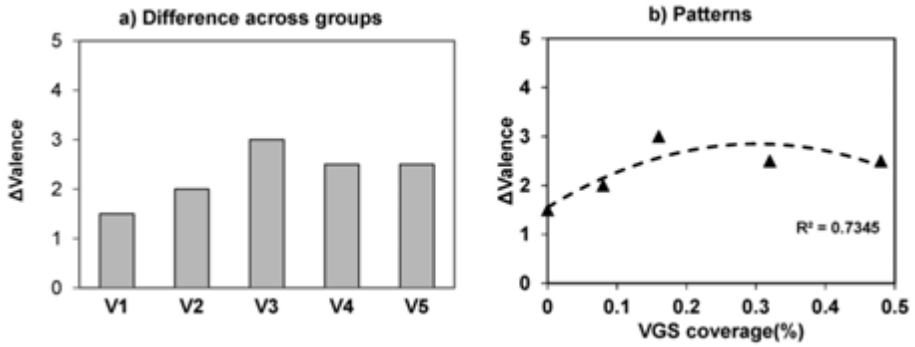

Fig.9. Participants' psychological effect across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

3.4 Outdoor behavioural intent

As depicted in Figures 10 and 11, individuals' willingness to visit, walk, and stay in V1 was significantly lower compared to V2, V3, and V4. Furthermore, the willingness to socialize in G1 was significantly lower than in V2 and V3. The relationship between VGS coverage and individuals' outdoor behavioural intent is characterized by an inverted U-shaped curve, indicating that both very low and very high levels of VGS coverage may decrease the desire to engage in outdoor activities, with moderate levels proving more conducive to positive behavioural intentions.

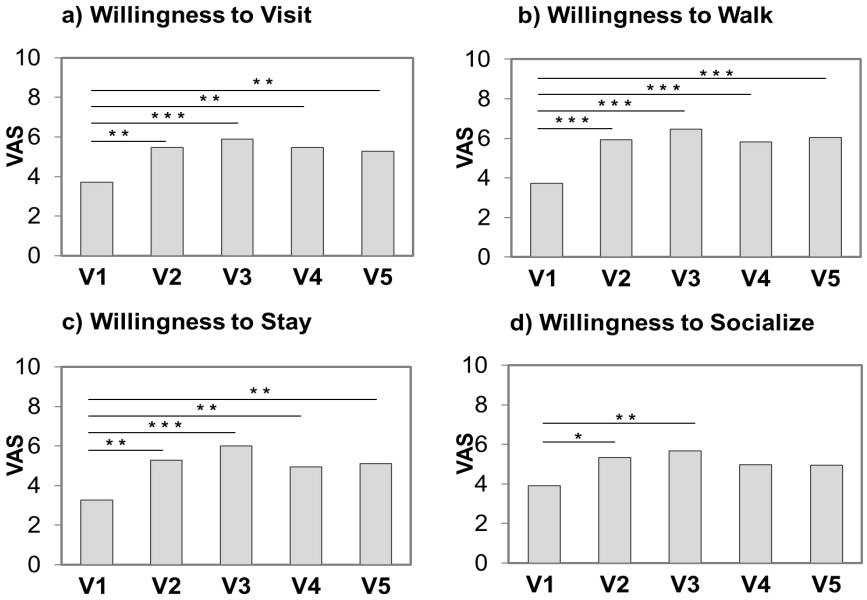

Fig.10. Participants' outdoor behavioural intent across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

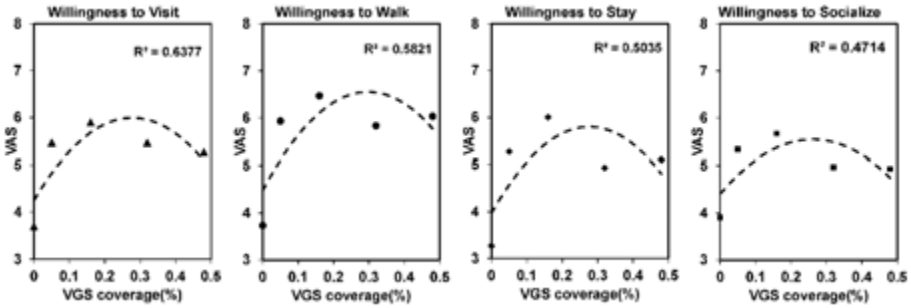

Fig.11. Patterns between the VGS coverage and participants' outdoor behavioural intent.

4. Conclusion

This study explored the potential of Vertical Greening Systems (VGS) to enhance urban space attractiveness and facilitate social interactions. Results indicate that VGS significantly enhance the visual appeal of high-density urban areas, thereby improving environmental quality perceptions. Such enhancements positively influence pedestrians' affective experiences, creating an inviting atmosphere that encourages walking, lingering, and socializing.

The relationship between VGS coverage and visual preference, perceived environmental quality, and outdoor behavioural intent is characterized by an inverted U-shaped curve, suggesting that both insufficient and excessive greenery can diminish these positive effects. The relationship between VGS coverage and perceived oppressiveness and stress levels is described by a U-

shaped curve. Eye-tracking data confirm that green elements are key visual attractors, underlining the importance of their strategic placement in urban design to enhance social interactions.

Enhancing Social Interaction in Urban Spaces: The Role of Vertical Greening Systems in High-Density Areas

Xiaojie SHEN*[1], Feng YANG[1]
[1]College of Architecture and Urban Planning (CAUP), Tongji University, Shanghai, China
2110280@tongji.edu.cn ; yangfeng@tongji.edu

Abstract: The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research, while intensifying urbanization presents growing challenges to the development of the nature in urban areas. The Vertical Greening System (VGS), an innovative approach that conserves land, emerges as a creative solution. However, its potential in enhancing social interactions remains under-explored. To bridge this gap, experiments were conducted to assess the impact of VGS on improving spatial quality, enhancing space attractiveness, and increasing pedestrians' willingness to walk, stay, and engage in social interactions. Results indicate that VGS serve as important visual attractors and significantly enhances the visual attractiveness of urban spaces, leading to improved perceptions of environmental quality. This enhancement positively affects the affective experience of pedestrians, creating a more inviting atmosphere conducive to walk, stay, and socialize. Eye-tracking data shows that green elements serve as important visual attractors, suggesting that their strategic placement in urban design is critical to promoting social interaction.

Keywords: Vertical greening system, Environmental perception, Affective experience, Social interaction.

1 Introduction

Continues urbanization has shaped oppressive streetscapes, leading to increased urban population and pressures of city life. The perceived overcrowding and increasing exposure to environmental stressors can significantly diminish individuals' evaluations of the built environment and their willingness to engage in outdoor activities. This, in turn, adversely affects both physical and mental health and reduces opportunities for social interaction, which are crucial for societal health(Zijlema et al., 2024, Luo and Jiang, 2022, Eizenberg and Jabareen, 2017).

The critical role of nature exposure in fostering prosocial behaviour and social connectedness is well-established in existing research. Nature environments not only provide necessary relief from urban stress but also serve as catalysts for social interaction by offering welcoming and livelihood communal spaces for gatherings and recreational activities(Hartig et al., 2014, Kaźmierczak, 2013).

However, intensifying urbanization presents significant challenges to the development and maintenance of natural environments within urban areas, leading to their decline and uneven distribution across cityscapes. Additionally, changes in lifestyle and the accelerated pace of modern life increasingly restrict the time people spend in nature. As Fuller and Gaston (2009) noted, interactions between urban residents and nature are increasingly mediated by informal green spaces, such as streetscape greening and pocket gardens, rather than traditional, large green networks.

In this context, the Vertical Greening System (VGS) emerges as an innovative solution that conservatively uses land while integrating accessible green infrastructure within high-density areas. Several empirical and experimental studies have highlighted the psychophysiological benefits of VGS in urban settings(Chan et al., 2021, Elsadek et al., 2019). Also, the potential of VGS to enhance the attractiveness of urban spaces, increase footfall, and promote social

interactions has garnered increasing attention(Goel et al., 2022), while it remains under-researched and requires further scientific validation.

To address the existing knowledge gap, this study utilized a virtual reality (VR) experiment to evaluate the effects of various streetscape scenes, featuring different coverages of VGS, on individuals' environmental perception, affective experiences, and behaviours. The primary research questions explored were: 1) How does VGS in high-density open spaces affect perceived environmental quality and visual attraction? 2) How does VGS influences pedestrians' affective experiences in urban settings? 3) Does vertical greening enhance pedestrians' willingness to walk, stay, and participate in social activities within these environments?

2 Methods

2.1 Experiment design

A total of 5 streetscape VR scenes were created, each featuring the same building form but varying coverages of VGS, as detailed in Table 1. Each scene comprised 6 panoramic photographs rendered from different positions along the street model to comprehensively depict the street's characteristics. Each photograph was displayed for one minute and shown twice in VR experiment, as shown in Fig.1. Finally, rendered sequence frame images were used to create five 40-second streetscape video segments for post-experiment surveys.

Table 1. Characteristics of streetscape scenes in the 5 experimental groups(G) and 5 videos(V).

Experiment groups	G1/V1	G2/V2	G3/V3	G4/V4	G5/V5
Coverages of VGS in VR scenes (%)[1]	0	8	16	32	48

[1] The coverage of VG in streetscape scenes was quantified by calculating the percentage of the façade covered by VGS relative to the total façade area of the street block.

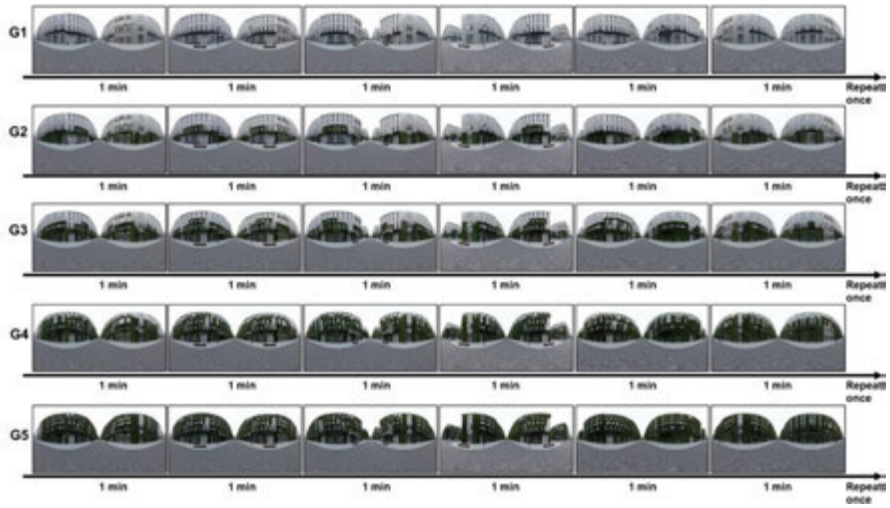

Fig.1. VR experimental stimulation design.

2.2 Participants

We recruited 30 healthy adults from Tongji University to participate in the study. Eligibility criteria required participants to be aged between 18 and 35. Individuals who had consumed tobacco, alcohol, drugs, or caffeinated beverages within 24 hours prior to the experiment, or who had engaged in intensive exercise within 6 hours of the experiment, were excluded. The study received approval from the Science and Ethics Committee of Tongji University, and all participants provided written informed consent before participating.

Prior to the experiment, we collected data on participants' socio-demographic background, chronic mental stress levels, nature connectedness, noise sensitivity, and other relevant covariates through a questionnaire. Participants were then approximately assigned to one of five experimental groups based on their survey responses, allowing for a rough control of these covariates across the groups. The descriptive statistics of their background information are presented in Table 2, and there were no statistically significant differences between 5 VR experiment groups.

Table 2. Descriptive statistics of the participants' background information.

Measures		Participants Mean (± SD) or Number (percent, %)					
		G1	G2	G3	G4	G5	V1 to V5

[1] *Nature connectedness*, describes a psychological state where individuals deeply care for and feel connected to nature, reflecting their innate biophilic tendencies(Capaldi et al., 2014). It serves as an indicator of the extent to which these tendencies are fostered or suppressed(Nisbet and Zelenski, 2013). Research shows that nature connectedness affects, moderates, and mediates the impact of nature exposure on mental health(Liu et al., 2022). In this study, we used 6-iterm and 7-point Nature-Relatedness Scale to measure an individuals' nature connectedness(Gong et al., 2024).

[2] *Noise sensitivity*, which refers to an individual's susceptibility and degree of reaction to everyday noises, was evaluated using the Weinstein Noise Sensitivity Scale (WNSS) in this study(Weinstein, 1978).

[3] *Chronic mental stress levels*, which have been shown to influence the mental effects of nature exposure on individuals(Shanahan et al., 2015), were assessed using the Perceived Stress Scale (PSS-10) in this study(Cohen et al., 1983).

2.3 Procedure

As illustrated in Figure 2, the experiment comprises three phases: preparation, testing, and post-testing.

In the preparation period, participants signed written informed consent and were equipped with the VR devices and biomonitoring sensors. Participants were then asked to close eyes and rest for 3 minutes while electro-dermal activity (EDA) data recording commenced. Subsequently, participants completed a self-reported scale to establish psychological baselines.

During the testing period, participants were divided into five groups and randomly assigned to one of five VR scenes. Initially, they were exposed to traffic noise for 5 minutes and completed a self-reported scale. This was followed by a 12-minute viewing of a VR scene along with the collection of eye-tracking data, after which they filled out the same self-reported scale again. Upon completion, all devices were deactivated and removed, and participants rated their level of discomfort during the VR test using a 5-point Likert scale (1 = very slightly or not at all, 5 = extremely).

After VR testing, participants were required to complete post-test surveys. They viewed five videos through an online link and immediately assessed perceived oppressiveness, environmental quality, visual preference, affective experience, and their willingness to engage in various outdoor activities in such environment. The videos were presented in a random order to prevent any sequence effects.

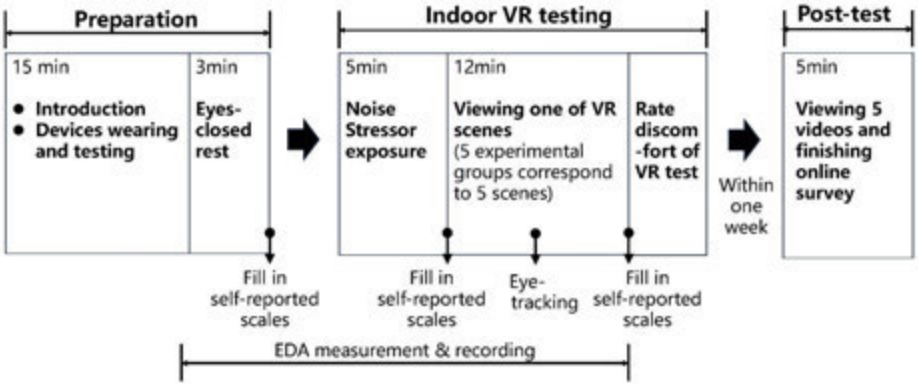

Fig.2. Experimental procedure.

2.4 Measures

2.3.1 Perceived oppressiveness and perceived environmental quality

Perceived oppressiveness (PO) is the subjective experience of feeling overwhelmed or dominated by a physical environment, negatively related to urban environmental quality(Asgarzadeh et al., 2012). Perceived environmental quality (PEQ) involves the subjective evaluation of a physical environment, encompassing an individual's multisensory perception of various environmental attributes. Both PO and PEQ have been identified as mediators in the relationship between an individual's environmental exposure and their psychophysiological responses and behaviours (Luo and Jiang, 2022).

We assessed participants' PO and PEQ in response to online videos by asking, 'Do you feel oppressiveness?' and 'How would you rate the visual quality/ safety level/ economic level of

the street environment depicted in the video?', respectively. An 11-point VAS, ranging from 0 (very low) to 10 (very high), was utilized for these evaluations.

2.3.1 Visual attractiveness

Self-reported visual preferences for online streetscape videos and eye-tracking data collected during VR testing were used to assess the visual attractiveness of the scenes. After viewing the five streetscape videos, participants were asked to rank the videos on a 5-point scale from 1 to 5, where 1 indicates the least liked and 5 indicates the most liked, with scores increasing progressively based on preference. Additionally, eye-tracking data collected during VR testing was utilized to analyse visual attention and identify hotspots within the visual stimuli.

2.3.3 Affective experience: psychological and physiological

As detailed in Table 3, the Self-Assessment Manikin (SAM) was employed to assess individuals' affective states through 9-point valence (from 1-unpleasant to 9-pleasant). In addition, individuals' physiological responses were measured using Skin Conductance Level (SCL), which represents individuals' arousal and stress level.

Table 3. Psychological and physiological measures.

Psychological and physiological measures		Description	Relationship with the stress level
SAM	Valence	Affective states	-
EDA	SCL (μS)	Arousal and stress level	Positive

2.3.4 Measures of outdoor behaviours

To measure individuals' outdoor behavioural intent, we asked participants, 'How willing are you to visit, walk, stay, or engage in social activities in the street depicted in the online video?' We utilized an 11-point Visual Analog Scale (VAS) for responses, ranging from 0 (not at all willing) to 10 (very willing).

2.5 Statistical analysis

Environmental perception data, including self-reported Perceived Oppressiveness (PO), Perceived Environmental Quality (PEQ), visual preference, and behavioural intent, were collected via a within-subject online survey. Differences in environmental perception and intent data across the five online videos were compared using one-way repeated measures ANOVA for normally distributed data and the Friedman test for non-normally distributed data.

The affective psychophysiological data collected from a between-subjects VR experiment design were analyzed using one-way ANOVA for normally distributed data and the Kruskal-Wallis H test for non-normally distributed data to identify differences across five VR groups. Additionally, two-way ANOVA models with post-hoc pairwise comparisons were employed to assess per-minute Skin Conductance Level (SCL) responses to the five VR scenes.

All data were presented as means, and for all comparisons, a p-value of less than 0.05 was considered statistically significant.

3 Results and discussion

3.1 Perceived oppressiveness (PO) and perceived environmental quality (PEQ)

As shown in Figure 3, the post-hoc tests indicated that the PO of V1, which had no VGS coverage, was significantly higher compared to V2 and V3. Conversely, the Perceived Environmental Quality (PEQ) of V1 was significantly lower than that of V2, V3, V4, and V5. This suggests that VGS can significantly enhance people's perceptions of street quality and reduce the oppressiveness of high-density streetscapes. However, it is important to note that when VGS coverage is excessively high, as in V4 and V5, the beneficial effects of reducing perceived oppressiveness in high-density streetscapes may diminish. As shown in Figure 4, the relationship between VGS coverage and PO is depicted by a U-shaped curve. Conversely, the relationship between VGS coverage and PEQ is represented by an inverted U-shaped curve.

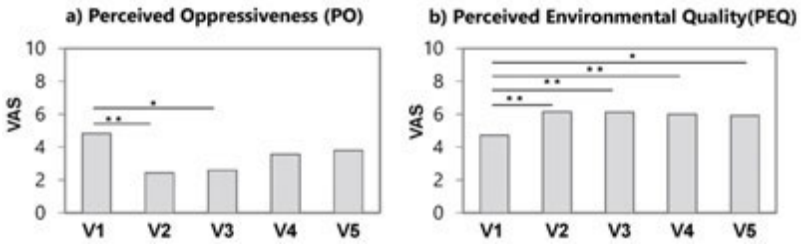

Fig.3. Participants' PO and PEQ across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

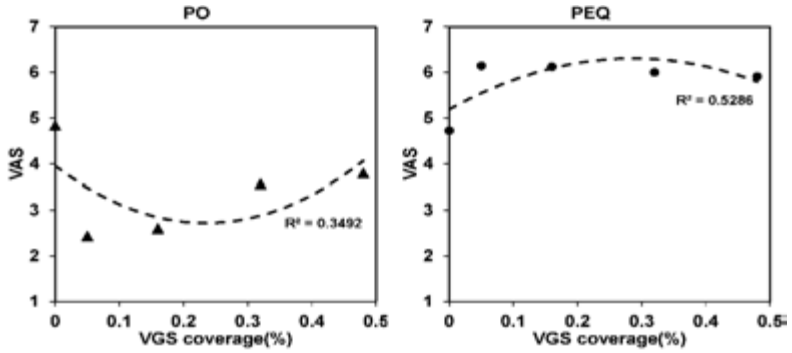

Fig.4. Patterns between VGS coverage and participants' PO & PEQ.

3.2 Visual attractiveness: visual preference and eye-catching factors

As shown in Figure 5, the coverage-response curve between VGS coverage and individuals' visual preference is depicted by an inverted U-shaped curve. Significant differences were observed in participants' visual preferences across five online streetscape videos with varying levels of VGS coverage. Specifically, preferences for V1, which had no VGS coverage, were lower compared to those with VGS coverage in V2, V3, V4, and V5. Statistically significant differences were noted between V1 and V2, V3, and V4. V3, which had the highest visual preference scores, also showing a statistically significant difference from V5, which had the second-lowest scores.

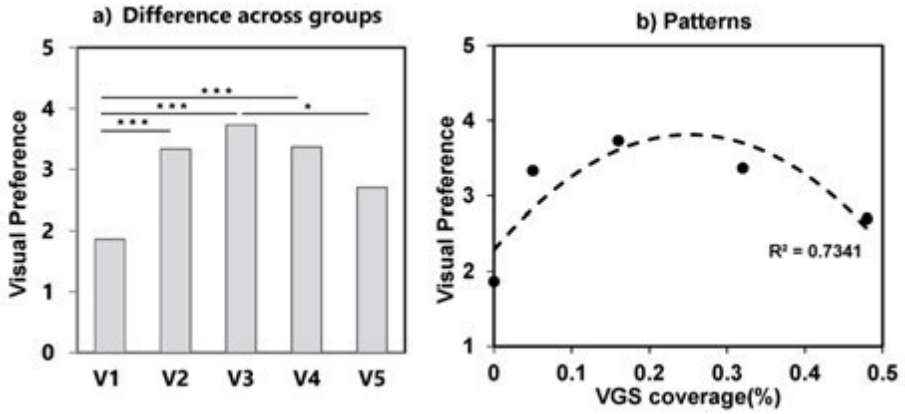

Fig.5. Participants' visual preference across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

After VR testing, eye-tracking hotspots were generated for five VR scene groups, namely, G1 to G5. As illustrated in Figure 6, participants in groups G1 (with no VGS) and G5 (with very high VGS coverage) tended to look straight ahead. They reported feeling oppressed by facades either devoid of greenery or heavily covered in greenery, mentioning that looking forward allowed them to see more sky. Conversely, in groups G2, G3, and G4—where vertical greening coverage was moderate—participants often turned their heads to appreciate the street facades, especially in G2 and G3, which had higher visual preference scores. This suggests that moderate VGS coverage can significantly enhance the visual appeal and of street facades.

Fig.6. Participants' eye-catching factors across 5 VR scenes.

3.3 Affective experience

In this study, we utilized traffic noise to simulate the mental stress commonly experienced by pedestrians in high-density urban areas, where exposure to environmental stressors like heat and noise is prevalent. We specifically investigated how streetscapes with varying levels of VGS coverage influence the affective experiences of pedestrians after these stressor exposures.

Changes in psychological data (*Δ*Valence) and physiological data (*Δ*SCL) before and after experiencing VR scenes were used to assess the effects of VGS on the affective states of stressed participants. *Δ*valence and *Δ*SCL were calculated using equations (1) and (2) respectively and are summarized in Table 4.

Table 4. Measures of the effects of VGS on participants' affective state

Measures	Calculation
*Δ*Valence	(1) *Δ*Valence = Valence $_{\text{scene experience}}$ - Valence $_{\text{noise experience}}$ '+' represents affective improvement
*Δ*SCL (μS)	(2) *Δ*SCL = SCL $_{\text{scene experience}}$ - SCL $_{\text{noise experience}}$

'+' represents arousal and stress Increasing

3.3.1 Physiological data

Our analyses using paired t-tests and Wilcoxon signed-rank tests indicate a significant increase in participants' physiological stress levels following noise exposure. Additionally, ANOVA results reveal no statistically significant differences in physiological data among the five groups after exposure to the stressor. Participants' mean ΔSCL across five groups during are displayed in Figure 7and Figure 8.

As Figure 7 indicates, statistically significant differences in ΔSCL across VR scenes begin to manifest after 6 minutes of exposure. Consequently, as illustrated in Figure 8, we compared the average ΔSCL after 6 minutes. The post-hoc tests reveal that the ΔSCL of G1 was significantly higher than those of G2, G3, and G4. The relationship between VGS coverage and ΔSCL is characterized by a U-shaped curve, suggesting that moderate VGS coverage can significantly enhance pedestrians' affective states.

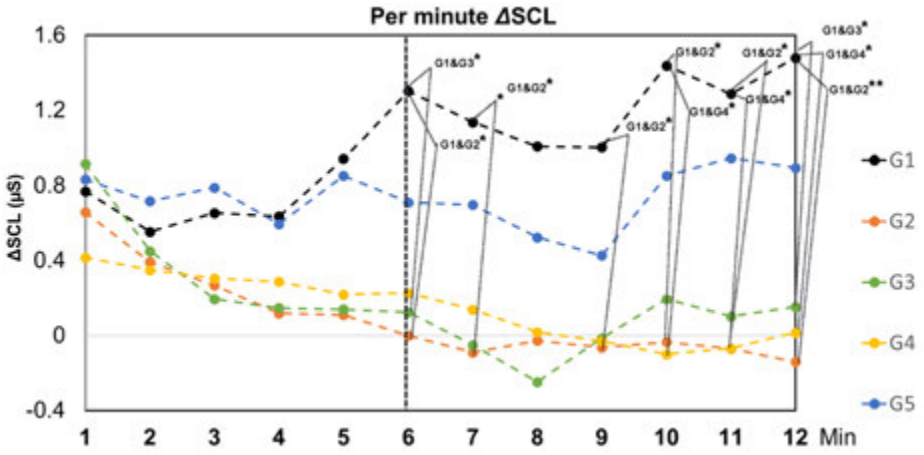

Fig.7. Pairwise comparisons of the estimated marginal means of per minute ΔSCL during VR scenes experiencing. *p < 0.05, **p < 0.01, ***p < 0.001.

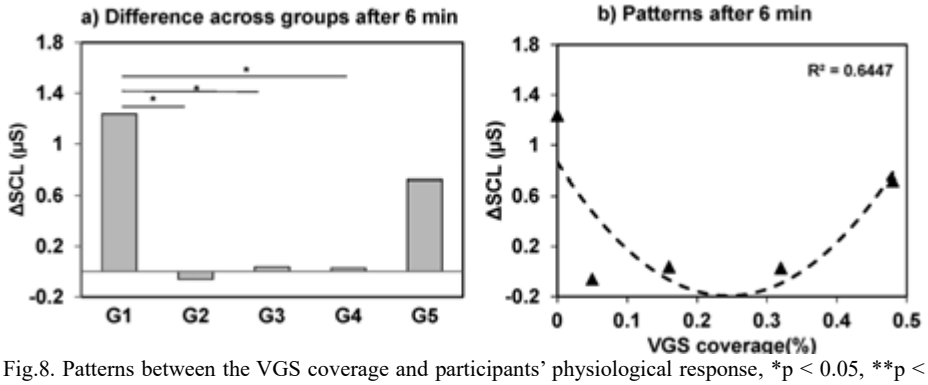

Fig.8. Patterns between the VGS coverage and participants' physiological response, *p < 0.05, **p < 0.01, ***p < 0.001.

3.3.2 Psychological data

As shown in Figure 9, although there were no statistically significant differences of psychological data. comparison between scenes still reflected important trends. The relationship between VGS coverage and Δvalence is characterized by an inverted U-shaped curve.

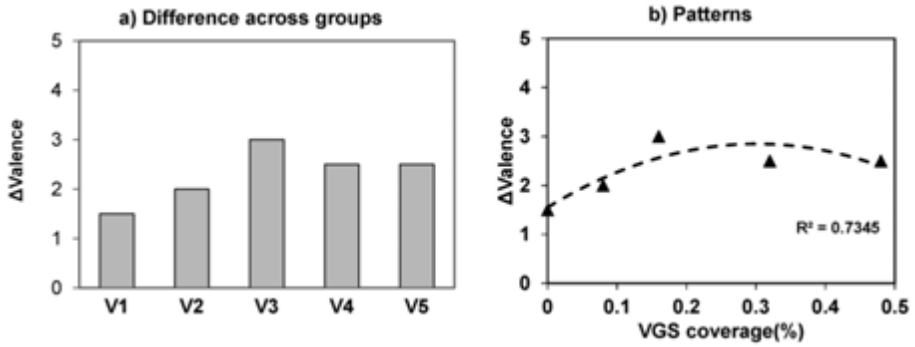

Fig.9. Participants' psychological effect across 5 streetscape videos and its relationship with VGS coverage, *p < 0.05, **p < 0.01, ***p < 0.001.

3.4 Outdoor behavioural intent

As depicted in Figures 10 and 11, individuals' willingness to visit, walk, and stay in V1 was significantly lower compared to V2, V3, and V4. Furthermore, the willingness to socialize in G1 was significantly lower than in V2 and V3. The relationship between VGS coverage and individuals' outdoor behavioural intent is characterized by an inverted U-shaped curve, indicating that both very low and very high levels of VGS coverage may decrease the desire to engage in outdoor activities, with moderate levels proving more conducive to positive behavioural intentions.

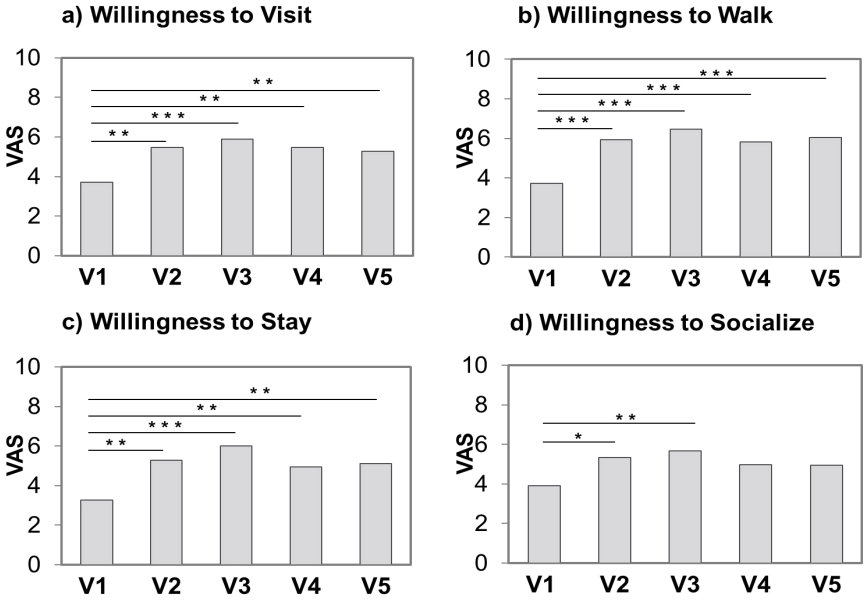

Fig.10. Participants' outdoor behavioural intent across 5 streetscape videos, *p < 0.05, **p < 0.01, ***p < 0.001.

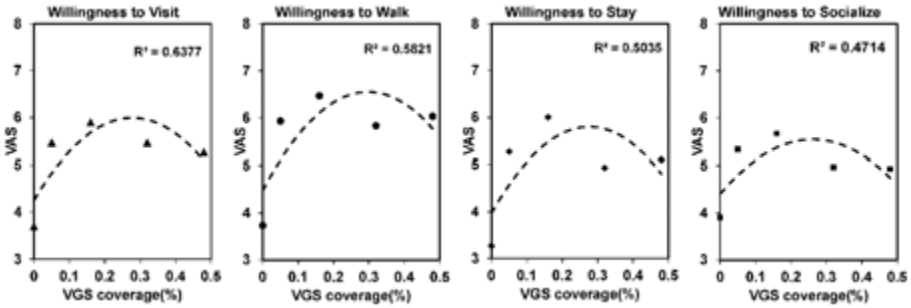

Fig.11. Patterns between the VGS coverage and participants' outdoor behavioural intent.

4. Conclusion

This study explored the potential of Vertical Greening Systems (VGS) to enhance urban space attractiveness and facilitate social interactions. Results indicate that VGS significantly enhance the visual appeal of high-density urban areas, thereby improving environmental quality perceptions. Such enhancements positively influence pedestrians' affective experiences, creating an inviting atmosphere that encourages walking, lingering, and socializing.

The relationship between VGS coverage and visual preference, perceived environmental quality, and outdoor behavioural intent is characterized by an inverted U-shaped curve, suggesting that both insufficient and excessive greenery can diminish these positive effects. The relationship between VGS coverage and perceived oppressiveness and stress levels is described by a U-

shaped curve. Eye-tracking data confirm that green elements are key visual attractors, underlining the importance of their strategic placement in urban design to enhance social interactions.

Abstract
This paper highlights mobility as a methods paradigm by reviewing mobile methods from a theoretical and empirical perspective, i.e., adopted for a study focused on socio-spatial mobilities of urban marginalised women (UMW) in peri-urban areas of New Delhi, India. The article discusses the approach and design of mobile methods for this case study, including mobile ethnography using new technologies like GPS. We highlight that mobile methods enable the study of significant elements like scale and everyday mobilities. We discuss the challenges and opportunities for researchers that come with the use new technologies within mobile methods. By doing so we highlight the significance of using mobile methods to explore new research techniques that present a holistic perspective towards understanding mobility.

Keywords: Mobile methods, Socio-spatial mobility, Scale, New technologies, GPS

Introduction
It can be said that the peripheries of society hold the capacity to transform their limited resources and barriers into settings for various kinds of opportunities. Despite the social and economic problems of the peripheral segment of the society, this study highlights their capability of self-organisation towards the potential to activate the mobility of women especially, towards more equitable mobilities. However, this discussion on opportunities of peripheries includes theorising and must offer a point of view. It is important to understand how this opportunity of peripheries for (urban marginalised) women in terms of spatial and social mobility be approached in scientific terms. In this context, what kind of methodology is suitable to facilitate the conformation of social connections and to recognise them for urban systems?

Mobilities are understood as a mesh of movement, meaning and practice (Salazar, Elliot and Norum, 2017). This complex juxtaposition opens the dialogue toward the multiple effects and approaches to understanding mobilities. Several scholars describe mobility as polymorphic and diversified concept that requires reaffirmation of theories related to culture, identity and transnational relationships (Salazar and Smart, 2011; Glick Schiller and Salazar, 2013). Besides mappable and calculated geographical movements, mobility is about interpretations and meanings that highlight ethical and political concerns along with certain practical issues. Mobility, as a concept

cuts through and links across various scales of movement, namely, from small-scale bodily movements to infrastructure or transport-related movements, to a non-physical type of movement such as global flows of finance or labour. Mobilities research considers the movement of not only people but also information and goods along with their impact on each other (facilitate or hinder).

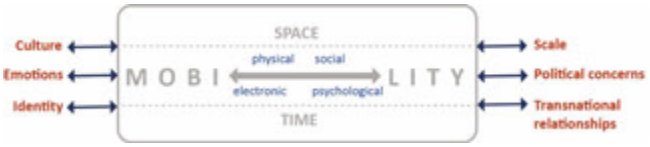

Figure 1: Mobility as a mesh of various types of movements.
Source: Adapted from Salazar et al.(2017); Svašek (2013); Ziegler & Schwanen (2011)

Mobilities research is multi-dimensional and interdisciplinary in nature that intersects with theoretical, social, technical and political constructs (Cresswell and Uteng, 2016). Most studies focusing on mobilities have dealt with different aspects of mobility separately. Several theorists argue that considering mobility in separate spheres may lead to a lack of interdisciplinary approaches (Sheller and Urry, 2006). The research on mobilities has generated links across different scales that connect different disciplines of humanities with sciences to produce a holistic and meaningful analysis, which is possible through an investigation of experiences created while moving (Sheller and Urry, 2016). This paper highlights mobility as a methods paradigm in a study investigating daily survival mobilities of urban poor women who are at social and spatial peripheries of the society and the city. The existing research methods do not do justice to the studies relating to the aspects of everyday mobility (Law and Urry, 2004). To understand the complexities of social, economic and political relations it is critical to not only investigate the movement of people, objects, information and ideas but also how they get mobilised when they interact with others (Garfinkel, 1967; Wittgenstein, 2009). This paper presents an in-depth understanding of the methods adopted in a study related to social and spatial mobilities of UMW residing in the peri-urban areas of New Delhi i.e., mobile methodology including mobile ethnography wirth new technologies like GPS. By doing so this paper highlights the significance of using mobile methods to explore new research techniques that present a holistic perspective towards understanding mobility.

Mobile Methodology

A growing interest in everyday life practices and their further investigation has brought mobility from merely being limited to a research field to the methods paradigm. According to Law and Urry (Law and Urry, 2004), the existing research methods do not do justice to the studies relating to the aspects of everyday mobility. To understand the complexities of social, economic and political relations it is critical to not only investigate the movement of people, objects, information and ideas but also how they get mobilised when they interact with others (Garfinkel, 1967; Wittgenstein, 2009). According to Laurier and Philo (2003), within the broader spectrum of society, relationships and networks emerge while people are on the move. They emphasise on the study of these micro-worlds that crop up as an impact of automobility on social relations and activity (Laurier and Philo, 2003; Laurier *et al.*, 2008). Various studies on mobility underpin the fact that there is a difference in the kinds of interactions that happen when a person is in motion than when stationary. Moreover, being mobile

brings about a different set of knowledge and identities to people who experience it (Hein, Evans and Jones, 2008). Thus, to understand and analyse the consequences of socio-spatial mobilities and its multi-disciplinarity, the following sections discuss the methodological considerations adopted for this research.

Weisner (1996) argues that research questions that engender the complexity pertaining to multi-disciplinary (mobility studies, urban informality, gender studies) research areas cannot be dealt with in one single method. In studies related to understanding the mobility of people, the strengths of both types of approaches (quantitative as well as qualitative) would provide to be beneficial in covering the width and depth of the research area. Moreover, Johnson et al. (2007) state that an effective mixed methods approach enhances the basic principle of validity of research findings. This concept of validation is termed *methodological triangulation* by Denzin (1989). Using a combination of multiple methods helps in utilising the strength of each method while overcoming their deficiencies (Denzin, 1989).

This research uses a combination of new technologies along with mobile methods and ethnography to reveal the inter-relationship between social and spatial mobility of UMW. According to Law and Urry (2004), the existing research methods reflect their insufficiency to understand the social aspects of movement particularly those characterised with complexity and elements of multiple chaos. To address this gap, it becomes essential to develop research methods that are 'on the move' and allow the researcher to focus on the social organisations that appear during various kinds of movements (Büscher and Urry, 2009). Combining mobile methods with new technologies allows researchers for applying cutting edge theory in geography and social sciences (Christensen *et al.*, 2011). Besides being of interest to academics, the mobile methods present their relevance to various public organisations in policy planning (Hein, Evans and Jones, 2008).

The methods are chosen considering the objectives of the study, i.e., to understand the consequences of relationship between social and spatial mobility of UMW. The research analyses the social structures or networks formed while performing the act of travel as a part of the daily routine of the UMW. It involves the study of everyday life or daily mobilities of these women in diverse social contexts. Following the elements of qualitative research, this study analyses the construction of social realities along with the social relationships that connect people. According to Miller and Dingwall (1997), social structures are a consequence of the 'bottom up' processes that take place within the society. Thus, to analyse these bottom-up processes, the research demands an in-depth investigation into the participants' daily mobilities. Moreover, the issues pertaining to scale and ethics, geographical boundaries and social imagination, class and gender, material culture and interdisciplinarity are all revealed through innovative mobile methodologies (Tarrius, 2000).

Understanding scale in mobility studies

In the studies related to mobilities, the scale does not only span across the geographic and demographic boundaries but incorporates all other macro-processes that describes the interconnectedness and visible and hidden networks of the society. These phenomena are termed *glocal ethnography* (Salazar, 2010), *global ethnography* (Burawoy, 2000*)* or as D'Andrea (2007) defines as *nomadic ethnography*. D'Andrea's (2007) further description of the concept elaborates upon the

nomadic approach that is required for the journeys and activities performed along the routes. According to Molland (2013), the methodology needs to accommodate the switch between the policy and the social world and terms it *tandem ethnography*. Multi-scalar ethnography addresses the issues related to change and focuses on the interfaces between mobility and institutions (society). It does this by understanding the concerns that people may have, by making certain interconnections and strategies between various aspects related to the daily activities of the people.
For studies that are concerned with following the patterns of movement (and not fixed to a particular site), it calls for *deterritorialised ethnography* (Merry, 2000) which entails a set of collaborative and interdisciplinary research methods producing a complex web for analysis (Coleman and Von Hellermann, 2012). The majority of mobility-related studies have focused on qualitative methods with a few examples of quantitative or mixed-method studies (Hein, Evans and Jones, 2008).

Mobility of UMW in New Delhi, India

Figure 2: Context map of Delhi showing the area where the participants live. These areas lie on the periphery of the metropolitan region of Delhi and fall outside the limits of the planned transportation system.

This study focuses on urban marginalized women living in the peri-urban areas of New Delhi in India. Most people living in the informal settlements of these peri-urban areas are migrant poor who have travelled from neighbouring states of Delhi like Uttar Pradesh and Haryana in search of employment opportunities. Among the various groups of women in India, the most vulnerable are the UMW. This group of women are marginalized from two perspectives. First, because they belong to the socio-economically weaker section of society and second, they are women. These are marginalized people whose rights have been violated and those who possess an insignificant amount of economic and political power (Massey, 2013). Due to various kinds of discrimination at socio-cultural and spatial levels, the UMW in Delhi face forced eviction with respect to the right to property and access to various other household assets. These exclusions, in addition to the greater share of household

responsibilities, have a significant effect on their travel choices and status (Anand and Tiwari, 2006).

Besides experiencing exclusions at a household level, women from marginalized communities also face several other challenges at the city level. Among the many cities in India, Delhi's reputation with respect to crimes against women is the lowest. Moreover, from a spatial perspective, the existing infrastructure of the city does not address safety concerns and thus restricts their movement to the interior of the house. These women are primarily employed in the semi-formal or informal sector[1] and often cannot afford to use any transport mode but walking. A study conducted by Bostock (2001) on low-income women also presents the numerous problems women face while walking, including fatigue, stress and psycho-social effects. According to Uteng (2012), the cultural aspect plays a crucial role in the positioning of gender with respect to mobility, namely, access to outer space and kinds of activities. Several studies highlight the impact of risks associated with travelling on public transport modes, such as sexual harassment and travel behaviour of women, where women tend to self-exclude themselves from certain activities hence limiting access to social, leisure and economic activities (Anand and Tiwari, 2006; Murray, 2016). Fear of space is one aspect of risk aversion that is related to the interaction of women with urban space (Pain, 1994). Due to this reason, they tend to return home early (to avoid risks like sexual harassment), and thus they lose out on employment opportunities (Tanzarn, 2008). However, Tulloch (2000) states that many factors contribute to risk experience and depend on spatial and social contexts. Thus, through the study of daily mobilities of UMW, this paper presents insights to inform the designing and planning of street experiments that facilitate enhanced access.

Methods

This research uses mobile methods like digital and mobile ethnography to focus on the daily mobilities of UMW. The study is divided into two main phases (Study I and Study II). The first part of Study I requires understanding the socio-demographic conditions of the participants through the means of unstructured ethnographic interviews. The second part of this study shifts the focus of the interviews towards developing a cohesive understanding of their daily routines. In-depth interviews were used as a preliminary method to understand the socio-demographic characteristics of the participants living in urban peripheral settlements of New Delhi. Subjective and experience-related questions, such as the description of their daily routines, travel experiences and incidents of sexual harassment, were asked during the ethnographic interviews. It was ensured that the interviews were conducted one-on-one and in private to make the participants feel comfortable so that they could share their experiences freely. These interviews also included a detailed explanation of their daily travel patterns. Through this description, information regarding their travel patterns was extracted for further inquiry. Along with this, travel diaries were also filled out for each participant[2]. These methods would help to identify the characteristics, motivations and barriers that affected the movement patterns of the participants. This

[1] The formal economy is marked by regular work, is legally sanctioned and is regulated through state intervention (Hart, 2006; Portes & Schauffler, 1992). Institutions that do not fall in the formal policy regulated environments and are more ephemeral and, not easy to categorise or define (Frederiksen, 2015; Kelsall, 2011) may be called the informal sector, informal arrangements or informal economy.

[2] In this case, there were limitations concerning the literacy level of the participants and thus the researcher filled out the travel diary during face-to-face interaction with the participants.

process gave the researcher a broad idea of the different journeys performed by the participants.

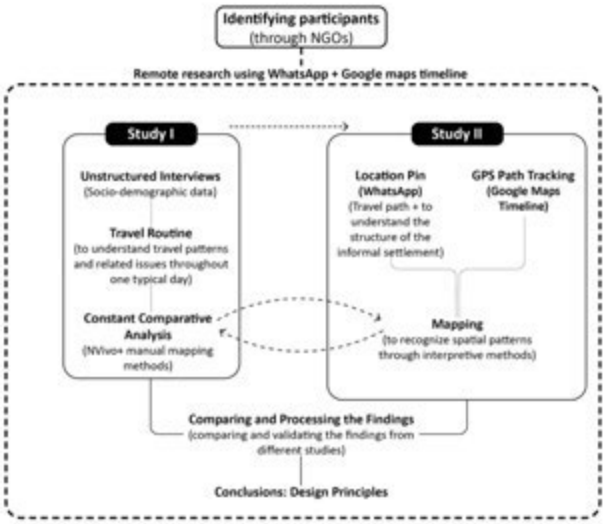

Figure 3 Methods adopted for the study.

Further, in Study II, mobile methodology is used for collecting information about the participants' daily movement through GPS technology. Hence, the second part of the study required collecting data about the path travelled by the participants for two weeks. This study adopted the use of phone GPS and Google maps timeline. This study was conducted during the Pandemic, with restrictions on mobility and social gathering. Thus, based on the availability and knowledge of the participants, appropriate tools (WhatsApp and Google Maps Timeline) were used for the ethnographic research[3].

The participants for the study were recruited by establishing contacts with two NGOs in Delhi that work with issues related to women or women empowerment[4]. Data collection was conducted through both face-to-face interviews and voice calls using WhatsApp[5]. The participants with smartphones were given detailed explanations about the entire process. Conducting remote ethnographic surveys with marginalized communities through digital means presents other challenges, such as dealing with technology handicaps. The researcher was required to educate the participants step-by-step with the help of screenshots along with voice calls on how to turn on the GPS location on their smartphones and how to share their current location on WhatsApp.

[3] While conducting preliminary research it was found that not all UMW owned a smartphone. Thus, the selection of participants was based on the availability and access to smartphones (with Internet and WhatsApp).
[4] Azad Foundation is an NGO that mainly works towards the capacity building by providing driving training to women from resource-poor communities. It has its centres in north, south and east Delhi. The other NGO is CEQUIN India, located in southeast Delhi in Jamia Nagar and promotes equal rights for women and girls.
[5] The data collection process began in February 2020 through face-to-face interviews. After interviewing fourteen participants and obtaining GPS data for five participants, the field study came to a halt in the second week of March 2020. During the total lockdown in New Delhi, India, people's mobility was affected the most and thus it was difficult to pursue data collection with the existing approach involving face-to-face interactions.

Particular instructions and guidance were provided to them, such as keeping their location setting turned on at all times for two weeks. Travel diary, along with the GPS tracking method, helped in the data triangulation that allowed the study to investigate small but important factors related to the daily travel routines of the participants.
To identify underlying themes and categories abductive approach (where codes emerge gradually) to constant comparative analysis or coding is applied for unstructured interviews. However, manual mapping is integrated into the analysis method to avoid overshadowing the computer software, which may lead towards missing finer details of the data (Silverman, 2015) and specificities of the phenomena. Mapping is used as an interpretive analysis method for GPS travel path data. The interpretive evaluation of the mapping process can help to demonstrate spatial patterns and provoke contextual queries (Hsu, 2014).

Reasons for adopting mobile ethnography

Based on the objectives of the research it is required to gather data that reports about issues related to accessibility, skills or competence and appropriation of the resources by the participants. It is suggested by Srinivasan (2008) that to measure accessibility it is required by the planners and designers to collect data that focuses on individual travel patterns. It is difficult to collect such data as it is not routinely collected in most countries. There is also a general understanding that to avoid relating mobility to fixity, it is required to focus on empirical mobilities that in turn calls for mobile theorisation and mobile methodologies (Büscher & Urry, 2009; Büscher et al., 2011; Cresswell, 2006; Urry, 2007). This research focuses on the investigation of social phenomena along with the movement through the lens of gender. Several scholars from the field of the mobilities paradigm advocate the use of atypical research methods that, along with the subject of research, are 'on the move' to capture intermittent mobility patterns (Cresswell, 2006; Urry, 2007; Büscher and Urry, 2009; Büscher, Urry and Witchger, 2011). According to Sheller (2010), these methods include analysis of people's interactions and conversations along their journeys, a mobile ethnography that involves movement with people and objects, observing transfer points, time-space diaries, textual or pictorial diaries, cyber research methods and cyber ethnography, and so forth. In recent years, mobile ethnography has been adopted in several studies related to mobilities. Transfer points, passages, stations, waiting rooms and baggage systems are a few examples of such sites of movement (Andersson, 2017). Although Sheller and Urry (2006) describe transfer points as immobile places that are necessary for mobility which include waiting rooms, cafés and airports. However, it would be suitable to situate other types of waiting areas like bus stops and other inter-change stations or places in this category. An important component of this research is the study of such 'places of in-between-ness' or 'inter-spaces' that are created through multiple mobilities while travelling, in-between events or in-between points of origins and destinations (Hulme and Truch, 2005). According to Watts and Urry (2008), travelling with the subjects of study and being a part of their routine journeys characterises the basic elements of mobile ethnography. This type of study that elaborates upon tracing the path travelled by the individuals is termed multi-sited ethnography (Marcus, 1998).

In-depth unstructured interviews

This research develops an understanding through the daily travel experiences of the participants to reveal the factors that have an impact on the mobility of UMW. It did so

by generating in-depth insights into participants' descriptions of their daily travel patterns (pre-Covid times) along with their socio-demographic information. Data collection was conducted through voice calls using WhatsApp (remote research). In-depth interviews were used as a primary method to understand the socio-demographic characteristics of the participants living in informal settlements of New Delhi.
Although remote research can be used as alternative to traditional data collection methods, it needs to be understood that it is heavily dependent on access and availability of technology to the participants and researcher. In this study, the socio-economic status of the participants did not allow them to make use of certain online methods such as emails or online surveys. Thus, the selection of the relevant technology that was available and easy to use for the participants became an important and challenging criteria (Ardévol & Gómez-Cruz, 2012). Based on this aspect, WhatsApp was selected as a research tool to conduct unstructured ethnographic interviews. During the first stage of research, it was found that not all women belonging to the studied marginalised group owned a smartphone. Hence, for the purpose of the study only those women were contacted and recruited who either owned or had access to a smartphone (along with internet and WhatsApp). However, that meant leaving certain women out of the study group either because of their inaccessibility to smartphones or technological handicaps or unavailability of internet data for using WhatsApp.

To recruit participants for the study, contacts were established with two NGOs in Delhi that work with issues related to women or women empowerment. With the initial reference from the two NGOs and through engaging in conversations in their local language (which is the same as that of the researcher herself), it became possible for the researcher to build connections and rapport with the participants which led towards conducting more interviews within a short period. This also meant that at the end of it the researcher might find herself overwhelmed with the amount of empirical data collected. Thus, it becomes important for the researcher to patiently sort and catalogue this data.[6] This approach to data collection revealed that the digital medium provided the participants with more confidence and control over what they wanted to share and discuss. If some participants did not feel comfortable using typing function, they had an option to send voice messages, which some of them found easy to use and less time-consuming. It was observed that due to the low literacy level of the participants, in some cases, the typing function acted as a barrier and thus required multiple rounds of communication using a combination of voice calls and voice messages, screenshots, and so forth. Also, in the case of text and voice messages, the digital medium provided them with an option to reply at their own pace. These factors gave them more control and privacy. This aspect enabled the researcher to establish a social bond with the participants without having any physical meetings with them even once.

GPS data collection
To obtain information that is based on the actual movement of the participants, GPS tracking was used in this study. According to Schlich and Axhausen (2003), a minimum

[6] This process of handling and processing the raw data eventually became very time consuming. Thus, it becomes important for the researcher to not get disoriented in the process of collecting data through digital means.

survey period of two weeks is required to have a longitudinal perspective focusing on the spatial behaviour of individuals. It is argued that for a survey that needs information on habitual and repetitive activities and travel patterns, a shorter period may yield appropriate data (Christensen *et al.*, 2011). The data recorded through GPS will be objective; however, it may have an objective or subjective meaning ascribed or that can be derived from it.

Hence, the second part of the study required collection of data about the path travelled by the participants for two weeks continuously. Conducting remote ethnographic surveys with marginalised communities through digital means presents other challenges, such as dealing with technology handicaps. Depending on the nature of the research and the type of data to be collected, the researcher may need to explain to the participants how to use certain functions or share certain data through digital means. For instance, in this study, this issue was specifically experienced while obtaining information about their daily travel paths. The researcher was required to educate the participants step-by-step with the help of screenshots along with voice calls on how to turn on the GPS location on their smartphones and how to share their current location on WhatsApp. The participants were reassured by the researcher about maintaining their privacy at any given time during and after the research. Besides challenges like building trust and maintaining the privacy of the participants, there appeared many other factors that made collecting this data remotely very difficult or limiting. For instance, many participants did not own a smartphone by themselves and were sharing the phone within their household. This meant that certain participants did not carry a mobile phone with them all the time (wherever they went) and thus it was not possible to get information on their travel patterns. Second, in some cases where the researcher was successful to educate and make specific settings on their personal mobile phones, there was no way for the participants to share their two-week travel data with the researcher due to the inaccessibility of a computer or laptop. Due to these limitations posed by the Pandemic and remote research, it was not possible to collect GPS data for all participants.

Figure 4: Google Maps Timeline data of two participants for one day.Source: Data extracted by Author

The participant data for each day was extracted separately as individual files. The data was extracted in KML (Keyhole Markup language) format for further analysis. During the process of GPS data collection, certain flaws and limitations also came to the forefront. For instance, for one participant the data for a particular day was missing. After following it up with her, it was found that the GPS location was unknowingly turned off for that particular day. In another incidence, an unusual travel path revealed that one of the family members had carried the participant's mobile phone on that day. It is understood that GPS data has certain shortcomings and at times may not provide a true picture of actual movements performed. Thus, the acquisition of data through other methods (ethnographic interviews, in this case) helps in overcoming these deficiencies and helps in data triangulation.

Mapping for visualisation of GPS data

Maps help in presenting a holistic picture of the case and are a great means of visual representation. Shadon and Dudek (2013) mention that maps help to reveal answers to how and what questions. After plotting the movement pattern on maps, the study followed up further by using ethnographic methods to get a better explanation of why questions. Mapping can help to recognise spatial patterns through its interpretive practice and provoke context-based questions. According to Hsu (2014), maps can introduce a completely new line of inquiry by making invisible patterns visible. For this research, QGIS will be used to visualise the collected data. GIS has the potential to respond to a more critical and qualitative research method. With the help of GIS, it is possible to visually represent the spatial nature of social processes, facilitate critical thinking and construct a theory based on qualitative and quantitative data (Kwan and Knigge, 2006). However, Pavlovskaya (2006, 2016) argues that although GIS holds the capacity to deal with complex relationships, non-quantifiable properties, unprivileged ontologies, and fluid human worlds, they cannot be used to represent either quantitative or qualitative studies.

The next step involved the mapping of the travel patterns of the participants using QGIS, understanding the context and their motivations. The purpose of the data generated through GPS is to scaffold or frame the ethnographic interviews, travel diary data and the interpretative analysis of the participants' movements. With the help of the GPS data, two kinds of maps are generated- the itinerary map showing the continuous movement of the participants and the sojourn map that highlights the places where most or least time is spent. In this study, the itinerary map generated by using GPS data was used for follow-up questions as an object of further enquiry into participants' everyday mobility that includes the places they visited and any additional information or experience they want to share related to their travel journeys.

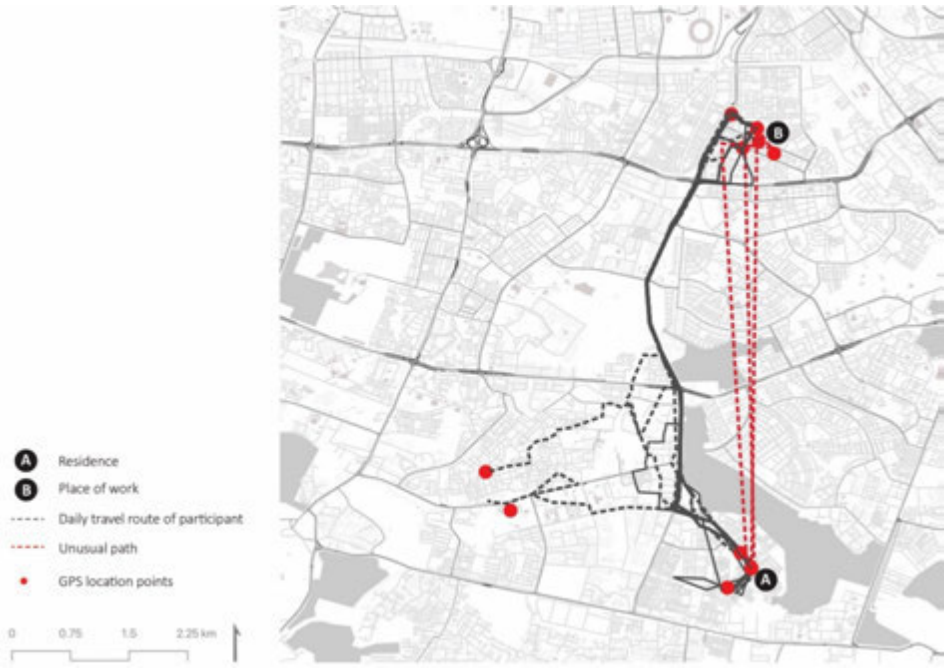

Figure 5: Map representing the two-week GPS data from Google Maps Timeline of one of the participants

The next step that followed the initial interviews with the participants involved getting to know specificities about their daily travel patterns. Time-geography diagrams were developed based on the mapped survey information which formed a layer over the base map of Delhi (Figure 6). Time geography refers to the representations of the paths travelled through space and time that are plotted along two spatial axes and one temporal axis. Time-geography is often used as a tool to explore mechanisms of societal change (1970). Developing on the work of Hägerstrand (2005), Thrift (2005) reflects upon the existence of human action in time and space. Thrift (Gell, 2021) highlights the relevance of time-geography within the realm of social theory. Time-geography is considered to be a strong visual representation of 'thereness'. Moreover, time-geography goes beyond social constructionism to highlight the physical constraints on human activity (2020). An overview of the variation in the movements of the participants is depicted through these time-geography diagrams.

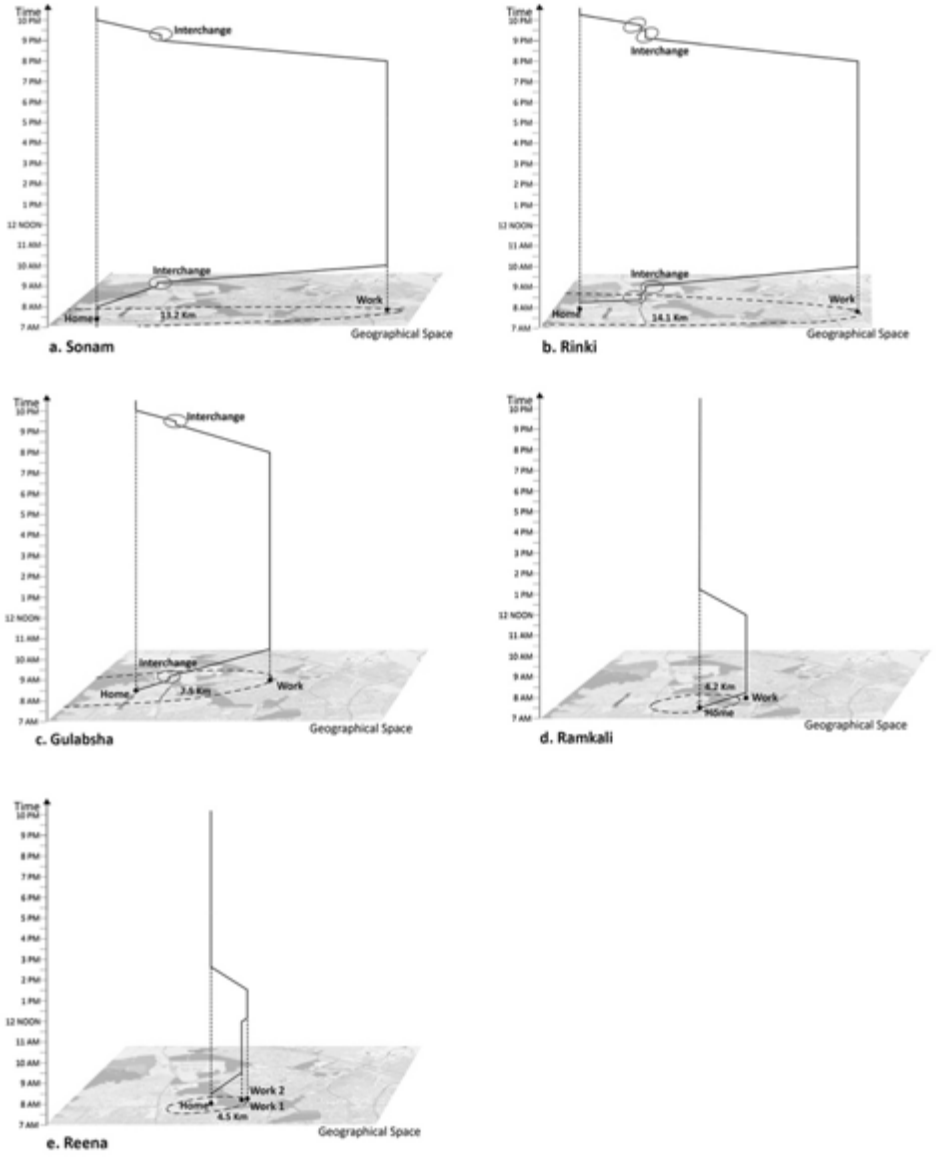

Figure 6: Travel patterns of the five participants are shown with the help of time geography diagrams. These are exemplified with elementary events, such as, travel; inter-change; arrive; stay; leave. Source: Gera & Hasdell (2020)

Discussion

More recently, there has been a focus on studying different types of mobility in reference to the society itself. This brings attention to investigating hidden meanings

associated with mobility that are related to socio-cultural factors, identities, informal networks within specific contexts. Mobile methods help Using mobile methods for a study related to mobility focusing on urban marginalised women and urban informality helps to highlight these concepts and presents a holistic perspective towards mobility. Supported by the literature the mobile methods approach for data collection helped to understand the interconnected socio-spatial factors that impact (enable or hinder) the overall mobility of UMW / people. Mobile methods enable to investigate and understand small and mundane everyday mobilities or immobilities that otherwise are ignored or taken for granted. Moreover, feminist researchers also highlight the importance of the analysis of daily mobility patterns (Hanson and Johnston, 1985; Butler and Bowlby, 1997; Law, 1999; Hanson, 2010).

These methods help to reflect on new perspectives that include socio-political inquiries besides focusing on spatial environments. Studying everyday mobilities using mobile methods presents a relational perspective by considering 'scale' as a significant factor. That is, it enables to understand the relationship of micro-level movements associated with the actor itself to those associated with mobile and immobile co-travellers and infrastructures. Besides 'scale' mobile methods bring attention to the aspect of temporality in mobilities study. For example, studying an actor on the move will also highlight other activities, conversations and non-movements and thus enables the researcher to discard the notion of linearity in studies on mobility. Mobile methods go beyond understanding mere spatial mobilities. They reveal interconnected factors which may occur on the move and help them to form temporal connections with social and spatial infrastructures to gain knowledge which may impact their mobility. It opens a dialogue towards multiple effects of mobilities.
Mobile methods enable the use of new technologies like the GPS to study and analyse mobilities of different entities. It enables to scale-up the investigation to reveal common patterns. Conducting the field study with a traditional ethnographic approach, the researcher is constrained by the physical fact that she can only be present in one place at a time. There may be instances when critical interactions take place at a time when the researcher is not around. Mobile methods help to take care of such situations and enables data collection with multiple participants at the same time. Using mobile methods also enables active participation of people within the process which gives them agency to share the required information with the researcher. Besides GPS, the use of ICT and social media platforms enable sharing of reliable data (from the participants) in real-time. These tools used as a part of mobile methods give a sense of trust and control to the participants. The participants feel more comfortable using these tools as compared to a device given to them by the researcher to carry with them. However, using new technologies within mobile methods present a challenge to engage and study mobilities of marginalised groups such as socio-economically weaker groups, especially women and children. Although the case study presented in this paper has used mobile methods with UMW, it highlights that there exist barriers in terms of ownership of new technology research tools, such as smartphones due to financial and social exclusions with respect to such groups. Also, a lack of technological know-how among these groups impacts data collection and sharing with the researchers. Thus, it is required to conduct more comprehensive mobility studies using mobile methods with marginalised populations to understand the potential of new technologies within this context.

How are youth living in ageing neighbourhoods?

A Case Study in the Central District of Shanghai

Yun Yu[1], Yi Huang[1*]
[1]Tongji University, China
[*]Email: huangyi@tongji.edu.cn

Abstract
With the construction of youth development-oriented cities, the phenomenon of housing/community youthification has emerged in the central districts of mega-cities. Communities in central mega-cities, which used to be mature, tend to have a significant ageing population and have formed their own cultural atmosphere and social relations. The living conditions of young people in these communities need to be studied. Taking Chuangyu 228, a youth-oriented guaranteed rental housing in Yangpu, Shanghai, as an example, the living conditions and satisfaction of young people are surveyed and analysed based on both the supply-side and demand-side perspectives from the physical, social, and cultural dimensions. The research provides empirical evidence of housing/community youthification in Chinese mega-cities and offers insights for optimising youth housing policies and community planning.

Keywords
youth apartment, youth community, affordable rental housing, youthification, youth-friendly city

1 Research Context

1.1 Real-world Context: Construction of Youth Development-oriented Cities and Youth Housing in China

In China, as innovation has become an increasingly important driver of urban development, young talent has also become the mainstay of urban social development. In January 2021, the Chinese government proposed to build youth development-oriented cities, and currently 60% of Chinese cities have proposed to build youth-friendly cities and communities. One of the most important strategies is the provision of youth-oriented affordable rental housing.

Although many youth housing units have been built in the suburbs, a significant proportion of them are located in the city centre in the context of urban renewal. On the one hand, the central urban area attracts young people because of its abundant job opportunities and great amenities. On the other hand, some communities in the central city have been built for a long time and are in urgent need of renewal, which can be seen as the frontiers of gentrification according to Neil Smith's rent gap theory. The government carries out a series of urban regeneration activities to re-invigorate the land's value and the city's vitality, of which the youthification of houses and neighbourhoods is one form.

1.2 Theoretical Context: Youthification Phenomenon in Housing/Communities in China's Mega-City Central Areas

Youthification is the contemporary lifestyle, demography, and socio-economic condition of the young ‘playing out in the landscape’ (Moos, 2016). From a spatial perspective, youthification

is manifested in the aggregation of the youth population in a given space. From a social perspective, youthification refers to the increase in youth discourse and youth cultural influence. Studies on gentrification often consider youthification as an indicator of gentrification, but Revington et al. (2023) argue that youthification is a different process from gentrification because youth include not only the middle class but also those in ordinary economic conditions. Research on age-based sociospatial differences has not been emphasised. In recent years, although there has been an increase in the literature on youthification, most of the studies explore the settlement patterns of young people at the macro city scale, and there is a lack of studies that explore youth residential characteristics from the micro block scale. At the same time, there is also a lack of empirical support for the possible neighbourhood effects of youthification. On the one hand, youth population aggregation may influence the values and behaviours of other age groups to have the status and qualities that young people have, thus making society more dynamic and creative. On the other hand, it may also lead to age-based spatial segregation and age discrimination (Luo, 2017). As for the mature neighbourhoods in the city centre, they usually have an ageing population and have developed their own cultural atmosphere and social relations. How young people live in these ageing neighbourhoods and whether they can integrate or not need to be examined. In addition, research on youthification based on the Chinese context is a relatively blank area. China's unique political system and economic and social background will further enrich the theory of youthification.

1.3 Research Question: Issues of Youth Living Conditions in Youthified Housing and Communities

Therefore, this study takes the youthification of housing in ageing communities as the research theme. Based on a dual perspective from both the supply side and the demand side, the article examines the living situations of youth from physical, social, and cultural dimensions, investigates the youth's satisfaction with their living conditions, analyses the problems therein, and proposes corresponding strategies. The study provides an empirical case of the phenomenon of youthification of housing from a Chinese megacity and enriches the theory of youthification. It also provides references for optimising youth housing policies and neighbourhood planning.

2 Research Design

2.1 Research Subject

Chuangyu 228, an affordable youth rental apartment within 228 Block is selected as the research subject.

228 Block is located in the Changbai Xincun Subdistrict of Yangpu District, Shanghai. Originally constructed in 1952, it was one of the first batch of "Twenty Thousand Households" worker housing projects in Shanghai, aimed at addressing housing difficulties for industrial workers. However, the "economical and practical" housing built under limited economic conditions at that time could no longer meet contemporary residential needs. From 2016 to 2023, the government carried out an urban renewal project in the 228 Block, constructing 450 sets of affordable rental housing targeted at youth, namely Chuangyu 228. Additionally, a series of community commercial and service facilities were established (Lacime Architects, 2023). As of December 2023, 426 households had moved in, with an occupancy rate of 96%. The residents include young talents from various industries such as the Internet, finance, and entertainment, mainly from nearby areas such as Wujiaochang, B-Link, Changyang Campus, and Fudan Software Park. The traditional worker's new village has been upgraded to the new generation of young achievers' community ecosystem.

Figure 1. Location of Chuangyu 228

The Second Residential Area of Changbai Road, where Chuangyu 228 is located, is a neighbourhood characterised by a significant elderly population. According to data from the Seventh National Population Census of China, in 2020, the proportion of elderly people aged 60 and above in the community was 33 %, with those aged 65 and above accounting for 22%, both higher than the average levels of 24% and 16% in Shanghai. Therefore, Chuangyu 228 serves as a representative case for studying youth housing and community in ageing neighbourhoods.

Table 1. Proportion of Elderly Population

	Aged 60 and Over.	Aged 65 and Over.
Shanghai	24%	16%
Yangpu District	32%	22%
Changbai Xincun Subdistrict	24%	34%
The second Residential Area of Changbai Road	22%	33%

2.2 Research Methods

A combination of questionnaire surveys, in-depth interviews, and on-site surveys is employed by the study to analyse the housing and community characteristics of Chuangyu 228 and the living conditions of its residents. The questionnaire survey is mainly utilised to understand the composition of young residents, the use of community places and facilities, social interaction within the community, and the community identity and residential satisfaction of the youth. In-depth interviews target both the staff of Changbai Xincun Subdistrict, Second Residential Area of Changbai Road, and Shanghai Yangpu Technology & Innovation Group to comprehend the renewal process and management of the Chuangyu 228, and the residents of Chuangyu 228 to achieve a deeper understanding of the questionnaire content. On-site surveys are mainly conducted to understand the housing conditions, distribution, and utilisation of surrounding public service facilities.

3 Youth Community Provision

3.1 Physical Dimension: Building a Home-Centred Residential Life Circle

3.1.1 Small-Scale, Sophisticated Housing Units

Chuangyu 228 provides small-scale housing units of approximately 40 square meters for young families of 1-2 people. These units possess balconies and private bathrooms and are fully furnished with high-quality wooden furniture (bedside tables, wardrobes, desks, sofas, double beds), and equipped with branded appliances (air conditioning, refrigerators, water heaters, televisions, washing machines, range hoods, induction stoves), as well as modular bathroom

systems and other furniture facilities. Surveys among tenants show that favourable living conditions are a significant factor that attracts them to choose Chuangyu 228 as their residence.

Table 2. Unit Types of Chuangyu 228

Unit type	A	B
Floor Area	35-40 ㎡	40-45m²
Floor Plan		

Figure 2. Interior Rendering of Chuangyu 228
Source: promotional materials for Chuangyu 228

3.1.2 Comprehensive Public Service Facilities

The apartment is located 800 meters from the Yingji Middle Road Station on Metro Line 8. Within a radius of 500 meters, there are 13 bus stops, making transportation extremely convenient. At the same time, through the provision of facilities at the levels of subdistrict, block and apartments simultaneously, a 15-minute community life circle centred around the apartment for young residents has been established.

At the apartment level, relying on the innovation and entrepreneurship resources of Shanghai Yangpu Technology & Innovation Group, the brand "Create+" is implanted into the apartment, providing office workstations, multi-functional halls, meeting rooms, and other shared space carriers, which can carry the functions of office negotiation, book reading, and socialising. A rooftop garden is built on the 12th-floor terrace of the apartment, where public activities such as camping and planting can be carried out. Provide a pet boarding warehouse to provide tenants with pet boarding services. The apartment also provides pet boarding facilities, offering pet boarding services to tenants.

Figure 3. Key Public Facilities in the apartment
Source: https://www.jfdaily.com/sgh/detail?id=1086968

At the block level, the 228 Block is positioned as a community commercial and service centre during the renewal, focusing on the complementary provision of the original surrounding living service facilities and configured with public facilities such as community canteens, fast-food stores, convenience stores, fresh food supermarkets, and municipal facilities such as public parking lots. In particular, it focuses on the needs of youth groups, introducing cafes, bars, fitness centres, boutique supermarkets and other businesses that attract young people. At the same time, 228 Block merchants offer a series of tenant-oriented discounts so that youth can access convenient, discounted services.

At the subdistrict level, the 15-minute living circle of Chuangyu 228 covers Changbai Xincun and Yanji Xincun Subdistrict. The mature neighbourhoods of the two subdistricts provide convenient basic living service facilities for the young tenants.

3.2 Social Dimension: Implementing Admission Mechanisms to Screen Residents

Chuangyu 228 offers 450 sets of standardised guaranteed rental apartments targeted at young people. Through entry policies, apartment types, and rental rates, it selects a homogeneous and stable tenant group.

3.2.1 Entry Policies

Chuangyu 228 is included in Shanghai's guaranteed rental housing management system and adheres to a unified admission system. Applicants are required to fulfil two basic requirements. First, they should be in-service personnel legally employed in Shanghai and their spouses or children. Second, they must not own any property in Shanghai. Alternatively, if the applicants, their spouse, or children own property or lease public housing within the seven central districts of Yangpu, Hongkou, Huangpu, Jing'an, Xuhui, Putuo, Changning, and Pudong New Area (inside the outer ring), the per capita residential floor area should be less than 15 square meters.

3.2.2 Rental Rates

The apartment rent is paid either with a one-month security deposit and one month's rent upfront or with a one-month security deposit and three months' rent upfront. Different from market-rate apartments, the unit prices for water and electricity are based on the standard rates for residential use. The apartment rent strictly follows the evaluation of relevant municipal departments, with a one-price-per-room policy. Rentals are offered at less than 90% of the evaluated price. For rooms with a floor area ranging from 30 to 45 square meters, the average monthly rent falls within the range of 3200 to 4600 yuan. The rent includes property management fees. Internet access is provided for free.

The lease contract period is typically not less than 1 year and not longer than 3 years. After the lease contract expires, if the occupants still meet the admission criteria after undergoing reevaluation, they may renew the lease. However, if they no longer meet the admission criteria, they should vacate the premises.

As a result, tenants of the apartment are mostly new white-collar workers with stable incomes but shorter working years and limited savings.

3.2.3 Unit Types

The apartment mainly provides one-bedroom units, and occupants must be the lessee themselves, along with their spouses and children. Therefore, the majority of tenants are young singles and married couples without children.

3.3 Cultural Dimension: Cultivating a Cultural Atmosphere for the Youth Community

3.3.1 Internal: Community Building

Chuangyu 228 actively carries out diversified and youthful community activities, such as regularly organising leisure and entertainment activities loved by young people such as board games and script-based role play games, as well as festive and holiday-themed events such as Women's Day Tulip Handicrafts and the Anniversary Carnival. These efforts aim to enrich the tenants' leisure time, foster a sense of community, and enhance young adults' sense of belonging and identity with the apartment's youthful culture.

In addition, spaces like the community service centre and the central lawn within the 228 Block regularly host various events organised by the street and city authorities, such as park fairs, lawn concerts, outdoor movie screenings, and community health clinics. These events encourage the young residents living in the apartment to participate.

3.3.2 External: Activity Constraint

Chuangyu 228 is a centralised living space for youth and is located in the northwest corner of the site. The spatial isolation from other residential buildings somewhat limits the interaction of youth with other age groups. Also, the tenants' social behaviour is subject to certain constraints by the leasing regulations established by the apartment. For example, Chaungyu 228, being a tightly managed gated apartment, is equipped with a facial recognition access system, allowing only residents to enter. Visitors are required to register at the lobby and are not allowed to stay overnight. It has been shown that gated management can provide tenants with discreet and secure private spaces, but may also reinforce the segregation of residents from other members of the community (Roitman, 2005; Wu, 2005).

4 Youth Community Living

4.1 Physical Dimension

4.1.1 Commuting

（1）Mainly Public Transit

Young tenants of Chuangyu 228 mainly commute by a combination of "walking/cycling + subway" and "walking + bus". The subway and cycling were the most popular modes of travel, both chosen by more than half of the respondents. Walking and buses were also chosen by about 30% each. In contrast, cabs and private cars were chosen by a lower percentage. This reflects the accessibility of public transportation around Chuangyu 228.

（2）Mainly Short Commutes

Overall, the daily commuting time of young tenants is relatively suitable, and the balance between work and residence is relatively good. The survey shows that 82% of the respondents have a one-way commuting time of less than half an hour. Among them, 55% of people have a one-way commute time between 15 and 30 minutes, while 27% have a one-way commute time

of less than 15 minutes. 18% of people have a one-way commuting time of between 30 and 45 minutes, which is relatively low. No one has a one-way commute time exceeding 45 minutes.

4.1.2 Use Frequency of Places and Facilities

（1）Within apartments: low use frequency of places and facilities

The results of the questionnaire show that the intelligent boarding kennel, VIP reception room, and shared meeting room are hardly being used. While some users opted for "at least once a week" or "at least once every two weeks" for the shared hall and rooftop garden, the majority still chose "less than once a month," at 64% and 73%, respectively. Apartment managers need to adapt and optimise the function and orientation of their facilities to better meet the needs of their residents. Apartment managers need to adapt and optimise the function and positioning of these facilities to better meet the needs of their residents.

（2）Inside the 228 Block: high variation in use frequency of places and facilities

According to the survey results, residents exhibit varying frequencies of use across different types of life service facilities and places within the 228 Block. Tenants most often use bars, cafes, milk tea stores and other space facilities that provide beverage vending and third-place functions, and more than 80% of tenants use them at least once a week. The use frequency of activity places and facilities, including outdoor public spaces (such as central lawn, small squares, vacant lots, etc.), and the 228 Sports and Health Centre, is also relatively high, with over 45% of tenants using them at least once a week. There are differences in the use frequency of dining facilities. Commercial snack shops, fast food restaurants, and branded dining establishments have higher use frequencies, with most people using them once every two weeks to once a week. However, nonprofit community canteens, which are popular among the elderly, are not very popular among young people, with most people using them once a month. In terms of shopping facilities, branded supermarkets and ordinary convenience stores have similar use frequencies, with most people using them once every two weeks to once a week. Other convenient commercial facilities, such as hair salons, eyewear stores, and nail salons, have lower use frequencies, with 64% of respondents using them once a month or less. The use frequencies of service facilities (community public health service station, community party service centre, union service station, etc.) and children's facilities are also low, indicating that the tenants of Chuangyu 228 are not the primary service clientele for these two types of facilities.

（3）Outside the 228 Block: low use frequency of places and facilities

Similarly, young residents exhibit relatively low use frequencies for external life service facilities and places. Among these, dining facilities (such as restaurants, cafes, beverage shops), shopping facilities (such as convenience stores and markets), and public spaces (such as parks, squares, fitness trails) have relatively high use frequencies, with over 46% of tenants using them at least once a week. Furthermore, leisure facilities (such as KTVs, bookstores, cinemas) also have relatively high use frequencies, with 36% of residents using them at least once every two weeks. The use frequencies of community cultural activity facilities (community cultural activity centres, cultural activity rooms) and medical facilities (hospitals, community public health service centres, and public health service stations) are relatively low. Specifically, 36% of tenants use these facilities at least once a month. The lowest use frequencies are observed for employment facilities and parent-child facilities, with less than 10% of tenants using them at least once a month.

4.1.3 Usage Hours of Places and Facilities

（1）Weekdays: usage hours tend to concentrate

The majority of respondents indicated that the most common period for using public service facilities and places is from 18:00 to 22:00 after work. Additionally, approximately 30% of respondents selected 14:00 to 18:00, while 20% opted for 8:00 to 11:00.

（2）Weekends: usage hours tend to disperse

The usage time of facilities and places on weekends is concentrated primarily in the noon and afternoon periods. In the survey, the highest proportion, 64%, selected the time range from 12:00 to 18:00. Following that, 55% of respondents selected the time range from 11:00 to 14:00. The third most popular option was "18:00-22:00," selected by 46% of respondents.

4.2 Social dimension

4.2.1 Resident Population

（1）Mainly highly educated single youth or young couples

The surveyed population all have a bachelor's degree or higher, with over 80% of respondents aged between 25 and 30, indicating that the majority are university graduates of about five years. Most of the respondents live alone, accounting for approximately 64%, followed by living with a spouse, with very few living with children. Overall, the residents of Chuangyu 228 are mostly single young adults or young couples aged 20 to 35, with an annual income of over 100,000 yuan and holding a bachelor's degree or higher.

（2）Mainly transitional living

The surveyed population is comprised of individuals with bachelor's degrees or higher. Over eighty per cent of respondents are between the ages of 25 and 30, indicating that the majority are university graduates who have been out of school for approximately five years. Most respondents live alone, accounting for approximately 64%, followed by those who live with a spouse, with very few living with children. In summary, the residents of Chuangyu 228 are mostly young singles or couples aged 20 to 35, with an annual income of over 100,000 yuan and a bachelor's degree or higher.

4.2.2 Neighborhood Interactions

Low frequency and shallow levels.

The study investigates the frequency of interaction between tenants and other residents in the community, including "greeting each other when meeting," "visiting or engaging in activities together," and "engaging in deep conversations or discussing intimate topics." The results show that the majority of respondents rarely engage in these three types of interactions. The percentages reached for each of the three interactions were 55%, 73%, and 82%, respectively. This indicates that young tenants at Chuangyu 228 tend to be conservative and cautious in their social interactions, with a lack of deeper connections.

4.2.3 Activity Participation

（1）Low participation in all types of activities

The study examined tenants' participation and willingness to participate in volunteer activities, community cultural activities, and interest-based clubs or groups. In general, residents exhibit low levels of involvement in all three types of activities. The results indicate that a negligible proportion of respondents participate in volunteer service activities, with only 19% having experience in interest-based clubs or groups. The number of individuals who participate in community cultural events is the highest, yet still less than 30%.

（2）Differential willingness to participate in various types of activities.

The proportion of individuals willing to participate in community cultural activities and interest-based clubs or groups is relatively high (over 45%), whereas the proportion willing to participate in volunteer service activities is low (9%).

4.3 Cultural Dimension

4.3.1 Perception of Community Boundary

Young tenants of Chuangyu 228 perceive the boundary of the community mainly based on their own daily activities, with less overlap with the boundary of community management. The majority of respondents (82%) perceive the boundary of the community to be that of 228 Block, while a smaller proportion (18%) view the boundary of the community as that of apartments. The area of Changbai Xincun Subdistrict and the area of the Second Residential Area of Changbai Road are not included in the youth's perception of the community.

4.3.2 Perception of Community Function

The function of 228 Block as perceived by the young tenants of Chuangyu 228 is firstly a place for leisure and entertainment, with a score of 3.18. Secondly, it is a place for consumption and shopping, with a score of 2.64 points. The third and final category is that of a place for community interaction, with a score of 2.36. Finally, it is a place for history and culture, with a score of 1.82.

4.3.3 Identity of Community Culture

The survey of young tenants of Chuangyu 228 reveals a low level of identification with the original culture of the community. Over half (55%) indicate that they know little or nothing about the history and culture of the 228 Block, while only a small proportion (18%) demonstrate a more extensive knowledge of it.

4.3.4 Sense of Community Belonging

The majority of young tenants (55%) surveyed exhibit a strong sense of belonging to their community. However, a notable proportion (36%) express uncertainty about their sense of belonging, while a smaller group (9%) report a "weak sense of belonging." No respondents indicate a lack of belonging or a strong sense of belonging.

5 Youth Residential Satisfaction

5.1 Overall Satisfaction

The survey indicates that the majority of Chuangyu 228 residents are either relatively or very satisfied with their living situation, representing over 90% of the total.

5.2 advantages of Living

Better housing conditions and more complete community service facilities are the main advantages of living in Chuanyu 228, recognised by over 75% of respondents. This demonstrates the importance young people place on housing and community hardware facilities. Three potential advantages of Chuanyu 228, including better value for money, easier commuting, and closer proximity to commercial centres, are also recognised by over 30% of respondents. In contrast, the option of having more peers only received 11.11% agreement, indicating that this does not seem to be a major factor influencing young people's housing choices.

5.3 Youth Development Support

（1）Primary support for basic living

The support in "meeting housing needs" and "providing diverse and convenient daily life services and facilities" is universally recognised by respondents, with over 70% of individuals considering the help "very significant" or "quite significant".

（2）More support for leisure and culture

The support in "obtaining rest and relaxation, maintaining physical and mental health" and "enriching spiritual and cultural life, showcasing cultural personality" receives considerable recognition, with over half considering the help "very significant" or "quite significant".

（3）Less support for socialisation and skill enhancement

The support in "expanding social circles, improving social skills," "acquiring life skills, enhancing social adaptability," and "providing opportunities to participate in public affairs, enhancing urban integration" is acknowledged by some respondents, with approximately 10% choosing "very significant" or "quite significant" help for each of the three aspects.

（4）Least support for work and family-related matters

In terms of "increasing employment opportunities, improving work efficiency, and obtaining economic benefits" and "providing elderly care and childcare services, sharing family care responsibilities," respondents' satisfaction is relatively low, with over half considering the help "very little" or "quite little". This result may be related to the residents' relatively stable employment and the minimal pressures of elderly care and childcare within their life cycle.

6 Conclusion

6.1 Boundaries between Young and Old Individuals' Lives are Clear.

There are notable contrasts between younger and older individuals in their utilisation of community facilities and space. In terms of temporal patterns, younger individuals tend to utilise community facilities in the evenings or on weekends, while older individuals are more active during the day. In terms of spatial preferences, younger individuals prioritise freedom and privacy, as well as consumer-oriented facilities, while older individuals tend to prioritise public outdoor spaces and facilities for public welfare. The young and the old share space and facilities to a certain extent, but they have few and shallow communications and are isolated from each other in terms of social relations. It can be seen that, as a form of housing supply for young people, concentrated rental housing aimed at young people inserted into communities has a limited short-term impact on the original spatial social structure.

6.2 Neighborhood Interactions Insufficiently Predict Youth Community Identity.

It is generally believed that positive interactions between neighbours can contribute to the formation of a sense of community identity. However, the findings of this study indicate that, despite a reduction in the frequency of interactions among young people in their neighbourhoods, their sense of community identity remains high. The reason lies in the pursuit of high living quality and the emphasis on privacy among young residents of Chuangyu 228. They collectively establish boundaries to maintain their personal daily life domains. By creating aesthetically pleasing and comfortable living environments, and enhancing the quality of life, they turn the community into a shared living space. This result reminds planners to reconceptualise the community lifestyle of youth. The creation of free, private and personalised spaces may be more important in youth housing construction and youth community planning.

6.3 Residential Expectations Influence Residential Satisfaction.

Due to housing size and residency rules, the majority of tenants in Chuangyu 228 are young, unmarried and living alone, viewing it primarily as a temporary residence. They predominantly

perceive it as a place to meet basic life needs, rather than fulfilling deeper needs such as skill acquirement or expanding social circles. Consequently, despite the community's inadequate support in these aspects, overall residential satisfaction among young residents remains relatively high. For youth housing and community planning, it is essential to enhance infrastructure and service levels to meet residents' basic life needs maximally. Additionally, providing diverse and flexible housing options and fostering a rich, vibrant community environment is crucial.

Embracing Diversity: Ararat's Role in Inclusive Urban Development and Migration in Rome

Angelina Grelle
Affiliation: DIST-Polytechnic of Turin
Email: angelina.grelle@polito.it

Abstract
This paper aims to contribute by spotlighting an example of inclusive practices aligned with the principles of open city, specifically focusing on a migrant community who have established a socio-cultural centre in Rome, called Ararat. Ararat nestled in Testaccio neighbourhood with its enduring presence, stands as a testament to the resistance and vibrancy of the Kurdish community, particularly noteworthy as the neighbourhood undergoes development and renewal as part of the National Recovery and Resilience Plan. By examining Ararat's journey, this paper seeks to extract valuable insights and lessons that can inform urban planners and policymakers engaged in inclusive urban development projects. The longevity and vitality of Ararat underscore the importance of incorporating the unique perspectives and contributions of migrants communities in the urban renewal process.

Keywords: Migration, Rome, Participation, urban renewal

Introduction

Migrations are widely acknowledged to be the main vector of change in cities. Nicholas De Genova (2015) argues that transnational migrations are the primary drivers of the transformation of urban space and social production in contemporary cities. Italy, and particularly its capital Rome, has always been reshaped by migrations. The Shish Mahal, for instance, the first migrant occupation experience between 1990 and 1991, marked a significant moment in the city's migration history. In recent decades, the policies of the European Union and right-wing governments have forced migrants into precarious and dangerous urban situations. The structures meant to support and integrate migrants have proven inadequate, either unable or unwilling to address their recurrent problems (Ambrosini, 2011). Italy is significantly impacted by 'secondary movements' of migrants—those attempting to reach other parts of Europe but who are either stuck in Italy or forced to return because it is their initial point of entry and the place where they can process their documents. Often secondary migration is described as the act of individuals seeking improved conditions (Wagner et al. 2019) outside the confines of legal migration channels, contrary to the stipulations of EU migration and asylum laws.

According to the 2021 Migration Report by the Metropolitan City of Rome, the city has historically served as a destination for internal migration and currently serves as the primary departure point for illegalized migration in Italy. This influx of people has generated various informal spatializations as individuals seek shelter during their transition period in Rome—some more stable, others highly temporary.

This paper focuses on a community in Rome primarily composed of 'secondary movement' migrants who regularly gather at a socio-cultural centre: the Kurdish socio-cultural centre of Ararat, situated in Testaccio, a historic and central neighbourhood of Rome. Campo Boario, the section of the former slaughterhouse where Ararat is located, was a significant point of shelter for migrants from diverse backgrounds. Although it was unorganized and perceived as dangerous, Campo Boario was one of the most cosmopolitan places in the city, embodying the surreal urban imagination of Pasolini and Fellini (Careri and Romito, 2005). Today, it largely reflects the impacts of globalization. Ararat remains the only enduring 'migrant' entity and

legacy within Campo Boario, now threatened by various PNRR (National Recovery and Resilience Plan) plans and projects surrounding the entire area and neighbourhood, despite no official communication or eviction notice being issued to the centre.
This paper aims to reflect on the possibilities for Ararat to establish a participatory process with the administration of Rome, emphasizing the 'on the move' component of its community. Situating the discussion within the literature on planning and migration, it explores how a migrant community can assert the right to speak for themselves, protect their presence in the space, and affirm their right to the city, as a concept based more on urban presence than ownership (Allon, 2013; Purcell, 2002, 2013). This study highlights the potential for migrant experiences to inform urban renewal and integration practices, presenting Ararat as a model for creating inclusive and participatory urban spaces.

Migrations and Planning

In recent years, urban and migration studies have addressed the migration-city nexus from many perspectives. The 'local turn' has highlighted the centrality of cities in migration studies (Briata, 2014; Çağlar and Glick Schiller, 2018). Cities are widely acknowledged as fundamental nodes of planetary fluxes (Brenner, 2013; Sassen, 2008) and are central to bridging together transnational political movements and migrations. International migration can have different impacts on cities: they can serve as arrival points for migrant communities aiming to settle (Saunders, 2010) or function as spaces of transition and stopover points (Iranzo, 2021).
The literature, especially in critical geography, has extensively explored the forms of inhabitation of people on the move (Bonfanti et al., 2022), generating by temporary, 'liquid' migrations (Black et al., 2010). These processes are sometimes not temporary but become extended periods of waiting (Bernardie-Tahir and Schmoll, 2018), which can occur multiple times during the migration journey. Scholars have addressed the spatialization of migration processes such as makeshift camps (Katz, 2017; Oesch, 2017), informal settlements, humanitarian camps, and squatting practices (Raimondi, 2019). Katz (2023) highlights how the EU's bordering regime creates urban border zones where migrants, aiming to move but forced to stay due to restrictive policies, generate temporary urban realities. These policies aim to illegalize migration, closing all legal avenues for individuals to move (Aru, 2022). Along with those explorations, scholars have highlighted how migrants and local activists create grassroots experiences to cope with the lack of an effective reception system (Caponio, 2005; Benson, 2019; Swerts & Nicholls, 2020; Tsavdaroglou et al., 2024). While informal formations in planning have gained significant relevance worldwide (Roy, 2005), attention to these informal practices is relatively recent in Western countries (Cremaschi et al., 2020). In planning studies about migration more research has been done on policy (Murillo, 2017), governance (Maptisa, 2019), and institutions (Landau, 2013; Barbarino et al., 2021). Another strand focuses on city-level policies that counteract national policies, creating grassroots solidarity experiences (Mitchell and Spake, 2018; Bauder, 2019; Bauder, 2021). Despite the growing interest in migration within urban planning (Bernt, 2019), migration is rarely addressed as a central strategic line or concrete policy in urban plans. Instead, it is often used as a demographic description tool (Skeldon, 2013). The literature provides few examples of how the participation of migrant communities can achieve long-term integration (Bessho et al., 2020). What remains highly underdeveloped is the participation of migrant communities in the planning process (Zhang et al., 2023), even less has been said concerning migrant communities that aren't settled but 'on the move' or about 'secondary movement'. This paper presents an experience of a migrant community that asserted their right to stay due to their continuative presence, as community not single members, in the space and acquired recognition opening a dialogue with the municipality members underling the potential of inclusivity in the urban landscape. In the next section, I will outline the methodology and present the early results of the research. This

includes contextualizing the presence of Ararat in Rome and reflecting on the possibilities this experience can add to the literature underlined above about 'people on the move' and planning.

Methodology

This study is based on ongoing ethnographic research in Rome. For this paper, a multi-methodological approach was employed, combining archive analysis, document analysis, and interviews to ensure a comprehensive examination of the research topic.

The archive analysis involved a systematic review of historical records and documents preserved in the archives of Stalker and Villaggio Globale. This allowed for the exploration of primary data that shed light on past events, organizational histories, and contextual backgrounds. The historical context provided by these archives is crucial for understanding the evolution and significance of spaces like Ararat in Rome's social and cultural landscape.

Document analysis complemented the archival work by critically examining various texts, including reports, memos, policy documents, plans, projects, newspaper articles, and other written materials. This method helped identify patterns, themes, and insights relevant to the research, facilitating an understanding of the formal and informal structures, processes, and communications within the studied context. Analysing these documents (with particular attention to resolution n104 and the subsequent regulation of the municipality of Rome) enabled a deeper insight into the policies and administrative decisions that have impacted the operation and existence of socio-cultural centres like Ararat.

Additionally, semi-structured interviews were conducted with key informants, providing firsthand insights and perspectives that enriched the data gathered from archival and document analyses. Twenty interviews were conducted with Kurds and Italians who engage with the space of Ararat, including municipality members. The interviews enabled the collection of nuanced, subjective experiences and interpretations that might not be evident in written records. These interviews were pivotal in capturing the perspectives of the Kurdish community and understanding their interactions with the broader urban environment of Rome.

Moreover, valuable information was gathered through participation in public events at Ararat, where members of the administration were involved. These events provided opportunities for informal conversations, which proved fundamental in gaining insights that might not surface in official meetings, interviews, or archival records. This informal dialogue helped fill in gaps and added depth to the understanding of the dynamics at play.

The triangulation of data from these various sources—archival records, document analysis, interviews, and participant observation—ensured a robust and comprehensive approach to the research. This method allowed for cross-verification of information, enhancing the reliability and validity of the findings. By relying on multiple data sources, the study could present a well-rounded narrative of Ararat's role in integrating migrant communities and its potential as a model for urban renewal and social inclusion in contemporary cities.

Ararat and Rome

Rome has traditionally been an immigrant city; throughout the entire 20th century, it welcomed a flux of people from southern Italy. In the 1970s, it recorded a growth in immigration from foreign countries mainly from the EU. By 2003, approximately 10% of all foreign residents in Italy lived in Rome. Today, Rome can be considered a departure city, according to Katz's definition: "a specific urban spatiotemporal typology emerging in particular geopolitical contexts of cities located just ahead of fortified and hostile border zones, where stranded migrants reluctantly remain while attempting to continue their journey" (Katz, 2023:2).

Due to the Dublin Regulation, many people are forced to stay in Italy to seek asylum, leading to a very complex and violent situation for those who must seek protection in Rome. The reception system is inadequate, involved in illegal practices, and run by a far-right government

that aims to prevent people from arriving in the country through exclusion, illegalization, and violence. This political situation makes life very difficult for people on the move in Rome. Throughout Italy today, migrants are often treated as intruders and threats to security due to anti-migration policies and political propaganda. Despite the presence of some non-governmental organizations and voluntary religious associations, there are not enough places in Rome that guarantee asylum and protection for refugees. The tragic news about the CPR (Repatriation Detention Centres) of Ponte Galeria in Rome perfectly describes the inhumane conditions that migrants face in the city.

In this complex landscape, a positive reality like Ararat emerges for the Kurdish migrant community. Despite Rome was never a settlement place for Kurds, the Kurdish migration it's relatively young in Italy. Until 1997, the influx of people from Kurdistan trying to reach families in Germany, France, and the Netherlands went almost unnoticed by the institutions. In 1997, the transit of Kurds was quite consistent for the time (4,500 between January and October 1997). The movement from southern regions of Italy towards those countries provoked the enforcement of the Dublin Convention. During this period, the so-called 'Kurdish emergency' erupted. Also, on December 27, 1997, 837 Kurdish refugees disembarked from the cargo boat named Ararat on the Calabrian coast - Ararat took its name from this boat and Mount Ararat, which, along with other mountains in Kurdistan, is considered the only safe place for Kurds, as in the famous novel *No Friends but the Mountain* by the Kurdish writer Behrouz Boochani.

With the arrival of Öcalan (the leader of the Kurdish freedom movement) seeking asylum in Europe and Rome, many Kurds came to the city. After Öcalan was arrested, the Kurds built a small village made of papers called "Cartonia" in Piazza Celio, which was later renamed Piazza Kurdistan. In 1999, with the support of associations, they occupied the building that is now Ararat. Even today, Rome, due to the lack of opportunities (work, housing, services), isn't the place where Kurds decide to settle. Currently, there are around 200 Kurds in Rome; a larger community can be found in the Grosseto area and in the industrial areas between Turin and Milan. The main occupation of Kurds in Rome is in restaurants, mainly kebab places. Despite this, Rome is a transit point in the movement within Italy and abroad; moreover, Ararat is the place where the community, including those from outside Rome, gathers for traditional events. According to Kurds in Rome, Newroz (the annual celebration of the spring equinox meaning freedom and liberation) celebrated in Ararat is the biggest and most beautiful celebration among other celebrations in Europe. Ararat is a relatively small building with an outdoor area. Ararat today serves as the 'cultural home' for Kurds in Italy. Kurds who have just arrived in Italy find shelter, support, and help there, along with Kurds coming from all over Europe who have no place to stay in Rome. It's a place where the community can share food, be together, and be in contact with political movements and cultural traditions.

Ararat in the "City of Arts" context

Testaccio, like many other neighbourhoods in Rome, is undergoing a significant renewal process. Known for being one of the most working-class districts in Rome, today it is undergoing profound change due to the influx of tourists and students. The neighbourhood hosts one of the biggest industrial archaeologies in the city, the ex-Mattatoio (former slaughterhouse) of Rome. It covers 107 square meters and is divided into two main areas: the Campo Boario, an open part consisting of stables for animals, and another section for the actual slaughtering. From an architectural perspective, the composition of the two spaces differs: the first is a vast open space surrounded by buildings, while the second consists of a series of parallel industrial sheds. Today, the entire complex is recognized as an industrial archaeological site and is under the protection of the Soprintendenza, the institution that manages and controls all historic sites in Italy, while the property remains under the Municipality of Rome, which can assign the space with the Soprintendenza's approval.

The complex is situated at the border of the neighbourhood near the Tiber River, the Monte dei Cocci (a small hill made of ancient amphorae thrown away during the Augustan period), and the Aurelian ancient city wall (272 BC – 279 BC).

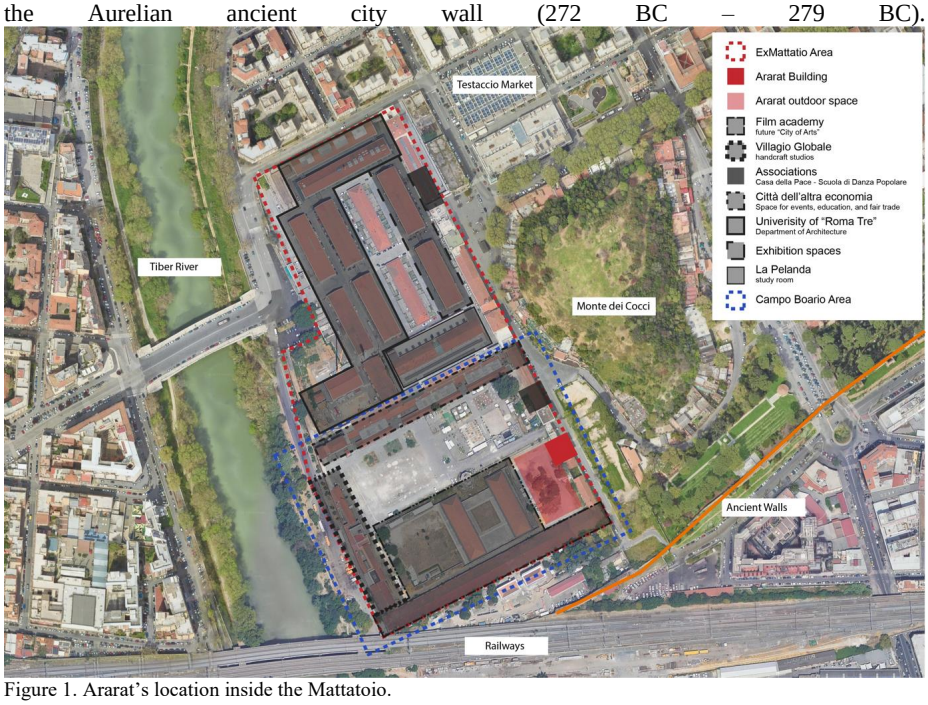

Figure 1. Ararat's location inside the Mattatoio.

Since the Mattatoio ceased operations as a slaughterhouse in 1975, the community has mobilized to prevent its acquisition by private companies. This space was left without any designated use in Rome's city plan until 2000 when the first comprehensive plan to keep the ex-Mattatoio public was presented. The first public institution to occupy the Mattatoio was the University of Roma Tre with its architecture department, followed by the Modern Art Museum of Rome (Macro). While these transformations began in the Mattatoio, a parallel spontaneous use of the space was going on in the Campo Boario side, the area of the complex more hidden from the neighbourhood that allowed various occupations to settle there. The space allowed migrants to find shelter as the issue of hospitality gained prominence in public debate. During the '90s, the Campo Boario was inhabited by different migrant communities, including the Kalderash (a nomad community skilled in working with raw iron), a Senegalese community, and other groups, especially from North Africa. These communities received support from one of Rome's longest-standing occupations in the Mattatoio, Villaggio Globale, which this year celebrates 34 years of activities. Villaggio Globale is one of the oldest occupations in Rome, established in 1990. Since then, it has played a pivotal role in the city's history of manifestations, integration, arts, and underground culture. By organizing events and concerts for cultural integration, it served as a sort of 'keeper' of Campo Boario at the time, according to activists and Municipality representatives.

The socio-cultural centre of Ararat is also situated on the Campo Boario side. In 1999, the building where Ararat stands today was reclaimed and occupied by the association Azad, Stalker, and Villaggio Globale in a collective endeavour. This collaboration marked the beginning of the socio-cultural activities that continue to shape the identity and use of the

Campo Boario area today. That year, the Biennale of Young Artists was taking place on the other side of the Mattatoio. The artist association Stalker was invited to the Biennale, and as a performative act, they decided to reclaim a space for Kurdish migrants who had recently arrived in Rome, within the already multicultural landscape of the Campo Boario. The workshop "From Cartonia to Piazza Kurdistan" saw the participation of architecture students, Kurds, and artists. During this time, they freed and took control of the space, which at the time was occupied by drug dealers and users, at the time the space was dangerous and decaying. Initially, Ararat was a space for Kurds and artists living together until the habitation needs of the Kurds became more crucial. The artists decided to leave the space to the Kurds seeking a place to stay in Rome, but over the years, this legacy and collaboration have remained.

Campo Boario began to change between 2004 and 2007 when the migrants communities were evicted to make space for the opening of the *Città dell'altra Economia* (CAE). CAE was supposed to be a space for the circular economy, grassroots initiatives, and sustainable economy. However, according to several activists and association members, it has lost its primary aim and now hosts events every weekend, such as food fairs and concerts, but has strayed from its initial goal of promoting a circular economy and fair market. Following CAE, the Academy of Arts opened in 2011, spaces for students in two pavilions in the area and built a wall to enclose the space. Today, the Academy is the main actor in the renewal of the Campo Boario, and much of the future of the space will be decided by their interventions. The Municipality's aim is to create the City of Arts, following the example of the *Matadero* in Madrid, an ex-slaughterhouse that became a multidisciplinary space for art creation. This will be implemented with the work of the Academy, the University of Roma Tre, and *Macro* (contemporary museum of Rome). Recently, May 2024, the open space of *La Pelanda* opened, it is a huge multifunctional study room that aims to be an aggregation point for students. Along with the projects that have seen the collaboration of the municipality and institutions and were already programmed, we must add the new projects financed by the PNRR general program *Roma Caput Mundi*. This program includes various projects around the entire metropolitan area, with five of the 335 projects planned just for the Mattatoio. These projects mainly focus on restoration and functionalisation, and one directly affects the space of Ararat – the perimetral walls. What's unclear right now is the destination that these spaces will have once restored. An informal process of participation has already started to ensure the permanence of Ararat in the building. The activists have repeatedly inquired with the Academy and the administration for an official statement on the safety of Ararat, but this hasn't happened yet.

Adding another level of complexity to the process are the requirements of Resolution n104 of the Municipality of Rome, approved in 2015. This resolution stated the total reconfiguration of any autonomously occupied space by associations and organizations situated on municipal property. The resolution suspended all previous concessions that need to apply according to regulations to be reassigned. It also stated that to reapply for the concession of municipal spaces, the occupants must continue to pay rent to maintain the advantage of reapplying. The regulation referred to in the resolution was published only in January 2023, leaving Ararat and many other associations in a state of limbo. In this regard Ararat holds a privileged position since, between 2006 and 2015, they signed an official concession with the administration, and when it wasn't renewed due to Resolution n104, they kept paying rent to not lose any privileged on the space. Moreover, during its 25 years of presence, Ararat has proved to be one of the most recognized and longstanding presences in the Mattatoio and in Rome by municipal members. While the call for assigning the spaces is open to the public, no participatory processes have been initiated to determine the use of the unassigned spaces in the city. An informal dialogue has started since the regulations and projects were presented, but no official communication has been given regarding the stay or eviction.

What's important to take into account along with political activism and its role in the migratory process of the Kurdish community, is that Ararat is the last 'open space' in the Mattatoio. Ararat is open every hour for everyone, maintaining a continuous presence during the day and night, even when there aren't events, recently in collaboration with the architects of *ARCHa* they set-up an open space for study inside Ararat garden always open. Ararat has been able to reclaim its presence in the space forcefully thought activism and collaboration, opening a dialogue with the administration of the city of Rome. Representative were also involved in public events at the anniversary of the centre on May 17-18 2024, to discuss its future and hopefully to reinforce the dialogue in order to find a solution beneficial for both the Ararat community and the Municipality.

Since its opening, the centre has maintained all collaborative solutions with the neighbourhood of Testaccio. Initiatives like "Noialtri Kurdi di Testaccio" in the Mercato Testaccio, a very famous and popular market in the neighbourhood, have strengthened their presence in the area. Additionally, architecture students from Roma Tre, under the Civic Arts program by Professor Francesco Careri, come back to Ararat every year to help set up the manifestation of Newroz (the Kurdish celebration of the spring equinox), which brings together the dispersed Kurdish community living outside Rome. According to Ararat's members, the 2024 event gathered around 3000 people.

To keep the connection with other realities around the city, Ararat often serves food at events as a way to both collect money and spread information about the Kurdish cause, creating points of connection with other freedom struggles and revolutionary forces.

What future for Ararat?

What is certain is that the Ararat centre is far from being a marginalized, closed circuit; it actively engages in collaboration with a broad network within the city of Rome. The work of local activists is crucial for the centre's functioning and success. Since the Kurdish community is not permanently settled in Rome, these activists serve as mediators and custodians of the centre's legacy, facilitating its operations and outreach efforts.

It remains unclear whether an actual participatory process will take place with the Municipality to ensure the continuous presence of Ararat. This uncertainty presents significant challenges, particularly concerning the sustainability of the centre's operations. In all the possibilities presented by the new regulation for Ararat, a compromise must be reached. One major problem they may face is the increase in rent, which could force them to vacate the premises. The regulation outlines several possibilities for Ararat to remain, but the most attractive solution, which would also ensure a high level of autonomy, appears to be finding a collaborative partner. An institution like a university or an academy could serve as a guarantor and help reduce the rent.

Despite the uncertain future of Ararat, the experience of migrants engaging in a process with institutions offers valuable insights. This can help us rethink how we conceive migration in contemporary cities. Migrants are not the problem; they can be the solution. The space of Ararat represents a potential model for the entire Mattatoio renewal, exemplifying the concept of an 'open city' and integration. This is not with a settled community of individuals, but with a community that is continually remade over time by people who stay in Ararat for varying periods, and that make the experience more interesting. During their waiting period for documents (which can sometimes last over a year), these individuals have the opportunity to engage with a thriving environment, connect with their culture, and participate in collective political mobilization. This helps them overcome the marginalization that illegalized migrants systematically face during their stopover process from one city to another. These achievements are largely due to the strong involvement and support of a group of dedicated activists who, for various reasons, find solidarity with the Kurdish community.

Ararat's experience demonstrates that migrants can be integrated into the urban renewal process in meaningful ways. By involving migrants in the planning and decision-making processes, cities can create more inclusive and dynamic urban environments. The ongoing informal dialogue between Ararat, the Academy, and the administration highlights the potential for collaborative solutions that respect the needs and contributions of migrant communities. The future of Ararat, while uncertain, is a testament to the resistance and adaptability of migrant communities. Their ability to form alliances with local institutions and activists underscores the importance of grassroots initiatives in shaping urban policies. As we observe the developments in Ararat, we can learn valuable lessons about the role of migrant communities in urban renewal and the creation of inclusive cities.

Ararat's integration efforts go beyond mere coexistence; they actively contribute to the cultural and social fabric of the city. As underlined by Homi Bhabha in his work *The Location of Culture* (1994), these efforts create spaces where cultural translation occurs, allowing for the negotiation of meanings, the creation of new cultural forms, and the navigation of power dynamics. The Kurdish socio-cultural centre shows that migrant communities, when given the opportunity, can significantly contribute to the vibrancy and inclusivity of urban spaces.

In conclusion, the Ararat centre's journey illustrates the potential of integrating migrant communities into urban renewal projects. Through collaboration with local institutions and activists, migrants can help create more inclusive and dynamic cities. As cities around the world face increasing migration, the lessons learned from Ararat's experience can guide the development of more effective and humane urban policies. The ongoing efforts to secure Ararat's future highlight the importance of participatory processes and the need for flexible, supportive frameworks that recognize the contributions of all community members.

Acknowledgments

I'm grateful to the entire Ararat community for their time, active engagement, and assistance in navigating the intricacies of this space.

All-round walkability condition to primary school in Milan

Carla Baldissera
Affiliation: Politecnico di Milano
Email: carla.baldissera@polimi.it

Abstract (up to 125 words)
As part of the wider debate on social justice and the right to the city, the research addresses the fundamental and everyday issue of accessibility to services, through slow mobility, for the most vulnerable populations, and highlights how certain inequalities take shape in public space. Therefore, an analysis of the accessibility of a specific and prototypical service, primary schools, is proposed in three exemplary cases located in different districts of the city of Milan, studying the accessibility at different scales and for different user profiles (in particular, a comparison was made between vulnerable and able-bodied people).

Keywords
Walkability assessment; profiled pedestrian network; accessibility of primary schools; disabled people; Milan

Main text

Schools' accessibility

The issue of 'access' to the school, or rather of its reachability, has been the subject of much debate. This is not understood from the point of view of criteria and policies enabling student enrolment, but considered in relation to the spatial dimension, and thus assessed as the necessary movement to reach the school complex. This has been addressed for some time and studied in different ways.
The first issue to consider is the ideal distance between home and the service itself. This is a dimension that falls within the sphere of proximity, or even the 15-minute city.

Service proximity

When discussing the proximity of services, it is essential to consider the findings of several major studies that have examined their role. In this paper, we present a hypothesis that attempts to integrate various aspects of planning that may have influenced these concepts.
In the planning of Barcelona, Cerdà had identified the modular structure as the key to composing the relationship between inhabitants and their services[1]. It began with the distribution of services with respect to residential lots and somehow indirectly hypothesised an ideal distance between them. The engineer defined the radius of action for each type of service (including green spaces) across the entire city, and then defined the corresponding catchment area, starting from the minimum unit of the city, i.e. the neighbourhood[2]. For example, the plan was to have at least one school in each neighbourhood. Since the second half of the 19th century, there have been other experiments that have refined the concept. However, we can already

[1] In Italy, the relationship between inhabitants and their services was established by urban standards. They were defined with Law 1444/68, through an ideal ratio of square meters of services, divided by type, per inhabitant.
[2] In his design, the city was structured with an orthogonal grid divided by a few large infrastructural axes. The structure included square-shaped blocks with rounded corners, with a side length of 113 meters. In its logic, a neighbourhood consisted of 25 blocks.

identify a precursor of what is known today as the 15-minute city in Carlos Moreno's theory in this hypothesis. The theory rethought planning by focusing on the proximity relationship between home and services. This was done to improve quality of life and reduce environmental impacts, with an increase in cycling and walking. From this core concept, various theories of chrono-urbanism developed.

School

Among the fundamental services to be considered in the conceptual field of proximity is schooling. The school plays a role in our lives at different stages, from the early years as students to adulthood as a waiting place for children/grandchildren, and also as the hub of a community of citizens that is structured around the school building object. The school has evolved into a hub for community interaction, serving as a gathering point for parents and neighbourhood residents of all ages. This is due in part to the introduction of extracurricular activities. It should be noted that this is not a uniform phenomenon across all schools. However, the introduction of non-educational activities, in the extracurricular time, is already having a significant impact on the role of schools, even if it is not yet at the same level as in the open schools network in Rome, where schools are becoming true civic centres with the community at the centre as the in the Di Donato primary school.

In light of the above, this contribution, the result of a master's thesis, addresses the issue of walkability conditions in the city of Milan, intending to understand them in the most inclusive sense possible. It considers the role of school routes in offering opportunities to the city's population.

In Italy, two fundamental regulations concerning schools and their relationship with the built-up area must be considered when contextualising the relationship between home and school.

Until the 1990s, the obligation to attend a specific school (usually corresponds with the nearest school) according to address of residence was in place, in line with the division of the territory into catchment areas. The definition of catchment areas, as areas of redistribution of inhabitants between the different school centres, resulted in the direct relationship between parts of the city and neighbouring educational institutions. The abolition of catchment areas allowed students to choose their preferred school. In addition, the introduction of school autonomy (law 59/1997 and D.P.R 275/1999) led to the delegation of criteria for accepting student applications to school boards and gave schools the opportunity to customise their educational offerings. This also created a system of competition between individual educational institutions. (Pacchi, Ranci, 2017)

In 1962, with the implementation of Law No. 1895, middle school became part of the compulsory education system. To meet the increased demand for space and classrooms, new schools were constructed in urban areas. At the same time, the most significant internal migration was occurring, with people moving from southern regions to northern Italy and to cities. This migration resulted in an immediate need for new housing. To meet these demands, new neighbourhoods were often constructed, often autonomous or self-sufficient, in which the educational service was also present. In other words, neighbourhoods were planned in a unified manner, not only providing new residential volumes but also different kind of services within the new neighbourhoods (educational, religious, commercial, etc).

Finally, in 1975, Decree Law 18 established the optimal location of schools in relation to their context, defining the ideal distance and maximum time to be used to reach the school according to different modes of transport. The regulation stipulated that the maximum distance to be covered on foot to reach primary schools was 500 metres, while the maximum distance for secondary schools was 1,000 metres. In the case of public transport, the times were approximated to a maximum of 15 minutes and 30 minutes respectively.

It is evident that these values are indicative of an optimal condition and not representative of reality. Therefore, it would be prudent to consider additional dimensions for assessing spatial dimensions and distances of access to school. As school choice is more freely available, it cannot be assumed that enrollees are resident only within the catchment area, let alone within 500 metres. Therefore, it is necessary to consider a proximity dimension that can be evaluated in relation to the time required to reach the service. The isochrones of 5, 10 and 15 minutes, respectively, should be considered with different modes of travel depending on the school grade in question, as this provides further support to the argument. It can be reasonably assumed that students in lower grade schools (kindergarten and primary) are more likely to walk to school than those in higher grade schools. Nevertheless, there are numerous instances in which the selection of an educational institution is influenced by factors such as familial convenience, often determined by the parents' commuting route, or other considerations related to the specific type of school, such as private institutions or other factors. This can result in children not attending schools that are geographically closer to their residences. In addition, at middle and secondary level, the increasing autonomy of students contributes to the choice (especially at the high school level) of schools further away from their homes and consequently the mode of travel may be by bicycle, public transport or private car.

Walkability

With regard to the issue of walkability, a number of proposals and forms of analysis have been put forward. One can discern a number of components that are more objectifiable, relating to the design of the space and the degree of effectiveness or efficiency with respect to the type of uses for which it is intended. In contrast, there are other components that are more subjective, strongly linked to individual experience. It is evident that both dimensions must be considered when analysing walkability. The objective components encompass all aspects pertinent to the design of the street section, which facilitates the use of the space by the widest possible range of users and citizens. Additionally, they include aspects related to the context, such as the elements facing the latter, not only in relation to the function they host but also to the design of the façades, among other considerations.

One challenge is determining which elements are to be assessed in the field of walkability and which can be quantified. It is also necessary to determine which of these aspects contribute to making a street ‘walkable’. This should be done not only to facilitate the route, but also to favour an all-round, wider and more comfortable use, thus mobilising and arranging the elements that potentially make a street lively, comfortable, safe and so on. In this context, the assessment of walkability is a complex issue that requires the development of a variety of measuring instruments. Furthermore, to consider the various aspects listed above, it is necessary to move from a broader scale of analysis to a micro-level scale, which allows all the components involved to be considered. (Boyce 2010, Blečić et al 2015)

The objective of this research was to assess walkability within the Milanese urban context, with particular emphasis on the objective component. The aim was to verify its usability by all, starting from an analysis of the conditions of the street space object and its characteristics.

It is clear that this is only one of the aspects that could be investigated when talking about walkability. However, it is important to evaluate how this infrastructure performs in terms of the most relevant aspects of movement, which must allow a plurality of people to move from one point to another in the city or territory. In this context, we will focus on aspects of street space use that are easy, comfortable and accessible. We will exclude contextual elements that allow the space to be inhabited, as well as those that only allow it to be used.

In this sense, when designed from the perspective of universal design, the street object represents an instrument of inclusion, or rather a potential instrument of integration, in several respects. If its use is guaranteed for all, the pedestrian space represents an area in which real

social inclusion can be established. In fact, it's the infrastructure on which various positive practices (such as the possibility of physical activity or community building) are based, but above all, it is the infrastructure that accommodates the most democratic and inclusive - theoretically within everyone's reach - and at the same time sustainable mode of transport: walking. For this to be feasible, however, it is necessary to ensure that the space is designed in such a way that people with different disabilities can enjoy the public space independently, without having to rely on other people. It can therefore be said that the design of the space is fundamental and necessary, but not sufficient for true inclusion, which only occurs under certain conditions. (Azzolino Lacirignola, 2011 and Conti, Garofalo, 2013)
In this study, the term 'walkability' is used to refer to a broad concept that encompasses the design structure of the space in order to ensure that it can be used by all, safely and comfortably. However, it also extends to certain contextual conditions such as the attractiveness and vitality of spaces, which depend not only on the conformation of the road infrastructure but also on what is around it.

All-round walkability in Milan
In light of the above, the Milan survey proposes an analysis that addresses walkability in relation to the school service and approach routes. It also examines all those aspects of space design that represent limitations to use by all users, with a focus on those with disabilities or the most fragile populations. We therefore adopted the perspective of universal and inclusive design, and then deepened the study, taking the same phenomenon to a finer scale.
Although a limited view of the phenomenon has been adopted (ignoring the context with regard to the attractiveness and vitality of spaces) and an attempt has been made to define the relationship with neighbouring services solely on the basis of pedestrian accessibility, it is possible and useful to identify those elements that may represent problematic elements in the movements of persons with disabilities, based on the data available at the various scales. For instance, the presence of accessible crossings, wide pedestrian paths, and signage for users with sensory disabilities are examples of elements that may require attention.
The municipal level analysis was represented by the construction of a walkability graph, weighted on a number of factors. This was done in the wake of the evaluation of the IAPI indicator developed by Pucci, Lanza and Carboni within the research EXTRA - Experimenting with City Streets to Transform Urban Mobility. This aimed to improve accessibility through forms of active mobility. The initial investigation within this evaluation focused on the elaboration and evaluation of walkability according to different indicators. Some indicators were related to the technical performance of routes, while others were related to the relationship with vehicular spaces (number of lanes, limited traffic zones).

A new and distinct version of the analysis model is proposed here, which focuses solely on the characteristics of pedestrian spaces. The list of factors taken into consideration has been modified and implemented with new parameters characterising the space, with the objective of enhancing usability and sharing for all. In addition to evaluating certain aspects of the space that are important in the walkability of able-bodied people, such as width, lighting, the presence of trees, etc., other fundamental elements for use by disabled users were identified from the literature and interviews conducted with experts who deal with disabilities. For instance, the presence of steps at crossings, the width of pavements, their paving, the existence of posts or vertical signs that can reduce the useful width, whether they are positioned in a central location, and so on.
It was therefore decided that the walkability of the area should be assessed in two different ways: for those who are able-bodied and for those who have mobility difficulties.

Two user profiles were therefore selected for assessment: the able-bodied and the mobility-impaired. The following table (Table 1) highlights the selected factors, including those that were included precisely to recognise accessible routes. Each indicator is assigned a value, which is either positive or negative. This reflects the relative ease or difficulty of the route compared to others. The values were selected from certain ranges or from the selection of certain performances considered to be good or average. For example, as far as the width of pavements is concerned, the reference value indicated is 2 metres, a value that greatly increases the quality of the space. This is a value that can be used by two disabled people at the same time. With regard to street furniture and orientation for people with disabilities (such as street lamps and trees), their presence or absence was simply recorded. However, account was taken of the different relevance of the conditions highlighted during the interviews or deduced from scientific texts. For example, the obstacle constituted by steps as opposed to ramps is a more relevant element than the presence of trees or road markings.
In each arc of the graph, a different value, between 0 and 1, was associated with each indicator: low the value, higher the impact on our experience of walking. If the indicator did not affect the conditions of the space, the value assigned was 1. Once all 11 elements considered had been evaluated[3], the average of the indicators was multiplied by a different average speed, depending on the profiles evaluated. The average speed used for the first profile (able-bodied) was around 3 km/h, while with reference to frail or disabled users, a speed of 2 km/h was chosen. The values selected were derived from existing literature, which typically exhibits somewhat elevated values (around 4 km/h for walking). Additionally, the necessity to halt and recuperate or to terminate at an intersection was also considered.

[3] The values chosen were derived from some information in the literature and then verified empirically through some interviews. A calibration of the impedance factor on the basis of user preferences would have been important and would have added more detail to the survey. In the IAPI index, for example, these values are determined from information provided by the residents themselves, for different profiles, through a questionnaire. In addition to the greater relevance of the data to the conditions and habits of the inhabitants, this information can be read in different contexts. In fact, if one imagines that the same questionnaire is proposed to different neighbourhoods in cities with different orography and morphology, it will be possible to identify variations in values depending on the context. Think trivially of the slope data in cities near headlands, or the difference in the assessment of certain obstacles (such as the high presence of bicycles leaning against the wall in some cities).

Urban elements	Indicator	Explanation	Source	Impedance factor - profile 1	Impedance factor - profile 2
Quality and performance of pedestrian path	Width of the sidewalk	The width of the sidewalk affects the walkability of spaces, particularly if it is less than 2 meters	DBT Milano Municipality	0,25	0,25
	Sidewalk material	The type of pedestrian path material (asphalt, cobblestone) affects the ease and continuity of walking	OSM	0,5	0,5
	Absence of trees	The presence of trees can be an element that brings environmental comfort	DBT Milano Municipality	0,5	0,5
	Absence of lighting systems / streetlights	The absence of lighting may affect the perception of safety.	DBT Milano Municipality	0,5	0,5
	Presence of tunnels or bridges	The presence of tunnels or bridges represent elements of potential insecurity and obstacles	OSM	0,25	0,25
	Presence of steps	The presence of stairs or steps makes movement more difficult and is a potential obstacle	OSM	0,25	0,25
Impact of the road	Hierarchy of the road	Roads with increased traffic may represent an element of discomfort	OSM	0,5	0,5
Quality and performance of path	Presence of dehor on sidewalk with width less than 4 meters	Dehors that occupy sidewalks less than 4 meters wide make the usable width of the sidewalks less than a comfortable condition.	DBT Milano Municipality and open data municipality	1	0,25
Zebra crossing	Absence of regulatory systems for crossings	The absence of regulation systems at intersections could be a reason for unsafe conditions.	OSM*	1	0,5
	Absence of ramps (kerb)	The absence of ramps could be such an obstacle as to make it impossible to use the pathway	OSM*	1	0,25
	Absence of podactyl systems	The absence of podiatric systems could be such an obstacle as to make it impossible to use the pathway	OSM*	1	0,25
	Absence of vibration systems	The absence of vibration systems could be such an obstacle as to make it impossible to use the pathway	OSM*	1	0,25

Table 1 - Indicators of walkability and related impedance factors. Highlighted in blue are the most important indicators for assessing walkability conditions for people with disabilities, the elderly, care givers, etc.
Source: author

Alongside the analysis of walkability for frail persons, the investigation of the quality of the space for a hypothetical normally able-bodied user was carried out, thus considering a generic

user with no particular needs. In this case some of the information previously evaluated, i.e. those describing performance qualities that make the use of the pedestrian space more pleasant, but do not condition its use, have assumed different weights depending on the relevance of the factors for the users considered. For example, the presence of a ramp for a person without motor or sensory difficulties is as indifferent or as relevant a factor as the width of pavements or the presence of trees providing shade. Certainly this image is reductive from the perspective of inclusive design, but it is important in order to have a term of comparison in relation to the state of the art and a touchstone for comparing the two profiles.

This hypothesis does not consider the subjective preferences of inhabitants with different needs who live in the city. This aspect is fundamental and should be juxtaposed with the objective conditions of space (density of obstacles), since inhabitants with different needs and in different territories perceive the same elements differently. For example, one factor that could not be considered in this study concerns the continuity of natural guides (walls) for people with visual impairments.

However, it is important to point out that certain circumstances that are common to all cities, such as the presence of lamp-posts and other obstructions, can be accompanied by other elements - just think of the bicycles that lean against walls in many cities in Emilia - which can become obstacles of a certain weight. Or, to take another example, the presence of cobblestones in a city like Milan, where the pavement outside the historic centre is almost entirely asphalt, is secondary to other obstacles. Narrow pavements or pavements without ramps at the ends make walking difficult.
The assessment of walkability according to these parameters allows us to study its possibile usability, at least in terms of the design aspects of the space, for the entire population. This could therefore be a useful tool for the municipality in order to identify priorities for intervention in public space, starting from a study of the physical conditions of pedestrian areas, which could be flanked by other levels of analysis (taking into account subjective perception, level of accessibility and some socio-demographic evalutation). It is also important to consider the needs of vulnerable groups, including people with disabilities, older people living alone, and those with income issues. Indeed, it is crucial to assess accessibility and accessibility to different services, including transportation and the buildings themselves. This is particularly important when identifying clusters of services for different populations.

Walkability toward primary schools
This analysis yielded an initial general cognitive picture of the walkability condition within the Milanese municipal territory. Based on this overall picture of the city of Milan, it was decided to focus on a specific service and study its walkability in the traditional 5, 10 and 15 minutes for one and the other user profile (figure 1 and figure 2), taking into account the characteristics of the pedestrian space. All public primary schools in the territory of the municipality of Milan were therefore examined.
A visual analysis allows us to identify the most problematic areas of the city. The resulting graph is therefore no longer 'neutral', as it is marked by the parameters selected above. Instead, it can be considered a weighted graph, in which catchment areas are considerably reduced. Put another way, a comparison between the isochrones developed on a clean graph and those calculated on the weighted graph shows a clear shrinkage in the size of the different isochrones, which are a reflection of the numerical data (walkable metres). As Pileri (2023) notes in his essay, echoing Socco's insight, the ‘small pervasive problems’ that arise in cities become more widespread over time, conditioning those who live in them from an early age. For this reason, it is crucial to consider the safety and quality of the routes people take from an early age, as

well as the construction of an imaginary of the city's spaces, which makes the inhabitants aware of the criticalities and opportunities it offers. Additionally, this approach aims to enhance the liveability of the locations frequented by the public.
It should not be concealed at this point that, although it was essential to obtain a snapshot on an urban scale of the current condition of walkability (also in order to provide a tool to be included in that list of toolkits that the administration uses to decide where to intervene), this is not sufficient to describe the public space in an exhaustive form.

Figure 1 illustrates the accessibility of primary schools in terms of the time required to reach the service. From the images, it is evident that profiles with varying needs, in terms of speed of travel and factors to be considered in the practice of walking, result in a more or less limited ability to reach a certain number of spaces. It can be reasonably concluded that the primary factor is the variation in walking speed. However, the reduction in catchment area is more pronounced due to the multitude of variables that must be taken into account.
Furthermore, the image illustrates the significant variation in the size of the isochrones across municipal boundaries. In the outermost contexts, the catchment areas are reduced due to either lower population density or the presence of substantial physical barriers, such as transportation infrastructure or significant green spaces.

In fact, it should be pointed out that the data available on a municipal scale are only partly representative of urban mobility conditions. It would be beneficial to conduct further research through the implementation of targeted surveys at the municipal level. This could involve integrating data on population density and the vitality of contexts, among other factors. Additionally, some aspects may only be discernible through field studies, which could serve to enhance the accuracy and reliability of the research.

And in order to test this more concrete perspective, a finer-grained survey was juxtaposed to the large-scale analysis, which also involved the redesigning of a number of pedestrian routes approaching a service, within a radius of 500m, routes selected from the assessments of catchment areas.

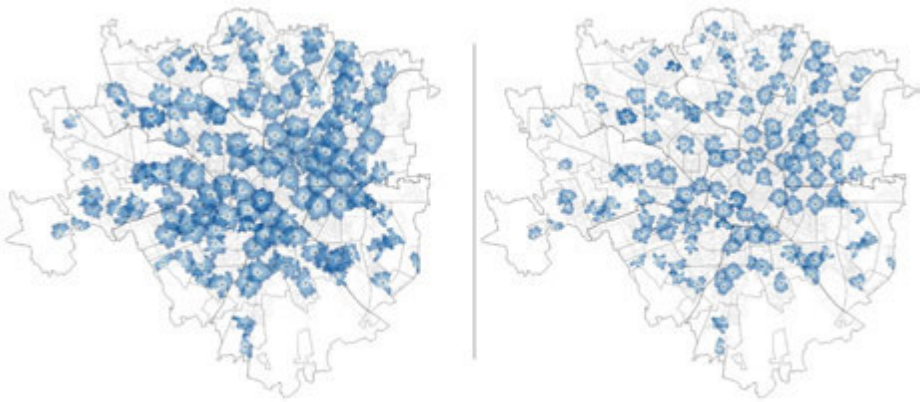

Figure 1 - The catchment areas were delineated at five, 10, and 15 minutes from the school, within walking distance for an average speed for the two profiles: the left profile represents an able-bodied individual and the right profile represents a profile with a fragile constitution. The first profile is

evaluated at a speed of 3 km/h, weighed against the conditions of walkability on the left. The second profile is evaluated at a speed of 2 km/h, weighed against the conditions of walkability from the access of primary schools on the right. The different shades of blue indicate the different thresholds of the walking isochrones: light blue 5 min, light blue 10 min, dark blue 15 min.
Source: author

Precisely in view of these conclusions and the important role that schools play, and could play in the future, with more flexible opening hours and increased activities aimed at the closer community (e.g. hosting services 'scattered' around the city), it was decided to focus on the presidia of education, particularly primary schools.
In order to sample varied and exemplary situations, three schools located in very different contexts were chosen; and three stretches of approximately 500 metres were obtained (by redesigning the public space, figure 2), the ideal average distance to travel to school from home or back. This operation made it possible to lay bare the limits of the analysis at an urban scale, due to the lack of detailed data, but also to highlight the presence of certain customs that are difficult to map, since they vary over the course of the day or in the short to medium term. Through redesigning, in fact, it was possible to record the presence of obstacles not highlighted at the urban scale. To give just a few examples, the placement of vertical signs, positioned in such a way as to make it difficult to pass, the existence of arches at driveways, but also the presence of street furniture placed in the pedestrian context by nearby businesses (figure 2).
This type of investigation, carried out at different times of the day, makes it possible both to witness social practices taking place in public spaces, and to record illicit uses of the pedestrian environment, linked to the illegal parking of cars on pavements, green spaces or pedestrian crossings, as well as the high use of outdoor areas at certain times of the day. These are all situations that make passing very difficult.
Finally, it should be considered that - as Pileri also discloses - a careful examination of this type makes it possible to study the frequency of appearance of obstacles or crossings encountered, and to identify their average value (Pileri, 2023) From these measurements, it is in fact possible to identify every how many metres the attention threshold must be activated to dodge an obstacle or to cross a road. The greater the distance, the better the perception of the space that the user will be able to enjoy in its continuity, in various activities and dimensions (chatting with friends, observing the landscape, etc.); if, on the other hand, this were very low, the enjoyment would be partial.
This line of reasoning, applied by Pileri to home-school routes, identifying critical points in children's walkability, can also be developed in relation to people with disabilities and highlight conditions that make walking fatiguing and frustrating (Pileri, 2023). If on an urban scale one can therefore measure the density of obstacles along an arc of a route, but without having information on their concentration, moving to the micro level one can perceive the weight of certain objective conditions: when walking through a certain space one is preoccupied by its conditions, to the detriment of other actions that the user could or would like to carry out at the same time (chatting, calling, etc.) and that could be disturbed or impeded.
In the case of schools, the elaboration carried out on a municipal scale, by means of isochrones, on the reachability of schools, could or, better, should be coupled with the consideration of other data (the number of students present in the school, the coexistence of several schools or other services in the same lots, the effects of interventions already carried out on the public space), and in this way one could better define the routes on which to intervene as a priority.

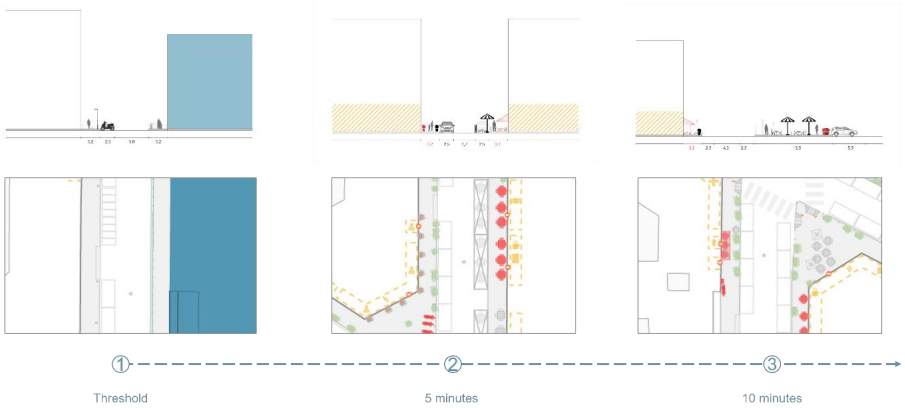

Figure 2 - Analysis of pedestrian conditions in the 500-metre approach, in an example case, the Stoppani primary school. All obstacles that can be seen along the route and that are not registered on the municipal scale are marked in red.

What's next

This type of research, which is increasingly being carried out on several user profiles, see the STEP UP project - Walkability for Women in Milan, is becoming an important resource for guiding interventions in public spaces. Indeed, depending on the profile and the service in question, they make it possible to assess its accessibility and also to identify, by theme, the spaces on which to intervene. One could also hypothesise the juxtaposition of this information with others related to the conditions of the service, the internal and relevant spaces of the latter, as well as others. Imagine, for example, in the case of schools, intervening in those contexts where the school has few spaces dedicated to the courtyard, restoring some of them by working on the threshold spaces. However, if these are mainly spatial aspects, there are other equally important aspects that could be taken into account. As explained by Paola Savoldi (2024), when choosing where to intervene from the point of view of proximity and spatial justice, it is also right to take into account other information, such as the socio-demographic conditions of the context or of the school's own users.

Innovative Tools For Building Child-Friendly Communities: The Development And Application Of Child-Friendly Neighbourhood (CFN) Built Environment Audit Tools, Insights From Shanghai

Ye Zhan, Yifan Yu
Affiliation: Tongji University, China
Email: zhanye@tongji.edu.cn
yuyifan@tongji.edu.cn

Abstract
Neighbourhood environment is an important carrier of children's daily activities, but traditional urban planning and design often ignore the impact of micro-scale built environment on children's environmental perception. In the central urban area of Shanghai, which is characterised by high-density human settlements, integrating child-friendly concepts to carry out community renewal requires more consideration of the actual basis and renewal results. This study innovatively developed a "Child-Friendly Neighbourhood (CFN) Built Environment Audit Tools" that can systematically evaluate the micro-spatial elements in the three types of spaces within the 5-10 minute living circle of the community, including community streets, outdoor public spaces, and residential environments, to finely identify community space problems and help formulate special renewal plans for child-friendly communities.

Keywords
Child-friendly, Child-friendly Neighborhood, Built environment audit, Micro-scale

1.Introduction

In order to protect children's vulnerability in the built environment, the United Nations Children's Fund (UNICEF) and the United Nations Human Settlements Program (UN-Habitat) jointly launched the "Child-Friendly Cities Initiative (CFCI)". The initiative points out that the level of children's welfare protection is the ultimate indicator of healthy settlements, democratic society and good governance. In China, child-friendly cities and community construction have also become increasingly hot topics. In 2021, China's "14th Five-Year Plan" clearly proposed to comprehensively promote the concept of child-friendly in-depth urban planning and build 100 child-friendly cities. At present, the focus of China's urban planning work has shifted from incremental construction to stock renewal, focusing more on the optimal allocation of spatial resources and the improvement of residents' quality of life.

In the context of urban renewal, it is very important to carry out the practice of child-friendly environment construction, especially the community built environment at the community scale. The quality and spatial characteristics of the community built environment are most closely related to children's daily activities and environmental perception, and are also the last link that has been ignored by planning and design for a long time. At present, there is little systematic problem diagnosis and practical guidance in the construction of child-friendly urban spaces in China at the micro-scale, especially in the design of community spaces at the human scale.
The insecurity of children's travel, lack of physical activities, and reduction of games and social activities involve many built environment elements in various spaces such as streets, public spaces, and comprehensive environments in the community, especially the built environment elements at the meso-micro scale.

Therefore, the significance of this study is to fill the gap in the identification and definition of micro elements at the human scale in the community from a child-friendly perspective in the context of high-density human settlements. This study aims to structurally determine which built environment elements should be identified and evaluated as components of child-friendly

community environments based on the existing research and practical experience of international child-friendly community environments and the local practices of typical communities in Shanghai. The research results are the development of technical tools that can comprehensively and concisely identify the built environment elements (especially the meso-micro scale) issues that are most closely related to children in the community. The improvement and enhancement of this part of the built environment can bring more tangible sense of gain to children. Through structured evaluation and diagnostic tools, the community can systematically sort out the numerous built environment problems from a child-friendly perspective. At the same time, it helps communities make renewal decisions under conditions of limited funding and space resources. In areas where professional forces are scarce, universal decision-making basis will help local and grassroots community practices and even the long-term tracking and supervision of the effectiveness of built environment renewal.

2.Method

2.1. Methodological framework

The main research steps of this study are as follows:

(1) Structural definition of built environment elements of child-friendly communities, determine which built environment elements at the micro-scale are closely related to the quality of children's living and should be identified and reviewed as elements of child-friendly community environment.

(2) Based on the review of domestic and foreign child-friendly environment research and practical experience, develop Child-Friendly Neighbourhood (CFN) Built Environment Audit Tools that can structure and systematically identify problems of built environment elements at the micro-scale (human scale) and support community child-friendly renewal decisions in a refined and concise manner.

(3) Based on the local practice of Jiangpu Road Street, Yangpu District, Shanghai, the child-friendly community built environment audit tool is applied to conduct community built environment audits from a child-friendly perspective. With the context of Shanghai's high-density human settlement environment as the background, the shortcomings of existing community built environment elements at the human scale are analyzed, and spatial problems are diagnosed and warned. Then, planning intervention tools are provided to customize corresponding spatial decisions and support the implementation of child-friendly concepts at the community level.

2.2 Development of the CFN Tools

2.2.1 Assessment Principles and Subjects

What kind of community environment should be created for children to meet the specific needs of children is the first question that CFN responds to. Through a review of the characteristics and practice focus of child-friendly environments at home and abroad, it can be seen that the rights of children to health, nutrition, education, child protection, social inclusion, water, sanitation and personal hygiene proposed by UNICEF in the Child-Friendly Cities Initiative (1996) correspond to the five child-friendly environmental interest frameworks of "health, safety, citizenship, environment and prosperity" proposed in the Handbook on Building Child-Friendly Cities and Communities (2017) and the Handbook on Child-Friendly City Planning (2018). Combined with the elaboration of the goals of child-friendly city construction in China's "14th Five-Year Plan Outline", the guiding ideology and basic principles of child-friendly cities clearly put forward in the "Guiding Opinions on Promoting Child-Friendly City Fitness" issued by 23 departments including the National Development and Reform Commission, it is

concluded that "safety, health and inclusion" are the characteristics of international child-friendly environment consensus (Figure 2.1).

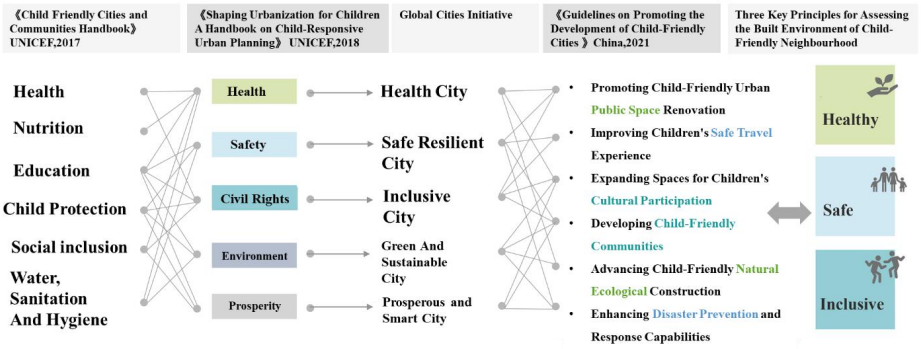

Figure 2.1

Therefore, based on the characteristics of international child-friendly environment consensus, this study proposes three principles for conducting child-friendly built environment assessment at the community level: (1) Safety principle: child-friendly environment can indicate various potential risks and provide children with material space elements and social supervision to ensure safety; (2) Health principle: reduce children's exposure to dangerous environments and provide children with environmental facilities to increase physical activities and participate in social life; (3) Inclusive principle: provide children with diverse services, fully respond to children's behavioral characteristics and activity needs at different ages, respect children's aesthetics and preferences, and create a spatial environment of appropriate scale, pleasant and comfortable for children.

The "Child-Friendly Community Built Environment Assessment Tool" (CFN Assessment Tool) proposed in this study is applied at the community level, with a special focus on the built environment within a 5-10 minute walking circle for children. In terms of assessment objects, it covers community streets and sections in areas frequently visited by children, outdoor public spaces, and residential environments in areas familiar to children. By stacking the three levels of community streets and sections, outdoor public spaces, and residential environments, the built environment elements within a 5-10 minute walking circle for children are comprehensively assessed from a child-friendly perspective. The construction system is shown in Figure 2.2, where community streets and sections are spaces where children's various travel activities take place. Outdoor activity spaces are places where children's recreational activities take place with certain spatial limitations, site designs, or activity facilities. Residential environment refers to the familiar area of children near their homes, usually within 100-200 meters of their homes, and no more than 300-400 meters (about 5 minutes for children to walk). In this study, residential area is a relative concept, referring to the environment composed of residential groups and surrounding environments that are similar in location or administrative affiliation to the residence of the child's family, and is physically or non-physically distinguished from the relatively complex external community environment.

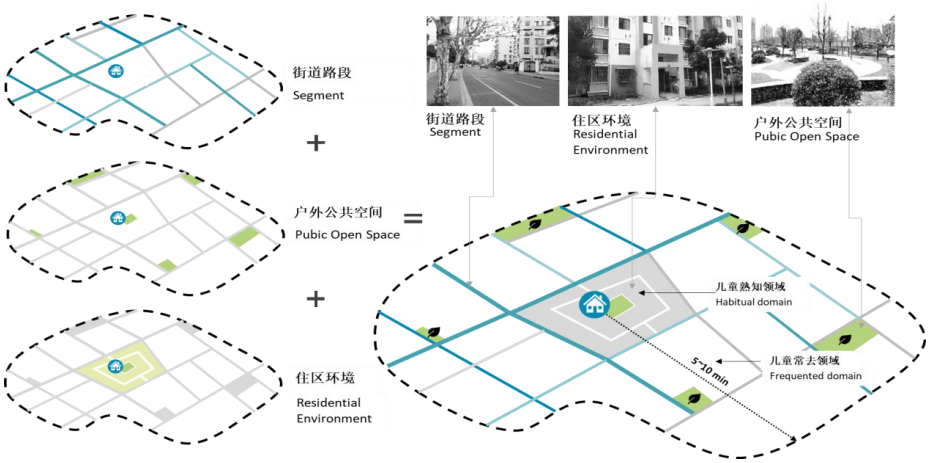

Figure 2.2

2.2.2 Review of Built Environment Audit Elements for Child-Friendly Neighbourhood Streets

In the field of child-friendly practice and research, this study selected the most representative policies and action plans of various countries, relevant design guidelines of international organizations, existing street built environment assessment tools and relevant policies and standards in my country for horizontal disassembly and comparison. It includes action plans and relevant policies related to child-friendly streets in different regions of eight countries, including Quebec, Canada, the United States, the Netherlands, and Australia, where in-depth practices have been carried out in the field of child-friendly; six design guidelines and guidelines related to streets from influential international organizations in the field of child-friendly: UNICEF, Bernard Foundation (BvLF), etc.; three street built environment assessment scales used in academic research and community practice; and five relevant guidelines and design standards issued by authoritative departments in China. Through disassembly and analysis, it is clear which street built environment elements are closely related to and cannot be ignored from the perspective of child-friendly, especially identifying the micro-elements that are easier to be improved in the context of stock renewal at the community human scale, so as to construct the evaluation content of child-friendly streets. The focus of child-friendly streets and traffic environments in terms of child safety, health and inclusion is sorted out. The complete scale is divided into 7 assessment dimensions and 17 assessment items, involving a total of 58 micro-built environment elements (Table 2.1). At the safety level, the focus is mainly on the stability of the motor traffic environment, providing a safe environment for children to walk and ride, ensuring the safety of children crossing the street, ensuring the safety of street ancillary facilities and barrier-free facilities, and providing street supervision and defense support for children's travel. At the health level, it includes providing children with clean and green street spaces, supporting and promoting children's walking, riding and other physical activities. At the inclusion level, it provides children with diversified and shared public services while ensuring the convenience of special services. Provide children with a comfortable and barrier-free environment for travel and the beauty and attractiveness of the street interface.

2.2.3 Review of Built Environment Audit Elements for Outdoor Public Spaces in Child-Friendly Neighbourhoods

The elements of this part of the scale are derived from action plans and related policies related to children's playgrounds and outdoor public spaces in different regions of seven countries,

including the United Kingdom, Wales, the Netherlands, Japan, and Australia, where in-depth practices have been carried out in the design of children's playgrounds and outdoor public spaces; and six design guidelines and guidelines issued by influential international organizations in the field of child-friendly design, such as UNICEF and the Play England Group. The complete scale is divided into 9 evaluation dimensions, involving a total of 30 micro-built environment elements. In terms of children's safety, it mainly involves three aspects: the surrounding environment safety of children's activity space, the safety of activity facilities, and the safety of landscape design. At the level of health principle, it mainly focuses on the potential of outdoor public space to promote the healthy growth of children, focusing on the support of outdoor activity venues for children's games, sports and other leisure physical activities, and the promotion and support of walking and cycling activities. At the level of inclusive principle, it mainly evaluates the comfort of outdoor activity space design for children, the diversified and convenient services, the slow accessibility of space and the attractiveness of design.

2.2.4 Review of Built Environment Audit Elements for Child-Friendly Neighbourhoods Residential Areas

Through the analysis of domestic and foreign experience, it is found that residential areas are familiar areas for children's daily activities, and the built environment elements involved cover both transportation space and recreational space. Therefore, the unit of the CFN tool review and statistics in this study is the residential environment, but the specific objects of the outdoor space reviewed can be divided into sections between residential buildings, outdoor public spaces in residential areas and comprehensive levels of residential areas according to the nature of activities supported by the built environment elements. The specific evaluation elements are composed of these three parts. The complete scale is divided into 7 evaluation dimensions and 18 evaluation items, involving a total of 55 micro-built environment elements. The assessment is conducted from the perspective of child safety, involving aspects such as traffic safety between residential buildings and children's travel safety between residential buildings. The traffic safety between residential buildings is examined from three dimensions: traffic organization between motor residential buildings, motor traffic stability and parking facilities. The travel safety between residential buildings is examined from three dimensions: walking and cycling organization, children's travel guide sign setting and residential safety facilities setting. The assessment is conducted from the perspective of child health, involving aspects such as space support for children's physical activities and facilities support for children's physical activities. The spatial support capacity of children's physical activity venues is examined from four dimensions: venue selection, functional zoning, venue design and landscape aesthetics. The facility support capacity of children's physical activity venues is examined from three dimensions: safety facility setting, activity facility setting and service facility setting. The assessment is conducted from the perspective of child inclusion, involving aspects such as the diversity and convenience of public services, the comfort of children's travel environment and the attractiveness of the environment. The convenience of public services in residential areas is examined from the configuration of children's life services and education services. The comfort of children's travel environment is examined from the comfort of walking and cycling roads and facilities. The attractiveness of residential environments for children's activities is examined from three dimensions: green space landscape between residential buildings, public art and architectural interfaces between residential buildings.

Table 2.1

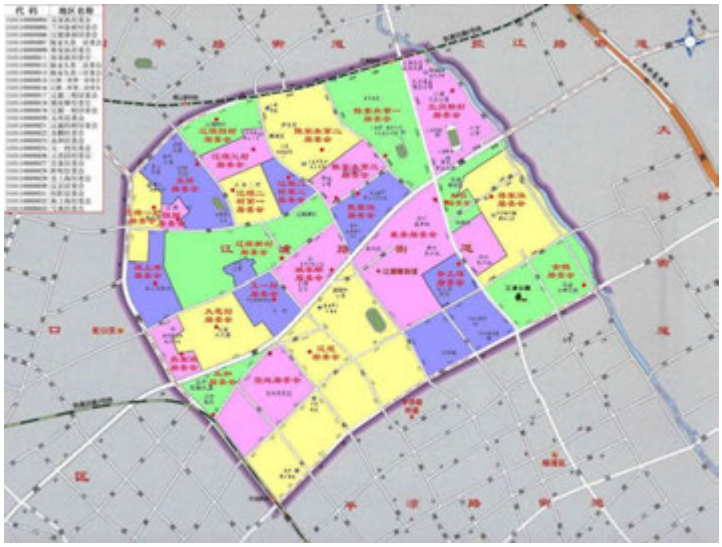
2.3 Application Practice of the CFN Tools

In order to test the applicability of the built environment assessment tool for child-friendly communities, the author conducted a built environment assessment of child-friendly communities in Jiangpu Road, Yangpu District, Shanghai. Jiangpu Road is located in the southwest of Yangpu District, Shanghai, from Lanzhou River to Kongjiang Road in the east, and from Dalian Road to Hongkou District in the west. It starts from Changyang Road in the



south and ends at Kongjiang Road in the north. The area under its jurisdiction is about 2.39 square kilometers, with 24 neighborhood committees (Figure 2.2). Based on the theory of urban residential morphology, Shanghai residential areas are divided into lanes, public housing and commercial housing areas. Among them, the residential types of lanes are Shikumen lanes or new lanes, which were mostly built in the 1930s and 1940s, and are generally row-style, two- or three-story residential buildings. Today's lanes are mostly characterized by small and compact outdoor spaces and old supporting facilities. Public housing refers to welfare housing developed and built by the government or state-owned enterprises and institutions for a large number of workers, which was built in the 1970s and 1980s. Commercial housing residential areas are the product of the rise of real estate development. The residential organization is no longer limited to the determinant type, and the point type and free type organization are rising. At the same time, residential buildings are no longer low-rise or multi-story, and the number of small high-rise and high-rise residential buildings is gradually increasing. At present, the Jiangpu Road area has formed a situation of multiple textures of public housing, lanes and commercial housing. The environmental characteristics of these three main types of residential areas in the area can reflect the characteristics of Shanghai's high-density human settlement environment to a certain extent. These three types of residential environments are also the main positions for child-friendly practices in the context of Shanghai's urban renewal. Therefore, this study will conduct a child-friendly community built environment assessment and review based on the selected Jiangpu Road area in Yangpu District. The review objects include 131*2 (both sides) street segments, 60 outdoor public spaces and 28 residential areas.

Figure 2.3

In order to interpret the CFN assessment results in a concise and intuitive way, the on-site review data is aligned and visualized with the geographic space in ArcGIS software. This includes constructing a double-sided assessment street segment line dataset to visualize the street segment assessment results, constructing an outdoor public space point dataset to visualize the outdoor public space assessment results, and constructing a residential area face dataset to visualize the residential environment assessment results and the community comprehensive assessment results (Figure 2.4).

Figure 2.4

3.Results

3.1 Comprehensive Evaluation Results of Child-Friendly Neighbourhood in Jiangpu Road Area

Taking the geometric center of each assessed residential area as the starting point and the 5-minute walk distance (400 meters) for children as the radius, the community life circle unit range of the assessment is delineated, and the street section assessment results, outdoor public space assessment results and residential environment assessment results within the assessment range are superimposed. From a child-friendly perspective, the micro- and medium-scale built environment elements of each community unit are comprehensively assessed.

Based on the comprehensive assessment results, horizontal and vertical comparisons between communities in the area can be carried out one by one to identify and judge common or differentiated built environment status issues. The on-site assessment was carried out in 28 communities in the Jiangpu Road area, including 2 lane residential areas, 10 public housing residential areas and 16 commercial housing residential areas. (Among them, the number of lane residential areas is relatively small, and they are collectively referred to as lane and public housing residential areas in the following classification). The evaluation results are divided into the upper quartile, median, and lower quartile of the overall score. Among the 28 evaluated community units (composed of the main residential area and surrounding streets and outdoor public spaces), 35.7% of the community units have relatively good child-friendly evaluation results (child-friendly comprehensive scores) based on the actual built environment, 20.7% and 34.5% of the community units have good and medium child-friendly evaluation results, and 6.9% of the community units have relatively poor evaluation results. In terms of the main residential area type attributes, the overall child-friendly evaluation results of the evaluated community units composed of public housing and lane residential areas and their surrounding environments are poorer than those of commercial housing residential areas. Only 8.3% of the community units have excellent child-friendly evaluation results, while this proportion is 56.3% in the evaluated community units with commercial housing residential areas as the main residential area type (Figure 3.1).

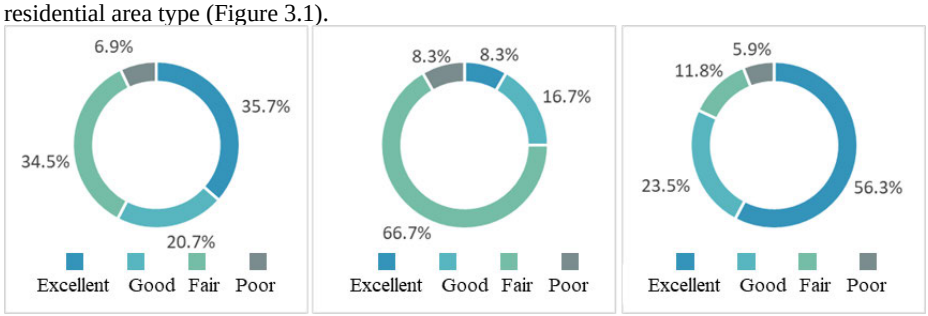


图 Figure 3.1 （Left: Overall communities Middle: Lanes and public housing communities Right: Commercial housing communities）

Through the geographic spatial visualization of the evaluation results in ArcGIS software, the spatial distribution of the evaluation results can be intuitively analyzed. In addition to helping the district to simply identify the comprehensive evaluation of the community, based on the sub-item evaluation results, the advantages and disadvantages of the three spatial dimensions of street sections, outdoor public spaces and residential environment can be further examined. In terms of the comprehensive evaluation results of child-friendly, the communities with relatively good practical foundations are concentrated in the west of Jiangpu Road District (east of Dalian Road) and the south of Zhoujiazui Road (Figure 3.2), and most of them are commercial housing communities (assessment units consisting of commercial housing residential areas as the main residential type and their surrounding environment). Communities with relatively poor practical foundations are concentrated in the north of Jiangpu Road District, and most of them are public housing and lane communities.

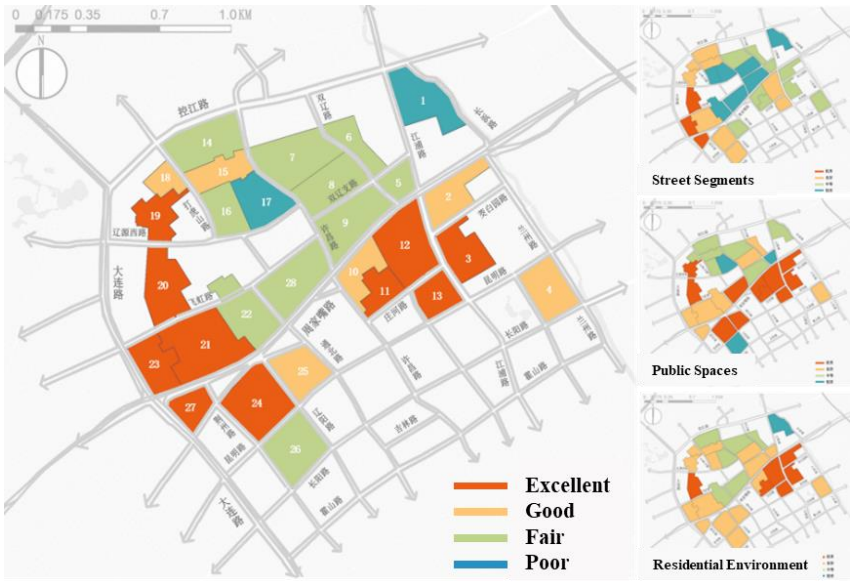

Figure 3.2

According to the CFN evaluation results, in the next step of the community environment adaptation and renewal decision-making, refer to the distribution of the "poor-excellent" situation on the actual basis, and divide the comprehensive child-friendly renewal of the community from level I (urgently in need of improvement) to level IV (optimization and improvement), child-friendly renewal of street sections, child-friendly renewal of outdoor public spaces and the order of child-friendly renewal of residential environment (Figure 3.3). According to the requirements of the evaluation items, the community built environment is gradually and targetedly rectified. Prioritize the rectification of the community built environment in the area in urgent need of improvement, which is an important bottom-line action. Improve and optimize the community built environment in the area with the highest evaluation standards, build a child-friendly community, and play a strong demonstration role.

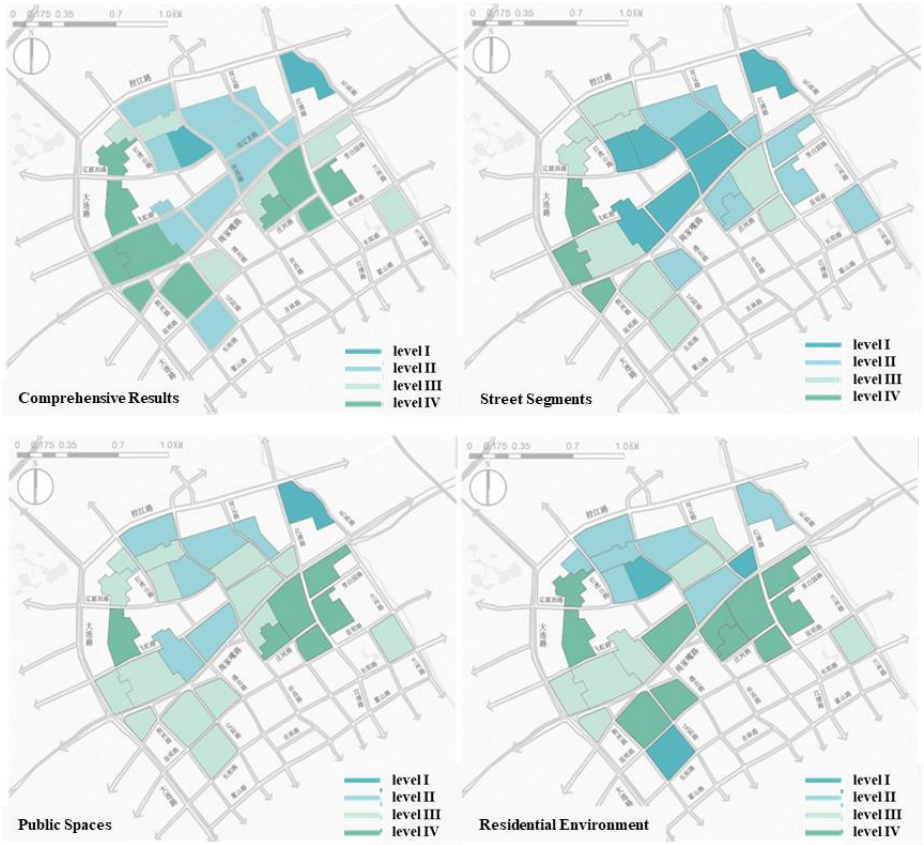

Figure 3.3

3.2 Evaluation Results of Street Segments in Child-Friendly Neighbourhood in Jiangpu Road Area

3.2.1 Child Safety Perspective

In terms of travel space safety, the area with good children's travel safety accounts for 25.8% overall, mainly located in the southern part of Jiangpu Road area (Figure 3.4), and the poor configuration area is mainly located in the middle and eastern part of Jiangpu Road area, accounting for 21.2%. Compared with the distribution of residential communities in Jiangpu Road area, it can be found that there is a certain misalignment between the areas where residential communities are concentrated in Jiangpu Road area and the areas with better configuration of travel space safety elements, which to a certain extent reveals the mismatch between children's travel safety needs and the actual basis, especially the road sections around the areas where alleys and public housing communities are concentrated in the middle of Jiangpu Road area have poor built-up environment, which should be paid attention to in the community child-friendly environment improvement action.

In terms of pedestrian space safety, the review indicators include the setting of pedestrian paths, the quality of pedestrian paths, and the standardization of temporary parking settings. As shown in Figure 3.5, in Jiangpu Road Subdistrict, the pedestrian space safety around the older communities in the north is poor, while the newly built blocks in the south are more complete. The southern section of Xuchang Road, Tongbei Road, and the southern section of Jiangpu Road are better equipped, while the eastern section of Feihong Road, Changbang Road, and Shuangliao Branch Road are poorly equipped, with major damage to the road surface, obvious traffic obstacles, and many other problems (Figure 3.6). During the assessment process, it was found that many non-motor vehicles or motor vehicles parked on sidewalks or non-motor vehicle lanes (Figure 3.7), which seriously affected normal traffic and brought safety hazards to children's travel. Similarly, at the level of cycling space safety, CFN road section assessment can help communities comprehensively review cycling space safety, including the setting of non-motor vehicle lanes, the gap between the actual basis of non-motor vehicle lane quality and the level of child-friendly cycling space safety configuration that should be achieved.

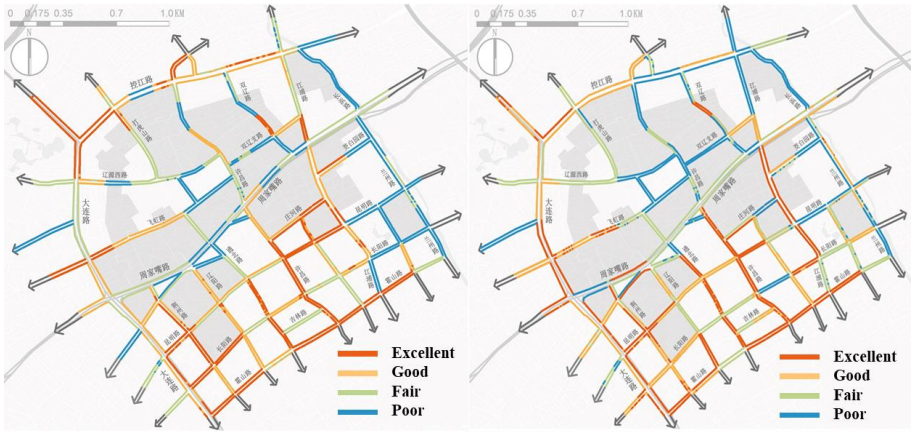

Figure 3.6

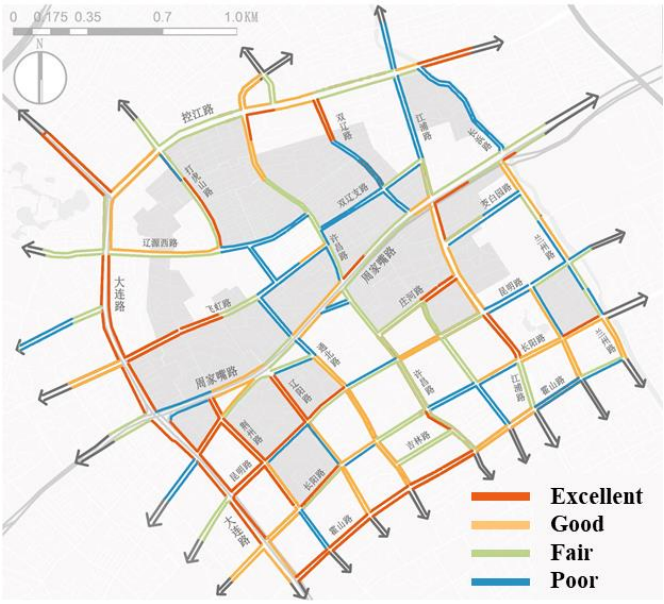
Figure 3.7

3.2.2 Child Health Perspective

The community should provide children with a clean and tidy street material space environment, which is closely related to children's health. In this section, the CFN tool mainly evaluates the material space environment elements that promote children's health, including the cleanliness of travel space (including cleanliness of walking and cycling space, cleanliness of resident activity places) and street greening conditions (including greening planting conditions and street greening maintenance quality elements). Overall, the comprehensive score is divided into quartiles, and the area with relatively good configuration accounts for 21.1% (Figure 3.8), which is concentrated in the southwest corner of Jiangpu Road Street, the southern section of Dalian Road, Jingzhou Road, Kunming Road, and the western section of Huoshan Road. Combined with the distribution of community types, it is found that this is an area where some commercial housing residential areas are concentrated. The proportion of relatively poor configuration is 20.3%, which is concentrated in the middle of Jiangpu Road Street. The area around the road section is the area where the central lanes and public housing communities of Jiangpu Road Street are concentrated.

Figure 3.8



3.2.2 Child Inclusion Perspective

Whether children enjoy various and convenient public services in urban street life is an important aspect of measuring the inclusiveness of children in the community. In the evaluation, the level of public services along the street is mainly evaluated from two aspects: public service facilities shared by all ages and special service facilities focusing on children. The evaluation of community street public service facilities shared by all ages includes five service elements: commercial services, cultural activities, daily travel, sports and fitness, and park green space. Special service facilities focusing on children include three service elements: growth education, child welfare, and maternal and child care. When the CFN evaluation tool was designed, the evaluation requirements for the configuration of public services and special service elements for children were formulated based on relevant practices and standards, and the evaluation was carried out accordingly, focusing on the accessibility of street public service configuration on sections covered by the five-minute walking circle of children. Overall, the configuration of

public services shared by all ages is better in the community living circle along Kongjiang Road, and the configuration of special service facilities for children is better in the places where the lanes and public housing communities in the north are concentrated (Figure 3.9; Figure 3.10).

Figure 3.9

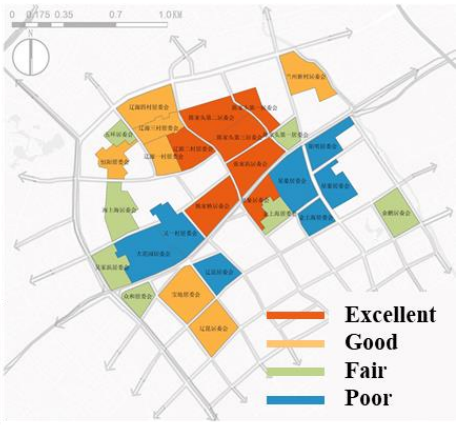


Figure 3.10

3.3 Evaluation Results of Child-Friendly Public Open Spaces in the Jiangpu Road Area

In this evaluation, a total of 60 community outdoor public spaces were evaluated (Figure 5.64). From the overall configuration (Figure 3.11), based on the upper quartile, median, and lower quartile of the overall score, 17% of the public spaces in Jiangpu Road Street were relatively well configured, and Yangming Jiangpu Point, Haishang Commercial Point, Liaoyuan Huayuan Point, Puhaoyuan Point, and Jinshanghai Public Space were well configured. Another 20% of public spaces were well configured, and 38% and 25% of public spaces were medium and poorly configured. In terms of the distribution of evaluation results of different types of public spaces (Figure 3.12), the public spaces in commercial housing residential areas had the best configuration of child-friendly elements, with 28% and 33% of public spaces being well configured overall, and only 6% of public spaces being poorly configured overall. Public spaces outside residential areas were second, with 22% and 17% of public spaces being well configured overall, 56% of public spaces being medium configured, and only 5% of public spaces being poorly configured. The actual foundation of public spaces in alleys and public housing residential areas is poor overall, with 54% of public space infrastructure items poorly configured, and only 4% and 13% of public space configurations being excellent and good overall.

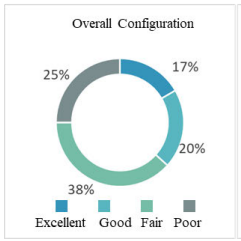

Figure 3.11

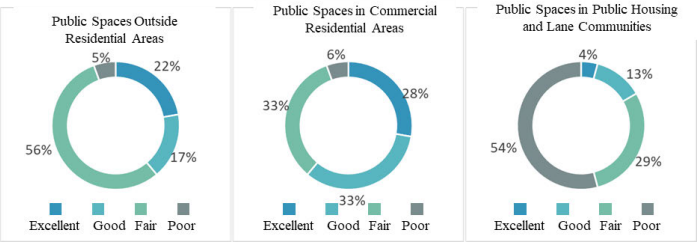

Figure 3.12

3.3.1 Child safety perspective

The assessment tool helps the community focus on the specific configuration shortcomings of outdoor public spaces from a child-friendly perspective, and examine them from a child safety perspective. The assessment dimensions include the safety of the surrounding environment, the safety of activity facilities and the safety of landscape design. The overall public space is best configured in terms of surrounding environment safety (Figure 3.13). 70% of the public space scores excellent in this dimension, and 61.7% of the public space configuration meets the evaluation requirements of the CFN tool (i.e. "setting location" and " Both sub-elements of "enclosed interface" are set for safety), and secondly, the configuration of landscape design safety is better, with 68.3% of the public space configuration scoring excellent. Overall, the safety of activity facilities is poor, with only 28.3% of public spaces configured as excellent. Judging from the configuration of different types of residential areas (Figure 3.14), the safety of the surrounding environment is the shortcoming of the allocation of public spaces outside the residential areas. Compared with the public spaces of commercial housing areas, lanes and public housing areas, only 50% of the public spaces are The proportions of the configuration being excellent and the other two types of configuration being excellent are 83.3% and 75% respectively. In terms of the safety of activity facilities and landscape design, the order of better allocation is public space outside the district, public space in commercial housing areas, and public spaces in alleys and public housing areas.

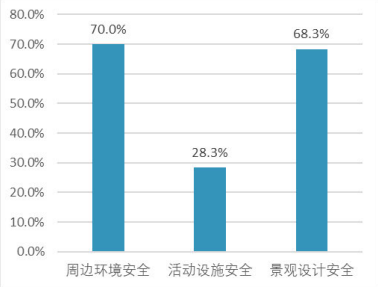

Figure 3.13

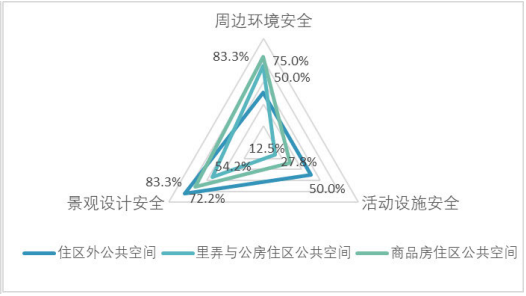

Figure 3.14

3.2.2 Child Health Perspective

At the level of children's health, the CFN outdoor public space assessment dimensions include three dimensions: support for walking and cycling activities, support for children's leisure physical activity space, and support for leisure physical activity facilities. At the level of children's health, the CFN outdoor public space assessment dimensions include three dimensions: support for walking and cycling activities, support for children's leisure physical activity space, and support for leisure physical activity facilities. Among them, the walking and cycling support assessment factors include whether there are facilities to promote walking and awake activities, such as fitness trails and cycling trails. In the leisure physical activity space dimension, the support provided at the venue space level is assessed, including the area of the activity area, the cleanliness of the venue, and whether there are corresponding support venues for leisure physical activities such as children's games and sports, including children's game space, children's ball or track and field sports space, and playable natural space. From the overall assessment data analysis (Figure 3.15), the public space in the entire Jiangpu Road area performed relatively average in the three dimensions of children's health. Among them, the assessment results of leisure physical activity space support were relatively good, with 33.3% of public spaces performing well, but only 3.3% of public spaces performing well. The second is walking and cycling support, with 11.7% of public spaces performing well and 1.7%

performing well. The support for public space leisure and physical activity facilities is relatively poor, with only 8.3% and 5% of public spaces being well and well configured.

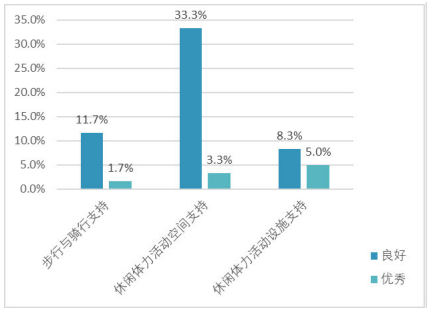

Figure 3.15

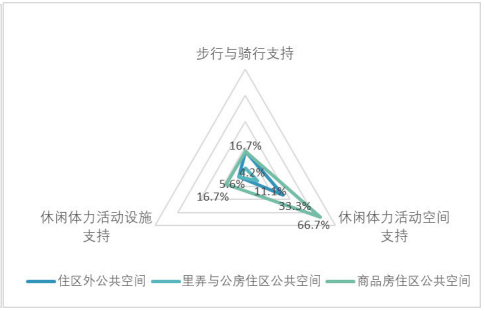

Figure 3.16

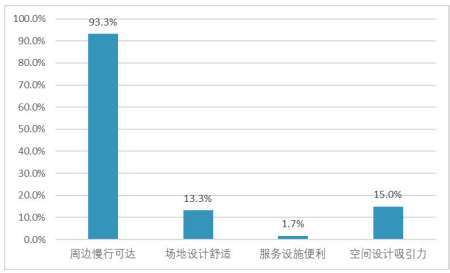
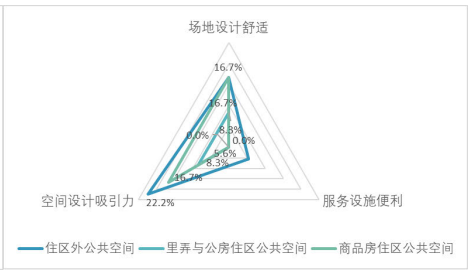
From the evaluation results of different types of residential environments (Figure 3.16), the configuration of public spaces in commercial housing residential areas in three dimensions is relatively good overall, especially in the dimension of children's leisure and physical activity space support, with 66.7% of public spaces being well configured. However, the public spaces in lanes and commercial housing residential areas are relatively poor in terms of children's leisure and physical activity space and facility support. Overall, it can be seen that there is a mismatch between "space" and "facilities" in the public space of Jiangpu Road Street. There is also a large gap in the configuration of public spaces in different types of residential areas. The main problem of public spaces in commercial housing residential areas is "there is space, but no facilities", while in the public spaces of lanes and commercial housing residential areas, children's activity support facilities and space are very scarce, which is manifested as "neither space nor facilities".

3.2.3 Child Inclusion Perspective

Child-friendly public spaces should be inclusive, so that all children can reach and use the space in a positive way, and the space design should respect children's preferences, provide children with comfortable, barrier-free venues and various convenient service facilities. Overall, 93.3% of the public spaces in Jiangpu Road are equipped with sufficient and reasonably located entrances and exits, and the surrounding areas can be reached by walking, cycling or public transportation. In terms of the comfort of children using public spaces, the performance is relatively poor in terms of the comfort of the site design and the attractiveness of the space design. Only 13.3% and 15% of the public space configurations can meet the CFN assessment requirements. The performance is the worst in the setting of convenient service facilities. Only 1.7% of the public space configurations can meet the CFN assessment requirements (Figure 3.17). Focusing on the shortcomings of the configuration of public spaces in different types of





residential areas, because the three types of public spaces perform well in the dimension of surrounding slow-moving accessibility, and are quite different from the requirements of several other dimensions, this item is excluded for analysis. The results show (Figure 3.18) that the status quo of the three types of public spaces at the level of inclusiveness has certain similarities. Overall, the public spaces outside residential areas performed well in terms of spatial attractiveness and convenient service facilities, with 22.2% and 5.6% of public space configurations meeting the assessment requirements for child-friendly communities. The public spaces in lanes and public housing performed poorly in terms of site design comfort, convenient service facilities, and spatial design attractiveness.

Figure 3.17 Figure 3.18

3.4 Evaluation Results of Child-Friendly Residential Area Environment in the Jiangpu Road Area

3.4.1 Child Safety Perspective

From the perspective of child safety, residential built environment should be evaluated. Residential areas should create a stable traffic environment for children, encourage children to walk and ride, and reduce travel injuries. The evaluation content mainly focuses on the safety environment between residential buildings in terms of traffic safety between residential buildings and travel safety between residential buildings for children at the micro-scale. Overall, no residential environment fully meets the evaluation requirements. The scores are divided into upper quartile, median and lower quartile. 34% of residential areas have excellent status in terms of child safety (Figure 3.19), 28% and 24% of residential environments have good and medium performance, and another 14% of residential environments have poor performance. Furthermore, there are obvious or even extreme differences in different types of residential

environments (Figure 3.20; Figure 3.21). The status quo of child safety factors in lanes and public housing residential areas is relatively poor. There is no residential area with excellent performance, 17% and 50% of residential environments have good and medium performance, and 33% of residential environments have poor performance. In the commercial housing residential areas, there are no residential areas with poor performance, 59% of the residential areas have excellent environmental performance, and 35% and 6% of the residential areas have good and medium environmental performance. Compared with commercial housing communities, the improvement of the built environment in the lanes and public housing communities in terms of children's safety is very urgent.

Figure 3.19 Figure 3.20 Figure 3.21

3.4.2 Child Health Perspective

Residential areas should support children's diverse physical activities and create a healthy physical activity environment for children in residential areas. Therefore, we focus on the design of public spaces in residential areas and examine the support for children's physical

activity spaces and physical activity facilities in residential areas. To ensure the consistency of the assessment, the detailed assessment elements in this part are the same as the CFN outdoor public space assessment elements. Only a brief description of the assessment results of residential public spaces and the gaps and shortcomings in the actual foundation between different types of residential areas is given. The above quartile, median, and lower quartile assessment results show that, at the level of children's health, 17.24% of the residential areas in the Jiangpu Road area have a relatively good environmental status configuration (Figure 3.22), 27.59% and 31.03% of the residential areas have a good and medium status, and another 24.14% of the residential areas have a poor actual foundation. There are obvious differences in quality based on reality between different types of residential areas (Figure3.23; Figure 3.24). In terms of children's health, only 8.33% of the residential environments in alleys and public housing areas are excellent, and 41.67% of the residential environments are poor. In commercial housing areas, 23.53% of the residential environments are excellent, and only 11.76% of the residential environments are relatively poor.

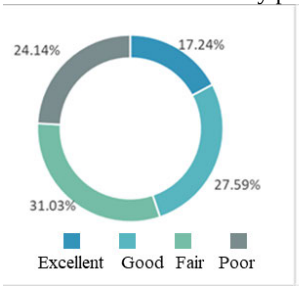


Figure 3.22

Figure 3.23

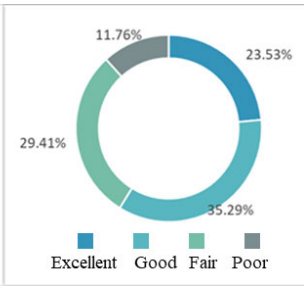

Figure 3.24

3.4.3 Child Inclusion Perspective

Compare the five dimensions of diverse and convenient public services, comfortable children's travel environment, and attractive environment, including green landscape between residential buildings, public art between residential buildings, and architectural interface between residential buildings, to better focus on the shortcomings of community built environment configuration. From the evaluation results, the overall performance of the comfortable children's travel environment in the residential area is relatively good, while the performance of the public art element between residential buildings is relatively poor (Figure 5.143). There is also a clear dislocation and difference in the configuration of good and bad elements between different types of residential areas (Figure 5.144). Lanes and public housing residential areas are better than commercial housing residential areas in terms of diverse and convenient public services, but are significantly inferior to commercial housing residential areas in other dimensions.

Figure 3.25

Figure 3.26

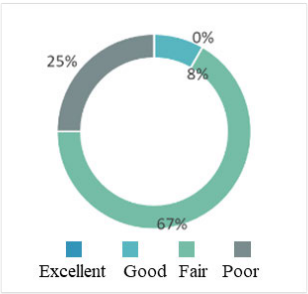

Figure 3.27

4.Ddiscussion

4.1 Assessment Aspects of Child-Friendly Neighbourhood Street Segments

In terms of safety, the speed limit area of the motor traffic calming design is insufficient and the design is simple. The safety of walking and cycling space is affected by problems such as road damage and traffic obstacles. There is a lack of child-friendly measures such as painted crosswalks for children to cross the street. There are safety hazards in the auxiliary facilities, and the common boards for humans and machines are not separated. The design of children's guide signs to improve readability and easy recognition is insufficient.

In terms of health, there are problems such as garbage dumping around the alleys and public housing communities, and some sections of the road are not greened. The width of the cycling path in the social activity environment is insufficient, and the design of street resident activity venues is not enough to support children's activities.

In terms of inclusion, the configuration of children's special service facilities around commercial housing communities is poor. In terms of children's travel comfort, some streets are equipped with child-friendly, brightly colored soft pavements that are easy to identify (Figure 4.1). There are few colorful soft pavements for children's travel comfort, and public transportation transfer facilities lack detailed child-friendly designs. The environmental attractiveness lacks child-friendly design, and there are messy electric poles, graffiti and other influences.

Figure 4.1

In general, in the subsequent child-friendly renewal of the community, the improvement measures can be roughly divided into five categories: first, to adjust the cross-section of the street pavement, such as widening the walking and cycling space; second, to add various child-

friendly street facilities, such as traffic calming measures, child-friendly travel guide signs, child-friendly crossing facilities, etc.; third, to optimize the child-friendly design of street landscapes, such as street greening, child-friendly street public art design, etc.; fourth, to enhance the various service functions of street children, such as life convenience, leisure activities, etc.; fifth, to formulate corresponding management measures. In particular, compared with some street built environment element updates involving limited resources and complex measures (such as street cross-section adjustments, etc.), some flexible and simple ones, such as adding various child-friendly street facilities, are often also the "shortcomings" that are in short supply in the actual basis.

4.2 Assessment Aspects of Child-Friendly Neighbourhood Public Open Spaces

In terms of safety, the safety assessment of the surrounding environment and landscape design of outdoor public spaces is good, but the safety assessment of activity facilities is relatively poor. The enclosure interface safety, landscaping and activity facilities are well maintained, but the lack of vehicle-ban facilities leads to random vehicle entry, and children's playgrounds are used as parking lots, especially in lanes and public housing communities. Instructions and information signs lack child-friendly design, and insufficient lighting facilities pose safety hazards.

In terms of health, the area of public space available for activities and the cleanliness of the venue are good, but the support for children's games and sports spaces is insufficient, especially in lanes and public housing communities. Children's game facilities, preschool game facilities, ball and track and field sports facilities are insufficient, and fitness facilities are not suitable for young children. There is a mismatch between "space" and "facilities", especially the problem of insufficient configuration of children's game facilities is more prominent.

In terms of inclusiveness, the surrounding slow-moving accessibility is good, but the venue design is comfortable, the space design is attractive, and the convenience service facilities are the worst. In terms of site design comfort, more than 70% of public spaces can meet the assessment requirements of site flatness, but only 30% of public spaces are paved with soft pavement suitable for children, and only 10% of public spaces are designed based on site color guidance (Figure 4.2). The recreational facilities are well-equipped, but the space design is not attractive enough, and there are problems with water management and safety protection.

Figure 4.2

4.3 Assessment Aspects of Child-Friendly Residential Area Environment

In terms of safety, the traffic organization between residential buildings in lanes and public housing areas is chaotic, and insufficient parking facilities for motor vehicles lead to messy parking, obstructing traffic and occupying children's activity space. The road surface is often high-difference, end cracks, and damage. There is a lack of special cycling organizations and facilities, which leads to interference between cycling, walking and driving. There are few child-friendly facilities in child-oriented signs, and there is no barrier-free design at the entrance and exit of the residential area.

In terms of health, the physical activity space for children in lanes and public housing areas is poorly configured, and the functional space and venue design of game space and sports space are insufficient. Only a few residential areas are equipped with complete safety facilities and children's activity facilities, and there are fewer children's game facilities and sports facilities.

In terms of inclusiveness, the children's travel environment is comfortable, public services are diverse and convenient, and the green landscape and building interface are good, but the public art elements are poor. Public services are richer in lanes and public housing areas, but other aspects are inferior to commercial housing areas. Commercial housing areas have better rest facilities and sunshade facilities, and green spaces and greening beside houses are common, while there are problems such as garbage and parking encroachment in green spaces beside houses in lanes and public housing communities.

Cluster green space provides environmental support for children in residential areas to contact nature. In the practice of international child-friendly communities, more emphasis is placed on the "playability" and "play value" of outdoor spaces such as open green space. Unlike traditional children's playgrounds, nature-based construction methods can allow children to interact more with nature. Based on this, the CFN residential audit reminds the community to pay attention to the playability of cluster green space and green space next to houses. The on-site audit results show that 64.71% of the cluster green spaces in commercial housing residential areas have designs that enhance children's "playability". The main construction method is to lay paths in the green landscape and place recreational facilities and fragmented venues (Figure 4.3).

Figure 4.3

5.Conclusion

By combing through the relevant policies, action plans and design guidelines for child-friendly construction at home and abroad, this study constructs a "child-friendly community built environment assessment technical tool" suitable for China's stock renewal background, covering multi-level spaces such as community streets, outdoor public spaces and residential environments. At the same time, relevant application methods are proposed, including development models, statistical and visualization methods and technical results. The application example of on-site assessment in the Jiangpu Road area of Shanghai shows to a certain extent that the constructed innovative tool has application value in community space problem diagnosis and planning decision-making intervention. Compared with the renewal of some community built environment elements involving limited resources and complex measures, some flexible and micro-community built environment elements are more scarce in the reality. The renewal of these elements is an important potential part for effectively exerting governance results and enhancing children's sense of gain.

After conducting on-site assessments from a child-friendly perspective, it is found that there is still a lot of room for the improvement of the child-friendly micro-scale built environment in existing communities. Taking street improvement as an example, it is very important to adjust the cross section of the street pavement, such as widening the walking and cycling space, but the implementation cost also increases accordingly. In particular, compared with the cross section adjustment, adding various child-friendly street facilities, such as traffic calming measures, child-friendly travel guide signs, and child-friendly crossing facilities, is more flexible and effective. The evaluation found that these are also the important parts missing from the existing built environment. Similarly, taking the improvement of outdoor public space as an example, there is a general mismatch between "space" and "facilities" in existing communities. Compared with the past, the problem of tight stock land resources has been deeply understood. In fact, the problem of insufficient configuration of children's play facilities in public spaces is also prominent, which is manifested as "there is space but no facilities" or "there is neither space nor facilities". Focusing on these important potential parts in child-friendly renewal can effectively play the renewal effect and enhance children's sense of gain in the practice of child-friendly communities.

In this study, only the common parts of the micro-built environment elements in the community involved in the relevant materials of child-friendly practices at home and abroad are sorted out and reviewed. In fact, due to unavoidable objective factors such as differences in national development levels and the diversity of existing built environments, it is very important to localize the evaluation tools for different built environment contexts. The system constructed in this study is only applied in the Jiangpu Road area, which has certain limitations. Furthermore, by expanding the application sample, expert review and interviews in the child-friendly field, the evaluation elements and evaluation rules can be iteratively updated, and the evaluation content can be dynamically adjusted, which can improve the reliability and universality of the evaluation tools. With the intelligentization of data collection methods, it provides the possibility of extensive and continuous environmental evaluation, which has further exploration significance for continuously improving the quality of life of children in the community and supervising the built environment of children's lives.

- Lisa Marie Brunner, Norwegian University of Science and University

Keywords: *Planning education, pedagogy, planning curricula, community engagement skills, sustainability skills, cross-disciplinary learning, trans-disciplinary learning*

We are in a time of major upheaval and change, including net zero ambitions and new approaches to seeing nature as having rights, such as rivers as stakeholders in decisions about the future. Planning has always involved working across disciplines, with engineering and economics as well as spatial analysis, but we now need to work more closely with ecology, natural science and landscape planners. The planning profession has an opportunity to make a game-changing contribution to shifts to a sustainable and just society, but this will require very different skills from those of the past.

Teaching about climate change and biodiversity loss can induce a great sense of eco-anxiety and anguish. As educators, we must consider how to balance optimism and eco-anxiety for ourselves and our students. At the same time as considering the voices of local communities and the natural world, we are tasked with delivering major infrastructure projects and events. What is our role as educators in helping students to navigate these tensions?

This track invites theoretical, methodological and empirical contributions on the role of planning education in helping secure sustainable and just futures, innovative pedagogical approaches to developing the necessary skills and competencies and navigating the tensions involved. The track also invites consideration of alternative routes for planning education, such as apprenticeships and real-life projects, and novel ways to encourage cross-disciplinary and trans-disciplinary learning.

Deep Learning-Driven Morphological Dataset and Analysis Methods for Chinese Campuses

Abstract

Modern campuses in China display distinct morphological characteristics, evolving to form unique patterns as subsystems within the urban environment. Hence, the approaches for comprehensive analysis for those urbanized Chinese campus morphology (UCCM) are important. This study proposes a framework for dataset construction and morphology recognition of UCCM, using visual representing learning methods. Computer vision technologies are used to acquire the morphology patches of 1257 campuses. We analyse the campus morphology with our proposed multi-dimensional morphometrics. Then, we constructed multiple morphological cluster maps for UCCM in terms of road, building and landscape, respectively. The cluster maps show significant compliance with human visual perception. Compared with classic morphometrics, our approach excels in learning implicit morphological characteristics with lower data processing demands and less reliance on expert experience.

Keywords: Urbanized Chinese campus morphology, Morphometric, Visual Representation, Self-organizing Map, Unsupervised learning

1. Introduction

With the expansion of higher education in this century, more universities and campuses have been established in Chinese cities, especially in suburban and nascent urban areas. These new campuses occupying larger footprints than their initial forms, responding to expanding enrolment and diversified functions. These urbanized Chinese campus morphology (UCCM) are often isolated from surrounding urban areas, evolving into a distinct subsystem within the broader urban network. They have changed the pre-existing urban fabric and ecological landscape to a significant extend.

A comprehensive recognition about morphology of those urbanized campus is required, since their form not only contributes to the shape of the city but also links to the efficiency of teaching and learning (Kenney, Dumont and Kenney, 2005). At the master planning level, modern campus morphology study involves various aspects such as campus circulation, built environment, spatial compactness, contextual responsiveness, and increasingly, landscape ecological patterning (Dalton, Hajrasouliha and Riggs, 2018). Most studies proposed strategies for campus urbanization based on practical experiences or comparative analyses of various campuses (Xu, Zhang and Rong, 2012; Zhang, Fisher, and Gang Feng, 2020; Meng *et al.*, 2023). There is a lack of specific classification criteria and a comprehensive morphological recognition framework, especially for these newly urbanized campuses in China. Urban morphology characteristics are twofold, encompassing both measurable and immeasurable aspects, such as quantifiable metrics and abstract prototypes. This complexity adds significant challenges to digital morphological classification for campus.

In this context, this study proposes an approach of the dataset construction and morphology recognition based on visual representation learning approach for the new urbanized campus form in China. We gather images and data on 1257 medium to large-scale higher education campuses in China from open-source mapping platforms. Image processing techniques are applied on high-resolution map tiles to address the challenge of incomplete data on campus, converting them into vector geographic graphics. Based on the dataset, we firstly analyse the UCCM with morphometrics in multiple dimensions, including site and context, roads, buildings and density, and landscape ecology. Furthermore, we deploy deep learning techniques to deal with visual features which are challenging-to-quantify. Utilizing the unsupervised Self Organizing Map (SOM), morphological cluster maps for Chinese campus are constructed, which facilitate to discover similarities and characteristic among campuses. Our research offers insights into the understanding of the morphology of campuses in China in two different ways, morphometrics and visual representation using deep learning. Morphological recognition based on visual representation methods has unique advantages, and integrating the two methods will be the focus of subsequent research.

Related work

Representing Campus Form

The Morphometrics approach has gained strong momentum in urban research, with the advent of new geospatial data and tools. It dedicates to describe the form through the quantification of geometry and relationship of urban elements. Separated dimensions are considered in multi-scale urban form, which often includes intensity, distribution, proximity, connectivity, complexity, diversity and form, etc. (Salat, 2011). Existing studies have proposed multiple metrics through interdisciplinary approaches and validated their effectiveness in characterizing urban form (Clark, Martin and March, 1975; Marshall, 2004; Berghauser Pont and Haupt, 2005). Morphometric on blocks and blocks assemblage hierarchies inform medium to large scale campus morphology studies, for their similar scales.

Researches on campus form focus more on the certain elements like buildings, roads or open space, using case studies and comparative studies (Dalton, Hajrasouliha and Riggs, 2018). Hajrasouliha proposed a framework for campus form dimension and campus score, based on the dataset of campuses in the United States. The form dimensions of campus can be categorized into seven: land use, compactness, connectivity, configuration, habitability, greenness, and cultural heritage, which are summarized in the three perspective of urbanity, greenness, and habitability of the campus(A. H. Hajrasouliha, 2017(a)). It was confirmed that campus scores based on morphometrics were associated with the quality of teaching and learning (A. Hajrasouliha, 2017(b)). As for campus planning in China, the Architectural Design Sourcebook (Volume 4, 2017) summarizes exemplary campus designs and standards, serving as a pivotal reference. The sourcebook provides a qualitative categorization of certain dimensions of campus morphology, while does not address the quantification of morphology or provide comprehensive data support.

Unsupervised Learning and Clustering

Morphological features are those connected with human visual and can usually be easily understood through visual interpretation (Wang, Huang and Biljecki, 2024). The recognition of images is highly inspired thanks to advances in computer vision (CV), while convolutional neural networks (CNN) led breakthroughs on learning features that entail the intrinsic characteristics from imagery data. The visual representation learning facilitates the simulation of human visual interpretation of morphology patches based on sample training with provided training objective. Based on figure-ground maps, unsupervised learning has been applied on morphological feature extraction and clustering of residential plots (Cai *et al.*, 2021) and village patterns (Wang, Tang and Cai, 2023), as well as retrieval of urban blocks (Mo *et al.*, 2024). The recognition of urban network is also widely studied based on images or graphs (Kempinska and Murcio, 2019; He and Aliaga, 2023).

SOM is a general-purpose nonlinear data clustering and visualization method, which creates continuous visual patterns on top of high-dimensional data (Vahid Moosavi, 2015). It has been

proved with high efficiency in architectural form clustering (Jiang *et al.*, 2023). A structured form-map is output, in which each grid unit represents a cluster of similar data, and the spatial distance between the grids expresses the distance of the feature embeddings of the data. It has been applied on the construction of structure form map (Fuhrimann et al., 2018), as well as retrieval of residential based on multimodal features (Cai, Zaghloul and Li, 2022). Considering there is no consensus in the categorization of Chinese campus morphology, unsupervised learning is applied and an atlas of campuses are constructed with SOM.

2. Morphological Dataset Construction

We comprehensively gather images and data on 1257 medium to large-scale higher education campuses in China from open-source mapping platforms (Figure 1). The amalgamation of graphical, imagery, and quantitative data is constructed and processed for four aspects: context, roads, buildings, and green spaces.

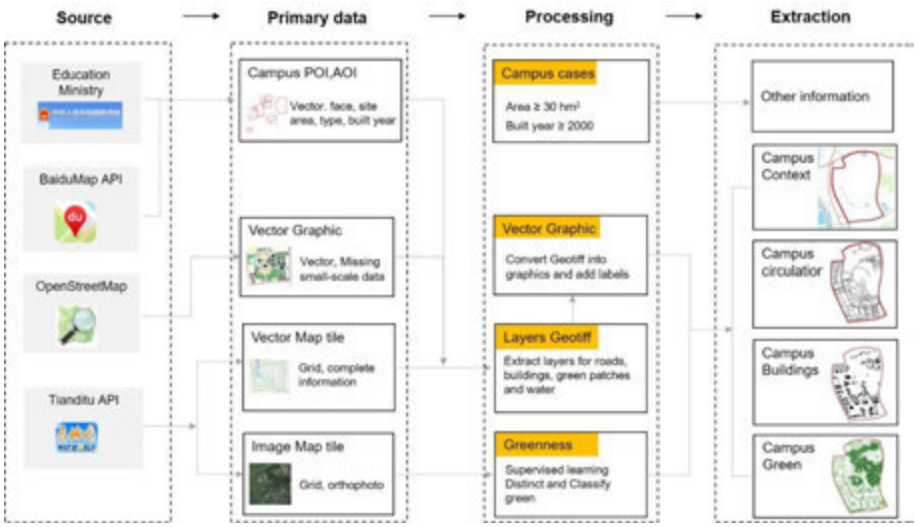

Figure1 Morphological Dataset Construction framework for urbanized Chinese university campus morphology.

2.1 Campus Selection

China's higher education institutions include both higher universities and higher vocational and technical colleges, which include private or public, vary in size, and have one or more campuses. In China's campus construction standards, campuses are classified as small, medium, large and extra-large according to their size (Figure 2). Among them, small campuses are those under 30 hectares, most of which were constructed earlier, with simple road networks and consist of a limited number of buildings. This study focuses on medium-sized campuses and above, which

have a certain complexity in their spatial organization and are more similar to urban forms at the neighbourhood level.

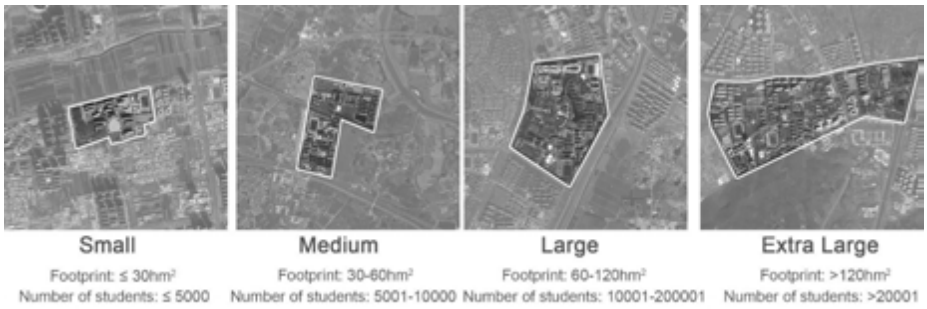

Figure2 Showcases of multiple scales of Chinese university campus from small to extra-large.

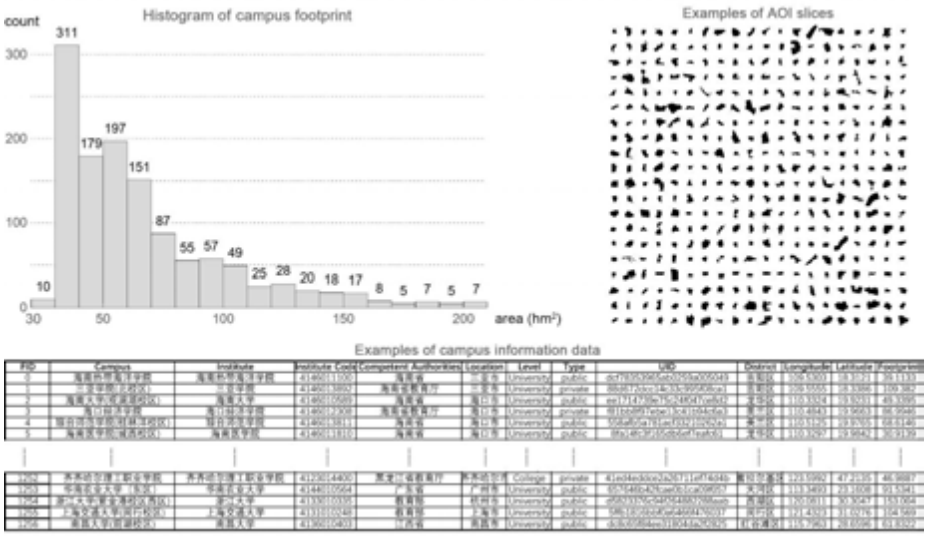

Figure3 Examples of the campus data in the dataset, including campus footprint (top left), AOI slices (top right), and GIS information (bottom).

In order to filter the campuses that match the size and further obtain their morphological data, it is first necessary to obtain the geographic data of campuses and their boundaries. With a list of 2756 higher education institutes from Chinese Education Ministry, the Points of Interest (POI) data for each school are query by school names. Each school may correspond to multiple campuses, while abundant POIs can be obtained through the institute names, including campuses, entrances, dormitory areas, etc. Screened by their name and type, 3442 POIs of university campus and 1044 POIs for college campus with UID code are obtained. Next, 3760 campus AOIs (area of interest) information are got by the UID code and processed on ArcGIS.

Among them, the campus divided by a county road with functionally intact parts will be treated as two. As a result, 1257 campus with area larger than 30hm^2 are selected (Figure 3).

2.2 Imagery Data Acquisition and Processing

There is a significant missing for geometric data of campuses in China, especially those located in suburbs or new towns, on widely-used open map platforms like open Street Map(OSM). To address this issue, we propose a method to extract information from map tiles acquired from online map platforms. After comparing different map platforms through experiments, it is founded that the Map World API provided by CNGISP (China National Geographic Information Public Service Platform: World Map, no date) excels for high timeliness and comprehensive data with zoom level up to 17.

The exact map tiles for campus are pinpointed and crawled with their geometrical information. Specifically, the column and row indexes of map tiles are calculated by longitude and latitude, according to the rules of Mercator projection transformations:

$$
\begin{aligned}
I_{row} &= Floor[2^{zoom} \cdot ((lon + 180)/360)]; \\
I_{col} &= Floor\left[2^{zoom-1} \cdot \left(1 - \frac{1}{\pi}\log(a)\right)\right] \\
a &= tan(lat \cdot \pi/180) + 1/cos(lat \cdot \pi/180);
\end{aligned}
$$

In which the value of zoom is 17. A 9*9 matrix of tiles around the centre point of each campus is crawled, which covers exactly the largest campuses.

The imagery data are then converted to GeoTiff format attached with geography data using GDAL, in order to interact with geographic elements, such as being clipped by campus boundary. Image processing techniques are applied to classify and extract data from them. From the vector map, roads, buildings, green and river regions are extracted by colour and converted to binary image using OpenCV separately. They also support further vectorization and analysis on ArcGIS. Meanwhile, the plant types are roughly distinct from the image map by mature supervised classification tool, labelling part of each type manually and then generating the whole results. Overall, our campus morphology patched consists of geometric elements of boundary, roads, buildings, water systems, and green spaces in and around the campus. (Figure 4)

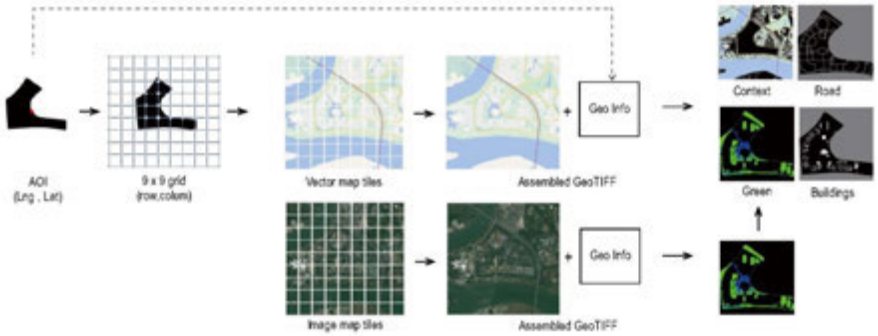

Figure 4 The acquisition and combination process of campus tiles, constructing the campus geometric data with multiple layers

3. Morphometrics for Campus

3.1 Dimensions and Metrics

Based on the characteristics of campuses in Chinese cities, this study attempts to focus on the campus form from four perspectives: site and context, roads, buildings and density and landscape ecology. Medium-and large-scale campuses in China are usually clustered, with a clear demarcation from the city. With the expansion of cities, neighbourhood of early campuses have developed into high-density region, while the new campuses built in this century, due to the tight urban land use, are mostly located in the outskirts of the city with more natural landscape. As a result, the site forms and contextual elements are quite different. Despite continued advocacy for school-city integration, most campuses have separate road systems which support vehicular traffic but not directly connected to urban roads. The buildings are laid out according to functional zoning, with the teaching area, dormitory area and sports area forming the core functions of the campus. At the same time, ecology is gradually being paid attention to in campus planning, considering the organization of green patches, the configuration of plants, and the relationship between green spaces and buildings. Therefore, from the four perspectives proposed in the previous section, nine dimensions of campus morphology can be delineated as shown in Figure 5.

Referring the method of urban morphometric, we summarize the metrics corresponding to each dimension as well as their calculations and the morphology element data required for the analysis. A case study has been conducted to verify the representation of this metrics.

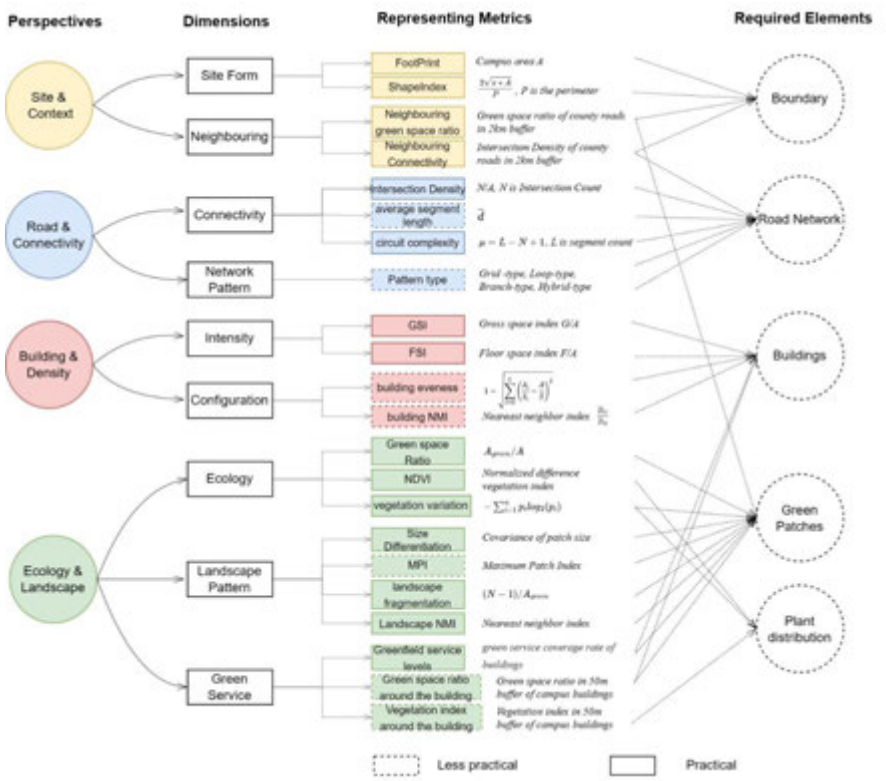

Figure 5 Morphometrics for Chinese university campus with multiple dimensions.

3.2 A case-study of Nanjing

For case study, 38 Campuses in Nanjing are selected to practice the analysis approach applying morphometrics (Figure 6). In order to obtain the geometry for the analysis, the binary image data of the various elements in the dataset are vectorized and assigned with attributes on ArcGIS. It is necessary to classify the road elements according to their width, to integrate water areas with green space patches and to give them a type definition, as well as to extract urban roads and landscapes within a certain range around the campus. Possible missing parts are supplemented and elemental attributes are refined in conjunction with the vector data acquired by OSM.

Figure 7 illustrates the ordering of morphological elements according to morphological metrics, which shows the coincidence of the metrics with human cognition.

Figure 6 The results of morphometrics of the 37 campuses in Nanjing

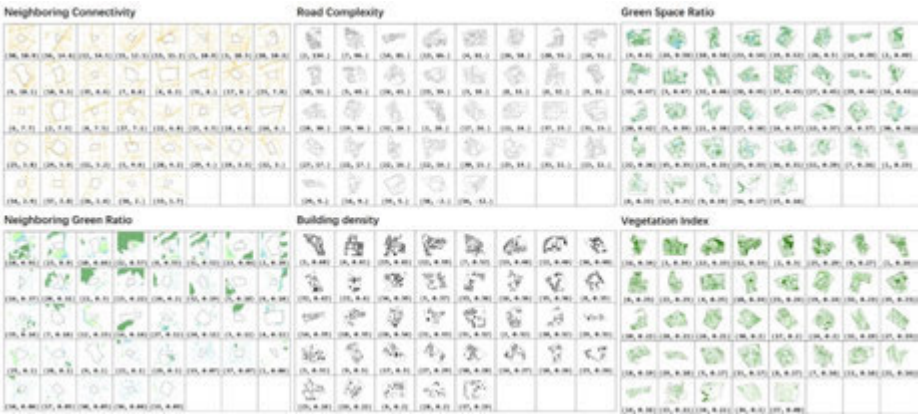

Figure 7 Sorting the selected 37 cases according to the morphological metrics, with the visualizations of corresponding geometric data.

The result implies that intensity-related metrics such as building density, road density, and green space rate are usually consistent with human cognition, while those related to spatial

distribution are relatively ambiguous. The calculation results of shows significant differences and some errors due to the choice of calculation units, differences in campus sizes, and localized missing data. Meanwhile, there are still some implicit features difficult to quantified, such as street pattern, and porosity of building groups, which are usually summarized qualitatively into categories with visual inspection by experts. Though some researches attempt to integrate them into the score system by assigning points, there is no uniform standard and requires considerable human labour.

4. Visual Representing Learning and Clustering

4.1 Visual Representing and data space

In contrast to 3.2 which vectorizes geographic images into geometric data, this section uses neural networks to extract features from morphological patches containing a single type of elements in image format. Among the four types of image patches of the campus, the cultural patches reflect the information of the campus site boundaries and the surrounding urban environment at a uniform scale, while the road, building, and landscape patches are scaled to fill the image at different scales to reduce the distraction of the campus scale and focus on the distribution of the elements. All image patches were scaled down to 256 x 256 pixels. We train feature extractors to extract high dimensional vectors from images for each type of campus patches separately, applying the neural network model. The training data is augmented with affine transformations including rotation and mirroring, resulting in eight times the amount of data compared to the original dataset.

The data space is visualized in 2-D with dimension reduction methods (Figure 8). Nonlinear dimension reduction methods, which have been proven to be efficient for high dimensional features, including UMAP, TSNE and Autoencoder, are tested separately to visualize extracted features. The results exhibit that the campus form gradients rather than falling into simplistic categories, which can be explained by the gradient distribution of both the size and form of Chinese campus. Therefore, compared with classic linear clustering methods like k-means, SOM is applied to achieve continuous visualization as a spectrum in a 2D space.

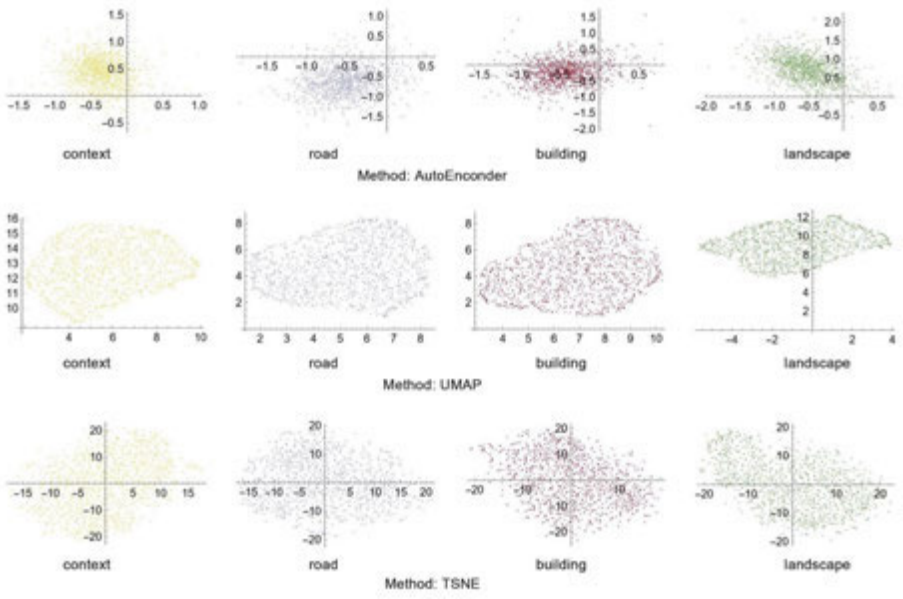

Figure 8 Visualization of High-dimensional vectors in 2D space after dimension reduction using 'Autoencoder' (top), 'UMAP'(middle), and 'TSNE' method (bottom).

4.2 Data Clustering using SOM

To achieve it, a fixed grid is first initialized with random real weights for each node. Then, the SOM is trained with randomly selected examples in the dataset. For each turn of the irritation, the best-matching unit (BMU) of each example is searched, which has a minimum Euclidean distance between its weight to the vector of example. Then the weight of BMU and its neighbours are updated according to Gaussian Neighbourhood Function, and the neighbourhood radius σ shrinks as iteration increasing:

$$g(i,j) = e^{-\frac{(c_x-i)^2+(c_y-j)^2}{2\sigma^2}};$$

$$\sigma = \left(1-\frac{u}{ite+1}\right) \times 0.6 \times d/2;$$

where c is the coordinates of BMU, u is the current generation and d is the counts of nodes in each dimension.

For our study, we build SOM for contexts, road, green and building configuration separately. After several parameter tests, a 15*15 SOM is trained by 12 iterations and 40000 examples are

selected for each turn. Then, we represent each grid cell with its most representative sample, to form a morphological cluster map. As a result, the characteristic distribution of UCCM is visualized.

In the campus context map, the combined effects of site scale, surrounding road distribution, and the distribution of natural and artificial landscapes on similarity can be observed. From left to right, there is a trend of increasing road network density and decreasing campus size, reflecting that large-scale campuses are more commonly situated in low-density urban areas. Several typical clusters and corresponding campus cases are extracted, with characteristics including: (1) adjacent to extensive natural landscapes, (2) situated in high-density urban environments with regular boundaries formed by orthogonal road networks, (3) with low surrounding development intensity and absence of natural landscapes, (4) relatively high development intensity with rich urban landscapes and irregular campus boundaries, and (5) coexistence of high-density urban landscapes and surrounding natural landscapes.

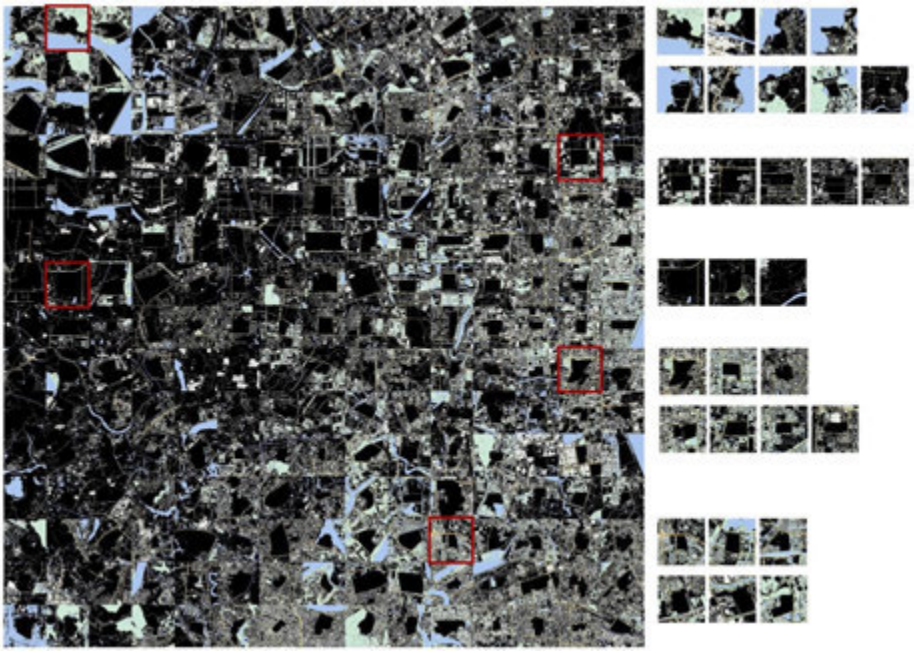

Figure 9 Representation of campus context cluster map and exemplary clusters selected from the map.

The cluster maps, reflecting the morphology of the campus park, are trained with uniformly sized masterplans in order to concentrate on learning of the structure. In the road map (Figure 10), there is a trend of transition from structured to natural from left to right. Grid and ring roads are commonly used features in organized campuses, with grid features particularly prominent

in large-scale campuses. In natural campuses, some exhibit branching structures, while others form irregular campus loops, showing a greater degree of freedom in form. The distribution of data in the building map is associated with both campus shape and building density, although differences in building distribution characteristics are not yet clear (Figure 11). From left to right, there is a trend of gradually regularizing campus shapes, while from top to bottom, there is a trend of decreasing density and organization. In the landscape map (Figure 12), campus landscapes become increasingly rich from top to bottom, while designed landscape water bodies is quite common in the overall campus layout. The campus in the upper-left corner of the map providing valuable references on landscape organization, with high diversity, fragmentation and equilibrium.

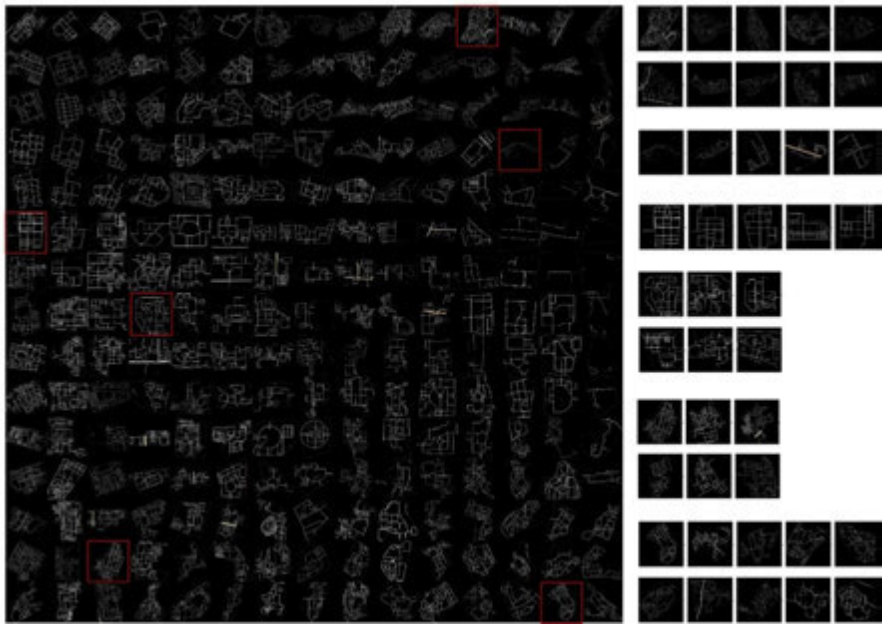

Figure 10 Representation of campus road cluster map and exemplary clusters selected from the map.

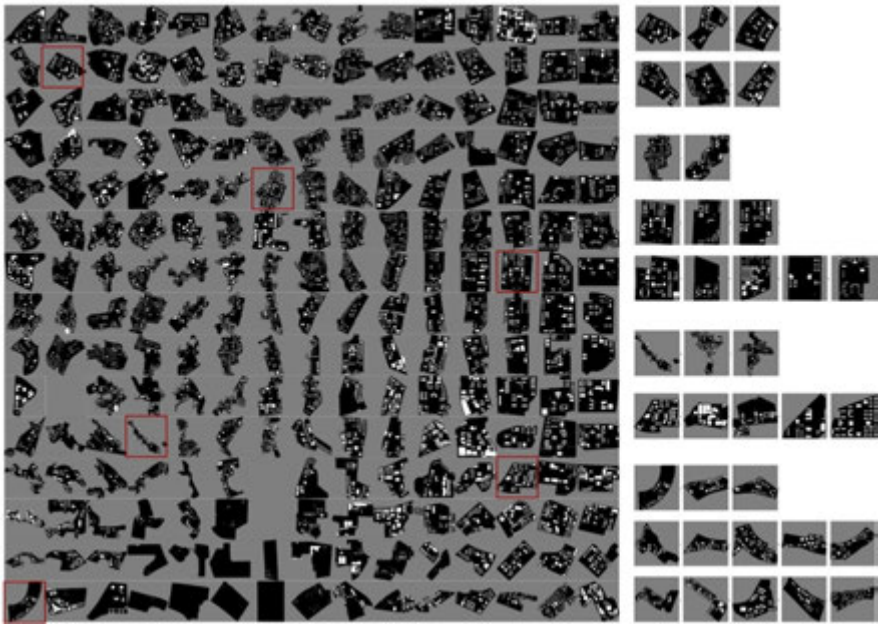

Figure 11 Representation of campus building cluster map and exemplary clusters selected from the map.

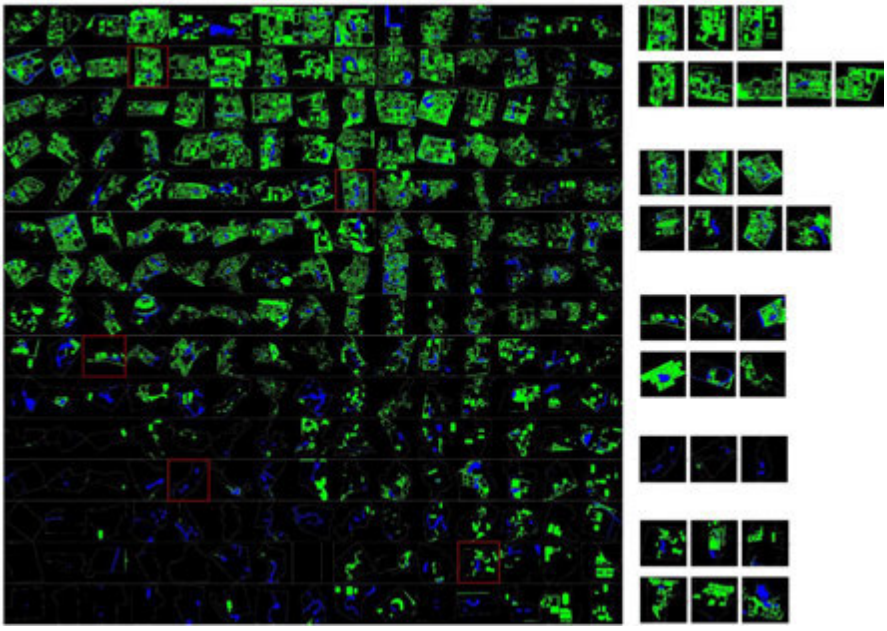

Figure 12 Representation of campus landscape cluster map and exemplary clusters selected

from the map.

Furthermore, these four morphological cluster maps can be correlated with campus objects, enabling multi-perspective linked analysis. For instance, the retrieval of corresponding morphology patches for campuses with similar context is supported.

5. Discussion

5.1 Comparison and Discussion

This study summarizes perspectives and form dimensions of Chinese campus and proposes a framework for morphology recognition based on deep learning. Through case studies, a comparison between visual representation learning methods and classical morphometric methods reveals the advantages and challenges of this framework.

Data Requirements and Technical Difficulty: Traditional morphometric methods rely on geometric data for specific algorithms, necessitating high accuracy and involving complex pre-processing. However, there is a notable deficiency in vector data availability for Chinese campuses on open-source platforms like OSM, while nationwide vectorization of geographical imagery poses significant challenges. Additionally, errors, omissions, or improper unit selection can result in substantial inaccuracies, as evidenced by our experiments. In contrast, visual representation learning extracts intricate knowledge from extensive image datasets, requiring lower data processing demands and exhibiting greater tolerance to data imperfections. Therefore, achieving a comprehensive understanding of nationwide campus morphology is more attainable through visual representation learning.

Representation Advantages of High-dimensional Features: The high-dimensional features extracted through visual representation learning cover multiple form dimensions of campus morphology, resulting in morphological cluster maps that align with human visual perception. This approach excels in capturing intricate feature characteristics such as structure, patterns, and shapes, which are often challenging to quantify. Furthermore, it reduces the dependency on expert experience and minimizes redundancies and incompleteness in indicator representations. However, classical morphometrics, as a foundational approach in morphological research, continues to play an essential role. Its algorithms are grounded in extensive human experience and have been empirically validated in numerous studies. Classical morphometrics advances in the assessment and grading of specific dimensions, facilitating the analysis of broader morphological issues spanning demographics, society, economy, and other domains.

Randomness and Interpretability: Traditional morphometrics produces a unique result for each indicator when employing the same data and algorithms. Conversely, variations in feature extraction methods and training parameters result in diverse outcomes during visual feature learning. This approach inherits the typical challenge of unsupervised learning, where training outcomes display a level of randomness, and optimal parameter configurations rely on experimental expertise. Furthermore, unlike single-dimensional indicators, the comparability

and interpretability of the obtained high-dimensional features and cluster maps are relatively constrained.

5.2 Future Opportunities

Inspired by limitations mentioned above, we proposed several directions for future work.

Integrating visual representing learning and morphometric methods. Classic morphometrics relies on human ingenuity and prior knowledge, among which manually selected metrics representing different dimensional features are integrated into multidimensional vectors. In contrast, visual representation learning relies on machine learning to extract high-dimensional embeddings from images. While these two approaches offer distinct advantages in morphological quantification, merging the two types of vectors is not straightforward. Exploring the integration of metrics and image feature extraction methods is also a significant focus in the current trajectory of urban morphology research (Cai *et al.*, 2021; Qin and Zheng, 2023).

Improving Feature Extraction Methods. Image features extraction based on neutral network has been widely applied in various fields. However, compared to common real-world photos, feature extraction for campus patches requires additional understanding of campus morphology. Therefore, fine-tuning and refining neural networks to address specific issues related to campus morphology recognition will significantly enhance the validity of visual representation. Recent studies have endeavoured to enhance models for urban morphology recognition research. For example, SimCLR is employed to guide feature extraction by maximizing mutual information agreement between different versions of the same image (Chen *et al.*, 2020; Wang, Huang and Biljecki, 2024). In subsequent research, we will integrate new model methods to experiment and validate the effectiveness of feature extraction.

Supporting generative design of campus. Existing design principles for campuses are often derived from a limited number of case studies, with the Architectural Design Sourcebook serving as a primary reference. By leveraging the nationwide campus dataset and the morphological analysis conducted in this study, it becomes feasible to systematically compile a set of rules and design methodologies for Chinese campuses. Furthermore, recent researches have been conducted to explore the generation of campus masterplans using advanced deep learning technologies, such as Generative Adversarial Networks (GAN), based on hundreds of Chinese campus cases. (Liu et al., 2021; Chen, Zheng, and Wu, 2022). The efficacy of the generation model could be significantly enhanced by expanding the dataset to encompass a nationwide range. Consequently, future endeavours will focus on integrating rule-based and case-based generative design methods to expedite the process of early-stage campus designs and provide decision-making support.

6. Conclusion

This paper proposes a deep learning driven framework for morphological dataset construction and analysis methods of Chinese Campuses. We compared the differences between deep

learning-based visual representation methods and classical morphometrics methods in the recognition of campus morphology. Firstly, by utilizing web data scraping and computer vision techniques, combined with integrating multiple sources of data such as map tiles and geographic information, we addressed the challenge of obtaining data on the morphology of Chinese university campuses. Secondly, based on the characteristics of Chinese university campus morphology, we integrated campus research with urban morphology indicators and landscape ecological indicators at similar scales. We proposed perspectives, dimensions, and measurement methods for the campus morphology, which were validated across 38 university campuses in Nanjing. In response to the limitations of traditional statistical methods, such as high data processing difficulty and limited visual representation, we introduced deep learning-based visual representation and morphological clustering methods. Using SOM, we developed morphological cluster map of Chinese university campuses, enabling morphological analysis and similarity retrieval across the entire dataset. This method provides important insights into the characteristics and issues of university campus morphology in the context of China's urbanization process, while also offering case support for the construction of new campuses.

However, we also discovered that traditional morphometrics methods still possess advantages that are difficult to replace, while deep learning methods suffer from low interpretability and the need for model optimization. In future research, we will further explore the potential integration of these two types of methods and focus on the discovery of patterns in campus morphology features based on datasets, as well as generative design.

Dynamic Visual Assessment of Urban Streetscapes: Hengshan Street in Shanghai as a Case Study

Xueling Wang[1]

1. College of Architecture and Urban Planning, Tongji University

Abstract

Objectives: By investigating the urban street-human perception nexus under "dynamic" walks, this paper aims to enhance urban streetscapes and optimize pedestrian experiences.
Methods: In this study, a dynamic visual assessment system, encompassing objective, subjective, and interactive components, was developed through a combined application of qualitative and quantitative research methods. The computational foundation of this system was strengthened by Geographic Information System (GIS) spatial analysis, image semantic segmentation algorithms, Partial Least Squares Regression in SPSS, and so forth.
Results: Reduced desire for space and pedestrian flow are caused by an increase in dynamic viewing frequency. The public's impression of street space is enhanced in terms of clarity, transparency, ease of use, and richness when there is a greater range of spatial hues within the field of view, a smaller building area, and more translucent and clear spaces.
Conclusion: The research results are of great significance to street spatial design.

Keywords

dynamic viewing, visual assessment of landscapes, interaction between subjects and objects, urban streetscape

1 Introduction

Urban streets are not only crucial carriers of transportation hubs, but also the most fundamental public product of a city, serving as an important slow-moving traffic system for citizens to carry out their daily activities. It holds significant importance for the physical and mental health of the public (Jacobs, 2006). When individuals traverse urban streets, whether they pause momentarily to observe their surroundings or stride rapidly through, they remain in a state of

"dynamic" observation, encompassing even periods of relative stillness (Xiong, 1984). The variations in visual angles and the adaptations in visual behaviors jointly enhance a profound sense of visual artistry within the dynamic urban landscape that is constantly in a "moving" state (Yang, 2019).

In this study, we address the interactive between the observer and the streetscape during the viewing state, specifically termed "dynamic observation," into the landscape visual evaluation index system. This methodology significantly beyond the traditional research, which primarily focused on the static relationship between "observer" and "environment" factors. Instead, it enables a multifaceted, three-dimensional correlation analysis that comprehensively considers the "subjective," the "objective," and the intricate "subject-object interaction." As a result, we derive profound insights into the observer's perception and the salient characteristics of the objective spatial environment, both of which are intimately tied to the dynamic observation state.

There are five sections in this study. A concise overview of the literature on the visual assessment of streetscapes is given in Section 1, which covers three essential aspects: the street's spatial environment, visual perception, and spatial behavior. We create a thorough assessment index system in Section 2 that considering the street spatial context, observer perception, and human behavior. The specific approach for measuring this assessment index system is described in Section 3, with an empirical measurement of Hengshan Road in Shanghai as the study region. A detailed overview of the outcomes of our measurement is given in Section 4. In Section 5, we utilize correlation analysis to derive findings about the complex relationships among the three elements of our assessment index system: behavior, perception, and street environment.

2 Literature review

The current quantitative research on street space predominantly adopts the fundamental logic of constructing an indicator system, which integrates technologies such as geographic information systems (GIS) and 3D software to visualize the morphological measurements of the street environment. In a comprehensive view, the objective index in urban street research generally encompass the urban skyline morphology (Zhang, 2001), degree of visual depth in urban space (NIU, 2013), Hierarchical levels of space (Peng, 2015), vision and spatial openness (Liu, 2009), comprehensive study of vision and space (Wang, 2013)， as well as visual perception with other factor (Cheng, 2017). The foundational data and their sources include: OpenStreetMap data, POI data, streetscape images, positioning system trajectory data, and elevation data (building heights, ground elevations). Specifically, we utilized machine learning algorithms and street-view data to measure the impact of street green view index (GVI) on walking time, and established quantitative evaluation metrics. The comprehensive study incorporated various data sources to gain a deeper understanding of the relationship between urban visual landscapes and pedestrian mobility (KI D, 2002). Utilize the theory of space syntax

to delve into the effects of spatial openness on social interactions, and subsequently establish a comprehensive analysis model that incorporates both two-dimensional and three-dimensional visual (NIU, 2019).

The research on subjective components mainly focuses on aspects such as street spatial safety and perceived scenic beauty, proposing factors such as accessibility, ease of reach, safety, comfort, pleasure, aesthetic appeal, imagery, enclosure, permeability, human-scale design, and cleanliness. Using methods such as questionnaires, data is collected on the public's satisfaction ratings of streetscape images. This data is then combined with the results of objective index of the images to evaluate the public's perception of landscape aesthetics (Shao, 2017).

In the study of the interaction between environments and perception, there is a diversity in data sources, technical approaches, and research focuses. Some scholars have employed qualitative "cognition" analysis, along with quantitative measures of building density and ratio of wall (Zhou, 2012). The research examines the correlation between the subjective and objective factors, focusing on the relationship between street environments and the duration of people's stay as well as their subjective perceptual experiences (Hu, 2009). Wilson et al. (2016) argue that the index of "safety" and "pedestrian-friendliness" play a decisive role in the perception of urban streets. Pyo et al. (2015) discovered that pedestrians on street sidewalks have a higher degree of perception of spatial environmental elements, leading to a corresponding higher level of walking satisfaction. Elements such as the space outside shops, the density of street trees, enclosed spaces, the travers ability of the street space, and space utilization can all affect subjective preferences and feelings. Li Yajuan et al. (2018) used GIS analysis to explore the spatial structural characteristics and external transportation connectivity of historical districts, as well as tourists' perception of the district's image and location. [19] The forementioned studies primarily integrate the derivative terms of perception and sentiment with existing big data, utilizing various scientific software technologies to qualitatively describe relevant index and quantitatively analyze spatial numerical values, ultimately leading to corresponding conclusions.

As individuals continuously move and change their behavior in objective environments, buildings and landscapes emerge or recede in a continuous manner within one's visual field. [20] Some scholars have explored the spatial environmental characteristics in a "dynamic observation" state from the perspectives of behavioral activities, preferences, and spatial vitality. Author Cheng Shi (2021), building on the concept of "landscape," has integrated new technological means and proposed a new method of "dynamic observation evaluation" that aligns with the characteristics of crowd viewing behaviors. Do N (2019) utilized various methods such as questionnaires, scientific observations, and spatial analysis to collect and analyze data, exploring people's activities, preferences, and behavioral patterns within these parks. Fard H R (2014) studied the relationship between the physical characteristics of plazas and behavioral patterns and specific activities through questionnaires and scientific

observations. Carmon (2003) employed case studies and theoretical frameworks to explore the influencing factors of street spatial vitality, including buildings, sidewalks, amenities, and other elements. Ewing R et al. (2014) examined the physical characteristics of urban streets and their edge spaces, focusing on objective index such as window ratios, street frontage ratios, and the number of street furnishings, to explore their impact on pedestrian traffic volumes. Li Y et al. employed a semantic segmentation method to explore the relationship between street width, transparency, and street vitality. Carmelino G et al. (2019) delved into the impact of the built environment on pedestrian vitality, considering key visual characteristics such as architectural form and proportion, streetscapes, materials and colors, spatial layouts and flow, as well as building façades and their elements.

From the perspective of research approaches, current studies have yielded numerous achievements in both objective quantification and subjective perception, and some have begun to explore the correlation between subjective and objective factors. Nevertheless, a thorough investigation that incorporates subjective, objective, and subjective-objective interactions is still absent in the research on index under the interaction between subject and object, which is still limited to the analysis of single-faceted features like human traffic aggregate. Research-wise, most of the studies that have already been done focus on "off-scene" static observations, ignoring the dynamic "in-scene" perception of the three-dimensional "space" that functions as the overall framework. In order to build a multi-dimensional study, they rarely consider the dynamic walking state of persons, such as walking routes and the vitality of walking places. In light of the research topic, this paper intends to investigate the relationship that exists between human perception, walking behavior, and urban streetscapes by means of an interactive study that includes three dimensions: "subjective," "objective," and " interactive components."

3 Establishing of the evaluation index system

Clustering analysis of premier research fields, we screened out the evaluation index of environment-perception that have relevant relationships and compiled an interactive relationship table of subjective and objective evaluation index (Tables 1).

Table 1. Relationship expressions of subjective and objective evaluation index (Liu, 2022)

Objective	The formula for calculating the correlation	R^2
Clarity	2.336 + 0.002×mean horizontal visual depth + 0.045×color richness	0.546
Transparency	2.574 - 1.677×architectural visual proportion + 2.250×sky view factor + 0.001×mean horizontal visual depth + 0.025×color richness	0.775
Relaxation	1.072 + 0.091×color richness + 6.663×green view index	0.641
Richness	0.929 + 0.089×color richness + 6.947×green view index	0.557

3.1 Establishing Objective Indicator System

Based on the analysis, three indexes are established for the objective index system, including spatial elements, spatial structure, and spatial vision. Specifically, spatial elements correspond to the openness of the sky, the visual proportion of buildings, and the green view index. Spatial structure corresponds to the horizontal visibility distance, while spatial vision corresponds to the color richness.

Table 2. Objective index and measurement methods (Huang, 2019. NIU, 2013. Dan, 2008. Li,2020)

Objective	Factor	Concept and formula interpretation	Formula
Spatial elements（B）	sky view factor（B_1）	Refers to the degree of the sky within the human visual field, which is the proportion of the sky within the "sphere of vision." B_1 represents the openness of the sky in a streetscape image, S_1 is the proportion of pixels identified as sky and S_0 represents the total number of pixels in each streetscape image.	$B_1 = S_1 / S_0$
	architectural visual proportion（B_2）	The building proportion of building area within the visual field, primarily including the building facade as well as its affiliated gray infrastructure. B_2 represents the visual proportion of buildings, S_2 is the number of pixels occupied by building facades within the visual field, and S_0 is the total number of pixels in the streetscape.	$B_2 = S_2 / S_0$
	green view index（B_3）	Referring to the proportion of green plants within the visual field. B_3 represents the green view index of a streetscape image, S_3 is the number of pixels representing trees, grass, plants, and other greenery in the image, and S_0 represents the total number of pixels in each streetscape image.	$B_3 = S_3 / S_0$
Spatial structure（C）	mean horizontal visual depth（C1）	Taking the observer's position on the street as the centre, 360° horizontal line of sight is projected around, and the maximum distance that the human eye can observe is limited. The average length of sight lines in all horizontal directions is denoted as C_1, and the length of the nth sight line is denoted as C_n	$C_1 = \frac{1}{n}\sum_{i=1}^{n} C_n (i \epsilon N^*$
Spatial vision（D）	color richness（D_1）	It refers to the richness of color factors. Extracting the brightness values of the color components R (red), G (green), and B (blue) from the streetscape images, and calculate the rg and yb values using the formulas: rg = R – G, yb = (R + G)/2 – B. Calculating the standard deviation σ and average values of rg and yb for pixel.	$D_1 = \sqrt{\sigma_{rg}^2 + \sigma_{yb}^2} + 0.3 \sqrt{\mu_{rg}^2 + \mu_{yb}^2}$

3.2 Establishing subjective index system

Four components of subjective evaluation indexes are selected: clarity (vague-clear), transparency (enclosed-open), richness (monotonous-rich), and relaxation (suppressed-relaxed).

Table 3. Subjective index and measurement methods

Subjective	two-level vocabulary	Concept
Clarity	vague-clear	The degree of sharpness and explicitness that a block's visual environment imparts to people is referred to as clarity. In contrast, pedestrians may need to continuously rotate their line of sight in order to observe and perceive the surrounding spatial structure, which can quickly cause physical and mental fatigue. The better the clarity, the faster pedestrians can perceive the surrounding spatial structure through visual observation.
Transparency	enclosed-open	The phrase refers to the streetscape's power of directional indications and sense of visual permeability. Pedestrians can more easily discern direction and rapidly identify the main forward direction of the roadway and adjacent spaces if the street space has better permeability. On the other hand, disorientation and a loss of orientation can quickly result from uniform obstruction of the field of vision in all directions.
Relaxation	suppressed-relaxed	The phrase describes how at ease pedestrians feel in the streetscape. Pedestrians feel more at peace in a street area the easier it is to navigate. On the other hand, they might feel uneasy.
Richness	monotonous-rich	The phrase describes the level of richness that pedestrians find in the streetscape. Pedestrians are more likely to feel engaged and intrigued about the street and its environs when it is richer, which makes them more receptive to the street. On the other hand, they can experience fatigue and boredom and be unable to enjoy a leisurely stroll down the street.

3.3 Establishing interactive index system

The term "human behaviour based on observation" describes a range of proactive-reactive behavioural patterns that people exhibit when they are in public areas. The spatial nodes that walking traverses are linked together to form a whole observation trail as these behaviours move across the area. The characteristics of spatial human flow distribution, often referred to as spatial vitality, are the dynamic observation states of many people overlapping, converging, and dispersing in the space.

We suggest the objective-subjective interaction index, which includes two indicator levels: the spatial vitality index and the frequency of dynamic observation of subjects in the guest space environment. This indicator serves as an evaluation metric for the dynamic observation of subjects.

When people watch landscapes in a space, their bodies and eyes follow certain trajectories, which are referred to as observation routes. The frequency of dynamic observation paths is defined as the ratio of the total number of observation paths in the neighbourhood to the overlapping times of different users' paths in the same location. The following are the precise steps in measurement: Gather walking trajectory data for the research area from a website (e.g., two-step path trajectory data), import it into a geographic information system (GIS), and overlay it with the spatial locations of observation points. Next, compute the ratio between the frequency of each sample point's path and the total number of paths using inductive statistical methods.

The spatial vitality index refers to the distribution state of spatial human flow formed by the aggregation and dispersion of people due to social, cultural, economic, and environmental activities. It is calculated by averaging the heat values of the same sample point at different time periods, resulting in the spatial vitality value of the sample point.

4 Method

4.1 Study area and sample collection

This study focuses on Hengshan Street in Shanghai as the research area. To ensure the accuracy, operability, and comprehensiveness of the evaluation results, a quasi-experimental simulation was conducted based on real-world conditions. Comprehensive consideration was given to factors such as street spatial elements, spatial structure, and visibility distance. The evaluation was conducted with 50m as a research unit, and the central line of the roadway was used as the dividing line to divide the west and east sidewalks of the block. Combining with the Chinese people's long-standing consciousness of "walking on the right side," we simulated the walking process and collected corresponding streetscape samples. Specifically, the east sidewalk adopted a walking route from south to north, while the west sidewalk adopted a walking route from north to south, simulating the way pedestrians walk in the street. The photos were taken at eye level, approximately 1.6 meters high, with a mobile phone's camera function in 1X zoom mode and full-screen photo ratio, every 50 meters apart[32]. At the same time, the positioning

function of the two-step path APP was activated, and a field photo was taken at each sample point as a reference for observation point location. The observation path files were also preserved, resulting in a total of 80 sample images (Figure 1), two kml file paths, and 80 points.

Figure 1. Schematic Diagram of Sample Images

4.2 Measurement methods for objective index

The calculation methods for objective index include streetscape image semantic segmentation, GIS spatial operation, and Colorimpact color analysis. Semantic segmentation is used to measure three objective indexes of spatial elements: sky view factor, architectural visual proportion and green view index. GIS is used to determine mean horizontal visual depth of the sample spatial structure, while the Colorimpact software is used to analyze the RGB color values in the sample images.

4.2.1 Semantic Segmentation of Streetscape Images

To begin preprocessing, the gathered streetscape image dataset is first imported into Adobe Photoshop. To prevent any potential segmentation errors caused by extremely large image resolutions, the image size is lowered to 1000 x 462 pixels. The processed images are next subjected to analysis using a visual image semantic segmentation, namely the CUG.HPSCIL image recognition tool. To determine the sample image's sky view factor, we segment the spatial elements and then extract the "03_Sky" from the segmentation results. In order to determine the visual percentage of building façades in the sample image, we additionally extract the "02_Buildings". Furthermore, the "05_rees," "10_Grass," and "18_Plants" from the segmentation results were added together.

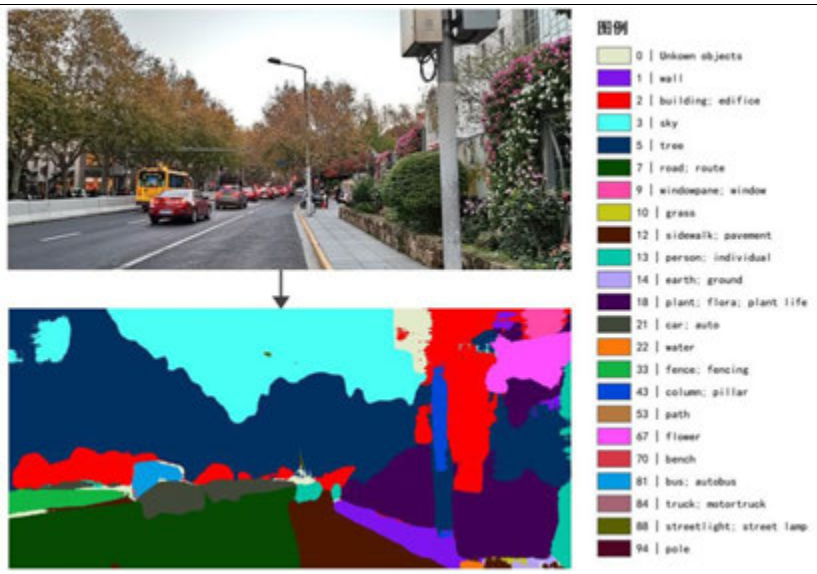

Figure 2. Image and semantic segmentation results for sample point East_02

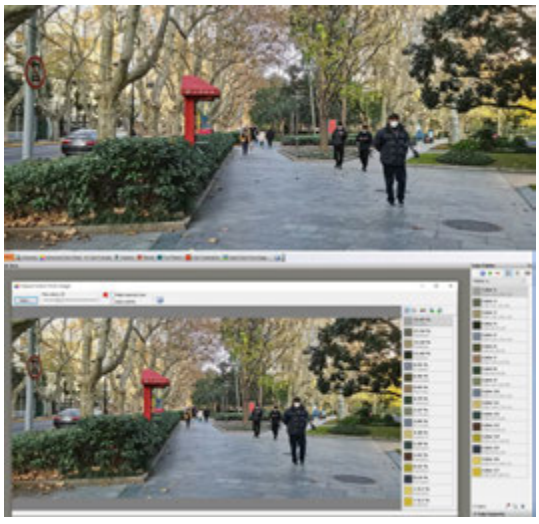
4.2.2 Colorimpact color analysis

Sample images are imported into Colorimpact, and the RGB color values that account for more than 0.1% of image are exported (Figure 3). These values are then recorded in an Excel document, and the final result is calculated based on the formula for color richness.

Figure 3. Color analysis results by Colorimpact



4.3 Measurement Methods for Interaction Index

4.3.1 Calculation of dynamic observation frequency based on pedestrian trajectories

Pedestrian trajectory data of the street is obtained from the official website of a walking app, and the data is preprocessed and cleaned to filter out valid user walking trajectories. The data is then imported into a GIS system, where it is overlaid with the spatial layout of buildings and other structures in the observed street for data visualization analysis, specifically the visualization of observation paths in the street space (Figure 4). By integrating the spatial data of observation points, the road is divided into two parts, and a buffer zone of 80 sample points is constructed with a buffer radius of half the road width, which is 8 meters. The number of observation paths within each sample point's buffer zone is then calculated and divided by the total number of observation paths in Hengshan Road, resulting in the dynamic observation frequency for that sample point. The relevant expression is:

$$Rx=n_x/N*100\% \quad (1)$$

Rx represents the frequency of observation paths for sample point x. Taking the eastern sample point 1 as an example, where the sample point number x is East_01, nx represents the number of paths passing through that sample point, and N is the total number of paths collected.

Figure 4. Visualization of two-step path trajectory data

4.3.2 Calculation of spatial vitality index based on Baidu heatmap

Based on the principles of randomness and pedestrian crowding degree, a random weekend day (February 12, 2023) and a weekday (February 13, 2023) were selected. The Baidu heatmap data was captured hourly from 8:00 am to 8:00 pm, resulting in a total of 26 heatmaps. Subsequently, the ArcGIS tool was utilized to define the projection and perform georeferencing. Multi-ring buffer zones were processed using half of the road width, which is eight meters, as the buffer radius. Heatmap areas within these buffers were then extracted to generate "street heatmaps."

The heat values were categorized into seven levels from zero to seven, quantized as zero, one, two, three, four, five, and six, with higher values indicating greater vitality in the sample space. The average heat values for different observation points on weekends were then calculated:

$$T_1=\sum_{i=1}^{n} T_n/N \quad (i\epsilon N^*) \qquad (2)$$

Among them, N represents the total number of heatmaps collected on weekends, which is 13, and Tn represents the heat value collected at different time periods on weekends. The average heat value for weekdays is calculated as follows:

$$T_2=\sum_{i=1}^{n} T_n/N \quad (i\epsilon N^*) \qquad (3)$$

N represents the total number of heatmaps collected on weekdays, which is 13, and Tn represents the heat value collected at different time periods on weekdays. Taking a week (5 weekdays and 2 weekends) as a cycle, the average heat value of the sample points is calculated as:

$$T=(T_1*2+T_2*5)/7 \qquad (4)$$

Through the analysis of the heat values of the sample, the spatial distribution patterns and characteristics of street vitality are finally calculated. A higher average heat value of the street indicates greater pedestrian flow and more vitality.

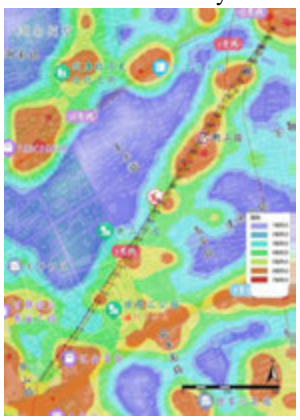


Figure 5 Weekend_13 , 20:00 Baidu heatmap data

5 Results

5.1 The result of objective measurement in Henshan Street

The quantitative results of objective index (Tables 4) show that the spaces with the best sky view are sample point _17 on the east side with view of 23 percent, and sample point _31 on the west side with view of 22 percent. The view of sample point _05 and point_12 on the east side and sample point _20 on the west side are all 17 percent, indicating that these two sample points have the largest area of visible sky.

Compared with the visual proportion of buildings, it is found that the overall visual

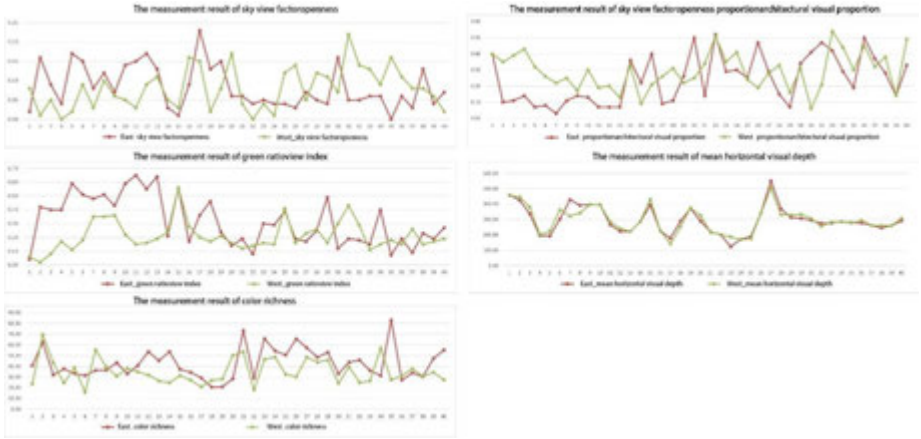
proportion of the sky in Hengshan Road is far lower than that of buildings, indicating that the building density in this area is greater than the sky area. The spaces with the smallest openness are sample point _35 on the east side, sample point _04 on the west side, and sample point _22 on the west side, with a sky visibility area tending to zero, indicating that the spatial closure of these three sample points is too high, and the spatial vision is seriously obstructed.

The fluctuation of horizontal visibility distances on both sides are similar, which may be due to the straightness of Hengshan Street and the similar ground elevations. Among them, the samples with the largest horizontal visibility distances are sample point _27 on the east side with a value of 550.21, and sample point _27 on the west side with a value of 504.82. The smallest ones are sample point _17 on the west side with a value of 141.11, and sample point _23 on the east side with a value of 123.29, showing a significant difference, indicating that the visual length of the studied street varies significantly.

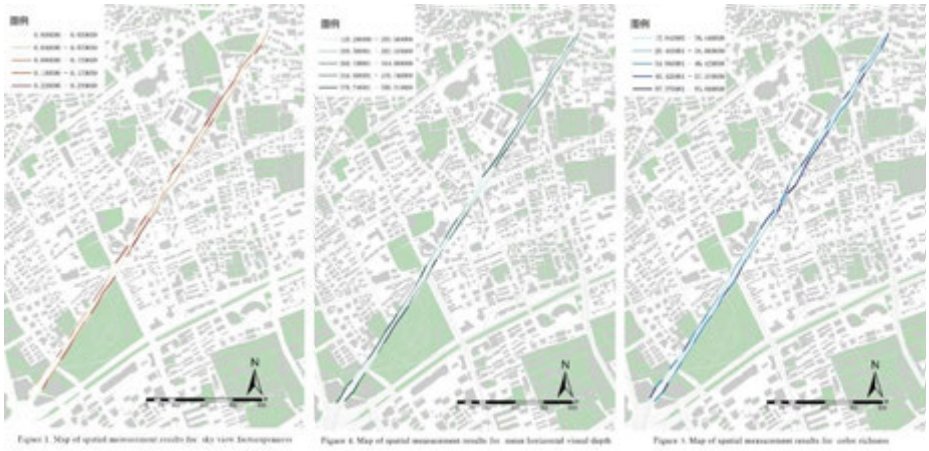
The three points with the highest visual proportion of buildings are sample point _31 on the west side with a visual proportion of up to 58 percent, sample point _22 on the east side with a visual proportion of 52 percent, and sample point _22 on the west side with a visual proportion of buildings at 51 percent. The maximum building area is far higher than the maximum sky area of 23 percent. The lowest building density is sample point _07 on the east side with a value of 3 percent, sample point _31 on the west side with a value of 6 percent, and sample points _05, 11, 12, 13 on the east side, with a visual area proportion of buildings at seven percent.

The three points with the highest green view index are sample point _5, point _11, point _12 on the east side, with green view indexes of 59 percent, 65 percent, and 64 percent in order. The green view index exceeds half of the overall visual proportion of 50 percent, indicating a very high green view index. The lowest green view index is sample point _01 on the east side with a value of four percent, sample point _01 on the west side with a value of 8 percent, and sample point _02 on the west side with a value of 1 percent. The three points with the highest color richness are sample point _35 and 21 on the east side and sample point _2 on the west side, with color richness values of 83.09, 73.21, and 69.51 in order. The lowest color richness is sample point _06 and 22 on the west side, with values of 15.84 and 18.00 respectively.

Tables 4. Objective index calculation results for each sample point on Hengshan Street



Using GIS to visualize the spatial results of the objective evaluation, as shown in Figure 6, the deeper the color, the higher the proportion of the skyline visual area, indicating a more open space. The maximum visual proportion of the skyline is 23 percent, while in some local areas, the skyline area is almost zero. The main reasons for this are two points: firstly, the street has a long history with rows of plane trees, covering most of the street space; secondly, the width of the motor vehicle lane on this street is approximately 16 meters, with buildings



standing on both sides, resulting in limited public space and a relatively crowded environment.

Figure 6. Spatial location map of objective index measurement results

The location of the building visual proportion in the street space shows that the maximum building visual proportion is up to 54 percent, mainly concentrated in the northern area. The southern part is a large commercial district with taller buildings, but they are a certain distance from the street. Additionally, the southeastern part is Xu Jiahui Park, where buildings are sparse.

Therefore, the distribution characteristics of the building visual area in the space are obvious.

The spatial location map of the average horizontal line of sight distance. Since the street is straight and has good permeability, the overall average line of sight distance value is relatively large.

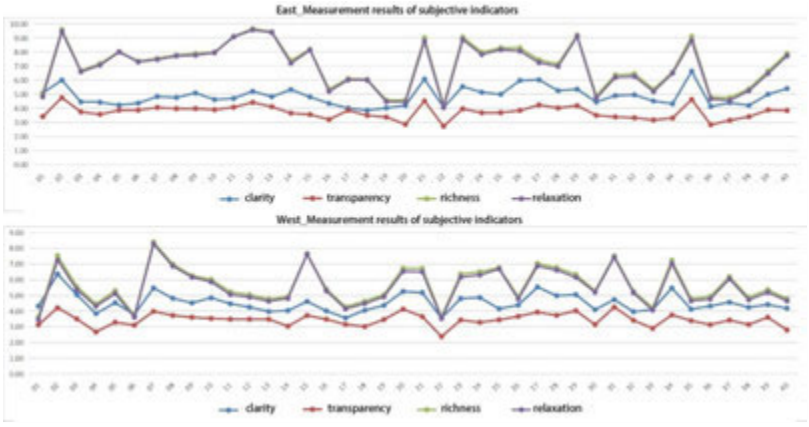
In terms of spatial distribution, it reveals that the green view index is dense in the south and gradually decreases from south to north. Especially along the border of Xu Jiahui Park, the green view index reaches 65 percent. This is because the pedestrian walkway in this area differs from the unilateral planting characteristics of other areas, featuring low hedges and tall plane trees, camphor trees, and other species on both sides. This section of the pedestrian walkway cleverly combines walking and jogging paths, attracting runners and greatly enhancing the spatial vitality of the pedestrian walkway. Furthermore, the hedges separate the pedestrian walkway from the roadway, making human activities less vulnerable and safer.

It expresses the spatial location characteristics of color richness, and the proportion of high-color areas in the entire street space exceeds half. The street district is rich in color variety and locally unified, creating a sense of integrity in the changing spatial vision.

5.2 The result of subjective measurement in Henshan Street

In terms of the correlation equations between environment and perception evaluation index from existing literature research, as well as the analytical results of the spatial environmental index of the sample points, we calculated the subjective index of clarity, transparency, relaxation, and richness. The findings indicate that the values of relaxation and richness in the Hengshan Road district are similar, but there are significant fluctuations in different spaces, resulting in noticeable differences in perception. In contrast, the differences in clarity and transparency are relatively small, resulting in a more homogeneous spatial experience.

Table 5. Subjective Index Calculation Results

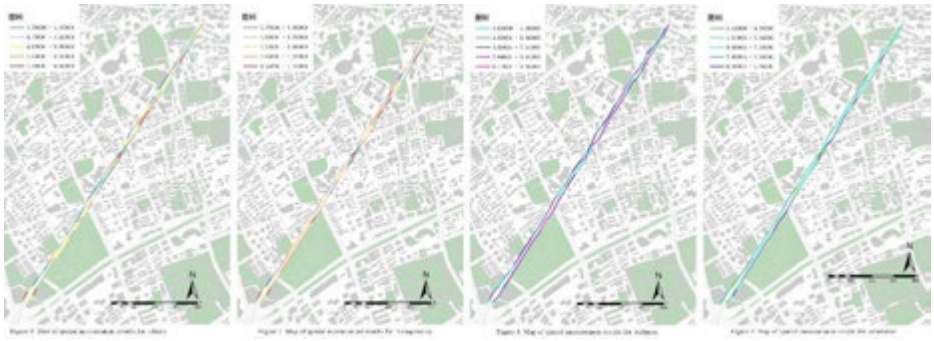


Using GIS to visualization the subjective index results, as shown in Figure 7, the distribution of clarity in the space reveals that areas that tend to create a sense of brightness are relatively scattered. The pedestrian walkway next to Xu Jiahui Park has a lower sense of brightness.

As shown, the darker the color, the better the spatial sense of transparency. The area next to Xu Jiahui Park has a higher sense of transparency, while the transparency of other streets in the area is also good, with few areas having low values.

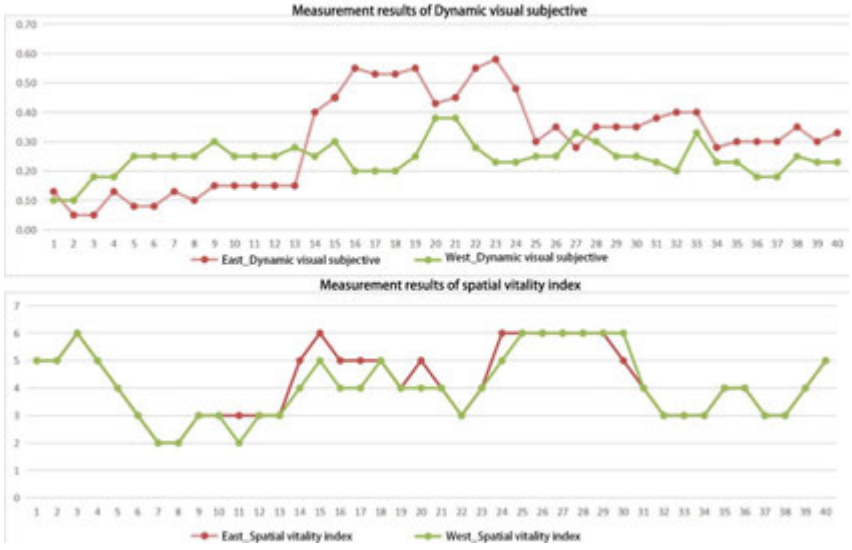
It represents the location maps of the sense of relaxation and richness. The pedestrian spaces close to Xu Jiahui Park tend to evoke a sense of relaxation and have a high spatial richness, indicating that spaces with high vegetation coverage, such as slow-moving pedestrian walkways, provide a positive perceptual experience for people.

Figure 7 Spatial location map of subjective index



5.3 The result of interactive index measurement in Henshan Street

Table 6. Interactive Index Calculation Results

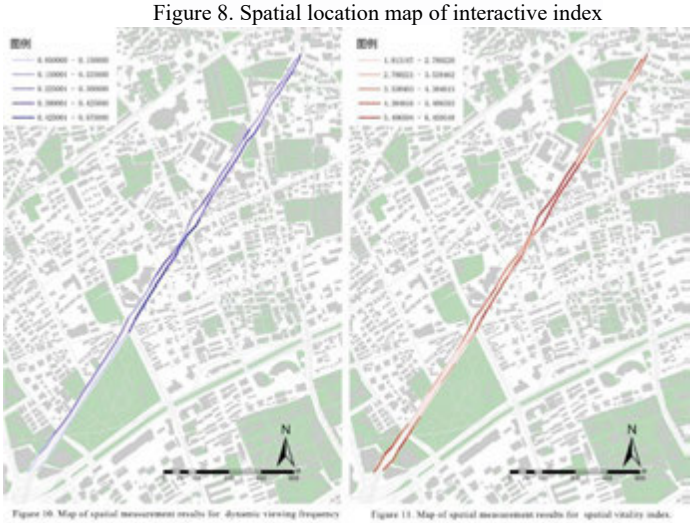


Based on the sample point calculation results, a statistical table of the dynamic viewing frequency for samples on both the east and west sides (Tables 6) have been compiled. The west side shows a relatively balanced spatial distribution of dynamic viewing frequency, while the observation points on the east side near Xu Jiahui Park have a lower pedestrian viewing frequency. As people approach the middle section of the street, the pedestrian viewing frequency increases. The possible reasons for this are as follows: when pedestrians approach Xu Jiahui Park, they may be attracted by the park's internal landscapes and activities. Additionally, this section serves as a jogging track, so to avoid crowding and collisions with other pedestrians, people may choose to change their route and enter the park to walk around.

According to the results of Baidu heatmap, that the high-activity areas are distributed in a "multi-core" point-like pattern in the streets; only eight points have fluctuating spatial heat values in the observation points on both sides of the same serial number; the highest heat value is six which is a high-activity block, and the lowest heat value is two, which includes three points. The maximum difference in heat values for the entire block is four; the areas with the highest heat values are mainly concentrated in serial numbers 24-29, with an average heat value of six, followed by the spatial heat values of serial numbers one-four. The analysis reason is that this area is connected to the Xuhui business district and is relatively easy to attract traffic.

Importing the frequency data of viewing into GIS for data visualization analysis shows that the darker the color, the higher the frequency of people's walking view of the space. Except for the slow-moving path next to Xuhui Park in the south, the frequency of viewing at other locations is high, indicating good utilization of the space for walking. The reason is that this area is connected to Xuhui Park, with multiple locations that can directly access the park. The public who uses walking to tour the streets prefer to enter parks with beautiful scenery, rich vegetation, and diverse spatial activities, which leads to a low frequency of viewing in this area.

Figure 8. Spatial location map of interactive index

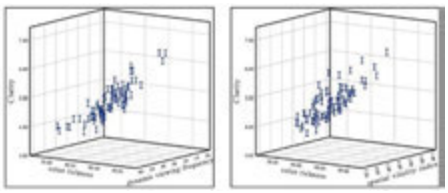


As shown in Figure 8, the darker the color, the higher the spatial vitality index, and the greater the average flow of people in the space. The Hengshan Road block does not have a high density of people throughout the entire route, but there are two distinct low-vitality areas in the middle. The high-vitality area in the middle is mainly due to that it is the entrance and exit of the subway Hengshan Road Station, which has a relatively high flow of people.

5.4 The Mechanism of Urban Street Dynamic Landscape

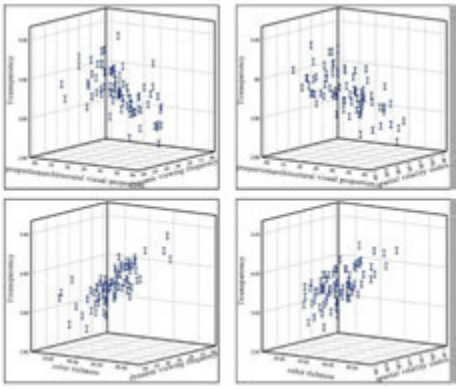
One dependent variable and two independent variables were used in a regression study using SPSS's Partial Least Squares Regression (PLSR) method. To be more precise, the first independent variable consisted of five objective evaluation indexes: sky openness, building visual proportion, green view index, average horizontal visibility distance, and colour richness. The other four subjective evaluation indexes were clarity, transparency, openness, and richness. The second independent variable was the spatial vitality index, dynamic viewing frequency, and landscape choice deviation under the interaction between the subjective and objective components. Sample data were used to explore the correlation between subjective, objective, and interaction index, specifically the subjective sensation characteristics under different "dynamic viewing" states and objective environmental characteristics. The indicator equations with a model fit $R^2 \geq 40\%$ were selected and output.

Figure 9. 3D scatter plot of clarity



The strong correlation results were visualized using a 3D scatter plot in SPSS. As shown in Figure 9, there is a strong correlation between richness, dynamic viewing frequency, landscape preference, and spatial vitality index. The relevant equation expressions are: Clarity = 2.981 + 0.046 * Color Richness - 0.356 * Dynamic Viewing Frequency, Clarity = 2.732 + 0.046 * Color Richness + 5.523 * Landscape Preference, Clarity = 2.834 + 0.046 * Color Richness + 0.017 * Spatial Vitality Index. The results indicate that the more diverse the spatial colors are, the clearer and more easily understood the spatial environment is perceived by people. Clarity has a negative correlation with dynamic viewing frequency, meaning that the higher the frequency of walking in the space, the lower the perception of spatial clarity. At the same time, clarity has a positive correlation with landscape preference deviation and spatial vitality. The more popular

the landscape space is, the lower the clarity is, while the higher the spatial vitality index, the

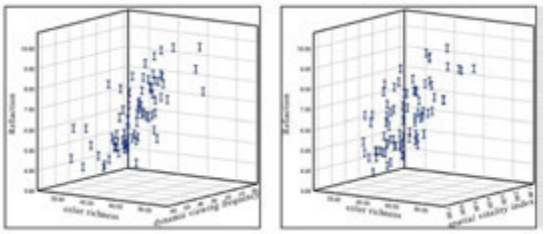


more dynamic and interpretable the space is.

Figure 10. 3D scatter plot of transparency

The sense of transparency has a strong correlation with building visual proportion, color richness, dynamic viewing frequency, landscape preference, and spatial vitality index. The correlation equations are: Transparency = 4.183 - 2.411 * Building Visual Proportion + 0.158 * Dynamic Viewing Frequency, Transparency = 4.208 - 2.370 * Building Visual Proportion + 0.303 * Landscape Preference, and Transparency = 4.018 - 2.406 * Building Visual Proportion + 0.050 * Spatial Vitality Index. These equations suggest that when there is less building volume in the space and a lower proportion of buildings in the visual field, the higher the deviation in people's preference for the spatial landscape, the higher the number of dynamic viewing routes, and the greater the flow of people in the space, indicating a higher sense of transparency and openness.

Figure 11. 3D scatter plot of relaxation



There is a strong correlation between the sense of relaxation and color richness, dynamic viewing frequency, landscape preference, and spatial vitality index. The specific equations are: Ease = 3.369 + 0.090 * Color Richness - 1.791 * Dynamic Viewing Frequency, Ease = 2.323 + 0.091 * Color Richness + 20.765 * Landscape Preference, and Ease = 3.183 + 0.090 * Color Richness - 0.071 * Spatial Vitality Index. These equations suggest that when there is a greater variety of colors in the space, with a decrease in the frequency of walking and viewing, a lower preference for the space, and less foot traffic, people tend to feel more relaxed and focused on

the environment and their own experience.

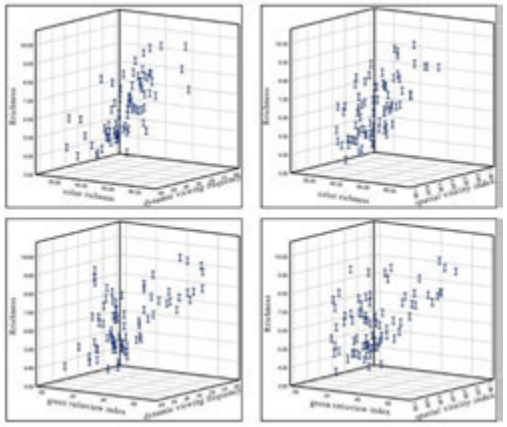


Figure 12. 3D scatter plot of richness

The three-dimensional scatter plot shows that people's sense of richness in spatial environments has a strong correlation with spatial colors, vegetation, walking routes frequency, landscape preference, and spatial vitality index. The specific equations are: Richness = 3.324 + 0.088 * Color Richness - 1.867 * Dynamic Viewing Frequency, Richness = 2.233 + 0.089 * Color Richness + 21.651 * Deviation in Landscape Preference, Richness = 3.130 + 0.088 * Color Richness - 0.074 * Spatial Vitality Index, Richness = 4.223 + 6.829 * Green View Index + 0.789 * Dynamic Viewing Frequency (R2 = 0.401, 0.412), Richness = 5.045 + 6.933 * Green View Index - 25.333 * Landscape Preference, and Richness = 3.745 + 6.812 * Green View Index + 0.167 * Spatial Vitality Index. This indicates that with more color variety in the space, fewer walking passages, lower preference for the space, and less foot traffic, people perceive a higher level of richness in the spatial environment and are better able to experience the objective environmental details. As the amount of green vegetation increases and the frequency of viewing also rises, people's preference for the space and spatial vitality increase, leading to a higher perception of spatial richness, indicating an increased ability to perceive the space.

From the comparative analysis of the images, the top three significant linear correlations are: Clarity - Color Richness - Dynamic Viewing Frequency > Clarity - Color Richness - Landscape Preference > Clarity - Color Richness - Spatial Vitality Index. The objective index of sky view proportion and average horizontal visibility distance have low correlation indices with subjective index and subject-objective index, indicating weak correlations. In urban street spaces, green view index mainly affects people's sense of richness, with a lower impact on subjective index. Among the objective index, building area and color richness significantly influence people's perception, and thus should be given priority consideration in planning and design.

6 Conclusions

The study takes objective urban street environmental index such as sky view factor, architectural visual proportion, green view index, mean horizontal visual depth, and color richness, as well as subjective index like clarity, transparency, richness, and relaxation, as independent variables. It also considers the interactive index between the subjective and objective under dynamic viewing conditions, including dynamic viewing frequency, and spatial vitality index, as dependent variables. The study explores the characteristics of streetscape that significantly influence the viewing behavior in urban street environments, as well as their visual perception features. Based on this, design methods are proposed to enhance the frequency of viewing, spatial vitality, and landscape preference in street spaces. The specific conclusions include the following three aspects:

Establishing interactive evaluation index system. Based on the subjective perceptions stimulated by the "dynamic viewing" mode in the objective environment, the study innovates the evaluation index system by adding index such as dynamic viewing frequency based on spatial positioning trajectory data and spatial vitality index based on pedestrian flow distribution status. These indexes are then combined with the subjective and objective index from previous studies to construct regression equations that are closer to realistic viewing conditions.

Qualitative and quantitative evaluation index system. Through data sources such as sample photo collection, spatial positioning data from the "two-step" app, Baidu Heatmap, OpenStreetMap street, building and road data, and GSCloud, methods like image semantic segmentation, GIS analysis, Colorimpact color analysis, and inductive statistics are employed to quantify the index system.

Summary of subjective and objective regression equations. Through partial least squares analysis in SPSS, the study found significant correlations between clarity, relaxation, and color richness, dynamic viewing frequency, and spatial vitality index; as well as between transparency and color richness, visual proportion of buildings, dynamic viewing frequency, and spatial vitality index.

Due to objective reasons such as weather conditions during photography, camera pixel quality, and seasonal changes, the sample images collected may not reflect the true appearance of the streets throughout the four seasons, and the relatively short time span of the samples may introduce certain experimental errors.

Due to the heavy traffic on the streets, the elements in the 360° panoramic photos collected on-site are severely distorted, with an imbalance in visual area proportion. Therefore, a static photography method was adopted as a second-best option, which may lead to incomplete observation point data and have a certain impact on the experimental results. Future research could incorporate behavioral patterns, such as stationary, mobile, and dynamic viewing speed, during the "dynamic viewing" state, employing methods such as eye-tracking experiments,

scientific observation, and trajectory tracking to expand the evaluation factors of the subjective-objective evaluation system and improve dynamic viewing evaluation index. The use of 360° panoramic photography can also be adopted to capture more comprehensive spatial environmental elements, improving the sustainability of the experiment. Alternatively, advanced technological means such as GoPro and anti-shake cameras can be utilized to collect spatial image samples of basic units for a more comprehensive perceptual evaluation study.

GeoSpatial Virtual Reality & Planning AR Laboratory for education in spatial planning

Author's Name: Katarzyna Rędzinska, PhD
Affiliation: Faculty of Geodesy and Cartography, Warsaw University of Technology

Email:katarzyna.redzinska@pw.edu.pl

Abstract
This paper presents outcomes from a pioneering educational project funded by Warsaw University of Technology during the 2022/2023 academic year. The project aimed to establish a mobile Virtual Reality (VR) Laboratory supporting teaching in geoinformation, spatial planning, urban planning, and architecture. Leveraging the expertise of the Faculty of Geodesy and Cartography and the Faculty of Architecture, the laboratory promoted an interdisciplinary approach to geospatial analysis and planning. The project comprised six tasks, including organizing the laboratory, conducting pilot implementations, and developing interdisciplinary workshop scenarios. Five pilot implementations utilized VR technology in various aspects of the spatial planning process, receiving positive feedback from students and partners. The project facilitated student engagement, exchange of teaching practices, and expansion of academic offerings.

Keywords: augmented reality, co-creation, collaborative design, geospatial technologies

1. Introduction

The significance of Virtual Reality (VR) technology in spatial planning education is increasing, aligning with its growing importance in related industries. Higher education serves as the primary application field offering a novel educational environment, an immersive teaching system, and opportunities for remote education. Despite over a hundred publications addressing VR technology applications in education, limited information exists specifically on its use in spatial planning. VR technology presents various opportunities in education, including immersive learning environments for visualization and 3D modeling, as well as creating diverse educational products. (Figure 1, Figure 2). However, challenges remain to be addressed.

VR technologies have the potential to revolutionize spatial and urban planning education by providing enhanced (immersive) learning experiences (Sanchez-Sepulveda et al., 2019, van Leeuwen et al., 2018, Pouke et al., 2019, Vats and Joshi, 2024), improving usability and effectiveness (Sanchez-Sepulveda et al., 2019, Zhang and Moore, 2014, Zuo et al., 2023), promoting stakeholders participation (van Leeuwen et al., 2018, Sabah et al., 2023), and offering realistic visualizations of urban spaces (Pouke et al., 2019, Schauppenlehner et al., 2018). Additionally, it enhances learning outcomes and student interest (Schauppenlehner et al., 2018). According to Vats and Joshi (2024), Wai Yie et al. (2023), Cicek et al. (2021), VR has the potential to engage students on a deeper level, making education more interactive and enjoyable, thus fostering curiosity, creativity, critical thinking, and problem-solving skills.

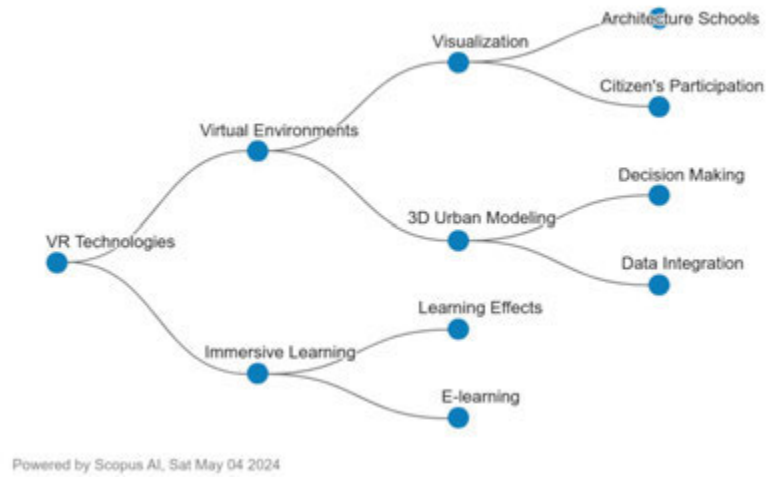

Figure 1. VR technologies applications in planning education

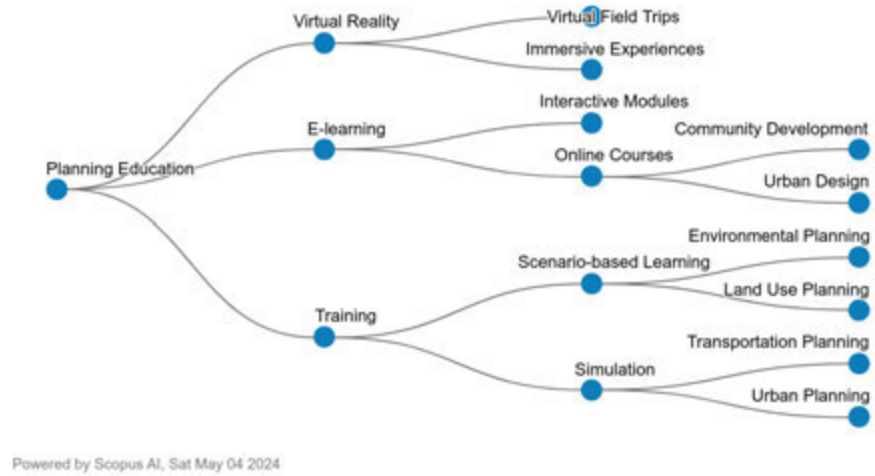

Figure 2. Various educational products using VR technology

As an Active Learning Tool VR involves visualization and interactivity with virtual dynamic and complex systems (Talbi et al., 2023, Vats and Joshi, 2024). Through skill development and training, VR offers opportunities to improve spatial understanding, engagement, motivation, and learning outcomes (Holubinka et al., 2023, Elaish et al., 2024, George et al., 2022). Stewart and Lopez (2021) claim that VR contributes to developing spatial visualization skills with increased student motivation and better performance (Figure 3).

VR supports collaborative design processes in architecture and urban planning education by facilitating remote, real-time collaborative work, and spatial comprehension (Wagemann and

Martínez, 2022, Tran et al., 2024). VR as a communication medium in urban planning and design provides decision-makers with access to a shared virtual space, impacting decision-making processes (Roupé and Gustafsson, 2013, Sanchez-Sepulveda et al., 2019). As such, VR serves as a social participation tool (Figure 4).

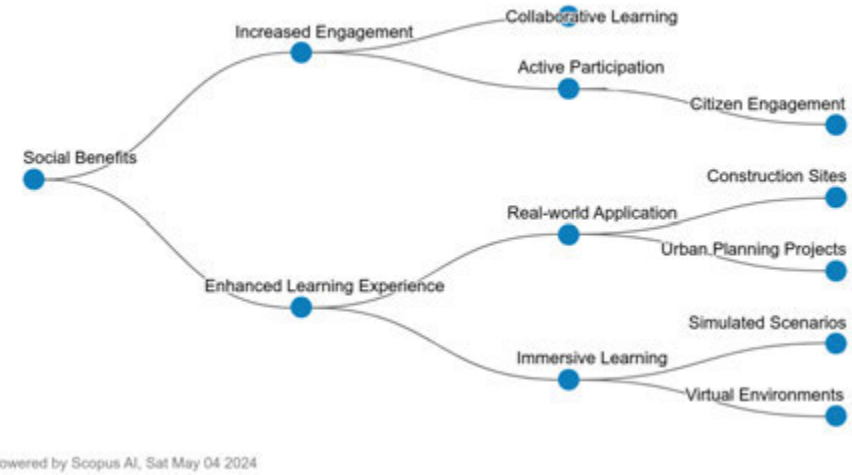

Figure 3. Students engagement in learning process involving VR technology

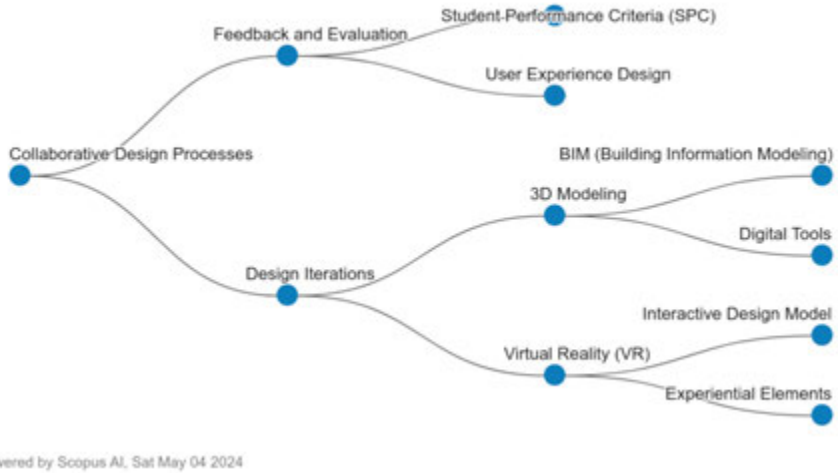

Figure 4. Supporting collaborative design process by VR technology

The interdisciplinary potential of VR technology spans spatial planning, urban planning, architecture, and geoinformation domains (Conesa-Pastor et al., 2022; Wu et al., 2021; Zang et al., 2021; Zhang and Li, 2021).

Regarding challenges in integrating VR technologies into planning education, there is a need to consider economic, technical, and ethical issues.

In terms of economic challenges, the high costs for content development and educator training have been identified as barriers to widespread and effective adoption in educational programs (Kencevski and Zhang, 2019), Additionally, the costs of hardware and software, ongoing maintenance, and the necessity for strategic planning and investment to effectively utilize VR in education pose significant economic challenges (Talbi et al., 2023, Vats and Joshi, 2024, Elaish et al., 2024). However, the potential benefits of improved learning outcomes and increased student engagement may offer a positive return on investment in the long term (Vats and Joshi, 2024, Elaish et al., 2024).

Technical challenges encompass integrating appropriate hardware and software, which can be costly and require regular updates to keep up with technological advancements (Wai Yie et al., 2023). VR equipment needs technical support and maintenance, including troubleshooting and software updates (Holubinka et al., 2023, McGrath, 2019). Moreover, ensuring equal access to VR technologies for all students, regardless of their socioeconomic background, is a significant challenge that needs to be addressed (Talbi et al., 2023, Vats and Joshi, 2024). According to Talbi et al. (2023), Riemann et al. (2020) Vats and Joshi (2024), and Rangarajan et al. (2024), the technological limitations of VR need to be overcome to ensure effective integration into education programs. As using VR requires technical knowledge, individual engagement in urban planning can be limited, and learning costs can hinder citizen participation (Sabah et al., 2023) (Figure 5).

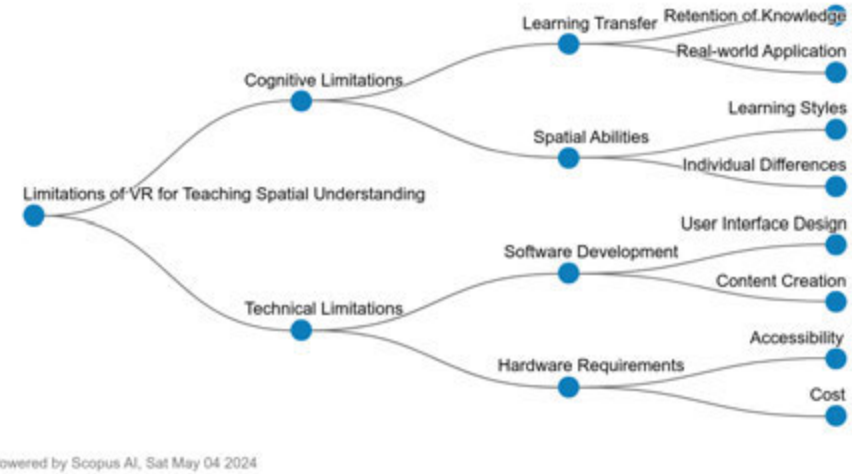

Figure 5. Limitations of VR for teaching spatial understanding

Ethical considerations associated with the use of VR technologies in Urban Planning Education relate to physiological and cognitive impacts, behavioral and social dynamics, and the need for ethics in practice in their use (Kenwright, 2018). Ethical considerations also include ensuring equitable access to VR technologies for all students (Talbi et al., 2023). Moreover, implementing VR in education requires addressing privacy and data security concerns related to collecting and using student data within virtual environments (Wai Yie et al., 2023) (Figure 6 and 7).

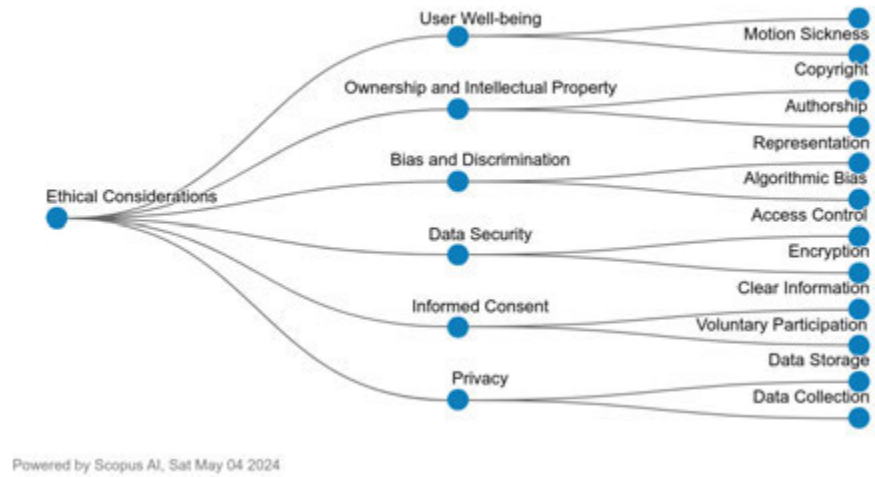

Figure 6. Ethical consideration in VR impemention into didactics

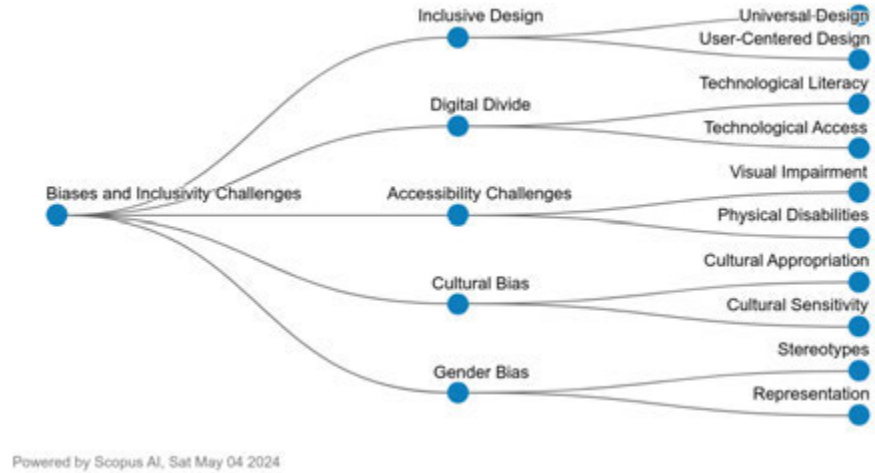

Figure 7. Biases and Inclusivity challenges

Further research is needed to understand the pedagogical effectiveness of VR in education and address associated considerations and challenges (Elaish et al., 2024, Holubinka et al., 2023).

This paper unveils the outcomes of a groundbreaking didactic project funded by Warsaw University of Technology (IDUB - Excellence Initiative - Research University) during the academic year 2022/2023. The project aimed to establish a mobile Virtual Reality Laboratory supporting didactics in geoinformation, spatial planning, urban planning, and architecture. Leveraging the distinct competencies of the Faculty of Geodesy and Cartography and the

Faculty of Architecture, the laboratory fostered an interdisciplinary and comprehensive approach to geospatial analysis and spatial planning. The goal of establishing the VR Laboratory was to enable:

- Activation of students through creative teamwork in solving design problems (spatial planning, urban planning, and architecture) in augmented reality.
- Skills development of geodesy and cartography students in processing geospatial data to create terrain and interior building models for Virtual Reality, and geoinformatics students in creating new geoinformation applications using VR technology (including creating Digital Twins).
- Exchange of good teaching practices through international cooperation by implementing joint, interdisciplinary, remote classes in VR/AR.
- Technological innovations, increasing academic teachers' qualifications in new digital technologies, and modern education methods.

2. Results

The project comprised six tasks: 1) organizing the laboratory; 2) conducting five pilot implementations in teaching; 3) developing an interdisciplinary planning workflow workshop scenario; 4) undertaking science popularization actions; 5) promoting among departments; and 6) formulating a future deployment plan. The pivotal aspect was the execution of five pilot didactic implementations, each employing VR technology for various purposes in varied learning environments and formulas within the spatial planning process. The interdisciplinary team conducted the implementations.

The first implementation was an international and interdisciplinary workshop in collaboration with landscape architecture at the American University of Beirut (AUB), Lebanon. It was integrated into an undergraduate spatial planning course on Revitalization projects led by Dr. Eng. Agnieszka Wendland. The workshop took place on December 15, 2022. It was organized by the Department of Geodesy and Cartography of the Warsaw University of Technology. During the semester, students prepared the study area model in the VR environment and uploaded useful objects to the library. The workshop was held in a VR environment using the GravitySketch® application. During the workshop, spatial planning students (GiK PW - one design group) co-created design solutions in cooperation with landscape architecture students of AUB, The Faculty of Agricultural and Food Sciences, Department of Landscape Design and Ecosystem Management. It was a real-time remote interdisciplinary and multicultural collaboration and co-creation in the VR learning environment. Thirty-five students participated in the workshop (20 online, 15 on-site). The on-site users could observe the workflow on the projector, computer screen, or phone, allowing more participants to engage in the process. Lessons learned regarding the benefits of the deployed workshop formula are: a) VR learning environment enabled a better experience of the space and conscious engagement, b) students have developed effective communication and collaboration skills, utilizing the VR platform for shared experiences, feedback, and collective design exploration; c) through interactive and immersive experiences, VR fostered motivation, participation, and a sense of enjoyment in the learning process, d) through iterative refinement and visualization in VR, students have honed their ability to make informed design decisions, optimizing the visual and functional aspects of the landscape (Dreksler et al., 2023).
The WiFi, Software and Hardware limitations were also observed. Data processing can be challenging on mounted gear with low computing power or low Internet connection. Most

students could only work 30-40 minutes at a time. The process could be chaotic if the group is to big or the students are not properly trained (Dreksler et al., 2023).

The creation of a new facultative course, "Systemic Design for Sustainable Development," was the second implementation. The course is accessible to all Erasmus students under the graduate specialization Mobile Mapping and Navigation Systems by Dr. Eng. Katarzyna Rędzińska. The course was chosen by the students and implemented in the summer semester 22/23. Six international and interdisciplinary students participated in the course. The course was held in the Arkio® software environment. It had a workshop formula using systemic design tools, PBL, and a learning-by-doing method in four-hour modules. The design challenge addressed the possible involvement of Warsaw University of Technology in the NetZero race campaign - redesigning the University Campus (https://unfccc.int/climate-action/race-to-zero-campaign). The Virtual (augmented) reality technology was used in the prototyping phase of the developed design solutions. This implementation provided evidence of the enhancement of student engagement and learning outcomes. Students developed collaboration and communication skills and teamwork. A small group of participants allowed to avoid chaos in the process. Short lectures, on-site teamwork on the systemic design templates (Jones and van Ael, 2022), and design considerations separated the 30-minute VR session. The technical limitations, such as WiFi, software updates, and hardware (battery efficacy), appeared similar to those in the first implementation.

The third implementation involved integrating a VR camera in a landscape planning course for graduate spatial planning students led by Prof. Adrianna Czarnecka. The course assignment was to plan nature-therapy trails in collaboration with the Urban Forests of Warsaw. Through the use of VR technology, students were able to exchange experiences of landscape perception in VR reality. The materials developed by the students will serve for educational purposes, implemented at the Center for Nature and Forestry Education led by the Urban Forests of Warsaw. They will potentially be used as an encouragement to visit Warsaw's forests or as an interactive guide. This implementation is an example of the socioeconomic environment's partner involvement. The above-mentioned benefits and limitations were also confirmed.

Practical testing of VR environment-developed models, including GIS and BIM technology, incorporated into three courses on cartographical modeling for graduate geodesy and cartography students was the focus of the fourth implementation. The implementations covered 46 students and were conducted by Msc Miłosz Gnat. The courses did not involve teamwork and co-creation. VR technology benefits provided enhanced student engagement and learning outcomes. As the headsets were connected to the computers, there were only limitations regarding the students' well-being (30-minute work time sessions).

Last but not least, the implementation allowed students to experience public spaces as blind persons in an undergraduate spatial planning course on Public Spaces Planning and Design. The implementation consisted of an interactive projection of a blind person's experience of public spaces, "Notes on Blindness" by TV Arte. The students were tasked with answering the question of how this experience would contribute to the understanding and consideration of the needs of blind people in the process of designing the spatial development of public spaces. The implementation was optional. The class was carried out in three groups of 10-15 people each. Similar to the previous implementation, it was an individual experience, enriching the urban design studio. It benefited by augmenting students' engagement and a better understanding of the need for universal planning and design.

Four science popularization activities enabled the testing VR technology as a participatory, co-creation tool.

3. Conclusions

The project's VR implementations provided evidence of the benefits of deploying VR technology in spatial planning and urban design education, as mentioned in the literature. The project's realization facilitated the activation of students through creative teamwork, the exchange of good teaching practices, the enhancement of teachers' qualifications in digital technologies, and the expansion of the didactic offer. All implementations received positive evaluations from participating students and partners.

However, the project also encountered challenges. Its outcome was to provide the VR Laboratory to ensure equal accessibility to the novel technology for students. The development of procedures and regulations can address the technological and ethical limitations. While challenges of integrating VR technologies into planning education exist, the opportunities for enhancing the educational experience and developing essential skills are evident from the literature and the project's results.

Implementations two, four, and five will continue in their present form. The international workshop will be embedded into a new optional joint course with AUB. Further research is crucial to understand the pedagogical effectiveness of VR in education and to guide future policy.

Acknowledgments

As a project leader, I extend my deepest gratitude to the entire project team for their dedication and invaluable contributions throughout the duration of this project. Special thanks to Prof. Krystyna Solarek, Prof. Dariusz Gotlib, Prof. Adrianna Czarnecka, Dr ing. Agnieszka Wendland, Msc ing. Monika Piotrkowska, Msc ing. Miłosz Gnat for their expertise, commitment, and tireless efforts in planning, implementing, and evaluating the VR implementations. I would also like to express our appreciation to Warsaw University of Technology IDUB - Excellence Initiative - Research University Dicdiactic Innovations for their support and funding, which made this project possible. Additionally, we acknowledge the cooperation and participation of our students, partners, and stakeholders, whose insights and feedback were instrumental in shaping the outcomes of this project.

Building Tomorrow's Urban Futures: Reflections on the "BuildDigiCraft" Project and the Pursuit of High-Quality "Baukultur" in Higher Education.

Abstract
The BuildDigitalCraft project (2019 - 2022) underscores the importance of education in fostering interdisciplinary knowledge exchange for creating high-quality urban spaces. It highlights a shift towards deeply integrating digital tools into professional practices while acknowledging societal concerns about digitalization in education. Findings indicate a significant evolution in our approach, moving from using digital tools as aids to deeply integrating them into professional practices. This article advocates for academia to serve as a facilitator of emerging modes of learning and promote scientific self-reflection. It emphasises the multidisciplinary nature of high-quality Baukultur and advocates for the intertwining of crafting qualities, tacit knowledge, and qualitative immeasurable aspects with digital, quantifiable, and data-driven qualities.

Introduction

Building tomorrow´s urban futures with the global population shifting increasingly towards urban areas, there is immense pressure on higher education institutions to prepare students to design and manage cities that are sustainable, resilient, and inclusive. **Fast-paced urbanisation** brings forth challenges related to infrastructure development, housing, transportation, and environmental sustainability. Higher education institutions, particularly those focusing on fields like architecture, engineering, urban planning, and related disciplines, are encountering a multitude of challenges in adapting to the evolving landscape of the built environment. Schools are facing increasing demands to prepare students for **rapid economic, environmental, and social changes**, for jobs that have not yet been created, for technologies that have not yet been invented, and to solve social problems that have not yet been anticipated (OECD, 2018).

Considering the rapid transformations in society, there's a growing imperative to redefine the broader educational objectives in higher education. This entails prioritising individual and collective well-being, providing tools for navigating complexity and uncertainty, fostering competencies for societal transformation, and guiding principles for moving towards eco-systemic change (OECD, 2018).

Increasingly, it's understood that the rapid pace of scientific and technological advancement demands a broad spectrum of knowledge, skills, attitudes, and values in practical application. This is a complex responsibility of equipping students with the knowledge, skills, and mindset necessary to address the diverse and interconnected challenges and a broad spectrum of issues ranging from engineering, architectural design and urban planning to sustainability, social equity, and technological innovation. Moreover, there is a growing importance of cross-disciplinary efforts in responding to these challenges. Students are those who if equipped in knowledge and skills will actively drive change.

Today higher education institutions are confronted with **increasing demand for digitalisation**. Digital technologies emerged already in the early 1990s, leading to a new era of culture and economics centred around data that has already transformed much of our production methods (Carpio, 2017). Now, they stand poised to revolutionise many aspects of our ways of thinking and doing things to adapt to the ongoing digitally driven transformation. In the rapid urban development and pressures on advancing digitalisation of workflow, there is a risk of neglecting the diverse perspectives necessary for long-term sustainability and well-being in cities.

In the technologically advanced and highly digitally driven professional work **the values and leading principles of traditional craftsmanship in the built environment**, contributing to the construction, design, and preservation of architectural landmarks and structures, need to be reintroduced and validated again (Bögle et al., 2022). There is a need for a fundamental change in the way "we are doing things" and the way "we communicate and collaborate with each other", and digital technologies play a major role in this transformation process. Digitalization is advancing as a fundamental concept also within higher education institutions, which calls for encompassing quality concerns across various dimensions (Tømte et al., 2019).

BuildDigiCraft was a three years´ project (2019-2022) established by eight universities in a Baltic Sea region as a joint research inquiry. Project developed and implemented innovative teaching and training modules for young scientists, PhD candidates and advanced master's level students and was introduced as a collaborative and cross-disciplinary exploration of three important thematic pillars in higher education anchored in the built environment: (i) knowledge, (ii) process and (iii) material. The project aimed to bring an understanding of the changing paradigm of building cultures in the digital age explored in the context of the relation between professional practice and higher education. The project allowed for a joint exploration of the questions related to today's craftsmanship: *how is the ongoing digital revolution affecting the work of designers, architects, engineers, urban planners, and other professionals responsible for the shaping of the built environment, and what opportunities arise from the available digital and data processing technologies for creating innovative solutions for design, construction, maintenance and management of buildings and cities* (Bögle et al., 2022)?

The project aimed for developing a shared understanding among project participants what is the high quality of the built environment in the digital age. And how do we measure and enhance the perception of its quality? It stressed that the common and

ultimate ambition of crafting the built environment and our engagement with it, involving aspects such as planning, constructing, renovating, and preserving should be built on the holistic concept of "Baukultur". The holistic concept of high-quality **Baukultur** encompasses all activities with spatial impact, from craftsmanship details to large-scale urban planning and the development of landscapes. It refers to all activities with spatial impact of all actors involved over time. In Europe Baukultur forms foundations for two key EU initiatives: the Davos Declaration (2018) and the New European Bauhaus- NEB (2020). BuildDigiCraft aimed to explore opportunities to further develop the concept of Baukultur in the context of a highly digitalized world and urgent re-definition of the roles of higher education in training future professionals.

The project collected significant and abundant material. The findings presented in this article were chosen specifically to tackle its primary inquiry: how higher education can facilitate the emergence of new learning methods in the digital age, preparing the next generation of planners and designers to responsibly shape high-quality built environments (Baukultur)? How to better address the need for a professional mindset change regarding digitalisation, the changing professional roles, and the ambition to shape high-quality spaces? How can higher education strengthen collaboration and knowledge exchange between professions of the built environment?

The paper is organised into five sections. The first presents previous studies addressing the digital revolution's impact on reshaping design and planning practices. The second explains the context of high quality Baukultur in the digital age. The third section introduces the BuildDigiCraft project, its aim and role in the development of an innovative higher education module, and the insights gathered from participants during organised training modules. The fourth section presents and discusses the idea of contemporary craftsmanship in the digital building culture (covering material, process, and knowledge). The final section further explores and discusses the role of higher education in training building professions in the digital era.

Digital Revolution and Transforming Design and Planning

Digitalisation is revolutionising our society and all actions related to our professional world, and the way we are dealing with physical space (Bögle, at al. 2022). The digital revolution has profoundly impacted design and planning disciplines across various sectors, reshaping the way professionals conceptualise, create, and implement projects. Carpo (2016) argues in *The Second Digital Turn- Design Beyond Intelligence* that every technological innovation only happens when technical supply pairs with cultural demands. This indicates that today´s building cultures adopted digital technologies in their daily professional work but in different ways over time. Carpo distinguishes the first and second digital turn. The first came in the early 1990´s and was expressed in producing variations, digital fabrication of not identical copies, digital mass customization and visualisation. The old professional knowledge and skills started to be used on new computational platforms. In the second digital turn building cultures have learnt to adjust more work to computers due to faster and better collection, transmission, processing of data, and in general problem solving. With the advanced use of new digital tools today´s computational revolution is begetting a new way of thinking, leaving much scope of work to computers which creates a brand-new science. The new kind of science that is inherent in most today´s AI applications, that are based on random testing, trials, and errors, looking for a precedent. This is a different approach than in traditional building and engineering cultures looking for

formulas and rules to predict desirable solutions. Examples of digital twins gathering data in virtual and augmented realities for collaborative and participatory processes present new possibilities for collaboration but also change perspectives on planning and decision support (Dembski et al., 2020).

In higher education **digitalisation** encompasses how the adoption of digital tools and platforms influences the interactions and operations of individuals and organisations within social and organisational contexts (Pinheiro et al., 2023, as cited in Bloomberg, 2018, p. 4). On the other hand, digital transformation (DT) represents a broader process involving significant organisational adaptation across various domains, in addition to effectively implementing digital platforms and solutions. Consequently, higher education must not only focus on integrating emerging technologies but also address the need to adapt to the increasing demand for digitalization in the workforce and the evolving roles within professions related to the built environment.

Digital technologies bring forth new viewpoints on digital processes, evolving knowledge, and materials/data, and when intertwined with the physical realm, they hold the potential to enhance the qualitative aspects of the built environment (Bögle, at al. 2022). They have not only enhanced the efficiency and effectiveness of design and planning disciplines but have also opened up new possibilities for innovation and creativity. By leveraging digital technologies and embracing interdisciplinary approaches, professionals can continue to shape the built environment in ways that are more sustainable, inclusive, and responsive to the needs of communities and individuals. Consequently, the fundamental mission of design and planning disciplines remains unchanged: shaping the objects we create and the environment we inhabit (Carpo, 2016).

In Europe this mission put an immense emphasis on achieving a higher quality of built environment as in the course of the transformation to a knowledge society, the importance of knowledge and expertise for companies and organisations is crucial.
The UNESCO International Bureau of Education (IBE) distinguishes between vertical and horizontal articulation in education (International Bureau of Education, 2016). Vertical articulation involves organising content within a knowledge domain over time, while horizontal articulation integrates content from different domains within a grade level. Much of the knowledge is "tacit knowledge". Today´s version of vertical and horizontal alignment seems directly linked to the digital and the question arises what happens when people digitalize or digitally share tacit knowledge. The digital transformation of tacit knowledge has a political and democratic dimension (Pedro Esteves Galvão Aibéo, Günther H. Filz, and Vishal Singh 2021), in architecture and planning, spanning from educational questions (Ylirisku and Filz, 2018), to design approaches (Ruan, Filz, and Fink, 2022) to the meaning of material, materiality and the digital for Baukultur (Popovic Larsen and Filz, 2023).

High Quality Baukultur and Digitalisation
The idea of Baukultur put a high-quality built environment in the centre of the work of designers, engineers and urban planners, applying it just as much to craft-related detail as to large-scale urban planning. For higher education in design and engineering schools, it offers a platform for methodologies and tools for future experts in those professions. Two key EU initiatives operationalizing the concept of Baukultur are the

Davos Declaration "Towards a European vision of high-quality Baukultur" from 2018 and the New European Bauhaus (NEB) Initiative 2020.

Those initiatives not only emphasise the need for a fundamental shift of mindset among those professions shaping the built environment, but even more significantly but address society as a whole for the first time focusing on the quality of their living environment. It aims to address pressing global challenges, both societal and climatic through the lenses of the built environment which is one of the key factors influencing those challenges as the Buildings and Construction sector is the largest emitter of greenhouse gases, accounting for 37% of global emissions for over 34 percentage of energy demand in 2022 (UNEP & YCE+A, 2023). To answer those challenges NEB aspires to bring together stakeholders from all domains (Pentahelix) – citizens, experts, designers, businesses, and institutions – to envision more sustainable cities and territories, not just in Europe but globally.

As described in the chapter above digitization is changing the way we are now shaping the built environment. The New European Bauhaus as a guiding framework among its other priorities is pivotal in defining how the ongoing digital revolution is affecting the work of designers, architects, engineers, and urban planners. Within the BuildDigiCraft project, we seek to examine new opportunities that arise from the available digital and data processing technologies for creating innovative solutions for the design, construction, maintenance, and management of buildings and cities (beyond standard workflows and material use). To nurture a high-quality Baukultur the fusion of physical and digital realms is becoming ever more intertwined, mutually fuelling each other. Hence, the craftsmanship qualities, tacit knowledge, and immeasurable nuances have to be interlaced with digital, measurable, and data-centric approaches. This synergy promises to prompt future high-quality Baukultur and the high-quality of spaces.
In January 2018, European Ministers of Culture convened at the Davos Conference on High-quality Baukultur in Europe to explore pathways toward enhancing the quality of the built environment. In pursuit of this goal, measures of the perception of a high-quality built environment were required. In 2020, the identical inquiry gained significance and ascended to the forefront of political discourse in Europe. Consensus was reached that the overall concept of high-quality Baukultur should be embedded in Europe on a political and strategic level. Within the BuildDigiCraft project Baukultur the context of the Davos Declaration was tackled through the following three aspects:

1. The current built environment, encompassing both cultural heritage assets and contemporary creation, should be perceived as a unified entity. Existing constructions serve as an important Baukultur reference for shaping the future design of our built environment.
2. All endeavours affecting the built environment, from detailed craftsmanship to the planning and implementation of infrastructure projects having an impact on the landscape, are manifestations of Baukultur.
3. Baukultur extends beyond physical structures to encompass the processes involved in its creation (Bögle, at al. 2022)

Most importantly, the concept of Baukultur transcended its niche among built environment experts but was officially endorsed at a political level, which happened together with the understanding that the built environment is not only the collection of the existing and newly designed building stock and infrastructure but also encompasses all the processes and activities required for its creation.

Based on such an understanding, the Davos Declaration gives further incentives to society, politics and science to rethink the current situation which is marked through disciplinary blinkers, ephemeral profit maximisation and digital automation, as well as confronted by major ecological and climatic challenges which may jeopardise the future of our planet. In terms of BuildDigiCraft Baukultur quality was measured against eight major criteria from the Davos System: Governance, Functionality, Environment, Economy, Diversity, Context, Sense of Place, and Beauty, giving a comprehension framework to measure the quality of the built environment.

BuildDigiCraft Project (2019-2022)

The BuildDigiCraft project aimed to develop and implement innovative educational training module tailored for young scientists, PhD candidates, and advanced Master's level students, focusing on both teaching and training aspects (Bögle et al., 2022). It allowed students and experts trained in design, architecture, engineering, urban planning, and related fields to focus together on the question of how to create high-quality Baukultur in the digital age. The program was part of a long-term partnership between eight universities in the Baltic Sea region. They share similarities in history, climate, landscape, and craftsmanship traditions. Despite these shared traits, each place and university has its own unique character and educational culture. In a joint collaboration, the represented research and educational departments of the eight universities managed to develop and realise a one year online training program, funded by the Erasmus+ strategic partnerships program.

The starting point of the program was the examination of new possibilities arising from the use of digital technologies for innovation in building design, construction, maintenance, and city management. It evolved then to a higher education discourse on the future of the professions of the building and planning sector, emphasising the need for a new work ethos and a more craftsmanship-oriented approach in a digitally impacted work environment.

The project builds on two leading concepts. First, "craftsmanship" is identified and introduced as a main guiding principle in the context of the ongoing digital transformation of the planning, design, and construction sector. Then, the concept of Baukultur is used to refer not only to the existing and contemporary building stock and infrastructure but also to the processes and activities required for their creation. The German term Baukultur was introduced by the Davos Declaration (2018) as an official term in the international professional language of the specialists of the built environment. With the help of the Davos Baukultur Quality System (2021), the high-quality Baukultur level of places can be defined based on eight criteria, which the BuildDigiCraft project takes reference.

The project brings these two concepts together by arguing that craftsmanship is essential for setting up the framework for designing a new path leading to a high-quality Baukultur in the digital age. The values and leading principles of traditional craftsmanship, such as dedication, pride in one's own work, and mindful and sustainable dealing with the building material, need to be re-introduced and validated in the context of the ever-growing digitally driven work environment. Moreover, they are highly needed for the creation and shaping of high-quality built spaces, which protect the environment, fit their purpose, add economic value, result in spatial coherence, connect people, create a sense of space, and are also aesthetically designed (based on the Davos Baukultur Quality System).

The exploration of the concepts of craftsmanship, Baukultur and digitalisation creates the holistic project framework of the project, calling for "high-quality Baukultur in the digital age through craftsmanship". This framework allows for knowledge integration between the interdisciplinary backgrounds of the participants of the BuildDigiCraft training program. Thus, different research questions, methodologies, design principles and theories as well as the different scales of the built environment – from the structural and architectural detail through the building to the urban level – can find common ground to mutually benefit each other. Hence, the project addressed a growing gap in the higher-education curricula of design and engineering schools, which indicates a clear need for more reflection space and interdisciplinary discussion on joint professional approaches for solving fundamental societal challenges. Within the training program, advanced students, and young researchers, as well as experienced teachers, were given a common platform to mutually elaborate on the core values and leading professional principles for achieving high-quality spaces. At the same time, the exchange and peer-review with other specialists of the built environment allowed them to get to know new professional perspectives, work methods and scale of interventions applied in other closely related disciplines. Participants gained new skills and competencies for navigating and collaborating with professionals of other disciplinary fields, with whom in the future they will be jointly responsible for shaping buildings, spaces, and also work processes. An exchange that is imminent once real projects are being developed.

What is the BuildDigiCraft´s training approach and how does the training work? BuildDigiCraft equips future professionals with a method for an intellectual reflection on any physical intervention in the built environment. With the help of the BuildDigiCraft scientific model experts of the built environment can better assess the quality of their work process as well as the quality of their intervention (Bögle, at al. 2022)- The model allowed the participants of the BuildDigiCraft training program to set their individual research within the holistic framework of "high-quality Baukultur in the digital age through craftsmanship."

The concept of Baukultur is deconstructed in the project down to its three core elements: the Process, the Knowledge and the Material (Fig 1]). Shaping and maintainance of the built environment results in complex and diverse processes and includes design, planning, construction, maintenance, and as well as end of use phase. In broader terms, these Processes are influenced by the available Knowledge and understanding of Material.

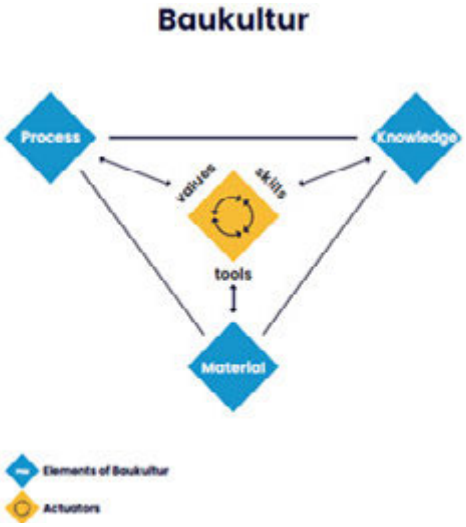

Fig. 1. BuildDigiCraft project triad model

The values, skills and tools serve to actuate the Baukultur developments and to carry out the Process (Bögle, at al. 2022).

Structurally the training programme was organised around four thematic blocks (Intensive Study Programmes - ISP), starting with the "Concepts and Fundamentals" going through to the "Digital Futures" and "Craft and Craftsmanship", culminating in a joint reflection on "Rethinking the Baukultur in the Digital Age" (Fig.2). Each training block built thematically on the previous one, at the same time in every block a new aspect was added, and a new work organisation was introduced. This allowed also for a non-consecutive participation in the separate program blocks. Each participant entered the interdisciplinary training program wearing their own "digital," "disciplinary," and "ethical" glasses ranging between a broad variety of thematic issues and questions related to the future of the built environment.
Prior to the beginning of each training block, selected participants received a set of preparatory tasks. The aim of these tasks was on the one hand to help participants present themselves at the beginning of the course, and on the other, to offer them guidelines for setting their individual research work within the scope of the BuildDigiCraft project. During the whole training program, three major sources of input were collected: (a) individual input by the participants, (b) input from the scientific team - in the form of supervision of the group work as well as contribution to the joint discussion rounds - and (c) external input coming from invited experts and renowned keynote speakers. The work formats which were used during the training range between individual presentations, supervised group work formats, intermediate and final group presentations, all accompanied by joint discussion rounds. Throughout each training block, the processes, knowledge, and material aspects in the individual projects were explored on the intersection level with the holistic framework of "high-quality Baukultur in the digital age through craftsmanship".

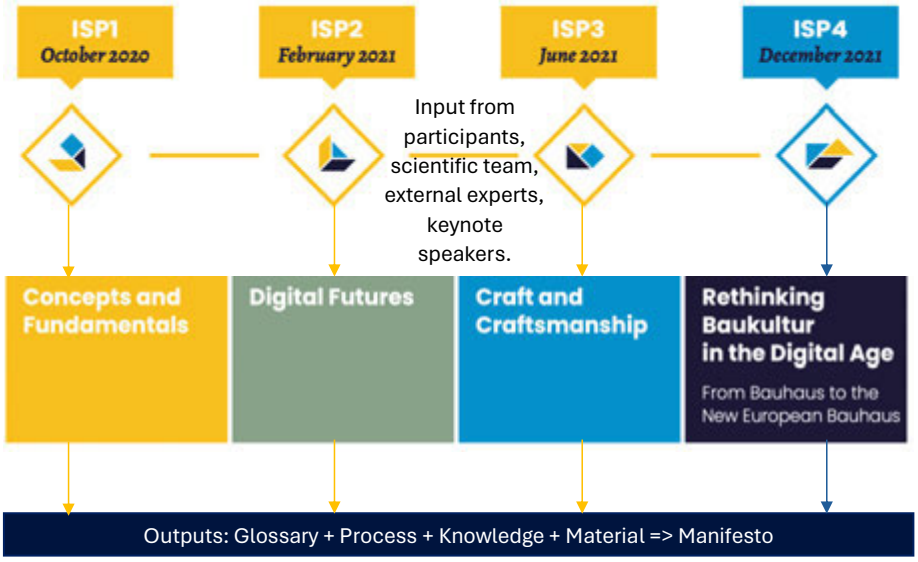

Fig. 2. Thematic framework and outcomes in the BuildDigiCraft project.

The BuildDigiCraft project also devised its own glossary, as highlighted in Figure 3. This glossary serves as an efficient tool for collaborative reflection on intricate research inquiries (Bögle et al., 2022). It offers an open methodological framework aimed at fostering a shared comprehension among project participants, achieved through a thorough exploration of concepts and ideas across different temporal and scale dimensions throughout the project's duration.

In the training program, participants were urged to continuously delve into the concepts and notions raised during discussions using a two-dimensional matrix model. This model encompasses the "focus" and "time" dimensions. The "focus" dimension, depicted on the x-axis, spans from "general" - accessible to a broad audience including non-specialists, to "specific" - utilised by professionals within their respective fields, and further to "narrow" - tailored specifically to the challenges of individual research projects like PhD or Master's theses of the training participants. On the other hand, the "time" dimension, represented on the y-axis, facilitates temporal analysis and interpretation of the evolving meanings and manifestations of notions and ideas across past, present, and future contexts.

The BuildDigiCraft matrix model generally built on the two-dimensional intersection of the main BuildDigiCraft concepts: Digital(isation), Craftsmanship and Baukultur on the "y" axis and the "Process", "Knowledge" and "Material" on the "x" axis (fig. 4). This allowed the participants of the training programme to explore the notions and concepts they posed both inwards - within their own focus and temporal scale, and outwards - within the overall project framework.

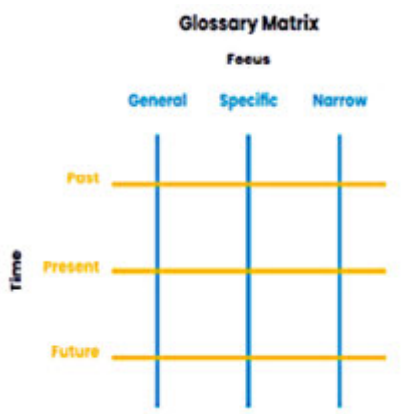

Fig. 3. Glossary matrix tool (Bögle at al., 2022)

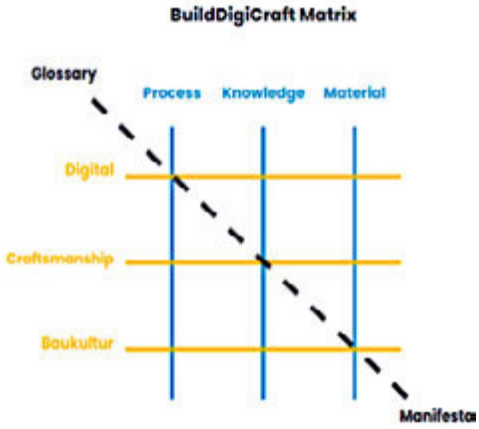

Fig. 4. BuildDigiCraft matrix model (Bögle at al., 2022)

The discussion outcomes of the BuildDigiCraft training programme together with the collected material from the two matrix models, as well as the material collected from the preparatory assignment tasks before each training block, were carefully post-processed and evaluated by the teaching scientific team. The collected material was explored, assessed, and classified using the BuildDigiCraft matrix model (Fig. 4). The project's involvement in discussions about contemporary craftsmanship in the digital era illuminated three essential professional domains: process, knowledge, and material. This understanding is vital for enhancing the role of higher education in preparing professionals for the digital age.

Redefining Today's Craftsmanship in the Digital Building Culture

BuildDigiCraft project aimed to broaden the understanding of the idea of craftsmanship in the digital building culture. Results from ISP3 presents that input on a wide range of topics in relation to the concept of craftsmanship in the digital age is introduced through the training, covering topics from digital disruption and the digital twin, through spatial planning, design, and construction, to the right to design, the link to heritage, and the fusion of arts and craft. Craftsmanship addresses in its essence quality, beauty, and resource efficiency. Craft values are deeply sustainable as their core value is quality and reducing wasteful approaches. It promotes a relation to sustainable material and techniques and offers tangible experiences through synergies of mind and hand while intimating satisfaction in achieving a level of mastery and highest quality.

Craftsmanship is associated with being humanistic and having artistic values that stand behind the work and the "material." Material is understood as both traditional building materials like "wood," but also data, emotions, and information from a community. Craftsmanship is thus transformed into the digital realm as representing, for instance, uninterrupted experiments, a special time quality as well as artistic quality.

The insights from project participants acknowledged that craftsmanship ethos in planning, designing, building projects is essential for strengthening the sense of belonging and commitment to the surrounding space. Digital technologies and "new" digital forms of material when linked to the onsite planning, design, construction process and knowledge production enable us to handle complexities of efforts.

There is a necessity of re-identification of the designer's work with the work of a craftsperson in the digital era (Caldenby, 2021). Digitalization highlights the importance of data and evidence-based knowledge, where the experience and place-based work of the designer need to be promoted. In the digital era, the qualities of craftsmanship that need to be sustained should include: "Materiality" (being real, not virtual), "Location" (being grounded), "Sustainability" (being adapted to nature), "Diligence" (being passive and professional), "Openness" (being vague), "Good life" (being human).

The BuildDigiCraft project generated an in-depth exploration of the fundamental aspects crucial in delineating contemporary professional domains for building cultures: Process, Knowledge, and Material, which participants addressed over the project's duration.

From the **Processes** identified as important for shaping and maintaining the built environment the project team chose to focus on the initial one - the design process (Bögle, at al. 2022). The design process is often overlooked as something invisible, not tangible. However, it is this series of decisions made in a design process that will eventually lead to poor or high-quality Baukultur. Designers involved in design processes of Baukultur have now access to new digitised, visualised and AI-processed information that was not accessible just a few years ago. If properly used, ideally it can help create a design process leading to higher levels of sustainability and cultural appreciation. However, digitalization also poses considerable risk, because design processes used to be regulated by industry standards and tradition. Those processes are now much freer, untransparent and less or not at all regulated. Therefore, the designers of today and tomorrow urgently need new type of design guidelines. BuildDigiCraft proposes such type of design process guidelines, that help designers reflect on the quality and values behind the performed by them design process in the digital context.

Knowledge and skills are key human capital elements of building a sustainable environment. This project guides and reflects on the important role of higher education in preparing the future generation of designers to take responsibility for shaping high-quality built environments, sharing knowledge and values of good craftsmanship. Moreover, exemplified results from the project show that in the age of digitalization and globalisation, there is an opportunity to use a wide set of digital tools for knowledge production and exchange.

The notion of **Material** and materiality was explored in the project beyond its pure and only physical form (Bögle, at al. 2022). Typically, physical material with all its characteristics/performance is described through data that is detailed, complex, and derived and presented in digital form. Whereas the (physical) material possesses the workability and formability that has historically been developed through tacit

knowledge and the craft of making. Currently, this is supplemented by material as data (data about the material) that facilitates better/more sustainable/ higher-quality design, architecture and building design. The two – the physical material and the digital material – are inseparable and without either of them, we would not be able to discuss material and materiality.

Higher Education in Training Professions for High-Quality Baukultur in the Digital Age

The contemporary role of academia has changed as it serves as a facilitator of emerging modes of learning, both knowledge production and knowledge exchange as described by Smith & Hairstans (2017). The new role of universities in advancing technological innovation and economic development as a "knowledge hub" defines a change for many universities from the late 20th century playing the role of "knowledge factory" for research, training, and commercialization until now. It seeks to animate indigenous development and innovation, spanning between industry, the government and society. High-performing institutions are those which effectively advance, distribute and recombine tacit knowledge. Some universities in parallel also serve as a 19th century "storehouse of knowledge," or a "knowledge factory" for research, training, and commercialization (late 19th century to the end of the 20th century). Community and non-governmental organisations (NGOs) play a special role in knowledge exchange fostering innovation in a particular sector or interest area.

The role and purpose of higher education in the built environment has increasingly come to be the preparation of young people across society to take on highly skilled positions in industry and society. The perspectives on knowledge production have evolved a lot, especially over the last decades when science faced growing demands for collaboration between researchers, and new research questions going beyond one discipline. Here more than ever, collaborating communities, researchers and decision-makers in building professions seek to tackle problems that require both specialised knowledge and integrative skills to cope with complexity.

In higher education, individuals should learn to grow in one's own work as professionals. Education and research should be directed toward how we can prepare individuals to grow in all of Aristotle's three categories of knowledge – episteme (scientific knowledge), techne (knowledge of craft) and phronesis (ethical knowledge). "Evidence-based design" is important but not always the right answer to wicked design problems in the built environment. The knowledge of the designer needs training to learn and implement the craftsman's practical knowledge: techne and evidence-based assessment related to episteme. Evidence-based learning is only a part of knowledge generation in higher education – the other involves individual learning.

The goal of the university is to create opportunities for students to make informed design decisions and explore phenomena-based knowledge. This includes learning about cultural values like the history of architecture and built environment (old and contemporary), humanistic understanding of design questions, state of the art and an awareness that every problem is unique involving phronesis. Students reflected on the "metacognitive knowledge" (Krathwohl, 2002) and learning to gain knowledge of general cognition as well as self-knowledge and awareness.

High-performing higher education institutions are those that effectively advance, distribute, and recombine tacit knowledge. The current role of the university as a facilitator of emerging modes of learning, knowledge production and information transfer embodies the necessity to combine all types of knowledge: explicit, implicit and tacit into the formal, semi-formal and non-formal tools of education, including the shift from teaching to learning. There is much explicit knowledge found in codes, and publications embedded within people and organisations. Still, the majority of knowledge regarding the built environment, including construction, is tacit or implicit. In academia, explicit knowledge in the form of data, records and documents (present in journal publications, databases, books, websites and videos) is relatively easy to disseminate. On the contrary, tacit knowledge is difficult to transfer by means of writing or speaking. It is embedded in people, organisations, societies, and cultures. It comes from experience, thinking, competence and commitment. In academia, tacit knowledge can be found in workshops, conference discussions, internships and exchanges.

Architecture, planning, engineering, etc. are professions where knowledge is about the ability of make well-grounded design decisions in complex situations. In the Reflective Practitioner (1983), the design theorist Donald Schön formulates the two fundamental concepts "reflection-in-action" (reflecting on the process) and "repertoire" (impressions, ideas, examples, and events) as essential elements of design /problem-solving work. It's individual and a result of experience, an extensive design practice based on reflection-in-action and a lifelong build of a personal repertoire.

The thorough examination of the project material through the lenses of Process, Knowledge, and Material - the foundational elements of Baukultur - marked a significant milestone in crafting a unified declaration of principles advocating for a fresh professional paradigm for superior built environments and work methodologies. In this context, the role of higher education for future professionals emerges as pivotal. The BuildDigiCraft scientific team's **Manifesto** not only provides contemporary and future professionals with both a methodological and contextual framework but also underscores the importance of higher education in shaping the next generation's understanding and practice. With actionable steps outlined in the Manifesto, higher education institutions can play a crucial role in equipping future professionals with the necessary skills and insights to navigate and contribute effectively to the evolution of high-quality Baukultur in the digital era (see Fig. 5).

The Manifesto for the BuildDigiCraft teaching method outlines six essential steps to enhance craftsmanship in the digital work environment of architects, engineers, and urban planners:

1. Acknowledge Elements Understand the components of Baukultur : Analyse your project by answering questions about the process, knowledge, and material you're using, as well as the values, skills, and tools involved.

2. Structure Your Project: Use the BuildDigiCraft matrix to organise your project along the axes of digitalization, craftsmanship, and Baukultur, as well as process, knowledge, and material.

3. Apply Glossary Matrix: Utilise the Glossary Matrix tool for your project.

4. Understand the Context: Recognize the changing paradigm of Baukultur in the digital age, considering aspects like the relationship between design and realisation, digital twin representation, and dealing with data.

5. Explore the context of Craftsmanship: Embrace craftsmanship's focus on quality, beauty, and resource efficiency, connecting with sustainable materials and techniques. Craftsmanship enhances the sense of belonging and commitment to a space and values humanistic and artistic qualities.

6. Make Tacit Knowledge Explicit: Share the symbiosis of material, design, and construction knowledge with others, bridging the gap between digital data and craftsmanship. Integrate craftsmanship skills into digitally driven projects for high-quality Baukultur in the digital age.

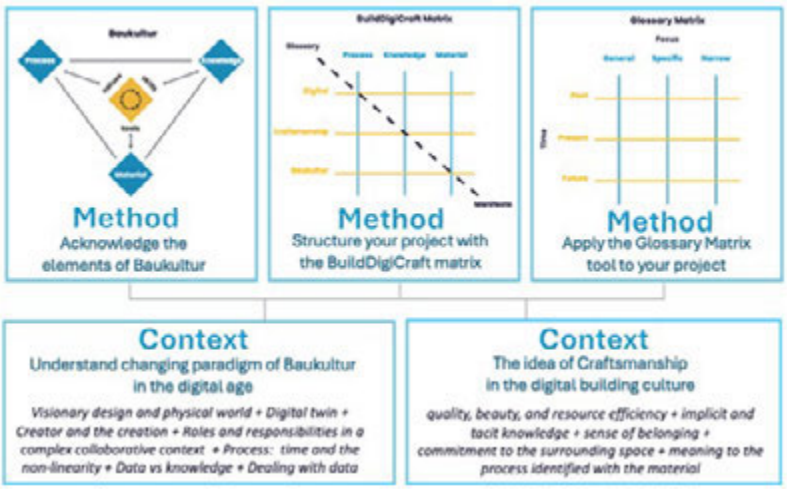

Fig. 5: The Manifesto as a "self- reflection model" and a user guide for the BuildDigiCraft interdisciplinary teaching method (Bögle, at al. 2022)

Discussion

The BuildDigitalCraft project developed between the years 2019 and 2022, overlapping with the beginning of COVID-19, presented an opportune moment to test digital platforms and discuss the utilisation of digital technologies for enhancing the shaping of the built environment. The BuildDigiCraft project findings demonstrate that our understanding of shaping the built environment has significantly evolved. The digital revolution is transforming our society and professional endeavours, profoundly impacting how we interact with physical space. Building on Carpo's (2016) distinction between the first and second digital turns, we see a shift from using digital tools merely as aids to integrating them more deeply into professional practices. This shift is driven by advancements in data collection, processing, and problem-solving, ushering in a new era where computers play a significant role in design and planning processes.

Digital twins, virtual and augmented realities, and collaborative platforms are examples of how digital technologies are changing perspectives on planning and decision-

making processes. They offer new possibilities for collaboration and participatory design, empowering stakeholders to engage more actively in shaping their environments. Despite these advancements, the fundamental mission of design and planning disciplines remains unchanged: to shape the built environment in ways that enhance quality and respond to the needs of communities and individuals. By leveraging digital technologies and interdisciplinary approaches, professionals can continue to innovate and create more sustainable, inclusive, and responsive built environments. This emphasis on achieving higher quality in the built environment is particularly pronounced in Europe.

The concept of high-quality Baukultur adopted by the Davos Declaration (2021), New European Bauhaus (2020) manifests itself in a multidisciplinary approach, encompassing notions such as built environment, cultural heritage, quality of life, social cohesion, well-being, resilience, and others. The impact factors, the areas affected, and the people involved form a complex set of units, the development into a holistic targeted system which is directly linked to the transfer of knowledge in a multidisciplinary environment. Principles defined for successful knowledge transfer – i.e., the provision of the horizontal flow of information, the rating and feedback, the time resource factor – can form the basis of an approach to building a high-quality Baukultur process

Knowledge, Process and Material became core elements of the thematic structure of the BuildDigiCraft project and much relevant for all design and planning work of disciplines anchored in architecture, urban planning, engineering. Additionally, the Glossary was co-created and discussed by project participants. These elements are considered very important for building a common platform for discussions and reflections among project participants representing different disciplines shaping built environment.

The results from the BuildDigiCraft project highlighted that the complex concept of shaping the built environment has evolved meaningfully due to the necessity of rethinking the role of science and its relationship to society and building cultures. As real-world problems become more complex, there's a growing demand for collaboration among various stakeholders, including academic and non-academic entities, to address interdisciplinary research questions. This interdisciplinary approach helped to realise that design, and planning professions may have different skills, and use different tools, but still can be unified by representing the same values. The essay "The many faces of knowledge" by Bernt Gustavsson (2000) gives an overview of concepts of knowledge that span from the three forms of knowledge formulated by Aristotle to contemporary discourses. He shows how Aristotle's three categories of knowledge – episteme (scientific knowledge), techne (knowledge of craft) and phronesis (ethical knowledge) – still hold relevance, not least for the application of knowledge in practice. In the higher education system these three forms of knowledge have been the framework for defining the criteria to be fulfilled for different academic exams.

Material in the digital era broadens the spectrum of purposes. Students and young researchers approach digital technologies easily and see them as promising endeavours for solving complex problems. There was a broad understanding among students that future building cultures will work on building models in the virtual world

to gather greater knowledge about the real world from simulations of data variables in these models. While technical and methodological skills are crucial, there's also room to explore broader themes and foster collaboration with emerging technologies like GPT, DALL-E, and others from OpenAI. By integrating these tools into the educational curriculum, students can gain a deeper understanding of how technology intersects with design, sustainability, and societal needs, preparing them for a more holistic approach to their profession. Moreover, the project reveals a shift in knowledge distribution, with a wider array of organisations and stakeholders contributing their expertise to problem-solving efforts.

In higher education, there's significant potential to incorporate overarching concepts like interdisciplinary training towards the goal of creating a high-quality built environment as a common value. The Manifesto arising from the BuildDigiCraft project encapsulated meaningful insights on navigating the complexity of professional craftsmanship in the digital era, while also emphasising the responsibility of shaping the built environment towards the creation of high-quality spaces (Baukultur). This emphasis is particularly vital when considering the diverse, intricate, and rapidly evolving urban landscapes of today. In higher education, our mission reaches far beyond the mere development of technical and methodological skills for self-reflection. Essentially, technical and methodological skills are crucial, but they should be seen as just the starting point. They lay the foundation for a broader educational experience that delves into understanding the complexities of one's professional field and the challenges posed by digitalization.

Conclusions

Higher education plays an indispensable role today in melding the intricate artistry of craftsmanship, tacit knowledge anchored in professional experience, and qualitative nuances with the precision of digital tools, quantifiable metrics, and data-driven insights. This synthesis is fundamental for nurturing the advancement of superior architectural and planning spaces through innovative processes aimed at cultivating a future defined by exemplary "Baukultur." In the end the fundamental mission of design and planning disciplines remains unchanged: shaping the objects we create and the environment we inhabit (Carpo, 2016). Advocates argue that interdisciplinary teaching and research leverage collaborative and creative strategies utilising digital mediums as a shared language. However, the digital realm encompasses more than just software; it encompasses methods of analysis, transformation, generation, fabrication, and monitoring.

Furthermore, digital data is heralded as tomorrow's essential material. Digitalization enables the development of new skills working with the complexity of data in the built environment and can provide efficient digital tools for seeking new research issues. Digital tools allow collecting of large amounts of qualitative data and working with different data sets. By merging data from several qualitative studies (metadata), research can pose questions that individual projects cannot raise.

Concurrently, the significance of preserving the essence of good craftsmanship in the digital age is underscored, entailing the collection, dissemination, and conversion of professional tacit knowledge into explicit knowledge. This entails creating design processes intertwined with a deep comprehension of physical materiality in architecture and urban planning. In the future, much more attention will be paid to

knowledge production and management in higher education supporting the transfer and creation of cultural values expressed in the Davos Declaration toward the vision of high-quality Baukultur. This involves learning how to apply conscious and well-debated design/problem solving, maintain and improve the qualities of places by construction, build social cohesion, promote environmental sustainability, or maintain and protect our cultural heritage.

In building tomorrow's urban futures higher education will need to strengthen training the skills of professional self-reflection that can only be done by interdisciplinary dialogue, intertwining of crafting qualities, tacit knowledge, and qualitative immeasurable aspects with digital, quantifiable, and data-driven qualities. This interweaving is seen as essential for fostering the creation of high-quality architectural spaces through creative processes aiming for a future high-quality "Baukultur". By adapting their curricula, fostering interdisciplinary collaboration, and promoting innovative thinking, these institutions can prepare future professionals to tackle the evolving challenges of urbanisation, sustainability, and social equity.

Abstract
The education of future urban planners and architect has been exposed to various global trends which influence our environment. Nowadays, the imperatives embedded into the 2030 Agenda, the European Green Agenda and the New European Bauhaus (NEB) represent a starting point for the preferred green transition which should contribute to the sustainable urban future. The University of Belgrade - Faculty of Architecture has been strengthening the environmental dimension on all levels of studies, and this paper will focus on the case of the Master program in Architecture_ Module Urbanism. The thematic and structural modifications will be discussed on the level of three courses - Sustainable City (obligatory), Ecopolis (elective) and the final/graduation work (Thematic research, Master Thesis, Master Project studio), also considering their results and public outreach.

Keywords: education, green transition, urban planning, architecture, Green Agenda, New European Bauhaus.

1 Introduction

The context of the contemporary life strongly affects our living environment, especially cities, as the major hubs of interaction, innovation and exchange. Urban nodes have always represented a spatial reflexion of our needs and aspirations, but also a setting in which emerging problems and conflicts have been displayed. Consequently, the importance of cities in the loop of socio-economic, technological and ecological changes has always been emphasised, while the role of urban planning and design, as well as architecture, has been recognised, tested, praised or criticised. In order to meet the latest challenges, some efforts have been made to create a solid global framework of action, synchronised with the 2030 Agenda for Sustainable Development and its goals (UN, 2015). On the European level, three documents were adopted in 2020: the New European Bauhaus (NEB), the Green Deal - a vision of Europe as the first climate-neutral continent (EU, 2020a) and the New Leipzig Charter - the broadest European policy for sustainable urban development (EU, 2020b).

The NEB initiative revolves around urban settlements, as the main generators of both global difficulties and solutions, while SDG 11 represents its starting point for building a resilient society. Based on the premises of new working possibilities, safe and affordable housing, efficient public transportation and green public spaces, the NEB program also underlines the principles of inclusiveness and participation (NEB, 2021). All these postulates are of crucial importance for the future generations of planners and architects and have to be included into the education process in order to ensure understanding and appropriate (re)action when facing urban reality and the accelerated dynamic of its change. Therefore, universities have had to strengthen their role in the environmental transition directed by the SDGs and the NEB objectives and intensify their application in the teaching process. The up-to-date models of learning have been introduced in order to ensure the harmonisation of the latest ecological trends, the adopted international declarations, ongoing research and professional practice.

In line with these activities and imperatives, the University of Belgrade - Faculty of Architecture has introduced a set of curricula modifications during the latest accreditation cycle (finalised in 2021/22), verified by both the National Entity for Accreditation and Quality Assurance in Higher Education (NEAQA) and the Royal Institute of British Architects (RIBA). Based on the 2030 SDGs and the NEB agenda, these changes contribute to the anticipated ecological transition of both the planning and architectural profession and have been positively validated by students, educators and practitioners.

In order to provide a better insight into these program changes, the paper will consider the development and application of three green-driven curricula for the courses conducted within the Master program in Architecture_ Module Urbanism: Sustainable City (obligatory), Ecopolis (elective) and the final/graduation work (Thematic research, Master Thesis, Master Project studio). The link between their content, global environmental agendas and the EU frameworks of/for sustainability will be established, while providing an insight into the results of their pedagogical process and public outreach.

2 New European Bauhaus vs. Educational Paradigms

Since 2018 and the adoption of the Davos Declaration, the environmental discourse of building and constructions has been gradually incorporated in many EU documents, as a signpost for the protection of our habitats. Due to this shift, the importance of architectural and planning profession was stressed, causing further changes in the strategical thinking focused on the sustainability and resilience of our future. The NEB initiative, essentially conceptualised as a culture-oriented EU policy, also follows this direction via the lenses of architecture and urbanism, merging the themes of sustainable development, aesthetics and inclusiveness. The prerogatives of multileveled integrative approach are considered within the social, ecological and technological spheres of future actions focused on the problems of intensified climate extremes, degraded environment and the consequences of COVID-19 (NEB, 2021).

Although the necessity to incorporate environmental imperatives into university curricula has already been addressed by various pedagogical initiatives since the mid 1960s, the rigid frameworks of inherited pedagogical approaches have frequently represented a serious obstacle to the updating of educational content and methodologies (Salama, 2009). Consequently, the planning and architectural schools have had to innovate their outdated programs, providing knowledge and skills adjusted to the needs of both the society and the profession, while continuously evaluating their real impact on society, space and overall sustainable development.

During the last 60 years, universities have been discussing and practicing various models of critical thinking in order to tackle a wide spectrum of ecological and social problems - from the New Design Pedagogy (mid 1960s - late 1990s), which focused on sustainable urban communities through the application of case studies, community-based design and participative curriculum models, over the impact of architectural education on society, urban/architectural space and its transformations (Beinart, 1981; Dutton et al., 1991; Crinson and Lubbock, 1994), to the role of architectural education for international practice/global exchange (Teymur, 1992) and the innovative methods used in design studios (Salama, 1995). The next period (mid 1990s - mid 2010s) was marked by the approaches related to the Critical inquiry and the Process-oriented design pedagogy (Salama, 2016), emphasising the role of flexible, integrated and evidence-based curriculum directed to contemporary problems and professional challenges (Boyer and Mitgang, 1996; Pilling and Nicol, 2000; Harriss and Widder, 2014). During the 2020s, the university programs were updated through the implementation of the

Interchangeable design pedagogies, the Community based design pedagogy and live project studios, also stimulated by the NEB platform (2021). All these steps, additionally supported by the latest digital tools, lead toward environmentally driven practice, based on global imperatives, inventive solutions and emerging theoretical frameworks.

3 Channelling the Action

The multiplying problems in/of our living environment, especially those concentrated or triggered by urban setting, have been thoroughly studied since the late 1980s, when the concept of sustainability was defined. Nowadays, the idea of sustainability is often accompanied by the concept of resilience, while their iterations and interpretations are included into contemporary theory and practice, strategies, policies and action frameworks. The NEB platform, as a specific stimulus for environmental transition, is also based on the ideas of sustainability and resilience, addressing them in an integrated manner, embraced by the schools of planning and architecture. On the theoretical level, the notion of sustainable development has been modified under the influence of the resilience theory (Holling, 2001; Folke et al., 2010; McPhearson, 2015), while its application in the sphere of urban systems has been gradually redefined, in accordance with their complex nature and the unpredictability of external influences. In line with this, the university programs have included the studies of many complementing, environmentally-driven concepts and principles - e.g. circular economy, green infrastructure or energy efficiency - which directly or indirectly address problems of cities, as the major nodes of global exchange and the unique testing grounds for innovative ideas oriented toward general well-being, economic growth and environmental quality. Since their importance has been recognised by various documents, their application could be considered as a necessity in the domain of spatial intervention and societal changes. Consequently, the actions highlighted by OECD (2020) instruct professionals to Rethink (stimulate local communities and raise their awareness), Regenerate (by increasing green infrastructure), Reduce (via strategies focused on resource footprint reduction), Reuse (by establishing sharing platforms) and Recover (resources and landfills). The application of these steps in education programs (and in practice) is usually directed to local public services (e.g. transport, waste, water and energy systems), while their real impact should be readable in the anticipated regeneration of natural environment.

The role of green infrastructure has also been tackled by a number of the EU documents and strategies anticipating a new development vision for the networks of natural and semi-natural areas. Able to provide ecosystem services and enhance biodiversity, green infrastructure, and its multi-scalar effect on space, stimulate social and territorial cohesion, sustainable development and overall human well-being (EU Commission, 2013; Simić et al., 2017). Therefore, its design should be considered in the process of architectural and urban conceptualisation and the introduction of upgraded typologies.

In line with these emphasised features and concepts, the NEB framework highlights their impact on built environment through the processes of co-creation, inclusion and cohesion, as well as three main pillars - design, delivery and dissemination. The interdisciplinary approach is favoured, while planners and architects should ensure the spatial manifestation of sustainability and resilience, also addressing the imperatives related to the sense of belonging, accessibility (both physical and digital), circularity, affordability and zero pollution (EU, 2022).

4 Introducing the Change, Implementing the Curricula

With the tradition of over 170 years, the education of architects and urban planners at the University of Belgrade - Faculty of Architecture has always been influenced by the unique context of Belgrade, the capital of Serbia and ex-Yugoslavia, an important node in Southeast

Europe. The current studies conducted at the Faculty are based on an integrated approach implemented by four departments (Architecture, Urbanism, Architectural Technologies, and History and Theory of Architecture and Art), providing a wide scope of knowledge and practical skills derived from technical and technological sciences, arts and humanities and social sciences. One of provided Master programs - Master studies in Architecture, consists of four modules (Architecture, Urbanism, Architectural Technology, Structural Engineering), all leading to the Master of Architecture title (M.Arch, with a reference to a selected module), also validated for RIBA Part 2 Status (since 2015).

The structure of studies is composed of several study units - Studios (design project, seminar), Module compulsory courses, Elective courses and Theoretical discourse (provided by all departments), Common compulsory courses (sociology/philosophy/economy) and Master diploma project (consisting of Thematic research, Master thesis, Master design and Master final project) and all of them integrate the NEB framework.

In the module Master in Architecture_Urbanism, entitled Sustainable City, both the theoretical/research-oriented courses and the design-studio underline connections between people and built environment while considering a number of topics related to sustainable and resilient development. The corses and studios are problem-based, facilitating the understanding of natural and socio-spatial phenomena, spatial typologies, processes and policies. The courses presented in the paper follow the same framework, although they belong to three different modes of educational curricula. The compulsory course Sustainable City 1 - Transformations is located in the first semester, Ecopolis is an elective course positioned in the second semester, while the Master diploma project is positioned in the fourth semester.

The first two courses are theoretical and research/project based, while the third one combines these approaches with the design-driven method in different phases. Due to the project orientation, the active participation of students is enabled, tackling a variety of location-specific problems though the experimental and innovative game-based curriculum (Chen and Hoffman, 2017) and the reflexive thinking and journaling (Kelly, 2006, 2010). Simultaneously, all three curricula apply predictive learning and future design while estimating the environmental impact of anticipated/planned changes.

Sustainable City 1 - Transformations represents a course which enlightens the trajectories of urban transformations used as the main stimuli of urban development. Conducted by Associate Professor Dr. Vladimir Mihajlov and Assistant Professor Dr. Ivan Simić, it considers the process of adaptation leading toward a sustainable urban future, as well as the contributing premisses. During the course, the importance and effects of SDGs and the NEB postulates are continuously emphasised, especially the topics of green urban transformation. Consequently, students are directed to critically perceive origins and effects of occurring problems, apply theoretical knowledge on urban design and the conceptualisation of urban communities, while considering planning policies and legislation influencing a final result. The course also introduces the relevant models of sustainable cities and lifestyles, greening strategies, resilient urban practices, as well as the use of sustainable materials. The curriculum is structured around ex-cathedra lectures, students' research (group work) and a pilot project proposal.

In line with the integral, multidisciplinary approach promoted by the NEB, the lectures include presentations of experts from various fields (e.g. landscape ecology, urbanism, biology, hydrology, geology, transportation, social sciences etc.), elucidating their professional insights. Students focus on different phenomena discussed by groups through a critical-argumentative

debates, and the course outcome is defined as a Civil Initiative Project Proposal. It is developed in a format which could be applicable for different funding options, potentially leading to the improvement of selected urban environments through the implementation of public innovations, tactical urbanism or business-driven sustainable solutions. The final assessment is based on the NEB criteria.

The inspiring example of this practice was implemented through the participation of Marina Papović, the operation development manager in CirEkon, who held two lectures on the application of circular economy in building process, emphasising several elements:

- the growing awareness related to the use of circularity,
- the need for a holistic approach to circularity in architecture,
- the focus on the process of recycling and circular economy during the design of buildings,
- the presence of inadequate product standardisation as a drawback for the transition into circular economy,
- consideration of building optimisation and the operational aspects of circular economy.

These lectures had two successful educational impacts. The first one was the participation of student teams in the 2021 CirEkon and EIT Food Competition for Engaging Citizens in Circular Economy, where one of the teams won the 1st award (Figure 1), while the second one was a workshop during the 2022 Balkans Go Circular international conference, where the most important experts in the field of circular economy presented various solutions for the regional and global challenges (Figure 2).

Figure 1: The project proposal for improving the sustainability of urban environment in Pancevo (Students: Emilija Drndarski and Sara Brkić. Supervisor: Associate Professor Dr. Vladimir Mihajlov) - 1st award at the 2021 CirEkon and EIT Food Competition for Engaging Citizens in Circular Economy.

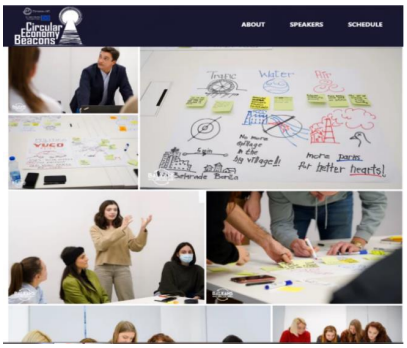

Figure 2: The workshop Balkans Go Circular: The database support to the Civil Initiative Project Proposals, organised by the EIT Climate KIC and CirEkon d.o.o. (Serbian Chamber of Commerce, 2022). The participants were students from the course Sustainable City (Source: https://circular-beacons.net/wrapping-up-the-year-with-balkans-go-circular-conference/)

The curriculum of the course **Ecopolis** encompasses diverse aspects of the ecological resilience of cities, their urban design, planning, adaptation and mitigation by introducing the contemporary ecological concepts of urban resilience which have significantly changed urban theory and practice over the last few decades. The students also learn about the vital role of green infrastructure in creating resilient urban environments, focusing on nature-based solutions (NBS) and addressing social, economic, and ecological challenges effectively. The analysis of the selected NBS projects, particularly those recognised as the finalists of the "Reconnection With Nature" category of the NEB Awards, enables students to gain an insight into the integration of natural, social and built components. Additionally, the course emphasises the role of biophilic design, circular economy and urban recycling, as well as the adaptive reuse of buildings, shifting the focus toward the efficient utilisation of resources and encouraging innovative design approaches to new purposes. The second part of the course is directed toward the application of presented models and strategies across the selected case studies in Belgrade or other Serbian cities.

The case selected for the 2024 spring semester is the area of Reva wetlands on the left bank of the river Danube, in the central Belgrade municipality of Palilula. This area is exceptionally important due to the wet habitats and marsh ecosystems created along the left bank of the river, on its course through Belgrade (Figure 3). Their role is multiple - in addition to being part of the flood protection system, these areas have rich biodiversity and a number of protected species of amphibians and birds. There are three nests of the white-tailed eagles in the area, representing an exceptional value for the urban ecosystem. In the context of climate change, this type of area could be considered as a carbon sink.

Figure 3: Bara Reva wetland (Source: Authors)

Due to the specificities of the curriculum and the selected case study, the teaching methodology of this course is also based on interdisciplinarity and the engagement of various actors - visiting scholars and practitioners (biologists, hydrologists, climatologists etc.), participating in both the theoretical and the applicative segment. The various local stakeholders, living and working in the area, or actively engaged in nature conservation, also play an important role. Consequently, the main local stakeholder is the White Heron association, which brings together the local residents from the settlements located in the hinterland of the Reva wetland and the banks of the Danube. Being actively engaged in protecting this area from excessive and unplanned urbanisation, they represent the most important source of information on the area and its problems. The association presented the genesis of settlements on the left bank of the Danube, mapped important spatial determinants during a workshop (Figure 4) and provided an insight into their vision of development - the Danube Park. This project envisages the rehabilitation of the Reva reservoir and the introduction of various contents - such as the Danube Park building, a network of pedestrian paths, a bird observatory, but also a cycling infrastructure as a part of the international routes Eurovelo 7 and 11, passing through this area. The students critically considered the proposed program of activities for the Danube Park, which was the starting point for their intervention proposals.

Figure 4: Meeting with the members of the local association White Heron (Source: Authors)

The theoretical part of the course provided basic theoretical principles of urban ecology and its links to urban design. The experts from various fields were invited as guest lecturers, while some of them also participated in several workshops with students, supporting their research and project ideas. One of them highlighted the role of nature based solutions in flood management (Dr. Ratko Bajčetić, Faculty of Environmental Management in Novi Sad) and contributed to the design phase of the Master plan of the Reva wetland. Additionally, the workshop held by Dr. Tanja Vukov and her colleagues from the Institute for Biological Research, opened the topics of mapping and description of the wetlands system in the case area (the boundaries of habitats, plant and animal species, zones of human intervention), supporting the further process of environmentally acceptable planning and design (Figure 5).

Figure 5: Workshop with the biologists from the Institute of Biological Research (Source: Authors)

The final step of the education process conducted during the program Master in Architecture_Urbanism represents a set of courses within the **Master diploma project**. The main idea of its complex task is to summarise the knowledge obtained during four semesters while applying various methods of research, formulation, conceptualisation, design and materialisation on a comprehensive urban and architectural program. The work during Thematic research, Master thesis, Master design and Master final project is individual, although supported by a mentoring committee and a supervisor, while the general framework and the focus area are predefined on the level of each studio. In line with the sustainability imperatives of the whole program, the objectives embedded in the NEB initiative are integrated into a thematic scope and further developed by students/candidates.

The example of the studio entitled NS 2030: ECO-HORIZONS (supervised by Professor Dr. Aleksandra Stupar in 2021/22) demonstrates this practice on several levels, simultaneously triggering environmental, social and technological manifestations of sustainable and resilient transformations. The students initiated the process by studying selected themes related to urban regeneration, industrial archeology, regenerative architecture, climate adaptation, flexible space or nature based solutions. The concepts of circular economy and energy transition were also taken into consideration, along with more specific themes (e.g. the integration of animals and insects into living and working environment). After the thematic research, their thesis used the general framework/topic as an initiator of both further research on the proposed site and the preferred concept of transformation, highlighting the identified urban phenomena, analysing representative cases, and finally defining a program for a project. The course is concluded by a public defence, which elaborates a concept, regulation and design of an urban area and its specific content.

The studio used a part of the industrial zone of Novi Sad as a polygon for intervention, focusing on the abandoned site of Agrohem, a fertiliser manufacturer, previously exposed to a significant pollution. The site is situated at the city entrance, nearby the connection of the Danube River and the Danube-Tisa-Danube canal. Taking into consideration the SDGs and the NEB principles, the anticipated transformation was also guided by the ideas of the Gaia hypothesis, supporting the setting of a new sustainable node, based on the active use of recycling, innovative business models and activities, green regeneration through biophilia and the reduction of carbon footprint.

The park of ecological and psychological renewal_biophilic design, by Milica Brajović, is a project driven by biophilia on all levels, merging the context, natural cycles and existential principles in order to regenerate the site, preserve resources and develop environmental awareness (Figure 6). The community cohesion is supported by the introduced activities, ensuring integration, increasing the interest for natural environment and, consequently, contributing to the sustainability of a created mini-ecosystem. The phases of the implementation are also planned in line with the imperatives of economic, social and environmental sustainability. This project later received the prize of the 2022 International Urban Planner Exhibition of Serbia (student category) and the annual award 'Milorad Macura', granted by the Institute for Architecture and Urbanism of Serbia for the best master diploma project in architecture (2023).

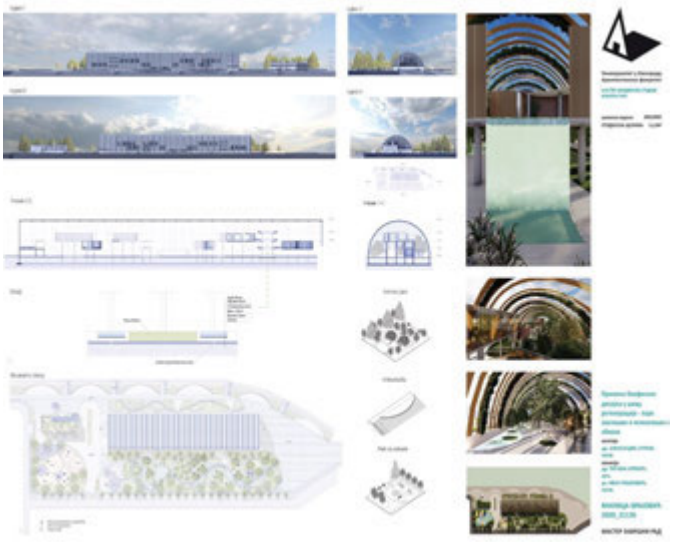

Figure 6: NS 2030: ECO-HORIZONS. The park of ecological and psychological renewal_biophilic design (Student: Milica Brajović. Supervisor: Professor Dr. Aleksandra Stupar)

The general framework of the ongoing Master studio project (also supervised by Professor Dr. Aleksandra Stupar, 2023/2024) uses the elements of the same environmental paradigm, included in the NEB agenda. Entitled Vista Alegre: The Kaleidoscope of Urban Innovation, the studio continues to explore the broad spectre of innovation - spatial, social and technological, highly integrated with ecological principles. During the Thematic research, students explored the general topics of sustainable transformations, focusing on more specific aspects according to their preferences - from urban regeneration, climate adaptation and alternative energy integration, to biophilic and biomimetic design. Due to project location being in Madrid, the students had several online workshops with local experts and guest professor Dr. Manuel Collado Arpia, discussing their research. The selected aspects and phenomena were developed in their theses, shaping the specificities of future project programs adjusted to the local context.

The selected area of Vista Alegre, within the Carabanchel district of Madrid, provided an interesting polygon due to its history dating back to the 18th century, when it appears in plans as a rural estate. Since then, the character, activities and ownership of the space have been transformed several times, leading to a state-owned, fragmented area, with multiple activities related to health, education, institutional services, as well as a botanical garden and public green spaces. Bearing in mind the unique physical, functional and natural characteristics, as well as the recognisability of this unit and its environmental potential, possible interventions could stimulate its opening toward the city, while respecting its inherited historical and social values. Based on the 2030 UN SDG goals and the current paradigms of resilient, eco, creative and healthy city - a city of well-being open to all - the possible interventions could target the landscape, public spaces and built fabric, a total or partial transformation and regeneration, as well as the (re)consideration of continuity and discontinuity.

Among the programs formulated within the theses - highlighting the concepts of learning cities, regenerative healing spaces, biophilic/nature inspired design, urban acupuncture and local

community activism - the project entitled Vista Alegre: Resilient ConnectScape (by Tamara Mladenović) could be distinguished as an inventive approach to urban resilience though socio-spatial defragmentation and connectivity. Inspired by the concepts of integral urbanism and the idea of learning from nature, the socio-ecological diversity is explored in order to enhance urban system resilience to various challenges. Examining the related theories and boundary perception, the complexity of urban space is determined, as well as the main problems and potentials. The project focuses on the development of a new social centre and a Resilient Hub, supporting long-term sustainability and adaptability, while instigating social cohesion. With an innovative combination of content and spatial units, relying on the natural elements of the site, the project aims to achieve a comprehensive resilience of the area and its neighbourhood (Figure 7).

Figure 7: Vista Alegre: Resilient ConnectScape (Student: Tamara Mladenović. Supervisor: Professor Dr. Aleksandra Stupar)

5 Conclusion

The presented courses support the ideas included into the 2030 SDGs and the NEB initiative, creating a stimulating learning environment focused on the occurring contradictions and uncertainties of contemporary urban life. The general ideas of sustainability and resilience are

tested on different spatial levels and scales, instigating the interaction between society, space and technology and potentially contributing to the increased environmental awareness of all involved stakeholders while increasing the general wellbeing.

The continuous upgrading and modernisation of university curricula is a necessity in a hyper-dynamic world, in which planners and architects could have an important role in transmitting the ideas of sustainability. The green transition should not be included only in the catchy titles of design courses but studied on both the theoretical and practical level, influencing the generations of future professionals whose ideas will shape urban reality in the years to come. At the same time, introducing the most recent topics and paradigms stimulated by the NEB ideas, global and local strategies and up-to-date visions and projects, certainly has an impact on the students' perception of emerging problems, the conceptualisation and evaluation of proposed solutions and the personal and collective responsibilities. Directing a path to eco-friendly actions, the master program Sustainable City highlights the key features of environmental change. Therefore, it could be also seen as a unique medium of networking, interchange and integration, providing a fertile ground for a crossover between the formal and informal flows of knowledge, supported by multidisciplinary experts and open to local specificities.

Track 11: Housing

HOUSING - Planning for affordable cities and new models of living

Chairs:

- Massimo Bricocoli, Politecnico di Milano
- Bruno Marot, Union sociale pour l'habitat
- Francesca Ferlicca, Sciences Po Paris

Keywords: *housing, housing inequalities, greening buildings, housing renovation, demolition policies, housing renovation; urban densification*

Housing has long been overlooked in the policies of most countries, but lately, the housing crisis has once again become a prominent issue. Could housing become a pivotal focus of policies once more? The shortage of affordable, secure, and high-quality housing for the working and middle-class population has had far-reaching consequences on their overall well-being, living standards, and fundamental rights. Housing is particularly susceptible to climate-related challenges and represents a substantial energy consumer. This creates an immediate dilemma, as eco-friendly housing solutions may unintentionally lead to social exclusion. The growing disparities in housing within Europe have the potential to undermine the progress achieved in green transition initiatives. Meanwhile, individuals with higher incomes have reaped financial rewards and benefited from favourable fiscal and economic conditions.

These factors have exacerbated the gap between property owners and income earners or recipients of social assistance, further intensifying the socio-economic exclusion faced by marginalised communities, such as migrants, refugees, racial and ethnic minorities, as well as other disadvantaged groups like low-income working-class individuals and the elderly. This has led to an increase in segregation, with socio-spatial divisions likely intensifying even further since 2011 due to the impact of various crises, including the climate crisis, the global financial crisis, challenges related to immigrant integration, the COVID-19 pandemic, and energy crises, all of which have exacerbated global housing inequalities.

This call will focus on housing as a game-changer. Topics include a recognition of new issues, actors and policies. Some examples may be the European Union's (EU) initiatives for a green transition and their effects on housing inequalities and the EU's strategy for adapting to climate change; the adoption of nature-based solutions to safeguard ecosystems; the impact of policies for greening buildings and housing renovation; the outcome of demolition policies and housing renovation; the Just Transition initiative potential innovations; more equitable policies on distributing benefits from the green economy; impacts of broader policies on urban densification and hub-based development…

Housing improvement in historic districts oriented towards the people's "sense of gain": A case of Shanghai, China

Miao Hu
Affiliation: Tongji University, College of Architecture and Urban Planning
Email: humiao@tongji.edu.cn

Abstract

In recent years, China proposed the concept of people's "sense of gain" as the highest criterion for measuring urban development. This paper explains the connotation of the concept and suggests it emphasizes comprehensive material and spiritual development, promotion of fairness and justice through community participation, and mechanism and policy innovation. In Shanghai's practices of housing improvement in historic residential districts, how does it foster a "sense of gain" among the communities? The paper reviews three housing improvement methods in Shanghai since the 1990s and examines their changes, efforts, experiences, and shortcomings from the aspects of the content of housing improvement, the degree and frequency of residents' participation, and mechanism and policy innovation. The paper suggests, that in Shanghai's housing improvement practices, the goals are shifting from the mere expansion of living space to considering spiritual aspects such as social relationships and place attachment, and active and deep community involvement enhances residents' satisfaction and the fairness of the renewal outcomes. All these contribute to increasing disadvantaged groups' "sense of gain".

Keywords: people's sense of gain, housing improvement, historic preservation, urban regeneration, Shanghai

0. Introduction

The people's "sense of gain" has emerged as a central concept in China's recent urban development. In 2014, China introduced the notion that the primary criterion for evaluating the effect of urban development should be whether the people experience a "sense of gain". This term embodies vital principles of fairness and inclusivity, aiming to ensure that disadvantaged groups share the fruits of urban development.

In historic districts, such as the historic center of Shanghai, live many disadvantaged groups, including the elderly, domestic migrants, and low-income individuals. Due to historical factors, they were "left behind" amid rapid economic development and significant social change following the Chinese reform in 1979. Their immediate aspiration is to improve old housing conditions, have private bathrooms and kitchens, and elevate overall quality of life. How does Shanghai address this issue and foster a "sense of gain" among these communities?

1. Concept of people's "sense of gain"

This paper begins by elucidating the genesis, context, and essence of the concept of people's "sense of gain". Originating from a directive issued by the Chinese central government during a 2014 conference, it emphasized the necessity of implementing a series of politically viable reform measures to effectively showcase the value of the reform agenda, thereby enhancing the public's "sense of gain". Subsequently, the concept of "sense of gain" gained widespread traction, featuring prominently in numerous official reports and formal discourse of the Chinese government. For instance, phrases such as "'Sense of gain is the ultimate test standard for government work and the ultimate goal of all work,'" and "'Sense of gain' has emerged as the litmus test for assessing the effectiveness of reforms," underscore its pivotal role in evaluating governance efficacy.

The term "sense of gain" primarily refers to the positive sentiment experienced by individuals following the dividends of political and economic reforms. It underscores the importance of ensuring that "everyone," particularly marginalized groups, perceives tangible material and spiritual benefits arising from social and economic advancements in their daily lives. Furthermore, this concept advocates for active public engagement in national or municipal development endeavors, enabling individuals to contribute to and partake in the resulting benefits. It bears resemblance to the proverbial notion of "no pain, no gain."

This concept reflects three shifts in China's current development:

1). Transitioning from a focus solely on economic growth and material infrastructure, such as GDP expansion and urban CBD construction, to a more holistic approach that emphasizes the sustainability and integration of economic, social, cultural, and environmental development. Evaluation of development now centers on whether everyone has access to essential resources like healthcare, education, employment opportunities, green spaces, and housing, rather than merely relying on economic indicators.

2). Increasing emphasis on fairness, justice, and inclusive development. Historically, China concentrated resources in certain regions, groups and industries to spur rapid economic growth, hoping to drive nationwide development. However, this approach often excluded disadvantaged groups, leading to their "sense of deprivation." For instance, urban renewal projects resulted in the demolition of older housing in city centers, replaced by upscale high-rise houses, office complexes, or Disneyfied historical tourist attractions. Yet, original residents had to leave their homes and move to remote suburbs, highlighting the need for a broader societal benefit. Hence, the concept of "sense of gain" underscores the importance of benefiting all, especially marginalized groups, through targeted social resource allocation, rectifying decades of neglect.

3). Reforming institutions and mechanisms to solidify the comprehensiveness, sustainability, inclusiveness, fairness, and justice of development efforts. The concept of the "sense of gain" aligns with the current trends in historical preservation and urban regeneration, which emphasizes protecting the daily lives of ordinary people in historic districts and encouraging residents' participation in community governance. In the realm of historical preservation, decades of development, influenced by concepts such as the Charter of Athens, the Charter of Venice, "historic urban landscape," and "urban living heritage," have led to a consensus: preservation efforts should extend beyond grand monuments to include "secondary" heritage closely linked to ordinary people's everyday lives, such as historical residential buildings and districts. Moreover, there is a growing emphasis on involving community stakeholders in preservation initiatives. Urban regeneration, also, has gone through the phase of large-scale demolition and reconstruction, focusing now not only on the improvement of the urban environment and economic growth, but also on the improvement of community environments, promotion of place attachment, and cultivation of community spirit through small-scale, resident-engaged "community planning.

Incorporating the notion of the "sense of gain," the preservation and renewal of houses in historic residential districts should: 1) prioritize the comprehensive advancement of both material and spiritual aspects of human well-being; 2) guarantee community participation rights and equity; 3) drive innovation in mechanisms and policies.

2. Review of the housing renewal process in Shanghai's historic districts since the 1990s

In chronological order, the paper examines how Shanghai enhanced people's housing conditions over different periods since the real estate boom in the 1990s.

Shanghai's central area is characterized by a significant number of historical houses, primarily comprising lane residences (Lilong houses) from the early 20th century concession period, blending Chinese traditional and Western architectural styles. Another prevalent type is the Workers' New Village, constructed for the working class in the 1950s following the establishment of the People's Republic of China. The construction of Workers' New Village continued until the 1990s when the Chinese real estate market flourished. These housing types form the fundamental urban fabric of central Shanghai.

These historical houses serve as tangible reflections of Shanghai's political, economic, social, and cultural evolution over time, embodying collective memories and everyday life experiences of its residents. Consequently, they hold significant historic preservation value. However, due to initial economic and technical limitations during construction, coupled with historical factors, these houses often exhibit issues such as aging structures, outdated floor plans, cramped living spaces, and a lack of modern amenities like independent and private kitchens and bathrooms. These factors render them incompatible with contemporary living standards and fail to meet residents' needs.

Presently, most residents inhabiting these historical houses are elderly individuals who have resided there for decades or low- and middle-income groups unable to afford new commercial housing. Many are former laid-off workers who experienced serious employment challenges during China's economic reforms in the 1990s. Additionally, some residents are domestic migrants seeking livelihoods in Shanghai and young recent graduates. These residents generally express a desire to renovate the old houses.

In the 1990s, China ceased large-scale construction and distribution of state-owned houses, pivoting towards vigorous development of the real estate market and renovating historical houses. Renovation efforts varied across time:

1) 1990s: reconstruction

In the 1990s, many historic houses in bad maintenance in Shanghai underwent reconstruction, involving the relocation of residents to new suburban homes and the demolition of old houses to make way for new high-rise residences aimed at the middle class.

In 1991, as part of market economic reforms, Shanghai implemented a housing reform plan, discontinuing the longstanding practice of providing subsidized welfare housing at very low rents and transitioning to the commodity housing market. Residents were required to purchase commodity properties if they needed new houses.

At that time, Shanghai faced a critical housing shortage, with the per capita living space remaining extremely low despite decades of worker housing construction. The housing area constructed in Shanghai from 1949 to 1990 was 2.8 times the total housing area of Shanghai in 1949. However, by 1990, the per capita living area in Shanghai was still only 6.6 square meters per person, with over 470,000 households residing in less than 4 square meters of space. To address this issue, the Shanghai Municipal Government launched the "365 plan" in 1992, aiming to increase the per capita living area to 10 square meters by the end of the 20th century

through the demolition of 3.65 million square meters of old housing with very poor living conditions.

Reconstruction of old areas, known as "Jiu Qu Gai Zao" in Chinese, involves the complete demolition of very poor old houses, predominantly Lilong residences of poor quality. Residents are compensated monetarily or provided with new suburban homes based on family size or the original housing area. Many former city center residents have been relocated to the suburbs, making this the primary method for improving housing conditions in Shanghai's historic center. Following the demolition of old houses, high-rise residential or office buildings were constructed on most sites to balance demolition compensation funds and stimulate Shanghai's economy. This attracted substantial foreign and domestic investment in real estate development, leading to rapid growth in the real estate sector. By 2002, real estate investment accounted for 30% of total social investment, establishing it as a key pillar industry for economic development.

This reconstruction method facilitated rapid economic development in Shanghai and also led to the creation of a significant number of new housing units within a short timeframe. By 2000, the per capita living area in Shanghai had exceeded 14 square meters, addressing a problem that had persisted for over 40 years. Many residents who previously lived in small, old Lilong houses relocated to newly constructed modern high-rise residential buildings, substantially improving their living conditions.

However, the drawbacks of this approach are evident. Before the reconstruction, these lower-income groups resided in the historical city center, benefiting from convenient transportation and comprehensive public services, including medical care, education, and entertainment. Moreover, numerous small local businesses provided affordable goods and services. Importantly, residents had fostered deep bonds and close social networks over time, offering mutual material and emotional support. As residents relocate to new suburban settlements, they lose access to the low-cost lifestyle and conveniences of the city centre, as well as the sense of belonging fostered by tight-knit social networks.

2) 2000s: Indoor repair and renovation

In the 2000s, indoor repair and renovation emerged as a prominent strategy for revitalizing old houses in Shanghai, known as “Zong He Xiu Shan” in Chinese. While preserving the primary structure of these buildings, modest kitchens, bathrooms, and other facilities were added. This approach gained traction since most of the low-maintenance historical Lilong houses were demolished in the 1990s and new historical preservation policies were implemented. This strategy particularly targeted old housing with better maintenance quality and a relatively recent construction time. As part of the renovation initiative, funds were allocated by the government to upgrade roofs, water supply, and power facilities. Additionally, small, detachable private kitchens and bathrooms were created within each household, replacing the previous communal arrangements where three to five families shared public facilities.

The advantage of this approach lies in allowing long-term residents to remain in their homes in the city centre, preserving established social networks and meanwhile offering the opportunity for improving living conditions. However, it is most effective for historical houses that have been well-maintained, but for those that have not been adequately maintained, this method may impose additional burdens on historical buildings without alleviating residential density.

3) 2010s: Restoration of old houses to their original appearance

From the 2010s on, there has been a trend towards restoring old houses to their original appearance, focusing on preserving historic features while addressing the aging structures and outdated interior floor plans by rebuilding, known as "Cheng Tao Gai Zao" or "Yuan Yang Chong Jian" in Chinese. Architects tailor indoor plans for individual households, providing private kitchens and bathrooms. Residents are given the choice to stay or relocate, with various compensation options provided.

Some historical buildings possess significant cultural value warranting preservation, despite their poor maintenance and lack of modern amenities for residents. Given the impracticality of adding a very small kitchen and bathroom inside these buildings, Shanghai implemented a new approach in 2016. The new method involves restoring the buildings to their original appearance, and keeping the historic features of the houses unchanged while reconstructing the internal structure and spatial layout. This process entails reducing the area of original public spaces like corridors and re-purposing them to accommodate private kitchens and bathrooms for each household. Additionally, to alleviate overcrowding and increase the available indoor space, Shanghai offers residents various options: They can choose to remain in their current homes, or to relocate to alternative residential areas, benefiting from monetary or housing compensation.

Compared to the indoor repair and renovation method of the 2000s, this approach offers several optimizations. It not only preserves the townscape, appearance, and features of historical buildings, but also repairs and restores aging structures, optimizes indoor spatial plans, greatly improves living conditions for residents, and preserves social relations in the neighborhood. This comprehensive approach considers architectural protection, improvement of living conditions, maintenance of social relationships, and residents' preferences regarding staying or leaving. Generally, residents express satisfaction with the outcomes of this housing improvement approach.

However, this approach also has drawbacks: it prioritizes the improvement of residents' living conditions, which entails renovating the indoor spaces and structures of historical houses. As a result, only the external appearance of the buildings is frequently preserved. Additionally, to accommodate the need for increasing indoor living space, restoration of historical buildings may inadvertently lead to changes in their width and height, altering the original size of these structures.

This approach also encounters certain challenges. For instance, when designers reallocate the expanded indoor spaces among households, they must ensure each household receives an equitable and comparable area for kitchens and bathrooms to prevent conflicts and dissatisfaction within the neighborhood. Additionally, after the meticulous restoration and renovation of historic houses, funded by the government, some residents opt to profit by renting their rooms to visitors at high prices rather than continuing to reside in the historic districts. This practice contradicts the original aim of preserving social relations within these areas.

3. Efforts and trends in housing improvement in Shanghai's historic districts from the perspective of "sense of gain"

The paper discusses Shanghai's efforts and trends in improving housing conditions in historical districts to give residents a better sense of "gain":

1) In terms of the content of the housing renewal

The urban reconstruction of the 1990s primarily aimed to swiftly enhance the overall housing situation in Shanghai's historic centre, expand the total housing area and alleviate the city's longstanding housing shortage. The emerging real estate industry was also heralded as the cornerstone of economic growth. However, the focus on providing new, larger, and modern housing largely disregarded the spiritual needs of residents experiencing extreme "housing poverty," including place attachment, interaction with neighbours, social relations, transportation convenience, access to public amenities, and affordable goods and services.

While some young residents express satisfaction or strong anticipation regarding relocating to new high-rise housing in the suburbs, many long-time residents are hesitant to leave their homes and neighbourhoods where they have spent a significant portion of their lives. Influenced by the traditional Chinese value of "settling down on their land instead of relocating," some elderly residents strongly dislike living in sparsely populated suburbs. Some citizens attribute the death of their elderly family members shortly after relocation to the move, while others prefer to sell their new houses in the suburban resettlement area and purchase second-hand homes near their original residences.

The indoor renovation strategy of the 2000s took a "conservative" approach, primarily focusing on integrating modern amenities like compact private kitchens and bathrooms into existing structures with minimal alterations to the building framework. This approach aimed to preserve the social dynamics of the neighborhood and residents' attachment to their original homes, safeguarding both the functional and emotional ties within their social networks. However, many residents perceive indoor renovation as a temporary and interim solution to housing issues, as overcrowded living conditions, outdated floor plans, and inadequate maintenance persist. Consequently, there is continued anticipation for more thorough housing improvement initiatives.

In the 2010s, restoration efforts take a more thorough approach, preserving the style, characteristics, and appearance of historical houses while repairing and reconstructing building structures and re-planning outdated or unsuitable indoor living space layouts. Additionally, original living patterns are maintained. Living in row-patterned low-rise dwellings, row-patterned multi-storey collective dwellings, or point-shaped high-rise dwellings, peoples' daily life can be significantly different. This approach prioritizes the preservation of social relations within neighborhoods and respects residents' preferences regarding staying or relocating. Residents express the highest satisfaction with restoration, as it addresses both material and spiritual needs.

2) In terms of community participation

The 1990s reconstruction process involved only two consultations: one regarding the community's willingness to proceed with the reconstruction project, and another concerning residents' agreement to sign contracts after the government formulated the compensation plan. Community decisions required unanimous agreement, forcing residents to either collectively accept relocation or remain in aging, crowded homes without improvement opportunities. Some residents felt compelled to agree with others' decisions due to pressure from neighbours and the

government, despite personal reluctance to relocate. Additionally, residents had almost no say in their relocation destinations.

In indoor renovation projects from the 2000s, the frequency and degree of residents' participation increases. Residents are initially asked to vote on whether to proceed with the renovation. Subsequently, representatives of residents gather opinions and demands in public meetings before designers formulate renovation plans. Following the completion of the preliminary plan, residents are consulted for feedback and suggestions. Once the plan is finalized, consent and signatures from each household are necessary before implementation. Compared to the reconstruction projects of the 1990s, resident participation in indoor renovation projects has increased both in depth and frequency. However, residents still wield limited direct influence over plan formulation, as indoor renovation plans are primarily developed by architects independently. Furthermore, public meetings often feature only resident representatives invited by local authorities, rather than the entire resident body. Additionally, indoor renovation plans lack sufficient flexibility and adaptability to accommodate the diverse needs of different households.

In the restoration projects from the 2010s, the spatial interests among the residents involved become much more complex, because both the building structure and interior space need to be completely reshaped. So the depth and times of residents' participation have also further increased. They are directly involved in the process of restoration design. As residents' "partners", the architects discuss repeatedly with each household about their needs of design from the beginning of the project and customize different plans and designs for each household. Details involve the size of the kitchen and bathroom they want, the combination of facilities, and even the location of the sockets. In addition, architects must coordinate residents' conflicts about the use of space to avoid injustice, such as the encroachment of public corridor space, or the uneven increase of living areas for different households in the restoration. In short, in the restoration projects from the 2010s, residents can participate in the entire process and even "control" the restoration design of their rooms in the historic houses. Residents put "efforts" in the restoration design, and thus "gain" satisfactory results of their renewed rooms in the historic houses. During the restoration process, complaints about injustice from residents are reduced.

3) In terms of institutional and mechanism support

The development of the community planner system, the introduction of various compensation policies, and the promulgation of relevant technical documents have provided support. In the reconstruction from the 1990s, the government did not appoint planners to contact the communities. Planners had little understanding of the communities and the communities had little understanding of the reconstruction plans. In the later stages of the indoor renovation project of old houses, the local government began to appoint specific planners to maintain long-term contact with the community to listen to the needs of community residents and their opinions on the plan. This approach gradually formed a more mature "community planner" mode, which was promoted by the Shanghai government in 2016. The role of "community planners" is pretty obvious in the restoration project in the 2010s: they are not only an intermediary between the government and the community but also professional and technical personnel who accompany residents to participate in the design process. Sometimes the community planner system also needs to recruit social workers, to coordinate neighborhood conflicts about the use of space, which are accumulated during a long time, so that the housing improvement project can go on smoothly.

4. Discussion

In short, this paper examines housing renewal in Shanghai's historic center and discusses the changes, efforts, and experiences in China's recent urban development oriented toward the people's "sense of gain". The goals of housing renewal are shifting from mere expansion of living space to considering spiritual aspects such as social relationships and place attachment. Active and deep community involvement enhances residents' satisfaction and the fairness of the renewal outcomes. All these contribute to increasing disadvantaged groups' "sense of gain".

The reconstruction of historic residential districts from the 1990s was more concerned with the increase in the total housing stock in Shanghai in a short period, the increase in per capita housing area data, and the elimination of extreme "housing poverty", which resulted in the relocation of many residents from the city center to high-rise residential buildings in the suburbs. Although residents' living area was increased and they had modern kitchens and bathrooms, they were deprived of convenient public services in the city center and emotional support from their old neighborhood. Residents have also few rights to choose whether to stay in or leave their old houses according to their wishes.

In the comprehensive indoor repair from the 2000s, residents' participation increased and every resident could express opinions during the plan publicity stage, although they were unable to further control the process of plan design and the "space production". Not only were private kitchens and bathrooms added to residents' rooms and living conditions improved, but it also took the preservation of residents' social relations into account, and residents can continue to live in the city center. However, residents still do not have many choices. They can only make a collective decision as a whole community: either all of them must accept the repair plan, or all of them must wait for reconstruction and relocation, or all of them must maintain the status quo unchanged.

In the restoration projects from the 2010s, residents, accompanied by community planners, were able to influence the process of the restoration design and "privately customize" the restoration plan for their rooms. It avoids injustice complained by the residents such as the uneven distribution of increased living area. They can choose to continue renting these rooms in the state-owned houses, purchase these rooms at discounted prices, or accept compensation and move elsewhere based on their wishes. This gives residents greater freedom and avoids the situation where the "minority obeys the majority". The current housing renewal project in Shanghai comprehensively considers factors such as historic preservation, improvement of living conditions, maintenance of social relations, and respect for the wishes of residents, so that residents have a greater "sense of gain" both at the material and spiritual levels.

However, the current housing improvement practice in Shanghai is still questionable. For example, there is a "contradiction" between historic preservation and the improvement of living. In the restoration projects from the 2010s, the government paid more attention to improving the living conditions of disadvantaged groups, so the indoor space was completely renewed and rearranged and the building structure was rebuilt, leaving only the appearance and main features of the historical building unchanged. Due to the need to increase available indoor space, the height and width of buildings often increase. This somehow injures the authenticity of historical buildings. As for historic preservation, the complete restoration projects in the 2010s are not as good as the "reversible repair" in the comprehensive repair projects of historic houses in the 2000s.

Towards an inclusive and developmental housing regime in Chinese megacities? Evidence from the implementation of the Affordable Rental Housing Programme in Shanghai

Author's Name: LIN ZHOU[1], CHEN CHEN[2]

Email: 2210271@tongji.edu.cn[1]; tjupchenchen@tongji.edu.cn[2]

Abstract

Affordable Rental Housing (ARH) is the latest social rental housing programme proposed by the Chinese government, which forms part of the social housing system and is primarily designed to alleviate the housing difficulties of the inflowing new citizens and young people in megacities, thus moving towards a developmental housing regime. Focusing on the implementing process of the ARH program in Shanghai, this study observed the location of ARH in the housing system, the project types, provision mode, spatial distribution, and affordability of ARH, then explored the tensions between the government and stakeholders through the conceptual lens of governance structure. This study enriches the conceptual and empirical understanding of ARH in China and enriches the understanding of housing regime transformation in China.

Keywords housing regime; rental housing system; affordable rental housing (ARH); public rental housing (PRH); Shanghai

1. Introduction

It has been long argued that the East Asia region is embarking on the so-called 'productivism welfare regime', however, certain East Asian societies such as Singapore witnessed the emergence of a developmental welfare regime. More recently, some scholars considered an ongoing transformation from a productivist housing regime to a more inclusive and developmental housing regime in China since 2016 when the central government encouraged the simultaneous development of the rental and sales markets. Particularly since 2020, the Affordable Rental Housing (ARH) programme was initiated as one of the three programmes that make up China's current social housing system, the housing regime transformation has become a debatable issue, stimulating debate over whether China is moving towards a more inclusive and developmental housing regime.

Esping-Andersen's "Worlds of Welfare Capitalism" has provided a powerful framework for comparative welfare state analysis(Esping-Andersen, 1990, Esping-Andersen, 1999). Upon this, Holliday introduced a fourth "productivist" welfare regime, which has subsequently become dominant in explanations of social policy and welfare system development in the more recently

industrialized East Asian economies(Holliday, 2000, p.706-723). The productivist welfare regime is characterized by the subordination of social policy to the overarching goal of economic growth. It entails minimal social rights that are contingent upon productive activity, the strengthening of productive elements, and the growth-oriented relationships among the state, market, and family (Holliday, 2000, p.706-723, Kim, 2015). But recently, scholars suggested Singapore as a developmental welfare regime. In the developmental regime, universal social investment underpins welfare provision, and social policy has proven to be an effective instrument for averting economic crises (Kwon, 2005, p.477-497). The developmental welfare regime offers a conceptual formula that goes beyond facilitating economic growth and aims to promote the simultaneous integration of economic and social development through significant social investment(Midgley and Tang, 2001, p.244-252).

The salience of the housing system to the welfare regime has been widely recognized in comparative research(Zhou and Ronald, 2017, p.253-276), and researchers have increasingly considered state approaches to housing as a welfare regime pillar(Kemeny, 2001, p.53-70, Ronald and Kyung, 2013, p.452-474). The housing regime refers to a typology of systems of power, which is determined by varying degrees of corporatism in economic and political decision-making. According to Kemeny'sapplication of Esping Andersen's approach to housing systems, the main characteristics defining housing regimes are related to the rental sector, and the basic distinction lies between dualistic and integrated (or unitary) rental systems(Kemeny, 2006, p.1-18). Societies with a dominant homeownership culture exhibit a 'dual rental market', where the private sector is strictly means-tested and always restricted to the poor. In contrast, countries with a 'unitary social rental market' have both private and public sectors operating under the same institutional arrangements and competing with each other. The dual system tends to marginalize renting, whereas the unitary system presents renting as a competitive alternative to homeownership. Singapore and Germany are widely considered as typical representatives of the unitary rental system. Some Chinese scholars suggested ARH programme will be an effective approach to compete with the private sector, which may help to turn China's rental system from a dualistic to a unitary system and shift from productivist welfare to a developmental welfare regime(Chen et al., 2014, p.534-550).

There has been a considerable amount of research related to China's rental housing system, housing regime, and long-term rental apartments (Lin, 2018, p.96-105, Chen et al., 2022, p.105442, He and Chang, 2020, p.592-616, Huang et al., 2021, p.102967, Li and He, 2023, p.1-25, Li et al., 2023, p.102715). A few researches are focusing on the emerging ARH programme in China(Li and He, 2023, p.1-25). However, as the newest rental housing project proposed by the central government, the implementation process of the ARH programme has received insufficient scholarly attention, particularly the roles of various agencies and several modes of governance in producing ARH.

Focusing on the implementing process of the ARH programme in Shanghai, this study observed the tensions and contradictions between the central and the local government and then explored the transition of provision modes in two stages through the conceptual lens of governance structure, to understand local government's adaptive strategies, which strive to balance top-

down political pressure with local fiscal interests, and the dilemma for different stakeholders.

The paper proceeds in a number of subsequent parts. The following section reviews China's housing system evolution in the past 30 years and the characteristics of ARH such as relevant policies, its concept, and target groups, and then locates ARH in China's current housing system. Section 3 introduces the methodology of qualitative and quantitative analysis of the ARH programme in Shanghai. This is followed by ARH provision modes in Shanghai, including two major provision modes, the spatial distribution of ARH projects and the affordability through in-depth field investigation. Section 5 aims to explain the institutional and governance transition of ARH provision in Shanghai through the conceptual lens of governance structure. The final section concludes the above empirical findings and considers how our findings and analysis of China contribute to theoretical debates on housing regime transformation.

2. Locating ARH in Chinese Housing System

2.1 Housing Regime Evolution in China

Before 1998, China's housing system was undoubtedly a productivist housing regime. Housing, as a basic benefit, was provided by State-owned work units to house their employees and was allocated based on hierarchy. By the 1980s the housing system was able to cover more than 90% of the urban labor force (and dependents) through public housing(Gu, 2001, p.91-111). This was like other socialist economies where low-cost housing functioned as a form of social wage(Huber and Stephens, 2010). Beginning in 1998, China completely abolished welfare housing and began to encourage market ownership housing and its financialization, in response to the 1997 Asian financial crisis. The transformation of urban housing from a welfare good to a commodity good greatly helped drive a consumption boom and economic prosperity in urban China. Local state revenue from the sale of residential housing land has played a crucial role in financing urban infrastructure investment since the 1998 reform(Man, 2011). This seems to be a shift from a productivist welfare regime to a liberal welfare regime. Under these circumstances and institutional arrangements, local governments were reluctant to implement large-scale public housing programmes.

The Economic Comfortable Housing (ECH) programme, which began in 1994 and was cancelled in 2013, was a national housing guarantee scheme designed to promote homeownership among low-middle-income households but has been flexibly implemented by local governments as a housing allocation for key workers[1]. The Cheap Rental Housing (CRH) programme, which started in 1998, had a very limited supply and was strictly limited to the poorest local citizens with serious living difficulties.

Between 2000 and 2010, the Chinese government's efforts in the housing security system

1 Key workers Normally defined as providers of essential local (usually public) services whose pay cannot be adjusted to reflect variations in the local cost of living – particularly in the cost of housing. Essentially public sector workers on national pay scales; most commonly teachers, nurses and police officers but who is included can vary between authorities.

included two other kinds. One is Capped Price Housing (CPH), which is targeted at middle-income households, and the sale price is set at around 70-75% level of comparable nearby market housing. The other one is Shanty Town Renovation Housing (SRH), which is reserved for households relocated due to urban renovation projects.

Public Rental Housing (PRH), which was started in 2010, aimed to accommodate a fifth of the Chinese urban population by 2015, as a significant progress in China's housing system. While CRH covers only the poorest local households, PRH is targeted at both low- and middle-income households who cannot afford decent housing at the market price and is accessible by not only permanent residents but also migrant workers. In 2014, the CRH was merged into PRH.

However, China still had a predominantly ownership housing system until then, with rental markets mainly existing in mega-cities with an inflowing population, and mainly consisting of the private rental sector. Public housing was substantially downgraded to a supportive role in the whole housing system(Chen et al., 2014, p.534-550). However, with the rapidly increasing market housing purchase and investment, the incredibly high housing prices exclude new citizens[2] and migrant workers, which may restrict the industrial development of mega-cities in China, and make home purchases increasingly unaffordable for low- and middle-income households. In 2016, President Xi Jinping asserted a new fundamental principle for housing policy, emphasizing that 'housing is for living, not for speculation'(Xinhua News, 2016[3]). For the first time, the Central Government has proposed the development of a housing rental market and the establishment of a housing system that combines renting and purchasing. To facilitate the simultaneous development of the rental and sales markets, the State Council (SC) and the Ministry of Housing and Urban-Rural Development (MHURD) issued a series of policies, with the intention of cultivating the private rental sector and accelerating the provision of long-term rental apartment (LRA).

The years from 2016 to 2019 witnessed China's central government supporting the construction of rental housing, guiding local governments to increase the supply of rental housing through a variety of approaches, including the construction of rental housing on new construction land, the compulsory allocation of rental housing in new market housing projects, and the conversion of idle and inefficiently utilized industrial plants and commercial office buildings into rental housing. A large amount of LRAs invested by market institutions have emerged. However, LRA was facing a crisis in China due to unsound financial regulation, and a considerable amount of literature has already examined in detail the rapid growth of LRAs in China in those years, and the broken capital chains and bankruptcies of LRA companies.

As a result, starting in 2020, China's central government proposed to carry out the construction of the affordable rental housing (ARH) programme, which aims to provide adequate and

2 The term 'new citizens' mainly refers to individuals who have relocated to cities for permanent residence due to factors such as employment, entrepreneurship, children's schooling, or seeking refuge with children.

3 Xinhua News. (2016). Housing is for living, not for speculation. http://www.gov.cn/zhengce/2016-12/16/content_5149066.htm.

affordable rental housing. For the first time, the national state clarified the top-level design of China's social housing system, put forward the construction of a social housing system with PRH, ARH, and Shared Ownership Housing (SOH) as the mainstay, and clarified the basic system of ARH and the relevant support policies (Fig.1).

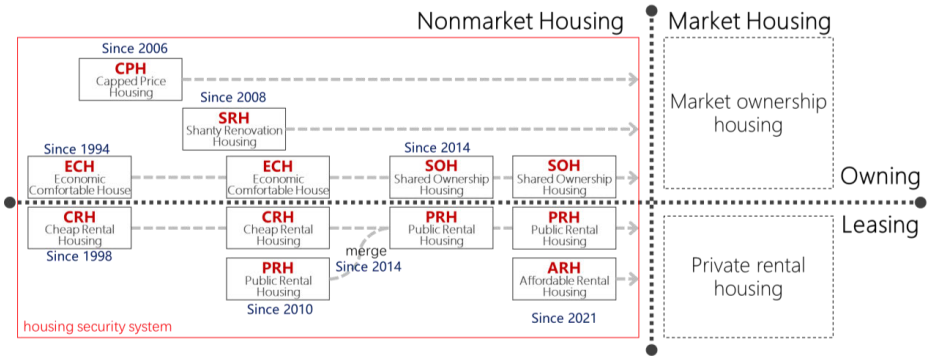

Fig.1 Evolution of Chinese housing system

2.2 The characteristics and roles of ARH in Shanghai

In the Chinese context, the ARH programme aims to provide comfortable, secure, and affordable rental housing with a price set around 90 percent level of comparable nearby market rents, to alleviate acute housing affordability problems faced by new arrivals and young working-class who migrate to megacities.

In the state's top-level design, PRH and ARH are two types of social rental housing, targeting different groups. PRH is provided to key workers, newly-employed workers and migrant workers, and low-income local households with limited per capita living space. ARH is provided to newly employed workers and migrant workers with fewer limitations. In Shanghai, for example, these two types of rental housing are also different in terms of the application process and rental price, but to fulfil the task indicators issued by the central government, PRH is also merged into ARH for quantity counting.

Taking Shanghai as an example, as a mega-city with serious housing difficulties for the inflowing population, Shanghai has been vigorously developing LRAs, talent rental housing(special discounts for highly educated groups), and rental communities since 2017, and designated some of these rental housing projects as ARH programmes later. Currently, the Shanghai Municipal Government has proposed a four-type housing system, including nonmarket rental housing, market rental housing, nonmarket ownership housing, and market ownership housing. Among them, the rental market is mainly divided into ARH (except PRH), PRH, LRA, and the former CRH (which has been merged into PRH) (Figure 2). Only the PRH projects are owned by the local government. The operators of LRA and ARH are similar, with a mix of private companies (real estate companies, hotel companies, rental agencies, etc.) and state-owned enterprises (SOEs), with SOEs generally operating a larger proportion of ARH

according to government directives. The centralized LRA can be added to the ARH by application of the operating company, subject to certain conditions. The provider, regulation, subsidies, rent price level, and target groups of these types of rental housing are differentiated, as can be seen in Table 1.

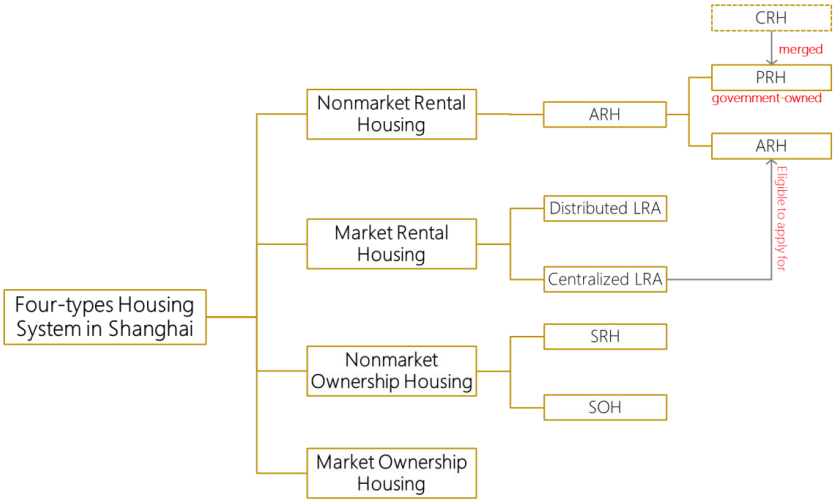

Fig2. Four-types housing system in Shanghai

Tab.1 characteristics of 4 types of public rental housing in Shanghai

	CRH (Cheap Rental Housing)	**PRH (Public rental housing)**	**LRA (Long-term rental apartment)**	**ARH (Affordable rental housing)**
since	1998	2010	2016	2021
Provider	Government	Government	SOEs & private companies	SOEs & private companies
Regulation	enclosed management	enclosed management	less regulation	overall supervision
Subsidies	High (land freely allocated, rental price subsidies, tax incentives)	High (land freely allocated, rental price subsidies, tax incentives)	Low (tax incentives)	Medium (Land supplied at cost, tax incentives, discounts on utilities)
Rental Price	Much lower than comparable nearby market housing	50-80% level of comparable nearby market housing	Market price	90% level or almost equal to comparable nearby market housing
Target Group	•very low-income local households	•Key workers •newly-employed	•Senior management of	•newly-employed workers and migrant

		workers and migrant workers •low-income local households with limited per capita living space	foreign enterprise •newly-employed workers and migrant workers	workers •middle-low-income local households with limited per capita living space
Floor Area Per Household	≤45m²	40-60 m²	Without limitation	≤70 m²

2.3 ARH designed to change China's dualistic rental system

According to official newspaper reports, at the end of 2022, there were approximately 8 million housing units in Shanghai, of which 2.1 million were rental housing, and these were made up of 1.8 million private rental housing, 100,000 LRAs, and 200,000 ARHs and PRHs. So, the rental market accounted for 26 % of the overall housing market, with social rental housing accounting for approximately 14 % of the rental market[4]. The municipal government of Shanghai committed to providing 400,000 units of affordable rental housing by the end of 2025, which consists of nearly 20% of the whole rental housing market. According to Kemeny's theory, the housing system in Shanghai was once a dualistic rental system, but the implementation of ARH driven by the state seems to be a step towards an integrated rental system, by improving rental housing quality and affordability to become a competitive alternative to homeownership.

3. Research design

3.1 Study area

We chose Shanghai's ARH project as the object of study because Shanghai, as China's economic centre, mega-city, and famous global city, has faced a large inflowing population for a long time, and therefore the housing problem is very serious, then the process of ARH implementation, the motivation of the local government, and the social impacts generated by the project will also become particularly noteworthy.

3.2 Methodology

This research employed both qualitative and quantitative methods. Firstly, we reviewed publicly available policies, legislative documents, and official news at both the central and municipal government levels. Then we collected land conveyance data from the official website[5], mapping urban rental lands from 2019 until now in Shanghai, and collecting statistics on new ARH assignments to each district in Shanghai from official planning documents.

4 Liberation Daily, report in Feb. 2023
5 www.landchina.com

Additionally, we conducted in-depth field investigations of 6 ARH, 2 PRH, and 5 LRA Projects (Tab.2, Fig.3) in Shanghai during June and July 2023, including participation observation, and semi-structured interviews with front-line staff of ARH operating companies. We also posted recruitment on the social network Xiaohongshu (Chinese top 3 popular social media applications) for tenants of PRH, ARH, and LRA in Shanghai, and collected 48 questionnaires of tenants from ARH programme, and 37 questionnaires from PRH tenants, as well as 67 questionnaires from LRA tenants.

Tab.2 details information on 13 projects for in-depth field investigation

No.	ARH project	Location	Operator	Types	Rental Units
1	Pujiang V-linker Community	No.20, Lane 131, Kanghua Road, Pujiang Town, Minhang District, Shanghai	V-linker	ARH	3116
2	City Wonder Community-Jiangyue Road	No.55, Nan Jiang Zhou Road, Pu Jin Sub-district, Min Hang District, Shanghai	City Wonder (SOE)	ARH	1080
3	Mofang Luheng Road Community	No.18, Linheng Road, Minhang District, Shanghai	Mofang	ARH	1255
4	Anxin Community Long dream Hongkou	760 Xijiangwan Road, Hongkou District, Shanghai	Anxin	ARH	440
5	Mofang (Ningguo Road Metro Station)	No.7, Lane 29, Longkou Road, Yangpu District, Shanghai	Mofang	ARH	250
6	SIUD-Xin Community	Lane 555, Xiulian Road, Xinzhuang Town, Minhang District , Shanghai	SIUD (SOE)	ARH	2562
7	Chenpin Apartment	No.1234 West Yan'an Road, Changning District, Shanghai	District government	PRH	116
8	Baodi Hongleyuan	Lane 76, Guangyue Road, Hongkou District, Shanghai	Baodi (SOE)	PRH&ARH	747
9	Creative Apartment - Bay Valley Community	Lane 1566 North Guoquan Road, Yangpu District, Shanghai	Creative Apartment (SOE)	LRA	852
10	Poyu hongkou Jiangwan Apartment	1400 Xinshi North Road, Hongkou District, Shanghai	Vanke	LRA	256
11	Yi-Mofang Apartment(Wujing ECNU)	No.5395 Longwu Road, Minhang District, Shanghai	Mofang	LRA	200

13	City Wonder Community - Huashan Road	No.161, Lane 1038, Huashan Road, Changning District, Shanghai	City Wonder (SOE)	LRA	104

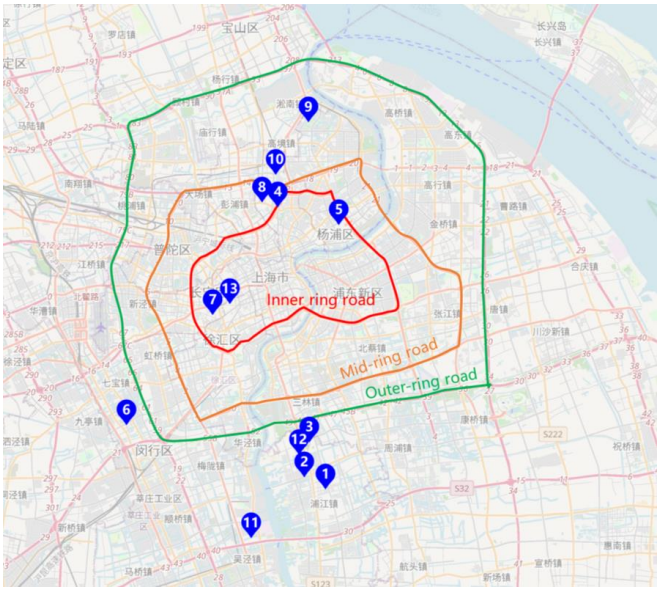

Fig.3 13 projects for in-depth field investigation

It is worth noting that LRA has access to ARH, while PRH and ARH could co-exist within one site or project, so all three types of rental housing were researched, for a better comparative study and a better understanding of the rental housing system in Shanghai.

4. ARH Provision and distribution in Shanghai

4.1 Two types of ARH Provision modes

ARH can be mobilized through two main channels: new construction and stock building conversion. There are five modes of land supply for new construction, including supporting land for industrial parks, collective construction land supply, unused land owned by enterprises and institutions, direct supply of Rental Housing Land('R4' in Shanghai, which means that the land can only be used to build housing for rent), and mandatory allocation of a certain percentage in market ownership housing). Of course, the most efficient way is to build ARH communities directly in R4 land, which often brings in several thousand units of rental housing in a single project, such as the SIUD-Xin Community (Fig.4; No.6 in Fig.3). Stock building conversion refers to the conversion of existing buildings that were not originally intended for residential use into ARH, or LRAs that have been converted from other types of buildings (industrial, commercial, office building) and can be incorporated into ARH through application, such as Mofang Luheng Road Community, which was converted from factory building (Fig.5; No.3 in Fig.3).

Fig. 4 SIUD-Xin Community

Fig.5 Mofang Luheng Road Community

LRAs applying for ARH need to meet several conditions. Firstly, the rent price needs to be no more than 90% level of the same type and quality of housing nearby (but this can be operated flexibly). Secondly, the products should be mainly small households under 70m^2 (at least 70% units of the project). Thirdly, the stability and the total living units are important, if the property rights of the building do not belong to the operating company, then the operating company needs to sign a lease contract with the property owner at least for 5 years, and generally need at least 50 rooms to be operated within the same plot. Fourthly, the rent will be regulated by the government's housing management department after being included in the ARH, and the price increase shall not be more than 5% per year.

By designing policies, the Government encourages former LRA companies to join the ARH and be subject to stricter regulation. One point is tax incentives and utility concessions. After joining the ARH, those former LRAs converted from non-residential buildings, which were originally required to charge utility bills according to industrial and commercial functions, can now be charged according to residential use (in terms of electricity tariffs, for example, the residential tariffs are about 60% of those for industrial use, and 40% of those for commercial use), which may be more attractive to potential tenants. The second point may be more important, after joining ARH, it is equivalent to getting the endorsement from the government, and the company can then issue REITs with this project as the underlying assets. therefore, at present, for LRA projects in Shanghai, unless they don't meet the conditions such as the household area, we have found in our interviews with front-line staff of LRAs, that the majority of the property owners and operating companies are willing to join the ARH, however, it is not easy to join the ARH even if meeting all the conditions, there is still a waiting list.

4.2 Three types of ARH projects in Shanghai

In terms of building form, ARHs can be categorised into community-type, apartment-type, and dormitory-type. The community type often consists of several buildings forming a gated community containing hundreds or even thousands of living units, such as Baodi Hongleyuan (Fig.6). This type of ARH is mainly located outside the Outer Ring Road in Shanghai. Apartment-type is generally composed of a single building, often originally used as factory

buildings, factory dormitories, office buildings, hotels, etc., such as Mofang (Ningguo Road Metro Station) (Fig.7). The dormitory-type is generally 4 and 6 beds in one room, serving blue-collar workers and employees in the service industries (waiter, courier, housekeeper, etc.), such as Anxin Community Long dream Hongkou (Fig.8), with the rent generally paid by the employers. If dormitories are not provided, this type of company may not be able to recruit a suitable labor force in Shanghai.

Fig. 6 Baodi Hongleyuan

Fig. 7 Mofang (Ningguo Road Metro Station)

4.3 ARH Distribution in Shanghai

The Shanghai Municipal Housing Authority has split the overall target of building 400,000 units of ARH down to the district level under the Five-Year Plan, setting individual targets based on the available land and the existing PRH and LRA. Among them, Pudong New District will build 120,000 units, and Minhang and Songjiang districts will build more than 100,000 units, with these three districts taking on more than half of the task. Since this quantity is a task that each district must complete, we can take the target value of 2025 as definite (Fig.9; Tab.3), and according to the news on the Internet, the districts have completed 80% of the target by the beginning of 2024.

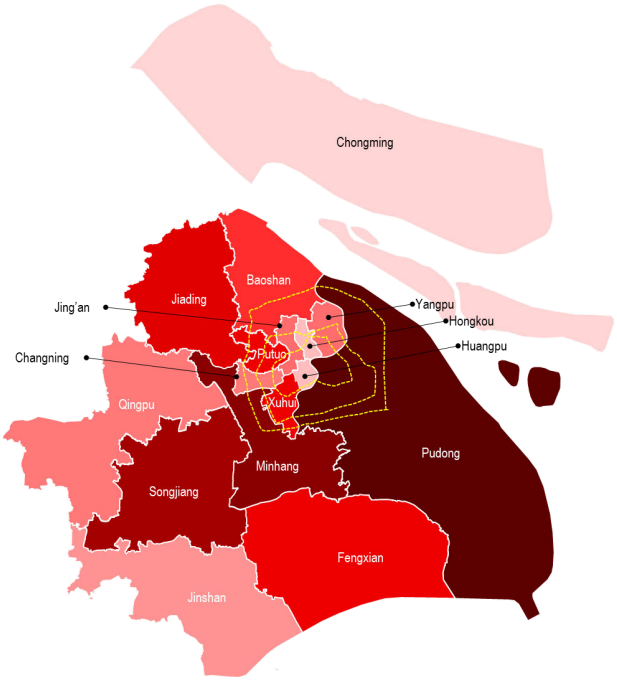

Fig.9 ARH units in 2025 targets split to district level

Tab. 3 ARH units in 2020 and 2025 targets split to district level

District	**Current ARH by the end of 2020 (thousand units)**	**Goals by the end of 2025 (thousand units)**	**New ARH mandates within 5 years (thousand units)**
Pudong	33.4	120.3	86.9
Minhang	16.1	62.9	46.8
Songjiang	23.00	44.4	21.4
Jiading	5.8	23.4	17.6
Putuo	13.0	21.4	8.4
Xuhui	11.8	21.0	9.2
Fengxian	7.2	20.0	12.8
Baoshan	3.7	18.2	14.4
Yangpu	4.9	13.4	8.5
Jing'an	2.4	12.6	10.1
Qingpu	3.9	10.7	6.8
Changning	1.5	10.2	8.7
Jinshan	5.2	9.6	4.4

Hongkou	1.8	6.2	4.3
Huangpu	1.0	5.8	4.8
Chongming	2.2	4.0	1.8
Total	**137**	**403.9**	**266.9**

There are manufacturing companies gathering in Pudong, Minhang, and Songjiang districts, thus gathering a large number of industrial workers and R&D personnel, who are often migrant workers and willing to live near their workplace, and the ARH project provides them with a convenient and comfortable rental environment. At the same time, the majority of these areas are located outside the Outer Ring Road and have lower land costs. In our field research, we found that large ARH communities such as Pujiang V-linker Community and SIUD-Xin Community, for example, are located outside the outer ring road of these districts, and generally have a metro terminal nearby, with at least half of the tenants in the community need to commute to the city centre for work via the metro. Even so, young people are still willing to endure a long commute, as there are not many ARHs in the central city (only more expensive LRAs). That means housing segregation and discriminatory site selection do exist in ARH programme.

When choosing ARHs in the suburbs, but not private rental housing in the city center at the same price, people in the questionnaire reflected that stability and privacy are their primary considerations. The fact that private rental housing may need to be shared with 1-2 roommates, may be suddenly withdrawn, may experience sudden price increase, and may require frequent negotiation with the landlord are not favored by the surveyed group.

4.4 Effect of the ARH Programme on Housing Affordability

The rising housing affordability crisis in urban areas has constituted a major threat to the future sustainability of urbanisation in China (Chen et al., 2010, p.877-901). Housing affordability in Shanghai and other Chinese mega-cities is very poor worldwide. According to the Numbeo website[6] in March 2024, the Price to Income Ratio (PIR) in the city centre of Shanghai remains outstandingly high among the global cities (Fig.10). So have ARH projects improved housing affordability in Shanghai?

6 https://www.numbeo.com/

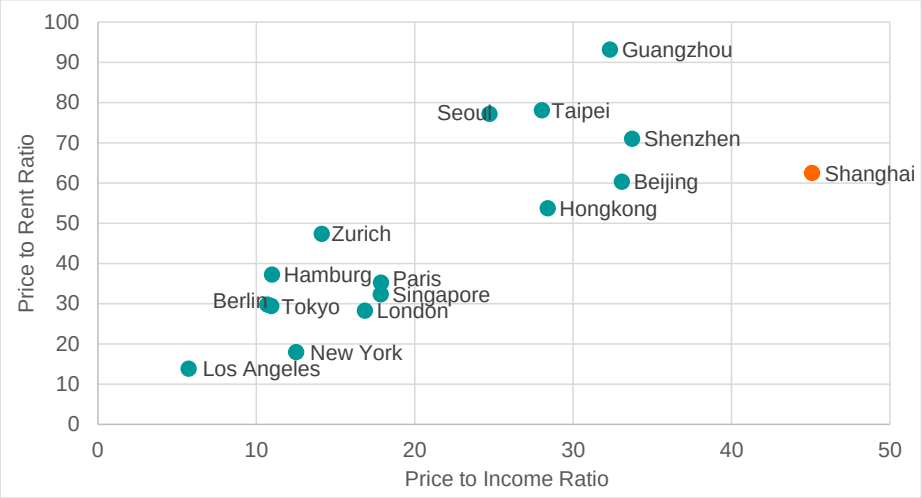

Fig.10 PIR and PRR of 16 global cities in 2024

According to Shanghai's policy on the ARH programme, the rental price of ARH shall be set by the ARH institutes or companies and reported to the housing management department of the local government for record. For ARH suppliers, the rental price should be less than 90% of the rent of market rental housing of the same quality in a similar location.

At the same time, it is stipulated that applicants for ARH are required to meet two conditions: firstly, they are legally employed and working in Shanghai; secondly, they have housing difficulties, which is precisely delimited, in principle, according to the family's per capita housing floor area of less than 15m^2 within the city centre of Shanghai.

However, according to our findings in field research, the rental price per square metre of ARH is not cheaper than that of ordinary private rental housing nearby. The policy provides for a 10% discount on the assessed price, but the assessed price can be declared by the ARH companies themselves. Sometimes, even the rental price will be higher since it comes with some additional service charges and higher-than-civil utilities. However, the total rental price is relatively low as ARHs are generally smaller, around 20 m^2 (usually for 1-2 persons living). This is because it is difficult to divide an ordinary private house or apartment into 20 square metre living units for rent. So as rents are not significantly cheaper, the application threshold in practice is often applied flexibly and does not require proof of housing difficulties.

Even so, the affordability of the ARH programme in Shanghai remains bleak. According to our questionnaire distributed to 48 ARH tenants, 37 PRH tenants, and 67 LRA tenants, only 18% of the tenants pay more than US$620 in monthly rent, which is also consistent with our interviews with housing agents, where a total rental price of RMB 4,000 (about US$620) is a clear watershed in Shanghai (Fig. 11). But even if total rental prices are kept in a reasonable amount due to small floor area, their housing affordability remains a challenge, with 23 ARH tenants' rent to income ratio above 30%, exceeding the international warning line(Fig.12).

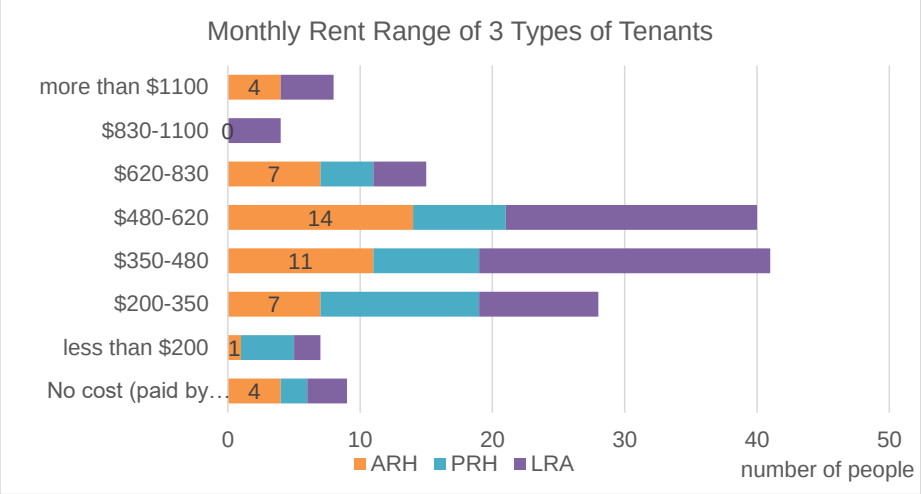

Fig. 11 Monthly Rent Range of 3 Types of Tenants in Questionaries

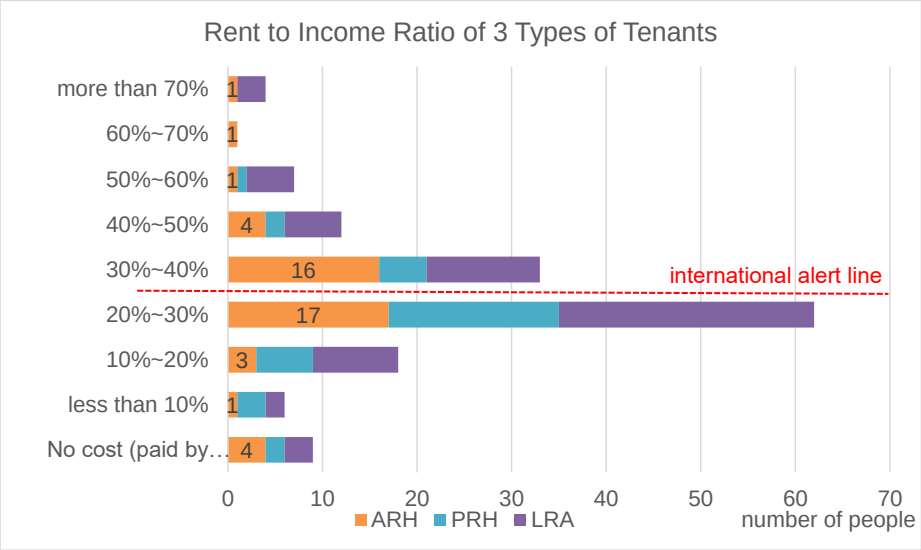

Fig. 12 Rent to Income Ratio of 3 Types of Tenants in Questionaries

A comparative study shows that the PRH is the most affordable (Fig.11; Fig.12). While it is worth noting that although the target groups of ARH and PRH seem to be relatively similar, the difficulty of applying for PRH is much more than ARH due to the more favorable price. PRH requires submitting a series of supporting documents and applications from the official system and queuing up for a limited number of units, and the waiting time is generally over 6 months for Shanghai, and you have to withdraw after 6 years of residence. Based on interviews, PRH can be categorised into two types, provided by the municipal government or district government.

PRH projects provided by municipal government are often available for all applicants, while PRH projects provided by district government are built with revenues from district governments and are more inclined to be rented to those who are conducive to the development of the districts. In the field investigation, we find that PRH projects may have a priority application channel. According to the interviews, we learned that the PRH programme in the district has priority access to key companies and key workers in the district and that the employers apply PRH together, often without a waiting list. In contrast, PRH is more affordable than ARH, but the supply amount of PRH is smaller than that of ARH because it requires higher government subsidies.

5. The Institutional and Governance Transition of ARH Provision

5.1 Two-stage development of ARH in Shanghai

According to the main provision modes, we divide the implementing process of the ARH programme in Shanghai into 2 stages——SOEs-led newly-built large-scale rental communities (from 2017 to 2021), and public-private governance to encourage converting previously underutilised commercial or industrial properties into ARH (from 2022 onwards).

Stage 1: SOEs-led newly-built large-scale rental communities (from 2017 to 2021)

We counted the supply of ARH, PRH, and LRA land supply on official websites from 2019 to the present (Fig. 13), and the most obvious supply peak occurred in 2021 when Shanghai supplied 2.7 square kilometres of R4 land (a type of land exclusively dedicated to the construction of rental housing, as mentioned earlier). The Central Economic Work Conference at the end of 2020 identified the construction of ARH as one of the key tasks of the economic work in 2021, proposing to mobilise 8.7 million units of ARH within five years, and requesting municipalities to prepare a five-year plan for ARH supply. In Shanghai, for example, only 137,000 units were available by the end of 2020, while 400,000 units will need to be completed by 2025. Under this intense political pressure, newly-built community-type ARH or PRH is a solution as each project can provide thousands of living units and the construction duration often takes two to three years, so local governments have seized on 2021 as a critical point to supply a large amount of land for rental housing.

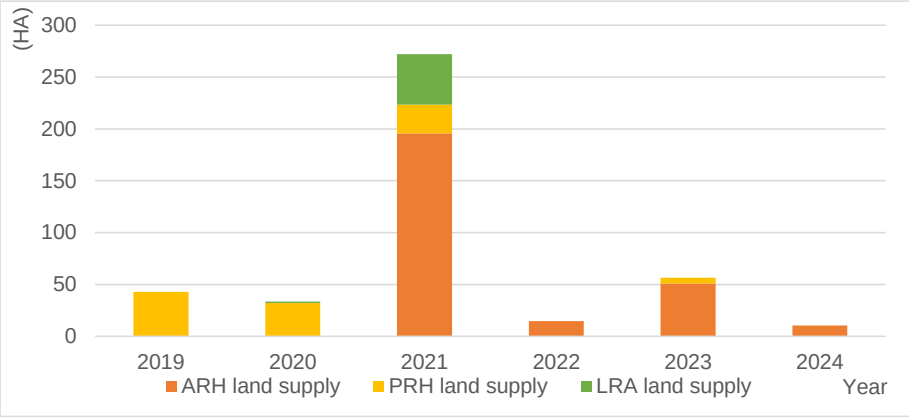

Fig.13 Land supply for rental housing from 2019 in Shanghai

In Shanghai, for example, R4 land is typically priced at one-third the price of market residential land nearby, but in practice, real estate companies are still reluctant to auction land to build ARH communities, and in our interviews with rental institutions, we found that the return on investment cycle for ARH building and operation is generally around 20 years. Against the backdrop of China's rapid economic growth over the last 20 years, few companies could accept this rate of return on investment. As a result, local governments have urged SOEs to act as the mainstay of ARH community building, auctioning off the R4 land. For example, two of the biggest SOEs in Shanghai, Shanghai Land (Group) CO., LTD created a new brand *City Wonder*, as well as Shanghai Chengtou Group Corporation created *Creative Apartment*, to build and operate the ARH community on their rental housing land.

Stage 2: Encourage converting previously underutilised commercial or industrial properties into ARH (from 2022 onwards)

On the one hand, it seems too late to fulfil the 2025 mandate by building new ARH communities after 2022. On the other hand, the supply of R4 land is almost at cost, in which local governments do not receive any land appreciation gain, and therefore have no incentive to continue supplying. At Stage 2, the local governments mainly focus on incorporating the original LRA into ARH, and converting the stock of vacant buildings into ARH projects through renovation and refurbishment. This may involve negotiating with the property owner of the vacant buildings and brokering a deal for them to cooperate with the LRA company to renovate it (Fig.14). The Shanghai Municipal Housing Bureau introduced incentives related to the conversion of non-residential stock into ARH in 2022, including the implementation of residential prices for water, electricity, gas and cable TV, as well as tax incentives such as value-added tax and property tax, low-interest loans and government subsidies, and the latest trend in 2023 is that only ARH can be used as an underlying asset for the issuance of publicly-funded REITs. This trend is also present in other Chinese mega-cities and super-large cities exist, with an intensive batch of local policies from 2022 to 2023.

This transformation poses higher governance requirements for local governments. First, it is not simple to find a stock of houses suitable for transformation, which tests the local government's familiarity with the current situation of real estate in the city and how to incentivise the owners of vacant buildings in the stock to participate in the transformation. Secondly, there are many difficulties in the process of renovating the stock buildings. China currently only has normative standards for new buildings, such as sunlight, sanitation, and fire protection standards, but no standards for the renovation of old buildings, and it is difficult for these buildings to meet the standards, which leads to the inability of many vacant buildings in the central urban areas to be converted into ARHs, which requires breakthroughs and innovations against the national standards from the local governments.

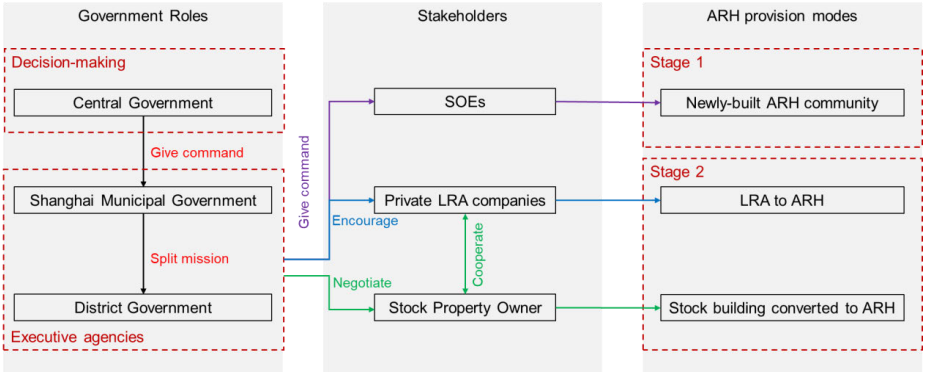

Fig. 14 Two-stage development and governance structure of ARH in Shanghai

5.2 The Institutional and Governance Transition in ARH Programme

The transition of provision modes between the two stages is due to several reasons, including the fiscal burden of local government, lack of available construction land, and the pressure under strong central government mandatory command. The role of the local government shifted from dominant to market resource coordinator, which requires less subsidies but higher demands on governance capacity. From interviews with the operators, we learned that the ARH programme is still a dilemma for local government, SOEs, and institutional investors, due to the lack of land value capture and limited return on investment.

6. Discussion and Conclusion

This study systematically examines the emerging ARH projects in China, taking Shanghai as an example, and systematically comprehends the policy background of the ARH proposal, its positioning in the housing system, the target groups, the provision modes, etc. It also carries out social investigation on the types of products, spatial distribution, and affordability of ARH, conducts a comparative study among ARH, PRH, and LRA, and then carried out interviews with operators, tenants, etc. The conclusion is that ARH is an attempt by the Chinese government to move the rental housing system from a dualistic to a unitary system. However,

ARH is still not enough affordable at present, and there is spatial segmentation for new citizens and young people.

More importantly, local governments and stakeholders are skeptical about the implementation of ARH projects. Local governments are more interested in fulfilling the tasks of upper-level governments, in which they will adopt alternative strategies, such as Shanghai's inclusion of PRH in the ARH statistics and urging SOEs to undertake ARH construction tasks. Due to the low return on investment, SOEs and private enterprises are less willing to participate in the construction of new ARH communities. In terms of converting stock or vacant buildings into ARH, or converting LRA into ARH, local governments have taken some incentives, but institutional innovations are needed before they can be rolled out on a wide scale.

This study enriches the conceptual and empirical understanding of the latest housing policies and the implementation process in China and enriches the understanding of the stage of the housing regime transformation in East Asia societies. It is still doubtful whether China has moved towards a developmental regime. As it stands, PRH is supplied at a lower price to the highly skilled and educated people that the city hopes to attract, employees of large companies, etc., while ARH is more expensive, which is still a productivist welfare regime. Whether ARH and PRH can be truly integrated and expanded in the future may be the path toward a developmental regime in China.

Dynamics, Mechanisms, and Benefits of Micro-Renewal in Urban Residential Areas: A Case Study of the Xiaoxihu Block in Nanjing

Jiwen Han[1], Li Bao[2]
[1]HAN Jiwen (School of Architecture, Southeast University), China, Jiwen_Han@163.com
[2]BAO Li (School of Architecture, Southeast University), China, baoli@seu.edu.cn

Abstract
As urban development paradigms shift, micro-renewal focused on enhancing the built environment and fostering a sense of identity has become a transformative pathway in China's urbanization process. Residential spaces, being the most critical elements of urban structure, frequently face complex challenges in their micro-renewal efforts: the constraints on urban construction capacity limit the impetus for innovation; the lack of effective implementation mechanisms impedes the progression of regeneration; and the pursuit of short-term economic gains often traps these spaces, preventing the enhancement of comprehensive benefits. This paper employs the micro-renewal of the Xiaoxihu Block as a case study, examining the sources of renewal impetus, the mechanisms of action, and the enhancement of comprehensive benefits, with the aim of providing a feasible model for sustainable micro-renewal practices in residential settings. The research findings reveal that: (1) the driving force behind micro-renewal is the incremental value derived from the operation of existing spaces; (2) the mechanism of micro-renewal involves the full-cycle participation of multiple stakeholders in public affairs; (3) micro-renewal is a process that holistically elevates environmental, economic, and social benefits, engaging with a diverse array of stakeholders and yielding synergistic effects.

Keywords: micro-renewal, dynamics of micro-renewal, implementation mechanism, benefits of micro-renewal

1. Introduction

In 2015, the United Nations promulgated the Sustainable Development Goals, which underscore that urban renewal is a critical strategy for achieving urban sustainability in the pursuit of improved living conditions, environmental remediation, and economic revitalization. Historically, urban renewal in China's residential spaces has predominantly focused on the secondary development of land(Liu et al., 2020), involving the large-scale demolition and reconstruction of low-quality existing residential areas within cities(Lai et al., 2017). This approach has restructured the original land property rights. Government, market entities, and society constitute the primary stakeholders in this process of resource redistribution(Li et al., 2018). Local governments augment their fiscal revenues and operational capabilities through the land transfer fees and expanded tax revenues generated by urban renewal. Simultaneously, they reinforce the legitimacy of governance by maintaining and enhancing the overall welfare of society(Liu et al., 2020). Market participants are primarily concerned with economic and efficiency gains, leveraging increased development intensity post-renewal—such as the "one-for-many" demolition and construction approach—to capitalize on land value increments through expanded spatial availability. They also seek to minimize transaction costs by reducing the time required for demolition. For homeowners, the substantial monetary compensation from property demolition, the improvement of living conditions, and the resolution of employment issues typically serve as their incentives to engage in urban renewal. Consequently, economic considerations have been the primary drivers and benefits during the era of large-scale demolition and construction in urban renewal(Shen et

al., 2021). However, numerous scholars have pointed out that the over-construction associated with this approach can lead to environmental issues, including the destruction of traditional urban landscapes and natural ecosystems(Hui et al., 2018; Wang et al., 2016). Additionally, social equity concerns have emerged, such as the disregard for residents' renovation preferences(Hin & Xin, 2011), the loss of tenant spaces(Wong et al., 2018), the disruption of community networks(He & Wu, 2007), the disappearance of mixed-use spaces(Zhou et al., 2017), and the loss of reasonable residential densities(Lee et al., 2017).

With the transformation of urban development approaches, the Ministry of Housing and Urban-Rural Development (PRC) issued a notice in 2021 titled "On Preventing Large-Scale Demolition and Construction Issues in the Implementation of Urban Renewal Actions," which explicitly mandates the strict control of "large-scale demolition, substantial addition and subtraction, and extensive relocation" within urban renewal initiatives(Tang et al., 2022). An increasing number of scholars advocate for the proactive adoption of micro-renewal methods to address the challenges of urban residential space stock(Li et al., 2019). Specific practices in various cities reveal that more and more existing residential areas have limited potential for incremental growth, or are even required to undergo de-growth. Consequently, the use of small-scale, incremental micro-renewal strategies, which enhance quality through the renovation and renewal of smaller-scale environments within plots, has become a significant approach to invigorating the continuous renewal of entire regions. This method focuses on the gradual improvement of existing spaces rather than drastic transformations.

Under the guidance of the "organic renewal" concept, micro-renewal attentively addresses residents' daily needs through a gradual and progressive approach. It respects the spatial reutilization of the built environment and emphasizes multi-stakeholder co-governance. This methodology seeks to enhance the quality and management of existing urban spaces, while preserving their fundamental layout and cultural continuity through practical strategies and methods of renewal, repair, and protection(Wang et al., 2023). However, the micro-renewal of residential spaces in Chinese cities currently faces several challenges: (1) Micro-renewal efforts often struggle with a lack of funding sources. Market entities see little profit due to limited urban construction capacity, and residents encounter complexities related to property rights. These issues inherently restrict the motivation to initiate such projects(Jiang et al., 2020). (2) During the renewal process, difficulties arise in coordinating the opinions of various stakeholders and in the flaws inherent to different cooperation models, often impeding the smooth implementation of micro-renewal initiatives(Zhuang et al., 2019). (3) Residential micro-renewal tends to focus predominantly on beautifying and organizing the physical urban environment, falling short in achieving a comprehensive enhancement of benefits(Shen et al., 2021). Moreover, existing research typically approaches urban residential micro-renewal from singular perspectives such as practical pathway design(Hui et al., 2021) and space optimization strategies(Tan & Altrock, 2016). There is a notable lack of systematic research summarizing the drivers, mechanisms, and benefits of renewal, which are insufficient to meet the theoretical research needs of China's urban renewal path transformation.

Therefore, the purpose of this paper is, based on an interpretation of the

essence of micro-renewal, to explore the following questions:

(1) What are the intrinsic drivers that initiate micro-renewal?

(2) What mechanisms ensure the implementation of micro-renewal?

(3) What are the comprehensive benefits that sustain micro-renewal?

This study delves into the dynamics, mechanisms, and benefits of urban micro-renewal, using the preservation and regeneration of Nanjing's Xiaoxihu Block as a case study. The research commences with a succinct literature review, followed by an exposition of the empirical data collection methods and a detailed description of the Xiaoxihu Block. The case study unveils intricate details concerning the driving forces, operational mechanisms, and resultant benefits, thereby elucidating the research findings. Consequently, this paper offers valuable insights and references for the strategic pathways and execution processes of urban renewal within the context of existing urban stock, making a noteworthy contribution to the scholarly discourse on urban renewal.

2. Urban micro renewal of residential areas

2.1 Spatial Logic of Urban Micro-Renewal

Since Molotch introduced the urban growth machine theory, this theoretical paradigm has become the dominant analytical framework for scholars to explain the driving forces behind urban development(Shen et al., 2021). Numerous scholars contend that spatial production is one of the most profitable means to achieve urban growth and serves as a primary catalyst for driving urban renewal projects(Liu et al., 2019). China's urban renewal during the period of incremental expansion also followed a similar logic of spatial production. However, as China's urbanization shifts from incremental development to stock renewal, the logic of spatial production based on real estate development and land finance profiteering is losing its economic foundation. The marginal value of land and various collateral assets as capital for spatial production is declining, and their mission is no longer confined to the regeneration of physical spaces such as old and derelict buildings(Shen et al., 2021). Resource integration and benefit reconstruction are among the key tasks of micro-renewal, with the logic of residential urban renewal shifting from spatial production to community building. Particularly in the context of the renewal of built environments, greater emphasis is placed on the social dimension, focusing on how to maintain the original social structure and property rights, facilitate collaboration and collective action among neighbors, and balance operability and fairness to enhance community vitality and the level of social governance. Consequently, the power of different stakeholders, the network of relationships and operational mechanisms, the role of social capital, and the comprehensive benefits generated by the micro-renewal process have become focal points of urban renewal in the new era.

2.2 Stakeholders in Urban Micro-Renewal

Influenced by the urban growth machine theory, most scholars have identified three key driving factors of urban development: municipal governments, business groups, and communities, as well as the relationships among them(Jiang et al., 2020; Liao & Liu, 2023; Wang et al., 2021; Zhuang et al., 2017). They have also examined how to balance between attracting investment to promote economic development and sharing the benefits. However, unlike the pursuit of economic benefits in urban renewal primarily involving land development, the purpose of micro-renewal is to

make comprehensive investments in and modifications to cities, renew urban functions, and repurpose urban space. It involves complex relationships among multiple stakeholders, which, aside from municipal governments, business groups, and community residents, also include designers, neighborhood committees, the media, and the public(Chou et al., 2023). It places greater emphasis on the granularity of distinct stakeholder groups. For example, residents could be further differentiated by their property rights, willingness to renew, and material conditions, while government departments entail multiple coordinating units such as the comprehensive planning bureau, the urban renewal bureau, and the housing bureau. Social organizations or individuals are no longer simply real estate dealers but involve multiple forces such as real estate, banks, and state-owned asset platforms(Li et al., 2024). Therefore, the management and coordination of stakeholders in urban renewal are particularly important.

2.3 Enhancing Benefits of Urban Micro-Renewal

Urban renewal is an inevitable process in urban development. Prior to 1860, the primary focus of urban renewal was to eliminate slums and improve the material living standards of residents. With the advancement of urbanization and the transformation of urban economic development models, the economic benefits brought about by land development have become the pursuit of both government departments and market entities. However, if the sole objective is to promote economic development, it is bound to harm the interests of vulnerable urban groups and lead to social injustice. Consequently, the goals of urban renewal have diversified to encompass social, environmental, and economic aspects(Chen et al., 2023; Nachmany & Hananel, 2023). On one hand, this involves the built environment as a carrier, with cautious and moderate modifications to the built environment to enhance the quality of living spaces, thereby addressing the supply-demand contradiction of public services, safeguarding the diverse demands of the people, and promoting social equity. On the other hand, it focuses on the management of complex property rights relationships during the process, striving to reach a consensus on renewal intentions and plans. The issues addressed by renewal have become more comprehensive and complex, providing optimized solutions and improving urban functions(Hao & Wang, 2023).

3. Research methodology

The empirical analysis of this study is primarily based on case studies. The research selected the southern part of the old city of Nanjing as the study area because it is a typical urban area that has fully experienced the tumultuous modern renewal process of Nanjing (Table 1), and can be considered a microcosm of the renovation of urban residential areas in China(Bai & Xu, 2023). The selection of the Xiaoxihu Block as a specific case study is for two reasons. Firstly, the Xiaoxihu Block underwent a long 9-year renewal period, becoming the first relatively mature micro-renewal project in Nanjing, allowing us to track changes over different time stages. Secondly, a five-party communication and coordination platform was established during the renovation process of the Xiaoxihu Block. The renovation has garnered broad social attention from the media, scholars, non-governmental organizations and the public, reflecting complex benefit and mechanism issues in the regeneration process. The data mainly come from in-depth interviews, non-participatory observation, and archival research. From March to April 2024, semi-structured interviews and literature research were conducted. Respondents included local

residents, shop owners, designers, and tourists still residing in the Xiaoxihu Block.

Table 1. The Urban Renewal Process in Nanjing

Renewal Phase	Stage One	Stage Two	Stage Three	Stage Four
Time	1978-1990s	Early 1992-2000s	2000-2015	Post-2015
Characteristics of Renewal	Distress-Driven Demolition and Reconstruction	Growth of Agglomeration-Propelled Demolition and Reconstruction	Extensive Demolition and Construction	Incremental Micro-Renovation
Participant Entities	Government-Led	Government-Led	Government-Enterprise Collaboration	Multi-Stakeholder Engagement
Primary Contradictions	Alleviating Housing Shortages	Pursuit of Economic Benefits from Rent Gap	Land Development Symbolized by Culture	People-Centered Approaches Addressing Daily Resident Needs

The renovation of Xiaoxihu Block exemplifies a model of incremental micro-updates, pioneering innovative strategies for the conservation and activation of heritage resources within the district. Located in the southern region of Nanjing's Qinhuai District, occupying an area of 46,900 square meters, Xiaoxihu Block is designated as one of the 22 historical and cultural areas in the "Nanjing Historical and Cultural Name Protection Plan (2010-2020)" (Figure 1), specifically within the Da You Fang Lane Historical and Cultural Area.The Xiaoxihu Block predominantly consists of residential land. However, due to its long exclusion from the old city renovation plans, the once-storied historical and cultural area had fallen into disrepair, with numerous dilapidated and hazardous structures. This led to a chaotic spatial layout, an extremely high population density, and rampant illegal construction, transforming it into a "shantytown"(Dong et al., 2022).By 2016, the division of property rights into 216 plots resulted in extremely small housing units, most of which lacked essential living facilities such as independent kitchens and bathrooms.There are a total of 810 households (2,641 people) in the renewal site, with an average household living area of only 22.14 ㎡, and an average per capita living area of only 11.65 ㎡, which is much lower than the per capita living area standard of 40.1 ㎡ in Nanjing.Additionally, scattered within the renewal area are various property types stemming from historical legacies, including private homes, public housing owned by institutions, government-owned housing, and industrial enterprise properties. When overlaid with the spatial layout, this creates a highly convoluted relationship among property rights.

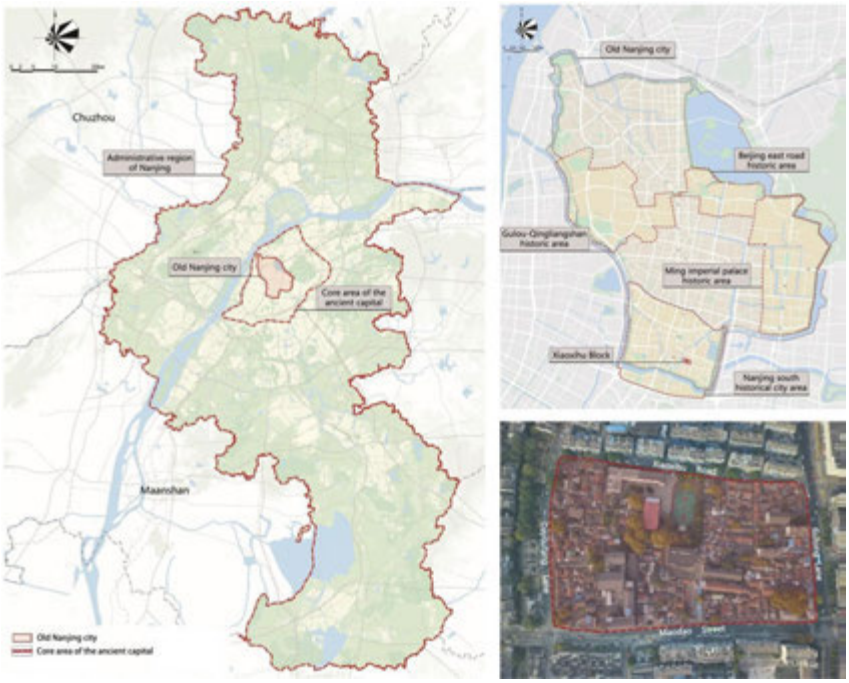

Fig. 1. Location and Boundaries of Xiaoxihu Block

The renewal of the Xiaoxihu Block commenced in 2015. To promote the regeneration of this area, the Nanjing City Planning Bureau and the Qinhuai District Government initiated a voluntary action program involving postgraduate students from three universities based in Nanjing to explore the methods of old city renewal in the southern part of the old city. In 2016, entrusted by the Qinhuai District Government and the implementing entity, the Nanjing Historic City Conservation Construction Group Co., Ltd., a team from Southeast University officially undertook the detailed planning and design of municipal facilities and demonstrative courtyards for Xiaoxihu Block. In 2017, following basic research and a survey of residents' preferences, the formal planning design and expropriation work began. The implementing entity conducted the expropriation, while the designer proposed preliminary planning solutions for the street system, municipal facilities, and public space layout. Residents were informed about the expropriation policies and expressed their relocation preferences. The expropriation work concluded in 2018, and the implementing entity began to advance the property rights transfer of expropriated land, planning the overall business format and layout. The designers completed the detailed constructive planning and planning results, formulated micro-renewal rules, and the government departments studied the micro-renewal work mechanism and policy innovation to ensure the smooth implementation of the micro-renewal process. The official micro-renewal construction started in 2019. The designer carried out the scheme design and rule formulation for key areas, the implementing entity conducted mapping and structural inspection of existing buildings, and initiated construction in key areas according to the planning scheme.

Residents participated in discussions on the scheme design during this process (Figure 2).

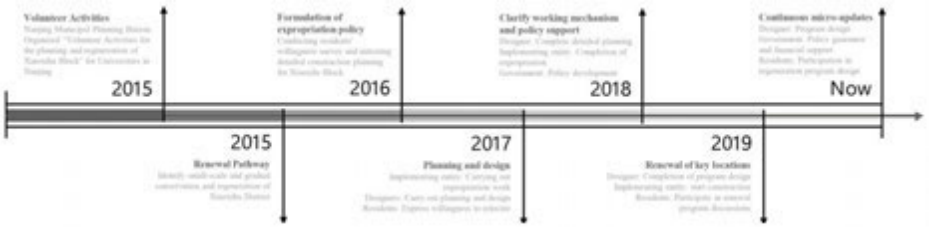

Fig. 2. The Renewal Process of Xiaoxihu Block

4. Dynamics, Mechanisms, and Benefits of Micro-Renewal

4.1 The Dynamics of Micro-Renewal: Determining the Initiation of Micro-Renewal

Urban renewal during the land development phase can achieve land value appreciation through capacity enhancement and functional replacement, thereby stimulating the market's motivation for renewal(Cao et al., 2023). In contrast, micro-renewal, constrained by strict spatial increment control, faces limited returns and can only realize marginal value appreciation through the reuse of existing spaces. The renewal of the Xiaoxihu Block, in addition to utilizing government financial subsidies, primarily relies on the operation of existing spaces for value enhancement, which is mainly reflected in the multifunctional utilization of existing buildings.

The architectural space reutilization in the Xiaoxihu Block's renewal is based on assessing the condition of use, functional classification, and spatial layout to reemploy building space resources for marginal profits. This is chiefly accomplished through functional replacement and enhancement. Functional replacement involves transforming underutilized buildings that no longer meet residents' needs into non-profit life support service facilities. The implementing entities achieve spatial value appreciation through the collection of space rent differentials and service fees. The former Chengnan Power Supply Company building, located at the intersection of Madao Street and Xiaoxihu Lane within the Xiaoxihu Block and rendered obsolete due to functional inadequacy, was vacated. Subsequently, designers repurposed it into a fire water tank, substation, and control center to fulfill the district's power and fire service needs(Dong & Han, 2022).

Functional enhancement, on the other hand, is achieved by reorganizing the functions of residential units and optimizing circulation layouts to improve the living environment. The renovated buildings can introduce commercial and other profit-generating facilities, capitalizing on space rent differentials for the accumulation of spatial assets(Liiu et al., 2022). The dilapidated housing located at the southeast corner of the Xiaoxihu Block, originally the significant Taoist temple Sanguantang, was redeveloped through an orderly site condition assessment. With the foundational goal of protecting and displaying historical sites, the renovation included the repair of traditional houses and the reorganization of street-facing properties to enhance the site's environmental quality. The introduction of hotels and restaurants among other business ventures has been designed to achieve financial balance (Figure 3).

Fig. 3. Comparison of Sanguantang before and after renovation

In summary, the value enhancement benefits of the redevelopment of existing space through the "investment-renovation-operation" model are primarily derived from three aspects: spatial rent differentials, basic property management, and revenue from value-added service management. A long-term, sustainable model of micro-profitable space operation fulfills the market entities' demand for economic viability.

4.2 The Implementation Mechanism of Micro-Renewal: Ensuring the Smooth Implementation of Micro-Renewal

Micro-renewal in urban residential areas not only requires attention to the enhancement of physical space quality but also necessitates the reconciliation of complex social interest conflicts. The decision-making process manifests itself in the multi-stakeholder participation throughout the full cycle of public affairs. Decisions are significantly influenced by the characteristics and relationships of the various participating entities, as well as the structure and mechanisms of the participation process.

4.2.1 The Holistic Workflow Mechanism for Micro-Renewal

Micro-renewal represents a distinctive approach to urban renewal, with its workflow divided into two principal phases: the urban renewal coordination stage and the micro-renewal implementation stage. During the urban renewal coordination stage, cities in China have established an operational system that follows a "city renewal action plan - regional renewal scheme - specific project implementation" framework(Tang et al., 2024). The urban renewal coordination stage in Nanjing comprises three steps:

(1) Formulation of the renewal plan: The participating entities include municipal and district-level functional departments and sub-district offices. Municipal departments are responsible for drafting urban renewal guidelines, while district governments compile urban renewal action plans based on the current built environment. These plans provide the conceptual foundation for the implementation of renewal schemes. In 2015, the former Nanjing Municipal Planning Bureau and other departments proposed a shift from "top-down expropriation" to "bottom-up renewal," clarifying the overall principle of old city renovation to be "seeing objects, people, and life," which guided the "small-scale, progressive, courtyard-by-courtyard" micro-renewal transformation of the Xiaoxihu Block(Han & Shen, 2022).

(2) Compilation of the renewal scheme: After assessment by government departments, the designated implementing entities, under the premise of

safeguarding public interests, must conduct thematic research for the area and formulate a renewal scheme. The renewal work of the Xiaoxihu Block is carried out by the state-owned enterprise Libao Group, which has developed a detailed renewal scheme.

(3) Implementation of renewal projects: This process requires the determination of renewal objectives, funding models, and other requirements based on the scope and type of renewal.

The specific implementation phase of micro-renewal primarily comprises three procedures:

(1) Micro-renewal project planning: In the Xiaoxihu Block, due to complex property rights, applications for renewal, based on different types of property rights, are initiated by property owners or tenants. Concurrently, the Planning and Natural Resources Bureau approves the renewal applications according to the rule requirements and provides the applicants with planning indicators, business functions, and other technical conditions for renewal(Han & Shen, 2022).

(2) Micro-renewal design and construction: This typically involves stages of preliminary research, scheme design, decision-making, and implementation, aiming to develop a renewal plan based on the investigation of the current residential environment and the exploration of resident needs. In the Xiaoxihu Block, in accordance with the "small-scale, progressive" renewal concept, the fragmented 810 property units were reorganized into a two-tiered system of "planning control units" and "micro-renewal units" based on the road network pattern, legal property boundaries, and shared architectural relationships investigated onsite(Han & Shen, 2022)(Figure 4).

Fig. 4. Two-tiered system of Xiaoxihu Block

(3) Micro-renewal management and maintenance: This process mainly involves

the maintenance of physical space environments, such as public service facilities, with the aim of promoting sustainable governance of living spaces. As the renewal of the Xiaoxihu Block encompasses various models, its management and operation modes are also diverse: resident-led modes, which self-serve and self-manage through the establishment of public service teams and hosting themed events, stimulating residents' active engagement in community transformation; and government and market dual leadership modes, formed by multi-level government financial incentive funds and property management companies, creating a multi-governance pattern.

4.2.2 Multi-Stakeholder Collaboration

（1）Stakeholder Engagement

Micro-renewal, in essence, is a form of social governance where multiple stakeholders collaborate in decision-making. Its sustainability is achieved through a shared understanding of the most rational division of labor under each stakeholder's comparative advantages(Zhuang et al., 2019). In the renewal process of the Xiaoxihu Block, to better balance the interests and wishes of all parties, a five-party communication and coordination platform has been established after years of exploration and refinement. This platform includes government departments, residents, designers, community committees, and implementation entities (Figure 5).

Government departments play the role of guiding forces and key administrators in the micro-renewal of residential areas. In the renewal process of the Xiaoxihu Block, these departments can be categorized into two types based on their dominant roles: municipal and district-level functional departments, and sub-district offices. The initiator of the renewal is the Nanjing Municipal Government. However, as urban renewal deepens, the original horizontal management structure, characterized by inefficient collaboration between departments, has proven inadequate to address the diverse challenges. On the foundation of achieving phased success in the Xiaoxihu renewal, the governance model for urban renewal has been further refined. Nanjing established its first district-level Urban Renewal Office, assembling a streamlined yet professional team by drawing on the expertise of various departments. Operating under the principles of "centralized unity, collaborative coordination, and practical efficiency," the main responsibilities of this office include overseeing and coordinating urban renewal efforts across the district, thereby facilitating targeted progress in urban renewal. The establishment of the Qinhuai District Urban Renewal Office has provided effective decision-making support and policy provision for the renewal of the Xiaoxihu Block.

Residents are the direct beneficiaries of urban micro-renewal in residential areas. Due to the complex property rights relationships within the Xiaoxihu Block, residents can be further categorized into private property owners, public housing tenants, and actual occupants, among others. The neighborhood is characterized by high population density, low income levels, and an aging population, leading to diverse opinions on staying or leaving, as well as varying needs for preservation and regeneration. Given the significant individual differences in residents' needs and their limited decision-making capabilities, most of them participate indirectly in the micro-renewal process through surveys or consultations.

Community committees play a significant role in the urban renewal process of the Xiaoxihu Block. On one hand, they provide flexibility and the possibility for residents to assert equal discourse rights. On the other hand, they ensure the effectiveness of micro-renewal planning and governance while also shortening decision-making times, thereby facilitating the implementation of projects.

Designers act as coordinators in the micro-renewal process, with the Xiaoxihu Block renewal primarily involving designers and community planners. The government-appointed responsibility planners play a leading role, providing professional guidance and technical services in planning and construction within their scope of responsibility, along with coordinating non-technical tasks. From a neutral perspective, they proactively identify and solve problems based on their professional expertise.

Implementing entities in residential micro-renewal, such as developers, investors, and property management companies, operate on market principles. They are responsible for financial support, construction supervision, and the routine management and maintenance post-update. These entities significantly impact the quality of the urban built environment and the improvement of infrastructure. In the Xiaoxihu Block renewal, the Libao Group is in charge of implementation.

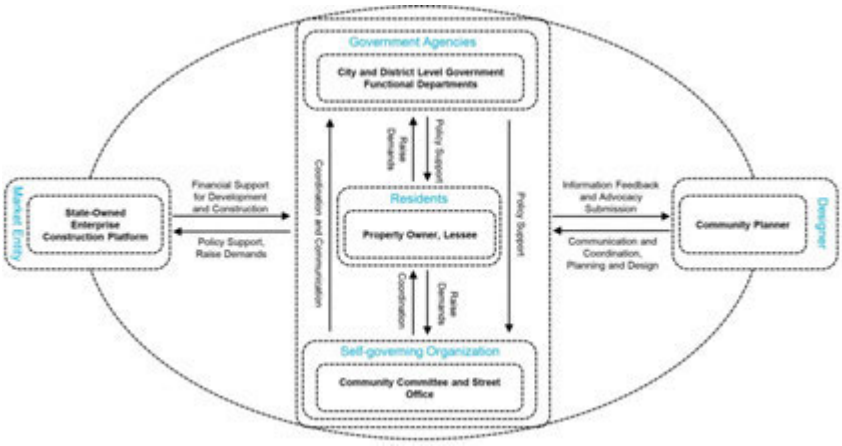

Fig. 5. Multilateral Governance Structure of the Five-Party Consultation Platform

（2）Participation Processes and Models

The complexity of the network involving diverse stakeholders determines that micro-renewal is a systematic project. Based on the diverse characteristics of residential buildings and land property rights in the Xiaoxihu Block, the implementation models for renewal can be categorized into three types: government-led, public-private partnership, and resident-initiated. The government-led model refers to the dominant role played by government departments throughout the entire micro-renewal process, directly intervening in specific processes and steps through coordination, construction, and operational management(Tan et al., 2020). In the Xiaoxihu Block renewal, this model primarily focuses on the renovation of old public

housing and public infrastructure. This process offers advantages such as process control and stable outcomes but also presents structural barriers to public participation and collaborative decision-making. The public-private partnership model involves the implementation entities taking a leading role in funding, planning, action, and operational management during the micro-renewal process(Huang & Jiao, 2018). For example, the "Shared Courtyard" in the Xiaoxihu Block is a public-private partnership initiative for residents unwilling to relocate but lacking the capacity for renovation. The implementation entity funds the transformation of private courtyards, and the homeowner agrees to open the courtyard to neighbors and tourists, taking on the responsibility of trimming the surrounding greenery. The resident-initiated model involves community self-governance organizations or residents as the renewal subjects, with responsibility planners and other social forces conducting planning and design, while government departments formulate policies and provide financial support. This model is primarily used for the renewal of privately-owned housing. The "Xu Residence" at 39 Madao Street is the first demonstration case of autonomous renewal in the Xiaoxihu Block, with a four-step technical renewal path: 1) the property owner submits a renewal application; 2) the government provides planning conditions and financial subsidies; 3) the renewal plan is compiled; 4) the renewal, construction, and renovation are carried out.

4.3 Comprehensive Benefits of Micro-Renewal: The Process Determining Sustainability

Micro-renewal represents a departure from the traditional model of urban renewal focused on the capitalization of space through incremental development. Instead, it moves towards a phase centered on the enhancement of comprehensive benefits with a human-centric approach. The positive impacts of micro-renewal are primarily manifested in three dimensions: environmental, social, and economic benefits.

4.3.1 Environmental Benefits of Micro-Renewal

（1） Enhancing the Quality of Residential Space Environment

The improvement of residential space environment quality is a direct manifestation of the goals in micro-renewal projects, particularly in residential areas, where it is closely associated with the local residents and stakeholders. In the case of the Xiaoxihu Block renewal, the following three aspects were prioritized:

1)Optimizing structural safety: The three-story east-west oriented brick-concrete public housing, located at the corner of Duicaoxiang, a T-shaped main alley in the middle of the Xiaoxihu Block, has aged over 30 years, with deteriorating structural integrity and poor living conditions. The renovation aimed to provide living spaces for the local residents' on-site resettlement and elderly care. The regeneration of the resettlement houses employed a combination of masonry structure renovation and steel structure addition on the top floor(Figure 6)(Bao et al., 2023). Through inspection, maintenance, and reinforcement of the building structures, a more stable and secure living environment was provided for the residents.

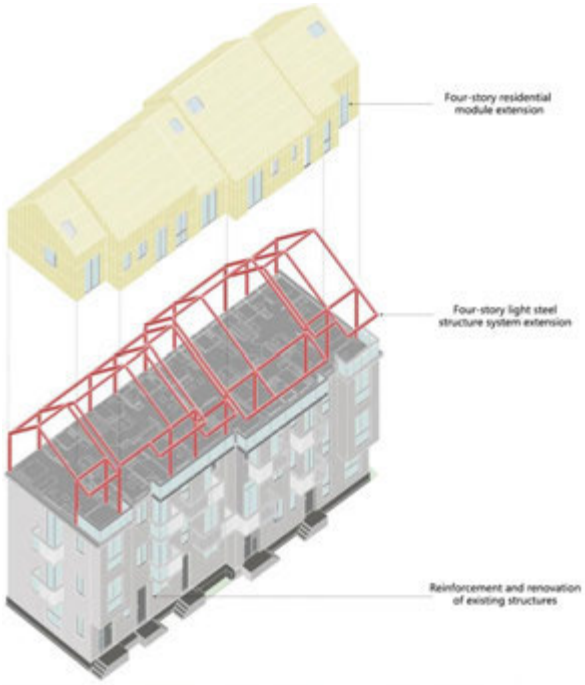

Fig. 6. Architectural structure optimization

2) Improving architectural functionality: The existing residential buildings in the Xiaoxihu Block addressed the aforementioned issues through two measures: On one hand, specific horizontal and vertical modifications, such as external wall additions, interior consolidations, and mezzanine installations, were implemented to increase the per capita living area and address the lack of kitchen and bathroom facilities. For example, in the renovation of the relocated resettlement houses, the inefficiently used space under the pitched roof and above the stairwell was redeveloped, transforming 18 previously "two-bedroom dark living rooms" into 23 fully lit units of various types, achieving an integrated enhancement of the building's functions and performance. On the other hand, the interior spaces were reconfigured with flexible methods such as movable partitions to improve circulation(Bao et al., 2023).

3) Enhancing building performance: The optimization of existing building exteriors and the application of green renovation technologies were employed to increase natural light and improve thermal insulation and heat preservation capabilities. In the reconstruction of the relocated resettlement houses within the Xiaoxihu Block, the added fourth floor posed potential light and sightline obstructions for other residents. The final adjustments included sealing and raising the windows of all balconies, twisting the walls to change the direction of the windows, and other methods to avoid interference and ensure ventilation and natural light(Bao et al., 2023) (Figure 7).

Fig. 7. Pre- and post-renovation relocation housing

In summary, the Xiaoxihu Block renewal project exemplifies a comprehensive approach to improving the quality of residential space environment, focusing on structural safety, architectural functionality, and building performance to create a more livable and sustainable urban community.

（2） Optimizing Outdoor Space Environment

The optimization of outdoor space environment primarily involves the improvement of infrastructure, the streamlining of road and traffic systems, and the enhancement of public space quality.

1)Improving infrastructure: For an extended period, the Xiaoxihu Block has grappled with outdated infrastructure and low environmental quality, necessitating urgent improvement and enhancement. To address this, the design team developed the "Micro-Utility Tunnel" technology within the narrow historical alleys. Unlike traditional direct burial of utility lines, this approach employs underground micro-utility tunnels for the installation of municipal utility lines, resolving the conflict between the small scale of historical alleys and the installation of utility lines, and addressing the management challenges of post-maintenance and update expansion .

2) Streamlining road and traffic systems: The Xiaoxihu Block project renovated the Xiaoxihu Alley and Duicaoxiang on the east side of the neighborhood to serve as lanes for motor vehicles and micro-fire engines, setting the narrowest width at 3 meters and the smallest turning radius at 3 meters for the cross-shaped internal streets. This configuration formed two main guiding axes in the north-south and east-west directions, reducing fire safety risks in historical areas while also providing possibilities for the installation of municipal infrastructure and the special passage needs of motor vehicles.

3) Enhancing public space quality: Along the north-south and east-west main guiding axes within the Xiaoxihu Block, designers have refurbished the paving, introduced public seating and sculptures, and created a pleasant atmosphere for leisure, thereby upgrading the neighborhood's external image for public display.

In summary, the optimization of outdoor space environment in the Xiaoxihu Block focuses on the enhancement of infrastructure, the improvement of traffic flow, and the elevation of public space quality, aiming to create a more livable, safe, and aesthetically pleasing urban environment.

4.3.2 Economic Benefits of Micro-Renewal

（1）Direct Economic Benefits

The direct economic gains in the renewal of the Xiaoxihu Block stem from the secondary development of existing space. This encompasses several key aspects:

1) Enhancing space operation efficiency and reducing costs: Due to the government's innovative property rights policy, the implementation entities in the Xiaoxihu Block can obtain the right to operate existing buildings and land without altering the original ownership relationships and land use rights. This reduces and avoids costs and risks associated with interest negotiations during property rights changes, thereby improving the efficiency of space utilization.

2) Diversifying industrial formats and increasing operational revenue: The functional transformation and efficient use of existing space resources in the Xiaoxihu Block aim to meet the needs of residents. The renovation or reconstruction of street courtyards after voluntary relocation by residents has added one community activity center, one comprehensive control center, two non-heritage cultural and creative studios, two learning spaces, two distinctive homestays, and nearly ten small shops to the neighborhood. The introduction of small-scale commercial and daily life convenience services has broken the homogeneity of format clustering. By targeting and addressing residents' differentiated needs, it has achieved high rental rates and operational vitality, diversifying business formats while increasing space operational revenue.

In essence, the direct economic benefits of the Xiaoxihu Block renewal are realized through the efficient use and functional transformation of existing space, leading to increased operational efficiency, cost reduction, and revenue growth.

（2）Indirect Economic Benefits

The indirect economic benefits of the Xiaoxihu Block renewal are the intangible gains resulting from the enhancement of the living environment. These benefits encompass the appreciation of residential space rents and property values, as well as the increase in cultural gains.

1) Appreciation of residential space rents: The improvement in living space environments and the enhancement of infrastructure due to the efficient use of existing space in Xiaoxihu can generate positive externalities and spatial spillover effects. This can lead to an increase in spatial rent differentials and potential ground rent levels.

2) Increase in cultural gains: The micro-renewal of the Xiaoxihu Block, while preserving the physical carriers such as the style and texture of the area, has given rise to new cultural scenes. The introduction of cultural and creative product shops, teahouses, and other cultural-displaying businesses within the neighborhood has realized the interactive integration of culture and economy.

In summary, the indirect economic benefits of the Xiaoxihu Block renewal are manifested in the appreciation of residential space rents and property values, as well as the enrichment of cultural scenes, contributing to the overall economic and cultural vitality of the area.

4.3.3 Social Benefits of Micro-Renewal

The human-centric urban micro-renewal for residential areas tends to promote the co-development of spatial renewal and social governance. This process increases resident participation, enhancing their satisfaction and sense of belonging.

(1) Multi-stakeholder participation: Unlike the "top-down" urban renewal mode that involves large-scale demolitions and constructions, the renewal of the Xiaoxihu Block emphasizes multi-stakeholder participation. Residents, especially during the stages of land expropriation and scheme design, transition into voluntary participants, collaborating and taking joint actions with the government and community planners.

(2) Innovative and diverse approaches: The renewal process integrates residents' wishes and explores various innovative paths, such as the lively "Co-living Courtyard" and "Shared Courtyard" models.

(3) Improvement of social population structure: The micro-renewal of living spaces can improve the social population structure. The enhancement of the physical spatial environment in Xiaoxihu after the micro-renewal has diversified the supply of rental housing and tenant groups, significantly influencing social population changes. The culture-led improvements have attracted creative industries and young people to the area, triggering "social mixing" and balancing the population structure against the backdrop of "double aging" (an aging population and aging infrastructure).

Cultivation of Grassroots Autonomous Mechanisms: Micro-renewal can nurture grassroots autonomous mechanisms and promote sustainable community governance. The five-party collaboration platform established during the renewal process of the Xiaoxihu Block serves as the main platform for residents to participate in community construction and contribute ideas. A community planner workstation was also established after the renewal, facilitating residents' collective participation in community affairs.

5. Discussion and conclusion

This study focuses on the conservation and regeneration of the Xiaoxihu Block in Nanjing. By reviewing literature and collecting empirical data, it delves into the renewal process and detailed dynamics of the Xiaoxihu Block, summarizing the intrinsic motivations, mechanisms, and comprehensive benefits of urban residential micro-renewal. The findings indicate: The driving force behind urban residential micro-renewal stems from the value appreciation of existing spaces, primarily through spatial operations. This can be achieved by the combined use of architectural space and the efficient enhancement of land value. The mechanism of micro-renewal involves the participation of multiple stakeholders in the entire cycle of public affairs. Decision-making is significantly influenced by the characteristics and relationships of different stakeholders and the structure and mechanisms of the participation process. And the about benefit, micro-renewal is a process that collectively enhances environmental, economic, and social benefits. The effects of these benefits are diverse and synergistic, targeting multiple entities. The study aims to provide a viable and effective model for sustainable practices in urban residential micro-renewal.

Funding

This study was supported by grants from the National Natural Science Foundation of China (project No. 52278012).

Acknowledgments

The author wish to express the sincere gratitude to the funding support to the research projects on which this paper is based, and to Prof. BAO Li for her kind help in proofreading the early version of this manuscript.

ORCID: 0000-0002-9423-6932

Abstract

This paper discusses fuel poverty in urban regeneration areas, as regeneration activites aim to improve socio-economic and structural conditions. Low Income High Cost method is adopted to assess fuel poverty, and a logistic regression is conducted to determine the factors affecting fuel poverty. The results indicate that fuel poverty level among households living in urban regeneration areas is 11.7%. Structural and design components such as aspect, size, heating duration and heating system, alongside global socio-economic factors like household size, employed households, and young children in the household appear to be influential on fuel poverty level. Structural and design factors can be addressed in future regeneration activities, while broader socio-economic factors require complex and large-scale interventions to deal with fuel poverty.

Keywords: Urban regeneration, fuel poverty, energy justice, energy efficiency.

1. Introduction

Urban regeneration, aimed at enhancing social, environmental, and economic conditions through the improvement of urban fabric, has been a longstanding focus of Türkiye's housing and development agenda. Regeneration interventions specifically concentrate on squatter settlements, which are characterised by challenges in infrastructure provision, low environmental quality, and substandard building conditions. Energy efficiency and accordingly fuel poverty, stand as prominent environmental and economic issues to which urban regeneration is expected to provide responsive solutions while enhancing energy justice. The buildings that replace squatter units needs to be higher quality with improved energy efficiency, thereby mitigating fuel poverty among residents of these settlements who exhibit heightened vulnerability to fuel poverty in terms of demographic and socio-economic characteristics, besides the structural conditions.

To understand how urban regeneration addresses fuel poverty, it is necessary to first determine the level of fuel poverty in these areas. Then, discussing factors influencing fuel poverty can help highlight problem areas in the housing units obtained through urban transformation, providing insights for future regeneration activities in terms of better design strategies and policies. This paper aims to identify fuel poverty level and explore the variables contributing to it, using Ankara's Mamak district as an example. In the following part, the concepts of fuel poverty and urban regeneration will be framed within the context of the literature. Study area will be introduced next, followed by the data and the method. After presenting the analysis results, the study concludes with a discussion and conclusion section.

2. Fuel Poverty

In the literature, it is relevant to describe fuel poverty as a subset of the broader concept of energy poverty. While both terms address issues related to the inadequacy and the inefficiency of energy resources for meeting basic human needs, there are certain distinctions between them. Fuel poverty is integrally linked to financial aspects of energy access which primarily focuses on affordability and is specifically concerned with the economic constraints that prevent households from heating their home to an adequate level or powering household devices (Moniruzzaman and Day, 2020). The condition is particularly identified by the proportion of income that is spent on energy, leading to excessive costs or not being able to allocate income for energy needs. Although early definitions of fuel poverty consider only heating, more recent and comprehensive definitions cover all residential energy needs including heating, cooking, lighting, and the operation of devices (Boardman, 2010; Hills, 2011; Moore, 2012). Energy poverty, however, is a more comprehensive framework which encompasses a wider range of issues. It includes not only affordability but also the physical access to modern energy services (Bouzarovski, 2014). This broader term covers the quality and reliability besides health and safety issues.

Spatial variations in energy poverty can be considered as the outcome of structural geographic injustices ingrained in different phases of energy systems as well as in the economic, cultural and infrastructural components of society (Bouzarovski and Simcock, 2017). Similarly, fuel poverty constitutes a multidimensional challenge, regarding household income, fuel prices, and the energy efficiency levels of buildings (Sovacool, 2015). In this context, squatter settlements exhibit an elevated risk of fuel poverty due to a significant proportion of vulnerable groups in terms of low-income, child and elderly populations, as well as low structural quality. Ho et al. (2012) mentions energy efficiency one of the problems in urban regeneration, while Ng et al. (2001) state that it is aimed to prevent the decline of the built environment and to upgrade the appearance and structural conditions.

Vulnerable groups in terms of low income, elderly, children, refugees etc. are more at risk of being fuel poor. However, the problem is also evident in the developed countries. Fuel poverty levels appear to ben 13% in England, 25% in Scotland, 12% in the Wales and 18% in North Ireland (Hinson and Bolton, 2021). In Belgium, fuel poverty is reported to be 14% in 2013, while in more recent studies, the value increases to 27.6% in Belgium (Lyons, 2021). The issue is related to socio-economic conditions as well as old housing stock with poor insulation. The only national-level study for Türkiye is conducted by Dogan et al. (2021) using 2018 data concluded that the fuel poverty levels are %17, %18 and %7 with regard to 10%, 2-median and LIHC criteria. The study of Senyel Kurkcuoglu (2023) asserted 23.6% fuel poverty for the city of Ankara using LIHC criterion.

It is expected for squatter settlements to have higher fuel poverty due to low income and structural issues. Urban regeneration suggests the potential alleviation of fuel poverty, primarily through improvements in building quality. The actual impact of urban regeneration on fuel poverty, however, remains an understudied issue in the existing literature. Therefore, this research investigates the impact of urban regeneration on fuel poverty, aiming to provide insights into whether urban regeneration activities enhance energy efficiency and accordingly decrease the levels of fuel poverty. In the following section, urban regeneration and its development in Türkiye is discussed.

3. Urban Regeneration in Türkiye

Housing development has been characterised by political and socio-economic realms of Türkiye. Candas et al. (2016) states that population growth, informal settlements and hazard-prone buildings and infrastructure are the most prominent issues in Turkish cities. Beginning in the second half of

the 40s, a substantial influx of rural migrants to urban areas was spurred by a combination of factors. On the one hand, there was an urban pull driven by job prospects, especially in the industrial sector. On the other hand, there was a rural push fueled by diminishing employment opportunities in agriculture due to mechanisation of production. Housing supply fell short of accommodating the needs of incoming residents, and the government struggled to implement timely solutions for rapid and affordable housing production. Consequently, informal settlements in terms of squatter areas, began to proliferate, offering a short-term solution to the housing shortage at the expense of exacerbating structural, environmental, and socio-economic issues. Throughout years, laws and regulations intended to prevent further illegal housing developments and upgrade the existing ones ended up with legalizing those areas particularly due to political concerns. Urban regeneration or rehabilitation efforts remained at plot or single structure scale, often entailing the replacement of one or two-story squatter housing units with multi-apartment story buildings until mid-2000s.

Urban regeneration can be considered as a government-lead initiative (Guzey, 2009; Oktem Unsal, 2015) with the objective of creating enhanced living spaces that are more sustainable and viable in socio-economic senses. The process aimed to replace the outdated and risky buildings and infrastructure with the new ones while upgrading the structural, environmental and social qualities. Although practiced for years, regeneration activities gained momentum with regulations that expedited the process and expanded the scale and the coverage of the projects put into effect in late 2000s. Municipality Law (No:5393, 2005) and the Law on Transformation of Areas under Disaster Risk which has been abbreviated in daily use as Urban Transformation Law (6306, 2012) particularly addressed to urban regeneration. The Urban Transformation Directorate was established within the Ministry of Environment, Urbanisation and Climate change, in accordance with the Urban Transformation Law. With all these developments, comprehensive and widespread urban transformation projects began in cities. This period is also characterised by the neo-liberal discourse focusing on the increasing urban land-rents and real estate development, while the process includes private sector actors as well as state institutions such as the Mass Housing Development Administration (Eren & Tökmeci, 2012). Gozozkut and Somuncu (2019) mention that although the legal bases is created, the sustainability of these areas following the completion of regeneration remains open to debate.

One of the areas that sustainable urban regeneration deals with is energy efficiency and resource use (Korkmaz, C., 2016; Gonullu Sutcuoglu and Kalayci Onac, 2022). Although the goals of urban regeneration are straightforward, the outcomes – especially those concerning energy efficiency – remain unclear and not being discussed in detail. There are some studies in the literature considering sustainability-oriented aspects which evaluate regeneration projects from environmental point of view besides the economic and social assessments, mostly through qualitative methods (Eren & Tökmeci, 2012; Uzun & Celik Simsek, 2015; Korkmaz & Balaban, 2020). Tuç (2018) mentions that the regeneration focuses on beautification and image-building through better environmental services and large green spaces in his study of North Ankara Urban Entrance regeneration project. Demirtaş (2019) and Korkmaz and Balaban (2000) discusses the same project while indicating the benefits of the provision of large green spaces and landscaping but lacking the adoption of renewable energy. Akkose (2022) states that urban regeneration practices in Türkiye lack sustainability approach while her study on Bursa Doganbey urban regeneration project concludes that environmental impacts have not been considered at all. However, none of these studies address to energy issues other than the criticism of not adopting the use of renewables.

4. Study Area

Ankara is the capital city, located at the centre of Türkiye. It has a temperate continental climate with colder winters and house heating expenses can be overwhelming in household budget in winter. The research focuses on the urban regeneration areas in Mamak district of Ankara (Figure 1) due to the high prevalence of squatter settlements in the district, which has been subject to widespread urban regeneration projects. Starting from the 1940s, an uncontrolled growth has been experienced in cities such as Ankara, İstanbul and İzmir, yet, due to the lack of adequate affordable housing provision to respond the rapid urbanisation, squatter areas formed (Uzun, 2006). Arik (2021) refers to a study conducted by the Ministry of Construction and Settlement in 1964 analyzing the thirteen largest cities of Türkiye in terms of the presence of squatter settlements, which noted that these areas used to constitute 64.4% of the total housing stock in Ankara, making the city with the highest rate in the entire country. Mamak locates at the eastern part of Ankara, which received many immigrants from the eastern part of the country for years (Gözözkut and Somuncu, 2019). Housing areas for middle- and higher-income groups are located in the western corridor, whereas squatter settlements emerged in the eastern, southern and northern fringes of the city (Duyar-Kienast, 2005). For a long time, Mamak was an area known for its squatter neighborhoods, thus urban regeneration projects are considered to change the image of Mamak for the better (Gözözkut, 2016).

Figure 1. Mamak District of Ankara

Four urban regeneration areas are selected, which cover urban regeneration areas: Gulseren Neighborhood, Altiagac Neighborhood, Derbent Neighborhood and Uregil Neighborhood (Figure 2). In Gulseren Neighborhood, 1222 squatter units have already been demolished. The first stage with 688 housing units and the third stage with 1219 housing units in high-rise apartments have already been constructed. The construction of the second stage with 1312 housing units are about to be completed while the activities in other stages are ongoing. In this study, only the first and the third stage areas, which have already been finalised are included. Urban regeneration in Uregil Neighborhood is the first stage of the North Ankara Urban Entrance Project was completed in 2015 with the transformation of 2160 housing units. In Altiagac Neighborhood, 1350 squatter units were replaced by 3881 residences in 25 point-blocks and more than 100 high-rise apartments. Urban regeneration activities are completed in the neighborhood, but not all flats have been occupied yet. Derbent Neighborhood also locates within the North Ankara Urban Entrance Project; however, the construction is still going on in the area so that only the completed residences are included in the

study, which are Zirve Residences, Ihlamur Residenzes and Palmiye Residences. The contractors for Uregil and Altiagac are private companies, whereas the residences in Derbent were undertaken by Portas A.S., a subsidiary of the Ankara Metropolitan Municipality.

Figure 2. Study areas

5. Data

Data is collected from 4 urban regeneration neighborhoods given in the precious section. All calculations are done at monthly level, since the data covers winter season only. The study includes a household survey with 400 participants. In the household survey, precise questions were asked to the respondents covering information about their household size, age distribution of the household, monthly income, monthly natural gas and electricity payments. These variables are utilised in fuel poverty calculations. Some additional variables in terms of the socio-economic characteristics of the household such as total employed individuals in the household, home ownership, receiving social help, household head's education level, as well as the energy-related and structural characteristics of their houses such as insulation, aspect and size of the house, and total heating months are included in the questions to understand the factors affecting fuel poverty. Descriptive statistics for the variables are presented in Table 1.

Table 1. Descriptive Statistics for the Household Survey

	N	Minimum	Maximum	Mean	Std. Dev.
Ownership (1 owner, 0 renter)	400	1	0	1.34	.473
Rent (TL/month)	400	0	5000	847.20	1413.36
Mortgage (TL/month)	400	0	2550	688.22	891.32
Household size (# person)	400	1	6	2.95	.99
Employed household (# household)	400	0	3	.96	.79
Income (TL/month)	400	3000	50000	17122.50	9209.11
Heating system (1:central, 2: individual)	400	0	1	1.10	.30

Insulation (1:yes, 2:no)	400	1	2	1.02	.14
Heating duration (# months)	400	3	7	5.69	.84
Social Help (1:yes, 2: no)	400	1	2	1.97	.17
Natural gas expenses (TL/month)	400	350	13000	1306.87	1799.44
Electricity expenses (TL/month)	400	100	4000	439.65	592.20
Aspect (1: North, 0: all others)	400	.00	1.00	.2975	.45773
Children under 5 (1:yes, 0: no)	400	.00	1.00	.2129	.40984
Size (1:Less than 80m^2, 2: 80-100m^2, 3: 100-120m^2, 4:120-150 m2, 5: 150m^2 and more)	400	1	5	2.94	1.56
Household head education (1:primary, 2:secondary, 3:high, 4:university, 5: graduate)	400	1	5	3.36	1.18

6. Method

This study covers a mixed method framework. First, fuel poverty level in the urban regeneration areas is calculated, then, a logistic regression is run to reveal the variables contributing to fuel poverty.

6.1. Fuel Poverty Assessment with LIHC Criterion

Fuel poverty does not have an agreed upon definition since some studies consider only the heating costs while particularly the most recent ones include energy costs of household appliances. The size and the scale of the issue varies with the definition (Moore, 2012), thus, assessment methods of fuel poverty have evolved over time with changing definitions and different perspectives. UK is at the forefront of research into fuel poverty, leading both in the study of its implications and in the development of methods to assess it. In the early 1990s, evaluation criteria started to be developed and included it in the policy documents in UK.

Isherwood and Hancock mentioned that the household with fuel expenses more than 2 median of the national average are in poverty (Osbaldeston and Liddel et al., 1984), while the term fuel poverty was not mentioned explicitly (Heindl and Schüssler, 2015). Brenda Boardman (1990) defined fuel poverty first, stating that household allocating more than 10% of their income to fuel expenses are considered as fuel poor, and the criterion was included in the official documents. Hills (2012) developed another criterion in fuel poverty assessment considering not only fuel expenditures but also household income with regard to national averages. The criterion, named as Low Income High Cost (LIHC) was published in the Fuel Poverty Methodology Handbook (FPMH) in April 2020 (BEIS, 2020). The most recent criterion, Low Income Low Energy Efficiency (LILEE) considers energy efficiency besides fuel expenses of the households, and was published in FPMH in 2022.

This study adopts LIHC criterion, and fuel poverty level is calculated accordingly. The assessment has two parts: income and fuel cost, while equivalent values of both with regard to household size are considered since different households have different spending requirements (BEIS, 2020). The equivalisation factors are taken from FPMH (Table 2)

Table 2. Equalisation factors for the fuel cost and income (BEIS, 2020)

Household	**Equalisation Factor**
	Fuel Cost
1 individual	0.82
2 individuals	1
3 individuals	1.07
4 individuals	1.21
5+ individuals	1.32
	After Housing Cost Income
First adult	0.58
Other individuals aged 14 and over	0.42
Individuals under 14	0.20

Income is the amount after mortgage and rent payments, and fuel costs include natural gas and electricity payments. Household net income and fuel cost are compared to corresponding threshold values, and the ones with lower income than the income threshold and higher fuel expenses than the fuel threshold are accepted as fuel poor.

6.2. Logistic Regression

After identifying fuel poor households, a logistic regression analysis is conducted to reveal factors influencing fuel poverty. Logistic regression is a statistical method used to model the probability of a binary dependent variable with one or more independent variables. The model estimates the coefficients, which represent the change in log-odds of the dependent variable with a unit change in the independent variable. In this study, output is a binary categorical variable (1: fuel poor, 0: not fuel poor). SPSS software is utilised for the binary logistic regression analysis.

7. Results

The results of the fuel poverty analysis with LIHC and the interview are presented in the following parts. First, the calculation of income and fuel cost thresholds for LIHC analysis is given, followed by the analysis of fuel poverty levels. Then, the findings of the content analysis are discussed.

7.1. Fuel Poverty

The fuel poverty level of the urban regeneration areas is calculated according to LIHC criterion. First, net incomes are calculated through subtracting the rent and mortgage payments from the monthly income. The fuel costs are the sum of average monthly natural gas and electricity bills. After the calculation of equivalised income and fuel cost, the values are compared to income and fuel cost thresholds. In the FPMH, the threshold values are the national median levels for both values. In terms of income, national median can be a reasonable threshold, however since the climate variations are high in Türkiye, median fuel cost of the whole country can be misleading. Moreover, natural gas unit prices and electricity distribution costs vary in different cities. Dubois (2020) discusses this issue as some local specificities might be existent while national level research may miss them, so that energy poverty analysis at regional level is suggested. Therefore, a benchmark value is calculated for Ankara, considering the average electricity and natural gas

consumption for a household with 4 people. Then, the value is equalised for a household with 2 people since the equalisation factors in Table 1 consider 2 people as the base value.

Income threshold is assumed to be the national median income level. Annual equivalised median household income is 83808 Turkish Liras (TL) for 2023 (Turkish Statistical Institute, 2024), which corresponds to 6984TL monthly, which sets the Low Income (LI) benchmark. Household with monthly income less than 6984TL is considered as LI.

A fuel cost threshold which is accountable for Ankara is calculated through average natural gas and electricity bills with the following method. Average monthly electricity consumption is 230kWh for a 4-person household (Chamber of Electricity Engineers, 2021), while the unit electricity price for residentials is 1.73 in the first quarter of 2023 (Rep. of Türkiye Energy Market Regulatory Authority, 2023)The monthly average electricity cost turns out to be 449.6TL including taxes 4-person household. Daily average natural gas consumption is 4.83m^3, which is equal to 145m^3 monthly, while the natural gas unit price is 5.06TL in 2022-2023 winter season in Ankara (BaskentGaz, 2024). Average natural gas cost turns out to be 859.7TL including taxes. Total average monthly fuel cost is, then, 1315.3TL. When the value is converted to a 2-person household, the benchmark value for high cost (HC) becomes 1229.3TL. Households spending more than 1229.3TL for energy bills are accepted HC. The households below LI threshold and above HC threshold constitute 11.7% of the entire sample according to LIHC criterion.

7.2. Logistic Regression

When he factors affecting fuel poverty are investigated, the binary logistic regression shows that the odds of being fuel power is decreased by being an owner, having children under age 5, and the number of households being employed, whereas increased by the household size, having individual heating system instead of central heating, and number of months required heating, having north-faced apartment, and very large houses (more than 150m^2) (Table 3). Other variables such as household head's education level, insulation and social help do not have statistically significant effects. In fact, 97.8% of the houses have insulation, which minimizes its distinguishing effect.

Table 3. Results of the binary logistic regression

							95% CI.for EXP(B)	
	B	S.E.	Wald	df	Sig.	Exp(B)	Lower	Upper
Ownership	-1.527	.547	7.785	1	.005	.217	.074	.635
Household size	.893	.211	17.858	1	<.001	2.442	1.614	3.696
Employed household	-1.969	.357	30.432	1	<.001	.140	.069	.281
Heating duration	1.066	.321	11.057	1	<.001	2.904	1.549	5.444
North Aspect	1.081	.444	5.942	1	.015	2.949	1.236	7.036
Very Large Size	1.277	.470	7.380	1	.007	3.584	1.427	9.004
Children under 5	-1.975	.618	10.210	1	.001	.139	.041	.466
Heating system	2.905	.696	17.426	1	<.001	18.260	4.669	71.416
Constant	-11.27	2.423	21.654	1	<.001	.000		

The logistic regression model was statistically significant $X^2(8, N=400)=79.624$, p= <.001, and the model explained 35% (Nagelkerke R^2) of the variance in fuel poverty and correctly classified 90% of observations.

8. Discussion

When the components of LIHC are investigated, it can be concluded that almost half of the households are low-income groups. It is reasonable that the area just went through a structural transformation that the residents' economic circumstances have not changed much. Households classified as HC, representing 21.2% of the entire sample, indicate that the fuel costs of nearly one in five households exceed average spending on energy in Ankara. Fuel poverty, which presents 11.7% of the households, is observed in lower levels than LI and HC groups, which can be concluded that either the ones with higher incomes are able to spend more for energy so that they turn out to be HC but not LI, or the household with LI could not spend more than average values for energy so that they are LI but not HC. The second group can be further investigated in terms of hidden fuel poverty. When the result is compared to the literature, it is evident that the fuel poverty levels in urban regeneration areas tend to be lower in general. When considering the studies conducted in Türkiye, this research indicates a fuel poverty level that falls between the rates reported by Dogan et al. (2021) at 7% for the national level and Senyel Kurkcuoglu (2023) at 23.6% exclusively for the city of Ankara.

Home ownership, household size, employed households, heating months, north-facing apartments, very large houses, young children and house heating system turns out be influential on fuel poverty. Home owners tend to be less prone to fuel poverty when compared to renters. When the number of employed individuals increase it becomes less likely to be fuel poor. Having at least a child under 5 years old also decreases the chances of being fuel poor, of which impact is the slightest among all variables. When at least one young child is present in the household, the family is 0.139 times less likely to be fuel poor. Increasing size of household affects fuel poverty in a positive way, so that large households are more likely be fuel poor. When the number of months increase for heating, fuel poverty risk increases as well. Indeed, some apartments may need to heat their homes for longer durations due to the lighting conditions as a result of housing design, having a vacant flat upstairs or downstairs, having individuals with critical health issues, etc. North-faced apartments receive less sunlight during winter, leading to higher energy consumption. As a result, their chace of being fuel poor increases 2.94 times compared to apartments facing other directions. Additionally, heating very large spaces is costly. Therefore, houses exceeding $150m^2$ increase the probability of experiencing fuel poverty by 3.58 times more than smaller houses. The most influential variable appears to be the house heating system while households with individual house heating are 18.2 times more likely to be fuel poor than the ones with central heating. It is plausible because central heating systems typically heat all spaces and rooms equally. In contrast, individual heating systems allow occupants to turn off heating in certain rooms, which can result in increased energy usage in other apartments and cooler overall building spaces.

9. Conclusion

Urban regeneration activities in Türkiye, particularly the ones targeting transformation of squatter settlements, are anticipated to improve living conditions by enhancing structural quality, efficiency, and environmental standards. Although the various aspects of urban regeneration have been discussed in the literature, environmental outcomes, particularly those related to energy, have been overlooked in the literature. The discussions in the existing literature revolve around the positive impacts of the providing large green spaces, while criticisms focus on the lack of adoption of

renewables in any urban regeneration projects. Fuel poverty, however, has not been addressed in the studies.

Fuel poverty is a multi-dimensional issue that arises from both the socio-economic situation of the household and the structural conditions of the housing units. The problem has a spatial dimension, leading to its prevalence in specific areas. Squatter settlements are those which has an increased risk of fuel poverty due to having low-income residents and low structural qualities. Urban regeneration is expected to eliminate fuel poverty in such areas by improving building quality and infrastructure. Therefore, this study focused on assessment of fuel poverty in urban regeneration areas, using Ankara's Mamak district. Due to its history of high rates of squatter settlements, Mamak has been subject to numerous urban regeneration projects. A household survey conducted in four different urban regeneration project areas in Mamak revealed that nearly one in every ten households experiences fuel poverty. The observed rate is lower than figures reported in the literature, but it cannot be argued that fuel poverty is fully eliminated after urban regeneration.

The analysis of the factors influencing fuel poverty provides valuable insights for future policies in urban regeneration. Structural and design strategies can be implemented to address the issues such as very large houses, north-facing apartments, longer heating months and individual heating systems, which are associated with increased probabilities of experiencing fuel poverty. The remaining variables are primarily associated with the broader socio-economic context, necessitating comprehensive policies and strategies beyond the scope of urban regeneration. For instance, state-level policies could be developed to provide mortgages with long-term low-interest rates, thereby facilitating home ownership and potentially reduce fuel poverty. Finally, further analysis can be conducted to determine the presence of hidden fuel poverty, where households struggle to allocate sufficient funds for energy expenses, leading to inadequate heating and limited use of other appliances.

On housing affordability. Questioning the European policy perspective in action

Abstract

Since the early 2000s, owning or renting a dwelling has increasingly become in Europe a toil for many. National policies have been reducing the investment on council housing and at the same time households' incomes and spending power are decreasing, putting low- or unstable-income people at risk of homelessness. As the "availability of" and "access to" decent housing has been dropping in many European large and medium-size cities, EU policies are trying to address policies for "affordable" housing solutions. While this term has been widely used in an economic perspective, affordability should tackle on a wider range of issues embracing financial aspects, solutions for social support, funding measures and spatial models, as tools to improve the conditions for "just" cities to thrive.

Keywords

Affordability; Social Housing; EU Policy; Urban Planning; Urban Regeneration

1 Beyond economic affordability: hypothesis and research leads

In this paper, a work outline around the concept of "affordability" in the production of housing in contemporary European cities and in connection to EU urban policies will be provided. The theme of "affordable living" is continuously more urgent: with a growing range of people in crisis, the starting point in the discussion will precisely be the current challenges and trends that design on accessible living is asked to develop with thoughtful and durable solutions. Living in Europe is increasingly hard (Bianchetti, 2016): in the past 20 years, waves of economic crisis and a severe post-global geopolitical instability have impacted on public- and private spending power, further deteriorated by neoliberal policies, inflation and fluctuations of raw materials and energy costs. This scaled down the availability to pay and living conditions of not only people in need but also those traditionally included in the "middle class". The negative demographic trends (combining falling birth rates and the aging population) and the crisis of the traditional welfare state have increased the demand for 'social and very social' housing (Saraceno, 2015; Tosi, 2017; Bricocoli et. al., 2021).

Approaches from individual governments on housing are diverse, but the topic is one of the priorities for the EU coordination policies. This is clear also from the growing number of observatories and platforms promoted by the European Union (EU) exactly on the housing approach, especially after the approval of the EU Urban Agenda and the 2020 European Green Deal. Here, "affordable" has become a recurring attribute for housing solutions throughout EU policies, tools and funding measures. As described in the following text, the term "affordability" opens towards a popular field in housing literature (Pittini, 2012; Heylen, 2023; Peverini, 2023; Bricocoli&Peverini, 2024), even if it is often considered in an uncritical and "comforting" way. Reinforced by with other repeated adjectives – such as "adequate", "accessible", "sustainable" – "affordable" is often used with the effect to reduce the discussion on housing policies (and on their impacts on households' costs) to a mere economic and sectoral equation. As known, affordability is generally defined as the ratio between the costs for the accommodation (rent or ownership) and the family income; alternatively, it is measured in relation to the housing cost overburden rate expressed as the share of households spending more than 40 percent of their disposable income for accommodation costs (OECD, 2023). However, beyond the economic and statistical definition, how affordability is defined and translated into concrete tools and actions should be carefully questioned. From this perspective, observatories and platforms become interesting sources to investigate for understanding the innovation fields and the perspective of the affordable housing that should inspire measures in national and local European policies.

Specifically, the paper offers critical investigations on the concept behind the word "affordability" as it is used in EU tools: policies, funding measures, and projects. In the EU-related platforms (i.e., UIA-Urban Innovative Actions initiative, New European Bauhaus, Horizon, etc.), there is a variety of planned or built case studies with a focus on housing policies: the emphasis is hence put on how the term affordability is translated into multi-layered planning and design solutions (i.e., health-care models in housing blocks, self-maintenance and self-

building, flexibility in design and allocation models), and into innovative and integrated housing and welfare policies.

Right up against the European elections, it is necessary to understand how the EU policies build up in local projects and if these can suggest more complex ways to articulate "affordability". This analysis could be useful to address the next housing policies, towards a 'just city' (Feinstein, 2010), in which housing can become again one of the pillars of welfare state (meaning an articulated set of public policies).

This research proposal will unfold at the Department of Engineering and Architecture in Trieste within two research projects, in which the topic of affordable housing is examined in urban contexts of large and medium cities. One project is focusing precisely on the topic of affordability: the research of national interest UAH – Unconventional Affordable Housing[1] will provide (re)definitions of affordability through investigation on policies, projects and practices in European case studies, as well as in local case studies at a closed level in the cities of the involved research units: Milano, Bari and Trieste. The other project, INEST - Interconnected Nord-Est Innovation Ecosystem, focuses in the Italian North-East area, between Veneto-, Friuli Venezia Giulia and Trentino Alto Adige regions, to knit active networks between universities, public research institutions and companies, with the future challenges of global economy and climate change in mind. Different scenarios will be tested in samples from the three involved Regions; amongst other topics related to the evolution of the environment, housing solutions for increasingly fragile targets will be especially explored in Venice as Trieste acting as pilot cases.

2 Setting and method

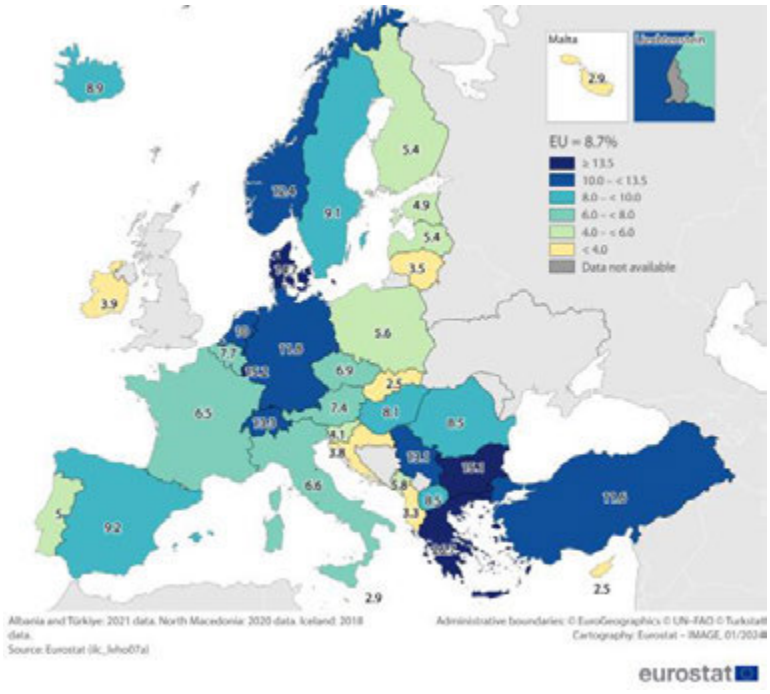
2.1 "Explosive conditions": new crises and housing demand

Since the early 2000s, owning or renting a house or a dwelling has increasingly become a toil for many European families and individuals. In 2022, 8.7 percent of the EU population spent 40 percent or more of their household disposable income on housing (Eurostat, 2022). In general, 'despite the variety of national housing policies, across the continent there is no longer a balance between wages and costs of living' (Cardini, 2023). Given this situation, three concomitant factors can be highlighted, which have further undermined the right to housing in many European contexts: the economic crisis due to the Covid-19 emergency, the touristification following the lifting of restrictions introduced to counter the pandemic, and, at the geopolitical level, the Russia-Ukraine conflict and the recent tensions in the Middle East and the Mediterranean region.

At a global level, the pandemic has drastically reduced households' earnings and spending capacity, widening social and economic disparities and exposing individuals with low or

[1] The project is funded with PNRR funds (2023-2025) and involves the Department of Engineering and Architecture (DIA) of University of Studies of Trieste, the Polytechnic of Milano and the Polytechnic of Bari.

unstable incomes (such as young adults, parents, singles, migrants) to a serious risk of housing instability (OECD, 2021b). Before the 2020 crisis, over a third of low-income tenants in countries of the Organization for Economic Co-operation and Development (OECD) spent over 40 percent of their income solely on rent, net of housing benefits (defined as "housing cost overburden rate"[2]). Housing affordability has been severely impacted by the restrictions and the related interruption of economic activities that have caused a significant increase in unemployment in many European countries. Eurostat data highlight that 16 percent of the European population lives in households that in 2021 reported a decreased income compared to the previous year, with an average decrease of 4.2 percent[3].



1 - Housing cost overburden rate, 2022 (percent) (https://ec.europa.eu/eurostat/statistics-explained/index.php?title=File:ILC_LVHO07A_values.png)

In Italy, 7.2 percent of households were severely overburdened by housing costs in 2020. This figure rises to 28.6 percent for households with incomes below 60 percent of the median income (Eurostat, 2021). There has been a significant increase in housing stress due to difficulties in paying rent or mortgage payments (reported to have increased by 95.9% and 88.8%, respectively) (Caritas, 2020). It is worth noting that this hardship has been temporarily mitigated by housing support measures implemented during the pandemic. However, soon these

[2] See Eurostat, Glossary: "Housing cost overburden rate", https://ec.europa.eu/eurostat/statistics-explained/index.php?title=Glossary:Housing_cost_overburden_rate, and paragraph 2.2 below.
[3] Data 2020 from dataset "F1N Change in household income", Eurostat, EU-SILC 2021.

measures were gradually phased out, leaving tenants facing a situation of great uncertainty (OECD, 2021c).

Touristification, which was somewhat halted during the pandemic but reignited soon after the restrictions lifted, has a significant impact on the real estate market, especially on affordable housing, within a broader context of deregulation, with policies unable to counteract the phenomenon (Gainsforth, 2023). In 2022, the total number of overnight stays in European Union in short-term rental accommodations booked through Airbnb, Booking, Expedia Group, or TripAdvisor increased by approximately 7 percent, further growing by an additional 13.8 percent in 2023.[4].

The tourism industry's resurgence has sparked a fierce competition between two distinct housing demands, leading to a significant shift of available housing from the traditional rental market to the short-term rental market, which promises significantly higher returns (FEANTSA, 2020). This shift has exacerbated existing eviction trends already ignited by many mid-2010s regeneration processes (Boschetti, 2023). Numerous studies have demonstrated that Airbnb has driven up rental prices (by as much as 7%) and reduced the availability of existing long-term rentals. It has also influenced housing purchase prices (increasing by up to 17%), further diminishing the availability of "affordable" homes (FEANTSA, 2020). As a result, when specifically referring to the rental sector, the “availability of” and “access to” decent housing is dropping in many European large and medium-size cities, where the effects of gentrification processes (also related to tourism) and higher market prices often combine with the impacts of internal and external migrations and poor maintenance of council housing stock (OECD, 2021c).

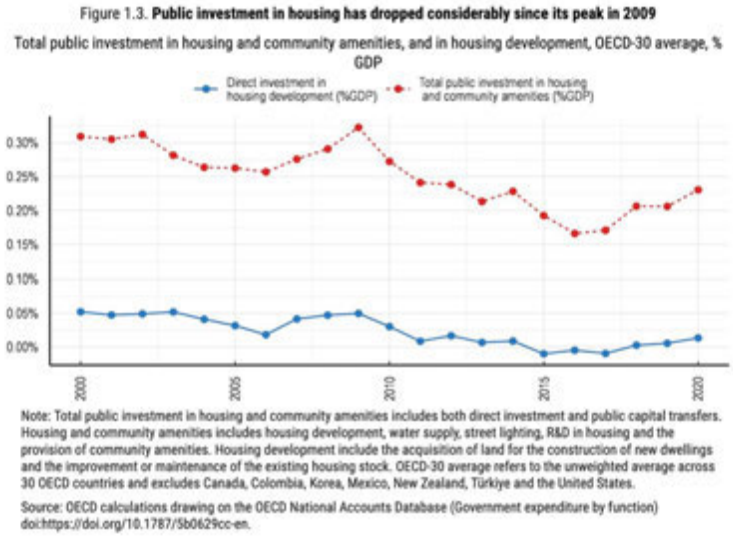
At the same time, the war conflicts at the doors of Europe and the Mediterranean, with their sanctions and trade fluctuations, have severely impacted the public expenditure, with a negative effect on the construction sector due to increased costs of building materials and energy supplies. According to Eurostat data, in March 2023, construction material prices in the European Union increased by 45.8 percent compared to March 2022[5]. This has in many contexts (eg. Italy) reduced the capacity for investments on housing, and especially on public/social housing estates. The war in Ukraine has triggered a generalized increase in prices, particularly affecting low-income families whose consumption basket is more sensitive to energy and food prices, further reducing disposable income for housing costs.

Therefore, it is crucial to examine housing conditions across Europe. EU-SILC data highlights that a significant percentage of European citizens live in precarious housing conditions or experience housing hardship. In 2020, it was estimated that 17.4 percent of population lived in overcrowded dwellings and 1.7 percent in dwellings lacking basic sanitation facilities. Italy stands out negatively with an overcrowding rate of 26.1 percent, almost double the European Union average, while 27.9 percent live in dwellings that do not meet minimum standards (leaky

[4] Data Eurostat 2023 from dataset “tour_ce_omn12, Short-stay accommodation offered via collaborative economy platforms by months, residence of the guest and NUTS1 and NUTS2 regions - experimental statistics”.
[5] Own elaboration based on Eurostat 2023, dataset: Construction producer prices or costs, new residential buildings - quarterly data.

roofs, damp walls, lack of a bathtub or shower, lack of an indoor toilet for exclusive use of the family, and lighting problems)[6].

The causes of this housing distress are diverse and complex: on one hand, the scarcity of affordable housing, the aging housing stock with a corresponding decline in public investment, and on the other, the diversification of housing demand, particularly among the elderly, people with disabilities, and other vulnerable groups (Tosi, 2017). The reduction in public investment in public housing stock has made maintenance and interventions on existing housing rarer, on the one hand, and has reduced the construction of new housing, on the other hand (OECD, 2021c). Among all the countries for which data are available, the amount of public funding for social rental housing as a percentage of GDP was higher in 2010 than in 2020 (OECD, 2019[7]).



2 – Total public investment in housing and community amenities, and in housing development, OECS-30 average, percent GDP (OECD, 2021c)

Housing in Europe is facing a significant challenge: a mismatch between the existing housing stock and the evolving needs and preferences of a diverse range of users. While the housing stock remains largely unchanged, the population is becoming increasingly diverse in terms of age, household composition, and lifestyle. This phenomenon, linked to factors such as population aging, the rise of single-person households, increased immigration, and changes in work patterns, exposes these categories to precarious housing conditions, with negative consequences on health, well-being, and quality of life. According to Eurostat data in 2021, 31.3 percent of households in the European Union consisted of a single person, the proportion of individuals aged over 65 years has increased from 16 percent in 2002 to 21 percent in 2022, and the percentage of individuals aged over 80 years has nearly doubled between 2002 and

[6] Data Eurostat 2023 from dataset “Living conditions and welfare”, EU-SILC 2023.
[7] Data OECD Affordable Housing Database from “PH1.1 Policy instruments and level of governance”.

2022. In 2022, 8 percent of people living in European Union were foreigners[8], with 3 percent being citizens of another European Union country and 5 percent from a non- European Union country. Overall, the foreign population increased by 12.2 percent between 2010 and 2020[9]. The multitude of user profiles asks for greater complexity in property management. In the absence of housing solutions, access to other citizenship rights and the welfare system is also reduced: a spiral that reinforces the personal condition of vulnerability.

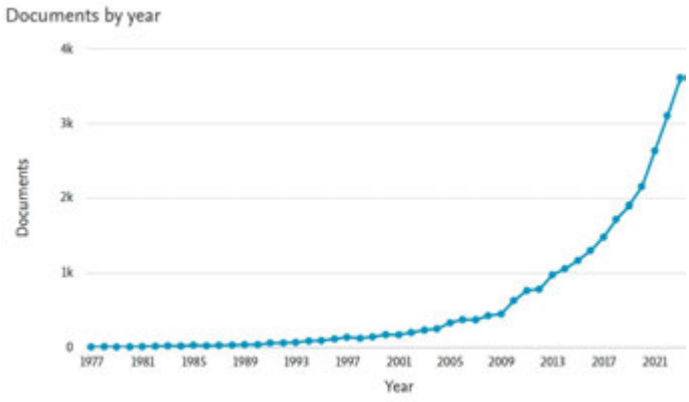
2.2 What We Talk About When We Talk About Affordability

Given this overall picture, no wonder that, especially after the approval of the EU Urban Agenda (2016) and the European Green Deal (2020), "affordable" has nearly become a "buzzword" for housing solutions throughout EU policies, tools and funding measures.

3 - Priority themes in the EU Urban Agenda (https://futurium.ec.europa.eu/en/urban-agenda)

The term "affordability" has gained increasing prominence in housing debates since the mid-1990s, appearing frequently in both EU documents and academic literature (Pittini, 2012; Granath Hansson, 2017; Heylen, 2023). A quick search on Scopus using keywords related to the field of interest and the European context reveals a surge in the use of the term coinciding with the consolidation of neoliberal policies in urban management across Europe in the late 1990s, followed by a series of financial and housing bubbles and economic crises (starting in 2007).

[8] Data Eurostat 2023 from dataset: "Demography, population stock and balance".
[9] Data Eurostat 2023 from dataset: "Migration (migr)".



4 - Number of papers on the theme “affordable housing” in the period 1977-2024.
The figure emphasizes a significant drop in the production related to the issue in the last three years (since 2021).

Studying documents and initiatives within Institutions of the European Union dealing with housing (directives, platforms, observatories) is helpful in grasping whether the idea of "affordability" in European policies can be broadened or refined. Strategic documents, often concise and clear, tend to offer a somewhat simplistic view, often focusing solely on the economic aspect of the issue.

In discussions surrounding "housing affordability" within European policy contexts, the focus tends to focus on the methods used for measurement (OECD, 2021a). There are various approaches to evaluating housing affordability, each with its own strengths and weaknesses. The price-to-income ratio (P/I ratio) offers a broad perspective on how housing prices relate to incomes across different markets and over time. However, this ratio has limitations, primarily because it relies on average price- and wage data, which can oversimplify the picture (aggregated data). The expenditure-to-income ratio (E/I ratio) considers the actual housing expenses of households, providing a more detailed and nuanced assessment of affordability. By examining household-level data, this measure offers insights into the diverse financial challenges faced by different groups and individuals. It encompasses two distinct methods of affordability measurement: the ratio method and the residual income method, both aiming to gauge the relationship between housing costs and household income (Heylen, 2023).

Both the (P/I) ratio and the (E/I) ratio, when constrained by a purely economic interpretation of affordability, show significant shortcomings. These metrics fail to capture essential aspects of housing affordability that extend beyond mere financial calculations. They overlook factors such as the distribution of housing costs and accessibility, mortgage expenses, access to affordable housing, and housing quality. Moreover, the arbitrary selection of affordability thresholds neglects the diversity of housing costs, incomes, and living standards across various regions and contexts. It is widely understood that housing is deemed "affordable" if it does not

exceed 30-40 percent of household income (Pittini, 2012; UN-Habitat, 2019; Eurostat, 2023). However, acknowledging the lack of a comprehensive and critical approach to how this threshold varies depending on territorial contexts is important: 'despite consensus across Europe on housing affordability being increasingly stretched, the idea of what is affordable is subject to national interpretations.' (Pittini, 2012).

Indeed, the concept of economic affordability widely varies in different Countries according to their different welfare policies, taxation frameworks, and overall costs of life. Furthermore, the explosion of social housing demands makes housing affordability a cross-cutting and multi-faceted issue. Questioning how the European policies provide for housing affordability has been practically interpreted in local projects and policies can therefore provide a valuable perspective to: i) understand if and to what extent economic, social and spatial issues can be more effectively integrated; ii) reframe and enrich this term and its operational meanings. As highlighted by Eurostat[10], two concepts can be used to broaden and refine the definition of affordable housing: the housing cost overburden rate and the overcrowding rate. These indicators, which measure the percentage of the population living in housing with excessive costs or overcrowding, respectively, provide valuable insights into the multifaceted nature of housing affordability and its impact on people's lives (OECD, 2021a).

To measure affordability, the use of "objective" indicators (house costs, rent, salaries, associated costs), easily measurable, can be further specified through the use of "subjective" indicators, which, through direct questioning of residents, contribute to questionnaire evaluation factors such as the availability of quality housing in one's city or neighborhood, the perception of security, as well as the perception of housing insecurity, which for example increases as incomes decrease but also with increasing job instability (OECD, 2021b; Heylen, 2023).

Despite the comprehensive framework, the limitations of these definitions and indicator systems do not exhaust the topic. Therefore, delving more closely into projects addressed by "affordable housing" policies seems like a useful step to then address the issue within ongoing research.

2.3 Methodology. Observatories and platforms, policies and projects.

This research delves into the complex landscape of European housing policies, where two fundamental documents set the overarching goals: the UN's 2030 Agenda for Sustainable Development and the Green New Deal, aiming for Europe's climate neutrality by 2050. Within this framework, additional documents like the Geneva UN Charter on Sustainable Housing, the Amsterdam Pact, and the related Housing Partnership Action Plan (2018) provide specific guidelines. Notably, the Renovation Wave Strategy (2020), aligning with the Green New Deal, prioritizes energy-efficient buildings and the reuse of existing housing stock, specifically through the Affordable Housing Initiative (AHI).

[10] For the following terms see the Eurostat Glossary: https://ec.europa.eu/eurostat/statistics-explained/index.php?title=Glossary:Eurostat.

Many of these housing policies prioritize climate concerns, emphasizing energy-efficient buildings and reduced environmental impact. However, it's important to note that affordable housing remains a critical area of study within these frameworks. Therefore, channels of financing and platforms promoting knowledge networks between local administrations and providing financial support for project realization were subsequently investigated: Horizon Europe, main EU funding channel with specific calls for both housing and "affordable" housing; Urban Innovative Actions (UIA), funding and monitoring entity; the New European Bauhaus (NEB), operational channel of the Green New Deal with a strong focus on the spatial and social "creativity" of the project proposals; URBACT, exchange and support network for local administrations, with housing and inclusion as one of the main focuses.

Finally, observers dealing with spatial policies and residential construction were selected, monitoring trends in the construction sector and bringing together stakeholders (builders, promoters, developers, housing agencies, but also...) from both spatial policy perspectives. These "containers" highlight virtuous and "exemplary" cases that can be scaled up to higher-level policies (design and spatial examples) or implemented locally (in the case of policies). Thus, attention was paid to Housing Europe; SHAPE-EU European Affordable Housing Consortium; Eurocities; Housing Solutions Platform; the Housing 2030 Initiative. From here, some case studies proposing innovative elements regarding the concept of affordability, effectively integrating spaces and policies, were selected and will be briefly described in the next paragraph.

The study work, in addition to consulting the documents available from the platforms, will be refined with further operations in the coming months. In-depth interviews with key stakeholders involved in the ongoing processes, including designers, administrators, third-sector entities, construction companies, will allow deeper exploration of various issues, including:

- a comprehensive review and analysis of the local regulatory framework that shapes the implementation of the case studies;
- financing mechanisms and long-term financial sustainability;
- spatial and technological solutions;
- impact on the community and lessons learnt;
- replication potential in other contexts.

The selected case studies will be refined and broadened through thematic lenses. With the other research units, we can develop thematic atlases that transcend geographic boundaries and themes within the affordability container.

The platforms consider a diversity of examples at a global level, even in peripheral and rural areas; however, this research focuses on European cases within medium or large cities. Look beyond Italy is useful, to seek "innovative" solutions and tools to bring into our national framework. This can be strategic, even in a later phase of work, to detect elements of innovation that may already be conventional or regulated in policies elsewhere. Urban areas appear to be the most stimulating dimension for research, as places where social inequalities become more

acute and entrenched. Precisely in cities, where individuals often lack established networks of mutual aid, familial or friendly, and are more vulnerable, access to an "affordable" home is essential to maintain an adequate standard of living and thus contribute more generally to social cohesion (Bricocoli in Peverini, 2023).

3 "Concrete" translations of affordability: relevant topics between spaces and policies

From the observatories and platforms that have been already mentioned in 2.2 section, we can identify a few housing projects and interventions, that more than others are physical translation of the affordability notion. Working on the analysis of design examples allows to verify how the concept behind their peculiar housing offer- which is the "being affordable"- is developed in relation to the supporting housing politics and issues at urban / territorial scale (green & blue networks, energy) and at close-up scale, overcoming a mere financial- and economic approach and offering "overall" solutions. The projects analysed in par.3 are identified as "exemplar" and meaningful case studies in the sources or developed within European financing frameworks. Amongst the selected cases, there are models for the integration between housing and welfare support (health and social assistance); for technological and construction solutions that make it possible to imagine reuse operations in the future or that make use of recycled materials (with consequent reduction of costs); for the relationship with the existing and often abandoned heritage of the urban contexts of intervention.

Working on the topic of affordability, these cases are interesting not only because they aim at reducing the direct costs of the dwellings, limiting them to the threshold of the 30% of the individual income, but because they implement models of "integrated" affordability. They hence integrate financing- and functional mix models in order to: combine the spaces of the single apartment with spaces for social- and healthcare services (Calcio, Belgium); grant the right to housing and support the access to jobs (Vivalla, Sweden); support housing spaces with services to create local communities (La Borda, Spain); contrast the risk of homelessness with multi-scale solutions (Homes for Good, UK). Beyond their innovative content and their overall quality, another criteria for the selection of these cases was that they refer to diversified frameworks of welfare models and somehow represent the different models of European welfare states; therefore they represent the different ways in which the "right to housing" is interpreted and – at what degree- supported from the public policies (Esping-Andersen, 1990; Piketty, 2014). In this perspective, we want to stress the relationship between the right to housing and the right to the individual and collective well-being (Secchi, 2013; Bianchetti, 2016), granted by the welfare policies[11], regarding which "housing" is the passkey.

[11] In this regard, the reference is to the classification of European models of welfare state offered by Salamon and Anheiher (1999, in Corbisiero, 2008) based on which degree States and Third Sectors are involved in the welfare provisions.

3.1 Containing housing costs with Community Land Trusts and innovating the health-care welfare with new co-living models

5 - Topic framework in UIA (https://www.uia-initiative.eu/en/topics)

As known, UIA Urban Innovation Actions is an EU channel of action to 'identify and test solutions for sustainable urban development' (UIA, 2020), that financed with the ERDF channel for the period 2014-2020 of projects with a high degree of innovation and in cities of at least 50.000 inhabitants, up to 80 percent of their overall investment. UIA was an especially interesting experience as the selected projects were supported as case studies and monitored both in the planning and the construction phase, both when in use; this approach allowed to create a multifaced knowledge bank, intervention toolboxes and guidelines to inspire policies at local level and support local administrations in the decision-making process[12].

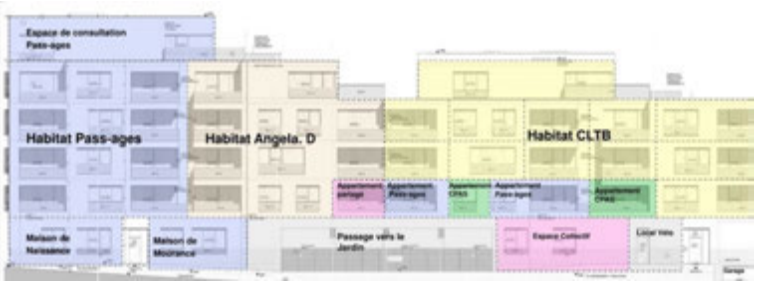
Amongst the realized projects, Calico in Bruxelles is a recently completed intervention (2021) offering innovative ideas for health care models in housing blocks. The project proposes a new governance model for community-led (co-)housing to contrast the severe lack of affordable housing in the metropolitan region of the Belgian capital. Indeed, rental- and buying costs on the free market has nearly doubled in recent years in Bruxelles; on top of that, families with an income of 1500 € or lower spend in average 60 percent of their income for housing and housing-related costs. As suggested by its acronym "CAre and LIving in COmmunity", Calico introduces innovations at the scale of the building (mixing housing units and shared spaces) and of the proximity spaces, offering housing solutions especially addressing the needs of low-income people as women at risk of homelessness (also elderly women), elderly people, families with migrant background.

[12] All information about Calico project in 3.1 comes from UIA website: https://www.uia-initiative.eu/en/uia-cities/brussels-capital-region.

The building houses 34 units and has a rather "traditional" housing scheme that mixes single- or family apartments with collective spaces and shared spaces at the ground floor. Calico's innovation rather lies in the financing- and management model. The financing (5 Meuro) was managed with the collaboration between a Community Land Trust (CLT) and the local government. The land acquisition cost and the financing of the community spaces in the building was managed by the Community Land Trust Brussels (CLTB), while the apartments are partly bought by cooperatives (20 units), partly acquired by CLTB that rents them out to people 50+ (4 units) or as Housing First options (2 units); a few others are put on sale with "social" prize (8 units).

The intervention of the CLT allows to contain the apartments' cost, separating the costs of the land from the costs of the units[13], and to hinder speculation, putting a cap on the sales' prize.

The innovative management can be identified in the presence of three property managers: as seen, CLTB, and other two cooperatives, Angela D. and Pass-Ages, that respectively fight gender exclusion in a feminist perspective and support intergenerational co-living models. In the building an innovative life-to-death health care model (overcoming the hyper-specialization of the Belgian health care system), is integrated. This was developed with the residents and aims at support continuously the residents, along different life-phases.

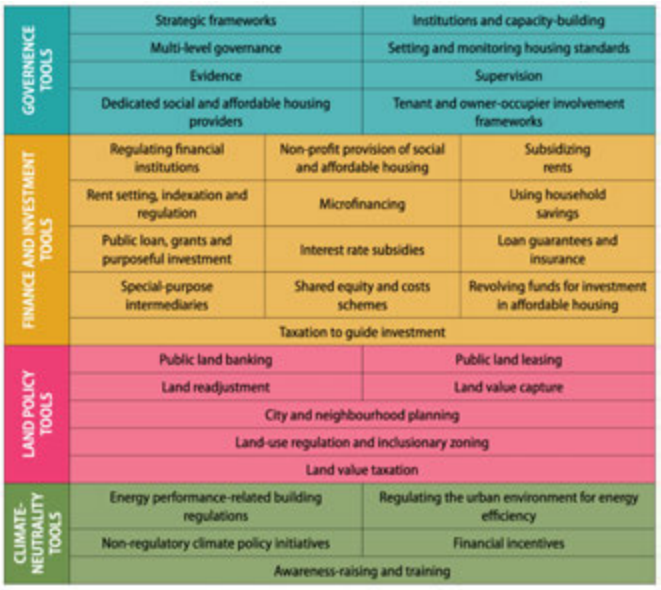


6 - Calico, building facade and managment diagram.
(https://www.cltb.be/calico/?lang=en)

3.2 From abandoned industrial sites to innovative cohousing models with the action of close-knit housing cooperatives

Housing 2030 is an initiative of Housing Europe, Unece and UNHabitat to collect pilot cases offering a set of 'effective policies for affordable housing in the UNECE region' (UNECE and Housing Europe, 2021), addressing housing policies at national level. The 2021 handbook, published during the pandemic, provides an articulated set of policy tools organized in thematic sections such as: governance, finance, land and climate-neutral housing.

[13] In Bruxells, CLTB manages to deduce the costs of the land from the selling costs as the building land is granted in "surface right". More information, here: https://www.cltb.be/how-does-it-work/?lang=en



7- Thematic toolkit and policy tools for affordability.
(UNECE, 2021, p. 20: https://unece.org/sites/default/files/2021-10/Housing2030%20study_E_web.pdf)

Amongst the case studies presented as examples of effective governance policy (multi-level governace and strategic frameworks), there is the Barcelona case, analyzed at both policy- and design level. As known, Spain has developed in the second half of 20th Century a welfare model that excludes the housing provision from the set of "essential services"; moreover, Spanish policies have traditionally supported access to private ownership, while tools for rent- and land leasing regulation, such as the 1964 LAU Urban Leases Act, and its following updates up untill 2013, had hardly an impact on the matter (Falagàn, 2019). In the national framework two issues could be noted: weak support policies combined with a harsh housing crisis in relation to the "property bubble", burst around the time of the 2008 financial crisis, leading in those years to a yearly +30 percent increase of the housing costs, that increased the housing tension in the Barcelona metropolitan area (Falagàn, 2019).

Therefore, since 2014 the Catalan government tried to cool down the situation with an innovative housing plan. The 2016-2025 PDHB New Barcelona Right to Housing Plan tries to deal with severe housing crises by: regulating the housing mix in new interventions (min. 30% of housing units should be affordable housing); encouraging the public operator in using a wide stock of vacant and dilapidated housing units; curbing the tourist pressure; facing the housing emergencies by connecting housing to social support.

8 - La Borda, Lacol Architecture Cooperative.
(https://miesarch.com/work/4554)

La Borda cohousing cooperative project (2014-2018)[14], was developed close to the issuing of the housing plan and is a positive case study for the PDHB implementation, both at level of financial- and social management, both at architectural level. The project was developed after a strong bottom-up process involving several associations in the Sants and La Bordeta neighbourhoods, that were actively trying to push the administration in reusing the former industrial sites of Can Battlò. The area had been disused and with prediction (not implemented until then) by the general plan of 1976 to regenerate it with mixed housing-services. La Borda was funded as housing cooperative within the project of Can Battlò to provide an alternative model of housing management and implementation based on ecologic and inclusive principles, according to which the housing is managed collectively and not by the single users/buyers. In 2015 the cooperative received the land from the municipality in a 75-years right of use (with the payment of a limited fee from the users); the building site was an empty lot in between the brownfield area and the city. Moreover, La Borda managed to finance the whole operation by involving Banca Etica, applying innovative models of microcredit and contribution by the inhabitants. From an architectural standpoint, the design was developed through an intensive participatory process between the cooperative members, involving a wide range of targets. The result is an articulated block in which the presence of collectively used spaces is relevant and the shared spaces work as filter between private- and collective, semi-public spaces. The structural solution with bearing structure in structural wood and aluminium- and steel light elements is combined with technologies for strongly reducing the energetic impact and the use

[14] All information regarding La Borda project in 3.2 comes from La Borda cooperative website: http://www.laborda.coop/en/, unless noted.

of water in the building, carrying out the ecologic values of the cooperative. The architectural value of the building, designed by Lacol cooperative of architecture, has been recognized at international level.

The interviews going deeper in the case study will be an opportunity to analyze the aspects related to the financial and concrete management of the spaces, after the first years of use.

3.3 Combining self-recovery and community support to regenerate social housing neighbourhoods

SHAPE-EU is a Housing Europe- and Eurocities initiative to support developers and local administrations in creating socially inclusive neigbourhoods, developing the social targets of the New European Bauhaus and the Renovation Wave. The project selected 100 Lighthouse Districts that "cast light" on the direction for the policies of intervention on the city to take to create of new neighborhoods (or work on the existing) that are socially sustainable, 'affordable and low impact on the environment' (SHAPE-EU, 2023). Among the SHAPE-EU cases, the work on the Swedish Vivalla neighbourhood in Örebro[15] seems especially interesting for our research work. Built in the "Golden age" of Sweden's welfare state as part of the Miljonprogrammet national housing program, Vivalla neighourhood has over time become a critical area, where isolation and social segregation were tangible. With 85 percent of the population with migratory backrounds, few services and poor connections to the rest of the city, Vivalla could be defined as an area "in crisis", with a high level of social tension.

The redevelopment project (2012-2024), managed by the non-profit housing company and landlord ÖrebroBostäder, with design by leading companies as White Arkitekter and Skanska building company, contributed to improve the physical spaces of the area, 'creating a safer and more positive residential environment'[16]. The collaboration between these actors addressed the intervention at architectural level, maintaining the existing low-rise townhouses, and improving the energy efficiency of buildings (by installing green roofs, photovoltaic- and solar panels, natural cooling systems, new doors and windows, and by working on new facades systems). At urban scale, the focus was the redesign and reorganisation of open spaces, to improve access to proximity spaces and strengthen the sense of safety, belonging and community; the improvement of the local network with the urban network of sustainable mobility; the implementation of community services (Trainstation center) for the involvement of younger residents.

[15] All information about Vivalla project in 3.3 comes from SHAPE EU website: https://shape-affordablehousing.eu/vivalla/, unless noted.
[16] Skanska, Vivalla Örebro: https://group.skanska.com/projects/57906/Vivalla%2C-Orebro.

9 - Vivalla Örebrö. Credits: https://whitearkitekter.com/project/vivalla-orebro/

The physical dimension of the intervention has in fact been associated with a strong social dimension. The recovery work of the existing was an opportunity to address the problem of unemployment suffered by many of the residents, through the Residents Builder program, an innovative initiative promoted by the housing company ÖrebroBostäder. This led to the involvement of approximately 80 jobless residents in a self-recovery process, where the building company worked together with the residents, providing specific training that might later allow access to the job market.

The project is significant for three reasons, two positive and one "debated". Firstly, it is an example of regeneration of social housing area, with a high quality architectural and technological project, which can suggest solutions elsewhere in many European contexts. Moreover, such physical- and spatial intervention was an opportunity to address the problem of social segregation through the concrete measure of training and employment of jobless inhabitants. However (and here it goes the aspect to be analyzed more in depth with ad-hoc interviews), it is not clear if the intervention will become a factor for exclusion or eviction rather than inclusion, with an overall investment of 100,000 € / unit and a significant increase in the rent price, from 90€/m2/year to 125€/m2/year; or if the increase of the direct housing costs will be offset by lower energy costs thanks to the retrofit and performance upgrade, and by the income stabilization of residents and a relative increase in their disposable income (Gustavsson&Elander, 2016), for a real economic “affordability”.

3.4 Housing agencies between public and private to recover the vacant assets and contrast the risk of homelessness.

The lack of warranty of the landlords regarding the renters often results in a mismatch between a high demand for housing and a large stock of vacant privately owned housing not on the market: this is one of the problems that the policies of affordable housing try to address

(Housing Europe, 2024). Another hot issue is the need of increase the stock of housing at affordable price to slow-down the current rise of homelessness (Housing Europe, 2024).

The 2021 Lisbon Declaration on the European Platform on Combating Homelessness and the establishment of the relevant EPOCH network made it evident that increasing the share of housing units managed as Housing First options and the structuring of Housing First policies in the broader frameworks of national housing policies is essential (Housing First Europe, 2024). In this perspective, Housing Solutions Platform is an initiative of Housing Europe, which together with the two European agencies that deal with homelessness and severe housing distress through Housing First policies (Feantsa and Fondation Abbè Pierre), focuses on policies and projects that address new housing paradigms to contrast homelessness.

Among the projects highlighted by the documents available on the platform, of particular interest for the ongoing research is the Scottish case of Homes for Good[17], in Glasgow. Homes for Good is an agency in the private sector, that operates as a property manager and acts as an intermediary between owners and low-income people or "on benefit", who receive state subsidies, and at risk of serious marginalization. The allocation of the housing spaces is managed according to the Housing First model, in which the allocation of the house is granted at the beginning of the support process and lasts for a limited time but sufficient to improve the situation of the recipients. The initiative is interesting as it focuses on the existing housing stock: Homes for Good buys vacant or abandoned houses (apartments but also single-family homes), renovates them with a high design quality and rents them for people with low – very low income or at risk of losing their homes.

HFG operates as a real estate manager acting both as an intermediary and guarantor for the owners, often reluctant to rent to people with low income and social problems; additionally, HFG deals with the renovation of the real estate, often directly involving beneficiaries, thus improving the sense of belonging and responsibility. This involves a mix of activities, such as property acquisition, social activities, property management and construction work, which the group has separated into separate companies within, each engaged in different sectors of intervention and with its own professionals.

[17] All information regarding Homes for Good in 3.4 comes from HFG website: https://homesforgood.org.uk/.

10 - Homes for Good. Photo credits: https://homesforgood.org.uk/

Since 2013, when HFG was born, about 300 dwellings have been bought and/or renovated, plus a further 200 private dwellings (which remain the owners) under their management. Moreover, the agency aims at upscaling its model at national level by multiplying its headquarters and by fostering interactions with public or private lenders; at the same time, HFG offers training for investors, social operators or administrators to activate similar paths in other contexts, always with the HF model as an operational background.

4 Discussion and conclusions: economic-, spatial- and social affordability

The platforms, observatories and projects observed highlight several relevant issues around housing affordability. As far as policy issues are concerned, the selected case studies are convincing as they overlap policies at different levels: the local- and the national framework interact seamlessly by using a varied set of tools (land- or property acquisition, management models, financing frameworks, connection with a wide range of departments in the local authority); at the same time, the projects show a strong collaboration between different actors, structuring bottom-up intervention policies (La Borda) or implementing much wider policies at local level (Calico). From a spatial point of view, in each example there is a strong attention to space, which becomes structural to achieve different goals, both directly related to the project (achieving community goals, as in La Borda, or offering supporting welfare, as in HFG and Calico), or linked to more general objectives: environmental sustainability and retrofit (Vivalla); reduction of land use and reuse of the existing stock (Vivalla, HFG, La Borda). The projects of Calico, Vivalla and La Borda, while working in different ways at the "neighbourhood" level, place strong emphasis on the inclusion of the project within a framework of wider urban dynamics, which consider accessibility and sustainable mobility, as well as the system of neighbourhood services, working in synergy with the intervention sites.

If "affordability", as seen in 2.2, is often associated with the relationship between housing costs and the disposable income of the inhabitants, the policies, platforms, and projects analysed, widens an “all-round” gaze on social-, management- and spatial issues. This approach, going back 70 years, inspired the construction of welfarist housing blocks in the “golden age”. However, the project for the ‘public city’ (Di Biagi &Marchigiani, 2009) arose from the Modernist heritage and surely it offered integrated housing proposals, but these were “flattened” on a single-family model and hung on the rampant post-war certainties, with a booming demography and rich state budget. Today, instead, policies and projects for the affordable housing in Europe have surely to commit to an integrated approach; however, it must face strongly variable conditions: increasingly different fragilities, of "ways of living", of funding channels, and at the same time with a declining demography and a welfare in severe crisis, in which the public withdraws, while increasingly hard issues should be addressed. Housing emergencies, ways of living, community building, social support and health for increasingly diverse targets characterize the near future. Therefore, finding evaluation, measurement and design tools is needed to turn from a mere economic “affordability” to an integrated affordability, with innovations in financing models, environmental networks, spatial solutions, support for the territorialization of the social-healthcare welfare.

From the analysed source and projects results that the current housing issue is an opportunity to redefine affordable housing by envisioning three scenarios of integration:

- Affordability as “health through life”: housing spaces are integrated with a health target, in which “health” firstly implies choosing healthy building materials and designing healthy, accessible, thermally comfortable individual and collective spaces; secondly, supports sustainable networks in the city; lastly, integrates housing spaces with policies to support inhabitants at different stages of life and to address different health needs.
- Affordability as living community: innovative forms of cohabitation impact on the composition of the space inside the buildings, on the articulation between built spaces and open spaces, on the involvement of operators to activate socio-health and training support paths.
- Affordability as inclusion: inclusion is carried out at different levels. At the urban level, this implies integrating policies to stem evictions from the central areas and multi-faceted models to support housing. At the level of the building or of the single housing unit, modular and energy-efficient solutions must be embedded with a high spatial quality and “design for assembly” strategies in mind. At the level of policies, socio-sanitary support paths related to homelessness and education to support job access must be activated, as well enabling models against homelessness risk.

In our pilot cases, in Friuli Venezia Giulia, Veneto and Trentino Alto Adige, these directions are valuable for coping with the worsening social conditions (demographic decline, reduction of available incomes, migratory flows, loneliness), combined with the contraction of public welfare, the increase of abandoned assets to be redeveloped, the territorial fragility linked to the impact of climate change and the increasingly outdated building stock, unprepared for new challenges.

The hints presented in this paper show some trajectories for regional and local policies and on three main nodes. Firstly, investing in the monitoring and observation of good practices, while collecting and "normalizing" data to guide policies, regulatory frameworks and plans, is strategic. Moreover, building on the experience of "pioneering" and virtuous cases can help scaling up new housing policies at the national level. Finally, it is necessary to work at the same time on policies and spaces, to allow on the one hand to implement policies (innovating them), on the other to propose adequate and fitting spatial solutions in projects, bringing the right to housing back at the heart of public intervention.

Social capital among public housing residents: A comparative study between mixed-income communities and independent public housing complexes

Hee-Jung Jun & Hyung Jeong

Sungkyunkwan University

Abstract
This study aims to examine whether there is a difference in social capital among public housing residents in mixed-income communities compared to those in independent public housing complexes. This study utilizes data from the 2021 Seoul Public Housing Residents Panel Study and employs logistic regression analyses. The empirical analysis shows that public housing residents living in mixed-income communities (i.e., social-mix housing complexes and buy-to-rent public housing) exhibit greater social capital compared to those living in independent public housing complexes. This finding suggests that living in mixed-income communities has an effect on enhancing social capital among public housing residents and thus helps alleviate problems associated with public housing.

Keywords: public housing, social capital, social exclusion

Introduction

Social capital is a crucial element for achieving positive outcomes in economic, social, and political realms, promoting sustainable communities (Fukuyama, 2000). However, public housing residents often experience lower levels of social capital, accompanied by social exclusion and discrimination. This phenomenon could be linked to the inherent structural issues in public housing. In many countries, public housing residents face social isolation and stigma, a situation mirrored in Seoul, Korea. Due to limited residential land, public housing in Korea is typically comprised of high-rise buildings within large complexes, making them distinct from conventional housing. Also, antisocial activities have been observed in public housing sites along with concentrated poverty. These problems together can negatively affect social capital among public housing residents.

In response to these challenges, Korea has developed various public housing programs. Initially, public housing primarily involved the construction of large complexes.

However, over time, the approach evolved to include social-mix housing complexes that integrate private and public housing units. Additionally, the government has started *buy-to-rent public housing*, purchasing existing low-rise detached houses for public housing from the private housing sector and thus moving away from the development of new, large-scale complexes. These later iterations of public housing may have a different impact on the social capital of residents, potentially alleviating some of the associated problems.

Despite the significant influence of public housing on residents' quality of life, there is a scarcity of research exploring how living in different types of, in particular, public housing in mixed-income communities is associated with the level of social capital. Addressing this gap, this study asks a research question, "*Is there a difference in social capital among public housing residents in mixed-income communities compared to independent public housing complexes?*"

To investigate the effect of public housing in mixed-income communities on social capital, this study utilizes data from the 2021 Seoul Public Housing Residents Panel Study, conducted by the Seoul Housing and Communities Corporation (SH). The logistic regression analyses show that public housing residents living in mixed-income communities exhibit greater social capital compared to those living in independent public housing complexes. This finding suggests that social mix indeed has an effect enhancing social capital among public housing residents and thus helps relive problems associated with public housing.

Literature Review

Public housing and social capital

As subsidized affordable housing, public housing is a major supply-side housing program for low-income households in many countries. For example, there are approximately

1.2 million public housing units in the United States, which makes up roughly 15-17% of the total federally subsidized affordable housing stock in the U.S. Approximately 17% of households in the UK live in social housing. In Korea, the number of public housing has been increasing and currently over 1.5 million units along its efforts for broader social welfare initiatives to ensure more affordable housing availability.

Since the Korean government introduced its first systematic public housing in 1989, the public housing program has been diversified over time and includes various types of public housing. The types of public housing are differentiated mostly by income level. The longer-term public housing (either permanent or maximum 50 years of residence) targets the lowest-income class, which pays only 30% of market rate rent while national public rental housing is for those who can afford 60-70% of market-rate rent living for a maximum 30 years.

The most critical issue about public housing across the countries has been concentrated poverty. Wilson (1980) points out that neighborhoods with high poverty rates struggle from a lack of role models and economic resources and thus lead residents not to being able to escape from poverty and learn socially acceptable behaviors. Like this case, large-scale public housing also concentrates poverty and caused various social problems. Pruitt-Igoe, the infamous public housing development in the US, is the representative case exemplifying problems associated with concentrated poverty. As a large-scale public housing development, the public housing site stood out in the neighborhood and thus residents experienced social stigma and isolation and the neighborhood struggled from crime and disinvestment.

Social capital refers to social relationships that facilitates collaboration and cooperation and thus allows to achieve socially, economically, and politically desirables

outcomes. Although differently defined by researchers, major components of social capital include trust, network, norms of reciprocity. Then, what is the state of social capital among public housing residents?

According to the ecological model, individuals' behaviors are influenced by individual and environmental characteristics (Handy & Xing, 2011). As social capital is also trust, network, and norms of reciprocity that individuals form with others, social capital can be also shaped by individual characteristics as well environmental characteristics. At the individual level, studies find that income, gender, age, education, and family types are related to social capital. For example, Bean (2005) finds that trust is lower among the youngest and the oldest age groups while middle-aged group exhibits higher trust in Australia. Tranter and Skrbiš (2009) find that education is positively relation to interpersonal trust. While public housing can positively affect social capital by providing housing stability, more studies are finding that living in public housing is associated with a low level of social capital. For example, Donoghue and Tranter (2012) find that social capital measured in trust is generally lower for public housing residents. Mullins and Western (2002) find that tenure is a key factor affecting non-housing outcomes and living in public housing results in lower perceived quality of life, health status, perceived health, employment status, and educational attainment, greater fear and experience of crime, and poverty rate.

Putnam (2000) also argues that a built environment is important in forming social capital. In the US, conventional suburban developments have been criticized as people spend more time in car and thus not provide opportunities to meet neighbors for casual talks. In supporting this criticism, a large number of studies find that social capital is greater in walkable neighborhoods (e.g., Leyden, 2003; Lund, 2002; Owen et al., 2007; Wood et al., 2008). By contrast, Jun and Hur (2015) finds that while perceived walkability enhances social

capital, physical walkability lowers social capital because of the spatial intersection between where physical walkability is greater (i.e., the inner-city neighborhoods in the US) and where socio-economic distress (e.g., higher poverty and crime rates) is greater. This study suggests that distressed socio-economic environment that is associated with concentrated poverty is likely to lower social capital. Given that the most critical issue about public housing is originated from concentrated poverty, social capital is likely to be lower in large-scale public housing.

Social capital and mixed-income communities

Developing mixed-income communities has been the alternative to the problems associated with concentrated poverty. For example, the HOPE VI in the US is to rebuild severely distressed public housing with market-rate rental housing, thereby developing mixed-income communities. Also, the UK requires including affordable housing for low-income class in building market-rate housing. Korea more recently adopted mixed-income development, so-called *social-mix policy*, in building large apartment complexes.

There are a few studies examining the effect of social mix policies. For example, Jun and Jeong's (2018) study is one of the few that examines the effect of mixed types on residential satisfaction. They find that the level of social mix, which varies from including only public housing in housing complexes (the lowest level) to including both public housing and market-rate housing in the same housing complex, either non-randomly (the medium level) or randomly (the highest level), exhibits a U-shaped relationship with residential satisfaction. In other words, residential satisfaction is higher in housing complexes with no social mix and with the greatest social mix, compared to those with a medium-level social mix. They posit that residential satisfaction is higher in complexes without social mix

because people generally prefer homogeneity and thus are more satisfied living in communities at similar income levels. Sohn and Ahn (2022) examine whether social conflicts exist in socially mixed housing complexes and find that the types of mixtures significantly influence these conflicts. Jun and Han (2020) compare the effect of discrimination on stress among public housing residents living in social-mix housing complexes with those in independent public housing complexes. They find that discrimination has a lesser effect on stress in social-mix housing complexes than in independent public housing complexes and posit that the structural differences of the social-mix housing complexes explain the variations in social networks and social control that reduce stress from discrimination among public housing residents. Although these studies provide insights into the effects of mixed-income communities on housing, they do not directly examine social capital among public housing residents in mixed-income communities.

Mixed-income communities differ from large-scale public housing complexes both in socio-economic and physical environments. Buy-to-rent public housing units located in low-rise residential areas alongside other private housing units, as well as public housing in social-mix housing complexes, are relatively hard to distinguish from ordinary housing in their neighborhoods. Additionally, public housing residents, particularly those in social-mix housing complexes, often live with higher-income families. In Korea, given that housing prices in low-rise residential areas are typically lower than those in large-scale housing complexes, not all buy-to-rent public housing residents live with higher-income families. Nevertheless, there is still a possibility that those living in buy-to-rent public housing may live with higher-income families, as buy-to-rent public housing units are allocated to the lowest-income class.

Based on the logic that we discussed above, we propose the following hypothesis:

Social capital is greater among public housing residents living in mixed-income communities than in independent public housing complexes.

Methods

Study area and data

The study area is the City of Seoul, the capital city, of Korea where population size is about 10 million as of 2022. To analyze the effect of mixed-income communities on social capital among public housing residents, this study utilizes data from the 2021 Seoul Public Housing Residents Panel Study, conducted by the Seoul Housing and Communities Corporation (SH). The SH is the entity that builds and manages public housing units for the City of Seoul. As of 2024, SH manages 221,681 public housing units (SH, 2024). The dataset encompasses data on elements of social capital, details on the physical aspects of the housing and neighborhood, and demographic characteristics. This comprehensive dataset is well-suited to evaluate the hypotheses presented in this study.

Methods and variables

To test the proposed hypotheses, we ran ordered logistic regression analyses as the dependent variables were measured as an ordinal variable on a 4-point Likert scale. The dependent variables are the three elements of social capital: trust, network, and norms of reciprocity. For the trust variable, we used the survey question, “Do you think you can trust the neighbors where you live?,” which has responses 1) very unlikely(=1) 2) unlikely (=2) 3) likely (=3) 4) very likely (=4). For the network variable, we used the survey question, “Do you network with your neighbors,” which has responses 1) I don't know who my neighbors are at all (=1) 2) I know who my neighbors are, but I don’t greet them (=2) 3) I greet my neighbors or have light conversations with them (=3) 4) I am familiar with my neighbors'

family matters or visit them frequently (=4). For the norms of reciprocity variable, we used the survey question, "Would you be willing to assist your neighbors when they need help?," which has responses 1) very unlikely(=1) 2) unlikely (=2) 3) likely (=3) 4) very likely (=4).

The primary independent variable is the types of public housing, which include buy-to-rent public housing that are socially mixed in ordinary neighborhoods, public housing within social-mix housing complexes, and independent public housing complexes. The proportion of each type of public housing is shown in Table 1. About 50% of total public housing in the sample is located in independent public housing complexes that refer to a non-mixed-income community. Approximately 30% of the public housing units in the sample are situated within social-mix housing complexes. These units can be categorized into two types: a randomly mixed type, where mixing occurs within a single building, and a non-randomly mixed type, where the mixing is organized by distinct buildings. Approximately 20% of the public housing units in the sample are buy-to-rent public housing, which were purchased from the private sector and are now leased as public housing.

<Table 1> Public housing type in the sample

Income mix	Type	N	%
Mixed-income community	Social-mix housing complex	387	30.0
	Randomly mixed	216	16.9
	Non-randomly mixed	167	13.1
	Buy-to-rent public housing	258	20.2
Non-mixed-income community	Independent public housing complex	638	49.9
Total		1279	100.0

Control variables comprise housing satisfaction with indoor facilities, housing satisfaction with outdoor facilities, neighborhood satisfaction, and demographic

characteristics, including sex(male=1), age (in years), education attainment (no education=1 to graduate school=6), marital status (married=1), employment (employed=1), years of residence (in years), household size, and household income (10,000 Korean Won).[1] Given that one's health status can affect social interactions, we also included the subjective health rating variable, which ranges from very unhealthy to very healthy (5-point Likert scale).

Descriptive statistics

Table 2 shows the descriptive statistics. The means of the trust, network, and norms of reciprocity variables are around 2.8, which suggests that the public housing residents are likely to trust their neighbors, greet their neighbors or have light conversations with them, and be willing to assist them when they need help.

For the control variables, all the means of the satisfaction with indoor housing facilities, satisfaction with outdoor housing facilities, and neighborhood satisfaction variables are around 3, which suggests that the survey respondents assess 'fairly good' for their residential environments. The mean age of the survey respondents is 63 years old.
Male and employed people account 50% of the respondents. The mean year of residence is

[1] The study conducted exploratory factor analysis (EFA) to consolidate the variables associated with satisfaction with indoor housing facilities, satisfaction with outdoor housing facilities, and neighborhood satisfaction, which were composed of multiple measurement items in the survey. Satisfaction with indoor housing facilities included four items: leakage and waterproofing status, painting and flooring status, heating and cooling system, and barrier-free design. Satisfaction with outdoor facilities included four items assessing satisfaction with amenities, green spaces, parking facilities, and security status. Neighborhood satisfaction comprised seven items measuring satisfaction with accessibility to public transportation, convenience, public facilities, cultural facilities, medical facilities, park, social welfare facilities, school and childcare facilities. The EFA employed principal component analysis and varimax rotation, with factor extraction based on Eigen values exceeding 1.0. The analysis revealed that housing satisfaction with indoor facilities and housing satisfaction with outdoor facilities were grouped into 'Factor 1' and 'Factor 2', each consisting of four survey items. Also, neighborhood satisfaction was categorized as 'Factor 3' with seven measurement items. Each factor was created as a single variable by averaging the satisfaction levels of the measurement items.

13.6 years old and the average household size is 2.45. The mean of the subjective health rate is around 3, which indicates that the survey respondents are characterized by having average health status.

	Family income	2658.59	2052.05	.00	12000.00
	Subjective health rate	3.04	.96	1.00	5.00

Results

Table 3 shows the ordered logistic regression analyses that examine the effect of living in mixed-income communities on each of the trust, network, and norms of reciprocity variables by including the buy-to-rent public housing and social-mix housing complex

variables. First, the trust model shows that the buy-to-rent public housing variable is statistically significant and positively associated with trust while the social-mix housing complex variable is not statistically significant. The network model shows that the social-mix housing complex variable is statistically significant and positively associated with the network while the buy-to-rent public housing variable is not statistically significant. Finally, both of the social-mix housing complex and buy-to-rent public housing variables are not statistically significant on norms of reciprocity. Although the effects of social-mix housing complex and buy-to-rent public housing variables, which indicate different types of mixed-income communities, are not consistent across the three models of trust, network, and norms of reciprocity, the results from the ordered logistic regression analyses, in general, suggest that social capital is greater for those living in mixed-income communities than for those living in independent public housing complexes.

Regarding the control variables, we found that satisfaction with outdoor facilities and neighborhood facilities are positively related to trust and norms of reciprocity. Male is less likely to network with their neighbors and have norms of reciprocity compared to female as expected. We also found that age, employment, marriage, year of residence, and subjective health rate are positively related to social capital.

*p<.1; **p<.05; ***p<.01

For the robustness of the models, we also differentiated the effect of randomly and non-randomly-mixed housing complexes as shown in Appendix 1. The randomly- and non-randomly-mixed housing complex variables are positively related to only network. These relationships are consistent with the result that the social-mix housing complex variable is positively related to network as in Table 3.

We also ran additional models to examine the relationship between public housing units in mixed-income communities and social capital by excluding those living in independent public housing complexes from the sample and including the non-randomly-mixed housing complex among social-mix housing complexes as the reference variable as shown in Table 4. We found that the buy-to-rent public housing variable is positively related to trust while it is negatively related to network. That is, the public housing residents living in buy-to-rent public housing are more likely to trust their neighbors but less likely to network with their neighbors compared to those living in social-mix housing complexes, especially, non-randomly mixed housing complexes. Given that the pooled sample models in Table 3 indicate that the social-mix housing complex variable, not the rent-to-buy variable, is also positively related to trust, the larger network may be due to various networking opportunities in large-scale housing complexes compared to low-rise residential areas. The randomly-mixed housing complex variable was not statistically significant in all of the trust, network, and norms of reciprocity, thereby suggesting that the level of social capital is likely to be similar between public housing residents living in randomly- and non-randomly-mixed housing complexes among social-mix housing complexes.

Conclusion

Public housing is essential for meeting the housing needs of low-income families. Yet, when public housing is concentrated in large complexes, it can centralize poverty, leading to social isolation and stigma for the residents, and potentially causing adverse effects on nearby areas. These structural issues can reduce social capital among public housing residents. As an alternative to the problems associated with concentrated poverty in large-scale public housing complexes, subsidized housing units have been provided in mixed-income communities, such as social-mix housing complexes and buy-to-rent public housing in Korea.

At the beginning of this study, we asked a research question, "*Is there a difference in social capital among public housing residents in mixed-income communities compared to independent public housing complexes?*" Based on this research question, we compared to social capital among public housing residents living in mixed-income communities with those living in independent public housing complexes by utilizing the SH data and logistic regression analyses.

The empirical analysis reveals that residents of public housing in mixed-income communities exhibit higher social capital than those in independent public housing complexes. We found that trust is greater among those living in buy-to-rent public housing located in low-rise residential areas, which are naturally mixed-income communities compared to those living in independent public housing complexes. Additionally, networks are more extensive among residents of social-mix housing complexes, which are designed to create mixed-income communities by housing both public and private units within the same complex.

Based on the findings in this study, we suggest some policy implications for public housing policy. First, public housing should be designed to facilitate integration between its residents and the general population, enabling those living in public housing to have more social interactions. Considering that social capital underpins socioeconomically desirable outcomes, public housing should be developed in mixed-income communities. This can be achieved by encouraging more buy-to-rent public housing and developing social-mix housing complexes that positively influence social capital among residents. Second, A more structured approach should be implemented to integrate public housing with private housing. Although the empirical analysis shows that social capital is generally greater for those living in mixed-income communities, it is not consistent across the three elements of social capital. Trust is greater only for those living in buy-to-rent public housing while network is greater only for those living in social-mix housing complexes compared to those living in independent public housing complexes. Norms of reciprocity did not exhibit a difference across different types of public housing. Given that all three elements of social capital are important for socially sustainable community development, it is important that public housing is designed to evenly increase each element of social capital.

This study contributes to the literature by comparing social capital among public housing residents living in mixed-income communities with those in independent public housing complexes, thereby exploring the impact of mixed-income communities on social capital. Nevertheless, this study still has limitations, including missing some factors that might affect social capital among public housing residents. For example, neighborhood characteristics such as income diversity can influence social capital. Future studies will need to consider more specific information about not only the characteristics of individual public housing units but also the characteristics of the neighborhoods where these units are located.

Abstract

Shanghai is a pioneer for urban heritage conservation in China. However, a sharp turn has emerged since 2018, where existing regeneration pathways for historic residential neighbourhoods are replaced by governmental buyouts, total demolition, and exclusive luxury housing redevelopments, facilitated by conservation masterplan revisions achieved through invitational expert participation. This paper examines the multiple self-contradictory goals that the local government plans or claims to achieve behind this sharp redevelopmental turn, and argues that these paradoxical goals – together with widespread debates and contestations across various realms that transform into coalitions of distinct stances – have necessitated the creation of a complex governmentality mediated through mainstream narratives about urban renewal. As a case study, we mapped sweeping land buyout, urban fabric change, and conservation masterplan breaches/revisions in Shanghai's Historic City Centre (*Laochengxiang*), and carried out discourse analysis based on text and video materials (n=393) to reveal dynamics of contestation, coalition formation, and governmentality production. While the Shanghai case echoes existing models such as state-initiated social engineering and state entrepreneurialism, emerging traits of "new municipalism" (manifested by self-mobilisation of non-government stakeholders) are also observed. With this perspective, we analysed risks and disparities in Shanghai's urban renewal movement, and discussed ways forward focusing on community agency.

Keywords: urban regeneration, historic district, contestation, governmentality, state entrepreneurialism, new municipalism.

1 Urban Heritage Conservation in Shanghai: Context and a Redevelopmental Turn

With a variety of heritage designations including 44 historic districts, 250 historic cityscape blocks and 397 historic cityscape streets, Shanghai is considered a pioneer for urban heritage conservation in China. In this section, we review the evolution of urban heritage conservation pathways in Shanghai as they relate to urban renewal agendas (Fig. 1 - Fig. 3), examine the sudden redevelopmental turn that resulted in the demolition of much of the city's historic fabric since 2018, analyse the multiple self-contradicting governance goals behind this sweeping city-led urban renewal movement, and raise our hypothesis that a governmentality is established to demonstrate achievement of these goals and resolve concerns and dissents regarding mass displacement, gentrification, and the loss of cultural heritage.

1.1 "Strictest Protection Measures": The Evolution of Urban Heritage Conservation Mechanisms in Shanghai

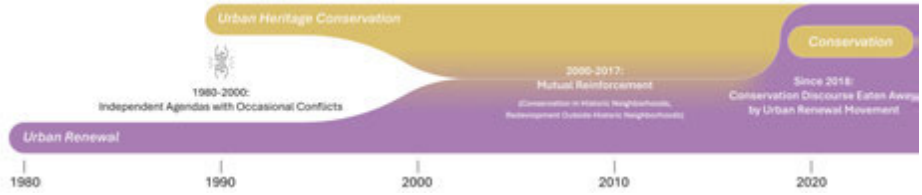

Fig. 1. Evolution of the relationship between urban heritage conservation and urban renewal in Shanghai.

1980s-2000: "Shanty Area Renewal" and Early Efforts of Heritage Conservation.

As China entered its marketisation and economic reform era, Shanghai's urban renewal project took stage in the 1980s. Early governmental focus was placed on evacuating "shanty areas" (棚户区) where per-capita housing area was less than 2 m^2, and portable toilet buckets, coal stoves, intertwined electric cables, and makeshift kitchens in corridors were prevalent (Shanghai Observer, 2018). Higher-rise and higher-value developments would be allowed block-by-block in these areas, as land was bought-up by the government and resold to developers, while existing residents were compensated by cash or apartments (either commodity housing or government-built resettlement communities, both largely in the suburbs) (Wu and Li, 2024; Chen et al., 2018; Chen, 2018).

Faced with drastic changes that started to happen in historic urban space, an awareness for cultural heritage conservation started to emerge. In 1986, Shanghai was designated among the second batch of China's National Historic and Cultural Cities. During the 1990s, early building-scale conservation efforts showed promising results: *Shanghai Municipal Regulations on the Protection and Management of Excellent Modern Buildings* was enacted in 1991, and by 1999, 398 such buildings had been designated (Zheng, 2017). Efforts for historic district conservation also took shape, as 234 neighbourhoods and 440 historic building clusters were identified. Nevertheless, due to a lack of enforcement mechanisms, some historic districts still witnessed wholesale demolition (Shao, 2016).

2000-2017: The Rise of Urban Heritage Conservation in an Expanding City.

New developments were concentrated in the outskirts, as Shanghai rapidly expanded into its suburbs and satellite towns in the early 21st century. In the city centre, salvaging cultural heritage became a consensus after the past decade of "great demolition and construction" (大拆大建).

Shortly after the promulgation of *Shanghai Municipal Regulations on the Protection of Historic and Cultural Areas and Excellent Historic Buildings* (《上海市历史文化风貌区和优秀历史建筑保护条例》, hereinafter *Shanghai Regulations*) in 2002, the city raised an agenda to establish "the strictest heritage protection measures"; as a move to operationalise urban-scale heritage conservation, conservation masterplans were formulated for 12 historic districts in the city centre, which were designed to replace detailed masterplans (控制性详细规划) for these areas and serve as sole binding documents regulating land use, development and redevelopment as they relate to built heritage (Shao, 2016, p. 3).

The last update of municipally protected heritage assets was made in 2017, with a range of designations that cover 12 historic districts in the inner-city, and 32 in the suburbs and Pudong New District; 397 historic cityscape streets, 79 historic cityscape rivers, and 250 historic cityscape blocks; 1,058 listings of excellent historic buildings (covering 3,075 individual structures), and 7.3 million m^2 of local alleyway housing (里弄, or *li*-long, as Shanghai's traditional local housing type blending Chinese courtyard and Western attached townhouse typologies).

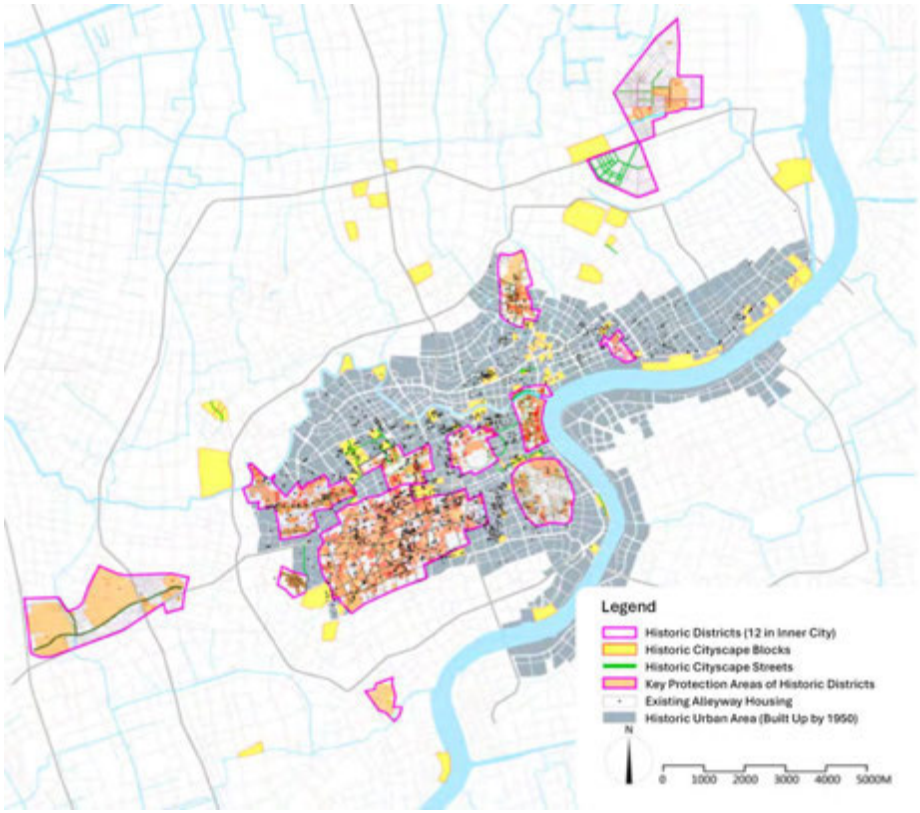

Fig. 2. Designated historic assets in Shanghai by 2017.

1.2 Three Typical Regeneration Pathways for Residential Historic Districts

Over the above two periods, flagship regeneration projects were carried out in several residential historic districts or neighbourhoods with higher heritage value and architectural quality, demonstrating three major pathways that represent local practice (Fig. 3) and showcase different stances in balancing heritage (in form and material terms), social, and economic values.

1) **Commercialisation-Oriented Restoration led by developers**, where local government and developers collaborate to turn a historic district into middle-class retail use while relocating existing residents and largely retaining the physical fabric.

2) **Fine-Grained Conservation based on government investment**, as historic districts with high architectural quality receive continuous governmental investments that help to acquire individually designated buildings and revitalise them into public cultural spaces, and subsidy the maintenance of historic alleyway blocks that serve as public or private housing.

3) **Mixed-Use Conversion initiated by local residents and partner stakeholders.** The most famous case for this pathway is *Tianzifang*, where local residents formed an autonomous association and rented unused industrial spaces and their alleyway housing units to artists and retail businesses under the support of local community council (街道), achieving the co-living of local residents, new migrants, and tourists.

1.3 A Sudden Redevelopmental Turn

After the "shanty area renewal" movement, urban renewal programs have been continued in Shanghai under the name of "old district renewal" (旧区改造) (Wan, 2022). However, much prudence was given to neighbourhoods with heritage designation or potentially worth preserving. In 2017, local government policies stressed that living condition improvement should be placed *under* the condition that old buildings in inner-city (such as various forms of alleyway housing) must be protected in principle and demolished only under exceptions (The Paper, 2017).

However, since 2018, many residential historic districts and neighbourhoods in the city centre have been targeted for urban renewal accompanying local administration changes. In 2020, the

city started a "three-year old district renewal battle" (三年旧改攻坚战), requiring old districts to be renewed "as fast and early as possible" (Shanghai Press Release, 2021). As an urban renewal agenda was written into the Central Government's *Outline of the 14th Five-Year Plan* in 2021 (Central Government of China, 2021), Shanghai raised an *Urban Renewal Action Plan* (SMBPNR, 2023) with a key goal to eliminate all "low-quality housing" (locally called "second-class dilapidated housing and below, or 二级以下旧里) in inner-city by 2025, which collocates substantially with the 7.3 million m^2 of alleyway housing that should be preserved, making them a targeted site of intervention (Huangpu District Housing Management Bureau, 2023; Zhang, 2021). By 2022, urban renewal for all major blocks of "low-quality housing" had come into effect (Shanghai Observer, 2022).

Fig. 4. Demolition and redevelopment in the current urban renewal movement. (a) An ongoing redevelopment project (Jade Fragrance Garden, Phase II) in *Laochengxiang*, 2022; (b) Qiaojia Road, *Laochengxiang*, 2024.
Source: (a) National Business Daily, 2022; (b) photo by authors.

Such rapid pace gives rise to a "total redevelopment" model applied to many historic neighbourhoods and districts – particularly *Laochengxiang* (老城厢), Shanghai's historic city centre – as an exact copy of the "great demolition and construction" movement in the 1990s (see Zhang, 2021). Governmental buyouts are prevalent, as land was cleared and resold for often luxury redevelopment, only sparing very few most important landmarks (see Knyazeva, 2022; Zhang and Wu, 2021). All local residents are relocated in the process upon cash compensation, with conservation masterplans or detailed masterplans revised (through the invitational participation of experts) to allow for unprecedented high-density redevelopments of 100 or even 150 metres (see Fig. 9(a)). Urban historic fabric is replaced by exclusive gated communities of upper-class attached townhouses and high-rise apartments, which completely alter socio-spatial patterns made up of historic buildings, streets, alleys, retail storefronts and public spaces, killing community vitality manifested in mixed uses and a mixed residential profile – the exact key characters that make alleyway housing blocks amiable spaces and self-supporting "cities within cities" (Zhao et al., 2023). While a short-term "triple-win" result is seemingly achieved for local government, developers, and residents, many areas with distinct

historic urban and social fabric – which constitute an important cultural infrastructure for global cities (UNESCO, 2013) – are permanently lost.

While there are still a few projects that adopt the "commercialisation-oriented restoration" pathway (e.g., Panlong Ancient Town), or even seek to reconstruct below-standard alleyway housing for existing residents out of governmental cost in an attempt to prove the continuity of "fine-grained conservation" (e.g., the Cloud Water Villas (云水别墅) in Hengshan Rd-Fuxing Rd Historic District, see Shanghai Observer, 2024), demolition and out-of-context redevelopment undoubtedly play a predominant role in the current urban renewal movement.

This government-led urban renewal movement shows a very strong character of state-led gentrification (He, 2019), and reflects the state entrepreneurialism model (Wu et al., 2022) where the state acts through the market, but also has broader political agendas beyond growth-machine logics. In fact, it may even be regarded as a case of "state-initiated social engineering" (Scott, 1999, 4), given the close collaboration between the government, developers, and government-owned land expropriation companies, as well as local community councils, neighbourhood associations (居委会), and conservation masterplan revision mechanisms being mobilised for the agenda.

On the other hand, counternarratives for conservation haven't been able to have any comparable agency, and as we will continue to show, a governmentality has been formed to attribute the dilapidation of historic districts to heritage itself, and create a binary opposition between heritage conservation and living condition improvement. In sum, the current urban renewal movement signals the abandonment of Shanghai's urban heritage conservation measures formed upon three decades of exploration, and leads to extensive disappearance of historic urban landscape as the city's heritage conservation masterplan fails to function.

1.4 Paradoxical Governance Goals, Contestations, and the Creation of a Governmentality

At the backdrop of this sharp and enormous redevelopmental turn, we ask the following questions:

- What are the goals that the local government plans or claims to achieve behind this sweeping urban renewal movement? How are top-down narratives and the combination of different types of regeneration/redevelopment projects utilised to support these goals?
- How are urban renewal campaigns received, debated and contested on-the-ground? What are the contradictory voices projected in different realms of discourse (specifically, the public, the academia, and social organisations / participatory political parties (民主党派) which serve an advisory role in China's urban governance), and how have them influenced the trajectory of this movement?

Our hypothesis is that there are multiple self-contradictory governance goals – whether explicit or implicit – in the urban renewal movement, including land finance, living condition improvement, and cultural heritage revitalisation, which are all written under the low-quality housing elimination mandate by 2025. Meanwhile, widespread debates and contestations have emerged across different realms of discourse, forming into coalitions of distinct stances. These conditions necessitate the production of a relatively complex governmentality mediated through mainstream narratives that renders urban renewal as a progressive movement, opposes heritage conservation against living condition improvement, reduces the scope of "cultural heritage",

frames heritage conservation as a result of urban renewal, and capitalises the cultural and historic connections of historic neighbourhoods to appeal to potential luxury housing buyers; it even manifests itself through flagship programs on intangible and cultural history, and sympathies displayed to local residents on their "bittersweet" experience. These techniques serve not only to resolve concerns and dissents, but also to demonstrate achievement of the government's own paradoxical goals. In the following sections, we seek to ground-truth this observation through policy, discourse and spatial analyses, featuring a case study of Shanghai's historic city centre (*Laochengxiang*).

To begin with, we argue that Shanghai's current urban renewal movement reveals the following self-contradictory governance goals:

- **Low-Quality Housing Elimination** as the overarching political agenda. Completion of buyout/expropriation programs in inner-city districts was celebrated as a major achievement of the local government in 2022, and was viewed as successful completion of a key agenda that involved three decades of effort (Shanghai Huangpu, 2022b).
- **Living Standard Improvement** as the justifying rationale. Extremely congested living environment, safety risks posed by exposed electricity cables, lack of basic living and sanitary infrastructure, and particularly, the persisting existence of portable toilet buckets ("马桶") have been repeatedly used as rhetorics to stress the living standard improvement dimension of urban renewal, which in turn serves to rally public support (especially support of local residents) and suppress pro-conservation voices (see for example, Xinhua News, 2019).
- **Cultural Heritage Revitalisation** as a side goal that is strongly claimed but barely achieved. While carrying out large-scale redevelopments that wipe away historic urban fabric, new concepts such as "urban fabric conservation" and "cityscape conservation" were constructed in local policies, to allow for practices that breach existing conservation masterplans (Zhang, 2021).
- **Land Finance** as an unspoken, but arguably the most important motive. State land ownership allows local government to use revenue collected between buyout and relocation costs and development right sale income to serve its needs or goals (see Wu, 2021). In Shanghai's case, many historic districts and neighbourhoods with dilapidated "low-quality housing" are located in the very core of the city, and are repeatedly sold for record-breaking prices: for example, several blocks in the Historic City Centre (*Laochengxiang*) were sold at ¥17.6 billion ($2.7 billion) in 2021; in 2023, 10 land tracts along the historic East Jinling Road (see Fig. 13) were sold for an astounding ¥22.1 billion ($3.15 billion) (National Business Daily, 2022; 2023).

As governmental buyout programs often manage to garner majority support by local homeowners, all these imperatives – except cultural heritage revitalisation – seem to work well with the urban renewal project on-the-ground. However, as we will show through the case of *Laochengxiang*, heritage conservation – both as a stated goal of the local government and a highly contested debate across different realms of the local society – is something that ultimately has to be responded to, and ostensibly resolved, through the creation of a govermentality embedded in mainstream narratives.

2 Contradictions, Debates, and Governmentality in Practice: The Case of Historic City Centre (*Laochengxiang*)

The city government-led wholesale redevelopment campaign was not implemented without controversy and pushback. Much of such conflict has focused on the Historic City Centre (*Laochengxiang*/老城厢) of Shanghai, a designated historic district of around 2 square kilometres that stemmed from Shanghai's indigenous walled city, and is commonly understood as the city's "origin point" (note 1). In this section, we use *Laochengxiang* as a case study to understand how existing heritage conservation masterplan is breached in Shanghai's urban renewal movement, and how contradictions and debates emerged across various realms into coalitions of distinct stances, and finally got resolved through the creation of a complex governmentality mediated through multiple mechanisms of public communication and political participation.

2.1 The Pilot Redevelopment Project: Jade Fragrance Garden (露香园)

Fig. 5. The location of *Laochengxiang*, based on a 1918 map.
Source: Library of Congress. Annotation by authors based on Zhou, 1999.

With more than 700 years of history, *Laochengxiang* is the origin of Shanghai's local culture. Labelled as "The Chinese City" in colonial-era maps, its historic urban fabric comprises streets filled from waterways, vernacular dwellings, temples/churches, administrative complexes, gardens, academies and public spaces (marketplaces, alleyways, and guild halls) surrounded by a city wall-turned circular road, offering a unique counternarrative juxtaposed with the colonial modernity embodied in the urban landscape of former British, American, and French settlements around it (Chen, 2004; Wang et al., 2017; Zhang and Wu, 2021; Qian, 2021) (Fig. 5). Buildings in *The Chinese City* historically possessed more informality than those in Western settlements, given their wooden construction and an often lack of sanitary systems such as tap water and toilet (Roskam, 2019, p. 107). Spontaneous and unregulated densification persisted for most of the 20th century, making *Laochengxiang* the densest area in Shanghai while exacerbating safety, congestion, and sanitary issues (Zhang, 2020; Zhang and Wu, 2021) (Fig. 6).

Fig. 6. Views of *Laochengxiang*. (a) The Yu Garden, a local landmark; (b) street view before current urban renewal.
Source: (a) - Tripadvisor; (b) - photo by authors, 2016.

By 2005 – when the conservation masterplan of *Laochengxiang* was made – some high-rise developments had already emerged within its boundaries (Fig. 7). Since then, a standoff between urban renewal and heritage conservation was achieved, leaving urban fabric in *Laochengxiang* largely untouched, except for occasional repairs and demolition of some illegal additions.

This fragile continuity was first disrupted in 2013, when a pilot luxury residential redevelopment project named "Jade Fragrance Garden" (*luxiangyuan*/露香园) (note 2) located in *Laochengxiang*'s northwestern corner went on market for pre-sale. Totalling 300,000 m^2 of floor area, the project incorporated attached townhouses, high-rise apartments up to 100m, club houses, and "two hotels of different formats" (Fig. 8(a)). According to historic sale data from local real property platforms Fang.com and Sohu Focus, high-rise apartments in Jade Fragrance Garden were initially touted at ¥80,000 ($13,000)/$m^2$ (as compared to an average ¥56,800 ($9,200)/$m^2$ within the city centre around the same time), with exceptionally large unit sizes of 200-570 m^2. In 2020, its attached townhouses were launched as a rare find in city centre at a price of ¥210,000 ($31,000)/$m^2$, while price for its high-rise apartments had risen to ¥140,000 ($20,700)/$m^2$ (Fang.com, 2013; 2024; Sohu Focus, 2024; SRETA, 2023).

Fig. 8. Urban fabric change brought by the Jade Fragrance Garden Project.
Source: (a) - BIDG; (b) (c) - illustration by authors.

Developed by a joint venture of two major municipal enterprises – Shanghai Municipal Investment Group and Shanghai Construction Group, this redevelopment totally eradicated historic fabric on its site, breaching important designations in *Laochengxiang*'s conservation masterplan (Fig. 8(b) & 8(c)). First of all, not all historic buildings that should be retained were retained, and among those that were spared, at least one (the Zhao Residence) was first demolished and then reconstructed as a "historic and cultural centre"; secondly, one of the only two remaining sections of *Laochengxiang*'s historic city wall was demolished in the redevelopment process; thirdly, while the townhouse-type redevelopment offers a somewhat context-aware scale (albeit presenting a hyper-gentrified image), it contradicts with the masterplan's regulation that new construction shall be strictly discouraged in the key protection area; and finally, intense high-rise developments broke *Laochengxiang*'s landscape continuity

and very sense of place (see Sohu Focus, 2024; Xinmin Evening News, 2012; Shanghai Evening Post, 2012; Shanghai Press Release, 2020).

Besides formal and material changes, it is the displacement and elimination of mixed uses and mixed residential profile manifested in this exclusive luxury redevelopment, as well as the privatisation of these urban blocks (public alleys between luxury townhouses have been guarded as of the authors' site visit in spring 2024) that ultimately killed the site's authenticity and vitality. Furthermore, very little of the site's cultural history is commemorated or spatialised in the project (except for its name, which refers to a garden that existed here until the mid-19th century), while it effectively capitalises on presenting a "Shanghai style blending the East and the West" and "inheriting and carrying forward the cultural context of *Laochengxiang*" (BIDG, 2024; CREDAward, 2021).

2.2 Sweeping Buyout Programs and Breached Conservation Masterplan

The Jade Fragrance Garden project set an example for what would follow on a sweeping scale for the whole Laochengxiang: exclusive luxury townhouses paired with high-rise apartments. Based on notices posted on Huangpu District Government's official website, we mapped land tracts that have been subject to governmental buyout and expropriation since 2015 (Fig. 9(b)), which constitute around 50% of the whole area of *Laochengxiang*. Along with another around 35% of the area that already witnessed large-scale redevelopment or had out-of-context buildings by 2015, *Laochengxiang* is placed under a massive process of social-spatial restructuring.

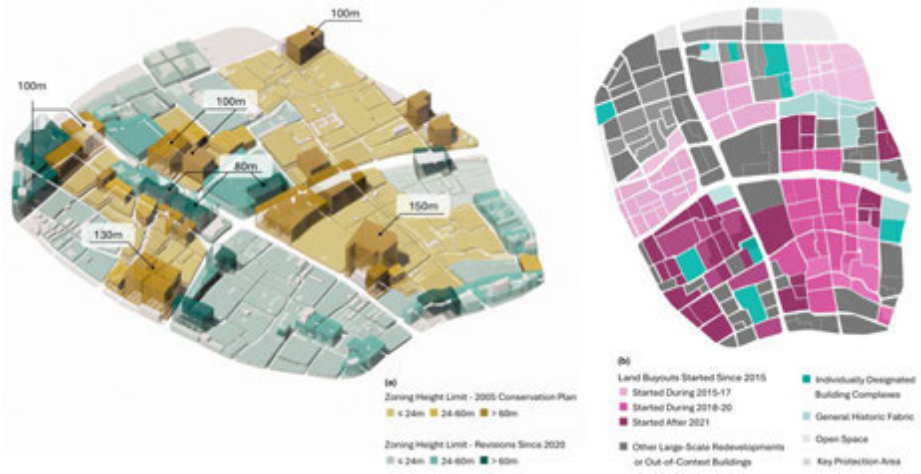

Fig. 9. Conservation masterplan revision and land buyouts in *Laochengxiang*.
Data Source: Huangpu District Government Portal; The 2005 Conservation Masterplan; Google Earth.
Illustration by authors.

On tracts where governmental buyout has been completed while redevelopment has not yet started, all residents have been relocated, and all ground-floor openings of existing buildings have generally been sealed with cement (see Fig. 13). While official narrative for this new round urban renewal is to "keep the buildings, and relocate the people" (*liufang buliuren*, or 留房不

留人, see Knyazeva, 2022), prevalent wholesale demolitions (see Fig. 4(b)) suggest that the very physical fabric is very well likely to be lost as well.

To understand how these sweeping changes were legalised against - and meanwhile predicated upon - the city's early 2000s conservation policy-making, we need to take a closer look into the details of *Laochengxiang*'s 2005 heritage conservation masterplan (Fig. 7) and its subsequent rezoning process (Fig. 9-10). In the 2005 masterplan, buildings in *Laochengxiang* were coded into six categories, from higher to lower heritage value:

1) "protected buildings" (保护建筑, 2.24% of the building stock), which are buildings subject to individual heritage designation and protection under other laws, such as Cultural Relic Protection Units under the *Cultural Relics Protection Law* (《文物保护法》) and "Excellent Historic Buildings" under the *Shanghai Regulations*;
2) "buildings to remain" (保留建筑, 5.38% of the building stock), which can be altered, but not relocated or demolished in principle;
3) "first-class general historic buildings" (甲等一般历史建筑, 7.43% of the building stock), which generally shouldn't be demolished, unless they are reconstructed in original forms;
4) "second-class general historic buildings" (乙等一般历史建筑, 20.48% of the building stock), which can be replaced by new buildings that fit into the historic context and fabric;
5) "buildings to be demolished" (应当拆除建筑, 13.04% of the building stock), which are out-of-context buildings built after 1949; and
6) other buildings (51.42% of the building stock).

This classification is accompanied with the designation of "key protection areas" (核心保护范围), where new construction and expansion is "strictly controlled" and floor area ratio (FAR) is not allowed to increase from the 2005 baseline.

Paralleling government buyouts, this conservation masterplan has witnessed multiple local revisions since 2020, many of which are backed by specific redevelopment schemes. Height limit for some blocks were loosened to 100 or even 150 metres (Fig. 9(a)), and major changes or breaches happened regarding previously instated rules (Fig. 10):

- Blocks of "second-class general historic buildings" (which constitute the expansive historic urban fabric in *Laochengxiang*) are almost always demolished, and replaced by townhouses or out-of-context towers depending on whether they are located in the key protection area or not.
- Most "buildings to remain" and "first-class general historic buildings" would also be demolished. Some of these designations are deleted in newer iterations of the plan, and some are lost during redevelopment implementation.
- Afterall, what seems to be spared are only "protected buildings", or those individually protected by other laws (see Knyazeva, 2022; Zhang, 2021).
- Key protection areas have been reduced to merely a context control area, compromising strict restrictions on new construction.

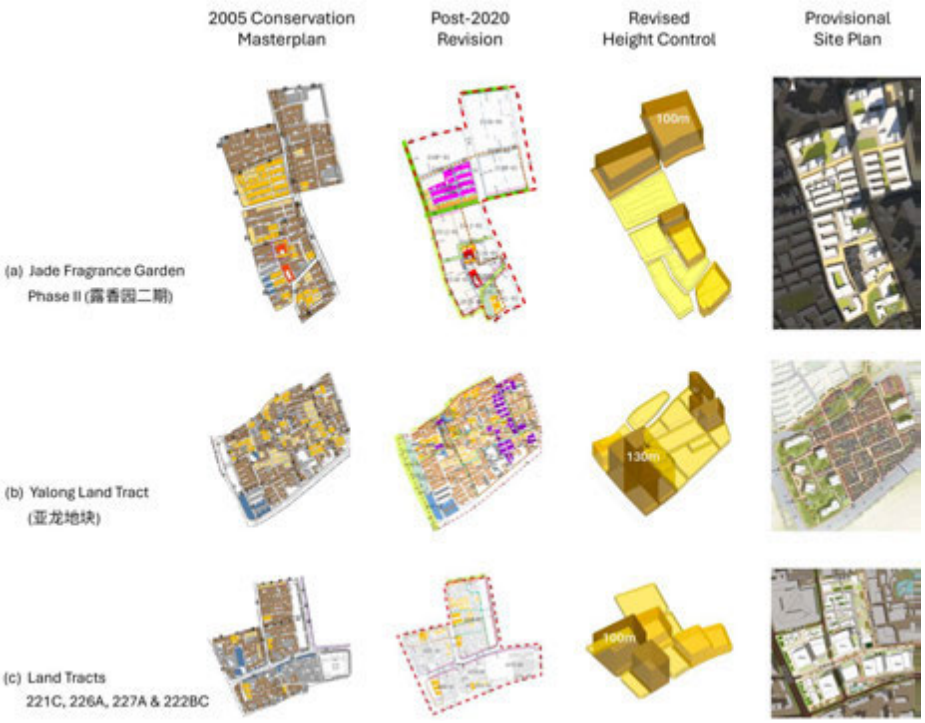

Fig. 10. Cases of conservation masterplan revision.
Data Source: Huangpu District Government. Illustration by authors.

While Shanghai doesn't yet have a public hearing process for rezoning, many of these changes wouldn't have been possible without the *special expert argumentation procedure* (专家特别论证制度) which involves the invited participation of experts within a pool. While pervasive zoning changes against heritage conservation principles demonstrate the shortcomings of invited participation, they are also in many ways predicated by flaws in the 2005 conservation masterplan, which include:

- An architectural significance-oriented approach that systematically downplayed the value of vernacular and indigenous historic urban fabrics of higher informality. Only around 15% of all buildings were designated as "undemolishable" (protected, buildings to remain, or first-class general), and the "key protection area" only covered around 27% of *Laochengxiang* (Zhou, 2016).
- Inconsistent building classifications and conservation guidelines among masterplans of the city's first batch of historic districts (twelve in the city centre), and a common lack of enforcement mechanisms. In *Laochengxiang*'s case, this has reduced the effectiveness of conservation masterplan to nearly zero.
- A relatively laissez-faire attitude to high-density redevelopments outside the key protection area. A significant number of blocks had already been zoned to 50-100m in the 2005 masterplan, especially those along the horizontal and vertical arteries that cut across *Laochengxiang*, and those in its periphery.

2.3 Widespread Contestations and Formation of Coalitions

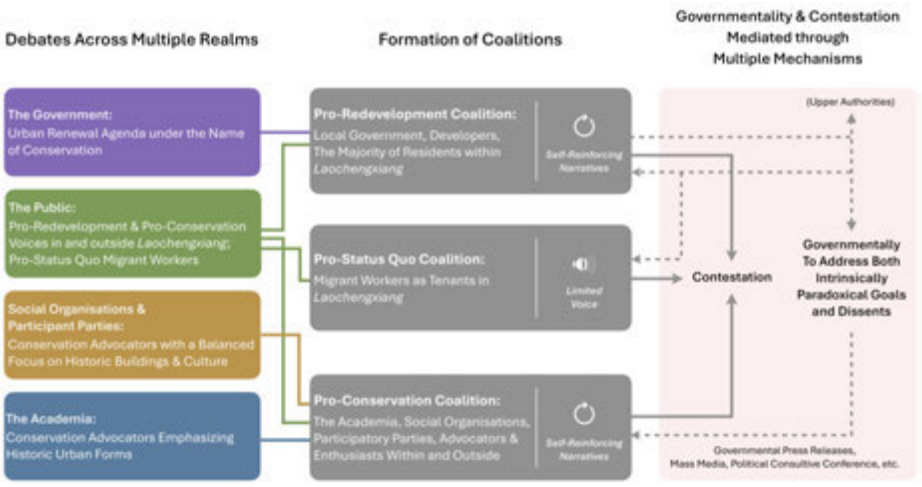

Fig. 11. The formation of coalitions and interactions between them in the widespread debate regarding *Laochengxiang*'s future.

The radical urban renewal movement has spurred polarised public responses and produced a ripple effect that gives rise to widespread contestations and debates. In the following two sections, we examine how debates across different independent realms overlap on, interconnect with and permeate into each other, forming three coalitions of distinct stances (pro-redevelopment, pro-status quo and pro-conservation), which leads to the contestation of ideas and the emergence of a top-down governmentality that are mediated through multiple mechanisms of public communication and political participation (Fig. 11). We argue that such governmentality serves dual purposes, as it addresses both the intrinsically paradoxical goals of the local government itself, and resolves dissents raised by other coalitions.

Our analysis employs a discourse analysis method and is based on evidence presented by publicly available materials including online posts (news articles, blog posts, social media posts, etc.), governmental planning and policy documents, press releases and correspondences, documentaries (*Farewell, My Humble Adobe* ("老城厢·上海的家") and *Reshaping Laochengxiang* ("重塑老城厢") by the *Doculife* channel of city-owned Shanghai Media Group), uploaded videos, academic papers, and particularly their comment sections whenever available. We gathered these materials through online search (see note 3 for detailed parameters), ending up with 289 online articles, 26 governmental documents, 34 journal papers, and 44 videos (including the 2 aforementioned documentaries), creating a total sample size of 393.

We first corralled these materials into four realms: the government, the public, social organisations and participatory political parties, as well as the academia. We then conducted a word-cloud analysis (through NVivo) for text-based materials to reveal the predominant stances and narratives in each realm, with results shown in Fig. 12.

Fig. 12. Word-cloud analysis of narratives by realm of debate.

Overall speaking, the governmental narrative highlights the buildings (it seeks to redevelop) and the residents (it seeks to relocate), while extensively uses the word "protection/conservation" (保 护) to explain its rationale. However, the "protection/conservation" keyword is accompanied by a long list of high-frequency terms associated with the sweeping movement of total redevelopment, such as "buyout/expropriation", "land tract", "community council", "contract signing", "construction", "push forward", "implement", and "initiate". Contrasting this narrative, the key perception of the public is "demolishment/relocation" (the Chinese word "拆迁" means both these two concepts), which suggests ongoing substantial changes to their built environment and loss of their memory and culture (as evidenced by keywords such as "in the past", "currently"/"nowadays", "to retain", "already", and a number of very specific locales, such as West Gate, South Gate, and Yu Garden). On the other hand, both social organisations/participatory political parties and the academia show a strong pro-conservation stance, with the former placing a more balanced focus between built heritage and cultural traditions, while the latter making a vociferous outcry for the protection of buildings and the integrated conservation of historic urban landscape (as evidenced particularly by multiple street-scaled keywords in this realm, including "street" itself (街道), "alleys" (街巷), and "alleyways" (里弄/*li-long*) as a specific local urban space).

Based on this overall understanding, we then examined collected materials piece by piece, to understand the nuances associated with the debates and paradoxes within each realm:

- **Governmental Narratives.** The actual behaviour of the local government is undoubtedly pro-total redevelopment. However, a number of its on-the-ground programs – such as exhibitions, lectures, workshops, oral history programs, and volunteering events where elementary school pupils introduce *Laochengxiang*'s vanished city gates on bus line 11 that goes along its boundary (Shanghai Huangpu, 2023b) – also incorporate a strong inclination to commemorate local heritage and cultural history. Nevertheless, these programs largely focus on the intangible cultural history of the area, without countering the physical wiping-away of historic fabric that characterises much of the debate around *Laochengxiang*.

- **Narratives in the Public Realm.** Public narratives around the redevelopment of *Laochengxiang* is particularly contested, as some online articles with explicit stances may garner more than 100 comments, igniting heated disputes among commentors. The broader *public* in examined materials may be characterised into the following four groups:
  a) Pro-redevelopment local homeowners. Homeowners in *Laochengixang* generally display a strong support for "old district renewal" (Zhou, 2018; Tang, 2019; Shanghai Huangpu, 2023a), which creates a wide divergence between them and pro-conservation experts. Some resident would ask: "why wouldn't those who fight for preserving *Laochengxiang* live here? We've had enough" (Jiang, 2019, comment section).
  b) Enthusiasts and conservation advocators in and outside *Laochengxiang.* Many bloggers, vloggers, photographers, and those lived or frequented *Laochengxiang* have come back to visit local shops again or record its daily life before it "loses connection and memories" (see NetEase Witness, 2019; SH Citywalk, 2021). A netizen questions the renewal movement, stating that the neighbourhood was demolished simply because it was "deemed valueless by the rich" (Yisanxian, 2021, comment section). Enthusiasts who live in *Laochengxiang* have also made much effort in studying, recording, and commemorating its history and physical remains, with a local journalist going through the lengths of publishing books at his own costs (Wang, 2020; Mi, 2020; Yi, 2023; Yan, 2024).
  c) The unheard pro-status quo voice of migrant tenants. By 2019, more than 40% (85,000) of *Laochengxiang*'s 200,000 residents are migrant workers (Zhang, 2020), who reside in small and subdivided units, and make an urban living upon the low rent associated with informality. They seem to possess a pro-status quo stance, as either the restoration required by heritage conservation or the displacement brought by urban renewal brings significant uncertainty to their livelihood (see Chen, 2023). Due to limited agency in urban politics and on social networks, their voices are heard not directly, but through attention given by the public news media.
  d) Advertorials by developers. Not unlike how the Jade Fragrance Garden project was advertised, advertorials for ongoing new developments are seen in the news media, singing praise to *Laochengxiang*'s cultural glamour as Shanghai's origin point, and claiming to have inherited such glamour through the creation of luxury properties. For instance, a project boasts "low-density Shanghai-style villas" that "uncover obliterated redolence from past days" and transform *Laochengxiang* from "Shanghai's origin" into "Shanghai's heart" (Shanghai Observer, 2023).

- **Social Groups and Participatory Political Parties.** China operates upon a multi-party collaboration system (多党合作制度), where the governing Communist Party is accompanied by eight other participatory parties serving advisory roles, through the Policital Consultative Conferences (政协) at multiple levels. In recent years, at least four participatory parties – Revolutionary Committee of the Chinese KMT (民革) (Zhan, 2022),

China Democratic League (民盟) (2018), Association for Promoting Democracy (民进) (Shanghai Observer, 2019), and Jiusan Society (九三学社) (2017) – have actively advocated for more serious and intergrated conservation of *Laochengxiang*'s cultural heritage and better recognition of its values via the political consultative conference platform. Generally, these recommendations showcase a strong focus on the human aspect of cultural heritage, addressing issues such as large-scale displacement, the hollowing local community, loss of intangible heritage and livelihood, and underutilisation of not-yet-demolished buildings. Meanwhile, various social groups and NGOs also contributed to create a more concerted effort (see Guo, 2019; Zhu and Wang, 2022).

- **Voices from the academia.** Local scholars in the fields of urban planning and heritage conservation have been long-time advocators of *Laochengxiang*'s integrated conservation as well. In a 2017 symposium on *Laochengxiang*'s *Past, Present and Future,* local scholars stated that "we can't see *Laochengxiang* disappear piece by piece in front of our eyes" (Website on Architectural Conservation, 2017). Particularly, many scholars have developed critical counter-narratives regarding the official rationales for redevelopment: Zhang (2021) used the word "constructive destruction" to describe the result of living condition improvement being established *against* heritage conservation efforts, and stated that "simplified movements may eradicate toilet buckets, but not poverty." Similarly, architectural historian Li Yingchun questioned "why can't we just have several good public toilets?" (see Jiang, 2019).

The analysis above reveals the intricacies that have emerged in the debates, narratives and stances *within* each realm, but what makes the *Laochengxiang* case even more complex and interesting is that like-minded groups have interconnected across realms in dynamic ways and formed coalitions based on their stances. In many cases, inter-realm collaboration serves to reinforce a coalition's narratives, casting a stronger social impact. Specifically, the following three coalitions are observed in the power struggle to define *Laochengxiang*'s future:

- **The pro-redevelopment coalition**, which consists of the local government, invited experts, city-owned or private developers, and the majority of local homeowners. The pro-redevelopment stance of local homeowners has made it possible for the government to paint urban renewal as a beneficial process responding to local residents' needs and outcries, as governmental press releases often portray senior local residents who have been yearning for living condition improvement throughout their whole life, and describe the applause and cheers when their dreams finally come true (Shanghai Huangpu, 2022a; 2023a; Tang, 2019; Doculife, 2023). Interestingly, the "masses of positive cases" during Covid pandemic is also used as a rationale for relocation, not unlike the role of toilet buckets (Tang, 2022b; Zhou, 2022).

- **The pro-status quo coalition.** As mentioned earlier, the pro-status quo coalition is mainly composed of migrant workers as tenants, who actually don't showcase a strong sense of alliance due to their marginalised voice and lack of partners in other realms of discourse.

- **The pro-conservation coalition**, represented by local academia, social organizations and participatory political parties, and conservation advocators and enthusiasts within and outside *Laochengxiang.* In fact, several leading scholars advocating for integrated conservation are themselves high-ranked members of participatory political parties, and have played a major role in the formation of policy suggestions and proposals raised by these parties. On-the-ground in *Laochengxiang*, local scholar Li Yingchun has collaborated

with architects and photographers in the survey of alleyway housing blocks under renewal, interviewing local residents and conveying research outcomes via multiple channels including exhibition, academic publication, and book for the public (see Mi, 2021; Sinan Books, 2018; Jiang, 2019).

2.4 Governmentality as a Coping Mechanism

What we have seen in this coalition politics is that first, conflicting voices have clashed and contested intensively with each other in the mass media space. While many of these outlets are ultimately owned by or connected with state-owned news enterprises, they have still managed to present complex debates in many nuanced ways. A plethora of online posts and self-produced reports have undoubtedly further nourished these debates.

More importantly, we observed a governmentality created by the pro-redevelopment coalition (largely the local government, but also like-minded developers) operationalised through mainstream narratives that seemingly resolve dissents and concerns from the pro-status quo and pro-conservation coalitions. Akin to Stenson and Watt's (1999) view that the "social" is reformulated instead of displaced in neoliberal governance, we argue that the heritage conservation imperative is not only suppressed in a binary manner against living condition improvement, but also reformulated and achieved in ostensible and reduced ways. Moreover, in *Laochengxiang*'s case, narratives of governmentality may also be used upwards to demonstrate to higher authorities that self-contradictory policy agendas (as we discussed in Section 1.4) have all been successfully implemented. These governmentality-embedded narratives are manifested along the following directions:

- **Rendering urban renewal as a progressive movement, particularly by stressing its living condition improvement dimension.** As we've discussed earlier, unsanitary and undignified state of living environment represented by tiny per-capita space, toilet buckets, and high rate of Covid infection have repeatedly been used to rally local resident and public support for urban renewal. More importantly, this also facilitates and justifies a binary opposition between urban renewal and heritage conservation. For instance, the Qiaojia Road neighborhood in *Laochengxiang* which possesses historic street patterns (filled from rivers and streams), local courtyard houses (Zhu and Wang, 2022) and histories of many important figures (see Shen, 2023) was deemed as the area of "worst architectural quality" (Tang, 2022a), where residents would have to "look up to the Oriental Pearl TV Tower with a toilet bucket in hand" (Tang et al., 2022). Along this line, dilapidation and degradation of the area is attributed to heritage itself, pro-conservation voices are easily viewed as objection to the provision of dignified living environment, and mass relocation in the name of living condition improvement paves way for intensive redevelopment that follows.

- **Claiming that the area's cultural heritage – which has been largely reduced to buildings with individual heritage designation – has been comprehensively preserved along with and as a result of urban renewal**, through the following ways:
  a) Reducing the scope of local cultural heritage. In an official reply to a political consultative conference proposal, Huangpu District Government frames local heritage conservation guidelines as to "conserve individual legally protected buildings outside key protection area, while regulating the amount and height of new construction within key protection area" (Huangpu District Government, 2021). This interpretation largely disregarded important designations in the conservation masterplan, paving ways for demolition and luxury redevelopments.

b) Framing heritage conservation as a result of urban renewal. Two frequently mentioned success stories in governmental press releases are the *Shuyin Building* (书隐楼) and the Confucious Temple, which are acquired by the government and conserved or restored during urban renewal (Tang, 2023; Shanghai Municipal Government, 2022). However, conservation of these landmarks doesn't necessarily have to happen through urban renewal, and there seems to be no mention of how selected conservation and restoration was achieved at the cost of eliminating expansive areas of historic fabric.
c) Capitalising on *Laochengxiang*'s cultural richness and historic connections, and equating conservation with luxury townhouse redevelopment. Many redevelopment projects have made extensive effort in framing *Laochengxiang*'s cultural, historic, and spiritual qualities as major selling points, while claiming to have "inherited" culture and history through their luxury townhouses that in fact wiped away *Laochengxiang*'s historic urban landscape.
d) Flagship programs and projects on intangible and cultural history. As we've discussed in Governmental Narratives (Section 2.3), besides the above interpretations that twisted the concept of heritage conservation, there are indeed official programs to commemorate and communicate local cultural history. However, they largely focus on intangible histories and memories, and have limited influence on the diminishment of physical and community fabric that is currently happening.

- **Sympathising with the place attachment of local residents, while painting displacement and relocation as a bittersweet experience for a brighter tomorrow.** "There will be housing that fits me somewhere anyways," says a young migrant tenant who works as a barista in an interview (The Paper, 2022); "I wouldn't be willing to live in the old place after experiencing my new apartment," says a senior citizen in *Farewell, My Humble Adobe*. While this may be the case for them, urban renewal may also be eating away affordable housing options in city centre for migrant workers in large, and there are actually many aged people who still choose to live by themselves in rental units nearby *Laochengxiang* due to the place attachment they can't give up (Li, 2023). These situations reflect the flip side of urban renewal, which Qin (2013) would call "domicide".

2.5 An Ignored Place of Contestation: Historic Neighbourhoods Outside Historic Districts

While *Laochengxiang* has grabbed the attention of a great amount of people who live in or care about Shanghai, there are other arguably no less significant historic neighbourhoods in-between historic districts that have been evacuated and sealed or are being razed. As Shao (2016) argues, since Shanghai's heritage conservation plans are designed to replace detailed masterplans of specific neighbourhoods, there lacks an urban-scaled spatial strategy for heritage conservation, and conservation efforts within fragmented historic districts have actually accelerated demolition outside and in between them. While many of these neighbourhoods are placed under newer types of heritage designations (such as historic cityscape blocks and historic cityscape streets), these statuses – like designations in *Laochengxiang*'s conservation masterplan – had very little impact on their redevelopment. Similarly, the site of a UNESCO Asia-Pacific Awards for Cultural Heritage Conservation-winning project – West Guizhou Lilong (UNESCO, 2022) – has also been sealed and evacuated as of spring 2024 (Fig. 13(5)). These notable cases are recorded in Fig. 13.

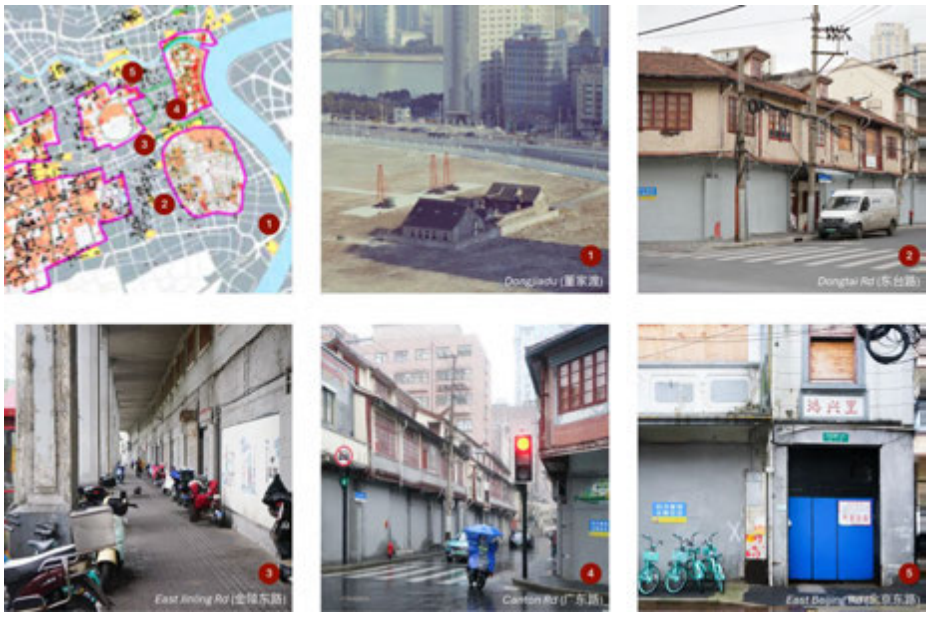

Fig. 13. Historic neighbourhoods under buyout/expropriation or redevelopment outside designated historic districts.

3 Risks and Disparities in Redevelopment-Oriented Urban Regeneration Practice

So far, we have demonstrated how a ferocious urban renewal movement happened in Shanghai's historic districts and neighbourhoods in recent years in breach of local heritage conservation masterplans, and how a governmentality is formed in mainstream discourse to ostensibly resolve dissents and prove the achievement of self-contradictory governance goals. While the governmentality embedded in mainstream narratives may produce a seemingly self-consistent rationale for the government, there are in fact multiple risks and disparities in this fierce redevelopment-oriented urban regeneration practice.

- The loss of vernacular historic urban landscape and urban spatial justice. The so-called "low quality housing" (or "second-class dilapidated housing and below") blocks – which generally collocate with Shanghai's 7.3 million m^2 of alleyway housing fabric – are crucial carriers of Shanghai's indigenous historic urban landscape, and manifest the grassroots side of Shanghai's urbanity which has been profoundly shaped by its long history as a hub for migrants and immigrants. The selected and biased conservation practice based on so-called "architectural significance" (Avrami, 2020) is therefore destroying both valuable historic urban fabric and the grassroots and indigenous lifestyle manifested in local communities (which made alleyway housing blocks unique *cities within cities*). The hyper-gentrification brought by a homogeneous upper-class population associated with luxury townhouses and high-rise apartments that come after demolition and displacement will inevitably exacerbate residential segregation and class stratification, further harming the social justice of urban space (Zhang, 2021).

- Inequities in governmental investment and the failure of neighbourhood self-governance. The systematic undervaluation of vernacular heritage with greater informality has caused great imbalances in governmental investment. Under the same mandate to "eliminate low-quality housing", residents in historic districts of higher architectural quality and socioeconomic status (for example, those who live in the *Cloud Water Villas* which is located in the former French Settlement and a middle-class neighbourhood today) would be able to enjoy fine-grained conservation schemes supported by substantial governmental cost, while many migrants and grassroots local residents in general alleyway housing blocks would have to be displaced or relocated. Meanwhile, neighbourhood associations – which should serve as a self-governing entity representing and reconciliating multiple forms of grassroots interests – have regrettably become a tool to persuade local residents to relocate under the municipal government's land finance imperatives.

- Unsustainable path dependency on land finance. The "total redevelopment" pathway undoubtedly produces the quickest and largest financial revenue for the local government. While land tracts of demolished historic districts in the city centre are sold at record-breaking prices, there is no guarantee that this model will work as well in outer-city neighbourhoods beyond these flagship projects, especially considering China's property market that is weakening and turning more volatile. On the other hand, our preliminary calculation suggests that it would cost the local government ¥0.87-1.22 trillion ($120-168 billion, note 4) to buy out all "low-quality housing" in Shanghai, which may imply a significant financial risk and burden.

4 Discussion: The Rise of New Municipalism and a Pending Refocus on Community

4.1 New Municipalism in Shanghai: A New Possibility?

In the Shanghai case, the intensive contestations across realms targeted at the government-led sweeping redevelopment movement did not significantly change the trajectory of this agenda – instead, they only facilitated the production of a governmentality. However, we observed the emergence of some traits of "new municipalism" in this process, manifested by:

1) The occurrence of multiple contestations and contradictions outside the governmental decision-making process, which reflects the inability of invited participation in reaching consensus;
2) Existing political participation tools (e.g., the political consultative conference platform) that have been used in an unprecedentedly efficient manner, and voices outside the government that have casted stronger and more frequent impact than usual;
3) On the heated debate regarding *Laochengixang*'s future, the spontaneous coalition of non-governmental stakeholders have emerged and made a presence in the forms of news reports, social media, social organisations, and academic events. In this case, the local academia serves as a key node linking participatory political parties, professionals, and local residents in a joined force to survey *Laochengxiang* and advocate for its conservation.

While the pro-conservation and pro-status quo coalitions didn't achieve any substantive self-governance in *Laochengxiang*'s urban space, we still found many similarities between the trends described above and the new municipalism movement currently taking stage in Europe (Thompson, 2021). We believe that creating a larger agency for spontaneously formed

coalitions by the broader public would be an effective way to balance the crises among state-market-society relationship in Shanghai's urban renewal movement; however, a focus should be placed on mechanisms to operationalise such agency (e.g., pro-bono lawsuits on heritage conservation), and fair attention paid to disadvantaged and marginalised groups (e.g., migrant worker tenants). The emerging concept of new municipalism has provided us with a valuable perspective to observe subtly changing power dynamics in China's urban governance.

4.2 Why Shanghai Matters?

We reckon that Chinese cities are embedded with multiple exceptionalities in terms of governance models and mechanisms, creating a dependency on specific urban theories (e.g., the state entrepreneurialism model – see Wu et al., 2022). However, the Shanghai case seems to demonstrate multiple connections to urban issue across the East and the West, as well as the Global North and the Global South. As we've discussed, the close collaboration between the government, developers, and government-owned land expropriation companies and apparent land finance rationales behind urban renewal display significant Chinese characteristics (see Wu, 2021); on the contrary, extensive debates, political (or potentially political) expressions, and formation of coalitions by stakeholders outside the government show traits of new municipalism. Along another axis, *Laochengxiang*'s informality represented by its disorderly built environment and high density is very similar to the typical environment of Global South cities, while its heritage valorisation system that largely builds upon architectural and material lexicons apparently follows Global North pathways (which may in part explain why the city's heritage conservation plan failed on this specific neighbourhood). These connections make conflicts in the regeneration of historic residential neighbourhoods in Shanghai relevant to broader urban contexts, and are thus worth further investigation.

4.3 Ways Forward – Updating Spatial Strategies and Refocusing on the Community

Laochengxiang's heritage conservation plan displays a discrete focus on architectural and spatial conservation. Ironically, it didn't end up protecting either the historic urban fabric, or local culture and lifestyle. Existing studies have raised many solutions in the spatial dimension, including: respecting the legal validity of conservation masterplan, and avoiding "constructive destruction" (Zhang, 2021); recognising the values of alleyway housing and vernacular heritage, and propelling integrated conservation instead of renewal upon demolition (Zhao et al., 2023; Zhang, 2021); developing enforcement mechanisms of conservation masterplan, and protecting the alleyway fabric through progressive and small-scaled regeneration (Zhang and Wu, 2021; Cai and Huang, 2022); facilitating gradual de-densification by allowing voluntary, household-by-household relocation (see Xinhua News, 2019); balancing governmental cost in urban regeneration through transferrable development rights (TDR) (Jiusan Society, 2017), etc. These solutions all correspond to our analysis on how the heritage conservation masterplan was breached. Although some studies expressed explicit attention to the human dimension of heritage (see Zhou, 2023), less recommendations have been made on community agency – which includes not only local residents, but also the broader public. On the agenda of "integrated conservation", we'd like to conclude with the following supplemental suggestions.

- A consensus is urgently needed to structurally revert the systematic undervaluation of indigenous urban heritage. The labelling of indigenous historic urban fabric with more informality as "dilapidated districts" caused the abandonment of urban heritage conservation measures formed in Shanghai upon decades of exploration, which reveals the

poignant need to rethink the values of urban conservation, by weighing the significance of Shanghai's root and origin point against architectural significance-based criteria.

- In practice, current demolition work must be halted, with the production of new conservation planning measures targeting deficiencies in *Laochengxiang*'s 2005 conservation masterplan. Key focuses shall be placed on more strict design review for renewal projects, and the creation of more refined streetscape design guidelines (like those adopted in Hengshan Rd-Fuxing Rd Historic District as an icon of fine-grained conservation, see Wang and Xue, 2021) to address the pairing of exclusive townhouses and high-rise apartments that greatly undermine street experience.

- The *Laochengxiang* case demonstrates that cultural heritage is inseparable not only with the local community, but also with the broader public as it serves as an important symbol of urban cultural identity. Regarding the human dimensions in heritage conservation practice, we believe that:
  1) More transparency should be given to the making and revision of local conservation masterplans by implementing public hearing procedures or similar measures, as they help address shortcomings of invited participation and the evasion of debates afforded by narratives of governmentality, and help achieve a healthier state-market-society relationship.
  2) The extremely explicit pro-gentrification and anti-grassroots stance of top-down urban renewal should be rectified before all local grassroots lifestyle and retail scenes are wiped away. Mandatory affordable housing requirements shall be incorporated into redevelopment plans, to better preserve the character of alleyway neighbourhoods and give basic care to the migrant tenants' rights to the city.
  3) An asset-based community development model shall be adopted, with more focus on investing on the community itself, vis a vis on the renovation, renewal, or demolition of built heritage. During the "Reshaping *Laochengxiang*" governance experiment carried out around 2016, local communities implemented micro fire stations, public kitchens and bathrooms under the support of district government, which enhanced the area's liveability, and spurred community vitality (Doculife, 2019). We call for a comeback to such community-based, acupuncture-mannered regeneration approach, where heritage conservation goals are achieved via investments on community livelihood, small businesses (e.g., craftsmanship and local eateries), and infrastructure that actually enhance day-to-day liveability.

Notes

1 The concept of *Laochengxiang* refers to both the historic walled city *(cheng)* and a strip of blocks outside the city wall along the nearby Huangpu River *(xiang)*. We use the word here to indicate only the historic district that covers the historic walled city (now an urban area surrounded by a circular road).
2 The official translation for the project is Aroma Garden. However, we use the literal translation "Jade Fragrance Garden" to reveal connection between the redevelopment project's name and the actual garden that existed in history on site.
3 Online search parameters for discourse analysis: Chinese keywords "Shanghai" + "Laochengxiang" + "Conservation" or "Old District Renewal" or "relocation" ("上海" + "老城厢" + "保护" or "旧改" or "拆迁"/"动迁") at Google and Baidu, and Chinese keywords "Shanghai" + "Laochengxiang" at academic publication platform CNKI, as well as more targeted perusal of local government portals for disclosed information. First 200 results are collected for each pair of keywords and website, when total results exceed this number. Repetitive materials, those solely referring to neighbourhoods outside the historic district, and those of little relevance to the current urban renewal movement are excluded from analysis.
4 This preliminary calculation is based on the estimation that overall cash compensation for each m^2 of alleyway housing (including bonuses and subsidies) would be around two times the housing price nearby. Upper-limit and lower-limit values are calculated by multiplying Shanghai's alleyway housing stock (7.3 million m^2) with 2 times the average housing price in 7 inner-city districts (around ¥84,000/m^2), and 2 times citywide average (around ¥60,000/m^2), respectively.

5 Conversion between CNY and USD is made based on estimated exchange rates in different years.

Research on Informal Residential Space Under Viaducts in Shanghai: From the perspective of Socio-spatial Transformation[i]

Jiaxin Qi[1], Yuhang Rao[1]

1. Department of Urban Planning, Tongji University, Shanghai

Abstract

Since 2019, China has prioritised high-quality development and a 'people-centric' approach in urbanisation, emphasising 'people-oriented' planning. This shift has highlighted overlooked spaces and needs, such as the informal use of space under viaducts in inner cities due to their accessibility and unused areas. Formal spatial transformations are cautious, addressing safety, sanitation, and publicity issues.

This article examines informal living spaces under Shanghai's viaducts, focusing on activities and social networks. It aims to summarise the activity characteristics and spatial patterns of informal use, identify lacking functional needs in urban spaces, and provide suggestions for urban transformation based on socio-spatial insights. The study employs participatory observation, semi-structured interviews, and archival studies to gather information. Typological morphology analysis is used to understand spatial patterns, while actor-network theory analysis reveals the transformation of social networks.

Key Words: Informal Residential Spaces ; Spatial Equity ; Urban Facilities; Space under viaduct

1. Introduction

1.1 Urbanization and Social Integration of Migrant Workers

There is a close relationship between urbanization and migrant workers in megacities. Firstly, the process of urbanization has had a significant impact on the migration and settlement of migrant workers (Chen & Liu, 2016). With the advancement of urbanization, rural labor has become an important part of the urban labor market. Migrant workers have made great contributions to the economic development and social construction of cities. Secondly, megacities are more attractive to migrant workers (Mohabir et al., 2017). Megacities usually

have more employment opportunities, richer resources, and better infrastructure, and these factors attract a large number of migrant workers to settle in cities (Mohabir et al., 2017).

In addition, urbanization has also brought social connections and interactions between migrant workers and urban residents. Such contacts and interactions have not only promoted the diversity and cultural exchanges of urban society, but also brought conflicts between different social groups. and fusion (Liu et al., 2012).

1.2 Migrant workers in Shanghai Have Difficulty in Settling Down and Social Isolation is Obvious

The dynamic monitoring survey on the process of citizenization of migrant workers in Shanghai shows that during the "13th Five-Year Plan" period, the income and living standards of migrant workers in Shanghai continued to improve, but overall, the willingness of migrant workers to stay and settle in Shanghai has declined. The main obstacle is expensive housing and It is difficult to settle down. (Wang L.,2021)

At present, the housing conditions of migrant workers in Shanghai are still far below the average level of residential housing in Shanghai. The simple and changeable housing environment will cause social isolation between migrant workers and surrounding communities and aggravate social conflicts, which is not conducive to the stability and inclusiveness of the community. shape.

1.3 Questions of Research

In summary, the link between urbanization and migrant workers in megacities is both economically interdependent and socially interdependent. While promoting urbanization and the development of megacities, attention should be paid to the protection of the rights and interests of migrant workers and the improvement of social welfare.

Therefore, this paper aims to analyze the living space and social network of migrant workers under the viaduct of Line 3 through social research methods such as space research and questionnaire interviews. Migrant workers' life line, analyzing the characteristics of social interaction between their living space and other spaces.

2. Analysis on Spatial Characteristics of Simple Migrant Workers' Housing Under the Viaduct of Shanghai Metro Line 3

2.1 Area of Research

The research area is situated under Shanghai Metro Elevated Line 3, a location that has been informally occupied for over six months, as illustrated in figure 1. The study is structured into two distinct levels of analysis.

The first level, Scope 1, delineates a spatial range extending 5 meters outward from the residential area of migrant workers, forming a boundary line. Within this scope, the study focuses primarily on the spatial activities and interactions of migrant workers. Detailed interviews and observations are conducted to understand the daily practices, spatial usage patterns, and immediate social interactions within this confined space. This level of analysis aims to capture the micro-level socio-spatial dynamics that define the everyday experiences of the migrant community.

The second level, Scope 2, encompasses a broader living circle with a radius corresponding to a 5-minute walk from the residential area. This scope is designed to analyze the characteristics of land use types and the spatial utilisation patterns by migrant workers within this extended range. By examining different spaces within this living circle, the study aims to summarise the spatial characteristics and life trajectories of migrant workers. It explores how they navigate and utilise various urban spaces, shedding light on the interplay between their living environment and broader urban contexts. Additionally, this scope analyses the social interactions between the migrant workers' living space and other urban spaces, providing insights into their integration and interaction within the urban fabric. This dual-level approach allows for a comprehensive understanding of both the immediate and extended socio-spatial dynamics affecting the migrant population.

Figure1: The Research Scope *Source: Author's own drawing*

2.2 Analysis of the Spatial Characteristics of Residential Points

The types of buildings adjacent to the study area predominantly consist of simple temporary structures and old-style lanes that are slated for demolition. Additionally, there are some small-scale commercial buildings, and the variety of space users is relatively limited.

Based on interviews and a thorough spatial investigation of the migrant workers' settlements, several key spatial characteristics have been summarised:

First, the physical and spatial environment of the migrant workers' residences is notably poor. The dormitories are situated directly beneath Shanghai Metro Line 3, which significantly disrupts the daily lives and rest of the migrant workers due to noise and vibrations from the trains above. This positioning highlights a critical issue of inadequate living conditions exacerbated by urban infrastructural development.

Second, on the south side of the residences and directly opposite the street intersection, there are two large-scale waste recycling and processing sites. These sites contribute to a degraded environmental quality, characterised by noise, pollution, and unsanitary conditions, further impacting the well-being of the migrant residents.

Third, the spatial location of these migrant worker settlements is isolated from the surrounding community. Interviews with waste recycling personnel reveal that this isolation stems from the surrounding old lanes undergoing redevelopment projects. The decision to locate the migrant workers' residences and temporary waste recycling operations under the viaduct was driven by considerations of spatial efficiency and the operational needs of construction projects. However, this arrangement neglects the living experience and social integration of the migrant workers, underscoring a significant disconnect between urban planning objectives and the socio-spatial needs of vulnerable populations.

This isolation not only physically segregates the migrant workers from the broader community but also limits their access to essential services and social networks, contributing to their social marginalisation. The study highlights the need for more inclusive urban planning that prioritises the well-being and integration of all residents, particularly those in precarious living conditions.

Figure2: The living environment of migrant workers *Source: Photographed by the author*

2.3 Analysis on the Law of Migrant Workers' Space Utilization

After conducting extensive research, it was observed that migrant workers regularly navigate the surrounding urban space, engaging in activities primarily related to dining, leisure, entertainment, and work, as illustrated in figure 3. By superimposing the activity patterns and spaces frequented by migrant workers with the existing land use, it was discovered that their actual utilisation of space is concentrated in construction sites and small-scale businesses located at the ground level of nearby residential areas. Notably, the large commercial complex situated within a five-minute walk to the east of their residential area showed no evidence of activity by migrant workers, as neither observations nor interviews indicated any usage of this space. This suggests a pronounced preference among migrant workers for patronising smaller, local businesses rather than larger commercial establishments.

In summary, the management of these settlements reflects a perception of them as transient spaces, with spatial allocators or managers not recognising migrant workers as a long-term, integrated component of urban society. Consequently, the physical and spatial environment of these migrant worker settlements fails to foster their integration into the broader urban social network. Instead, the current spatial configuration exacerbates the isolation of migrant workers from other urban communities.

This isolation is further reinforced by the lack of infrastructural and social amenities that facilitate interaction and integration. The spatial segregation underscores the broader socio-spatial dynamics in urban sociology, where marginalised groups are often confined to peripheral and inadequately serviced areas. The findings indicate that without intentional urban planning efforts to create inclusive spaces that encourage social cohesion, migrant workers will remain segregated, perpetuating a cycle of exclusion from the socio-economic benefits of urban life. This scenario calls for a reevaluation of urban policies to incorporate inclusive practices that address the unique needs of migrant workers, ensuring their seamless integration into the urban fabric.

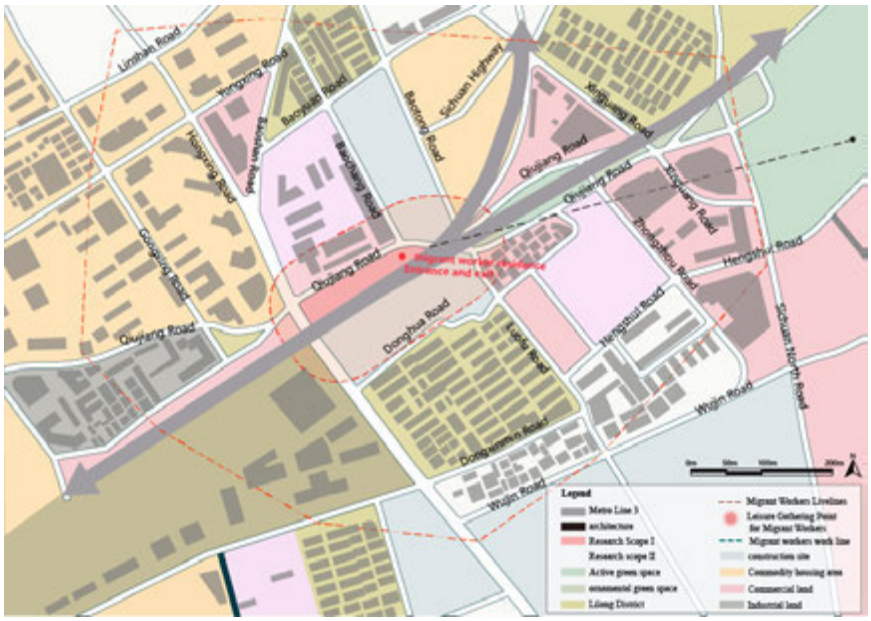

Figure3: Analysis of land use around migrant workers' settlements *Source: Author's own drawing*

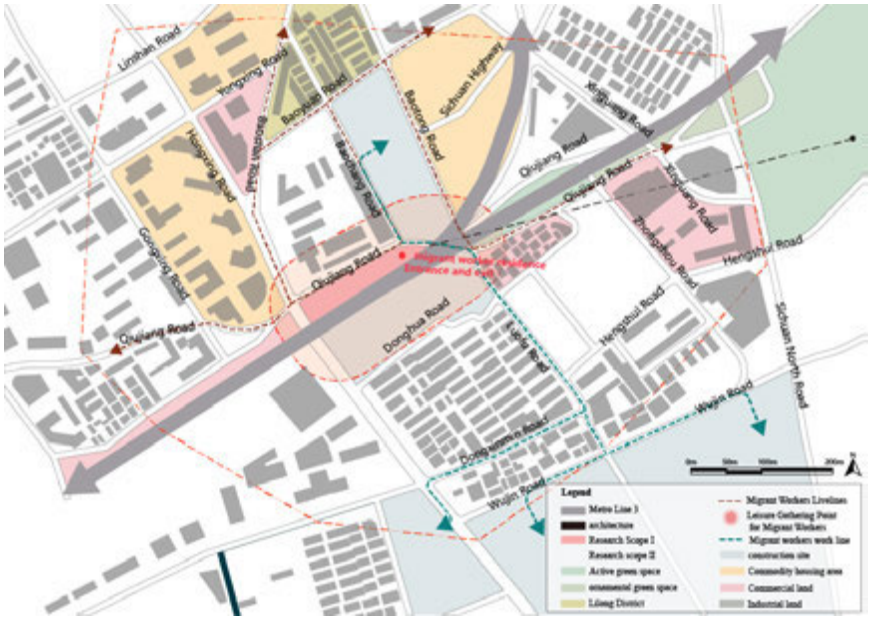

Figure4: Analysis of land use around migrant workers' settlements *Source: Author's own drawing*

3.Characteristics of the Social Network of Migrant Workers' Settlements

3.1 The Inner Social Structure of Migrant Workers

The internal social structure of the migrant workers has developed into a tightly-knit circle with the contractor at its core. According to interviews, the majority of the migrant workers residing in this area originate from Anhui Province and have been uniformly recruited by the construction team. The contractor and the workers share a common background, being acquaintances from the same village, which has fostered a stable and cooperative relationship. This cohesive social network, characterised by strong internal bonds, significantly contributes to their weak connections with surrounding communities and the broader urban social networks (Lu Wenrong, 2019).

The investigation also revealed the presence of occasional temporary migrant workers who reside in green parks outside the designated temporary residences. These individuals are unable to secure long-term positions because they are excluded by the entrenched social network of acquaintances within the migrant worker community. Consequently, their integration into the urban social fabric is even more tenuous, further highlighting the barriers to social cohesion and integration faced by these temporary migrants.

This phenomenon underscores a critical issue in urban sociology: the role of strong internal networks in perpetuating social exclusion. While these networks provide essential support and stability within the migrant community, they simultaneously act as barriers to broader social integration. The closed nature of these networks limits the opportunities for new migrants to connect with established urban residents and access the resources available in the wider urban environment.

Figure5: Temporary migrant workers outside the migrant workers' residences *Source: Photographed by the author*

3.2 Group Interaction Between Migrant Workers And Surrounding Communities Under the Viaduct

Firstly, a service-oriented group of migrant workers congregates around the periphery of their residential areas. As depicted in figure 6, retail vendors position themselves at the entrances and exits of these areas, selling daily necessities to the migrant workers. While the prices of these goods are relatively low, the variety is haphazard and there is a notable lack of quality assurance. This phenomenon highlights a significant issue: the inadequacy and inconvenience of formal business service facilities for migrant workers.

In addition to retail vendors, waste recyclers also play a prominent role in this informal economy. These recyclers collect second-hand home appliances from nearby communities slated for demolition. They refurbish and repair these items before renting or selling them, often directly targeting the migrant worker population. During the day, these recyclers choose to remain outside the residential areas of migrant workers. This choice of location is strategic for several reasons. Firstly, it places them in close proximity to waste recycling stations, facilitating their operations. Secondly, migrant workers constitute a critical consumer base for such refurbished goods, making this arrangement mutually beneficial for both the recyclers and the workers.

This phenomenon can be understood within the framework of urban sociology, where informal economies often emerge in response to gaps in formal service provision. The clustering of retail vendors and waste recyclers around migrant worker residences illustrates the adaptive strategies employed by both service providers and consumers in marginalised urban spaces. These

informal activities not only cater to the immediate needs of migrant workers but also reveal the underlying socio-economic dynamics that shape their everyday lives.

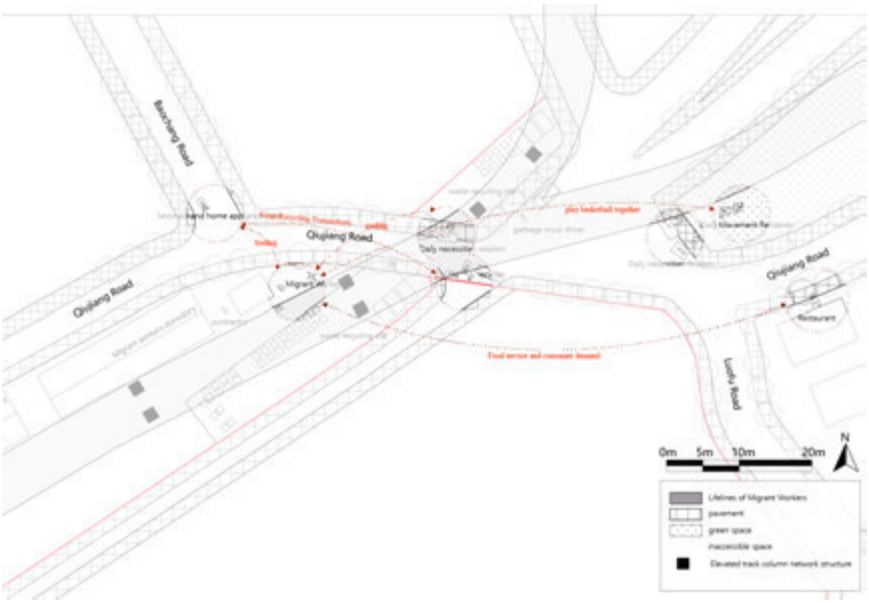

Figure6: Analysis of the social space network of migrant workers' settlements Source: Author's own drawing

Secondly, the interaction between migrant workers and the surrounding community residents is relatively limited. Despite the physical proximity of these groups, meaningful social integration remains sparse.

Besides the retail vendors and waste recyclers mentioned earlier, there are also fast food restaurant owners who set up in the vicinity to cater specifically to the dietary needs of the migrant workers. These eateries are a significant feature of the informal economy, providing affordable meals that fit the budgets and schedules of the workers. Additionally, residents from nearby communities frequently visit the area, particularly to utilise the local parks for recreational activities.

Interviews conducted with both migrant workers and local residents reveal a minimal level of social interaction between the two groups. While some interaction does occur, such as migrant workers playing basketball with local residents, these engagements tend to be superficial and do not extend into deeper social relationships or networks. The interaction remains largely limited to these casual encounters, with little evidence of further social integration or the development of meaningful connections.

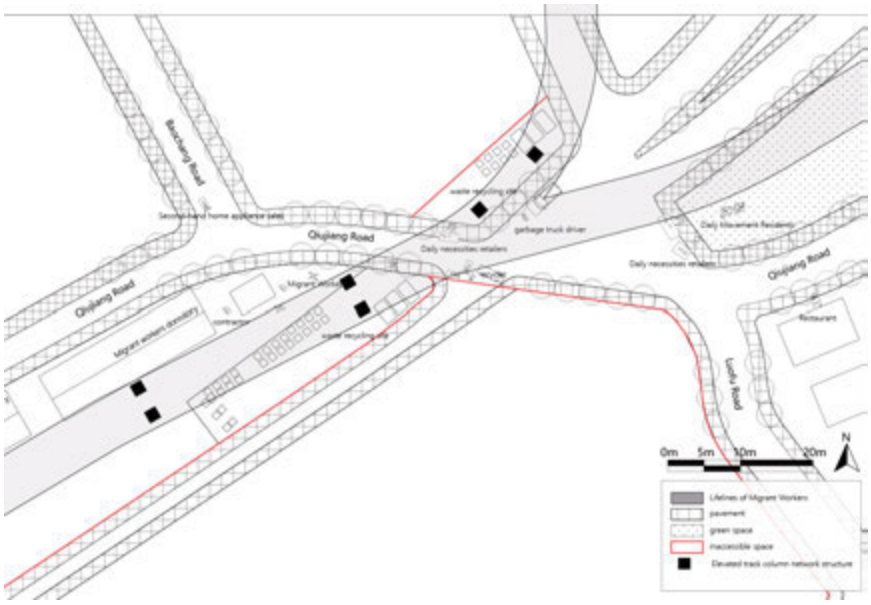

Figure7: Analysis of crowd activities around migrant workers' residences *Source: Author's own drawing*

The spatial distribution of retail vendors and waste recyclers around migrant worker settlements reflects broader socio-spatial dynamics. These service providers strategically position themselves in areas with high demand and minimal competition from formal businesses. This spatial arrangement highlights the intersection of economic necessity and urban planning.

In conclusion, the service-oriented activities around migrant worker residences in Shanghai reveal significant insights into the socio-economic and spatial dynamics of urban marginalisation. The clustering of retail vendors and waste recyclers around these areas highlights the inadequacies of formal service provision and the adaptive strategies employed by both service providers and migrant workers. Addressing these issues requires a comprehensive approach that includes improving formal service facilities, integrating informal economies into formal systems, and fostering social cohesion through inclusive urban policies. By doing so, cities can create more equitable and supportive environments for all residents, including migrant workers.

Meanwhile, Public spaces, such as parks, play a crucial role in facilitating social interaction. The fact that some level of interaction occurs during recreational activities, like basketball games, suggests that these spaces hold potential for fostering greater social integration. Enhancing the inclusivity and accessibility of public spaces could encourage more frequent and meaningful interactions between migrant workers and local residents. Urban planning initiatives that promote mixed-use spaces and community-building activities could be

particularly effective in this regard.

4. Conclusion and Discussion

4.1 Summary of the Living Space and Social Integration Characteristics of Migrant Workers in Big Cities:

4.1.1 Limited Spatial Activities:

The research indicates that migrant workers have a restricted range of spatial activities. This limitation stems from the significant proportion of their daily schedule dedicated to work and rest, leaving minimal time and space for leisure and entertainment. Surrounding public service and recreational facilities are predominantly fast food outlets and high-end malls, lacking diverse options catering to varying preferences.

4.1.2 Network Relationships and Social Structure:

Migrant workers tend to establish relatively stable network relationships within their immediate social environment. However, the structure of these networks is often straightforward. Notably, proximity to green spaces like parks and engagement in activities such as basketball contribute positively to their social integration. Effective public space design can enhance these networks, facilitating greater social inclusion.

4.2 Strategies for Enhancing Migrant Workers' Living Environment and Social Communication in Urban Areas:

4.2.1 Improving Housing Selection and Living Conditions:

Due to the limited possibility of improving the living quality of migrant workers in the short term, it is possible to consider the possibility of supplementing community functions through external spaces around some residential sites when planning the residential layout of migrant workers.

As far as possible, ensure that the site is located in a residential area or a living area, and some micro-green space adjacent to it can be considered to provide public activity space for migrant workers. By optimizing the space points, more optional spaces and activities are provided for the lives of migrant workers, thereby promoting the integration of migrant workers into the local social network.

4.2.2 Establishing a Five-Minute Living Circle Evaluation System:

The simple houses that farmers live under viaducts usually lack public service facilities and social support networks. In the construction of the five-minute living circle, migrant workers should be considered in the allocation of public service facilities as urban permanent residents.

4.2.3 Utilizing Micro Spaces for Community Enhancement:

Due to limited urban construction resources, it is not easy to provide suitable housing options for all migrant workers at this stage, such as collective dormitories, public rental housing or affordable low-rent housing. However, based on the current space environment, multi-functional embedded reconstruction is carried out to realize the basic public service functions of the residential area, and to improve the community functions of the simple housing. For example, when providing basic

Measures such as drug supply, placement of community furniture, and creation of a simple living room in the community.

4.2.4 Regular social assistance and public services:

Provide free or low-cost medical services, including regular health checks. Provide educational opportunities, including compulsory education, vocational training and skills upgrading courses, to improve the educational level and employment opportunities of farmers. Organize social workers and volunteer teams to provide farmers with social services such as consultation, legal assistance and psychological support.

Abstract
In Europe, access to affordable rental housing is increasingly recognised as a priority issue, particularly for individuals facing multifaceted distress or temporary and precarious employment. By addressing multiple dimensions of poverty, the Housing First (HF) approach challenges traditional emergency responses, framing access to housing as a comprehensive and diversified set of preventive actions against homelessness. Since 2015, HF has gained recognition in Italy, although its implementation remains limited. This paper explores the spatial conditions, target populations, stakeholders, and both material and immaterial resources that could facilitate the integration of HF into structural policies for affordable social (and 'very social') rental housing. The case study focuses on Trieste, a medium-sized Italian city where the risk of homelessness is significant due to demographic aging, migration flows, and an insufficient supply of public housing.

Keywords: Rental Housing Affordability; Social and Very Social Housing; Housing First; Trieste.

1. Introduction

For several decades now, the call of the UN *2030 Agenda for Sustainable Development* to provide access for all to adequate, safe, and affordable housing and basic services has become a pivotal issue in the international policy debate. In this perspective, actions toward affordable housing are understood as "a ladder out of poverty of families", carrying crosscutting benefits on many other fields of welfare policies (Habitat for Humanity, 2021, p. 5). During and after the COVID-19 pandemic and lockdowns, discussion has intensified, highlighting how the lack of a decent home can provoke uneven impacts on urban populations, worsening the life conditions of those who already suffered from multiple factors of poverty and deprivation (Ayala et al., 2022). Even though the direct correlations among these factors, the geographical spread of the disease, contextual housing conditions, and the overall availability of welfare facilities were complex to measure (Burlina and Rodríguez-Pose, 2023), across Europe people experiencing homelessness were among the most affected by COVID-19. "At the same time, vulnerable groups were even more exposed to the risk of becoming homeless, either due to the looming threat of eviction as their income decreased dramatically, or due to the dangerous situation the pandemic placed them in" (Rahman, 2020). Today, the impacts of concurrent economic, social, and political crises (e.g., inflation, surging energy and food prices, job insecurity) make access to a decent home a difficult goal for a growing number of people to achieve.

This situation emphasises not only the importance of housing as a fundamental social determinant of health and well-being but also what the *Universal Declaration of Human*

Rights stated in 1948, namely that housing is a right, and that preventing the risk of homelessness – in its various expressions – is one of the pivotal missions of welfare policies (The Shift, 2024). Furthermore, the faculty to afford housing constitutes a precondition for the access to a wider range of civil rights (e.g., to political representation, employment, healthcare, education), and related public support. The housing crisis is an impediment to secure equal opportunities especially to fragile groups of people; therefore, it is a strategic field of action for filling in economic and social gaps toward full citizenship for all (Mazzucato and Farha, 2023; Rajagopal, 2023). However, if available welfarist forms of housing policies are still primarily addressed to families and individuals who can afford at least a low rent, the 'very social' demand expressed by households in severe poverty or extreme housing hardship is generally taken over by public economic and social assistance measures, often resulting in emergency responses to homelessness. A 'treatment first' approach prevails, with access to a decent dwelling coming only after a long and uncertain path toward social and economic reintegration, from the dormitory to a stable home. The Housing First (HF) approach deeply questions this paradigm.

Starting with a general reflection on the demand and supply of rental affordability in the European context, this paper investigates the possibility of moving beyond a fragmented and sectoral application of HF, by analysing the operational perspectives and resources needed for its upscaling to a structural urban policy. The paper specifically refers to the activities carried out by the University of Trieste as a partner of the ongoing research projects *UAH! Unconventional and Affordable Housing* (2023-25) and *INEST – Interconnected Nord-Est Innovation Ecosystem – Spoke 4* (2022-25), both co-financed by Italy's EU-funded National Plan for Recovery and Resilience (PNRR). The focus is on the Italian situation, and a specific case study. The assumption is that a growing, plural 'grey area' in the demand for rental housing still receives inadequate responses, calling for a revised conceptualisation of housing affordability. In this regard, the deconstruction of some housing policy paradoxes and the analysis of HF perspectives provide valuable insights for addressing the housing crisis and its many forms. The purpose is to help conceive access to a home not only as a starting point toward independent living but also as a complex set of preventive actions against the risk of homelessness. Fieldwork in the city of Trieste (IT), in collaboration with local stakeholders, offers an opportunity to explore these issues. The aim is to provide inputs for transforming still informal practices into more stable affordable rental housing projects and policies.

2. Rental Affordability: A European Housing Question

Although the available figures provide only a partial and patchy overview, across Europe, housing demand from people at risk of poverty or social exclusion, as well as the number of homeless individuals, is on the rise. The mismatch between this demand and the limited supply of affordable rental housing constitutes a specific dimension of the contemporary housing question, laying at the very heart of the distressed social and economic conditions affecting many EU citizens.

2.1 An Increasing Gap Between Social Demand and the Offer of Rental Housing

In 2022, 95.3 million people (22% of the EU population) were at risk of poverty or social exclusion, namely they lived in households in at least one of the following conditions:

being below the threshold set at 60% of the national median equivalised disposable income after social help given by central, state or local institutions; suffering from severe material and social deprivation, and being unable to meet the costs of basic necessities (e.g., pay for unexpected expenses, afford rental payments, or keep home adequately warmed); having working age members whose work-time was equal to or less than 20% of their total potential during the previous year (EUROSTAT, 2023a). Overall, the critical economic situation of households was largely influenced by the proportion of disposable income spent on housing costs. In 2021, this share reached an average of 19% in the EU, while for people at risk of poverty it stood at 38%, heavily impacting incomes that were already below the national median (EUROSTAT, 2023b). The greatest increase in expenses was borne by tenants. However, for many people, securing a home has become an increasingly difficult condition to achieve. With a 70% increase from 2009 to 2019, the number of homeless individuals sleeping rough or in emergency/temporary accommodation each night in Europe is now estimated at 700,000, with significant differences across countries (Fondation Abbé Pierre – FEANTSA, 2022; Housing Europe, 2023).

A view of changes in the housing offer helps understand the root causes of this situation. Considering that in the EU a third of citizens live in rented flats, and that this is the primary solution vulnerable households turn to, rental housing affordability is a major concern. From 2010 until 2022, average rents increased by 19%, considerably outpacing income growth. This provoked, on the one hand, a particularly precarious situation for tenants in the private rental market (46% felt at risk of needing to leave their accommodation) and, on the other hand, an upsurge in the number of households applying for social housing (namely, housing provided at below-market prices by public, private, non-profit actors, the third sector, and cooperatives) (Housing Europe, 2023). However, in the EU, the share of social housing in the rental sector is currently estimated at only 8% of the total housing stock, with significant cross-national differences (OECD, 2020, 2023).

The underlying factors driving the rental housing affordability crisis are strongly related to the structural economic shifts that have happened during the last decades. “Housing is increasingly treated as a financial instrument and a tool to accumulate capital and make profits. As a result of escalating rents, people find themselves living in poor, overcrowded accommodation and often risk eviction” (Farha, 2021). “The social housing available has also declined in some countries since 2010, partly due to a fall in public investment in housing and the sale of social housing to tenants in some countries” (European Economic and Social Committee, 2024). This pairs with diminished public financial support and inadequate legal safeguards for low- and middle-income tenants facing excessive housing costs also due to sharp rise of energy bills in old and poorly insulated homes.

2.2 The Contextual and Multiple Dimensions of Housing Poverty

The establishment of quantitative indicators and thresholds is at the core of the definition of housing affordability, as well as of international and national efforts to address it. However, understanding housing affordability merely as a calculation based on a minimum standard (typically 30-40% of housing costs – e.g., price, rent, utilities, etc. – as a percentage of household disposable income) reveals significant theoretical and operational limitations when applied to individuals facing multifaceted distress,

those temporarily unemployed, or with too precarious a job to afford renting on the private market. Strong is, therefore, the need to question a simplified definition of this concept, and its use both in investigating housing needs and supply and in building consistent actions and policies (Haffner and Hulse, 2021; Peverini, 2023; Bricocoli and Peverini, 2024). In this regard, the issues of poverty and risk of poverty must be carefully analysed. The precariousness of households' economic and social conditions is not easy to measure, due to its ever-changing nature and the overlapping factors involved (Habitat for Humanity, 2024).

The perspective of having difficulties in making ends meet is common not only among households spending at least 40% of their income on housing, whether rented or owned (Eurofound, 2023). The link between poverty and housing expenditure transcends abstract metrics, while the commodification of the housing sector makes contextual trends in the real estate market, along with their territorial imbalances, highly influential (Arbaci et al., 2021). An increasing disproportion between the overall cost of living (e.g., for utilities, transport, etc.) and stable income plays a major role in worsening the conditions of critical households, with more severe impacts on those living in dynamic metropolitan and urban areas where costs are higher (Engelen et al., 2016; Moscarelli and Peverini, 2023). Moreover, for many people, housing needs are becoming highly changeable throughout their lives (e.g., for temporary and mobile workers, students, etc.), while the limited availability of affordable rental housing limits the choice of where to settle (even temporarily) and reduces the attractiveness of cities and territories, with significant consequences on their demographic, social, and economic assets.

Other important factors relate to the uncertainty of households' income and composition. In fact, "housing vulnerability" is becoming an increasingly widespread risk (Bouillon et al., 2015). In addition to extreme poverty, housing deprivation, and the rise in migrant flows often leading to homelessness, this also refers to the social and economic frailties affecting individuals who were previously part of the 'low-medium class' and have since slipped into situations of housing distress (Hick, Pomati and Stephens, 2024). The reasons for this are multiple: from the social and demographic transformations that have occurred in recent decades, leading to profound changes in the composition of the 'family' (e.g., an increase in one-person households and single-parent families), to the growing number of people whose incomes suddenly collapse (e.g., due to job loss, divorce, retirement, a decline in income purchasing power, and emergencies related to medical or other expenses). Housing and employment insecurities represent a dual and strongly interconnected form of precarity. Since 2008, the number and types of so called 'working poor' have been increasing across Europe, largely due to the lack of adequate government measures protecting against flexible, occasional, and often low-wage employment (Ficocelli, 2020). If "layoffs have become a normal feature of precarious work", fluctuating and uncertain earnings jeopardise the ability to pay a rent, making "evictions […] become a normal feature of precarious housing" (Desmond and Gershenson, 2016, p. 3).

These frailties affect an increasingly diversified 'grey area' of the population that has not yet fallen into extremely critical conditions, but whose intermittent and uncertain disposable income threatens access to the private rental market (which is too expensive), and eligibility for public housing rental offer (too limited). As the grey area expands and becomes more diversified, the boundaries between different levels of

housing poverty (from hardship to deprivation and homelessness) grow more fluid and indistinct.

3. Exploring a Grey Area in Italian Affordable Rental Housing

Given the significant differences among EU countries (in terms of demand, supply, and housing policy systems), an overview of the specific dynamics and characteristics of the Italian context is necessary. The aim is to question whether, and to what extent, a growing grey area of social demand is addressed by public-driven rental housing policies.

3.1 Who Rents in a Country of Homeowners?

In spite of the lack of a national observatory on housing conditions, the overall picture is fairly clear. As a result of the policies developed since the post-war period (Filandri, Olagnero and Semi, 2020), Italy is indeed a country of homeowners: out of a total of 26 million households, 70.8% live in their own homes, 20.5% (5.2 million) live in rented accommodation, and 8.7% in a house under usufruct or free of charge. Overall, the percentage of tenants and individuals living rent-free is significantly lower than the EU average (24.9% compared to 30%).

Renting is more common among less affluent households (e.g., older and younger single individuals, young couples, single parents with children, and people who are unemployed or have migrant backgrounds), with more than 45% of poor families living in rented flats under recurrent overcrowding conditions (Freguja, 2022). Out of the total number of Italian households, 15.9% consider their income insufficient to meet basic needs, and 5.1% as severely insufficient (the latter generally being self-employed or unemployed individuals, aged 35-54, often with children) (Nomisma, 2021). For 1.7 million families rent affects income by more than 30% (e.g., young single persons with less than 35 years, single parents with children, migrants) (Nomisma-Federcasa, 2016). These numbers are likely to rise in the near future: today, in Italy, not only has the share of individuals living in absolute poverty reached 10% (5.6 million) of the overall population, but many people are at risk of poverty while claiming to be employed (11,5% of the total 23.3 million workers) (Caritas Italiana, 2023). As a consequence, since 2008, evictions have increased approximately 8% per year, with 90% of the cases due to arrears in rent payments (Nomisma-Federcasa, 2016; Freguja, 2022). According to the Italian Ministero dell'Interno (https://ucs.interno.gov.it), after the partial moratorium during the pandemic, between 2021 and 2022 there was a sharp upsurge both in the number of eviction requests submitted (more than 99.000, +199%) and in those actually carried out (more than 30.000, +218.6%). The number of individuals suffering from severe housing exclusion is equally worrying: according to the permanent census of population and housing produced by ISTAT in 2021 (https://www.istat.it), 96,197 people were registered as homeless and without a fixed address. These figures highlight not only a plural and growing housing emergency but also a dramatically inadequate response from public policies.

3.2 A Forgotten Field

This is not the place for a review of the long history and extensive technical and political debate on the housing question in Italy, its strong ties with the evolution of urban

planning instruments, and the repeated and unsuccessful attempts to reform land tenure and limit private land income (see, among others, Indovina, ed., 1972; Ferracuti and Marcelloni, 1982; Padovani, 2017; Cucca and Gaeta, 2018; Storto, 2018). However, some key milestones will be recalled to highlight how, since the 1990s, national rental housing policies (and their two main action pillars) have seen a significant retreat of public intervention, with a shift from viewing housing as a social service to considering it as an investment asset.

The first pillar is *edilizia residenziale pubblica* ('subsidised' or 'council housing'), intended for low-income workers. From the INA-Casa Plan (1949-63) (Di Biagi, ed., 2010), through the *piani di zona* (local plans) for popular and affordable housing (Law no. 167/1962) and the decennial housing programme (Law no. 457/1978), to 1998 and the end of the funding mechanism based on the levy on workers' payroll (GESCAL), supporting the building sector and responding to housing demand were understood as intertwined goals. The majority of available council housing was built during this period, even though the rent of flats was already conceived as a temporary solution, leading to rent-to-own schemes and eventual full ownership. At the end of this phase, housing policies underwent further changes. In 1993, Law no. 560 allowed Council housing Institutes (IACP) to sell up to 50% of their properties in order to cover the maintenance costs of the remaining assets, as well as the budget deficit caused by low revenues from tenants' rents. In 1997, IACP were converted into public economic agencies. As a result, the production of subsidised housing collapsed from an annual average of 18,000-20,000 units in the 1980s to 9,000-4,000 units per year in the 2000s, and more than 210,000 flats were sold from 1993 to 2014 (approximately 22% of the estate managed before) (Storto, 2018; Bricocoli et al., 2021).

The second pillar of Italian housing policies is *edilizia convenzionata* ('agreed housing'). While aiming to induce the private market to offer tenants stable and affordable rental conditions, it has always played a residual role. In 1978, Law no. 392 established the so called *equo canone* ('fair rent'), a maximum rent calculated as a percentage of the value of the dwelling (based on its typology, size, urban location, and maintenance conditions) that private providers were required to apply for a minimum of four years. However, the effects were the opposite to the intended goal: many flats became vacant, were illegally rented, or sold. In 1998, Law no. 431 abolished the previous one and revised the overall framework for housing leases: municipalities and local housing stakeholders were given the responsibility for setting maximum rents, discounts on local taxes for rental providers were introduced but agreed rental contracts were reduced to a minimum of three years. Recent responses to the housing crisis are even more controversial. The so called 'housing plan' and the definition of 'social housing' established in 2008 by Law no. 133 clearly fit into the financialisaton process of the housing sector. While explicitly targeting a wide range of social groups within the grey area, the public actor limits its role: on the one hand, to providing various benefits to private investors; on the other hand, to constructing a financial system that also absorbs funds previously allocated to IACPs. In fact, in social housing interventions, the proportion of agreed rental housing (understood as a temporary condition leading to sale), rent-to-own dwellings, and those for sale largely depends on the financial return of private investments, while tenant selection is based on the amount and stability of their income.

Today, as a result, the supply of affordable rental housing in Italy is still primarily provided by council housing agencies. They manage around 700,000 dwellings, and if we add approximately 250,000 units owned by other public actors, the total represents only 4% of the national rental stock; 14% of these units are vacant due to lack of maintenance. The number of pending applications on council housing waiting lists is around 650,000 (Bricocoli et al., 2021). However, many requests do not even meet the eligibility criteria to be included on these lists (e.g., due to insufficient years of residency).

3.3 Working at the Crossroads: Affordable, Unconventional, and Informal Housing

In Italy, the right to housing is at risk, and existing policies do not provide satisfactory solutions. The available council housing stock is largely insufficient to meet the diverse needs and conditions of households, and the age of the buildings and flats often makes them unsuitable for new lifestyles and household sizes. In other words, not only is the demand for affordable housing increasingly elusive and grey, but so too are current housing policies, due to their inertia in adapting to deep social and economic changes, as well as to the dramatic shrinking and ageing of the Italian population which threatens the sustainability of the overall welfare state system (Ascoli and Bronzini, eds., 2018).

The assumption of this paper is that new perspectives for social rental housing, as well as its spatial and management solutions, need to be explored by working at the crossroads of social and very social housing demand and supply. The hypothesis is that public-driven social rental policies can strengthen their role and expand their fields of action by building new alliances with private assets and actors, the third sector, and other welfare measures. From this standpoint, several key concepts guide the 'action-research' developed in Trieste and described hereafter:

- Affordability. This term is understood not only in its broader and contextual dimensions (e.g., referring to rent and overall housing costs in specific urban areas), but also in relation to the variability of households' income (e.g., in the case of the working poor), as well as other social and economic vulnerability factors. The aim here is to go beyond a purely economic conceptualisation of affordability, to include other important aspects (e.g., the reconstruction of social and spatial relationships) that can support individuals with uncertain employment and family circumstances in maintaining their autonomy and rebuilding their life prospects.
- Unconventional. This term refers to a highly diversified housing demand, often expressed by households that were previously not considered a target group for social and very social housing policies. This variety calls for the development of responses that are more tailored and flexible in several respects, such as: the size and spatial arrangement of dwellings, which cannot be easily standardised according to fixed household types and living practices; the range of welfare facilities and services that, in addition to housing, must be provided to support specific vulnerability conditions (e.g., those related to age, loneliness, health); and the adaptation of rents and lengths of stay based on the beneficiaries' individual needs.
- Informal. The final key concept refers to the areas of experience the research focuses on. In Italy, the lack of an effective affordable rental housing policy has led to the search for solutions through a set of often fragmented and

experimental housing practices, which have not yet been institutionalised but could provide valuable insights for developing more diversified and structured public-driven policies.

4. Narratives, Approaches, and a Context

Starting from this interpretative framework, three methodological nodes guide the research carried out by the University of Trieste. The first involves a critical deconstruction of some paradoxes at the root of Italian housing policies, and their inertia in adapting to changes in target groups and solutions. The second node refers to an in-depth analysis of the Housing First (HF) approach. Although HF has gained formal recognition in Italy in recent years and demonstrated its effectiveness, it still tends to remain within the realm of informal practices. Finally, the third node addresses the relevance of the Trieste case study and the methodology used to investigate it.

4.1 Paradoxes

4.1.1 Sectorisation – Complexity

A first paradox of Italian social rental housing policies lies in the strict sectoral organisation of the entry modes and types of responses that underpin the overall housing system, understood as “the full range of inter-relationships between all the actors […], housing units and institutions involved in the production, consumption and regulation of housing” (Bourne, 1981, p. 26).

When considering subsidised, agreed and social housing, eligibility is determined on the basis of households’ disposable income and their ability to meet established rent thresholds. These conditions are assessed during target selection and at the time of entry. Once households enter a specific housing channel, they remain there for a duration set by contract. In subsidised housing, this duration often becomes indefinite, while the lack of periodic checks on tenants’ conditions contrasts with the increasingly rapid changes in household composition and income. The impact on the limited availability of this type of housing is evident: what was intended as a temporary and supportive measure often becomes a long-term (even permanent) allocation for the few families able to access the rankings.

In fact, in response to the growing demand for very social housing from people suffering from severe poverty, solutions must be sought outside the ‘ordinary’ channels of social rent. Housing for the poor falls under various forms of specialised care, distinct from those provided for the general population (Donzelot, 2005). The passive role assigned to the recipients often leads into more structural conditions of marginality, leaving them ‘trapped’ in a vicious cycle of assistance and, in some cases, ‘victim blaming’. In this context, ensuring that poor people have access to decent housing is still considered an indirect task of public policy. Public action is generally limited to the provision of social aid and economic support for household incomes (and, indirectly, for free market rents), while housing emergency solutions for the homeless (e.g., temporary shelters, dormitories, other reception facilities, and precarious cohabitations) are often delivered with the support of the third sector, with limited attention to the quality of housing arrangements and their capacity to foster independent living. From this perspective, poverty is seen as an obstacle to achieving

decent housing conditions, but the potential role that housing can play as a protective and proactive factor takes a back seat (Tosi, 2017). Today, the growing number of working poor and households that are even temporarily at risk of vulnerability clearly highlights the weakness and ineffectiveness of these approaches.

Adding to this, the demand for social and very social housing is generally addressed without considering the potential interactions with the critical economic situation also affecting an increasing number of small property owners, who find it difficult to maintain a second home and pay property taxes. Due to the often-modest quality of this private housing stock, its unattractiveness to the private and tourist rental markets, and the need for extensive renovation, the number of vacant or underused flats is growing. Indeed, putting them back into circulation at social rent could offer new opportunities for affordable housing policies. However, at present, only a few Italian initiatives attempt to reconcile the needs of renters and owners by creating local public rental agencies that, in exchange for agreed social rents, offer landlords tax reductions and guarantees in cases of arrears (Daglio et al., 2021).

4.1.2 Housing – Services

A second paradox, closely related to the previous one, concerns the economic and social resilience of welfare state policies as a whole. Responding to an impoverished social demand by lowering council housing rents on the one hand, and increasing financial subsidies to people in emergency situations on the other, is hardly sustainable. This is even more true when these two solutions are conceived and managed by different municipal sectors and agencies, which often struggle to coordinate their measures (on housing, access to jobs, social services and healthcare), and lack an integrated monitoring system to help calibrate material support to households' actual needs and their real capacity to afford housing costs – whether on the public or private rental market. To break this vicious circle, rental housing should be conceived and managed as a service in itself; namely, as a pivotal material support for ensuring full citizenship and social cohesion, and as a pillar of the "foundational economy" understood as "the economic space where those goods and services that are essential to individual and collective well-being, and constitute the infrastructure of everyday life, are produced and distributed" (Dagnes and Salento, eds., 2002, p. 13; translated by the authors). Adopting this perspective implies substantial work across several operational fields.

A first field concerns the expansion and diversification of affordable rental housing supply, in order to properly address various degrees of households' economic need and autonomy, avoid the concentration of the most problematic situations, and promote social mix. In this regard, one solution is to incentivise the creation of subsidised and social housing by including them within established planning standards (such as provisions for education, healthcare, culture, green spaces, and sports areas) and local town planning regulations. This concretely means granting building permits for housing in publicly or privately owned areas that were previously designated for other welfare-related facilities. When doing so, however, the spatial and social effects of this choice should be carefully considered, directing interventions toward sustainable solutions (e.g., from further land consumption to the regeneration of existing unused public assets) and ensuring the quality and affordability of the provided housing supply (Bricocoli, 2017; Bricocoli and Sabatinelli, 2019).

A second operational field concerns the necessity, when addressing severe social vulnerability, of integrating other services within or adjacent to housing accommodations (e.g., services supporting elderly people aging at home). In Italy, examples can be found in single- or multi-target social and supportive co-housing projects, often originating from specific funding programs (e.g., those delivered by banking foundations) with the active involvement of the third sector, and leading to innovative spatial and management solutions. Even though these experiences are multiplying, they generally remain exceptional and isolated practices, primarily targeting higher-income social groups. Cohabitation is also a common solution for assisted vulnerable groups and the homeless. However, in these cases, it often fails to overcome the limitations of institutionalised and depersonalised solutions, and to achieve spatial quality standards beyond the minimum threshold of decency (Costa, 2022; Costa and Minora, eds., 2023). In fact, when addressing distressed situations, the relationship between housing and services should become even closer, more continuous, and better tailored to the needs of individual recipients and households.

In fact, in the most critical social situations, not only securing a flat at an affordable rent but also keeping it often proves to be a highly problematic objective. Poor housing conditions, lack of work, and limited access to fundamental services and amenities are key components of the precarious living conditions of many individuals and households; therefore, they should be addressed together, at least initially, with almost daily support. The reference here is not to an on-demand management of problems and conflicts that may sporadically arise from the cohabitation of different individuals, but to a truly person-centred approach to constructing and delivering the quality and temporal intensity of both material and immaterial services (including job opportunities). Clearly, such an approach cannot limit itself to rethinking housing as mere spatial support, but must expand its operational scope to involve a broader reframing of 'territorialised' and community welfare systems, alongside the integration of innovative forms of estate and social management for dwellings and their tenants.

4.1.3 Funding – Reforms

Finally, a third paradox concerns the mismatch between the evident need to innovate housing policies and the political inability to allocate sufficient resources and effort to this purpose. In Italy, this is one of the most worrying aspects, as confirmed by the measures and funding provided by the PNRR.

Within the Plan, the building sector undoubtedly plays a central role, with resource allocation estimated at between 40 and 50% of the total €235 billion provided (including REACT-EU investments and those from the complementary fund). However, the issues of social and very social housing occupy a secondary position. They are fragmented into several interventions which, although valuable in themselves, fail to contribute to the formulation of a cohesive policy – one that is driven by a clear assessment of the scale and priority of demands and needs. Approximately €25.5 billion are allocated to rental and temporary housing solutions: student housing (about €1 billion), housing for the elderly and disabled (totalling €1 billion), and temporary housing and night shelters for the homeless (€450 million). Additional funds are dedicated to: energy and seismic efficiency of public and private housing (nearly €14 billion); urban regeneration and social housing plans and projects (€9 billion,

distributed among the Innovative Housing Quality Program PINQUA, projects aimed at reducing situations of marginalisation and social hardship, and Integrated Urban Plans) (Governo italiano – Presidenza del Consiglio dei Ministri, 2021). Housing is one component of these plans and projects; however, their primary focus is on urban renewal, in continuity with the programs implemented over the past 15 years – from the Piano Città (Plan for cities) launched in 2012 to the Piano Periferie (Plan for urban peripheries) established in 2016. Moreover, all the previously identified paradoxes remain: a rigid subdivision of intervention types (and the funds allocated to them) by categories of recipients; the separation between social and very social policies; and a prevailing focus on enhancing the material and economic value of public and private housing stock (Caritas Italiana, 2022). The PNRR offers no indication about the necessary reform of rental housing policies, such as one marked by: a significant increase in supply; innovative synergies among the resources and capabilities of public, private, third-sector, and civil stakeholders; integration of dwellings and services; and adequate support for the development of innovative management and spatial solutions.

4.2 Housing First as Prevention of Homelessness

Building effective responses to the demand for affordable rental housing from a 'grey area' of the population requires a deep rethinking of both the rigid rules and procedures currently in place for accessing subsidised, agreed, and social housing, as well as the ways in which social assistance measures are provided. This leads to working within a 'policy gray area', where the lack of adequate rental housing policies stands out as a critical issue but also allows for experimentation. Therefore, looking at innovative (and somewhat still informal) approaches, such as Housing First (HF) – a housing-led response to homelessness (FEANTSA, 2011) – gains interest. Since the 1990s, HF has spread across North America and Canada. Over the past 15 years, it has also been implemented in Europe, where in 2016 the Housing First Europe Hub was founded by the Y-Foundation (Finland) and FEANTSA (the European Federation of National Organizations Working with the Homeless). Implemented at different levels and in more or less structured ways depending on the context, HF has proven effective in providing homeless people with access to supported apartments, generally found in the private housing market (Pleace and Bretherton, 2013).

HF principles are based on a critical reflection on the paradoxes previously highlighted. Housing is understood as a starting point: this overturns the more traditional 'staircase model', which views access to stable accommodation as the final step after a rehabilitative pathway, often beginning with a shelter placement. In other words, according to HF, having a home is truly conceived as a universal human right. Consequently, in order to access a dwelling, it is not necessary to meet specific requirements or behave in a certain way (e.g., abstaining from alcohol or drugs), as is generally asked for by social assistance. The assumption is that individuals should have the power of choice and control over their own lives, be listened to, and be empowered "to choose the right combination of support for themselves" (Pleace, 2016, p. 30). Accompanying services are offered (e.g., healthcare, training, and job placement) but they are not mandatory for maintaining the accommodation, nor do they follow a 'one size fits all' approach. Instead, they are designed to be flexible, adaptable over time and space, and tailored to meet the needs and specificities of life paths. In this sense, HF challenges the often-punitive attitudes of welfare state

assistance. Another key goal is the individual's social integration within a community where they can find stability, reducing the risk of returning to homelessness. In summary, HF goes beyond prioritising housing: its innovative scope lies in the provision of a home plus a broad set of services, aimed at promoting autonomy over time through the creation of highly customised enabling conditions.

In this perspective, the main goal of housing-led approaches is to develop effective solutions not only for taking care of the homeless by minimising the duration of their stays in temporary placements, but also for preventing homelessness itself. As a result, the pool of potential beneficiaries for HF expands significantly, reaching a more diverse segment of the population at risk of becoming homeless (Jones, Albanese and Revelli, 2022). This expansion entails broadening HF's operational fields and networks. "Housing First works best when it functions as part of an integrated, multi-agency homelessness strategy, alongside prevention, and low intensity emergency accommodation services. […] to get the full benefits of Housing First it needs to be part of a systems wide governance approach […] rather than a standalone intervention addressing homelessness for a sub-group of people with high and complex inter-related needs" (ivi, p. 5). The call is for "a structural and operational shift in the governance of homelessness", and for setting "a new goal for the system by looking at HF from a rather different perspective than that of policy design […] When we talk about governance in the context of homelessness, we talk about every stakeholder involved in the field […] – and the ways in which they work and the directions that they are working towards" (Demos Helsinki and Housing First Europe Hub, 2022, pp. 7, 8).

In Italy today, more than 1,000 individuals live in HF accommodations managed by municipalities and the third sector (fio.PSD, 2024), compared to 292 in 2019 (fio.PSD, 2020). The increasing number of HF projects, along with the establishment of the Housing First Italia Network in 2014 by FIO.psd (an association active in studying and raising awareness about severe adult marginality), signals a shift away from an emergency-driven approach to housing hardship. Specifically, HF is not only proposed as an initiative targeting people with complex difficulties, but also as a lever for systemic change in policies. The aim is to solve the problem of homelessness, not merely manage it, by placing short- and long-term housing at the centre, and integrating it into a broader framework of housing and social policies (FIO.psd, 2024).

Since 2015, with the publication of the *Guidelines for Combating Severe Adults Exclusion* by the Italian Ministry of Labor and Social Policies (Ministero del Lavoro e delle Politiche Sociali, 2015), HF has received full recognition. However, projects remain sporadic, often developed on the initiative of the third sector, and involve a limited number of individuals compared to those seeking shelter in the traditional assistance circuits. In this context, the €450 million allocated by the PNRR to temporary housing and night shelters for the homeless (with target of 25,000 individuals) only partially addresses the recommendations to strengthen HF as a service provided by the National Plan of Social Policies and Interventions (2021-2023). While these financial measures indeed represent a step forward, they are not enough. Moreover, the PNRR fails to address several key critical issues: the difficulty in finding available public or private rental housing, exacerbated by the competition from more profitable sectors such as tourist rentals; the imposition of a 24-month time limit on projects, which directly contradicts HF principles; and the lack of any reference to the third sector and its crucial role in consolidating good practices and building new territorial alliances

between public and private stakeholders. What is missing is a radical shift toward a "network approach", based on a robust "link with the territory" and its communities, and "the construction of local partnerships" aimed at scaling up already existing, albeit not yet stabilised, "fruitful collaborations between public administrations, associations of small owners and social and housing cooperatives" (Casalino and Bergamaschi, 2022, p. 51; translated by the authors). These partnerships are essential to "the transformation of HF experiences into tangible opportunities for the restart of life paths through a gradualness of objectives", and the active involvement of recipients (Ibid).

4.3 Action-Research: Trieste as a Case Study

How can we proceed to define an operational framework that, drawing on the principles of HF, can guide housing policies toward new solutions for social and very social rental affordability? This question drives the research activities that are currently being carried out by the University, focusing on the case study of Trieste. This medium-sized city, with a population of about 199,000 inhabitants and located at the north-eastern border of Italy, provides an opportunity to investigate social, demographic, and economic trends and challenges common to many other 'intermediate' urban contexts – those that are neither metropolitan nor dispersed – across Italy and Europe (Lanzani, ed., 2024). Here, social marginality and housing hardship have not yet reached the most severe levels; nevertheless, the growing awareness of the housing crisis has prompted some local actors to experiment with innovative housing-led approaches.

In Trieste, available data – though partial and fragmentary – paint a picture of social and housing vulnerability, driven by multiple factors:

- Demographic decline and an aging population trend above the national average. According to the latest ISTAT census, over the past decade, the population has decreased by 4.45%, coupled with an old-age dependency ratio of 271.3% (compared to Italy's figures of -1.15% and 193.3%, respectively). The rising demand for welfare services coincides with a lack of economic resources, alongside a growing need for solutions that allow people to age in place.
- Migration flows due to the location on the Balkan route. The Italian Consortium for Solidarity (ICS) reports that, between January and September 2023, more than 12,000 arrivals were recorded, of which 70% were single men and 19% were unaccompanied minors. Approximately 13% of these migrants stopped in Trieste (ICS, 2023). The decision to stay largely depends on the outcomes of asylum applications.
- Inadequate social rental housing stock, vacant dwellings, and tourist pressure. The regional Territorial Agency for Housing of Trieste (ATER) manages over 12,300 public dwellings (almost 11% of the city's total; 93% are subsidised housing, and 14% are municipally owned). Around 9% of the city's population resides in these units (approximately 40% of the renters in Trieste). Due to insufficient maintenance, much of this stock (nearly half of which is over 50 years old) suffers from significant energy and spatial inefficiencies (ATER, 2021). Meanwhile, the demand for subsidised housing continues to grow, now reaching nearly 3,000 applications (D'Amelio, 2024). The issue of vacant real estate is significant: in 2020, there were an estimated 12,000 vacant housing units (2,000 managed by ATER and 10,000 privately owned) (Novacco, 2020). The impact of 'touristification' is also strong and combines with the consistent presence of students and researchers (around 29,000). As a result, this is

leading to an increase in short-term and unaffordable rentals, which are affecting the most vulnerable segments of the population.

Given the lack of coordinated knowledge and the absence of structured housing policies, questioning the complex relationships between local rental housing supply and demand, and their potential evolution, is far from simple. To this end, in 2023, the University of Trieste launched an action-research project understood as a field-based, reflective, and interactive practice (Schön, 1984).

The first steps consisted in mapping local actors, and identifying key stakeholders. Three in particular are the main players with whom, since 2024, a formal agreement has been signed, and research activities constantly discussed: Caritas Trieste, the social cooperative Lybra, and the voluntary organisation Comunità di San Martino al Campo. They are today the most active bodies in the promotion of projects based on the HF model. In 2023, they jointly participated (and won) the call delivered by the Social Services of the Municipality, addressed to the co-design of an integrated system for the accommodation of the homeless and of individuals in conditions of severe marginality. Although the call limits its activities to 2024, it also includes HF and co-housing solutions, demonstrating the willingness to test innovative approaches. However, if we sum up the dwellings owned by Caritas and the Municipality (including those that will be renovated with PNRR funds), the units addressed to HF and housing-led projects do not reach today the number of 30.

The lack of houses to be used for HF is a strong obstacle to the development of this policy. To overcome it, local stakeholders are well aware of the importance to share their resources, match different funding opportunities, and overall rethink the very social housing supply chain (from ownership, maintenance, support, and social and economic accompaniment). With the help of their experiences and points of view, further research was developed in the field. As a result, a first collection of local still ‘informal’ and tentative housing practices promoted by the Municipality, the third sector, and ATER was identified and in-depth analysed to highlight their achievements and failures, as well as enabling and impeding conditions for scaling up to more structured and ordinary policies. This is a fundamental step to avoid retracing the paths of past punctual experiments that, often referring to specific multi-problematic targets, remained stuck in policy sectorisation and failed to consolidate. In order to escape these traps, working in between affordable and unconventional, social and very social rental housing clearly appeared to be a good way. Consistently to this, two complementary moves were put in place: expanding and diversifying the parterre of local actors to dialogue with (from the public and the third sector, to labour organisations, property and housing associations, social and economic foundations, cultural and economic communities’ representatives); and understanding the conditions and beneficiaries to refer to, as well as the set of tangible and intangible resources to mobilise and by whom.

In April 2024, one first discussion table on affordable housing in Trieste was organised, bringing together a wide range of actors to address several crucial issues (Fig. 1): Which real estate assets (both public and private) can be made available to enhance the supply of rental housing at social and very social rents? What obstacles exist, and what conditions and tools can be implemented to overcome them? What management processes and procedures – both for real estate and social services – can ensure the economic viability of innovative and unconventional projects and policies? The call for

a permanent space for discussion on affordable housing was clearly expressed by all the stakeholders the research reached out to. A follow-up meeting of the table was therefore scheduled for June 2024, aimed at further networking skills, experiences, and opportunities for co-designing and co-implementing social and very social housing projects. Meanwhile, University's investigations are continuing through in-depth interviews and debates with specific actors on the key themes that emerged during the previous phases.

5. Discussing Rental Housing Affordability in Trieste

In Trieste, there is a strong presence of a variety of actors, resources, and experiences in the fields of social and very social rental housing, promoted by the Municipality, ATER, foundations, and the third sector (social enterprises). Despite being fragmented and discontinuous in both time and space, they offer a valuable starting point for developing new responses to a pressing demand. One of the main critical issues, however, is that the actors involved are often overwhelmed by urgent matters and a lack of personnel. This prevents them from dedicating the effort needed to examine their practices, correct them, and eventually redirect their approaches. The discussion table organised by the University was precisely designed to offer an opportunity for self-reflection, critical thinking, and the sharing of issues and ideas. It provided insights into some key levers for conceiving new housing projects and policies, based on stronger collaboration among public, private, and third-sector actors.

5.1 Actors and Actions in Search of Direction

One recurring issue emerging from the discussion is the lack of a framework capable of bringing the various innovative housing practices tested in Trieste into coherence.

Regional Law no.1/2016, *Organic Reform of Housing Policies and Reorganisation of ATER*s, attempted to address this problem. The Law recognises the fundamental importance of housing as a significant factor for inclusion, social cohesion, and quality of life, and promotes a variety of forms of intervention (including those related to rent and ownership, subsidised, agreed and assisted housing). Its goal is to systematise public-driven housing measures and policies through territorial governance and the participation of the actors involved in the housing supply chain. To achieve this, the establishment of integrated tools and processes is foreseen, such as: a regional commission and an observatory on housing policies; local response desks to collect and match data on housing demand and supply; and local permanent forums for discussion involving public, private and social actors, aimed at representing the needs of the different territories, and co-designing innovative projects funded by annual regional funds (Marchigiani, 2015). However, the main weakness of the Regional Law lies in its implementation. Neither the regional observatory nor the local response desks have been established. Moreover, in Trieste, the local housing forum has operated intermittently; over time, it has shifted between the direction of different municipal departments (from Estate Management to Social Services), and more recently, it has been scheduled only sporadically, tied to the equally sporadic allocation of regional funds for innovative projects. In fact, the Municipality has missed the opportunity to create a housing steering committee, while the management of social rental housing still primarily remains in the hands of ATER which, however, faces several difficulties (from the scarcity of ordinary regional funds for the timely maintenance of its housing stock to increasing arrears in rent payments). In parallel, a variable mix of foundations, social-private, and other third-sector organisations collaborate with the Municipality in offering very social housing. This often occurs through specific agreements that also ensure the use of public dwellings for social scopes, but fail to provide a clear direction toward shared visions and long-term goals.

Indeed, a significant weakness of the Trieste housing system is the difficulty in creating and maintaining stable networks among local actors, despite the presence of specific expertise, strong place-based know-how, and practices in innovative welfare services management. This particularly refers to the *Habitat-Microareas. Health and Community Development* programme, which, since 1998, has been operational in a number of urban districts in the province of Trieste. The program is the result of a joint partnership between the Local Health Agency, ATER, and the Municipalities of Trieste and Muggia. This ‘proximity welfare’ initiative has been implemented through a territorialised system of social and health services, addressing the care needs of spaces and people in urban areas with a strong prevalence of subsidised housing, and through the active participation of institutions, residents, and the third sector. One of the spatialised tools of *Habitat-Microareas* consists of setting up a ‘social concierge’ office in each neighbourhood, acting as a reference point for both service demand and supply, a help desk for maintenance requests, and a civic centre for organising activities with residents and fostering community building. From its start, the program has been conceived as an alternative way of constructing adequate responses to specific and complex needs, leveraging all the spatial, social and economic resources available in place (Marchigiani, 2022). In the last years, however, these objectives have gradually changed. The social concierge offices are now mainly used for the provision of basic healthcare support and the re-routing of requests to central institutions. Nonetheless, this approach has become embedded in the mindset of many local

actors, still providing operational inputs for future integrated housing-and-services solutions.

5.2 Fragile Attempts of Cohabitation

In general terms, experiments in the field of solidarity co-housing – due to their more versatile nature compared to the public housing access system – offer valuable insights for accommodating diverse target groups with specific needs. The potential to create partially self-managed communities stands out as an interesting added value when aiming to reconstruct social support networks contributing to the strengthening of individuals' and households' autonomy, especially in the context of pathways out of emergency and highly institutionalised housing.

Different practices developed in Trieste belong to this field, showcasing a variety of spatial solutions, urban settings, target groups, promoters, funding models, and a mix of services (e.g., social housing, solidarity condominiums, assisted housing for the elderly and disabled, co-housing for mothers with children) (Fig. 2).

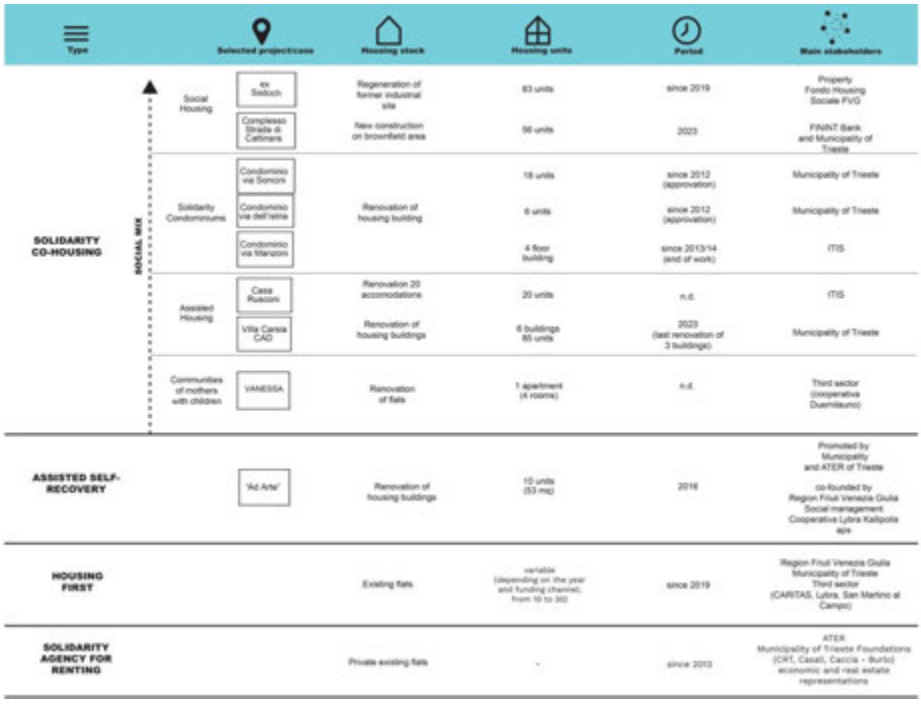

Figure 2 – Trieste. A selection of recent solidarity co-housing projects and initiatives, 2024. Source: V. Novak.

Yet, what the investigation of these practices highlights is a common difficulty in creating a real social mix, due to the limited number of available dwellings relative to demand, as well as inadequate real estate and social management. As a result, these initiatives remain exceptional and episodic.

In particular, the only social housing intervention implemented thus far in Trieste under Law no. 133/2008 has proven ineffective in addressing rental housing demands at affordable prices. Due to the economic constraints imposed by the public-private financial system underlying this type of projects, the balance between owned and rented housing penalises the latter, while rents are too high for the spending capacity of households facing housing hardship.

5.3 Locked Housing Assets

The large number of vacant private dwellings constitutes both a severe problem and a potential resource. As already mentioned, many flats in the city remain empty for extended periods, due to a lack of economic resources for renovation and maintenance. Moreover, even when the quality of the apartments is too low to meet either ordinary or tourist demand, owners generally prefer to turn to the rental market, even if this means running the risk of becoming entangled in long and expensive eviction lawsuits.

In Trieste, the take-off of the Solidarity Agency for Renting was hindered not only by these factors but also by the lack of incentives and conditions capable of competing with the revenue from the free market. After an initial attempt in 2009, the Agency was relaunched in 2014 by the Municipality under ATER's management, with the involvement of several housing stakeholders. The goal was to promote social and agreed rental arrangements of private dwellings by offering guarantees and tax relief to their owners. However, several obstacles emerged: the financial support initially provided by a banking foundation could hardly cover the establishment of an initial and modest guarantee fund to promote rent reductions, cover potential arrears, and repair costs after damages; the management process (including the evaluation of dwellings at the start and end of the rental period) was too demanding to be integrated into ATER's regular operations; and, overall, the poor response from private owners (a direct consequence of these conditions) weakened the political will to allocate local tax abatements for this purpose.

To transform the Solidarity Agency for Renting into an effective tool, a radical rethinking of its fields of action, as well as its financial and operational procedures, is needed. As discussed with the local Association of small property owners (UPPI), a real incentive for shifting from the private to the social rental market should involve substantial relief from housing-related costs (e.g., renovation expenses, and payment of state and local taxes), as well as a significant reduction in the risks associated with arrears and evictions. In this context, a new type of Agency should be created. It could, for example, be managed by third-sector organisations in partnership with the Municipality, with at least partial support from public and/or private funds to compensate for the low rents received. Acting as intermediaries between private interests and public goals, and playing the role of both real estate and social mangers, third-sector organisations would be tasked with 'taking custody' of private dwellings and their overall associated costs for the duration of the lease. However, to ensure the long-term economic viability and the scalability of this service, a feasibility study should be developed to assess the benefits and risks for all parties involved: for small property owners, in comparison to the returns offered by the private market; for third-sector entities, with particular attention to tax conditions and potential reductions; and for the Municipality, in

comparison to the costs associated with the social and economic support traditionally provided by public assistance systems.

To unlock vacant private and public housing, lowering renovation costs is another pivotal issue, as repeatedly emphasised in meetings with local stakeholders. Also in this case, Trieste provides examples from which lessons can be learned. Since several years, ATER has offered households on the waiting list the option to carry out small self-maintenance interventions in exchange for a discount on rent. This solution has proven effective in bringing back into circulation vacant dwellings that do not require major rehabilitation. The self-recovery of entire vacant buildings, however, is more complex. This type of intervention was tested between 2014 and 2016 on a municipally owned building managed by ATER, but without success. The project was supported by third-sector organisations and led to the creation of a inhabitants' cooperative, to which surface rights on the property were to be granted. The initiative encountered a crisis when, lacking real estate and financial guarantees (the surface right is not considered ‘bankable’), the cooperative was unable to secure the mortgage necessary to cover the gap between renovation costs (reduced by their labour) and the funds provided by Regional Law no. 1/2016 (Marchigiani et al., 2019). Nevertheless, this experience offers useful insights. Many of the challenges could perhaps be overcome if surface rights, the future inhabitants’ engagement process, and self-recovery efforts were directly managed by an intermediary organisation providing the necessary guarantees in exchange for collecting (at least partially) social rents from tenants.

6. Open Conclusions: Toward Solidarity Neighbourhoods

The case study of Trieste helps reflect on how new public-driven policies can address the dramatic increase in social and very social demand for affordable rental housing, by involving various stakeholders and resources, and focusing on place-based, local spatial, social, and economic conditions. The goal is to move beyond a sectoral approach, in order to avoid the rigid regulation of access to different housing channels, break down the segregation of target user groups, and address the persistent shortage of available dwellings and services, as well as their integration. From this perspective, several crosscutting issues emerged from the extensive outreach activities conducted during the research, providing inputs for the development of future housing pilot projects in Trieste.

A key general consideration is that, in order to deliver and implement well-informed and effective housing policies, there is a strong need to build structured and integrated knowledge across several aspects: the availability of public and private housing stock and its maintenance status; the social demand, including its various shades of vulnerability; and the broader set of measures provided by economic and social welfare assistance, which are more or less directly aimed at addressing housing poverty and the risk of homelessness. The reference here is to a local housing observatory, understood not just as a means of building a dataset, but as a space and practice for activating a solid network of local actors, and supporting synergistic approaches to rental affordability. Who could be responsible for the practical development of this initiative remains an open question. Perhaps the University, as is happening in other Italian contexts (Consorzio Cooperative Lavoratori di Milano et al., 2024), but this would still require a strong commitment from all housing stakeholders – particularly

public ones – to support and rely on the interactive knowledge that the observatory can produce.

Intensive and sustained funding and effort in the implementation of innovative rental housing projects, as well as their scaling up, is indeed a fundamental requirement and should become a central issue at the national, regional, and local government levels. The current lack of public resources prevents significant action on both existing public and private housing assets, and their adaptation to new demands and lifestyles. It also limits the availability (for both owners and tenants) of stable guarantees to support housing affordability, and hampers the concrete realisation of the right to housing and of HF as a truly preventive approach to the risk of homelessness.

The strategic role that 'intermediate' actors can and should play in renovating housing policies and solutions is another, equally important, aspect to consider. Reflecting on future perspectives for very social rental housing does not mean proposing the creation of a specific (and lower-quality) housing supply for the poor. In fact, today, the term 'poor' encompasses a diverse set of individuals and households, with economic and social conditions that can change rapidly. As such, it resists easy categorisation, both in terms of the duration of rental accommodations and the spatial solutions traditionally proposed by public housing. To effectively address this diversity and foster a genuine social mix within the same dwelling or building, housing and services must be integrated through careful and customised social, economic, and co-habitation management. All these activities require specific expertise and skills, as well as more flexible, person-centred working styles, which are rarely available to municipalities and council housing agencies.

Another consideration is that public assets can be a powerful driver for developing more complex housing projects, also involving other underused or neglected estates, owned not only by small private actors but also by entities controlling larger properties. To move forward in this direction, it is necessary to go beyond an approach focused solely on the valorisation of individual buildings and begin incorporating public spaces and services into urban regeneration processes at the neighbourhood scale. The research team is currently working on these issues with the goal of developing a pilot project in Trieste. The underlying assumption is that taking the neighbourhood as the appropriate scale and field of action can help create a social mix, organise community-building activities, bring together a wider set of material and immaterial resources necessary for implementing differentiated rental housing solutions, and manage various facilities and amenities. At the same time, involving local actors who work on the ground and provide services can help generate a sense of trust within local communities, which may eventually and incrementally attract additional resources and participants (Fig. 3).

The shift from the concept of solidarity co-housing to that of solidarity neighbourhood is the direct result of discussions held during the table on affordable housing organised by the University of Trieste, followed by a series of meetings with Caritas, Lybra, and other stakeholders interested in co-designing a pilot project. These actors include ATER, Fondazione Caccia-Burlo (a charity founded in the early XXth century, currently active in housing for the poor), and ITIS (a public health organisation that has promoted co-housing and community projects, as well as the establishment of a 'social concierge' office next to its operational headquarters). The location of various buildings owned or

managed by these actors in the same neighbourhood (Barriera Vecchia), within a consolidated area of Trieste, was a key factor in shaping the vision of how to create a territorial combination of dwellings and services. In particular, the spatial diversity of these buildings, along with their integration into an urban sector rich in facilities and well connected to the city centre by public transport, provides an opportunity to enhance both social and spatial mix. Additionally, these conditions enable the inclusion of self-recovery processes, and at least partial self-management of social and economic activities open to both the neighbourhood community and the wider city (e.g., a restaurant and/or a B&B in one of the buildings). From this perspective, integrating housing and economic activities not only offers new job opportunities for tenants, but also generates revenue for the stakeholders involved in the cases of arrears. In other words, the solidarity neighbourhood model is seen as an effort to concretely translate the concept of "location affordability" – that is, to integrate the spatial, social, and economic dimensions of this concept in a way that avoids "phenomena of progressive segregation and selection, or filtering-down, of the population based on income" (Bricocoli and Peverini, 2024, p. 60; translated by the authors).

Abstract
During the 2010s decade, Portugal witnessed a steep surge in house prices, akin to trends in other European countries. This work aims to: i) analyse the reasons that led to the increase in housing prices in Portugal; ii) discuss the impacts of COVID-19 on the housing market; iii) study the evolution of housing prices during the pandemic; iv) understand how the COVID-19 pandemic has affected the housing market. The analysis adopts a quantitative approach and is based on official data from 2016 to 2023, providing a comprehensive view of the housing market in Portugal before, during, and after the pandemic. Preliminary findings suggest that the pandemic had minimal impacts on the housing market.

Key-words: housing, housing market, real estate, Covid-19, Portugal

1. COVID-19 and public health

Over the past 100 years, developed countries have not been significantly affected by major epidemics, partly due to advances in modern medicine, hygienic-sanitary conditions, antibiotics, and vaccinations. The last generations have not experienced a global disease's devastating and uncontrolled spread (Loomis, 2018).[1] Although developed societies have considered themselves immune to epidemics and pandemics, the COVID-19 global pandemic revealed several weaknesses and new challenges.

Infectious agents have impacted humans from their very inception. It is thought that the interaction between these agents and humans increased significantly during the Agricultural Revolution and the onset of sedentarization when humans started to cohabit in delimited spaces (Loomis, 2018). Throughout history, diseases have influenced battles, caused the decline of civilizations, helped spark revolutions, and, above all, shaped the history of humanity (Oldstone, 2010; Snowden, 2020).

The Industrial Revolution led to an increase in the population density of urban spaces. With this revolution came a new working class living in precarious dwellings, which provided ideal conditions for contagious outbreaks (Laxton and Rodger, 2013; Loomis, 2018). Sanitary improvements to urban spaces started in the middle of the 19th century, primarily due to cholera, measles, and tuberculosis outbreaks in some of the largest European cities. These public health interventions generally enhanced people’s quality of life and transformed the experience of those living in urban areas (Bassett, 1993; Belchem, 2006; Laxton and Rodger, 2013; Loomis, 2018, Snowden, 2020; Antunes, 2021b).

Large cities have always been prone to the spread of infectious diseases, as is the case with COVID-19. In more recent years, the growth of large metropolitan areas, high population densities, overcrowded houses, inadequate transport networks, urban sprawl into forest habitats, globalization, and the expansion of international road, rail, port, and air transport connections have created endless opportunities for the spread of infectious diseases (McNeill, 1998; Loomis, 2018; Snowden, 2020; Oldstone, 2010). As stated by the United Nations, urban areas have become the pandemic's epicentre, with an estimated 90 per cent of all reported COVID-19 cases (UN, 2020).

1.1. The Portuguese housing market before COVID-19

Between 2010 and 2020, the Portuguese real estate market underwent substantial changes and was presented with new challenges (Farha, 2017; Antunes, 2018, 2019a, 2019b; 2020; Mendes, 2018a, 2018b; Santos, 2019; Franco et al., 2019; Gonçalves et al., 2020; Xerez et al., 2020). Briefly, these changes were motivated by internal and external factors:

- Internal factors include political and legislative decisions, such as the liberalization of the rental market, the creation of incentives for foreign investment, compassionate legislation for short-term rental, and the legal-normative facilitation of rehabilitation interventions.

- External factors were those that were hard to control in the globalized market, such as the investments of international real estate funds and hotel groups, the growth of urban

[1] Although epidemics were common in some of Portugal's most significant cities until the end of the 19th century, the country had not suffered from pandemic outbreaks since the Spanish Flu in 1918 (Rodrigues, 1990, 1995).

tourism, the emergence of new forms of housing use, such as short-term rentals (reducing the houses available in the market), and the wide variations in European Central Bank interest rates.

These internal and external pressures are visible in large Portuguese and other European cities. These factors are often associated with phenomena such as “housing financialization,” “touristification,” and “gentrification” (Brenner et al., 2012; Aalbers, 2012, 2016, 2018; Colomb and Novy, 2016; Wetzstein, 2017; Hughes, 2018; Lees and Phillips, 2018; Fuller, 2019).

In summary, the Portuguese real estate market underwent major changes in the decade before the outbreak of the COVID-19 pandemic. Following the conceptualization suggested by Antunes & Seixas (2022), we debate some factors contributing to the current housing market scenario.

- Liberalization of the rental market: since the 1990s, substantial changes have occurred in the Portuguese rental market. First in 1990 with the legal framework "Regime do Arrendamento Urbano" (RAU [Urban Lease Regime]), later replaced in 2006 by the "Novo Regime do Arrendamento Urbano" (NRAU [New Urban Lease Regime]). While in the case of the RAU it is possible to speak of "normalisation" in the rental sector, after several decades of protectionism, the years that followed brought an apparent liberalisation of the market, which reached its peak in 2012, with the wide-ranging legal changes introduced to NRAU (Antunes, 2018, 2020, 2021a; Mendes, 2022). It should be emphasised that the legal changes made in 2012 came as a result of the impositions in the 'Portugal: Memorandum of Understanding on Specific Economic Policy Conditionality', signed in 2011 as part of the Troika's intervention (i.e. the International Monetary Fund, the European Commission and the European Central Bank) (Antunes, 2020). The legal changes made in 2012 clearly liberalised the rental market, seeking to promote its dynamics at the expense of contractual protections for tenants, which was particularly visible when it came to so-called 'old contracts' (contracts signed before the Urban Lease Regime of 1990) (Antunes, 2020). For some authors, this rental market liberalisation led to gentrification (changes to the social fabric) and touristification, aided the conversion of residential dwellings to touristic spaces (hotels, hostels, and short-term rentals (Mendes 2016, 2017, 2018, 2019, 2020; Carvalho et al., 2019, Lestegás, 2019; Lestegás et al., 2019).

- Housing policies promoting homeownership: another critical factor was the historical housing policies that preferred homeownership. According to IHRU (2015), between 1987 and 2011, 73% of the funding provided in the State Budgets for housing was used for "interest rate subsidies on mortgage loans". This political strategy prioritised access to homeownership through mortgage loans, which were only accessible to the middle class, leaving out the lower-income households (Antunes, 2020).

- Fiscal exemptions for foreigners: more recently, it is worth highlighting the fiscal exemptions that arose due to the 2008 financial crisis. In the last 15 years, various legal structures have been created to attract foreign investment, such as the ‘Special Tax Regime for Non-Habitual Residents’ in 2009, the ‘Residence Permit for Investment purposes’ (better known as the “Golden Visa”) in 2012 or, more recently, the fiscal incentives for “digital nomads” (Antunes, 2020). These measures aim to attract foreign capital, promote economic growth, and create opportunities for the host country and

investors. However, these political measures, notably the Golden Visa, have affected the housing market, including price increases and public disapproval, especially in urban areas (Santos & Strohmaier, 2024).

- Growth of urban tourism: the growing attractiveness of urban tourism can be linked to increased investment in short-term rentals (STR) (Arias-Sans and Quaglieri-Dominguez, 2016; Cocola-Gant, 2016; Gurran and Phibbs, 2017; Wachsmuth and Weisler, 2018). STR can be understood as providing rooms or entire houses to guests (tourists) for short periods, often publicized on digital platforms (e.g. Airbnb). This accommodation type has become increasingly popular in urban tourist destinations, such as Lisbon, as it allows property owners to earn additional income. At the same time, holidaymakers enjoy experiences that are closer to local daily life and generally more affordable (De Barros & Novo, 2023). With the increase in tourists visiting Portuguese cities, there is a greater demand for STR. An example of this is the exponential boost in the number of STR spaces in the municipality of Lisbon, which went from an almost non-existent reality in 2010 to more than 20,000 STR spaces in 2020 (Antunes & Ferreira, 2021). Concerning the municipality of Lisbon, Antunes & Ferreira (2021) questions specifically about the STR 'how much is too much', from the perspective that each dwelling used for tourist accommodation has no residential use for a local family, thus potentially removing that dwelling from the housing market. The same authors also found that Lisbon downtown concentrates 14% of all STR in Portugal. Due to this set of factors, STR has come to be associated with contemporary urban phenomena such as 'touristification' (Barata-Salgueiro, et al., 2017; Seixas, 2019a, 2019b; Antunes & Ferreira, 2021), 'gentrification' (Mendes 2016, 2017, 2018, 2019, 2020; Carvalho et al., 2019, Lestegás, 2019; Lestegás et al., 2019) or even the 'financialization of housing' (Santos, 2019; Tulumello & Allegretti, 2021; Drago, 2021).

- The international appeal of the Portuguese real estate market: the growing international attraction of the Portuguese real estate market is also perceptible in the increase in real estate transactions carried out by foreign citizens and global real estate funds. In the case of private individuals, this has been mainly due to increased interest in living in Portugal (or buying a second home in the country), while in the case of international funds, the reason is due to the recognition of a profitable investment that also works as a secure financial asset. Lisbon and Porto entered directly into the international real estate investment circuit as some of the more attractive cities in the European market for real estate and tourism investment (ULI and PwC, 2019).

- Legal-normative facilitation for rehabilitation interventions: It should also be pointed out that since the 2010s decade, building rehabilitation has been favoured over new construction. Various mechanisms have been created for this purpose, such as the 2014 "Regime Excecional para a Reabilitação Urbana" (RERU), which softened the standards imposed by the "Regulamento Geral das Edificações Urbanas" (RGEU), making interventions less costly and demanding. In addition, financial mechanisms were created, such as the "Instrumento Financeiro para a Reabilitação e Revitalização Urbana", known as IFRRU 2020 and co-financed by European funds (Antunes, 2018; Xerez, Rodrigues & Cardoso, 2018; Seixas & Antunes, 2019; Antunes & Seixas 2022). The preference for rehabilitating rather than building has decreased the number of dwellings built in Portugal. For example, in 2022, only 20,156 dwellings were built, a figure that can be compared with the 115,154 dwellings built in 2001 (the lowest was

recorded in 2015, with 7,148 dwellings built).[2] It therefore seems rational to assume that the number of homes built during the 2010s, an average of 16,000 per year, may have contributed to not increasing supply adequately, limiting the number of homes entering the housing market. Also, in this context, it should be noted that in 2022, the residential construction sector accounted for around 3.9% of GDP in Portugal, which is lower than the EU average of 5.9%.[3]

- Euribor rates: another element in understanding the Portuguese housing market is the role of Euribor rates. About this topic we can identify two critical moments: i) during 2008/2009, there was a period of all-time records for Euribor, reaching around 5%, triggering a series of events, including an increase in household effort rates, an upsurge in bad debt, an inflow of dwellings onto the housing market and a decrease in the housing prices due to excess supply face low demand; ii) Euribor interest rates decreased until reaching negative values in 2015 (a trend that has recently been countered by an increase since the beginning of 2022). That is to say that between 2015 and 2021, the Euribor rate was negative, assuming a mortgage was more accessible and not so expensive. This perception of financial solvency contributed to a rise in house prices, as most families were willing to go further with their purchase price. Likewise, this is especially important as Portugal is a country where mortgages are monopolised by variable rates rather than fixed rates, as is commonly the case in the rest of Europe (Costa, et al., 2023).

Among others, these changes contributed to the increase in the housing prices in Portugal. In the Lisbon municipality, the average cost of a square meter was €1,875 at the beginning of 2016; by the beginning of 2020, the average cost reached €3,111. Although this increase is not connected to economic improvements or increases in net income in Portugal, it has affected housing prices in the purchase and rental markets. For real estate investors, this decade represented the "golden years" of Portuguese real estate. However, for individuals looking for a home, the price increase led to less housing accessibility and higher effort rates (Seixas & Antunes, 2019; Antunes & Seixas, 2020; Antunes & Seixas, 2022).

1.2. House prices in Europe

Portugal is one of the EU countries where housing prices persist in rising faster (Eurofound, 2023; Deloitte, 2020, 2021, 2022, 2023). Between 2010 and 2019 in the EU, housing costs increased by 8% for homeowners and 23% for tenants. The highest increases among tenants (over 40 %) were recorded in Portugal, Poland, Greece, Bulgaria, Estonia, and Latvia (Eurofound, 2023). Data on the evolution of house prices in the European Union, provided by Eurostat, confirms not only the trend of housing price rises in Portugal but also the fact that it has led the way over the years, along with countries such as Estonia, Luxembourg, and Hungary.

[2] "Completed dwellings in new construction for family housing", Statists Portugal.
[3] Residential construction - annual data, % of GDP, tipsna50, Eurostat.

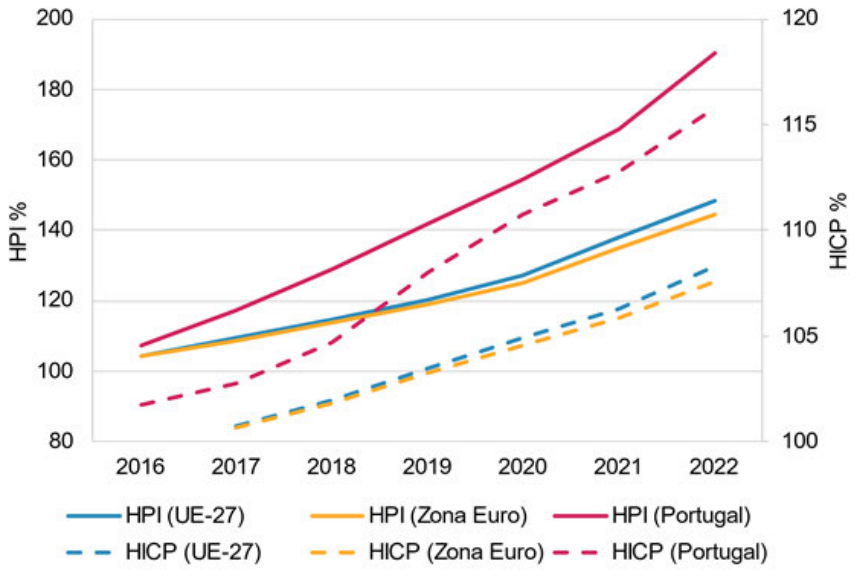

Figure 1 – Evolution of house price index (HPI) and harmonized index of consumer prices (HIPC). Source: Eurostat.

According to Figure 1, it is possible to establish that not even COVID-19 has ended the housing market rise trend, with house prices increasing throughout the European Union. It should be noted, however, that recent Eurostat statistics from 2023 show that influential European housing markets, such as Germany and France, have witnessed a small downward in housing prices for the first time in several years.

2. COVID-19 in Portugal

The following timeline presents an overview of the evolution of COVID-19 in Portugal:

- On March 2, the first cases of COVID-19 were confirmed: two men who had returned from Italy and Spain.
- In the following weeks, the number of cases multiplied, including in public institutions such as schools and universities. On March 11, the World Health Organization declared the COVID-19 outbreak a global pandemic.
- On March 16, an additional 331 daily cases were confirmed, reaching a total of 1,157 cases, and the first death was documented. The Portuguese government decreed a "state of alert" nationwide on the same day. In this period, schools, universities, and various private and public entities decided to close indefinitely.
- On March 18, 2020, the government took a decisive step. It officially declared a 'state of emergency,' effective the following day, to limit the spread of the disease and the loss of lives as much as possible. The 'state of emergency' was renewed twice and ended on May 2, 2020. The "state of emergency" set the Portuguese population under lockdown.

During this period, citizens were prohibited from leaving their homes (with minor exceptions). The police controlled road movements within the country. The borders with Spain were limited to transporting goods, and international airports were closed for civil flights.

- On May 2, the "state of emergency" was lifted, and the country entered a "state of public calamity" (less severe for civil rights than a "state of emergency"). From that moment on, citizens could leave their dwellings without facing legal problems, and some economic activities restarted, but with restrictions. The borders were opened, and the government attempted to promote tourism, an important source of revenue for the country's Gross Domestic Product. Efforts were made to return to a normally functioning society (a so-called "new normal"). Even so, several measures were implemented to ensure social distancing during 2020. In 2021, there were other small moments of public health crisis.

The following timeline traces the spatial spread of COVID-19 during 2020:

- In March and April 2020, most cases were concentrated in northern Portugal, particularly in the Porto Metropolitan Area and more industrialized municipalities.

- In the following weeks, the pandemic grew, reaching the central region of Portugal. For example, on March 29, the Ovar municipality was the target of a cordon sanitaire, which lasted for 15 days.

- In May and June 2020, the focal point of the epidemic moved to the Lisbon Metropolitan Area, which began to register more than 50% of the country's new daily cases.

- At the end of May, official briefings and press releases announced that some more deprived communities (slums) in the Lisbon Metropolitan Area were facing high contagion rates, creating hotspots of contagion.

- In June, COVID-19 cases began to decline, and the government moved the country back to a "state of alert" (the lowest level). However, the Lisbon Metropolitan Area was placed in a "state of contingency" (an intermediate level) due to the higher number of infections in that region. Additionally, 19 parishes in the Lisbon Metropolitan Area remained in a "state of public calamity" until the end of July due to their very high new daily cases. These parishes around Lisbon are generally associated with lower-income households who use overcrowded public transport and must continue working during confinement. At the end of July, the situation in these 19 parishes normalized and the "state of public calamity" ended. The entire country remained in a "state of alert," except for the Lisbon Metropolitan Area, which endured in a "state of contingency".

- At the end of August, the number of new daily cases began to balance out, reaching a level between the Lisbon Metropolitan Area and the northern region of Portugal.

- Since then, COVID-19 cases have remained at lower levels than before, except for a few periods, such as at the beginning of 2021, when the government again limited various economic activities and services due to a new strain of COVID-19.

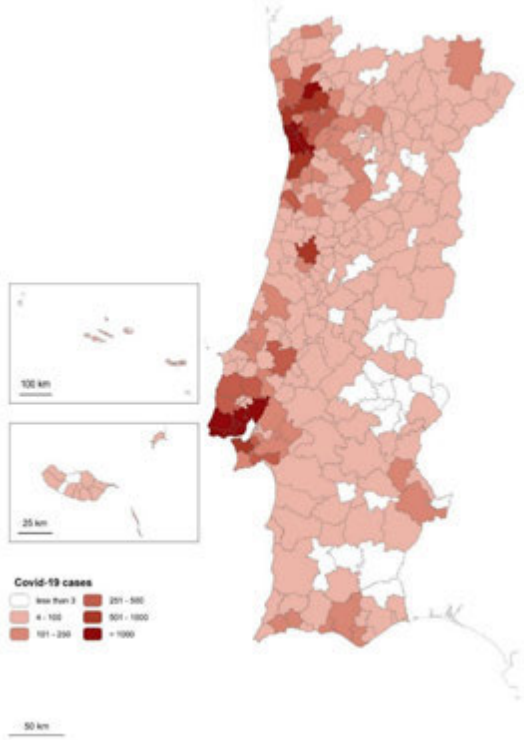

Figure 2 – Covid-19 cases in Portugal until August 31, 2020. Data source: Directorate-General of Health.

As shown in Figure 2, the most affected municipalities in Portugal were located on the coast. Some municipalities in the countryside experienced a few COVID-19 cases, while others were unaffected. This spatial difference allows us to draw a dichotomy between the Portuguese coast, which is mostly rural and contains small or medium cities.

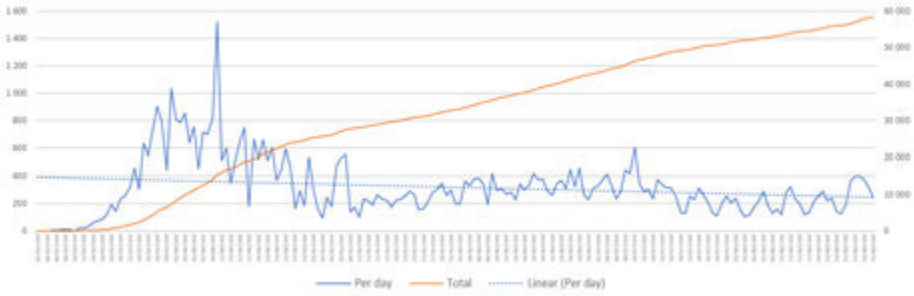

Figure 3 – COVID-19 cases in Portugal, per day and cumulative cases (between March 2 and August 31). Data source: Directorate-General of Health.

According to the Directorate-General of Health, until August 31, 58,012 cases of COVID-19 were identified in Portugal, with 41,961 people recovered and 1,822 deaths. During August, the

number of infected people stabilized, reaching between 200 and 300 new daily cases (Figure 3). To prevent further difficulties with the return to work and the start of the new school year, the government announced that the country would enter a "state of contingency" starting September 15. his declaration aimed to prevent the country from returning to a "state of emergency," the most severe level, which led to the lockdown in March and April. However, new small lockdowns had to be implemented in 2021 for outbreaks of lower intensity.

2.1. COVID-19 and the Portuguese housing market

As discussed earlier, in the second half of the last decade, the housing sector underwent an increase in international investment, the growth of urban tourism (especially the short-term rental), the touristification of Lisbon and Porto, higher pressures in the real estate market, the gentrification of downtown areas, and a surge in residential prices and effort rates for households.

In the first months of COVID-19, several doubts were raised from an academic and political point of view as to whether the COVID-19 outbreak and its economic and social impacts could have consequences on the housing market and possibly break the upward trend in housing prices, launching a period of uncertainty and unpredictability.
COVID-19 also brought new concerns about the difficulties of households paying rent and home mortgages. As stated by the European Commission, the COVID-19 pandemic "*it is a severe public health emergency for citizens, societies and economies. It is putting national health systems under severe strain, disrupting global supply chains, causing volatility in financial markets, triggering consumer demand shocks and having negative effects across various sectors. It is threatening people's jobs, their incomes and companies' business. It has delivered a major economic shock that is already having serious repercussions in the European Union*" (EC, 2020b:1-2).

In response to the COVID-19 pandemic, Portugal adopted several emergency policies to contain the pandemic and provide relief to affected households, enforced in 2020 and 2021. It is also vital to highlight that the European Union decided to apply a broad economic stimulus to European countries in response to the pandemic crisis. The "Portuguese Recovery and Resilience Plan" was an essential support for the national economy, with a substantial part of the funds received being applied to matters related to the housing sector (Portugal, 2021).

3. Housing market: quantitative analysis

The quantitative analysis proposes identifying spatial and temporal patterns using statistical data from Statistics Portugal (Instituto Nacional de Estatística [INE]). We also formulated a theoretical-quantitative model called the 'Housing Access Index' (HAI) for this quantitative analysis. The formulation of the HAI (Figure 4) makes it possible to understand how access to housing has evolved in Portugal by correlating housing prices and household income. The methodological analysis presented in this paper has been developed in previous studies which analysed spatial and temporal housing dynamics in the Lisbon Metropolitan Area (LMA) (Seixas & Antunes, 2019; Antunes & Seixas, 2020; Antunes & Seixas, 2022).

'Housing Access Index'

Mortgages	Rental market
$AHV = A \times B$	$AHV = C \times B$
$HAI = \frac{MP}{HI} \times 100$	$HAI = \frac{AHV}{HI} \times 100$
HAI: Housing Access Index. **AHV:** Average Housing Value. **A:** Median value of dwelling sales (€, by municipality, per m^2).[1] **B:** Average usable floor area of dwellings (m^2, by municipality).[2] **HI:** Household Income (€, municipality).[3] **MP:** Mortgage Payments.[5]	**HAI:** Housing Access Index. **AHV:** Average Housing Value. **C:** Median rental value for dwellings (€, by municipality, per m^2).[4] **B:** Average usable floor area of dwellings (m^2, by municipality).[2] **HI:** Household Income (€, municipality).[3]

Notes

[1] '*Median value per m^2 of dwelling sales*', from Statistics Portugal.
[2] '*Average usable area (m^2) of conventional dwellings of usual residence*', from Statistics Portugal.
[3] '*Median value of gross reported income per tax household*', from Statistics Portugal.
[4] '*Median house rental value per m^2 in new lease agreements of dwellings*', from Statistics Portugal.
[5] Mortgage (monthly payments, simulation):
- Mortgage of 90% of HAI;
- 30-year mortgage;
- Euribor 12 months;
- Spread 1.000%;
- Other compulsory costs (insurance, etc.).

Figure 4 – Housing Access Index.

As portrayed in Figure 4, the HAI calculation is subdivided into two formulas: homeownership and rental market. The HAI for buying a house is calculated in two stages: i) based on data collected from the INE, the average price of housing is calculated by multiplying the "median value of the square metre" and "average usable surface area of family dwellings"; ii) the mortgages are calculated based on bank simulations (considering the conditions mentioned in Figure 5), and the HAI value is obtained after weighting with net family income. In its turn, the HAI for renting is also based on multiplying the "median value of the square metre" (for renting) by "the average surface area of family dwellings", followed by weighting with net family income, from which the HAI is obtained. These calculations are always carried out and repeated for a given territory at a given time.

Figure 5 – NUTS II, Portugal.

For this research, the HAI were calculated for house purchases for NUTS II (Nomenclature of Territorial Units for Statistics II, in Portugal) and the Autonomous Regions of Azores and Madeira between 2016 and 2022 (Figure 5). Regarding renting, the calculation was made for the same statistical units, but between 2017 and 2022. This means that the analysis carried out in this paper is essentially national, but the observation is subdivided on a regional scale. It should be noted that a new statistical division came into effect in January 2024, reorganizing the distribution of Portuguese NUTS II and III, which this work already considers.[4]

3.1. Access to housing: housing purchasing

According to Table 1, between 2016 and 2022, the square metre price rose sharply in all the NUTS II, with the same scenario occurring in the Autonomous Regions. Table 1 also provides an insight into the different rhythms, trends and spatialities of housing appreciation.

[4] These changes mainly concern the NUT II Lisbon Metropolitan Area (LMA), which was annulled and subdivided into NUT II Grande Lisboa and NUT II Península de Setúbal. This work already respects the new statistical organisation. Still, the LMA figures are maintained to better understand the national/regional evolution.

	2016		2017		2018		2019		2020		2021		2022		Variation Rate (%) (2016 - 2022)	
	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH
Norte	692	29	731	31	795	31	869	33	977	37	1 065	37	1 169	38	69	31
Centro	575	24	600	25	652	25	679	25	784	29	815	28	861	28	50	17
Oeste e Vale do Tejo	600	24	627	25	665	25	702	25	815	29	865	29	923	29	54	21
AML [previous]	1 125	31	1 210	34	1 283	34	1 355	35	1 535	40	1 668	41	1 885	44	68	42
Grande Lisboa	1 139	32	1 250	35	1 451	39	1 698	44	1 875	48	1 998	49	2 241	51	97	59
Península de Setúbal	784	24	838	25	928	27	1 038	29	1 184	33	1 350	35	1 513	37	93	54
Alentejo	586	23	581	22	639	23	651	23	685	24	717	23	746	23	27	0
Algarve	1 222	48	1 296	49	1 424	52	1 562	56	1 721	61	1 836	61	2 095	66	71	38
R. A. Açores	611	25	645	26	677	26	737	28	807	29	867	30	939	31	54	24
R. A. Madeira	974	36	1033	38	1 143	40	1 197	41	1 258	42	1 310	41	1 481	43	52	19

In 2016, the NUTS II that topped the list for square metre prices for house purchases were Algarve (1,222€/m2), Grande Lisboa (1,139€/m2), Autonomous Region of Madeira (974€/m2) and Península de Setúbal (784€/m2). However, this changed by 2022, with Grande Lisboa (2,241€/m2), Algarve (2,095€/m2), Península de Setúbal (1,513€/m2) and Autonomous Region of Madeira (1,481€/m2) taking the lead.

Regarding the results of the HAI for house purchases, it can be seen in Table 1 that between 2016 and 2022, the highest HAI values were found in the NUTS II Algarve, Autonomous Region of Madeira, Grande Lisboa, and Norte. However, there have been some changes in their position over the years. In this analysis, the Algarve region has the highest HAI (i.e., house prices and net incomes have the most significant gap). Table 1 also shows that Grande Lisboa and Península de Setúbal were the statistical units with the most important variation in the square metre price, with HAI values over 90%.

3.2. Access to housing: rental market

The HAI for renting tends to be higher than the HAI for buying, indicating more difficulty accessing the rental market. In most of the NUTS II, the price of the square metre is on a steady upward trend, apart from the Alentejo and Autonomous Region of the Azores, both of which showed a slight decrease in 2021 compared to 2020, and the Autonomous Region of Madeira, where there was a drop from 2019 to 2020 (Table 2).
In 2022, the NUTS II with higher square metre prices were Grande Lisboa (9.97€/m2), Peninsula de Setúbal(7.50€/m2), Algarve (7.05€/m2) and Autonomous Region of Madeira (6.81€/m2). However, the rate of change shows a different pattern, as the top are Península de Setúbal (60%), Grande Lisboa (53%), Norte and Algarve (41%).

Table 2 – Evolution of the square metre price and HAI, when renting a house, in the NUTS II regions, Portugal, between 2017 and 2022. Source: Statists Portugal and own elaboration.

	2017		2018		2019		2020		2021		2022		Variation Rate (%) (2017 - 2022)	
	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH	m²	IAH
Norte	3.83	53	3.96	52	4.36	55	4.72	59	5.00	60	5.41	62	41	17
Centro	3.25	44	3.35	44	3.56	45	3.76	47	4.07	48	4.28	48	32	9
Oeste e Vale do Tejo	3.31	44	3.42	43	3.65	45	3.89	47	4.20	49	4.48	49	35	13
AML [antiga]	6.06	56	6.50	58	7.54	65	8.42	73	8.68	73	9.29	75	53	32
Grande Lisboa	6.53	61	7.02	62	7.68	68	8.58	74	9.35	79	9.97	79	53	31
Península de Setúbal	4.68	47	4.94	48	5.87	54	6.22	58	6.84	62	7.50	64	60	37
Alentejo	3.45	44	3.52	43	3.56	42	3.83	45	3.82	43	3.95	42	15	-3
Algarve	5.00	56	5.27	64	5.93	70	6.54	79	6.74	78	7.05	77	41	38
R. A. Açores	3.48	47	3.57	46	3.85	48	3.97	49	3.95	47	4.37	49	26	5
R. A.Madeira	5.15	63	5.32	63	6.00	68	5.98	67	6.15	66	6.81	69	32	11

In the case of renting, the HAI shows more significant regional heterogeneity, particularly in the variation rate (2017-2022), where the Algarve is the NUTS II that suffers the most significant increase (38%), while in NUT II Alentejo the HAI decreases by 3 percentage points. Thus, although there are different rates, all the statistical regions, except for Alentejo, show a generalised upward trend in the HAI.

4. Access to housing: exploratory lessons

4.1. Contemporary trends

Over the last decade, access to housing in Portugal has been progressively limited, both for buying and renting. The HAI values observed make it practically impossible for average-income households to purchase or lease a house. The analysis carried out in the previous chapter refers to NUTS II. At the same time, when analysed on a municipal scale, the situation is much more complex, with territories experiencing very high housing prices that are out of line with national average incomes.

As mentioned, the evolution of regional patterns is highly heterogeneous. However, the rise in the square metre price is a generalised reality throughout the country for buying and renting. Regarding purchasing a home, in 2022, some statistical regions showed high HAI values, namely the Algarve (HAU 66), followed by Grande Lisboa (HAI 51), the Autonomous Region of Madeira (HAI 43), Norte (HAI 38) and Península de Setúbal (HAI 37).

Regarding renting, all the NUTS II and Autonomous Regions had an HAI above 40. The situation is dire in the NUTS II Grande Lisboa (HAI 79), Algarve (HAI 77), Autonomous Region of Madeira (HAI 69), Península de Setúbal (HAI 64) and Norte (HAI 62).

It should also be noted that this heterogeneity is caused by the considerably unequal housing price rises in the different territories, which may indicate socio-geographic mutations. This disparity in price rises reflects the regional complexities of the housing market. It suggests an evolving socio-geographic and demographic dynamic, with potential future impacts on the structure and distribution of the population.
The data suggests that renting requires more financial effort from families than buying (Figure 6). This situation highlights significant weaknesses in the housing needs of lower-income social

households, who generally opt for renting. This situation also negatively impacts the population's residential mobility, which is low in Portugal. Consequently, the difficulties in accessing housing are growing both in buying and renting.

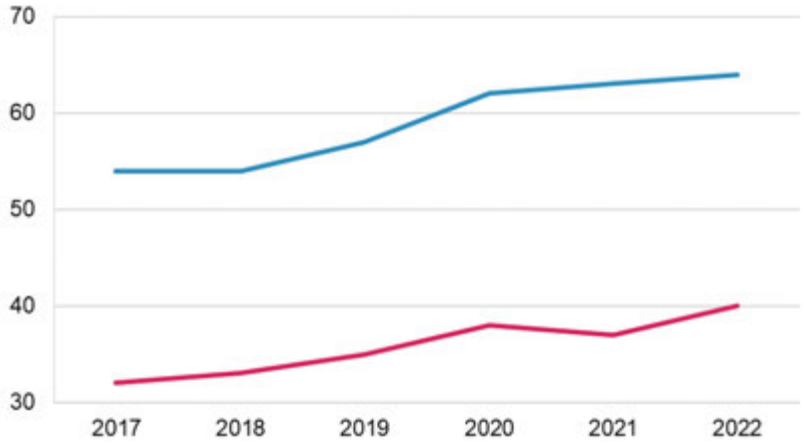

Figure 6 – Evolution of HAI between 2017 and 2022, NUTS II, Portugal. Red line purchasing market and blue line rental market.

In general, it is possible to identify that in Portugal, access to housing has been made difficult continuously since 2015, placing this topic on the academic, political and media agenda. Therefore, it is not surprising that housing is an established right (ie. the right to housing) in various international declarations and protocols, for example, in the Constitution of the Portuguese Republic (Antunes, 2021a). In this context, it should also be noted that vulnerable populations, such as people experiencing homelessness, immigrants, refugees and low-income households, face additional challenges in accessing mortgage loans, meaning they are compelled to turn to the rental market (formal and informal). In addition, these lower-income households, or migrant and historically stigmatised communities, often face discrimination in the rental market, increasing the problem of access to housing (Costa, 2023).

4.2. COVID-19 impacts and new challenges

As can be seen from the analysis above, the COVID-19 pandemic has not had a significant impact on the housing market. Although during 2020, there were several doubts about the real estate market's ability to continue its upward trend due to all the social and economic setbacks posed by the pandemic, the data confirms that the trend of house price growth has not been broken.

Although some stagnation or even small falls can be identified in 2020 and 2021, the Portuguese housing market has continued the trend it has been on since 2015, with the price of homes growing in both the purchase and rental markets.

More recently, Portugal and Europe faced new challenges that could impact the housing market, such as the inflationary crisis, the war in Ukraine, and the rise in interest rates decreed by the European Central Bank. Although the data present in this paper are not temporally comprehensive for rigorous analysis, it can be indicated that in Portugal, none of these new

challenges had an impact on the housing market in 2022 or 2023, according to the new existing statistical data. Nevertheless, quite recently, in 2023, some critical housing markets, such as France and Germany, recorded their first annual drops in several years, possibly because of inflation and high interest rates. The spread of this change to other markets cannot be ruled out in the future.

For all these reasons, Portugal's governments have initiated various housing policies and strategies in the last decade to relieve the problem of access to housing. Of particular note in 2018 was the “Nova Geração de Política de Habitação” (New Generation of Housing Policies), which had no significant impact on the housing market. Later, several extraordinary measures emerged in the context of COVID-19, as discussed in this paper.

More recently, new strategies have been presented. In 2023, the centre-left government introduced the "Mais Habitação" (More Housing) housing strategy, which included various efforts, such as rental support, mortgage support, restrictions on short-term rentals, coercive use of vacant private housing and rent control. After extensive political and public debate, these measures were implemented at the end of 2023. Already in 2024, the Portuguese government changed, and the new centre-right government presented its housing strategy, called "Construir Portugal" (Building Portugal). This housing strategy maintained previous policies that supported rents or mortgages but revoked less consensual ones, such as restrictions on short-term rentals and the coercive use of vacant private homes. The new policies are also more market-related, with various tax exemptions and support for private companies and housing cooperatives.

The debate that took place in 2023 and 2024 around housing policies is quite interesting, as it highlights the ideological differences in the Portuguese political spectrum when it comes to the problem of housing. In fact, in Portugal, the 'centre-left' and the 'centre-right' proposals are quite divergent, even in the most moderate parties. This situation is not unique to recent years, and the political divergence, the permanent abolition of previous policies and the dissolution of previous strategies is a long-standing problem in Portugal, which does not allow for the consolidation of stable and durable housing policies.

5. Final considerations

In the second half of the 2010s, house prices began an upward trend that can be identified in most European countries. It can be verified that since 2015, Portugal has been one of the European Union countries that recorded the most significant annual rises. This situation has led to greater difficulties in accessing housing, in a pattern that is widespread throughout Europe and, as has been recognised. On the European and national scene, there have been no significant trend breaks during COVID-19 (in 2020 and 2021), as might have been expected during the suspension of economic activity and lockdowns.

Looking particularly closely at Portugal, it is possible to understand that the NUTS II most under pressure are Algarve, Grande Lisboa, and Península de Setúbal. It could thus be indicated that there is a differentiated situation in the Algarve and Lisbon Metropolitan Area; these statistical regions are generally under more pressure than the others.

However, as indicated above, it should be emphasised that the observation restricted to NUTS II has some analytical limitations, as, for example, can be noted in NUTS II Norte, which covers very different realities from the "deep countryside" and the urban concentration of Porto

Metropolitan Area. Nevertheless, although Porto Metropolitan Area is not directly analysed in this study, as it is a NUTS III and not a NUT II, its situation on access to housing is not as severe as in the NUTS II Algarve and Lisbon Metropolitan Area (Grande Lisboa and Península de Setúbal). However, as expected, the figures for the Porto Metropolitan Area (as NUTS III) are very different from the NUT II Norte. These and other limitations of this study can only be overcome in a more comprehensive and disaggregated analysis, which, using a multi-scalar approach, can carry out spatial-temporal analyses of NUTS II, NUTS III, municipalities, and parishes following the development of this project.

The trends have impacted the Portuguese housing market in the last decade and highlighted housing as a financial asset. Access to housing has a direct impact on people's quality of life and well-being. During the last decade, the right to housing, the right to the city, and spatial justice were not priorities in public policy discussions. As these trends evolve, they threaten to exacerbate urban inequalities and metropolitan fragmentation. Eventually, this could worsen socio-spatial segregation and create "exclusive zones" for the wealthiest citizens and "excluded zones" for the poorest, producing further social and urban tensions.

Considering the above, Portugal today faces a clear problem of access to housing, which is generalised throughout the country and more significant in large urban areas, particularly under pressure. Regarding access to housing, real estate appreciation has not been accompanied by increases in household income in the same proportion and pace, thus conditioning access to housing year after year in a situation that no longer only affects the lower-income households but the middle class in general.

Track 12: Futuring

FUTURING - Planning as a game changer: utopias and dystopias vs missions, models, scenarios, pathways, actions and politics of change

Chairs:

- Tijana Dabovic, University of Belgrade
- Dimitri Toubanos, Ecole d'Architecture de Paris-Val-de-Seine
- Abdallah Jreij, Politecnico di Milano

Keywords: *future, time, space, spatio-temporal, baseline, timeline, modelling, scenarios, forecasts, pathways, transitions, alternatives, politics, action, change, collaboration, urgency, uncertainty, level of certainty*

Behold all of you, shamans, prophets, Nostradamus -, Jules Verne - and Kubrick- wannabees, charlatans with YouTube channels - Here come planners to change the game of storytelling the future - the most powerful stories made to change the minds and wrongdoings on all life on Earth!

Come planners - show us how to wake up corrupted politicians, hypnotised consumers, hungry money makers, crazy innovators, angry activists and the ones we left behind! Tell us all and invite us to your well-organised, knowledge-based rewilding regional designs, urban labs, digital twins, energetic communities, nature-based solutions, place-making tools and degrowth platforms!

In the age of increasing collective vulnerabilities and responsibilities, this track explores planners' knowledge, skills and values in imagining and navigating societies towards a desirable future 10, 20, 50 or 100 years from now.

Which scenarios of sustainable development would you see coming to life? Discuss different approaches and purposes of making spatial scenarios -descriptive, normative, predictive or exploratory: do you develop Three Horizons or the Cascade Model Strategy? All those who make their stories by modelling STEEP (social, technological, environmental, economic and political) trends and their spatial impacts are invited to come and unpack their black boxes.

We invite you to reveal your forecasting technique, future-proofing, and backcasting knowledge. Please discuss with us the skills and values behind the well-organised, knowledge-based rewilding regional designs, urban labs, digital twins, high-tech or IA-driven metropolises, energetic communities, circular economy action plans, low-tech and bioclimatic resolutions, resource-saving proposals, nature-based solutions, place-making tools and degrowth platforms! The future at stake needs both game-changing storytelling and actions.

As such, how does your proposal construct a new narrative for a desirable future?

Does it pursue philosophical, ethical and political approaches, such as the Conservation ethic of Gifford Pinchot, the Utilitarianism of Jeremy Bentham and John Stuart Mill, the Preservation ethic of John Muir or John Ruskin, or the Deep Ecology of Arne Naess?

Is it linked to an economic perspective, pursuing Goergescu-Roegen's thesis on "entropy" (1971), conducting to "decrease" approaches, or does it follow Robert Solow's or John Hartwick's « weak sustainability » thesis?

On top of the new narrative, how does your proposal translate to concrete actions? Is it a new form of utopia or a feasible scenario?

If such, what innovations or technical renewal are necessary to make it happen? Finally, what constraints and controversies do your game-changing scenarios face, either political, economic, social or technical?

The track welcomes abstracts addressing, but not limited to, the following sometimes overlapping themes:

- future as a domain of freedom and domain of power;
- utopian/dystopian narratives, missions and their purpose - sustainability, climate action, climate justice;
- technical forecasts and projections, their purpose and methods;
- tools for making collaborative and innovative scenarios and pathways;
- sustainable spatiotemporal transitions - concepts, methods and politics;
- cross-scalar futuring - from global to local futures and back and forth;
- practice of co-construction of practical alternatives

Individualized Perspective on Spatial Restructuring of E-commerce Villages: A Case Study of Village Q in Shaanxi Province, China

Liangkai Deng , De Wang*
College of Architecture and Urban Planning, Tongji University, 1239 Siping Road, Shanghai 200092, China

Abstract: The introduction of e-commerce in rural areas is profoundly reshaping the modes of production and lifestyle in these regions, altering the developmental trajectories of villagers, and promoting the restructuring of rural spaces. This study uses Q Village in Shaanxi Province, China,as a case study, employing semi-structured interviews, activity log surveys, and sales data analysis to explore the spatial restructuring of the rural e-commerce landscape from an individual perspective. The findings reveal: (1) E-commerce provides unique developmental pathways for rural individuals, enabling them to transcend traditional kinship and geographic constraints and establish a nationwide economic network, thereby enhancing their economic income; (2) E-commerce expands the sales reach of rural individuals, shifting the traditional geographically-based economic patterns towards regionalization; (3) E-commerce transforms the traditional organization of production spaces in rural areas, moving from a village-centered to a layout centered around fields, residences, and towns; (4) Under the influence of e-commerce, the living time of rural individuals is compressed by production demands, increasing temporal pressures on individuals. These results offer insights for developing and constructing rural spaces influenced by e-commerce.

Keywords: E-commerce Villages; Spatial Restructuring ; Individualization ;Rural Revitalization

1. Introduction

The development of rural e-commerce is a crucial pathway for achieving rural revitalization. According to the "China Rural E-commerce Development Report (2021-2022)" released by the China International Electronic Commerce Center, online retail sales in rural China reached 2.05 trillion yuan in 2021, accounting for 15.66% of the national online retail sales, representing a 129.2% increase compared to 2016. The advancement of online e-commerce has brought significant opportunities to rural development and has profoundly impacted the spatial structure of rural areas.

Related studies indicate that e-commerce platforms based on "de-geographical centralization" algorithms have broken the traditional geographical constraints on spatial flow(Krivý,2018,p.15), enabling rural areas to integrate into a broader regional cooperation system. Simultaneously, e-commerce has altered the internal operational mechanisms of rural areas, with interactions between virtual and real spaces driving the restructuring of rural spatial patterns. From a regional perspective, under the influence of e-commerce technology, rural elements have shifted from a unidirectional flow to a multidirectional flow between urban and rural areas and regions(Zhang, et al.,2014,p.6), giving rise to new industrial division chains and spatial organization models(Chen&Luo,2020,p.69), thus restructuring the economic geographical space of rural areas. From the internal system of rural areas, the introduction of e-commerce has spurred the rise of numerous rural industries, leading to a

* Corresponding author.E-mail addresses: dewang@tongji.edu.cn

diversification and de-agriculturalization trend in rural employment(Zhang, et al.,2022,p.207). The village space is transitioning from agricultural spaces to commercial spaces, and multifunctional spatial units incorporating production processing, design and development, and innovation are emerging(Zhou,2016,p.69), though residents' living spaces are also being compressed(Zhang, et al.,2019,p.954). Government support, industrial foundation, and elite-driven factors are key to the formation of e-commerce villages, further triggering a series of changes such as the "urbanization" of rural land structures, "commercialization" of spatial functions, "de-agriculturalization" of industrial development, and "non-localization" of social relations(Yang,2021,p.3076).

"Individualization" is a concept proposed by Ulrich Beck(2001)that reflects the trend of social change, referring to the process by which social members exert subjective initiative to detach from traditional institutions and ties. E-commerce provides a new pathway for the individualization process in rural areas, allowing rural individuals to quickly build new identities within the village using the convenience brought by e-commerce platforms, "detaching" from traditional urban-rural relations and rural social relations based mainly on kinship and locality, and "re-embedding" into new types of urban-rural relations and rural social relations centered on e-commerce platforms. Under the logic of algorithms and platforms, labor relations have shifted from traditional employment relationships to "platform-individual" relationships(Wu&Li,2019,p.137), and individuals' daily lifestyles and their perceptions of surrounding spaces are increasingly reliant on the internet(Longhurst,2016,p.135; Nafus&Sherman,2014,p.1793). Additionally, under the influence of the internet, rural individuals are part of larger spatial-scale groups and networks, enabling them to grasp new knowledge and ideas and apply them to rural development（Yang,2021,p.3085）, promoting economic development, the status of female subjects, and the reconstruction of social relations in rural areas(Xin,et al.,2022,p.1306).

Overall, current research on the reconstruction of rural areas by e-commerce often focuses on macro and meso-level changes in economic forms, power relations, and spatial distribution, with fewer studies focusing on the micro-level individualization processes that highlight the spatial reconstruction induced by e-commerce. Most research subjects are concentrated on industrial e-commerce villages, with results on land use, spatial function transformation, and development mechanisms being less applicable to rural areas primarily engaged in agricultural e-commerce. In terms of research data, most case studies are based on semi-structured interviews, lacking more refined research data to discern the impact of e-commerce on spatial changes in rural areas. Based on this, this paper, from the perspective of individualization, takes the e-commerce behavior of individuals in Q Village, Shaanxi Province, China, as the object of analysis to explore how rural individuals actively learn and utilize e-commerce technology in the process of engaging in e-commerce, promoting rural economic development, and reshaping rural production and lifestyles, thereby revealing from a micro perspective the mechanisms and spatial effects of individual behavior driving rural construction.

2 Research content and data collection

2.1 Research content and methods

This article selects Q Village in Shaanxi as the research subject and Mr. Y as the core case study, adopting an individualization theory perspective to explore the development trajectories of rural individuals, the organization of rural individual living time, and the reconfiguration of rural individual production space under the influence of e-commerce. The specific research contents are divided into the

following four parts: First, through a narrative analysis of rural individuals, it examines the motivation, trajectory, and effectiveness of their e-commerce entrepreneurship and discusses the impact of e-commerce on the changes in individual development paths. Second, it investigates the characteristics of regional economic linkages and division of labor collaboration of rural individuals under the influence of e-commerce, focusing on the sales scope of their agricultural products and collaborative network relationships. Third, it analyzes the differential characteristics of rural individual production space organizations under the varied outcomes of e-commerce dissemination. Lastly, it examines the changes in the allocation of residents' daily living time due to the influence of e-commerce.

2.2 Research Data

This study primarily employs methods such as participatory observation, semi-structured interviews, and activity log surveys to conduct semi-structured interviews with six villagers in Q Village regarding the changes in agricultural production and life in the village under the drive of e-commerce. It also collects data on the personal development history of the villagers, daily activity logs during the busy farming period (recording the type of activity every 15 minutes), GPS trajectory data, and daily mobile app usage data(Table 1). This approach aims to explore the impact of e-commerce on rural spaces from both qualitative and quantitative perspectives, focusing on individualization.

Table 1 Basic information of the 6 interviewees.

ID	Identity	Gender	Age	Online Sales Proportion（%）
1	Mr.Y	Male	56	100
2	E-commerce Intermediary	Male	60	100
3	Partial Online Sales Villagers	Female	69	80
4	Partial Online Sales Villagers	Female	75	50
5	Offline Sales Villagers	Female	71	0
6	Offline Sales Villagers	Male	76	0

3 Individualization Perspectives on E-commerce Rural Spatial Reconstruction

3.1 Changes in the Pathways of Rural Individualized Development Under the Influence of E-commerce

Before the introduction of e-commerce in Village Q, sales prices could only sustain the villagers' daily living needs. Around 2013, a group of villagers who had been working outside the village, along with some recent university graduates, brought e-commerce skills back to the rural area. They combined these skills with the local cultivation of kiwifruit, initiating entrepreneurial ventures. Mr. Y, a representative of those from Village Q who returned from working outside to start businesses, utilized the internet knowledge and skills he acquired while working away from home. By integrating e-commerce sales with the village's specialty agricultural products, he became the pioneer of e-commerce entrepreneurship in Village Q and a leader in driving local prosperity. Mr. Y said:

"Traditional agriculture was insufficient to support the economic needs of his family, prompting him to migrate to Dongguan, Guangdong, in 1998 to seek higher income and provide financial stability for his household. However, by around 2012, facing a downturn in the furniture manufacturing sector he was involved in, geographical separation from his spouse, and the upcoming high school education

of his child necessitating parental guidance, he returned to his village in 2013. Leveraging his urban living experiences, the internet skills he acquired, and the kiwifruit cultivated on his family farm, Mr. Y utilized e-commerce platforms like Taobao and WeChat to market his products to former city coworkers and their families, achieving impressive sales figures. "

Traditionally, the physical marketplace yielded around 3-5 yuan per jin (half a kilogram) for kiwifruit, whereas online sales enabled pricing between 6-10 yuan per jin, effectively doubling the unit sale price. With the burgeoning demand online outpacing supply, Mr. Y expanded beyond selling his own produce; he began purchasing kiwifruit from fellow villagers at above-market rates to assist in their sales efforts. This e-commerce venture not only delivered higher profitability for the sale of kiwifruit but also substantially increased the happiness and satisfaction within the community households. Mr. Y expressed :

"since he commenced the online sale of kiwifruit, the demand was so strong that his own harvest was insufficient, prompting him to also sell produce from neighboring villagers. This initiative significantly elevated his family's economic status—from an annual income of 50,000-60,000 yuan over a decade ago to a current annual household income of around 150,000 yuan. The revenue generated enabled him to expand his agricultural operations, purchase urban property for his children, and support their matrimonial needs. "

3.2 Restructuring of Rural Individual Regional Economic Spatial Connections under the Influence of E-commerce

3.2.1 E-commerce has restructured the spatial linkage between individual villagers and the regional economy, expanding the coverage area of product sales.

The utilization of e-commerce has enabled Mr. Y's production to form an extensive flow of online transaction information and offline product transportation. The real-time communication between online sales personnel and customers continues to shape a robust stream of information regarding product quality, price, after-sales service, etc., alongside considerable cash flow. The information flow and product flow together constitute the advantages of the commodity transaction model and have significantly facilitated the establishment of long-distance spatial networks. For ease of analysis, the spatial distribution pattern of product sales is illustrated (Figure 1) based on the 695 sales orders Mr. Y processed from September 2022 to November 2023. Using the natural break method, the ranks are divided into five levels to intuitively reflect the strength of connection between Mr.Y. as an individual and different cities. Looking at the individual network sales space, compared to traditional physical sales, the economic linkage of individual villagers has significantly increased, covering 107 prefecture-level cities nationwide. In contrast to the traditional sales scope of direct sales to a single province, the Internet has expanded the sales reach of agricultural products. Mr. Y stated:

"Before the advent of the internet, kiwifruits were sold directly to merchants. Once the merchants took the fruits, they would transport them directly to fruit markets in Zhejiang and Jiangxi to sell to distributors, who would then sell to retailers, and finally, the fruits would reach the consumers. The sales scope that I could access was just within the village. After the internet came into play, my family's kiwifruits have been sold all over the country."

Figure 1 The number of delivery orders to each destination from Mr.Y.

3.2.2 Expansion of the Division of Labor and Collaboration System from Local to Regional Under the Influence of E-commerce

Individual villagers selling agricultural products online have reshaped their relationships with regional division of labor and collaboration systems. Under the influence of the Internet, a new business model has emerged, strengthening the connections and division of labor between urban and rural areas. The traditional individual sales model of agricultural products mainly involved merchants purchasing directly at the doorstep or selling to local markets and nearby towns, with the individual's sales radius and scope being quite limited. However, with the rise of e-commerce, villagers can now sell their agricultural products to any place within the country. To seize this business opportunity, many villagers have begun to experiment with online sales. The key to online sales lies in expanding sales channels, which requires the division of labor and cooperation between urban and rural areas. In this new model, households, predominantly residing in rural areas, mainly take responsibility for growing, packaging, and shipping agricultural products, while other family members and their friends gradually assume the role of online sales agents, selling through their own social circles, thus forming a regional network division of labor pattern (Figure 2). Mr. Y remarked:

"Initially, my online sales primarily targeted acquaintances in Dongguan, Guangdong, whom I knew through work. Subsequently, as relatives and friends from other regions tasted and appreciated the quality of our fruits, they began promoting them on their respective digital social platforms, leading to the formation of a stable cooperative network for distribution. Presently, my distributors are situated in cities like Shanghai, Suzhou, Harbin, and Baoji, where they facilitate the annual sale of several tens to hundreds of boxes of kiwifruits. Following the expansion of sales channels, my son and daughter-in-law also participate in marketing our fruits through their online social networks, returning home to assist with production during peak agricultural seasons."

Figure 2 Individual Regional Division of Labor and Collaboration Network

3.3 Diversification of Local Production Spatial Organization under the Influence of E-commerce

The increase in economic income further influences changes in production organization. In the cultivation of kiwifruit, e-commerce has not changed the villagers' traditional paths for purchasing agricultural inputs. Due to high-quality requirements for kiwifruit, villagers generally rely on traditional rural kinship and geographical social relationships to purchase pollen and fertilizers. Mr. Y said:

"There are also pollen and fertilizers available online at lower prices, but we dare not buy them because we don't know about the quality. We use a large amount, which relates to the selling price of kiwifruit; we must ensure quality and quantity. Also, there is no guarantee of after-sales service online,

so we generally buy from acquaintances in the village or town. The quality is good, and there is after-sales service. Generally, acquaintances charge us only after the kiwifruit is sold, so we do not need to pay in advance. "

In the sales aspect, the dissemination method in the village mirrors the general technology spread, where Mr. Y's success quickly catalyzed the learning and replication among neighboring villagers. This spread, leveraging social networks, follows kinship, geographical, and professional ties, eventually forming a wave-like spatial diffusion(Wang,2023,p.130). However, due to technical, social capital, and market access barriers in online kiwifruit sales, the sales models have diversified into fully online sales, partially online sales, and traditional offline sales at the household level. Specifically, villagers engaged in fully online sales market their agricultural products exclusively through the internet; those in partially online sales use their own and their distant relatives' or friends' social media platforms to sell some of their produce, with the majority still sold physically; and those in entirely physical sales directly market their goods to local or distant merchants. Compared to the traditional village-centered production space organization, the advent of e-commerce has led to noticeable differences in the organization of production spaces around fields, packaging points, purchase locations for distant merchants, and local merchants' buying spots due to the variation in sales models (Figure 3). Specifics are as follows:

In the realm of urban and rural planning and geography, the translation of the sales models in the context of e-commerce influence on agricultural practices is as follows:

Villagers engaged in fully online sales: Around the key nodes of online sales, a local support spatial system of "fields—residential areas—courier points" has formed. Due to the large volume of online sales, the primary method of dispatch is courier services for door-to-door pickup.

Villagers engaged in partially online sales: A hybrid virtual and physical collaborative space system of "fields—residential areas—village—town" is established. As the volume of online sales is relatively small, the main dispatch method for these villagers involves transporting goods to logistic points at the town or village level, while physical sales predominantly occur through direct pickups by merchants at the village.

Villagers engaged in traditional physical sales in the digital age: Different support spaces have formed, such as "fields—residential areas—village purchase points (for distant merchants)" and "fields—residential areas—town purchase points (for local merchants)." The primary method of dispatch in these models involves direct pickups by merchants at the designated purchasing locations.

Figure 3 Local Spatial Organization of Different Sales Models

3.4 Compression of Living Time under the Influence of E-Commerce

Under the influence of e-commerce, individual villagers in agricultural product e-commerce villages have experienced a significant change in the rhythm of their daily living time. Compared to traditional agricultural product sales models, online sales not only enhance economic income but also impose more time pressures on their lives.

A comparison of daily living time and mobile phone usage between villagers who sell online and those who do not reveals that during the busy farming season, villagers engaged in kiwifruit sales (both online and offline) work an average of 17.19 hours per day, with only 0.63 hours allotted for leisure. In contrast, villagers operating under traditional sales models work a total of 7.65 hours, with 5.13 hours dedicated to leisure (Figure 4). Evidently, the development of e-commerce businesses significantly compresses villagers' personal living time. Under traditional models, they need only complete basic production processes like picking and sorting before selling the fruit to middlemen. However, in the e-commerce era, villagers not only have to complete these traditional processes but also invest considerable time and energy in online order handling, video shooting, and other promotional activities. These additional e-commerce operational tasks substantially occupy the time originally intended for rest and personal life. Furthermore, the time rhythm of e-commerce sales is much tighter. During peak sales seasons, villagers need to constantly monitor online orders and prepare shipments promptly to meet the demands of distant consumers. This real-time sales model forces them to adjust their daily routines, enhance work efficiency, and ensure immediate responsiveness. Additionally, e-commerce platforms' requirements for product presentation increase the workload for villagers. They are required not only to take high-quality product photos but also to edit promotional videos. Tasks traditionally performed by professional teams have now become essential skills for individual villagers, posing significant challenges to their time and energy. Mr. Y said:

"Before the advent of the internet, peaches were sold directly in the fields, with trucks arriving during the day to collect and transport them by night. Evenings were spent chatting at the doorstep or watching television at home before resting. However, with the shift to e-commerce, there is a constant need to process orders and dispatch goods throughout the day and night, as purchase times vary and volumes can be high. This requires continuous loading of goods in the evening to ensure delivery within 48 hours. Thus, the introduction of the internet has extended working hours, with busy nights followed by some time on the mobile phone before sleep. Sometimes, when there's nothing to eat at home, purchases are made online. Mr. Y is primarily responsible for handling orders and shipping during downtime, and also takes videos while working. After busy evenings, he spends his leisure time editing short videos for promotional purposes. "

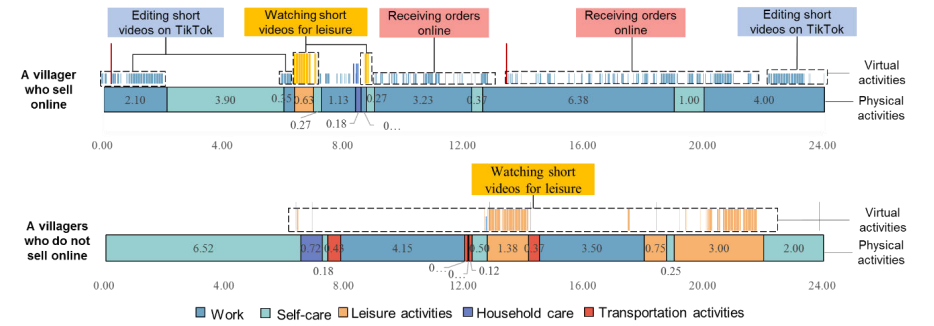

Figure 4 Comparison of daily time utilization between villagers who sell online and those who do not.

4 Conclusions and Research Prospects

4.1 Discussion and Conclusions

4.1.1 E-commerce Empowering Individualized Development Pathways from Urban to Rural Areas

The introduction of e-commerce has provided rural individuals with new economic development pathways, enabling them to transcend traditional geographical limitations and proactively integrate into broader socio-economic networks. This restructures the spatial connections between rural areas and regional economies, thereby accessing more developmental resources and opportunities. This process of identity "re-embedding" through individual agency promotes the transformation of rural social structures and brings new dynamism to rural economic development. It also encourages many villagers who have worked in cities to return to rural areas, using their acquired knowledge to further promote rural development. To fully leverage the potential of rural individuals in the e-commerce sector, it is advisable to encourage the cultivation of distinctive rural e-commerce brands that align with local resource endowments and industrial strengths. Through policy support and the establishment of e-commerce demonstration bases, rural individuals can be guided to focus on local specialty products to meet the personalized needs of urban and rural consumers, continuously enhancing their competitiveness in the e-commerce market.

4.1.2 E-commerce Inducing the Reshaping of Rural Spatial Relationships

The introduction of e-commerce has driven the restructuring of the economic space in rural areas. Through e-commerce platforms, rural individuals, previously limited by geographical constraints, can now overcome traditional spatial distances and establish cross-regional distribution networks that cover both urban and rural areas. This enables them to break away from the insular and singular local economic patterns, expanding connections with external markets and significantly enhancing their economic development space. Additionally, the advent of e-commerce profoundly affects the organization of local production and sales spaces in rural areas(Luo&He,2017,p.36). Research has observed that the demand-driven nature of e-commerce prompts farmers to consciously adjust traditional planting structures and

production methods, such as adopting standardized agricultural practices to meet the demands of the e-commerce market. In terms of sales space organization, towns not only continue to provide traditional services like fertilizer sales but have also added new functions such as selling packaging boxes and offering courier services, thereby strengthening the connection between towns and villages.

4.1.3 E-commerce Empowerment: Contradictions and Balance in Rural Production and Living

The introduction of e-commerce has not only increased the economic income of rural areas but has also significantly compressed the villagers' leisure time. Under the online sales model, villagers are required to invest substantial time in handling orders, packaging, shipping, and other e-commerce operational tasks, which drastically reduces their personal leisure time. This adds more time pressure to the already busy rural life, potentially jeopardizing the physical and mental health of the villagers. This contradiction between economic development and quality of life reflects the dual nature of rural development empowered by e-commerce. On the one hand, e-commerce opens new channels for rural economic development, providing villagers with unprecedented opportunities for wealth accumulation. On the other hand, excessive involvement in e-commerce operations can lead to an imbalance between work and life, compressing leisure time and affecting the experience of well-being. Finding a balance between the economic benefits brought by e-commerce and the quality of life is an issue that needs careful consideration in future rural revitalization practices.

4.2 Research Prospects in Urban and Rural Planning and Geography

E-commerce is emerging as a pivotal force in the socio-economic spatial reconfiguration of rural landscapes. It not only avails rural inhabitants of unprecedented developmental prospects but also crucially redefines the organizational morphology of indigenous production systems. This trajectory of spatial reconfiguration heralds e-commerce as an instrumental catalyst in the resurgence of rural areas. To date, this investigation has concentrated on the influence of e-commerce on rural restructuring from a micro-perspective. Prospective studies in urban and rural planning and geography might extend the scope to embrace a broader array of subjects and enhance the sample magnitude to encompass a more diverse spectrum of agrarian household profiles. This approach would more comprehensively encapsulate the intricacies of rural spatial reconfiguration facilitated by the advent of e-commerce.

Abstract
With China's rapid economic development and continued urbanisation, the contradiction between urban expansion and land resource use has become increasingly prominent. The study site is located in the gully area of the Loess Plateau, where soil erosion is a prominent problem. The acceleration of urbanisation further complicates the spatial contradiction between production, life and ecology. In the context of ecological civilisation construction, it is crucial to study the spatial evolution of production-life-ecology in the county. The study indicates that the production space in Huangling County is fragmented, the living space is inefficient and the ecological space is fragile. Consequently, a comprehensive management strategy to protect the production space, optimise the living space and regulate the ecological space is proposed.

Production-Living-Ecological space; Spatio-temporal evolution; Collaborative governance; PLUS model

Full text

0 Introduction

The rapid development of China's urbanisation is often more concerned with the economic benefits that can be gained, often neglecting the improvement of the comprehensive benefits of land resources(Liu and Sun 2020). The Loess Plateau, as a typical soil and water loss region, not only faces long-term ecological pressure for urban development, but also the complex topographic environment severely restricts the rapid advancement of urbanisation. In 2019, the Ministry of Natural Resources explicitly proposed that territorial spatial planning should be aimed at building intensive and highly efficient production space, livable and moderate living space, and unspoiled and beautiful ecological space. With the gradual entry into the transition of urban development in China, the optimisation of the “production-living-ecological” space coordination in the loess plateau region at the development stage has gradually received hot attention from planning academics(Wang, Sun et al. 2020, Liu, Huang et al. 2023).

The collaborative governance of county “production-living-ecological” space is directly oriented towards solutions, and is an important aspect of the coordination and optimization of national spatial resources. Currently, studies on the collaborative governance of county “production-living-ecological” space often start from the two core aspects of classification system and optimal spatial layout, and have formed a diverse research system(Zou, Wang et al. 2018, Cui, Zhu et al. 2020, Gao, Yang et al. 2022). From the perspective of research content, although the current research generally attaches importance to the scientific proof of the coordination of the “production-living-ecological” space, most of the research focuses on the use of the established results to analyse the current situation, while the “production-living-ecological” space often takes a certain amount of time to unfold, so it is important to carry out collaborative governance on the basis of analysing the evolutionary patterns and future development trends of the “production-living-ecological” space in a long time series.

1 Data sources and research methodology

1.1 Overview of the study area

Huangling County has a total area of 2,292 square kilometre, and the geomorphological types within the regional scope are complex and diverse. The eastern loess plateau surface area is part of Luochuan tableland, which is the main area of agricultural activities in the county, and more than 70 percent of the production space is distributed here; the western mountainous area belongs to loess hills and soil and rocky mountainous areas, and more than 80 percent of the ecological space, which is dominated by forests, is concentrated here; and the river valley and

river channel area, which is mainly the valley of the Discouragement River and its terraces, is the living space It is the main distribution area of living space. In recent years, as the urbanisation process continues, more and more urban construction activities have begun to encroach on cultivated land and grassland in an uncontrolled manner, and under the influence of a series of policies such as "grain for green project" and "cultivated land requisition-compensation balance", structural imbalance has begun to appear in the internal development of the region.

1.2 Data sources

The land use data used in this paper come from the publicly released 30m-resolution land cover dataset by the team of Professors Yang Jie and Huang Xin of Wuhan University, which is based on 5,463 visually decoded samples and has an overall accuracy of more than 80%; for the spatial environment data, the population distribution, GDP, spatial interpolation of mean annual temperature, spatial interpolation of mean annual precipitation, and distribution of soil types are from the Resource and Environment Science and Data Centre (https://www.resdc.cn/); road data and watershed data are from the National Geographic Information Resources Catalogue Service System (http://www.webmap.cn/); and DEM data are from the Geospatial Data Cloud (http://www.gscloud.cn/).

1.3 Research methodology

1.3.1 Classification of “production-living-ecological” space

The classification method based on land use type is more suitable for analysing the spatial and temporal evolution of “production-living-ecological” space, and the study area is divided with reference to the classification system of the dominant function method, combined with the actual situation of territorial spaces in Huangling County (Liu, Liu et al. 2017, Jiao, Yang et al. 2021)(Table 1).

Table 1. Land use classification system of “production-living-ecological” space.

Spatial categorisation	Dominant function	Land use type
Production space	Agricultural production activities	Cultivated land
Living space	Urban and rural living activities	Construction land
Ecological space	Regulation and maintenance of regional ecological security	Woodland,Shrubland, Grassland, Water area

1.3.2 PLUS model

The PLUS model can effectively simulate the complex evolution of multiple land classes. Based on various types of acquired data on land use drivers in Huangling County, the Land Expansion Analysis Strategy (LEAS) and the CA model based on multiple types of stochastic patch seeds (CARS) are used to simulate the land use types of Huangling County in 2025 and 2030, and the combination of land use data of each year can show the “production-living-ecological” space of Huangling County in its entirety history and future changes.

1.3.3 Land use transfer matrix

The land use transfer matrix describes the quantitative structure and spatial distribution characteristics of regional land use type changes. According to the relationship between the changes in land use data of Huangling County from 1995-2030, a number of two-dimensional matrices are obtained, and by analysing the obtained transfer matrices, the transformation

between different land categories is obtained, which can be used to analyse the land categories that have changed in different years, as well as the location and area of change.

1.3.4 Spatial conflict model

The spatial conflict model is often used to quantitatively characterise the state of conflicts between land uses, and according to the quantitative analysis of three dimensions of the spatial complexity index, spatial vulnerability index and spatial stability index of the six periods of land use data in the study period in Huangling County, the spatial conflict intensity index is obtained through comprehensive calculation, which can be used to assess the degree of coordination of the “production-living-ecological” space. The lower the spatial conflict intensity, the higher the degree of coordination.

2 Characteristics of spatial evolution in Huangling County

2.1 Spatial aggregate characteristics of staged evolution

The results of the evolution of the total amount of “production-living-ecological" space in Huangling County show that the production space is decreasing, the living space continues to grow, and the ecological space is relatively stable in the time period of the study. The study is divided into three phases based on the increase and decrease of each type of space (Figure 1).

The first phase was from 1995-2005, during which the changes in the “production-living-ecological" space were relatively stable, with production space and living space continuing to grow and ecological space continuing to decrease. The ecological space decreased by 4.37 square kilometre while the production space increased by 2.33 square kilometre, and both the decrease in ecological space and the increase in production space were the largest in the study period, which shows that the urban development of Huangling County in this period was mainly based on agricultural production, and the additional cultivated land caused a large amount of damage to the ecological space.

The second stage is from 2005-2010, in which the “production-living-ecological" space changes drastically, the production space decreases and the ecological space starts to increase, while the living space increases further. During the study period, the total amount of production space decreased for the first time by 10.03 percent and the total amount of ecological space increased by 1.22 percent, which indicates that along with the rapid advancement of urbanisation, the urban development of Huangling County has adjusted its dominant production mode and paid more attention to the protection of the ecological environment.
The third stage is from 2010-2020, in which the evolution of the “production-living-ecological" space has intensified, and the changes in production space and living space have gradually increased, while the ecological space has maintained its growth. After 2010, the average annual decrease in production space reached 2.43 percent, and the average annual increase in living space reached 45.82 percent, both of which were the largest in the study period. At this time, the total difference between the "production-living-ecological" spaces in Huangling County becomes more and more obvious.

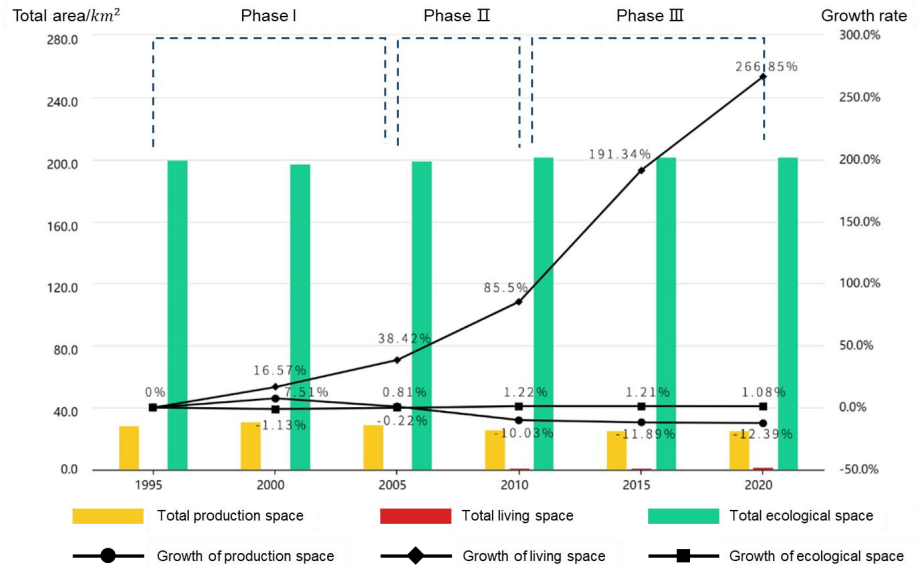

Fig.1. Evolution of spatial aggregates from 1995 to 2020.

2.2 Characteristics of spatial transformations dominated by production space

According to the five-period land use transfer matrix of the “production-living-ecological" space in Huangling County during the study period, the Sankey diagram of spatial transfer was drawn, from which it was found that the production space played an important role in the process of mutual transformation of the “production-living-ecological" space, and that the interchange between production space and ecological space, as well as the conversion of the production space to the living space, were the main spatial interaction modes (Figure 2).

From 1995-2010, the total amount of production space transferred to ecological space remained at a relatively large stage, with a cumulative transfer of 129.18 square kilometre during the study period; unlike this, the transfer of ecological space to production space experienced a process of growth, then decrease and then growth of the total amount of transfer, with a cumulative transfer of 60.28 square kilometre, which suggests that the early stage of urban development focuses on ecological environment maintenance, while the importance of cultivated land is gradually increased as urban problems gradually come to the forefront. From 2000-2015, the transfer of production space to living space in Huangling County increased period by period, reaching the peak in 2015, and then the transfer dropped, which shows that the construction speed of urban development is gradually slowing down, and the production space has been protected to a certain extent.

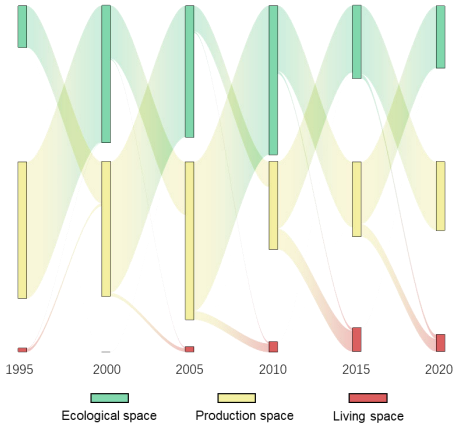

Fig.2. Evolution of the spatial transition from 1995 to 2020.

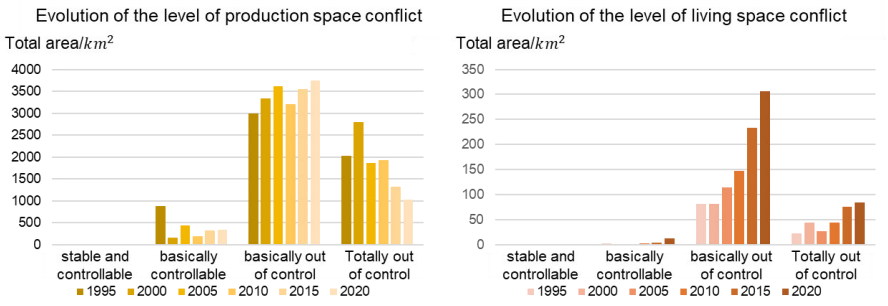
2.3 Spatial conflict characteristics of asynchronous change

Based on six periods of land use data in Huangling County, the conflict index of the “production-living-ecological" space is calculated, and the change process of the degree of coordination of the “production-living-ecological" space in a long period of time is analysed. It is found that the degree of coordination of the “production-living-ecological" spaces is inconsistent, with the production space and living space in a long-term uncontrolled state, and the ecological space in a long-term controllable state (Figure 3).

During the study period, the production space has the lowest degree of coordination, 60.61 percent of which is in a long-term basically uncontrollable state and does not change, and 32.51 percent of which is in a completely uncontrollable state but has been alleviated year by year since 2000; the degree of coordination of living space is also poor, with the long-term basically uncontrollable and completely uncontrollable spaces occupying 75.02 percent and 23.11 percent respectively and deteriorating year by year during the study period; the degree of coordination of ecological space is relatively good, with 76.37 percent of the space in a long-term basically controllable state and remaining relatively stable, but 23.62 percent of the space in a long-term out-of-control state cannot be ignored.



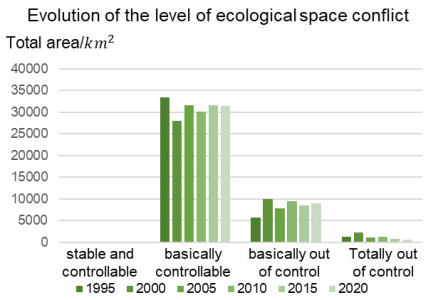


Fig.3. Evolution of "production-living-ecological" spatial conflict from 1995 to 2020.

3 Summary of spatial evolution mechanisms and Issues in Huangling County

3.1 Mechanisms of spatial evolution

3.1.1 Progressive development period (1995-2000)

The period from 1995-2000 was the period of progressive development of the “production-living-ecological" space in Huangling County. Although urban development had already begun in this period, the low level of development and the complex topography of loess gullies limited the agglomeration capacity of the city, and therefore, the integration of production space and living space, which was mainly based on traditional farming, remained the mainstream in this period.

With the rapid growth of population in Huangling County, on the one hand, a large number of labourers carried out residential construction in the areas around the towns, and faced with the disorderly construction, the county government strictly regulated the living space in that period, which made the living space decrease and revert to the production space; on the other hand, the income of the new labour force mainly comes from agricultural production activities, so land reclamation is more frequent in this period, and the production space expands while the ecological space decreases. As the total amount of high-quality cultivated land in the Loess Plateau region itself is limited, the selection of new cultivated land is very difficult, with part of the new cultivated land choosing to encroach on ecological space around towns and cities and subsequently being forced to fallow, and the other part of the cultivated land being concentrated in loess gullies, resulting in the complication of the overall pattern of production and ecological space, and a decline in spatial coherence.

3.1.2 Period of fluctuation (2000-2010)

The period from 2000-2010 was a period of fluctuating development of the “production-living-ecological" space in Huangling County, during which industrial production, mainly coal mining and processing, gradually became the main driving force for urban development, and a large number of surplus agricultural labourers began to move to non-agricultural industries, with urban construction activities becoming more and more active.

Around 2000, the first round of grain for green project was launched in Huangling County, and the land with poor farming conditions was gradually transferred to ecological space, which increased the ecological space and improved the overall coordination between production space

and ecological space, but along with the gradual widening of the gap between urban and rural areas, the excess rural population began to concentrate in the urban areas, the negative impacts of rapidly advancing urban construction activities on the coordination of production and ecological space have gradually become obvious. On the one hand, the loss of population in rural areas has led to the abandonment of cultivated land, and on the other hand, with its favourable geographic environment, the valley area has become the focus of land development, and a large amount of high-quality arable land has been occupied, additional cultivated land is often cultivated on the sidewall of loess gully, loess tableland surface, and loess gully by villagers as a unit. As a result, a large number of fragmented ecological and production spaces appeared, leading to another reduction in spatial coordination. Supplementary cultivated land in this period was far less than the reduction of activities such as urban construction as well as abandonment of land, so the total amount of production space declined.

3.1.3 Green transformation period (2010-2020)

The period from 2010-2020 is the period of greening transformation of the “production-living-ecological" space in Huangling County, during which the problems of environmental pollution and food security in the process of urbanisation have gradually come to the fore, and with the proposal of new urbanisation in 2012, the importance of the production and ecological space has been significantly increased, and the traditional development mode, which is mainly based on industrial production, has begun to change.

In the process of rapid urbanisation, the expansion of living space has increased the encroachment on production space and ecological space. On the one hand, the more complex spatial patterns have led to a continuous decline in the coordination of living space; on the other hand, although the supplementary cultivated land is still unable to make up for the loss of cultivated land, the county government has begun to pay attention to the protection of the quality of new cultivated land, and inefficient cultivated land, such as sloping cultivated land, has gradually been replaced by ecological space under the policy of grain for green project. In contrast, the coherence of ecological space in this period declined to a certain extent, mainly due to the fact that the grain for green project that lasted for more than ten years had seriously changed the local vegetation structure, and the single species of forest land and the loss of a large amount of shrubland and grassland had caused the development of ecological space to be stagnant.

3.2 Summary of space issues based on development projections

Through the analysis of the evolution characteristics and evolution mechanism of the “production-living-ecological" space in Huangling County, it can be found that its development is the result of the long-term accumulation of natural, social and economic factors under the leadership of policy factors, so the prediction and analysis of the development evolution of the “production-living-ecological" space is one of the necessary steps in the collaborative governance of the “production-living-ecological" space.

In order to verify the reliability of the simulation results of the PLUS model, firstly, the land use data of Huangling County in 2017 and 2020 were used to give the relevant driving force data and parameters to obtain the simulation results of land use in 2023, and compared with the status quo situation in 2023, and the Kappa coefficient was greater than 0.7, which indicated that the model had a high degree of credibility. Therefore, further using the current land use data in 2023 to simulate the land use results in 2025 and 2030 under the natural development

scenario, the study found that the problems in the long-term evolution of the “production-living-ecological" space in Huangling County from 1995-2030 are mainly concentrated in the following three aspects.

3.2.1Evolution of production space fragmentation

In the long-term development of production space in Huangling County, since the Loess Plateau region itself has less high-quality arable land, a large amount of supplementary arable land is concentrated in loess gullies, loess gully slopes, and loess plateau borders, etc. It is found that in the future, Huangling County will still maintain an average annual reduction of production space of 1.73%, and the production space in loess gulleys and loess plateau borders will further increase. However, on the one hand, the shortage of agricultural labour cannot be effectively improved in the short term, and the long-term cultivation of new cultivated land cannot be guaranteed; on the other hand, the complex topographic conditions of loess gullies and the soil and water environment of loess plateau borders, which are prone to erosion, will continue to affect the farmers' motivation to cultivate, so that these long-term unavoidable production problems will seriously affect the spatial stability of the development of the space. Combined with the time-space distribution of spatial conflicts and the comparison of satellite maps, the spatial coordination between loess gullies and loess plateau areas has not been effectively alleviated, and the new cultivated land has continued to appear in a complex spatial pattern under the requirement of the annual target of the total amount of cultivated land, and has been intermittently abandoned under the long-term negative impacts of the natural environment and other factors, so that the production space in these areas will continue to evolve in the direction of fragmentation in the future(Figure 4).

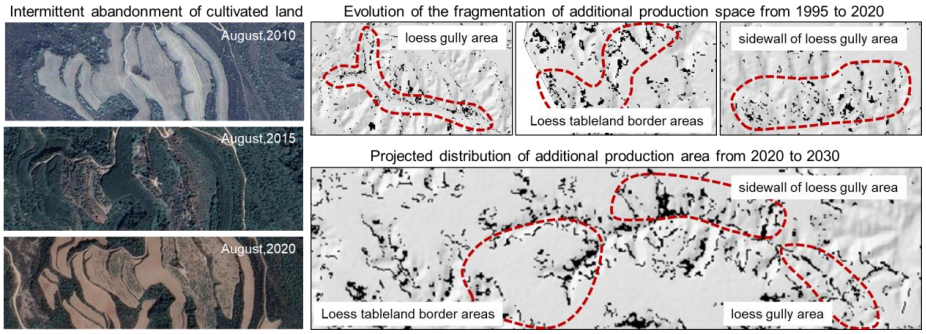

Fig.4. Evolution of production space fragmentation.

3.2.2 Non-stable expansion of living space

In the process of construction of living space in Huangling County, the rapidly developing urban economy and urban construction activities are closely related. Valley area has become the first choice for urban development by virtue of its flat terrain and dense river distribution, because the limited construction space in valley area cannot be reasonably matched with the rapid increase in the construction demand, so the living space along the valley area spreads continuously to form a long and narrow belt-shaped space form, and even part of the living space is connected with the ditch bank of the valley, which not only leads to the disorderly distribution of the living space but also seriously affects the overall stability. In the future urban development, the living space in the valley area will further increase, the expanding narrow space not only makes the urban spatial layout inefficient, at the same time, linear elements such

as rivers, high voltage lines and railway lines seriously damage the integrity of the urban form, coupled with the construction of land to change the catchment environment of the valley, the valley ditch bank suffers from more serious rainwater erosion, thus affecting the safety of the living space itself. Therefore, the living space in these areas is destabilised for future development(Figure 5).

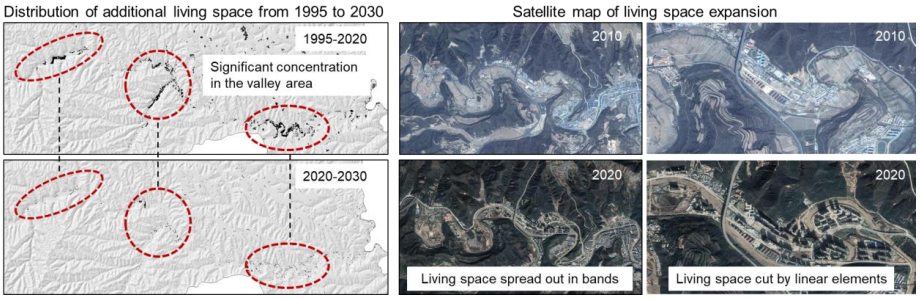

Fig.5. Non-stable expansion of living space.

3.2.3 Binary polarisation of ecological space
