the control session the government only discussed their goals, and then led the PT company and start-up present their options. Then, the government presented their vision on being a 15-minute city with a strong PT backbone, which meant that that they would go for densification and an upgrade of the train station. Since these options were quite long-term, they were looking for more complementary short-term innovations by the PT company and start-up. The government was open about their budget and asked whether the companies also had money to invest into the plan. The companies did not reply directly but stated that they had some budget but extra investment from the government was necessary. The start-up presented its innovations as short-term solutions, and the PT company presented itself as a reliable partner that could provide door-to-door services in a flexible PT system. The government selected on-demand transport from the PT company as an option that links with densification, and the mobility hubs from the start-up as an option that could function as a switch between the rural areas and inner-city area. In the second negotiation round started, the government still wanted to strengthen the existing PT network, so they selected bus lanes as an option for the plan. The shared scooters option from the start-up was also selected, but only when the scooters were replaced by e-bikes in the mobility hubs. The start-up pushed for its own innovation (autonomous vehicles) though because this option had higher profit estimates. The PT company presented their real-time data dashboard as an innovation option that fitted with the demand-responsive transport option. The bus lanes were also added by the government because that was not expensive. After the calculations by the assessment agency, it became clear that the sustainability goal would not be reached by 2040. Therefore, the government asked for other options so that the goal could be reached. The options presented by the start-up (autonomous shuttles and drones) were rejected by the government because of institutional problems and lack of willingness by politicians, but the electric buses from the PT company were added to the final plan because this option gave a reliable decline of emissions.

In the intervention session, the government had a similar 15-minute vision for the city, based on the densification and train station upgrade. The government was open for options as presented by the companies and mentioned that the transport market was free to join for all without additional investments by the government. Then, the PT company and the start-up started to present their options to the government and emphasized the synergy effects of combining some of their options with other innovations. For example, the mobility on demand option was selected because it had a synergy effect with mobility hubs. And the mobility hubs were firstly selected by the government because it would fit with their vision of the 15-minute city. All players were open about their budgets. Both the PT company and start-up were pre-selecting options that they thought would be most cost-effective and fitting with the sustainability goals of the government. After some calculations made by the government, they thought there would be room for extra investments to achieve their sustainability goals. Therefore, they added shared scooters, digital twins, data analysis and parking tariffs based on the expectation that the overall designed system would have such synergy effects. These synergy benefits would outplay the initial investment costs. After the calculations by the assessment agency, it became clear to the players that more action was necessary but that no investment budget was available anymore. Therefore, a deal was made by the government to add the data dashboard along with the electric buses from the PT company, and the autonomous shuttle along with the bus lanes from the start-up. It was agreed upon that the potential extra benefits because of the expected synergies would be used to cover the extra investment costs of the innovations.

To sum up, the chosen mobility plan in the intervention contained more investments and innovations than the plan in the control session. Although in both sessions all money was spent,

the players in the intervention session agreed upon more positive estimates of costs and benefits than in the control session. Also, they used money from potential future benefits as investment money in the present. Both in the control and intention session, players looked for a balance between land-use measures and mobility measures, as well as combining long-term measures with short-term measures.

4.2.2 Effect of intervention on mindset and synergy

In the control session, players were quite hesitant to share their budget to other players. Only halfway the game, budgets were openly shared. There was quite some uncertainty and competition in the control session between the PT company and the start-up. For example, when presenting their mobility-on-demand system, the PT company said the following about the options presented by the start-up:

"We want to be reliable. I like the scooters [by the start-up], but they can also break easily. With our buses you know that things will not break. Our service is more about the first and last mile, integrated into the PT network."

The competitive language seemed to be a direct consequence of the condition on synergy that was given to the players, namely that there would be a 10 percent bonus for the individual options when combined with other options from their own portfolio. The uncertainty that was there about the options and budgets of both companies was also strategically used by the government was a way to push the companies to make sharper offers, or to challenge a company to think along with the governments' vision. The government acted here as selector and mediator of innovations, by choosing for innovations that fitted with their vision of the 15-minute city. In general, the start-up was struggling in the control session to be a partner because of the condition on mindset that described that the PT company and government did not have any prior experience with the start-up. The effect of this condition can be illustrated by the following discussion on how to distribute the investment costs of the mobility hubs:

Start-up: "If you could provide more investment in the hub as a government, we have more money available to look into something complementary to the hub, for example the digital twin"

Government: "But when we have a more qual investment in the hub, that would make you also committed to deliver these services. Otherwise there could be a tendency that you say, the hub is nice, but we do other things now."

On several moments in the control session, the government did not choose to collaborate with the start-up because 'local politicians did not like it' or because of politicians 'not willing to take a lot of risk' (as described by the conditions on mindset). In the final stage of the game, the start-up did try to sell the autonomous vehicles and drones, but this was rejected because the government expected that it would take too much time and that the innovations were too new. Here, the uncertainty of innovations influencing the short-run made the government choose for the more reliable option of the PT company.

In the intervention session, however, there was almost no competition at all between the three different players. The PT company thought along with the government by pre-selecting options that would fit their goal of sustainability, not out of self-interest. Also, the PT company and the start-up were actively looking for synergies between the different options, so that it would have the largest emission effect for the government. At first, the start-up framed the estimations for its innovation in a positive way, by referring to a maximum effect at a minimum cost. Because

the PT company was honest about the ranges of effects of innovations, the start-up chose to be open about the ranges as well, 'because we have a good-relationship with the government' as described in the intervention conditions on mindset.

Just as in the control session, the government functioned as selector and mediator in the negotiation process of innovations. But, in contrast to the control session, the players were from the beginning open to each other about their innovations, budget and were collaborative in terms of discussing how each innovation would fit with another innovation. This resulted in the end in agreeing upon a deal where potential future profits of the start-up (then: scale-up) and PT company would be used to fill the gap of initial investments in the now. This deal could be made because the government 'trusted on the good experience and expertise of the start-up'.

4.2.3 Strategies to deal with uncertainty

In comparing the control session and intervention session, we can see similar and different patterns of how players dealt with uncertainty. These patterns are displayed in Table 3.

Table 3: Observed strategies to deal with different types of uncertainties in sessions

Strategies in Control Session	Strategies in Intervention Session	For type of uncertainty
Start with a vision that links specific elements together		System and governance
Be open with other players to ask what options they have in their portfolio		Governance
Finding win-win combinations that provide synergy		System
Being closed on what to spent	Being open on what to spent	Governance
Comparing and framing with innovations of competitor	Collaborate and present options together to the government	Governance
Use optimistic scenario of innovation estimates		System
Use the average scenario of innovation estimates		System
Assuring equal investment shares as government for compliance	Willingness to fund innovations that benefit the government	Governance
Saving budget as government as robustness measure	Spending all budget to achieve the sustainable goals	Governance
Choosing based on what is familiar, institutionalized and you have experience with	Choosing based on trust and positive earlier experience	Governance
Choosing the reliable option	Choosing the option with greatest potential effect	System

We found in both sessions that the government had the lead with stating a vision, and asking the companies what they could offer for the sustainable mobility plan. Also, we found that in both sessions the government was looking for synergies, either based on their developed vision (control session) or the synergy cues on the play cards (intervention session). After the initial phase, however, we see different patterns that can be traced back to the different intervention conditions in both sessions. Where in the control session companies were more competitive, players in the intervention session actively worked together as a team. In the control session the government made explicit choices not to collaborate with the start-up based on conditions that describe bad earlier experiences and risk-averse politicians. In the intervention session, the

choice was made by the government to just experiment and trust the start-up to develop its innovations further with co-funded investments.

A final game element to compare the control and intervention session by is the reaction to the stress-testing scenarios as presented by the independent assessment agency. It was striking that in both sessions the government chose to have a 15-minute vision as a basis. It was therefore also concluded by players that this scenario would be no problem in the future. Also for the other two scenarios, players were positive about the robustness of their initial plan and did not make any changes other than adding innovations so that the sustainability goals would be reached. For example, in the intervention session it was mentioned that in the second scenario of higher individualized mobility, there would be more taxes that could be spent on enhancing the public transport system, and that individualized transport such as shared scooters could be scaled up so that demand would be met. The discussion around the measures of responding to different scenarios remained pragmatic, also because of limited time.

5. Discussion

Developing a serious game requires to create a balance between meaning, reality and playfulness for players (Harteveld et al., 2009). In general, participants found the game quite realistic in terms of collaboration dynamics between different actors, and the uncertainties of innovations that were interwoven in the game. Also, participants appreciated the calculations by the assessment agency and treated its outcome as meaningful based on the expectation that a 'true' model lied behind these calculations. The city map and the play-cards were appreciated by the participants as an engaging way to negotiate about the mobility plan. However, participants did mention that in real life different stakeholders would not talk and negotiate as open as was done in the game. In practice, governments are bounded by concessions and laws that forbids them speaking to companies in an informal way as it could lead to an uneven level playing field in terms of knowledge and information. Also, the element of political uncertainty and media dynamics was mentioned as a relevant in real-life decision-making processes that was missing in the game.

The measurement of how large the effect is on decision-making behaviour due to interventions on mindset and synergy is dependent on specific conditions such as the background and experience of players or the facilitator. However, we can still compare the control and intervention session, by viewing the serious game sessions as a form of case study research in a controlled experimental setting. We indeed found patterns that interventions on mindset and synergy lead to more collaborative strategies to deal with uncertainty by actors, as hypothesized in literature in the field of psychology (Baas et al., 2011; Grant & Berry, 2011) and public-private partnerships (Roumboutsos & Pantelias, 2014). These patterns are not occurring uniformly though. Both in the control and intervention session, players displayed the willingness to look for win-win situations and synergies. However, in the control session, inhibiting conditions made players negotiate also in a competitive way with a focus on reducing uncertainty from an individual perspective, whereas this behaviour was almost absent in the intervention session. Players in the control session were willing to negotiate together when it fitted their vision or strategy, and when this was not the case a player used the inhibiting conditions as an (opportunist) argument not to collaborate. In psychological terms, it seems that the inhibiting conditions in the control session led participants to go into a prevention focus (Higgins, 1998), while participants in both the control and intervention session also made choices based on a promotion focus. This promotion focus might be caused by a positive attitude of participants towards adaptivity and finding the best solution in the game. In the post-game survey and de-brief of the control session, participants mentioned that they acted

collaboratively and consensus-finding, while this is only half the story when looking at actual decision-making behaviour in the game. This re-call bias suggests that participants are indeed willing to look for synergies and collaboration (promotion-focus), but not at the moments when this does not fit with their own agenda or strategy (prevention-focus). In other words, they were not willing to tackle the uncertainties together in a co-development style. This had also an effect on the outcome of the game. Where in the control session all investments were neatly covered and distributed over the game, players in the intervention agreed on a plan that was more open and flexible in terms financial coverage.

A critical reviewer of this study could pose that we merely instructed players to behave differently, instead of observing different individual choices due to the intervention conditions we put them in. There are some reflections to make about this point. Firstly, we observed that players acted naturally in the game, and we saw that different frames and role descriptions were not used ad-hoc but in line with players' overall decision-making behaviour. Secondly, participants told in the de-brief that they were not aware of the interventions during the game, which makes it less probable that they merely acted by blunt following the instructions. Finally, the overall aim of the game was to put players into different settings, so that a difference could be measured between these settings. So even when players did pick up on the different instructions and acted accordingly, it would not make the outcomes of this study less valuable because it proves that specific behavioural conditions affect indeed the overall decision-making process and corresponding negotiation outcome.

It is of course the question how these results can be translated to actual decision-making practices, beyond the controlled experimental setting of a serious game. Future research could look into the application of interventions in real and ongoing cases using game-theory (Bekius et al., 2021), combined with psychological theory on mindset (Dweck, 2006). Together, such interventions could form strong behavioural triggers to inhibit responses to uncertainty based on reduce and control, and stimulate response based on collaborate and experiment (Akse et al., Forthcoming).

Another more theoretical direction for future research could investigate finding clearer relationships between stable personal attitudes, local conditions, and the display of promotion and prevention focus while dealing with uncertainty. Also, future research could look into different types of conditions and cues that might help or hinder stakeholders in making robust and adaptive plans. For example, under which conditions does the upfront mentioning of a stress-test stimulate stakeholders to make a more adaptive plan, and when triggers it stakeholders to make a more conservative plan? Further development of experimental settings could be a way forward here.

The serious game sessions were played by practitioners with a background in Dutch mobility planning, which is highly focused on consensus-finding compared to other institutional contexts (Koppenjan & de Jong, 2018). Playing the game with practitioners working in different institutional settings might provide insight in how uncertainty and interventions affect decision-making practices in for example more competitive transport markets. Such participants might have different experiences and attitudes towards uncertainty, which could alter the effectiveness of an intervention on mindset and synergy.

6. Conclusion

This game study was set up to assess the effect of interventions on multi-actor decision-making behaviour related to uncertainties. A game setting simulated the context of a government, public

transport company and a start-up negotiating about innovations to put in a sustainable mobility plan. In this setting, interventions on mindset and synergy were intended to change the behavioural conditions in which actors make decisions under uncertainty. This application of the serious game is novel, as most games on complexity and uncertainty have the aim of learning or decision-making support (Bekius et al., 2021; Leclercq et al., 2023).

We found that in both the control and intervention session, participants were willing to collaborate and look for win-win situations, but that in the control session participants were also applying control strategies for their own organization to reduce uncertainty, because of the inhibiting conditions on mindset and synergy. These responses to uncertainty made the overall negotiation process less collaborative, which led to a less flexible and open mobility plan than in the intervention session. More experimental sessions are necessary however to validate these findings.

The results of this study in a controlled setting can be used for building larger intervention and training programs in ongoing cases, to change actors' mindset, competencies, and adaptive capacity in dealing with uncertainty. Combing a psychological perspective with decision-making and governance approaches for uncertainty has proven to be a fruitful way to experiment with and test the effectiveness of interventions for collaborative approaches to deal with uncertainty.

Abstract
Coastal erosion is a critical issue in the Mediterranean Basin, heavily impacting vital coastal industries like tourism, agriculture, and fishing. Climate change compounds these problems, worsening floods and storms. To counteract the risk of erosion and flood, «hard» engineering-based approaches have been used, often prove ineffective and undesirable effects. Recognising the need for a shift, the international community advocates for Integrated Coastal Zone Management and Nature-based Solutions. Participatory actions involving local communities and stakeholders need to be provided to facilitate collaboration and consensus-building and to enhance peoples' perceptions. Through a case-study analysis in the Metropolitan City of Bari (Italy), this paper tries to understand if policy-makers and stakeholders acknowledge and consider the newly proposed methods for coastal risk management as a potential alternative or supplement.

1. Introduction

The Mediterranean Basin faces huge challenges, mainly due to high anthropogenic pressures and its climatic borderline balance (EEA, 2020). It is defined as one of the most critical erosion hotspots in Europe, heavily affecting the main economic industries along the coast (beach tourism, agriculture and fishing activities) (EEA, 2020). Moreover, climate change exacerbates the impacts of other phenomena such as floods and storms (UNEP/MAP and Plan Bleu, 2020). Traditionally, to deal with such complexity and to reduce the vulnerability of the Mediterranean coastal areas, "hard" engineering-based approaches have been used to counteract the risk of erosion and flood (e.g. through the construction of groins and breakwaters). However, such measures have led to ineffective and, most of the time, undesirable effects (Motta Zanin et al., 2023).

As a matter of fact, the necessity to change perspective to manage coastal risks has been recognized by the international debate and new solutions have been identified as alternative or complement solutions (e.g. Nature-based Solutions) (Motta Zanin et al., 2024). Moreover, a more comprehensive and systemic approach, compared to sectoral perspectives, has been designed, namely Integrated Coastal Zone Management (ICZM). A key aspect of the ICZM Protocol refers to the need to define necessary measures to ensure an appropriate involvement of the various stakeholders, in all the phases of formulation and implementation of coastal and strategies, plans and programmes or projects (Turner and Bower, 1999).

For the effectiveness of the ICZM process, participatory actions involving local communities and stakeholders as well as techniques and analysis tools providing information necessary for the follow-up of projects and for decision-making, need to be provided (Motta Zanin et al., 2023). This would allow an improvement of communications and consultation, facilitating collaboration and consensus-building, enhancing stakeholders' and local communities' perceptions of the adopted solutions and, thus, their knowledge and understanding (Slovic, 1987).

Within this frame, this work tries to answer the following key-question:

Are policy-makers and stakeholders acknowledging and considering the newly proposed methods for coastal risk management as potential alternatives or supplements?

To answer the key-question, we selected a case-study in the Mediterranean basin: the Italian Metropolitan City of Bari in Puglia Region (Southern Italy). As the only Metropolitan City in Southern Italy facing the Adriatic Sea, we identified it for two main reasons: (i) the governance system at the metropolitan scale as the most efficacious level for the implementation of solutions for coastal risk management; (ii) the complexity of the City due to its physical, environmental, socio-economic and institutional characteristics.

2. Methodology

To analyse the case-study, we developed a Participatory System Dynamics Model (PSDM), by following the methodology described by Valencia Cotera, Egerer and Máñez Costa (2022). It consists of five incremental work steps (Figure 1) and allows to outline a shared understanding of a problem, within a complex and dynamic system characterised by wicked problems and, most of the time, multiple conflicting interests.

Within this frame, this paper focuses on the preliminary results of the first research phase, based on the first four steps of the process:

01) stakeholder analysis, identifying actors, representing public and private bodies, with different kind of responsibilities (management, regulatory, economic, social and environmental);

02) semi-structured individual interviews, guided by the building of individual mental model maps, to understand each actor's perception of coastal risks. The mental model maps represent the "status-quo" of the coastal area of the Metropolitan City of Bari, in which the social and ecological components of the coast, the main activities and uses, the existing regulatory and planning system, and the existing risks and impacts are correlated (causal links);

03) desktop work, consisting in the analysis of each individual model and the building of the collective preliminary model outlining a general overview of the system by ranking the recurring variables and relationships;

04) building of the group model through a workshop where all actors discuss the variables and causal links of the coastal risks for the Metropolitan City of Bari emerged from the individual interviews.

3. Framing the case study

The Metropolitan City of Bari is the only one in Southern Italy facing the Adriatic Sea. The coastline is heavily urbanised through medium and large-sized urban settlements (six municipalities including the capital and coastal towns) separated by limited undeveloped areas (Figure 2). The undeveloped zones are sensitive both for landscape and environmental reasons, as they are subject to hydraulic and geomorphological hazards, and for settlement reasons, linked to the pressure of tourist, productive, and commercial interests.

From a hydro-geomorphological perspective, the territory's structure comprises rocky terraces, gradually descending parallel to the coastline. The surface hydrography consists of incisions and river-karst valleys, called "lame", developed in the predominantly limestone or calcarenite bedrock. Due to the permeability of the carbonate substrate, the "lame" have an episodic hydrological regime, with flood events occurring during significant rainfall. The catchment basins of the "lame" form a fan-shaped surface with its apex roughly corresponding to the settlement of Bari (Borri and Calace, 2017).

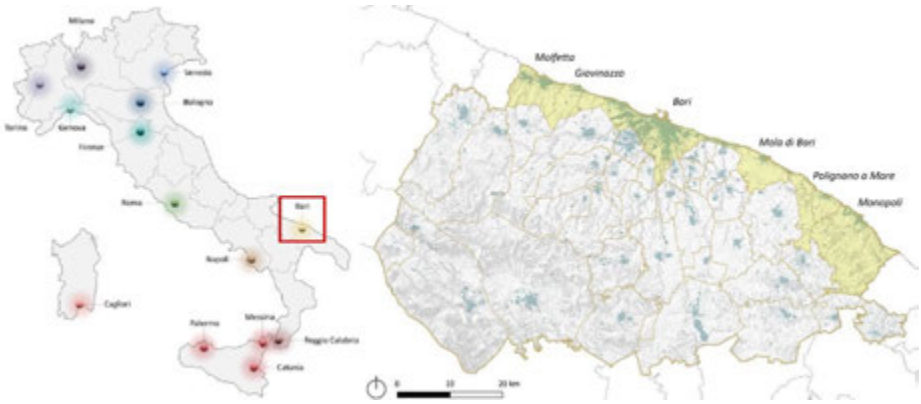

Figure 2 – Location of the case study (left); distribution of coastal municipalities in the Metropolitan City of Bari (right). Source: authors' elaboration

In addition to their hydraulic function, the "lame" today represent the main elements of naturalness along the metropolitan coast, as well as the ecological connectors between the sea and the hinterland. As described by the Territorial Landscape Plan of Puglia Region (2015), they host vegetational and faunistic habitats that have adapted well to changing environmental conditions. Along the Bari coast, there are few other natural areas, mostly located in peri-urban agricultural areas, while wetlands have disappeared.

Despite the high degree of artificialisation of the metropolitan coast, the seabed holds significant natural value, so much so that it is protected as Special Conservation Areas of the Natura 2000 Network. Indeed, the biocenosis of finely calibrated sands and the Poseidonia oceanica seagrass are of strategic importance for maintaining marine biodiversity (Regional Territorial Landscape Plan, 2015).

In general, the coastal morphology of Bari lacks articulations, except for those detailed ones due to localised erosive processes caused by karstification and marine action. The coast is predominantly characterised by low rocky formations (44.55%) with a rather homogeneous trend (Figure 3) (Regional Coastal Plan, 2012). Indeed, marine abrasion platforms gradually slope towards the sea and end with nearly vertical walls, typically not exceeding 1.5 meters in height. These surfaces have variable depths (about 10 meters) with widespread karst corrosion features such as caves, small basins, and coves. There are also stretches of high rocky coastline (23.42%) with cliffs of varying slopes, with elevations not exceeding 12 meters (Regional Coastal Plan, 2012).

The first settlements of the main centres aligned along the coast (Molfetta, Giovinazzo, Mola di Bari, Polignano a Mare, and Monopoli) with their related anthropic works (33%) were born in the coves of the rocky coast. There are also some stretches of sandy coastline (4.6%) or pebbly (0.97%), fed by weather and marine movements or by collapses of coastal banks: sandy beaches at the foot of the rocky coast within coves and small natural recesses or artificial beaches created through sand deposition; sandy stretches near the mouths of the "lame" (Regional Coastal Plan, 2012).

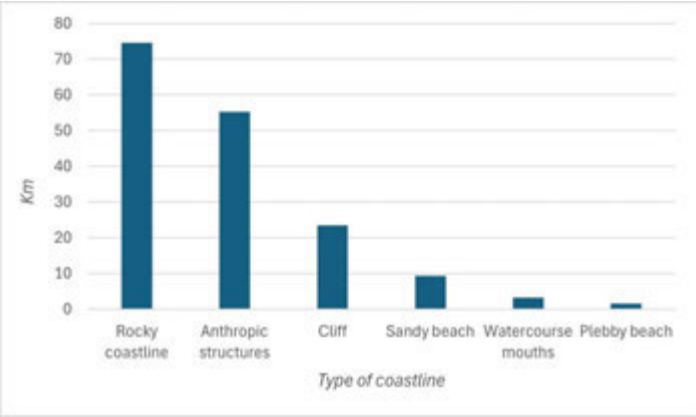

Figure 3 - Coastal morphology of the Metropolitan city of Bari. Source: authors' elaboration from data of Regional Coastal Plan, 2012

Considering the type of coastline, erosion of the sandy coast is only in a few stretches, mostly in the territory of Molfetta and Monopoli, while stretches of coast characterised by cliffs are at risk of landslides and collapses. Conversely, the orographic and geomorphological conditions of the territory produce significant hydraulic hazard phenomena that have repercussions on sediment deposition at the mouths of the "lame," as well as risks for existing urban developments (Mossa, 2010; Bisantino et al., 2016).

The Metropolitan City of Bari represents a unique settlement pattern resulting from a slow process of polycentric and articulated urbanisation, characterised by a strong "radial" dependence between smaller centres and the capital (Borri and Calace, 2017) and especially between inland centres and coastal municipalities of medium to large size (Figure 4).

Indeed, on the metropolitan coast, there are six medium to large-sized municipalities: Molfetta with 57,245 inhabitants, Giovinazzo with 19,232 inhabitants, Bari with its coastal areas with 316,212 inhabitants, Mola di Bari with 24,323 inhabitants, Polignano a Mare with 17,464 inhabitants, and Monopoli with 47,847 inhabitants (ISTAT, 2024). The urban load of these municipalities entails a dense network of water distribution with seven final outlets of wastewater directly into the sea. The strong settlement pressure has also been influenced by the dense network of road and rail infrastructure that characterises a clear separation between the coast and the hinterland.

Harbour infrastructures are another determining factor of anthropic impacts, as they generate large flows of goods and people. Indeed, on the metropolitan coast, there are 11 ports of various categories, which testify to old traditions related to fishing and trade, and new uses related to tourism, recreational boating, and water sports: one of international economic importance (Bari), one of national economic importance (Molfetta), eight of regional and interregional economic importance (Giovinazzo, the coastal areas of Bari, Mola di Bari, and Monopoli), and one tourist (Polignano a Mare) (Law No. 84/1994 "Regulating port organisation and activities"). Transformations of coastal areas for the construction of ports and docks often have not adequately assessed the induced effects on meteomarine equilibria, leading to significant alteration of sediment transport. In fact, the major harbour infrastructures (Molfetta to the north, Bari in the centre, Monopoli to the south) constitute the boundaries of the physiographic units[1] of the metropolitan coast.

[1] Physiographic Units are stretches of coastline where natural features or anthropogenic works do not allow the entry and/or exit of solid transport, due to wave motion and littoral currents.

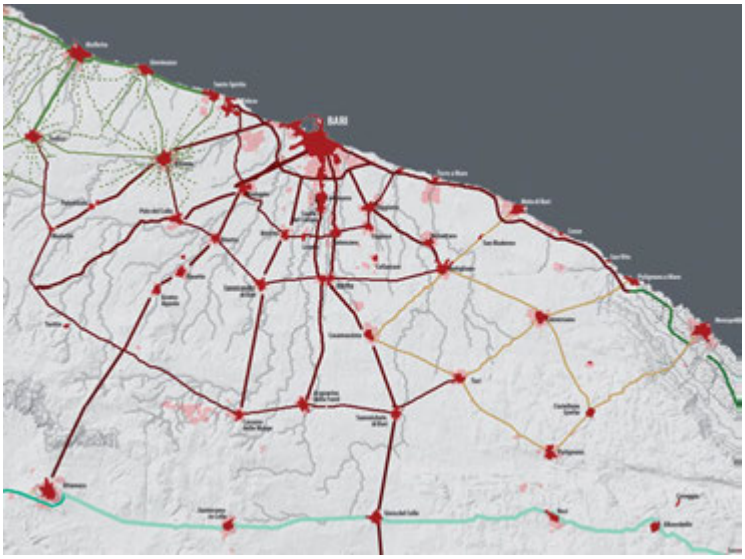

Figure 4 - Distribution of urban settlements of the Metropolitan City of Bari. Source: Territorial Landscape Plan of Puglia Region, extract from document 3.2.6

The stretches of coastline enclosed between urban centres have undergone significant transformations since the 1960s to promote local beach tourism, not only for residents but also for the population coming from inland centres. This has led to a strong privatisation of coastal zones through the construction of accommodation facilities, beach resorts, and seasonal holiday homes in agricultural areas and near the "lame", often in conflict with municipal urban planning instruments and hydrogeological structure plans. The dispersion of settlements along the coast has produced numerous impacts in terms of both use and accessibility and hydrogeological risk. In the last 10 years, tourist flows have grown considerably with visitors from both national and international territories (Potito and Quercia 2023), also thanks to the enhancement of historic centres and elements of the historical-cultural heritage scattered in peri-urban areas, and to the regeneration and creation of new public coastal spaces (public beaches, areas equipped for water sports, reuse of disused industrial buildings, etc.) (Calace et al. 2020).
Indeed, all coastal municipalities of the metropolitan city are implementing policies to enhance the coast while attempting to manage critical issues and impacts. From the analysis of policies and planning of municipal administrations, both common themes and objectives emerge, linked to environmental dynamics and the enhancement of urban identity related to fishing and trade, as well as specific aspects characterising individual territories: water pollution caused by sewage discharge and industrial waste disposal (Molfetta and Giovinazzo); saline contamination of agricultural soils (Giovinazzo and Monopoli); accessibility and use issues linked to high beach tourism pressure (Polignano a Mare and Monopoli); enhancement of areas that have resisted urban sprawl, rich in heritage stratifications and still linked to agricultural activities (Bari and Polignano a Mare); valorisation of different coastal urban identities (Bari) (Calace et al. 2020).

3.1 The governance system of the Metropolitan City of Bari

We have considered the case study of the Metropolitan City of Bari, because the governance system at the metropolitan scale could be the most efficacious level for the implementation of solutions for coastal risk management. The Metropolitan level of government, established in Italy with Law No. 56/2014, has competences for the governance of a vast area and for the promotion and coordination of socio-economic development. The statutory objectives of the metropolitan level can promote the implementation of integrated actions for the reduction of anthropogenic pressure on the coast, risk mitigation, and the enhancement and sustainable development of territories. So far, to date, the Bari system still struggles to practice true governance, understood as adaptive forms of multilevel and multi-actor collaboration in which actors, driven by divergent interests, interact to formulate and achieve common objectives (Torfing et al., 2012), in a 'trading zone' that allows for partial innovations attributable to strategies even in conflict with each other (Balducci, 2013). Instead, a highly planned yet fragmented system emerges, with multiple sectors and levels of governance that find it difficult to interact synergistically (Figure 5).

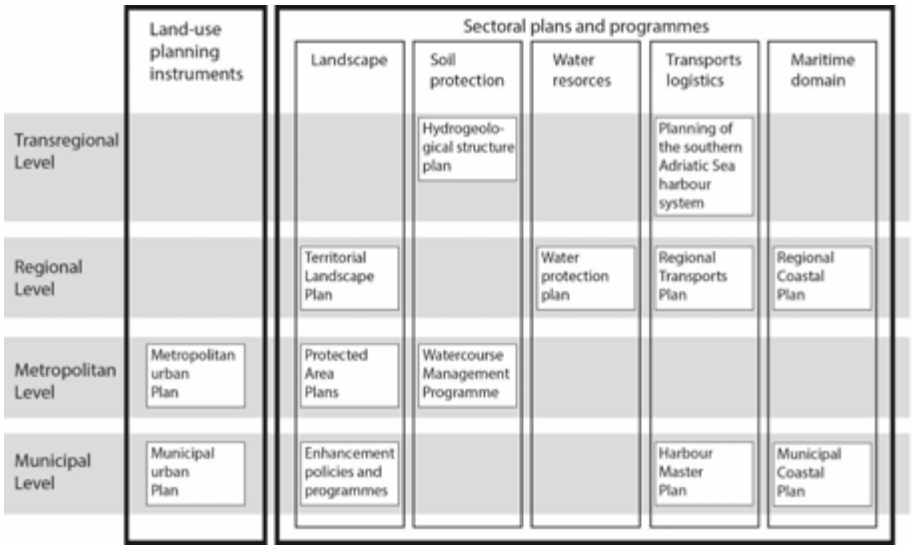

Figure 5 - Planning and programming tools for coastal management. Source: author's elaboration

The Hydrogeological Structure Plan, which came into effect in 2005, has a prescriptive content that establishes admissible interventions in areas prone to hydraulic and geomorphological hazards but does not provide project management guidelines. On the other hand, the Water Protection Plan, which came into effect in 2009, has a forward-thinking policy for wastewater discharges into the sea, foreseeing the relocation of discharges and promoting water reuse policies.

Port planning, according to national Law No. 56/2014, is the responsibility of municipalities or supra-regional authorities depending on the rank of the harbour, involving actions to expand port infrastructure and redevelop port-city interaction areas.

The Regional Coastal Plan, which came into effect in 2012, outlined the framework of coastal sensitivities and criticalities and defined the main choices for coastal management, in line with environmental and landscape constraints. Management rules must be further developed at the municipal level with Municipal Coastal Plans and only concern the strip of maritime public property, often very narrow due to erosion phenomena. These plans have very limited

competencies (coastal recovery and zoning of concessions for bathing establishments, fishing, trade, water sports) and are inadequate compared to the complexity and intensity of environmental and landscape dynamics.
The Regional Territorial Landscape Plan (RTLP), which came into effect in 2015, is now the only reference for an integrated coastal management approach. It adopts the concept of the 'coastal zone' as a transition area between sea-coast-hinterland encompassing cities, rural areas, infrastructure, and protected areas. The RTLP pursues the objectives of enhancing and redeveloping natural and anthropic elements, enhancing the resilience of the coastal ecotone, and safeguarding and enhancing undeveloped areas.
Urban planning and territorial planning instruments operate at the municipal and metropolitan levels. All municipalities still have very dated urban plans (from the 1970s-1990s) that envisaged intense urbanisation for residential, industrial, commercial, and tourist purposes but are promoting numerous projects for waterfront and public space redevelopment through ministerial funding (European Regional Development Fund and The National Recovery and Resilience Plan). Instead, the Strategic Plan for the Metropolitan City of Bari, still under development, proposes 11 strategic actions including the "Metropolitan Waterfront and Marine Economies" action. It assumes the following objectives: (i) coastal consolidation and enhancement of the entire Bari metropolitan area coastline; (ii) enhancement of the natural landscape characteristics to make it more attractive; (iii) the waterfront as an identity element for communities and an economic and social engine for territorial growth. At present, these objectives have not yet resulted in an organic programming of measures and actions for the territories and do not provide concrete answers for climate change. Nevertheless, these objectives can help municipalities align their planning and programming instruments, increasing the effectiveness of individual interventions on the coast.

3.2 Setting the PSDM process for the Metropolitan City of Bari

To set the Participatory System Dynamics Model process, we started by identifying the key actors to be involved (Phase 1). First, we defined a list of stakeholders including representatives of public bodies (at the regional, sub-regional, metropolitan and local scale), of economic activities (agriculture, tourism, fishing) and of NGOs (Table 1).
Our main goal was to include different typologies of actors with different responsibilities in managing the coastal area of the Metropolitan City of Bari (management, regulatory, economic, social, tourism and environmental). Moreover, we used the snow-ball sampling method to strengthen the stakeholders identification and reduce the chances of leaving out important parties.

Table 1 – Selected actors for the Participatory System Dynamics Model process in the Metropolitan City of Bari

Institution	Typology	Type of responsibility	Scale
Acquedotto Pugliese S.p.a.	Investee Company	Management	Regional
Puglia Region – Landscape protection and enhancement	Public	Regulatory	Regional
Puglia Region – Coastal and harbor public domain	Public	Regulatory	Regional
Puglia Region – Parks and biodiversity protection	Public	Regulatory	Regional

Apulian Water Authority	Public	Regulatory, management	Regional
Regional Agency for environmental prevention and protection - ARPA	Public	Regulatory	Regional
Basin Authority	Public	Regulatory	Sub-regional
Port Authority	Public	Management, regulatory	Sub-regional
Terre D'Apulia Reclamation Consortium	Public	Management, regulatory	Sub-regional
Superintendence of archeology and landscape	Public	Regulatory	Metropolitan
Metropolitan City of Bari - Environment	Public	Regulatory	Metropolitan
Municipality of Bari – Urban planning and development	Public	Regulatory	Local
Association of beach concessionaires	Trade association	Economy	Local
Coldiretti agriculture Association	Trade association	Economy	Local
I Gabbiani di Costa Ripagnola Association	NGO	Environment, social	Local
Litorali	NGO	Environment	Local
Pugliarte Association	NGO	Social, tourism	Local
ASD Lo Stroppo Association	NGO	Economy, social	Local
Mola di Bari Fisherman association	Trade association	Economy	Local
Confagricoltura Bari	Trade association	Economy	Local
Confcommercio Bari	Trade association	Economy	Local
Puglia Promozione	Public body	Economy, tourism	Metropolitan

To prepare Phase 2, consisting in the individual semi-structured interviews, we set a guide of questions divided in four main topics (Figure 6): i) definition of the socio-ecological system; ii) identification of the main activities and uses on the coast; iii) identification of the socio-economic rules/control on the coast; iv) existing threats and impacts on the coast.

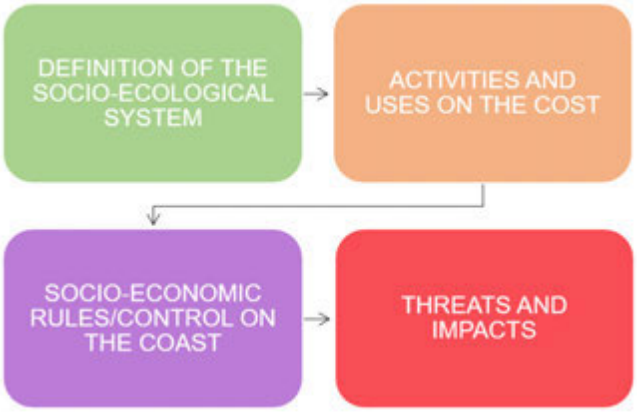

Figure 6 – Structure of the individual semi-structured interviews. Source: author's elaboration

The individual interviews are conducted to build individual qualitative mental models. Each model is represented as a Fuzzy Cognitive Map (FCM), composed of oriented graphs with feedbacks, which consist of nodes (or concepts), being the variables, and weighted arcs (or connections) (van Vliet, Kok and Veldkamp, 2010). During the interview each participant is directly involved in the creation of the individual model by following the structure described in Figure 6. This phase helps to refine the perception of each stakeholder to represent their personal perspectives and to deepen the understanding of the issue and prepare for Phase 3.
Phase 3 consists in a desk analysis, necessary to build a preliminary qualitative model (PQM) based on the information gathered from the individual interviews. As stated in Valencia Cotera, Egerer and Máñez Costa (2022), this phase has the aims of i) forming a broad understanding of the system's behaviour and ii) compiling a comprehensive summary of stakeholder perceptions. In this phase, all components emerged from the Individual mental models are analysed and ordered. Only variables present in all individual models are considered and boundary conditions are set by classifying the components and relationships into tiers (Table 2).

Table 2 – Classification of components and relationships into Tiers

COMPONENTS	**TIMES MENTIONED (%)**
C-Tier 1	>50
C-Tier 2	25-50
C-Tier 3	<25
RELATIONSHIPS	**TIMES MENTIONED (%)**
R-Tier 1	>75
R-Tier 2	50-75
R-Tier 3	25-50
R-Tier 4	<25

We consider only components of C-Tier 1 and C-Tier 2 and relationships of R-Tier 1, R-Tier 2 and R-Tier 3. By incorporating only the components mentioned by the majority of stakeholders, we are able to build a basic framework to capture the collective perception of the system.
The last Phase consists in the Group Model Building (GMB), through a Workshop with the participation of all actors identified in Phase 1. During the Workshop and with the guidance

and moderation of two facilitators, participants discuss and decide the main components to place in the model, following the same structure used for the Individual interviews (Phase 2). The facilitators guide the workshop by taking into consideration the elements that emerged from the preliminary model to bring out any aspects that are overlooked. However, facilitators do not show the preliminary model to the participants because it could modify stakeholders' feelings and create bias and framing effects.

4. Results and discussion

The Participatory System Dynamics Model developed for the Metropolitan City of Bari helps us to understand if policy-makers and stakeholders acknowledge and consider the newly proposed methods for coastal risk management as potential alternatives or supplements.

First, we deliberately decided not to give a definition to the extent of the coastal area of the Metropolitan City of Bari to the actors involved, as we wanted to comprehend their own understanding of the system.

In fact, from the preliminary qualitative model (Figure 7) built in Phase 3 we realise that actors do not perceive the coast as a sea-coast-inland transitional zone as defined by the Regional Territorial Landscape Plan. They mention only the coastline and no reference is given to the relationships with the system of the ephemeral rivers "lame" and the inner territory of Murgia.

Moreover, most of the participants give much attention to the predominance of beach establishments used for bathing by residents and tourists and less recognition is given to residential, agriculture, fishing and harbour activities. The touristic use of the coast, and mainly the management of the state property by beach concessionaires, is recognised to be cause of beach privatisation and consequently to anthropic pressures leading to an increase of hydro-geomorphological risk and coastal erosion. The coexistence of these activities results in land consumption, high water footprint, large amounts of solid waste, and pollution of marine waters, impacting seagrass and the attractiveness of beaches for bathing.

However, the presence of poseidonia is recognized only as a waste that produce pollution. Such aspect highlights the low level of actors' knowledge on the importance that poseidonia could have as a Nature-based solution for coastal protection, manly to reduce flooding and erosion risk. As a matter of fact, the PQM lacks in components related also to the presence of "hard" engineering-based solutions to counteract the risk of erosion and flood such as groins and breakwaters. Another aspect not emerging from the model is climate change and its negative impacts. This could be due to the fact that climate change is seen as a global issue that is not reflected on a local scale.

The actors perceive coastal erosion as a main issue for the Metropolitan City of Bari as directly caused by anthropic pressure (harbour activities, beaches privatisation, tourism).

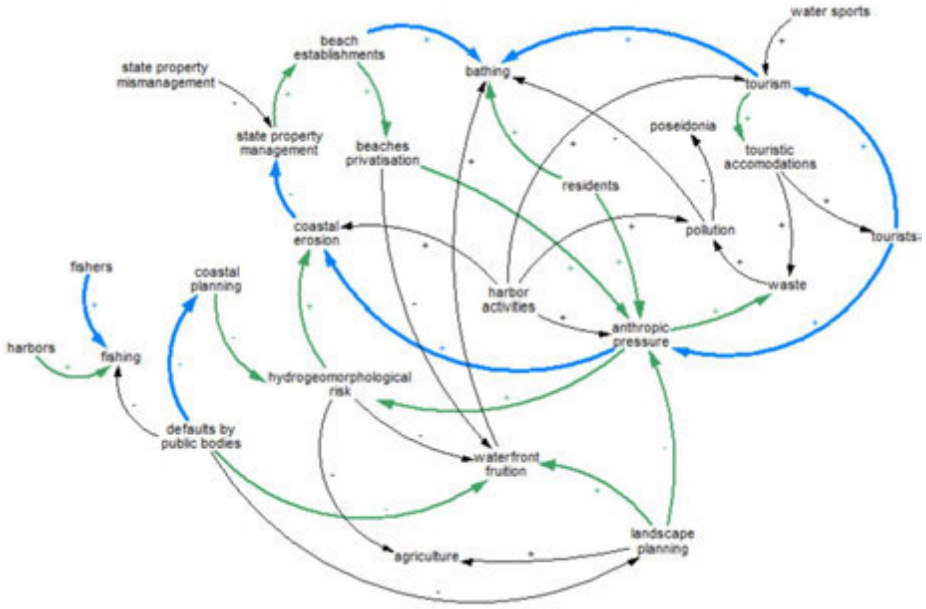

Figure 7 – The preliminary qualitative model - PQM (Phase 3) built from the analysis of the individual interviews (Phase 2) with the presence of C-Tier 1 components. The arrows' thickness represent the Tier level, R-Tier 1 with low effect relationships in black, R-Tier 2 with considerable effect in green and R-Tier 3 with strong effect in blue. The "+" and "-" indicate the positive or negative effect related to the cause. Source: author's elaboration

The strong perception of the problem is linked to episodes of collapses and landslides along the predominantly rocky coast, jeopardising the viability of economic activities regulated by state property management. Participants identify bathing and tourism as both a problem and activities at risk due to difficulties in management, routine maintenance, and coastal supervision. Hydrogeological risk is also perceived as one of the main issues along the coast, especially as actors recall past flood events that caused severe damage to settlements and populations. This risk is mainly attributed to urbanisation in flood-prone areas and widespread soil sealing, resulting in challenges for waterfront enjoyment and agricultural production.

Landscape planning, with relation to the Regional Territorial Landscape Plan, is recognised to be a relevant instrument to counteract anthropic pressures and to allow a better fruition of the waterfront. On the contrary, the fruition of the waterfront is perceived as hindered by defaults of public bodies. In particular, this deficiency leads to problems related to the difficulty of implementing coastal planning at the local scale.

This is in line with the reality, as no municipality in the Metropolitan City has a current Municipal Coastal Plan. Furthermore, participants widely share dissatisfaction with the current planning systems, which are too fragmented and sectoral. The complexity of regulations and defaults by public bodies cause many problems in the management choices of coastal uses (fishing, ports, bathing), interfering with coastal redevelopment scenarios promoted by landscape planning.

During the workshop, participants ignored the emerged themes from the Preliminary Qualitative Model (PQM) to enable an objective and unbiased formulation of the Group Model Building (GMB).

From the Group Model (Figure 8) built during the Workshop with all actors involved in Phase 2, we can say that most of the components and relationships deriving from the PQM are confirmed. In this phase, the actors have deepened the correlations between uses, impacts, role and plans, highlighting the following aspects.

Figure 8 – The group model – GMB (Phase 4) built during the Workshop with the actors involved in Phase 2. Source: author's elaboration

The actors have undoubtedly produced a more organic vision of anthropic pressures, linked not only to sea-related tourism and urban centres in general, but also to infrastructure, industrial areas, settlement sprawling and agriculture. In particular, they pointed out that settlement expansion is the main cause of land consumption, with direct repercussions on coastal erosion, hydro-geomorphological risks and sediment management, and that urbanisation results in the reduction of birdlife and coastal habitats. The actors also deepened the impacts caused by agriculture: (i) extraction of groundwater for agriculture causes saline intrusion into the underground aquifer and its depletion, to the disadvantage of agricultural production; (ii) agricultural discharges into the sea that require the implementation of water protection plan policies and measures related to the reuse of purified wastewater and waste treatment efficiency systems.

The topic of the state property management, already extensively emphasised in the PQM, was further explored for the following issues: (i) the need to improve the management of water discharges because they change the balance of the poseidonia, causing it to be deposited on beaches and making it difficult to manage biomass; (ii) the need to improve coastal planning through integration with landscape planning (protection of the biodiversity of lame and archaeological assets) and a more correct distribution of uses, because supporting services for the fruition (mobility and parking) cause impacts on the environment and landscape.

5. Concluding remarks

The initial findings deriving from the Participatory System Dynamics Model process set for the Metropolitan City of Bari indicate that decision-makers and stakeholders do not perceive the

complexity of the coastal zone as a sea-coast-inland transitional zone. Although hydro-geomorphological hazards, and coastal erosion in particular, are mentioned, there is no reference to approaches to manage them. Moreover, there is no recognition of climate change as the primary cause of risks and pressures on their coastal areas. This perception is conditioned by the vision of the existing problems related to the equilibrium of the coastal system and may be influenced by the absence of detailed predictive scenarios.

In the meantime, they are aware about the risk of erosion and of pollution caused by the urbanistic transformations, both caused by the "hard" engineering-based approaches used for the last decades, and by the future impacts caused by the touristic, residential and commercial development.

Furthermore, actors view Nature-based Solutions positively in an abstract sense, but they may not be applicable in highly anthropised contexts with significant socio-economic conflicts. Especially stakeholders at the regional level, with regulatory and management responsibilities, demonstrate knowledge of Nature-based Solutions, including those projected to circular resource management. However, they do not consider them applicable for several reasons: (i) the economic-settlement development interests of an already highly populated territory that does not allow for short-term relocation hypotheses; (ii) the difficulty of intervening in the adaptation or replacement of existing infrastructure, networks and facilities; (iii) and the coexistence of too many sector planning tools along the coast, with sometimes conflicting interests, which do not allow for the experimentation of innovative and forward-looking management solutions.

To overcome the approach of resolving specific conflicts in the short and medium term, a comprehensive framework is necessary. This framework should combine methods, data sources, and theories, detailed climate change scenarios to address the partial perception of stakeholders and change perspective to manage coastal risks.

Abstract

In response to the impacts of climate change, the increasing risk of flooding has traditionally been addressed by identifying flood-prone areas using floodplain maps to regulate land development. However, the interconnected dynamics of runoff in the river basin and levee effect have highlighted the potential threats posed by residual flood risk. Consequently, this paper integrates residual risks and flood source areas into flood risk management within the river basin. Utilising the SOBEK model, this study simulates three flood scenarios—without levees, with existing levees, and with failed levees—to conduct flood hazard analysis and flood source-to-impact analysis. Based on these findings, this paper proposes land use management strategies aimed at enhancing water resilience through strategic spatial planning in the face of climate change.

Keywords: flood risk management, spatial planning, residual risk, flood source area, SOBEK model

1. Introduction

As climate change escalates, the frequency and severity of extreme rainfall events are increasing significantly. Taiwan's extensive and mountainous terrain, characterised by steep slopes and fast-flowing rivers, presents significant challenges for water retention, often resulting in frequent flooding. Traditionally, flood threats like these have been mitigated through structural flood control measures designed to protect urban areas. However, research into the "levee effect" indicates that reliance on structural flood control in flood-prone areas can foster a false sense of security among governmental bodies and local communities. This misplaced confidence may cultivate an illusion of enduring immunity from flooding, thereby accelerating development within floodplains and consequently amplifying long-term flood risks (Di Baldassarre et al., 2018; Ding et al., 2023). Moreover, as climate change intensifies, not only do the frequency and intensity of extreme rainfall events increase, but the existing standards of flood protection facilities also reach their limits, failing to entirely eliminate flood risk (Associated Programme on Flood Management, 2017). Incidents surpassing these thresholds may result in levee overtopping or breaches, representing significant residual flood risks (Serra-Llobet et al., 2022). In light of this, there has been an increased focus on the importance of non-structural measures in flood risk management. The Intergovernmental Panel on Climate Change (IPCC) in its Sixth Assessment Report advocates a holistic approach that integrates both structural and non-structural measures in managing flood-prone zones. Serra-Llobet et al. (2022) emphasise the effectiveness of regulatory flood maps in reducing exposure and vulnerability by either prohibiting or limiting development in high-risk areas.

In the context of disaster management, it is emphasised that disaster mitigation can be achieved through spatial planning, thus minimising flood risk (Hartmann, Slavíková, and Wilkinson, 2022). In the integration of spatial planning and flood risk management, flood hazard analysis often utilises flood maps as a basis for risk assessment in land management policies for flood-prone areas. However, these maps are only the final output of hydrological modelling, which

leads to the formation of flood-prone areas not only due to natural topographic factors, but also as a result of human development, which is a significant driver of flooding. Changes in land use due to development reduce the infiltration capacity of the soil, thereby increasing surface runoff and peak flood volumes (O'Donnell and Thorne, 2020). Furthermore, when considering the spatial scale of entire river basins, there are flood risk externalities within the system: land development changes in upstream areas are likely to increase flood threats downstream, demonstrating the spatial interconnectivity between flood source areas and flood impact areas (Seher and Löschner, 2018; Chang, H.-S., & Hsueh, P.-R., 2023).

In conclusion, traditional spatial planning has predominantly focused on identifying flood-prone areas using flood maps. However, this approach frequently overlooks the residual flood risk associated with levee failures and the equitable distribution of runoff within comprehensive river basin management. Consequently, this paper aims to address the limitations of considering only flood-prone areas in flood risk assessment. It examines the variances in flood hazard levels both with and without levees and explores the residual risks should these defences fail. Additionally, this study integrates river basin management to reassess the spatial correlations between flood source areas and flood impact areas, aiming to develop strategic spatial planning to meet the challenges posed by climate change.

Initially, this study will establish three flood simulation scenarios: without levees, with existing levees, and with failed levees. Subsequently, through flood hazard analysis, it will generate flood hazard maps for each scenario, considering changes in flood spatial distribution and land use. This process will also entail the creation of a Composite flood risk zone map that categorises areas into high, medium, and low flood risk zones. Moreover, a flood source-to-impact analysis will chart the spatial distributions of flood sources areas and flood impact areas within the river basin for each scenario. Based on these variations in spatial distribution under each scenario, a comprehensive flood source area map will be developed.

Following this, the study will develop land use management strategies predicated on varying flood risk levels and outline responsibilities for flood management in primary flood source areas. These measures are crucial for flood risk management strategies in response to the challenges posed by climate change. Ultimately, this paper will simulate four flood risk management scenarios: no change, a land use management policy based on flood risk zones, flood responsibility in primary flood source areas, and a combination of land use management policy and flood responsibilities. The study will evaluate changes in flood risks across these scenarios and devise strategic spatial planning based on flood risk assessment.

2. Methodology

To explore the residual flood risk associated with levee failure and the spatial relationship between flood source areas and impact areas within the river basin management, this study will employ the SOBEK model as the flood simulation software. The SOBEK model, jointly developed by Taiwan's Water Resources Agency and the Dutch company WL | Delft Hydraulic, is also the model used for creating the current flood inundation maps in Taiwan. As shown in Figure 1, the research will establish three flood simulation scenarios: without levees, with existing levees, and with failed levees (Figure 1a). It will then conduct a flood hazard analysis and produce a composite flood source and impact analysis a flood source-to-impact analysis (Figure 1c). The study will formulate land use management strategies based on different flood risk zone levels identified in the Composite flood risk zone map, and assign flood responsibility in the primary flood source areas depicted in the composite flood source area map, as part of the main flood risk management strategies in response to climate change challenges (Figure 1d).

Finally, the study will simulate and compare the outcomes under four flood risk management strategies scenarios: no change, a land use management policy based on flood risk zones, flood responsibility in primary flood source areas, and a combination of land use management policy and flood responsibilities (Figure 1e). It will assess the more effective flood risk management strategies.

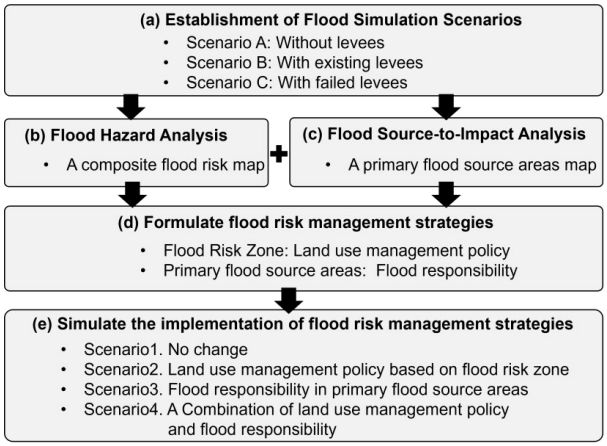

Figure 1. Research framework

2.1 Establishment of Flood Simulation Scenarios

This study will establish three flood simulation scenarios as shown in Figure 2, to explore the variations in flood hazard levels and the spatial distribution of flood source areas and flood impact areas with and without flood defence infrastructure, as well as under conditions of defence failure. Scenario A "Without levees" assesses the flooding situation under a 200-year return period rainfall scenario without any flood control infrastructure, representing the "inherent flood risk" of the area. Scenario B "With existing levees" evaluates the flooding situation under the current flood defence standards for a 200-year return period, representing the "existing flood risk" of the area. Scenario C "With failed levees" assesses the flooding situation when levees are overtopped, exceeding the 200-year return period flood defence standards, with climate change or extreme rainfall events used as the simulation rainfall scenarios, representing the "residual flood risk" of the area.

The outcomes of scenario A "Without levees" and B "With existing levees" will reflect the changes in the spatial distribution of flood risks with and without flood defence infrastructure, identifying areas where flood hazard levels are inherently high despite reduced flooding due to the construction of defences. The outcomes of scenario B "With existing levees" and C "With failed levees" will reflect the flood threats posed by levee failure under future climate change rainfall scenarios or extreme rainfall events, highlighting areas where residual flood risks are overlooked due to the protection afforded by flood defences.

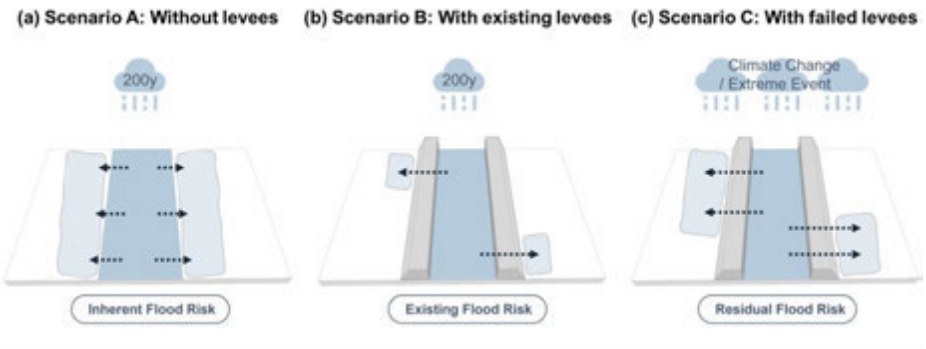

Figure 2. Flood Simulation Scene Setup

2.2 Flood Hazard Analysis

As shown in Figure 3, this study utilises the SOBEK model to simulate three flood scenario settings and conducts flood hazard analysis to explore the variations in flooding under conditions with and without levees, as well as in cases of levee failure. Initially, three flood hazard maps will be generated: one for without levees, one for existing levees, and one for failed levees (Figure 3a). Scenario A "Without levees" reflects the inherent flood risk based on topography without any flood control measures, showcasing areas with high flood hazard due to natural geographical factors. Scenario B "With existing levees" illustrates the existing flood risks under the current 200-year return period flood protection standards, where flooding still occurs. Scenario C "With failed levees" displays the residual risks in the event of levee overtopping during future climate change-driven rainfall or extreme rainfall events, highlighting areas with potential flood threats.

Subsequently, an overlay analysis of the flood hazard maps from the three scenarios will be conducted (Figure 3b). This analysis will particularly focus on comparing scenario A "Without levees" and B "With existing levees" to identify areas where flood situations have decreased due to the construction of levees but still possess inherent high flood hazard. It will also compare scenario B "With existing levees" and C "With failed levees" to pinpoint areas at risk of flooding beyond the protection standards during climate change-induced or extreme rainfall events. Lastly, by overlaying information on land use map, current land use status, and future development plans, a Composite flood risk zone map will be drawn (Figure 3c). This map will categorise areas into high, medium, and low flood risk zones, serving as a foundation for formulating spatial flood risk management strategies.

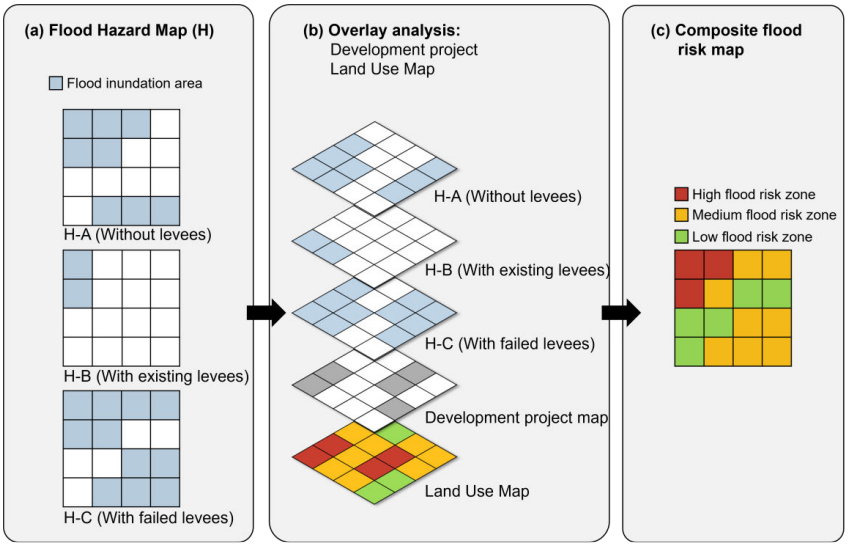

Figure 3. Flood hazard analysis research design

2.3 Flood Source-to-Impact Analysis

Considering the interconnected impact of surface runoff within river basin, it is challenging to distinctly delineate flood source areas from impact areas due to the mutual influences of runoff across upstream, midstream, and downstream regions. This study will employ the Flood Source-to-Impact Analysis (Vercruysse et al., 2019; Chang, H.-S., & Hsueh, P.-R., 2023) as illustrated in Figure 4, to re-examine the flood volumes generated by flood source areas and the spatial distribution of impact areas within the river basin.

(i) Divide Calculation Grid: Grids are delineated based on regional topography and land use;

(ii) Baseline Rainfall Scenario (BS): Simulates surface runoff under a baseline rainfall scenario with uniform rainfall across all grids, resulting in a flood depth (Fd_{BS}^{R}) ;

(iii) Grid i Rainfall Scenario (i): Sets zero rainfall for a specific grid 'i' (meaning no rainfall in grid 'i') while maintaining uniform rainfall across the remaining grids to simulate surface runoff, resulting in a flood depth (Fd_{i}^{R}). This step is repeated sequentially for each grid treated as grid 'i';

(iv) Flood Source Identification: Compares the Baseline Rainfall Scenario with the Grid i Rainfall Scenario. The difference in surface runoff distribution between the two scenarios $(F_i = Fd_{BS}^{R} - Fd_{i}^{R})$, identifies the contribution of grid 'i' to flood generation in other grid units.

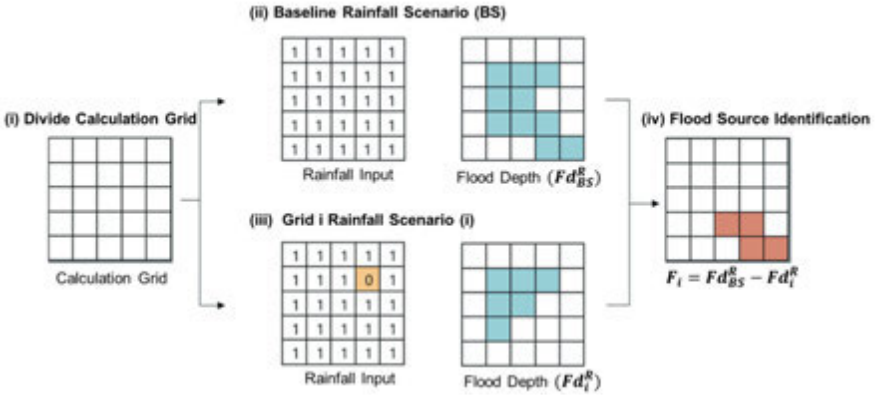

Figure 4. Illustration of Flood Source-to-Impact Analysis
Source: Vercruysse et al., (2019); Chang, H.-S., & Hsueh, P.-R., (2023)

As illustrated in Figure 5, this research has established three flood simulation scenarios for conducting flood source-to-impact analysis, resulting in the production of three maps of flood source and impact areas under conditions of without levees, with existing levees, and with failed levees (Figure 5a). Subsequently, an overlay analysis of these three maps will be performed to compare the flood source areas and flood impact areas across the scenarios. This analysis assesses the changes in the spatial distribution of flood source and impact areas under conditions with and without levees and in various rainfall scenarios. Additionally, this analysis includes overlaying data on land use map and land development map (Figure 5b) to identify the main and undeveloped flood source locations. Finally, a composite flood source area map will be created (Figure 5c), which will serve as the basis for formulating responsibilities for flood responsibility in primary flood source areas.

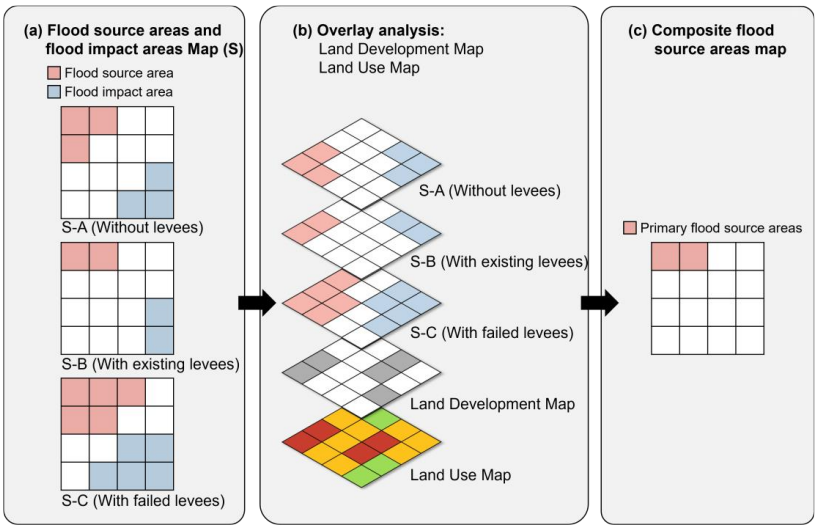

Figure 5. Flood Source-to-Impact Analysis research design

2.4 Formulate Flood Risk Management Strategies

The Composite flood risk zone map considers areas facing potential flood threats during climate change rainfall scenario or extreme rainfall events; the composite flood source area map identifies primary flood source areas likely to develop in the future. To implement strategic spatial planning based on flood risk, this study will formulate appropriate land management strategies for different flood risk zones: high flood risk areas will be designated as prohibited zones (to prevent new development), medium flood risk areas as restricted zones (allowing new developments but with specified development intensities and required flood mitigation measures), and low flood risk areas as development zones (encouraging concentrated new developments). Additionally, principal flood source areas will be assigned responsibilities for managing the excess runoff, which involves implementing measures to mitigate flooding impacts, thus ensuring equity in managing flood risks in the river basin management. Consequently, this research adopts land use policy for flood risk zone and responsibilities for flood source areas as crucial strategies in spatial flood risk management.

2.5 Simulate the Implementation of Flood Risk Management Strategies

To investigate the variations in flood risk under different flood risk management strategies, this study establishes four flood management strategy scenarios: Scenario 1 "No change" which retains current flood management practices; Scenario 2 "Land use management policy based on flood risk zone," prohibits development in high flood risk zones and restricts development intensity in medium flood risk zones while implementing flood mitigation measures; Scenario 3 " Flood responsibility in primary flood source areas," involves setting flood mitigation measures in primary flood source areas, taking responsibility for excess runoff; Scenario 4 " A Combination of land use management policy and flood responsibility " integrates flood risk zones with flood responsibilities under river basin management. The SOBEK model is used to simulate flooding under these four flood risk management scenarios, comparing changes in flood risk across scenarios to assess the most effective flood risk management strategies in response to flood threats under climate change.

3. Results

This study utilises the SOBEK model to simulate three flood scenarios: without levees, with existing levees, and with failed levees, and conducts flood hazard analysis to simulate flooding for each scenario. This approach offers a more comprehensive inclusion of land flood hazard levels prior to levee construction, as well as considers areas facing potential flood threats from climate change-driven rainfall scenarios or extreme rainfall events. It also considers land use and future major development plans to produce a Composite flood risk zone map, which categorizes areas into high, medium, and low flood risk zones. Additionally, through flood source-to-impact analysis, the spatial relationship between flood source and impact areas within the river basin is re-examined, with consideration of land use and land development to produce a composite flood source area map, identifying primary flood source areas responsible for excessive runoff.

Furthermore, based on the Composite flood risk zone map, the study formulates appropriate land use management strategies to guide suitable land use, preventing high-density development in areas of high flood risk to minimize potential loss of life and economic damage. Preliminary strategies include prohibiting new developments in high flood risk areas, restricting development and implementing flood mitigation measures in medium flood risk areas, and promoting intensive development in low flood risk areas. According to the composite flood

source area map, primary flood source areas should take flood responsibilities, due to their excessive runoff contributing to flooding in impacted areas. Finally, the study simulates flooding under four flood risk management strategy scenarios, assessing the impact of flood risk zones and flood responsibilities, and formulates strategic spatial planning responsive to climate change, effectively reducing flood hazards and equitably distributing excessive runoff.

4. Conclusion

This paper is grounded in a spatial planning perspective, aiming to overcome the constraints imposed by traditional flood inundation maps used for land management in flood-prone areas. It assesses alterations in flood hazard levels under scenarios with and without levees, and in the event of levee failures, redefining the spatial dynamics between flood source areas and flood impact areas from the perspective of river basin management. Three flood simulation scenarios—without levees, with existing levees, and with failed levees—have been established using the SOBEK model for flood simulation. Initially, this research analyses changes in the spatial distribution of flood hazard levels through flood hazard analysis. It identifies areas at potential flood risk, culminating in a Composite flood risk zone map that categorises regions into high, medium, and low flood risk zones. Moreover, flood source-to-impact analysis investigates spatial variations between flood sources and affected areas across these scenarios, resulting in a composite flood source area map that pinpoints primary flood origins. Concurrently, flood risk management strategies are developed based on land use considerations. New developments are prohibited in high flood risk zones; development is constrained, and flood mitigation measures are mandated in medium flood risk zones; responsibilities for managing excess runoff are allocated in primary flood source areas to address the equitable distribution of runoff. This study also evaluates variations in flood risk among different flood risk management strategies.

In conclusion, in response to the severe threats and uncertainties posed by climate change, this research integrates residual flood risks and the spatial relationships between flood sources areas and flood impact areas into comprehensive flood risk management. It advocates for strategic spatial planning based on land flood risk and water management responsibilities. From a land-use management perspective, this strategy aims to prohibit development in high-risk areas, guide appropriate spatial development, and ensure fairness in river basin management by assigning flood responsibility to flood source areas. The objective is to harmonise land development imperatives with flood risk management, thereby establishing a resilient spatial planning framework that is responsive to climate change.

Abstract

This paper considers into urban resilience by drawing insights from Ukrainian citizens who have firsthand experience with the risks of war, aiming to provide practical lessons and examples to enhance urban adaptability and preparedness. Their unique perspective enriches the discourse on urban resilience in EU cities, shedding light on the challenges faced in the aftermath of conflict. The narrative begins by highlighting the stark realities experienced by Ukrainian citizens due to the lack of preparedness in their cities, setting the stage for an exploration of resilience issues post-conflict. Key areas of concern include energy system resilience, with real examples emphasizing vulnerabilities and the need for EU cities to fortify their energy infrastructure. This paper contributes to academic discourse while offering pragmatic lessons to inform policies and practices, fostering resilient, compassionate, and inclusive cities ready to face future uncertainties.

1.Introduction

In the face of urbanization and globalization, the resilience of cities has become a paramount concern. As urban environments evolve and face various challenges, from climate change to socio-political unrest, understanding and bolstering urban resilience is imperative for ensuring the safety, stability, and well-being of urban populations. The authors consider the realm of urban resilience through a unique lens, drawing insights from Ukrainian citizens who have firsthand experience navigating the complexities of conflict and its aftermath. The backdrop against which this exploration unfolds is Ukraine, a nation that has grappled with the devastating impacts of war in recent years. Through the eyes of its citizens, we gain invaluable perspectives on the realities of urban resilience in the midst of crisis. The aim of this research is twofold: to illuminate the challenges faced by Ukrainian cities during the conflict and to extract practical lessons and tangible examples that can inform and empower urban resilience efforts, particularly within the European Union (EU).

The journey begins by immersing ourselves in the stark realities confronted by Ukrainian citizens as they contend with the ravages of war. In Ukrainian cities, where the prevailing sentiment was often one of disbelief in the possibility of conflict, the unanticipated and unprecedented challenges underscored the critical importance of preparedness. This introductory narrative lays the foundation for a comprehensive examination of resilience problems encountered ongoing-conflict, with a specific focus on three key dimensions: the energy system, transportation, and the provision of bomb shelters.

Within the energy system, disruptions wrought by conflict reveal vulnerabilities that demand attention. Real-life examples gleaned from the experiences of Ukrainian citizens shed light on the strains placed on energy infrastructure and the urgent need for reevaluation and fortification of energy resilience strategies in EU cities.

The provision of bomb shelters emerges as a crucial but often overlooked aspect of urban resilience. Drawing on the experiences of Ukrainian citizens, the importance of robust and accessible shelter systems is underscored, prompting EU cities to assess and enhance their own shelter infrastructure to

ensure the safety and well-being of their populations during emergencies (Deepak, 2022; UNESCO, 2023; Olcese, 2024).

The insights garnered from Ukrainian experiences serve not only as a reflection of past challenges but also as a beacon guiding future resilience efforts. By examining tangible challenges and practical solutions, this paper aims to prompt a reevaluation of urban planning paradigms, emphasizing the imperative of proactive preparedness and dispelling notions of implausibility regarding conflict. Ultimately, the lessons gleaned from Ukrainian cities contribute not only to academic discourse but also to the development of policies and practices that foster cities resilient in the face of uncertainty, compassionate in their response, inclusive in their design, and well-equipped to navigate the complexities of the future.

2.Aim of the paper

The paper aims to provide EU cities with a robust framework for enhancing their resilience to conflicts and other uncertainties, ensuring the safety, stability, and well-being of their residents. The insights from Ukrainian citizens serve as a valuable resource, offering a unique perspective that enriches the discourse on urban resilience and highlights the necessity of comprehensive and forward-thinking planning in the face of potential crises.

3.Overall situation with Ukrainian cities

The full-scale war in Ukraine is one of the most brutal in recent decades. The last time Europe saw such destruction was in the 1990s, when fighting broke out in Yugoslavia. Despite the absurdity of war in the 21st century, russian troops continue to target civilians and commit war crimes.

According to estimates, as of the beginning of 2023, the russian army has launched about 5,000 missiles and 3,500 air strikes against Ukraine. The invaders launched almost 1000 more strikes using kamikaze drones. These figures do not include shelling from artillery and multiple launch rocket systems (Visit Ukraine Today, 2023).

Base on investigation of the Kyiv Schools of Economics (Kyiv School of Economics, 2024), the total documented damages inflicted upon Ukraine's infrastructure due to Russia's full-scale invasion stand at a staggering $155 billion, inclusive of the destruction caused by the explosion of the Kakhovka Hydroelectric Power Station dam in June 2023. This assessment, derived from the "Russia Will Pay" project conducted by the KSE Institute team, in collaboration with various ministries including the Ministry for Communities, Territories and Infrastructure Development, the Ministry of Health, and the Ministry of Economy, as well as the National Bank of Ukraine, reflects a grim reality of devastation and loss. The escalation in the overall damage is attributed to the widespread destruction across various sectors, including housing, industry, energy, education, and healthcare. Housing, in particular, bears the brunt of the devastation, with nearly 250,000 buildings damaged or destroyed, amounting to an estimated direct loss of $58.9 billion.

Infrastructure damage has reached $36.8 billion, while direct losses in industry and businesses stand at $13.1 billion. The destruction of numerous enterprises, both private and state-owned, underscores the severe economic repercussions of the conflict. The energy sector alone has incurred direct damages of up to $9 billion, exacerbating the challenges in restoring vital services to affected areas (fig.1-2).

Total estimate of infrastructure damage by industry in monetary terms, as of January, 2024

Property type	Damage, $ billion
Housing	58,9
Infrastructure	36,8
Assets of enterprises, industry	13,1
Energy	9,0
Agriculture and land resources	8,7
Education	6,8
Utilities	4,5
Forests	4,5
Transport	3,1
Healthcare	3,1
Trade	2,6
Culture, sport, tourism	2,4
Administrative buildings	0,5
Digital infrastructure	0,5
Social sphere	0,2
Financial sector	0,04
Total	**154,9**
Ecology*	16,4

*Environmental damages are calculated as damages from air emissions and are not direct damages of real estate or other assets of Ukraine

Figure 1. Total estimate of infrastructure damage by industry in monetary terms (January 2024)

Figure 2. Damaged and destroyed infrastructure objects of Ukraine total

Here are some key points illustrating the extent of destruction caused during the conflict:

1. **Kyiv.** Russian missile attacks have targeted civilian areas in and around Kyiv, the capital of Ukraine. An apartment block was hit by a Russian missile, resulting in significant destruction (fig.3).

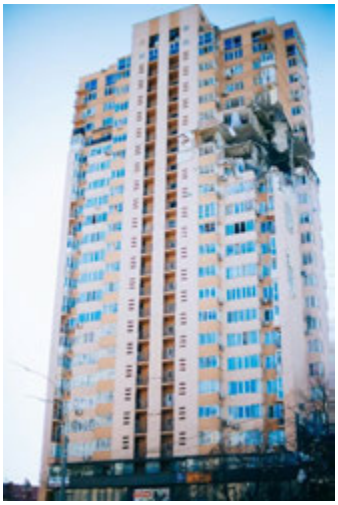

Figure 3. A destroyed house in Kyiv
(Photo retrieved from: https://unsplash.com/)

2. The city of **Irpin**, located northwest of Kyiv, has also suffered severe damage due to artillery and air strikes. Residential areas have been almost completely destroyed.

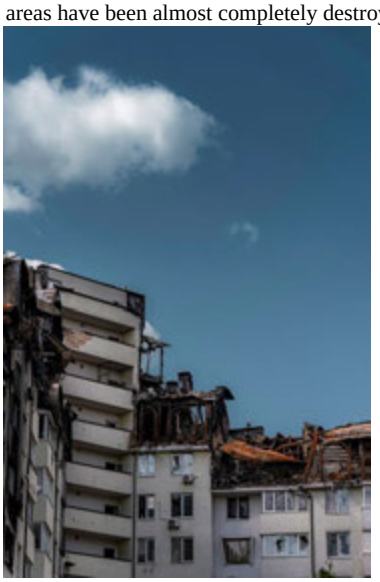

Figure 4. A destroyed house in Irpin
(Photo retrieved from: https://unsplash.com/)

3. **Kharkiv**, Ukraine's second-largest city, has been intensely bombarded by Russian forces, causing significant damage to its center.

Figure 5. People Hiding from Bombing at a Metro Station, Kharkiv, Ukraine (Retrieved from: https://www.pexels.com)

4. In **Borodyanka**, a town northwest of Kyiv, Russian airstrikes have destroyed several residential buildings, leaving the area in ruins.

Figure 6. Destroyed house in Borodyanka (Retrieved from: https://www.pexels.com)

5. **Chernihiv**, northeast of Kyiv, has faced heavy shelling, resulting in casualties and damage to schools and residential buildings

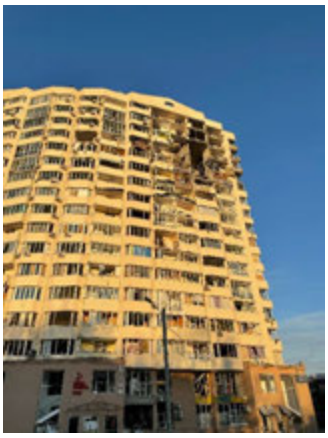

Figure 7. Destroyed house in Chernihiv

4.Residents insights about the war risks

There was interviewed representatives from such cities as Kyiv, Irpin, Cherkasy, Kharkiv, Gysin. Understanding the firsthand experiences of citizens living through war-torn regions provides invaluable insights for bolstering urban resilience strategies in EU cities. The challenges faced by Ukrainian residents during times of conflict shed light on critical areas that demand attention for enhancing preparedness and adaptability in urban environments.

1.Security Challenges Faced During the War. Ukrainian citizens encountered significant security challenges, particularly during the early stages of conflict:

- Lack of air raid alarms during initial missile activity left residents vulnerable to potential strikes, highlighting the need for reliable early warning systems in urban areas.
- Residents grappled with the unknown locations of bomb shelters, resorting to improvised hiding spots and facing heightened anxiety due to the lack of clear guidance from authorities.
- The absence of clear directives or programs from governmental bodies exacerbated residents' sense of insecurity and contributed to confusion regarding safety protocols.

2.Mobility Challenges During the War. Mobility became a critical issue for residents navigating the urban landscape amidst conflict:

- Residents faced difficulties accessing distant bomb shelters during air raid alerts.
- Suspension of public transportation compounding mobility challenges and leaving many without viable shelter options.
- Shortage of fuel at gas stations especially in the first year of the war made it difficult to use personal vehicles.

3.Energy-related Issues Encountered. The war brought about disruptions to energy infrastructure, posing significant challenges to daily life:

- Attacks on energy infrastructure led to widespread power outages, impacting essential services such as cooking and elevator access.
- Scheduled power outages necessitated residents to adapt their routines, while darkened streets and non-functional traffic lights heightened safety concerns and necessitated careful route planning.

4. Recommendations for Enhancing City Resilience. Insights gleaned from the experiences of Ukrainian citizens offer valuable guidance for bolstering urban resilience in EU cities:

- Implementing autonomous energy systems, ensuring widespread access to bomb shelters, and relocating critical facilities away from densely populated areas.
- Establishing stockpiles of essential supplies and creating emergency response bases to facilitate swift aid distribution during crises.

- Equipping households in industrial areas with chemical protection gear to mitigate potential industrial accidents.
- Installing comprehensive air raid alarm systems to provide prompt and clear alerts to all residents, enhancing overall safety and preparedness.
- Improving governmental transparency and communication to empower residents to make informed decisions during crises, thereby fostering a sense of security and trust in authorities.

5.Discussion

Incorporating insights from Ukrainian citizens into urban planning and resilience initiatives can significantly fortify EU cities against the uncertainties of conflict, ensuring the safety and well-being of their residents. This comprehensive approach involves several key strategies, which are essential for creating urban environments that are both resilient and adaptable in the face of potential crises.

First, enhancing infrastructure resilience is crucial. Cities should invest in renewable energy sources and backup power systems, such as solar panels, wind turbines, and local battery storage systems, to maintain essential services during disruptions. Additionally, constructing robust bomb shelters in all new buildings, and retrofitting existing structures to include accessible and well-equipped shelters, can significantly enhance civilian safety.

Improving mobility solutions is another vital component. Developing resilient public transportation networks that remain operational during emergencies, such as using fuel-efficient or electric vehicles with backup power sources, can ensure that residents can reach safe locations swiftly. Designing transit stops and routes to include protective structures that can serve as temporary shelters during attacks will also help safeguard commuters.

Strengthening communication and information systems is critical. Implementing advanced air raid and disaster alert systems that provide clear, real-time information to residents is essential. Integrating these systems with mobile apps and public broadcasts ensures widespread awareness. Governments must establish clear, consistent communication channels to provide residents with accurate information and actionable guidance during crises. Regular updates and preparedness drills can foster trust and readiness.

Emergency preparedness and response must also be prioritized. Creating reserves of food, water, medical supplies, and other essentials in strategic locations throughout the city will ensure quick access during emergencies. Conducting regular emergency response training for both officials and residents can improve overall preparedness and resilience. Educational programs should focus on survival skills, first aid, and the use of emergency shelters.

Community engagement and inclusivity play a significant role in urban resilience. Building strong community networks can enhance collective resilience. Initiatives that encourage neighborly support and cooperation can create a more unified and resilient populace. Ensuring that urban planning processes include input from a diverse range of community members, especially those who have experienced conflict, can lead to more comprehensive and effective resilience strategies.

Industrial and environmental safety should not be overlooked. Establishing stringent safety measures for industrial zones, including regular inspections and emergency response plans, can mitigate risks associated with industrial accidents. Protecting and managing urban green spaces and water resources can enhance resilience to both man-made and natural disasters, providing critical resources and refuge areas during emergencies.

By integrating these strategies into urban resilience frameworks, EU cities can better withstand the impacts of conflict and create safer, more adaptive, and supportive environments for their residents. These measures ensure that cities are not only prepared for emergencies but are also places where communities can thrive despite the challenges posed by uncertain times.

6.Conclusion

The insights gained from Ukrainian citizens who have endured the ravages of war offer invaluable lessons for enhancing urban resilience in EU cities. This paper has highlighted the urgent need for cities to be prepared for the uncertainties of conflict by focusing on several critical areas:

infrastructure resilience, mobility solutions, communication systems, emergency preparedness, community engagement, and industrial and environmental safety.

By prioritizing the development of autonomous energy systems, EU cities can ensure the continuity of essential services during disruptions, reducing their dependency on centralized power grids and increasing their overall resilience. Constructing robust bomb shelters and retrofitting existing structures to include accessible and well-equipped shelters will significantly enhance civilian safety during emergencies.

Improving mobility solutions, such as developing resilient public transportation networks and designing protective transit stops, ensures that residents can swiftly and safely reach secure locations during crises. Strengthening communication systems through advanced air raid and disaster alert mechanisms, coupled with clear and consistent information from authorities, can empower residents to make informed decisions and foster a sense of security and trust.

Emergency preparedness and response are vital components of urban resilience. Establishing stockpiles of essential supplies and conducting regular training for both officials and residents can enhance overall preparedness. Educational programs focused on survival skills and first aid are crucial for ensuring that the population is well-equipped to handle emergencies.

Community engagement and inclusivity are also essential. Building strong community networks and ensuring that urban planning processes include input from diverse community members, particularly those with firsthand experience of conflict, can lead to more comprehensive and effective resilience strategies. Inclusive planning fosters social cohesion and resilience, making cities more unified and prepared for adversity.

Finally, ensuring industrial and environmental safety through stringent safety measures, regular inspections, and the protection of urban green spaces and water resources can mitigate risks and provide critical resources during emergencies. These measures can contribute to the overall well-being of residents and enhance the city's ability to withstand both man-made and natural disasters.

Incorporating these strategies into urban resilience frameworks can enable EU cities to better withstand the impacts of conflict and create safer, more adaptive, and supportive environments for their residents. The experiences of Ukrainian citizens can serve as a valuable guide, demonstrating the importance of proactive preparedness and the need to dispel notions of implausibility regarding conflict. From these insights, EU cities can develop robust, resilient, and inclusive urban environments that are well-equipped to navigate the complexities of the future, fostering a culture of preparedness and adaptability.

Abstract

At the confluence of two rivers, the Grenoble Metropolitan area of France is a fabric of municipalities surrounded by Alpine massifs. Despite the absence of a major flood since 1859, flood risks persist, further amplified by climate uncertainties. We investigated how institutional structures manage these evolving risks. From previous research using Q-methodology, we found tensions related to spatial and jurisdictional aspects of flood risk management. To gain a deeper understanding of the temporal aspects not apparent from the Q-method study, we conducted a thematic analysis of seven interviews of study participants who hold managerial positions. Even though the interviewees were well aware of flood history and climate change, regulatory and policy mechanisms often impede the mobilisation of a long-term view into flood risk management strategies.

Keywords: flood risk governance; policy myopia; institutional inertia; thematic analysis; France

1 Introduction

Urban planning presents various "wicked" problems that are complex, multifaceted, and pervasive throughout socio-ecological systems (Rittel and Webber, 1973). Managing these problems is challenging as they involve multiple interrelated and co-evolving processes with no single best solution. Similarly, stormwater and flood risk management are wicked problems that operate within the context of evolving hydro-social systems, both constrained by and co-evolving with existing socio-cultural settings, land use patterns, governance structures, and infrastructures (Holling, 1973; Armitage *et al.*, 2009; Montanari *et al.*, 2013; Hommes, Hoogesteger and Boelens, 2022; Arik, 2024). Most water infrastructure and policies in developed areas are rooted in the concept of 'stationarity,' which uses the past hydrological regime to determine the envelope of variability for current and future water management decisions. In the face of increased uncertainties related to climate change, the assumption that hydro-climate systems exist in a fixed envelope of variability risks implementing inadequate infrastructure planning and water management strategies (Milly *et al.*, 2008; Sivapalan and Blöschl, 2015; Nair and Howlett, 2017). However, better capturing the uncertainty posed by evolving hydro-climate systems remains a major science and policy challenge. As a result, well-tested engineering methods based on stationarity remain prevalent in water infrastructure planning and management approaches (Brown, 2005; Harries and Penning-Rowsell, 2011; Milly *et al.*, 2015; Meng *et al.*, 2022; Robert, Quercy and Schleyer-Lindenmann, 2023).

To better meet the pace of evolving climate challenges, the concept of 'path dependency' helps conceptualise how the past shapes possible futures through current societal structures and systems (Haasnoot *et al.*, 2013, 2020; Bruley *et al.*, 2021). In other words, existing societal

structures can limit future pathways for adaptation to changing risks and climate uncertainties, even if there are known strategies to reduce risks. Some scholars explain the persistence of these societal structures in terms of reproduction, equating it to 'social inertia' by suggesting that institutions reproduce themselves over time, which causes self-reinforcing dynamic that resists directional changes even if the status quo is maladaptive (Mahoney, 2000; Barnett *et al.*, 2015). These pathways add a layer of complexity to managing flood risk as they can be hard to predict and can hinder the implementation of climate-adaptive flood risk management strategies even when they are known or have a contingency of supporters who work in flood risk management.

Therefore, the range of implementable climate change adaptation actions depends on the alignment of implementable strategies, scientific knowledge, governance processes, infrastructure lifecycles, and political and social will. Our study investigates whether the institutional structures match the spatial and time scales necessary to manage evolving flood risks. We focused on the Grenoble metropolitan area of France, where we interviewed 62 specialists who are members of an advisory committee in flood risk management. For this, we used Q-methodology paired with semi-structured interviews. The Q-method helped identify issues related to the jurisdictional mismatch in the scale of risk prevention and crisis management (Arik *et al.*, 2023). As jurisdictions are socially constructed, it makes sense that tensions related to spatial scaling would emerge from the study of perspectives. However, a temporal perspective of flood risk management did not emerge from the Q-method study. To go deeper into the temporal aspects, we conducted an exploratory analysis for this paper focusing on the interviews of seven study participants with managerial positions representing diverse perspectives, prompted by retrospective and prospective questions. We investigated how they learn from Grenoble's history of flooding and incorporate climate change knowledge into their decision-making.

2 Background and methodological notes

2.1 Setting the scene

This study was conducted in the Grenoble-Alps Metropolitan area (Grenoble-Alpes Métropole, GAM) of France, a region with a rich historical context in flood risk management. With a population just short of 450,000 (INSEE, 2022), this medium-sized metropolitan administrative entity governs an agglomeration of 49 individual municipalities. While each municipality has its own mayor and public officials, the agglomeration provides an inter-municipality governance structure to facilitate cohesion across planning efforts and public services. Notably, within the last ten years, all water-related responsibilities were transferred under the purview of GAM, and the municipalities no longer have the power to act, except for sanitation. GAM comprises a flat and densely developed valley, surrounded by less urbanised regions situated at the foothills of the surrounding mountains. Over a hundred steep torrents descend from these mountain massifs, flowing into two major rivers—the Isère and Drac Rivers, which converge in the City of Grenoble. The urbanisation of the valley was significantly influenced by the flooding regime of these merging rivers and surrounding torrents. A period of disastrous floods from 1600 to 1859 prompted major engineering efforts to curtail the flooding (Cœur, 2003). Consequently, since 1859, the valley has not experienced a major regional flood. However, the region experiences regular localised flooding, landslides, and torrential flows along the periphery, and the risk of catastrophic flooding remains a concern for the region (Creutin et al.,

2022). Alongside these flood events, the concentration of flood risk oversight and responsibility has evolved over centuries from hyper-decentralized to hyper-centralized and levels in between (Renou, Brochet and Creutin, 2020). Currently, GAM oversees most flood management and financing, but certain responsibilities are distributed across different levels of government, requiring cooperation. Table 1 provides an overview of key actors in flood risk governance in the region.

Table 1. Relevant flood risk management actors and their roles, represented on the committee for the management of aquatic environments and flood protection, CoMAPI.

Actors	**Flood Risk Governance Roles**
GAM (Grenoble Alps Metropolis)	GAM is the intercommunal government structure that governs 49 municipalities, including the City of Grenoble. Through the GEMAPI law enacted in 2018, GAM is responsible for aquatic environment management and flood prevention, particularly the smaller waterways not under the purview of SYMBHI. Through GEMAPI, GAM also collects a tax to fund these efforts and organises the CoMAPI, a committee of actors (as described in this table) who play an advisory role in aquatic environment management and flood prevention decisions.
SYMBHI (Joint Association of the Isère River Basin)	SYMBHI is the public body responsible for the planning and management of the South Isère River and Drac River basins, and it plays a key role in waterway management and flood risk prevention for the major rivers.
Regional agencies of the State	These include the water agency, the forestry agency, and the health department, among others. The health department has a prominent role in crisis management, especially for significant events.
Municipalities	Each of the 49 municipalities within GAM has an autonomous government, including a mayor and a town hall. The mayors are responsible for crisis management and coordination in the event of local flooding but do not carry direct responsibility for flood risk management.
Riparian landowners and riparian landowner unions (ASAs)	Riparian landowners are legally responsible for managing their streambanks. Historically, they transferred this role to riparian landowner unions, which collected fees and could access the stream reaches for management activities. Many of these unions have been eliminated in the region, but riparian landowners remain responsible for maintaining their streambanks.
Other stakeholders and associations	These include, for example, the electricity company (EDF) that manages hydroelectric dams in the basin and associations concerned with biodiversity or recreation.

2.2 Q-method and beyond

Studying wicked problems has multiple modes of entry and requires drawing wieldy boundaries around an inherently complex system (Holling, 2001; Hou, Li and Song, 2022). Because of the complex nature of wicked problems, mixed-methods approaches offer a means to look at multiple aspects of a problem (Mertens, 2015). Q-methodology (QM) is a mixed method increasingly used to study subjectivity related to complex issues (Dziopa and Ahern, 2011;

Zabala, Sandbrook and Mukherjee, 2018; Dieteren *et al.*, 2023). Using data reduction techniques, QM enables researchers to understand complex, multi-dimensional issues through a digestible set of perspectives. For this paper, we outline the findings of a QM study we conducted (Arik *et al.*, 2023) and how we take the study further through a thematic analysis of interviews.

2.2.1 Q-method insights reveal local-level gaps in hazard management

The Q-method uses an "inverse factor analysis" to study the associations between peoples' viewpoints rather than grouping people according to their characteristics (Stephenson, 1936, 1977). This is carried out by asking several participants ("P-set") to individually react and rank a set of stimuli ("Q-sample") relative to one another according to a semi-normal grid ("Q-sort"). Generally, the Q-sample is a set of non-provable statements pertinent to a particular subject. Principle component analysis or data reduction techniques are then used to identify similar perspectives from the Q-sorts. Several studies have mobilised QM to identify differing perspectives on flood risk governance or stormwater management (Cousins, 2017a, 2017b; Rittelmeyer, 2020; Arik, 2022; Tafel *et al.*, 2022). As a part of this study, we used QM to uncover tensions within the governance of flood risk in GAM; the full description of this part of the study is published in Arik et al. (2023). Briefly, the study included 32 statements, of which we asked participants to sort according to a semi-normal grid ranging from -5 (strongly disagree) to +5 (strongly agree). In total, we had 62 participants and collected 55 sorted sets of statements from members of CoMAPI or similarly affiliated flood risk management specialists.

Our study revealed three different perspectives (see Figure 1). The first group we identified as "Hydro-experts" tended to have a global 'point-of-view' and a specialised background in flood management. In this case, the expression 'point-of-view' can be understood verbatim as it refers to a characteristic that structures the overall perspective and flood risk management in GAM generally. The second and third groups represented participants connected to flood risk management at a local jurisdictional scale, dubbed the "Hydro-generalists" and "Hydro-operators." The Hydro-generalists were typically elected officials of periphery municipalities responsible for crisis management. They were concerned that blame would fall on the mayor for any unattended management of flooding hazards, even if stream management is not their responsibility. The Hydro-operators were local technicians who worked on everyday management issues, particularly current or formally associated professionals of an ASA, which are being phased out within the institutional space. Both of these latter groups observed a similar management gap of smaller streams under the jurisdiction of GAM caused by the administrative complexification of access to private land in cases where private landowners are not maintaining streambanks on their property.

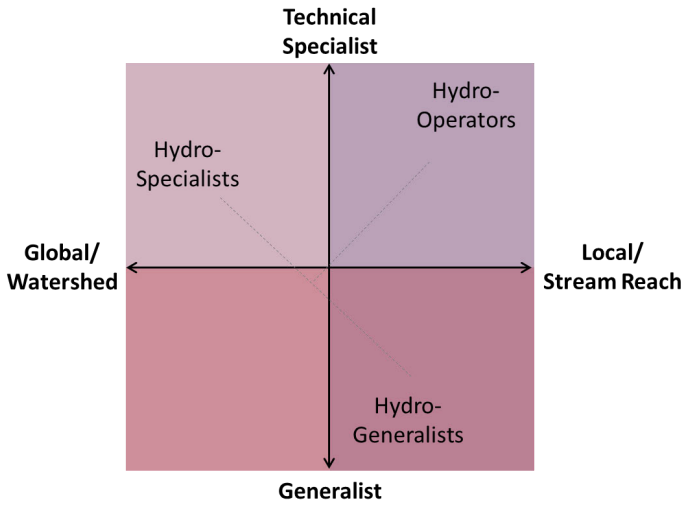

Figure 1. Orthogonal characteristics of the three perspectives identified through the Q-method. The hydro-specialist perspective of flood risk management is that of a technical specialist with a global or watershed view, the hydro-operator perspective is also that of a technical specialist but with a more stream-level view, and the hydro-generalist perspective is a generalist with an on-the-ground point-of-view.

While QM does not determine the percentages of a sample population that ascribe to a particular viewpoint, we found it striking in our analysis that a great majority of participants correlated with the Hydro-expert perspective. Our findings, therefore, revealed a large unity among the flood risk management actors of the region. However, we also noted differences in ideas between the Hydro-experts and the latter two groups, which represents friction along the 'fringe' of the body of CoMAPI actors. This raises a question of the right balance between the scale of governance and the orchestration of roles and responsibilities within an integrated flood risk management architecture under GAM. The separation of these groups reflects real or perceived insufficiency of measures in the institutional arrangement to address management issues affecting local municipalities. Efficiencies might be found at the jurisdictional scale of GAM in terms of watershed management, harmonisation in planning, and strategic investments in projects and infrastructure. However, these efficiencies need not come at the cost of incorporating issues that arise in a local context and likely require better institutional mechanisms to connect management scales from the bottom up.

2.2.2 Going deeper through interviews

While the QM study revealed friction related to the jurisdictional mismatch in the scale of roles and responsibilities between actors in charge of flood risk management and crisis management, it revealed little about the temporal aspect. To explore this further, we conducted a thematic analysis of semi-structured interviews. For this qualitative analysis, we first identified participants with current or former decision-making or policy-influencing roles in flood risk management at the scale of GAM or the greater watershed (ca. 20, based on their titles and our knowledge of their roles). Since many participants fit this profile, we used the principal

component correlations to select a more manageable sample of seven participants representing a range of views, including five representing the Hydro-experts (out of 44) and one each from the Hydro-operators and Hydro-generalists (out of 3, respectively). Specifically, we visualised the correlation values of the first six principal components (PCs) using Chernoff faces (Chernoff, 1973; Wolf, 2019), which captured 82% of the explained variance. From the facial plots, we selected a sample of participants aimed to capture a wide range of views based on their 'facial characteristics.' We explain the Chernoff faces and our selection more in Appendix A.

During the interviews, we asked a range of questions relating to the QM study statements, the participant's experience with floods and risk management, the impacts of climate change, and the evolution and needs in risk management. For this paper, we were particularly interested in the following questions asked of interviewees:

- What are your sources of information about climate change and its impacts? Do you take climate change into account in your flood management-related work? In what way(s)?
- Have your views of flood management evolved [during your career]? Do you think flood management practices, in general, have evolved [particularly in what you have witnessed during your career]?
- What do you believe is necessary to bring all the different actors within GAM to the table to work together on flood risk management? Or do you see obstacles in what already exists?

Note that the interviews were conducted in French, and relevant material was translated for this paper. The interviewees for the thematic analysis included a director associated with GAM, a president of a biodiversity association, a city resiliency leader, a mayor and a vice mayor of different municipalities, an environmental service lead for a State agency, and a former president of an ASA. All of the interviewees were well-experienced and represented a diversity of backgrounds.

3 (A)synchronicity in the temporal outlook on flood risk management

While the Q-method allowed us to identify misalignment in the jurisdictional scaling of flood risk management and crisis management, the interviews gave us insight into the misalignment of temporal aspects of management. Several aspects of temporality were revealed through the interviews, with most interviewees thinking multi-decades into the past and future to describe how that affects their daily functions or the set of flood risk management problems to tackle.

3.1 Policy myopia: A problem too abstract

Not surprisingly, climate change was well-accepted as a critical problem in flood risk management. However, no one admitted climate change was well-mobilised in flood risk management. However, some pointed to efforts, especially personal, toward learning and integrating climate change knowledge in their work. For example, this interviewee talks about the inability to take into account potential climate change impacts because of current regulations:

> [Climate change is] on the radar, and every time we work, we say "yes!" But we don't know [how to include it in our work] because the regulations don't necessarily include it...In concrete terms, the sizing of projects is based on [the flood risk prevention plan]. So even if we're worried […the project] may be undersized […], in reality, we give authorisation based on regulations that don't necessarily take [climate change] into account. – *city resilience program leader*

Similarly, another interviewee references a comparable lack of regulation and guidelines, and adds what they are doing personally to understand the subject better:

> [About the basin's master plan for water development and management] there are about ten pages of broad principles, but there's nothing else: No instructions from any ministry on the subject. No technical notes. No regulatory reflection. So, professionally speaking, apart from a few technical days organised by the Rivière Rhône-Alpes Auvergne Association or things like that, there's nothing. Then, from a personal point of view, I seek information myself. I'm thinking about taking on a trainee or a part-time employee to set up a method to suggest modelling [based on IPCC projections] without necessarily imposing it on project managers. – *state agency head of environmental services*

Nair and Howlett (2017) aptly refer to the concept of 'policy myopia,' where long-term uncertainty is not adequately incorporated because short-term certainty is better known and understood. This myopia may contribute to or reinforce the institutional and cultural inertia that upholds the status quo, even when flood risk managers see the importance of taking a longer-term view.

Reflecting on the past was, in some ways, easier for interviewees because of lived and learned experiences. One interviewee suggested that experiencing or seeing major climate change-related flood disasters has served to increase awareness and can change perceptions strategies needed for better flood risk management:

> Our colleagues in planning today are much more aware than they were 10 years ago […] At one point, the departments, or rather the various players, were somewhat in denial about the risk. I also think well-known tragic events may have changed their perception, like [Cyclone] Xynthia and what happened in Germany last year [2021]. – *metropolitan director of environment and public services*

The same interviewee also pointed out that an ironic barrier to improved flood risk management in GAM is the lack of recent disastrous flood events. Similar to the concept of the 'dike paradox' (Vinet, 2008; Haer *et al.*, 2020)—an expression capturing the irony of flood protection infrastructure encouraging development in flood-prone areas—the interviewee suggests a lack of historical memory of flooding leads to a sense of security, creating an absence of risk culture:

> You might find it strange, but I think the biggest obstacle we have, locally, is that the last [major] flood was in 1859, which is not on the scale of human memory. When there are recurrent floods, the knowledge of the risk is maintained, and no one questions the

> wisdom of taking any measures...people don't realise that rivers can be devastating here. – *metropolitan director of environment and public services*

These ideas suggest that even with technical knowledge of climate change impacts or historic flooding, a long-term view can become too abstract without proper support structures or mechanisms to incorporate this knowledge. In other words, technical and scientific knowledge of long-term flood risks will likely be underutilised when it exists within social, political, and institutional structures that favour the certainty of a short-term view. Some interviewees alluded to elected officials either helping or hindering climate change adaptation, however, there was a sense that the lack of ability to mobilise adaptation strategies was beyond their control.

3.2 Systems Inertia: A (frustratingly) slow evolution toward (hopefully) better

The interviewees' outlook often reflected expressed or muted emotions when recognising their professional role within a larger system beyond their control. On one hand, they found it frustrating when they perceived inaction or slow change. On the other hand, most could also identify positive outcomes that gave them a certain level of hope, which seemingly motivates their continued work:

> It's complicated [and slow]. But we're getting there. Well, [more like] we're going. When you see the people who work on floods in local authorities, syndicates, etc., there are many young, super-trained, super-savvy people […] Among the technical-administrative intermediaries, I find that the overall level is super good with really committed people who believe in [climate resilience] and think transversally, horizontally. However, action takes time because [there is] a heritage, an inertia. But, yes, it's changing in the right direction. – *city resilience program leader*

In this sense, as with the concept of path dependency, a long, sometimes invisible, history can have a huge impact on the current possible trajectories. Like the law of physics, Mahoney (2000) describes social inertia as processes that are set into motion towards a particular outcome that stay in motion and continue to track that outcome. Many processes embedded within social-infrastructural systems add to inertia, thus creating a perception of slow and incremental change and tension in the aspects of time incongruency. On the one hand, there is a stagnant viscosity to the reality, while on the other, there is an accelerating desire for change.

3.2.1 Technical limitations to adaptation: Do what can be done, where it can be done

Several case studies explore the concept of inertia as an impediment to climate adaptation action. One common finding is the persistence of traditional engineered approaches in institutional cultures and development regimes of territories (Harries and Penning-Rowsell, 2011; Meng *et al.*, 2022; Robert, Quercy and Schleyer-Lindenmann, 2023). In GAM, there was a similar sentiment expressed by some interviewees that the urban fabric cannot easily accommodate changes:

> The problem we're facing isn't that we don't know what needs to be done; it's that we're intervening in a city that's already built up, and the main problem is that the rivers have been corseted; they don't have enough space. Now we have to make do, or more that it's

> complicated to give them more room to roam. The Isère Amont [upstream restoration project] is typically about giving space back to the river. Although the structures are very man-made, they still reflect the idea that you have to let the water spread out so that it doesn't cause as much damage downstream. – *metropolitan director of environment and public services*

Another technical obstacle that slows progress relates to the sheer magnitude of expenditures needed for even minor adjustments to water or wastewater infrastructure networks. These infrastructure assets have a value on the order of magnitude of multi-billion euros and have been built over centuries. Therefore, as one interviewee explains, spending €10 million a year on water or wastewater infrastructure improvements touches only about 1% of the infrastructure. Thus, climate resiliency actions—as interpreted by several interviewees—need to include efforts to 'live with flooding' or reduce its destructive capability when there is an event. For example, ensuring that ground-level floors are floodable in exposed areas. Additionally, elevating less 'fixed' infrastructure, such as telecom equipment and cables, can help reduce vulnerability.

Many interviewees referred to the problem of surface artificialisation adding to the flood risk. There was a widespread agreement that "pouring concrete" needs to stop, and the cities need to de-artificialise or re-permeabilise developed areas. Several interviewees connected the idea to concepts of being "more ecological" or "green." Specifically, one interviewee had a tightly integrated view of managing climate and biodiversity. In urban areas, creating greater opportunities for biodiversity while improving climate resilience:

> We're working with our partners to integrate biodiversity; to create a city where nature is part of the design, such as de-impermeabilising (sic) and buildings with native plant garden programs to make them better adapted to climate change. – *local chapter president of a national environmental protection association*

As this same interviewee pointed out, climate change impacts also create technical limitations in managing mountain spaces for either flood risk management or biodiversity. For example, climate change impacts in the mountains, including changing snow altitude, changes in snowfall timing, increased fire impacts, and higher temperatures, are already putting certain species at risk and impacting flood risk. However, no further mitigation can be done at some point, whether it is species loss or hydrological changes.

3.2.2 Institutional stagnation: Bureaucratic delay and knowledge loss

Across the board, interviewees expressed a general 'slowness' in implementing flood risk management projects or strategies, with one interviewee alluding to a tanker needing to turn. Often, scales referenced in terms of waiting to 'get something done' are on the order of decades. This institutional slowness was rightfully a source of frustration for the interviewees. While it is undeniable that institutions are incorporating climate resilient flood risk management practices at a slower rate than managers would like to see and the rapid pace of climate change. However, what is unclear from the interview discussion is how much of the slowness is a tactic to either kill a project or avoid public or political scrutiny. Some interviewees directly pointed to a "political blockage" to implementing projects or better strategies:

> Something that might work on the technical side can be completely swept away because the two elected representatives are tense. We [on the technical side] don't feel it too much because we're dealing with a subject that's quite well agreed upon […] In a lot of departments, sometimes they've worked for six months setting up a project and then at the last minute, it's scratched. When it comes to collaboration […] the political issues must be ironed out. – *city resilience program leader*

In another example, an interviewee recounted a sediment removal project with the State and indicated being dismissed when they suggested that the amount of sediment removed was insufficient for getting ahead of a problem:

> It's annoying because we don't go any further than the existing problem. In other words, we're not going to solve the problem. We're going to wait and see. – *former president of an ASA*

Regarding collaboration on flood risk management, CoMAPI is supposed to serve that role for GAM, with GAM as the coordinator. However, several interviewees expressed dissatisfaction with the role that CoMAPI plays, suggesting that its role is somewhat ineffective in consulting, knowledge mobilisation, and collaboration. For example, this interviewee specifically talks about the CoMAPI meetings:

> I get the impression that the meetings are much more focused on sharing information than consulting actors. What is lacking and what, in my opinion, is difficult to implement are real consultation committees between the various parties responsible, i.e., the municipalities, GAM, and the State. – *former president of an ASA*

An issue that seemed to be circulating among several interviewees with more local roles, and similar to what we found in the QM study, was the idea that GAM is not organising well with the municipalities to incorporate on-the-ground realities into their flood risk management responses:

> For me, GAM needs to step up and better involve the municipalities. Because [municipalities are] the first point of contact locally. Also, everything passes through a municipality, local knowledge and so on. – *mayor of a municipality*

Another interviewee elaborates on the history of this relating to the transfer of responsibilities from the ASAs to GAM, resulting in a loss of information and confusion about roles and responsibilities:

> Flood protection disappeared when the responsibility was transferred to [GAM…] For a long time, people thought [GAM] would [maintain the streams and torrents]. Whereas that is not the case […] As a result, the owners no longer know where they stand when there's a problem or who they should call. There's a loss of communication, a loss of information. Yes, a very significant loss of information because I sincerely believe that homeowners no longer know who's looking after what. – *former president of an ASA*

While CoMAPI offers an important structure for collaboration, there seem to be aspects that could be improved to address these issues raised. However, the question is, at what cost? This interviewee aptly describes the reality that effective collaboration requires time, and time is costly:

> When [collaboration] works, you can't see it, but it takes up a huge amount of time. Organisations don't think about coordination time. For me, it's more of a global thing: If we want people to work together, we need to make it something we can quantify and pay for. – *city resilience program leader*

On the one hand, the frustration over the slow pace of implementing projects and acting toward climate-resilient strategies was palpable among the interviewees. There was an across-the-board agreement that better collaboration is needed (partly prompted by an interview question), especially to have more holistic management of flood risk and to mobilise on-the-ground knowledge. However, the time outlays of such solutions are rarely considered. In other words, effective collaboration also requires a significant investment of time (Renou *et al.*, 2024), and although it might lead to better management outcomes and is needed to address certain issues, spending more time on collaboration would be unlikely to assuage the perceptions and criticisms about slow implementation.

3.2.3 The movement of ideas: Optimism in turnover

While thinking about present-day obstacles might have prompted a sense of frustration for the interviewees, asking them to reflect on the changes they have seen during their careers tended to expose an optimism in the ability to actually enact some of the changes that they would like to see toward climate resilience and better connecting flood risk management to environmental management.

> From what I've seen, there's been a generational shift. With the 'resilience label'—which you can criticise—I saw a shift from those who said, "We'll be able to prevent it" to those who said, "In fact, it's going to happen." And that, for me, really changed the perspective and the way we acted. – *city resilience program leader*

However, from the experiences recounted, there seem to be many layers of interconnected processes, some of which have changed and others which have not. The above quote refers many to ideational shifts, which they then describe as "percolating slowly" into how flood risk management is handled even though the generational shift was "noticeable." This was similar to another interviewee:

> We have a rich history in the Isère, but a lot has changed in 10 years. However, my perception of the issues and my technical perception have changed relatively little. In other words, I'm convinced we must include as much [environmental management] as possible in our policies. – *state agency head of environmental services*

Even those who are impressed by the changes (generally, the younger interviewees) admit that much of the technical knowledge has remained the same for the last 20-30 years. The

descriptions indicate the significant role that political and social values play in flood risk management, even when it is viewed as a technocratic exercise.

However, not all changes within the evolution of flood risk management were viewed as positive. For example, one interviewee talks about some of the changes and events they've witnessed during their career as clearly climate change-related. At the same time, at other times, they have been unconvinced about whether an event was linked to climate change or lack of maintenance. They give a specific example of when they were younger, there were road maintenance workers; now, they do not exist, and they see that the drainage backs up quickly leading to flooding. These issues relate to the previous section, the loss of information, and the lack of a mechanism to mobilise on-the-ground issues to the level of GAM. While the evolution that most interviewees referenced relates to institutionalising widely accepted concepts, such as holistic and integrated management, it is important to realise that this change in the institutional structure has also led to the loss of other institutional structures that served a critical function.

4 Conclusion

In this paper, we investigated the spatiotemporal aspects of flood risk governance to understand the alignment (or misalignment) of spatial and time scales needed to continue to manage evolving flood risks. Our study took place in the Grenoble metropolitan area of France, where we explored how flood risk managers considered spatial and temporal scales in their work missions. The investigation was conducted in two parts. The first uncovered scaling issues using the Q-method, which helped identify tensions related to scaling management actions and jurisdictional boundaries. Overall, this highlighted the need for better knowledge mobilisation between actors at the local and watershed level, and better distribution of roles between risk management and crisis management. A deeper exploration via seven interviews of policy influencers of diverse backgrounds highlighted some of the ways in which temporality comes into play (or not) in flood risk management. Our analysis suggests a misalignment between policy actions and long-term objectives. This misalignment is exacerbated by myopic policy decisions, which favour short-term certainty even if technical solutions are known. The study also highlighted the persistent issue of systems inertia, where technical limitations, slow institutional responses, and ideational stagnation often impede progress towards more climate-resilient flood risk management. Despite these challenges, the interviewees were generally hopeful for the future as they recounted changes seen during their careers with shifts in thinking and adopting new approaches.

Drawing lessons from the findings, there is a subtle recognition of the importance of investing in the less tangible aspects of flood risk management such as relationships and knowledge mobilisation, instead of solely focusing on material or institutional structures. Often, seeking an alignment of spatial aspects in flood risk management can dominate the dialogue when the alignment of temporal aspects is also critical, even though aspects of time add more uncertainty to already challenging management issues. This raises the crucial question of how 'time' can be integrated as a more common factor in the collective retrospective and prospective views of flood risk management as an approach to better adapting to wicked problems.

Acknowledgements

This work is part of a collaboration between the Université Grenoble Alpes and the Grenoble Alpes Métropole, the Metropolitan authority of Grenoble conurbation (deliberation 12 of the Metropolitan Council of May 27, 2016). Part of this work was funded by the IND-EX project with the support of the Auvergne Rhône Alpes Region in France.

Appendix A

As a visual aid for selecting the seven participants for this study, we used a plot of Chernoff faces. Figure A1 shows the facial outputs according to the first six PCs and the seven selected participants. Chernoff's faces are a method to visualise multivariate data in a form that is more relatable for the human mind than graphical plots and can be used as an aid in discrimination analysis, for example. Chernoff faces use the PC correlation values to modify facial characteristics. For example, we associated PC1 with head shape, meaning Q-sorts with the highest PC1 correlation values show larger, blockier faces. Meanwhile, low correlation values show smaller, rounder faces. Using Chernoff faces to visualise the Q-sort data provided us with a more objective way to select interviews for this exploratory study rather than selecting based on our prior interactions or connections to the participants. For example, of the participants that

fit the profile, we tried to ensure that there was a range of nose sizes to capture the range of views comprising PC5.

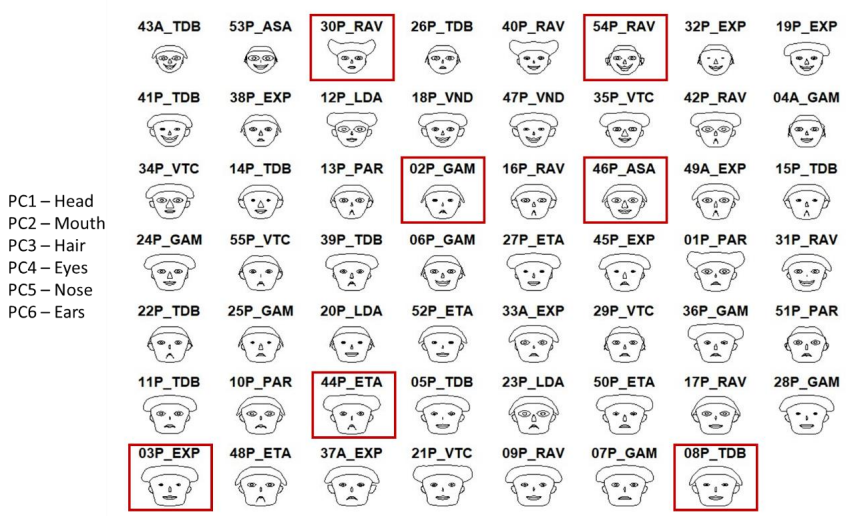

Figure A1. Mapping of Chernoff faces based on the correlation values to the first six principle components. For this paper, faces highlighted are participants selected to investigate the temporal aspect of flood risk management.

RISK MANAGEMENT FOR URBAN HERITAGE: THE CASE OF IZMIR

Abstract

Risk management for cultural heritage is a significant issue in conservation and management studies. The Convention Concerning the Protection of the World Cultural and Natural Heritage states that ensuring a good state of conservation of the property is a requirement for inscription on the World Heritage List. This paper aims to develop a preliminary site-specific methodology for the urban heritage, the case of historic centre of Izmir, which is the management site of the Historical Port City of Izmir in the Tentative List from 2020. Although risks are diversified, the scope of this paper is limited to physical risks affecting the spatial environment. The site-specific methodological approach is constituted based on key sources of ICCROM and UNESCO and adopted for the urban heritage of Izmir.

Keywords: Risk Management, Cultural Heritage, Historic Centre, Izmir, Historical Port City of Izmir

1. Introduction

"Cultural heritage is always at risk" states Stovel (1998, p.17) in *Risk Preparedness: A Management Manual for World Cultural Heritage*, one of the earliest noted sources in risk management for cultural heritage. Stovel (1998) explains principles including importance of advance and integrated planning not just for buildings but also for associated context and landscapes, adopting preparedness requirements compatible with conservation principles, and inclusion of users in the process of planning. He draws a planning framework as preparedness, response and recovery phases for the risks of fire, earthquakes and related disasters, flooding, armed conflict, and other hazards.

Managing Cultural World Heritage (2013) is a significant resource manual, mentioning risk preparedness is one of the key considerations for the management system. In the context of risk management, *Managing Disaster Risks for World Heritage* (2010) is the specific resource manual published by UNESCO. The manual states that disaster risk management (hereafter DRM) should be an integral part of a site management plan and linked to local, regional, and national management systems. DRM plan is designed to eliminate or mitigate negative impacts of disasters on heritage values, which is outlined in statement of Outstanding Universal Value (OUV). The DMR plan is consisted of three phases, namely before, during, and after disasters (Figure 1). For each phase, the manual determines relevant studies to be followed.

With a similar approach, *A Guide to Risk Management of Cultural Heritage* (2016), prepared by ICCROM, Government of Canada, Canadian Institute, provides a scientific model and methodology for risk elimination and assessment for cultural heritage. Risk Management is a future oriented and continuous study, which has six main steps: context, identify, analyse, evaluate, treat, and monitor (Figure 2).

For the case of Izmir, there are several noted sources. *The Provincial Disaster Reduction Plan (called IRAP in Turkish)* is prepared by Izmir Governorship Provincial Disaster and Emergency Directorate in 2021. For the whole province, earthquake and tsunami, landslide and rockfall, flooding, industrial facility accidents and CBRN events, fire, disasters due to meteorological events and climate change, medical geological disasters and pandemic diseases are assessed, evaluated and mitigation strategies are presented.

The Historical Port City of Izmir Site Management Plan (2022-2027) defines the heritage sites with diversified values, historical background, social and economic structure, current management system and other relevant plans on the site. The plan with a vision of "The port and trade city of the eastern mediterranean, the beautiful Izmir's multi-layered cultural heritage created by the effect of co-existence will be conserved, sustained and promoted" introduces guiding policies, sets goals and an action plan. The Goal 5, "Risk management of the historical port city of Izmir will be activated", describes necessary actions to be taken regarding both physical aspects and social and economic issues in risk management.

The recent project, *Developing Risk Management in the Historical Port City of Izmir*, aims to develop a study methodology specific to the site with the participation of relevant stakeholders. This ongoing study is also in line with this paper, which is constituted based on the research question of *how to develop a methodologic approach for risk management for the historic centre, specifically for the case of urban heritage of Izmir*. Hence, the study focuses on before any disaster event, risk preparedness and mitigation activities that deal with hazards affecting the built environment, which are earthquake, flood, fire, landslide and rockfall. Although, social and economic risks are significant aspects of the Site Management Plan, they are not in the scope of this study.

For this purpose, based on the main steps clarified in the key sources published by UNESCO and ICOMOS, a case study is conducted. Specific data for the case of urban heritage of Izmir are gathered from diverse sources, mainly the key sources mentioned previously. The data are analysed and evaluated with thematic maps prepared via CAD (drawing) software. Afterwards, preliminary strategies for risk identification, reduction, monitoring and revision processes are determined.

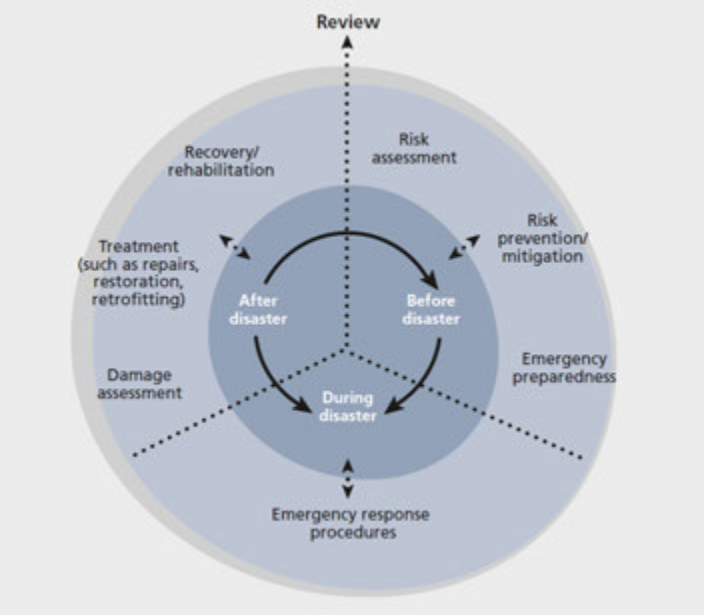

Figure 1: Disaster Risk Management Cycle

Figure 2: Risk Management Cycle
(Source: A Guide to Risk Management of Cultural Heritage, 2016; p.15)

2. Scope and Context

Izmir, located on the Aegean coastal area of Türkiye has been a significant settlement and cultural hub in the Mediterranean Basin since Neolithic ages. The story of the Historical Port City Izmir is consisting of three different areas and diverse periods of Izmir, one of which are the oldest Izmir established in Yeşilova and Yassıtepe mounds from Neolithic period, secondly as Old Smyrna, during the next period called Hellenistic, and the third Izmir as the historic urban centre living around 2500 years (Figure 3).

Cultural significance of the Historical Port City of Izmir mainly based on its location on Bornova plain near to the Gulf of Izmir, interaction with the sea and trading activities in the Mediterranean basin with diversified routes throughout the history. Meles River on the eastern site of the management area, the Gulf of Izmir on the west, and Pagos Hill on the eastern south are natural edges of the historic urban centre.

Figure 3: Historical Port City of Izmir

The site has been conserved and managed based on conservation master plans and the Historic Port City of Izmir Site Management Plan (2022-2027), and faces various hazards such as earthquakes, fires, floods, landslides, and climate change, as well as social and economic risks. Under the Goal 5 of the management plan, specific targets, and actions are determined to eliminate, mitigate, and adopt these risks.

This study is in line with the site management plan but focuses on the historic urban centre and physical risks affecting the spatial environment. To clarify the scope and context of the study, values and cultural characteristics of place, present state of conservation, and stakeholder participation strategy are explained as follows.

2.1. Values and Cultural Characteristics

The historic centre of Izmir is a multilayered heritage and continues its formation. The city was established on the layers of Smyrna Ancient City of Hellenistic times, later formed as a traditional Ottoman city with a bazaar, afterwards as a modern city with national architectural elements, and today as a living heritage place with diverse cultural values. The historic urban centre has diverse cultural characteristics and can be conceptualised in different character areas (Figure 4):

1. Coastal Areas: This area gives the main characteristic of a port city, the coastal site as an interaction place of historic city centre and the gulf. The pier was constructed in the Ottoman period and significantly increased trading activities and led to modernization of the city. The rectangular narrow parcels facing to the gulf presents a modern urban layout. A modern port system, a customs house, ferry terminal, bank, commercial and residential buildings give characteristic of the area. Between Pasaport Ferry Terminal and Konak-Pier custom house, the original pier line of the Ottoman times has survived today.

2. Mimar Kemalettin Modern Bazaar: Covering the architectural elements of Ottoman Period, the area is a commercial zone of modernization period. Buildings with corner towers, corner entrances, window layouts changing in each floor, horizontal and vertical window mouldings, tile panels, reliefs and carved ornament motifs, and wide eaves (Aslanoğlu, 1980) are typical features of the area. The stock exchange building, old Greek National Bank, Kardiçalı Khan are among characteristic buildings in the place.

3. The Historic Kemeraltı Bazaar: This Ottoman bazaar is one of the biggest bazaars in the world, covering an area approximately 270 hectares. The bazaar was constructed with the infilling process of the ancient inner harbour between 16th and 19th centuries (Beyru, 1992). The urban morphology of the bazaar, composed of commercial parcels and gated khans in the narrow and long streets leading to the pier area, is largely preserved today. The five mosques, which are named as Hisar, Kemeraltı, Şadırvanaltı, Kestane Pazarı and Başdurak are located in Anafartalar Street, which is the main axes presenting shoreline of the ancient harbour.

   Trading activity, both from sea and land routes shaped the urban fabric. For instance, fevkani mosques were constructed to accommodate commercial activities, and khans were designed to provide storage, accommodation, also passageways between streets. Unlike the typical foundation-based approach seen in other Ottoman settlements, the khans in the bazaar were erected through a collaborative effort among merchants, reflecting a unique social model in this vibrant trading hub. Public squares, khans, passages, bazaars, and business centres, mosques, synagogues, hotels, hammams, sebils, and shadirvans, are among cultural heritage components of the living bazaar.

4. Public Administrative Facilities: Konak Square is the historic administrative centre of Izmir. The square and coastal shore are located on the infilled area, which was an ancient harbour in the 16th century. The Clock Tower, the Governor's Office, Izmir

Metropolitan Municipality Area[1], and Yalı Mosque, all together compose the administrative node. Close to the square, Elhamra Cinema and National Library, Gureba-i Muslimin Hospital and Beyler Streets are located, which contributed to public facilities of the area.

5. Trade, Production, and Storage areas of Kestelli: Adjusted to the Historic Kemeraltı Bazaar, the area covers trade, small production, and storage uses. The building typology is also similar to the historic bazaar.

6. Residential Quarter of İsmet İnönü Street: The residential quarter adjusted to historic Kemeraltı Bazaar. Two-storey Izmir houses with a basement, staired street in İsmet İnönü, mansions with decorated façade and interiors are significant features. These residential quarters functioned as houses for those working in Kemeraltı Bazaar. Mosques, churches, synagogues, hammams, sebils, shadirvans, and fountains are components of the residential areas.

7. Residential Quarter of Damlacık: The area is a vista point on the upper elevation. The area has a residential characteristic with limited registered buildings, close to the open green area of Cicipark.

8. Basmane Train Station and Environs: Basmane Train Station and environs is a gateway and transit point, connecting the city with its hinterland and welcoming people coming to the bazaar via railway or caravan in the past. Nearby, there are hotel regions, where Izmir houses were transformed into accommodation facilities. Basmane Train Station, hotels along hotels street, and train station warehouses behind the station gives general characteristics of the area.

9. Residential Quarter of Basmane: Basmane quarter at the east of İki Çeşmelik street is the main residential quarter of the historic city. In the past, mainly the Turkish population and Jewish population were settled in this area. Dead ended street and organic pattern, two storey Izmir houses, and a few conserved *cortijo* houses (shared housing units for collective living, built by Jewish people in the Ottoman time) are characteristic spatial organisation of the area.

10. Components of Smyrna Ancient City: The historic urban centre is a multilayered cultural heritage and Smyrna Ancient City gives the overall ancient layer. Smyrna Acropolis, Smyrna Agora, Smyrna Theatre, Harbour Bath, and the ancient residential area Altınpark are seen in todays' living heritage place. Some parts of trade pathways are also still visible. The modern İki Çeşmelik street and the Roman road is the cardo maximus, while Anafartalar street is decumanus maximus in Roman period. Although the wideness of these street changed in time, the route and several remains have been conserved. Significantly, Caravan Bridge on Meles River has been conserved with its form and still sustains its function.

[1] Izmir Metropolitan Municipality building was located in this area previously. However, the building was damaged due to the 2020 Aegean Sea earthquake and demolished in 2023. The metropolitan municipality announced plans to build a monumental metropolitan building in this area, based on an architecture project competition. (https://sehirmeclisleriyarismasi.Izmir.bel.tr/yarismanin-amaci.html, Access in 31.03.2024)

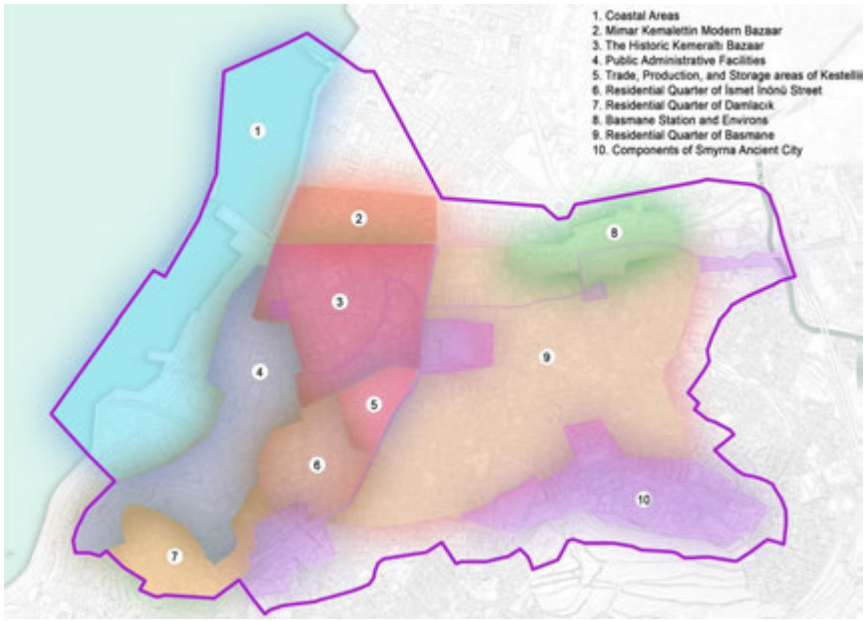

Figure 4: Values and Characteristics of Historic Centre

2.2. State of Conservation

The historic centre of Izmir is also determined as a management site in the legal framework. The management site is 372.40 hectares and is composed of diverse categories of conservation areas, which are Urban Conservation Areas, Historical Conservation Areas, Archaeological Sites, Natural Sites and Urban Archaeological Sites. Almost half of the management site is registered as Urban + 3rd Degree Archaeological Conservation Area (Table 1, Figure 5).

Table 1: Conservation Areas in Management Site (prepared based on source: The Historical Port City of Izmir Site Management Plan, 2022, p. 30-31)

Conservation Areas	Size (ha)
Urban + 3rd Degree Archaeological Conservation Area	167.10
Urban Conservation Areas	8.34
Historical Conservation Areas	80.59
Archaeological Conservation Areas	38.86
Natural Conservation Areas	8.98

Besides, there are 1730 registered cultural properties, including 1153 examples of civil architecture, 371 industrial and commercial buildings, 60 religious buildings, 59 cultural buildings, 52 administrative buildings, 13 archaeological remains, 7 water structures, 4 cemeteries, 4 monuments, 3 military buildings, 2 streets, and the Port Bath-Gymnasium structure. Moreover, the Historic Kemeraltı Bazaar covers 13.1 hectares of urban and archaeological conservation sites and includes 403 registered cultural assets.

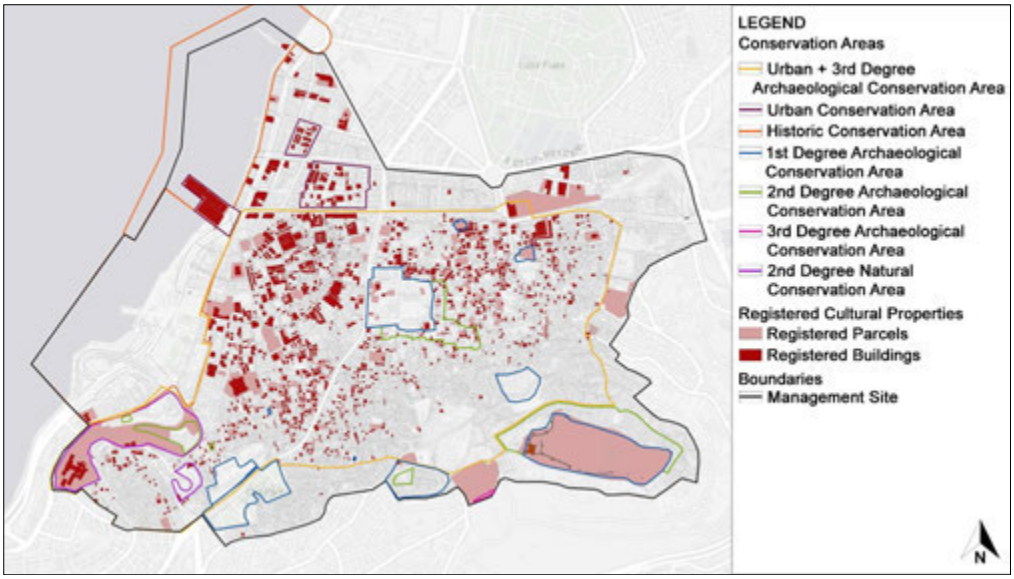

Figure 5: Conservation Areas and Registered Buildings
(prepared based on source: The Historical Port City of Izmir Site Management Plan, 2022)

2.3. Stakeholders

The stakeholders are categorised as public authorities of central and local governments, universities, professional chambers, NGOs, local community, authorised public-private partnership, and private sectors serving public services.

Public institutions hold the main responsibility in conservation and management. Universities in Izmir province are significant actors to improve knowledge about the site and conduct research on the site. Professional chambers both represent professions' perspective and monitor activities on the site for the public. Non-governmental organisations mainly comprise trade unions and sustain communication among tradesmen, both owners and renters of shops. Authorised public private partnership conducts projects mainly on restoration of buildings with other partners. Several companies provide public service of electricity at local level.

For disaster risk management, public authorities, NGOs, companies providing public services, and authorised public private partnership are determined as stakeholders who are to be worked in collaboration, provide advisory, and required data including statistical information. Universities and professional chambers are defined as stakeholders who provide advisory. Local communities are main users of the site, including headmen, tradesmen, and visitors. All stakeholders are also responsible for informing the public and involve in risk management studies (Table 2).

Table 2: Main Stakeholders in Risk Management and Participation Strategy

Institution		Key Duties	Strategy
Public Authorities	İzmir Governorship	Provincial Civil Supervisor	Collaboration, Advisory and Data
	İzmir Provincial Directorate of Disaster and Emergency	Disaster management planning, general coordination on emergency situations	
	Izmir Provincial Directorate of Environment and Urbanization	Built environment, urbanization	
	İzmir Provincial Directorate of Culture and Tourism	Conservation of cultural heritage	
	İzmir No. 1 Cultural Properties Conservation Regional Board	Conservation of cultural heritage	
	Directorate of Smyrna Ancient City Excavation	Conservation and scientific research	
	İzmir Development Agency	Financial support, local development	
	2nd Regional Directorate of Turkish State Meteorological Service	Weather forecast, notice	
	İzmir Metropolitan Municipality	Provincial public services	
	Izmir Provincial Police Department	Rescue in emergency	
	Provincial Gendarmerie Command	Rescue in emergency	
	Konak Municipality	District public services	
Universities	Dokuz Eylül University	Scientific research	Advisory
	Ege University		
	İzmir Institute of Technology		
	İzmir Katip Çelebi University		
	İzmir Democracy University		
	Yaşar University		
Professional Chambers	UCTEA Izmir Provincial Coordination Board	Public monitoring and information	Advisory
	Chamber of Architects İzmir Branch		
	Chamber of Landscape Architects İzmir Branch		
	Chamber of Geological Engineers İzmir Branch		
	Chamber of City Planners İzmir Branch		
NGOs	Union of Chambers of Tradesmen and Craftsmen of İzmir	Trading activities	Collaboration, Advisory and Data
	İzmir Historical Kemeraltı Tradesmen Association		
PPP	Historical Kemeraltı Construction Investment Trade. Inc. (TARKEM)	Conservation and restoration	
Public Service Companies	GDZ Electricity Distribution Joint Stock Company	Public service	
	Türkiye Electricity Transmission Inc. 3rd Regional Directorate	Public service	
	Türkiye Electricity Distribution Inc. 12th Regional Directorate	Public service	

3. Identifying Risks and Presenting Mitigation Actions

The historic centre of Izmir is both susceptible and exposed to the risks of earthquake and tsunami, landslide and rockfall, fire, and flood. To identify risks, statistical data of past disasters and emergency response preparedness on the site at present are analysed. The frequency of disasters is also indicated.

3.1. Earthquake and Tsunami

The Gulf of Izmir and its surroundings are full of intense fault lines; thus this region is identified as "magnificent seismological area" (MTA, 2005). According to Earthquake Hazard Map of Türkiye, prepared by AFAD in 2018, Izmir provincial area is located in the red zones with a high probability of earthquake hazard prevails (Figure 6), experiencing earthquakes with the magnitude of 6, in every ten years (Uluğ, 2017).

The fault lines which potentially affect the centre of Izmir are the Karşıyaka fault line of 35 km (Çiğli-Bostanlı-Karşıyaka Bornova) at the north and the Izmir fault line of 40 km (Güzelbahçe-Narlıdere-Balçova-Izmir centre) at the south. Besides, Gülbahçe (Karaburun fault), Uzunada, Seferihisar (from Gulf of Sığacık to Güzelbahçe) and Tuzla (from west of Kuşadası Bay to Orhanlı-Gaziemir-Izmir centre) fault lines have potentially effects on the city. Each fault line is considered to have a possibility of creating an earthquake with 5-6 magnitude (Izmir Metropolitan Municipality, 2020).

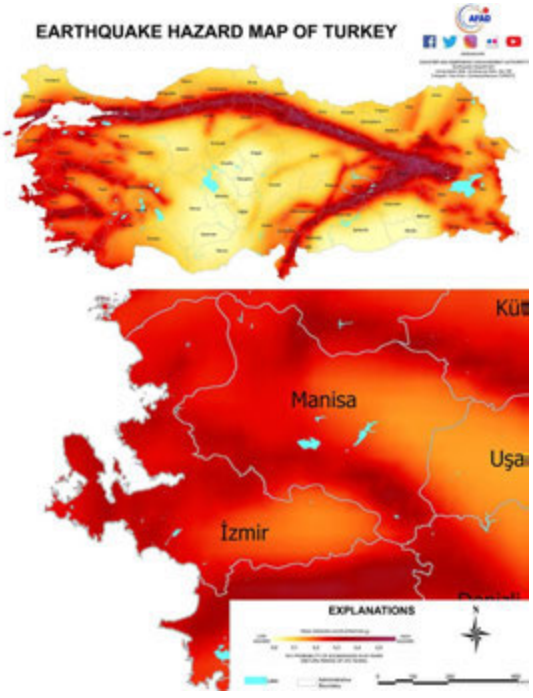

Figure 6: Earthquake Hazard Map of Türkiye and Detail of Izmir
(illustrated based on the source: AFAD, 2018)

The ground condition is also significant for settlements where earthquake seismic waves can be felt and highly affected. Depending on the general tectonic structure of the Aegean Region, the Gulf of Izmir and its surroundings are located in a depression zone where the opening regime still continues. Hence, the region is under the influence of faults, some of which that cannot be monitored from the surface may cause earthquakes. The coastal areas, where mostly settled, are composed of young sedimentary alluviums (İzmir Metropolitan Municipality, 2018).

The Historic Kemeraltı Bazaar and environs were formed with the filling of the inner harbour of ancient times, which was a process spanning 400 years (Beyru, 2011). Different periods infilling processes with alluviums, from antiquity to the 19th century not only changed the urban morphology but also cause more vulnerable ground conditions.

The carrying capacity of these areas is quite weak, magnifying seismic waves several times above normal. More critically, the ground might have high liquefication probability, creating very adverse conditions for the settlements (Uluğ, 2017). Earthquakes trigger soil layers, causing to softening and loss of strength. Similarly, liquefaction is the loss of the bearing feature of the ground due to dynamic effects. Liquefaction events in soil are mostly observed in water-saturated coarse-grained soils, such as coastal areas (İzmir Metropolitan Municipality, 2018).

Although detailed surveys are needed to identify ground conditions, assessments based on previous studies (İzmir Metropolitan Municipality, 2018) shows that the historic city centre of Izmir is located on risky ground, and high and middle probability of liquefaction (Figure 7).

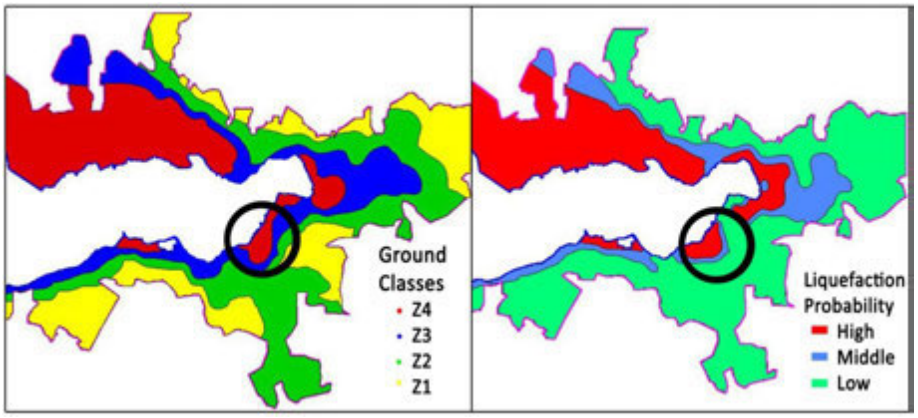

Figure 7: Ground Classes and Liquefaction Probability
(illustrated based on source: Izmir Metropolitan Municipality, 2018)

The major earthquake events that occurred since the 1900s and affected Izmir are analysed (Table 3). It is seen that earthquake events occurred around Aegean Sea, Karaburun-Chios, Lesbos-Doğanbey-Sisam affect Izmir. When the magnitude of the earthquake was around 5, buildings were damaged. While the magnitude is around 6, it causes mainly casualties and the collapse of buildings. Also, tsunami events occurred as secondary hazards when the magnitude was higher than 6.5, around the coastal areas of rivers or Aegean Sea in 1955 and 2020 (MTA, 2005; MTA, 2020; Izmir Governorship Provincial Disaster and Emergency Directorate, 2021; AFAD, 2024).

It is also known that settlements at the coastal zone of Aegean Sea and Eastern Mediterranean Sea are located at the riskiest areas regarding tsunami, mainly due to Hellenic and Cyprus subduction zones. For instance, the 2020 dated Aegean Sea Earthquake was followed by a tsunami at south of Izmir, reaching 200 meters distance according to witnesses. Historically, a tsunami with magnitude of 5 occurred on the coast of Izmir. Tsunami waves up to 5 metres high may reach to the southern part of Türkiye, which also affects Izmir (Izmir Governorship Provincial Disaster and Emergency Directorate, 2021).

Since, there are 44 earthquake monitoring stations in Izmir (İzmir Governorship Provincial Disaster and Emergency Directorate, 2021). Seismic Microzonation studies are ongoing by the Izmir Metropolitan Municipality to determine exact locations of fault lines (Izmir Metropolitan Municipality, 2023).

Table 3: Major Earthquake Events in and around Izmir in last hundred years
(prepared by the authors based on MTA 2005 and 2020; Izmir Governorship Provincial Disaster and Emergency Directorate, 2021; AFAD, 2024)

Date	Time (UT)	Latitude (N)	Longitude (E)	Depth (km)	Intensity (Io)	Magnitude (M)	Note
19/01/1909	04.57	38	26.5	60	IX	6	**Foça Earthquake** Centre: Around Güzelhisar, Menemen and Foça districts Casualties: 8 people died. Collapse of 700 houses, damage to 1000 houses

3.2. Landslide and Rockfall

Landslide hazard is seen around the southern part of Kadifekale's slopes, and rockfall is seen northwest of management area boundaries in Kocakapı district. Landslide and rockfall risks are related to geological formation of soil, geological features, and also effects of water, flooding and earthquakes.

Eastern part of Meles River is covered with clayey marl and tuff, and Neogene limestone on the top, and slopes of Pagos hill is covered with andesite (Figures 8, 9, and 11). Gecekondu buildings are located in these areas in general. The steep slope is also damaged due to water from surrounding houses. Thus, Kadifekale and its surroundings were declared as "Disaster Exposure Area" due to landslide risk and should be afforested with the decisions of the Council of Ministers in 1977, 1981, 1998, 2003, and 2013 in order to prevent the landslide risk (Figure 10) (Izmir Governorship Provincial Disaster and Emergency Directorate, 2022).

The area in Kocakapı district is andesite, and rockfall event occurred at nearby outcropped clay schist, where rainwater causes degradation of clay shales and steep cliffs to slide. This area was declared as a "Disaster Exposure Area" due to rockfall with the decisions of the Council of Ministers in 1981 (Figure 10) (Izmir Governorhip Provincial Disaster and Emergency Directorate, 2018).

The landslide hazard is driven by earthquakes or rainfall. The landslide susceptibility shows that southwest of the historic urban centre is under moderate and high degree of landslide susceptibility, while Kadifekale and its southern part are under susceptibility degree (Figure 8).

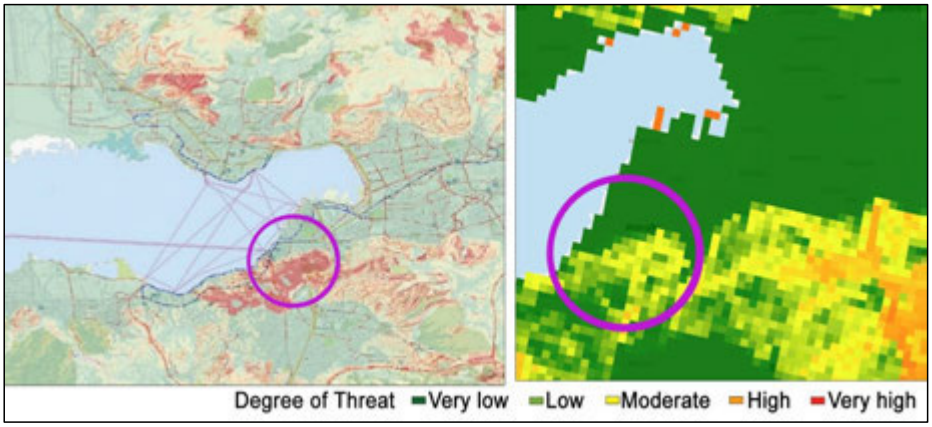

Figure 8: Resilience to Landslide (illustrated based on sources at left: Izmir Governorship Provincial Disaster and Emergency Directorate, 2021,p. 137; at right Ministry of Environment, Urbanization, and Climate Change, 2023)

According to Izmir Metropolitan Municipality Fire Department statistics, emergency rescue studies for landslide events were conducted in Sakarya neighbourhood in 2023, and Ülkü and Sakarya neighbourhoods in 2021 for the years between 2019 and 2023.

For mitigation, Kadifekale Urban Renewal Project was conducted in the Disaster Exposure Area of 42 hectares, at southern slopes part of Kadifekale, in the early 2000s. With the decision of the Izmir Metropolitan Municipality Council dated 20/07/2006, expropriation studies were conducted, and buildings were demolished. Then this area was afforested (Mutlu Kılıç & Göksu, 2018). Public engagement and social studies are still ongoing, conducted by the municipality.

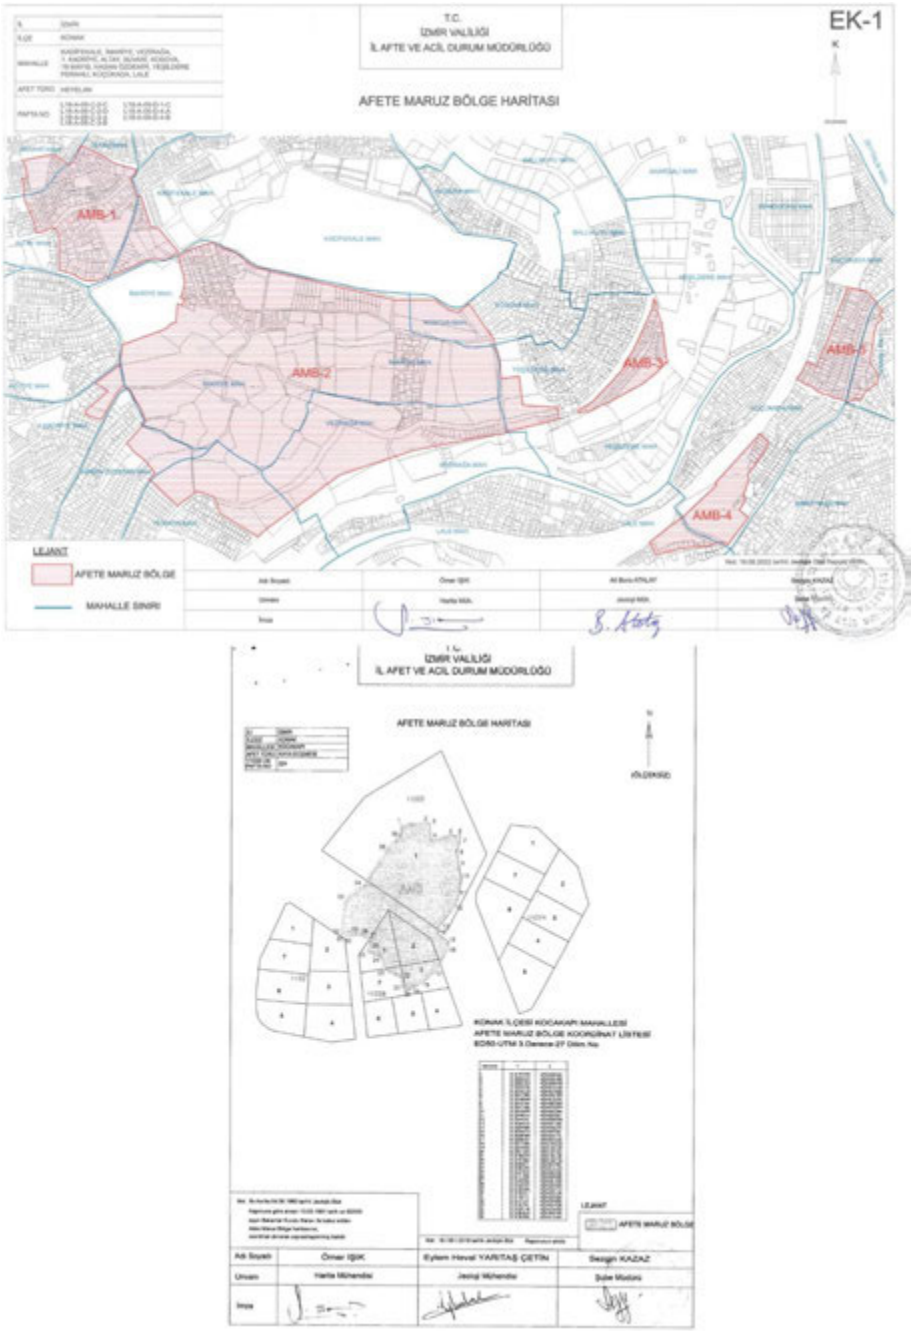

Figure 10: Disaster Exposure Areas in Kadifekale (above) and Kocakapı (below) (Source: Izmir Governorhip Provincial Disaster and Emergency Directorate, 2018, p.22; 2022, p.12)

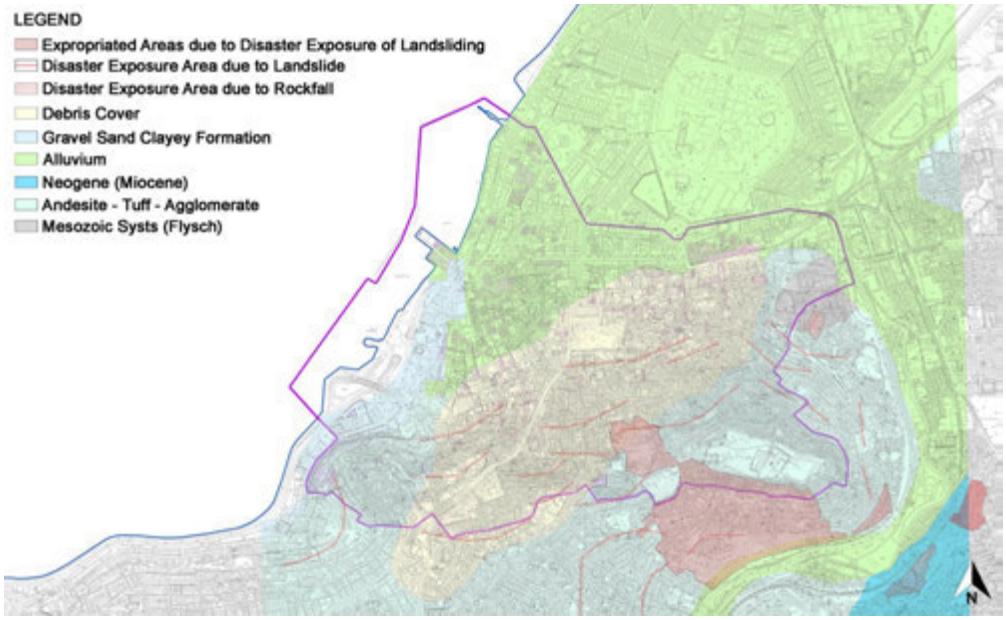

Figure 11: Geological Structure and Disaster Exposure Areas

3.3. Fire

Historic city centre of Izmir has suffered fire events in its history many times. One of the most significant fire events occurred in 1922, which caused around 300 hectares of the city to burn.

According to Izmir Metropolitan Municipality Fire Department statistics, around a thousand fire events in total were fought in the management site between 2018 and 2023 (Figures 12 and 13). Fire events mostly occurred in buildings, garbage areas, workplaces, transformers, and electrical infrastructure respectively. The fire events occurred in buildings, mostly housing units and abandoned buildings. It is also known from the site observations that old and inadequate electrical infrastructure in the buildings causes fire events.

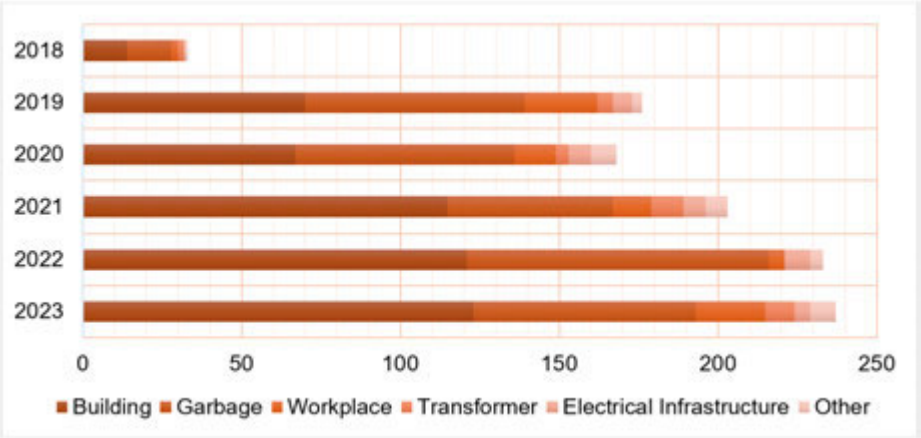

Figure 12: Fire Events in the Historic City centre of Izmir Between 2018 and 2023 (produced based on the source National Smart City Open Data System, 2024)

Izmir Metropolitan Municipality Fire Department statistics show that there are 57 hydrants, and 9 of them are also near to the fire cabinet. Most of the hydrant and fire cabinets are around the Historic Kemeraltı Bazaar, Mimar Kemalettin Modern Bazaar, and public buildings. It is seen that there are limited hydrants, especially in the Basmane residential area.

Figure 13: Fire Events and Response Equipment

3.4. Flood

Enclosing the historic city centre, Meles River is located in Küçük Menderes River Basin. It is known that especially the Meles River has overflowed since antiquity. Heavy rain with the effects of climate change, hydrogeological features, uneven urbanisation, land cover change with impermeable surfaces and damages on natural vegetation are several causes of flooding (Ministry of Agriculture and Forestry, 2019).

Küçük Menderes River Basin Flood Management Plan identifies that Meles River is risky and determines 500-, 100-, and 50-years recurrent flooding models. In the Q 500 model, the historic city centre would be partly affected. In total 3.855 people, which is 3% of the district population, would be affected including Alsancak region for 2018. It is projected that the population would increase to 4.150 by 2025. Also, economic damage would be around 10-225.000 TL around the historic city centre. The plan also determines six vulnerability factors for cultural heritage and flooding risk (Table 4).

Table 4: Disaster Vulnerability Factors for Cultural Heritage at Flooding Risk (Source: Küçük Menderes River Basin Flood Management Plan, 2019, p.323)

Vulnerability Factors	Details
Topography	• Current altitude (Altitude) • Surface water flow paths
Slope	• Upstream source of flood • flood susceptibility
Building Density	• Land value per tread (ground surface) • Land use
Distance from Riverbed	• Distance of the area at risk of flood from the riverbed
Drainage System and Soil Type	• Vulnerable population and critical infrastructure facilities • Soil drainage • Soil moisture • Soil appearance within fragile ecosystem balance • Soil composition
Distance from Road	• Distance of cultural property from the road

Konak district with the Meles River is considered risky since flood impact areas may affect low lands and ground floors of several buildings. According to models Q10, Q50, Q100, and Q500, the Meles River overflowed three times in 1976, 2000, and 2011 between 1962 and 2010 (İzmir Governorship Provincial Disaster and Emergency Directorate, 2021). Hence, overflowing occurred three times in 50 years.

Besides, it is known that periodic heavy rains cause floods on several scales especially in the Historic Kemeraltı Bazaar. According to Izmir Metropolitan Municipality Fire Department statistics, 433 flooding events and water withdrawal interventions were conducted in the management site between the middle of 2019 and 2023. In total, 275 flooding events were intervened, while 124 small scale, 29 larger scale, and 5 middle scale water withdrawal interventions were conducted in the time period (Figure 14 and 15). The highest interventions to flooding events occurred in different times, mostly in September in 2020, in January and February in 2021, in October in 2022, and in October and December in 2023.

The past flooding event in the figure 14 indicates that flooding events occurred in line with dry stream beds. Besides, land cover is mostly impermeable concreate materials that make

infiltration of rainwater difficult in the historic centre, except from open green areas and Mimar Kemalettin Modern Bazaar. The change of land cover in time, from permeable surface to impermeable ones such as asphalt or concreate, drove the impacts of flooding.

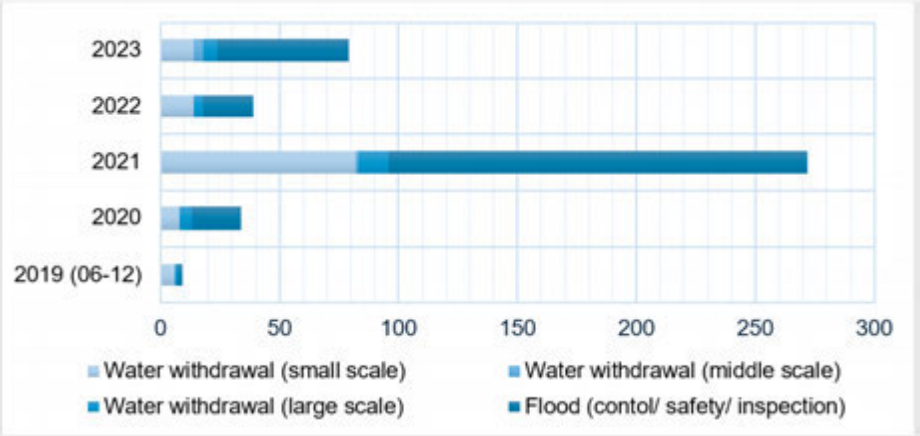

Figure 14: Fire Events in the Historic City centre of Izmir Between 2019 and 2023 (produced based on the source Izmir Metropolitan Municipality Fire Department statistics, 2024)

Today, effective studies are carried out on the risk of flooding and inundation. In order to prevent flood disasters in the area, Early Warning Meteorology Radars and Automatic Meteorology Measurement Stations were established in the city. The Enclosure Infrastructure Project carried out by the Izmir Metropolitan Municipality regarding this risk element is considered as an essential step to eliminate the risk.

With the project, it is aimed to improve the drinking water and wastewater infrastructure network in the region. The First Stage Belt Infrastructure Project aims to discharge rainwater that causes flooding in Kemeraltı area from high elevations during heavy rains, and a pumping station is also being built. Within the scope of these works, it is aimed to renew the drinking water and wastewater network in Fevzipaşa Boulevard, Gaziosmanpaşa Boulevard and Eşrefpaşa Street and to strengthen the existing infrastructure in the region (as cited in Nizamoğlu et al., 2022).

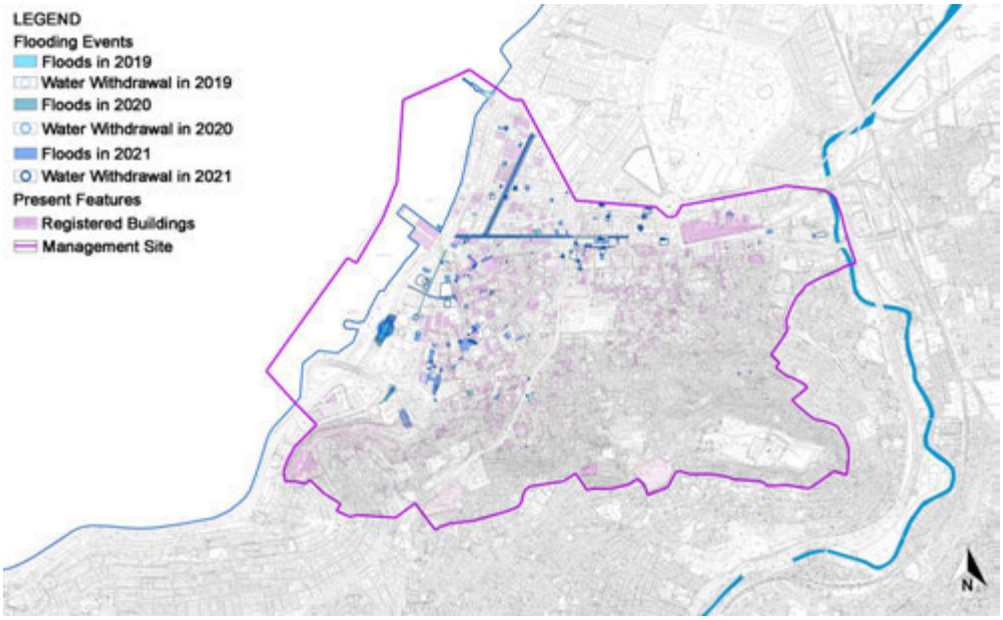

Figure 15: Flood Events and Water Withdrawal Interventions

4. Risk Analysis and Evaluation

The main steps for analysis and evaluation determined in *A Guide to Risk Management of Cultural Heritage* (2016) are followed regarding the risks affecting the built environment.

The analysing step is conducted based on a matrix that shows expected occurrence about how often these hazards may occur, and impact about loss of value (Table 5). In the ABC scales, letter A represents the frequency of the disaster event or rate of occurrence of a damaging process, letter B shows expected loss of value in each item of a heritage asset, and letter C indicates how much the heritage asset value is affected; in other words, how significant is the part of heritage asset affected by the risk. And the combination of the letters A, B, and C is the magnitude of risk (Pedersoli Jr. & Antomarchi, 2016).

Table 5: ABC Method Table (Source: Pedersoli Jr. & Antomarchi, 2016; p. 64, 65, 70)

A-Score	How often does the event occur? (years)	B-Score	Fraction of value lost in each item	Word guidelines	C-Score	% of the value of the heritage asset	World guidelines
5	~ 1	5	100 %	Total or almost total loss of value in each affected item	5	100 %	All or most of the heritage asset value is affected
4.5	~ 3	4.5	30 %		4.5	30 %	
4	~ 10	4	10 %	Large	4	10 %	Large fraction
3.5	~ 30	3.5	3 %		3.5	3 %	
3	~ 100	3	1 %	Small	3	1 %	Small fraction
2.5	~ 300	2.5	0.3 %		2.5	0.3 %	
2	~ 1000	2	0.1 %	Tiny	2	0.1 %	Tiny fraction
1.5	~ 3000	1.5	0.03 %		1.5	0.03 %	
1	~ 1000	1	0.01 %	Trace	1	0.01 %	Trace fraction
0.5	~ 30000	0.5	0.003 %		0.5	0.003 %	

The occurrence is categorised as rare events, which occur less often than about once every 100 years, common events, which occur many times per century, and cumulative process, which occur continuously and frequently. Besides, level of priority and magnitude (level) of risk (hereafter MR) are determined for evaluation. The scale of MR values classified based on the priority, which is catastrophic ($13.5 \leq MR \leq 15$), extreme ($13 \leq MR \leq 11.5$), high ($11 \leq MR \leq 9.5$), medium ($9 \leq MR \leq 7.5$), and low priority ($7 \leq MR \leq 5$).

For the case of urban heritage of Izmir, risk analysis and evaluation are conducted based on present features of the site and past disasters (Table 6). For earthquake risk, it is known that 157 earthquake events with a magnitude higher than 3.5 occurred in Izmir and surroundings from 1900 to 2015 April. A total of 38 earthquakes with magnitudes around 4-5, 15

earthquakes with magnitudes around 5-6, and 3 earthquakes with magnitudes above 6 occurred in the region (İzmir Governorship Provincial Disaster and Emergency Directorate, 2021). Earthquakes occur frequently, while earthquakes with magnitudes higher than 6 likely occur every 38 years. Earthquakes can be determined as common events and A score is given as 3.5.

Although the exact route of the fault lines is not known due to Seismic Microzonation studies are not finished yet, present maps of AFAD illustrate that the Izmir fault line is crossing through the management site. The effect of an earthquake would be diversified according to distance from the fault line. Hence, potential effects for three zones are hypothetically drawn, which are the first affected zone in 150 meters from the fault line, the second zone in 500 meters distance, and the third zone in 1000 meters distance (Figure 16).

The liquefaction risk is illustrated (Figure 17) based on infilling interventions throughout history. The oldest infilled area is considered as having less risks since the area would be more stabilised when compared to the recent infilled areas. Hence, ground stabilities are ranked from safest to the most liquefaction risk as, not intervened areas as the most stabilised, followed by the first infilled areas of Kemeraltı Bazaar, then second period infilled areas in the years between 1400-1850, the third period infilled areas between 1850-1905, and lastly infilled areas between 1905-1997. The third and fourth periods infilled areas are having the most liquefaction risk in coastal areas.

In this sense, a possible earthquake would affect almost all of the site, while coastal areas are more vulnerable due to liquefaction risk. Besides, the historic earthquakes shows that earthquakes in Izmir and environs affects the site. Thus, the B scale is given as 5. Since almost all parts of the heritage would be negatively and directly affected by the earthquake, C score is also determined 5. As a result, MR of earthquake is 13.5, which is a catastrophic priority.

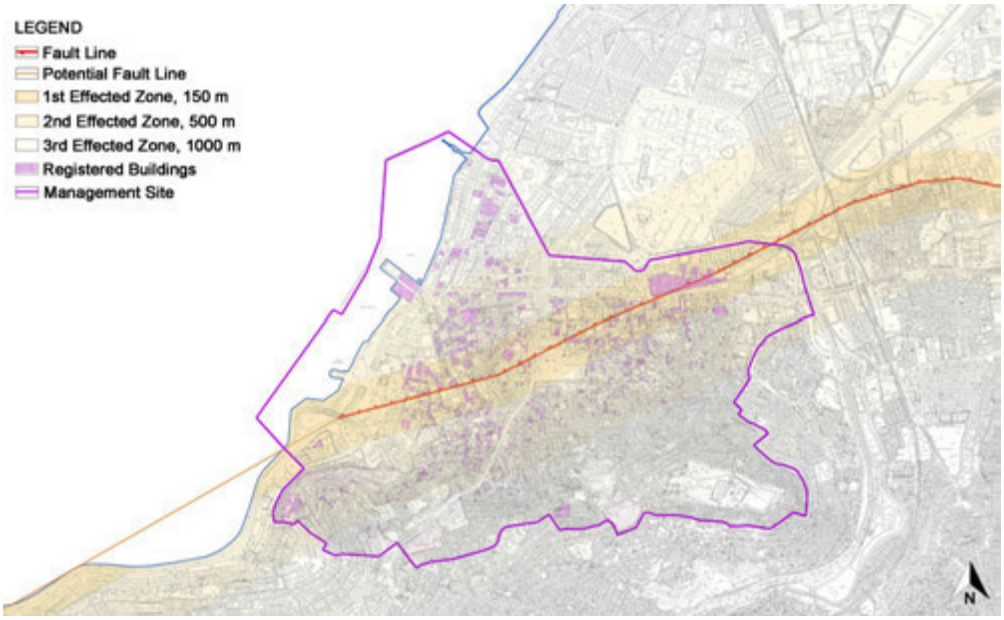

Figure 16: Active Fault Lines in Izmir and Environs

28

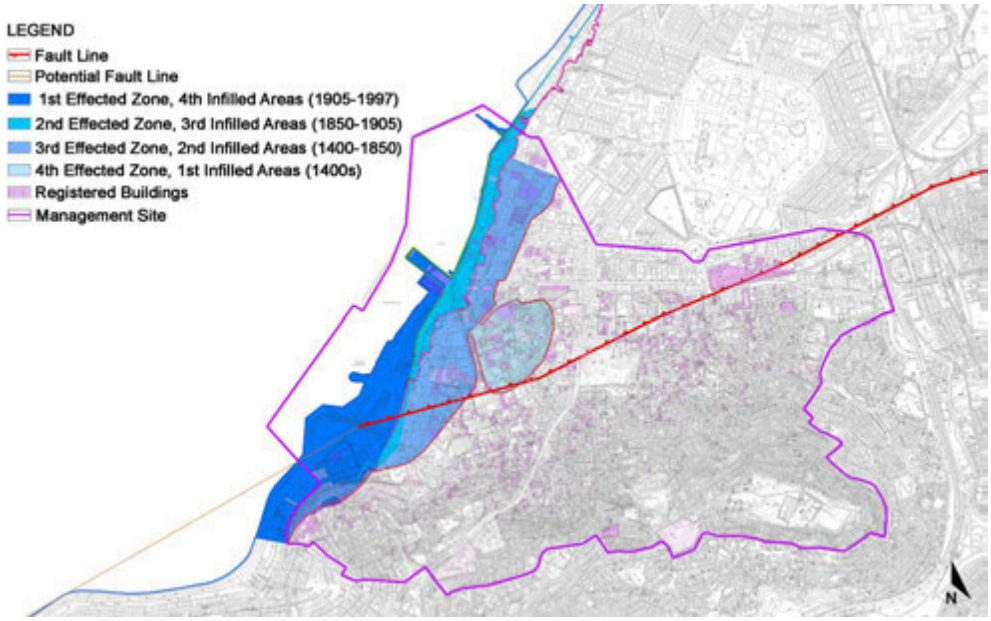

Figure 17: Ground Classes and Liquefaction Probability

29

Tsunami events rarely occurred after earthquakes, most at the southern part of Izmir, not ever occurring around the historic urban centre. Hence, the frequency of tsunami around the historic centre is considered as once in every 300 years and A score as 2.5. Although, Disaster Risk Reduction Plan for the Izmir Province (2021) perceives that 500 meters from the coastal area could be affected by tsunami, a hypothetical map is drawn to show maximum reaching areas of sea level rise (Figure 18).

For this, both infilled areas and topographic conditions are taken into consideration. It is perceived that higher slopes and high-rise buildings at coastal areas would limit the sea to reach inner parts, while Kemeraltı Bazaar area and its northern part would be more affected. The damage would be in between small and large, B score is given as 3.5. Mostly Kemeraltı Bazaar and coastal zones would be affected, which is a small but valuable part of the whole site. And the C score is given as 3. In total, MR value is 9, which is a medium priority to response.

Although there is limited data available for landslides and rockfalls, three landslides were responded to by the Fire Department of the municipality in five years. With this data, the occurrence frequency of landslide and rockfall events can be thought as once or twice a year. Hence, landslide and rockfall for the site are cumulative processes and A score is 3.5. Landslide and rockfall may affect a small part of a heritage item, and B score is to be 3. Also, a tiny fraction of the historic city would be affected, and C score would be 2. In total, the MR of landslide would be 8.5, which is a medium priority.

Both fires and floods occur several times every year. Fire and flood are thought as cumulative processes, and A scores for both are 5. Since fires are more destructive than floods, causing irreversible damage to heritage items, B score of fire is given as 4. The fraction of loss in flooding would be in between large and small, and B score is given 3.5. Hence, MR score for fire is 13 and for flood is 12.5, having extreme priority.

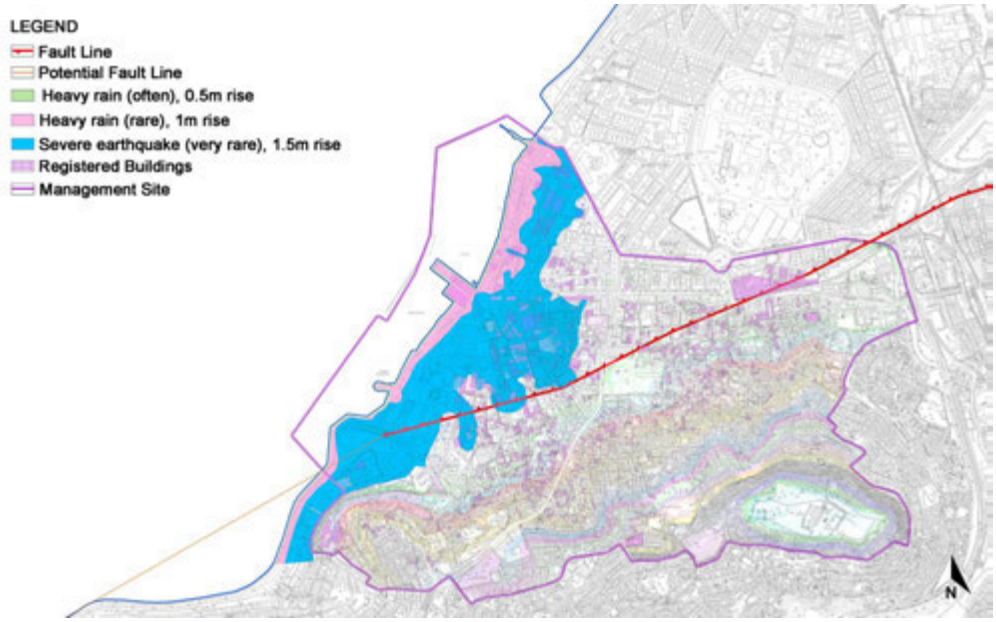

Figure 18: Probability of Sea Level Rise

31

Table 6: Evaluation of Risks for the case on Urban Heritage of Izmir

	A (How often does the event occur?)	B (fraction of value lost in each effected item)	C (% of value of the heritage asset)	MR (A+B+C)	Level of priority
Earthquake (M ~ 6)	3.5	5	5	13.5	Catastrophic priority
Tsunami	2.5	3.5	3	9	Medium priority
Landslide and Rockfall	3.5	3	2	8.5	Medium priority
Fire	5	4	4	13	Extreme priority
Flood	5	3.5	4	12.5	Extreme priority

The scenario can also be varied according to uncertainty of the event. For this sense, magnitude of the risk can be presented in three values, regarding most likely, low estimate, and high estimate of the relevant scores.

Scenarios for possible disasters:

- Most Likely Scenario: The earthquake with a magnitude of over 6, caused by the Izmir fault, caused to collapse of high-rise buildings and unauthorised structures in Kemeraltı Bazaar and its surroundings, and the destruction of some of the cultural assets and the permanent damage of some of them due to both the earthquake and the destruction of other structures.

- High Estimate Scenario: The fire, which occurred due to a leak in a registered building with an outdated electrical infrastructure in the historic Kemeraltı bazaar, caused the roof to burn and the adjacent buildings to be damaged.

- High Estimate Scenario: After the severe earthquake, fire incidents occurred as a result of the collapse of high-rise buildings and buildings with excessive air conditioning and irregular power lines in the Historical Kemeraltı Bazaar, the closure of roads made the intervention difficult, and the roofs and interiors of registered buildings were permanently damaged.

- High Estimate Scenario: Extreme weather events and sudden rains driven by climate change caused the Gulf of Izmir to overflow, damage on the Clock Tower and its surroundings, submergence of the ground floors of shops, fires due to electricity leakage in some buildings, and permanent damage in some buildings.

- Low Estimate Scenario: After the severe earthquake, the sea overflowed, causing the buildings in the historical city centre to collapse and get damaged, Konak Square and its surroundings were flooded, and the Izmir Clock Tower and the coastline got damaged.

- Low Estimate Scenario: The sea flooding that occurred after the severe earthquake, combined with the irregular electrical infrastructure problem, caused fires to break out

in Kemeraltı Bazaar, high-rise buildings collapsed, and cultural assets got damaged, and coastal buildings suffered permanent damage as a result of floods and fires.

A specific vulnerability analysis methodologic framework for the urban heritage of Izmir is defined based on vulnerability criteria and analyses for identified risks (Table 7 and Figure 19). The vulnerability criteria are determined for all risks, earthquake, tsunami, landslide, fire, and flood. Based on value and cultural characteristics of determined zones, a matrix is drawn for evaluation.

Accordingly, (3) the historic Kemeraltı Bazaar is the most vulnerable place regarding overall risks, which is followed by (4) public administrative facilities, (5) trade, production, and storage areas of Kestelli, (1) coastal are, and (9) residential quarter of Basmane.

Regarding vulnerability criteria for all risks, (9) residential quarter of Basmane is the most vulnerable place which has low accessibility of roads, less open green areas, and limited emergency response equipment. The zones of (1) coastal areas and (4) public administration facilities are the most vulnerable to earthquake risk, which are followed by (3) the Historic Kemeraltı Bazaar and (2) Mimar Kemalettin Modern Bazaar. These places are vulnerable due to spatial pattern, building density, liquefaction risk, ground condition with some effects of infilling interventions as well as proximity to fault line and ground condition.

Tsunami is mainly a risk for (1) coastal areas, while landslides threaten mostly (10) components of Smyrna Ancient City, which is Kadifekale and surroundings. Fire risk is high in (3) the historic Kemeraltı Bazaar, and (5) trade, production, and storage areas of Kestelli. These places are close to uses that drive fire risk, such as small workshops or easily flammable products. Due to the uses of shops, streets are problematic for accessibility. Moreover, the lighting system is mostly improper with disorganised cables and lamps.

Flooding is a most widespread threat for the historic centre, affecting most of the zones. Only, (10) components of Smyrna Ancient City and (2) Mimar Kemalettin Modern Bazaar are more resilient compared to other zones. Since the characteristic zones are mostly covered by concrete materials, infrastructural and spatial organisational problems are driven by proximity to coastal line and height from sea level, flooding becomes a more and more significant risk for the historic centre.

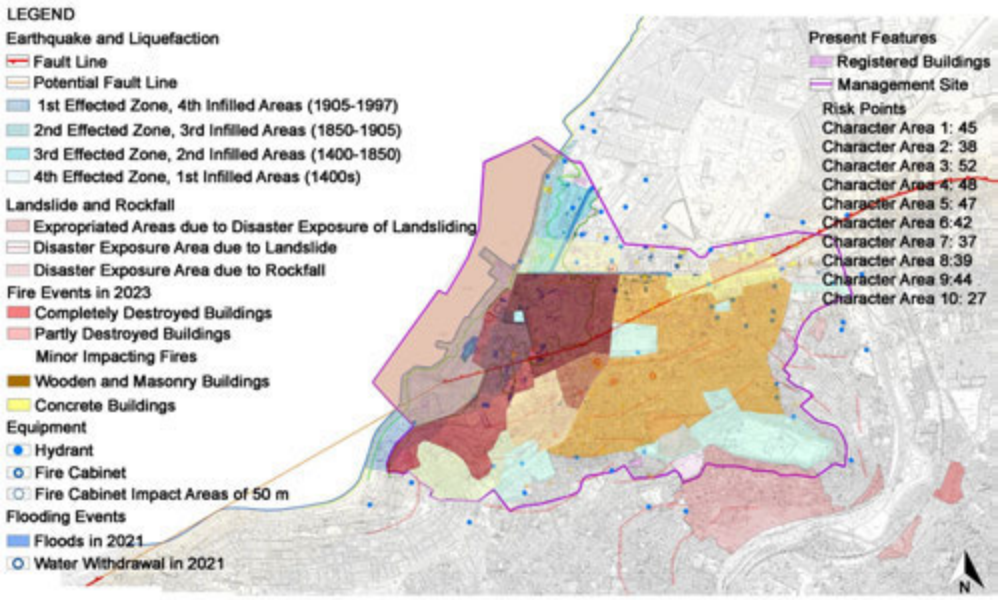

Figure 19: Synthesis of Risk Analyses

5. Proposals for Improvement of Risk Treatment Strategies

According to analyses and evaluations, preliminary strategies for elimination, adaptation or mitigation risks are determined in regard to cultural values of the site.

For all risks:

- To increase accessibility within the historic centre, parking problems and occupation of small shops in the streets are to be prevented in the historic Kemeraltı Bazaar.
- Small compatible vehicles and transportation facilities are to be utilised for residential quarters of İsmet İnönü Street and Basmane.
- Emergency response equipment including early warning system, emergency buttons, and monitoring cameras sensitive to heat, as well as hydrants and fire cabinets are to be increased in number and upgraded in technologic quality.
- Emergency gathering areas are to be developed. Several buildings are to be functioned as emergency gathering points, especially in trade, production, and storage areas of Kestelli and residential quarter of Basmane.
- As determined in the Site Management Plan, heritage information and documentation must be sustained, detailed inventory of buildings and cultural characteristic zones are to be regularly updated and data is to be secured.
- Specified studies to increase public awareness on precautions before disasters, behaviours during disasters, and recovery processes after disasters are to be conducted.
- Periodical training is to be organised for capacity building of public authorities on how to respond during and after disaster events.

For earthquake and tsunami risk:

- Prevention and mitigation strategies are to be developed and reviewed based on seismic microzonation studies.
- Spatial plans including conservation plans and master plans are executed fully. Building densities must be audited by relevant public authorities to be appropriate with the plan decisions.
- Emergency monitoring systems are to be placed in the coastal areas to monitor sea level rise, gather data periodically and sustain information for future estimations and planning studies.

Landslide and Rock Fall:

- Specific interventions must be taken in the Disaster Exposure Areas around Kadifekale. Housing areas are to be expropriated and afforestation studies are to be conducted by the public authorities in cooperation with relevant stakeholders. Since these are radical interventions, public participation and involvement of locals and residents should be ensured. Spatial interventions should sustain social and economic empowerment strategies, in this manner, social inclusion policies should be determined and implemented sensitively regarding diversified cultural backgrounds of locals.
- Kocakapı neighbourhood and other areas close to Meles River should be monitored regarding rockfall risks. Similar interventions like expropriation and public participation in Kadifekale should be taken for the disaster exposure area due to rockfall.

Fire:

- Trade of fireproof products in the historic Kemeraltı Bazaar is to be encouraged.

- Small shops and workshops in the historic Kemeraltı Bazaar and trade, production, and storage areas of Kestelli are to be regularly audited by the relevant authorities.
- Street shelters are to be designed with an appropriate height from the street, fireproof materials, and compatible with the cultural heritage.
- More hydrants are to be placed in residential quarters of İsmet İnönü Street and Basmane.
- Lightening systems in the historic Kemeraltı Bazaar, public administrative facilities, trade, production, and storage areas of Kestelli, and residential quarter of Damlacık are to be reviewed. Besides, old electricity infrastructure of the buildings is to be detected and renewed in the historic centre.

Flood:

- Küçük Menderes River Basin Flood Management Plan determines measures for Meles River as pre-disaster period, which are building a canal with retaining walls (masonry and concrete materials) and improvement of bridges and transition structures on the river between 2020-2024. For the basin scale several measures are determined, such as introducing green roof, plant rain ditch, permeable pavement, permeable asphalt, rain tank, bioretention and infiltration ponds. These measures are to be evaluated and adopted for the historic centre in regard of compatibility to cultural heritage values.
- Since land cover change significantly drives flooding risk, permeable surfaces are to be used in the historic centre, concrete surfaces can be preferred only in main roads.
- Some buildings have remained below street level due to infrastructure studies. These inappropriate interventions must be reversed.
- Old infrastructure facilities such as water collection channels in residential quarters of İsmet İnönü Street and Basmane are to be renewed. The cultural layers of the past must be taken into account in the renewal studies.
- Intervention including expropriation can be taken to create open green axes according to dry stream beds. Continuity of open green areas should be sustained within the historic centre.

6. Proposals for Monitoring and Revision Processes

The main responsible stakeholders for implementation, monitoring, and revision of risk treatment strategies are public authorities. The whole process of risk management is to be conducted with collaboration of universities, professional chambers, NGOs, PPP, and public service companies. Main strategies for monitoring and revision processes are determined:

- A database to collect data about risk management strategies is to be established by the relevant public authorities. This database is also utilised to collect data and documentation of past disasters.
- A risk management working group consisting of experts from public authorities, academics from universities, representatives of professional chambers, NGOs, PPP, and public service companies is to be constituted.
- Main duty of the risk management working group is periodically collecting actual data and monitoring processes within their corresponding authority.
- A risk management monitoring board is to be constituted with involvement of senior representatives of the whole stakeholders.
- The working group and monitoring board together would evaluate the progress and obstacles faced during the processes of implementation and monitoring. Also, new emerging threats either due to risk management strategies or unpredicted events are to

be discussed. Required regulatory actions are to be taken with consolidations of stakeholders.

7. Conclusion

This study presents an example of a preliminarily risk management process for urban heritage sites, suggesting a methodology to open new discussions for further studies. This paper is an attempt to encourage conducting an integrated risk management plan with participation of the stakeholders, based on detailed surveys to identify risks, including specified parts such as action programmes with responsible authorities and allocated resources, monitoring indicators, and evaluation forms.

Risk identification, analyses, and evaluation, as well as strategies for risk reduction, monitoring, and evaluation are determined in a general perspective which should be further studied and expanded. Studies not just in the scale of area but also in the building scale should be conducted. The impacts of different hazards influencing one another and threats occur due to the dynamics of the place, such as adjacent order, adjoint electricity infrastructure, narrow roads with low accessibility, should be taken into consideration. Based on more detailed analysis, more specified strategies for mitigation and adaptation should be determined.

Cultural heritage places are threatened by many factors, either due to human induced factors or natural factors. It is significant to take actions effectively and comprehensively regarding human, technical, and financial resources. Pre-disaster risk studies are fundamental to eliminate risks on cultural heritage and decrease costs of recovery and rehabilitation after disasters. The overall aim is to be the conservation of urban heritage, which are significant to humanity, as of public interest for today's and future generations and beyond.

Saturation as urban crisis.
Understanding Anthropocene from two flooded cities of the Global South

Abstract (up to 125 words)
The paper proposes to shed light on the articulation of global processes typical of urban trajectories in southern cities and crises at the local scale, based on a comparative analysis in two cities frequently affected by floods, Dakar (Senegal) and San José (Costa Rica). In doing so, the paper aims to clarify the notions of 'crisis' and 'disaster' in urban contexts in the Anthropocene by linking them to that of 'saturation'. We highlight three results. First, using flooding as an example, saturation sheds light on the processes that shape cities and their disasters. Second, saturation highlights the specific ways in which water interacts with urban environments. Finally, the findings touch on the capacity of actors to cope with these crises.

Key words: city, floods, crises, Anthropocene, saturation

Full text

1. Thinking crisis through a process of saturation in the Anthropocene

The crisis refers to a state of uncertainty often linked to an exceptional, accidental but disruptive event that shakes the ordinary up and reduces the time available for decision-making (Godard et al., 2002). The event can be a natural or technological disaster that has happened and damages assets. It can also be an anticipated event that has not yet happen, but that leads actors to take decisions under stress. It might be crisis without an actual event (Tazieff, 1977). The notion is directly related to the capacity of the decision-making process to deal with the extraordinary beyond all fields of expertise or knowledge (Gilbert, 2007; Rey-Thibault, 2022). Some authors will distinguish crisis from rupture, the latter leading to a whole other path, as in the former, the organisational structures are not completely questioned afterwards (Guilhou and Lagadec, 2002). In urban environments, the literature highlights how the concentration of populations and problems, the interconnectedness of networks and overlapping systems of governance can lead to thresholds being crossed (Robert 2012). The notion is related to the suddenness of a probable disruption, implying changes in the ordinary functioning of organisations.

Complementing this work, this paper aims to clarify the notion of crisis and disaster in urban contexts on the basis of the Anthropocene by linking it to that of ‘saturation’. The aim is to integrate more systematically the crises that have been neglected by much of the work on the urban and disaster studies, which have focused on exceptional events and leaving aside crisis related to long terms process of accumulation. Within the literature, notions such as the *neglected disasters* (Wisner and Gaillard, 2009) or the *small disasters* (Gaillard et al., 2014) have pointed this long-term crisis. The first category refers to disasters which, because of their less exceptional and long-term nature (such as drought, environmental degradation and

poverty), attract less public and media attention. The second refers to small-scale events that affect a certain type of population on a daily basis and therefore do not evoke earth-shattering responses (Gaillard et al., 2014). More recently, the notion of slow disaster emphasises this long-term *process* by which disaster happen, beyond the event (Knowles, 2020). By amalgaming the notions of "creeping disaster" (Rosenthal, 1998) and "slow violence" (Nixon, 2013), it also points toward the necessity to understand the properties of affecting elements, that are not entirely social construction but also material entities with their own dynamic, to understand disasters. In the context of the Anthropocene, the notions of small, neglected and slow disasters become particularly enlightening. Following these paths, we aim, to shed light on the links between crisis as stated events, and crisis as long-term disasters as the Anthropocene is also the time of "concatenation of both slow- and quick onset events" (Steffen et al., 2021, p. 162). By doing so, we question what has been approached differently in the literature. We also put into perspective the "normal" situation, often characterized by the fragility much more than stability.

Now, the time of the Anthropocene corresponds to a time of critical events, and of uncertainty as to their intensity (Reghezza-Zitt, 2019), but through other related concepts developed by the social sciences, such as 'capitalocene' (Moore, 2017) or 'accumulocène' (Fressoz, 2020), the Anthropocene gives the opportunity to rethink lifestyles, economic activities and their material emanations deployed at least since the end of the 19th century, which are the material expressions of the anthropogenic geological transformation (Fressoz, 2020). From this perspective, the Anthropocene is also the time for dealing with the materiality that the human species has moved, extracted, burned and agglomerated, and finally inherited in the long term, and with which it must contend in a changing climate. From an Anthropocene perspective, a crisis is not just seen as an exceptional moment, an event, or a catastrophe, as a break with what already exists (Sierra, Gustiaux and Leclercq, 2020). It is not only a one-off disturbance leading to specific practices for dealing with it that are likely to evolve over time (Gueben-Venière and November, 2020). The crises can also be seen as processes of accumulation and transformation of matter, social practices and techniques which allows to consider the (temporal and spatial) continuities between crises. In the context of floods in the urban South, we refer to this process as a process of saturation.

In chemistry, the notion of saturation refers to "the limit of a substance's ability to dissolve or absorb another". In hydrology, it refers to "the state of a medium [...] whose interstitial voids are completely filled with water"[1]. In its current sense, the concept is used to describe a historical process of accumulation, densification and intensification, leading to a point of discharge by the medium in question, or transformation of the latter (in this case a substance). It seems to us that this notion can be useful for thinking about disasters linked to urban flooding in the Anthropocene for two reasons. First, the notion of saturation emphasises the process rather than the event: to say that a system, substance or environment is saturated is to point toward the historical and material depth of its state. The process of saturation leads to a tipping point at which a gentle return to 'normal' is difficult when not impossible. In this respect, the temporalities involved in the saturation process reflect both the history of the 'forcing' factors that changed environments, and the particular state in which it finds itself at the saturation point: characterised by great (permanent) instability, or by the tipping point into another state. This particular state is the second aspect of the concept that interests us. At the point of saturation, the properties of agents, social forms and relationships are, or could, transformed depending of the intensity of the pressure, the relationships between actors, and their history. We will see that,

[1] Centre National de Ressources Textuelles, 26-07-2023, « Saturation », https://www.cnrtl.fr/definition/saturation

in the case of urban environment, these transformations are far from mechanic processes but include different interactions implying weather, geo-urban landscapes, and ways of leaving and governing these landscapes.

Thus, although the Anthropocene has undoubtedly radicalised the questioning by offering a common spatial and temporal scale, that of the planet, to numerous studies interested in the environment, climate change, forms of pollution and disasters (Bonneuil and Fressoz, 2013). However, the articulation of these scales with those constructed and investigated for a long time by social and environmental scientists remains problematic (Clark, Szerzinsky, 2021). This paper takes the saturation process as a way to investigate urban environments that are both site specific geo-ecological settings, and a global assemblage that produce their own vulnerability (Tsing, 2015).

Moreover, thinking of human collectives as geological forces (Clark, Szerzinski, 2021) implies articulating an approach to the environment as a social construct to another that see the material limits of geo-ecosystems (Charbonnier, 2017). In order to do this, saturation appears to be a boundary terms capable of characterising these socionatural milieu that have thus 'entered' the Anthropocene and their disruptions. Using the case of flooding in two cities in the South, Dakar and San José, we will attempt to show what the 'saturation' of these environments poses as a specific problem, and how it impacts the traditional analysis of disasters in urban environments.

2. A comparative approach of two flooded cities from the South

One of the challenges posed by the Anthropocene lies in the global nature of a phenomenon whose effects are nevertheless unevenly distributed in time, space and between social groups. In addition, by forcibly or voluntarily bringing all social, political and 'natural' formations into a single space-time characterised by global crisis, the concept has been accused of reproducing the colonial gesture of recalibrating the world on the scale of a Western perception and knowledge regime of its disruptions (Davies, Todd, 2017). Clearly situated in the field of the humanities and social sciences, but at the same time careful to put forward 'other' perspectives, at once situated but capable of complementing, amending or contradicting 'the' global theory, our approach consists of understanding global transformations through comparison, by situating these transformations, in the city and in the South, through ethnography method (Robinson, 2022). The table 1 shows the method declined in different qualitative data collection strategy in each research.

Table 1. Qualitative methods

Method	Dakar	San José
Semi-structured interviews	59 (Inhabitants, Local/national practitioners, private actors, ONG, public authorities)	52 (31 inhabitant, 16 practitioners, and 5 private experts)

Immersive observations resulting in notebooks	Total of 2 years living in Dakar between 2015 and 2019 *(work with community organisation, following of large scale mitigation projects and municipal mitigation efforts, several month living with municipal flood manager in an impacted neighborhood…)*	In total 3 years living in San José between 2014 and 2018 *(e.g. observation of public lectures on risk management for public actors and of trainings for citizen participation in risk management; city walks; participation in a citizen early warning system).*
Analyses of documents and archives	Documentation of several mitigation projects. Press review: 600 press articles from 1987 to 2009	Archives of local risk management committees; of the Municipality of San José and of the Ministry of environment. Press review: 51 press articles from 1944 to 2015.

This approach seems to us to have a twofold interest. The first is heuristic. By comparing situations specific to two urban contexts separated by thousands of kilometres and an ocean, the comparison reveals similarities and differences that are particularly interesting for understanding the dynamics of 'global' phenomena, and for tracing their contours. Thus, the fact that this comparison contrasts two thesis fields (Guevara Viquez, 2020; Leclercq, 2020), carried out by their authors at roughly the same time and using similar methods and questions, not only provides information about their common scientific background, but also provides tools for delimiting, naming, grouping or separating phenomena and categories whose scope sometimes remains relatively vague (Candea, 2016).

Secondly, by situating ourselves in the South and seeking to define what the city as a material, social and political environment produces and reveals in terms of socionatural disturbances, this comparison responds both to long-standing calls in urban studies (Robinson, 2006), sustainability studies (Horlings et al., 2020), and more recent calls in Anthropocene studies (Yusoff, 2018), to give an equivalent place in theory to subaltern sites and actors. To do this, we sought to establish equivalences and *a posteriori* comparisons between phenomena and experiences that we approached through qualitative methods in working-class neighbourhoods of Dakar and San José, two cities affected by flooding that is both recurrent and directly linked to their forms of urban planning.

3. Results

3.1 Urban landscape formation: waterscapes in global encounters

The Anthropocene, with the advent of extreme events, rising water levels and droughts, poses problems of water surplus and shortage. We propose to approach the problems of surplus water, accumulation and stagnation, generating floods in cities, which are multiplying, generating specific forms of 'urban waterscapes' (Goh, 2019), modes of inhabiting, and calling for expertise and public responses (Leclercq, 2020; Guevara-Viquez, 2020). Theses crises results from the accumulation in time and space of practices and techniques aiming to modify, control, orient the behaviours of water. This process of accumulation redefines the temporality of the crisis, not as a moment or an event, but as a material thickness that transforms watersheds.

3.1.1 Terraforming the niayes in the Cape Verde peninsula

On the Cape Verde peninsula, the hydrographic network has been characterised since the Quaternary by the presence of lakes or wetlands, regularly of permanently under water, in the foothills of the sand dunes due to an outcropping water table (Fall, 1986). This network, known as the "niayes", is modified by alternating wind regimes and the accumulation of fluvial sands that shape the dune formations, as well as by the interaction between marine currents and the groundwater network fed by rainfall. Highly dependent on the climate, these particular ecological formations are also very fertile, and provided the Lebus who settled on the peninsula from the fifteenth century with a terrain that was both suitable for cultivation and for resisting the Cayor armies from the 1790s onwards (Sylla, 1992). In 1857, colonial settlers bought land on the tip of the peninsula and developed the Dakar colonial city, which became the capital of French West Africa in 1902 and concentrated most of the country's commercial and industrial activities, attracting a very large population in search of work. Typical of the spatial forms of colonial exploitation, this polarisation led to the rapid expansion of the city across the entire peninsula, reshaping the landscape of the niayes.

Continuing the "sanitation" work begun in metropolitan France, which stemmed from the hygienist movement and involved draining wetlands and "containing" urban fertile lands (Fournier, 2007; Morera and Morgan, 2019), the French colonists drained the "marigots" at the tip of the peninsula. These operations, carried out from the end of the 19th century onwards, were in some cases combined with the installation of wastewater and rainwater drainage networks (Faye, 2017). However, the meagre investments made at the time were never enough to make up for the lack or inadequacy of collective facilities in the vast majority of the urban area. These changes to the hydrographic network were also combined with ongoing drainage work to transform wetlands into market gardens, used by the settlers to separate the French neighbourhoods from the indigenous ones, but also by the Lebus and even by new arrivals from French West Africa as the capital expanded and demanded food.

The expansion of the colonial city was very different from the colonial dream. From the Lebus villages, in the interstices of the colonial city and on its margins, a large number of neighbourhoods developed, described as “irregular”, escaping the cadastre and the water and energy networks (Faye, 2017). Accused of contributing to the spread of disease and of 'cluttering up' the urban landscape, their inhabitants were evicted from their homes, sometimes in exchange for building plots located far from the urban centre. This approach was taken up again after independence for urban planning reasons, leading to the expansion of Pikine and Guediawaye, in the north and east of the peninsula. From the 1950s to the end of the 1980s, the servicing of plots of land allocated for building purposes often included a minimal sewerage network, with residents having to connect to it themselves or install individual sewerage systems. These new centralities systematically gave rise to the production of a new "irregular" town on its flanks and along the roads in a context of exponential population growth throughout 20th century. The drought of the 1970s and 1980s in the Sahel had a decisive impact on the urbanisation of the niayes. By contributing to the drying up of certain wetlands, the latter provided fertile ground for regular and irregular urban expansion, and thus prepared the way for some of the flooding that occurred in the 1990s and 2000s, after the drought ended and the rainfall pattern changed (Chagnaud *et al.*, 2022). During this period, the suburban districts started to regularly suffer from stagnant water that displaced entire neighbourhoods, led to a phenomenal rise of hydric and vectorial illnesses, and to major disturbances of social life (school closures etc.). But because it was affecting *waa banlieue*, considered as marginal people, this phenomenon was not considered as a public problem (Leclercq, 2019). It is only during the 2000’s, when the rise of water table level and the soil sealing coefficient reached a

certain level, that the entire agglomeration started to floods, and that the State authorities and international donors began to handle it.

3.1.2 Piping watercourses, soil sealing, and floods in San José

San José's structuring role in the urban development of the so-called Central Valley starts in the middle of the 19th century, and in particular from the end of the 19th century related to the development of coffee farming (Carvajal Alvarado and Vargas Cullel, 1983). Commercial activities linked to the agro-export model were concentrated in San José (Quesada Avendaño, 2011). Later, as in many Latin American capitals, the phenomenon of metropolisation starting in the 1950's is reflected in the tertiarization of the productive apparatus, the disappearance of land used for agriculture and the development of the property market and speculation (Dureau et al., 2006; Hall, 1976). The population of the urban-metropolitan area rose from 322,823 in 1950, to 1,105,679 in 1981. Despite the existence of planning instruments, these urbanisation trends continued after 1980, with horizontal urban expansion, without any increase in density, in areas with complex topographies (Hardy, 2005). In the course of this transformation process, the canals built to irrigate the coffee-growing fields became drainage canals for urban water.

San José's sewage system was built at the end of the 19th century (Quesada Avendaño, 2011). Several canals and streams formerly used for agricultural activities were then covered over to become part of the sewerage system (Alvarado Rojas, 2014).

Wealthy neighbourhoods were the first to benefit from the installation of the changes. The working-class districts had to wait a few decades to be connected. (Quesada Avendaño, 2011). The urbanisation process that created the metropolitan area between 1940 and 1970 reproduced these trends and adapted to the coffee strategy In this process, property developers invade protected areas, underestimate the flow of watercourses and even erase them by levelling the land to build streets and houses on their original axis (DRENACA, 1977).

This process of piping is punctuated by the phenomenon of flooding, which is gradually becoming associated with a problem of urban development (Guevara Viquez, 2020), and not exclusively as problem only related to poor areas (Guevara Viquez, 2019). The floods of the late 1960s and early 1970s marked a turning point. The municipality of San José commissioned the DRENACA study, drawn up in 1977, which was supposed to result in infrastructure works to increase the drainage.

Along with this process of transformation of basins, city actors tend to forget the watercourses. Mapping of the stormwater network in San José is almost non-existent, even though the lack of information on technical networks is a major challenge for their management in a context of climate change (Denis, Florentin 2022). The managers know only 30% of the network, which is currently being re-registered (Guevara Viquez, 2020). Most rivers and streams are channelled and buried, hidden by buildings. When they are not covered, the watercourses are lined by walls and their beds become very narrow, particularly at bridges, which function like dams during rainfall (Morales Soto, 2012).

Thus, the two cases show the historical accumulation of people, techniques and practices that shape landscapes from wetlands and agricultural lands to two-sided urban "waterproof" area in order to feed the demand of local and global shifting political economy. These processes transform the hydrographic basins into a new entity. The challenge of the Anthropocene is to rediscover urban waterscapes as they are, i.e. urban watersheds made of underground sewer-rivers, working-class swamp districts, polluted streams and urban flood plains. These processes

challenge the hydrological knowledge as well as the sociological one needed to deal with the flood crisis. In the South, where hygienist movement and the related process of city canalization has often merged with precarious urbanization, partial urban planning and public services (Bierschenk and Olivier de Sardan, 2014), this allow us to better understand the ways by which some groups and people are becoming vulnerable to different flood manifestations.

3. 2 Saturation shaping the living spaces

3.2.1 Living in a changing hydrographic basin: from slow to flash floods in San José

This process of transformation can be illustrated at the level of Barrio Luján, a working-class neighbourhood in the old town centre in the south-east of San José. Its development began in the 1920s and intensified in the 1950s. The socio-economic profile of current residents corresponds to craftsmen, blue-collar workers and small shopkeepers with an intermediate level of general qualification[2]. It is a neighbourhood heavily affected by flooding from the *Ocloro*, whose basin has been 100% sealed with the urbanisation process in San José (Guevara Viquez, 2020). This river is 6.85 km long and has a catchment area of 6.196 km². Its flow behaviour and the changes to its bed can be likened to "quebradas", a type of "gully", an element of the hydrographic system that operates particularly during heavy rainfall (Metzger and Peltre, 1996), with rapid, even violent overflows. The transformation and coverage of the riverbed at the scale of the neighbourhood is associated to the expansion of a dairy factory from 1950 to the 2000's, when most of its activities where displaced to the west of the Vallee.

The flooding in Barrio Luján is accentuated by the process of urban sprawl. Many of the residents we met grew up in the district between 1950 and 1970. Their stories take us back to the San José of another era, dotted with fields of fruit trees and pasture, over which the river slowly overflowed without affecting the houses. This overflowing was to the north and not to the south, unlike today:

> Bernardo: Let's just say that what was flooding was the little square over there […] on the other side of the river. And all that [the land near the river] was full of vegetation, where we used to play at the time [...] Let's say the river overflowed but there was plenty of room. [B. Barrio Luján, June 2017]

Heavily affected by the floods of the early 1970s, the district was included in the DRENACA works. The work took until the 1990s to complete. The measures involved covering part of the River Ocloro and building a secondary canal to divert excess water upstream from Barrio Luján. As long as it reduces the impact of overflows, work on the sewerage system is a popular option:

> Flooding was continuing and we heard that they were doing a project called DRENACA […] We could see the difference: it rained and the river hardly overflowed [Beth, Barrio Luján, who moved to the neighbourhood in the 1980s].

Thus, over the course of the twentieth century, the development of the sewerage system in San José was shaped by crises and recurring floods. While the network is being deployed to reduce overflows, it also shapes today's flooding, as we will see in the last part of this paper. The construction and extension of the sewage system has a feedback effect on the crises affecting the city today (Coates, 2022).

[2] Data collected in February 2017 from the National Institute of Statistics and Census (INEC).

3.2.2 Accumulation, stagnation, progression of the floods and of the water networks in the suburbs of Dakar

In the municipality of Djiddah Thiaroye Kao, raised in the 1960's and 1970's from the Pikine resettlement neighbourhood onwards in the suburbs of Dakar, the first floods started at the end of the 1980's. At this time, ancient cultivated "bas-fonds" transformed into houses and courtyards during the drought period, started to fill up again forcing people to live their house during the rainy season. This phenomenon gained in force and intensity during the 1990's, leading the government to consider a first resettlement plan in 1994, that was never achieved because of the opposition of certain households (some of them had already been displaced during the 1960's because of the "clearance" of Dakar "slums"). That "return" of the rains eventually combined with a periodic rise of the level of watertable (Ndao, 2015) - because of the rainfall intensification and beside its general trend decline - led to a very different flood dynamic than the San Jose one. Here, the problem was not the sudden and violent manifestation of water, rather than its progressive accumulation and progression, leading to the progressive abandonment of house, or to the backfilling of others. This dynamic eventually intensified after 2004 and the stop of the pumping of the groundwater-table for the alimentation of Dakar with potable water for sanitary justifications (Leclercq, 2017), leading to its rise, one of the major flooding event at the agglomeration scale, and the intensification of neighbourhood's socio-material transformation.

> M. Diop: It started in Leona in 2005. The floods were a bit far away. But it came year after year, it came up towards us. [...] And so it was in 2009 that we [our school] were flooded. The water was almost 1 metre high. [...] So we closed the school, we stopped our activities, and it was only in 2011 that we started again. But from 2009 to 2011, there was nowhere to go. The neighbourhood was overrun... [...]
>
> Romain: Did that have an impact on your students?
>
> M. Diop: Oh yes! We lost a lot of pupils, a lot! They left. So yes, it had an impact on us. We've lost almost 60% of our pupils. [...] Here now, the population is practically poor... With the flooding, the level of poverty in the town has increased even further. [...] You know, let's talk about the consequences. The abandoned houses. The families who abandoned their homes had the means to do so, so they went and rented somewhere else. Now poor families live in these houses.
> *M. Diop - Headmaster of the Léona Franco-Arab school, interview conducted the 27 june 2016 in one of the classrooms.*

2005 was a major outbreak for the entire agglomeration, leading to the forced resettlement of thousands of people during several month (several years for some of them) and to the launch of the first national urban adaptation policy. The point of this paper is not to get back to this policy building process that have been described elsewhere (Schaer, Thiam and Nygaard, 2018; Bottazzi, Winkler and Ifejika Speranza, 2019; Leclercq, 2019, 2023), but to point out the overarching processes that gather our two different cases. As in San Jose, the main response of the public authorities, national and international, had relied on the channelization, and eventually the displacement of flooded affected people. After 2010, the State and the World Bank started a major drainage infrastructure project, that is still undergoing, following the watersheds tops and depressions in order to cover the whole suburban area. But here again, that channelization did not operate in a fixed environment. All along the last two decades, Dakar was also the object of major road infrastructures and pavements projects (Melly, 2017), some of them directly related to the needs of water evacuation through the new drainage networks.

As this way of producing the “out of water” city was expending, inhabitants started to not only backfill and seal their own houses, but also entire roads and neighbourhoods. Far from disappearing, the floods now displace through waterproof roads and sealed neighbourhoods from the top of the dunes to their feet, sometime until the sea, and sometime until the next low lying point where they remain trapped.

In our work, saturation directly refer to the bifid process of channelization on one hand – that had been conducted first as a way to build a “sanitized” city for the wealthier and the dominants – and of overflow, stagnation, choking, accumulation on the other – when the entanglement with very unequal socio-material landscapes produces different types of floods. If the channelization could have been a very specificity of the urban form since ages and in very different contexts (Chwałczyk, 2020), what make it different from the 1950’s in some cities of the Global South is that it interacts with a fast and very large process of groups and land transformation, and in a context of huge power imbalance within the city production. The urban demographic explosion, the polarisation of national economies within few city centres, the generalization of grading and levelling, of concrete, cars and the associate infrastructures, and the inequalities reflects into the material production and setting of the city, confronted with very different hydroscapes. What’s interesting here, is that besides these different hydroscapes and, at the end, different urban-hydroscapes flooded in different ways, the same solutions are used, producing the same horizons of an “out of water” city. Defining a process as well as a situation, the saturation/saturated city appears to be produced and reproduced through this power imbalance, that define and redefine who is affected and in what extend.

3. 3 Saturation and power reconfigurations: living on the edge

The notion of 'saturation' offers an opportunity to think both about the limited “capacities” (Tousignant, 2018) of actors living in an uncertain environment, regularly submitted to variable crisis. The question is not really how to transform the environment to stop the flood, but who, where and how the flood will affect (Chahim, 2022). The uncertain nature of water manifestation in saturated urban watersheds is thus pointing toward the different capacities to deal with different behaviours of water at different urban scales.

In saturated urban environments, the attempts of individuals and groups to protect themselves from flooding almost systematically have an impact on the exposure of their neighbours. In the suburbs of Dakar, the backfilling of one house often leads to flooding of the neighbouring other, while abandoning another can lead to the formation of a water accumulation point, degrading the neighbourhood symbolically (the empty space quickly becomes a dumping ground) and concretely (water rises by capillary action in the walls of neighbouring houses, Leclercq, 2022). The ability to take action, on one's house, street, neighbourhood or any other part of the urban space, then depends on the ability to mobilise money, matter, relationships, or to produce and direct public action, making it possible to be on the "right" scale - i.e. the scale that determines the flow, infiltration or stagnation of water within the space to be "protected from water" - using the "right" method - i.e. the method that is best suited to the behaviour of the water that we wish to avoid. However, the scale and method are far from obvious; on the contrary, they are the subject of active research punctuated by trial and error (Leclercq, 2019; 2017) and are intrinsically political.

Whether at local or city level, acting collectively on pumping out a low point (Leclercq, 2019), or on draining an entire catchment area (Leclercq, 2023), produces 'winners' and 'losers' of the city out of water. When a parastatal agency involving the Senegalese government and the World Bank redefined the master drainage plan for Dakar on the scale of the city's catchment area,

they chose to fight the accumulation of water by favouring its "natural" flow, determined in part by the topography of the Cape Verde peninsula, and at the same time evicting the inhabitants located along the route of these flows. When neighbourhood organisations succeed in mobilising international NGOs and institutions to resume pumping a water table that has become too high, thereby flooding part of the suburbs (Leclercq, 2017), they make some of the flooded neighbourhoods more or less liveable, and in so doing act on the forms of exposure that structure them. In a saturated hydro-urban catchment area, the ability to mobilise more than human forces - run-off, infiltration and water storage capacities - and to modify the environment in order to do so, depends on urban actors ressources (Clark, Szerzinski, 2020). Behind exposure to risk or access to resources lie infrastructures, forms of urban planning and institutions that organise the production and maintenance of a city that produces its own exposure to flooding (Chahim, 2022), and over which certain individuals, groups, and not others have the capacity to act.

In San José, we see these power imbalances in handling the flooding between the historical responses of the dairy products factory in Barrio Lujan, the current responses of the new real estate actor in the neighbourhood, and the inhabitants' responses. Because the phenomenon is long-standing, and the work to reduce it is spread over time, residents have learned to live with it. In the landscape of the district, one can see the handcrafted devices visible in the facades of the houses: the inhabitants erect small walls, concrete or zinc barriers to prevent the entry of water in their houses. When it happens in the streets, flood is undermined, inhabitants live with it, even though they remain isolated. Residents also have permanent watch strategies (Gueben-Venière, November, 2020): they observe the clouds in the distance, listen to the force of the rain or torrent and decide to act accordingly (Guevara Viquez, 2023; 2019). When the artisanal barriers are breached and the water enters the houses, the residents mobilise to demand a response from the public authorities and from the neighbourhood's main employer, the dairy products factory that stayed in Barrio Lujan for over 50 years, which was also affected by the floods. Archives of minutes of meetings between representatives of the neighbourhood and the factory show the discussions of the various nuisances that the factory could generate during the 1990's. Although the company claims to be a victim of flooding[3], its response to it (to dig canals) gives a glimpse of the resources it can mobilise to deal with the situation, thereby reassuring local residents and easing tensions in the exchanges. Furthermore, the modification of the riverbed was one of the topics of debate back then as it was during the fieldwork: *"Listen, the assistant of the Municipality says to me "but the thing is that you put yourself in the river's natural field of expansion" and me "Damn! We got into the land of the river!", until I said "no", and I started to say "no, madam! Look at this, this, and this!*". Inhabitants associate the riverbed modification to the floods and hold the factory responsible for it.

Today, these power imbalances concern the use of the part of the riverbank land sold by the factory, which is currently empty and functions as a riverplain zone. A project of three residential towers is to be carried in the area. In order to develop it, the real estate company has to carry out works to increase the river's drainage capacity, widening the riverbed and encroaching on the protection zone[4]. The latter was not respected when the factory buildings were still standing. Since their demolition, this protection zone has been the subject of debate at the Ministry of the Environment, pitting the local residents, the company and the local authority, which supports the project, against each other (Guevara Viquez, 2020).

[3] One example is the minutes of 10 July 1995.
[4] A ten-metre protective strip along the riverbed that should not be built Law 7575 ("Ley forestal") of 1996.

Far from being only a question of "money", "coordination", "under-equipment" or "resilience", as emphasized by a post-positivist approach of the disaster supported by donors, authorities and a vast majority of engineers and scientists, the floods in those cities challenge the capacity of the channel system itself to evacuate water in an unequal and distributed maintenance regime (Pontille and Denis, 2017), and within a context of self-urbanism (Chiodelli and Grazioli, 2021) and fragmentation of public action (Lavigne Delville, 2017). As the statistic data would eventually show, it is not the deprivation and exposition that generate floods, but its articulation with economic growth and huge urban development projects that characterize a lot of cities of the Global South (Rentschler *et al.*, 2023).

4. Discussion and conclusions

Based on a situated approach, the paper sheds lights on the articulation of global processes typical of the urban paths in Southern cities and local scales. Through the notion of saturation, we show the processes of accumulation of expertise, practices and their materiality around the idea of channelization that, in interaction with hydroscapes marked by a particular pattern of urbanization, generate floods in two cities. In doing so, we propose to point out the temporal and spatial continuities between crises in the context of the Anthropocene. Following Knowles, we believe that these distinctions in time and place are "its self a form of politics, a politics of disaster amnesia, cutting effects from causes, and from futures" (2020, p. 203). Through 'saturation', we call to open the scope to approach crisis and disasters in the Anthropocene.

The common features we raised are however deploying on very different geo-ecological landscapes and timeframes.

In Dakar, the confluence of the city, the *niayes* geological formation and the monsoon regime generates problematic floods due to the slow progression, the stagnation, and the transformation of water, leading to abandonment of houses and epidemic problems. In San José, the process of metropolisation encounter the inter-tropical regime and the morphology of the micro-basins in an intra-montane valley lead to rapid and violent flooding. In contrast with the Dakar case, the problem seems to be the accumulation and the velocity of water. In both cases, however, saturation of the soil and of the networks seems to result from a waterproof-canalised urban planning model that imprinted its path, even if not realised, to the whole watershed.

Second, the comparison reveals a time lag in the public problematisation of the phenomenon. In San José, flooding became a topic of discussion in the 1960s, whereas in Dakar it was not until the early 2000s that the issue was publicly acknowledged, despite the fact that the suburbs suffered from floods since the early 1990's (Leclercq, 2020). This pre-San José approach to flooding might lead one to believe that the problem would have very different temporal characteristics today. What we can see, however, is that the problem is recurrent and persistent, sometime in the same neighbourhoods, sometime displacing from one neighbourhood to another, always taking the form of an unpredictable but persistent threat that targeting specific communities. This "on the edge" situation seems to be a characteristic of the saturated urban landscapes, pointing toward the unequal exposition to this very temporality. As pointed out by various authors using different frames (Nixon, 2013 ; Chahim, 2022), the Anthropocene is here not referring only to the great divide between North and South, but also to shifting temporalities within the cities and the neighbourhoods that put some of their inhabitants at risks more than others, redefining inequalities through this question : who is able to handle the hydro-forces within saturated urban watershed ?

In spite of differences, in both cases we see classic infrastructural responses aiming to tame and channel water, but also to "catch up" the vulnerable city that expanse quickly, both spatially and in term of population growing. If the water channels are considered as a necessity, both by hydrologists, urban planners and inhabitants facing floods, it also reflects a "bottleneck" in urban public policies and their capacity to change in these contexts (Melly, 2017). However, we saw that in saturated contexts, the different capacities to deal with the water forces has consequences at every scales, and that this power imbalance is the main driver of the reconfiguration of environmental inequalities. In this context, it become crucial to open the black box of water infrastructure in order to ask who is defining, controlling, managing them, how to reach and maintain "at the good scale", and is this solution the best suited for reducing environmental inequalities at the city scale (Leclercq, 2022).

The limited capacity for public action in the Global South doubles environmental inequalities in the Anthropocene, as the question of power becomes central. Large-scale action depends on resources, but also on the ability of actors to mobilise and exert pressure at different levels (private, local or national). The article thus highlights the importance of addressing the Anthropocene and the challenges posed by climate change not only by strengthening the infrastructure itself, but also by adopting situated approaches. The stakes are high in terms of knowledge of these hydro-urban basins, new urban environments (Hardy, 2005), in order to act in a changing context. Social science approaches can shed light on the long and spatial temporality of material saturation, capturing situated practices, including those of local residents, and thus facilitating the formulation of appropriate solutions beyond the exceptional event.

Abstract
The proliferation of global crises, such as climate and war-related issues, underscores the need for resilience assessment in urban systems to restore balance and achieve sustainable development. Despite extensive resilience research, a gap remains in adopting a common concept and effectively integrating resilience assessment into operational planning. This gap is especially critical in conflict contexts requiring rapid recovery. This paper aims to identify causes behind this gap and suggests integrating a federated urban resilience model into digital platforms. Focused on the case of Ukrainian cities, the preliminary findings from a cooperation project between the HafenCity University Hamburg and the German Corporation for International Cooperation (GIZ) GmbH, aim to enhance planning approaches for rapid recovery and sustainable urban growth, applicable to various crisis-affected contexts.

Keywords: urban resilience, digital tools, rapid recovery, conflict, Ukraine.

1. Introduction

Urban Systems are becoming ever more complex. As urban centres are becoming denser and population growth is dramatically shifting to urban areas, the frequency of natural and anthropogenic disasters in cities seems to be correlatively increasing (Council & Hov, 2013; Hoffmann, n.d.). The consequences of unexpected disaster events also evidence higher economic impact on its governments (Mohr et al.,2022). The planning of cities must devise new approaches, as well as agile and rapid means of planning for long-term solutions in view of the uncertainty of such events. Traditional planning comes to the limits of its capacities to deal with such circumstances.

In the context of rapid urban planning strategies, particularly in the adaptation to natural or man-made disasters (such as cities recovering from climate-related flooding or enduring war conflict) resilience frameworks emerge as crucial solutions. They optimize variables like uncertainty, which comes with risk and unexpected threats (OECD, 2019; Folke, 2016). Nevertheless, despite the existence of numerous models and frameworks, the integration of resilience-based strategies into operational instruments for urban planning has not been consolidated. Existing instruments for resilience assessment are mostly intended for higher level of policy and governance, but not fully integrated yet into the strategic planning practice at the local level. (Krishnan et al., 2023; Sharifi & Yamagata, 2018).

Based on a preliminary literature review and the empirical work carried out during an ongoing project in the context of Ukraine´s rapid recovery during and in a post-war situation, the first objective of this paper is to show the significance of integrating urban resilience assessment methods into the practical realm of strategic spatial planning. A secondary objective of this paper is to open a space for further exploration and debate towards reducing the identified gap between theoretical resilience frameworks and practical urban planning tools. An essential aspect to explore is the identification of current obstacles hindering the effective incorporation of urban resilience assessments into digital spatial platforms. The discussion section argues how digital tools can potentially address this gap and contribute to both rapid recovery and sustainable growth in conflict contexts. The outcome of this contribution should extend toward further research and implementation measures which should provide insights towards innovative integration and adaptation of urban resilience models into spatial planning practices and instruments, enhancing their utility in the realm of rapid urban planning strategies.

2. Theoretical Framework

2.1. Challenges faced by urban planning

As cities expand and evolve, the myriad of components that they hold are becoming increasingly intertwined and dynamically influential upon each other. Dynamic analyses have proven necessary to assess urban challenges from a scientific perspective, i.e. city-science and complexities of flows and networks (Batty, 2012), in opposition to a static and fragmented perspective which would otherwise focus merely on isolated parameters of the urban morphology, such as its physical characteristics. From the perspective of urban planning strategies, innovative approaches must be adopted to identify the source of urban challenges and understand the connections between its triggering parameters. Not only transdisciplinary perspectives (holistic approach, system thinking, adaptive governance) are enough to prepare for the formulation of solutions, but also innovative instruments to dissect the problems and their causes are urgently demanded.

In this sense, understanding cities as complex and adaptive systems allows to better recognize the interdependent relations of flows, material, and relationships inherent to cities (Alberti, 2016; Batty, 2009; Bettencourt, 2021; Ortman et al., 2020). The complex character of cities stresses the concentration and interdependencies of assets, systems, functions, flow, and population. Moreover, hazards and risks to which urban areas are exposed, have shown greater impact upon occurrence. For instance, in the cases of natural disasters such as the Haiti Earthquake (2010), the Sichuan earthquake (2008), Cyclone Nargis (2008), the European heat wave (2003) (Dickson, et al., 2012), or anthropogenic disasters such as the COVID-19 pandemic (2019) or the recurrence of armed-conflicts in such areas as Ukraine, Afghanistan or the Middle East, have led to devastating consequences not only on the physical, but also economic, environmental, and socio-psychological levels, especially for urban dwellers.

The correlation between the growing trend of global urbanization and the levels of risk and vulnerability in urban environments still demands further research (Leichenko & O'Brien, 2008; Cutter, 2021). In combination with the notion of hazard, understanding *threat* is an important part of the equation. Agents capable of triggering a potential hazard can be linked to a specific situation. From a complex-systems approach, resilience and by extension concepts such as risk, threat, and vulnerability share common patterns and interrelations. A city, as a dynamic network of interconnected activities and resources (e.g. human, natural, and built environment) can therefore be more vulnerable to any given risk or threat, triggering hazardous situations. Given the higher risks cities face, risk analysis has become more of a common practice, adopted not only by financial or cyber-security sectors but also by insurers advising the governance sector at higher levels. From this risk assessment practice, certain frameworks have also gained relevance within the field of spatial planning. Furthermore, these concepts and frameworks have been applied and transferred to other specific complex-systems fields of study such as cybersecurity, insurance and governance (World Economic Forum, 2022; Rangu, et al, 2024; Alibasic, et al, 2017). Such existing workflows can potentially offer a relatable scheme capable of serving as a reference amongst to-be proposed resilience frameworks for urban planning.

Endeavours on developing urban resilience frameworks resulted in several thorough efforts from different agencies, mainly governmental and of international development. Such frameworks (for instance, City Resilience Framework by 100RC; UN-Habitat City Resilience Profiling Tool, Resilient Cities Scorecard, by IBM and AECOM; City Resilience Index by ARUP and Rockefeller Foundation; Urban Resilience Indicators by the European Commission's joint Research Center; among others) often require complex metrics for rigid standards, making it difficult to rapidly operationalize such frameworks or provide guidance to further planning and projects (Datola, et al. 2022; Figueiredo, et al, 2018; Meerow, et al, 2016; Da Silva, 2013; Jabareen, 2013). Hence, a flexible tool adaptable to each specific case, data availability, and local expertise might prove useful to be operationalized for planning strategies under scenarios of uncertainty.

2.2. Considerations of urban resilience concepts for planning

Resilience comes into play as a relevant concept for planning, as it can inform how ready a system is to face a given risk and react towards recovery (Ribeiro and Goncalves, 2019; Datola, 2023). Within the specific context of urban systems, urban resilience is a crucial measure towards the achievement of sustainable development (Li et al., 2014; Meerow et al., 2016). It contributes to a better understanding of the interdependencies and trade-offs of the various urban sub-systems constituents of any city, including infrastructure, social networks, economic

structures, and environmental factors (Derrible et al., 2023; Chelleri, 2012). It also considers risk assessments to draw adaptation and mitigation measures. It aids in the balance between the redundancy and efficiency of a system´s resources. Urban Resilience can drive towards long-term sustainability, by withstanding shocks and maintaining stable urban environments over time.

The advantage of urban resilience, as Goldschalk (2003) notes, is that it is not a state bound to specific patterns or urban form. It offers flexibility to respond to each specific urban condition, and by doing so, fostering creative thinking to achieve it. Such quality opens a wide range for adaptability in the approaches that each of its frameworks addresses. Furthermore, through the awareness of the complex, dynamic, and open nature of urban systems, the need for a holistic, integrated and yet flexible (i.e. easy to adapt to each individual urban and disaster situation) approach to achieve urban resilience is acknowledged when understood in this way.

Nevertheless, how are resilience measures effectively integrated into the common workflows of planning approaches at more local levels of cities is still cumbersome in many cases. Measures can be planned for, in view of known risks faced by cities, but when uncertainty is also a determining factor, and the functional network of cities has become not only more complex but also vulnerable, solutions are more difficult to be devised. Interdependencies among correlating factors, and their cascading effects upon impact are still hard to identify and even measure (Cimellaro et al., 2019).

2.3. Artificial disasters in conflict contexts

Cities facing post-shock damage and subsequent reconstruction must carry out innovative policy and planning approaches in the midst of critical situations (e.g. emergent but fragmented plans, sudden inflows of aid, weak legislation, unregistered displaced people, scarcity of resources, unstable economy) all against the need for rapid recovery. Added to the complexity of this task, is that of coordinating activities across multiple levels of governance, understanding which measures are carried out at the national level and at the local level. Once again, resilience is a pertinent approach, as it is based on a conception of urban contexts as a composition of sub-systems within a larger system (Folke, 2016; Chelleri, 2012). This approach opens the scope of addressing challenges in the midst of rapid recovery, with considerations of time and scale dependencies, and allows the segregated understanding of parts of a system, in order to devise effective solutions for specific situations.

Differences between natural and artificial disasters.

It is, however, important to mark the distinction between two determining factors: the type of disaster and the context of the situation. The type of disaster affecting an urban system can be natural _e.g. earthquakes, flash floods, volcanic eruptions_ or they can be anthropogenic _e.g. an industrial leak of pollutants or the failure of an entire city´s electrical grid system due to lack of maintenance. Both types of disasters can have specific causes, but its impact on an urban system´s failure might be more dependent on the system´s conditions at the moment of impact. An urban system can also be broken down into two relevant context situations, when it comes to assessing resilience: stable or unstable. A significant distinction can be made on how disasters would affect an urban system, depending whether this finds itself in a stable (peaceful) condition or in a more vulnerable (conflict) condition (Fig. 1). Further knowledge on this topic,

collected from empirical cases, should shed insight on new and relevant parameters to take under consideration for an adapted resilience framework for urban planning measures. The definition of an urban resilience model which considers this differentiation could inform more about the different impacts of disasters, understand their behaviour according to this distinction of the urban system (stable or unstable) and the way they unfold and their path of cascading effects differently.

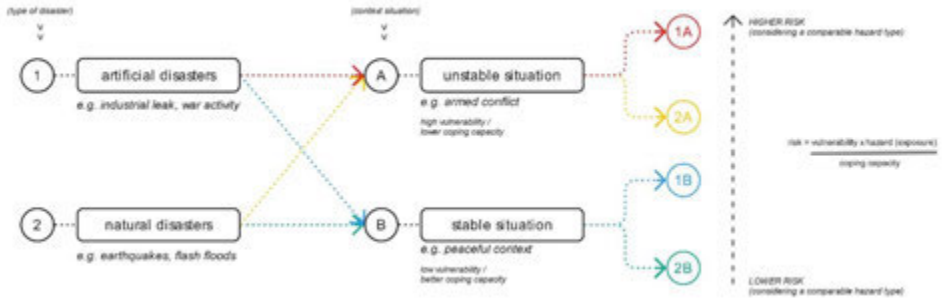

Fig. 1. Scenarios of Resilience assessment based on type of disaster combined with its context situation (authors, 2024).

The relationship between resilience and conflict.

Studies have coincided in the strong correlation between resilience and armed conflict (McCandless & Onbargi, 2023). However, this correlation has been identified in more studies from the perspective of disasters causing conflict, rather than in the opposite direction, when it comes to cause and effect contexts (Elfversson & Höglund, 2023; Rosvold, 2023). More extensive research has been conducted from the perspective of understanding how vulnerable areas impacted by disaster (e.g. climate-related) have a higher tendency of dealing afterwards with escalating conflict, in other words, how disaster consequently shapes conflict (Fig. 2).

On the other hand, when it comes to research on how areas already undergoing conflict are dealing with its low resilience capacities, less research is found and nevertheless it is still heavily demanded (McCandless & Onbargi, 2023; Rosvold, 2023). This refers, in opposition to the previous case, to the specific case of conflict triggering negatively the level of risk of disaster in a given situation, affecting a system's resilience. This first assessment collected from the available literature overview sheds light on the importance of exploring further what pre-existing conditions of areas undergoing conflict should be registered and acknowledged into a resilience framework for recovery planning.

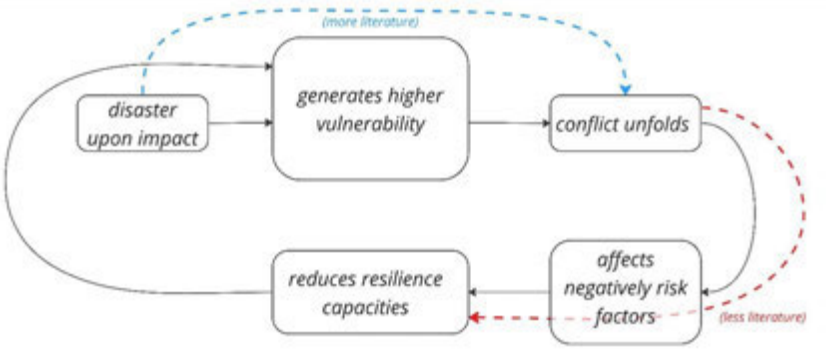

Fig. 2. Correlation between disaster and conflict and its coverage in literature (authors, 2024).

The case of Ukraine.

The case of Ukraine is a fitting case to explore these two correlating situations. One of the most pressing challenges in the current situation for Ukrainian cities is the accelerating criticality of space after assessing damage coverage in the country, caused by ecosystems erosion, bomb-mining, leakage of industrial substances after explosion or scattered military debris. It has intensified the challenge for planning across different actors and levels. Policy-makers and planners, along with central governments and local administrations, must define priorities when the country is in urgent reconstructive demand of housing allocation, without compromising other land use demands, such as those of economic or environmental nature, agricultural activity or protection of natural ecosystems (Shnaider et al., 2024).

Another example is the volatile numbers of internally displaced people (IDP) in Ukraine since the beginning of the war. The ongoing conflict has generated additional pressure on already vulnerable areas within the country, due to the constant shift in the numbers of the registered population within each city. Registration and up-to-date record keeping of IDPs is difficult to maintain track of, in view of the constant attacks (World Bank et al., 2022), and planning for an uncertain population number is cumbersome.
A third development brought on by the war situation has been the massive influx of financial aid received by the country. This has been identified by some as an unforeseen reaction which in turn might accelerate, in the long term, unprecedented urban development or even the integration of the country into the EU (Fiott, 2023; Ukraine's Path Towards EU Accession, n.d.). From the field of international strategic support this can be seen as a case of "silver linings" opportunities (Grant et al., 2023). For this to produce a successful outcome, strategic plans and measures must be realigned to be able to achieve both goals, i.e. focusing on fast reconstruction and deep transformation of the country (Rozmaritsyna, 2023).

3. Digital Tools for Urban Resilience

In view of the exposed need to reconsider planning strategies for rapid recovery scenarios and to draw multi-dimensional capacities of planning processes and instruments, it seems relevant to seek for solutions that can address a better understanding of cascading effects upon impact and interdependencies between parts of an affected urban system, under each context. Digital tools can help to model and understand complex, dynamic systems, as they can speed up planning processes by enhancing access to relevant data, synthesizing knowledge needed for

planning and decision-making. This may accelerate the generation of new output data, in the form of analysis for concrete planning activities (e.g. citizen participation, satellite image analysis, automated design assessment) facilitating agile and iterative evaluations, such as scenario comparison, design and check or rapid urban design prototyping (Noennig et al., 2023). Integrating digitalisation to urban resilience framework should be considered as a relevant option for accelerating these needed analysis, iteration, and decision-making activities toward more transparency in the restoration of a balanced urban system after a disruption.

The current findings from our ongoing research, within the framework of a cooperation project in Ukraine supported by the German Corporation for International Cooperation (GIZ) GmbH, address the identified need to incorporate digital tools into a proposed urban resilience framework for the case of Ukraine´s rapid reconstruction planning strategies. Our research has been based on a mixed approach between literature review on the theoretical background on resilience and urban systems, and also empirical knowledge collected through different sources, i.e. workshop sessions with members of the local authorities from different cities in Ukraine, webinars with NGOs working on site since 2022, the collected knowledge on site on behalf of the GIZ as our funding partner in this project, and collaborating researchers, both from Ukraine and externals, currently carrying out as well implementation projects in the country.

In this sense, the specific research-based activities in our project focus on defining the necessary components in a federated model for urban resilience, adaptable to Ukraine. One of the preliminary reflections from this process is that certain urban-related characteristics arising from the specific situation of conflict are still to be integrated into such a federated urban resilience model. Examples of these conflict-generated characteristics are e.g. shelters, massively displaced population or aggravated land-use distribution. Others are still to be outlined.

From the set of frameworks analysed, the similarities in the hierarchical organisations of dimension, sub-dimensions, components, and indicators were identified (Fig. 3). On this basis, a simplified set of four dimensions constitute the first step of the framework. Considering the specific situation of conflict, the relevant dimension distributions are social, economic, institutional, and physical. The natural ecosystem is included into the physical dimension of the urban system, as a fitting measure from other frameworks, to better cluster common components with overlapping characteristics, i.e. environmentally protected areas, public space, water bodies.

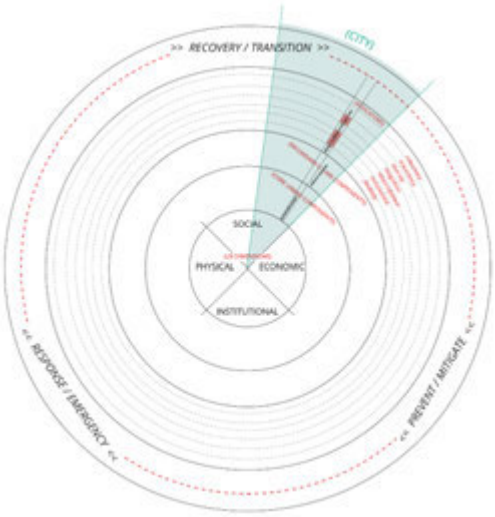

Fig. 3. Diagrammatic Chart of the proposed UR federated model scheme for the Ukraine Case (authors, 2024).

Considering the Cities Resilience Index (Rockefeller Foundation & ARUP in Da Silva, J., 2013) as one of the most adaptable references in terms of its composed set of indicators for resilience assessment, a further step in clustering components under each dimension is assumed to group sub-components in a system and better classify indicators and metrics. The final step of this process will be to identify at the indicators level of the proposed diagrammatic chart (Fig. 4) an additional set of indicators capable of measuring the new and needed urban characteristics, endogenous of an urban system undergoing conflict situations. These should be located within the proposed diagram, within fitting components and its host urban dimension.

4. Discussion

The upcoming phase of the ongoing research project will test the federated model for the urban resilience assessment in Ukrainian cities, with the objective of collecting learnings and insights on the following formulated research-related inquiries:

- On the topic of urban conflict: The outcome of the implementation of the proposed federated UR model should contribute to further identification of conflict-intrinsic urban parameters, and the need to measure their effect through newly proposed indicators. This should provide insights on how conflict, different from natural disasters, incorporates different variables, such as anthropogenic action and reaction, and to what extent these can condition the possibility of achieving a resilient urban system.

- On the topic of vulnerability and uncertainty during conflict: Based on the previous argument, it can also be discussed in what way resilience models should not be generalized and framed equally for contexts in peace and those in conflict, when facing any kind of unexpected disaster.
- On the paradox of urgency versus feasibility*:* It is in those areas with utmost urgency where the availability of up-to-date and reliable data is most difficult to be collected. From the

empirical work regarding resilience assessment to be carried out in the Ukrainian context, it is expected that a series of recommendations can be collected, in the form of learnings on how to deal with this paradox which hinders the faster take-up of digital tools for the realm of planning. The topic of overcoming urgent demands under scenarios of high uncertainty is, in any case, relevant for further study.

- On the impact of implementing digital tools for planning to address crises: Can digital and spatial tools implemented to contribute to the assessment of UR, indeed achieve faster iteration and formulation of more rapid responses in planning? The proposed model must be validated with the necessary actors, e.g. planners, authorities, citizens and regulators, in real-context scenarios, in order to address this question.

5. Conclusions

With the increasing complexity of urban systems, driven by rapid urban growth, densification, and population shifts, the risks to which cities are exposed become ever more relevant to address, encompassing challenges that combine multiple urban dimensions simultaneously. Hence, the importance and relevance of resilience frameworks that can inform about the interdependencies and adapt to each particular urban circumstance seem necessary. Furthermore, in an integrated manner, such frameworks can lead to planning strategies not only to lay out projects but also to monitor and steer its progress. The integrative character would not only be limited to planning experts but also serve as a platform to inform, collaboratively assess, and plan among various stakeholders.

Digital tools collect enough qualities to potentially address this gap by enhancing visualization, multiple scenarios validation, and quantitative deliberation of outputs which should facilitate decision-making for rapid reconstructive planning. It is nevertheless still necessary to carry out further research and validation through implementation projects to adapt a fitting urban resilience model (a federated model) into understandable digital platforms, which can ultimately address the needs of contexts in conflict, those facing not only climate-related disasters, but also artificial disasters. The critical need to incorporate novel urban resilience models and methods into strategic spatial planning is underscored.

The longer-term transference of the outcome of this research into operational activities toward more effective rapid planning for urban reconstruction could also be potentially supported by the assessment of other similar cases of contexts facing conflict, recovery and reconstruction, such as Israel, Palestine or Afghanistan.

Further research should help understand what is temporary and what remains (planned and built infrastructure, for example) when addressing fast recovery *versus* sustainable growth in a post-conflict context. The integration of digital tools supported by a validated resilience model which allow the formulation of more accurate decisions can potentially address two important challenges faced by planning in the coming years, meaning which solutions are designed for fast recovery and which are designed for long-term sustainable development.

Acknowledgments

The presented research has been conducted within the framework of a cooperation project supported by the German Corporation for International Cooperation (GIZ) GmbH.

Abstract

Just under 100,000 inhabitants live in the Bassa Pianura Friulana (Lower Friulian Plain), Italy, an area spanning a complex system of artificial and natural infrastructures, located at the northernmost point of the Adriatic Sea and bordered by a vast lagoon. During the summer season, the 130-kilometre coastline hosts over 3 million tourists. At multiple scales, the hydrographic system faces increasing anthropogenic pressures and is hierarchically structured, which may not align effectively with the efficient functioning of the territory. Consequently, the area is persistently exposed to risks from unexpected climatic events, resulting in significant imbalances such as floods, droughts, and storm surges. Artificial water management networks, however, do not fully mitigate the operational challenges of the territory.
This article initiates a discussion on research efforts, exploring tools, projects, and potential solutions to enhance the resilience and adaptability of artificial territories in response to transformations in both coastal and inland urban areas. The research aims to identify and highlight the conflicts between human and natural spaces, drawing on insights from Urban Political Ecology studies rather than a design-driven approach as often seen in landscape urbanism.

Keywords: climate change, planning transition, blue & green infrastructure.

1. Introduction: climatic emergencies

Several recent investigations provide compelling evidence that the boundaries of climate change and biosphere integrity are entering a phase of increasing and interconnected risks. Influential research analyses current phenomena - climate conditions and temperature trends - identifying a threshold of 2.7°C global warming, which will be exceeded during the 21st century unless substantial emission reductions are implemented. Only under these conditions could air quality improvements be achieved, potentially reversing temperature trends after approximately 20 years, with positive effects on various climatic factors over extended periods (Brondizio et al., 2019; IPCC, 2023; Pörtner et al., 2022).
Since the early 2000s, the worsening systemic changes have directly contributed to nearly a doubling of global disasters, predominantly driven by climate change. Approximately 90% of these events are hydro-meteorological in nature, while the deadliest catastrophes stem from geophysical events.[1] The urgent nature of the matter is also emphasised by the United Nations,

[1] If countries do not implement a prevention approach that incorporates risk reduction into decision-making in all sectors, the number of global disasters is likely to increase significantly each year, from 400 in 2015 to 540 in 2030. This would represent a 40% increase. In the past two decades, for example, earthquakes and tsunamis have been

which in recent years has intensified efforts to guide climate-vulnerable countries in adopting Disaster Risk Reduction protocols (Albrito P., 2023). Shifting conditions and persistent climatic imbalance are pushing planet Earth beyond the safe operating space for humanity. Six of the nine boundaries related to climate and Earth system changes have been violated, underscoring the need to evaluate the impacts of anthropogenic factors on the Earth system within a complex systemic framework. Currently, anthropogenic disruptions to the environment – such as climate change, biodiversity loss, and pollution – are often addressed as isolated issues. This approach ignores the nonlinear interactions and resulting aggregate effects on the overall state of Earth system (Richardson et al., 2023). Extreme weather conditions and adverse atmospheric phenomena are becoming increasingly frequent, exerting a greater impact on daily life, undermining economies, and exacerbating social inequalities [Beck, 1986; 1992; Secchi, 2014]. Time appears insufficient to alter the trajectory of current, uncontrolled development, which is increasingly dependent on the exploitation of natural resources, despite the need for implementing measures to counter worsening conditions. (Heynen, Swyngedouw, 2003). Adverse environmental events and related risks are becoming more and more impactful. For these reasons they need to get comprehensive regulatory frameworks. Compliance with legislation, a commitment to sustainable development programmes through concrete actions aimed at strengthening territorial resilience, and an awareness of the delayed response by public institutions in addressing the climate emergency are essential conditions for tackling the current fragility of territories without further delay. At the national level, Italy is implementing measures that contribute to the enactment of European policies on environmental protection and on adaptation and mitigation strategies in response to climate change. [2]

responsible for 58% of casualties, causing huge economic losses; in 2022 alone, estimated losses as covered by insurance were around $120 billion [UNDRR, 2020].

[2] Here the list of the Italian government's measures aimed at achieving the European Agenda's climate neutrality goals by 2050: National Strategy for Adaptation to Climate Change (SNAC), which is the act expressly directed to address adaptation at the national level and was issued by the Ministry of Ecological Transition in 2015; Long-term Low-GHG Emission Development Strategies (2021); Plan for Ecological Transition - PTE (2022), which constitutes a National Plan for Adaptation to Climate Change as a tool for coordinating and updating a range of environmental policies, including those on climate change mitigation and adaptation. There are other relevant national acts on climate change adaptation with cross-cutting or sectoral character, including: Cultural Heritage and Landscape Code (2004); Environment Consolidation Act (2006); National Strategy for Sustainable Development (2017); Civil Protection Code (2018); Protect Italy Plan 2019-2021 (2018); Climate Decree (2019), which introduced provisions aimed, primarily, at defining a national strategic policy for combating climate change and improving air quality; National Plan for Hydrogeological Risk Mitigation (2019); National Integrated Energy and Climate Plan (NIPEC); National Plan for Recovery and Resilience - NRP, submitted under the Recovery and Resilience Device under the Next Generation EU (2021); National Plan for Prevention of Heat Effects on Health - Guidelines for Prevention (2019); PP9 Environment, Climate and Health Program - PNP 2020-2025 (2019); National Forestry Strategy (2022); National Biodiversity Strategy 2030 (2022); National Strategy for Sustainable Development 2022 (2023); Guidelines for Climate Audit of Infrastructure Projects in Italy 2021-2027 (2023).

[3] iNEST – Interconnected Nord-Est Innovation Ecosystem model is based on the extensive use of information and communication technologies and digitization, and aims at the development of innovative technologies for people's well-being and the dissemination of culture and economic and entrepreneurial growth. The research was co-founded by European Union – Next Generation EU, grant no. ECS00000043 – CUP J43C22000320006, Piano Nazionale di Ripresa e Resilienza (PNRR - IT), Mission 4 "Education and Research", Component 2, Investment 1.5, Interconnected Nord-Est Innovation (iNEST) Ecosystem, Spoke 4 (https://www.consorzioinest.it/en/city-architecture-and-sustainable-design-2/). In this context, the study being developed by the group of urban planners

iNEST is a consortium based on the extensive use of information and communication technologies and digitization, and aims at the development of innovative technologies for people's well-being and the dissemination of culture and economic and entrepreneurial growth. The research was co-founded by European Union - Next Generation EU. The research iNEST - Spoke 4 has as its object of study is the inter-regional territorial system of Triveneto: the macro-region of northeastern Italy, consisting of Friuli-Venezia Giulia (FVG), Veneto and Trentino Alto-Adige, being a key area for the Italian economy among the richest, with 12% of people,14% of GNP, and 20% of Italian exports (iNEST, 2023). The research team of the Department of Engineering and Architecture (DIA) of the University of Trieste, identified the territory of the Bassa Pianura Friulana (Lower Friulian Plain) as a case study (Figure 1), better defined as a pilot project task. It serves as a pivot between the whole project and its testing.

Figure 1: Low Friulian Plain in the context of Italy.
Source: the authors.

The Lower Friulian Plain serves as a sensitive indicator of physical changes resulting from anthropogenic transformations of the environment and ongoing shifts in climatic conditions, which generate risk situations linked to the increased frequency of extreme meteorological events (ARPA FVG, 2023). Its unique geographical position lies in being a low-lying coastal area facing the northernmost saltwater basin of the Mediterranean Sea, making it directly exposed to fluctuations in sea levels. The small urban centre of Marano Lagunare (45°46′ N; 13°10′ E; 2 m a.s.l.), situated on the shores of its namesake lagoon, is an ideal reference point for this situation. Additionally, the Lower Friulian Plain is characterised by the interplay between the advancing sea along a discontinuous coastline interrupted by lagoons, and an

affiliated with the Department of Engineering and Architecture at the University of Trieste (DIA) for the Spoke 4 - City, Architecture, Sustainable design, research topic 1 e 2. In particular, 11 'Ecosystems' projects were financed in Italy, for a total amount of 1.3 billion euros. These are networks of state and non-state universities, public research institutes, territorial public bodies, other highly qualified and internationally recognised public and private entities. Each Ecosystem intervenes in areas of technological specialisation consistent with the industrial and research vocations of the reference territory, both regional and supra-regional, in order to promote and strengthen the collaboration between research institutes, the production system and territorial institutions. iNEST refers to the Triveneto territory, and is divided into 9 'Spokes', i.e. specific thematic networks. Leader partner of Spoke 4 is the Iuav University of Venice. Active partners in the research are CORILA; CRESME and the affiliated Universities: University of Padua, University of Udine and University of Trieste - Department of Architecture and Engineering (DIA), where, as far as research topics 1 and 2 are concerned, the research unit referring to urban and territorial studies is co-ordinated by E. Marchigiani and sees the participation of S. Basso, P. Cigalotto, M. D'Ambros, T. Frausin.

extensive inland water system comprising rivers with varying seasonal flows and a dense network of irrigation canals that support an extensive agricultural economy.
Approximately 100,000 residents live permanently in this area, and in the summer season, its 130 kilometres of coastline attract over 3 million tourists. The exposure to risks from extreme meteorological events and anthropogenic pressures can lead to significant disruptions in the broad, everyday use of this territory (Figure 2).

3. "Networks" and "ecologies" in the Lower Friulian Plain. Territorial functioning at various scales

The Lower Friulian Plain coincides with a vast intermunicipal territory (754 sq. km, 97,856 inhabitants; ISTAT, 01.01.2023) that corresponds to an extensive inter-
municipal territory encompassing 34 municipalities and situated between the Tagliamento River to the west – one of the main rivers of northern Italy – and the Isonzo River to the east; the Adriatic Sea to the south; and to the north the first inhabited strip
of a low wetland intersected by a line of resurgent waters. The profile between land and water presents a low coastline and a double overlook of a lagoon and marine environment. The coasts

present sandy beaches from marine and fluvial deposition, sloping into the shallow waters of the Upper Adriatic and heavily anthropized at the coastal urban centres of Lignano and Grado. Overall, the lagoon system covers about 16 q km (length 32 km; average width 5 km). It is possible to interpret the structure of this territory through a dual perspective. One approach describes the area in terms of "networks." The other, in a complementary fashion, uses the concept of "ecology" to characterise this territory. Here, we employ the term "ecology" not in a strictly scientific sense, but rather as a descriptive method, akin to the usage adopted by Reyner Banham in the past. [4] Furthermore, as a compelling interpretative metaphor for the complexity of urban habitats, natural ecosystems, and their interconnections, it is essential to clarify that the term "ecology," as applied in this phase of analysis of settlement systems in the Low Friulian Plain, does not imply an ecological interpretation of the natural environment of human beings. It is, however, valuable to refer to Richard T. T. Forman, who has recently explored the concept of Urban Ecology in a way that helps refine the understanding of "ecology" and the approach of "ecological reading" proposed here. [5]

The network system primarily defines the Low Friulian Plain and is structured through four main networks: the *mobility network*, the *environmental net*work, the *energy network*, and the *water network*. The *mobility network* is defined by a complex infrastructure system with different densities. In the east-west direction, major roads and rail routes — forming one of Europe's infrastructural corridors — connect tourist and industrial hubs along the coast. In the north-south direction, there is a more intricately layered local network close to the rivers. Running parallel to the Trieste-Venice route and along the Stella and Cormor rivers is an extensive network of rural roads supporting the slow-paced road network.

The environmental network is defined by the Marano and Grado lagoons and the remnants of lowland forests, which serve as key nodes within a network of protected areas classified under the EU Natura 2000 legislation. Rivers and canals act as potential ecological corridors that extend inland, taking on the character of linear parks (e.g.: Parco dello Stella). The *energy network* defines a territory that is transitioning from being a consumer of externally produced energy to an active player in clean energy self-production. This shift is driven by the rapid expansion of photovoltaic fields, supported by private initiatives, alongside biogas facilities and

[4] Borrowed from the context of natural science disciplines, the term "ecology" has long been part of the vocabulary of urbanism and planning and is used to observe, read and interpret space and place. In particular, the direct, learned, and innovative reference is to the word "ecology" used by Reyner Banham when describing the city of Los Angeles in 1971. In Banham's famous text, "ecology" is understood as a product of the interaction between physical features of a place, environmental elements, climate and forms of living, between physical and cultural landscapes. Banham understands and uses reading for ecologies by considering the different fabrics and structures of an urban setting as a whole. What the author introduces is the idea of considering settlement systems in relation to their own "ecology" that identifies them by inherent socio-spatial characteristics: that is, within a geographical, social and historical context. Reading by ecologies in this sense stands as a method of study and at the same time "an open scheme, suitable for heterogeneous observation and heterogeneous subjects" (Vidler A. in Banham, 2009: XXVIII). It restores the characters and conformation of places according to the perspective of their possible evolution. Reflection focus on the overall configuration of the observed settlement systems. The ecological study presupposes the recognition of possible spatial units, Banham would say.

[5] In Forman's definition, "Urban ecology studies the interactions of organism, built structures, and the physical environment, where people are connected. (...) Built structures are a key to urban ecology. Organism-environment interactions are simple ecology, whereas inserting buildings and roads into the interactions transforms the subject to urban ecology" [Forman T. T., 2014: 3-4]. This assumption moves from the hypothesis that settlement systems are describable as different spatial type mosaics where flows and movements through the mosaic create a dynamic system - again to refer to Forman. (Forman, 2014: 4) and to emphasize the effectiveness and importance of proceeding according to an interpretation and reading by 'ecologies'.

hydroelectric intakes. The *water network* in the Low Friulian Plain is characterised by a scarcity of aqueducts, replaced largely by artesian wells, which are frequently associated with private users.

The extraction from aquifers for residential, industrial, and agricultural purposes is widespread and substantial, leading to increased waste and growing challenges in resource management. The sewage disposal network is connected to a system of wastewater treatment plants, which come under strain during the summer. From a morphological perspective, when observed from a distance, the networks overlap within a framework of complex and diverse structures, shaping the configuration of a sprawling, low-density urban landscape. Within this spatial organization of the territory, reticular system of urban patterns lacking clear geometric order are discernible, featuring clusters of varying sizes that are mostly disconnected from main linking routes (Secchi, 1995).

The "ecologies" of the Low Friulian Plain are conceptually understood as territorial areas where settlement structures are complementary and interdependent, in relation to infrastructure systems and natural elements – the blue and green networks – to which they are linked. As mentioned, this definition is metaphorical, and here it is evoked with a renewed interpretation. The aim is to ascribe to the term "ecologies" a meaning as epistemologically robust as possible. In this context, an "ecological reading" highlights and explores the potential to advance the study of settlement systems by introducing the necessity of adopting new descriptive frameworks. These frameworks would enable a deeper understanding of territorial structures, addressing future interpretative and design challenges. In this context, within the territory, it is possible to describe various intersecting and overlapping territorial ecologies, layered upon one another with multiple points of conflict, understood as "critical frameworks" that draw attention to the interactions between human and non-human agents across different scales, the dynamic relationships between the biosphere, ecosystems, populations, and communities, and their vulnerabilities (Centis et al. 2024). These interactions make the Low Friulian Plain a distinctive case study for exploring the dynamics of a coastal territory, which here extends beyond a conventional urban waterfront to encompass a vast, evolving landscape. From the inland to the coastline, some "ecologies" are recognized: (i) the "productive cities of the European corridor" formed from a large-scale comb-like infrastructure (motorway and railway) of European significance, which connects to the industrial port area of Porto Nogaro. This area is traversed by substantial international commercial flows that extend seaward along the intercontinental routes of the Adriatic; (ii) the "inhabited street" aligned with State Road 14, along which lies a string of service centres and dispersed recent developments that have lost their historical connection with the ancient waterways system. However, these areas remain threatened by opposing phenomena of flooding and the risks associated with the increasing emerging of heat islands in urban context; (iii) the "city on water" which consists of small-scale territorial infrastructures linked to subsistence economies, particularly those associated with inland waters. These include landing stages with minimal facilities designed to accommodate small boats, areas for fishing and lagoon activities, small docks, fishing ponds, and traditional lagoon huts (known as *casoni*). Within the complex interaction between freshwater and saltwater, it becomes crucial to address the relationship between water infrastructure and the inhabited system structure; (iv) "leisure and tourism city" economically based on temporary tourist accommodation in coastal resorts, large-scale tourist camping village, and cultural attraction urban centres (e.g., Aquileia), all of which are threatened by storm surges and rising sea levels. In the background of this portrayal, shaped by interconnected and overlapping ecological systems, one can distinguish the rural settlements and the scattered isolated farmhouses of land

reclamation, largely abandoned and reduced almost to ruins, fallen into disrepair. The conflicts between the various ecologies are concentrated at the land-water interface, along the perimeter surrounding the lagoon, which constitutes a fragile area, radically transformed over the past century and subject to a range of diverse risks.

4. Lower Friulian Plain: the hydraulic machine and blue nets of a high-risk artificial territory

The Lower Friulian Plain represents the northernmost land of the Mediterranean, bordered by a body of saline water and directly exposed to fluctuations in sea level, with varying altitudinal levels. Until the mid-19th century, the landscape was defined by extensive floodplain forests and permanent meadows, [6] which have since been reduced to isolated fragments of natural habitats. Over time, the Lower Friulian Plain has been altered through the drainage of marshes, rivers and streams forced within their own embankments, the construction of canal infrastructure, and, lastly, the practice of agriculture. This has led to a comprehensive and systematic regulation of surface waters and the reshaping of these territories. A new spatial configuration was gradually consolidated, largely through significant land reclamation projects, predominantly carried out during the 20th century. [7] The aim was to make the land agriculturally productive and to strongly structure the territory, reshaping the landscape forms and imposing a new rationalised design of the land composed of a limited number of elements and materials (Feruglio, 1926; Feruglio, Mori, Soresi, 1931).

A system of agricultural enterprises with medium- to large-scale cultivated fields thus characterised the new configuration of the natural and productive open space system, leading to the development of an economy based on intensive monoculture (Felcher, Strazzolin, 2019; Zilli, 2019).

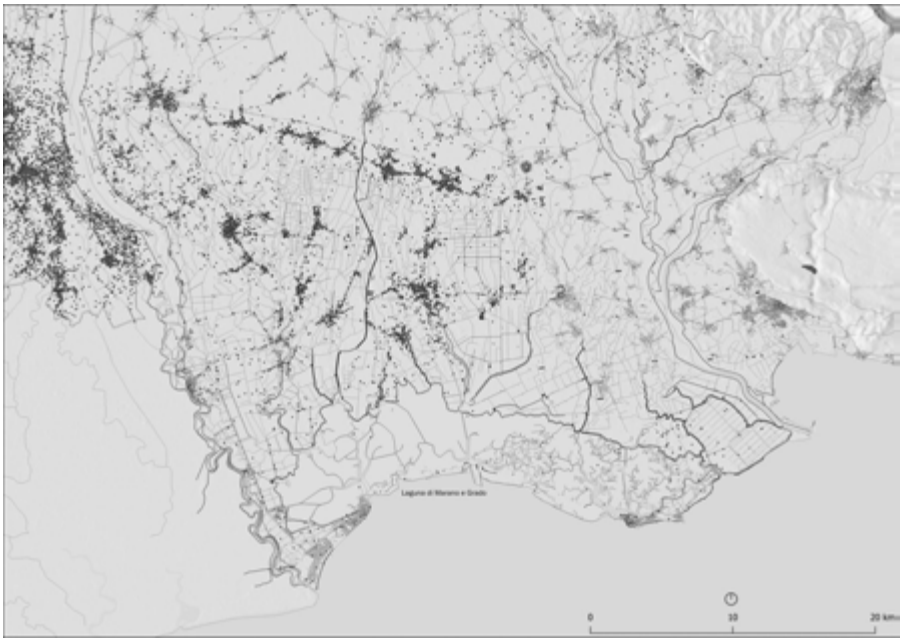
In the management of the territory, the priority has always been the collection of water to control its flow, initially slow and natural, then regulated and distributed in a rationalised manner through irrigation and reclamation works on an ever-increasing scale. The natural order of the past wetland environments has been disrupted and reduced to an artificial order, tending to separate the natural environment from the anthropogenic and agricultural space.

Today, the defining yet almost imperceptible characteristics of this territory are its topography and an extensive, strategically distributed network of mechanical water-pumping stations. The relatively uniform elevation ranges from approximately 10 metres above sea level in the spring zone, gradually descending southward to reach levels around zero hydrometric elevation. In the peri-lagoonal area, the terrain of the Low Friulian Plain falls below sea level. Currently, the Pianura Friulana Land Reclamation Consortium (Consorzio di bonifica Pianura Friulana) is one of the principal monitors and managers of this territory. It oversees coastal defence embankments and conducts maintenance operations across nearly the entire lagoonal boundary, which spans 80 kilometres, along with an additional 500 kilometres of embankments along

[6] From a comparison of Anton Von Zach's Kriegskarte (1798-1805) and Giuseppe Malvolti's Map of Friuli (1818), it is possible to see how wooded areas and stable meadows begin to shrink in extent.

[7] The reclamation of this territory is an ancient fact. In the past, its conformation was modified by natural phenomena (river floods, coastal deposits and bradyseismic movements) and as result of actions to drain swampy lands and marshes. The first systematic and most important operations can be traced back to the interventions made by the Republic of Venice from the 16th century onward.

major rivers flowing in the consortium's jurisdiction. [8] In total, the area under management extends over 78,277 hectares – representing approximately one-tenth of the entire surface of the Friuli Venezia Giulia Region – subjected to constant monitoring and safeguarding measures. [9] Based on the type of water runoff flowing across the area, the Consortium's territory is divided into zones of natural drainage, alternating drainage, and mechanical drainage. [10] In the circum-lagoonal area, 23,700 hectares correspond to depressed zones; here, water must be constantly removed and mechanically lifted by pumps, [11] as the land is situated below mean sea level or below the average hydraulic head of the main watercourses that naturally drain the territory, and, in any case, below the maximum tidal level (CPBF, 2021; Felcher & Strazzolin, 2019; Tosoratti, 1997) (Figure 3). In the second half of the 20th century, the prevailing development paradigm fostered an expansion of the territory, which now reveals an insufficient degree of infrastructure and spatial configurations required to enhance its efficiency and manage its resources effectively, particularly concerning water usage, agricultural land, and the growth of residential settlements. Describing the soil of this territory as a sort of "hydraulic machine", capable of managing water use and drainage with high efficiency, brings to light a paradox. To understand this, it is essential to consider the extensive network of pumps distributed mainly in peri-lagoonal areas,



[8] Example of this are the embankments along the entire lagoon front between the Tagliamento River and the Isonzo River raised to a height of 3 meters above mean sea level after the 1966 flood.
[9] The Consortium also controls the High Plain area above the resurgence line, which covers an additional 123,127 hectares.
[10] Natural and mechanical drainage channels cover a total of 2,228 km.
[11] On the territory of the Lower Friulian Plain there are 33 water-water plants with a discharge capacity of 163 m3/s and a consumption of about 5 million kWh/year; irrigation plants consume 16 million kWh/year.

Figure 3: Built-up areas, hydrographic network, embankments,

Source: the authors with Cristian Crovatto, 2024.

which keep the Low Friulian Plain dry by discharging water into rivers and the sea, preventing potential flooding. Added to this are the increasing demands for potable water for domestic, agricultural, and industrial uses, with substantial extraction from the groundwater table, which risks progressive depletion. [12] Moreover, the water supply and sewage networks require evaluation, as parts need modernisation and are insufficiently deployed to serve the entire urbanised area, particularly with significant gaps in the peri-lagoonal zones. [13]

This paradox becomes evident when observing that, despite extensive infrastructural development, the Low Friulian Plain is inadequately equipped to handle water emergencies (Zini, 2011; Bendoricchio, 2024). The critical environmental conditions are further exacerbated by widespread subsidence and saline intrusion, which are poorly monitored phenomena. [14] One longstanding risk in this region, now intensified by climate change, is river flooding. Hydraulically, this area presents distinctive characteristics (Figure 4).

[12] The left Tagliamento zone is in semi-equilibrium quantitatively because withdrawals are theoretically offset by recharge; however, the drawdown of water to the right Tagliamento zone depletes the quantities available on the left.

[13] The CAFC Spa - Acque del Friuli is in the process of drafting an Aqueduct System Interconnection Masterplan that envisages future scenarios of the aqueduct system in the FVG Region and Eastern Veneto, identifying interconnections and future sources of supply to the system in order to increase the degree of resilience of the entire FVG aqueduct system, and as a single model for monitoring intake works and drafting Water Safety Plans.

[14] Both phenomena are not extensively monitored: there are no updated large-scale data to formulate aions to counteract their effects.

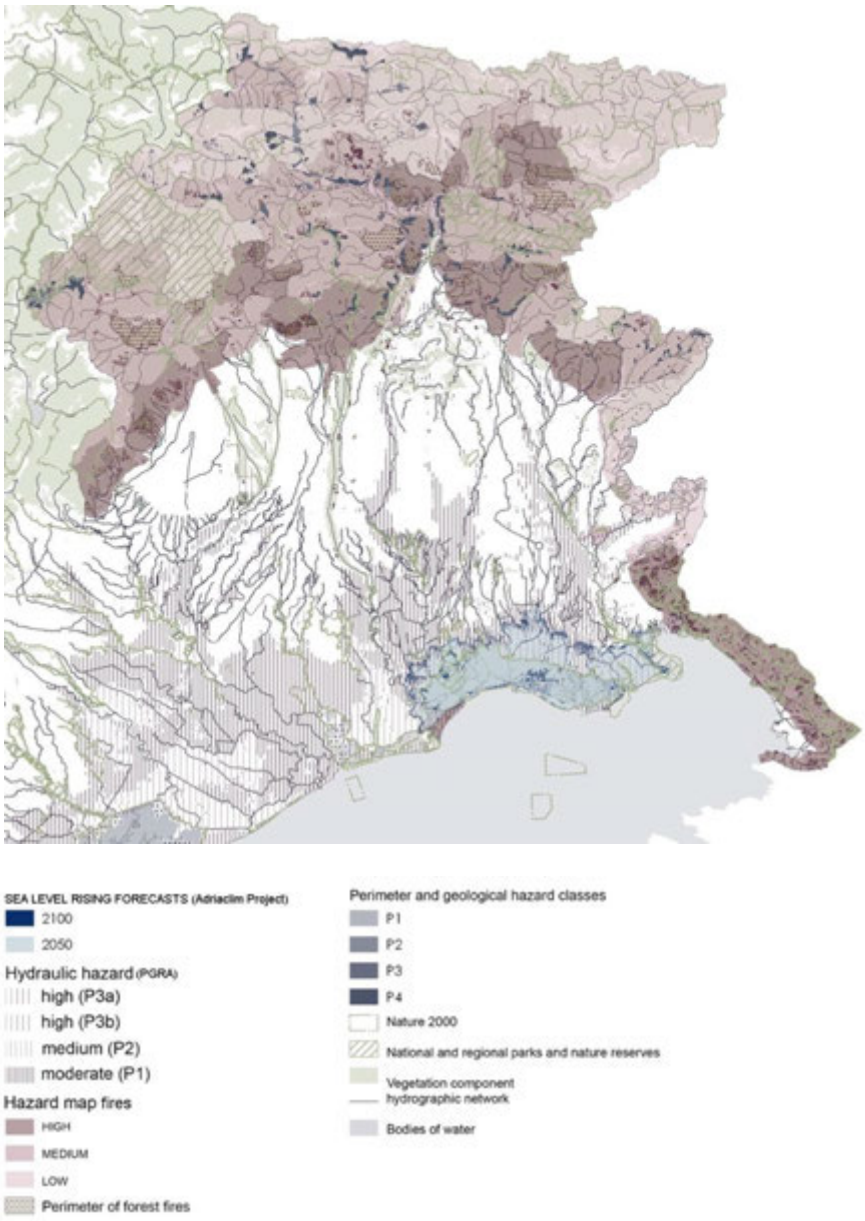

Figure 4: Vulnerabilities in Friuli Venezia Giulia Region.
Source: the authors with Eleonora Ceschin, 2024.

The short distance between the Alps and the sea, high rainfall in mountainous areas, the torrent-like nature of rivers with sudden surges, and the presence of spring-fed rivers have historically led to recurrent flooding issues, exacerbated by current climatic change. Coexisting with risk

has been a long-term feature of lowland territories. The canalisation and embankment works on rivers, predominantly found in these areas, do not provide an adequate solution to problems rooted in the past, nor can they effectively address the increasing risks anticipated in the future. The reduction of river flows due to hydroelectric diversion and other extractive uses appears to have indirectly caused the raising of riverbeds, increasing flood risks during extreme events. In the predominantly artificial hydraulic network of the upper and lower plains, there is ongoing debate to restore and to rewild segments of the "blue network" as an alternative to the construction of "grey infrastructure" solutions, such as flood detention basins. From the perspective of climate neutrality, devising alternative configurations for this territory entails rethinking territorial hierarchies, beginning with the establishment of new spatial relationships between environmental and anthropogenic components within a framework of expansive open spaces (Secchi, 1989). This approach must also acknowledge the current 'environmental phase' of land reclamation (Duca, 2003), which calls for a renewed dialogue with the agricultural landscape.

5. Across the River and Into the Trees: the uses of soil, ecological network and risks

Forests, meadows, rivers, and the lagoon were once the components of a lush, silvo-pastoral environment that characterised the plains below the spring line. The lowland forests, primarily oak woodlands, extended across the intermediate zone, forming
integral elements of a socio-economic system that spanned thousands of hectares until the First World War. Other woodlands occupied the spring belt and riverbanks, with sediment deposits gradually shaping the plains. To the north of the forests lay a belt of wet meadows, springs, and marshes; to the south was the shifting boundary with the lagoon. As recently as 1850, 58% of the circum-lagoonal area was covered by pastures, forests, and marshlands, with only 28% devoted to arable land. Large tracts of communal land allowed an organisation of isolated rural villages within a landscape half cultivated and half uncultivated. The abolition of rights over communal land disrupted this social balance, reducing many community members from land-users to rural proletariat. Simultaneously, by the late 19th century, a class of medium and large landowners and agribusinesses emerged, initiating a transformation of the landscape. With the construction of water pumps along the peri-lagoonal belt from the late 1920s onwards, many transitional wetland areas were reclaimed, while northern zones remained marshy. The hydraulic reclamation planned between the two World Wars was partially completed only after 1950. Meadows and forests disappeared, along with
marshlands, pastures, and ponds that once constituted a complex transitional environment between the open lagoon and cultivated highlands. The current landscape (Figure 5) reflects an industrialised agricultural environment of low ecological value, where only a few remnants of isolated lowland forests remain. Rivers have been channelled, and peri-lagoonal embankments demarcate the lagoon. Some protected areas (Natura 2000 Network) at river mouths preserve isolated sites of great

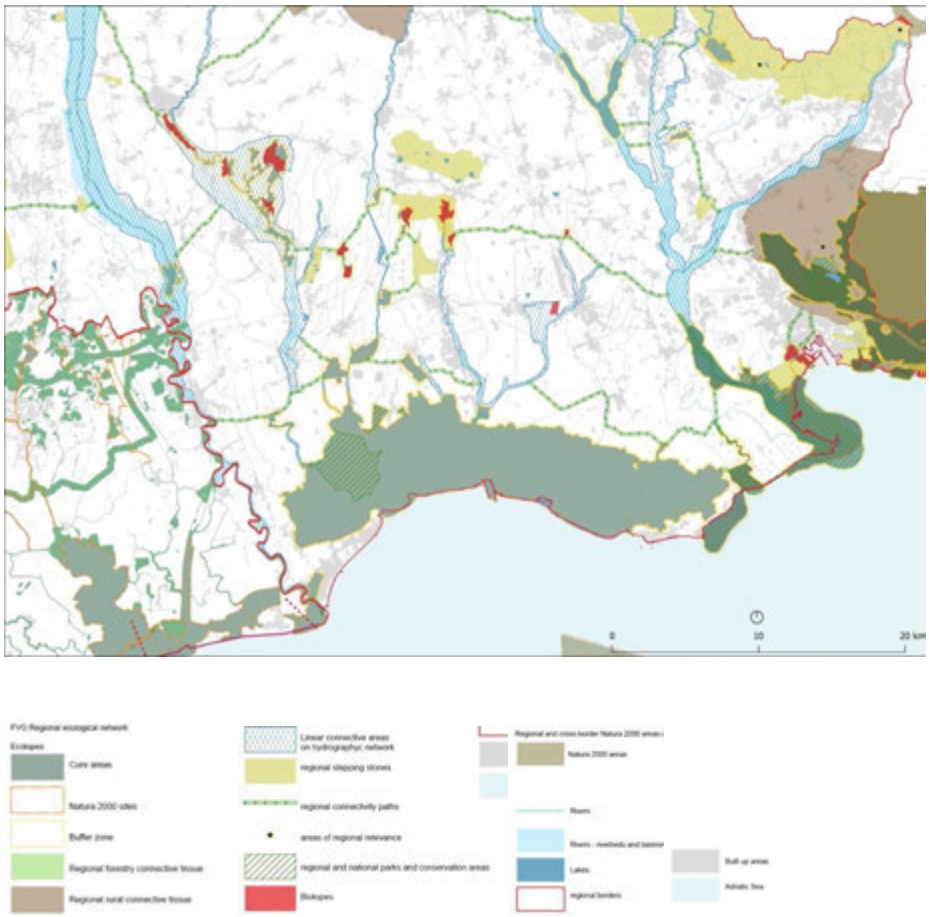

Figure 5: Ecological network of Lower Friulian Plain from the Project of Regional Landscape Plan, 2018. Source: the authors with Eleonora Ceschin and Cristian Crovatto, (elaboration of IRDAT data), 2024.

ecological richness. In recent years, projects have been initiated to strengthen and restore a more extensive ecological network and to reconnect forests, rivers, and the lagoon. A persistent risk, now heightened by climate change, is river flooding, a unique hydraulic challenge in this region. In the same way, Nature-Based Solutions (NBS) are being considered, for example, to address the risks of declining pollinator populations and biodiversity loss, a particularly serious issue in the highly simplified landscape of the Low Friulian Plain dominated by intensive agriculture. Some projects propose solutions involving the restoration and enhancement of landscape heterogeneity and the development of ecological networks of multifunctional natural and semi-natural areas, including forested zones.

6. Networks and ecologies at risk

"Networks" and "ecologies" – describe in paragraph 3 – are subject to severe challenges and increasing risks, with varied implications depending on the morphology and resilience of the affected areas (Figure 6). It is essential to examine the impacts of changes in both natural and human-modified environments in diverse contexts, primarily driven by climate change. A key objective of the ongoing research is to identify the specific impacts and, consequently, the necessary mitigation or adaptation measures to be implemented. While this section does not detail that aspect of the work, it is possible to highlight the most critical issues and project domains within which to construct a framework for reflection on a macro scale of the territory, to guide future work and suggest further avenues for investigation. At present, three key issues can

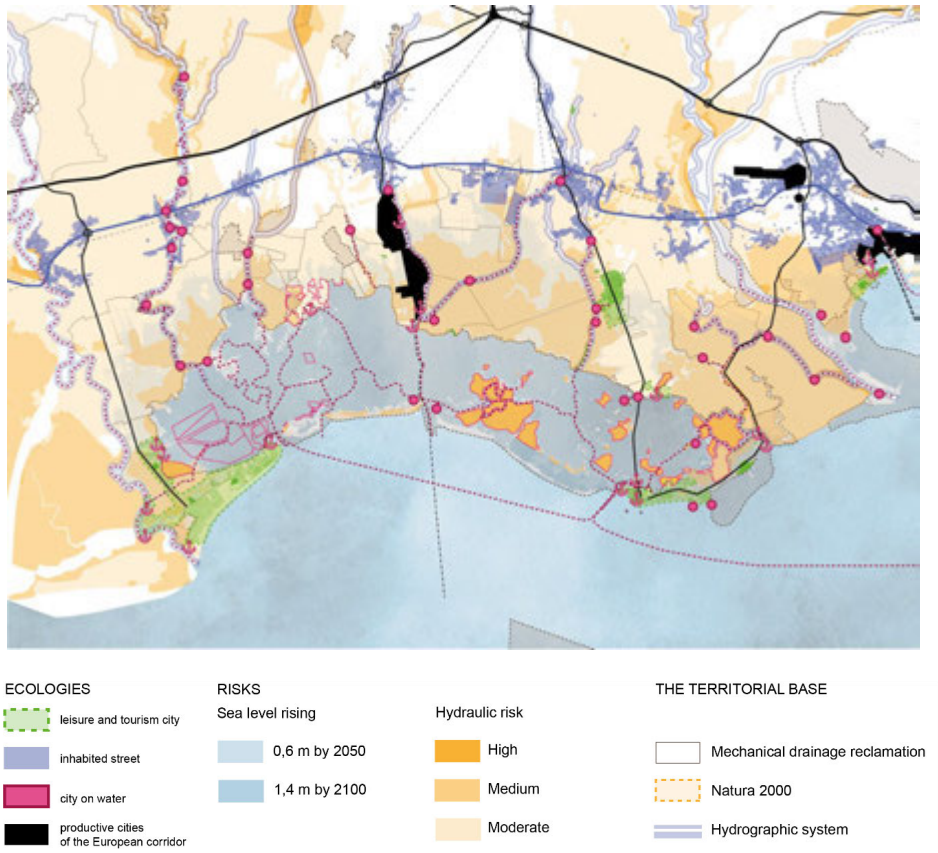

Figure 6: Ecologies, risks, hydraulic hazard (PGRA), Sea level rising forecasts (Adriaclim Project), network of the Lower Friulian Plain (Project of Regional Landscape Plan, 2018).
Source: the authors with Eleonora Ceschin and Cristian Crovatto, 2024.

be considered, without prioritising their order, to structure the perspective: 1) sea-level rise, 2) water abundance and scarcity, and 3) rising temperatures. These are among the most significant

macro-level issues directly affecting the Lower Friulian Plain. Together, these factors contribute to increased risk levels, and their combined impact implies a deterioration in living conditions across different contexts. In particular, the risks associated with rising mean sea levels primarily affect the "leisure and tourist city" and the "waterfront city." These two "ecologies" are impacted differently due to their direct exposure to tidal variability. For instance, on the coast, seasonal storm surges are becoming increasingly frequent, directly impacting urban centres like Lignano and Grado. The western coastal zone, characterised by sandy terrain, offers limited protection to urbanised areas, at the cost of erosion and the need for continual seasonal beach replenishment. [15] To the east, situated on an island, nearly all of Grado's urban area is inevitably exposed to the cyclical effects of tides (Bezzi et al., 2021). On one hand, water scarcity is intrinsically linked to these areas, largely due to the high seasonal influx of tourists, which significantly increases potable water consumption during the summer, concentrating demand during a short period compared to the rest of the year. During the summer season, the number of tourists stays averages over 3 million, primarily concentrated in the two main seaside centres of Lignano and Grado. On the other hand, the abundance of water resulting from heavy downpours predominantly challenges urbanised areas with higher levels of soil impermeability. The peri-lagoonal area, extending towards the hinterland, is also subject to potential flood risks due to the pronounced altimetric depression that characterises it. Continuous embankments protect one-third of the Low Friulian Plain from the average sea level, which is approximately 2 metres above the zero sea level mark. To ensure continuous protection against water intrusion and backflow, there are also 33 pumping stations [16] that enable this extensive territory to remain dry. A network of 2,228 km of natural and mechanical drainage channels further supports its proper functioning. The productive cities within the "European corridor" and the service and residential centres defining the ecology of the "inhabited road" appear to be more protected from the aforementioned emergencies. While not immune to the risks of water accumulation and drought, they are better equipped; unlike the peri-lagoonal areas, which are less serviced, this part of the plain benefits from a more extensive potable water distribution network. Rising temperatures and the resulting formation of heat islands affect the urbanised areas across all the described ecologies, with the greatest impact where proximity to natural areas is limited or where urban greenery is scarce. It can be said that the inner zones—aligned with the ecologies of the "productive cities" within the "European corridor" and the "inhabited road"—where urban mobility is highest due to extensive infrastructure, experience a higher concentration of heat islands as average seasonal temperatures increase.

7. Conclusion

As environmental degradation intensifies and climate change becomes a result of this worsening condition, it is imperative to reconsider environmental networks, especially in coastal regions. Certain issues emerge as evaluation markers in ongoing research, underscoring the need to develop hypotheses that go beyond mere concepts. There is an urgent need to rethink the relationship between humans and the environment, not as a matter of separation, but by

[15] Studies by the Region FVG have estimated the amount of sand needed for seasonal nourishment of the shoreline at 70,000 cubic meters, which grows to 200,000 cubic meters following storm surges). Con-causing the reduction of the sandy shoreline cordon is the confluence of the mouth of the Tagliamento River, which affects a large area, increasing the risks due also of possible freshwater flooding.

[16] The discharge capacity of the water pumps is 163 m3/s. Their consumption is about 5 Million kWh/year.

seeking strategies that foster improved coexistence. This includes exploring new frameworks that complement the concept of networks, such as the mosaic, kaleidoscope, or pluriverse (di Campli, Gabbianelli, 2022). The research is oriented towards a project concept based on relationships between different ecologies, practices, and forms of inhabitation. This presents an opportunity
to rethink networks in relation to climate change by considering at-risk zones as potential new core areas, expanding spaces of naturality. A significant advantage lies in the potential to integrate biodiversity considerations across all areas of planning, rather than confining them solely to green and blue networks. Connecting different areas within the territory to build landscapes does not necessarily require spatial continuity, but rather complex, multi-layered design approaches capable of establishing multidisciplinary, multi-scalar relationships. The spatial challenge is to activate biodiversity and new settlement forms across various ecologies: in industrial areas, residential zones, standardised areas, and particularly in agricultural regions. A priority, on one hand, is to redefine spaces for experimentation where urban and territorial projects can be re-evaluated, initiating a collective debate supported by design explorations and prototype formulations. As Viganò (2023, p.145) notes, "the design of the transition requires changes that we are not politically and economically equipped to implement and legislate." On the other hand, there is a need to develop shared visions and projects across different levels of public administration and multidisciplinary expertise, capable of designing across multiple scales rather than in a fragmented manner. The EU's missions provide clear guidance, offering a new approach to addressing some of Europe's most significant challenges. In this regard, Friuli Venezia Giulia stands out, being one of the few Italian regions to join the first of the five missions, "Adaptation to Climate Change," with the objective of achieving climate resilience by 2030, promoting innovative solutions for climate adaptation, and supporting cities and communities in building a more resilient society.
Planning must manage the coexistence of differences (worlds, species, social groups, etc.) rather than their separation. To this end, the Friuli Venezia Giulia Region established the "Technical-Scientific Working Group on Climate" in 2022. In the case of the Low Friulian Plain, attention is focused on at-risk areas, with 75.2% of the territory vulnerable to flood or sea-level rise risks. The emphasis is on a project centred around the reorganisation of water resources across various scales. For instance, the concept of *a net zero water territory* should become a shared objective, not only for the Low Friulian Plain. In this context, viewing all at-risk areas as project opportunities allows new themes to be incorporated into territorial planning efforts.

Track 18: Actor Constellations

ACTOR CONSTELLATIONS - Public, private and third-sector actors in planning processes

Chairs:

- Martine Drozdz, Ecole des Ponts ParisTech
- Stefanie Dühr, University of South Australia
- Sila Ceren Varis Husar, Slovenská technická univerzita v Bratislave

Keywords: *planning agencies, consultants, public participation, power relations, urban politics, local democracy, planning knowledges*

Public sector planning agencies are today operating in a shared power world. Declining capacities (and with it often declining in-house expertise) in the public sector have contributed to the rise of private sector consultants playing an increasingly significant role in plan-making and development assessment processes. At the same time, community groups and associations have become more concerned with changes to their urban environments, sometimes resulting in opposition movements that may significantly delay the implementation of urban development projects.

In this track, we are interested in the relationship between these different groups of planning actors and how their interactions are shaping planning decisions and urban development outcomes. We invite conceptual and empirical contributions that shed light on the sometimes conflicting and sometimes cooperative relationships between these actors. Contributions that deal with the current practices around how information and knowledge are produced and used by different actors in planning processes are welcome. In this track, we are keen to discuss the implications of the changing landscape of planning actors on the approach to managing urban planning processes and on the distribution of power between different actors in determining urban development outcomes.

Governance

Innovations in Semi-Formal Tools and Multi-actor Cooperation for Urban Design Governance: The Practice of City Chief Designer System in China

Shufen Hu[1]

[1]College of Architecture and Urban Planning, Tongji University
hushufen0608@163.com

Abstract: Urban design governance is the process of state-sanctioned intervention in the means and processes of designing the built environment in order to shape both processes and outcomes in a defined public interest, advocating for the establishment of a system of actions and decisions composed of diverse entities. The current development trajectory of Chinese cities has shifted from a period of rapid growth to a phase of high-quality development focusing on stock space, and urban design as a mode of planning and control has received more and more attention. A new form of urban design governance has emerged in key areas of development in some mega-cities—the City Chief Designer system. The City Chief Designer system serves as a semi-formal governance tool, bridging the gap between the hard-power governance of government authority and the soft-power governance of non-governmental organizations. This study divides the development of City Chief Designer system into three stages: the implicit development period, the establishment of the mechanism period, and the optimization and adjustment period. It summarizes the practical role of the system in driving the effectiveness of urban design operations, and investigates the interactive relationships among diverse participants. The study dissects the role of the system as a semi-formal design governance tool, analyzes power shifts and institutional reforms, and discusses the problems of the system, aiming to provide insights for optimizing the governance system of future urban design.

Key Words: Historical institutionalism; Urban design governance; Semi-Formal Tools; Multi-actor cooperation; City Chief Designer system

1 Introduction

By 2023, China's urbanization rate had reached 66.16%. The continued rapid urban development has also brought about a series of new problems and challenges, including inefficient resource utilization, environmental pollution, and loss of regional culture. Currently, China's urban construction is transitioning to high-quality development. Urban design, as a professional means of providing higher-quality urban living environments and public services (Wang and Liang, 2024), has received significant attention in recent years for its ability to meet the demands of high-quality development in the new era. The "Guidelines for Urban Design in Territorial Spatial Planning" issued in 2021 pointed out that "urban design is an important component of the territorial spatial planning system, a vital support for high-quality development of territorial spatial planning, and runs through the entire process of territorial

spatial planning, construction, and management."

At the same time, improving the urban governance system, enhancing urban governance capabilities, and increasing urban quality and competitiveness are trends in urban development. Urban design governance, as an important aspect of improving urban governance capabilities, has gradually attracted attention. Coordinating planning, construction, and management is an important manifestation of the modernization of the urban governance system and governance capabilities. In recent years, various regions in China have carried out a large number of urban design practices, but they face many challenges during the implementation phase, including the ineffective resolution of discrepancies between the implementation of urban design at the meso- and micro-levels and the existing institutional framework.

The position of City Chief Urban Designer represents an important innovative exploration for China in promoting high-quality urban development and transitioning urban design governance. A systematic study from this perspective can provide an intuitive understanding of the semi-formal tools and the composition and relationships of multiple stakeholders in China's urban design governance.

2 Governance turn of urban design in China

2.1 Traditional urban design

The concepts and methods of modern urban design were introduced to China at the end of the last century. Traditional urban development primarily relied on regulatory planning as the main control method, and urban design mainly followed architectural traditions, with morphological design directly affecting urban spatial forms.

2.2 Urban design regulation

Due to the involvement of a series of public interest motivations in urban design, state intervention has become increasingly widespread, and the depth and manner of state intervention have also been continuously changing. The normative guidance approach, which is too extensive and lacks targeted regulatory planning as a control method, has brought about problems such as resource waste, infringement of public interests, and environmental pollution. Urban design is considered to be able to optimize these issues, and its importance as a public policy has begun to emphasize the implementation of design control based on public spaces (Wang and Liang, 2024). During this period, a series of urban design transmission mechanisms such as technical guidelines and additional regulations emerged. The principles of urban design were incorporated into local urban planning technical management regulations or directly into regulatory planning. As technical management regulations and regulatory planning are the statutory basis for local scheme review and management, the incorporated urban design principles also have a certain legal effect, guiding and controlling specific development and construction activities to a certain extent. However, this model faces implementation issues

such as technical formalization and blurred lines between rigidity and flexibility in urban design control, and its effectiveness is not as expected.

2.3 Urban design governance

The current role of the Chinese government is shifting from directly intervening in economic and social affairs to providing public services, formulating rules, and maintaining fairness as regulators. It emphasizes government efficiency and responsibility, promotes public-private cooperation, enhances transparency and public participation, and is undergoing a transformation from management to governance. National recognized interventions are implemented in the methods and processes of built environment design to ensure that the design process and results better serve the public interest, and it is recognized that the process of design governance should be continuous and permeate through all stages of a project from inception to completion.

In response to the difficulties in coordinating interests, vague evaluation standards, inadequate technical responses, and difficulty in grasping intervention intensity in the urban design operation process, the renowned British urban design scholar Matthew Carmona proposed the concept of "design governance" in 2016. Design governance is the application and extension of governance concepts in the field of urban design, providing references for the development of transitional period urban design in China (Feng, 2021). Urban design governance is the process of state-sanctioned intervention in the means and processes of designing the built environment in order to shape both processes and outcomes in a defined public interest (Carmona, 2016). This concept advocates for establishing an action and decision-making system composed of diverse actors such as experts, investors, and citizens around the government, and optimizing the urban design operation process through formal and informal governance tools (Zhu and Tang, 2019). Essentially, it explores the basic principles of state intervention in urban design.

2.4 Semi-formal urban design tools

In the field of public policy research, government tools refer to various instruments, methods, and actions adopted by decision-makers to guide environmental and organizational actors in achieving specific policy outcomes. Since the 1990s, the rise of neoliberalism has led to a proliferation of available government tools, with tools or means to address public policy issues rapidly spreading. Some scholars have used typological approaches to study and classify existing government tools (Hood, 1983; McDonnell and Elmore, 1987; Schneider and Ingram, 1990; Salamon, 2000; Lascoumes and Le Gales, 2007). Schuster proposed five categories that could represent the "implementation of government urban design policies," namely operations, regulations, incentives, establishment, and information (Schuster， 1997). Based on this, Carmona categorizes design governance tools into formal and informal. Traditional formal design governance is primarily led by government departments, utilizing formal government tools such as laws, regulations, technical standards, and public policies to intervene in urban

material environments through planning and design, thereby ensuring that the design process and results align with the public interest. It is a "hard" governance approach relying on government power. Informal design governance tools represent methods used by third-party organizations, other than the government and the public, to indirectly participate in the urban design process. These methods lie between "traditional" design management and "private" corporate management, lacking legal safeguards and constraints. They constitute a "soft" governance approach intervening in the design and implementation process of the built environment. (Table 1)

Since urban design implementation in China is integrated into the planning management process, it possesses most attributes of formal design governance. However, due to the government's not necessarily possessing the strong professional capabilities required for urban design, and the relatively low level of development of non-governmental institutions in China, there exists a "semi-formal" design governance state (Wang, 2022). The government commissions professional technical organizations or teams to complement formal design governance, authorizing non-governmental department teams or organizations as leading actors in the multi-stakeholder governance network, and employing a mix of formal and informal design governance tools for design intervention. Semi-formal design governance practices currently emerging include the Chief Urban Designer system, community planner system, etc.

Table 1 Characteristics of formal, semi-formal, and informal design governance tools

	Governance entities	**Governance tools**	**Governance approaches**
Formal design governance	Government planning management departments take the lead.	Primarily utilizes formal tools such as laws, regulations, technical standards, departmental regulations, and administrative permits.	Relies on the power-based "hard" governance approach.
Semi-formal design governance	Non-governmental public institutions, but government-funded.	Combines formal and informal design governance tools.	A "flexible" governance approach between "hard" and "soft".
Informal design governance	Non-governmental organizations or citizen groups.	Primarily relies on informal governance resources and tools such as research and advocacy.	A "soft" governance approach relying on informal resources.

3 The Connotation and evolution of the City Chief Designer System

3.1 The connotation of the City Chief Designer System

The City Chief Designer system originated from the need to address the temporal and spatial separation issues in urban design formulation and implementation. Similar practices include the collaborative system of architects in the United States, coordinated architects in

France, expert advisory teams in Germany, and chief supervising designers in Japan. The City Chief Designer system entails local governments hiring experts and their planning and design teams to serve as regional city chief designers. These designers, commissioned by the government, leverage their professional technical expertise to provide services such as technical coordination, professional consultation, and technical review during the urban design and implementation processes in designated areas. This ensures that public interests are not infringed upon and that designs are effectively implemented. Essentially, this system serves as a flexible supplement under the rigid top-down control regime of government management departments. It aims to promote effective coordination between management and technology through institutional improvements, thereby better safeguarding core elements such as public interests, exhibiting characteristics of semi-formal design governance tools.

3.2 The evolution of the City Chief Designer System

This study takes historical institutionalism as its analytical perspective and divides the development of the Chief Urban Designer system in China into three stages: the implicit development period, the establishment of the mechanism period, and the optimization and adjustment period.

3.2.1 The implicit development period (Before 2018)

The development goals of cities, and even the phased development goals of cities, are continuously being adjusted, and the implementation paths face a series of choices, which is an important test for the subsequent services of urban design. For some key development areas of cities, the involvement of local planning and design teams is often long-term and may involve many different projects. The goals and orientations of planning and design also evolve continuously. For example, in the Shenzhen Bay Super Headquarters Base in Shenzhen, the Shenzhen branch of the China Urban Planning and Design Institute has been involved in a series of projects including protection and development planning, conceptual planning, and urban design over nearly twenty years. It witnessed the evolution of its positioning from a single "coastal urban residential area" (2001) to a compound "coastal cultural and business centre" (2004), and then to a "super headquarters base" (2007) (Figure 1). Although there is no specific employment contract for this long-term tracking of planning and design, the planning and design team effectively plays the role of city chief designers in overall planning and coordination for the region. The service usually accompanies dynamic planning and design work, including from planning intent to design blueprint, and then to the process of implementation construction (Wang, et al, 2022).

Figure 1 Changes in the Shenzhen Bay Super Headquarters Base Scheme Over Twenty Years

3.2.2 The establishment of the mechanism period (From 2018 to present)

In 2018, the Urban Planning and Land Resources Commission of Shenzhen Municipality issued the "Shenzhen Key Area Chief Urban Designer Trial Measures " (hereinafter referred to as the "Trial Measures"), establishing the City Chief Designer system in key areas and proposing relevant requirements for selection, service, and management, aiming to strengthen the planning, design, construction, and management standards of urban key areas through institutional establishment. Subsequently, Zhengzhou, Wuhan, and Foshan have successively promulgated implementation measures for the City Chief Designer system, and Longgang District of Shenzhen has formulated the more detailed "Implementation Rules for the City Chief Designer System in Longgang District" by referring to the "Trial Measures" of Shenzhen Municipality and combining with the actual situation of Longgang District. Meanwhile, the City Chief Designer system has been practiced in various regions, typical examples include the Shenzhen Bay Super Headquarters Base and the International Convention and Exhibition Centre in Shenzhen, the International Financial City and Pazhou West Area in Guangzhou, and

the West Bank Media Harbor, Expo B Zone, and Hongqiao Business Centre in Shanghai. These practices aim to improve the overall development and construction quality of regions by employing City Chief Designer teams mainly composed of planning and design units. However, there are significant differences in specific work content and practices among these practices.

Due to the lack of unified institutional documents issued by higher authorities, there are significant differences in the exploration and institutional provisions of the City Chief Designer system in key areas across different regions, mainly reflected in the service targets, work content, and whether the land has been granted (Table 2).

Table 2 Relevant institutional documents and requirements of the City Chief Designer system in key areas across different regions

City Name	**Document Name**	**Release Date**	**Main Content**	**City Chief Designer Responsibilities**	**Service Period**	**Whether participation in relevant design bidding and competitions is permitted**
Shenzhen	Shenzhen Key Area Chief Urban Designer Trial Measures	2018	Implement the City Chief Designer system in key areas throughout the city, determine selection and management tasks	Provide technical coordination, professional consultation, and technical review services to construction management departments	3 years	Yes, but the scale of buildings undertaken should not exceed 15% of the total planned new construction in the area
Zhengzhou	Zhengzhou Key Area Chief Urban Designer Trial Measures	2021	Employ City Chief Designer in 32 core blocks and other key development areas of the city, determine selection, service, and management requirements	Provide administrative decision-making assistance to planning and construction competent authorities, including technical coordination, professional consultation, and technical review services	3 years	Yes

Wuhan	Wuhan Key Functional Area City Chief Designer System	2021	Implement the City Chief Designer system in 14 key functional areas, the City Chief Designer team will provide long-term urban design guidance and technical support for project proposals	——	——	——
Longgang District of Shenzhen	Implementation Rules for the City Chief Designer System in Longgang District	2021	Applicable to major planning studies, technical standards issuance, and project construction implementation in the district. Determine responsibilities, work content, requirements, and processes, and propose evaluation criteria for the Chief Designer team	Regional-level planning coordination, core control area planning control transmission, and project-level quality improvement	3 years	Yes, registration is required
Foshan	Foshan Key Area Chief Designer Trial Measures	2022	In key areas determined by administrative agencies based on the city's development priorities and the distribution of construction projects, determine selection and management tasks	Provide decision-making consultation to relevant functional departments, including technical coordination, professional consultation, and technical review services	2 years	Yes, but the scale of buildings undertaken should not exceed 15% of the total planned new construction in the area

3.2.3 The optimization and adjustment period (From now on)

China's urban development has transitioned from the traditional period of incremental

growth to an era of stock development, where large-scale new projects are becoming increasingly scarce, and urban renewal is becoming the mainstream of future urban development in China. Although the origin of the City Chief Designer system and its current stage primarily apply to large-scale new construction projects, its important role in effectively implementing planning and design intentions, safeguarding public interests, and improving regional quality remains significant in urban renewal projects. While maintaining its characteristic advantages, how to make adjustments to better adapt to the needs of projects in the era of urban renewal is an important challenge that the City Chief Designer system will face in the future.

Furthermore, contracts for City Chief Designer typically involve large amounts of money (for example, the contract amount for the City Chief Designer of the Shenzhen Bay Super Headquarters Base, with a planned land area of 1.17 square kilometres, is 58 million yuan, whereas the contract amount for the overall planning of Shenzhen Municipality is only 31.57 million yuan). However, in recent years, local finances across the country have gradually tightened, making it difficult to support such large expenditures. History has shown that when resources are scarce, politically expedient measures may overlook the significant role played by design governance tools. Therefore, how to optimize the development of the City Chief Designer system in the context of limited local government financial resources in the future becomes crucial.

4 The multi-actor cooperation of City Chief Designer System and the existing issues

4.1 Participating actors and their main roles

The work of the City Chief Designer system spans the entire process of project planning, construction, management, and operation, involving complex coordination among multiple stakeholders and disciplines. Due to the lack of unified technical and implementation standards for the City Chief Designer system, there are significant differences in exploration and innovation across regions, leading to diverse compositions of participating actors. However, the main actors typically include government entities, City Chief Designer teams, construction unit, land developers, land design units, and the public (Figure 2).

Taking the participation of actors in the City Chief Designer system at the Shenzhen Bay Super Headquarters Base as an example, government entities include the Housing and Construction Bureau of Shenzhen Municipality, key projects management office in Bao'an District and so on. The composition of the City Chief Designer team includes a Development and Construction Command, responsible for decision-making and approval; an office within the municipal planning and construction management department, responsible for coordinating administrative tasks among various relevant departments; Shenzhen Investment Holdings Co., Ltd., responsible for all public construction and operations; and the City Chief Designer team, responsible for coordinating technical teams from different design units, comprehensive transportation teams, municipal teams, landscape teams, and other professional teams,

effectively integrating the results of multiple disciplines to achieve the best overall outcome. Land developers include 15 companies such as OPPO, JD.com, China Merchants Bank, Vanke, and Tanyin, etc., while land design units include 11 companies such as Foster, GMP, and Zaha Hadid Architects, etc. It can be seen that the implementation of the City Chief Designer system in key urban areas involves such a wide range of stakeholders and a large scope of work complexity.

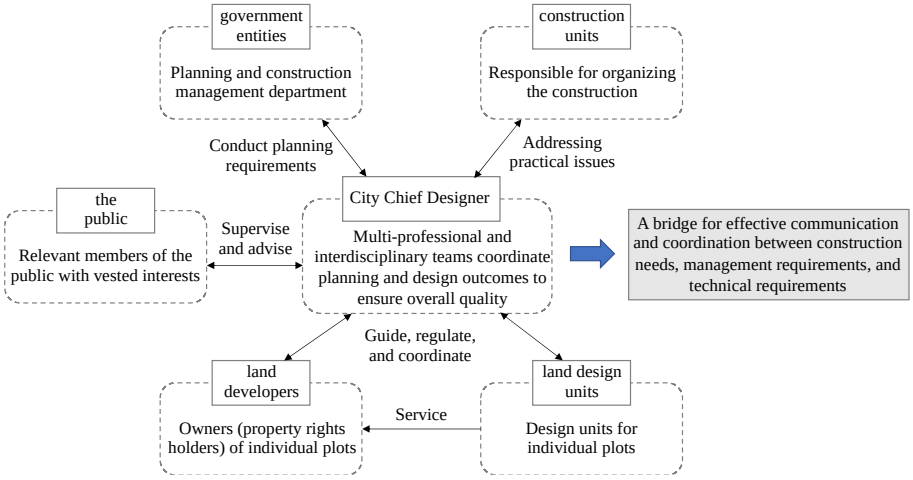

Figure 2 Participating subjects and their relationships

4.2 Existing issues

4.2.1 Unclear boundaries

As the City Chief Designer system is still in the early exploration stage, there is limited and insufficient in-depth research regarding its conceptual boundaries, work boundaries, and the flexibility boundaries of control. This lack of clarity has led to numerous problems in the actual implementation.

Regarding work boundaries, although the implementation methods in various regions have roughly defined the work content of the City Chief Designer, local governments often expect the City Chief Designer to address all issues in project development and construction after hiring them. Moreover, they hope that the City Chief Designer can devote all their time to the project. However, many aspects of the project are not within the expertise of the City Chief Designer, and the City Chief Designer team usually handles many other projects simultaneously. These issues arise due to the lack of clearly defined work boundaries.

Regarding flexibility boundaries, compared to regulatory planning, the control elements of the City Chief Designer system have greater flexibility. This characteristic of design control

is both a feature of design guidance and a conflict focal point in the scheme review process. Excessive control by the City Chief Designer may affect the creativity of landowners and design units, leading to homogenization of design schemes. However, insufficient control may be exploited by developers, compromising public interests and public spaces. Therefore, the lack of clarity in the flexibility boundaries of City Chief Designer control will lead to many problems, which is one of the key issues that need to be addressed in the current system optimization.

4.2.2 Difficulty in coordinating various actors

On the one hand, the institutional factors determine the close relationship between the City Chief Designer and the government, which puts this system in a dilemma to some extent. The City Chief Designer is very susceptible to the influence of government departments in the decision-making process, making them appear weak. Although the City Chief Designer seems to have considerable power, they are still part of the government's design department and receive funding from the government, which at least partially restricts their independence. The decisions of the City Chief Designer may be interfered with by the decisions of the management department, and the hiring party hope that the City Chief Designer is an independent third-party technical entity, but it is difficult to achieve in reality without considering the intentions of the higher authorities.

On the other hand, due to the complexity of the interests of multiple stakeholders, various actors may hinder the decisions of the City Chief Designer. For example, architects may perform poorly in scheme reviews, government decisions may be influenced, other design institutions may not support due to competitive relationships, and developers may feel that their autonomy is diminished. These stakeholders may oppose the City Chief Designer. system and the decisions made by City Chief Designers due to considerations of their own interests.

5 Conclusions

The transition from a single decision-maker to collaboration, from top-down power relations to interactive power relations, and from static management to dynamic and continuous governance make the City Chief Designer system an important innovative exploration for China to promote high-quality urban development and transition in urban design governance. The pursuit of better design by the City Chief Designer system is not limited to the narrow aesthetic level but involves comprehensive considerations of functionality, sustainability, economic feasibility, social equity, and more. The City Chief Designer system has established a mechanism that enables the needs of various fields and departments to be better coordinated, leading to better decision-making, promotion of key project implementation, efficiency improvement, and quality enhancement. However, as the City Chief Designer system is still in its early stages of establishment, many complex issues exist in terms of both system and implementation, requiring further optimization to meet the needs of development. This article takes the City Chief Designer system as a starting point, introduces the concept of design

governance, analyses the connotation of China's urban design governance transition, semi-formal governance tools, and the composition and role of participating actors, hoping to lay the foundation for further exploration of China's design governance and the development direction of future urban design governance.

Abstract

Positive Energy Districts (PEDs) are put forward as a building block to facilitate the transition towards climate-neutral cities and sustainable energy systems. While PEDs are pivotal for realising climate objectives, the concept is difficult to apply in existing, underprivileged neighbourhoods, because it underestimates social and political dimensions of neighbourhood energy transitions, and therefore risks to perpetuate or even exacerbate energy injustices. This research uses a spatially-sensitive approach to scrutinise energy injustices and rethink vulnerability stigmas. Drawing on the concept of urban transformative capacity, the paper develops a four-track approach focusing on collective-inclusive visioning, collective actions, institutional-community co-evolution and socio-technical innovation to foster collective agency. This framework serves as a basis for further case-study research aimed at achieving just urban transformations.

Keywords: underprivileged neighbourhoods, Positive Energy Districts, urban transformative capacity, place-based, collective agency.

1. Introduction

Transforming the energy system fairly and inclusively is a vital challenge in the face of the climate crisis. Positive Energy Districts (PEDs) are put forward to transition towards climate-neutral European cities and energy transitions. They are promoted as crucial building blocks to realise the UN Sustainable Development Goals, the European Green Deal objectives, the Mission on Carbon-Neutral and Smart Cities, and to implement the Renovation Wave

(European Commission, no date). Positive Energy Districts are defined as energy-efficient and energy-flexible urban areas or groups of connected buildings which produce net zero greenhouse gas emissions and actively manage an annual local or regional surplus production of renewable energy (JPI Urban Europe / SET Plan Action 3.2, 2020). However, this approach has predominantly been technical and infrastructural in nature, often overlooking the social and political challenges of the neighbourhoods it seeks to transform. Justice and wellbeing issues related to PEDs are missing (Truffer, Murphy and Raven, 2015), consequently, they fail to contribute to a just energy transition. This is particularly true in underprivileged neighbourhoods, where energy injustices become tangible and could be exacerbated by energy transitions, as a consequence of unequal distributions of burdens and benefits, non-inclusive decision-making processes, and a misrecognition of structural and historical inequalities (Jenkins *et al.*, 2016; Williams and Doyon, 2019).

It remains uncertain in theory as well as in practice in what ways PEDs can help achieve just transitions (Hearn, Sohre and Burger, 2021), and commonplace approaches to PEDs can even increase exclusion, energy poverty and other inequalities (Hearn, Sohre and Burger, 2021). In this paper we therefore explore the main challenges and resulting energy injustices, when dealing with energy transitions in underprivileged inner-city neighbourhoods and aim to identify a conceptual framework to foster the 'transformative capacity' of such neighbourhoods. Firstly, we theoretically explore the different injustices related to energy transitions faced in underprivileged neighbourhoods. Secondly, we argue that adopting a place-based approach is necessary to scrutinise these energy injustices and to connect energy transition strategies with a neighbourhood's socio-spatial realities. We emphasise how PED-strategies often fail in adapting their approaches to underprivileged, often dense inner-city neighbourhoods. Thirdly, we explore how fostering collective agency rather than strengthening the vulnerability stigma provides steps towards inclusive energy transitions. Fourthly, we explore how the concept of 'urban transformative capacity' can be applied to underprivileged neighbourhoods to address what we term the urban transformation paradox. We introduce this concept to emphasise how such neighbourhoods face injustices on the one hand, and display spatial, social and institutional transformative potential on the other hand. Lastly, the paper develops a four-track approach based on these dimensions of transformative potential, to foster the urban transformative capacity of underprivileged inner-city neighbourhoods, as an incentive for further case-study research.

2. Energy justice and underprivileged neighbourhoods

Energy justice addresses justice issues in energy access, use and policymaking to overcome inequality (Feenstra and Özerol, 2021). Sovacool and Dworkin (2015, p. 436) define the concept of 'energy justice' as 'a global energy system that fairly disseminates both the benefits and costs of energy services, and one that has representative and impartial energy decision-making'. Energy justice research typically deals with 'the triumvirate of tenets', including distributive justice, justice as recognition, and procedural justice (McCauley *et al.*, 2013). Respectively, these relate to fairness in the distribution of burdens and benefits, the recognition given to different socio-cultural identities, and fairness in the decision-making process (Schlosberg, 2007; Jenkins *et al.*, 2016; Bouzarovski and Simcock, 2017).

The urban poor living in underprivileged neighbourhoods are confronted with distributional, recognition and procedural energy injustices (Bouzarovski and Simcock, 2017). The socio-spatial characteristics of these neighbourhoods, such as the quality and energy efficiency of the built environment, public and collective infrastructure, demographics, income, class and

ownerships structures, social networks, cultural and behavioural factors etc., influence both the barriers and opportunities for sustainable transformation (Dietz, 2002; Boardman, 2010; Robinson, Bouzarovski and Lindley, 2018; Knox, 2019). These factors play a role in shaping the context for sustainable development initiatives. Using the concept of energy justice, the next paragraphs highlight how underprivileged neighbourhoods face disproportionate challenges in realizing an energy transition.

Distributional energy injustices are inequalities in how the burdens and benefits of energy systems and energy transitions are distributed, and therefore 'who wins and who loses from transitions' (Bouzarovski and Simcock, 2017). Distributional injustice is strongly related to socio-spatial inequalities (re)producing energy deprivation in particular spaces and social groups (Bouzarovski and Simcock, 2017; Simcock and Petrova, 2018).

As argued by Walker (2009), distributional inequalities have a spatial expression and constitution. Inhabitants of underprivileged neighbourhoods face disproportionate burdens as a consequence of enhanced energy insecurity related to the energy transition (Carley and Konisky, 2020).

Concentrations of low-income households contribute to higher levels of energy poverty in underprivileged neighbourhoods (Bouzarovski and Simcock, 2017). A low income typically serves as a fundamental factor associated with energy deprivation. However, it overlaps with several other social and political identities that may deepen the state of deprivation, such as education, race, ethnicity, religion, gender, age, class, disability and health status. The burdens of rising energy prices disproportionately affect individuals at the intersections of these characteristics (Großmann and Kahlheber, 2018; März, 2018). For instance, because energy costs represent a larger proportion of their income, these individuals are not only more vulnerable to rising energy prices, but also have limited capacity to adapt to climate change impacts, such as affording cooling systems (Knox, 2019).

Uneven distributions of economic resources intersect with material deprivation, particularly evident in underprivileged neighbourhoods characterised by low-quality housing (Bouzarovski and Simcock, 2017; März, 2018). Low-income households typically live in the worst quality housing (Boardman, 2010; Bouzarovski and Simcock, 2017). Emergency buyers[1] or (social) renters here face heightened vulnerability, lacking the financial resources to invest in energy efficiency measures or access renewables (Carley & Konisky, 2020; Vanderstraeten & Ryckewaert, 2019).

Inhabitants of underprivileged neighbourhoods often lack access to energy transition opportunities. Mainly higher incomes can utilise low-carbon and efficient technologies (Carley and Konisky, 2020), which can be explained by the high upfront costs of these technologies (Angel, 2016; Carley and Konisky, 2020). Living conditions in underprivileged neighbourhoods can restrain access to climate-friendly energy solutions as well (Carley and Konisky, 2020). The dense morphology in underprivileged neighbourhoods, limited open public space (Knox, 2019), and higher concentrations of (social) renters may limit opportunities to integrate renewable energy systems, such as photovoltaics (Middlemiss and Gillard, 2015; Knox, 2019; Derkenbaeva *et al.*, 2022).

Recognition injustice manifests itself as a failure to recognise different perspectives rooted in social, cultural, ethnic, racial, and gender differences (Jenkins *et al.*, 2016). Central to

[1] An emergency buyer is someone that purchased a lower-quality property out of necessity, lacking the financial means to invest in bringing the property to a satisfactory standard

misrecognition are cultural and institutional processes of disrespect, denigration, insult and stigmatization (Walker, 2009). The devaluation of certain groups is intertwined with and manifests itself through the misrecognition of places (Walker, 2009). Place stigmatization and misrecognition may lead to certain spaces to be chosen for development before others. As a consequence, certain places in the daily life of poor individuals, or certain ethnic groups, are neglected and poorly served (Hastings *et al.*, 2005; Hastings, 2009; Walker, 2009). Local governments' lacking willingness or ability to provide resources contribute to a non-prioritised status for energy and infrastructure development (Golubchikov and O'Sullivan, 2020), reproducing vulnerabilities of different places even more (Bouzarovski *et al.*, 2017).

For instance, in the European context, Renewable Energy Communities (RECs) have been introduced as a key tool for citizen-led energy transition (Hanke, Guyet and Feenstra, 2021). These communities enable citizens to actively engage in local and collective energy systems (Caramizaru and Uihlein, 2020; Hanke, Guyet and Feenstra, 2021). While empowering consumers to joing RECs has potential to contribute to energy justice, vulnerable consumers remain underrepresented (Hanke and Lowitzsch, 2020). Multiple studies have highlighted that these initiatives often take place in affluent communities (Goedkoop and Devine-Wright, 2016; Caramizaru and Uihlein, 2020; Hanke and Lowitzsch, 2020; Kaandorp *et al.*, 2024). Moreover, REC members are mostly middle-aged men with higher incomes and educational backgrounds (Radtke and Ohlhorst, 2021; Kaandorp *et al.*, 2024).

Injustice arises as a consequence of the limited recognition of underprivileged groups to take advantage of these kind of energy initiatives. Agenda's targeting environmental issues are prone to remain 'socially blind' and policies that stimulate the energy transition, such as incentives for renovating or the uptake of renewables, mainly benefit middle-income households. The misrecognition of the daily life of households in energy poverty widens social inequalities and may even lead to a reduced public support for climate policies (Juwet, 2020; Carrosio and De Vidovich, 2023; Fransolet and Vanhille, 2023).

Misrecognition in energy transitions also plays a role in terms of the types of knowledge and the disciplinary perspectives that are represented in transition processes. Already in the 1980s, Laura Nader sharply analysed the dominance of technical perspectives in energy transition debates, underestimating the social, behavioural and political dimensions of energy transitions (Nader, 1980, 1981, 2010). More recently, for example, Juwet and Deruytter unravelled how the implicit planning processes of the Flemish network operator, and its positioning as a 'neutral', 'apolitical', technocratic and operational actor, misrecognise the territorial and societal dimensions of infrastructure planning and energy tariff structures (Juwet and Deruytter, 2021).

Procedural injustices are a consequence of lacking public participation and deliberation (Newell and Mulvaney, 2013). Decisions regarding the allocation, utilization, and the consumption of energy for specific purposes often occur out of the public eye and seldom within democratic forums (Newell & Mulvaney, 2013). For instance, 'strategic planning exercises' leave no room for responding directly to both climate change and social justice imperatives because they occur at a scale that is too broad for local residents to identify the local impacts and their implications (Steele *et al.*, 2019). Moreover, the technocratic nature of the energy sector, characterised by secrecy and arcane technical knowledge makes public involvement even more challenging (Szulecki, 2018). As a consequence, underprivileged groups are confronted with unfair decision-making processes (Bickerstaff, Walker and Bulkeley, 2013). Decisions related to energy systems often occur 'over the heads' of marginalised groups,

exacerbating social and economic inequalities. Addressing energy injustices and holding accountable the responsible parties is often challenging because they are frequently powerful elites or multinational corporations (Newell and Mulvaney, 2013).

At the same time, and importantly, research on energy transitions itself also usually fails to involve citizens and even participatory research approaches rather focus on professional stakeholders and only involve citizens to a very limited extent (Huttunen *et al.*, 2022). Participatory action research offers interesting potential for energy transition research that aims to contribute to more just urban transitions. It places the researcher next to the practitioner as 'expert', fostering emancipatory and collaborative goals.

3. Place-based approaches to district level energy transitions

Previously we have discussed the interconnection between injustices in underprivileged neighbourhoods and energy transitions, highlighting the relationship with their socio-spatial and socio-political characteristics. This calls for a spatially-sensitive approach that enables to tailor PEDs to unique needs, aspirations and dynamics to different specific contexts.

The concept of Positive Energy Districts explicitly draws attention to the scale of the district or neighbourhood as a promising scale to realise systemic transformation of the energy system and the built environment. However, the discourse around PEDs often remains placeless and many early PED cases involved greenfield development rather than the transformation of complex, existing inner-city neighbourhoods. While a strict interpretation of PED ambitions focused on energy efficiency, renewable energy and flexibility (JPI Urban Europe / SET Plan Action 3.2, 2020) is more aligned with new-build developments, recent discussions about the PED framework challenge this limited technological perspective. In order to be able to apply the PED framework to existing urban contexts, it requires a broader view emphasizing key considerations such as governance, awareness, stakeholder ecosystems, participation, and context sensitivity (DUT, 2024)

Indeed, the specific spatial, social, cultural, historical, governance and political characteristics of a neighbourhood shape the barriers, obduracies and opportunities for transformation. Understanding this context is therefore key to develop not only more effective but also more qualitative and inclusive transition strategies and solutions. Geographers have emphasised the need to understand how transitions play out differently in different geographical, socio-political and institutional contexts (Coenen and Truffer, 2012; Bridge *et al.*, 2013; Rutherford and Coutard, 2014; Binz *et al.*, 2020). Spatial planners and designers have shown how energy system transformation is, and historically was, connected to transformations in landscape, urban morphology and spatial quality (Owens, 1986; Sijmons *et al.*, 2014; Sijmons, 2017; Asarpota and Nadin, 2020; Juwet, 2022), and have visualised how energy system transformation at the neighbourhood scale can be linked with densification, urban renewal, introducing collective infrastructures, greening or soft mobility modes (van Bolhuis *et al.*, 2016; Hubrecht *et al.*, 2020; Juwet, 2020). Moreover, our discussion on energy justice illustrates how inequalities in energy poverty or access to sustainable energy solutions are strongly connected with social and spatial neighbourhood characteristics (Bouzarovski and Simcock, 2017) such as building morphology and energy efficiency, ownership structure, demographics, public neighbourhood infrastructures, etc. Using a spatially-sensitive lens is then crucial to address 'place-based deprivation' (Robinson, Bouzarovski and Lindley, 2018). Moreover, it helps to recognise the unique realities and contexts of different areas, and to address the needs and aspirations of inhabitants of underprivileged neighbourhoods. A place-based approach may moreover

emphasise the value of local knowledge to address community-specific needs (Elmallah, Reames and Spurlock, 2022).

Context-specific dimensions of energy transitions are particularly tangible at the neighbourhood scale, where socio-spatial barriers and opportunities become visible, and where initiating transformation and developing alternative solutions requires multi-scalar collaboration between different levels of government, civil society organizations and citizens. Neighbourhood energy strategies then involve shifting power relations and new coalitions between public, private and civil society stakeholders and citizens, new energy governance and new business models (Avelino and Wittmayer, 2016; Wolfram, 2016; Köhler *et al.*, 2019). These strategies need to respond to the specific morphological, institutional, legal, social and behavioural conditions

4. From a vulnerability stigma to urban transformative capacity and collective agency

Underprivileged neighbourhoods are often characterised as 'vulnerable' and deprived of quality, agency and opportunities for change. We argue it is vital to challenge this idea of 'vulnerability' as 'inevitable' in underprivileged neighbourhoods by focusing on opportunities and capacity for transformation (Weatherill, 2023). While such neighbourhoods indeed face overwhelming challenges for transformation, overemphasizing 'vulnerability' risks to limit possibilities for transformative change and increase stigmatization. On the contrary, concepts such as 'empowerment', 'agency' or 'collective action' may allow to resist 'vulnerability' and understand transitions as transformative processes involving a disruption of current pathways, and radically altering existing urban structures, cultures and practices (Wolfram, Borgström and Farrelly, 2019).

Reframing underprivileged neighbourhoods in transitions then requires to recognise the inherently political character of transitions, involving diverging and often conflicting interests and ideas, and producing 'losers' as well as 'winners' (Coutard and Guy, 2007; Shove and Walker, 2007; Meadowcroft, 2009; Rutherford and Coutard, 2014; Healy and Barry, 2017; Köhler *et al.*, 2019; Williams and Doyon, 2019). However, energy transitions research and transition management approaches have been criticised for underestimating and obscuring these politics of transitions (Shove and Walker, 2007; Kenis, Bono and Mathijs, 2016). Sierhuis et al. (2023), voice similar concerns about PEDs as experimental hubs for renewable energy solutions and as transformation areas towards more sustainable urban futures but failing to clearly address their political dimension. In particular, Shove and Walker (2007), and Kenis et al. (2016), raise fundamental questions about whether societal transformations can be 'managed' and about the framing, legitimacy and inclusivity of transition management approaches. For example, its focus on 'frontrunners' in transitions risks to create exclusionary processes where the voice of underprivileged or non-hegemonic citizens is not heard. They call for an explicit acknowledgement of power relations, conflict and contingency as constitutive in processes of societal change (Kenis, Bono and Mathijs, 2016). From a similar 'power' perspective, Avelino and Wittmayer (2016) conceptualise transitions as involving shifting power relations between state, market, community and third sector actors. Moreover, Avelino and Rotmans distinguish different types of power in transitions and different power relations, specifying power 'over', 'more' power than, and 'different' power (Avelino and Rotmans, 2009). Adopting this perspective, and articulating the politics of transitions, allows to shift the focus away from 'vulnerability' or 'lack of capacity' or 'limited agency' to questions of power and politics; it allows excluded voices, discourses or visions from outside the hegemonic social order to be heard; and it opens up opportunities to challenge the status quo and facilitate social

transformation (Kenis, Bono and Mathijs, 2016; Mikulewicz, 2018; Sierhuis, Bertolini and Van Winden, 2023).
We argue that highlighting the potentiality, agency, and capacity of underprivileged neighbourhoods, instead of addressing 'vulnerability' as inevitable or intrinsic, is a step towards energy justice. We use ‘urban transformative capacity’ (UTC) (Wolfram, 2016) as a critical concept in addressing the challenges faced by underprivileged communities, positioning itself as a counterbalance to vulnerable conceptions. This approach shifts the narrative, it underscores the inherent capacities of underprivileged neighbourhoods to initiate and sustain change.

Urban transformative capacity is always and necessarily political since it strives for deep and holistic urban change, shaped by agency and interactions within certain spatial-material settings (Wolfram, Borgström and Farrelly, 2019). It is invariably marked by contestation and social struggle: the determination of which urban future will materialise is influenced by the dynamics of urban transformation (Wolfram, Borgström and Farrelly, 2019). Developing urban transformative capacity should aim to nurture and harness diversity and contestation in order to enable justice (Wolfram, Borgström and Farrelly, 2019).

Urban transformative capacity identifies what enables cities and urban stakeholders to initiate and perform transitions by identifying the required abilities to forge new system arrangements (Wolfram, 2016). Developing agency and empowerment are key for developing urban transformative capacity. Instead of an all-encompassing approach, opportunities and strategic priority interventions need to be identified. In line with our argumentation above, this implies a place-based approach. As Wolfram (2016) argues, “place strongly conditions the characteristics of e.g. social needs, communities, institutional thickness, leadership and practical experiments, while providing an essential frame for the cognitive processes related to system awareness and foresight (Wolfram, 2016, p. 129)”. Therefore, the development of urban transformative capacity must depend on strategies and interactions that are specific to the place (Wolfram, Borgström and Farrelly, 2019). However, as the author underlines, it cannot be developed locally alone.

While the framework of urban transformative capacity refers to the transformative capacity of stakeholders, places and processes – both as a capacity source, and as a subject of transformation, the ‘spatial’ or ‘place’-dimension of this transformation remains underconceptualised. By adopting a place-based approach, we can identify the types of capacities and characteristics of underprivileged neighbourhoods that can drive urban transformative change, i.e. “disrupting current pathways by deeply and radically altering existing urban structures, cultures, and practices (Wolfram et al., 2019, p. 437). Such a perspective reveals an ‘urban transformation paradox’: while underprivileged neighbourhoods are indeed confronted with many interrelated characteristics that complicate energy transitions, they also offer opportunities for transformation that can be linked for example with morphology, ownership structure, stakeholder landscape, spatial qualities, social networks or infrastructure projects.

5. Towards a four-track approach to urban transformation for PED’s

As we have argued, addressing energy justice in PEDs requires a place-based approach which is based on identifying the transformative capacities that can cultivate inclusive opportunities for collective agency. However, while recent work has conceptually outlined the different interdependent components of what transformative capacity can entail, as well as its targeted outcomes (Wolfram, 2016; Wolfram, Borgström and Farrelly, 2019), we aim to respond here

to the need for an operational framework to address challenges of collective agency and institutional change in a place-based way. In order to do so we have developed a four-track approach to foster the urban transformative capacity of underprivileged inner-city neighbourhoods, which focuses on diverse yet interrelated components.

The proposed four tracks all respond to the outlined issues regarding energy justice and are specifically oriented at the challenges of fostering place-based transformative capacities of underprivileged neighbourhoods. Firstly, we emphasise the importance of engaging local residents as well as institutional stakeholders in collective visioning (track 1). Secondly, bottom-up actions can instigate behavioural change and tie in with everyday needs and concerns (track 2). Thirdly, this framework argues how lasting and inclusive transitions require the co-evolution between public and community stakeholders (track 3) as well as between social and technological innovations (track 4).

The tracks can be read as conceptual perspectives but also be developed into participatory methodological approaches to research collective agency in neighbourhood energy transitions. They are an incentive for further case-study research, for practical application and further operationalization. Each of these four tracks is (theoretically) elaborated below.

5.1 Collective visioning

The development and implementation of PEDs relies heavily on visions and visioning processes to inspire both policy programs and local action towards sustainable systems change and just energy futures (Kantabutra, 2020). Visioning processes can both articulate long-term goals and guiding principles for urban planning as well as align policies and stakeholders collaborations towards achieving sustainable energy futures (McPhearson, Iwaniec and Bai, 2016).

Visions can provide a framework for monitoring progress and adjusting strategies to stay on track towards realizing sustainability goals or PED targets, reflecting the specific requirement and opportunities of a particular context (Späth and Rohracher, 2010; Trutnevyte, 2014). However, visions and visioning processes can come with justice concerns when structural inequalities are not fully recognised. Therefore, they need to take into account the contextualised and unequally distributed agency of people to both act upon and change such visions. Collective and inclusive visioning processes are vital to ensure critical examination of existing transitions, in order to emphasise energy justice as a fundamental criterion and strive for equality and equity, both formal and substantive, within energy systems (McCauley *et al.*, 2013; Revez *et al.*, 2020).

Visioning processes can foster transformative capacity by translating abstract concepts of sustainable energy futures into more concrete agendas, reflecting the specific requirements and opportunities of a particular context, in terms of energy potentials, actor constellations etc. (Späth and Rohracher, 2010). Doing so, collective-inclusive visions can outline a radical departure from the current path and develop urban transformative capacity in underprivileged neighbourhoods (Wolfram, 2016). When a community shares a vision, it can give them a sense of capability, endurance, commonalty, and agreed-upon objectives (Parkhill *et al.*, 2015) and clear reasons for engaging in social action (Parkhill *et al.*, 2015). A shared vision is grounded in a sense of the common good, shared experiences, culture, and perspectives on the world and collective action (Silk, 1999).

5.2 Collective actions

The second track researches how bottom-up and collective PED actions can mobilise collective agency and behaviour change. In line with Horvath's (Horvath, 1999, p.221) definition of social action, we define bottom-up and collective PED action as the 'participation of local communities and stakeholders in PED initiatives to influence the outcome for the benefit of the people and the community. Developing participatory methods to identify and set up bottom-up and collective PED actions requires a place-based approach, as context is significant to foster collective social action (Parkhill *et al.*, 2015).

Bottom-up and collective PED actions seek to respond to the structural injustices that constrain the agency of individuals and communities in underprivileged neighbourhoods (Lennon, Dunphy and Sanvicente, 2019; Gaupp, Constantino and Pereira, 2023). They aim to empower local communities to actively participate in more meaningful and democratic low-carbon energy transitions. This can foster a sense of ownership, develop capacity, and increase responsibility among local residents (Hoffman and High-Pippert, 2010; Parkhill *et al.*, 2015). Not only does this lead to more sustainable solutions, it also garners widespread support (Musall and Kuik, 2011; Lennon, Dunphy and Sanvicente, 2019), crucial to achieving sustainable transformation towards low carbon systems (Coy *et al.*, 2021). In addition, collective participatory PED actions can mobilise behavioural change. By strengthening community engagement and social networks among neighbours, positive behaviours can spread more easily through peer influence (Gaupp, Constantino and Pereira, 2023).

Bottom-up and collective PED actions foster transformative capacity precisely by centring on inhabitants' everyday lives (Ortiz Escalante and Gutiérrez Valdivia, 2015) and focusing on meeting social needs (Wolfram, 2016). To transform sensitive living environments whilst addressing social needs, community participation, and empowerment, it is crucial to leverage commonly held community values and beliefs (Hoffman and High-Pippert, 2010), as well as connect and amplify local social and spatial assets and initiatives (Kretzmann and McKnight, 1993). This collective effort builds transformative capacity within communities towards sustainable development.

5.3 Institutional-community co-evolution

This track responds to the insight that energy transitions benefit from the co-evolution of institutional, material and relational change (Sareen and Haarstad, 2018). We argue that in order to address the complexities of equitable energy access, distribution and justice, public institutions and community stakeholders need to engage in a dynamic reciprocal relationship where both influence and permanently adapt to each other's actions and needs over time. In order for government-shaped energy policies and resource allocation to be equitable and effective, they have to be informed by the needs, experiences, and input of the communities they serve. Community stakeholders, including residents, local organizations, and advocacy groups, possess valuable knowledge about their unique energy challenges, priorities, and aspirations. By actively engaging with these stakeholders, public institutions can gain a deeper understanding of the specific issues faced in underprivileged neighbourhoods and co-create solutions that are responsive to local contexts and concerns (Burke and Stephens, 2017).

In underprivileged neighbourhoods, where energy injustices are often most pronounced, the co-evolution of public institutions and community stakeholders is particularly critical. Transition issues are frequently addressed in a fragmented manner, focussing on separate issues, without

taking into account the advantage of other agendas (Huntjens and Kemp, 2022). Energy transitions in underprivileged neighbourhoods requires the rethinking of institutional and community structure in a more integrated way. By working together, co-evolutionary partnerships can help address the intersecting challenges of (energy) poverty, environmental degradation, and social exclusion, while at the same time building more resilient and empowered communities (Baker, 2019). The co-evolution of community and public stakeholders directly respond to the imperative of procedural and recognition justice, involving the active participation, and the recognition of the voices of diverse stakeholders, eventually contributing to more distributional justice as well.

A collaborative approach to energy governance not only fosters trust and accountability between public institutions and local communities but also enhances the transformative capacity of both parties. For public institutions, it enables them to develop more inclusive and effective policies and programs to address systemic inequalities and promote social justice. By centring on the voices and experiences of marginalised communities, public institutions can better identify and dismantle barriers to energy access and affordability, increasing energy justice (Elmallah, Reames and Spurlock, 2022). Similarly, community stakeholders benefit from this co-evolution process by gaining increased influence and agency in shaping energy decision-making processes and outcomes. By actively participating in policy development, planning processes, and resource allocation, communities can advocate for their own interests and priorities, ultimately leading to more equitable and sustainable energy systems.

5.4 Social and technical innovation

Decarbonization is a multidimensional challenge that requires co-evolutionary interactions between technologies and societal groups (Geels *et al.*, 2017). As energy transitions in particular are socio-technical challenges (Geels *et al.*, 2017), we need to move beyond the dominant technology-driven conceptions of these processes (Suitner, Haider and Philipp, 2023). This track puts forward the necessity to intertwine social and technological innovation in order to overcome systemic lock-ins and to support late adopters towards positive energy district. A social innovation perspective distinguishes itself from traditional (technological) innovation through its iterative alignment with concrete societal needs, inclusive practices and its embeddedness in local capacities by creating new (social) business models, actor networks, governance modes, policy interventions or organizational entities, p. 1500). Moreover, social innovation can help to embed new practices in a specific spatial context by aligning the transition process to regional capacities (Suitner, Haider and Philipp, 2023).

Low carbon technological innovations can come with justice tensions in underprivileged neighbourhoods. The lack in access to and information on decarbonisation technologies (Sovacool et al., 2019) can lead to disparities in agency, where underprivileged inhabitants are being pushed into more passive roles (Sovacool et al., 2019). Additionally, initiatives solely focused on technological innovation overlook the reality that certain neighborhoods may not be ready to integrate these innovations into their dwellings (Halleck Vega, Van Leeuwen and Van Twillert, 2022). This oversight is compounded by the failure to recognise the need for behavioral adaptation alongside innovative technologies, further widening existing injustices, particularly among marginalised communities. It is noteworthy that individuals in energy poverty often already use energy efficiently, without innovative technologies (Paone & Bacher, 2018).

In order to strengthen transformative capacity on the neighbourhood scale, socio-technical innovation processes need to foster local agency and be embedded in a place-based institutional context. Doing so, 'opportunity spaces' for innovation can be created that build on regionally specific preconditions, temporally specific configurations of knowledge, institutions and resources, and specific local capabilities (Suitner, Haider and Philipp, 2023).

6. Conclusion

Transforming the energy system inclusively is critical in the face of the climate crisis. Positive Energy Districts (PEDs) are put forwards as a building block for climate-neutral urban transitions. In this research paper we address how applying PED approaches in underprivileged neighbourhoods requires better recognition of spatial, social and political energy transition dimensions. So far, the PED framework falls short to address the complex and interrelated injustices related to energy transition in underprivileged neighbourhoods. There is a risk that PEDs can increase exclusion of energy vulnerable people, exacerbate energy poverty, and potentially even stigmatise the energy poor (Hearn, Sohre and Burger, 2021), rather than contribute to inclusive and just energy transitions. This paper foregrounds the concept of urban transformative capacity in an effort to theorise more inclusive and just PED strategies. It proposes a four-track conceptual approach that responds to energy justice challenges in underprivileged neighbourhoods.

The concept of energy justice provides a useful lens to unravel energy transition challenges in underprivileged neighbourhoods and unravels how distributional, recognition and procedural injustices are related to socio-spatial neighbourhood characteristics. We argue in order to contribute to just transitions, PED strategies should be place-based approaches that acknowledge and leverage the socio-spatial and socio-political contexts of underprivileged neighbourhoods. We introduce the 'urban transformation paradox' as a way to challenge vulnerability stigmas by focusing on collective agency and empowerment, and by recognising social, spatial and institutional neighbourhood characteristics that offer opportunities for transformative change.

We respond to this problem statement by introducing a four-track approach to foster urban transformative capacity and address energy injustices in underprivileged neighbourhoods through different points of departure: (1) collective visioning, (2) collective actions, (3) institutional-community co-evolution and (4) socio-technical innovation. This four-track approach aims to foster the urban transformative capacity of underprivileged neighbourhoods.

Further research should translate these theoretical 'tracks' into practice in different case study neighbourhoods, as four components of fostering urban transformative capacity in underprivileged neighbourhoods. Firstly, such case study research can produce valuable insights to refine the PED framework and inform just energy transition policies. Secondly, the four tracks can also be interpreted as different methodological approaches to research and foster neighbourhood transitions in a participatory way. They can be developed into concrete participatory research methods, tested and critically evaluated in different case study contexts, and contribute to more inclusive energy transition research. Thirdly, the four-track approach can be used to co-produce, test and implement concrete governance tools for neighbourhood energy transitions, such as collective actions, new coalitions, governance structures or business models and use comparative case study research to evaluate whether and how such tools could be translated, expanded or upscaled to other neighourhood contexts.

Impact of Development Process of Cultural Tourism on the Authenticity of the Production Space of Cultural Heritage Sites

Wang Jiang
Affiliation:Tongji University
Email:594328498@qq.com

Abstract
Production space is an important resource for the survival of local communities. In the process of cultural tourism development, the entry of external resources and the demand of the market will change the original economic production of the heritage site. Different subjects such as local residents, operators from other places, local governments, and planners will continue to recreate the production space. This paper takes Xizhou Ancient Town and Zhoucheng Village in Yunnan Procince, China as examples. Xizhou Ancient Town made full use of rice field resource combined with land transfer procedures, introduced social enterprises to concentrate on farming, and held a "Rice Culture Festival" to create the "Xi" brand of agricultural products. On the basis of the original production tradition of tie-dye handicrafts, Zhoucheng Village renovated the abandoned state-owned factory building as a tie-dye museum, integrating sightseeing, display, production, experience and other functions, moving the production work from the original private family workshop to a public cultural place, and further promoting the communication between local villagers. In these two cases, the changes of spatial ownership and function are led by the government and planning departments, which have injected new connotations into the regional agricultural and handicraft traditions. In the process of cultural tourism development, planning, as a leading role with legal effect, should use key spaces as carriers to guide the functional positioning of the region. At the same time, an operation platform should be built to provide positive guidance for cultural heritage sites under the principle of authenticity.

Keywords
authenticity, production space, cultural tourism development, Xizhou Ancient Town, Zhoucheng Village

1. The connotation of “authenticity” in heritage protection

1.1 Understanding the development process of the concept of "authenticity" in the space-time dimension

The word "authenticity" evolved from the Greek word "authents", including both meanings of "authority" and "origin" (阮 and 林, 2003). In the 1960s, the concept of authenticity was officially introduced into the field of heritage protection. In 1964, the Venice Charter proposed that historical monuments be "authentic and completely passed on"; in 1977, the first edition of the Operation Guidelines for the Implementation of the World Heritage Convention clearly defines that "authenticity is not limited to the original form and structure, but also includes changes and additions that have artistic and historical value in the historical process"; the Nara Authenticity Document in 1994 further expanded the scope of authenticity, emphasizing that each culture can define the connotation of authenticity according to its own characteristics.

Scholars from China such as Luo Zhewen, Liu Lin'an and Ruan Yisan introduced the concept of "authenticity" into the domestic academic community(阮, 1998). Subsequently, the principle of "authenticity" has become a core issue in heritage protection and utilization work. With the continuous deepening of research, the connotation of "authenticity" has been expanded in both dimensions of time and space(曹 and 李, 2019).

In the time dimension, the formation of cultural heritage sites itself is the result of the joint accumulation of historical features, social culture, material environment and life scenes within a certain geographical scope. Cultural heritage sites are absolutely not limited to a specific, fixed historical time node, and there is no such "original" or "most representative" state. Each generation has the characteristics of that period, and the new generation is constantly creating characteristics. The pursuit of reappearance of a certain period is a denial of other periods. The focus of heritage protection has gradually expanded from museum-style authentic reproduction to respecting reasonable changes in each era.

In the spatial dimension, built heritage cannot exist without the environment. The environment is a complex, and built heritage is a part of it. A complete environment includes not only the artificially constructed physical space, but also the surrounding natural ecology, the built environment, the people living in it, and the culture inherited based on people's behaviors and activities. The role of a specific environment is decisive for the individuals in it. It is this complex environment that breeds specific cultural heritage. Just as in the field of natural ecology, the key point of studying biological units is to study the protection of the ecological environment; in the field of urban heritage protection, the key point of heritage is also the protection of the cultural environment. In the process of assessing the value of heritage and utilizing resources, various elements in the environment should be fully recognized and interact with each other. The scope of application of authenticity should extend from individual historical buildings to neighborhood protection, and then to the protection of the overall style of villages or towns.

1.2 Understand the multiple meanings of “authenticity” under the guidance of goals

As a principle of cultural heritage protection, authenticity is difficult to define in precise terms, and there is no unified evaluation standard that includes degree, form, scope, etc. Authenticity is one of the indicators of the compatibility between heritage and its cultural connotation. It will continue to change with the standards of value judgment, and the definition chosen depends on the protection purpose hoped to be achieved. Protection is based on change and development. Protection is not for restoration but for regeneration. It is the filling of gaps in the relics of historic sites and the inheritance and innovation of artistic craftsmanship development.

To sum up, authenticity is not an end point for measuring the degree of authenticity, but a development process similar to cultural construction. The purpose of authenticity protection is not to verify and reproduce historical details, but to restore and support an organic and dynamic system that integrates traditional culture and wisdom, witnesses traces of historical evolution. Such system is self-organizing, sustainable, and viable. Starting from the purpose of protection, authenticity should respect both historical reality and the construction of each period, paying attention to both the historical truth of the object and the current experience of the subjective group. It is a comprehensive principle based on a dynamic development perspective, covering natural and artificial environments, and taking into account characteristic regional culture and local daily life.

2. Spatial evolution characteristics in the process of cultural tourism development

2.1 Analysis of the needs of aboriginal people in the process of cultural tourism development

2.1.1 Daily life needs from a protection perspective

The indigenous people of the heritage site who have lived here for generations follow the given rules such as traditions, habits, and customs, and complete daily life such as production, consumption, and social interaction over and over again. As a product of the harmonious coexistence of human beings, resources, and the environment, traditional settlements contain valuable construction wisdom. Traditional crafts, folk customs, and festivals developed basing on local hydrogeographic conditions, natural climate, and native plant resources are the collective memory of local residents and have important life guidance and emotional value.

2.1.2 Cultural inheritance needs from a development perspective

The details of the daily life of the indigenous people in the heritage sites and the practices that have been embedded in people's behavioral habits and ideas over a long period of history all have become unique elements of local traditional culture in the eyes of the outside world. This is due to the differences in physical geography, folk culture and other factors between different regions. Today, when Internet communication and long-distance transportation are highly developed, it is important to discover, inherit and spread local traditional culture. This is not only a necessary way to build cultural confidence and identity within indigenous groups, but also an effective way to make full use of local resources and promote regional economic development.

2.2 Analysis of the influence of external forces in the cultural tourism development process

2.2.1 The driving effect of cultural products from an external perspective

The behavior of external institutions and external operators coming to cultural heritage sites to choose residence and employment is itself the result of the high-quality resources of heritage sites attracting external resources. Its intervention in heritage sites will also further bring in external resources including funds, construction plans, cultural promotion, operation and management models, etc(车 et al., 2019). Based on foreign perspectives and foreign experiences, traditional culture has been exhumed and redeveloped, and is sold to a large number of people in the form of packaged and symbolic products. On the one hand, culture is a dynamic product based on subjective feelings and is constantly being revised and constructed in the context of each generation. The profound traditional culture of heritage sites also needs to meet the needs of modern aesthetics and cultural consumption. It can be said that it is the packaging and secondary creation that strengthen the expressiveness and artistry of traditional culture, making it a cultural consumer product that meets the spiritual needs of modern people. The design of local tourism brands, the maintenance of tourism resources, and the creation of a tourism consumption environment with the intervention of external resources provide a lot of opportunities for displaying culture and reviving traditions, which can effectively strengthen the effect of cultural communication and bring economic and social benefits to the region. On the other hand, the business behavior itself is a kind of commercialization, and the characteristics of products are repetitive and standardized. The boundaries between artistic enhancement, cultural innovation and inventing and fabricating are blurred. In reality, a large number of commercial operations oriented toward instantaneous traffic and short-term economic benefits will bring about negative impacts such as the homogenization of tourism resources, out-of-control commercial development, and the disappearance of urban life landscapes.

2.2.2 Regional quality promotion effect from an internal perspective

The objective reason why a large amount of cultural heritage has been preserved is largely related to the region's lagging development in social, transportation, cultural and other aspects. Taking Yunnan Province as an example, due to the geographical environment of high mountains, rapid rivers, alternating mountains and dams, and the distribution characteristics of ethnic minorities living together in large and small settlements, there is little exchange or even isolation between settlements, forming a pattern of cultural diversity. The pattern also provides a shielding condition for the inheritance and long-term continuation of native culture. This has resulted in Yunnan still retaining a number of characteristic towns including Dali Ancient City, Xizhou Ancient Town, Weishan Ancient City, Dayan Ancient Town, Shuhe Ancient Town, Shaxi Ancient Town, Heshun Ancient Town, etc(刘 and 王, 2019). Behind the original, antique and characteristic residential buildings and the spatial layout of streets and alleys, there are a lot of problems of low building quality and poor quality of the residents' physical environment. In today's era of urbanization and modernization, the optimization of human settlements has become an important direction for the revitalization of historical and cultural blocks. Modern services such as electronic screens, surveillance, and wireless networks brought by external resources are of great significance to improving the livability of blocks.

In addition, the intervention of external resources can also help local communities re-examine the value of their own traditional culture. In an environment where local cultural products are packaged and symbolized, aboriginal people will also use it as an important way to identify their cultural identity, tell their own stories and rebuild their pride in local culture, thus strengthening the ethnic identity and awareness of the protection and inheritance of traditional culture.

2.3 Analysis of the authenticity of production space taking Xizhou Town, Dali as an example

The original production spaces of cultural heritage sites are mostly agricultural operations and facility spaces dominated by agriculture, and workshop-like spaces dominated by small-scale industry or handicrafts. On the one hand, urbanization has had an impact on agriculture and handicraft production in traditional villages and towns. The remaining labor force has moved into larger cities to work, leading to the exodus of some indigenous people. On the other hand, the development of tourism focuses on the resource advantages of heritage sites. External capital and operators conduct element exploration and artistic enhancement of the original space, injecting commercial and service attributes into a single production space, transforming it into a diversified complex space(毛 and 杨, 2020). This article takes Xizhou Town in Dali as an example for analysis.

2.3.1 Agricultural production space—taking Xizhou Ancient Town as an example

The topography of Xizhou is mainly alluvial flat dam. Streets, lanes, and courtyard buildings are embedded among mountains, rivers, and fields, closely integrated with the surrounding large open agricultural rice fields, forming a small town style that combines living and farming. It fully demonstrates the historical process of Xizhou Ancient Town, which once relied on agriculture and commerce as its pillar industries.

In the process of village tourism development, relying on the beautiful local pastoral scenery, the characteristic ecological agricultural landscape of Xizhou Rice Field was preserved after the expropriation for the protection and development of the ancient town. It has become a popular spot for tourists to take photos, and it is also an iconic spot for the integration of culture and tourism in Xizhou. The local government has led the introduction of many new agricultural

partners, such as Dali Ancient Tourism Town Xizhou Pastoral Development Company and Huayu Ranch, and has successively sold 13,000 hectares of land, focusing on the development of ecological recycling agriculture and sightseeing agriculture. Since 2017, Dali Ancient Tourism Town Development Company has continued the traditional farming model on the more than 3,300 acres of land that has been transferred, planting rapeseed in the early spring and rice in the late spring.

In terms of agricultural production, concentrating land resources to carry out large-scale planting has increased land yields. The average annual production of more than 1,000 tons of grain and an output value of more than 3 million yuan is the inheritance and development of the regional farming tradition. The expanded green organic agriculture, experiential ecological agriculture and sightseeing agriculture further enrich the connotation of agricultural production. It makes full use of modern planting technology and combines regional cultural communication to create a comprehensive development model of agriculture, culture, and tourism. In terms of fixed job supply, surrounding villagers are recruited for production and planting, with an annual labor volume of approximately 20,000 people. In terms of driving vitality, new forms of rural tourism such as specialty restaurants, house rentals, and Bai folk style B&B hotels around the rice fields are booming rapidly. The number of "cafés" alone has reached nearly 20. In terms of cultural communication, the "Rice Culture and Art Festival" was held in the autumn, and the organic rice brand "Ximi" and the organic rapeseed oil brand "Xiyao" were launched. There were also folk custom display activities such as the traditional harvest celebration ceremony of the Bai folk group and the experience of intangible cultural heritage crafts, presenting profound cultural connotations. This new green agricultural production pattern guided by the government with market-oriented operation, industrialized management, and socialized services can be said to follow the principle of "authenticity" in the context of the times. On the basis of continuing the farming tradition, it has increased villagers' income internally and created a regional brand externally.

2.3.2 Handicraft production space—taking Zhoucheng Village as an example

Xizhou Town deeply explores the spiritual connotation of national culture and continues the rural custom of the early Republic of China that "the town is a market, the village is a workshop" and “one village has one skill, no competition for mutual benefit". The 13 villages under its jurisdiction insist on creating branded local products, such as felt making, spinning wheel making, silverware, etc. Using the collective thinking of traditional communities to create a unique local art landscape. A regional business alliance community is also formed among different villages.

Zhoucheng Village in Xizhou Town is one of the areas in China that retains the most complete traditional tie-dying craftsmanship and has a long history of handicraft and commercial development. For the local residents of Zhoucheng Village, every process from isatis root cultivation, indigo fermentation, plate making, flower tying to dip dyeing is not only a basic skill passed down from generation to generation, but also an important source of family economy. In the 1980s, a state-owned tie-dye factory was established in the village. After the state-owned factory closed down in 2004, Zhoucheng tie-dye returned to the form of a small workshop where families can weave, tie, dye and sell their work. Inspired by foreign tourists, villagers gradually tried to develop tie-dye experience projects in family workshops. They also integrate artistic elements from other regions, experiment with color dyeing, and innovate various fashionable tie-dye products based on traditional blue and white tie-dye techniques. With the assistance of the Municipal Cultural Administration Office, the original village

collective tie-dye factory building was preserved and renovated, and a new house courtyard was built according to the traditional style of Bai folk residences of "three squares, one screen wall, four combined with five patios". This became the first tie-dye thematic museum, covering the exhibition area, experience area, and teaching area. Bai villagers in the village were recruited to provide guided tours, tie-dye teaching, and product production. With the changes in the socio-economic environment, tie-dye production in Zhoucheng Village has gone through the process of individual-collective-individual. This includes both the villagers' spontaneous competition and exploration, as well as the guidance and support of the local government. In terms of space, the original family-style workshop model makes the handicraft production space and living space highly mixed. The museum adopts a production method jointly with the community, changing the production form of individual workshops in the village with front shops and back houses, and courtyards as workshops. It reuses the "factory" as a collective production space and brings together villagers with tie-dying skills in a public art space. For villagers, the place where they engage in handicraft production has changed from private courtyards to public museums. In addition to making dyeing products, villagers also continue to communicate and interact with other craftsmen, venue operators, and foreign tourists. They not only gained economic income, but also had a more direct and close connection with society. In the process, they further recognized and passed on their own ethnic culture. The original factory space with a single function of manual production has been transformed into a comprehensive communication and experience space integrating handmade manufacturing, cultural display, and cultural tourism services. The elderly Bai people explaining and tying flowers in the museum have also become a unique scenery in the living display of intangible cultural heritage. Xizhou Town insists on building a characteristic industry of "one village, one skill" and has achieved branding and commercialization transformation for the traditional skills of each village. It provides jobs and economic sources internally, spreads local culture externally, and even attracts a large number of highly educated young people to start businesses here, injecting new vitality into the inheritance of traditional crafts.

3. Summary

Authenticity is the primary principle that should be followed in the protection and development of cultural heritage sites. On the one hand, the connotation of "authenticity" is rich and inclusive, and there is no exact standard or evaluation system. Starting from the principles of respecting the historical value of each period, sustainable development, and preserving ecological heritage, the various elements of the environment and the diverse subjects within the heritage site are all part of the authenticity connotation of local cultural development. For cultural heritage sites, appropriate cultural tourism development is necessary to fully utilize the value of local cultural resources and enhance local economic benefits. Moreover, the process of spreading and communicating with the outside world is also an opportunity to widely promote and promote the inheritance of local culture. In the process of cultural tourism development, heritage sites are constantly being pushed to the market as a unique space and cultural resource. Under this circumstance, the traditional self-sufficient agricultural and handicraft production models are bound to be impacted and changed. On the other hand, the requirements for authenticity are also strict. We respect the protection and transformation but do not condone magic transformation, fake antiques, or copying of foreign experiences. The boundaries between them require the planning to play the role of direction guidance and bottom-line control.

This article focuses on production space, taking Xizhou Ancient Town and Zhoucheng Village as examples to analyze the changes in their agricultural space and handicraft space in cultural tourism development from the perspective of authenticity. The commonality between the two

is that the main ownership of the original production space has been changed through land transfer and other methods, a unified design in terms of positioning and function, and new functions such as sightseeing display, tourism services, and cultural experience have been integrated into the traditional production process. These changes retain the local agriculture and handicraft traditions, and combine market demand and modern technology to give it more diverse forms and connotations. They are active expansion and exploration under the principle of authenticity. The Rice Culture and Art Festival, various "Xi" agricultural product brands, and the tie-dye museum that integrates sightseeing, display, production, and experience can also be said to be the preservation of authenticity in this era. This contributes to the living survival of the rice field landscape and the tie-dye process itself, injecting vitality into them.

Abstract

This contribution presents the outcomes of an analysis of urban policies and plans in Italy where the objectives of UB safeguarding, restoration, provision, and enhancement are explicitly acknowledged. The objective is to understand the interface between biodiversity and urban policies and identify guidelines and strategies for reorienting the action of city governments towards conserving and enhancing UB. The survey has a two-fold focus, respectively, on the urban policies adopted at regional, sub-regional, municipal levels, and on the spatial plans in charge of translating the general objectives identified in policies into concrete actions, and monitoring their implementations. The research findings show that, while at the European and national levels, a clear trajectory of policies regarding urban biodiversity can be observed, at the local level policies mainly have a sectoral focus as well as an ambiguous impact on UB and lack tools and mechanisms for monitoring their implementation. Concerning the plans, the survey highlighted the pervasive, although rhetorical, diffusion of UB strategies and actions in spatial plans. Nevertheless, the scarce integration between thematic and statutory plans results in the difficulty of implementing and monitoring in an integrated way the objectives related to the protection and restoration of urban biodiversity.

Keywords: urban biodiversity, urban policies, spatial plans.

1 Introduction

Since its recognition as a major global challenge at the Cities for Life Summit parallel to the 11th meeting of the Conference of the Parties to the Convention on Biological Diversity (CBD) held in Hyderabad (India) in 2012, Urban Biodiversity (UB) has become a central topic in science and policy worldwide. Indeed, several research have pointed out the potential that cities have in supporting a broad array of plants and animals but also in playing a critical role in biodiversity conservation with initiatives that enhance residents' knowledge and stewardship of biodiversity (Secretariat of the CBD, 2012). Nonetheless, there are still several challenges and obstacles to overcome when scaling up the key benefits of UB through effective policies and plans in cities.

This contribution presents the outcomes of an analysis of urban policies and plans in Italy where the objectives of UB safeguarding, restoration, provision, and enhancement are explicitly acknowledged. The research is conducted within the framework of the National Biodiversity Future Center (NBFC) (2022-25), one of the five national research centers funded by the Italian Recovery and Resilience Plan within the NextGenerationEU program, aimed at aggregating and sustaining the scientific research on biodiversity in the different national territorial contexts. The three-year project was funded to aggregate and sustain scientific research at the national level to understand, monitor, preserve, and restore biodiversity in the marine, terrestrial and

urban ecosystems of the Italian peninsula, making it a central element of country's sustainable development. The goal of the NBFC is to investigate different levels of biodiversity and establish technological innovations to identify new products, processes (Bioprospecting) and solutions (Nature-Based Solutions–NBS) for promoting its economic, social and environmental value for communities (BenDor *et al.*, 2015; Chan *et al.*, 2016).

The research activities promoted by the NBFC refer to three main areas of study: marine, terrestrial, and urban. These areas are connected by the "One Health" strategy and the principle of «not causing significant damage to the environment» (DNSH). The purpose is to provide a holistic and pragmatic vision of biodiversity and identify sustainable management strategies for achieving this vision (WHO *et al.*, 2022). In particular, this article is part of the research activities conducted by Spoke 5 of the NBFC dedicated to investigating biodiversity in cities and urban areas. In Italy, the surface area occupied by high and medium-dense urban areas constitutes the 27.5% of the country's territory and the cohabitation between human beings and other living beings is made complex by the structural absence of nature in cities and the high fragmentation of natural spaces in urban areas, considering that only 2.7% of the territory of the provincial capitals is classified as urban greenery (ISTAT, 2014). At the same time, biodiversity in the city provides multiple benefits for urban communities which concern several environmental, health, social, and economic aspects (Müller, Werner and Kelcey, 2010).

Cities appear to be the places where the functional biodiversity is largely neglected with the presence of many groups of *taxa* (for example plants) that historically have had an aesthetic and ornamental role, but which do not belong to the local eco-regions, where the state of soil quality is scarcely known, and where the presence of plant and animal species is in continuous competition with the presence of humans. Therefore, in urban areas, beyond focusing on the conservation and monitoring of existing biodiversity, it is necessary to work on the development of strategies, guidelines and actions aimed at restoring and/or improving functional biodiversity and promoting the provision of ecosystem services (Woodruff and BenDor, 2016; Salata, 2023).

The research of the Spoke 5 is divided into 7 activities ranging from mapping the quality of soils and ecosystem services, to integrated and sustainable planning and design strategies, and to the management of interventions aimed at ecological and environmental restoration. As part of Activity 3 aimed at developing integrated and sustainable planning and design, the state-of-the-art on the relationship between policies, planning and urban biodiversity was investigated, identifying attributes, drivers and regulatory and strategic devices for contributing to strengthening the patterns of animal and plant diversity in cities (Nilon et al., 2017; Pierce et al., 2020).

Methodologically, the analysis relies on a mapping activity of the relevant urban policies and plans adopted by the provincial capital cities in Italy addressing UB in its multiple benefits. The objectives are to understand the interface between biodiversity and urban policies and identify guidelines and strategies for (re)orienting the action of city governments towards conserving and enhancing UB. The survey has a two-fold focus, respectively, on the urban policies adopted at regional, sub-regional, municipal levels, and on the spatial plans in charge of translating the general objectives identified in policies into concrete actions, and monitoring their implementations (Nilon et al., 2017). The first level emphasizes the discursive construction of, and the tools/mechanisms employed for, UB policies and their multi-level and multi-actor dimensions oriented to downscale general objectives from the EU and national levels to the local level (Uchida et al., 2021). The second focuses on the sectoral and thematic plans addressing UB, with attention to investigate the relationships with the statutory spatial plans and identify the relevant objectives, indicators, targets and resources for supporting the implementation of UB objectives (Pierce et al., 2020).

This research article is structured in five parts after the introduction; the following section two refers to the research background related to the topic of urban biodiversity and

planning from a general point of view. Afterwards, the sections three and four refer to methodological approach used for undergoing to the analysis related to public policies and urban planning procedures for biodiversity in Italy. Section five and six treat the discussions and conclusions consecutively, related to the emerging nodes from the disintegration between policies and planning rules and regulations related to the implementation of urban biodiversity actions and monitoring.

2. Research Background on urban biodiversity and planning

The concept of bringing nature and biodiversity to cities and urban areas is not new; the notion that surrounds the history of urban biodiversity research and practice dates back to the urban ecology studies from the 1980s (Nilon *et al.*, 2017; Rega-Brodsky *et al.*, 2022). While urban biodiversity is intertwined with the development of several associated sub-disciplines of urban forestry, urban wildlife, and urban nature conservation; the importance and impact of nature on citizens of cities is observed in social studies, cultural and urban planning, design and management. The research by Ossola, Irlich and Niemelä (2018) puts in evidence the importance of urban biodiversity as an ecological term interchangeably used with urban green space and urban green infrastructure, which is mainly underlined in some disciplines such as urban planning, landscape architecture and environmental management. The current landscape of research on urban biodiversity shows a mismatch between discourses and practices, mainly due to the lack of measurable actions in urban greening plans, as well as a lack of governance specificity and consistency across multinational scales and city scales particularly (Pierce *et al.*, 2020).

Meanwhile as the research on urban biodiversity advances, since 2020 the European Union has launched the Biodiversity Strategy 2030 to put biodiversity on the path to recovery for people, climate and the planet. The strategy is composed of specific actions, targets and includes relationships with other related strategies such as the Green Deal, the climate change adaptation plans and other food policies (such as the Farm to Fork Strategy) tackling nature restoration, protection and adaptation to resilient ecosystems. Another turning point in the year 2022 when the already mentioned Conference of Parties (COP 15) has adopted the Kunming-Montreal Global Biodiversity Framework (GBF)[1] which builds on "*The Biodiversity Plan"* that commits all parties to setting national targets by 2030. Specifically, targets 12 and 14 focus on urban planning for human well-being and biodiversity as well as on integrating biodiversity in decision-making at every level into policies, regulations, planning and development processes.

In Italy, the declination of the EU Biodiversity Strategy came in the form of the *"Strategia Nazionale Biodiversità 2030"* known as SNB 2030 (MASE, 2023), in the year 2023. That outlines a vision and sets 18 actions distributed along eight areas of interventions to *"bring nature back into our lives"* focusing on health, climate and economy. At the urban level, the most relevant aspect of this strategy is the promotion of urban greening and diffusion of nature-based solutions (NBS) in the urban and peri-urban green ecosystems which is one of the main 18 actions described in the Italian biodiversity strategy (Action B.10). It is also worth noting that the downscale from the EU Biodiversity Strategy implies for European cities and towns of at least 20 thousand inhabitants to develop "ambitious urban greening plans" with a particular stress on the importance of collaborative processes and inclusion of citizens and other stakeholders, and cross-departmental working and integration with other urban development aspects (European Commission, Eurocities and ICLEI, 2022).

One of the most interesting aspects of both strategies whether at the European Union level or the Italian national one, is that their implementation requires multi-disciplinarity of governance, active and shared management approach as well as constant and effective

[1] https://www.cbd.int/gbf

evaluation and monitoring for tracking the planned actions at the local level (Mahmoud *et al.*, 2021). Several research related to urban biodiversity and urban greening reiterate the concept of multi-level policies and multi-actor governance as an intrinsic aspect of urban biodiversity planning (Uchida *et al.*, 2021; Nilon, 2023; Lazzarini, Mahmoud and Pastore, 2024). This attention to the urban biodiversity and governance aspects delves into the need of alignment between stakeholders' values, the community needs, and the possible organizational support to forwarding the implementation of actions at the local level through partnerships and collaborations (Soanes *et al.*, 2023).

3. Mapping the urban biodiversity policies

As mentioned above, the research investigates public policies that deal with urban biodiversity. The definition of public policy is diversified in the literature (Bobbio *et al*, 2017). In this paper, by public policy we mean not only policies that deal with an issue that is perceived and defined as collective, but we look at policies developed by public bodies. Increasingly populated urban areas – by 2050, 70 % of humans will live in cities – are at the center of the global policy debate creating a sustainable and resilient future for cities (UN-Habitat, 2024: 54). The role of biodiversity in the city is addressed as a collective issue: international and national public bodies recognize that biological diversity is essential for species life, ecological balance and the ecosystem services it provides. To examine the variety and the interrelationship of public policies that deal with urban biodiversity in Italy, we considered it necessary to study the different levels of government and land management: from the European level to the national level, and then to delve into the local level for some case studies. We investigated eight northern Italian regions: Valle d'Aosta, Piedmont, Liguria, Lombardy, Trentino-Alto Adige, Veneto, Friuli-Venezia Giulia and Emilia-Romagna. This in-depth study stems from the need to understand possible alignments between the policies at different levels having the specific goal to preserve, enhance and restore urban biodiversity.

In this perspective, we put European, national, regional and municipal (Italian provincial capitals) policies in relation. The research sought to understand the tools that public actors deploy to address the challenge of implementing urban biodiversity. To this end, we investigated not only policies that deal centrally with the issue of urban biodiversity, but also policies centered on other issues that address the issue of urban biodiversity in a secondary manner, such as those that deal with forestation, sustainable development, climate change and agriculture. Public actors deploy both substantive (Hood, 1983) and procedural policies (Howlett, 2011). Substantive policies regulate through the imposition of obligations or prohibitions and related sanctions. These are policies that compel the implementation of processes to protect and increase biodiversity. Substantive policies are policies based on incentives or disincentives to encourage precise processes that result in calls for tenders that encourage and finance projects supporting urban greening. Examples include the Climate Decree Call for Proposal 2019 (Bando Decreto Clima) and the Forestation Programs 2020, 2021 related to the National Recovery and Resilience Plan (Programmi di Forestazione del Piano Nazionale di Ripresa e Resilienza). Procedural policies are guidelines or strategies that direct without binding. In this case, if policy-makers – when deciding – do not have all the elements to adopt a specific measure or standard and can prefer to design a pathway in which other actors can specify the content of the policy. Emblematic cases are the EU Biodiversity Strategy 2030 and the Italian Biodiversity Strategy 2030.

4. Mapping the urban biodiversity: a focus on the greening plans

As far as the level of plans is concerned, the research involved an activity of mapping of the spatial plans dealing with urban biodiversity in provincial capital cities in Italy. The objective is to understand which planning instruments the municipal and metropolitan

administrations adopt to protect, restore, and increase urban biodiversity. The mapping led to the identification of various typologies of planning instruments, where urban biodiversity takes on different forms, meanings, and degrees of cogency. Due to the significant role that the issues related to urban biodiversity assume and the policy consideration given to this typology of plan by both the EU Commission and the national government, attention was oriented to map and investigate the Greening plans.

Within this framework, the research has seen a systematic mapping of the Greening plans adopted by the provincial capital cities in Italy. The main policy reference for the Greening plans in Italy is the document of "Guidelines for the management of public green spaces" which was published in 2017 as an instrument for implementing the Law 14 January 2013, n. 10 "Regulations for the development of urban green spaces" (Norme per lo sviluppo degli spazi verdi urbani). The document was drafted by the National Committee for the Development of Public Green Spaces, a multidisciplinary group of experts formed by the Ministry of Environment to monitor the interventions introduced by law n.10/2013. It is aimed at responding «to the widespread need to have homogeneous technical guidelines on the national territory to support governmental policies for the rich and biodiverse green heritage of our cities» (Committee for the Development of Public Greens 2017: 4). The document recognizes three specific tools for the planning, programming, and management of public green spaces: the Green Census (Censimento del verde), the Green Regulation (Regolamento del verde) and the Greening Plan (Piano del verde).

Within this contribution, attention is oriented to the Greening plans which the Guidelines define as the policy instrument in charge of strategically addressing the problems and challenges linked to the integrated planning, management and monitoring of green areas.

The research has conducted a survey of the Greening Plans' documents on the websites of the provincial capital administrations, carried out between April and December 2023 in collaboration with the other researchers from the University of Florence and the University of Molise involved in Activity 3 of the Spoke 5 of the NBFC. The information collected through the survey was subsequently validated with the ISTAT survey "Environmental data in cities" updated to 2021, coordinated by the Statistics Office of the Municipality of Venice. The survey contains data on the Greening plans, the arboreal survey (bilancio arboreo) and several other issues related to the monitoring of the implementation of law 10/2013 in the 109 provincial capital cities in Italy (ISTAT, 2021).

At a methodological level, due to the still limited diffusion of the Greening Plan in our country as outlined in the Guidelines document, the research also took into consideration the Green Infrastructure Strategies and Action Plans. While the former share with the Greening Plans the objective to outline a strategic framework for green planning, the latter are more focused on the implementation dimension of the plan, giving space to strategic actions, and investment priorities for the improvement and valorization of the natural capital.

The mapping led to the identification of 19 Greening Plans and Strategies adopted in the provincial capital cities and 3 Greening Plans currently being developed (Greening Plan of Florence, Rimini, and Ascoli Piceno). 3 cases (Pisa, Cagliari, Sondrio) concern greening plans approved before 2017, while the remaining 16 refer to recent plans, approved during the last five years. An interesting aspect concerns the distribution of the mapped plans across the national territory: the north-south disparity is evident with the localization of the plans mainly in the central-northern Italian regions, with only two Greening plans mapped respectively in the southern regions (Avellino and Matera) and one in the island regions (Cagliari). Overall, the image shows a scarce diffusion of this instrument in our country: in the 109 Italian provincial capitals, the Greening Plan is present in less than 2 cities out of 10.

5. Discussions

As anticipated in the previous sections, the study of public policies on urban biodiversity has allowed some general considerations to emerge on the panorama of European policies as a fertile ground for the budding of national policies, on the type of policies currently dealing with this issue, and finally on the relevance of the theme of urban biodiversity in the various instruments investigated.

Firstly, the European Green Deal ushered in a new era of public policies on the environment and biodiversity (European Commission, 2020a). From agriculture to climate policy, there is a convergence of goals on the protection, enhancement and restoration of biodiversity. Among the various and numerous areas of research of the European Green Deal, some policies deal centrally with the relationship between nature and the city. Regarding the research area 'Environment and Oceans', one of its 11 actions is the EU Biodiversity Strategy for 2030, a policy that is also relevant to urban spaces. Action Trackers Nos. 51, 52 and 53 give indications on how member states are to draw up 'Urban Greening Plans' for cities of over 20,000 inhabitants. In addition, one of the four actions of the EU biodiversity strategy is the New Nature Restauration Law, a bill including urban areas among the ecosystems to be restored by setting targets to be reached in 2030 and 2050 for green areas. In this context, Italy's 'National Biodiversity Strategy 2030' was drawn up, adopted in August 2023 and aligned with European guidelines. This strategy constitutes the reference document about biodiversity for the entire national territory. This policy also addresses urban biodiversity by reaffirming the goal of implementing ambitious urban greening plans. The Italian 'National Biodiversity Strategy 2030' affirms the importance of urban green systems in cities and nature-based solutions (NBS) to provide ecosystem services to citizens. Encouraging their implementation in the urban environment allows cities to increase biodiversity and system resilience and to adapt to climate change. Biodiversity can provide multiple benefits, such as improved air quality and social benefits.

The second consideration concerns the role of urban biodiversity in the policies mapped. At the national level, few policies address the issue of urban biodiversity in a central way. The protection of urban biodiversity is a secondary and consequential objective of urban policies that directly address other issues such as sustainable development or climate change. The same situation can be observed at the local level. Taking Emilia-Romagna as an example, the region has not produced any policies explicitly focused on urban biodiversity in the last 10 years. Also, regarding provincial capital municipalities, the only document identified is the Guidelines for the management of biodiversity in public and private green areas (Linee guida per la gestione della biodiversità nelle aree verdi pubbliche e private) adopted in 2022 by the municipality of Piacenza. The other policies identified at regional, metropolitan and municipal level deal with urban biodiversity in a secondary or marginal manner, having as other topics as their focus: forestry, sustainable development, climate change and agriculture. Concerning forestry we mapped the Regional Forestry Plan (Piano Forestale Regionale, 2016), the Guidelines for Metropolitan Forestry (Linee Guida per la Forestazione metropolitana, 2021); concerning sustainable development we have the Metropolitan Agenda for Sustainable Development (Agenda metropolitana per lo sviluppo sostenibile, 2019), the Urban Transformation Agendas for Sustainable Development of Piacenza, Ferrara, Ravenna, Modena, Cesena, Rimini, Forlì, Reggio and Parma (Agende trasformative urbane per lo sviluppo sostenibile – ATUSS, 2023); concerning climate change we have the Climate change mitigation and adaptation strategy (Strategia per la mitigazione e l'adattamento per i cambiamenti climatici, 2015), the Jobs and Climate Pact (Patto per il Lavoro e il Clima, 2020), the Reggio Breathes programme (Programma Reggio Respira, 2016), the Local Adaptation Strategy Reggio Emilia (Strategia locale di adattamento Reggio Emilia, 2021), the Green strategy for Bologna's urban climate (Strategia del verde per il clima urbano di Bologna, 2022), the Bologna Resilient City (Bologna Città Resiliente, 2020); and concerning agriculture we have the Regional Programme European

Regional Development Fund 2021-27 (Programma regionale FERS), the Rural Development Completion 2021-27 (Completamento Sviluppo Rurale). On the one hand, this analysis has allowed us to deduce that there is a commitment to integrate different themes and various axes of urban development even if they are always linked to the environmental aspects, but on the other hand, we observe that the role of urban biodiversity in these documents is sometimes merely rhetorical.

The last consideration concerns the type of policies currently in place to protect and increase biodiversity in cities. According to the investigations done, at the European level, if we consider that the New Restoration Law is only a bill for now, the EU Biodiversity Strategy for 2030 is a procedural policy that devolves to the member states the drafting of instruments for the implementation of the defined objectives. At the national level, the Italian Biodiversity Strategy for 2030 is also a procedural policy, while Law no. 10 of 2013 is the only law that gives indications and obligations on the development of urban green even if it does not give precise indications on urban biodiversity. This law has been followed by other procedural policies – the Guidelines for urban green management first indications for sustainable planning (Linee guida per la gestione del verde urbane prime indicazioni per una pianificazione sostenibile, 2017) and the National Urban Green Strategy (Strategia Nazionale del Verde Urbano, 2018) – that address and encourage the planning and design of green areas at different scales (territorial, urban, architectural) but that have actually led to the development of few thematic plans.

As far as the analysis of greening plans is concerned, we mentioned in the previous section that the recency is an important aspect characterizing the sample under investigation. Most of the Greening plans have been adopted in the past 6-7 years, with just three plans adopted before 2017. Despite the still scarce diffusion of this instrument in Italy (less than 2 provincial capital cities have an adopted greening plan), the analysis shows that the Guidelines introduced at the national level are slowly producing an impact on the elaboration and adoption of greening plans throughout Italy, providing a useful framework for the local administrations that manifest the political commitment to develop a greening planning framework. Another catalyst is the already mentioned EU Biodiversity Strategy that calls on the European cities and towns of at least 20,000 inhabitants to develop Urban Greening Plans including "measures to create biodiverse and accessible urban forests, parks and gardens; urban farms; green roofs and walls; treelined streets; urban meadows; and urban hedges" (European Commission, 2020b: 13). In the case of the EU Biodiversity Strategy, the reference goes to the "Guidance for cities to help prepare an Urban Greening Plan", which was adopted as a draft version in 2022. The guidance stresses the importance of the collaborative process underlying the Greening plan elaboration, including the need for working with citizens and other stakeholders, and for cross-departmental dialogue and integration with other aspects of urban development, from mobility and health, air and water, to energy and climate adaptation (European Commission, Eurocities and ICLEI, 2022). While in some Greening plans the relationship with these documents of guidance appears to be clear and direct, it is interesting to notice that other cases show a different pathway which is related to specific EU-funded projects that display knowledge and economic resources for their elaboration. For instance, this is the case of the Green Infrastructures Action Plan of Ferrara adopted in 2019 as an outcome of the Interreg Project PERFECT (Planning for Environment and Resource efficiency in European Cities and Towns) or the case of the Bologna Urban Climate Green Assets Plan, which comes as one of the results of the LIFE Clivut project (Climate Value of Urban Trees).

A second relevant aspect emerging from the analysis concerns the structure of the Greening plans. The research has pointed out a high level of heterogeneity and differentiation in the contents and arrangement of the plans. Despite the identification of some basic contents that the greening plans *should* have according to the National Guidelines (Pastore and Lazzarini, 2024), the weight that the Greening plan gives to the analytical and strategic dimensions varies

significantly from plan to plan. In some plans, the analytical part prevails over the strategic one, which means that the description and investigation of the local green system is rich and articulated, but this is not accompanied by a set of effective strategies and actions for supporting the transition towards greener and more resilient urban spaces. In others, the strategic and/or design dimension is dominant but the analytical part that should be at its basis is not sufficiently developed.

This differentiation also translates into the role that the objectives and strategies related to urban biodiversity have in the greening plans. For instance, some plans, as the one of Avellino, treat the topic of biodiversity mostly working on consolidating and completing the ecological network of the municipal territory, strengthening the connections between the protected natural areas present in the hinterland and the urban green spaces located in the town. Other plans, such as the one of Padova, introduce a set of specific objectives, strategies and actions explicitly tackling biodiversity. These rely on a survey made by local experts to monitor the diffusion of selected animal species in specific areas of the municipality.

One problem that emerged from the analysis concerns the weak commitment to implementation characterizing the majority of the greening plans investigated. Several plans do not specify which devices, tools, mechanisms, and processes are needed to implement the objectives and strategies. It is also often reported the lack of specification of the economic and human resources that would be required to bring those objectives to implementation. Despite this weakness, the greening plans mapped make an extensive use of quantitative indicators to monitor the actions included which mainly refer to the increase of both habitat area (e.g., total green surface area, number of trees and their canopy cover, etc.) and biodiversity performances (e.g., number of animal species or percentage of tree species diversity reported in each portion of green area) (Lazzarini, Mahmoud and Pastore, 2024). One open issue concerns the lack of quantitative targets that should accompany the monitoring indicators for preserving or increasing biodiversity habitats and species. Indeed, greening plans often introduce a set of specific indicators for monitoring the achievement of biodiversity objectives and actions, but they do not establish any specific quantitative target for these objectives, making their commitment to implementation weak.

6. Concluding remarks

From the research conducted, our observations are mainly considering the evident challenges from integrating urban biodiversity objectives between the EU and national to the regional and local level, even though the European policies and roadmap clearly facilitate the adhesion to increasing urban and blue greenery to improve quality of life and well-being in cities.

On one hand, and in some rare cases, the national policies and local policies align with the same vision on urban biodiversity conservation, restoration and increment, as highlighted in the case of Bologna. On the other hand, the urban greening plans are clearly sectorial, and in some cases, they do not dialogue with other thematic plans also operating on urban development themes that could have actions related to urban biodiversity in them. A clear disintegration happens at the spatial planning level whereas the planning regulations and thematic plans operate locally in municipalities and in cities abiding by the statuary planning laws and regulations that, nonetheless, do not get combined with each other towards creating a wider urban nature strategy at a larger scale, except in some cases.

Another disintegration happens within the same municipality governance level itself; in some cases, the technical knowledge and expertise needed for developing an urban greening/nature plan are sitting within the directorate of urban planning and do not dialogue with other sectors or directorates such as the mobility and infrastructure, health and built environment, etc. This disintegration is however a challenge that should be looked at from

within the governance process of the urban biodiversity strategy itself, by increasing the dialogue between stakeholders, citizens and decision-makers while trying to break silos circles.

Abstract
In recent years, the sharing economy has revolutionized urban tourism, shifting from traditional hotels to amenity-based house stays facilitated by platforms like Airbnb. Istanbul, Turkey's most populous city, with approximately 16 million annual visitors, has seen a significant presence of Airbnb listings, particularly in the Beyoğlu district. This study delves into Airbnb's impact on Istanbul's urban tourism, focusing on Beyoğlu. By analyzing the spatial characteristics and development disparities of Airbnb listings, closely tied to city centres and major tourist attractions, the research utilizes spatial analysis to understand Airbnb's impact amidst varying socioeconomic and environmental conditions. Utilizing data from InsideAirbnb.com, the analysis highlights that a significant number of Airbnb listings are strategically located near key tourist attractions such as Taksim Square and Istiklal Street, enhancing accessibility for tourists. While these accommodations drive consumer spending towards small businesses and foster cultural exchange by enabling guests to engage deeply with the local community, challenges such as disruptions to neighborhood dynamics and residential tranquility also arise. The study emphasizes the importance of balanced urban planning and regulatory strategies to harness Airbnb's benefits while mitigating its adverse impacts, ensuring that Beyoğlu's growth as a tourist hub enhances both visitor experiences and community well-being.

Keywords: Airbnb, peer-to-peer accommodations, sharing economy, urban tourism, Istanbul

1. Introduction
In recent years, the rise of the sharing economy, particularly platforms like Airbnb, has significantly transformed the landscape of urban tourism worldwide. This paradigm shift brings forth not only new opportunities but also challenges in understanding its impacts on local economies, communities, and urban dynamics. Within this context, this study focuses on Airbnb accommodations in the vibrant Beyoğlu district of Istanbul, with a specific emphasis on the iconic Cihangir neighborhood, renowned for its cultural richness and touristic appeal.

Leveraging data sourced from insideairbnb.com, our analysis delves into the spatial characteristics, socio-economic factors, and the overall influence of Airbnb on Beyoğlu's local tourism economy. Through a methodical approach encompassing proximity analysis, socio-economic exploration, and trend examination, this study aims to provide a comprehensive understanding of Airbnb's role within this urban ecosystem.

By juxtaposing insights garnered from the broader Beyoğlu dataset with detailed analyses of Cihangir-specific reviews, the study endeavors to shed light on the nuanced interactions between Airbnb, urban tourism, and community dynamics. Through this exploration, it aims to discern the extent to which Airbnb contributes positively to the local economy and cultural tourism in Beyoğlu, while also identifying avenues for sustainable growth and community development.

The subsequent sections will commence with a literature review to contextualize the study within the existing body of research on urban tourism and the sharing economy, thereby

establishing a robust theoretical framework for the analysis. Following this, findings will be represented with an overview of the dataset and methodology employed, followed by a detailed analysis of Airbnb accommodations in Beyoğlu and Cihangir. Subsequently, the research will delve into the implications of our findings within the broader context of urban tourism and the sharing economy, offering insights for future research and policy considerations.

2. Literature Review

In scholarly discussions concerning the sharing or platform economy, a significant portion of its expansion is attributed to the rise of peer-to-peer (P2P) accommodation providers, exemplified prominently by Airbnb. These platforms have become the subject of rigorous debate within academic circles owing to their multifaceted impacts across various facets of the tourism and hospitality sectors, spanning socio-cultural, economic, and environmental realms (Hall et al., 2022). While certain scholars accentuate the positive aspects, such as enhanced accessibility and flexibility for travelers, others underscore the negative ramifications, including heightened competition with conventional lodging establishments and the potential disruption of local communities.

The proliferation of Airbnb and analogous platforms has precipitated spatial transformations within urban landscapes, prompting concerns regarding their implications for neighborhood dynamics and community welfare (Curto et al., 2022). Empirical evidence suggests that the spatial distribution of short-term rentals often clusters around city centres and tourist hubs, exerting discernible impacts on local housing markets and exacerbating socio-economic disparities. For example, investigations conducted in cities like Turin, Barcelona, and Melbourne, as demonstrated by Curto et al. (2022), illuminate how the prevalence of short-term rentals correlates with factors such as income levels, educational attainment, and housing characteristics, thereby influencing their spatial distribution across diverse neighborhoods.

Furthermore, the expansion of Airbnb has elicited inquiries into its role within the dynamics of urban tourism, particularly within mid-sized cities characterized by heterogeneous economic landscapes (Ioannides et al., 2019). Inquiries conducted in locales such as Utrecht shed light on Airbnb's potential to catalyze the expansion of tourism bubbles, particularly within nascent neighborhoods undergoing socio-cultural transformations. These phenomena underscore the exigency for nuanced policy responses that navigate the intricate interplay between tourism development, housing markets, and community welfare.

The spatial dynamics of Airbnb accommodations within Istanbul's Beyoğlu district are examined in this study. Findings are parallel to researches from other global cities, notably London. (Liqing La et al., 2022) Observed distribution pattern is similar to London, where Airbnb listings concentrate around tourist attractions and in peripheral urban zones, suggesting strategic placement to enhance tourist accessibility: a trend likely mirrored in Beyoğlu. The economic and social impact of Airbnb on local communities is a focal point, echoed by Alexander's 2018 research on Airbnb in Melbourne (Alexander, 2018). Insights reveal how Airbnb influences housing markets and urban planning, posing challenges and opportunities for Beyoğlu's residential dynamics and urban development strategies. Policy implications derived from comparative urban analyses, such as those by Alexander, stress the need for comprehensive planning strategies to manage Airbnb's impacts. Similar approaches recommended for Melbourne advocate for urban sustainability and resident welfare, offering valuable insights for Beyoğlu's policymakers.

Insights from Benítez-Aurioles and Győdi provide a framework for understanding Airbnb's broader economic implications (Benítez-Aurioles, 2019 & Győdi, 2019). The study emphasizes competition with the traditional hotel industry and the need for adaptive economic policies that has a potential to adapt Beyoğlu's tourism sector. Spatial analyses (Gutiérrez et al., 2017) highlight Airbnb's strategic placement within urban landscapes, influencing real estate dynamics and socio-economic disparities, findings that likely resonate in Beyoğlu., Like Gurran's examination of housing markets and community welfare (Gurran, 2018), incorporating recent scholarly explorations into Airbnb's impact on urban environments enriches our understanding of Beyoğlu's situation. This holistic approach ensures a well-rounded exploration informed by global trends and practical insights, vital for developing effective policies and strategies tailored to Beyoğlu's unique context.

In conclusion, the literature on Airbnb and the sharing economy furnishes invaluable insights into the evolving contours of urban tourism. By scrutinizing the socio-economic, spatial, and cultural dimensions of Airbnb's influence, scholars contribute to a nuanced comprehension of its impacts and the formulation of efficacious policy interventions. Looking ahead, interdisciplinary research endeavors are imperative to address the multifaceted challenges and opportunities engendered by the integration of sharing economies into the urban fabric.

3. Methods and Materials

This research aimed to investigate the landscape of Airbnb accommodations within Istanbul's Beyoğlu district, with particular attention to the Cihangir neighborhood (Figure 1), renowned for its appeal to tourists. Utilizing data sourced from insideairbnb.com (https://insideairbnb.com, 2023), the analysis delved into the spatial characteristics, socio-economic dimensions, and their interplay within the local tourism economy. The methodological framework involved several sequential steps, including the meticulous curation of listings by district, detailed proximity analyses concerning notable tourist attractions, comprehensive exploration of socio-economic variables, and a longitudinal examination of evolving trends.

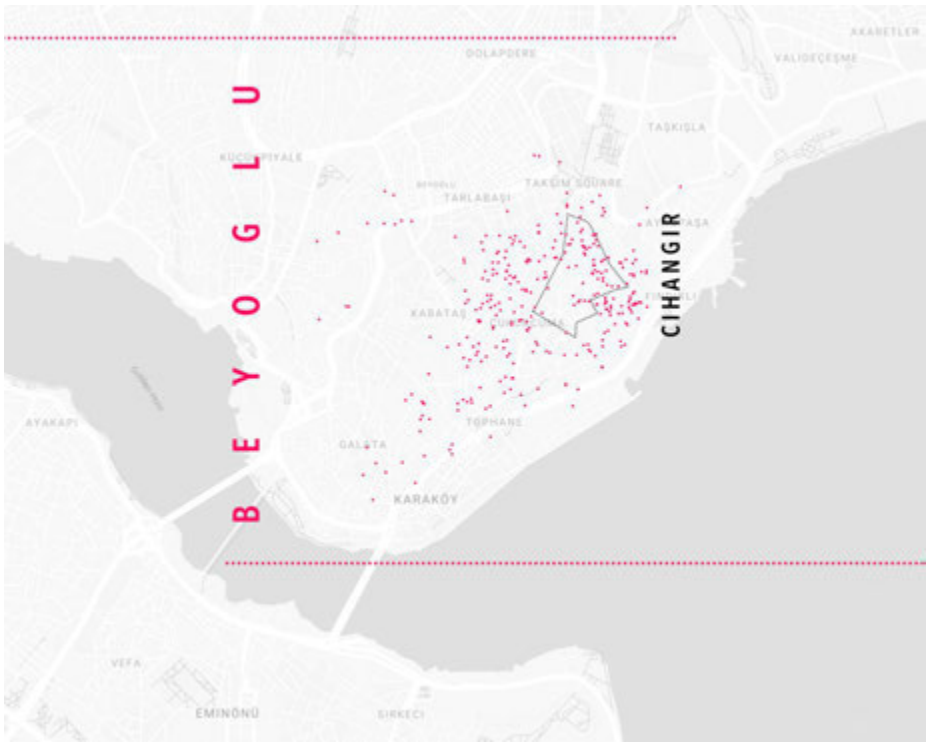

Figure 1: Map of the case area (produced by the authors, 2024)

By the end of 2023, Beyoğlu emerged as a host to a substantial inventory of Airbnb rental units, totaling 34,446, with 18.6% of Istanbul's listings concentrated within this district, constituting 6,393 units, exclusively comprising entire home offerings (Figure 2). Among these, 452 units were situated in Cihangir, thus forming the central focus of this inquiry. The analytical scrutiny concentrated on these Cihangir-based rental units, excluding those without prior rental history or those garnering fewer than 10 reviews, culminating in a comprehensive assessment of 312 units.

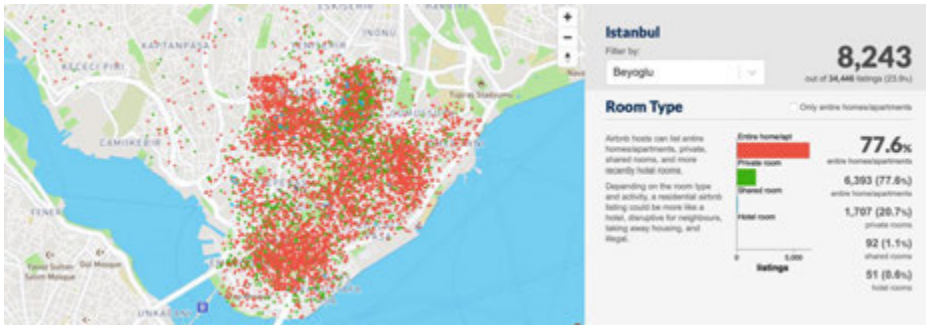

Figure 2: A graphical visualization for Beyoğlu on the website Inside Airbnb (https://insideairbnb.com, 2023)

The analysis focused on spatial characteristics, socio-economic factors, and their influence on the local tourism economy as outlined in the paper. This included assessing proximity to tourist attractions, the socioeconomic status of neighborhoods, and the distribution of Airbnb listings across Beyoğlu. The data provided contained a detailed listing of Airbnb accommodations in Istanbul, including location descriptions, URLs, and reviews. To align with the study's focus on the Beyoğlu district, the following phases were taken:

- Phase 1: Listings were filtered by district to isolate entries specific to Beyoğlu based on the neighborhood overview or any district identifier present in the data.
- Phase 2: Spatial analysis
  Proximity to Attractions
  - The examination commenced by assessing the proximity of accommodations to key tourist attractions. Leveraging latitude and longitude data from the dataset, distances were calculated to prominent landmarks in Beyoğlu, including Taksim Square and Istiklal Street.
  - The majority of listings are situated in close proximity to Taksim Square, with distances ranging from approximately 0.46 km to 0.77 km. This close proximity is likely to enhance their appeal to tourists seeking convenient accommodation options.
  - Listings also boast close proximity to Istiklal Street, a prominent shopping and cultural hub in Istanbul. This proximity offers visitors easy access to shopping, dining, and nightlife experiences, further enhancing their attractiveness.

  Accommodation Features
  - The listings exhibit a diverse range of bed arrangements, suggesting accommodation options suitable for individuals as well as larger groups. While the dataset lacks information on the number of bedrooms, the provided number of beds offers insight into the accommodation's capacity.
- Phase 3: Pricing Dynamics
  - Prices display variability, potentially influenced by factors such as proximity to key attractions, bed capacity, and other amenities not explicitly detailed. Prices display variability, potentially influenced by factors such as proximity to key attractions, bed capacity, and other amenities not explicitly detailed. For example, the average nightly price for homes is 3,002 Turkish Lira, with an annual average income of 198,803 Turkish Lira, indicating a diverse array of accommodation options catering to different market segments.
  - Economic Impact: Trend analysis examined the distribution and evolution of listings over time, and their relationship with local economic data such as housing prices and income levels.
- Phase 4: Socio-economic analysis explored variables related to the socioeconomic status, such as perceived neighborhood quality from listing descriptions and review sentiments.

4. Results

This study adopts a content analysis methodology to delve into the keywords and sentiments expressed within guest reviews sourced from Insideairbnb.com. Leveraging the comprehensive features of the MAXQDA program[1], the analysis process is structured to meticulously explore

[1] MAXQDA is a qualitative data analysis software that facilitates in-depth exploration and interpretation of textual, audio, video, and image data. It offers a range of powerful tools for organizing, coding, and analyzing qualitative data, making it an invaluable resource for researchers conducting content analysis and qualitative research (https://www.maxqda.com, 2023).

the textual data, enabling the identification of underlying themes, patterns, and trends. By employing content analysis coupled with sophisticated analytical tools, this research aims to gain nuanced insights into the perceptions and experiences of Airbnb guests, contributing to a deeper understanding of the platform's impact on urban tourism dynamics.

Review analysis utilized natural language processing techniques to extract keywords and sentiments from guest reviews, providing insights into overall guest satisfaction. By examining the content of reviews, common themes and sentiments expressed by guests regarding their stays in Beyoğlu's Airbnb accommodations were identified. The analysis yielded the following key findings:

- *Cultural and Scenic Appeal:* Guest reviews frequently highlight the proximity of accommodations to cultural sites and scenic areas, such as seaside bars in Cihangir, underscoring Beyoğlu's vibrant nightlife and aesthetic allure.
- *Location Advantages:* Many reviews underscore the strategic positioning of accommodations, emphasizing their proximity to key areas within Beyoğlu and well-known streets, which enhances their appeal to guests.
- *Neighborhood Characteristics:* Discussions in reviews often emphasize the safety, beauty, and historical richness of Beyoğlu's neighborhoods, indicating that guests value these attributes when selecting accommodations.
- *Proximity to Taksim:* Numerous reviews specifically mention the proximity to Taksim Square as a significant factor for tourists seeking convenient access to Istanbul's central attractions, highlighting its importance in guest satisfaction.
- *Safe and Established Areas:* Safety and the established nature of the area emerge as recurring themes in guest reviews, reflecting a preference for secure and well-known locales among guests.

The text from neighborhood reviews was analyzed to identify common themes or sentiments that might have influenced guests' experiences. This analysis aimed to understand what guests valued most about their stays in Beyoğlu and could have implications for review scores. Simple keyword extraction was utilized to identify frequently mentioned terms in the neighborhood descriptions. The results of this text analysis are as follows:
"Istanbul": Indicates the broader geographic reference, emphasizing the location within the city.
"Galata" and **"Taksim"**: These are specific areas within Beyoğlu, known for their cultural and historical significance as well as vibrant nightlife and shopping options.
"Istiklal": Refers to Istiklal Street, a famous pedestrian street in Beyoğlu, lined with shops, cafes, and historic sites.
"Street", **"Square"**, **"Minutes"**, **"Walk"**: These terms suggest that proximity and ease of access to attractions are important features.
"Restaurants": Highlights the culinary experiences available in the area, which is a key attraction for many visitors.

The top keywords extracted from the reviews offer insights into the aspects guests most frequently mention in their reviews for Cihangir Airbnb listings:
"Apartment": The most common term, likely reflecting discussions about the accommodations themselves.
"Great", **"Location"**, **"Place"**, **"Stay"**: These words highlight positive experiences related to the quality of the stay and the geographic convenience of the accommodations.
"Clean", **"Nice":** Often associated with guests' satisfaction with the cleanliness and overall appeal of the places they stayed.

"Host": Indicates that interactions with hosts are a notable aspect of guest experiences, which can significantly affect their overall satisfaction.

To offer more nuanced insights, we conducted a detailed sentiment analysis, focusing on specific categories mentioned in the reviews, such as cleanliness, location, and interaction with hosts. This approach allows us to understand how different aspects of the stay contribute to the overall sentiment. Detailed sentiment analysis results by category, targeting specific aspects of the Airbnb experience, yielded the following average sentiment scores:
Cleanliness Sentiment: 0.378 - This score indicates a generally positive sentiment when reviews mention cleanliness, reflecting satisfaction with the cleanliness of the accommodations.
Location Sentiment: 0.419 - Similarly, this score demonstrates a positive sentiment, suggesting that guests often appreciate the location of their accommodations in Cihangir.
Host Sentiment: 0.427 - This category yielded the highest sentiment score, indicating very positive experiences with hosts. It highlights good service and hospitality as significant factors contributing to guest satisfaction. Analysis of guest reviews uncovers a strong theme of community interaction, with many guests appreciating the "local" experience facilitated by their hosts. This includes participating in local festivities, visiting neighborhood markets, and engaging with local artists. Such interactions underscore Airbnb's role in enhancing cultural exchange and deepening guests' understanding of Istanbul's diverse cultural tapestry.

The average sentiment score of the reviews stands at approximately 0.345, suggesting a generally positive sentiment among guests. This score indicates that the majority of reviews convey favorable experiences, potentially reflecting satisfaction with both the accommodations and the neighborhood attributes of Cihangir. The sentiment and thematic analysis of the reviews from Airbnb listings in Cihangir indicate a generally positive guest experience, with significant emphasis placed on the quality and location of accommodations, as well as cleanliness and host interaction. These factors play a pivotal role in upholding high guest satisfaction levels and can offer valuable insights for Airbnb hosts in Cihangir to enhance guest experiences even further.

4.1. Spatial Analysis

To explore the spatial experience of guests, the urban context, and the architecture and interior design of Airbnb accommodations in Beyoğlu, we focused on elements within the reviews that specifically mentioned the physical aspects of the spaces, their aesthetic appeal, and their integration into the urban environment. Terms and phrases within the reviews related to these themes, such as "design", "architecture", "spacious", "layout", "modern", "traditional", "style", and "urban", were identified. This helped us to capture insights related with the spatial and architectural characteristics of the Airbnb listings in Beyoğlu. This focused analysis was performed to provide insights into the spatial and architectural experience of guests.

The focused analysis on the spatial experience, architectural design, and urban context of Airbnb accommodations in Beyoğlu provided the following insights based on the frequency of related terms in the reviews:

Interior Design & Architecture: 274 mentions - Guests often noted elements of design and architecture, such as style, modernity, and traditional aspects of the interiors, suggesting their importance in the guest experience. While not as prominently mentioned as other factors, comments on unique architectural features and modern interior design were frequent, aligning with literature on "Interior Design" and "Architecture" codes. This underscores the significance of visual and functional appeal in guest satisfaction, with mentions of "modern amenities" and

"beautifully designed interiors" reflecting appreciation for contemporary and traditional styles alike.

Review data emphasized the significance of amenities in elevating the guest experience, with specific mentions of "comfortable beds," "well-equipped kitchens," and "spacious bathrooms" aligning with detailed amenity codes such as "Beds," "Kitchen," and "Bathroom." Additionally, the frequent discourse on views and environmental comfort elements like air conditioning and heating provides further support for themes categorized under "Functional" aspects related to space quality and usability.

Listings often highlight the architectural uniqueness of the properties, which may range from restored Ottoman-era homes to modern apartments with panoramic city views. For example, a listing might describe, "Our home combines Ottoman architectural grace with contemporary design, featuring high ceilings and large windows overlooking the Golden Horn." Guests frequently express their appreciation for these features, with comments like, "The architecture of the place was a blend of classic and modern, which really added to our experience of the city."

In terms of interior design and space quality, hosts frequently leverage interior design as a selling point, showcasing how spaces are tailored for comfort and aesthetic appeal. A typical description might read, "Designed with a keen eye for style, our apartment features bespoke furniture and art pieces that complement its historical context." Reviews support this focus, with guests noting, "The beautifully decorated interiors made our stay feel luxurious and comfortable, a perfect retreat after a day of touring."

Urban Context & Experience: 533 mentions - Significant mention of the urban experience, including the vibe of the neighborhood, local community, and the general atmosphere, was observed. This indicated that guests appreciated accommodations that integrated well with the urban environment and provided a genuine experience of city life in Beyoğlu.
These findings suggested that while the interior design and architectural elements were appreciated, guests placed a higher value on the functionality and quality of the space, as well as the broader urban experience offered by the accommodations. This could be a key consideration for Airbnb hosts looking to improve their offerings, as well as for urban planners and local policymakers aiming to integrate tourism more deeply into the urban fabric of Beyoğlu.

To provide a detailed analysis of the *"Urban Context and Experience"* theme from the Airbnb reviews in Beyoğlu, the focus was on extracting and interpreting guest comments that discussed the interaction between the accommodations and their urban environment. This included examining how guests perceived the neighborhood's atmosphere, the characteristics of the local community, and the overall city life surrounding them. The sample reviews gathered under this theme highlighted various aspects of how guests perceived and interacted with the urban environment in Beyoğlu. Here's a breakdown of the key elements derived from these reviews:

Neighborhood Atmosphere: Descriptions of the ambiance, vibe, or spirit of the neighborhood as perceived by the guests. Guests appreciated the local ambiance, noting the vibrancy and cultural richness of the neighborhood. For example, one review mentioned enjoying the local cafes and glimpses into Turkish life, suggesting that the neighborhood's character significantly enhanced their experience.

Local Community and Culture: Observations about the people, cultural practices, and daily life in the neighborhood from the guests' perspective. Many reviews highlighted interactions with the local community or observations of daily life, indicating that the social environment was an integral part of the urban experience. Comments about children playing in the streets or local customs provided a deeper connection to the place.

Proximity to Urban Amenities: Many Airbnb listings in Beyoğlu underscore their proximity to Istanbul's cultural and historical landmarks, such as museums, historic mosques, and art galleries. For instance, a host highlights, "Just a five-minute walk from the famous Galata Tower and the bustling Istiklal Street, our apartment offers guests a chance to immerse themselves in the city's historical charm." Reviews often express appreciation for these locations, with one guest noting, "Loved being so close to major attractions, it made our cultural excursions easy and enjoyable."

Accessibility and Convenience: Guest reviews commonly highlight the ease of accessing public transportation, facilitating exploration of Istanbul. One review mentions, "The proximity to the metro station made it effortless to explore the city, from historical sites to modern shopping areas." Listings also mention amenities like cafes, markets, and nightlife within walking distance, indicating the urban convenience that Beyoğlu offers. For example, one listing states, "Surrounded by local cafes and vibrant street markets, our location is perfect for those who want to experience Istanbul's lively urban life."

Challenges and Concerns: Some reviews also discussed challenges related to the urban context, such as difficulty navigating backstreets, the condition of sidewalks, or the general maintenance of the area. These insights were crucial for understanding potential areas for improvement in urban planning and tourism management.

These findings suggested that the urban context of Beyoğlu significantly shaped guests' experiences, with cultural vibrancy, community interaction, and accessibility playing key roles. Understanding these aspects could help stakeholders in tourism and urban planning capitalize on strengths and address any weaknesses. This detailed insight into the urban experience could guide improvements in local infrastructure, cultural engagement strategies, and overall hospitality practices to enhance the attractiveness and functionality of urban tourism environments like Beyoğlu.

4.2. Economic Impact Analysis

Looking at the annual earnings, Figure 3 shows an increase in income as the length of stay increases. This indicates that longer-term rentals generally yield higher total income. However, the highest earnings are not in the range of 241 days or more, but rather in medium-term rentals (such as 91-120 days). This may be due to the popularity or higher prices of medium-term rentals. Additionally, according to the graph, as the rental duration of Airbnb properties in Beyoğlu increases, there is a general downward trend in the number of properties used. While the highest number of properties is in the range of 1-30 days, this number slightly increases for 241 days or more, but is less than other duration ranges.

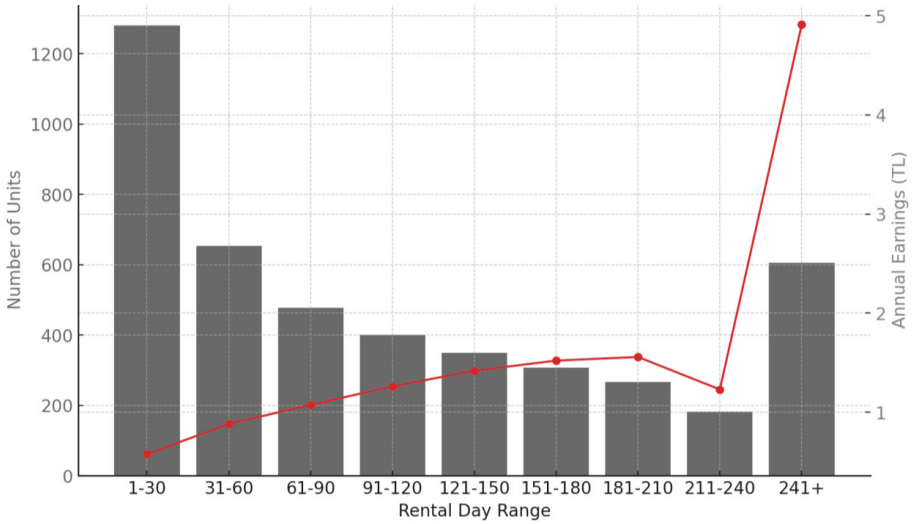

Figure 3: Beyoğlu Airbnb rental periods and annual earnings

The analysis of listing descriptions reveals a noteworthy trend wherein local amenities feature prominently, indicating Airbnb's substantial influence on the local economy. Specifically:

- Restaurants: These are mentioned 1,325 times, underscoring their significance to guests seeking dining options during their stay.
- Shops: With 1,308 mentions, the presence of nearby retail establishments emerges as a key consideration for guests, reflecting the convenience and accessibility of shopping opportunities.
- Markets: Mentioned 425 times, the presence of local markets highlights the appeal of proximity to fresh produce and other goods for Airbnb guests.
- Cultural Sites: These are referenced 387 times, indicating the interest of guests in exploring cultural attractions within the vicinity of their accommodations.
- Tourist Sites: With 608 mentions, the proximity to tourist hotspots emerges as a major selling point for Airbnb listings in Beyoğlu, catering to travelers keen on exploring popular landmarks and attractions.

These findings suggest a strategic positioning of Airbnb listings in Beyoğlu, capitalizing on the allure of local economic and cultural amenities to enhance their appeal to tourists. Reviews further substantiate this trend, with guests frequently mentioning nearby attractions and businesses:
"The location is also phenomenal, a short walk to museums and galleries which enriched our cultural experience."
"His flat is well situated for easy access for local festivals and markets."
"This is a very happening area with many shops and cafes which add to the vibrant neighborhood feel."
"You can find shops, coffees, and restaurants nearby which makes it very convenient."

Overall, the emphasis on local amenities in both listing descriptions and guest reviews underscores the symbiotic relationship between Airbnb accommodations and the broader economic and cultural landscape of Beyoğlu.

4.3. Socio-Cultural Impact Analysis

The analysis of the text for socio-cultural impacts revealed several key insights into how Airbnb might have influenced the local culture and community in Beyoğlu:
"Historic": Mentioned 1,002 times, highlighting the significance of historical aspects of the neighborhood in attracting guests.
"Neighborhood": Mentioned 790 times, reflecting the emphasis on the local community and environment in listing descriptions.
"Traditional": Mentioned 126 times, indicating the value placed on traditional elements of the local culture.
"Community": Mentioned 62 times, showing some focus on community engagement or aspects.
"Heritage": Mentioned 46 times, underscoring the cultural heritage of the area.
"Local Life": Mentioned 9 times, which could indicate a lesser focus but still present interest in the everyday life and experiences of local residents.

In terms of host-guest Interaction; the data highlighted the significant role of hosts in shaping the Airbnb experience. Positive interactions, characterized by personalized tips and warm welcomes, were highly valued by guests, aligning with the "Host-visitor relations" and "Communication" codes. These interactions often extended to include local recommendations and assistance with navigating the city, underscoring the importance of host engagement in shaping the social dynamics of guest experiences. Host descriptions and guest reviews often highlight the personal touch provided by hosts. For example, a host might offer, "I love sharing my local knowledge with guests, from hidden gems to the best dining spots." Guests frequently appreciate this interaction, with reviews stating, "Our host's recommendations transformed our visit; we felt like locals thanks to his insider tips."

Some reviews reflect direct interactions with the local community facilitated by Airbnb. A guest shared, "We attended a neighborhood festival recommended by our host, which was a highlight of our trip, giving us a true taste of local culture." Hosts also mentioned community engagement in their listings, such as, "We support local businesses and encourage our guests to visit nearby artisans and cafes, helping to sustain our vibrant community."

While Airbnb brings numerous benefits, it also poses challenges to traditional neighborhood dynamics. Some residents express concerns over increased noise and a shift in neighborhood character due to the influx of tourists. This aspect of the socio-cultural impact calls for a balanced approach in managing Airbnb's integration into community life to maintain the authenticity and tranquility of residential areas.

Additionally, when evaluated in terms of community engagement and security; while less explicitly emphasized in the review data, indications suggest that guests prioritize secure accommodations and feel more comfortable when safety features are clearly communicated, in line with the "Security" codes. Occasional references to engaging with the local community and participating in neighborhood activities imply that Airbnb can facilitate deeper social interactions, although further detailed data collection could enhance understanding in this area.

5. Discussion and Conclusion

Drawing upon insights derived from both the comprehensive Beyoğlu dataset and the detailed Cihangir reviews, we assert that Airbnb exerts a substantial positive influence on both the local economy and cultural tourism within the Beyoğlu district. Our analysis not only underscores

the favorable impact of Airbnb on urban tourism in Beyoğlu but also underscores prospects for sustainable growth and community advancement.

Urban context is a significant indicator for Airbnb experience and consummates with the home experience, neighborhood atmosphere, culture involvement, accessibility and proximity to tourism attractions. The Airbnb usage affects the economy of tourism venues like restaurants, shops, markets and tourism sites. Due to the location of Beyoğlu in Istanbul, social engagement and consciousness on historical aspects of the neighborhood and local life works as a motivator for socio-cultural dynamics in the region.

Thematic examination reveals that Airbnb listings in Beyoğlu serve as integral components of the tourism infrastructure, seamlessly merging urban living with tourist experiences. These themes illuminate how Airbnb enhances guest access to cultural and social facets, offers aesthetically pleasing and functional living spaces, and fosters community engagement.

Furthermore, sentiment and thematic analyses of the Cihangir dataset underscore key factors contributing to guest satisfaction, including accommodation quality, host responsiveness, and property location. To further elevate guest experiences, Airbnb hosts in Cihangir are encouraged to prioritize maintaining high standards, leveraging location advantages, and enhancing host-guest interactions.

The content analysis underscores the multifaceted role of Airbnb in shaping urban tourism landscapes. By deepening tourism integration into the urban fabric, Airbnb facilitates distinctive experiences often absent in traditional accommodations. However, the integration of short-term rentals into urban areas necessitates cautious consideration of their effects on local communities and urban dynamics.

Additionally, our analysis confirms a significant correlation between literature-derived codes and themes identified in Airbnb reviews, particularly in functional and cognitive domains. The physical attributes of accommodations, encompassing design, amenities, and maintenance, significantly shape guest experiences. While social interactions, primarily facilitated by hosts, also wield considerable influence, more explicit data on broader community engagement and security could further enrich our understanding in these realms.

This systematic approach guarantees rigorous analysis of the dataset and its seamless integration into the broader academic discourse of the paper, enriching theoretical discussions on urban tourism and the sharing economy with empirical depth. For further research, these findings could be contextualized within the broader urban ecosystem, examining Airbnb's impact on Beyoğlu's urban landscape and comparing it with similar trends in other global cities to identify unique or common patterns.

Abstract

The concrete industry in the Ruhr region faces critical challenges, including primary raw material shortages and the need to reduce anthropogenic greenhouse gas emissions. Immediate action is essential as primary resources remain necessary even with secondary raw materials being used, and cutting emissions is crucial to mitigate climate change. This research proposes that establishing a Resource-conserving Concrete Hub (RCH) can positively affect the image and efficiency of Resource-conserving Concrete by unifying key stakeholders and integrating new participants. The Ruhr region, with its dense population, rich industrial history, and polycentric structure, seems to provide an ideal setting for implementation. Although current data on urban mining is insufficient for precise planning, as a material registry has not been implemented yet, the study identifies promising locations, particularly the Essen city harbor, as prime candidates for advancing the RCH concept and therefore boosting urban mining practices within Germany.

Keywords: Resource-conserving concrete, Urban Mining, Recycling hub, Location-Allocation analysis, Ruhr area

1. Introduction

Concrete, due to its material properties, is an inherent component of modern construction, leading to a global demand for the building material like no other (Miller et al., 2016). In 2020, according to the Global Cement and Concrete Association (GCCA, 2023), approximately 14 billion m^3 of concrete were produced worldwide. This trend can be attributed in part to factors such as a growing global population, increasing urbanization, and a continuously expanding global economy (UNEP, 2022). Resulting in a threefold increase in demand over the past 40 years (UNEP, 2021).

However, due to the high demand and therefore production of the mineral building material, challenges such as resource security, as well as climate and environmental protection, are gaining increasing relevance. For instance, during the production process of concrete, approximately 280 kg of CO_2 are emitted per cubic meter of the building material being produced (LANUV, 2021), making the production of concrete responsible for around 8.6 percent of anthropogenic climate potent emissions (Miller et al., 2016). The high amount of climate potent greenhouse gas emissions in concrete production can be attributed mainly to the production process of clinker for Portland cement production - an elemental component of concrete - and partly to the transport of the building material and its primary raw materials (Miller et al., 2016; LANUV, 2021).

Due to the high demand, sand is considered one of the most heavily exploited resources worldwide after water (UNEP, 2022). The extensive extraction of this mineral resource also has negative effects on regional ecosystems and the water cycle (Albrecht-Saavedra and Lippelt, 2015). Consequently, a significant portion of the remaining raw material reserves in Germany has been protected from further extraction efforts by conservation initiatives, leading to potential regional shortages of primary raw materials as the industry has failed to transition early to alternative secondary raw material sources (VDZ, 2022; Elsner, 2018). Such scarcity increases distances to be traveled, further negatively impacting the environmental footprint of the raw material, and consequently of concrete as a building material, while also intensifying the economic and (geo-)political pressure on business and political entities to explore alternative sources of raw materials (Arora et al., 2017; Fluchs and Neligan, 2023; Hilgers and Becker, 2019).

As such, Urban Mining of construction and demolition waste (CDW) can serve as an alternative source within the Circular Economy (CE), being necessary to face upcoming raw material shortages. By utilizing locally sourced recycled aggregates (RA), the demand for primary raw materials can be reduced, thereby lowering extraction levels. Additionally, it helps prevent the landfilling or inferior recycling of materials classified as waste according to the Waste Framework Directive, through downcycling processes. Within the framework of the CE, materials obtained from dismantled structures are sorted and processed before being reintegrated into concrete production and ultimately used in construction (Müller, 2018).

In Germany, mineral CDW constitutes the largest material flow within the national waste balance, amounting to 229.4 million tons (55.4 %). Out of this total, approximately 95 percent (218.8 million tons) are classified as non-hazardous waste and are thus eligible for recycling (UBA 2022c). However, only materials categorized as construction debris, totaling around 59.8 million tons, are suitable as RA in concrete production and therefore eligible for being reused in building construction (bbs 2021; Müller 2018).

A majority of all mineral CDW in Germany undergo further processing (89.7 %). However, the recycling rate of these waste materials is only 33.7 percent (bbs 2021), with the definition by bbs encompassing downcycling processes such as usage in road substructures. Consequently, the use of RA in the production of resource-conserving concrete (R-Concrete), and thus an adequate recycling process in line with the CE, is exceedingly low, at approximately 0.9 million metric tons (VDZ 2021).

While the substitution of sand and gravel can notably alleviate the impacts of the described raw material shortages, reducing climate potent greenhouse gas emissions in concrete production necessitates the substitution of clinker in cement production. This substitution is already practiced on a large scale, resulting in a 30 percent reduction in clinker and thereby nearly the entire greenhouse gas emissions in cement production through the use of fly ash and slag sand (VDZ 2022; VDZ 2020). However, due to the planned coal phase-out in Germany and the transition to hydrogen in the steel industry, a significant reduction in the availability of both substitutes is expected in the near future (Voland and Westendarp 2021; Holcim Deutschland 2021; acatech 2023). Current research and initial practical attempts indicate that the current substitutes can be replaced by RA from construction waste processing; however, further research and experiments are needed to implement this on a similar scale (Kytzia and Stürwald 2021; Müller et al. 2020; Holcim 2023). The VDZ (2022) predicts the share of RA in concrete production to reach around 26 percent by 2050.

Consequently, the concrete industry is currently undergoing a transformation out of necessity. In order to sustainably remain competitive and meet the climate targets outlined in the Paris Climate Agreement, a restructuring of current processes is imperative to transition the linear economic system to a CE.

Thus, this study develops a concept of an Resource-conserving Concrete Hub (RCH), which aims to consolidate relevant stakeholders in one location and thereby enables the utilization of synergies. In doing so, the concept of an RCH is being based on, but not limited to already existing concepts (e. g. Müller and Kurkowski (2017) and Zabek et al. (2024)). Building upon this, the identified location factors of the stakeholders are transferred to the Ruhr area through a spatial analysis to identify an ideal-typical location for its implementation.

2. Methodology

2.1 Development Of A Resource-efficent Concrete Hub (RCH) Based On Expert Interviews And Literature Review

The primary aim of developing an RCH is to achieve high-quality and efficient processing of mineral construction waste of dismantled buildings and the utilization of recycled aggregate in concrete production, which is then used in building construction. Additionally, a modular system is developed, which can be adapted based on existing local requirements as well as site conditions and aims to enhance the hub's accessibility to a broader audience.

This is based on a transformation from the currently limited mineral material cycle in the concrete industry (see Figure 1) towards a circular cycle based on urban mining of secondary aggregates and their usage in concrete and cement production (see Figure 2).

The concept of the RCH is based on three semi-structured expert interviews conducted with representatives from Remex (construction waste processing), Holcim (concrete and cement production), and Madaster (provider of a materials passport) in early 2023. The information gathered from the interviews was compared with existing literature, particularly a feasibility study by Müller and Kurkowski (2017) in the Rhenish lignite mining area, and best practice examples such as those by Feeß (Heinrich Feess GmbH & Co. KG 2023) in southern Germany.

Based on this, a catalogue of requirements for the core businesses was subsequently developed, serving as the basis for the site selection process.

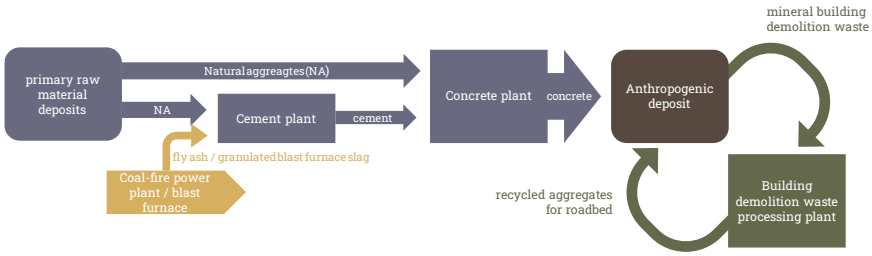

Figure 1: current and primarily linear system of concrete production.

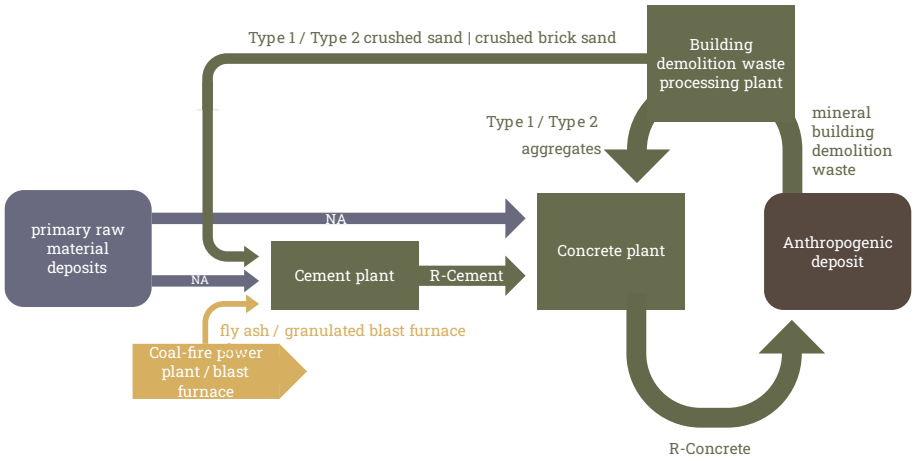

Figure 2: possible circular economy in concrete production.

2.2 Spatial Analysis With Geo Information Systems (GIS)

The objective is to identify specific regions and zones within the Ruhr region as a representative area, conducive to the establishment of an RCH. This entails conducting a Location-Allocation Analysis. Initially, emphasis is placed on the concrete evaluation of hard location factors, namely secondary raw material accessibility for the construction waste processing facility and the market viability for R-Concrete. To prevent peripheral zones within the study area (Figure 3) from being disadvantaged, data within a 20 km radius is also factored in, with the exclusion of areas in the Netherlands due to data limitations. Subsequently, the chosen areas from each category undergo a reevaluation to assess their suitability within the local context, thereby eliminating unsuitable locations like sites being completely surrounded by residential uses or not adequately connected to existing feasible road infrastructure.

Figure 3: Study Area | Data Source: GEOportal.NRW (2023).

The applied network layer is based on a dataset from Geofabrik (2023), which consists of data derived from OpenStreetMap. Further processing of the data regarding intersection points is required.

Based on the identified location requirements described in Chapter 3.2, cement plants, coal-fired power plants, and port areas located in the Ruhr region are considered as potential sites separately. The areas designated in ALKIS as commercial and industrial zones are filtered based on their distance to residential areas (overlaid with a 250 m buffer) and size (3.05 hectares).

For the indicator of secondary raw material availability, there are no data available for the study area regarding material availability or demolition volume. Therefore, the formula proposed by Müller (2018) is employed, where the population serves as an indicator for calculating the amount of construction waste (Figure 4). Census data from the most recent census conducted in 2011 (Statistische Ämter des Bundes und der Länder 2011) are used as the basis for this analysis as they are found to be the most recent data based on their scale. To further refine the respective areas, the data from each one-square-kilometer grid cell are transferred to the built-up areas within the corresponding square. However, due to data limitations, drawing conclusions about the generated construction waste based on population density is not feasible, resulting in only a weighting being considered.

$$Catchment\ Area = \frac{Annual\ \ Capacity}{Population\ \ Density\ *per-capita-volume}$$

Based on

catchment area in km²

annual capacity in t

population density in inhabitant/km²

*per-capita-volume in t/inhabitant*a*

Figure 4: Equation used for assessing the expected availability of secondary raw material based on Müller (2018).

As a demand indicator, construction activity within the municipalities is applied. A high-quality and available information source is the completion of residential and non-residential buildings within the last 10 years at the municipal level in square meters of floor area (IT.NRW 2022). The application of this dataset is based on the assumption that construction activity and concrete consumption are strongly positively correlated, although this correlation is not precisely quantified. By using the average of the data from the last 10 years, possible fluctuations (such as the completion of a new housing development within a rural municipality) within the dataset are expected to be better balanced. These data were also intersected accordingly with the ALKIS settlement areas, open spaces such as cemeteries and parks being excluded beforehand.

To assess a site's suitability for establishing the core elements of an RCH, it is therefore necessary to integrate both of the indicators described earlier. Since the respective values are in different units of measure (people and square meters), a simple multiplication is not appropriate. Therefore, it is necessary to group the values into categories, opting for categorization based on natural breaks (Jenks (ESRI 2023)). The data are standardized on this basis and divided into five groups. The layer containing the census data is considered a suitable scale for this purpose, as it evenly subdivides the entire study area into 1 km² squares. A larger scale is deemed too coarse, while a smaller scale increases the data inaccuracy of the secondary raw material indicator, as the original information is based on the shapefile of the 1 km² parcels used. To increase the weighting of densely populated areas with extensive construction activity compared to regions with low population and below-average construction activity, it is decided to multiply the two categorized indicators (1 to 5) together in a final step. Consequently, the range between "sparsely populated and low construction activity" to "densely populated and high construction activity" is 1 to 25.

3. Results Of Interviews: The Concept Of A Resource-conserving Concrete Hub (RCH) And Its Location Factors

3.1 The Concept

A new proposal for an RCH is suggested to overcome the limitations of current demolition waste recycling systems and to fulfill the future demand for Recycled Aggregates (RA). Existing systems face logistical challenges such as fragmented operations across various sites and communication gaps among stakeholders (Remex 2023; Holcim 2023; Madaster 2023;

Zabek et al. 2024). Typically, a building is being demolished by a demolition company, in the following recycling companies collect construction and demolition waste from demolition sites, then transport it to their recycling plant and to consumers, e. g. concrete mixing plants, after recycling, involving multiple intermediate steps. This fragmented approach leads to high transportation costs and therefore environmental impacts due to repeated material handling and long-distance transportation. Transportation is identified as the primary environmental impact during the recycling of demolition waste (LANUV 2021; Hilgers and Becker 2019). Consequently, consolidating stakeholders at a single location reduces travel distances or even ways and can furthermore improve communication between the different stakeholders.

The core of the RCH consequently consists of processing facilities: the cement plant, the construction waste processing plant, and the concrete mixing plant, as these are essential for the production of R-Concrete. Depending on factors such as the size of the site and demand, this core group of companies can be expanded to include additional stakeholders.

The expansion of the RCH in this work is divided into four categories: *Complementary businesses*, *education and research*, *services and institutions*, and *public stakeholders* (Müller and Kurkowski 2017; Zabeck et al. 2024; Holcim 2023; Remex 2023; Madaster 2023).

The group of *complementary businesses* comprises companies involved in various aspects of the R-concrete recycling process, complementing the functions of core businesses. Benefits of integrating those, who are directly involved into the recycling process, e. g. demolition contractors, is emphasized due to the coordination required among stakeholders (Holcim 2023). The potential for knowledge spill-over in the form of Porter Externalities is expected. However, spatial proximity does not reduce transportation distances in this particular example, as demolition contractors still need to travel to the demolition site and return machinery to their premises after completion. Nevertheless, they do benefit from the central location of the RCH as well. On the other hand, logistics companies specializing in construction waste benefit from proximity due to localization effects, significantly shortening the distance traveled after delivering construction waste, thereby minimizing empty return trips. However, these companies benefit minimally from dynamic agglomeration effects. To further promote the use of RA beyond R-Concrete production, additional businesses should be established to utilize RA as a secondary raw material. The production of brick substrates or precast concrete enables the utilization of those secondary raw materials which, due to their suitability or volume, are not eligible for concrete production, while utilizing industries still benefiting from the same agglomeration effects as the core businesses (Müller and Kurkowski 2017).

Integrating *educational and research* facilities within the RCH is expected to foster collaborations between these institutions and other companies within the RCH, enabling practical education and industry expert involvement. This synergy can enhance expertise and therefore stimulate demand for R-Concrete. For monitoring R-Concrete production, sampling by external entities is essential (Holcim 2023, Remex 2023). This task can be delegated to the university, scientific institutes, or specialized labs, benefitting from efficient oversight due to proximity (Zabek et al. 2024).

The group *service industry and institutions* encompasses architecture, planning, and engineering firms, along with authorities and industrial associations. Integrating these stakeholders can facilitate knowledge exchange within the RCH, potentially increasing the consideration of R-Concrete as a construction material in building projects. Furthermore, the

needs of service companies in R-Concrete production can be better addressed and potentially accommodated. As a result, the presence of service companies can enhance the expertise of all involved actors and stimulate demand for the material. Further, establishing reputable service companies within the RCH elevates the site's profile, attracting attention to R-Concrete and enhancing its image as a building material. Soft agglomeration effects, alongside tangible location factors, are crucial for the hub's success as a service destination. Incorporating municipal stakeholders and industry-specific associations demonstrates official confidence in the secondary building material, aids in site profiling, and streamlines quality assurance through simplified monitoring channels.

Including event spaces and gastronomy as services being open to the broader *public* within the hub can have multiple benefits. For example, integrating event spaces, as demonstrated by Feeß (Heinrich Feess GmbH & Co. KG 2023), allows companies within the RCH to showcase their progress publicly. A cooperation with a university is conceivable due to its demand for lecture halls, as both require similarly sized facilities. External events can also attract individuals from outside the field to the RCH, positively influencing public perception of R-Concrete, thereby improving its current negative image (Remex 2023; Holcim 2023; Madaster 2023). To showcase the material's versatility and expertise, the establishment of an exhibition ground for events such as the Solar Decathlon or circular construction-themed fairs is necessary. Likewise, implementing gastronomic offerings can invite external visitors to the RCH, while providing lunchtime benefits for workers and students. The incorporation of green and blue infrastructure can also have a similar effect, enhancing the appearance and sustainable function of the commercial and industrial district, especially during times of climate change.

However, the concept avoids integrating multiple core processing plants of the same type. This assessment is based on the limited operating radii of these facilities, determined by ecological, economic, and technical factors. If the capacity of a plant is exceeded, it is therefore considered more sensible to place additional facilities outside the RCH to maximize operating areas and minimize transportation routes. This can accordingly have a positive impact on the ecological footprint and cost-effectiveness of R-Concrete.

Therefore, the establishment of an RCH can be deemed beneficial. It is important to note that it is a mixed-use high-quality commercial and industrial district, with its conceptual center being the core businesses. However, due to their emitting nature, a certain distance between the industrial and the other areas is necessary to avoid conflicts. Green and blue elements can help create this distance, while elevation differences can also aid in overcoming these challenges.

Concluding, the presented concept of an RCH focuses primarily on stakeholder knowledge exchange, reducing transportation distances, and improving the image of recycled building materials. Therefore, stringent collaboration among stakeholders is essential to realize these aspects fully; otherwise, potential benefits may remain untapped. While the impact of soft location factors on the success of core businesses is considered secondary, they are mandatory for other stakeholders, particularly office and public uses.

Additionally, using recycled building materials during the hub's construction phase can facilitate the establishment of both service and core businesses involved from the outset. It can also create a living laboratory, demonstrating the feasibility of a high-quality district built with recycled materials, thereby helping to reduce reservations about their use.

3.2 The Location Factors

As the design of the RCH entails a modular system centered around the core enterprises of R-Concrete production (construction waste processing plant, concrete mixing plant, cement plant), with the remaining actors being variable, the subsequent discussion focuses solely on the spatial requirements of these core stakeholders.

Given limited impact of globalization on supply chains within R-Concrete production, the selection of processing plant locations aligns with Weber's Industrial Location Theory. This implies that proximity to raw material suppliers and customers predominantly dictates site selection (Farhauer and Kröll 2013). Analyzing various transportation modes and networks aims to minimize transportation costs, thereby mitigating ecological and economic burdens. Figure 5 depicts the salient location factors pertinent to the three involved enterprises, illustrating their mutual complementarity. It underscores that diverse location requirements coalesce rather than conflict, emphasizing the interconnectedness of stakeholders in R-Concrete production. Notably, three pivotal factors in location selection emerge across stakeholders: location within an industrial area, Distance to residential areas and good road connection. Therefore, good street connection sites ideally situated in urban industrial zones yet maintaining distance from residential areas to sustain demand and resource availability while safeguarding sensitive land uses are considered ideal locations.

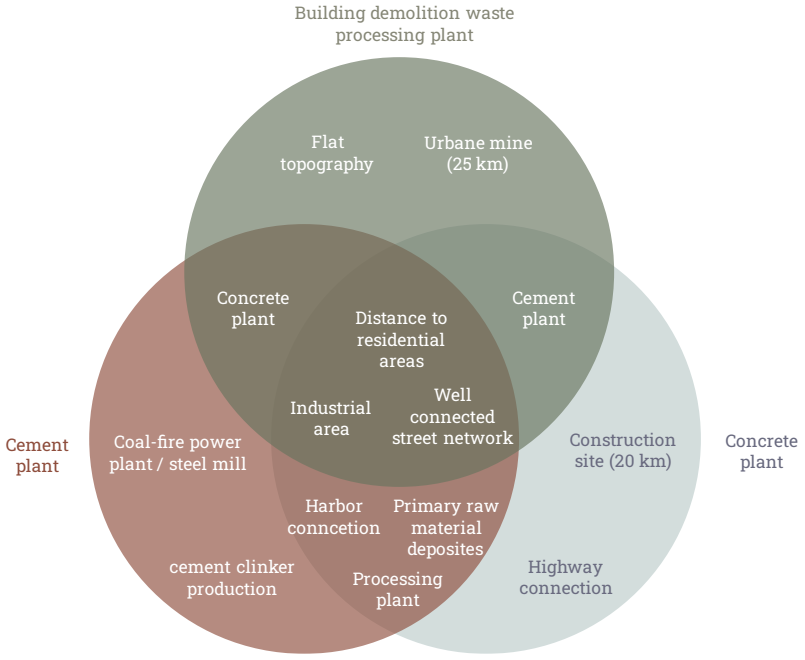

Figure 5: Location Factors of an RCH.

Hence, when selecting a site for the RCH, it is important to consider maintaining a sufficient distance from sensitive land uses, although this distance cannot be universally quantified.

Additionally, high demand for construction materials, a comprehensive supply of construction waste, and good accessibility to the site are fundamental requirements.

Further, economic factors make integration with an existing cement plant highly advantageous. If such a plant is being planned, careful consideration should be given to integrating an RCH, especially the remaining core enterprises. However, establishing a cement plant as part of the implementation of an RCH is considered challenging. Therefore, already existing plants may be a well suited location for being extended by an RCH and hence should be considered within the location analysis.

The establishment of an RCH is particularly suitable in close proximity to water bodies also as these can be used to transport necessary primary aggregates. Although, it might not be as relevant for concrete production today, the region's limited availability of local primary aggregates will likely make importing them from further regions necessary in the future (Holcim 2023; Remex 2023; Elsner 2018). Furthermore, part of the dock area can enhance the site’s appearance and be developed into a waterfront promenade, expected to have a positive impact on the other stakeholders. Therefore, port areas and areas adjacent to a canal are considered particularly suitable.

Former power plants and coal-fired power plants, on the other hand, are suitable for the establishment of an R-Concrete Hub due to their large size, high existing sealing rate, and established industrial use. Additionally, many of these plants have established connections to the waterway network. The dismantling of existing structures can also serve as a catalyst to establish the concept further.

In general, consideration should be given to selecting sites that are already sealed. The establishment of an RCH on greenfield sites may be necessary in certain cases but should only be considered as a last resort due to the project's sustainable nature, after all alternatives have been exhausted.

For further site analysis, additional exclusion criteria are applied to narrow down the areas to be considered. Accordingly, only existing industrial areas with some distance to residential use and large enough to accommodate at least a construction waste processing and a concrete plant (about 3.55 ha according to Müller (2018) und Holcim (2023)), cement plants, port facilities, and coal-fired power plants are taken into account.

4. Results Of The Location-Allocation-Analysis

The Ruhr Area is of particular interest as a case study region for implementing an RCH due to various reasons. According to the Geologischer Dienst Nordrhein-Westphalen (2022), the local primary resource reserves of gravel and sand are projected to last for 21 and 33 years, respectively. However, due to extraction limitations, supply shortages emerged as early as 2017, leading to significant increases in primary resource costs (Elsner 2018; Hilgers and Becker 2019). Consequently, the exploration of alternative resource sources through urban mining is attributed particular significance for this region, leading to a higher need for action.

Additionally, the Ruhr Area covers an area of 4,438 km² divided into 53 municipalities with an average population density of 1,149 inhabitants/km² (RVR 2021), making it one of the fifth largest metropolitan regions in the European Union with around 5 million inhabitants (Statista 2022). The region's rapid development during the industrial revolution has resulted in a

structurally heterogeneous polycentric region, consisting of independent large, medium, and small towns, which are considered unique in Germany and Europe (Reicher 2022). It is expected that this regional structure will facilitate the implementation of an RCH, as it allows for placement not only in peripheral areas but also in the region's center as well as providing high enough resource flows.

Expanding the study area to include a 20 km radius around the Ruhr Area's borders results in a total area of 11,227 km², encompassing or intersecting 159 municipalities in North Rhine-Westphalia. Of the 2,535 km³ designated as settlement areas according to ALKIS within this expanded area, representing areas eligible for development excluding existing open spaces within municipalities, 52 percent are within the Ruhr Area, despite it occupying only 39.5 percent of the total area. Within the Ruhr Area, the proportion of settlement areas is particularly concentrated in centrally located municipalities, where their share of the total area is particularly high, such as Herne (58.4 %), Oberhausen (56.4 %), Bochum (53.2 %), Essen (52.0 %), Gelsenkirchen (51.6 %), and neighboring municipalities.

The spatial distribution of the population within the study area per square kilometer, based on the 2011 census, is illustrated in Figure 6. Within the Ruhr region, the central residential areas of the municipalities of Duisburg (≤ 14,756 inhabitants/km²), Dortmund (≤ 14,741 inhabitants/km²), Gelsenkirchen (≤ 2,415 inhabitants/km²), Oberhausen (≤ 12,380 inhabitants/km²), and Essen (≤ 11,365 inhabitants/km²) stand out due to their particularly high population density. The northern part of the Ruhr metropolis is comparatively sparsely populated, with larger uninhabited areas noticeable, while in the east, the municipalities of Hamm (≤ 5,672 inhabitants/km²) and in the south, Hagen (≤ 7,793 inhabitants/km²), emerge as local population centers. Outside the Ruhr region, apart from the state capital Düsseldorf (≤ 18,401 inhabitants/km²), the municipalities of Krefeld (≤ 1,791 inhabitants/km²) and Wuppertal (≤ 13,709 inhabitants/km²) are present.

According to available data, of the total approximately 8.73 million inhabitants within the study area, around 5.06 million people are located within the Ruhr region, accounting for 58 percent of the total population.

Figure 6: Inhabitants / km² | Data Source: Zensus 2011 (2011); GEOportal.NRW (2023).

Figure 7 depicts the average annual newly constructed area in square meters per square kilometer between 2010 and 2020. Unlike the population data, these are processed data available only at the municipal level, hence the figure presented shows the overall construction activity reflected on settlement areas and again merged with the raster used in Figure 6. The final step was undertaken solely to establish a consistent visual representation; the calculations were conducted based on the results of the first two steps.

In general, it can be observed that within the Ruhr region, the municipalities of Kamen (520.69 m²/km²), Essen (503.92 m²/km²), and Dortmund (479.11 m²/km²) had the highest average newly constructed areas per square kilometer of municipal area. Conversely, the lowest construction activities occurred in Breckerfeld (31.53 m²/km²), Rheinberg (52.46 m²/km²), and Schermbeck (61.24 m²/km²). Expanding the scope of analysis reveals that the construction activity during the study period in Düsseldorf, with 953.41 m² of newly constructed area per square kilometer of municipal area, was 83 percent higher than in Kamen. Other municipalities with comparatively high construction activity include Neuss (574.97 m²/km²), Straelen (537.82 m²/km²), and Hilden (504.10 m²/km²).

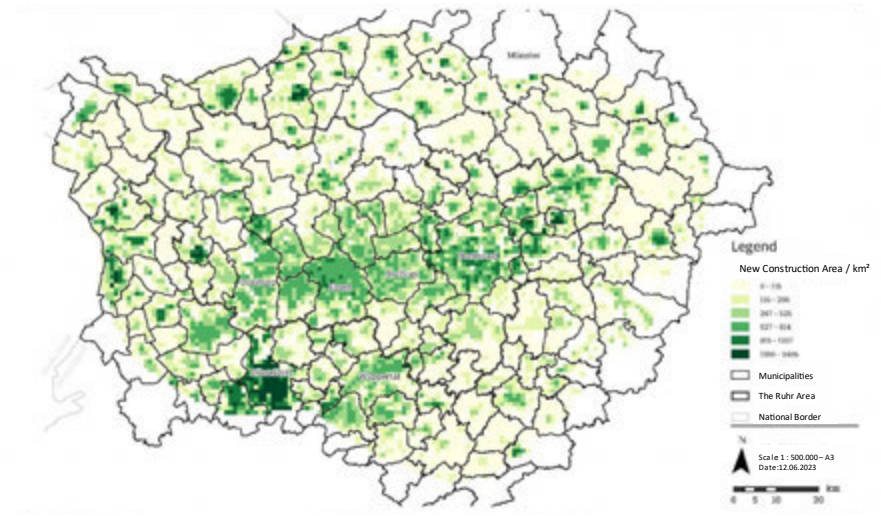

Figure 7: Construction Activity | Data Source: IT.NRW (2022); GEOportal.NRW (2023).

For further computation, the integration of both datasets is mandatory. The derived values, ranging from 1 to 25, are depicted in Figure 8. A total of 9,430 km² grids receive a score equal to or less than 5, of which 7,028 km² grids receive the lowest score of 1. Only 356 km² grids are rated 15 or higher, among which 17 km² grids achieve the maximum score of 25. All top-ranking areas, due to their high construction activity and dense population, are located within the municipal boundaries of Düsseldorf. This analysis emphasizes not only Düsseldorf but also the central Ruhr metropolitan areas, as well as Krefeld and Wuppertal.

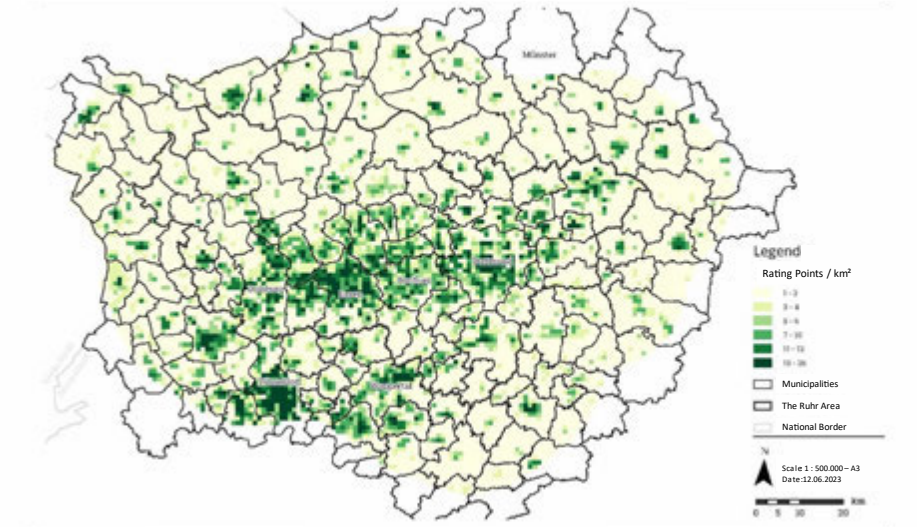

Figure 8: Rating Points / km² | Data Source: Zensus 2011 (2011); IT.NRW (2022); GEOportal.NRW (2023).

Figure 9 illustrates the results of the location-allocation analysis, aiming to identify the region with the highest expression of an indicator within its corresponding catchment area. The focus of the indicator for R-concrete demand (red point) is based on the completed new construction areas per municipality. The catchment area for this analysis spans 20 km, the distance within which the construction material can be transported without losing its qualities. The selected parcel is situated in the southern part of Duisburg, adjacent to the urban area of the state capital, Düsseldorf. The surrounding region exhibits relatively low development but benefits from close proximity to a highway interchange. The catchment area fully encompasses the municipality of Mülheim an der Ruhr, as well as significant portions of Düsseldorf, Krefeld, and the Ruhr metropolitan municipalities of Duisburg, Oberhausen, and Moers. Within the entire catchment area, an average of 336,195 m² of usable area is completed annually, making it the highest value among the points under consideration.

The point within whose catchment area the indicator for the volume of generated construction waste—the 2011 population density—is most pronounced (blue point) is located in Essen. The catchment area for this analysis spans 25 km, the distance within which the transport of construction waste is environmentally and economically more sustainable than the use of primary aggregates. The determined centroid, concerning population density, is in close proximity northwest of Essen's main railway station (1 km). The catchment area of the parcel dominated by commercial use almost entirely covers the Ruhr metropolitan cities of Essen, Bochum, Mülheim an der Ruhr, Gelsenkirchen, Gladbeck, Oberhausen, Bottrop, Hattingen, Herten, and Herne, as well as large parts of Duisburg and Dinslaken. In total, around 2.65 million people lived within the catchment area of the selected location in 2011.

The outcome of the analysis, based on the data from both indicators, identifies a centroid in the western part of Bochum-Wattenscheid (green point). The catchment area for this analysis spans 20 km. Within this area, the mean of the usable area completed between 2012 and 2021 amounts to 307,523 m², and the total population sums up to 1.92 million individuals. Unlike the previous analyses, the indicator values no longer rely on the settlement area but solely on the parcels used for site selection. The sum of the scoring points for the 774 considered parcels amounts to 5,418.

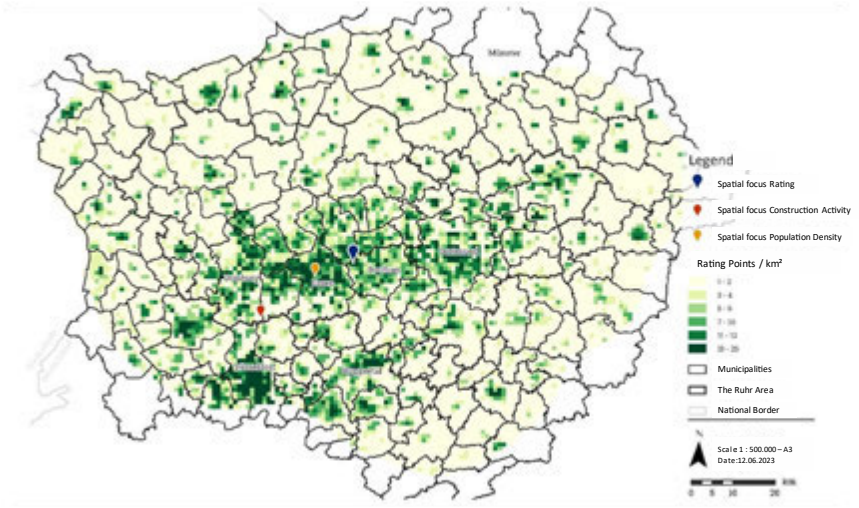

Figure 9: Spatial Focal Points of Population Density, Construction Activity and Rating Points | Data Source: Zensus 2011 (2011); IT.NRW (2022); GEOportal.NRW (2023).

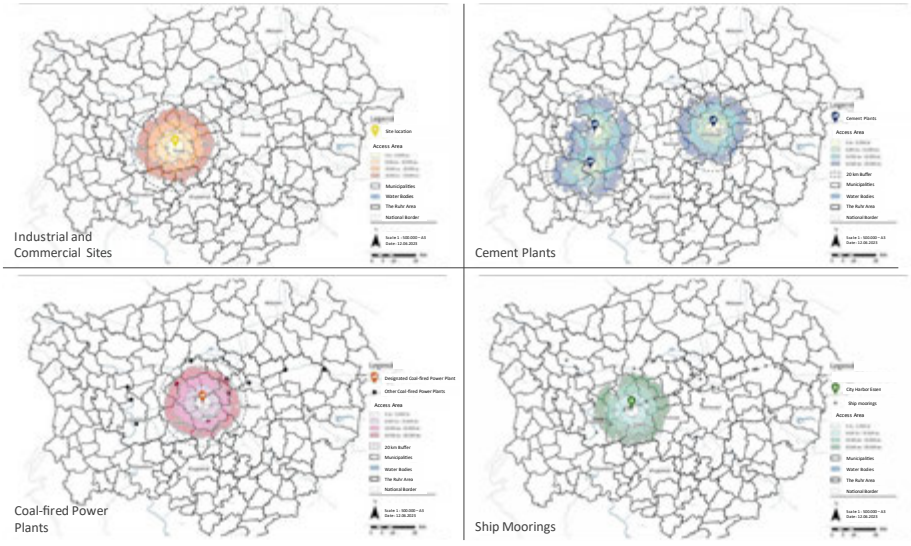

Figure 10: Calculated Catchment Area of Different Locations Performed on the Results of the Location-Allocation-Analysis | Data Source: Zensus 2011 (2011); IT.NRW (2022); Geofabrik (2023); GEOportal.NRW (2023); Bundesnetzagentur (2022).

Designation	Rating (pts.)	Supply (inhab.)	Demand (m^2)	Catchment area (km^2)

Demand_max	-	-	336.195	-
Rating_max	5418	-	-	-

Table 1: Comparison of the characteristics of investigated indicators according to identified locations.

Table 1 presents a summary of the findings outlined in Figure 10. Upon direct comparison, the comparatively low population values of the three cement plants, as well as the limited expression of the demand indicator regarding the plants in Duisburg, are striking. Conversely, the values of the prioritized harbor location, as well as the two power plants, are relatively close to each other and form the mean concerning the results of all sites. A categorization into three groups is also supported by the rating system (cement plants | power plants and harbor | commercial and industrial area). However, a detailed examination reveals that the ratings within the groups are not always consistent with the actual expressions of the indicators, albeit the differences are relatively minor. Regarding the research findings, it can also be noted that the average catchment area of the depicted sites is 728 km². Since the utilized distances are 20 km, on average, 57.9 percent of a circle with a radius of 20 km is covered. Here, the catchment area of the prioritized commercial and industrial site is notably large at 69.7 percent, while that of the cement plant in the north of Duisburg is relatively small at 47.9 percent. The average constructed area within the respective catchment areas amounts to 272,066 m², with the area derived from the commercial and industrial areas exceeding the average by 15.2 percent, and cement plant in the north of Duisburg falling 22.2 percent below the average. The population located within the sites' catchment areas averages at 1.63 million people, with values varying significantly between the site in the center of Essen (2.64 million) and the location of the Dortmund cement plant (1.08 million).

5. Identification Of An Ideal Location Within The Ruhr Area: Validation Of The GIS-Analysis

The analysis of demand concentrations within the Ruhr area and its periphery reveals Düsseldorf municipality as a significant influencer in determining the location of the demand hotspot, owing to its notably high construction activity. This influence is particularly

pronounced due to extensive urban development projects undertaken in recent years, exemplified by the development of entire urban quarters (cf. Quartier Central). However, indicators in the immediate vicinity (up to 7.5 km) exhibit relatively modest levels. According to Holcim (2023), a substantial proportion of deliveries from a concrete plant occur within a radius of 10 km. Consequently, the region identified as the hotspot appears comparatively unsuitable for establishing a concrete plant. Therefore, the choice of Düsseldorf as a site should seemingly be explored within a different study, and its consideration for a suitable location within the Ruhr area should be tempered accordingly.

The population density, as an indicator of supply, is particularly pronounced within the Essen center based on the analysis results. Within a catchment area of 867 km² around the prioritized industrial and commercial area, 2.64 million people can be reached. This represents 52.2 percent of the Ruhr area's population, despite the catchment area covering only 19.5 percent of its land area. Unlike construction activity, municipalities southwest of the Ruhr area do not appear to play a significant role in this analysis.

The comparative analysis between the region with the highest accessibility – the industrial and commercial zone near Essen's urban core – and the one with the lowest connectivity – the grinding and mixing facility in northern Duisburg – elucidates fundamental distinctions contributing to a diminished catchment radius. Notably, the catchment zone of the top-performing site exhibits a complete absence of unconnected areas within its scope, indicative of exceptional connectivity likely attributed to the absence of significant open expanses such as forests, fields, or protected areas. Conversely, the northern Duisburg area features numerous such expanses, notably the Rhine River and the Kirchheller Heide in the northeast, markedly impeding accessibility. Furthermore, the natural obstacle of the Rhine and the absence of a nearby bridge hinder connectivity, particularly in the northwest region of the site. A detailed examination of the Essen central area also unveils non-concentric catchment zones, with deficiencies in the southern and northwestern sectors, suggesting a rural environment with comparatively limited connectivity, as inferred from population density.

The analysis outcomes reveal substantial variances between the area of a simple 20 km radius circle (1,256.6 km²) and the actual catchment area delineated by a road network (867 km² to 602 km²), even within densely inhabited regions like the Ruhr area. In this instance alone, the actual catchment area represents only 69.7 percent and 48.2 percent of the circle area, respectively, underscoring the intricacies of urban connectivity.

The location-allocation analysis performed to ascertain the requisite number of facilities for comprehensive coverage of the Ruhr area concludes that a total of 15 facilities are necessary. However, uncertainties persist regarding how many of the designated facilities can procure adequate raw materials and demand to ensure seamless and profitable operation. Particularly in less urbanized locales such as the Ennepe-Ruhr district and the Wesel district, the viability of sustaining such facilities is dubious. The resultant map from the analysis distinctly delineates regions featuring significant unconnected areas in the road network, notably the Rhine River in the west and the municipalities of Breckerfeld and Haltern am See.

Upon closer examination of the locations identified through the Location-Allocation Analysis, it is evident that not all areas are suitable for the implementation of an RCH. For instance, due to accessibility constraints and the anticipated heavy traffic from trucks associated with an RCH, the centrally located industrial and commercial area in Essen is deemed unsuitable. Similarly, the area of the cement plant in the north of Duisburg, which is relatively difficult to

access, is also excluded. Conversely, the coal-fired power plant in Bochum is excluded due to its direct adjacency to residential areas on multiple sides.

The sites in Dortmund and Duisburg are particularly advantageous because there is already a cement plant located at these sites. Given the high investment costs, it must be considered that implementing an RCH at another location may have to do without the cement plant component. Nevertheless, the evaluation of these sites in the Location-Allocation Analysis is significantly lower compared to other sites. Additionally, these sites lack the address-forming characteristic of the areas in Essen and Herne, which can utilize proximity to water to attract other companies and stakeholders to the location.

For the implementation of a new RCH, however, the Essen city port is perceived as an ideal location. This is attributed to its excellent connectivity and central position within the core metropolitan areas of the Ruhr region, potential integration into existing industrial structures, and the presence of blue and green infrastructure. Additionally, the city's plans for the reorganization of the port (Stadt Essen, 2022) and the development of the Freiheit Emscher (Freiheit Emscher Entwicklungsgesellschaft mbH 2023), which aims to enhance adjacent areas, are viewed positively, as they offer the potential to act as catalysts for the implementation of an RCH.

6. Conclusion

As stated, the concrete industry in the Ruhr region faces critical future challenges, including primary raw material shortages and the necessary reduction of greenhouse gas emissions to meet Paris Climate Agreement targets. Addressing these issues is urgent, as primary resources will still be needed alongside secondary raw materials due to legal and static requirements of Resource-conserving Concrete (R-Concrete), and reducing carbon emissions is essential for mitigating anthropogenic climate change.

The research presented highlights that the formation of a Resource-conserving Concrete Hub (RCH) can substantially enhance the perception and effectiveness of R-Concrete itself. This enhancement is achieved by not only unifying the three primary stakeholders to streamline the R-Concrete production process but also by incorporating additional participants from the construction and planning industry as well as the public sector. Further, the Ruhr region presents optimal conditions for this initiative due to its high population density, industrial heritage, and polycentric structure, making it an ideal location for the implementation of an RCH.

However, due to inadequate data on the extent of the urban mine, the analysis performed does not provide a precise volume estimate that could serve as a foundation for detailed planning. Therefore, in order to facilitate effective reuse of construction and demolition waste and ensure accurate site planning regarding an RCH, the establishment of a material registry is expected to be crucial. Despite this limitation, the study offers new insights into the spatial dynamics of R-Concrete production and identifies specific locations within the Ruhr metropolitan area for further investigation. The Essen city harbor area, in particular, emerges as a promising site, especially due to its connectivity and infrastructure. As this area is currently the subject in a master planning process, it presents a timely opportunity to further develop and implement the RCH-concept developed, thereby boosting urban mining practices within the entire region.

Urban Forestry Plan: an overview through different contexts, governance and policies

Maria Chiara Pastore, Claudia Parenti, Lucia Ludovici, Corinna Patetta
Polytechic of Milan,
mariachiara.pastore@polimi.it, claudiaida.parenti@polimi.it, lucia.ludovici@polimi.it, corinna.patetta@polimi.it.

Abstract

Urban forestry plans became an essential integrated tool in urban planning to promote adaptation and mitigation policies and strategies in contemporary cities.

This contribution presents a selection of plans developed in different countries, applying a structured critical interpretation to bring out and compare innovative elements and weaknesses to trigger a challenging comparison between American and European cities. This work frames the Forestami research project within the international urban forestry context to measure its impact and relevance and to address further activities.

The research reveals a heterogeneous approach and results by countries due to different political and cultural contexts to define which are the critical elements that each plan should use to contribute to the sustainable development of the territory.

1. Introduction

Urban forestry concept, developed in the 19th century in America, refers to an integrated, multidisciplinary and 'flexible' (Moeller, 1977) discipline which considers individual green space elements as part of an integral system (Miller, 1997; Konijnendijk & Randrup, 2004) by defining "the design, planning, establishment and management of trees, woodlands and associated flora and open space" (Ball et al., 1999, p. 325) to promote human well-being and urban biodiversity conservation. Urban forestry promotes the implementation of woodland, tree groups, individual trees, and associated open spaces, tending to emphasise the complete role of the forests rather than just their economic provision.

This discipline, widely developed in North America first and then in Europe, refers both to vegetation management within built-up areas both to the one located on the edge of the city (Randrup et al., 2005). Therefore, this different scale-based approach regards the implementation of trees in cities and urban contexts and the management of forests in large national parks and ecological corridors; defining a broad, aware and complete vision that recognises the important role that nature has in the urban territory.

Within the international scene, governance institutions addressed the urban greening topic through several planning and prescriptive levels, deliberating laws and regulations at different government degrees and defining new innovative approaches (Konijnendijk, 2003). The number of plans, laws, and research promoted recently underline a growing interest in sustainable planning and the emergence of urban forests as an integrated tool to contrast climatic transition, better citizens' well-being and health, and promote environmentally fair cities (Nilon et al., 2017, Pierce et al., 2020)

This contribution frames the Forestami research project - which started in 2018 to plant 3 million trees in the Metropolitan Area of Milan - within the international urban forestry context to measure its impact and relevance and to address further activities. It aims to explore urban forestry plans operating in different contexts and environments to define a common ground and develop a critical interpretation for grasping key concepts useful to enrich the possible goals and tools of the Forestami project. Within the broader context of the project research, analysing

effective case studies allows us to measure opportunities and limits of existing plans and provide an overview of actual urban forestry discipline assessment.

The paper analyses seven cases in Europe and the USA, selected among a wide range of international plans. These have been an interesting comparison for achieved results, goals and governance proposals. The inquired cases are Austin, Cleveland, Philadelphia and San Francisco in the US and Barcellona, Birmingham and Manchester in Europe (fig. 1). The comparison was also applied to the Forestami experience. The analysis shows preliminary results, highlighting interesting trends in the discipline.

Fig. 1 Description

2. Recognition of urban forestry tools: methodology and first results.

The research operated through analysing plans and projects developed over time by municipal and metropolitan authorities to study the strategies applied to implement urban forestry as an adaptive and mitigating tool. The first research phase identified 29 plans and projects distributed worldwide (tab.1), operating a screening on several cities, inquiring about the presence of urban forestry plans and projects, including diverse legislative and normative tools that complement urban forestry. The screening, operated in 2022, represents a partial framework of the topic assessment, considering the number of existing plans and language constraints since the research was conducted mainly in English.

We identified three main categories of interest based on chosen key concepts considered relevant for current research trends on urban forestry: (i) green and health, (ii) governance, and (iii) ecosystem services. These key concepts have been used as lenses to read the plans and enhance the main innovative features for urban forestry (tab. 1).

(i) The **Green and Health** topic embraces the concept of nature as a fundamental element for people's health and well-being. Trees and forests can provide direct and indirect benefits (Mitchell et al, 2007) to the environment by reducing temperatures (Schwaab et al., 2021), reducing pollutant levels (Nowak & Greenfield, 2018), and on people's health by reducing stress and depression (Kondo et al., 2018),improving attention and restoration levels, enhancing social cohesion and promoting physical activities (Lachowycz et al., 2011).
Plans that work primarily with this theme are designed to consider citizens' and

socio-health needs, reflecting on the relationship between the urban environment and its effects on human well-being.

(ii) The **Governance Strategies** topic indicates existing governance approaches and planning mechanisms challenged by multifunctionality across temporal and spatial scales (Asadzadeh et al., 2023).
These strategies describe innovative tools to engage stakeholders at different levels and comprise active discussions and debates with citizens, enhancing critical aspects of forestation, innovative funding methods and engagement of stakeholders, as well as citizens' and companies' involvement in planting and monitoring activities. It also reflects upon the public or private initiative and the opportunity urban forestry could represent for social inclusion, offering job and building a local community network.

(iii) The **Ecosystem Services** (Pinto et al., 2022) theme identifies plans that focus on increasing public awareness by measuring the economic value of urban nature. By this, with accurate communication and an overall valuation, the strategy is to raise awareness of forestry socio-ecological values and identify the potential of afforestation intervention on the economic public budget.

Table 1. Recognition of plans and projects

The analysis reported the complexity and heterogeneity of implemented approaches from different cities worldwide.

The first consideration resulted in the diversity of normative and legislative tools. We identified different normative and administrative tool: (a) Strategic Plans provide spatial and strategic planning guidelines, (b) Integrated strategic Plans are an integration of an existing broader plans regarding a sustainable vision, (c) Masterplans are projects that provide spatial guidelines to design specific context, (d) Participative Tool concerns plans entailing citizen participation as a critical feature.

Because of this complexity, with the aim to investigate the plan tool as an important device to strengthen urban forestation, we mainly referred to the cases of the (a) Strategic Plan and (b) Integrated Plan, selecting interesting cases to reflect upon the following research themes.

The first research question inquired how cities face urgent and relevant issues related to climate change, investigating the effective interventions and their impacts.

The second reflection was carried out on the different governance processes (public and private) relevant to transferring the goals within public policies. In this field, it results interesting to investigate the differences between bottom-up and top-down approaches, as highlighted by Sanz et al. (2022).

The last investigation regarded the innovative engagement and communication implemented tools, referring to specific contexts and reflecting upon their replicability in other territories.

The research selected 7 main cases to deepen from the USA and Europe. These two contexts provide an interesting comparison due to various historical, environmental, and legislative factors, aiming to highlight common characteristics and strengths of each plan that can constitute the basis for structuring a comprehensive forestation plan. The comparison also

brings attention to the distribution of the Urban Forestry Master Plan planning tool within public planning. In Oceania, it is quite an adopted approach in cities, while in South America, Asia and Africa, there are mostly afforestation projects that, showing anyhow, a great growing interest for the topic.

3. The legislative context of the USA and Europe

Concerning the legislative framework, we found substantial differences between the USA and European approaches to the topic of urban forestry.

The plans selected within the North American context have been mainly conceived by state obligations, defined through established and unified legislation.

The establishment of the first United States Department of Agriculture (USDA) dates back to 1875, leading to the inception of the Forestry Department a year later, aimed at safeguarding the country's existing forests (Johnston, 1996). Simultaneously, the enaction of various acts, including the "Forest and Land Management Act", outlined a program to assess the benefits of urban forests. Another significant initiative was the creation of the 'Tree City USA Grant Program' to develop a comprehensive inventory of vegetation to enhance green spaces within cities. This program, developed by the Arbor Day Foundation, saw participation from 16 states and 42 voluntary communities. Furthermore, in 1990, the National Urban and Community Forestry Council was established to oversee and manage policies and projects related to urban forestation.

The obligation to draw up forestation plans emerged after the 2008 “Farm Bill”, an Act for which each Member State was responsible for evaluating the conditions of trees and forests in US territories and consequently developing "Strategic Plans for landscape conservation, forest protection and the increase of public benefits deriving from natural capital". These State Forestry Action Plans, initially developed and completed by all Member States in 2010 (Sambeek, 2017) and updated in 2015, were revised in 2020 by all 59 Member States (USDA, 2021). These plans establish effective worktables and are accompanied by strict economic planning for federal, statal, local and private resources to achieve national forest system conservation objectives. In addition to the action plans developed by individual states, the Department of Agriculture provides technical and economic assistance for forestation projects. It draws up monitoring reports on the state of US forests, evaluating and quantifying their ecosystem services.

Currently, the laws issued regarding urban forestation are about 105: in this context, the United States underlines how urban forestation, citizens' health, inclusion, and energy saving are strictly current and interconnected themes, moving towards an interdepartmental and multidisciplinary approach.

On the contrary, Europe has a different normative framework since the European Union does not include all the continent countries (as the UK), and its member states benefit from greater legislative autonomy than US. The Green Deal directive presented in 2019 is undoubtedly incisive, aiming to achieve climate neutrality by 2050 and planting 3 billion trees. Sinergically, with this directive, the promulgation of two plans -the European Strategy for Biodiversity 2030 and the Strategy for Forestry 2030- highlights the importance of forestation in urban environments for the well-being of citizens and the achievement of the objectives of the Green Deal. Moreover, the Nature Restoration Law is currently under approval, with the aim to restore degraded ecosystems in all member states, help achieve the EU's climate and biodiversity objectives and enhance food security. In this regulatory framework, many large European cities are therefore starting to equip themselves with plans to achieve climate neutrality objectives, adopting specific tools for urban forestation, as done by London, Barcelona, Paris and Milan. Despite the context being more uneven and linked to the national regulatory situation, there is

a progressive diffusion of the forestation, suggesting its adoption as a valuable tool for achieving community objectives.
Similarly, in the United Kingdom, the 2008 Climate Action Plan was updated in 2019 with the objective of zero net greenhouse gas emissions by 2050. This goal can be achieved by drafting the three-year action plans: the first plan refers to 2021-2024 and pursues the initial goal of creating 30,000 hectares of new forests annually by 2025. In particular, the role of the Forestry Commission Department is essential; it supports forestation policies and projects and the collection of available data, promoting for more than ten years the mapping of ecosystem services given by trees in cities. Moreover, in the United Kingdom, it is possible to observe a tradition linked to the active participation of citizens, who, since the 1990s and 2000s, have formed themselves into organised groups, meeting the interest and involvement of the administrations, as in the cases of Birmingham and Manchester. The first laws and urban forestry plans based on the US model were indeed promulgated in the United Kingdom.

In Italy, there is no defined national legislative panorama on forestation. At a national level, ISPRA (an Institute for Environmental Protection and Research) draws up reports on the State of Natural Capital in Italy. The regions in the Regional Territorial Plans identify the ecological corridors and the elements to be safeguarded, such as regional and national parks. They can determine some guidelines for protecting and safeguarding the existing natural heritage. Municipalities with more than 15,000 inhabitants have the legislative obligation (L. n. 10/2013 and guidelines of the Ministry of the Environment 2017) to draw up the Municipal Green Plans, tools that design the urban, peri-urban, agro-silvicultural structure of the city, providing guidelines for the creation of new green areas within the general urban planning. The green plan configuration differs from a real forestation plan, but it is currently the only defined legislative instrument that can have planning effects.

This tool has not yet become fully operational within urban management and planning activities at a local level. For example, only 11 provincial capitals in northern Italy adopted a green plan (Lazzarini et al., 2024), showing the necessity to improve the planning approach to urban greening.

4. An overview of selected Urban Forestry Plans

The selection of the 7 case studies identified plans presenting both particular elements of innovation in governance and strategy tools, in communication and the active involvement of stakeholders and citizens, and both when covering the role of 'pioneer plans' for specific themes that others have incorporated. For these reasons, the selected plans stand out for the approach used in addressing relevant environmental and social issues, constituting an accurate model that other cities can replicate in their forestation plans.

The proposed approach is a critical analysis conducted using this structure:

- City's state of the art: Why an afforestation plan?;
- Plan's goals and mission;
- Governance;
- Plan structure;
- First feedbacks;
- Additional communication activities and plan promotion tools if present.

The plans strengths are described below and divided based on the key concepts identified.

4.1 Green and health

The *Cleveland Tree Plan*, established in 2013 by the municipality's initiative and created in collaboration with the Cleveland Tree Coalition association, proposes a careful survey of the city's current state. Starting from assuming that trees are the only public infrastructure that increases in value over time (the more the trees grow, the more the benefits provided increase and the greater the impact on the health of the inhabitants), a precise mapping accompanies the Plan, assigning different environmental parameters that positively and negatively influence the health of citizens to each district and neighbourhood.

The plan showed a correlation between tree canopy distribution and citizens' health: in the districts where the loss of tree canopy was more significant it was found a reduction in the inhabitants' health, given the incidence of hospitalisations and the widespread presence of respiratory problems and cardiovascular disease in a variation between 3 and 4% depending on the distribution of the tree canopy. This approach aims to promote a fair distribution of the tree canopy to reduce health disparities.

The city of San Francisco has one of the lowest tree canopies among US cities (13.7%), being located in an arid and not naturally forested area.

The forestry plan, *Urban Forest Plan San Francisco*, adopted in 2015, allows for effective maintenance of trees and identifies new public and private areas to be forested to build a shared public vision for the city's development, involving various local actors and promoters. Three main actions divide the Plan, and their implementation follows different strategies and different time thresholds: rows of trees along the roads, parks and open spaces, and buildings and private properties.

The Plan addresses the relationship between citizens' health and the presence of green areas by implementing and managing trees along the streets. Ensuring shaded paths, safe streets, and a homogeneous distribution of trees throughout the city are the prerequisites for its implementation.

According to a previous analysis made by the municipality, it identifies the most popular routes, the safest ones and those suitable for different types of inhabitants (for example, elderly, disabled, people with strollers, and children), also proposing guidelines to make the street safer and healthier according with the type of traffic. In this sense, the forestation project becomes an urban regeneration tool that provides cultural, social and environmental benefits. The Plan addresses the relationship between citizens' health and the presence of green areas by implementing and managing trees along the streets. Ensuring shaded paths, safe streets, and a homogeneous distribution of trees throughout the city are the prerequisites for implementing the Plan. According to a previous analysis made by the municipality, it identifies the most popular routes, the safest ones and those suitable for different types of inhabitants (for example, elderly, disabled, people with strollers, and children), also proposing guidelines to make the street safer and healthier according with the type of traffic. In this sense, the forestation project becomes an urban regeneration tool that provides cultural, social and environmental benefits.

4.2 Governance

The *Green Plan Philadelphia,* reformulated by the administration in 2020 under the name *Philly Tree Plan*, is a strategic plan that pays attention to social aspects, guaranteeing equity and sustainability objectives that will improve the current state of the city, increasing the trees in the poorest neighbourhoods where most minorities live, also directing investments and development projects.

The Plan's base is the existing survey, which relates the tree canopy distribution to the income levels, the total population, the population affected by respiratory diseases, and exposure to high-temperature levels. For example, the survey records more deaths due to heat stroke in the hottest areas, where the temperature increases by around 6°. Those indicators are a part of the

priority map created in collaboration with the citizen organisation Community Voices Steering Committee. Three levels of priority have been identified: poverty, health problems (such as respiratory diseases and stress disorders) and temperatures. The overlapping of these three issues generated a priority map, allowing the identification of the areas most needing forestation interventions.

Concerning governance, it is significant the inclusion of the association 'Tree Philly' to develop the Action Sheet and strategic guidelines based on different problems identified from a continuous dialogue with citizens and stakeholders. For each problem, the Plan develops an action according to an intervention program and defines further proposals that citizens can remark on.

In Austin, *Austin's Urban Forest Plan* was implemented in 2012 to counteract a prolonged drought that had significantly reduced the presence of trees in the city.

Rather than defining a goal to be reached in a limited time, as other American Cities did, the municipality adopted a broad, long-term vision to establish guidelines for every City Department to manage the urban green infrastructure. The Plan proposes a critical approach, integrating the USDA tree canopy forecast, which requires cities to reach different tree canopy thresholds depending on climate.

The Plan's five goals include implementing a sustainable and resilient forest, improving tree management and care, growing a fund for each Department, protecting and preserving biodiversity and preserving ancient trees. With these defined goals, the municipality developed the 'Austin priority map', which assigns different environmental, social, economic and sanitary parameters for each city's district that, once crossed and overlapped, display the prioritisation of forestry projects according to the different sites.

Birmingham is the second largest English city by population, with over a million trees and large parks; since 2020, it has been among the Tree Cities of the World. However, due to the city's shape, urban greenery is mainly concentrated in peripheral areas, leading to unequal distribution and consequent non-uniform accessibility.

Due to the presence of such a large arboreal heritage and the need for its management, at the beginning of the 2000s, the administration promoted a strategy for the protection and maintenance of trees without allocating funds to implement biodiversity, causing a reaction among citizens. The protest over the lack of a vision for the city's green transformation led to establishing a working group in the City Council to promote the definition of the first "Birmingham Tree Policy" guideline report. The experience of the Council led to the creation of the "Birmingham Tree People" association, which became one of the leading promoters together with the municipality.

This first experience guided the development of the *Urban Forestry Master Plan* in 2021, created in collaboration with the municipality and the Birmingham Tree People association, which defines a vision for the forestry of the city in thirty years, providing a line of action for the first decade 2021-2031. The first part of the Plan defined a prioritised mapping based on the importance of the targets, which became the basis for defining subsequent lines of action. Moreover, the definition of a Tree Board allows coherent management of all the topics analysed. In this way, the administration provides a tool through which citizens can directly report problems relating to the state of trees to promote better heritage management.

In 2017, the tree canopy of Barcellona stood at around 25% and was characterised by an uneven distribution in the urban territory. In early 1995, the municipality promoted various plans for

managing and maintaining city trees, whose aims merged in 2013 into the '2030 Biodiversity Plan', created to increase urban greenery by 1 m2 for each inhabitant.

At the same time as the promulgation of constantly updated Biodiversity Plans to achieve the Carbon Neutral objectives for 2050, the municipality, in 2017, promoted the *Trees for Life* Forestry Plan for the thirty years 2017-37, which focuses its action on planning and managing the tree heritage of the city, to complete the 2030 Nature Plan.

The latter promotes a vision for implementing tree capital, divided into ten strategic lines, each including different actions defined in a temporal action program. The Plan also defines different areas of intervention according to the ratio of square meters of tree canopy per inhabitant for each city district. Plantations must be prioritised following equity, strengthening biodiversity, and integrating the metropolitan scale and connections.

An interesting strategy the municipality defines is the "Mans al Verd" program 2020-2023, a plan to promote citizen participation in maintenance and management projects of public green areas. The program presents different projects directly involving residents, inviting citizens to take care of the trees and shrubs by "adopting" them and providing the necessary resources for their care.

4.3 Ecosystem services

The *Manchester City of Trees* Plan was born from the experience that began in the 1990s of the "City of Trees" citizens' movement, which, during its work, found the support of institutions and administrations, promoting since 2019 a strategic plan drawn up following the ecosystem services mapping carried out with the I Tree software.

The Plan is part of a political context in which forestation is strongly encouraged and works on a metropolitan scale. Institutions have already promulgated plans for reducing emissions, the first of which is the Great Manchester Environmental Plan 2019-2024.

After evaluating the benefits reported by the existing assets, the Plan defines a priority mapping that identifies the areas to carry out strategic plantations, aiming to work on the different trees' benefits. Citizen participation in planting interventions is fundamental. City of Trees coordinates their engagement, offering tutorials to teach tree maintenance and organising collective planting events that also systematise the individual initiatives of citizens, who can implement tree capital even in private areas.

5. Critical comparison of plans

The proposed approach used to analyse the plans reveals the different approaches used by cities, allowing the understanding of the context of plan development and within which it operates and interacts with the territory.

This contribution highlights the common use of multidisciplinary tools, which are part of governance strategies and are shared by multiple sectors of the city, allowing the achievement of sustainable objectives by working on the political, economic and social front. All forestation plans work in parallel on several themes. However, the proposed classification (fig.2) highlights only the innovative approaches to compare the investigated plans in an interpretative approach.

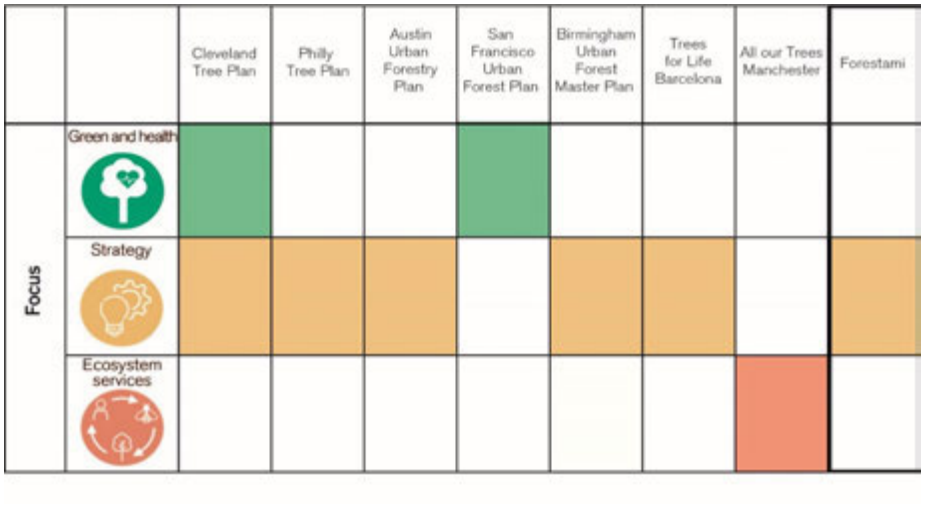

Figure 1. Strenghts of each examined Plan

In particular, the health topic emerges primarily in the USA, widely treated in different forms, e.g., in Cleveland with a focus on the increase in diseases and the loss of tree canopy, in San Francisco, paying particular attention to the quality of the busiest streets. In Europe, however, since the forestation discipline gained importance in urban planning only in recent years, the plans are more focused on formulating strategies useful for involving various local and institutional actors and evaluating ecosystem services linked to forestry interventions.

In America, therefore, the topic of forestation and well-being has been discussed for almost a decade; the monitoring information for the plans, unlike in Europe, is complete and exhaustive, and the plans themselves, now revised and updated, integrate principles that guarantee social equity, in order to use forestation as a tool of urban, environmental and social regeneration.

The legislative point of view also constitutes one of the main differences. While in the USA, the legislation requires individual states to formulate a forestation plan with the support of the Forestry Department, in Europe, the autonomy of individual states results in legislative fragmentation.

The directives formulated by the main governmental body, the European Union, are perceived as guidelines by individual member states but do not always become part of the legislation, even though many European cities have recently promoted the definition of plans for greenery and biodiversity. Promoting urban biodiversity is then not related only to the urban forestry plan tool, but it is conceived in other planning approaches, such as the Barcelona Nature Plan demonstrates. The United Kingdom, on the other hand, stands out as one of the leaders of forestation in the European context. Therefore, this partial examination returns only to the context of the forestry plan, remembering that, at the same time, other cities are equipping themselves with other tools, such as the Biodiversity Plans.

In the USA plan, the municipality is always involved in the plan formulation, with initiatives that sometimes involve and activate local organisations but are mainly promoted by public bodies. Even in Europe, public bodies support many plans, but looking at some citizens' initiatives necessary to start these processes, as in Birmingham and Manchester, is interesting.

		Cleveland Tree Plan	Philly Tree Plan	Austin Urban Forestry Plan	San Francisco Urban Forest Plan	Birmingham Urban Forest Master Plan	Trees for Life Barcelona	All our Trees Manchester	Forestami
Governance	public	■	■	■	■	■	■		■
	private	■							■
	citizens				■	■		■

	citizens	■	■	■	■	■	■	■	■
	third sector	■						■	■

Figure 2. Engagement and governance levels

From the plans comparison (fig.3), it is, in fact, clear that most of these have a public nature, characterised both by the initiative, often carried out by individual municipalities, and by the participation of financiers and partners. Instead, the Birmingham and Manchester plan stands out for the approach that involves more citizens and private entities, combining the requests of a plan with a bottom-up approach that meets the needs of associations and communities in parallel.

While the governance and financiers are primarily public, the presence of public partners and the involvement of citizens in the plan's activities are a constant for all plans.

This comparison shows that the level of governance employed does not influence the level of engagement: even public plans work in close contact with citizens and local realities (less with the third sector), and even bottom-up plans manage to obtain financiers and partners public.

5.1 Comparison with Forestami project

In Italy, one of the most relevant forestation projects is Forestami, born in 2018 by a research of Polytechnic of Milan, to plant 3 million trees and improve air quality in the metropolitan city of Milan, through constant dialogue between public administrations, universities and bodies operating in the territory, citizens and companies, and the construction of memoranda of understanding that mark the shared commitment to sustainable change in the territory.

In this context, the project is not defined by a legislative obligations, but it is raised by the cooperation of different entities that operate together in the territory to achieve a common objective.

Collective planting activities and cultural dissemination carried out by various training events are a part of the project that also involves schools and citizens and establishes the commitment to participate in the collective change of the territory.

The Forestami project, although not born with a superordinate planning nature, is comparable with the plans described above for these three main reasons: a) the scale, 2) the cultural value, and 3) the governance.

In fact, Forestami includes a broad territorial dimension, not dealing only with a limited area; its spatialisation has characteristics that interact with planning tools. Then it has a collective nature that communicates with the public and private sectors.

And finally, if governance is one of the main strengths, the project has also started reflections on green issues and health and ecosystem services in recent years.

It constitutes an important reference in the Italian context as it holds a public partnership with various bodies, including cultural ones, which operate in the area at all government levels.

6. New perspectives for Urban Forestry plans

As previously mentioned, the elements highlighted in this research can be used in different ways and on different levels to investigate effective tools to improve urban forestry plans in Italy. Public and private governance, citizen engagement, and site-specific objectives adaptable to local, environmental, political and economic contexts are the essential elements that emerged from an analytical synthesis.

Starting from the analysis of the selected plan, the first consideration regards the governance point of view; the public interest in shaping the vision and providing an economic base is crucial for the structure and composition of multidisciplinary teams (Ordóñez et al., 2019).

From an engagement point of view, we underline the interest in the active involvement of citizens through training and participatory events, the sharing of the plan goals with stakeholders and associations, the engagement of local entities that deal with sustainability already present in the territory with the consequent creation of new job opportunities, and the involvement of minorities such as social groups of different cultures and religions. These elements are relevant points involving the constant construction of a dialogue between the administrations and the inhabitants of the cities, which also guarantees the reduction of disparities. However, it is necessary to provide effective tools to measure the impacts of these interventions on the social realm.

Another fundamental aspect resulting from the analysis is the plan's flexibility and its goals, which are closely related to the context's environmental, social, and political conditions, by analysing and reading the state of the art of the city. In this way, considering the challenge of climate change (Gill et al., 2007), it is possible to guarantee a gradual transition in the territory. Then, the constant temperature increasing and the severe droughts that have affected almost all urban contexts led to a significant loss of tree canopy and the reformulation of various plans. In this sense, the proposed objectives cannot only be quantitative but also aim to improve our cities' urban, environmental, and social quality.

Plans can then treat open green spaces and health themes by using the mapping tool, which precisely identifies the spaces that contribute to the psychophysical well-being of people, determining their distribution and accessibility. Verifying the fair distribution of trees in cities is fundamental to guarantee environmental justice, whereby all citizens benefit equally from open spaces by reducing disparities (Wolch et al., 2014,Sharifi et al., 2021). Plans also often use mapping as an interactive and participatory tool in which citizens can acquire an awareness of the environmental quality of the neighbourhood in which they live, which forestation interventions will be carried out and the degree of priority of the interventions.

The lack of defined and complete European and Italian legislation has consequences on planning balances, whereby the most capable territories and cities, with more economic resources and knowledge, spontaneously initiate virtuous forestation plans and projects.

Therefore, it clearly emerges the importance of a public coherent legislation that directs the definition and programming of forestation plans sharing common objectives and concretely contributing to the sustainable development of the territory.

Pending comprehensive and unified legislation on urban forestry, the recommended best practices and highlighted features should aim for urban forestry plans to be recognised and conceived not merely as sectoral plans but as integrated development tools within territorial governance frameworks.

Dispositive-disposition dyads as a lever for change-making: the reconfiguration of school spaces promoted by the Metropolitan Regeneration Program of Bologna

Mauro Baioni
Università degli studi Roma Tre
Email: mauro.baioni@uniroma3.it

Abstract
The paper discusses the modernization of school facilities, to address contemporary educational and social demands, as a critical issue for the public sector. The study focuses on the "Progetto Scuole Terre di Pianura," part of the Metropolitan Regeneration Program in Bologna, which aims to reconfigure school spaces to foster educational and social initiatives. The paper critically examines how public officials (disposition) engage with technical and regulatory frameworks (dispositive) to implement local projects. It underscores the crucial role of public officials in interpreting and applying these frameworks to achieve effective urban regeneration, navigating the complexity of public administration in resource-constrained environments.

A phase of return on public assets: new dispositive-disposition dyads

The current legacy of school facilities is one of the most significant outcomes of public investment, which received a decisive boost from the obligation to develop regulatory plans through the application of urban planning standards introduced in 1968 by an interministerial decree[1]. After decades of application, local governments have obtained land and structures that have contributed significantly to shaping and creating hierarchies in urban contexts of large and small municipalities.

Today, many reasons justify the need for a new cycle of interventions, incorporating different lines of reasoning (Annese, 2016; Chipa, Mangione, 2022; Renzoni, Donadoni, 2022). The modernization of facilities and the articulation of learning spaces relates to the affirmation of more inclusive educational projects attentive to environmental challenges. The effects of some significant social changes (such as the generalized decrease in the number of children per family, the collapse of the population in mountainous and hilly areas, the reproduction of pockets of educational poverty pose the need to rethink the geographies and functioning of the school infrastructure. The opening of schools to other socio-cultural functions and the interdependence with other public spaces that complete the educational offer (libraries and cultural spaces, gyms and spaces for practicing sports as an activity included in the educational path for all, spaces for outdoor lessons) suggest a rethinking of the role and layout of schools

[1] The obligation to develop regulatory plans was introduced by Law 765/1967. Subsequently, Decree 1444/1968 mandated the reservation of minimum quantities of green spaces and public services or those of public interest, at a rate of no less than 18 square meters per inhabitant. Both measures remain in force.

as nodes of a “fundamental infrastructure” (Collettivo per l’economia fondamentale 2019), based on proximity relationships.

New perspectives and new forms of intervention on schools find opportunities for experimentation through the territorialization of national and regional public policies, which promote and support local initiatives through calls for projects. The need to translate general objectives and instances into local initiatives changes the role, agenda and approaches of local actors (administrators, public-private networks) and cities, understood as recognizable collective actors in decision-making processes (Bifulco, 2016).

Within this context, the theme of the AESOP congress can be understood by examining how the Public Administration manages the implementation of public projects and policies. This occurs in a phase marked by increasing contradictions, as the complexity of managing local changes grows while internal resources and capabilities diminish.

More specifically, we want to reflect on the relationship between dispositives and disposition as a determining factor for the permanence of a space for action. We use the term "dispositive" to mean a heterogeneous set (Agamben, 2006) that incorporates the complex of relationships that is built around and starting from the definition of technical artifacts, such as plans, regulations, projects. We understand by "disposition" the way in which individuals - in this case public officials - position themselves in relation to dispositives, in terms of agency and attribution of meaning.

To reflect on this theme, the present contribution critically revisits an initiative promoted in four small towns in the plains of Bologna, in which I was personally involved as a consultant for the public administration: the "Progetto Scuole Terre di Pianura, included in the Metropolitan Regeneration Program promoted by the Metropolitan City of Bologna and financed by a fund established to promote urban regeneration in areas of greater socio-economic fragility. The project translates the call for proposals' goals of increasing accessibility and energy efficiency in public buildings by redefining relational spaces (courtyards, entrances, service structures, thresholds, and pathways) in four preschools to promote educational and social initiatives.

After illustrating the fundamental contents of the project and the main stages of its implementation, the text dwells on the dispositive-disposition dyad, that is, on the relationship that was determined between the Metropolitan program, the local Project and the public officials responsible for their implementation.

The Metropolitan Regeneration Program and the “Progetto Scuole”

Following the 2014 institutional reform, the Metropolitan City of Bologna has equipped itself with the entire spectrum of tools to exercise its role as a federating body, in relation and cooperation with the Municipalities and the Unions of municipalities[2]: the Strategic Metropolitan Plan, the Metropolitan Plan for Sustainable Mobility, the Bologna Charter for the implementation of the 2030 Agenda, and the Metropolitan Territorial Plan.

[2] A Union of municipalities is a local authority formed by at least two municipalities to exercise certain functions. The Union shall have legal personality, statutory, regulatory, organizational and financial autonomy and its own political and management bodies. The metropolitan city of Bologna is subdivided into 50 municipalities, 45 of which are associated in 7 Unions.

The Metropolitan Strategic Plan[3] has provided the general framework of objectives to be territorialized and has made explicit the overall intentions and priorities for action including the promotion of urban redevelopment and regeneration projects in areas characterized by lower quality and/or urban and building degradation, economic and social marginality, to enrich public facilities and promote sustainable mobility, avoiding land consumption.

This indication is operationalized by the Equalization Fund, which is set up by The Metropolitan Territorial Plan[4] to ensure the financing of regeneration programs through a share of the planning fees due to urban expansions producing land consumption. The fund has a compensatory and solidarity character towards the territories not directly involved in urban transformations and is also intended as a lever to attract additional resources necessary to promote territorial rebalancing (Baioni et al, 2019, 34).

Its initial implementation benefited from already available resources. A grant of €700,000 from the Ministry of Infrastructure and Sustainable Mobility was used by municipalities and Unions for the preparation of technical and economic feasibility projects[5] concerning the works to be financed with the fund's resources. In line with MIMS guidelines and the objectives of the PSM, the design focused on interventions for energy autonomy, energy efficiency, and the reduction of energy poverty, with supra-municipal or metropolitan significance, and primarily involving existing public buildings.

Subsequently, a Call for the composition of the Metropolitan Regeneration Program was issued, with a total budget of 2.3 million euros. All Unions and a single municipality submitted proposals based on the feasibility projects, for a total of 54 interventions. The selection was made through two criteria, to which the same weighting was attributed: the economic, demographic and social fragility of the municipality[6] and the quality of the proposal (giving 3/5 of the score based on the strategic and urban dimension). Following the evaluation, the Program was composed of 15 interventions and approved on 29 November 2023.

The formation of the program is not episodic. It is part of a process initiated by a series of national calls[7] that have already stimulated a season of public initiatives. Metropolitan City intends to contribute through the formation of the Metropolitan Programs, on a biennial basis. For this purpose, the Metropolitan City has provided guidance tools (Guidelines for Metropolitan Regeneration Programs) and set the Workshops for Metropolitan Regeneration, to train and support local initiatives.

[3] Approved by Council Resolution of Città Metropolitana di Bologna no. 34 of 11 July 2018.
[4] Approved by Council Resolution of Città Metropolitana di Bologna no. 16 of 12 May 2021
[5] Technical-economic feasibility projects are the preliminary level of design of public works. Introduced by Decree-Law 50/2016 and confirmed in the new Procurement Code entered into force in 2023, they provide all the information to define the characteristics of the work.
[6] Metropolitan City carries out periodic monitoring of the demographic, social and economic fragility in the municipalities, the results of which are published online.
[7] The most relevant initiatives are the Innovative program for housing quality (DM 7 October 2021); the Extraordinary Intervention program for urban redevelopment and suburban safety (DPCM 25 May 2016); the Integrated urban plans, established by the Recovery and Resilience Plan of Italy (approved on 13 July 2021 by Decision implementing the European Council).

The Union of Municipalities Terre di Pianura[8] submitted the "Progetto Scuole delle Terre di Pianura" for funding. The initial impetus was given by the technical structures of the urban planning office, which is entrusted with the associated exercise of the management, urban and territorial planning functions under municipal jurisdiction, with the indirect assistance of the author, as a consultant for the urban planning general plan being drafted. From the outset, the proposal was oriented towards broader objectives beyond merely reducing energy consumption and physically upgrading the facilities. The funding for the feasibility project was viewed as an opportunity to define a comprehensive action plan addressing the three key aspects of school spaces previously mentioned: learning environments, new social demands, and the relationship with the urban context.

The project's report emphasizes that the pandemic's enforced denial of school attendance has made everyone more aware of their influence on the individual and social sphere. As stated by Alessandro D'Avenia, writer and professor, the poor habitability of schools is a determining factor in inducing young people to seek a digital elsewhere, where they can be better off. Moreover, the report underlines that schools are not monads. They shall be considered as condensers of relationships that primarily involve children, their companions and teachers, but which can extend, through the action of groups and associations, to large segments of the population. This broadening of perspective was made possible thanks to the formation of a working group composed of researchers and university professors, and professionals (architects and engineers)[9].

The interventions in the four preschools[10], one in each municipality, include:
- The reconfiguration of outdoor spaces and paths that connect schools to other services present in urban centers and public transportation nodes
- The implementation of interventions in service spaces to make the school more welcoming to associations and groups involved in social activities (threshold spaces in Altedo, a multi-purpose community space in San Gabriele, a multi-purpose laboratory in Minerbio and a solar greenhouse in Cadriano).

The proposals were profiled to the physical-functional characteristics of each school facility, the needs identified through dialogue with the teaching staff, and the detected relationships with the surrounding area. The discreet direction carried out by the urban planning office allowed the working group to engage in collective work sessions and moments of discussion with sector managers, school principals and teachers. The contribution of the various expertise has proved to be fruitful. The results of university-level research have been incorporated, ensuring prerequisites for immediate implementation. This has been achieved by calibrating the feasibility projects for progressive implementation in phases, according to available funding, the first of which is secured by the Metropolitan Program.

[8] The Union Terre di Pianura is a local authority established in 2010 that covers a territory of 177 square kilometers, located between Bologna and Ferrara, with about 40,000 inhabitants.
[9] The working group of Politecnico di Milano, coordinated by Cristina Renzoni, provided scientific support. Angela Ceresoli (ABC studio), with Mauro Baioni (PUG consultant), oversaw the framework project. Massimo Bernardelli and Angela Ceresoli (ABC studio) were responsible for the elaboration of the four feasibility projects. The analysis of plant engineering was developed by Emilio Morandini. Kiez Agency contributed to the drafting of guidelines for an inclusive approach to the equipment of public spaces.
[10] Preschool of San Gabriele (Baricella), Preschool of Altedo, Preschool “R. Caldarone” in Minerbio, Preschool “Fresu” in Cadriano (Granarolo dell’Emilia).

Moreover, the project offered concrete tools to extend future action. The interpretation of recurring situations regarding accessibility conditions, the relationships between schools and other proximity facilities, and the multifunctionality of spaces translated into indications for the general urban plan. The design criteria on mobility, accessibility in application of the Design for All principles, on the treatment of relational spaces (thresholds, entrances) and open spaces in application of NBS principles have been incorporated into guidelines for future public works planning, including those that can be carried out by private entities when promoting urban transformations.

Between Dispositive and Disposition

To reflect on the relationship between dispositives and disposition, I made use of two interviews with Mariagrazia Ricci and Francesco Selmi (Metropolitan City of Bologna) and Irene Evangelisti (Union of Municipalities of Terre di Pianura), the technical officials who dealt with the formation of the program and the preparation of the proposal, respectively. The interviews were conducted on May 9 and 10, 2024 and were based on the following three questions:

- What is the space for action created by the Metropolitan Program / by the local project?
- What is the space for action that you have created autonomously, having to follow the program, especially with respect to the political mandate and the sensitivities of the administrators?
- What are the enabling conditions for expanding the space for action?

Regarding the dispositive, the technicians of the Metropolitan City underlined the value of the program in terms of empowering the territories. The program prompted the technical structures of the Unions and individual municipalities to overcome the habit of operating in the existing city through single interventions defined by the logic and procedures of public works. This possibility was only seized in two instances, to concretize urban-scale reasoning already in place on energy communities or to propose innovative solutions (like Terre di Pianura). On the other side, compared to previous calls that had received few applications from municipalities, in this case the number of proposals exceeded the overall amount of the allocation.

For the head of the municipal office, the value of the dispositive is linked to the possibility of proposing a lateral perspective on general themes to overcome reductionist approaches based on the "problem-solution" binomial. The call created a space for action because it didn't impose codified solutions (such as the purchase of a tool or the use of a technology) but allowed for the formulation of proposals commensurate with the specificities of the territories and their ability to intercept emerging trends at the local scale. In small municipalities, however, to seize this opportunity is by no means obvious. In the eyes of technicians, it is a problem to give up a

practice that relies on strict sectorization and simplified problem-solution approaches that do not include multidisciplinarity and skill integration.

The Metropolitan City emphasized the broad degree of autonomy left by the administrators. The promotion of the calls was prompted by the technical structures, in the presence of general political guidelines. Political support was easily obtained due to the interest in backing local authorities and the possibility of communicating concrete results. At the Union scale, political figures expressed interest in securing funds to reduce energy costs, without engaging in discussions about the nature of the proposals.

The broad freedom left to officials is counterbalanced by the lack of recognition of their initiatives. The organizational forms of public administration are rigidly profiled for the governance of ordinary proceedings. For the municipal technician, freedom and initiative go together if "you have a little courage" and – as Manzoni has Don Abbondio say - "courage, if one doesn't have it, one can't give it to oneself." That said, the interviewees lament that the public administration does not value a proactive attitude towards innovation, unlike professionals – driven by work interests – and the University – for which research and experimentation are constitutive of its mandate. Those who work in public administration remain in the middle, without a client and without incentives.

The technician from Terre di Pianura highlights a paradox arising from this gap: while public administration is required to make rapid decisions, the reliance on outdated or standardized solutions fails to address emerging issues and results in 'acting without being contemporary,' leading to overall ineffectiveness. To overcome this impasse, the Scuole project was built through a "coalition of perspectives" between public administration technicians, professionals and academics. The triangulation gave greater depth to the proposals, allowing to incorporate the results of research, to put them into concrete practice, and to demonstrate the practicability of the solutions to both other professionals and other local administrations, with a pedagogical effect. The formation of working groups including external resources to the public administration should therefore be encouraged.

As for the future, all three interviewed recognized the availability of economic and technical resources, the redefinition of internal organization, and regulatory changes as enabling conditions. Among the enabling conditions, the presence of the urban planning offices at the scale of the Union of Municipalities was seen as a guarantee to ensure minimum conditions for action, especially in small municipalities, and to overcome the segmentation of initiatives by sector (urban planning and public works) and areas of competence (education, sports, culture, social assistance).

Open Strands

As Giovanni Michelucci (2022, 230), a prominent figure in Italian architecture, observed, the "most immediate traces" of the country's transformation are recognized in the school-city relationship. In the second half of the twentieth century, "school and city found themselves submerged by that same growth that they had hoped for" (ibid). Today, the material, organizational and symbolic legacy of the long period of public equipment of cities constitutes a key place to test the public sector's ability to respond to present-day issues.

The case of Bologna offers, in this regard, some interesting insights into the possibilities for action at the local scale.

The transformative capacity at the local scale rests on a series of interdependent components (Wolfram, 2016) referring to three main fields:
- preconditions of agency/interaction (governance between communities of practice and leadership)
- path-deviant envisioning (from initial experimentation to programs based on awareness of the challenge)
- working on (innovation embedding, social learning, political-administrative action). Following the initial affirmation of pioneering practices, change is produced through actions of acceleration, stabilization, scaling-up and diffusion in which institutions can play a proactive role, since they are able to act on the "structuring conditions that configure the very possibility of agency" (Martin, 2019). The equalization fund, the metropolitan programs, the presence of the Unions' urban planning offices can be considered as enabling dispositives. To realize their potential, however, the disposition of the officials is crucial. The case described confirms how decisive public officials are in their skillful assembly of internal and external resources on their own initiative.

In conclusion, if we recognize the value that the location, conditions and functioning of schools have for the present and the future of communities, especially in fragile contexts such as small municipalities on the margins of metropolitan areas, an integrated vision must be promoted - as indicated in the special session to which this contribution contributes. In this perspective, the role of the public administration and, more specifically, of the technicians involved in the promotion and planning of urban scale interventions is decisive.

Beyond the specific perimeter of the interventions on educational infrastructure, therefore, the case of Bologna offers some suggestions about the "set of capabilities" required by public administration: "namely, the ability to adapt and learn; ability to align public services and citizens' needs; ability to govern resilient productive systems." Mazzucato's considerations (Mazzucato and Kattel, 2020, 257) seem to be particularly apt, not only to address the wicked questions of the relationship with market initiatives, but also to give quality to actions on a local scale, in a condition characterized by increasing instability and uncertainty.

The diffusion and stabilization of innovative proposals - as in any transition process - are influenced by dynamics that go beyond the technical sphere and pertain the configuration of the dispositives and the resulting space of action. The dispositive-disposition dyad, which is formed regardless of intentionality, can be consciously considered to mobilize resources, even without comprehensive reforms, to overcome the segmentation of competencies and the rigid dualism between internal planning and outsourcing.

Abstract
Aging in place is an increasingly discussed topic in the study of urban aging, especially in light of the new challenges of our century: population aging and urbanization. Understanding the interaction between individuals and their environment is critical to promoting healthy longevity. A mixed-methods case study in the Italian city of Bergamo examines this relationship, focusing initially on two models of aging in place: senior housing and home ownership. Preliminary data reveal individual differences in social life and in the use of urban space between the two groups. The research, which aims to investigate how to support healthy "aging in place", could involve policymakers, urban planners, and architects in promoting inclusive and age-friendly urban environments, by introducing a new perspective to aging in place studies.

Keywords: Aging in place, age-friendly city, healthy longevity, empowerment, inclusion

Topic and theoretical focus

The 21st century has to face two important challenges: the aging of the population and the continuous urbanisation of land and urban growth (especially in some areas of the planet). The World Health Organization (WHO, 2017) and the United Nations (UN, 2019), dedicate a lot of attention to them, promoting projects and good practices to sustain the shaping that the world is living, and relative challenges in social, economic, cultural, and political, that it's called to face. It's properly this intersection of population aging and urban environments that is the privileged field in which fits "urban aging", an increasing field of research all over the world.

However, the prevailing perception of aging as a 'problem' or 'economic burden' on society (Phillipson, 2013) persists, hindering efforts to empower older individuals and communities. A paradigm shift is needed to embrace a holistic view of aging that recognizers the active role older adults play in shaping their aging trajectories and promoting healthy longevity, in a lifespan course perspective (Morganti, 2022). Initiatives such as the WHO's Age-Friendly City program (WHO, 2007) aim to create urban environments that are conducive to the well-being and participation of older adults by addressing multiple domains such as housing, transportation, and social inclusion. This underscores the importance of both the physical and social environments in enhancing the quality of life for older individuals, which is consistent with scholars' emphasis on the significance of place in the aging experiences (Skinner, Andrews, and Cutchin, 2016).

Within this context, there is a strong emphasis on conceptualizing aging in place (AIP) as an achievable and valuable objective (Vasunilashorn, et al., 2012), driven by two main factors. Firstly, it responds to political movements advocating for support for older individuals,

particularly in the face of uncertainties about the sustainability of welfare systems (Pynoos et al., 2008). Secondly, it reflects the individuals' desire to remain in their own homes (see, for example, Golant, 2020) and the recognition of the importance of place for older people (McGrath and Hand, 2021). This concept has been integrated into public policies in many countries, such as the United States (Metlife, 2010) the United Kingdom (Lofqvist et al., 2013; Hammarström and Torres, 2012; Sixsmith et al., 2014), and Australia (Stones and Gullifer, 2016), where it serves as a strategy to conserve resources (Greenberg and Schwarz, 2012) and empower older people by expanding access to support services, that enable them to maintain their independence (Stones and Gullifer, 2016). In some cases, such as in the UK, housing-related programs aim to support older individuals in maintaining and enhancing their residences, facilitating extended periods of independent living at home. The rationale behind such initiatives lies in the belief that informal support networks are more cost-effective than institutional care (Wiles et al., 2011).

Since its inception, the concept of AIP has evolved, as highlighted by Rogers et al. (2020). The term originated in 1978, with Grass and Wiseman, focusing on the growing number of older adults. It gained traction in the 1990s, with increasing emphasis on the significance of familiar environments, albeit with vague descriptions. From the 2000s onwards, the literature diversified with various definitions of AIP, becoming a central concept, particularly for policymakers, as noted by Vasunilashorn et al. (2012).

Nevertheless, the definition of AIP remains an open topic, encompassing functional, symbolic, and emotional attachments and the importance of homes, neighbourhoods, and communities (Wiles et al., 2011). Multiple disciplines approach AIP from different perspectives, leading to varied definitions and interpretations. To better understand the concept, there is a need for a comprehensive definition that integrates its heterogeneity and complexity. Aging in place stimulates reflections across various fields and sparks critical discussions about its theoretical ambiguity and its implications for spatial justice and inequality (Finlay et al., 2021). To summarize the different definitions of AIP, three main categories are often considered when it is studied: people, places, and time (Rogers et al. 2020).

In this contribution, we propose to study aging in place by exploring the nuanced interplay between individuals and places, focusing on older adults living in the city, so in the dimension of "Aging in (urban) Place".

The research selects the Municipality of Bergamo as a case study due to its well-defined spatial, social, and institutional conditions, which exemplify those of a "medium-sized city". Medium cities are urban entities of significance within Italy, representing approximately one-fifth of the country's residents, with a population ranging between 200,000 and 500,000 inhabitants (Organisation for Cooperation and Economic Development, 2014).

Bergamo stands in the Lombardy Region, the most populous Italian region with nearly 10 million residents and 1,504 municipalities across 12 provinces, with Milan as its capital. Located in northern Italy, the region spans 23,860 square kilometers, with terrain divided almost equally between plains, hills, and mountains. It sits at the crossroads of routes linking the Mediterranean and Central Europe. The city of Bergamo has over 120,000 inhabitants and serves as the capital of the province, which boasts more than 1.1 million residents. It is a city with a complex spatial structure. It is internally organized into 22 neighbourhoods, which are characterized by the presence of both ancient and modern urban fabrics, affected in the 20th century by important processes of urban growth. At the same time, this city is part of a large megalopolis that runs from East to West, incorporating various cities and metropolitan areas (Torino, Milano, Padova).

Due to its characteristics, Bergamo represents an example of a "medium city" useful for the definition of an analytical-interpretative model applicable to other urban contexts. This research, in fact, represents a first exploratory phase that will provide us with useful indicators

to develop a more complex analysis model, which will attempt to involve the entire Bergamo population over 65, which is around 30,000 people. This innovative multidimensional and multilevel methodology to examine the correlation between urban environments and longevity could produce results applicable to similar medium-sized cities across Italy.

Since we believe that studying the subtle space between people and contexts, and their relationships, can be crucial in offering opportunities to promote the empowerment of individuals for their healthy longevity within the city, the research question we ask ourselves is how to study the urban context not as a neutral space, but as a place of constraints and possibilities for older adults so that it can constitute for them opportunities for healthy longevity or limitations (not only physical) that lead people towards potential trajectories of fragility.

Research objectives

Focusing on the small geographic areas (neighbourhoods) that characterize mid-sized cities, the research aims to analyse individuals and places, to understand how the different possibilities of aging in place can contribute to healthy longevity. To achieve this, a comprehensive understanding of the older adults in urban areas and their interactions with urban spaces is essential. By adopting a bio-psycho-social and ecological model of development throughout the lifespan (Bronfenbrenner, 1979), with a strong multidimensional and multilevel connotation, we intend to give importance not only to the AIP choices of individuals and the creation of their proximal relationships, but also to the role of the entire system surrounding the individual capable of determining them. Through the creation of a complex methodological model of analysis, the project intends to understand how urban space can prove to be a constraint or a resource, when placed in relation to the motivations to move, the personal characteristics of individuals and the urban spatial variables. Starting from the individual level up to the macro context, we intend to analyse not only the physical barriers that could hinder everyday life in the city, but also the cognitive ones. In other words, an analysis is proposed able to integrate the psychological and complex determinants of individuals into the concept of space. The outcomes of this research will be able to provide suggestions to support AIP policies in the city, allowing the redesign of more inclusive urban spaces capable of supporting active aging and healthy longevity. This new methodology for investigating the relationship between cities and longevity could ultimately produce results that can be generalized to other medium-sized Italian cities.

Research methods

The research focuses on the Municipality of Bergamo as a case study due to its distinct spatial, social, and institutional characteristics, making it an exemplar of a "medium city" suitable for developing an analytical-interpretative model applicable to similar urban contexts. The methodology chosen for the indicated objective is the mixed-method case study (Curry et al., 2009; Phillips et al., 2013). The study, which has two main focuses – people and places – adopts an epistemological complex approach, in a biopsychosocial and ecological perspective of development throughout life (Bronfenbrenner, 1979), and integrates the determinants indicated by the WHO for the creation of Age Friendly cities (WHO, 2007).

Two groups of individuals over 70-year, living in two different AIP models situated in two different neighbourhood in the city of Bergamo are analysed as case study. One sample group is composed by 16 aged persons (14 females; 2 males) living in their home and attending activities in an association dedicated to older adults placed in “Sant’Alessandro” neighbourhood. The other group is composed by 13 older adults (11 females; 2 males) living in a senior house (a group of independent apartments organized around common services) situated in “Borgo Palazzo” neighbourhood. This housing model is particularly interesting for

our research as it is the first form of independent senior living not only in Bergamo but also in Italy. The reference neighbourhoods of the two sample groups are almost similar: residential and central in the city of Bergamo.

Starting from an individual perspective the research assesses the healthy status by quantitative measurements and the motivation to empower in aging by qualitative method. The first step of the study is a qualitative interview (audio-recorded) lasting approximately thirty minutes, composed by three questions aimed at investigating the motivations for aging, resources and difficulties during this process, the motivation of certain housing choices and how much and how the space around them (neighbourhood) home is used. The second part of individual analysis is made using quantitative measurements, and represents a multidimensional evaluation of the participants, resumed in four dimensions: Cognitive, Functionality in daily life, Emotional state, Quality of life.

This first part of the analysis allows us to have a complete and in-depth picture of the older adults, not only from a health point of view, but also in terms of thoughts, life stories, needs and motivations, also in relation to the use of urban environments.

Preliminary results

The preliminary results are about the qualitative and quantitative data on the individual focus. With the current analysis, we will delve into the examination of qualitative data, which proves to be more revealing and thought-provoking.

Into the sample we had to drop out two subjects. As shown in Table 1, the definitive sample is composed by 13 over 70 years old living in the senior house (2 males; 11 females); and 14 people living in their homes (2 males; 12 females).

Table 1
Socio-demographic and self-reported health details of participants.

	Own Homes	Senior House	total	% of total
Population				
total	14	13	27	100%
famale	12	11	23	85%
male	2	2	4	15%

Qualification				
Elementary School	1	1	2	7%
Secondary school	2	5	7	26%

High school	10	6	16	59%
Degree-Para-university diploma	1	1	2	7%

From an individual perspective preliminary quantitative data revealed no significant differences between the two groups. These two case studies appeared, in fact, to be similar in the four dimensions examined. On the other hands, qualitative preliminary data reveal differences between the two groups, in particular in the personal aspects of empowerment in aging, in social life, in the motivation of the housing choice, and in the use of urban environment. Several themes are emerged during the interview, some about their life histories, resilience, needs, thoughts, while some others about the current life in the AIP model chosen, and their relationship with urban environments.

Starting the analysis with the first question posed to them, about them perceptions of aging and about resources and difficulties linked to this period of life, the two groups appear quite homogeneous. For both the themes of sociality, physical health and safety appear to be very important. Among the resources, sociability is most often cited, while among the difficulties, motor fragility or the loss of independence, in some cases forced, mostly emerge. Some of them raise the issue of the stereotype of old age, emphasizing their role and dignity as self-determined people, before being tied to the sole label of "old". Below we report a reflection proposed by one person of "own homes" group on this regard: *"but what also annoys me in quotation marks, these stereotypes, which surround this passage of life, that up to a certain point you can do some things, after that you cannot do others, however this also has a value socially, because you still feel , I'm labelled, you don't belong to that age group, okay, you're allowed to do things, after which I don't know you go beyond that, so you already seem out of the sphere, let's say, of a certain type."* In both two groups, we observe stories of resilience, where moments such as the death of children, widowhood, or COVID are indicated as very difficult times in life.

Analysing the question relating to housing choice, for the group of individuals who have chosen to live in their own home, emerge the issues of autonomy and attachment to the place in which they have lived for most of their lives. All the subjects interviewed decided to live in the home in which they are located autonomously and independently. This choice seems to reveal a good degree of empowerment in one's aging process. As highlighted by the literature (Rowles, 1983; Degnen, 2016), place attachment where one has lived throughout one's life seems to have a strong connection with healthy longevity, particularly due to the presence of a great relationships between people and places, which encourage movement and social networks, and, as a consequence, the maintenance of active aging. The group interviewed, in fact, has a good social life, thanks also to attending the association two days a week as a point of reference and input for reflecting and doing activities. Deficiencies in this sense are highlighted if the person finds himself in difficulty from a motor point of view and is therefore dependent on third parties for his travel, whether on foot or by car. Out of fourteen interviewees, most are independent in their travels. Almost half of them drive a car, while the others travel by other means such as public transport, bicycle, or on foot. Only one person needs to be accompanied even for very short journeys. The meetings that the association proposes also allow them to have a moment of discussion and cultural enrichment. In addition to this, those affiliated with this group regularly participate in exhibitions, concerts and guided tours of the city and trips out of the city, encouraging movement, sociability, and curiosity to learn. Furthermore, from the analysis of the interviews, a good degree of awareness and self-determination regarding one's aging emerges. For example, during an interview, an 80-year-old woman, with a good degree of physical and mental health, states: "*I want to be a "subject" until the end, and I decide on my own*", also adding how it was fundamental throughout her life to make conscious choices capable of orienting her towards healthy aging. Some of them, in recent years, have become actresses, accepting the challenge of putting themselves on stage. Urban

space appears to them as the place where they can carry out their services, but also where they can carry out the activities they prefer.

The qualitative data obtained from the older adults living in the senior house reveal that the choice of this specific form of housing is guided by two main concepts: the sense of security and the need for sociability. Among the reasons why a certain housing choice is made, in fact, the theme of loneliness stands out a lot, either as an event that has already happened or something that is feared. Most of them urged their children to look for a possible solution away from loneliness. Differently from the group that lives in their own home, for the "senior house" sample, the attachment to the place is rather poor, since they mostly come from elsewhere. Only three persons was resident in Bergamo city, including one in the same neighbourhood. In fact, the latter, appears to continue to move easily within the city. Some of them miss their home and the place in which they have always lived, while some complain that they have not found what they thought, because loneliness is an element that continues to stay, despite believed they would defeat it thanks to such a place. Only three residents declare that they went to the senior house by their own choice, the others mostly demonstrate that they received an address from their closest family members. Among the latter, however, there are those who maintain a certain degree of self-determination, having in fact accepted and chosen to live there, while others are dissatisfied and have given up on the idea of returning to their home, even though they want it. In other words, they experience the choices made by others (generally their children) with extreme passivity. Another important theme emerged is the need of security. Many individuals have opted for this housing model to enhance their sense of security. They expressed concerns about potential falls or health issues when alone at home. Additionally, this living arrangement offers greater ease of movement compared to their previous residences.

The older adults who have chosen this housing model generally have a daily routine that unites the residents. There is great participation in the proposed activities, but in general, they do not organize other activities on their own initiative inside or outside the senior house. The structure organizes daily moments in which to meet, including outdoor activities, from shopping to the use of leisure services, such as the cinema, but only some of them participate in the latters. The use of urban space is, in fact, mostly relegated to the satisfaction of some needs. Only a few of them continue to maintain their independence, participating independently in the activities proposed by the Municipality and taking advantage of leisure services, such as the gym. The others feel hindered in the use of urban spaces, both for reasons contingent on the city (e.g. traffic), and because they do not know the spaces or do not feel safe in moving around, also due to a fragile walk.

Preliminary conclusion, future research, and study implications

From our preliminary findings, we can draw some initial conclusions.

The group of people who live in their own homes seems to be more aware and empowered about their aging trajectory. Furthermore, the latter seem to be in a more favourable situation capable of supporting healthy longevity. In fact, attachment to the place, as also supported by the literature (Rowles, 1983), allows them to keep social networks active within their community, favouring, as a consequence, good sociability, and a certain degree of mobility within of the city, both protective factors considered fundamental to supporting active aging (Holt-Lunstad et al., 2010; Hause et al., 1988).

In contrast, living in a senior house appears to limit activities within the city, possibly due to the availability of services within the facility and a lesser attachment to the place by the older adults' residents. This situation raises the question of how to increase the relationship of senior house residents with the broader community and urban environment. Furthermore, the high degree of sociability that could act as a protective factor for those who live in their own homes (Holt-Lunstad et al., 2010; Hause et al., 1988) seems not to be so present in the group of

individuals who live in the "senior house", who tend to feel lonelier. This reflection prompts us to consider how we can help these residents increase their social interactions. These insights and questions will guide the next steps of our research, as we seek to improve the quality of life for the over 65 population in Bergamo through comprehensive analysis.

Since the research is ongoing, to have a complete a multidimensional and multi-level photography of the analyse the interaction of people with urban spaces we will proceed to run a participant ethnographic observation (Geertz and Leonini, 1988) combined with spatial analysis (e.g. functional and morphological setting; presence of physical barriers or limitations) in order to understand the differences on using spaces in depending of the role/motivation to move in the city. We think that the use of ethnographic observation will be fundamental for the research because it allows a more accurate understanding and complete with the individual and spatial characteristics that determine the use of city space in the context of Aging in Place. It also allows us to collect qualitative field notes, which will help focus attention on topics deemed important to research participants. For the in-depth analysis of the latter will be carried out in specific focus groups (Morgan, Krueger, King, 1998). The collaboration with urban planners and geographers will also allow the analysis to be conducted in the 22 neighbourhoods of the city of Bergamo, focusing on: 1) Demography 2) The story 3) The spatial organisation, which will be explained in: - Prevalent uses and functions - Service system - Mobility - Environmental ecological system. The spatial analysis will result in the creation of specific maps of the 22 neighbourhoods analysed (Software QGIS®).

The research presented constitutes an initial exploratory phase, offering valuable insights for the construction of a more sophisticated analytical model, to involve the entire population over 65 in Bergamo, also through automated data collection.

A possible implication of this study could be the involving of policymakers, urban planners, and architects, in order to propose new empowerment possibilities of urban spaces for aging individuals. Moreover, this study will contribute to introduce urban and services innovation that can turn cities into age friendly and affordable places for people who decide to adopt an AIP model. In particular this research will contribute to innovate Bergamo as a city of longevity. This will be congruent with the World Health Organization proposal (WHO, 2017) and with the concepts of inclusion and equality suggested by the NextGeneration EU (next-generation-eu.europa.eu).

Transhumance routes as tourist destinations: a concrete opportunity for inner areas or a romantic suggestion?

Antonella Marlene Milano
Polytechnic University of Bari, Italy-
DICATECh - Department of Civil, Environmental, Land, Building Engineering and Chemistry
antonellamarlene.milano@poliba.it

Abstract
The ancient practice of transhumance has generated on a large part of the Mediterranean territories a heritage of an intangible type (linked to the historical, cultural and socio-anthropological value), and of a material type, consisting of the infrastructures used for centuries to move herds, characterised by intrinsic landscape and environmental qualities.
In recent years, a renewed attention is emerging towards transhumance and the routes used for this purpose. In various European contexts a growing number of initiatives linked to the promotion of transhumance and to the enhancement of its routes are being implemented, both thanks to the bottom-up contribution of local associations and to top-down policies and projects.
The research collects the ongoing experiences related to transhumance from the Italian, French and Spanish context, with the purpose of providing a contribution to answering the following questions: can transhumance be converted into a tourist experience with positive effects on the territory? How can the ancient transhumance routes be reconverted into infrastructures for slow tourism, enhancing the identity culture linked to it?

Keywords: transhumance, slow tourism, experiential tourism, inner areas

1. Transhumance, sheep tracks and tourism: three concepts that sometimes overlap

1.1 Transhumance

In recent years, interest in transhumance as a phenomenon with cultural, ecological and territorial development value has been steadily increasing. This is due, on the one hand, to the growing visibility deriving from the UNESCO recognition (Belligiano et al., 2021) given in 2019 to the practice of transhumance (on a candidature promoted firstly by Italy, Austria and Greece, and then extended in 2023 to Albania, Andorra, Croatia, France, Luxembourg, Romania and Spain), and, on the other hand, to the flourishing of various initiatives aimed at

promoting the cultural, social and folkloristic aspects linked to transhumance, promoted both at an institutional level and bottom-up. The most recent recognition of pastoralism, of which transhumance is one of the highest expressions, came with the declaration of 2026 as the International Year of Rangelands and Pastoralists by the United Nations.

According to recent studies (Nori, 2022) about one-fifth of agricultural land in Europe is devoted to extensive livestock breeding, covering several tens of million hectares, most of it concentrated in the Mediterranean area. Pastoralism has always been linked to mobility as a survival strategy for centuries, embracing different forms such as nomadism, transhumance, migration and pasture rotation (Fernandez-Gimenez & Le Febre, 2006). Transhumance is practised in areas that feature complementary pastures or forage resources located at different altitudes (Bunce et al., 2004; Santillo Frizell, 2010). It can be distinguished into two types: vertical, consisting of short displacement from the pastures in the mountains to those on the plains; and horizontal, connecting different climatic areas hundreds of kilometres apart through journeys that take days or weeks. As Braudel (1985) described, the latter is the one that 'moved torrents of animals and shepherds between the Southern Alps and the Crau, between Abruzzo and the *Tavoliere delle Puglie*, between northern Castile and the southern pastures of Extremadura and Don Quixote's La Mancha'.

In recent decades pastoralism mobility has decreased dramatically and livestock farmers are becoming sedentary, adapting their practice to new circumstances, or, in some cases leaving the herding sector (Fernandez-Gimenez & Le Febre, 2006). As a result, in spite of the many recognised values of transhumance, its diffusion as a necessary practice for animal welfare has been declining since decades. The reasons are mainly two: the general spread of intensive livestock farming, and the replacement of transhumance on foot by journeys made first by train and, since the 1950s, by truck (Bieber 2010; Toulze 2022).

Nevertheless, nowadays in some areas transhumance is still practised. Among those the most known is the Provence-Alpes-Côte d'Azur (PACA) region in southern France; in this area, around 600,000 head of cattle spend their summertimes in the mountains (Figure 1), while 90,000 move to the coastal departments during winter each year (Maison de la Transhumance, 2022).

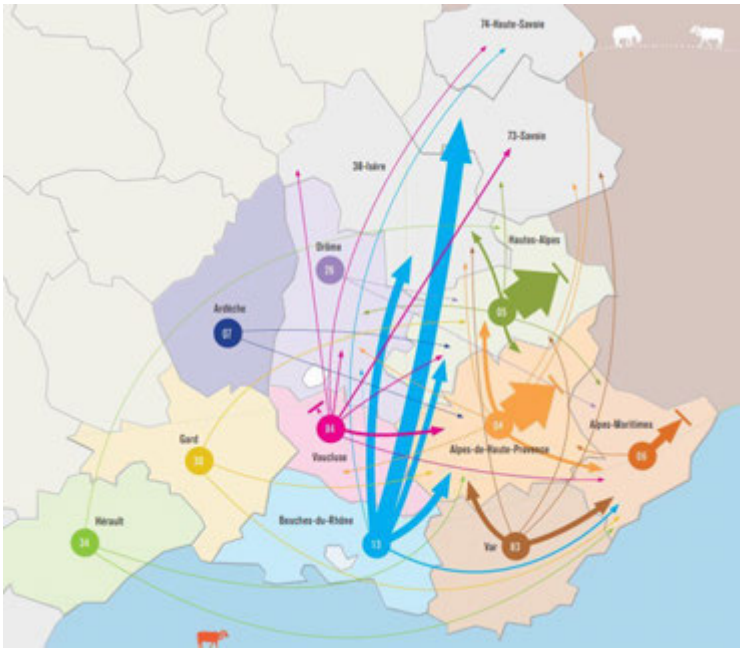

Fig. 1. Summer sheep transhumance in the Provence-Alpes-Côte d'Azur region, France, in 2021. Source: *Transhumance de la Provence aux Alpes*, Maison de la Transhumance

1.2 Transhumance routes

Transhumance usually followed established itineraries along green routes where animals could feed themselves during the travel. These long grassy roads, found in most of the Mediterranean countries, often present similar features. They can be articulated in networks of paths hierarchically structured into principal (111 metres wide *tratturi* in central southern Italy; 75 metres wide *cañadas* in Spain; between 50 and 100 metres wide *drailles* and *carraires* in the south of France), and secondary ones (*tratturelli* and *bracci* in Italy; *cordeles*, *veredas* and *coladas* in Spain). Transhumance routes also acquire local denominations in different regions of the same country, as it happens in Spain where they can be called *azagadores*, *cabañeras*, *camins ramaders, ligallos* or *ardibideek* (Villalvilla Asenjo, 2000).The transhumance routes are dotted with rural architectural elements offering resting zones, shelter and services to animals and shepherds, such as drinking troughs (Figure 2), bridges to count the animals, bakeries, small churches, shearing houses (Figure 3), etc.

Fig. 2. Left: A drinking trough near the Real Cañada Soriana, in the province of Castilla y Leon, Spain. Photo by the author. Fig. 3. An old shearing house (*palacio de esquileo*), near Sepúlveda, close to the Cañada Real Segoviana, in Spain, transformed into a wedding venue. Photo by the author.

These roads are characterised by specific vegetative features, since transhumance has contributed to the creation of valuable sylvopastoral landscapes and natural habitats (Gómez Sal & Lorente, 2004). Moreover, in different countries all over the Mediterranean area, drove roads are marked with stone elements that allow them to be recognised (Figure 4). These are called *cippi* in Italy and *mojones* in Spain.

Fig. 4. Left: *cippo* along the *tratturo* Melfi-Castellaneta, near Poggiorsini, Italy. Photo by the author. Centre: stone element marking a *draille* on Mont Lozère, France. Over the centuries, the combination of natural and anthropic elements linked to the practice of transhumance has generated a clearly identifiable landscape that, when well preserved, is widely recognisable. The extent of the transhumance routes varies in different geographical contexts. The country with the most extensive transhumance routes network is Spain, where they count up to 125,000 linear kilometres with a total extension of 420,000 hectares (Burgos, 2007), equal to about 1% of the national territory. In Italy, the officially recognised sheep-track network stretches along 5 regions in the centre-south of the country measuring a total of more than 3,000 km. Along the Alpine arc, despite transhumance has been practised for thousands of years and is still consistent, the routes used for this purpose have not been systematically identified and mapped, nor subjected to specific protection regimes until recent time. In France, the ancient transhumance routes, which originally overlaid the ridges of hilly regions, since the 19th century have been gradually replaced by other routes through the valleys (Fabre, 1997).
Land ownership is another key feature of transhumance routes. While in central-southern Italy and Spain the sheep track areas are still state-owned and their management is a regional responsibility (a legacy of the complex management system of the *Dogana della Mena delle Pecore* on the one hand, and the *Consejo de la Mesta* on the other), in other geographical areas the land is often privately owned. In France, the picture of the ownership of the transhumance routes is quite varied: some are private areas, others are owned by municipalities, state or pastoral syndicates. For instance, in Languedoc most of the *drailles* belong to private landowners but shepherds were guaranteed to use them free of charge; on the other hand, the *drailles* between the Crau and the Alps were public lands, but for their use shepherds had to pay taxes to the municipalities, which took charge of their maintenance (Biber, 2010). Currently, collective pastoral organisations have a key role in pasture maintenance, managing a total of about 600,000 hectares in the French massifs (Toulze, 2022).
Another key aspect that distinguishes transhumance networks is their state of preservation. Over the decades the transhumance routes have also seen an unavoidable decline that has led to their abandonment, or, in worst cases, to privatisation, urbanisation and heavy infrastructure. In some cases the public property of transhumance routes has been a major incentive for public administrations to build infrastructure of all kinds on them (roads, railways, electrical conduits,

sewage collectors, telephone poles, etc), without having to resort to expropriations (Villalvilla Asenjo, 2000). Reconstructing the current extent of the transhumance networks and classifying their state of conservation is a fundamental task that local governments are facing in order to enable their protection and enhancement.

1.3 Slow, experiential and rural tourism

In recent years several bottom-up initiatives and public policies are exploring the touristic development of transhumance and its heritage. Transhumance has been practised mainly in inner and rural areas, nowadays often corresponding to marginal regions affected by shrinkage, depopulation, ageing and unemployment. Tourism is recognized as a strategic sector for the economic development of inner areas (Espon, 2017) although it can not be seen as the only solution to problems affecting them (Pelc & Koderman, 2018). Moreover, as several studies on the risks of overtourism show (Dodds & Butler, 2019), tourism also has negative impacts, especially on fragile territories.

The type of tourism usually linked to transhumance belongs to three categories: slow, experiential and rural tourism. These three types of tourism present specific features although they slightly overlap.

As analysed by Pileri and Moscarelli (2021) in their literature review on slow tourism, three different meanings are associated to it: 1) a way of travelling in opposition to mass tourism; 2) a low-carbon impact tourism, i.e. using alternatives to air and car travel; 3) an experience seeking authenticity of the territory. This third interpretation of slow tourism overlaps with that of experiential tourism, defined as a type of tourism that calls for active participation, involvement, and even immersion (Edgell & Swanson, 2019). Experiential tourism has been defined as a type of tourism that 'encourages visitors to actively participate in the experience and promotes activities that draw people outdoors, and into cultures and communities' (Smith, 2006 :3). Experiential tourists seek memorable experiences made possible by the people they meet, places they visit, activities participated and memories created.

Lastly, the third type of tourism considered is rural tourism, defined by the UNWTO as 'a type of tourism activity in which the visitor's experience is related to a wide range of products generally linked to nature-based activities, agriculture, rural lifestyle / culture, angling and sightseeing'.

The initiatives that are being implemented aim on the one hand to promote transhumance as an activity that fully embodies the definition of experiential tourism, and, on the other hand, to adapt transhumance routes as ideal infrastructures for slow and rural tourism (Meini et al., 2018; Belliggiano et al., 2021). Recent studies have highlighted the growing tourist appeal that the pastoral world, and transhumance-related activities in particular, exerts (Ruiz Morales et al., 2024), at the point that a new niche tourism - defined 'pastoral tourism' (Sauer et al., 2022) has been identified. Experimental projects aiming at promoting new initiatives that combine transhumance and experiential tourism have been developed also in collaboration with universities and research centres (Pilla et al., 2022).

The aim of this paper is to provide a contribution to answering the following questions: can transhumance be converted into a tourist experience with positive effects on the territory? How can the ancient transhumance routes be reconverted into infrastructures for slow tourism, enhancing the identity culture linked to it?

2. Transhumance promotion events in Italy, France and Spain

In order to approach the first research question, a survey on the transhumance-related initiatives was conducted. The study area has been limited to Italy, France and Spain, since, as Braudel (1985) states, these three countries are transhumance regions par excellence. Moreover, among Mediterranean countries, they present similar socio-cultural and economic features, as well as a similar development level of the tourism sector[1].
A total of 237 transhumance-related initiatives that take place periodically in Italy, France and Spain were listed. These include transhumance festivals, livestock fairs, and any type of public event that directly involve transhumant sheep, goats or cattle. The identified initiatives are mainly of a socio-cultural kind and do not pretend to be a reliable indicator of the real rate of persistence of the practice of transhumance. In addition to transhumance events, also a few traditional transhumances with a real or potential impact on tourism were analysed.

The survey was carried out through web searches and documentary sources where available in literature. Particularly useful were the websites of associations working to safeguard transhumance (*Trashumancia y Naturaleza* in Spain, *Maison de la Transhumance* in France), and the tourism promotion websites of certain regions (Catalonia in Spain, Trentino in Italy). In addition, online searches were carried out using "transhumance" and the name of each of the regions of the three countries under study as keywords. Itinerant initiatives taking place over several days and touching different cities were counted as a single event, while all locations touched by the initiative were reported in the map (Figure 5).

[1] However, the three countries record different levels of development in the slow tourism sector. In France, the association '*Agir pour un tourisme responsable*' has been operating since 2004, issuing a label that indicates the sustainability of tourist packages proposed by travel agencies. In Spain, the popularity of the Pilgrim's Way to Santiago has given great impetus to the affirmation of slow tourism in recent decades. In Italy, this type of tourism has been consolidating in recent years, thanks also to institutional initiatives, such as the recognition of 2016 as the national year of slow tourism by the Ministry of Culture.

Figure 5. Location of the 237 transhumance-related initiatives taking place in Italy, France and Spain. Icons in grey indicate initiatives that are no longer active. Digital version of the map available at: https://www.google.com/maps/d/u/1/edit?mid=1Ig0t5Vm_sBhYdCR7HkUMhBHbtDt55P0&usp=sharing

Transhumance-related initiatives were classified according to the following categories (Table 1): 1) Transhumance festivals: folkloristic events celebrating the local culture linked to pastoralism, usually organised by associations with the collaboration of local authorities. Often these initiatives are organised to enliven the passage of transhumants through urban centres, with a programme of activities revolving around it. In other cases, the events are organised by municipalities or local associations with the main purpose of promoting local culture, folklore and enogastronomy, with animals having a secondary role. The activities that usually animate transhumance festivals are tastings (cheese, wine, seasonal products), music and dance performances, craft markets, conferences, workshops, exhibitions, historical re-enactments, exhibitions of ancient crafts, etc. 2) Traditional transhumances organised by livestock farms, which, although not involving celebratory or collateral events, exert a certain media and touristic appeal; press articles, documentaries or film productions have been dedicated to them. 3) Participatory transhumances, understood as experiences in which external actors and tourists can participate (for free or upon payment of a fee). This opportunity is provided by intermediaries (travel agencies or associations), or directly by the livestock farms that conduct the transhumance. Their tasks include promoting the initiative, collecting adhesions, and offering all the necessary services to allow participants to follow the transhumance (food, accommodation, transfers, possible excursions, etc.). 4) Livestock fairs including collateral activities appealing to a general public. 5) Animal parades in city centres to assert the value of pastoralism and transhumance. 6) Other activities of a different kind.
Initiatives that could be classified in two or more categories were placed in the most related category. In the analysis of the initiatives the focus was placed on those of greater relevance

from a tourism point of view, and in particular those falling under category 3) Participatory transhumance and experiences open to the public.
24 of the 237 analysed initiatives -or 10%- are not currently active; these are 17 transhumance festivals, five traditional transhumances and two activities of other type.

Event	Italy	France	Spain
1) Transhumance festivals or similar	74 (12 of which no longer active)	54 (2 of which no longer active)	43 (3 of which no longer active)
2) Traditional transhumance with media coverage	12 (3 of which no longer active)	1	7 (2 of which no longer active)
3) Participatory transhumance, experiences open to the public	2	2	4 (1 of which no longer active)
4) Livestock fairs	7	7	16
5) Claiming parades	0	1 (along Champs Elysées in Paris, organised only in 2022)	1
6) Other	1 (Transhumance Walk on Horseback)	1 (Transhu Pic-Nic)	0
Total	**96**	**66**	**71**

Table 1. Transhumance-related initiatives in Italy, France and Spain.

Given the vastness and heterogeneity of the data found, it was decided not to include in this study cultural initiatives linked to transhumance that do not directly involve animals (conferences, round tables, exhibitions, film festivals, etc.).

2.1 Italy

55 of the 97 transhumance-related initiatives identified in Italy take place in the Alpine areas of the north of the country (Fig. 6). These initiatives are linked to the practice of mountain pasture (*alpeggio* or *monticazione)*, i.e. vertical transhumance, and mainly involve cattle herds. An important exception is that of Val Senales which takes place between Italy and Austria and involves more than 4,000 sheep. In the conducted survey, only those involving urban centres, mainly small mountain villages, were listed, while public events of *alpeggio* taking place at mountain pastures were not included. According to a study by Corti (2004), in 2003 *alpeggio* events were already quantified at 212, with an estimated 12,000 participants.

The transhumance along the Alpine arc acquires different names depending on the regions: in Trentino Alto Adige and Veneto is called *desmontegada*, while in Valle d'Aosta is known as *désarpa*. It is celebrated with festivals and public events that amplify the appeal that the passage of the cattle herds, usually decorated with garlands of flowers, already constitutes in itself.

Figure 6. Transhumance-related initiatives taking place in the north of Italy

The initiative with the greatest national resonance is called *Transumando* (Fig. 7) and takes place in Bressanvido (Veneto). It is the longest vertical transhumance in Italy, involving 600 head of cattle over a distance of 80 kilometres. Since the first edition of the Bressanvido transhumance festival in 1998 to date, the transit of the herds has turned into a multifaceted itinerant event including concerts, conferences, shows and workshops. The 2023 edition of *Transumando* took place over 10 days and included, in addition to the traditional transhumance festival, the Festival of Agriculture and the Festival of the cheese producers from the province of Vicenza; according to the organisers the event was attended by over 20,000 participants.

Fig. 7 - *Transumando*, Bressanvido. Source: https://www.transumandobressanvido.it/

Another noteworthy initiative in the Alpine area is the Transhumance of the *Bergamini*, organised by the association *Pastoralismo Alpino*, an initiative that proposes a series of events and activities along the itinerary of cattle transhumance between Bergamo and Brescia, lasting ten days. The first edition took place in 2019 and each year a different route is planned, touching different towns.

In the central Italian regions, only nine transhumance-related initiatives have been identified, three of which are no longer active. Among the noteworthy initiatives is the Transhumance March between Falasche (Anzio) and Jenne, in Lazio. This is a re-enactment of the ancient sheep transhumance, now in its 31st edition in 2023. The march is carried out on horseback along a route that lasts five days and crosses 16 municipalities, connecting two natural parks (Simbruini and Castelli Romani).

In southern Italy and the islands, a total of 34 transhumance-related initiatives were identified (Fig. 8). While in Abruzzo and partly in Molise transhumance concerns essentially sheep, in the other regions, particularly in Campania, Basilicata and Calabria, it is mainly the movement of herds of *podolica* cows that keeps the practice and celebration of transhumance alive.

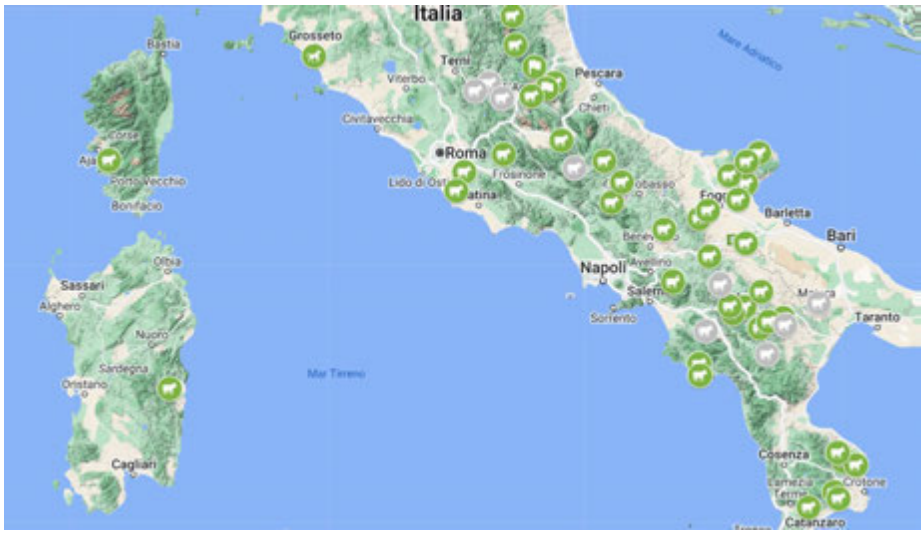

Figure 8. Transhumance-related initiatives taking place in the central-southern Italy

One of the most interesting initiatives in Abruzzo is the transhumance organised by a livestock farm in Anversa degli Abruzzi (*La porta dei parchi)*, which offers tourist packages that include the possibility of following the seasonal transhumance of its flock of sheep, as well as accommodation at its agritourism facility. The experience includes two days of transhumance for a total of 39 km in a high-value landscape and a total stay of four days and three nights. In 2023 the complete package had a cost of 390 euro per person.

The other initiative that allows visitors to participate in a transhumance journey is defined by the organisers as the first example of a long-distance 'participatory transhumance' in Italy and features a herd of *podolica* cows. It takes place between Oppido Lucano and Tito, in the Basilicata region, along a route of about 50 km covered in two days. The initiative is promoted by the livestock farm that conducts the transhumance (*Masseria Santorsa*) and is organised in collaboration with the association *Fuorisentiero*. The participation fee for the 2023 edition was 30 euro for both days and included the shuttle service and an overnight stay at a refuge, or alternatively in a camping tent. The initiative was first carried out in November 2021 and takes place twice a year.

In southern Italy other major initiatives feature livestock farms that persevere in the practice of transhumance, which over the years has become an event that generates curiosity and interest among citizens. Particularly noteworthy is the longest horizontal transhumance in Italy, taking place between Frosolone (Molise) and San Marco in Lamis (Apulia). The transhumance is led by Carmelina Colantuono and involves 300 *podolica* cows walking 180 km in four days, twice a year. The passage of the herd is in itself a major attraction, to the point that it has caught the attention of the international press.

A similar experience is organised by the Moscariello family, who from Montella (Campania) lead their herd of *podolica* cows to Lake Capacciotti (Cerignola, Apulia), 130 km far away. Again, there are no festivals celebrating transhumance, but its practice is in itself an element

of fascination, such that it was the subject of a recent film production (*Sulla via dei padri*, by Bruno Palma).
A slightly different case is represented in the Apulia region by the transhumance of flocks of the *Gentile di Puglia* breed of sheep from the Carrino livestock farm between Borgo San Giusto (Lucera) and the village of Santa Luciella, in the Dauni Mountains, along the *tratturello* Foggia - Camporeale. The itinerary includes the crossing of the historical centre of the city of Troia by 700 sheep (Fig. 9), generating an attraction that since 2018 (the year of the first transhumance festival in Troia) to date has been enriched by other activities, such as representations of scenes of rural life and demonstrations of dairy art.

2.2 France

In France (Fig. 10), transhumance historically mainly affected the southern regions of the country. Of the 66 identified initiatives, almost half (30) take place in the Provence-Alpes-Côte d'Azur (PACA) region. Almost all the initiatives identified in this area concern sheep transhumance (56 out of 66), an activity that still has a relevant economic value due to cheese production (Toulze 2022).

Figure 10. Transhumance-related initiatives taking place in France

France is the country where the *fête de la transhumance* format was first implemented in the 1970s, that from the 1990s onwards was quickly replicated in different locations in the south of the country (Garnier & Labouesse, 2015). The origin of transhumance festivals as we know them today arises from the desire to recreate the festive moment of flocks crossing urban centres that in the past marked two key moments in social life: the summer and winter solstice (Duclos, 2016).

An important boost to the spreading of initiatives supporting transhumant pastoralism, especially in Provence, has been given by *La Maison de la Transhumance*, a centre for the interpretation of Mediterranean pastoral cultures whose objective is to defend the practice of transhumance and to spread its knowledge. In the PACA region, known for important events such as the festival of Saint-Rémy-de-Provence and the fair of Saint-Martin de Crau, 11 new initiatives have been created since 2020, demonstrating the growing interest in the topic and the effectiveness of the communication strategies carried out in recent years.

Despite the numerous initiatives in the PACA region, none of them was identified as belonging to the category of participatory transhumances. The research then focuses on the Rocamadour-Luzech transhumance in Occitania and the *Route de la Transhumance* between the Pyrenees and New Aquitaine.

The first was a transhumance started in 2009 and organised by the Luzech / Labastide-du-Vert landowners' association, the *Transhumance en Quercy* breeders' association, the local government of the *Département de Lot* and volunteers. The main motivation behind this transhumance was to reduce the fire risk, which became a priority following a major fire in the area in 1998. The route is about 70 km crossing natural parks and mediaeval villages. The distance is covered in five stages (each 12 to 16 km) by 400 animals including sheep, donkeys and horses. Six towns are crossed by the herd, and convivial moments are organised at each stop. The transhumance is widely promoted online at the institutional websites of local authorities and through social networks. According to reports on local sites, in 2023 more than 500 people participated in the first day of the transhumance (Fig. 11), and 130 people attended

the dinner at the end of an intermediate stage. Joining the transhumance is free of charge and participants are guaranteed logistics all over the journey. On the institutional website of the organisers, eighteen accommodation facilities of different types are featured, offering 550 beds overall.

Fig. 11. A break moment during transhumance Rocamadour-Luzech near a pond. Participants are outnumbering animals. Source: https://transhumance.lot.fr/le-programme

La *Route de la Transhumanc*e is a 280-kilometre route that engages 600 sheep during three weeks, from Lac d'Estaing, in the High Pyrenees, to Aillas, in the Gironde département. The initiative has been organised by the association *La Route de la Transhumance* since 2001 with the collaboration of the municipalities reached by the route, which actively contribute to the organisation by covering the costs of security and communication. Transhumance is promoted locally with printed material, and globally through a website active since 2014. Participation in the transhumance is free of charge but participants are asked to become members of the association by paying a membership fee of 20 euros, which is used to meet organisational costs. No data was found on the number of participants in the transhumance or any of its stages.

2.3 Spain

In Spain (Fig. 12), transhumance-related initiatives are present all over the country, counting 71 total events, with a higher concentration in Navarra (11 in an area covering 10,391 km²), Catalonia (19 in an area covering 32,108 km²), Castilla y Leon (16 in an area covering 94,225 km²). The identified initiatives mainly concern sheep transhumance (42); fewer are cattle transhumance (22), often linked to taurine breeding in the Pyrenean area and in Navarre; in seven cases transhumance engages both sheep and cattle. The Spanish transhumance-related initiatives are quite heterogeneous: alongside the transhumance festivals following the format found in Italy and France (called *artzai eguna* in the Basque Country), there are other types of

events such as shearing festivals (*fiestas de esquileo*), religious festivals (*romerías* or short pilgrimages), and horseback excursions accompanying transhumant herds (especially in Navarre and Castile and Leon). In addition, in Catalonia most common events are livestock fairs (13 out of the 19 initiatives identified in this region). Over the years these events have been converted into attractions with gastronomic stands and various types of activities, such that they are included among the tourist attractions on local promotional sites.

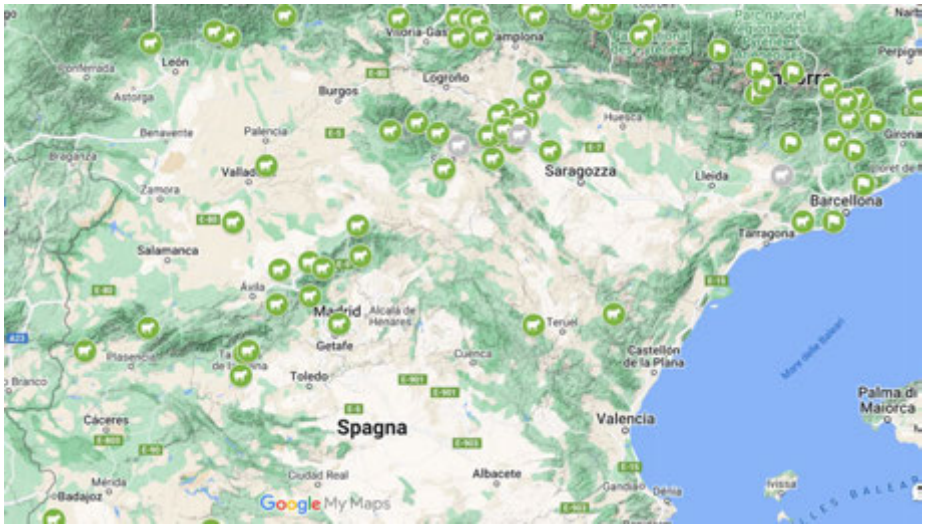

Figure 12. Transhumance-related initiatives taking place in Spain

Spanish public opinion is strongly catalysed by the great transhumance festival that takes place every year in the centre of Madrid in October (Figure 13). This event is organised since 1994, first by the association *Concejo de la Mesta*, then, since 1997, by the association *Trashumancia y Naturaleza*, whose aim is to promote the importance of transhumance, protect the sheep tracks, and claim for the adoption of a national strategy to safeguards extensive pastoralism. Shepherds and animals from all over the country (1,200 Merino sheep and 200 goats) take part in the event, creating an unusual and impressive sight. The parade, which reaches its climax in the re-enactment of the moment of the payment of the traditional fee (*maravedíes*) to the municipality, is preceded by a series of initiatives at the Environmental Education Centre in the Casa de Campo park, where the flocks temporarily stay. Collateral activities include promenades with the flocks particularly conceived for children, cheese-making and poetry workshops, photo exhibitions, among others. At the time of its creation, the transhumance festival in Madrid wasn't meant to be a tourist attraction at all. However, over the years, growing media attention contributed to turn it into a unique tourist attraction, featured on the city's tourist promotion page as one of the most awaited events. No data has been found on the number of participants in the festival in recent years, but according to media reports thousands of people pour into the streets of the Spanish capital every year, including both residents and tourists.

Fig. 13 *Fiesta de la Trashumancia* 2018, Plaza de Cibeles, Madrid, Spain. Photo by the author.

Among the most important events that take place every year in Spain there is the *Sanmiguelada*, the sheep transhumance in the Bardenas Reales natural park in Navarre, which crosses the historical centre of Carcastillo. The transhumance, which has been repeated annually since the Middle Ages, has recently been joined by complementary activities to broaden the attractiveness of the event to a wider public, such as gastronomic tastings, a market of traditional products and demonstrations of ancient crafts. Every year thousands of people witness the passage of the flocks in El Paso, from where 15,000 sheep transit to their winter pastures. However, the number of transhumant sheep has been declining significantly in recent years, partly due to climate change that is altering the seasonal and rainfall cycles.

Among those identified in Spain, the most interesting initiative concerns a sheep transhumance from Castilla La Mancha to the city of Soria (39,000 inhabitants), in the *Mancomunidad de Tierras Altas*, along the *Cañada Real Soriana Occidental*. This initiative, called *¡Somos Trashumantes!*, allowed tourists to follow a transhumant flock of more than 1,000 sheep during three days of walking, for a total distance of 30 km, in early July. The flock passes through the small town of Oncala, a village that once played a key role in the *Mesta* territorial system, hosting a Museum of Transhumance. Nowaday the village is almost uninhabited (70 inhabitants). In addition to sheep transit, activities such as counting, shearing demonstrations and the preparation of typical dishes (*migas del pastor*) were organised. The logistics of the initiative was entrusted to a local travel agency specialised in ecotourism. Places available to participate in the full experience were limited to 16; the participation fee was 179 euros, including two nights in a bivouac (alternatively, two nights in a hotel raise the fee up to 335 euros). The format adopted by *¡Somos Trashumantes!* embodies a model that supports the

practice of transhumance while providing an innovative tourism experience. However, since the tourism offer proposed is totally anchored to the practice of transhumance, unforeseen events that compromise its feasibility may occur. In 2023 the event did not take place because the flock of shepherd Eduardo del Rincón was stranded in Ciudad Real due to health restrictions imposed by the spread of the sheep pox virus, while for 2024 edition, no data was found.

2.4 Considerations on events promoting transhumance in Italy, France and Spain

The analysis of the initiatives identified in the three countries reveals different ways of understanding transhumance and different ways of developing the tourism potential linked to it. The types of event identified, in fact, range from events that turn into tourist events even though they originate from needs linked to the practice of transhumance (Troia, Rocamadour, the *Sanmiguelada*), to events that originate almost exclusively for the purposes of attracting tourists, evoking transhumance through folkloristic expressions, but in fact not including it in any way.

In general, the most widespread format is that of transhumance festivals, lasting just one day, or at most two to three days, almost always coinciding with weekends. The programming of the events almost always includes activities of a different kind that extend beyond the moment of the passage of the animals, where foreseen. Although transhumances are phenomena that by definition are on the move and involve different territories, the initiatives identified are almost always organised by a single municipality.

Despite a certain level of uncertainty due to the difficulties experienced at tracking the date of creation of all the initiatives, it is found that a considerable number of events among those analysed (48 out of 237, i.e. 20% of the total) were organised after 2019, i.e. after UNESCO recognition. This denotes a renewed interest in the topic, for which a new perspective in terms of tourism has been developed in recent years. In some regions of northern Italy, a boost to the organisation of events promoting transhumance and pastoral culture is due to regional political will, implemented by Lombardy Regional Law no. 14 of 2022, followed by Piedmont Regional Law no. 12 of 2024, which provide, among other things, for the institution of a regional transhumance day and allocate an *ad hoc* budget for this purpose.

While new transhumance festivals are flourishing, however, there is also a decrease in the number of traditional transhumances still active. Of the 19 listed in the survey, six have ceased to be practised in recent years. Although the road to the tourist enhancement of transhumance has now been opened up with diverse experiences, the involvement of shepherds and stakeholders from the livestock sector should remain a precondition, especially since there are very few people left working in this sector. As the case of transhumance in Soria shows, in order to develop the tourism potential of transhumance, it is necessary to support those who practise it in their struggle to maintain their activity alive. In this scenario, the key role of actors such as the *Maison de la Transhumance* and *Trashumancia y Naturaleza*, which not only promote the dissemination of the culture of transhumance, but also offer practical, logistic and legal support to livestock farmers, must be recognised and encouraged.

Due to its uniqueness and rareness, transhumance offers concrete opportunities to develop out-of-ordinary tourist experiences. Following a thousand animals for several days, walking at their

pace, experiencing life as a shepherd is undoubtedly a travel concept that meets the increasing demand for total escape from everyday life. While ensuring unique experiences for external participants, participatory transhumances also provide a complementary economic income for livestock farms.
The economic impact of the tourist attractiveness of transhumance is difficult to estimate due to the scarcity of data and monitoring of events. As a sample, the case of the Rocamadour-Luzech transhumance was in-depth analysed. Data on the accommodations available in Rocamadour via the booking.com website on the transhumance week and the following one were collected. The analysis showed that there is no consistent variation in occupancy rates in the hotels of the city between the two periods. As a result, it can be deduced that, in this kind of context, transhumance attracts either proximity tourists, who do not need to spend nights away from home, and/or tourists who prefer accommodation types not included on booking.com, such as collective dormitories. The feeling is that, with a few exceptions (Saint-Rémy en Provence, Madrid), at the moment the transhumance-related events are mainly attractors for proximity tourism, since they are seen as opportunities to live the unique experience of the incursion of the pastoral world into cities.

3. Slow tourism along the transhumance routes

Another development perspective linked to transhumance concerns the possibility of transforming the transhumance routes into walking or cycling itineraries. Their reuse for tourism purposes is a target that most local governments have set themselves. As an example, in Spain, the introduction of new uses along the sheep-track network, compatible with and complementary to transhumance, such as transit on foot or by other non-motorised means, is reported in the national legislation (*Ley de Vías Pecuarias*, 1992).
In order to approach the subject, three emblematic cases have been analysed as follows.

3.1 La Routo, France-Italy

The Routo is a cross-border hiking route consisting of 33 stages between Borgo San Dalmazzo, in the Stura Valley, Italy, and Arles, in the Crau Plain, in Provence, France, for a total of 540 km (Figure 10). The French part of the route (400 km) is part of the circuit of the national *Grandes Randonnées* trail network. The itinerary runs along routes that are still used for the summer transhumance, so that the tourist use of the route coexists with the original use for sheep farming.

Figure 10. The itinerary of the *Routo*. Source: https://larouto.eu/it/

The itinerary crosses several protected areas, pastoral landscapes, and historic towns until reaching the city centre of Arles. The French section of the route was completed in September 2022, the Italian one in October 2023. For the promotion of the itinerary a web page was launched, as well as a complete guidebook available for online and physical purchase.

La Routo is the result of almost twenty years of synergies between the *Maison de la Transhumance* and the *Ecomuseo della Pastorizia* di Pontebernardo (Fabre 2016).

The case of *La Routo* represents a model of comprehensive enhancement that involves not only the route itself, but also the intangible aspects linked to it. This makes it a cultural project with social and economic impact, rather than a simple trekking route. In fact, in addition to the physical itinerary, the project reconstructs a chain of productive and economic activities related to pastoralism. Under the umbrella of *La Routo* a line of hiking clothing made with local wool was developed, dairy products from local farms are sold along the itinerary, livestock fairs and transhumance events are networked, cultural events (exhibitions, art installations, lectures, festivals and documentary screenings) are organised, restaurants proposing traditional pastoral dishes at km0 are reunited under the *Routo* label.

Although it is difficult to assess the impact on the territory of *La Routo* since no data was found on the subject, the total length of the itinerary and its cross-border nature suggest that travellers would spend more than one day along the route. Therefore, they need to stay overnight, get refreshments and make purchases during their journey, thus generating an impact on the local economy.

3.2 The *Vías Pecuarias* network of the Community of Madrid, Spain

The case of the Community of Madrid concerns the network of transhumance routes that fall within the regional territory. The Community of Madrid has a total of 4,104 km of transhumance routes (*vías pecuarias*), amounting to a total of more than 13,000 hectares, corresponding to the 1.64% of total regional area (De los Ríos Carmenado & Hernandez Aguado). Approximately one third of these were included in the *Descubre tus cañadas* project, an initiative started in 1998 which aims to create 74 new hiking itineraries accessible on foot, by bicycle or on horseback along the *cañadas* and secondary transhumance routes of the region. The itineraries, grouped in 17 geographical areas, are between 5 and 35 km long, each walkable in a single day, counting a total extension of 1,150 km. The routes vary in contexts crossed, lengths and altitude, meeting the preferences of different types of users, from experts to kids. A free downloadable guidebook has been published for each geographical area, as well as gpx tracks are available for free use. Along the routes, project signage, consisting in the traditional element of the *mojón* with the graphic symbol developed for the project, has been installed.
In 2005, a complementary project to *Descubre tus cañadas* was launched by the Community of Madrid: the *TRASHUMAD* project (González, J. A. M., 2011). Its main objective was to promote the regional transhumance routes among citizens to encourage their use as hiking and cycling itineraries.
Unlike *La Routo*, the *Descubre tus cañadas* project does not seem to have undertaken an ambitious multi-level and multi-sectoral strategy for the enhancement of the tangible and intangible transhumance heritage, since its focus is mainly on the accessibility and promotion of the routes as hiking trails. However, in a context such as Madrid, a metropolitan area inhabited by approximately 5,000,000 people, the importance of this purpose should not be underestimated. Equipping transhumance routes as public infrastructures for slow mobility embodies a concrete opportunity for a vast multitude of citizens to reconnect with the natural environment and with local history. This is all the more valuable in a context in which the demand for natural spaces at a short distance from the city is such that it has led to the overcrowding of the natural areas near the city. As an example, since 2021 the regional park of *La Pedriza*, north of Madrid, is no longer accessible to the public on holidays to reduce anthropic pressure on it.
So far, no data were found concerning the economic impact of the reconditioning of the Madrilenian sheep-track network as hiking and cycling routes. However, since these are usually one-day itineraries, accessible within 1-1,5 hours from the city centre, there are reasons to believe that typical users are proximity tourists. Thus, the economic impact is deemed to be limited, especially in those cases where routes do not cross towns or villages.

3.3 Tourism development along the sheep-tracks of Molise, Italy

In Italy, an important project is currently underway for the tourist development of the sheep-tracks in the Molise region, and in particular for the enhancement of six *tratturi*, two *bracci* and two *tratturelli* for a total of 325 km, distributed in 36 sections. The project also involves 59 municipalities, most of which are suffering from a marked depopulation process. The project, known by the acronym CIS (*Contratto Interistituzionale di Sviluppo*), is financed with

state funds with a total budget of more than 129,000,000 euro. Besides making the paths accessible and equipped, and connecting them with 77 historic villages, the project aims at creating ecological corridors for biodiversity along the routes by planting 40,500 new trees and maintaining 850 hectares of existing forest. The masterplan is currently being developed by an interdisciplinary group, being the planning part in charge of Stefano Boeri Architects.
The case of Molise cannot be fully analysed, as it is still at the planning stage. What stands out, however, is the ambitious scope of the project, its top-down genesis and the (so far) lack of involvement of local stakeholders, excepting municipalities.

3.4 Considerations on slow tourism routes along transhumance routes

The three examples illustrate very different approaches in tackling the enhancement of sheep-track networks as a tourist destination. The experience of *La Routo* shows how the continuous action over time of local actors, combined with strategic vision and synergies, can materialise complex projects, in which tourist use is one of the components of the economic and socio-cultural activation of the territory. In this case, the result was reached through a long process of stakeholder involvement at different levels and scales, from single pastures to cross-border vision.
The cases of the Community of Madrid and Molise share some features, since they both are top-down projects, and they both concern the enhancement of several transhumance routes in their regional territory, rather than a single itinerary. However, the two projects differ in several aspects. First of all, the potential users they aspire to catch: while in the case of Madrid users easily come from its extended metropolitan area, in the case of Molise potential proximity users are limited to the 300,000 inhabitants of the towns touched by the project; this implies that the aspired users are supposed to be mainly tourists coming from abroad. Another key aspect is time: while in the Madrid region the first actions for the enhancement of the sheep-track heritage were started as early as 1998, and the gestation process of *La Routo* lasted 20 years, for the CIS Molise project the timeframe for the design and implementation of the planned actions is extremely compressed, from 2023 to 2026. The economic resources are another aspect that makes the difference with the other cases: although the fundings used for the Spanish initiative are not known, and those of *La Routo* are only partially identified (Interreg V-A France-Italy ALCOTRA 2014 - 2020, among others), it is highly probable that they did not benefit from such a high budget as that of CIS Molise. Lastly, another key aspect is the involvement of stakeholders and the engagement of the local population, which in the case of Molise seems to be one of the most challenging aspects.

4. Conclusions

The growing attention to transhumance, proved by the proliferation of celebratory events and the spread of tourism development projects centred on the recovery of its routes, is an incentive to strengthen the tourism potential of the inner areas. However, the search for visibility and the ambitions of tourism development linked to a subject that has become topical, sometimes seem

to be pushing more towards promotional and celebratory activities than towards the preservation of the practice of transhumance and its heritage.

The experiences analysed show that territories are rapidly acquiring awareness of the potential of transhumance as an economic driver linked to tourism. Transhumance and its routes, however, constitute a heritage that may prove to be strategic in the development of inner areas, not only in terms of tourism, but also ecologically, economically and culturally activating. A territory in which transhumance is a living and tangible practice, with visible repercussions all year round, is able to propose a cultural, landscape and gastronomic offer that goes beyond the single event or the trekking path. These features make it more attractive in the eyes of users seeking quality tourism, and produces positive repercussions on local dynamics. Moreover, the historical and cultural uniqueness of transhumance routes, together with the multiple expressions of its economic value, are key aspects that distinguish a transhumance route from many other existing slow tourism routes.

As stated by Curci & Gaeta (2019), the challenge for the future of transhumance lies in restoring a territorial scene that allows pastoralism to positively accompany the presence of tourism without being reduced to mere folklore. In this direction, the growing multifunctionality of transhumance farms may constitute a drive towards responsible tourism and the green economy (Bindi et al., 2022).

Lastly, the interest and enthusiasm of a growing number of people towards transhumance is such that there is reason to believe that it could be converted into a trending niche, a 'transhumance tourism' that would lead travellers to discover events and routes on the theme around different contexts. This pushes the tourism development of transhumance to a next level: networking different regions and geographical areas that are united by this practice.

Abstract
This contribution refers to a cooperation between ENSA Paris-Belleville and University of Naples Federico II concerning the Build Back Better of the Italian hamlet of Sant'Eusanio Forconese that was struck by the 2009 earthquake.
Considering the complexity determined by the current multiple crises, the reconstruction process has to be rethought. Within these transformation processes and their corresponding temporalities, place-based academic activities – e.g., through living labs – merging together education, research and third mission can represent a tool for activating, boosting and guiding public engagement, strengthening networks and renovating policies. Since the "*Intervenir dans un territoire à risque: vulnérabilités, enjeux, opportunités*" workshop experience, universities will be proposed as game changers.

Keywords: Build Back Better, living-lab, territorial sustainability, third mission, time-based design.

Introduction

This contribution refers to a cooperation between ENSA Paris-Belleville (France) and University of Naples Federico II (Italy) started in 2023 and concerning the case study of Sant'Eusanio Forconese (L'Aquila, Italy). The activity focused on the Build Back Better of this Italian hamlet that was destroyed during the 2009 earthquake, a seismic event that struck 56 villages.
Both academic partners carry out research related to risks investigating the topic through a design-based approach to understand risks' repercussions in terms of landscape transformation – both in its material and immaterial dimensions – and operational innovation. Such an approach aims at a broader territorial sustainability that takes into account the multiple factors of crisis and especially the time parameter.
The paper in the first part outlines the crisis condition of the territorial system analysed in the research, describing the peculiar overlapping of crises that characterises the inner and marginal Italian territories also referring to a significant historical progression. Furthermore, with reference to two main post-disaster phases, the contribution will provide a synthetic institutional analysis aimed at describing the responsibilities and relationships of the various players involved. Finally, it highlights how the complex coexistence in space and time of multiple crises determines the need to rethink in both theoretical and operational terms the project within the post-disaster design. In this multi-crisis context, the needs to step back from the dominant techno-centric approach and to create opportunities for innovation arise with strength. In the second part, in the light of the framework previously outlined, the teaching and in-field research

experience – considered as an arena of innovation – carried out in Sant'Eusanio Forconese is presented in terms of methodology and outcomes. In the end, what has been mentioned above will be the material discussed in the theoretical and methodological proposal that is advanced in the third and final part of the contribution.

Which context? The definition of a peculiar geography of risk

The Italian territory and its history are atavistically marked by hazards, but more importantly, the relationship between progress, project and risk finds specific conditions of existence.

Moreover, the areas exposed to greater seismic risk in Italy are the Apennines, which constitute a complex territorial system in which infrastructure and urban settlements, with varying degrees of density and intensity, define ever-changing conditions of co-existence with a topography that varies its characteristics along the entire peninsula. In this sense, the classification of Italian municipalities proposed by the DAStU of the Politecnico di Milano is interesting, by means of 13 classes it interprets characteristics such as: the degree of rurality of the territories, with a gradient ranging from the most inner territories to the most urban ones; geo-morphological condition, identifying mountainous and coastal areas; and population density, from the most sparsely populated municipalities to the most densely populated metropolitan areas (Curci, Kërçuku, Lanzani and Zanfi, 2023). The classification proposed by the Politecnico di Milano enables a finer and broader reading of Italy's territorial polycentrism, which is by now constrained too much by the normative definition identified in the National Strategy for Inner Areas (Barca, Casavola and Lucatelli, 2014).

Indeed, it is becoming increasingly important to recognise that this territory corresponds to a multitude of landscapes, although the most common imagery is that of small hamlets (Barbera, Cerosimo and De Rossi, 2022) perched on hilltops or lying on slopes. Yet these more historic urban settlements are flanked by territories defined by: small and medium-sized enterprises, the largest industrial or productive landscapes, the urban sprawl of recent decades, the landscapes of illegal building and large non-places that have become cornerstones of the ever-expanding peri-urban. In these territories, social relations and communitarian interactions, the production of culture and quality of life, economic conditions and productive activities, the perception of distances and modes of travel, and the ways in which the territory is transformed and built are profoundly dissimilar to what we are used to experiencing in Italian cities. Although the idea of an inevitable concentration in metropolises that is beneficial to everyone still seems too common (Barca, 2018), the characters of exceptionality and difference referred to above are also a necessary premise in order to recognise in these territories resources and opportunities that have found in the Covid-19 pandemic an exceptional opportunity for new narratives (Fenu, 2020).

Within this complex system made up of large territorial disparities (Coppola, Del Fabbro, Lanzani, Pessina and Zanfi, 2021), particularly interesting for the research and educational activities to which this contribution refers is the trans-regional territorial system that has been hit several times by disastrous earthquakes in the last twenty years. Considering the earthquakes of the Umbro-Marchigiano Apennines in 1997, of L'Aquila in 2009, of Emilia Romagna in 2012 and of Central Italy in 2016, we have inherited – almost seamlessly from the Emilia Romagna region, in the north, to the Lazio region, in the south – a territory that still displays considerable traces of these events as much in the reconstruction sites as in the temporary heritages that still remain.

Furthermore, the fact that a large part of these territories lies in those project areas identified by the National Strategy for Inner Areas – defined by the lack of basic facilities such as education, health and infrastructures – renders the overlapping of a geography of risk with an Italian geography of physically inner and socio-economically marginal territories. In this sense, the disastrous seismic events that have followed one after the other have considerably aggravated

the crisis condition of the Italian internal landscapes (Guidoboni and Valenise, 2012). These phenomena have acted as accelerators of the depopulation processes that characterise these territories and have damaged – sometimes completely compromising – those material and immaterial heritages of which inner Italy is a rich witness. In this sense, the risk related to seismic phenomena in inner areas is increased by the general ageing and obsolescence of the built heritage – of which depopulation is a concomitant cause – which has as a direct consequence a condition of serious widespread vulnerability (Dolce *et al*., 2020).
Therefore, in this paper the territories described so far are observed through the lens of seismic risk, which is mainly investigated with reference to the two main phases of the territorial transformation: the early recovery phase, to which generally correspond temporary housing and equipment settlements, in its actual and potential relations with the long reconstruction processes of the heritage damaged or destroyed by the earthquake.

Central Italy: a land of disasters and multiscalar reconstructions
The multiplication of crises is exacerbated and therefore even more tangible in those territories where there has been a recurrence of the event in a short period of time. Moreover, this condition enhances the plurality of narratives that could contribute to defining the histories of these places and events. In cases of temporal recurrence and spatial proximity, there is an amplification of the possibility of getting the same story by adopting the point of view of multiple actors (inhabitants, municipal administrations, representatives of national institutions, etc.). This is useful in order to compare, on the one hand, the processes and projects carried out, and on the other, the relationship of stakeholders with the inequalities and disparities that the emergency condition determines or exacerbates by suddenly questioning previous balances. So, we will mainly consider the earthquakes of 1997, 2009 and 2016 and then outline an institutional analysis in relation to the last two.
Following the earthquake that struck the Umbro-Marchigiano Apennines in 1997, the Civil Protection promptly mobilized in the first emergency phase, being able to rely also on a considerable number of volunteers who reached the affected areas. Yet the vulnerability of the historic buildings, on the one hand, and the settlement pulverization, on the other, were elements that put a strain on the early recovery phase for the provision of mobile housing modules such as prefabricated shelters and containers to that part of the population that did not have habitable housing anymore. This condition was made even more complex by the desire not to uproot communities from their places of belonging, which on the other hand represented an important psychological advantage for those affected by the loss of their homes that are places of individual memory and family life, but also a basic economic value (Guidoboni and Valenise, 2012). It is also considered significant that during the 1997 earthquake, for the first time, technical guidelines were provided for the realization of the urbanization works of housing settlements understood as urban systems capable of ensuring the reconstitution of the primary functions necessary for communities: for the first time, in order to reduce the vulnerability of urban systems, it was decided to intervene in an integrated way on entire parts of cities (Imbroglini, 2018). Ultimately, on the 1997 earthquake, Guidoboni states: "the form of housing assistance provided was internationally unsurpassed in terms of implementation time, scale and quality" (Guidoboni and Valenise, 2012, p. 374).
On the occasion of the earthquake of 6 April 2009, the largest number of damaged buildings and victims was in the historic centre of L'Aquila, the capital of the Abruzzo region. The Civil Protection Department on this occasion demonstrated great speed in the first aid operations and in the temporary accommodation of the evacuees. On 28 April 2009, the government issued Decree-Law No. 39, which was followed by the allocation of 14 billion 767 million euro for reconstruction – estimated in 10 years – of which about 1/3 for the reconstruction of private buildings and 2/3 for public buildings (Guidoboni and Valenise, 2012). Besides the

management of temporary housing solutions in the tent camps set up, in hotel facilities or in accommodation outside the province, the government financed the C.A.S.E. project (Complessi Antisismici Sostenibili ed Ecocompatibili) with 792 million euro, through which 185 buildings were to be built. These high-quality residential buildings constructed in record time housed more than 12,000 people at the end of January 2010. The post-earthquake emergency was tackled in an unprecedented way by proposing a huge program of new constructions to be completed within the emergency timeframe, these buildings were neither temporary nor permanent but a strange combination of the two (Bassoli, 2010). At the same time, approximately 2,300 inhabitants were relocated in 3,535 wooden houses (Dolce, 2010) built on 141 sites by the M.A.P. (Moduli Abitativi Provvisori) programme, conceived for the purpose of providing temporary housing mainly in small towns outside the municipality of L'Aquila, i.e. villages located in the inner and marginal territories mentioned above. Despite the considerable means and resources employed to address the problem of housing security, due to the mass relocation of the inhabitants, community and work relationships were compromised because the problems of housing continuity and the recomposition of urban life, which is the objective of any reconstruction, were not specifically addressed (Guidoboni and Valenise, 2012). Moreover, the fate of the inhabitants and of that huge programme of new construction completed in record emergency time remains uncertain. These settlements have become a public housing stock that contributes to a public debt that increases year by year. Because of this, and confirming the centrality of the polycritical scenario in which we are immersed, it is interesting to highlight how, through funding allocated under the NRRP (National Recovery and Resilience Plan) following Covid-19 pandemic, possible redevelopment strategies are being outlined for this heritage.

The seismic swarm that occurred between August 2016 and January 2017 affected a wide area, leaving traces in a territory divided between the regions of Abruzzo, Lazio, Marche and Umbria. On this occasion, since the beginning of the emergency phase, the DPC has operated in order to make the evacuees stay as little time as possible inside the tent camps, although due to the perduring seismic phenomenon and the increasingly critical weather conditions, the scenario has progressively become more complicated. To this end, alternative temporary housing solutions were immediately identified: a contribution for people finding a new accommodation on their own (C.A.S. – Contributo per Autonoma Sistemazione), hospitality in hotel and public facilities and the use of empty or underused houses and public assets (Della Valle and Romania, 2019). The housing solutions implemented in the emergency relief phase were followed by the provision of S.A.E. (Soluzioni Abitative d'Emergenza) in favour of citizens previously living in destroyed or seriously damaged and therefore uninhabitable houses.

Starting from these intricate histories of reconstructions and temporariness, it is possible on the one hand to detect advances and trends in terms of planning and processes and on the other hand to identify some municipalities affected during more than one event, determining the coexistence or reuse of temporary solutions from different periods and the overlapping of reconstructive processes.

Central Italy: a plurality of projects, a complex normative framework and networks of experts

In the framework of an analysis of the institutions involved, it is first of all fundamental to clarify that the main post-earthquake design interventions – the provision of temporary housing in the early recovery phase and the reconstruction – in Italy involve different processes, times and actors. In Italy, the provision of temporary post-earthquake housing solutions is a task of the State and is part of the duties of the Civil Protection Department (DPC) – a structure of the Presidency of the Council of Ministers – responsible for managing not only the emergency relief phase but also the early recovery phase. Instead, reconstruction is managed by special

offices in charge through the promulgation of emergency law decrees that follow the occurrence of damage.

The Civil Protection Department acts in accordance with the Civil Protection Code introduced by Legislative Decree No. 1 of January 2, 2018. Six offices with specific tasks and competences report to the Head and Deputy Head of Department. Office III 'Planning and emergency infrastructure interventions' is the one that mainly deals with projects and processes related to temporary facility provision. In addition, various Centres of Expertise deal with specific topics providing services, data, elaborations and technical-scientific contributions in specific fields.

Concerning the M.A.P. project, the supply of the residential units was assigned by the DPC to five companies that won the public tender launched after the earthquake, while the urbanisation works were managed by the municipalities of the earthquake area. Also because of this double assignment of responsibilities, on the one hand, there was a widespread condition of degradation of residential buildings due to inadequate technical and design choices, and on the other hand, at the urban and landscape scale, the interventions turned out to be in most cases unsuitable to determine any form of urbanity, sometimes even compromising the urban systems concerned due to their not effective temporariness.

The S.A.E. residential units, on the other hand, were the object of a call for tenders issued by Consip – on 9 April 2014, therefore in peacetime differently from the M.A.P. programme – which in the framework of a 6-year Framework Agreement established a set of organisational procedures, standards and technical characteristics for the supply of post-disaster temporary housing. The DPC was in charge of selecting the economic operators to be commissioned for the supply of up to 18000 temporary shelters throughout the country and for an estimated value of EUR 1.2 billion. In addition to the supply, transport and assembly of the S.A.E. modules requested by the local authorities, the selected economic operators were required to define the settlement layouts and executive projects of the urbanisation works of the areas – proposed by local authorities – and the foundations on which to install the housing units (Oggioni, Chelleri and Forino, 2019).

From these two recent Italian experiences in emergency management, it can be positively deduced that the approach and strategies identified in 2016 have successfully addressed some of the failures that occurred in the system proposed in response to the 2009 emergency. In fact, on the one hand, a considerable improvement in the technical and architectural quality of the houses provided under the S.A.E. programme can be observed – apart from specific design faults in some of the realised projects – and a major procedural change in the allocation of urbanisation works and residential modules to a single actor can be detected. Although, on the other hand, the neglect concerning the provision of public spaces and the urban quality of the settlements, the failure to relate them to the pre-existing urban structures, and the lack of foreshadowing of possible future scenarios in which these assets do not become waste but resources has remained almost unchanged.

Currently, the DPC, by means of Consip, has a Framework Agreement for emergency housing solutions that in case of disaster will be implemented by the company that won the tender.

One of the main distinctions that can be drawn between the emergency relief phase managed by the DPC and the reconstruction phase – which is instead the responsibility of regional and municipal authorities – is the relationship with the communities. In the emergency relief phase following the disaster, the community is a passive actor receiving support and assistance provided by the DPC, while during the reconstruction phase the local authorities work – in the most virtuous cases, even in peacetime – to structure a vision, i.e. a strategic policy oriented towards the definition of a shared scenario that is more or less predictable. This foresight work – which often matches prevention work – outlines political strategies that increasingly involve participatory practices in which communities are challenged to be active participants in decision-making processes. In this context, there is an intermediate phase – the phase of early

recovery – in which the approach is unclear; the approach described in reference to the emergency relief phase frequently recurs, i.e. the population is subjected to the decision-maker's choices without contributing to the definition of any shared vision. Yet, having now ascertained with a retrospective view that the phase distinguished by the provision of temporary post-emergency buildings is far removed from the concept of temporariness – increasingly tending towards permanence – in the early recovery phase it would be necessary to adopt an approach more similar to that of reconstruction than to the one of emergency relief. In this sense, the need to negotiate the maximisation of the speed of decision-making processes with the ability to assist a collective and strategic vision of future developments is evident (Oggioni, Chelleri and Forino, 2019). Towards this same direction, the new Civil Protection Code also identifies as a strategic objective of the Department the increase of intersections between ordinary planning and prevention.

Furthermore, the endowment of temporary structures should also be reconsidered in relation to a more synergic and balanced interplay with other measures used during the 2016 earthquake – such as the *Contributo di Autonoma Sistemazione* (C.A.S.) or the temporary use of disused buildings – to be proportioned according to the urban, social and economic specificities of the different contexts affected by the disaster. This desirable interplay of means would first of all foresee a profitable interaction between bodies and strategic actions as well as an interconnection between crises (for instance, the phenomenon of abandonment in the inner and marginal Italian territories) that could represent useful premises for the construction of future scenarios of territorial sustainability.

Instead, the reconstruction phase is managed with a multilevel central governance structure with strong cooperation of the state, regions and municipalities. With reference to the 2016 earthquake, the Extraordinary Commissioner of the government for the repair, reconstruction, assistance to the population and economic recovery of the territories of the regions of Abruzzo, Lazio, Marche and Umbria establishes the overall damage situation and estimates the related financial needs, coordinates the reconstruction and repair of buildings, oversees the support activities for businesses located in the affected territories and the recovery of the socio-economic fabric in the areas affected by the earthquakes, and promotes the implementation of seismic microzoning for the municipalities concerned. Moreover, as a result of the above-mentioned polycritical condition, the Extraordinary Commissioner is entrusted with functions and tasks on the Urgent Measures related to the National Plan for Complementary Investments to the NRRP. In tandem with the Extraordinary Commissioner, the four affected regions have established as many Special Offices to ensure the joint exercise of functions, activities and services in the affected areas. The objective of the special regional offices is to ensure, in agreement with the National Commissioner, that the reconstruction activity is effective and is based on cost-effectiveness and efficiency principles.

In conclusion, these processes and projects bear witness to a long-standing Italian history in the field of post-disaster design – in the broadest sense – consisting of successive verifications and refinements. What emerges is a great competence that certainly sees in the National Civil Protection Department an excellence and in the special offices for reconstruction progressive experiments that reinforce the strength of approaches and processes. In addition, the rootedness of an experimental and evolved technocentric approach, among the most up-to-date in the world, is evident.

At the same time, our intention is to focus on three aspects that are becoming increasingly important and central: the multiple timeframes of the actions implemented and the different temporalities of the institutional and political actors involved in these complex processes is crucial; the complexity of multi-critical scenarios becoming increasingly undeniable determines a necessary questioning of intervention processes and practices due to multiple timeframes and complex challenges; the intertwining and overlapping of policies and funds requires more

rooted and elastic strategic visions that valorise potentialities and projects related to territories and communities.

The USRC: a possible trigger for a game change

In the light of the above, considering the complexity determined by these multiple crises – both local and global – the reconstruction process cannot be considered as a mere reconstruction of the destroyed heritage.

In this sense, the general approach and the procedures developed by the Special Office for the Reconstruction of the Crater Municipalities (USRC - *Ufficio Speciale per la Ricostruzione dei Comuni del Cratere*) constitute a good practice centred on a broader idea of urban regeneration and territorial development, both for the valorisation of local resources and for the strengthening of communities and social relations.

The USRC was established (by Law 134 of 7 August 2012) in December 2012 and has been operating since April 2013. Its establishment followed the end of the state of emergency that arose after the earthquake of 6 April 2009. The USRC supports municipalities in drawing up Reconstruction Plans and provides technical assistance for public and private reconstruction, promotes its quality and carries out financial monitoring. Under the jurisdiction of the USRC are the 56 municipalities in the seismic crater (except for the city of L'Aquila, which is under the jurisdiction of the Special Office for the Reconstruction of L'Aquila) and the more than 100 municipalities outside the crater.

The specific interest for the USRC lies in two interconnected factors: the time gap from the disastrous phenomenon in reference to which it operates and the interpretation it provides of the reconstructive act in terms of sustainable territorial development.

Indeed, in contrast to the sharp fragmentation of competences and temporalities of intervention described above, the USRC is an innovative actor that is currently experimenting with operational methods through which it can build bridges with possible future scenarios.

The innovative experimentations that the USRC is conducting are rooted in the desire and effort to look towards the end of reconstructive processes by attempting to interpret with a systemic approach the multiple crises that the territories in which it works are going through. The assumption underlying the work carried out by the USRC seems to be the belief in the need to operate in the territories, where managing local change has become more challenging, nuanced, and intricate.

Within this approach, the USRC pays considerable attention to the need to improve urban quality, first of all by rethinking the public spaces of the villages under reconstruction and therefore the relationships between inhabitants, where this category should be reconsidered as a system of multiple social groups that will live these territories within different temporalities. In fact, the involvement of the inhabitants in the reconstruction processes is crucial in order to increase both a culture of inhabiting and a culture of risk. Both require a conscious and updated local culture of the territories to be rethought in the new post-disaster geographies.

In particular, an interesting device identified to frame urban regeneration projects is the definition of four cultural, thematic and historical Routes (*Cammino dei Francescani, Cammino tra i Vestini, Cammino della Baronia, Cammino Grande di Celestino*). This territorial revitalisation strategy is of great interest for two main reasons. First of all, through the device of the route – that is par excellence a way to appropriate and understand the territory – the USRC seeks tangible and intangible connections with other territories not damaged by the earthquake, and this means the construction of new narratives that transcend risk while addressing it. Secondly, the history and actuality of these places are addressed, reinterpreting them within a contemporary relational system that becomes an opportunity for community building through collaborative methods envisaging participatory processes aimed at analysing and discussing the inhabitants' needs and dreams in order to define sustainable future prospects.

These processes are fostering and triggering the cooperation of actors who were previously not in dialogue, tending towards the overcoming of a mere technical approach and a disconnected sequence of interventions whose temporalities failed to define fruitful synergies.
In this sense, the public sphere and market actors are reconnecting, also leading to an enhancement of the material and immaterial heritage of local communities and an increase of their skills and potential (e.g., in terms of ecological transition or ability to attract and manage funding). However, urban growth and redevelopment often conceal unsustainable social and environmental costs. More and more people are calling for an approach that rebalances urban ecosystems and rebuilds the natural environment. Therefore, the need to rethink design in both theoretical and operational terms in post-disaster planning becomes evident.

The Academic Franco-Italian Partnership: an urban innovation arena

Nowadays, Sant'Eusanio Forconese (AQ) is pursuing the reconstruction process, representing a good practice – among the 56 affected villages under the jurisdiction of the USRC – in terms of the percentage of private housing rebuilt. Although, in addition to the Covid-19 pandemic, which has represented a dramatic event worldwide increasing social and economic vulnerabilities, other phenomena such as depopulation – a typical characteristic of the Italian marginal and inner areas – are overlapping with the crisis caused by the earthquake.
Whitin this complex scenario, following the Covid-19 pandemic, Italy has been the recipient of "National Recovery and Resilience Plan" funds. In this framework, the municipality of Sant'Eusanio Forconese had the opportunity to implement a design proposal for a strategic building on the site of a former school that coincides almost perfectly with the barycentre of the new urban system configured by both historical and "temporary" settlement. This project demand became the premise for the international, transdisciplinary and place-based academic collaboration we are referring to. The teaching and in-field research experience conducted in the municipality of Sant'Eusanio Forconese is presented in terms of methodology and outcomes, and referring to the several stages in which it has been structured.

- A week-long in situ workshop involving many different stakeholders.

The philosophy behind this academic initiative is to provide an arena for meetings and debates between different stakeholders. Each speaker was invited to give his interpretation of the challenges and vulnerabilities of the Italian territory. The operational experts involved in emergency management following the 2009 earthquake and the reconstruction stakeholders introduced in the previous part of the article presented their projects and discussed them. The participation of researchers in risk management, architecture and the human and social sciences helped to consolidate expert knowledge of the area, and also to take a reflexive view on preconceptions and implemented projects.
Organizing the workshop in situ is a fundamental principle of this initiative. The territory is seen as a player in its own way. Living in the area for the period of the workshop enables students and professors to take account of the multiple realities that coexist. The inhabitants of the villages and their administrators, the existing architecture (of different typologies), the natural ecosystems, the infrastructures and networks make up a mosaic of humans and non-humans that is occasionally undermined by seismic hazards. The representations of these various actors impose multiple temporal and spatial considerations that must be taken into account when thinking about the Italian inner areas.
At this stage of the workshop, the technical, social and sensitive aspects are documented by the student architects taking part at the workshop. Also, some debates are organized with the speakers to give a better account of existing realities and to break down prejudices and any cultural, technical or social ethnocentrism.

- Development of projects in France and Italy and feedback on students' projects from stakeholders in the field to help them reflect on the issues at stake.

The aim of this workshop was to propose projects concerning a "strategic building" on a site suggested by the Sant'Eusanio Forconese village council.
In the framework of this initiative based on the collaboration of two academic teams and the participation of students from two different European institutions, the discovery of the case study and the project site is essential as the approach is based on the specific features of the local area.
A series of projects are proposed following the diagnostic phase developed during the stay in Sant'Eusanio Forconese. On the one hand, these projects question the temporalities of the site in relation to the temporalities of the natural territory (e.g. the seasons), those of human activities (e.g. transhumance) and those of seismic hazards (crisis, prevention and reconstruction). On the other hand, spatial scales are also questioned and challenged: is the project on the scale of a plot, of the village of Sant'Eusanio Forconese, or of a network of villages in the Crater? In this way, the projects question the predefined perimeters of action to propose a new perspective on the challenges and vulnerabilities of the territory. According to these two main topics – the interpretation of time and space – architectural media has being questioned while the use of Art has made it possible to express the multiple sensitivities of humans and non-humans. In this sense, connections have been established between the various narratives of other territories inhabited by the participating students: inhabiting a risky or unsettled territory becomes a kind of shared common heritage. The presence of humans in their ecosystem is questioned. The act of building, discussed by Martin Heidegger (1958) in terms of building, living, being and caring, is at the heart of the discussions on the proposed projects. Finally, the discussion and comparison of projects conceived in the academic context with the expertise of professionals generates very interesting debates around standards, funding, technical possibilities and climatic and environmental issues, and more generally about the contemporary idea of inhabiting. In this sense, the strategic buildings projects developed propose multiple narratives of the area no longer restricted to disaster management.
In conclusion, since this European academic experience, several concepts can be discussed and developed further:
- The project as a medium for consultation viewed through different timeframes;
- The need for a new narrative of the territory and a renewal of approaches to concertation, which must involve citizens more as active players in their resilience, without depriving the city's political players and managers of their missions and prerogatives. This new narrative must also take account of existing architectural and urban typologies, and go hand in hand with a re-examination of the act of planning, to include natural ecosystems as active fundamental components rather than as a support object for territorial planning.
- Taking care of the site: the humans and non-humans who structure it should be the leitmotiv of a Build Back Better approach to this Italian territory. Reflections on the regeneration of nature and also on the socio-economic resources of the inhabitants should therefore be at the heart of the project. In this sense, deconstruction can be an approach for better territorial and social constructions, since it tends to allow the regeneration of nature on sites that are no longer suitable for construction.

Conclusions: the university as a possible game changer

In this multi-risk Italian context, which challenges us with the spatial and temporal complexity of the issues and vulnerabilities, how can universities contribute to questioning approaches to risk management and territorial reconstruction?
Through a multi-disciplinary academic approach, the university aims to create arenas that challenge the dominant technocentric approaches by bringing together a variety of stakeholders, enabling them to share their expertise and take part in the process of intervening in the area (political players, economic players, planning professionals and, lastly, local residents).

In addition, through a European university partnership, this academic approach creates levers for concerted action and for taking a critical view of prejudices and preconceptions about the studied areas. Thus, by playing the role of mediator, the university is contributing to a renewal of questions about reconstruction, risk management and planning.
In conclusion, universities can play a central role as game changers. Within the transformation processes inherent to contemporary transitional landscapes concerned by multiple heritages and their corresponding temporalities, place-based academic activities – e.g., through living labs – merging together education, research and third mission can represent a tool for activating, boosting and guiding public engagement, strengthening networks and renovating policies.

Abstract

This paper explores the importance of urban health in contemporary urban planning. It aims to address the question on how planners can actively contribute to knowledge and practices related to urban health, promoting equality and equity in future cities through empowerment and participation. The study analyses the strategies and initial steps of the method used by E-city, a long-term university program at the University Paris-Est Creteil since 2020. Focusing on intersectionality dynamics in planning and urban health from interviews with project leaders and professionals, survey data, and participation observation, valuable lessons from the E-City program aim to inspire a new generation of planners committed to intersectional approaches to urban health planning.

Keywords: intersectionality, pro-equity, urban justice, uncertainty experimentation

Introduction

The focus on empowerment and participation in urban planning is increasingly crucial for fostering more sustainable, liveable, and healthy cities. Pressing issues such as climate change, environmental hazards, emissions, pollution, international conflicts, and global disparities have brought attention to existing urban challenges such as isolation, stigma, and poverty cycles, exacerbating the adverse impact on urban environments. The COVID-19 pandemic has highlighted urban health as a critical concern, exposing intricate social, environmental, and economic discrepancies and inequalities in urban areas and among their inhabitants (Williams et al., 2023). Urban experts have stressed the need to incorporate comprehensive approaches to urban health into urban planning. This is crucial for advancing our understanding of the social determinants of sustainable development goals (Ramirez-Rubio et al., 2019), gaining insights into subjective well-being within the built environment (Mouratidis, 2021), and supporting the lasting inclusive development of communities (Mohamed et al., 2020).
The paper addresses these gaps by explicitly acknowledging urban health in urban planning, beyond providing health care services (Ramirez-Rubio et al., 2019). The main research question is how planners can actively contribute to knowledge and practices concerning urban health, bringing urban equality and equity to future cities. By highlighting empowerment and participation as critical elements, this paper introduces an innovative framework that inspires

planners to adopt a pro-equity approach in thinking and acting for future healthy, sustainable, and just cities.

The paper establishes an intersectional framework that combines empowerment and participation to planning theory and urban health reserach. Both strands of research acknowledge stakeholder engagement and the existence of multiple and conflicting knowledge claims while emphasising the importance of nurturing 'active subjects' capable of taking ownership of their situation and conditions. Patsy Healey's concept that 'planning practices have the potential to shape not just the physical qualities of places but their political ambience' (Healey, 2008, p. 380) prompts consideration of planning communicative rationalities that promote 'empowerment' through participatory democracy (Healey, 1997).

Empowerment and participation are crucial in discussions about sustainable development and urban health (WHO Regional Office for Europe, 2002). These strategies not only help to resolve conflicts and build consensus but also make people feel involved and heard, empowering them to experiment with changes and perceive the impact of their actions on their everyday lives. Empowerment and participation are essential not only for legitimising processes but also for integrating local knowledge into specific policies for different groups and contexts, fostering a sense of ownership over issues related to the quality of places and social conditions. Although uneven power dynamics can influence planning processes (Bailey, 2010), it is essential to recognise that planning is never neutral. Urban health, therefore, plays a crucial role in fostering active participation and shaping governance spaces at the centre of planning for sustainable, healthy, and just cities (Foley, 1997; Campbell, 2018).

The paper presents a novel approach to urban health planning, and delves into the E-City program, an initiative launched by the University Paris-Est Creteil University in 2020, with a planned duration of a decade. The program aims to comprehend social inequalities in urban health and their determinants within the French/Parisian/Ile-de-France context through a cohort of university students. Additionally, it seeks to function as an incubator of urban actions. The paper's primary focus is to scrutinise issues of empowerment and participation from an intersectional perspective, utilising a qualitative interpretation of the E-City method. Findings derives from engaging in focus group meetings, conducting interviews with proponents and professionals of the program, interviewing project leaders, collecting insights from student surveys, and participation observation.

The E-City program activates a young generation of students, giving feedback on the service campus and municipalities to expand local knowledge and support and empower a new generation of ambassadors and a new generation of intersectoral planners. The paper concludes by drawing lessons from the ongoing progress of the E-city program on the complexity of interactive governance forms, interdisciplinarity and transdisciplinary dynamics with academia, governmental, and professional institutions. Planning needs to face many uncertainties over the unpredictability of complete knowledge over the future (Pløger, 2023; Lissandrello et al., 2023) hopefully leaving "no one behind" (UN Agenda, 2030).

Theoretical Framework

'And if so, what is the hope that a more participative model can address the challenges of promoting more liveable and sustainable urban places for the many and not just the few?' (Healey, 2008: 379)

Empowerment and participation in planning

In planning, the issue of empowerment and participation has been a long-lasting issue since the 1960s. It concerns public involvement, advocacy and collaborative planning, and inclusive

partnerships. Participation has various meanings and processes that lead to citizen control (Arnstein, 1969), but not all can be considered empowering. However, collaborative and deliberative planning theories consider empowerment and participation as essential processes linked to power dynamics for collective and social intelligence. Empowerment is, therefore, a social learning process valuable for advancing a critical participatory democracy (Foley, 1997) and occurs *through* the planning process (Healey, 1997; Forester 1999). By involving citizens in deliberative forums, citizens can express different expectations, awaken open possibilities for new planning practices (Booher, 2008), and create arenas by bringing voices to monitor formal government actions (Kam Ng, 2008). As urban futures cannot be predicted (Albrechts, 2008) or 'owned' (Pløger, 2023), the engagement of citizens in the imaginative work of the future is essential to create common imaginaries of wishful urban futures. Recognising and valuing diversity is a crucial prerequisite for finding solutions that reflect people's needs and moving towards urban justice, equality and equity (Perrons & Skyers, 2003).

The formation of collective intelligence and the opportunity for citizens to be heard through the planning process remain still controversial. Participation and empowerment depend on the ability of citizens and communities to have a voice, be heard, and turn their voices into opportunities for action. In other words, empowerment and participation depend on methods of public engagement, often strongly influenced by the opportunities of institutional design within governance practices (Torfing & Sørensen, 2008). While empowerment and participation have been long integrated into a planning vocabulary in procedures and routinised planning practice in European and Western cities and countries, performing participation and dealing with empowerment still suffer from unequal and exclusionary conditions (Petersen, 2008). Although local government policy documents and strategies, as well as global institutions, embrace participation and empowerment as principles, citizens too often remain outside the decision-making arena at the local level. The issue of redistributing resources and acknowledging the need for fairness and equal opportunities is often overlooked. As a result, solutions to create more equitable urban policies and sustainable cities are often ineffective. Additionally, the current planning mindset tends to maintain existing power imbalances and exclusion, which is a significant challenge to overcome.

Contemporary urban society sectoral policies such as energy, mobility and nature-based solutions continue to be dominated by a techno-democracy embodied in narrow ideals of 'good' citizenship (Roy & Neveu, 2023) and more often lead questions on social acceptability (Warren et al., 2012) of pro-environmental behaviours for critical policies to twist into a 'corrective' individual behaviour – in the morality our common future (World Commission on Environment and Development,1987). However, urban planning concerns the nexus of complexity in which urban environmental exposure, the quality and affordability of housing, the opportunities for transportation networks, green and public spaces, socio-economic services, urban communities' identity. Urban change depends, therefore, on complex dynamics – not only planning decisions or governmental authorities alone – but on what often are framed by the theory of change (e.g. Popay, 2010): the system interaction of individual behaviours, routinised social practice and structural and institutional regulation and dynamics of change on multiple levels and temporalities (Geels & Turnheim, 2022; Lissandrello, 2020). The dynamics of empowerment and participation in planning for more agonistic deliberative democracy (Mouffe, 1999) entail consistently challenging the political community by considering when and how planners and urban managers should revitalise or support protests or pacify troubled situations. There is a concern that claims for empowerment and participation may replicate a managerial "business as usual" approach, which limits the space for agonistic forms of democratic practice and intersectionality. Empowerment is a necessary social learning process for promoting critical participatory democracy and revolve around the fundamental concept of "working on problems with people" to bolster democratic processes (Foley, 1997; Forester, 1999).

Empowerment and participation in urban health

Empowerment and participation have been central concepts in urban health research and policies (WHO, 1986). Since the United Nations Conference on Environment and Development (1992), the concept that health actions should be carried out by and with people rather than on or to people. This concept involves enabling people to actively participate in defining the issues that concern them, making decisions about factors that affect their lives, formulating and implementing policies, planning, developing and delivering services, and taking action to achieve change (WHO Regional Office for Europe, 2002). In the field of public health, the implementation of no-smoking policies in the 2000s showed that government-led decision-making, also known as 'top-down' policy interventions or 'control over', effectively addressed complex issues like protecting the health of all citizens. The COVID-19 pandemic has highlighted the critical and complex nature of public health issues, with a high degree of uncertainty about future unforeseen impacts. Addressing this uncertainty and ensuring the effectiveness of health policies requires a collective commitment from all of society. In response to the challenges posed by the COVID-19 pandemic, communities have proactively devised autonomous measures to address the uncertainties and enduring impacts of prolonged isolation, remote work, and mobility constraints. This situation has manifested in the form of community-driven solidarity initiatives. A noteworthy observation is that uncertainty can catalyse heightened awareness and empowerment. For instance, localised endeavours have surfaced amid the pandemic to promote mutual assistance by sharing facilities and spaces. Furthermore, utilising public spaces has transformed the pandemic, expediting implementing tactical urbanism projects, such as temporary bicycle lanes, street-level terraces, and urban gardening.

In the context of change management, planners and urban managers must mitigate change's disproportionate impact on underprivileged communities. Therefore, urban planners and managers must ensure that these already disadvantaged communities are not unfairly burdened with the added challenges that come with change. The essential aspects of empowerment and participation in urban health policies involve defining and implementing techniques to promote good local governance (Carly, 2003), effective community participation, and support of disadvantaged communities through social capital and capacity-building. Studies have shown that health promotion is now seen as a form of empowerment in itself (Amdam, 2010). According to Ramirez-Rubio et al. (2019), cities are experiencing significant demographic and epidemiological changes, leading to substantial health inequalities, such as segregation by social class, gender, age, or ethnicity within or among city neighbourhoods. Therefore, urban health is a crucial issue that plays a fundamental role in guiding the UN's sustainable development goals, particularly in issues related to empowerment and participation, which have long been discussed by the World Health Organization (WHO) and the European WHO Healthy Cities initiatives.

According to the WHO, behaviour change involves the organisational behaviours of intermediaries, including leadership, agenda setting, policy formulation, adaptive management, network formulation, innovation, teamwork, and implementation at strategic, tactical, and operational levels. However, most existing literature on empowerment and participation in community involvement comes from Europe and other high-income countries. Community participation and empowerment have evolved from specific ad-hoc or occasional events to an integrated strategic component that significantly influences the health-related sustainability issues in urban development (Scriven et al., 2023). The need to build participatory community networks and, specifically, to empower socially excluded people must be addressed in urban health. There are increasing and well-founded concerns that participation in urban health is

often a superficial 'tick box' process in which unequal power relations remain unaddressed, compromising the potential of participatory processes to achieve more significant equity and justice (Egid et al., 2021). It is crucial to consider reflexivity when engaging in critical discussions about the roles of stakeholders about privilege and power and how these roles impact urban health research and practice. Popay (2010) proposed the theory of change in urban health, outlining four approaches involving individuals, social practices, and system change in empowerment and participation: informing, consultation, co-production, and community control.

Urban health planning: An intersectional approach to empowerment and participation

The COVID-19 pandemic has highlighted the importance of urban health in urban planning, providing valuable insights to improve urban preparedness, adaptability, and resilience during emergencies. However, current planning theory and practice still need to consider urban health from an intersectional perspective. Planning theory and urban health research shares similar concerns on empowerment and participation, but from different ontological and epistemological perspectives (Pineo et al., 2020) that reflect the division between natural and social sciences, such as positivism and social constructivism. Scholars have highlighted the diversity of goals, values (Lee & Zarowsky, 2015), and ethics (Campbell & Marshall, 2002) among those who aim to "reduce suffering and improve health" and those who instead manage change in urban environments. However, the dynamics of power are a common point of intersectionality. In both planning theory and urban health, positions of power (such as planners and health practitioners) and those seeking empowerment (like citizens and clients) must work together to establish the conditions needed for empowerment (Laverack, 2006). An inspiring aspect is that both planning theory and urban health research have emphasised that — practitioners (must) act as advocates, enablers and catalysts for empowerment. Participation and empowerment require a synergistic interaction between individual empowerment, organisational empowerment, and broader social and political actions (Laverack, 2006, p. 36).
Urban health research views public participation not as a 'ladder' (Arnstein, 1969) but as a 'wheel' of participation (Davidson, 1998) and emphasises the ongoing collaboration across institutions, encompassing the responsibilities of actions ("top-down") and the empowerment of citizens and communities to take action ("bottom-up"). This approach intertwines health, well-being, and sustainable development with urban societal equity and equality (Dooris & Heritage, 2013). Creating intersectionality between planning theory and urban health research involves integrating ideas such as advocacy and communicative planning (Innes & Booher, 2010) to address social and health inequities in cities (Williams, 2020) and adopting a "relational, health equity-oriented approach to planning" (Corburn et al., 2015, p. 267). This approach enables planners to evaluate the prevailing values and assumptions (Collins, 2000; Fincher & Jacobs, 1998; Sandercock, 1998, 2000; Williams, 2020). The active involvement of the public, particularly vulnerable groups, in planning processes can effectively reduce inequalities and enhance social cohesion. This approach, known as an empowerment strategy, is closely tied to social justice. In this context, social justice aims to ensure equitable access to resources and rights for all social groups. When applied to urban health planning should enhance the active role of citizens in producing, reproducing, and representing urban spaces as socio-spatial processes (Soja, 2013) within a specific urban socio-economic context.
Urban health planning is here considered a lens to uncover urban gentrification and the segregation of specific urban areas, focus on how urban planning can enhance urban health impacts without perpetuating social and urban disparities and recognise that proximity does not always guarantee accessibility (Glock & Gerlach, 2023).

The E-City Program

The E-city program, established in 2020 with an envisioned lifetime of a decade, focuses on understanding the social and environmental factors that affect population health in urban areas. The program aims to investigate social inequalities in urban health and their determinants. Urban health is a significant and complex topic that has been widely acknowledged. It involves individual behaviour but goes beyond behavioural changes and includes values, equity, and social justice issues. The E-city program has established four main objectives since its inception. The first objective is to improve the quantity and quality of existing public health data. Often, data exist but are too fragmented, dispersed across several authorities, institutions, and organisations, and temporarily gathered according to projects and may only be partially utilised.

Public health data are vulnerable because they can quickly become outdated when studying urban health equity and equality. Therefore, the program's primary focus is to build a database that specifically addresses these questions, serving as a tool to collect and exchange data and regularly monitor them. This approach aims to empower individuals and communities by giving them control and understanding over their data. The second objective of the E-city program is to create the conditions for advancing interdisciplinary knowledge in urban health research. The study of urban health involves various research fields coming together to comprehend the impact of the urban environment on health.

Some directions in urban health research are exploring different factors that affect health in urban areas, identifying potential ways to improve health, and understanding the various influences on health in cities, such as environmental, social, and lifestyle factors, as well as integrating knowledge from various fields such as medicine, environmental science, natural sciences, data analysis, humanities, and social sciences. Urban health research considers different viewpoints to tackle complex urban health challenges. The third objective is to create a transdisciplinary approach that can serve as a tool for political decision-making. Understanding urban health dynamics can help shape public policies that are more value-driven, equitable, and just by informing ongoing monitoring and diagnosis that can influence urban planning and the testing and development of solutions. The E-City program integrates urban space and environmental quality with health concerns.

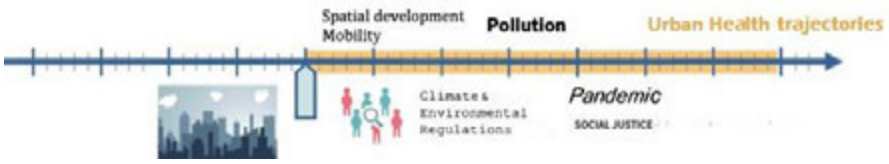

Figure 1 – the concept of urban health in the societal transformation in the E-city program

The program aims to establish a public health monitoring system in urban areas, creating an 'urban cohort' as a living laboratory for citizen science and open science that includes developing a data platform to collect, utilise, and share information. The E-city program aims to analyse the long-term effects of social and environmental factors on urban populations, such as noise, environmental risks, and pollution, which impact social, demographic, and lifestyle dimensions. Lifestyle changes require a wide range of skills to improve citizens' quality of life and health and evaluate public policies. The E-city program involves various skills within the University Paris Est/UPEC, including 32 research institutes with interdisciplinary approaches.

It seeks to build on past experiences, successes, and initiatives from diverse disciplines and research groups.

Description of participatory methods used in the E-city program

The E-city program is designed as a tool focused on an urban community around which partners can align themselves and structure projects. It also serves as a platform for mobilising customised scientific expertise, funding innovation, and fostering scientific collaboration to address major societal issues. The program is based on creating experimental teamwork for diagnostics, data interpretation, and experience feedback. E-city serves as a platform for addressing urban health issues by bringing together data, people, and resources for researchers and institutions. What sets the E-city program apart is its comprehensive approach to urban health, considering socio-environmental factors. This comprehensive approach positions E-city as a hub for interdisciplinary research, aiming to design an urban ecosystem as a real-world laboratory - essentially bringing the University into the city and the city into the University.
The urban population cohort is a crucial element for empirically analysing territorial data. The E-city program aims to establish an inclusive research program with flexible parameters, promote scientific freedom, and encourage innovative methodological approaches. The E-city program's transdisciplinary and inclusive scientific research aims to benefit the Paris Ile-de-France metropolitan area by enhancing the ability to account for urban dynamics.
The vision of the E-city program is to create a network to gather data about urban health in a participatory and empowering manner. The E-city program does not rely on predefined tools that are not based on local problems and knowledge. In many cases, local knowledge is often overlooked. By prioritising local knowledge at the end of the research process, it is difficult to understand how the context changes and how enduring social inequalities persist. In E-city, local knowledge is central to the research process and is dynamic, involving active experimentation with the community.
As illustrated in the program diagram (Fig. 1), E-City collaborates with a wide range of private and public partners, including municipalities, regional authorities, associations, and companies. A continuous dialogue with these representatives of metropolitan society regarding current needs and questions about urban health and well-being issues leads to research projects that align with the holistic vision of the E-City program. These projects are co-designed with local and territorial stakeholders and researchers from the interdisciplinary scientific community of UPEC University.
In addition, E-City actively generates research projects by inviting researchers from other universities and public or private research institutes to submit project proposals. E-City maintains regular communication with the research community to identify and develop specific projects that align with the overall research goals of the E-City program. In collaboration with the 42,000 students at UPEC University, the students at E-City contribute to research data collection through scientific surveys. Multiple surveys are conducted annually, and a dedicated interdisciplinary committee of researchers oversees the ongoing methodological adjustments. The survey results are analysed and discussed in research seminars and workshops throughout the survey process.
The research projects conducted with E-City partners aim to achieve three types of results:
1. Creating scientific knowledge shared with various research communities and disseminated through papers, workshops, and conferences. The scientific results are also shared with citizens and public institutions, and locally specific methods for shared language and lifelong learning are co-created at the local level.

2. Generating operational outcomes for public or private practitioners and providing recommendations for public policymakers. These operational results aim to co-construct collective action in urban health.
3. Emphasising the link between research and education, E-City uses the scientific results from cohort surveys as input for developing teaching methods and topics. E-City conducts workshops and seminars with students from different faculties. Additionally, E-City participates in "citizens' students' conventions" (CCE), a participative and deliberative arena where critical societal issues are co-constructed and collectively decided.

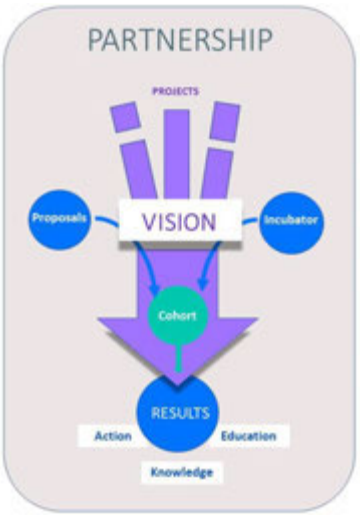

Figure 2 – the concept of partnership for empowerment and participation of the E-city program

The E-city program is based on a holistic approach to urban health, seen as a vision of a system and a set of guiding principles (autopoiesis). The "auto-poietic" approach follows an "abductive" epistemological logic as a continuous process of gaining knowledge and refining practices through learning by doing and reflecting on experience (Aliseda, 2006). This approach is rooted in embracing and navigating uncertainties rather than seeking to control or eliminate them. It acknowledges the impossibility of fully predicting the future but encourages a reflective approach to action. The vision of a system that evolves through learning and reflective practice is implemented through citizen participation, intersectoral and interdisciplinary cooperation, and the deliberate attempt to co-produce interdisciplinarity and transdisciplinarity within public policies.

Thinking of urban health as a self-generating system

The concept of autopoiesis, derived from the Greek words "autos" (self) and "poiein" (create), refers to a system's ability to learn and adapt to changing circumstances by reorganising its structure, such as roles, functions, processes, and tools. A system that exhibits autopoiesis is self-referential, establishing its own frames of reference. Its individual components, actions, and interactions continually sustain it, creating a dynamic and self-sustaining environment (Maturana, Varela, 1980).
John Urry offered a compelling example of autopoiesis in the context of automobility, describing it as a system comprising interconnected social and technical practices that have reshaped civil society (Urry, 2000, p. 190). The system of automobility encompasses not only the car as a manufactured object but also as a consumer product, a complex of mechanical components, an environmental factor, a mode of mobility, an economic instrument for trade and consumption, and a prevailing cultural narrative. Additionally, it involves the economies of car dealerships and fuel distribution, as well as specific interactions with urban spaces. These various dimensions interact, generating and sustaining mobile civil societies that rely on the automobile system, influencing the characteristics of space, time, residence, and social interaction (Urry, 2000; Urry, 2004; Gartman, 2004). The concept of an E-city revolves around creating a living system that establishes its dimensions through data, the participation of citizens and researchers, their interactions, and assemblages. It aims to develop the capacity to

continually learn, iterate learnings and reflections (Schön, 1983), and self-produce itself constantly.

Developing a shared language

It is essential to have a shared understanding and use of language to strengthen arguments, enhance communication, and build connections and alliances among involved parties (e.g. specialised terminology, different ways of presenting and representing information, and communication protocols) (Habermas, 1984). Language serves as a tool to increase participation and broaden access to knowledge and resources in participatory democracy, establish platforms for deliberation, and empower citizens to become active political participants (Schön, 1983). The E-city program aims to establish a shared language through various communication methods and spaces for deliberation. The goal is to provide ongoing platforms for discussion where urban health issues can be shared, debated, and collectively defined. The fundamental principle is that interpersonal communication helps share qualitative and reasoned arguments to establish a shared understanding without disregarding individual, non-universally accepted interpretations. As a result, E-City regularly hosts: 1. Discussion seminars with experts, known as "Café E-City"; 2. Podcasts featuring experts and citizens; 3. Citizens Students Conventions (CEE); 4. Round table discussions with associations and institutions.

Co-creative research methods to analyse the surprising facts

The E-City programme follows an "abductive" epistemological approach, which involves introducing new ideas into the research process and treating it as a creative endeavour where surprising facts can be crucial. This approach allows for questioning established assumptions and validating empirical results. The abductive epistemological logic combines abduction, deduction, and induction as a methodological framework. This approach is beneficial for researching complex urban systems with numerous interrelated health issues.
Different representations of value (e.g., sentimental, economic, cultural) are used to co-produce opinions and formulate objectives regarding desirable futures in urban development, raise awareness, mobilise, consult, understand, share, and experiment.

The E-City Programme proceeds incrementally

From the beginning, E-City has taken a comprehensive approach to urban health, avoiding a narrow focus on any specific research area related to sectoral planning and urban health. By working inclusively with various partners, E-City has gradually evolved and experimented to develop solutions without assuming they are final. To identify research needs from academic and operational partners, E-City prefers a spontaneous and flexible approach to organising research projects, gaining democratic approval for the collaborative process. The approach is iterative and negotiated, embracing uncertainties along the way.

Insights from focus group meetings, interviews, surveys, and participation observation

The first phase of the E-city program (2020-present day) has tested the concept of a comprehensive vision for a healthy urban environment. The initial months of its activities have been dedicated to mobilising scientific stakeholders through a tailored platform focused on implementing the first phase of the urban cohort. This phase consisted of establishing a scientific environment to advance research on urban health. It involves creating experimental

sites for action research, interpreting field diagnostics, and utilising data and experience feedback. Additionally, empowerment initiatives have been implemented to involve students and local stakeholders in the operational processes.
The research projects for the student's cohort focused on land use planning. They included topics such as "Understanding the problems of isolation and health deprivation of a growing ageing population" (Val-de-Marne), "Involving students in research into the health and well-being trajectories" (UPEC/ERASME), and "Urban planning for blind and partially sighted people" (Guyot Center for blind and partially sighted people).
These research projects focused on training a new generation of intersectionality planners, with students being supervised in multiple urban design and spatial planning curricula. Additionally, students received training in meanings and empowerment theories through workshops and master-tutored workshops. During the training, consulting companies and experts who were E-City members participated in the Network for the Regional Plan for Health and Environment. Professionals from different departments and institutions in the Ile-de-France region participated in interdisciplinary seminars.

Communication is Key

The development of E-city's activities is supported by communication efforts to publicise the research program and promote its activities. This is done through various platforms such as LinkedIn, targeting professionals and students in the process of professionalisation, as well as those interested in working with the E-city team. The purpose is to present the progress of projects, especially those related to the territories. Additionally, activities are promoted on Instagram to target students in the UPEC cohort. All E-city projects are also featured on the E-city/University website.
Furthermore, E-city has collaborated with the EUP to launch an Interfaces podcast. Co-hosted with the Chair in Planning Greater Paris, Interfaces aims to bridge academic research, society, and territorial authorities, giving researchers, students, experts, and activists a voice. The popular podcast format can effectively share essential research elements at EUP, UPEC, and neighbouring universities. It can also be used for targeted communications within other research and local communities.
In addition to the podcast, targeted publications such as the booklet with the first results of the student cohort are being distributed to UPEC students. These publications present the first analyses using graphic work to engage the audience produced by work-study students. The communication work supporting each E-city project aims to achieve the following objectives: raising awareness about the E-city program, which is part of UPEC's overall strategies, promoting projects carried out within the University and in collaboration with local partners, and popularising and disseminating the anticipated research results to the general public. Starting with students and the support of UPEC scientists, the E-city highlights the strengths of UPEC. The podcast "Interfaces" consists of academic research and diagnostics, presenting initial results on the exposure of society and urban areas. The first series of "Interfaces" focused on the environmental exposures of urban areas (July 2022), while the second series was about the management of the exposure of urban areas (March 2023). A third series presented the first results of the cohort (March 2024).

The Student Cohort at Paris-Est Créteil University

Today, there are two main initiatives in E-city: the student cohort, which will continue, and the general cohort. The student cohort focuses on subjects that provide a framework for ERASME,

a state-funded university project aimed at transforming the University to be more locally embedded in the eastern and southern parts of Greater Paris. This cohort is linked to student empowerment and was essential in constructing the E-city program. Methodologically, the student cohort provides an opportunity to develop learning about the approach, while thematically, it is a strategic focus on its own. The idea is to start working with diverse competencies that connect research on urban health. The student cohort is, therefore, a testing phase and a call for colleagues and partners.

The term "students' cohort experience" refers to a particular group of students in a specific location. These students are all at a critical juncture in their lives, which is significant for their education, chosen fields of study, and future endeavors. The student cohort is a critical element that allows the E-city program to provide opportunities similar to ERASMUS, addressing the specific needs at UPEC.

The E-city approach involves engaging with students and the campus service. The student body is diverse, and it's important to account for the changing demographics as new students enter and graduate each year. Additionally, the survey should adapt to the students' circumstances as they enter or complete their studies, considering changes in their attitudes, health, and behavior. The student body is being studied to gain insights into their health and to raise awareness about the issues students may face. This approach also allows for testing the structure of the student body and reaching the entire student population quickly, all in one day through the campus service.

The student cohort is established as a key component of the E-city program, following three main steps:

1. Development of a questionnaire in collaboration with experts and students, collected through stands and meetings with sociologists, health geographers, and mental health medical professionals.
2. Launch of the student cohort in coordination with university services, including the campus health service, the office for personal data protection, and the Department for Student Studies and Life.
3. Anticipated enrollment of approximately 2,000 new participants annually over ten years, enabling UPEC to assess and address the needs and expectations of the student population through concrete actions, including research-based teaching and opportunities for experimental research. The ultimate goal of the student cohort is to empower students by integrating local knowledge, fostering awareness and confidence in their health, and enhancing their ability to take action on health-related issues and their place.

Figure 3: Tutored workshop with the Master 2 AUDE-EP (Paris School of Urban Planning) for the assessment of students' well-being at the UPEC campuses.

The Survey on Urban Health

The student cohort is based on a questionnaire that aims to be holistic. It covers multiple and transversal themes to understand urban health determinants. Urban health is defined by the WHO as "a state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity". The cohort questionnaire should enable E-city to investigate the factors influencing the lifestyle and health trajectories of students with a multifactorial approach to explore what contributes to students' well-being, success, and overall quality of life. This will involve examining aspects such as the social and urban environments of individual students, their health trajectory, and the resources available to them, including infrastructure and financial resources.

For this survey, the E-city team initially collaborated with students to gather feedback on their concerns regarding participation in the student citizen convention. They also used existing surveys, such as the OVE. Additionally, the work was performed in close collaboration with various university services (SSU, DEVE) and researchers in the fields of psychiatry, geography, and sociology. Furthermore, the E-city team addressed regulatory issues by collaborating with the DPO.

The survey was created in 2022 and tested in the first wave in Spring 2023. The results were analysed in the first few months of 2024 and covered the following themes: socio-demographic characteristics (ten questions on individual situation such as place of residence, gender, and age), course of studies and student life (twenty questions on academic background, workload, and perception of university environment), environment/living situation/activities (fifteen questions on housing, daily mobility, and everyday behavior), personal situation (twelve questions on financial resources, family support, and episodes of discrimination), and health situation (twenty questions on perceived personal health, mental health, seeking care, and diet).

The experimental approach to connect the University and territory

The E-city program also serves as an incubator, implementing action research in the area. It acts as a meeting point where communities present their needs, fostering relationships between universities (and research actors) and the local area. This involvement integrates students into the societal issues of the territory, promoting a pedagogical approach.

In 2023, the Department of Val-de-Marne contacted the E-city team, seeking to leverage scientific expertise, coordination skills, and connections with the university community, including researchers and students. They wanted us to conduct a study tailored to the specific needs of the Val-de-Marne region. This interest led to an experimental project focused on the ageing population with consultation in the Haie Griselle - La Hêtraie district in Boissy Saint Léger and Limeil Brévannes.

The objective of the survey for the departmental council of Val-de-Marne is to improve consideration of the needs of older people and people with disabilities in priority neighbourhoods. This action is dedicated to priority neighbourhoods because ageing populations will affect all territories, but it promises to be more rapid in some urban areas.

Public policies usually focus on active populations and families, and they need to address the needs of populations that are losing their independence and getting older. The aging population in these areas encounters daily challenges such as unsuitable housing, limited mobility, access to services, and isolation. The department's commitment to an experimental approach was unanimously approved by the elected representatives of the Departmental Council in December 2020 during the adoption of the departmental autonomy plan.

The Haie-Griselle / La Hêtraie district has been chosen as the focus of the experiment because it is one of the 20 most deprived neighborhoods in Val-de-Marne according to the ranking by

the Department's Observatory of Social Housing Neighborhoods (OQHS). The aging process is particularly pronounced in the neighborhood, with a significant 70% increase in the population aged 75 and over in Priority Neighborhoods (Quartier Prioritaire de la Politique de la Ville) between 2013 and 2018. The district's population is also declining (5024 in 2018 compared to 5301 in 2013). It is unique in that it is a residential park and is affected by an urban renewal project of regional interest (PRIR).

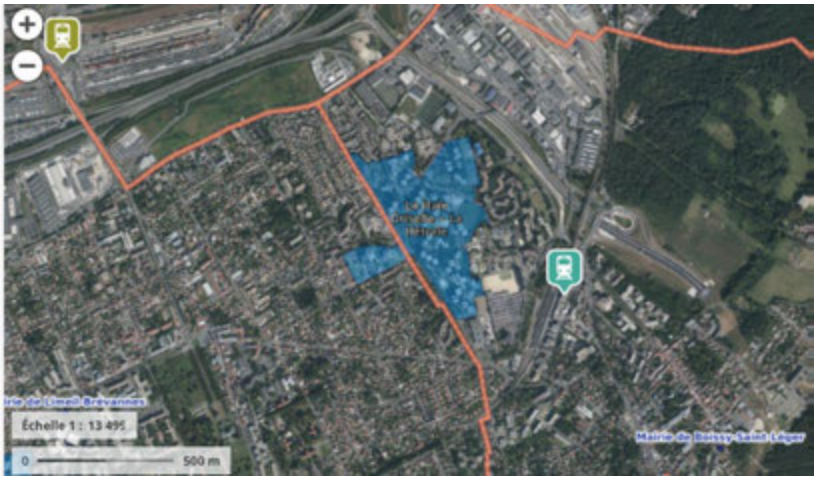

Figure 4: Haie-Griselle / La Hêtraie district

The project's objective within the E-city program is to conduct an experimental consultation process in the La Haie Griselle – La Hêtraie district on the issue of an ageing population, taking advantage of the district's urban renewal operation (NPNRU). The students will be involved in the analisis of the ageing experience using various methods such as field observations with photos, participatory workshops, and semi-structured or biographical interviews. The goal is to understand how the residents of the Haie-Griselle - La Hêtraie district experience ageing. The aim is to improve their access to rights, housing, public spaces, and prevent social isolation. The E-city team will use both qualitative and quantitative tools such as questionnaires, field observations, photovoice, participatory workshops, and semi-structured interviews to gather information and work with our partners to plan concrete actions for the aging population.The project requires the mobilisation of actors and partnerships. The project sponsors (CD94) regularly organise project implementation meetings and monitor meetings with stakeholders (CD94 members, their elected officials, and GPSEA for the NPNRU aspect) throughout the project duration from October 2023 to September 2024.
From October 2023 to January 2024, a group of students in the Master of Education Sciences program at the University of Paris-Est Créteil has conduced research on the intergenerational aspect as part of an intensive seminar. Additionally, from October to March 2024, a group of students in the Master 2 AUDE-EP program at the Paris School of Urban Planning is working on public spaces, involving observations, interviews, participatory workshops, and an assessment of the use of space.; and from February to September 2024 a Master student in health geography (University of Nanterre and Créteil) on an internship for five months is working on qualitative tools with isolated people; and from May to July 2024, a student on an

internship for three months is carrying out interviews with stakeholders, and help the restitution of data to identify concrete actions in the region.

Lessons from the E-City Program

The E-City program has several expectations for UPEC, the scientific community, and local communities. The program aims to produce scientific findings on urban health by monitoring a cohort over time. Findings are expected to contribute to a better understanding of life trajectories, the factors contributing to inequalities, and scientific challenges. The cohort model, which explores the interplay between urban health and planning issues, has the potential to help in developing future scenarios through co-design.

Local knowledge has proven to be essential from an operational perspective. It is vital not only for understanding the community but also for implementing various forms of engagement and experimentation in urban areas with residents and the urban population. This helps to make participation and empowerment being at the center of co-creation processes to enhance people ability to act in the face of the challenges they encounter. Establishing living labs and engaging in the co-production of public action in a tangible manner requires a significant level of commitment.

The E-city program offers two types of lessons. The first type involves scientific research on urban health, focusing on understanding the relationship between urban environmental exposure to noise, risks, and pollution, and the health conditions of the urban population. Data on potential health trajectories contribute to understand inequalities, and conditions of urban inhabitants. The second type of lesson focuses on engaging urban stakeholders in co-producing knowledge about urban health determinants, overcome issues of inequality, and define pathways to empower people through information on health determinants, risk factors, and learning about socio-environmental determinants. This involves experimentation in living lab contexts, prototyping solutions, and neighborhood houses to establish trust and co-produce public action. An essential aspect is the evaluation of public policies (ex-ante, in-itinere, ex-post) related to health, urban conditions, and lifestyles.

Vulnerable Group of Young Generation University Students

In the first wave of the student cohort, nearly 1000 participants took part in a survey. The cohort has gathered research material from various fields including health geography, health economics, psychiatry, and sociology. The results aim to provide more detailed insights into the students' conditions, which will be used as feedback for University services. The findings will be compiled into an annual report and presented in Autumn 2024. In Spring 2023, student internships and workshops will be conducted, focusing on "health profiles and living environment." Additionally, a new questionnaire will be enriched with a new round of surveys from the second student cohort, to be submitted in Autumn 2024.

The findings from the survey of the first group of students were discussed in a workshop that included experts in health geography, health economics, psychiatry, sociology, and urban planning. The workshop helped the E-city team to analyse the survey data and identify disparities in access to higher education and graduation, as well as the challenging living conditions experienced by certain students. It was also identified perceived health issues among students, difficulties faced by certain student groups in accessing public health services, and concerning signs of potential comorbidities.

Figure 5: Workshop with multidisciplinary experts interpreting and discussing the first data aquired through the first wave of the survey of the student cohort (March 2024).

Vulnerable Neighbourhoods of Ageing Population

Challenges of the experimentation-consultation project in the Haie-Griselle - La Hêtraie district. The work areas approved by COPIL (June 15, 2022) focus on five main aspects:
1. Communication about the neighbourhood's redevelopment to assess communication needs and methods within the PRIR (Project of Regional Interest) framework.
2. Neighborhood accessibility and movement within the space (user journeys) to evaluate building accessibility, road layouts, and shared spaces (residential areas, thoroughfares). Identifying traffic routes, resting places, and public spaces such as benches.
It is adapting housing for the older population to enable them to stay home and understand existing devices, using technical aids and the services offered by home care and medical facilities and focusing on social life, citizenship, and measures to prevent loss of autonomy. Planning prevention systems and actions such as sports, cultural activities, and leisure, adapting local services, and promoting community activities are essential for enhancing social life. The project also focuses on changing perceptions of old age and disability by studying how older populations are represented and their role in the community and promoting intergenerational activities. This project requires the participation of professional staff to conduct this action research.

Conclusions

The E-City program's vision and strategies have led to significant opportunities for establishing partnerships with the EUP to address participation and empowerment in urban health. The themes addressed by the E-City program are directly related to the concept of a "Healthy City" and show intersectionality with youth and the ageing population, which is likely to be of interest to future generation of planners and research-based educational activities in the Paris School of Urban Planning.

The E-City program has achieved a significant outcome through the collaborative effort of the students' cohort. The "E-City students cohort" underwent a 2-year preparation phase, during which various methods and techniques of communication, awareness, participation, and collaboration were tested. A methodological framework was continuously tested with segments of the student community, and it was consistently improved to align with the students' capacity to comprehend and engage with the E-City program, considering their individual living and working conditions.

The COVID-19 pandemic has had a significant impact on urban health conditions, especially for students. Many students were confined to their small apartments and had reduced access to learning resources, facilities, and amenities. These impacts continue to affect the mental health and well-being of many students today. The latest E-City survey has revealed interesting findings on the urban health conditions of students at UPEC and has raised important questions for sustainable planning. The survey found that the time spent in transportation for commuting to the University has a negative impact on students' working conditions, with 56% spending less than 1 hour in transport and 12% spending more than 2 hours. More than a third of the students need to work to pay for their studies, and almost half are facing significant financial challenges. These findings are important because of the accessibility of universities in outlying urban areas. How can we enhance accessibility through various modes of transportation? What options are available for providing financial assistance to local students?

Another important aspect related to urban health and planning is young people's mental health. According to the E-City survey, half of the students regularly experience bad moods, sadness, and anxiety. A quarter of the students have had panic attacks, and 5% seem to have psychotic issues. It is crucial to understand the causes and sources of these mental health problems. Are these issues based on pathologies? Are they severe? What initiatives can be improved to ensure the best care for young generation with their participation and empowerment?

The rapid growth of cities poses significant challenges on urban health planning. Over 55% of the world's population lives in urban areas, and this number is expected to increase to 68% by 2050 (Santos-Tapia et al., 2024). It is crucial to rethink planning in relation to urban health, with participation and empowerment as key aspects of this intersectionality. Citizens need right to access information, voice their opinions, and participate in decisions related to urban health planning for more sustainable equity, equality, and social justice to promote healthy urban contexts. This means to face experimentation and uncertainty (Zepf & Ramirez-Cobo, 2022).

Within the E-City program, the university campus service has implemented new and innovative approaches to delivering services that could bring future benefits to students. These benefits include support for mental health, training focusing on positive future scenarios, and enhanced social capital. There is a growing awareness that issues such as transportation, financial assistance, and guaranteeing a more positive vision of the future are essential for the younger generation. Rapid urbanisation has impacted traditional social bonds and cultural affinities, affecting the ageing population (Galea & Vlahov, 2005). The E-city program has therefore identified a role for the University to lead the way for equality and equity and identifying some crucial vulnerabilities for a new generation of intersectional planners. There are communities to empower in numerous ways in health provision, such as education, security, maintenance, and planning activities in the context of place-making, solidarity needs and possibilities, and social practices. Planners need to adopt intersectional frameworks to discuss and debate future visions based on ethical principles, future generations, and communities where will be essential promote equality and social justice by collaborating to create knowledge, identify crucial aspects, and develop models to cultivate practice and education on inclusive urban health planning.

Achieving proximity in Public Space: Inclusion, Flexibility and Accessibility

Abstract

The city of proximity can be defined as a city able to offer to all its inhabitants everything they need to live, work and have fun to be reached on foot or bike in no more than 20 minutes (Moreno, 2020).
An important factor is that the city of proximity has to be created with the support of a wide process of participation with the actors involved and interested in its realization.
Starting from these premises, this study - carried out in the framework of the research project PRIN 2020 SUMMA #20209F3A37 - aims at presenting the process of participation and the proposed project interventions for the regeneration of the former fair of Rome, interested by dismission and then isolation from the rest of the neighbourhood. As a result, the 25 principles Charter of Proximity - flexible, inclusive and updatable - was realized, which consists in a holistic tool for design or verify proximity in an area and assure equitable accessibility (Sepe, 2023).

Keywords: public space, proximity, inclusion, flexibility, accessibility

Introduction

The city of proximity can be defined as a city able to offer to all its inhabitants everything they need to live, work and have fun to be reached on foot or bike in no more than 20 minutes.
Proximity - as Jane Jacobs (1961) states - allows people to exchange knowledge, ideas, ways of thinking to generate diversity. It is necessary to create the right conditions to make a place accessible to everyone as each place is different from the other; the diversity of the city is also based on the fact that so many people with different tastes, needs and abilities are close to each other. The conditions for diversity are: the different parts of a district must perform more than one primary function and must ensure the presence of people with different hours who can use many facilities in common; roads need to be well connected to each other in order to generate interest and further uses; the district must provide services, activities and goods with a different range of prices, especially accessible; there must be a dense concentration of people who are in that place for different purposes. The combination of these conditions results in vibrant districts and cities with - at the same time - good economic effects.
In continuity with these ideas, 15-minutes city (Moreno, 2024) arisen to offer more and new possibilities of use within the same place: a cinema can become a laboratory of ideas in the morning or a nightclub can act as a gym in the afternoon. Residents must have ease of access to goods and services, each neighbourhood must have a variety of housing types in terms of size and accessibility levels, including economic ones, and be close to the workplace. To achieve proximity, city plans, regulations and zoning need to be updated to ensure public services, infrastructures and public spaces accessible to all, as well as schools, small health facilities and retail including fresh product shops and pharmacies (Moreno 2020).
An important factor is that the city of proximity has to be created with the support of a wide process of participation with the actors involved and interested in its realization.
Starting from these premises, this study - carried out in the framework of the research project PRIN 2020 SUMMA #20209F3A37, within the ISMed-CNR Unit (with the author's responsibility) and the relative agreement between Sapienza Università di Roma and ISMed-

CNR, that has among the objects to create guide lines for resilient, healthy and flexible places Carmona, 2019; Corburn, 2009; D'Alessandro et Al., 2015; Gehl, 2010, 2016; Koohsari et Al., 2013), – aims at presenting the process of participation and the proposed project interventions for the regeneration of the former fair of Rome, interested by dismission and isolation from the rest of the neighbourhood, realized in the framework of the 2022-23 Urban Planning Course at DICEA Sapienza University of Rome by the author of this study and her students and the Charter of the Proximity.
As a result, the author has ideated the 25 principles Charter of Proximity, that consists in a tool for design or verify proximity in an area. The Charter is an holistic tool - flexible, inclusive and updatable - that can be adaptable to any kind of sites to assure a proximity with both equitable accessibility and attention to place identity (London, 2020; Madanipour, 2011; Montgomery, 1998; Sepe, 2023; Sim, 2019).

Urban regeneration and proximity

Inclusive regeneration

Urban regeneration consists of an integrated approach between vision and action for the resolution of various problems related to disadvantaged urban areas in order to improve their socio-economic, physical and environmental conditions with actions such as the requalification, recovery and conservation of heritage.
To the term regeneration must be added the term sustainable understood in its triple meaning (Sepe, 2021-2023), although as Evans and Jones (2008) affirm it can create ambiguity on what weight to give to the environmental, social and economic component, determining that greater emphasis can be placed in the regeneration processes on one element instead of another depending on the developers' goals (Davies, 2002).
Indeed, in the most recent studies for this purpose, additional key elements of sustainability in relation to the planning system have been identified, namely: cohesion and social inclusion; protection and enhancement of the natural environment; prudent use of natural resources; sustainable economic growth; integration of sustainable development into development plans (ODPM, 2004). This highlights the importance of integrating the components and not just ensure their presence (Forrester, Snell, 2007).
Each transformation operation may have to undergo changes due to sudden crises of different types; it is important to be able to guarantee the resilience of places and their adaptation which require flexibility of all the involved components and at all levels.
The kinds of connections between people and place are increasingly growing. Social infrastructure in urban regeneration areas is an important element in sustainable development and must have equal access for residents. It is also important to remember that stakeholders do not have equal rights and powers in the transformation process. Stakeholders in urban regeneration projects must include not only public administrators at different levels and stakeholders in the private sector, but also citizens and, in particular, those who live close to urban renewal projects.
A dynamic relationship must be created between different actors who share objectives agreed together and which must be pursued through the understanding of mutual needs and benefits (Brinkerhoff, 2002). Similarly, the creation of green and blue infrastructures is fundamental to guarantee ecological sustainability, economic regeneration and proximity. Cultural networks are another important element in sustainable regeneration as they have the potential to improve social cohesion and the city's brand. Accordingly, urban planning attentive to perceptions of one's heritage can improve interaction with this and the surrounding urban environment, with a positive effect on the health and liveability of the place. Accordingly, the integration of all the infrastructures will be the key factor to ensure more sustainable connections.

The monitoring of the regeneration process throughout its path is also important to obtain more sustainable results and improve existing programs by modifying the proposed solutions with others that are more adequate to actual needs.

Indeed, the holistic approach to the design of places is an approach that considers all the components that determine their implementation in terms of sustainability, healthiness and liveability, as well as all those involved in a logic of integration and inclusion. The holistic approach (Lehmann, 2010; Xu, 2011) can be read in various Charters, Agendas, Principles, International Reports which in recent decades have formed the framework within which local Agendas have been built. Some principles of the New Urban Agenda and of the 17 Sustainable Goals which constitute an important reference for the contents of this Book will be reiterated below.

Many principles that are contained in the Agenda concerns topics related to public spaces, liveability, healthy and inclusion. It was adopted during the UN-Habitat III Conference which was held in Quito in October 2016. It represents - as can be observed in the following principles - "a shared vision for a better and more sustainable future" (UN-Habitat, (2016).

Principle 36. "We commit ourselves to promoting appropriate measures in cities and human settlements that facilitate access for persons with disabilities, on an equal basis with others, to the physical environment of cities, in particular to public spaces, public transport, housing, education and health facilities, public information and communication (including information and communications technologies and systems) and other facilities and services open or provided to the public, in both urban and rural areas". This principle sets out a very important element for the health of places, i.e. facilitating access for people with disabilities in public spaces and built structures but also in the sphere of communication and information, allowing inclusive access to tangible and intangibles of a territory.

Principle 37. "We commit ourselves to promoting safe, inclusive, accessible, green and quality public spaces, including streets, sidewalks and cycling lanes, squares, waterfront areas, gardens and parks, that are multifunctional areas for social interaction and inclusion, human health and well-being, economic exchange and cultural expression and dialogue among a wide diversity of people and cultures, and that are designed and managed to ensure human development and build peaceful, inclusive and participatory societies, as well as to promote living together, connectivity and social inclusion".

The important points that are expressed in this principle concern the promotion of public spaces of all types that have different functions - an important aspect even in times of pandemics in which it is important to have different uses to be carried out outdoors - and that are designed and above all managed to promote a dialogue between all. Public space, if it is of quality, is also able to promote health and well-being in those who live it, but also economic and cultural exchange.

Principle 67. "We commit ourselves to promoting the creation and maintenance of well-connected and well distributed networks of open, multipurpose, safe, inclusive, accessible, green and quality public spaces, to improving the resilience of cities to disasters and climate change, including floods, drought risks and heat waves, to improving food security and nutrition, physical and mental health,

and household and ambient air quality, to reducing noise and promoting attractive and liveable cities, human settlements and urban landscapes and to prioritizing the conservation of endemic species".

In this principle, the issue of resilience to environmental disasters is associated with that of creating networks of public spaces, understood as places that can help improve resilience along with other aspects such as air quality and the liveability of urban landscapes.

Principle 118. "We will encourage national, subnational and local governments to develop and expand financing instruments, enabling them to improve their transport and mobility

infrastructure and systems, such as mass rapid-transit systems, integrated transport systems, air and rail systems, and safe, sufficient and adequate pedestrian and cycling infrastructure and technology-based innovations in transport and transit systems to reduce congestion and pollution while improving efficiency, connectivity, accessibility, health and quality of life".
This principle highlights the improvement of all transport and mobility infrastructures in the logic of integration on the one hand but also of safety and healthiness on the other. Reducing air pollution due to transport systems also has a positive effect on slow mobility systems – and proximity - and therefore on the quality of life.
Before the III Un-Habitat Conference, in 2015 the General Assembly of United Nations Member States the 2030 Agenda for Sustainable Development was adopted and 17 Sustainable Development Goals (SDGs) provided (UN, 2015). The Goals contain strategies to improve health and education, reduce inequality and incentive the economic growth. These include: 1: End poverty in all its forms everywhere, 2: End hunger, achieve food security and improved nutrition, and promote sustainable agriculture, 3: Ensure healthy lives and promote well-being for all, at all ages, 4: Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all, 5: Achieve gender equality and empower all women and girls, 6: Ensure availability and sustainable management of water and sanitation for all, 7: Ensure access to affordable, reliable, sustainable, and modern energy for all, 8: Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all, 9: Build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation, 10: Reduce inequality within and among countries, 11: Make cities and human settlements inclusive, safe, resilient, and sustainable, 12: Ensure sustainable consumption and production patterns, 13: Take urgent action to combat climate change and its impacts, 14: Conserve and sustainably use the oceans, seas, and marine resources for sustainable development, 15: Protect, restore, and promote sustainable use of terrestrial ecosystems, manage forests, combat desertification and biodiversity loss, and halt and reverse land degradation, 16: Promote peaceful and inclusive societies for sustainable development, provide access to justice for all, and build effective, accountable, and inclusive institutions, 17: Strengthen the means of implementation and revitalize the global partnership for sustainable development.
These 2030 Agenda goals present a holistic approach as the principles concerning the 2016 New Urban Agenda. Topics such as resilience, inclusion equity, health, safety, sustainable economic growth, resilient infrastructures, nutrition improvement are some of those in common between the two Agendas and constitute the wider framework of the proximity regeneration topic.

Proximity
The proximity city is a city able to offer all its inhabitants everything they need to live, work and have fun to be reached on foot in no more than 15-20 minutes.
The starting point of the 15-minute city model, conceived by Carlos Moreno (2020), is that it needs to move from urban planning to planning urban life. This can be achieved by creating a 15-minute city in a compact area accessible to all and where people can live, work, take care, refuel, have fun and educate themselves. To preserve the quality of life for Moreno, two components must be changed, namely time and space. To this end, a new urban planning must be created with other rhythms of life and ways of using the urban space in order to access the main functions of the city; it is a question of transforming the monofunctional urban space into a polycentric city, connected and with public spaces accessible to all.

In this way, active mobility on foot or by bicycle can be promoted by reducing the use of the car and long journeys by public transport. All the actors of urban life are involved in this transformation as for its realization it is necessary to connect the demand of the inhabitant with the offer through different actions: creating an adequate mix of social, economic and cultural functions, increasing public spaces of meeting, transforming the streets into spaces of free movement for walking or cycling and rediscovering hyper-proximity.

The city of proximity offers more and new possibilities of use within the same place: a cinema can become a laboratory of ideas in the morning, a nightclub can act as a gym in the afternoon, but also bring art and culture on the street with digital cultural platforms or to raise awareness of historical traditions with multimedia technologies. The desired city is in solidarity and participation where there is exchange, creation and mixing.

Accordingly, the way of living and staying in the city changes thanks to the "multifunctional features" that allow to reduce the travel to reach theme, making proximity accessible even to the most fragile (Moreno, 2020).

The principles of proximity city therefore include: residents must have ease of access to goods and services, each neighbourhood must have a variety of housing types in terms of size and accessibility levels, including economic ones, and be close to the workplace of the people, the residents they have to breathe clean air and more people can work close to home or remotely thanks to the diversity of work spaces available (smaller offices, co-working spaces, etc.).

To achieve proximity, city plans, regulations and zoning need to be updated to ensure public services, infrastructures and public spaces accessible to all, as well as schools, small health facilities and retail including fresh product shops and pharmacies. This could be achieved with: the opening of shops on the ground floor of the main streets; the expansion of school courtyards, the transformation of abandoned lots and street spaces into small gardens or pocket parks; the construction of small-scale offices; and light industry spaces.

Flexible use can concern buildings and public spaces, and, in the longer term, cities can encourage the design of reversible buildings that are designed to be easily converted for different uses by decreasing demolitions and reconstructions with economic benefits and in terms of greenhouse gas emissions. (Bergevoet, Van Tuijl, 2016; C40 Cities Climate Leadership Group, C40 Knowledge Hub, 2020).

It is therefore necessary to territorialize the short distance multicentralities by creating urban commons where to live, work, have fun and educate itself and where elements such as water, air, time, space are at the centre of new urban issues.

In the proximity city, the way of experiencing the city also changes: we move from suffering mobility to chosen mobility, hyper-proximity leads to new socio-economic models, plants and biodiversity become an integral part of this approach. Density must in fact be understood in a reasoned way with green connectors to be made with living materials present throughout the life cycle to be combined with internal green spaces, roofs, squares and streets that foster social bond. Green spaces in the compact city are an attractive factor as they are places where people can take a break near their home by reducing forced mobility.

For Moreno, the services available must then be optimized with the use of digital technologies and collaborative models, transforming digitization into an inclusion factor and creating new generation multimodal public services.

Technological innovation can contribute profoundly to the improvement of services for citizens: the multitude of data available can become social objects and be designed for new uses in which new technologies and social inclusion are linked: from personalized public health to open spaces for culture, from open collaborative systems to the best quality of life for the third and fourth age.

Accordingly with the concepts illustrated above, the emblematic case of the former fair of Rome, interested by dismission and then isolation from the rest of the neighbourhood, will be illustrated.

The case study: methodology and results

The methodology used for the case study of the former fair of Rome is constituted by the collection and overlapping of both primary and secondary data. The primary data are constituted by the site visits (with photos, perceptive surveys, analysis of the built environment, mobility system, green system, and main users and uses), the study of the planimetries of the place and its surroundings (related to the built environment, mobility system, green system) and the proposed project interventions. The secondary data are constituted by the bibliographical research of the history of the former fair, the general regulatory plan variant, and the process of participation.

Accordingly, the case study will be illustrated in relation to: a brief history of the place; the 2011 variant of the 2008 general plan of Rome (Italian acronym P.R.G.); the results of the 2015 process of participation carried out by the Rome municipality and the 2020 agreement for the redevelopment of the former fair approved by the Municipal Assembly; the outcomes of the analysis of place and the proposed project interventions carried out in the framework of the Urban Planning Course at DICEA Sapienza University of Rome by the author of this study and her students according to the achievements of both the analysis and the 2015 process of participation also in relation to the questions related to proximity.

Fig. 1: Rome, the study area with, starting from the right side, the former fair pavilions, the sport centre, the parking, the market, the second parking, the Mario Picchi park.

The project of the former fair of Rome is linked to the Universal Exhibition of Rome, scheduled for 1942, which was then blocked by the war, and until 1959 the Roman trade fairs took place in different areas from year to year.

In 1959 the Rome fair was completed, on the great urban artery of Via Cristoforo Colombo which connects Rome with Ostia. This is a temporary headquarters, which will remain in service for almost half a century. Over time, conferences, business tourism and large public administration competitions were added to the traditional trade fair activities. In 2006, a new headquarters was built, which takes the name of "New Fair of Rome", on Via Portuense close to the freeway to Fiumicino.

Then the 2011 variant of the 2008 general regulatory plan of Rome was carried out. It reports that the area of the former Rome fair is located in a consolidated city context, made up of: twentieth-century expansion fabrics of medium and high density, free construction and public greenery in close proximity to the Tor Marancia estate and the Appia Antica ancient park; a primary component of the network characterized by highly natural areas with the ditch system and the hydrographic network; and a component of completion of the system of connections with the ecological network, identified by areas with a strong anthropization character, for

which regulatory guidelines are envisaged aimed at redevelopment through specific environmental projects.
The objective is to activate the regeneration process which involves the location of a new settlement integrated with the context and with the ongoing transformations, based on innovation and quality, from a settlement, morphological and environmental point of view, with uses that are both integrative and complementary to existing ones.
The connoting character of the intervention takes the form of the structuring of a new residential settlement, equipped with commercial, office and public services facilities that integrate the existing or planned facilities within the neighbourhood.
The area is here conceived as a space that can be enjoyed mainly on foot, reducing incoming traffic to a minimum and isolating the routes in order to guarantee safety and tranquillity. Surfaces intended for non-residential activities must contain functions that are compatible and sustainable by the fabric within which these will be inserted.
With respect to the quantity, 67000 sm are for the built environment, of which 65% is intended for residential construction (and social housing), 20% destined for non-residential and 15% for flexible uses, a 28 m buffer zone (2011, Roma Capitale).
Then, a wide process of participation was carried out by the Municipality of Rome (2015). The listening process took place through participatory planning workshops between citizens, neighbourhood associations and the municipal administration, the results of which will be illustrated below in relation to three systems: built environment, green and mobility. With respect to the built environment, the first request was to think about the new interventions with a view to integrating them with the neighbourhood outside the former fair conceiving this as a continuum. It was also requested that the new neighbourhood be permeable and permeated with the rest, open and welcoming and that it becomes an opportunity to create the missing services. To this end, among the decisions, it was asked to review the surface area intended for residential use in favour of non-residential uses considered more urgent for this area, without prejudice to the economic-financial balance of the intervention. As regards residences, the laboratory requested to have buildings with the ground floor used for services, commerce, and other non-residential neighbourhood functions to create a living urban fabric even in the evening. The share of residential construction at controlled prices will also have to be distributed rather than concentrated in a single building.

Fig. 2: Rome, the wall of the former fair pavilions,
from the Via Cristoforo Colombo axis

Fig. 2: Rome, the former fair pavilions,
from the main entrance

In this regard, the possibility of creating individual large buildings which could constitute a visual and physical barrier to the internal spaces was excluded.
The creation of a multifunctional hub is also required with services distributed according to the rule of permeability with the other functions; and beyond realize retails and services within the ground floors of the residential buildings, it was required that these are designed in continuity with the rest of the new built system.
The activities proposed for the multifunctional hub should include: craftsmanship, business creation (start-up), spaces of intersection and cross fertilization between professions and trades, artistic and cultural activities, scientific, technological and environmental activities, educational activities.
With respect to the local services level, it was required to create a nursery and children's school, a comprehensive school, a health centre, and student accommodations. Particular attention is also required for the integration of disabled people into the social fabric they belong to, which could be realized through laboratory of art in its various forms.
Regarding the green system, the laboratory of participation expressed the desire to use part of the standard green areas as a garden with particular attention to biodiversity. In this regard, it was proposed to create compatible, functional and capacious community composting plants with respect to the settlement and surrounding areas.
The residents of the area could bring the wet waste and in exchange obtain useful fertilizer for the gardens, terraces and greenery of the area. Furthermore, the design of the new green system must be integrated with a system of internal squares, with green areas and pedestrian and cycle paths which will form public spaces that relates the buildings and connects the area with the surrounding neighbourhood.
This natural barrier will be open in some points – such as the urban gardens - with a path that will create a large green surface meant as a meeting place for the new neighbourhood and where the multidisciplinary hub will be located.
As regards to the mobility system, the new residential buildings should occupy the site of the former fair area according to a fabric system permeated with cycle and pedestrian paths, greenery and small squares that connect the area to the rest of the neighbourhood. The main connections must ensure sustainable and innovative mobility with privilege for public transport.
To protect against noise and air pollution generated by the heavy traffic on Via Cristoforo Colombo, the 28 m buffer zone envisaged by the variant will have to become a green area and public car parks acting as a natural filter through modelling of the terrain and the planting of various tree species useful for this purpose. The road surface of the Colombo section in front of the former Fair must be made with sound-absorbing materials as a further measure to reduce noise pollution.
The laboratory finally requested that the new buildings and streets be realized with simple and effective maintenance to prevent the new project interventions from degradation. To guarantee maintenance, it was required the greatest use of materials and methods that achieve the highest possible degree of maintainability of the materials and new artefacts, with characteristics of the materials and of the design definition suitable for defence against vandalism. It is also required to build buildings that are totally self-sufficient from an energy point of view as a model of the new housing culture.
As a result of this participation process, on 15 December 2020, the agreement for the redevelopment of the former fair of Rome area was approved by the Municipal Assembly; this reduces the amount of building construction available to 44 thousand sm, instead of the 67 thousand sm previously envisaged, of which 80% for residential construction (of which 20% social housing) and the remaining 20% destined for services. The agreement also provides for the complete transformation of the site in via Cristoforo Colombo with the demolition of the buildings and their replacement with new public and private functions.

According with the aforementioned information and the three systems – built environment, green and mobility - the analysis of the area concerning the sites bordered by Via Cristoforo Colombo and Via dell'Arcadia, Via di Grotta Perfetta and Viale di Tor Marancia, carried out in the framework of the Urban Planning Course, results as follows.

As regards the built environment, the analysed shapes a rectangle that in sequence presents: a park; a sport centre in use; an asphalt open space used for parking; an asphalt open space for market that is an important point of socialization; another asphalt open space used for parking; a non-completed sport centre in a state of abandonment; a little sport centre in use; the former fair pavilions bordered by a wall with many graffities that are not used and in a state of abandonment and totally asphalted. Close to the study area there are: a residential area of good quality, the Lazio Region building, a Roma Tre University building, a church, and an ambulatory.

As regards the green system, within the area there was observed the Don Mario Picchi park characterized by a not used playground, some benches, a path for pedestrian, lawn and trees with lack of care and suitable lighting. In the surrondings there are many little green spaces, and the Tor Marancia and Appia antica ancient park.

As regards the mobility system, the big axis which characterizes the margin of the area is the Cristoforo Colombo with 9 car lanes for a 25 metres section, a long lane of trees in the centre and a cycle lane with a lack of furniture reserved for cyclists: few meeting and stopping points (the only one is inside the Don Mario Picchi Park), E-Bike charging points, bike parking racks. It was also noticed an interruption in the cycle path in the intersection with Via dei Georgofili. Furthermore, despite the dense presence of shelters along via C. Colombo, the other streets, parallel and transversal to it, have no spaces dedicated to the bus stop, creating a congestion of the urban traffic. More in general, there are few connections for pedestrian, cycle or bus routes, which enhance the different parts of the study area, resulting disconnected and isolated.

From the perceptive analysis it was observed that: the visual perception of the wall that perimeters the area of the former Rome fair appears as a very strong delimitation which both does not allow for integrity with the urban context and constitutes a closure of the view with the surroundings; there is a strong and not agreeable sounds coming from the means of transport in Via Colombo; there is poor quality of the pavements in several streets and uncultivated and neglected flowerbeds; there is a sustained pace in via C. Colombo, via Tor Marancia and in some neighbourhood streets such as via Mario Musco.

Finally, as regards users, despite the proximity to the university, the residents are predominantly elderly, and there are also few families and children.

As results of those analyses and process of participation, the project interventions identified include the following.

First of all, it was decided to consider the 2020 municipality agreement that considers 44000 sm as a built area instead of the previous 67000 sm deliberated by the 2011 regulatory plan variant. The general idea was creating a place of identity continuity, a sort of sequence of wholly accessible open-air spaces – the sum of these shapes a rectangle – crossed by a long path that from Via di Tor Marancia to Via di Grotta Perfetta connects all the sequence of spaces.

As regards the built environment system, it will contain all the necessary services to be reached in no more than 15-20 minutes by foot or bike, namely: already existing functions for the inhabitants – the market and the sport -; some new ones according with the desires of locals, namely social housing with commercial ground floor; residences for students; a multifunctional centre and an open-air amphitheatre for different kinds of performances; art and music laboratories for people with disabilities and the elderly; shops, restaurants and bar open also in the evening.

Accordingly, the idea was to create an only one area as a sort of multifunctional and multigenerational place, - which takes into account both the urban identity, flexibility and

liveability - and that can change uses in different hours (e.g. a school can became a gym in the afternoon or shops can become laboratories of art in the evening). For this reason, it was decided to recover one of the existing warehouses of the former fair – the most identitarian one -, transforming it into a cultural hub, where various types of cultural activities can be carried out inside, creating a community centre of reference for residents.
Furthermore, it was decided to realize the new residential buildings with "pilotis" on the ground floor where various commercial environments are located and public activities can be included, such as libraries, study spaces, recreational spaces to offer services for every age group.
To make the area accessible to the various inhabitants of the neighbourhood, it was decided to insert a car park under the buildings.
As regards the green system, it was decided to reduce the waterproofed ground - improving the permeability of the soils - and the ground occupied by cars, and to separate the whole area from Via Cristoforo Colombo with a green filter that protects the area from both air and noise pollution. To enhance the greenery, it was decided to plant various trees on the paths and include pocket parks and parklets for the new residences and along the new and existing buildings that can create occasions for sports and physical activities, breaks, conviviality and socialization for all and with games for disabled and elderly people.
As regards the system of mobility to improve the proximity: the new path which connect the new area should include a pedestrian and bike lanes; Via Cristoforo Colombo should be decreased in terms of car lanes substituting these with trees and green spaces; all the existing transversal streets should be improved as regards the quality of the materials and furniture; new or recovered path should be designed to both connect the built environment with the different services and the green spaces of the study area with those of the surrounding and to realize a real continuity between new and old; and billboards and signs should be inserted for a suitable orientation. Finally, artistic elements during the path which connects the sequence of spaces of the area should be realized in the framework of laboratory of community with materials coming from dismissed pavilions of the former fairs and graffiti parts of the wall with borders the former fair, creating a further element of identity connection with the place and attachment from the inhabitants.

The proximity Charter

As a results of the process of participation and of both the analysis and proposed design interventions, the Charter of proximity was carried out by the author. This was presented at the 6° Biennial of Public Space titled Proximity and public spaces, that was held in Rome in May 2023. Objectives of the following Charter are to constitute a flexible, inclusive and updatable tool and become a sort of guideline for all interested to verify or realize proximity in public space. These objectives are important as cities change always more rapidly, and the 25 principles Charter has to be updatable accordingly. Also, the flexibility is important because not all places are the same and the principles must be adaptable to different peculiarities in an optic of inclusion.
The proximity city is a city where the main services can be reached in no more than 20 minutes on foot or by bicycle.
1) In order to create the city of proximity, places of identity continuity into which to divide it must be identified, depending on the size and organization of the territory.
Urban identity, understood as a set of characteristics that makes a place unique and recognisable, is in fact an important element so that proximity is not only related to functions but also to identity. All in reference to the size of the area it is intended to connect.
2) Urban continuity must be identified through a participatory process involving the main stakeholders of that specific place.

The participation process, as in any transformation activity, must be activated by identifying the main interested actors involved or to be involved in order that all the people who in different ways will be the users of the places and connected services can not only accept the changes but actively support these in their success.
3) The organization of proximity places must be entrusted to an organization that is the contact person for management and monitoring.
To ensure that the subjects involved in the proximity process are adequately connected to each other, it is useful constitute an organization capable of dealing with the management and maintenance of proximity spaces.
4) To facilitate the achievement of services in no more than 20 minutes, it is necessary to create or improve pleasant, attractive, healthy and liveable pedestrian and cycle paths.
To facilitate the reaching of proximity, it is not only necessary to create pedestrian and cycle connections, but to create pleasant and attractive routes connected to open spaces, squares with designs, quality furnishings artworks and equipment.
5) To allow everyone - the elderly, children, people with disabilities - to reach the services in no more than 20 minutes, the use of electric public transport must be encouraged.
In addition to creating pleasant routes, it is necessary to think about their use being as inclusive as possible, also providing routes for small electric minibuses for fragile people and children. Cycle-pedestrian connections and those for electric minibuses must be designed considering suitable separation.
6) To create proximity, it is necessary to create communities, i.e. actions, policies, projects that favour the aggregation of people.
It is also necessary to encourage the creation of actions capable of bringing people together by supporting communities of citizens who can decide together to transform small parts of territories or buildings to create reinvented aggregations.
7) Proximity must be understood from a perspective of temporal and spatial flexibility, i.e. adaptability to the peculiarities of places and changing needs and users. Proximity services concern:
8) commercial services: food shops with all categories of food, retail shops with all the main goods needed for daily living, local markets, repair and cleaning shops (laundries, tire changes, etc.)
9) health services: clinics, polyclinics, clinics, for blood tests, blood pressure measurement, medications, vaccinations, sociological consultation, and everything needed for prevention and satisfaction of the main social and health needs
10) educational services: nursery schools and schools of all levels
11) cultural services: neighbourhood libraries, pop-up reading points, small theatres, exhibition galleries
12) leisure services: attractive, liveable public spaces, with activities for all age groups and abilities
13) sports services: gyms, outdoor sports equipment, playgrounds, spaces for inclusive physical activity
14) catering services: restaurants, bars, catering places
15) leisure services for pets: off-leash and/or play spaces dedicated to dogs
16) care and well-being services: shops and/or centres for beauty and personal care
17) digital services: digital coverage of the area
18) work services: co-working spaces
19) separate waste collection services: dedicated areas that are liveable and accessible
20) worship and religion services: churches, oratories, places of worship.
Principle 7 to principle 20 concern the services to be included to create proximity. These services can be expanded or reduced, but also modified with a view to a flexible proximity over

time and adaptable to different or sudden needs. No place is the same as another, as different are populations and their needs, which are combined with those of city users, visitors and users of various types.

21) The services should be located in existing buildings with a view to regeneration and multipurpose use of the spaces.

In order to avoid land consumption, physical services must be placed in existing buildings with a view to multi-use at different times, so that a building can be used at different times of the day for different purposes.

22) The proximity of services must be combined with the proximity of greenery and open spaces

Green spaces are another important element to consider in the construction of proximity in a vision of a network between existing green spaces and the naturalization of mineral spaces to create paths attentive to the healthiness of people.

In continuity, the creation of local urban gardens should also be taken into consideration.

23) Places of identity continuity should have signs and billboards, including digital ones, indicating services, activities and points of interest to be reached within 15-20 minutes.

To facilitate orientation and offer a coordinated visual identity in the nearby city, adequate billboards and signs must be created that make the places and services to be reached in a short time immediately understandable. Digital systems such as QR codes can be integrated into the signage which provide further information on proximity services.

24) Proximity is an important factor for the valorisation of places and cultural resources from an inter-scalar and multi-scalar network perspective.

Proximity can be an opportunity to enhance little-known cultural resources, murals, small sculptures, landscapes which, crossed or flanked by pedestrian and cycle paths, could be revealed or observed with greater attention.

25) The new polarities created by proximity constitute new territorial models that will contribute at creating new urban identities capable of adequately comparing with pre-existing ones.

The paths to obtain proximity will finally create new polarities and with them new movements of people and ideas but also new identities not overlapping with the previous ones but intersecting.

Conclusions

The study - carried out in the framework of the 2020 SUMMA PRIN research project that has among the objects to create guide lines for resilient, healthy and flexible places - has illustrated the questions related to proximity regeneration both in theoretical and empirical terms. The city of proximity can be defined as a city able to offer to all its inhabitants everything they need to live, work and have fun to be reached on foot or bike in no more than 20 minutes. Strongly connected to these concepts are the flexibility, important to obtain change uses of places and buildings, inclusion, to assure that proximity is for all and in particular for fragile people and accessibility, to create a network of public spaces open and well connected.

The empirical parts were related to the study case of the former fair of Rome dismissed in 2006 and then in state of abandonment, waiting to be regenerated. The case study was illustrated in relation to: a brief history of the place, the 2011 variant of the 2008 general plan of Rome, the results of the 2015 process of participation carried out by the Rome municipality, and the 2020 agreement for the redevelopment of the former fair approved by the Municipal Assembly; and the outcomes of the analysis of place and the proposed project interventions carried out in the framework of the Urban Planning Course at DICEA Sapienza University of Rome, according to the achievements of both the analysis and the 2015 process of participation also in relation to the questions related to proximity.

In the proposed design of project interventions, it was decided to consider the 2020 municipality agreement that considers 44000 sm as a built area instead of the previous 67000 sm deliberated by the 2011 regulatory plan variant. The general idea was creating a place of identity continuity, a sort of sequence of wholly accessible open-air spaces crossed by a path that from Via di Tor Marancia to Via di Grotta Perfetta connects all the sequence of spaces. Accordingly, the idea was to create an only one area as a sort of multifunctional, inclusive and multigenerational place, - which takes into account both the urban identity, flexibility and liveability - that can change uses in different hours and in which all the necessary services can be reached in no more than 15-20 minutes by foot or bike.

As a final result, the 25 principles Charter of Proximity was illustrated, which consists in a holistic tool for design or verify proximity in an area and assure equitable accessibility.

Objectives of the following Charter are to constitute a flexible, inclusive and updatable tool and become a sort of guideline for all interested to verify or realize proximity in public space. These objectives are important as cities change always more rapidly and not all places are the same, and the 25 principles should be updatable accordingly in an optic of inclusion.

Evaluation and Spatial Governance Strategies for Old Residential Areas' Renewal and reconstruction in Urban Downtown Districts: A Case Study of 70 old residential areas in Changzhou ,China

HU Pan , Sun Keyi, Cheng Jialu, SHI Yu

Affiliation:School of Architecture, Southeast University
Email:hupan@seu.edu.cn

Abstract

As vital components of urban renewal efforts in old city districts, old residential areas play a crucial role in rejuvenating regional vitality, enhancing residents' well-being, and fostering sustainable economic and social development in cities. Taking the example of the transformation of old residential areas in the Zhonglou District of Changzhou City over the past three years, a comprehensive assessment is conducted.By integrating the theory of a full life cycle, a holistic evaluation system for the renovation of aging residential communities is established to assess the project comprehensively. This evaluation system focuses on three dimensions: space, services, and culture, in order to evaluate overall resident satisfaction across all elements.Finally, long-term governance strategies are proposed from four dimensions: government governance, social operations, engineering projects, and economic funding.

Keywords

Old residential area,Renewal evaluation, Spatial governance

Introduction

With the accelerated process of urbanization and rapid population growth, some old residential areas face the imminent threat of decline and contraction, posing a critical issue of how to rejuvenate these communities (Schenkel, 2013). Old residential areas, integral components of urban downtown districts, need to consider various influential factors including multi-stakeholder participation (Bovaird, 2007), preservation of historical heritage (Said, Aksah, and Ismail, 2013), infrastructure upgrading and redevelopment, resident satisfaction (Gu et al., 2019), and the diverse needs of marginalized groups (Clark, Kearns, and Cleland, 2016). The renewal of old residential areas holds paramount significance in revitalizing regional vitality, enhancing resident well-being, and fostering the sustainable development of urban economics and social aspects.

On the practical front, Singapore, Japan, and Western countries initiated urban renewal projects in the 20th century, tailoring innovative transformation models to address issues such as elderly care and employment for low- and middle-income groups based on their respective development contexts. Tokyo actively engages in the transformation of old residential areas, exemplified by projects like Hanada and Takashima, leveraging both governmental and private sector efforts to create multi-party agreement platforms that ensure smooth renovation processes. Regions like Sweden, Denmark, and the Netherlands prioritize community aging adaptation and eldercare service facility configurations. In the Eastern New York Neighborhood Plan in the USA, there's an emphasis on the mixed-use of community street spaces, highlighting the shaping of public areas during transformations.

Compared to international efforts, China's old residential area renovations started relatively late. Since its initiation in 2020, significant progress has been made but challenges such as long-term operation difficulties and governance shortcomings have emerged. In July 2023, China's Ministry of Housing and Urban-Rural Development issued the "Notice on Solid Progress in the Renovation of Old Urban Residential Areas in 2023," proposing qualitative and quantitative analyses to evaluate the current phase of renovations and strengthen the analysis of experiential issues.

As phases of old residential area renovation projects are complete, many Chinese cities are evaluating and providing feedback on completed work at the district level. The Ministry of Housing and Urban-Rural Development surveyed residents of old residential areas in eight pilot cities in Shandong, Zhejiang, Shanghai, and Suzhou in 2022, focusing on residents' subjective satisfaction. Cities like Tianjin's Binhai New Area, Ningbo's Fenghua District, and Nanchang's Donghu District are conducting annual performance evaluations of old residential area renovation projects. Changzhou, as one of Jiangsu Province's pioneering cities in old residential area renovations, has numerous typical samples for evaluation, aiding in systematically addressing issues and demands during renovations and improving management methods and resource allocation for future projects.

Literature review

Research on the renovation of old residential areas mainly includes aspects such as policy analysis, renovation models and strategies, and community governance. In terms of policy analysis, some scholars analyze the advantages and disadvantages of policy samples through textual analysis of renovation policies and quantitative evaluation (ZHANG et al., 2022); while others analyze the policy systems and implementation measures for the renovation of old residential areas in domestic and foreign cities (Lu , 2023). In terms of renovation models and strategies, scholars usually conduct research around a certain element involved in the renovation of old residential areas, such as spatial renovation(MA et al., 2021), sponge-city transformation (LI, GU and WANG, 2019), funding input (LI and ZHANG, 2019), etc.; or from the perspective of micro-renovation (CAI , YANG and LI , 2017), community renewal (Dai , Wang and Dong , 2019), etc., exploring the content and countermeasures of renovating old residential areas. In terms of community governance, some scholars analyze the conditions for social forces' participation and the ways of benefiting, constructing a community governance system for social forces to participate in the renovation of old residential areas (XU and XU, 2020); or from the perspective of resident participation, analyzing the paths and strategies that promote resident participation in governance in the renovation of old residential areas (LI, GU and ZHU, 2020); there are also scholars exploring informal governance models based on communities from the perspective of community administration (ZHAO , LIU and WEN , 2023).

Research on the evaluation of renovation projects for old residential areas is still in its early stages. Researchers usually evaluate the implementation effects of renovating old residential areas from a specific perspective, with significant differences in indicator selection. Some papers have evaluated the effectiveness of renovating old residential areas in a specific aspect

from perspectives such as environmental suitability (LI and WANG, 2016), aging-friendliness (HU, MA and HUANG, 2021), comprehensive environmental improvement (ZHANG, LI and GU, 2021), material space renewal (WEI, 2022), etc.; while others have started from the perspective of project performance evaluation (LI, SI and BAI, 2021), analyzing the comprehensive benefits and outputs of renovating old residential areas.

Through a review of existing theoretical research, it becomes evident that the evaluation of renovation projects in old residential areas encompasses various dimensions. Nevertheless, a comprehensive evaluation system addressing the entire project life cycle remains absent, with a limited number of studies offering comprehensive reviews and summaries of renovation efforts in old residential areas. Drawing upon existing research and practical experiences, this study examines the renovation of old residential areas in Zhonglou District, Changzhou City, employing life cycle theory to develop an evaluation system and establish an evaluation framework at the district level for such renovations. Subsequently, empirical research is conducted.

Research Demands and Objectives

Research Demands

1. The renovation of old residential areas is influenced by various factors such as the scale of construction, construction era, construction subjects, personnel composition, spatial location, and more. It is urgent to propose classified and graded renovation and optimization strategies through scientific evaluation. Effectively enhancing residents' satisfaction is one of the important goals of the renovation work.

2. The factors influencing satisfaction are diversified, including the cultural atmosphere of the community, the organization of activities, personnel composition, and the situation of residents' families. To more effectively guide future work, it is necessary to conduct scientific and systematic research to accurately identify the core contributing factors that enhance residents' satisfaction before and after the renovation, precisely match residents' needs, and effectively improve their satisfaction.

Research Objectives

Based on the two core demands mentioned above, this study aims to establish an evaluation framework with the following objectives:

Incorporating the concept of a full lifecycle, this study comprehensively considers the types of renovation and facilities involved in the renovation of old residential areas. It evaluates the entire renovation process from multiple dimensions, including the output of renovation projects, the quality of renovation works, the management of renovation operations, and the comprehensive benefits of renovation. This evaluation framework encompasses multiple stakeholders, such as residents, community (street) leaders, property management companies, and construction companies.

Furthermore, this study aims to verify the accuracy of the evaluation results by surveying residents' satisfaction after the renovation. Through questionnaire surveys comparing

satisfaction levels before and after the renovation, as well as satisfaction with individual elements and among key demographic groups, this study aims to scientifically identify the proportion of satisfaction improvement brought by the renovation of the community. This will provide sufficient data support for the implementation of future work.

Finally, based on the evaluation content and results of these two parts, this study aims to summarize the experiences and issues encountered during the renovation process and propose long-term governance strategies for community renovation from multiple dimensions.

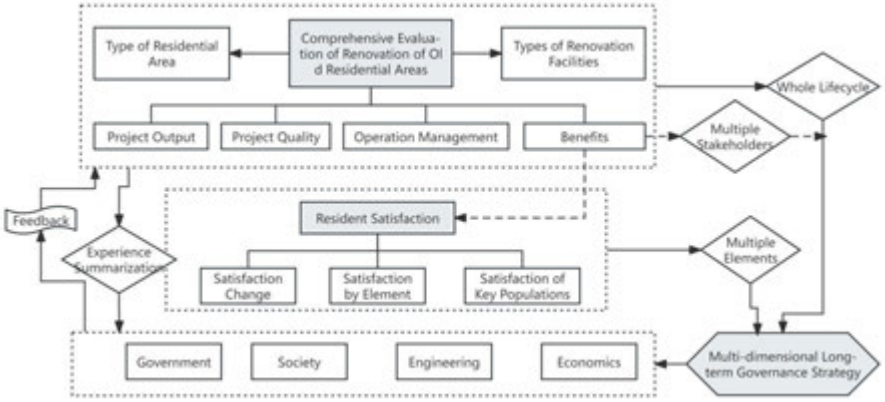

Figure 1 Research Framework

Research Design and Methodology

Construction of a Comprehensive Evaluation System for Renovation

The concept of the whole lifecycle, originating from project management science, is used to describe the various stages of a project from its inception to its completion. The application of the whole lifecycle theory to the evaluation of renovation projects in old residential areas helps align the evaluation chain with the various stages of the renovation project. This approach establishes a comprehensive evaluation process that integrates problem identification, resource allocation, implementation planning, supervision and feedback, as well as summary and improvement. It avoids issues such as incomplete element selection and biases in evaluation focus, providing a basic framework for the implementation, management, and evaluation of future renovation projects in old residential areas.

In light of the planning and construction characteristics of renovation projects in old residential areas, the whole lifecycle of these projects can be divided into four main stages: pre-decision stage, implementation and renovation stage, operation and maintenance stage, and benefit evaluation stage. By further aligning the evaluation process with each stage of the whole lifecycle, an evaluation system for renovation projects in old residential areas can be constructed (Figure 2).

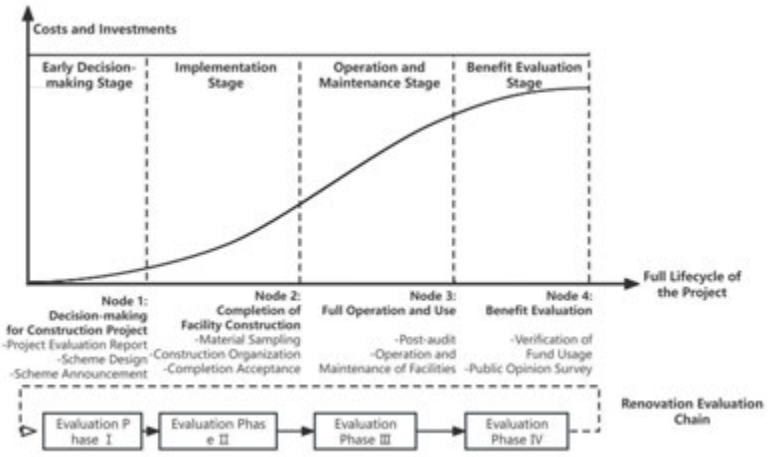

Figure 2 The lifecycle stages of renovation projects in old residential areas

(1) Early Decision-making Stage

Prior to the design of the renovation scheme, it is necessary to conduct a physical examination and assessment of the current operational status of the old residential areas to identify the main issues they face. During this stage, various methods such as field research, interviews, and big data analysis are typically employed to comprehensively evaluate the internal and external environments of the old residential areas. A comprehensive project evaluation report is then formulated. Next, based on the results of the physical examination and assessment, a list of renovation projects for the corresponding old residential areas is compiled. By considering residents' renovation preferences and funding estimations, renovation projects with urgency and feasibility are reasonably selected. This ultimately leads to the formation of a planning and design scheme with clear objectives, reasonable implementation plans, and high recognition among the residents. The indicators of this stage reflect the completeness of the physical examination and assessment results as well as the renovation project list.

(2) Implementation Stage

The implementation stage of the renovation of old residential areas involves multiple aspects such as authorization, execution, supervision, and management control of the renovation projects. During the implementation process, apart from focusing on the completion of construction objectives and the engineering benefits generated by the project, attention should also be paid to residents' satisfaction with the construction progress and the collection and feedback of public opinions. Residents should be encouraged to participate in supervising the renovation process. At the end of the implementation stage, acceptable renovation results should be achieved, with the project accounting settled and residents' feedback addressed appropriately. The indicators of this stage mainly focus on the engineering construction progress during the renovation process as well as the construction status of various facilities at key completion milestones.

(3) Operation and Maintenance Stage

The operation and maintenance stage of the renovation project for old residential areas is a crucial part of the entire lifecycle. At this stage, the spatial renovation and facility configuration for the old residential areas have been fully completed. It is necessary to establish corresponding operation and maintenance institutions or organizations and establish a long-term management mechanism for the residential areas to ensure the sustainable operation of the renovation projects. The quality of operation and maintenance is directly related to whether the project can effectively radiate and drive surrounding areas, and it also influences residents' evaluation of the project. The indicators of this stage assess the operational management status of the old residential areas based on the completeness of institutional systems and actual communication.

(4) Benefit Evaluation Stage

For the completed renovation of old residential areas, a "looking back" process should be implemented. Through the evaluation and measurement of the project's implementation benefits, a comprehensive understanding of the actual outcomes of the project's implementation should be obtained. Incorporating the evaluation and analysis of the renovation benefits of old residential areas into the lifecycle stage of the renovation project helps the government to make a deeper judgment on the social and economic benefits generated by the renovation project. The indicators of this stage demonstrate the benefits brought by the renovation project from both economic and project recognition perspectives (Table 1).

Table 1 Comprehensive Evaluation Index System for Renovation of Old Residential Areas

Primary Indicators	**Secondary Indicators**	**Explanation of Indicators**
Early Decision-making Stage	Type of Residential Area	Proportion of improvement and upgrade renovation projects among the types of community renovation projects
	Types of Renovation Facilities	Whether the types of renovation are comprehensive
	Number of Renovated Facilities Produced	Output of renovation and construction of facilities in old residential areas
Implementation Stage	Civility in the construction process	Whether the implementation process of the project construction meets relevant safety and civilization management regulations
	Qualification rate of renovation works	Operational and maintenance status of completed renovation projects
Operation and Maintenance Stage	Completeness of Management Organization	Whether the organization and business management system of the project implementation unit is sound
	Effectiveness of multi-stakeholder communication	Whether the communication channels between residents, construction parties, and the government are complete
Benefit Evaluation Stage	Project recognition	Residents' recognition of the project
	Efficiency of economic investment	Whether the improvement in residents' satisfaction is proportional to the capital

	investment per unit of renovation area in the community

Satisfaction Evaluation System and Questionnaire Design

Based on the "Technical Guidelines for Renovation of Old Residential Areas in Jiangsu Province (2021)"(jsszfhcxjst.jiangsu.gov.cn, n.d.) and the "Technical Guidelines for Renovation of Old Urban Residential Areas in Jiangsu Province (2022)" (jsszfhcxjst.jiangsu.gov.cn, n.d.), this article draws on the widely referenced evaluation systems for physical spatial environment and public service levels in existing research . By combining emotional value evaluation methods based on residents' perceptions, a comprehensive satisfaction evaluation system encompassing three dimensions of "space + service + culture" and 22 indicators is constructed. The Likert five-point scale is adopted to collect and analyze data on a per-element basis.

Among these, satisfaction with the spatial environment is the most obvious and intuitive aspect of the renovation of old residential areas, and it is also the core content of the early renovation work. Satisfaction with supporting services involves various aspects such as hygiene, parking, elderly care, property management, and safety, reflecting the comprehensive renovation level and humanistic care. Cultural satisfaction covers content such as cultural atmosphere creation, information communication, and dispute resolution efficiency, demonstrating the fine level of renovation and the changes in life brought about by the renovation. In addition, further attention is paid to changes in satisfaction before and after the renovation, as well as the impact of the renovation on surrounding areas and residents' activities (Figure 3).

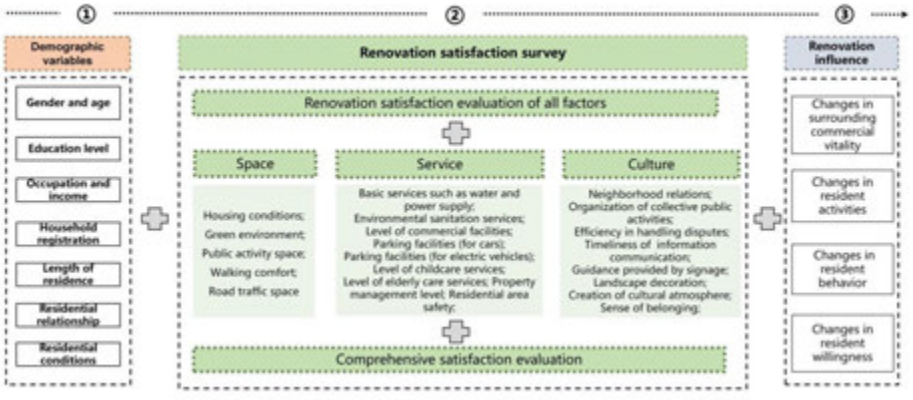

Figure 3 Questionnaire Design and Evaluation Indicators

Research Objects and Data Processing

The Zhonglou District of Changzhou City, located in the central area of Changzhou City, Jiangsu Province, is a core urban area with a long history. In recent years, some old urban residential areas in Zhonglou District have faced issues such as aging infrastructure and incomplete facilities, necessitating renovation and upgrading works. The renovation projects for old residential areas in Zhonglou District of Changzhou City are carried out on a street-by-

street basis, with the old residential areas within the area being classified into two types: improvement type and upgrading type[1].The research objects of this study are 70 old residential areas in Zhonglou District of Changzhou City that started renovation and upgrading from 2020 to 2022 (all built before 2000). More than 90% of them are located in the old city revitalization demonstration area of Zhonglou District, covering both the inner and outer parts of the old city of Changzhou. From 2020 to 2022, a total of 49,126 households were covered by the renovation, with a total building area of 4.0386 million square meters.

Through a comprehensive survey of the implementation of renovation in 70 old residential areas in Zhonglou District, Changzhou City, 1200 valid resident questionnaires and quantitative data on capital investment and engineering construction in each residential area were obtained. Among them, a judgment matrix (see formula 1) was constructed, and the 1-9 scaling method was used to compare the relative importance between renovation evaluation indicators. A questionnaire for judging the importance of indicators was designed. Experts from planning institutions, universities, and street management departments were invited to score the importance of the indicators. Decision-making expert Meta-decision software Yaaph was used to process and analyze the data, obtaining the weight values of the renovation evaluation indicators（Table 2）.

$$A = (a_{ij})_{m\times n} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \quad (1)$$

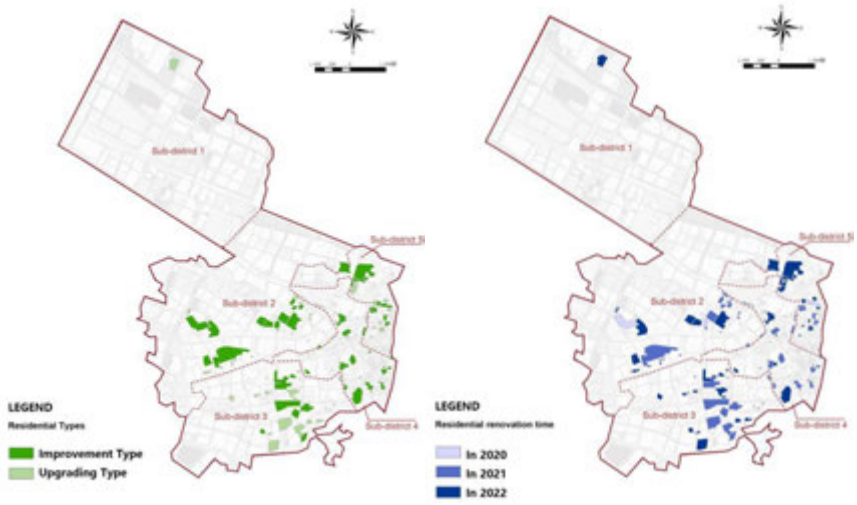
Note: a_{ij} represents the ratio of importance between row factor i and column factor j. When a_{ij} is 1, the two indicators are equally important. The larger the number, the higher the importance of row factor i compared to column factor j.

Table 2 The weight of the evaluation index system

Primary Indicators	Weight Values	Secondary Indicators	Explanation of Indicators
Early Decision-making Stage	15.48%	Type of Residential Area	7.79%
		Types of Renovation Facilities	7.69%
Implementation Stage	39.22%	Number of Renovated Facilities Produced	16.29%
		Civility in the construction process	10.86%
		Qualification rate of renovation works	12.07%
Operation and Maintenance Stage	15.55%	Completeness of Management Organization	10.53%

[1] According to the "Technical Guidelines for Renovation of Old Residential Areas (Creation of Livable Residential Zones) in Jiangsu Province," improvement-type renovations emphasize improving residents' daily lives and enhancing the environmental facilities of the community, while upgrading-type renovations focus more on improving social service provision and enhancing the quality of life.

Benefit Evaluation Stage	29.75%	Effectiveness of multi-stakeholder communication	5.02%
		Project recognition	9.92%
		Efficiency of economic investment	19.83%



(a) (b)

Results

Comprehensive Evaluation Results of Renovation

In accordance with the performance scoring and rating method outlined in the "Measures for the Administration of Performance Evaluation of Project Expenditures" issued by the Ministry of Finance , the total evaluation score is set at 100 points and divided into four tiers. Specifically, a comprehensive score of over 90 points is considered excellent, 80-90 points is considered good, 60-80 points is considered passable, and below 60 points is considered in need of improvement. For the secondary indicator level, the weights of each indicator are converted into specific scores based on a hundred-point system, and the scoring criteria remain consistent with the comprehensive scoring standards. Based on the comprehensive evaluation results of the renovation, the residential areas can be divided into four categories: demonstration communities with excellent renovation results, communities with good evaluation results, qualified communities with one or two shortcomings, and general communities whose evaluation results need to be improved. Figure 5 displays the comprehensive evaluation results of the four types of communities. It should be noted that some scattered residential buildings, due to the limited scope of renovation and the lack of representative data results, are not included in the evaluation results indicated on the map.

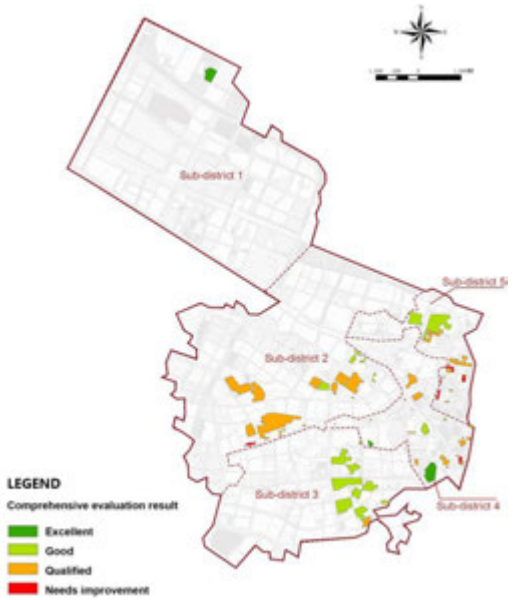

Figure 5 The comprehensive evaluation results of the renovation project

Based on the scoring results of each stage of the life cycle of each residential area, it is found through comparison that:

(1) Excellent and good demonstration residential areas in renovation have made sufficient preparations in terms of preliminary scheme design, engineering construction organization, and later operation and maintenance. Moreover, the construction units have also adopted finer manufacturing techniques, optimized construction methods, and more durable construction materials during the construction process to ensure the effectiveness of various facilities.

(2) For the old residential areas with problems, the main issue is that the effect of the renovation project is difficult to meet various requirements throughout the renovation process of the old residential areas. For example, in terms of building construction, some apartment blocks in some residential areas have issues such as peeling walls and balcony leakage, which have not been promptly addressed during the renovation; in terms of additional parking spaces, some residential areas are limited by their own site conditions and need to vacate parking spaces by reducing green activity spaces, leading to conflicts among residents of different ages; in terms of landscaping, due to the lack of professional greening management teams or property companies, the greening management and maintenance work after the renovation of old residential areas is difficult to carry out in a timely and effective manner; in terms of facility renovation, some old facilities in some residential areas have not been replaced in time, and there are also phenomena of secondary damage after replacement.

Evaluation Results of Residents' Satisfaction

The evaluation results indicate that since the renovation of the old residential areas in Zhonglou District, the satisfaction of the residents has significantly improved, with an overall increase of 21.87%. Specifically, the satisfaction levels in the spatial dimension, service dimension, and cultural dimension have increased by 25.32%, 21.44%, and 19.78% respectively (Figure 7). Among the single factors, the improvement in walking comfort stands out the most, as the partial separation of pedestrians and vehicles, road hardening, and the improvement of public spaces have significantly enhanced the quality of daily life for residents. Additionally, through the renovation, most of the residential areas have added access control and garbage classification facilities, leading to a notable increase in satisfaction with environmental hygiene and community safety. Furthermore, the integration of cultural elements of some neighborhoods with wayfinding signage design during the renovation has been widely recognized by residents.

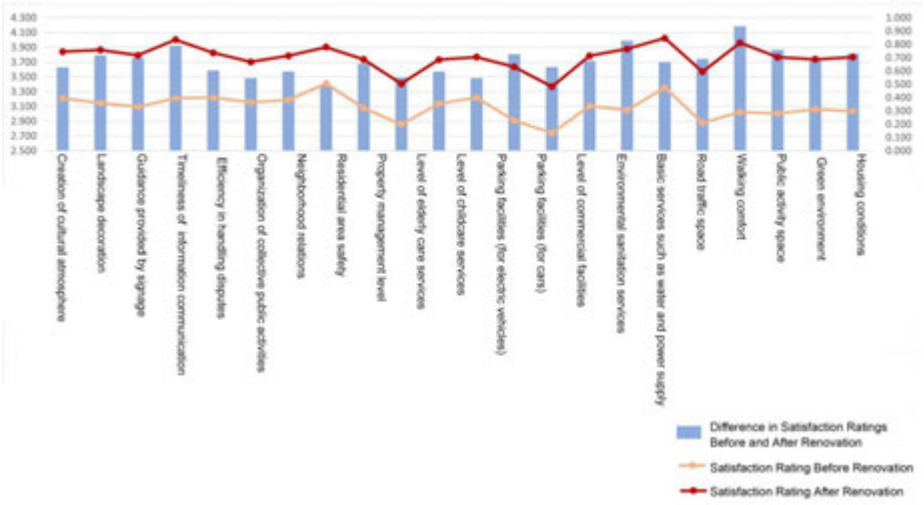

Figure 7 Changes in Satisfaction Ratings for Different Factors Before and After Renovation

However, the difficulty of parking for motor vehicles remains the most prominent issue in old residential areas. Additionally, problems such as inadequate property management, a shortage of human resources, and insufficient introduction of property management companies in old residential areas have generally affected the satisfaction ratings for property management.

The proportion of elderly individuals in the renovated old residential areas is generally high, and whether their living needs have been met during the renovation process has become an important factor influencing satisfaction. The changes in satisfaction among the elderly population towards various facilities before and after the renovation are basically consistent with the overall situation. However, satisfaction levels in areas such as elderly care, parking, and greening are relatively low (Figure 8). The focus on elderly care facilities during the renovation process was not high, and the main renovation content involved elderly canteens and meal assistance services. Although some neighborhoods provide elderly canteens and meal

assistance services on a community-basis during the survey, this service has not yet been popularized in all residential areas. Furthermore, the elderly population often has a high demand for green environments, which conflicts with the demand for parking spaces among other younger and middle-aged groups. The improper management of parking spaces by property management companies later on has led to chaotic parking, which not only encroaches on the activity spaces and green spaces of the elderly but also poses safety hazards for their travel.

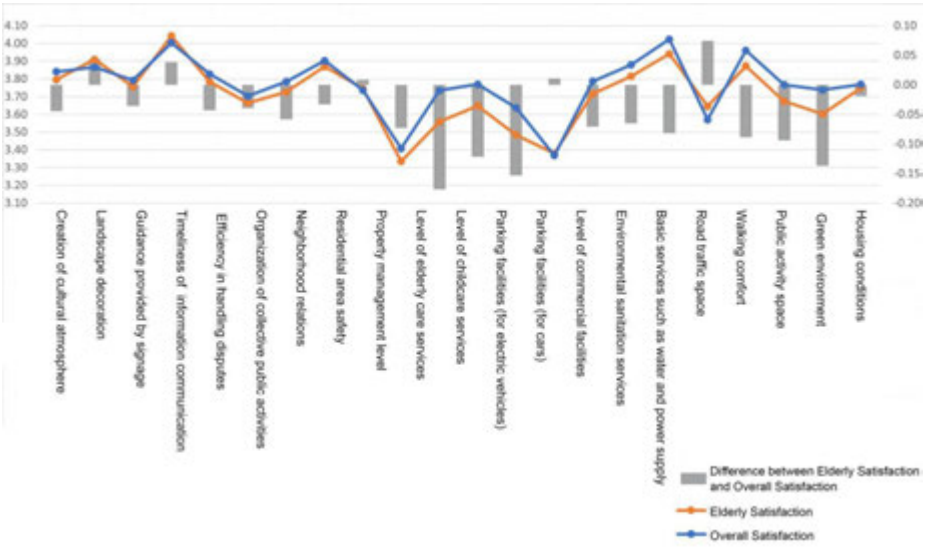

Figure 8 Comparison between Satisfaction of Elderly Groups and Overall Satisfaction

Summary

In recent years, the number of old residential areas included in the renovation scope in Zhonglou District has continued to increase, with the renovation involving a wider range of diverse content and increasingly rich connotations and levels. Through a comprehensive assessment, it can be found that the current core contradiction mainly manifests as a focus on renovation over management. Particularly, difficulties in introducing property management after renovation and the lack of flexibility in using remaining funds have led to a large number of issues arising in the later stages of the residential areas. These issues include patches of bare soil in the green spaces, unmanaged parking spaces, inadequate garbage classification, and difficulties in rapidly accessing firefighting facilities. These problems have seriously affected residents' evaluation and satisfaction with the renovation results.

Suggestions

Based on the analysis of existing issues and the interpretation of relevant policies, this paper draws on the experience of old residential area renovation from both domestic and international contexts to propose targeted long-term governance strategies for the renovation of old residential areas from four dimensions: government, society, engineering, and economy

Dimension of Government Governance: Improving Long-Term Management and Emphasizing Multi-Dimensional Linkages

Optimize the long-term management mechanism, advocate a multi-party co-governance system, and establish a governance system with the participation of grassroots party organizations, community residents' committees, owners' committees, and property management enterprises. Strengthen the leading role of grassroots party organizations in party building and coordinate the handling of various mass affairs; stimulate the supervisory role of owners' committees and actively participate in the follow-up management and effect feedback of the renovation plan; promote cooperation between property management enterprises and party organizations to jointly promote community governance activities. Provide multiple information transmission channels and combine online platforms to timely report community governance information and ensure the right to know for residents in the community. Establish long-term management evaluation standards, normalize the work of conducting "look-back" assessments on the renovation of old residential areas, and conduct graded and categorized acceptance inspections on the management effectiveness of renovated old residential areas.

Dimension of Social Governance: Encouraging Multi-Party Participation and Implementing Classified Management Models

Encourage property management enterprises to actively participate and explore diversified property management models. Research a trinity model combining government underwriting and trusteeship, residents' self-management, and property enterprise management based on the principle of "one community, one policy." For communities that do not meet the conditions for introducing market-oriented property management, an owner self-governance management model can be adopted. For communities that already have property management enterprises, it is necessary to actively promote service upgrades to meet residents' high-quality needs and stimulate enterprise enthusiasm through market-oriented means. Reduce property management costs and minimize "small, scattered, and isolated" communities through management models such as "connectivity, merger, and trusteeship."

Dimension of Engineering Governance: Addressing Facility Shortcomings and Promoting Facility Upgrades

Regularly conduct self-inspections of infrastructure renovation projects, coordinate with communities, and organize construction units to actively make rectifications to ensure smooth and level roads and unobstructed drainage systems in the community after renovation, safeguarding residents' basic daily travel environment. Enhance the quality of housing through improved technological processes, promote the adoption of technologies and materials that are innovative, mature in process, meet quality standards, and have controllable costs, maintain the unity of styles and materials for the renovation of old residential areas in different districts, and achieve organic integration with the cultural heritage and stylistic characteristics of the community. Scientifically assess and accelerate the updating of infrastructure pipelines and ducts with potential safety hazards such as water supply and heating systems, and strengthen the supporting infrastructure for fire safety.

Dimension of Economic Governance: Innovating Financing Models and Using Special Funds Flexibly

Innovate pilot fund sharing and sharing mechanisms, improve fund allocation rules, and raise renovation funds through general public budgets and government bonds. Pilot the introduction of a flexible fund use mechanism, where a smaller proportion of land transfer income from newly added residential land can be extracted as special funds for the renovation of old residential areas, with the remaining portion allocated according to regulations. Increase government financial support, attract market forces to participate, encourage qualified state-owned enterprises to participate in the renovation as scaled implementation and operation entities, and further explore various funding methods.

Conclusion

Based on the concept of a full lifecycle, this article constructs a comprehensive evaluation system for the renovation of old residential areas, aiming to provide a scientific and reasonable evaluation standard for relevant departments to accurately grasp the issues and contradictions in the renovation of old residential areas. An empirical analysis of the renovation of 70 old residential areas in Changzhou City shows that there are still core issues such as insufficient public participation, prominent contradictions in the needs of different groups, inadequate facility maintenance, and a lack of long-term management mechanisms during the renovation process of old residential areas. In the future renovation of old residential areas, it is necessary to further combine the characteristics and needs of the renovation of old residential areas in the region, identify the positioning of the management subject, straighten out various relationships, strengthen the multi-level linkage management model of district-street-community, focus on establishing corresponding operation and management organizations or platforms at various stages of the project's full lifecycle, and explore the formation of sustainable renovation and management models for old residential areas.

Abstract

As one of the main concerns of urban studies, more and more scholars have paid attention to the interaction of the government, community, residents and other stakeholders in the process of urban renewal, as well as the significance of participatory planning for the sustainability of cities. Strikingly, however, there are few studies on the gender dimensions of participants. In fact, in an urban renewal project in Yulin Community of Chengdu, I observed that women were the major participants in the process. Therefore, this study uses the theory of intersectionality to analyse the three different female groups in this urban renewal project, including professional women, female community workers and female resident activists. The diverse rights, knowledge, ethics and other backgrounds held by different female groups led to complex participation motivations, processes and outcomes, to fill the research gap of the gender dimension in the participation process.

Women's Participation in the Context of Urban Renewal in China: A Case Study of Yulin Community in Chengdu

Abstract

As one of the main concerns of urban studies, more and more scholars have paid attention to the interaction of the government, community, residents and other stakeholders in the process of urban renewal, as well as the significance of participatory planning for the sustainability of cities. Strikingly, however, there are few studies on the gender dimensions of participants. In fact, in an urban renewal project in Yulin Community of Chengdu, I observed that women were the major participants in the process. Therefore, this study uses the theory of intersectionality to analyse the three different female groups in this urban renewal project, including professional women, female community workers and female resident activists. The diverse rights, knowledge, ethics and other backgrounds held by different female groups led to complex participation motivations, processes and outcomes, to fill the research gap of the gender dimension in the participation process.

Key Words

Urban renewal; Women's participation; Intersectionality; Feminism; Space power relation

1. Introduction

In China, urban renewal is mainly carried out through a "top-down" model, in which the central and local governments are responsible for renewal projects and make most of the investment (Ma et al., 2021). However, with the prosperity of social economy, the development of urban diversity and the awakening of civic awareness, the traditional "top-down" planning method is no longer applicable to current urban renewal processes in China (Li et al., 2019). Urban renewal has to pay more attention to the needs of multiple stakeholders. Since 2007, the Law of the People's Republic of China on Urban and Rural Planning introduced by the Central Government of China has clearly stipulated the basic requirements for public participation in planning processes, and vigorously advocated public to participate in the process of urban planning. Public participation is considered as an effective method of urban regeneration, which can play a crucial role in sustainable urban development (Hui et al., 2021, Li et al., 2020). Therefore, in current Chinese government-led renewal projects, "participation" involves not only the government participation represented by the project working group entrusted by the local government, but also includes the public participation of the residents' committee of the community and the homeowners (Ma et al., 2021). Existing research on urban renewal participation also mostly focuses on the interaction among stakeholders such as governments, project working groups, communities and residents and their influence on the final results of urban renewal (Tan and Altrock, 2016, Zhai and Ng, 2013, Zhang and Li, 2016).

In the 2023 urban renewal project in Yulin Community in Chengdu launched by the Ministry

of Housing and Urban-Rural Development, which I participated in as an intern, I found that women's participation is obviously higher than that of men, and they also maintain an absolute advantage in quantity. 1 As the working group of this project to undertake government work, our working group was entirely composed of women. 2 The staff of the community neighbourhood committee were mostly females. 3 Female residents, such as housewives and female art workers, generally had more positive attitudes towards urban renewal than male residents. Women played an irreplaceable and important role in urban renewal. In fact, there have been several scholars demonstrating the importance of female participation in community development through studies of female staff of the community residents committee (Yingjie Wang, 2023, Yinxu, 2022), and female residents activists (Yinxu, 2022). But their research objects are mostly confined to specific female groups, and there are very few systematic discussions of the three different groups of women in the participation process.

Therefore, this paper tries to fill the research gap on the gender dimension of the participants in the process of urban renewal in China from the perspective of feminism. Taking the renewal project in Yulin Community as an example, this study tries to use the theory of intersectionality to analyse the three different female groups: professional women in the working group, female staff in the community and female resident activists, which is aimed to integrate the seemingly "loose" involvement of women in the renewal project and analyse the oppression and empowerment of ethics and power involved behind various female participants, so as to try to answer the following questions. Why most involved in the urban renewal project are women? What are the motivations and processes for women to participate in urban renewal projects? What are the potentials and limitations of female participation?

This paper is structured as follows. In Section 2, it will briefly introduce the case of Yulin Community in Chengdu, China; in Section 3, it will outline the methods and analytical framework of this study; in Section 4, it will analyse the dynamic path of women's participation in detail taking renewal as an example; in Section 5, it will discuss the impact of these women's participation on urban renewal and feminism, as well as the possible future development direction of women's participation. At the end of this article, Section 6 draws a brief conclusion and the significance of this study for women's rights and gender-equal urban development.

2. Case Study

Taking Yulin Community in Chengdu as an example, we try to analyse the reasons, processes and results of women becoming the main force of public participation in urban renewal projects.

Yulin is located in Wuhou District, Chengdu, which is a typical old community in the centre of Chengdu (Figure 1). Most buildings in the community were built in the 1980s, and most of them are walk-up buildings on six to seven floors. With the collapse of the unit system, the general ageing of buildings, the imperfect infrastructure, the growth of the urban floating

population and other practical reasons, Yulin started to show signs of decay (Chen, 2023). According to the data of the seventh national population census in 2020, there are more than 21,000 people in Yulin, among which the ageing population (the population over 65 years old) accounts for 15.8 percent, while the ageing population in Chengdu only accounts for 13.6 percent. The ageing situation of the community is pretty prominent. How to rebuild the cohesion of Yulin and make up for the shortage of infrastructure has become an urgent problem to be solved.

In addition, Yulin Community has a unique background characteristic. In 2016, Yulin was unexpectedly exposed to the wider public for a folk song called "Chengdu". Yulin has overnight become the most famous living area in Chengdu, the cultural image of Chengdu and well-known in China. More and more artists and musicians come to the community. They buy or rent apartments in Yulin and turn them into studios. The various small bars, coffee shops and tea houses located in the community have become a gathering place for all kinds of art circles. It is no exaggeration to say that Yulin can be called the cradle of modern art in Chengdu now.

In 2017, Yulin Community officially launched an urban renewal project. In 2023, Yulin was listed by the Ministry of Housing and Urban-Rural Development as one of the first 10 pilot cities to "deepen the pilot system of Urban (Health) Check-up". As one of the key steps of urban renewal in China, the main task of Urban (Health) Check-up is to conduct a comprehensive investigation of the real situations of the community infrastructure and the built environment, so as to lay a solid foundation for the more targeted implementation of urban renewal and transformation in the future.

In one sense, as the designated pilot community of the central government's urban renewal project, Yulin is a very representative case of urban renewal in China, which can reflect the overall trend of the renewal process of old communities in Chengdu, China. Moreover, under the unique background of Yulin, the influx of artists challenges the social stereotype of women, promotes a more diverse and inclusive social development, and stimulates the change in the community, which is crucial to promoting the development of feminism.

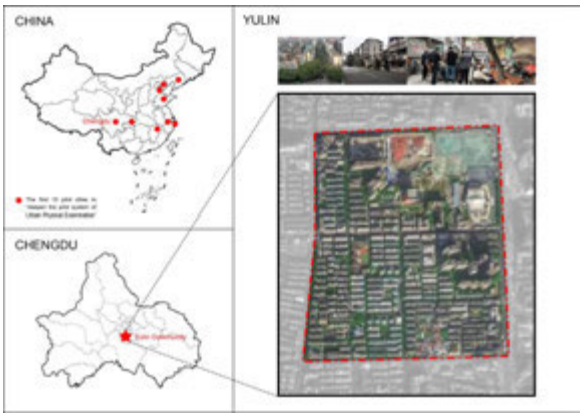

Fig. 1. Location of Yulin Community

3. Methodology

Intersectionality, as an important analytical framework in gender studies, was proposed by Kimberle Crenshaw (Crenshaw, 2013a). By discussing the unique experiences of black women, Crenshaw illuminates their intersecting causes of inequality, particularly along race and gender lines (Crenshaw, 2013a, Crenshaw, 2013b). Intersectionality emphasizes the interrelationship of multiple factors in individual identity, such as gender, race, class, etc., which are intertwined to form unique social status and experience, thus revealing the multi-level inequality and inequality that exists in different social groups. Discrimination. For Chinese society, the intersectionality derived from the black feminist movement shows a strong focus on the oppressed and effectively resists oppressive forces such as capitalism, patriarchy, racism, heterosexism, etc., which can preserve vulnerable groups and marginalized groups to provide powerful weapons (Sun, 2023). It is of great significance to the improvement of Chinese feminism and the development of social and spatial justice in China.

Therefore, in order to answer the questions raised above, this study uses the intersectionality theory to analyse the three female groups, including working women, female community workers and female resident activists, observed in the field during the process of Yulin Renewal Project in August and September 2023. The diverse rights, knowledge, ethics and other backgrounds held by different female groups lead to complex participation motivations, processes and outcomes. In particular, in Chinese social culture, structural factors such as state power and grass-roots organizations cannot be underestimated or ignored (Sun, 2023). A deep understanding of the dynamic participation paths of women of different social identities in urban renewal projects can help identify inequalities and make recommendations for improving social systems and spatial planning.

4. Result

4.1 The Working Group Was Entirely Composed of Professional Women.

The four members of 2023 Yulin Urban Renewal Project's working group were all women. This may be the result of unequal power structure in the workplace and gender inequality in planning sectors. Cities are often planned and designed by male dominance, and women are underrepresented in the planning industry (McDOWELL and Walkerdine, 1969). Male planners tend to be more easily responsible for large urban planning projects, such as urban general planning projects, while female planners are in a relatively weak position and can only work for small urban renewal projects. In addition, because of China's current diverse and complex planning realities, the project working group must pay more attention to the link of public participation (Hui et al., 2021). It is widely believed that women can better coordinate the complex interests in the urban renewal process in a more delicate and gentle communication way than men. Therefore, female planners are generally considered to be more conducive to urban renewal projects than male planners.

Therefore, as members of the working group, professional women have the expertise in urban renewal. We were involved by the "institutional arrangement", which has a certain passivity. After informing the community neighbourhood committee about this project, they organized relevant activities, such as indoor lectures, pilot project seminars, etc., to the neighbourhood committee staff and homeowners introduced the purposes, processes and needs of this project, and guided them to participate in the subsequent activities of urban renewal. In general, the working group, as a representative of state power, not only needed to be responsible for various negotiation work related to the grassroots neighbourhood committee and homeowners, but also was required to be responsible for the results of the final urban renewal project.

4.2 The Staff of the Community Neighbourhood Committee Was Almost All Female.

It was observed that only two of the more than ten staff members of Yulin Residents Committee were men. The personnel composition of the community neighbourhood committee is largely regulated by the traditional ethics in China, which affects the behaviour, attitudes and choices of different gender groups (Sun, 2023). On the one hand, community work is favoured by women because of its stability and proximity to home; on the other hand, men have to try their best to leave this low-income industry because of great life pressure.

The staff of the community neighbourhood committee directly facing the homeowners, needed to keep in touch with the masses. At the same time, they also had to help the government to complete good community management and service, like reducing the contradiction between owners and between owners and the working groups. They obtained professional knowledge training by participating in the indoor lectures organized by the working group, thus assisting the working group to better carry out the project and encouraging the owners to participate in relevant seminars. As a grass-roots organization, the community neighbourhood committee helped to improve the quality of local urban

governance and alleviate the social conflicts in urban renewal at the micro level.

4.3 Most of the Owners Involved in the Renewal Project Were Women.

In this project, female residents tended to be more actively involved in community activities. According to the data of the fourth Chinese Women's Social Status Survey in 2021, women are still the main force of family activities in China, and undertake the main internal family labour such as caring for children and supporting the elderly. They use the community space and play an important caregiver role in society more often than men, so they need planned urban projects to support them in this role (Ortiz Escalante and Gutiérrez Valdivia, 2015). Particularly, in the Chinese patriarchal context, the women outside governments' system as the marginalized social groups, such as housewives, are restricted by the traditional social ethics. They intentionally use institutional paths to express their interests, improve their status in the community, and alleviate the inequality of power in the male-dominated state (Guan and Liu, 2021). Not only that, a large number of female artists in Yulin also pay more attention to gender equality and female power than ordinary property owners. They are more active in expressing their desire for women's voice, challenging the traditional gender ethics, and calling for women's equal society through various media. Naturally, they didn't want to miss the opportunities and channels to participate in such public affairs as urban renewal, play a role at the level of community, and strive for gender equality. Feminism grew in the community and in the city.

Therefore, female residents, artists, etc sought possible ways to express their spatial demands by actively participating in relevant activities organized by the working group. For them, their competition for space was their right to be seen, be heard and have a direct impact on the country and society (Mitchell, 2003). Public participation in urban renewal projects could be seen as a powerful weapon against gendered cities by vulnerable and marginalized women.

5. Discussion and Conclusion

5.1 The Motivations of Different Groups of Women Who Are the Main Population Involved in Urban Renewal Are Complex Due to the Intersection of Identities.

The professional women in the working group are passive participants due to gender inequality in the workplace and specific gender role stereotypes; while community female staff and female resident activists who are influenced by social ethics and avant-garde artistic atmosphere, are active participants in order to work more stably or to improve their status in the community and alleviate the inequality of gender power.

5.2 Women's Participation in Urban Renewal Has Significant Advantages.

5.2.1 Women's Participation Means the Spatial Empowerment of Individuals and Collectives of Women, Especially Marginalized Housewives.

They exercise their civic power by participating in the process of urban projects. Collective empowerment can make the knowledge and experience of women, especially marginalized women, visible and provide a platform and space for them to have a voice for themselves (Ortiz Escalante and Gutiérrez Valdivia, 2015). In a patriarchal society, public participation, as a political and social channel, can be used by marginalized female social groups to express their reasonable demands, give more autonomy to manage their lives, and improve their status in the community. Women's participation alleviates the traditional male-dominated spatial power relations to some extent.

5.2.2 Women's Participation Is Conducive to Building More Inclusive and Gender-equal Cities.

Traditional "top-down" urban planning generally considers the interests and needs of men, but rarely considers the special needs of women (Beebeejaun, 2017, Garcia-Ramon et al., 2004). Women participate in urban renewal projects by virtue of their gender advantages, so as to strengthen the public's attention to spatial deprivation in women's daily lives and make up for the neglect of urban renewal under the traditional "male perspective" or "asexual perspective" theory on the needs of female groups, who account for half of the total population. Therefore, we can pay more attention to the voices of women, fill the gap in gender knowledge, and make the city more inclusive and equal.

5.3 Women's Participation in Urban Renewal Has Certain Limitations.

5.3.1 Women's Participation Only Provides a Repair Reference for Urban Renewal, but Cannot Directly Influence Urban Decision-making.

Public participatory planning for urban renewal in China is still at the initial stage (Hui et al., 2021). Even though there was a participatory shift happened in China emphasizing the importance of public participation, the impact of communities and homeowners in the statutory planning process is still limited (Beebeejaun, 2017, Guan and Liu, 2021). Although most owners are positive about government-led urban projects and keen to participate, they cannot fully participate because the process setting is not carefully designed (Ma et al., 2021). Almost all public participation activities are distributed in a variety of disconnected, unrelated and fragmented environments. This hinders the formation of inter-community and inter-regional coordination and the emergence of awareness beyond the local environment (Guan and Liu, 2021). This also results in participatory activities in China largely disconnected from political decision-making (Beebeejaun, 2017, Guan and Liu, 2021). Moreover, as mentioned above, urban space is usually designed and planned by men, and women have insufficient representation and leadership in the urban planning sectors (McDOWELL and Walkerdine, 1969). This has led to the planning departments and local governments being ostensibly open to supporting the principles of powering women and potentially accepting the idea of their involvement in consultations on important issues in a particular location. However, in a patriarchal society, men have political and economic power that women do not access, and use this power to create a male-dominated ideology. They are

often more reluctant to commit to incorporating women's views and ideas, let alone allowing women to intervene directly in actual changes in the city (Ortiz Escalante and Gutiérrez Valdivia, 2015).

5.3.2 Women's Participation Strengthens the Stereotype of Gender Roles to Some Extent.

Judith Butler's gender performativity suggests that gender is not an inherent identity, but a social construct that is constantly realized through action. Gender performance may reinforce stereotypes ideas and social expectations (Butler, 2020). The involvement of professional women in the working group adhered to traditional gender norms and expectations that women are more advantageous in negotiations, thus fuelling the perpetuation of traditional gender values. This reinforcement of stereotypes due to performativity further negatively affects individuals, which can limit women's work choices through harmful gender norms.

5.4 The possible future direction of women's participation.

5.4.1 Change the Unequal Power Structure of the Workplace.

In the workplace, continuous efforts can be made to address the power imbalance by subverting traditional gender norms and gender role stereotypes. By guaranteeing gender quotas, diverse training and flexible work arrangements, we can drive dynamic changes in power in the workplace and create an equal and inclusive working environment.

5.4.2 Change the Male-dominated Social Structure.

Formal and informal training on urban planning from a gender perspective is an important strategy to overcome the gender inequality barriers encountered in urban transformation (Ortiz Escalante and Gutiérrez Valdivia, 2015). It helps to make more planners aware of the need to engage women actively in urban renewal projects. This strategy requires a stronger political commitment at the institutional level to enable structural changes to promote gender equality.

5.4.3 Expand the Influence of Public Participation.

The main problem with China's participatory planning is that the existing participation does not fully receive public opinions. In particular, the perceptions of the government are consistent with the professional views of the private sector like the working group, but are far from the perceptions of the citizens, which ultimately leads to the neglect of the public voice (Liu et al., 2022). According to Bingsheng Liu et al., in the performance evaluation, the stakeholders should be required to measure the level of public participation in China's urban renewal projects, so as to overcome the problem of insufficient influence of public participation (Liu et al., 2022).

6. Conclusion

This paper explores the dynamic path of Chinese women's participation in urban renewal based on observations and secondary resources. In order to protect the rights and interests of participants in this urban renewal project and avoid possible sensitive information involved, this paper mainly uses existing literature and research results to conduct an intersectional analysis of the phenomenon of Chinese women becoming the main participants in urban renewal. This allows for a broader understanding of the complex motivations, processes and outcomes involved in participation behind the phenomenon. However, it must be acknowledged that the use of limited primary data may result in the reliability and accuracy of this study being affected by the researcher's subjectivity.

However, the above research still has certain potential and significance. By using an intersectional approach to study the relationship between gender, power, space and knowledge behind different female participating groups in the Yulin community renewal project process, it explains the role of women in urban renewal in China. phenomenon of the main actors in the process. (1) Due to the unequal power structure and gender role stereotypes in the workplace, the project working group was forced to be composed entirely of professional women. As representatives of the government, they led the entire urban renewal project; (2) Influenced by traditional social ethics As a result, almost all the staff of community residents committees are women, and most of them actively join this industry; (3) More female residents actively participate in the urban renewal process and seek opportunities to voice their demands for women's space.

Female participation in the urban renewal process has alleviated the traditional male-dominated spatial power relationship to a certain extent, helped planners fill the gaps in gender knowledge, and made the city more inclusive and equal. However, it has to be admitted that women's participation provides more of a patchwork reference for urban renewal, but cannot directly influence urban decision-making, and to a certain extent strengthens gender role stereotypes.

But this does not mean that women's participation is useless and unimportant. Urban planning and renewal from a gender perspective is a necessary means to eliminate gender discrimination in cities and ensure women's empowerment. This study critically reflects on women's participation in urban renewal practices not only as a conscious and purposeful questioning of the male-dominated planning industry and participatory planning, but also as a way to provide adjustments from a gender perspective for the sustainable development and stability of cities. Urban renewal not only requires the active participation of more women, but also requires more profound structural changes at the social level to promote gender equality.

Abstract (up to 125 words)
Harbin is a city historically shaped by its railway heritage. The construction of the Chinese Eastern Railway, a railway linking Europe and China, has rapidly transformed Harbin from a fishing village to an international metropolis in just half a century. The railway brought expatriates to Harbin, as well as European planning concepts to China. In the process of rapid modernization, Harbin's unique urban form is based on a Western urban texture, overlaid with localized planning ideas. Thus, understanding the historical development and preserving the spatial morphology of Harbin's historic core are key research goals. This research employs the spatial syntax framework to decode the urban axis model of Harbin across four distinct developmental epochs. By quantifying the local integration indices of these axis models, our investigations divulge that the burgeoning expansion of Harbin's urban footprint and the establishment of novel districts have not fundamentally disrupted the historical urban axes. This study contributes to our understanding of urban adaptation and suggests ways to preserve these unique urban features.

1.Introduction

For a long time, the protection of cultural heritage and urban development have been in a contradictory, opposing and complex relationship. How to balance development and conservation is an important issue in urban planning and heritage conservation. In 2011, UNESCO formally adopted the Recommendation on Historic Urban Landscapes (HUL), which proposes to perceive the heritage objects from the perspective of value linkage and historical stratification. It expands previous perception of heritage and points out a new direction for historical conservation.

Historic districts are predominantly situated in city centres, reflecting the unique interplay between natural geography and the city's historical and cultural traits. These districts embody the tangible results of social change, economic growth, and local cultural developments.

Consequently, an in-depth exploration of the laws governing the amalgamation of urban space and its evolutionary traits is crucial for the preservation of historical continuity and the scientific protection of historic urban areas.

Since the advent of typomorphology, urban characteristic studies have embraced spatial and temporal dimensions. Spatially, it is posited that complex urban spaces are composed of specific morphological units. Analyzing these units from local to global scales provides insights into the structure and characteristics of the space. Temporally, emphasis is placed on the evolutionary processes of phenomena, deconstructing the relationships between space and societal and cultural dynamics through a historical lens. This approach helps reconstruct the logic of fragmented forms to elucidate the historical evolution of urban spaces.

The theory of space syntax, pioneered by Professor Bill Hillier, is instrumental in quantitatively analyzing urban space networks. This theory uses the human aspects of urban spaces as a lens to assess the connectivity and integration of these spaces, thereby enhancing our understanding of the relationship between societal structures and spatial layouts. Applying space syntax in preserving historic areas and their morphologies is an effective method. Time is a critical element in analyzing regions' characteristics and developmental patterns.

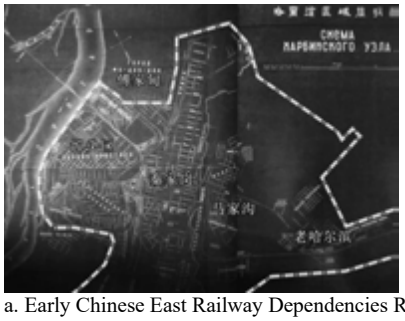
This study employs the space syntax methodology in the historic district of Harbin, which exhibits distinct spatial morphology characteristics. The research questions are: 1) What are the urban morphological characteristics of Harbin with the logic of historical time? 2) What are the evolutionary laws of spatial morphology at different historical stages under the quantitative model? 3) In the face of the existing urban morphology, how should future urban planning be controlled to protect the spatial characteristics of the city?

2.Methology

2.1 Site and case

Harbin, located in the north-east of China, is a city born because of the railway, and it took only 50 years for Harbin to become an international metropolis from a small fishing village. The spatial structure and form of Harbin reflects the modern international planning ideas and strong colonial atmosphere, which is a historical witness of the vicissitudes of the city and a typical practice of modern planning concepts.

The scope of the study is the historical urban area of Harbin (Fig 1) . It is a area that reflects the city's early planning and construction idea This also covers the "Historic District" as defined in the Harbin Historic City Protection Plan.



a. Early Chinese East Railway Dependencies Range

b.gaze to the research scope

Fig.1 Research case

2.2 Historic urban morphology materials

The construction of the CER in 1898 was an opportunity for Harbin's urban development. Many foreign engineers and workers gathered here to form the first urban area. Since then, the prototype of Harbin's modern city began to unfold. Subsequently, multiracial people gathered here and constructed their own ideal space, forming a unique urban form and architectural style, which made Harbin win the "Paris in the East" titles.

According to the historical news and the ownership of the city management, the urban development of modern Harbin can be divided into "1898-1932: the period of Tsarist construction and influence", "1932-1945: the period of Japanese construction and management", "1945 to the present: the period of modernisation and development". Therefore, based on the available historical map resources, 1932, 1946, 1975, and 2018 were selected as four-time slices to quantify the urban form.

Fig2 City maps of four development periods

2.3 Data collection

A line shape file is created in ArcCatalog, and the roads are extracted from the planning drawings or satellite maps of the four periods to form the axial maps of each period as the primary data of the model. In this paper, the DepthMap software platform is used to analyse the spatial shape, and the spatial shape features are discovered through the statistical analysis of several parameters, such as connection value, integration degree, comprehensibility and synergy degree.

3.Results

3.1 Characteristics of early urban planning

Streets are an essential part of urban space. Its planning and construction not only reflects the development stage of the city, but also influences the organisation of social activities and residents' way of life. The form of Harbin road network is influenced by planning ideas and regional functions, adopting an ideal and existence of regular geometric form, common layouts are square grid type, circular, radial.

In the early period, port area road construction in line with the Songhua River and railway line alignment, the formation of diagonal grid layout. After the opening of the port, Qinjiagang in the new railway station lot formed a combination of square grid, radial and fan-shaped network of road forms, baroque formalism style. During this period, the city was divided by the railway to form clear zones, and the road construction within each zone was gradually improved.

The structure formed during this period was the prototype and foundation for the formation of the city of Harbin. The railway station is located in the city's centre and connects the two districts. The city's landmarks and churches control the centre of gravity of the two zones. The urban planning was based on the railway, with clear functional zoning, centred on St. Nicholas Square in Qinjiagang (now Nangang District), with Dazhi Street and Hongjun Street as the cross-axis, of which Hongjun Street extends southwards to connect with Old Harbin (now Xiangfang District). In the port district (now Daoli District) to the Jingwei Street as the central axis connecting the dock and railway station, and derivatives of the branch to the riverside for the secondary axis, the Central Avenue. The axes of the two districts are linked by the railway station, reflecting the main nature and function of Harbin in the city's early days.

Fig.3 Characteristics of early urban planning

3.2 Evolution of urban form

From the quantitative results of the spatial syntax, the axes of the historical urban area are stably inherited and prominent (fig.4).

Referring to the topological principle, the local integration degree of the urban axis model is calculated by the spatial syntax to extract the axes of the urban area at four different development stages. The results of the analysis show that the expansion of the city and the construction of new districts did not have too much impact on the axes within the historic urban area and that Nangang District developed east-west at the beginning of the construction with Dazhi Street as the central axis, and then gradually added several roads perpendicular to Dazhi Street as the auxiliary axes of the spatial development structure. The spatial axis of the historical urban area in Dori is stable, with Jingwei Street and Central Avenue, and the commercial activities in the urban area are carried out accordingly. The urban axis's stability reflects the spatial pattern's stability to a certain extent.

The results of the spatial syntax analysis show that since the Japanese colonial period, the degree of integration of the north-south axis of Hongjun Street has gradually weakened. In contrast, the east-west axis of Dazhi Street has strengthened. At the same time, the degree of integration of the road appears to be higher in the west and lower in the east, which shows that the city of Harbin has leapt forward to the west in the direction of development. From the colonial period to the eve of reform and opening up, Nangang and Dawri historical city roads in the average integration of a significant increase in urban axes also occurred a reasonable increase, which is Harbin in the "First Five-Year Plan", "Second Five-Year Plan" period of the country's key industrial projects, the city to the industrial as an opportunity for development and construction. Industry as an opportunity for development and construction is closely related. After entering the modern period, the city expanded around the central city in a dense and orderly manner. The large-scale road grid surrounded the historical city. Nangang District increased the number of sub-axis perpendicular to Dazhi Street, such as the education street, Haicheng Street, Gogol Street, etc., which is closely related to the construction of large-scale municipal facilities such as bridges and underground passages.

Secondly, the planar texture of the landscape corridor is preserved, but the sense of spatial place is weakened, and genes are hidden. In the process of urban modernisation and development, a large number of high-rise buildings have changed the spatial scale of the original streets, lacked a sense of order and blocked the view corridors so that these contrasting spaces are not well presented and have a low recognition in the urban structure, such as the contrasting corridors of the Beixiu Square and the railway station. In addition, the destruction of landscape nodes and the change of function also led to structural invisibility, such as the disappearance of St. Nicholas Church and the change in the functional nature of the Correctional Square, which weakened the structure of the triangular-shaped square in Nangang District.

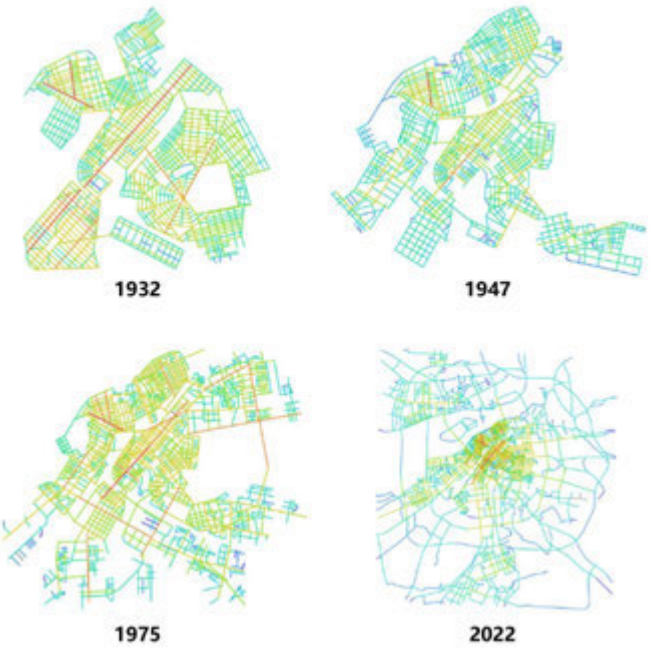


fig.4 Evolution of urban form

3.3 Urban planning control strategies

The planning idea of Harbin's early garden city and the unique form of the road network have created a wide variety of view corridor in the city. The recognisability of the linear pattern in the city usually comes from the spatial perception of the residents. Therefore, the protection of the axes and corridors in the historic urban area should be based on visual guidance, construction control, restoration and shaping of a distinctive urban image.

The linear pattern of the Harbin Historical Centre is preserved, and the form of the city roads and squares is still present, which provides the basis for strengthening its spatial characteristics. The enhancement of the linear pattern in the city is divided into two aspects: one is to control the capacity of the historic city based on the visual landscape, focusing on the visual landscape of the central historic nodes and the visual landscape of the axial roads.The other is to sort out the street interface of the axial space, including the improvement of the street façade and street greening. It is expected that through the combination of the two, the urban axes and landscape corridors will be clarified to enhance the recognisability of the spatial characteristics.

In terms of architectural capacity control, through the study of the different psychological feelings generated by different visual distances and angles between people and the built environment, the height of the background environment of the architectural groups at the central historical nodes and the height of the buildings on both sides of the axes and roads are controlled, to shape the landscape characteristics of the historical space. First of all, when

viewing architectural details, the angle of elevation of 45° is the best viewing angle; when viewing architectural groups, the angle of elevation of 18° is the best viewing angle, which is projected to meet the D/H≤1 and D/H≤5 spatial scales of the street when viewing historical buildings and groups of historical buildings, respectively (see Figure 5-b). For example, when controlling the capacity around Central Avenue, in order to strengthen the architectural form of the axial interface, the background height should satisfy H ≤ D. The red line of Central Avenue is 15m, so the height of the new buildings along the street should be lower than 15m in principle, and the height of the background buildings should be increased according to the distance from the centre line of the road. Secondly, according to the scale of the street outline in the urban area, the building height restriction conditions outside the road red line are determined (see Figure 5-c). On both sides of the urban main road, the upper limit of height control is 16m in the range of 100m outside the red line of the road; the upper limit of height control is 24m in the range of 100-200m; and the upper limit of height control is 50m beyond the range of 200m. On both sides of the urban secondary road, the upper limit of height control is 12m in the range of 50m outside the red line of the road; the upper limit of height control is 24m in the range of 50-100m; and the upper limit of height control is 50m beyond the range of 100m. In summary, the above analysis results in the building height control map of the historic urban area (see Figure 5-a).

Regarding street interface management, the control of the road red line is changed to the overall management of street space. Existing planning, design, and specifications for the road red line within the cross-section, municipal and landscape requirements, and the lack of both sides of the building interface and open space are the overall considerations. Therefore, based on restricting construction activities within the red line of the road, the building interface should be regulated, including all kinds of illegal private construction and plaques protruding out of the road, to ensure the smoothness of the sight line within the corridor. Coordinated planning of street green space facilities, open space, activity facilities, etc., to meet the traffic capacity demand and promote the integration of street and neighbourhood development. Restore the early Harbin street greening forms, such as street gardens, courtyard greening, etc., beautify the axes and revitalise the corridors to achieve the role of pedestrian flow guidance so that the connecting paths of the historical elements in the urban areas of the recognisability of the overall linear pattern to strengthen the overall pattern.

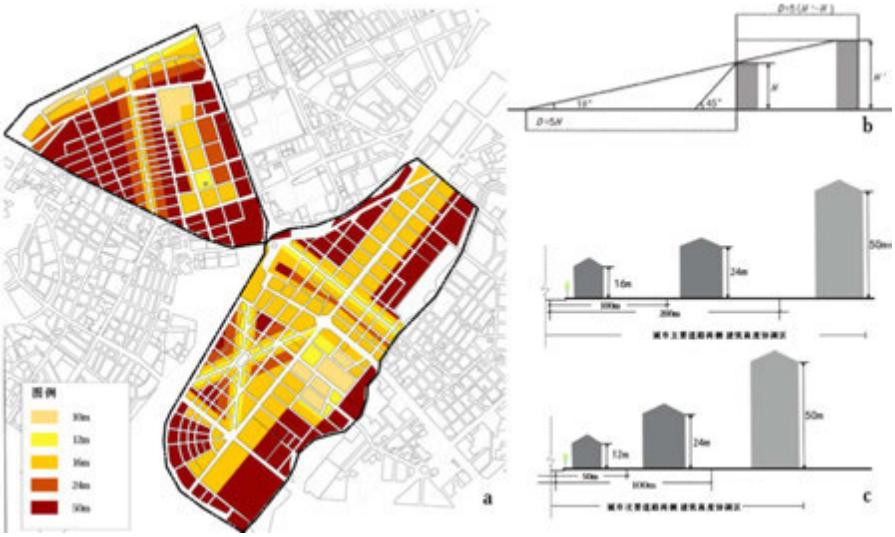

Fig.5 Urban controlling stratigies

4.Conclusion

Spatial characteristics in historic districts represent the systematic combination of spatial elements, shaped by historical stratification and embodying profound spatial meanings. This paper adopts a historical perspective, using space syntax as a quantitative tool to analyze Harbin's urban morphological characteristics and evolutionary patterns. Given the current urban form, this study suggests focusing on two main aspects for future urban planning and preservation: controlling the intensity of building constructions and clearing streets.

The proposals aim to achieve a scientific and sustainable approach to the preservation of the spatial characteristics of historic districts. By employing space syntax, we can effectively quantify and understand the complex interplay between Harbin's historical timeline and urban space, offering a strategic basis for preserving the city's unique architectural heritage and texture. This approach not only ensures the protection of significant historical elements but also facilitates the functional modernization of the city, balancing heritage conservation with contemporary urban demands.

Inhabiting the rural space. Reflections on the housing emergency of seasonal workers in agriculture

Abstract
The intensification of migratory movements towards the European context from the global South is a clear sign of the unstoppable prospect of international mobility, legal and illegal, of populations as a result of changed geo-political conditions, environmental crises and disasters, poverty and economic uncertainty (Blasco, et al., 2023). These dynamics produce reverberations in terms of demographic transition, imbalance in local economies towards parallel and opaque labour circuits, and spatial transformations in the territories where refugees reside and transit. The contribution intends to focus on the informal settlement of Borgo Mezzanone, where about 4,000 migrants reside on a temporary and permanent basis, engaged in the activity of harvesting agricultural products according to the cyclical nature of the agri-food chain. The contribution is the result of the action-research work carried out by the ArCoD Department of the Polytechnic of Bari for the technical-scientific support of the Apulian Municiities beneficiaries of Measure 5C2 investment 2.2 Integrated Urban Plans for the overcoming of illegal settlements to combat the exploitation of workers in agriculture.

Keywords: informality, migration, housing policy

The presence of migrants, increased by the intensity of legal and illegal flows along maritime and land routes in the Mediterranean basin (Zupi, 2023) (Eurostat, 2023) (IOM, 2024) (Fondazione ISMU, 2024) (Frontex, 2024), imprints on the territories signs, movements and changing transitional practices due to the variety of legal conditions of individuals (asylum seekers, migrants under international protection, refugees, deportees awaiting repatriation), the diversified needs, including labour needs, that underlie as many life projects. These factors are also associated with the ineffectiveness of migrant reception and integration policies in guaranteeing indispensable rights, today still oriented towards emergency, securitarian and incongruous approaches concerning the minimum standards expected (ISPI, 2018) (Caritas Italiana, 2022).

The conditions of arrival in first landing territories such as Italy, often with illegal landings (Frontex, 2021), together with the scaled-down institutional response, trigger a short-circuit such that migrants without legal status have limited access to fundamental civil and social rights, finding in 'opacity' the adaptive survival solution. This opacity can be recognised in the inscrutability of informal settlements and in the separateness of the lives migrants lead within them, far from the urban space of rights; together with the unpredictability of individual choices and paths, these are the conditions that determine a state of resistance and protection of identity from the outside. The same legal-administrative indeterminacy that ousts migrants from the rule of law persists despite the relevant traces they produce in the territories to satisfy their needs (housing, work, social), and it is what allows them to disregard hetero-imposed orders and preserve individual integrity and autonomy (Glissant, 2019) (Rondot, 2022).

In rural contexts, the self-construction of shelters and shacks with makeshift materials reduces 'hyper-visibility' (Cancellieri & Ostanel, 2015) and inserts migrant workers into circuits of labour exploitation in the fields. The state of housing uncertainty and precariousness (Cannari et al., 2000) is thus catalysed by the demand for work in the agricultural economy to which they respond to an attempt - in vain - of self-determination and acquisition of autonomy concerning a system that offers them limited possibilities of social mobility and improvement of their quality of life (Doctors Without Borders, 2018) (Osservatorio Placido Rizzotto FLAI-CGIL, 2022) (Directorate General for Immigration and Integration Policies, 2023). It is a complex phenomenon, which has acquired relevance and public, as well as political, domain following the first extensive survey on the phenomenon of squatter settlements in Italy returned in the Research Report on The housing conditions of migrants working in the agri-food sector (Giovannetti, Miscioscia, & Somai, 2022), carried out by the Ministry of Labour and Social Policies and ANCI in collaboration with Cittalia[1].

The survey provides a nationwide cognitive framework of the housing conditions of migrant workers and, as the results show, it challenges the widespread belief that exploitation of migrants in agriculture is a stigma of the South; rather, it highlights how it also affects northern agricultural districts, according to product harvesting cycles and the periodic mobility of workers (Placido Rizzotto FLAI-CGIL Observatory, 2022). This aspect is not secondary in the phenomenon representation, usually polarised in circumscribed geographical areas and through defined settlement categories that reduce the spatial domain in which migrants act and normalise the repertoire of produced housing practices. The report provides a new snapshot of the housing vulnerability of migrant workers engaged in agriculture, although it is affected by partiality and incompleteness because it is built on voluntary participation by municipal administrations in completing the administered questionnaire[2]. Furthermore, the choice to consider the municipal administrative dimension for studying the phenomenon and the subsequent allocation of the NRRP resources to Municipalities with settlements in critical conditions overlooks both the observation of the phenomenon on a large scale, where the dynamics of migrant mobility in rural areas emerge, from settlements to agricultural fields, and the regional institutional level in defining territorial strategies with the integration of actors, assets, and local resources.
Thus, if the survey methodology at the municipal scale made it possible to obtain the precise location of settlements and the indicative presence of habitual residents, neglecting the periodic fluctuations towards productive enclaves along the national territory, the empirical survey[3] is

[1]On 29 July 2021, the Directorate-General for Immigration and Integration Policies of the Ministry of the Interior signed an agreement with ANCI for the implementation, in collaboration with Cittalia, of an «Action Plan to support local authorities in the processes of inclusion of foreign citizens and interventions to combat labour exploitation in agriculture and caporalato», which provides for among other things, the creation of a national mapping of the presence of foreign workers employed in agriculture, with a focus on precariousness and housing hardship, in order to provide the cognitive basis for the adoption of the ministerial decree of distribution in fulfilment of the specific NRRP Measure, discussed below.

[2] From October 2021 to January 2022, the survey aimed at mapping was conducted by administering a questionnaire to all 7904 Italian Municipalities, of which 3,851 Municipalities responded, with an average participation rate of 48.7%. In the South, the participation rate stands at 45.1%. Out of the total surveyed, only 608 Municipalities reported the presence of migrant workers employed in the agri-food sector. It is noteworthy that about 70% of the municipalities where the workers' presence had been identified in previous research and had already been recipients of specific interventions and policies (the so-called Super-Priority Municipalities) responded to the questionnaire (Giovannetti et al., 2022)

[3] In the absence of detailed information, the questionnaire administered to the Municipalities provided a numerical figure «that roughly takes into account the fluctuations of the phenomenon over the course of the year» (Giovannetti et al. 2021; p.39).

imprecise, also about the variations of seasonal residents and the social (singles, families with children present) and legal (regular/irregular status) composition of the subjects.

The municipal dimension is limiting and reductive concerning the complexity of the dynamics taking place in rural territories, moreover, precisely in the institutional perspective of defining public policies (social, housing and labour) for migration management and the provision of resources to overcome the usual emergency and discontinuous responses over time.

From these general reflections, the contribution focuses on the Apulian regional territory, where the case study under consideration is geographically placed and concentrates on possible operational modalities to respond to the condition of absolute housing emergency (e.a.a.) (FEANTSA, 2005) of migrant workers by assuming informality as a condition to define a new settlement strategy.

How to overcome illegal settlements of migrant workers in agriculture

It is relevant to recognise that the opportunity offered by the NRRP with Measure 5C2 investment 2.2 *Integrated Urban Plans for overcoming illegal settlements to combat the exploitation of workers in agriculture* is the first national policy oriented towards the problem of settlement and labour illegality, which allows to use of funds to prepare solutions for improving housing conditions and exiting the circuits of illegality for seasonal workers[4]. The Measure effectly finances an ambitious housing policy, which, while ignoring the complex legal status of the target subjects (asylum seekers, refugees and displaced persons), is aimed at recognising the 'right to housing' within a regulatory and institutional framework that is indifferent to the construction of labour, social and migration policies. This action marginally addresses the issue of immigration, since actions to overcome illegal settlements and combat undeclared work provide a response circumscribed only to the housing and employment problems that concern migrants in the process of integration into the new society. Therefore, the first critical issue concerns the migration policies underlying this measure, traceable in subcategorical form to the investment axes with which the plan is organised, but vague in focusing on the social target of these interventions, consisting to a significant extent of irregular migrants, whose number has increased due to the rigidity of the Bossi-Fini Law of 2002 (Caritas Italiana, 2022). The indistinct treatment of individuals with different personal situations, united by the double condition of immigrants and workers, in addition to eluding systemic ways to address the issue, complicates the implementation of interventions with respect to the variability of numbers between regular and irregular migrants and therefore between those entitled and those not, according to the Italian legislative statute. A second critical aspect is given by the institutional and territorial level assumed for the interventions, which are attributed to the competence of the municipalities benefiting from the resources due to the location of the illegal settlement, without taking into account the movement flows to reach the neighbouring countryside, where the migrants work[5], as well as the procedural and spatial complexity of

[4] Out of a total funding of 200 million euro, about 96% of the amounts are destined to the South of Italy where agriculture and product processing are the driving economic sectors that have absorbed a substantial share of human resources of foreign origin who have arrived in Italy and are included in irregular labour circuits (Leogrande, 2008) (Macrì, 2022). See the distribution table annexed to the Ministerial Decree of 29 March 2022, no. 55, Decreto di Riparto Risorse relativo all'intervento M5C2 Inv. 2.2, GU Serie Generale n.108 del 10-05-2022, available at the link: https://www.gazzettaufficiale.it/eli/gu/2022/05/10/108/sg/pdf

[5] In the case of Borgo Mezzanone, an administrative offshoot of Manfredonia in close relation with the Municipality of Foggia, workers' movements are of the order of tens of kilometres to agricultural fields in

exceptional works, which are therefore of supra-local rank, connected to the construction of large numbers of beds, to be carried out in a shorter time than the ordinary administrative procedures, interacting with other institutions (*primarily*, the public housing authorities)[6].

In this perspective, the overcoming of informal settlement, understood as the spatialisation of survival using 'dwelling wiles', in contrast to regulatory systems and shortcomings in the externalisation of reception management (Rahola, 2003) (Ippolito et al., 2021), tries, with the limits already outlined, to define a condition of entitlement given by two prerequisites: the allocation of housing and the support of social infrastructures to overcome the state of segregation. Therefore, the terminological choice of characterising migrant workers' settlements as 'squatters' seems inappropriate, as it associates this phenomenon with the practice of uncontrolled building that has been inverted in the Italian context since the Second World War. Connoted in the disciplinary literature as a practice of necessity in response to housing hardship in the post-war years and subsequently speculative in areas of scenic value, squatting, as a mode of individual self-determination, constituted the initial spontaneous response of the less well-off classes to social fragilities and the ineffectiveness of housing policies, then the pervasive individualisation of valuable coastal areas (Chiapperino, 2023); it was carried out in contrast to regulatory and urban planning regulations and availed itself, above all, of political connivance, manifesting an evident concurrence of guilt between individuals and institutions (Clementi & Perego, 1983) (Cremaschi, 1990) (De Lucia, 2006) (Zanfi, 2008) (Curci et al., 2017). The settlements of migrant workers in rural spaces, although the outcome of spontaneous construction production outside of regulatory apparatuses, encapsulate an attempt at survival and resistance to the formalised system of rights and norms that has sclerotized the residents' condition of subordination and segregation. In contrast to the contexts of building squatting dominated by individualism expressed by one's housing unit, ghettos constitute collective spaces of coexistence of informal practices (Laguerre, 1994) (Roy, 2005), with a flexible and adaptable character even in accommodating temporary residents, and forms of resistance to rigid institutionalised statutes. In recognising multiple points of contact and overlap between the concepts 'informal' and 'abusivo'[7], often used as synonyms ascribable to the sphere of 'everyday life'[8], it is possible to trace informality as a broader and more capacious field in holding together not only the building and housing dimension but also the cultural and social one, also because it better represents the precariousness and instability (physical, temporal) of migrant workers' existence.

The belief, based on what has been said previously, is that an effective project for overcoming migrant workers' squatter settlements should assume two conditions: i) improving settlement

other Municipalities; in the absence of private and public means of transport, recourse to forms of subordination to the 'caporale' is the practice.

[6]In addition to the criticalities highlighted above, the national programme has a strong constraint, dictated by: (i) the timeframe of the NRRP, which envisages in 3 years the implementation of the planned and financed interventions, (ii) the limitations related to the institutional process initiated, which was initially very rigid also about (iii) the objectives and expected results that over time have become somewhat blurred, given the cancellation of the mission unit initially identified and the uncertain transfer of the management of the programme from the competence of the Ministry of Labour, (probably) to the Ministry of the Interior or perhaps Defence (with an obvious shift to the security dimension), both equally lacking in adequate competences in the field of public works.

[7] These two conditions also differ in their treatment in the literature; in fact, squatting has a clear geographical connotation in the Italian and Mediterranean context and affects the building process. The informal is investigated in the territories of the Global South characterised by poverty and backwardness as a condition that permeates different aspects of existence.

[8] The sociology of everyday life, of which de Certeau is one of the main exponents (de Certeau, 2010), recognises practices in social existence that escape legal and institutionalised orders.

conditions by identifying housing solutions that facilitate processes of 'familiarisation with "diversity"', ii) pursuing legalisation processes by avoiding the extensive elimination of any non-institutionalised form; that is, preparing to experiment and test the negotiation spaces currently allowed by informality to subjects caught in the grip of the migrant category.
Unfortunately, the rigid target and milestone architecture of the NRRP, necessary to define a *timeline* governed by relevant national and European goals, has projected the settlement solutions project from preparation to implementation, avoiding relevant intermediate phases of sharing (on technical solutions, on the process) with the super-ordinate bodies (Region, Superintendence, Basin Authority), and on the real needs with the third sector associations active in the squatter settlements, the trade unions constantly engaged in integration actions and support to labour regularisation (in particular FLAI CGIL), and the representatives of the slum residents. The absence of a process aware of the plurality of issues at stake and stakeholders and, due to the tight timeframe of the Plan, the preclusion of opportunities for mutual listening between those implementing the intervention, migrant workers and settled communities does not allow for the triggering of integration processes that could on the one hand avoid the abstention of participants, and on the other the triggering of social conflicts (Annese et al., forthcoming).

Action-research for Borgo Mezzanone: spatial and settlement strategy

In this framework, there is the contribution of the three regional universities (Polytechnic of Bari, University of Bari, University of Foggia) involved in a framework agreement for the technical-scientific support to Apulia's local administrations, beneficiaries of resources for overcoming informal settlements of migrant workers, in the definition of Local Action Plans (LAP)[9]. The work, initiated at the intermittent urging of the Apulia Region and the Prefectures, was addressed to four municipal administrations and continued only with the Municipality of Manfredonia[10]; from the outset, it aimed to develop a territorial strategy coordinated by the Municipality of Manfredonia (FG) itself, which was entrusted with 54 million euro resources, but oriented towards investments and transformations in the territory of the Municipality of Foggia. The primary objective was to intercept the dynamic dimension of the settlement phenomenon and its territorial fluctuations with the strategic vision of supra-local sectoral plans, thus increasing the complexity of the process, but aiming at the valorisation of an already existing heritage and the underlying territorial system. The experience has represented an opportunity for synthesis between wide area objectives and the local dimension of the problem, as in the practice already established by the new territorial management tools defined in Apulia since 2001 (Apulia Region, 2007).

[9] The Local Action Plan thus foresees a share of residences (infrastructural part) to be realised as new construction but also conversion of existing under-utilised assets (equal to 70% of the funding) and intangible actions (social integration, provision of services and forms of community welfare, equal to 30% of the funding) to support populations. Subsequently indicated LAP.
[10] As a result of the technical round table with the beneficiary Municipalities of the NRRP Measure in question, the support of the ArCoD Department of the Polytechnic of Bari was provided to the Municipality of Manfredonia and for the initial application phases of the Municipalities of the Capitanata of San Severo and Cerignola and Turi in the Bari area. This is a significant figure when compared to the size of the economic resources allocated by the distribution these are Municipalities with highly critical situations and huge and exceptional funding compared to the technical capacity of the municipal offices. The Municipalities benefiting from ordinary amounts operated autonomously, often in continuity with previous actions, such as the Municipality of Carpino.

The consultancy work carried out from 2022 to the present[11], identified the key elements of the vision, expressed in the infrastructural and non-infrastructural components, for overcoming the informal settlement located along the disused runway of the former military airport of Borgo Mezzanone, seeking to provide a housing, employment and social integration response to the migrant workers living there.

Thanks to the support of the most committed forces on this front (scholars, trade unions, and the Third Sector), the references to these territorial strategies have been outlined in the candidate LAP by the Municipality of Manfredonia (FG). The informal settlement is located on the border with the Municipality of Foggia and close to one of the hamlets built during the agrarian reform of the 1930s, a strategic location concerning the Tavoliere agricultural production areas and the infrastructure network that innervates it. Along the former aeronautic runway, shacks and temporary housing modules hybridise the formal and militarised space of the CARA and the container settlement (Tarsi & Vecchiarelli, 2021) (Vecchiarelli, 2023), and, particularly during certain periods of the year characterised by greater demand for labour, arrive to host up to 4,000 foreign farm labourers, including permanent and nomadic workers. These conditions lead to phenomena of marginality, physical and social degradation and illegality, as well as fuelling the phenomenon of 'caporalato'.

The strategy, therefore, had the primary objective of proposing alternative solutions to the 'temporary' ones dictated by the emergency, in favour of lasting strategies, discarding the housing experiences so far realised in Italy of large settlements in which to 'concentrate' a large number of agricultural workers, which have often proved to be a total or partial failure (Mira, 2022), as the experience of the 'Gran Ghetto' located in this territory (between Rignano Garganico and San Severo) teaches us. The orientation, therefore, was for the identification of housing solutions distributed throughout the territory, capable of activating processes of inclusion and integration of workers that could lead them to attain the status of 'inhabitants' and 'citizens'.

The Territorial Strategy

The research action, therefore, started from the long-standing territorial structure of the Tavoliere, present in descriptive traditions, of the *Pentapolis*, centred on Foggia, which dialogues in a sort of *Christallerian* model with the *agrocities* of Lucera, San Severo, Manfredonia and Cerignola (fig.1). On this system, in turn, is inscribed the lower-ranking settlement system, also conceived 'as a crown' in the phase of populating 'the latifundial desert' of the Capitanata cereal-growing areas by the Opera Nazionale Combattenti (ONC) between the late 1930s and the early years of the new decade, at the height of the war (Pennacchi, 2010). These were small 'foundation towns', such as Segezia and Incoronata, and rural hamlets, such as Borgo Cervaro, Borgo Giardinetto, San Giusto and Arpinova, which are now underused hamlets. Designed and built as 'service centres for an agricultural community, they developed around a square, having all the features, including architectural ones, to best fulfil their function' (Pennacchi, 2010), in these settlements Concezio Petrucci and the other designers selected by the ONC emphasised as they had already experimented on a national scale in other founding villages (Aprilia, Fertilia, Pomezia) the public and collective parts (square, main street, church,

[11] Now, the strategy defined from an infrastructural point of view has not been supported by the analyses and interpretations of social and economic data, attributed to the other universities participating in the protocol.

Casa del Fascio, schools, commercial arcades) around which the city would progressively grow with its residential fabric.

Fig. 1. Territorial system, Pic by Letizia Chiapperino

This 'crown' settlement system (fig.2) was well integrated and has a strong character in the deep countryside of the Tavoliere, which led in the palate to the shared choice with local institutions, to nominate the centres built to the south of the Foggia territory in the redistribution hypothesis of the 4000 migrants of the Mezzanone ghetto. Starting from the east, these were the arch formed by Borgo Mezzanone (a hamlet of Manfredonia), Incoronata, Borgo Cervaro, Segezia and Borgo Giardinetto, later reduced in the course of the project sharing processes on national and local inter-institutional tables, to just the three centres of Segezia, Borgo Cervaro and Borgo Mezzanone (fig. 3 - 4 - 5).

Fig. 2. Territorial strategy, Pic by Letizia Chiapperino

Fig. 3. Borgo Segezia, Pic by Nicola Cavallera ©

Fig. 4. Borgo Cervaro, Pic by Nicola Cavallera ©

Fig. 5. Borgo Mezzanone, Pic by Nicola Cavallera ©

In the proposed settlement strategy, these villages constitute an important spatial capital in the deep countryside capable of accommodating new agro-urban communities, based on a polycentric system of small settlements, placed 'in proximity' to one another and related to the

Tavoliere's *agro-towns* through a dense network of roads. This system, of which Foggia constitutes the fulcrum, still retains its settlement and 'infrastructural' value, since it best interprets the Tavoliere as a plain garrisoned by a constellation of 'poles' of different rank.

This choice is not based on a banal neo-Enlightenment vision, which sees in the origin of the construction carried out by the ONC, with the cultivation and populating of the countryside, the hypothetical renewal of a strategy that is now outdated by time and history, but rather a 'patrimonialist' vision of this territorial system, neither merely historical nor aesthetic, which from the front of its proactive potential for territorial transformation can offer an answer to overcoming the ghettos, avoiding the failed experiences of the large container camps.

Hence, small foundation towns and hamlets are not a mere testimony of the past, but an important presence that establishes links between different places and times: the long life of these extraordinary urban nuclei and the tight timeframe provided by the NRRP for the implementation of the Integrated Urban Plan. Ultimately, this option looks at the heritage theme in the sense of the *Heritage of Living,* which poses the question underlying all interventions that have a relationship with the modern, questioning how, today, we can consider ourselves heirs of that season and at the same time how the notion of heritage is being rewritten, at a time when we can no longer call ourselves modern (Andriani, 2010).

This territorial strategy linked to settlements then hinges on the vast Daunia area in the great landscape enhancement design of these areas outlined by the PPTR (Regional Territorial Landscape Plan) (Apulia Region, 2015), which proposes the territorialist vision of its scientific coordinator Alberto Magnaghi, which programmatically addresses the 'regional landscape producers' and offers an open tool that goes beyond traditional reconnaissance and constraint visions to the benefit of a proactive position, which is articulated in five Strategic Scenarios as five 'Implicated Projects' of the regional landscape in strong integration with each other.

Of these Scenarios, the LAP's proposal mainly crosses two, because they are pertinent to the long-lasting settlement structure referred to in the previous paragraph: *The City-Countryside Pact* and *The Slow Mobility Infrastructural System*(Apulia Region, 2015).

The integration and overlapping of elements referable to these strategies, to their visions, to pact forms and resources put in place by the Region for the realisation of specific sectoral projects (landscape and mobility) suggest the territorial design of the new settlement system underlying the IUP instrument. The cereal-growing 'deep countryside' can be progressively transformed into 'peri-urban countryside' with the new conditions created by the necessary enlargement of the residential areas of the ONC hamlets, through specific zoning plan modifications, for a new housing offer that is structured between the extremes of new residential complexes for the demand for permanence and the bivouac of temporary and reversible dwellings for the needs of nomadism. Worker-inhabitants, in perspective, would thus be located in a diffuse way in the territory they refer to, in proximity to working contexts, in spatial conditions that can favour productive autonomy for self-subsistence as much as for proximity trade, being able to stimulate new supply chains and entrepreneurship in the space.

Indeed, the peri-urban countryside lends itself to direct and cooperative forms of cultivation, as well as the provision of new ecosystem services[12].

The slow mobility system, on the other hand, reinterprets the road connecting the three centres as an infrastructure for cycling and public transport, guaranteed by intersecting regional mobility policies (Regional Sustainable Mobility Plan, Regional Tratturi Plan). The ONC villages road starting from Segezia stops at the other end in the passenger and freight railway junction of Borgo Cervaro, and crosses the Tratturo Regio on its route, which branches off into this territorial system starting from Foggia. This is the infrastructural system that could allow new residents to reach the regional capital, as well as to join the regional rail transport system. The hypothesis of activating subsequent actions capable of making workers self-sufficient in both work and individual mobility, for example by providing bicycles or defining a dedicated bike-sharing service, also appears consistent with the hypothesis of breaking free from recourse to the Caporale, which today represents the only possibility of getting out of the informal camps for all travel needs (Tarsi, 2020).

The settlement strategy

The absence of residential heritage to be rehabilitated in the above-mentioned Hamlets ONC imposes the need to intervene with new buildings to meet the housing demand of Borgo Mezzanone's residents, who could acquire an active role in the definition of the domestic space, but above all of the relational space. This perspective stands in discontinuity with the approaches followed so far, with settlement solutions that are recurring emergency model of the camp through the use of containers, and with the modalities defined by Measure 5C2 of the NRRP, which eludes the direct and active involvement of the recipients of the interventions[13]

Within such a complex territorial system, the settlement strategy intends to measure and accommodate the informality of migrant workers' spontaneous settlements by experimenting with design flexibility as a principle of spatial organisation capable of accommodating the socio-cultural diversity and permanence/temporality needs of the inhabitants, distancing itself from hetero-imposed assertive modes, and as an opportunity to recognise the aptitude for space production, as witnessed by the different practices of living in informal slums. This perspective can be found in the reflections and experiments developed in the 1970s, by Habraken in Holland[14] (Habraken, 1974) and Maurios and Kohn[15] in France, in contrast to the city of the Modern Movement by proposing a building process that reduces the technical and formal control of the designer in favour of the active involvement of the future inhabitant (Bianchetti, 2020). This new conception, developed mainly at the building scale in the period of innovation of the construction process with prefabrication, disrupts the predetermined character of the

[12] The planned establishment of an Agrarian Multifunctional Park supports the physical and infrastructural connection of the three centres involved in the redistribution of the Mezzanone ghetto workers.

[13]This closure to opportunities for confrontation, as well as increasing the condition of *protracted displacement of* migrants forced to leave the ghetto and move to accommodation that does not meet their personal needs, could limit the effectiveness of interventions.

[14] Founder in 1964 of SAR (Stiching Architecten Research), his studies on residence according to '*support/ infill*' principles were followed up in the non-profit 'Open Building' movement that is still active today. See website:https://www.habraken.com

[15] Authors of the *Les Marelles* intervention carried out in Val d'Yerres in France used constructive experimentation to achieve maximum architectural flexibility of residences (Herrou et al., 1975).

modern space defined on «...uses corresponding to normalised groups of needs» (De Carlo, 1973) in favour of a space of relationships in which social activity and capacity for appropriation are fostered through the flexibility and modularity of spaces (Viganò, 2023). If transposed to the urban dimension, it allows the inhabitants to recognise margins of action and responsibility and to exercise claims and appropriations of space that contribute to defining the 'right to the city' in Lefebvre's conception.

The outlined elements try to clarify the directions along which the research work is trying to intervene on the condition of invisibility of workers and informal settlements. In this sense, one agrees with the thesis that invisibility is a condition, perhaps resulting from the desire for opacity, but certainly, tension is «between what one wants to make visible and what one wants or cannot but keep invisible» (Balducci, 2023:339), which shifts the responsibility for leaving subjects in oblivion into the realm of political will (and action).

The proposed solutions, on the technical-administrative feasibility of which the study will continue, try to enhance the attention and prospects for change, i.e. to offer the opportunity of the choice of solutions (housing, mobility) different from those we have had so far, which show new attention, and thus support the emergence in the visible of individuals. The research thus aims to stimulate a political culture of intervention that does not devolve to voluntary work, and which in turn can foster cultures of integration and sociability, as a tentative - but not protracted - way of responding to the problematic dimension represented by the informal ghettos of workers in the agricultural sector.

Equally, we are aware that this strategy cannot be decisive, but the governance identified is the optimal institutional condition for achieving further results, notwithstanding the need to innovate welfare and labour policies.

Abstract
Small public urban green space is a category of urban public space characterised by its abundant quantity and widespread distribution. In many cities, like Karaköy in Istanbul, rapid development and privatisation are impacting city dwellers' well-being and ecological health. Over the years, the current state of urban green spaces in the city are declining. We believe these small public spaces need to be reclaimed and prioritised. Through this paper, we aimed to illustrate how even small public spaces can be transformed to green space. We conducted literature review and employed Jan Gehl's observation. Our findings suggest innovative solutions maximising the usability of existing spaces, by integrating adaptable design concepts that promote community engagement and enhance aesthetic appeal within sustainable parameters.

Keywords: *reclaiming green space, community health, public spaces, small space, privatisation impact.*

1. INTRODUCTION

Green spaces are essential urban infrastructures, especially in densely populated urban areas (Verheij et al., 2023). Urban parks and green spaces provide essential ecosystem services and public benefits (Wu et al., 2023). However, the scarcity of large open spaces is a significant issue in densely populated urban areas. This shortage makes urban green spaces, crucial for sustainable development and community well-being, highly valuable especially in high density cities (Akpinar, 2016). Haase et al. (2014) highlights the significant role of these urban green spaces in contributing to biodiversity, local climate regulation, and providing recreational opportunities. Moreover, the importance of green spaces for ecological sustainability and urban biodiversity (Kabisch et al., 2016). Significance of urban green spaces in densely built environments is also highlighted, emphasising their contribution to linking landscapes and communities (Benedict & McMahon, 2006). While urban green spaces serve various functions, including social, recreational, and cultural purposes, it also provides economic and environmental benefits (Haq, 2011). In addition, urban greenery aims to boost property values by improving aesthetics and functionality (Chen et al., 2022). In densely populated cities, the positive effects of green spaces are well-studied. They help reduce stress, enhance social cohesion, and contribute to overall mental well-being (Hartig et al., 2014; White et al., 2013). With rapid urbanisation on the rise, integrating green spaces into urban planning and policymaking has become more important (World Health Organization, 2016), supporting the idea that green space is a fundamental right.

Although it is widely acknowledged that green spaces have a positive impact on urban residents, the availability of such spaces in densely built cities adds another layer of complexity. This study suggests that the provision of small public urban green spaces could be a solution to this issue. According to Fei & Mao (2020), small public spaces constitute a distinct category within urban public spaces, they are widely distributed and compact. Since 1960, an increasing number of academics have recognized the importance of small public spaces and have researched methods to examine their utilisation (Hou et al., 2020). Small public space is one of the key built environment elements that provide venues for a variety of activities, may have a major impact on the quality of people's lives, and could even potentially contribute to both the physical and mental health of residents (Gilles-Corti, 2006). Research has shown that small

public urban green spaces offer numerous benefits, including improving self-perceived mental health regeneration (Peschardt et al., 2012). However, further analysis is needed to determine whether expanding these features is an effective approach for enhancing cities' liveability (Peschardt et al., 2012). Designing and evaluating small urban green spaces can promote the development of "green cities," mitigating the negative effects on well-being caused by rapid urban development (Jia et al., 2016). Ensuring an adequate supply of public green spaces is a vital aspect of achieving densification that effectively contributes to the development of more sustainable cities. While research on Small public urban green spaces is still limited, this study aims to address this gap by examining the availability of small public spaces and their relationship to urban green spaces.

We acknowledged the benefits provided by small public urban green spaces in an urbanising world are undeniable. Our research focuses on the main question: “How can green spaces be reclaimed in small public spaces?” We aimed to understand the intricate relationship between prioritising small public spaces and maximising their availability for urban green spaces. This will contribute to more informed urban planning decisions, ultimately enhancing the quality of life in these distinctive urban settings. This approach helps understand the relationship between urban development, community health, and environmental sustainability in small spaces. The structure of this paper includes an introduction emphasising the need for and solutions to enhancing small green spaces, a literature overview, a framework for reclaiming green space in a small urban space, a methodology section, and an analysis of Karaköy's public space as a project case study. Then, the paper concludes with a discussion of these findings.

2. DESIGNING SMALL GREEN PUBLIC SPACES WITHIN DENSE URBAN CONTEXT

A comprehensive framework for such projects must consider multiple factors to ensure maximum efficiency and functionality (Xi et al., 2024). In the quest to reclaim green spaces within the densely populated area, we need to consider the relationship between design elements and the established criteria for community health. The literature underscores the value of play and relaxation areas in fostering social interaction—a key aspect highlighting the importance of inclusive play structures and restful green corners for community well-being (Francis et al., 2012). The interaction among users is another criterion that can be enhanced by the thoughtful selection of trees and plant species (Kuo et al.,1998), which not only encourages gathering but also bolsters environmental and mental health through increased biodiversity and aesthetic appeal. Furthermore, the vital role of community engagement in maintaining and enhancing these urban green spaces (Krasny & Tidball, 2012), such as leisure facilities and community gardens, plays a significant role in promoting physical health and creating platforms for community engagement in urban spaces (Holland, 2004). The design's inclusivity, ensures that green spaces are seamlessly integrated into the urban environment (Amin, 2006), offering a welcoming embrace to a diverse populace. This inclusiveness is reflected in the presence of pedestrian pathways and public seating areas that cater to various needs, resonating with Gehl's (2011) principles for successful public spaces.

Table 1: *Pillars for the design of public green space (Source: Author’s*

Reclaiming Green Space		
Research keywords	**Criteria**	**Design Element**

Community Health (Kuo et al., 1998; Francis et al., 2012; Krasny & Tidball, 2012; Holland, 2004)	• Community Engagement • Users Interaction • Leisure Facilities • Access to greenery (experimental) • Impact on Ecology Viability	• Play • Relaxation area • Trees • Plant species selection
Public Space (Gehl, 2011; Amin, 2006)	• Openness and access • Inclusive design • Integration with the urban fabric	• Community gardens • Pedestrian pathways • Public seating areas • Interactive installations
Small Space (Zhong et al., 2023)	• Efficient Space Utilisation • Open Activity and Flexible Use • Vertical space utilisation	• Micro parks • Green walls/ Vertical gardens • Multi-tiered planters
Privatisation Impact (Hou & Rios, 2003; Angotti, 2008)	• Equity in space distribution • Public vs. private space delineation • Community rights to green space	• Public space protection • Public access agreements

In addressing the challenges of limited spaces, the need for efficient utilisation of space through open activity design, echoing the versatility of micro-parks and vertical gardens in providing green relief in urban density (Zhong et al., 2023). Furthermore, the equitable distribution of these spaces ensures that they serve as public assets rather than private commodities (Hou & Rios, 2003), emphasising the importance of public space protection and accessibility agreements as noted by Angotti (2008). The literature review (Table 1) forms the basis of this framework, we summarised research keywords from different studies with the aim to reclaim green space in densely urban areas. It highlights the importance of urban green spaces for city vitality, supporting this design approach and showing the link between human well-being and urban design. This study aimed to develop a systematic framework for cities facing similar challenges in transforming small urban areas. We evaluated the reclamation green space based on four criteria: community health, public space, small space, and privatisation impact. Then, we integrated design elements based on all research keywords and criteria.

3. METHODOLOGY

3.1 Case Study: Karaköy Public Ferry Square in Istanbul

Istanbul, with the population of 15,907,951 (Turkish Statistical Institute, 2022), experienced significant transformations due to rapid urbanization and development. Although these changes have facilitated economic growth, they have also caused urban sprawl and had adverse environmental and social effects (Erbas 2013). In recent years, public spaces in Istanbul have been losing their natural characteristics at an accelerated rate compared to the past. Today, public space in Istanbul, especially those who located in the waterfronts are predominantly developed with minimal natural green spaces and parks (Turkuoglu & Secmen, 2019). Public spaces located on urban waterfronts are considered valuable and unique because they combine natural water features with green spaces to fulfil the physical and social needs of urban residents (Turkuoglu & Secmen, 2019).

While there is no doubt that green space provides multiple benefits, the green space per person in Istanbul is only 7.04 m² (IBB, 2020), significantly lower than the minimum of 15 m2

suggested by the Ministry of Environment and Urbanization in Turkey, and even below the World Health Organization's recommendation of at least 9 m2 per person. Istanbul is divided into 39 districts, and there is a noticeable disparity in green space distribution across these districts, with most districts lacking sufficient urban green spaces. In Beyoglu, the district where Karaköy is located, the rate of green space is 2.7 m2 per person (Figure 2). Recent research indicates (Figure 1) that Istanbul ranks last among world cities with a green area ratio of 2.2%. Oslo leads with the highest green area ratio of 68%, followed by Singapore (47%), Vienna (46%), Chengdu (42.3%), and Zurich (41%). Alongside European cities, Asian cities also feature prominently in the top rankings. (World Cities Culture Report, 2018).

Figure 1 International Green Space Map (Source: Istanbul Buyuksehir Belediyesi in 2018).

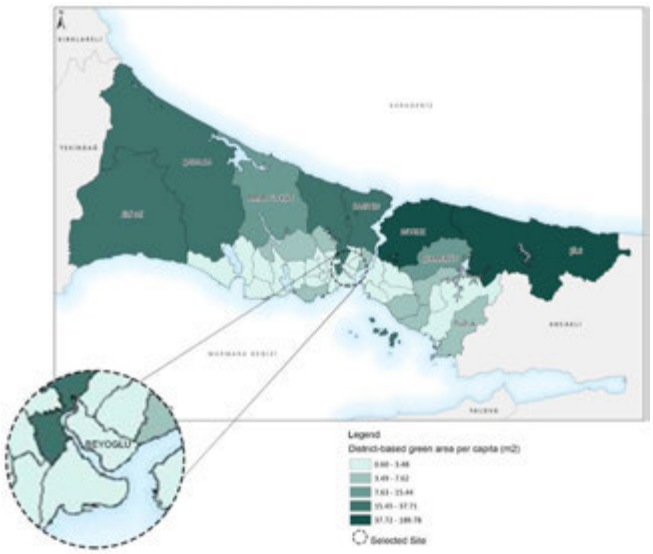

Figure 2 Istanbul's district-based green area per capita in m2 (Source: Istanbul Buyuksehir Belediyesi in 2018).

Figure 3 Beyoglu district zoning plan in 2023 (Source: Istanbul Buyuksehir Belediyesi).

Our study area, Karaköy where the ferry square is located (Figure 3), is one of Istanbul's public space waterfronts and one of the oldest and most historic districts of the city. This transformation highlights the challenge of integrating the available small public spaces within a rapidly developing environment. Karaköy is rich in heritage, balances the preservation of its historical identity with contemporary urban demands (Tepeli & Ocakci, 2017). Despite the limited size and the availability distributed in the upper-scale context, Karaköy have become vital for community engagement and cultural expression. These spaces, characterised by a blend of old and new architectural styles (Celik, 2023), especially after the redevelopment of Galataport as the major changes in the area, brought the area as a one of main public points.

Figure 4 Views from waterfront & current physical conditions of the site (e.g.: lack of seating areas, and ordinary facade designs) (Source: Author's).

The small public spaces in Karaköy, with the plan to integrate with the green spaces, play a crucial role in enhancing the urban fabric's health and vibrancy. Karaköy waterfront was specifically chosen for its status as a transient area, predominantly used for passing through rather than for specific activities, while there are more potential uses of the public square. The aim is to transform this space into a more vibrant and interactive area, encouraging community engagement and activities beyond just transit. Unfortunately, the redevelopment in Karaköy, as in many urban areas, is a decrease in green spaces due to development pressures and rapid urbanisation. Privatisation, a significant factor in this transformation, often prioritises commercial development over public spaces, impacting the availability and accessibility of green areas. Green spaces are crucial for increasing user interaction as they provide communal areas for socialising, relaxation, and engagement with nature, fostering a sense of community and enhancing the quality of urban life (Catel et al., 2008; Young et al., 2004). Integrating more green spaces in Karaköy can combat the negative effects of urban density, creating a healthier, more vibrant, and interactive urban environment.

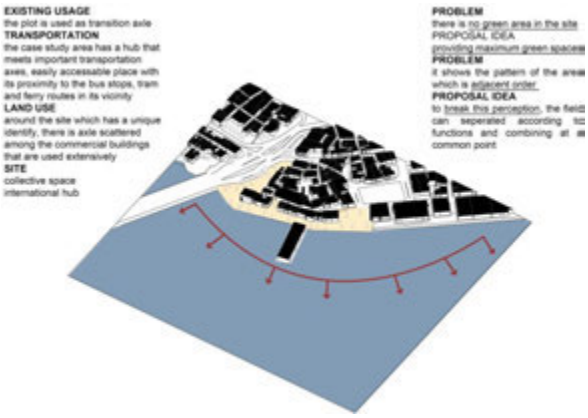

Figure 5 Image Diagram of the Site (Source: Author's).

Additionally, the specific selection of Karaköy for this study leverages its ongoing transition from a traditional to a more modernised urban area, which presents unique challenges and opportunities for green space integration. The neighbourhood's compact size and high population density make it a prime example of where small-scale interventions could have significant impacts. The transformation of underutilised or underappreciated small spaces integrated to active green areas could serve as a model for other urban centres facing similar issues of space constraints and urban densification. This approach not only aims to reclaim green space but also to redefine the function and perception of these areas to support sustainable urban living and ecological resilience.

3.2 Research Focus and Assumptions

Our research primarily concentrates on exploring how small public green spaces can be reclaimed and optimised for resident's use in dense urban areas like Karaköy, Istanbul. We formulated the following assumptions to guide our inquiry, based on the extensive literature review and observational methods by Jan Gehl:

1. Transforming small public spaces into green areas significantly enhances the ecological health and aesthetic appeal of urban environments, contributing positively to community well-being.
2. Community engagement and upkeep of urban green spaces increase their effectiveness and sustainability.
3. Adaptable design solutions that incorporate green elements, such as vertical gardens and micro-parks, are crucial in maximising the utility of confined urban spaces.
4. The integration of small green spaces into urban planning is essential for sustaining urban biodiversity and improving residents' quality of life, even in highly urbanised settings.

To substantiate these assumptions, our methodology encompasses a mixed-methods approach, employing both qualitative observations and quantitative data analysis. This methodology is implemented specifically in Karaköy, Istanbul, focusing on the detailed observation of existing public spaces and their current use and potential for transformation into vibrant, green areas.

3.3 Analysis and Synthesis

We conducted a thorough analysis of the space in the study area, and we considered the available size, location, and existing infrastructure. In this section, we present the findings of our analysis using Kevin Lynch's framework and Jan Gehl's analysis method to understand the urban design elements and the physical characteristics of the site in Karaköy, Istanbul. From the findings, we prioritised the integration of greenery to maximise the use of limited space and we proposed design aims to transform Karaköy into a vibrant and sustainable urban space, while keeping the harmony of historical preservation and contemporary urban living.

3.3.1 Site Analysis

For the site analysis, we used Kevin Lynch's framework (Figure 6) to bring forth the distinct of urban design elements in Karaköy. Lynchian techniques help create memorable and legible urban spaces, potentially enhancing residents' sense of attachment to the city (Larice & Macdonald, 2007). The Galata Port's emergence as a key node redefined the area's dynamics, overshadowing traditional squares and leading to a decline in their use. The ongoing construction nearby further impacts this landscape. This primary objective is to revitalise these public spaces, enhancing their functionality and appeal while preserving Karaköy's unique historical and cultural identity, thereby fostering a more engaging and vibrant community environment.

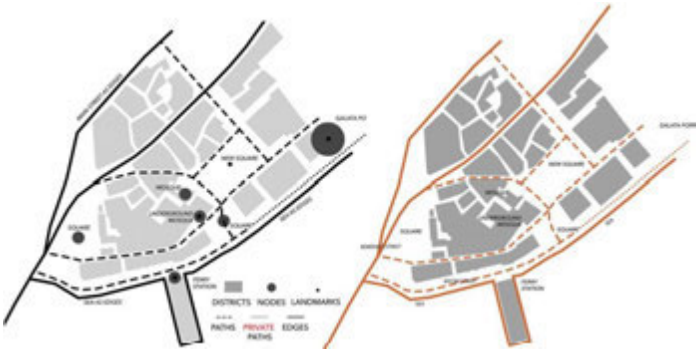

Figure 1 Lynch Analysis (Left) & Circulation Analysis (Right) (Source: Author's).

In this circulation analysis (Figure 6), this study examined the movement within Karaköy, noting its connectivity via tramway, ferry, and bus. Post-urban transformation, the focus shifted towards Galataport, leading to increased usage of the waterfront and squares primarily for transit purposes. Three potential squares were identified, and the removal of a multi-story parking area opened new possibilities for creating additional public space, further reshaping the area's dynamics, and offering opportunities for enhanced public engagement and revitalization.

3.3.2 Jan Gehl's Analysis – Physical Characteristic of the Site

Gehl (2011) analysed the relationship between urban space activities and the quality of the physical environment by categorizing activities into three types: necessary activities, optional activities, and social activities. Gehl argues that each of these types of urban space activities has different dependencies on the physical environment. We employed Jan Gehl's method for detailed observation of public spaces and human behaviour, this study gained insights into the utilisation of Karaköy's areas. We categorised activities into 'necessary,' like shopping or walking to bus stops, and 'optional,' such as jogging, sitting on benches, or fishing.

This distinction helps in understanding the engagement level in the public spaces of Karaköy. It becomes clear that while necessary activities are prevalent, there is ample scope to enhance optional activities, thereby enriching the social and recreational value of these spaces.

Figure 2 Physical Characteristics of the Site (Source: Author's).

Using Gehl's public space observation method from the questions how many, when, where, what, who, and how long, the analysis of Karaköy Square reveals that the ferry station, positioned at the forefront of the square, supports high pedestrian volume due to its 500-passenger capacity, peaking when ferries arrive, especially when ferries dock, but the train station sees less foot traffic. The square was frequented by individuals mainly aged 20-60, however as this study observed, there was a lack of family engagement. Moreover, activities range from necessary ones like transit to optional leisure pursuits, yet the space serves largely as a pass-through rather than a destination. The aim is to enhance this space's use, encouraging visitors to linger and engage more deeply with the environment.

3.3.3 Image Diagram

The detailed Image Diagram (Figure 10) provides a comprehensive look into Karaköy's urban framework. It's currently a transit route, characterized by the movement of people rather than a place where they stay and engage. Figure 8 shows the current situation of the proposed site as a hub; it has strong connections to Istanbul's public transport, making it easily accessible. The area's identity is shaped by the prevalent use of commercial buildings, which define its character. Despite being an important collective space, the issue stems from a notable lack of green areas, which are important for the quality of urban life, especially for the users. Addressing this, the proposal recommends introducing greenery to revitalize the space. Additionally, the area's spatial organization is reconsidered by the proposal, which suggests diversifying the layout to encourage various functions to integrate at a central point, fostering a more dynamic and interactive environment.

Figure 3 Current Situation of Proposed Site (Source: Author's).

~~3.~~4 DISCUSSION – A PROJECT CASE OF KARAKÖY

After analysed and synthesised the space in the study area, it reveals that the emergence of Galata Port has transformed the area's dynamics, leading to underutilized squares and a focus on transit use, especially post developments aimed at enhancing transport connectivity. The study identifies an opportunity to enhance optional and social activities within these spaces to enrich the potential of recreational value. Observations indicate that despite high pedestrian volumes at Karaköy Square, it serves mainly as a thoroughfare rather than a destination. The proposed redesign aims to introduce more greenery and reorganise the spatial layout, transforming the square into more vibrant, sustainable urban space that fosters a dynamic and engaging environment, improving the overall quality of urban life.

4.1 Discussion: A Design Approach for Karaköy Ferry Square to reclaim as an urban green space

We created a conceptual design approach along with the design program for a small public space to urban design that emphasizes the efficient use of limited space for green areas, the integration of technology for enhanced user experience, and the importance of community engagement in sustaining these green initiatives. This design approach aims to create an inclusive and dynamic environment while maintaining the density of the pedestrian flow in the area. This plan could serve as a model for other urban areas facing similar challenges of space limitation and the need for sustainable development.

Figure 4 Strategies for Design Plan & Program Diagram (Source: Author's).

Figure 5 Program Image Diagram (Source: Author's).

We emphasise the efficient use of space through a multifaceted approach to urban greenery, designed to enhance both environmental sustainability and community well-being. Firstly, the plan includes physical green environments, areas where individuals can physically interact with nature. These spaces are traditional in nature, such as parks and gardens, designed to encourage active engagement with the environment and physical activity. Next, the visual green experience (VR) zones offer a unique, sensory way to experience greenery, potentially augmented by virtual reality technologies. Visual and sensory interactions with diverse plant life can enhance individuals' preference for and satisfaction with urban environments (Horiuchi et al., 2014; Greiner et al., 2004). This innovative element aims to educate and immerse visitors in diverse plant life and ecological settings without the constraints of physical space. Additionally, the plan incorporates temporary designs & seasonal changes, which use modular and adaptable installations that can be altered according to the seasons. This not only enhances the design flexibility of the area throughout the year but also meets the changing ecological and recreational needs of the community (Siu & Wong, 2015). Vertical greenery & green facades are another aspect, where vertical and building-integrated greenery are utilized to maximize the green space without expanding the footprint. This strategy involves the use of green walls and vertical gardens that are irrigated by harvested rainwater, making it a

sustainable option for urban greening. Vertical greening systems not only improve urban air quality but also reduce the urban heat island effect, making them an essential component of sustainable urban development (Susca et al., 2022)

Lastly, the introduction of a community engagement application highlights the plan's focus on interactive and participatory urban management. This mobile application is designed to keep the community informed about local green space events and initiatives, allowing residents to participate actively in the planning and enjoyment of their environment. It serves as a platform for feedback and engagement, ensuring that the green spaces serve the needs and preferences of those who use them. Incorporating a mobile application into Karaköy's urban development plan could significantly enhance user engagement (Borchers et al., 2023), particularly among the youth. This app could provide information on events and activities in the area, fostering community involvement and interaction. Alongside temporary and portable furniture designs, such technological integration would add to the dynamic and adaptable nature of Karaköy's public spaces. These initiatives align to make Karaköy's green spaces more accessible and enjoyable and ensure a harmonious blend of historical background and contemporary urban living. However, with Istanbul's seasonal changes, it needs to be mentioned that plants are planted based on the season as an opportunity to experience a sense of green according to the season.

4.2 Strategies

As a result of these proposed strategies, innovative green initiatives are being introduced to maximise the green space within the area. This project aims to integrate a variety of green elements: physical green spaces for recreation, visually engaging green experiences for education, adaptable designs for seasonal dynamism, vertical greenery to maximise limited space, and a smart app to enhance community engagement.

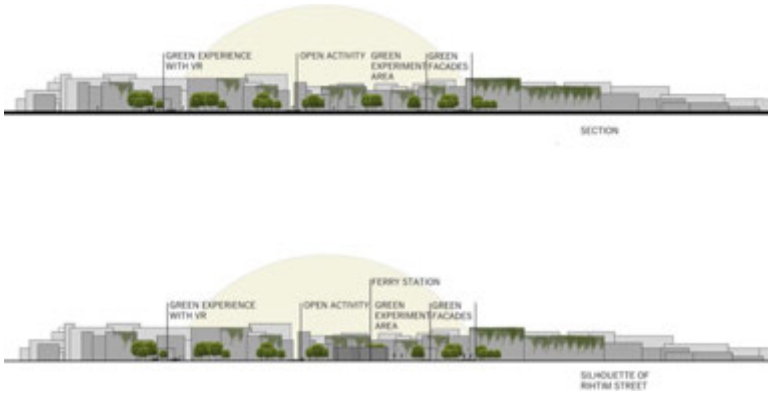

Figure 6 Section and Silhouette of the Site included with Strategies (Source: Author's).

Table 2 *Strategies for the design proposal (Source: Author's)*

Strategies	Visual	Aim	Successful Example	Expected Impact

Physical green environment		To create a tangible green environment in Karaköy that provides physical interaction with nature, enhances urban greenery, and offers recreational spaces for the community.	The High Line in New York City is an excellent example of converting an old railway line into an elevated green walkway.	-Improved air quality and provide natural shading. -Increased opportunities for physical outdoor activities, promoting health and wellness. -Enhanced green diversity and habitat provision in the urban setting.
Visual green experience		To develop an area where plant types and ecological concepts are explained through visual and sensory experiences, fostering educational engagement and aesthetic appreciation.	The Prinzessinnengarten in Berlin is a community garden where locals grow their own food and plants, fostering community interaction.	-Increased environmental awareness and education among residents. -Enhanced sensory experience, contributing to mental well-being and stress reduction. -A visually appealing urban landscape that attracts more users to visit
Temporary Design and Season Changes	 	To implement adaptable and temporary green designs that evolve with Istanbul seasons.	Nature Playground in Valbyparken, Copenhagen, which uses natural materials and encourages interactive play.	-A continuously changing landscape that keeps the urban environment fresh and engaging. -Educational insights into the seasonal aspects of plant life and urban biodiversity. -Encouragement of repeated visits and sustained interest in the green space.
Vertical Green and Green Facade		To incorporate vertical green structures and green facades in Karaköy, maximising green space in areas with limited ground space.	Bosco Verticale in Milan, Italy, integrates plants into its high-rise design, improving air quality and biodiversity.	-Innovative use of vertical space for greenery, increasing the total green area. -Improved building aesthetics.

Smart App for Community Engagement		To develop a smart application that facilitates community interaction, and participation in green space activities, and provides educational content about urban sustainability.	Love Your Park app in Philadelphia, USA. Allows residents to find local parks, learn about events and volunteer opportunities, and provides a platform for feedback and suggestions	-Strengthened community bonds through shared engagement in green initiatives. -Easy access to information and resources for sustainable urban living. -Increased participation in community events and environmental stewardship programs

4.5. CONCLUSION

The research conducted in Karaköy brings critical new insights into the integration of green spaces in small public urban areas, particularly through innovative and adaptable design solutions suitable for densely populated cities. This study breaks away from traditional urban design norms by demonstrating practical ways to transform minimal urban spaces into productive green areas. By employing micro-parks and vertical gardens, the research showcases how even limited spaces can be maximised for ecological and social utility, challenging the conventional approach to urban green spaces. One of the notable contributions of this study is its emphasis on adaptable design. The research highlights the use of modular and movable green infrastructures, such as portable garden installations and seasonal green walls. These adaptable solutions cater to the dynamic needs of urban environments and can be modified in response to seasonal changes and urban demands, offering a flexible alternative to the fixed nature of traditional green spaces. Furthermore, the study redefines the ecological role of small green spaces in urban settings, positioning them as integral elements of urban ecology. These spaces are portrayed not just as recreational areas but as crucial nodes that contribute significantly to urban biodiversity, thus enhancing their role from mere aesthetic enhancements to vital ecological assets.

The research also emphasises a community-driven approach to the management of green spaces, where local involvement extends beyond usage to encompass planning and maintenance. This participatory approach ensures that the green spaces meet the specific needs of the community and are more likely to be sustainable in the long term. Finally, the study offers new perspectives for policymaking, suggesting that urban planning should prioritise not only the inclusion of green spaces but also the incorporation of flexible designs and community involvement as central components of urban development. These insights advocate for policies that foster resilient urban environments, adaptable to both human and ecological needs, thereby enhancing the sustainability and liveability of cities.

One primary limitation is the scale and transferability of findings, as insights derived from Karaköy may not directly apply to different urban settings with varying cultural, economic, and environmental characteristics. There's a need to examine whether these design solutions can be effectively implemented in diverse urban landscapes to establish their broader applicability. For future research, comparative studies across different cities would be valuable to understand the universal applicability of the strategies developed in Karaköy. Longitudinal studies could provide data on the long-term ecological and social impacts of green space

interventions, offering a clearer picture of their effectiveness and sustainability. Furthermore, detailed economic and environmental impact assessments could elucidate the costs, benefits, and ecological impacts of these green initiatives.

Social Media Text Mining and Flood Disaster Analysis of Small Towns in Southern Shaanxi Qinba Mountain Area Based on Deep Learning

Xin Zhao [1], ZuoBin Wu [2]

[1 2] Department of Urban and Rural Planning, School of Architecture, Xi'an University of Architecture and Technology, China

ABSTRACT

The advent of the dataization era has made social media a new trend and tool for analyzing and managing flood risk. This paper aims to use the BERT-BiLSTM-CRF method to analyze the information on social media such as Weibo, and extract the content related to the flood of small towns in the southern Shaanxi Qinba mountain area. Firstly, we use python crawler to crawl the text data on social media such as Weibo, and then preprocess the data, including removing stop words, punctuation marks, emoticons, etc. Secondly, we use the BERT-BiLSTM-CRF method to perform named entity recognition on the text data, identify entities such as place names, person names, organization names, etc., and annotate them in BIO format. Then, we use methods such as geodetector to geocode the identified place name entities, obtain their latitude and longitude coordinates, and match them with the flood data of small towns in the southern Shaanxi Qinba mountain area, and analyze their flood distribution and flood relationship. Finally, we use flood risk analysis methods, such as flood frequency analysis, flood depth analysis, flood loss analysis, etc., to evaluate the similarity and difference of Weibo information and urban flood risk, and explore the impact and reflection of Weibo information on urban flood risk. In addition, using the high-precision risk analysis method of social media analysis, the flood risk and danger of small towns in the southern Shaanxi Qinba mountain area are evaluated, and the potential impact of flood disaster on the spatial characteristics of small towns is analyzed. The innovation of this paper lies in the combination of deep learning methods and flood analysis methods, extracting the information related to small town floods from large-scale social media data, providing new data sources and analysis methods for towns flood prevention and disaster reduction, and considering the impact factors of flood disaster, providing reference for small town planning and development.

Keywords: Flood Disaster Analysis, climate change, Flood resilience strategies, Small Town Planning, Social Media Text Mining

1. Introduction

In recent decades, climate change has led to an increased frequency of natural disasters, posing severe threats to urban areas and resulting in significant social and economic impacts(Chang et al., 2021). Under the influence of global warming and urbanization, extreme rainfall events and the subsequent urban flooding have become increasingly common. The frequency and intensity of urban flooding in major densely populated cities worldwide are expected to rise substantially. Statistics indicate that floods account for over 30% of the total economic losses caused by natural disasters globally(Shamsuddin, 2020). Floods are among the most destructive disasters on Earth, posing a substantial threat to large populations. Due to

meteorological factors and observational limitations, traditional data sources on flood disasters are increasingly inadequate for addressing the growing frequency of such events(Chen et al., 2020).

To minimize the impact of disasters and enhance recovery, urban resilience is crucial for cities to withstand and recover from external disruptions. Urban resilience, as an advanced approach to addressing natural hazards, has become a key concept and is highly emphasized in scientific and policy discussions(Shi et al., 2021). Due to the interplay of various factors such as cultural adaptation, social, and economic development, the concept of urban resilience is complex and multifaceted, making the creation of universally applicable metrics challenging. As illustrated in the table, research on urban resilience reveals our progressively refined understanding of the concept. Holling introduced the concept of ecosystem resilience, distinguishing between engineering resilience and ecological resilience, and then applied the concept of ecosystem resilience to human social systems, proposing evolutionary resilience(Sharifi, 2019). Engineering resilience emphasizes the system's return to its original state after a disturbance, while ecological resilience prioritizes system balance. On the other hand, evolutionary resilience prioritizes learning and innovation to adapt to new environments(Liu et al., 2020). Although there is no unified definition of urban resilience in the current literature, a relatively consistent understanding exists. Urban resilience refers to the capacity of urban systems to maintain their functionality in the face of natural or unintended disasters, encompassing social, economic, ecological, and infrastructural functions. Various stakeholders implement a series of measures through learning and experience to address and adapt to current and future challenges.

Social media have already established people's connection with other people living both in and beyond the boundaries of urban areas through real-time interaction, crowdsourcing, and accessibility, which strengthens the relationships among social groups. It is a well-known fact that Weibo helps in the retrieval and dissemination of information during urban research on disaster awareness and response. Meanwhile, human behavior related to real-time disaster could be dug out, hence of critical importance under the background of social perspectives of urban resilience, compared with those from the traditional information sources. With the wide application of social media data, social media, with enormous strengths in the dissemination of information, are increasingly one important channel for disaster communication and also an important source for rapid and comprehensive disaster assessment. The use of social media data in flood risk analysis contributes a new method for disaster management. In this way, it can complement traditional flood risk assessment through real-time data and provide a basis for urban planning and disaster response. Through the BERT-BiLSTM-CRF model, flood-related information from Weibo is extracted and geocoded to allow the identification and analysis of flood events in small towns in the southern Shaanxi mountain area of Qinba, and the work shows that the combination of deep learning with social media analytics has the potential to significantly advance flood forecasting and response planning in small towns.

2. Methodology

As shown in Figure 1, This process flow chart shows extraction and analysis information in a Flooding Scenario on Weibo using the BERT-BiLSTM-CRF Model. In data collection, a crawler is used to collect text data resources on Weibo. There follows a step of text preprocessing to exclude from it the so-called "stop-words," punctuation, and other redundant information. Here, the BERT-BiLSTM-CRF method applies named entity recognition, and annotation of place names, personal names, and the names of organizations in BIO format was applied. Then, the place names are geocoded to get its longitude and latitude coordinates by the geodetector, matching with the small town-related data of floods in the southern Shaanxi Qinba mountain area. The flooding analysis in this case is the step to examine the spreading and relationships of flooding. The appraisal examines the commonalities and the disparities between the Weibo information and urban flood risk. Equally, it reflects on the implications for flood risk and hazard in small towns.

Figure 1: Weibo Flood Information Extraction and Analysis Process

2.1 Study area and data

The study area is the Qinba Mountain region of southern Shaanxi, which has a large number of rivers, including the Han River, running through southern Shaanxi. The geographical location and meteorological conditions make the Qinba Mountain region in southern Shaanxi highly prone to heavy rainfall and flooding. In July and August 2020, this region had a huge amount of rainfall, most areas were submerged in water, inducing floods. Therefore, this paper attempts to extract location and water level information related to the flood disaster in social media information. The present study was based on the spatial and temporal characteristics of the selected data after extraction, to explore the process of urban inundation in relation to exposure information. Posts published on the Sina Weibo platform from July to August 2020 had been retrieved and, as shown in this table, key fields comprise the user ID, time stamp, content, and check-in position. The direct scraping of web data removed the sources of sensitive attributes before data collection, but the fields of user nicknames and IDs had not been collected in advance in order to meet the requirements of user privacy protection. We will only collect data captured from the positions of posts on the platform using Python web scraping techniques.

2.2 Acquisition of social media data using web crawlers

The number of users of the Sina Weibo platform is the largest among social media platforms in China. The first-quarter financial report for 2023 indicates that the company had 593 million monthly active users as of March 2023, having increased by approximately 11 million compared to the same period a year earlier. Of this, 95% came from mobile monthly active users. In March 2023, the average number of daily active users was 255 million, an increase of about 3 million over the same period last year. With the so many users, this provided a strong support for this work(Wang et al., 2020).

Information on Weibo will have the characteristic of timely information dissemination. Once the public opinion event bursts, there will be an instant discussion among tens of millions of users, which may cause the hot topic to rise to the top of the headline in real-time hot search, updated once every minute. Python-based web crawlers are used for extraction of social media data on Weibo, and the target information contains user ID, account category, tweet creation time, spatial coordinates, and content information, including text, images, and videos. The timestamp of the tweet is used to classify the check-in data into several time intervals, and the spatial coordinates can be used to determine the geographical location where each tweet has been published. The text content of each tweet is examined in order to find whether the tweet is related to the research topic. In the first place, this keyword search can be an effective filter in translating unstructured data using the specific words and phrases. The approach allows for tuning to fit specific needs and objectives, which means the author can create results that can be reproduced under different sets of circumstances. Yet, if the keywords are nonsensical or sufficiently generic, then the search results can be imprecise and in some cases reflect inaccuracies, given the current need for appropriate keywords to be selected and most appropriate to be refined.

In this study, the keywords used for data crawling include location-specific terms such as "Lueyang County," "Nanzheng District," "Xunyang City," "Pingli County," "Ningqiang County," "Hanyin County," "Ziyang County," "Yang County," "Zhen'an County," "Hantai District," "Langao County," "Xixiang County," "Zhenba County," "Liuba County," "Chenggu County," "Foping County," "Shangzhou District," "Zhenping County," "Baihe County," "Shangnan County," "Danfeng County," "Zhashui County," "Luonan County," "Ningshan County," "Shiquan County," "Shanyang County," "Hanbin District," and "Mian County." Additional keywords include "waterlogging," "flooding," "water inundation," "water immersion," "water rise," "water disaster," "internal flooding," "flood disaster," and "flooding disaster."

2.3 Extracting address entities in Sina Weibo texts

2.3.1 BERT-BiLSTM-CRF model

Extracting location names from text falls under the domain of Named Entity Recognition (NER) in Natural Language Processing (NLP)(Zhang et al., 2020). NER involves identifying structured information, specifically entities with distinct meanings, from unstructured text. Compared to English NER, Chinese NER is more challenging due to issues like segmentation ambiguities and polysemy in the Chinese language. Techniques for implementing NER include

rule-based methods, unsupervised learning methods, feature-based supervised learning methods, and deep learning methods, with the latter being the most widely applied.

Recently, deep learning has achieved significant breakthroughs in the NLP field. When applied to NER, it can learn complex hidden representations without the need for elaborate feature engineering and extensive domain knowledge(Devlin et al., 2018a). For example, Mai et al. used a coupled model of BERT, Bidirectional Long Short-Term Memory (BiLSTM), and Conditional Random Fields (CRF) to identify Chinese place names, referred to as the BERT-BiLSTM-CRF model(Devlin et al., 2018b). BERT (Bidirectional Encoder Representations from Transformers) is a pre-trained model derived from the Transformer architecture, used for various NLP tasks. It operates in two main steps: pre-training and fine-tuning. Compared to traditional neural network language models, BERT has achieved state-of-the-art results in several NLP tasks, including text classification, text similarity, intelligent question answering, text annotation, and named entity recognition(Cui et al., 2021). The BiLSTM model consists of forward and backward LSTMs, allowing it to learn the structure of sequences in both directions, effectively addressing the challenge of distinguishing different sentence sequences. The input to the BiLSTM model is the word embeddings obtained from the BERT model, and the output is a score probability matrix for each label corresponding to each word. Additionally, the LSTM units comprise memory cells and three gates—input, forget, and output gates—that control their inputs and outputs. The CRF model simulates Chinese grammar through conditional probabilities, constraining the model's output to conform to grammatical rules and ensuring the accuracy of the output.

2.3.2 Extracting Process

After conducting tokenization and encoding of the text data, it is passed through a pre-trained tokenizer. The rbt6 is a pre-trained Chinese model from hfl that has been fine-tuned through training on a large Chinese corpus and shows excellent performance in Chinese text tokenization tasks. The main goal of the tokenizer is to change the raw text into a format that a model can understand, using the model language knowledge learned from a huge corpus to improve the text data's tokenization accuracy and model input normalization. A custom dataset class was defined to load and process the text data. A class with a data loading function to load and preprocess text data is able to load data from the local disk and filter data to ensure quality and high efficiency in model training. In particular, it thins out sentences with more than 512 tokens, since unnecessarily long sentences might waste computational resources and degrade the model's performance. The dataset class was written to implement the basic idx and getlen methods, which work with data loaders and, in this way, significantly increase flexibility and efficiency in data processing.

A data collation function was written to organize batch data into formats to be input into the model. Mainly, the code participated in: encoding of the input text in a way that may be further transformed into the form of tensor to perform further processing in the model; padding of the labels to assure that the length of the label is the same as the input text; forming the batch data, which will later participate in the model training and evaluation process, so that raw data is transformed into directly processable format to assure the uniformity and completeness of

data input. After preprocessing, a pre-trained BERT model as a feature extractor is used. Since the BERT model has been trained on such a humongous corpus, it generates super quality text representation. The pre-trained model loads and makes a person fully use the huge amount of linguistic representations learned from the big corpus and enhances a lot of performance for the downstream task.

A Bidirectional Long Short-Term Memory (BiLSTM) layer on top of the BERT module is then added to extract sequence features. In a BiLSTM layer, due to the characteristic of bidirectional information transfer, realizing the retention of dependencies that lie on both sides of a word corpus, so the feature representation is more abundant. A Conditional Random Field (CRF) is added to the top of the BiLSTM layer in a sequence labeling task. The major benefit of the CRF layer is that it essentially models the dependencies between the labels. Consequently, it is improving the accuracy of the label prediction. The realization of a training function, to include the following steps: First, the definition of the optimizer and loss function. Second, data are loaded in batches. Features are extracted and then input into the model to obtain the feature vector, which will be used for forward computation to obtain the prediction result. Third, calculate the loss between the prediction result and the true label and carry out back propagation to update the model parameters; finally, save the trained model parameters for subsequent test and prediction. The cross-entropy loss function, in the process of training, is adopted to compute the difference between the predicted results and the true labels. The gradient descent method is adopted to optimize model parameters, thus enhancing the model performance step by step.

3. Results

In this article, we have effectively applied the BERT-BiLSTM-CRF model for processing data on the social platform Weibo to extract information related to floods in small towns in the Qinba Mountain area of southern Shaanxi. We collected social platform text data using Python web crawlers and preprocesses this data, which includes the deletion of stop words, punctuation marks, emojis, and other non-relevant parts. The named entity recognition of the text data was also carried out to obtain place names, personal names, and organization names as entities and were annotated according to the BIO format rules. Then, the identified place name entities were geocoded for the extraction of their corresponding latitude and longitude. In Figure 1, it can conveniently be understood that flood points that were extracted from Weibo data were so successfully mapped to obtain the distribution of floods in the form of visualization.

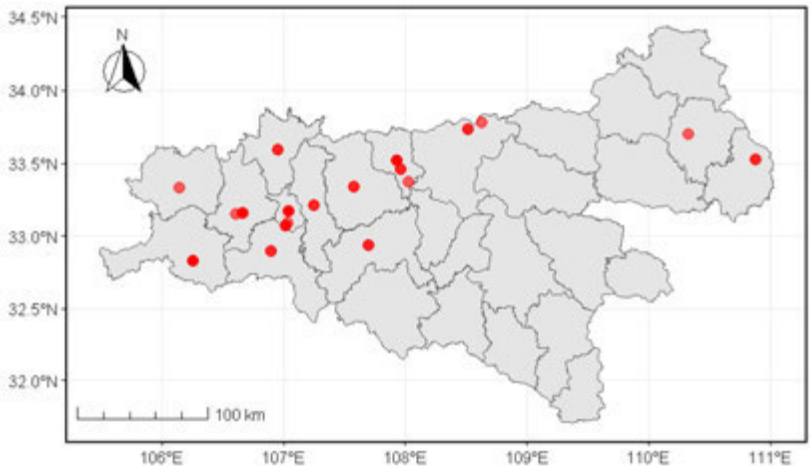

Figure 3: Flood Distribution Map of Towns in the Qinba Mountain Area of Shaanxi

We performed spatial analysis and visualization of flood points in small towns of the Qinba Mountain area in southern Shaanxi. Based on kernel density estimation on the flood data in 2021, 2022, and 2023, we presented the spatial distribution characteristics and trends of the flood points. We successfully located the flood points in these three years and extracted the flood information from Weibo. The flood information was converted into coordinate points and marked on the map. The density distribution of the flood points is represented using blue lines and filled polygons. We compared the distribution of the flood points in different years. We conducted the analysis of the spatiotemporal changes in flood risk, which provided important information for flood risk management. Figure 4 is a comprehensive map where all the kernel density analyses are combined. The red points represent filtered flood points, and the blue lines and polygons represent the kernel density estimates of flood points. This way, we are not only able to see the position of each flood point but also to understand the distribution density of the flood points in the whole area. These analyses promote our understanding of the distribution of flood points in small towns of the Qinba Mountain area in southern Shaanxi and provide a scientific basis for future flood prevention and urban

planning.

Figure 4: Comprehensive Flood Point Distribution and Kernel Density Map in Small Towns of the Qinba Mountain Area, Southern Shaanxi (2021-2023)

We made a more detailed spatial analysis of flood points in small towns of the Qinba Mountain area in south Shaanxi. By integrating multi-year flood data, we not only counted the number of flood points in each geographic location, but also visually presented the flood point density on the map with gradient colors. We managed to read the flood point data within the three years of 2021, 2022, and 2023 and converted them into sf objects. We counted the number of flood points of each shapefile and summarized them to compare each year of data. As to the amount of flood points, we used gradient colors from yellow to deep red to present the geographical area, which is the density of a number of flood points, and contribute to an intuitive risk assessment. We made a full-map visualization with all the shapefiles merged in which the distribution of the flood points could be read from the fill colors. Figure 5 provides a comprehensive visualization of the flood point density in small towns within the Qinba Mountain area of southern Shaanxi from 2021 to 2023. Using gradient colors ranging from yellow to deep red, the map highlights the varying density of flood points across different geographical areas. Each color represents the density level, with yellow indicating lower density and deep red indicating higher density.

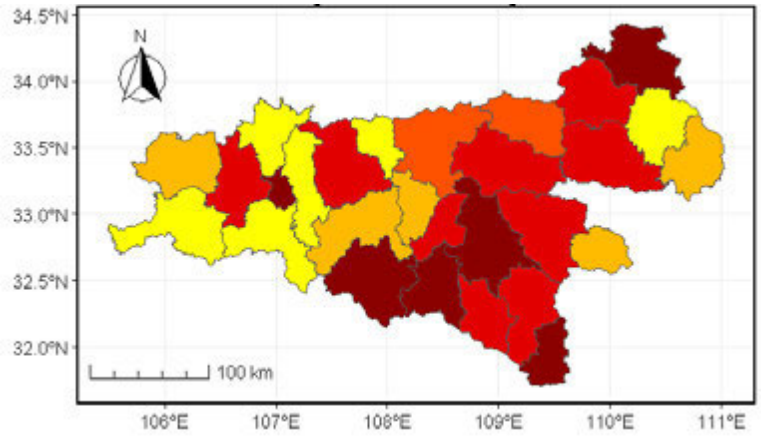

Figure 5: Gradient Map of Flood Point Density in Small Towns of the Qinba Mountain Area, Southern Shaanxi (2021-2023)

This is more reliable for the monitoring of the risk of floods in the small towns in the Qinba Mountain region of southern Shaanxi, and it can offer compelling data arguments for the flood prevention measure and the urban planning provided in the later sections.

4. Conclusion

This research has pioneered a novel way of urban planning and disaster management by combining the analysis of social media information with advanced deep-learning methodologies to evaluate flood risk in small towns of the Qinba Mountain region in southern

Shaanxi. We have effectively extracted and processed the flood information through Weibo with the BERT-BiLSTM-CRF model and thereby obtained a comprehensive understanding of the spatial distribution and features of flood events in this region. Our approach was to gather large-scale social media data using Python web scrapers and then pre-process the data carefully by filtering out irrelevant data. The BERT-BiLSTM-CRF model was used to extract and categorize named entities of place names, which were then geocoded to extract their actual latitude and longitude. With the help of this, the spread of floods in small towns over a few years could be visualized and interpreted to extract meaningful insights into the temporal and spatial patterns behind the flood risks.

The results showed that the use of deep learning and its combination with social media analytics was possible to realize real-time flood risk assessment and urban planning. The spatial analysis and visualization of the flood points played an essential role in managing flood risk and urban resilience planning. The combination with the multi-year flood data enabled us to assess the population density and distribution of the flood points, thereby providing a scientific basis for the formulation of effective flood prevention measures and urban planning policy. This research also demonstrates the necessity to incorporate social media data in the disaster management system, as it provides a comprehensive and real-time source of data that supplements the traditional approaches. The incorporation of advanced computational methods and multi-objective optimization algorithms in urban planning could help to improve the accuracy and reliability of flood risk analysis as well as enable urban development, which is more robust and sustainable.

Abstract

The article discusses Iraq's historical cities facing challenges of reconstruction amidst large-scale destructions, emphasising the complexity of contemporary urban redevelopment, exacerbated by climate change. It proposes a replicable planning approach employing adaptable modelling strategies tailored to each city's needs, allowing for independent implementation by local administrations. The progressive strategy, adaptable to specific characteristics, uses tools like linear attractors and matrices. These tools facilitate the design of repeatable solutions and rule-based urban transformations, ensuring a balance between public-private spaces and green areas. The approach aims to create resilient, climate-responsive urban environments, tested in four northern Iraqi cities, to foster positive transformations and mitigate climate impacts. Ultimately, the proposed scenario seeks to cultivate urban environments that thrive amidst evolving climate conditions while ensuring community well-being.

Keywords

Climate change adaptation, settlement scheme, climate justice, resilience.

Introduction

Iraq hosts some of the oldest continuously inhabited cities in the world. The historical significance of its urban areas is enormous, representing millennia of human civilisation and cultural heritage. However, the Iraqi territory has recently borne the brunt of extensive destruction, leaving its cities in ruins. The devastation wrought by conflict, warfare, and natural disasters fully displays the task of rebuilding and revitalising these once-thriving urban centres. Moreover, the increasing impact of climate change compounds the urgency of reconstruction. As temperatures rise and weather patterns become progressively unpredictable, the country must confront new challenges that threaten to worsen existing vulnerabilities. Addressing climate change issues is not merely an option but necessary for Iraq's future prosperity and resilience; local authorities must devise a series of strategies tailored to the specific needs of each city, recognising that more than a one-size-fits-all approach will be needed in the face of such diverse urban landscapes. Indeed, from the ancient city of Babylon to the modern metropolis of Baghdad, each urban centre in Iraq possesses unique characteristics, vulnerabilities, and opportunities. Rebuilding and adapting these cities to withstand the impacts of climate change requires a nuanced understanding of their contexts (Berke and Campanella, 2006). In cities where the ruins of ancient temples and palaces stand as a testament to the city's

storied past, reconstructions must incorporate heritage preservation alongside climate resilience.
Furthermore, efforts to improve water management and conservation are essential to ensure the sustainability of Iraq's cities in the face of dwindling water resources. This may involve the implementation of rainwater harvesting systems, the restoration of wetlands, and the promotion of water-efficient technologies (Al, 2022). This requires investment, especially in green infrastructure, to mitigate the urban heat island effect and provide natural cooling solutions (Quigley et al., 2018). Ultimately, the reconstruction of Iraq's cities in the wake of large-scale destruction and the face of climate change is a significant task that requires a multifaceted approach (Birkmann and Von Teichman, 2010). Based on these assumptions, the research seeks to identify a replicable approach for effecting urban transformation across various scales, which aims to uncover a framework that can be adapted and applied across diverse urban contexts (Burkhard et al., 2012). The strategy uses linear attractors, such as rivers and roads, as pivotal elements driving development and transformations. These linear features serve as the cornerstone of the approach, intersecting with different types of urban fabric within the chosen contexts. Linear attractors and fabric types converge in a matrix, representing a design code's structure based on forms and parameters. Seeking to overcome a colonialist approach, the research outcomes were directed towards a flexible strategy that can be interpreted according to local design cultures. At the same time, flexibility makes it possible to imagine a system that can be adapted to different needs from time to time, making it easier to combine mitigation, adaptation, and resilience-building measures to address these numerous challenges.

Case study

The research outlined within the article specifically targets four cities in northern Iraq, designating them as the primary focal points for investigation and analysis.
The first city selected is Al-Dour, part of the Saladin Governorate, located on the Tigris River's left bank. The city is between Samarra and Tikrit and lies near Baghdad's main road with Mosul. Regarding the connection with the major regional/national transport network, Al Dour lies along the main road that connects Tikrit to Samarra, on the eastern bank of the Tigris River, and it could represent a crucial traffic point for the future development of the area; tourism, agricultural activities, and industry are the main sectors of the City. Al Dour is located rightly along the primary road running along the eastern bank of the Tigris River, which is the junction point towards the road that leads eastward to Tuz. The City's geographical location represents an important node for the movement of passengers and goods on the vertical axis, which links Mosul and the southern governorate. The city's university campus is vital to the regional and national educational system. Also, the tourism potentiality of Al Dour includes many natural areas along the river Tigris, archaeological sites which give the city touristic importance, and increased economic potential by providing rest and food stations for tourists, shops and coffee shops and recreational areas serving this purpose. (Figure 1)

The second city is Al-Sharquat, located in the Saladin Governorate on the west bank of the Tigris. It is one of the oldest cities in Iraq, and being in ancient times, the center of the Ashur Empire played a fundamental role from the archaeological perspective at the national level. The city of Sharquat lies 13 km east of the main road connecting Baghdad with Mosul, almost 320 km north of Baghdad. Two main roads run along the eastern and western banks of the Tigris River, linking the area to Samarra. In contrast, another main highway between the capital of Tikrit and Tuz covers the east-west axis. Regarding the connection with the major regional/national transport network, Sharquat is less than 15 km from the main road linking

Mosul to Baghdad, and it could become a crucial centrality for the area's future economic development, primarily associated with touristic historical and natural attractions. Sharquat district is historically significant because it was the ancient capital of the Assyrian empire. In the district, there are 272 surveyed archaeological sites. Those sites go back to different historical periods, mainly from the Assyrian period, with some historical sites belonging to the Islamic period. The most important is the Ashur Castle, even if the site needs more basic infrastructure and services to fulfil its full touristic potential. The Castle has been on the World Heritage List UNESCO since 2003, and due to the lack of maintenance, the recent armed conflicts, and the proximity of the construction of a dam entailing partial flooding and seepage, the settlement has been on the List of World Heritage Dangers. (Figure 2)

The third one is the city of Bajii, which is located on the west bank of the Tigris and in the Saladin Governorate. The city is considered a connection point between North and South, located 50 km north of Tikrit, the District capital, and 210 km north of Baghdad in the middle of the way to Mosul. The city is a critical junction of the national railway network. This makes the city an important transportation hub and a resting place for travellers between south and north. Baiji is crossed by the railway line connecting the town with the Sharquat district, Mosul to the north, and Tikrit, Samarra, and Baghdad to the south. Also, another railway line connects Baiji with Kirkuk to the east. This line is currently out of service, but if it is reactivated, it will promote the transfer of goods between Baiji and Kirkuk, contributing to the region's economy and reducing heavy vehicle traffic between Baiji and neighbouring cities. The city represents a crucial traffic point for the area's future development; tourism, trade, and industry are the main sectors in the city positively affected by the location of Bajii along this critical way of traffic. Baiji has the largest refinery in the whole country and is the most industrialised city in the Saladin Governorate. Its industrial compound, one of the largest in Iraq, made the city known as the “Industrial City of Iraq”. The presence of big factories and a good transportation connection ensures the city has a dominant position at the Governorate and national level. Thanks to its economic and strategic significance, Baiji plays a vital role at the Governorate and national level. (Figure 3)

Figure 1. The city of Al-Dour

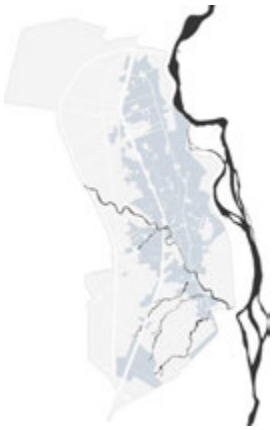

Figure 2. The city of Al-Sharquat

Figure 3. The city of Bajii

The last city selected is Mosul, the capital of the Nineveh Governorate. Mowṣil is the name the Muslim Arabs gave to ancient Nineveh, the capital of the Assyrian Empire, one of the oldest cities in the world. The site of Nineveh is located on the eastern bank of the Tigris River, while Mosul was built on the western bank. Rich in history and traditions, Mosul is a crossroads of trade and cultural exchange. It has witnessed over time the alternation of different civilisations and has been emblematic of the peaceful coexistence of other cultures in the same country, Iraq. Arabs, Kurds, Armenians, Turkmen, Christians and Syriacs coexist harmoniously. In the contemporary period, Mosul has seen its population grow impetuously, making it the third largest city by population in Iraq, after the capital Baghdad and Basra. A fertile agricultural region surrounds it, and some oil fields are nearby. A commercial centre of upper Mesopotamia, favoured by the railway linking Basra and Baghdad with the Turkish rail network, it has considerably developed its industrial sector: a refinery, cement, and textile and food factories. In the three years of occupation by the Islamic State, which had chosen it as its capital, the many battles fought left behind physical, cultural and social rubble. The war left the city with massive destruction in the infrastructure and with around 1M displaced, with an urgent need for reconstruction, in particular the housing sector (Saeed et al., n.d.). Since February 2018, UNESCO has been promoting several initiatives involving the reconstruction and rehabilitation of some of the city's sites with the support of the Iraqi government and the UN Secretary-General. The initiative aims to reconstruct its monuments and historical sites and focuses on empowering the population to change the city's fortunes through culture and education. The action, therefore, develops on a double track: on the one hand, the restoration and rehabilitation of cultural assets, and on the other hand, the revival and strengthening of educational institutions and cultural initiatives.

In conclusion, the chosen cities have the right characteristics to be used as test sites. Furthermore, considering the use of linear attractors as the main design tool, described in the following paragraphs, the four cities are most suitable for the purpose of the research. On one hand, the selected cities follow one another along the Tigris River's banks, one of the country's major historical and cultural landmarks. The Tigris and the Euphrates formed the landscape of ancient Mesopotamia, which was the cradle of Western civilisation in the past. The banks of the Tigris are characterised by a fertile agricultural landscape that, at the same time, is home to significant natural sites and some of the country's major archaeological sites. On the other hand, they follow each other across the main road and railway connecting the capital, Baghdad, with the north of the country. These two linear elements hold, in the first case, historical-cultural, social, and environmental importance, while in the second, they are strategic and commercial. For this reason, these linear elements have been identified as the major factors governing the principles of transformation.

Theoretical framework

To address a complex issue that requires a multidisciplinary and multi-scalar approach, we have relied on several topics that allow us to see the urban transformation from several points of view. Considering four Iraqi cities as test sites, the need to look at the transformation of urban space in a decolonial way was explored as a first issue. From the perspective of containing neo-colonial approaches, we referred to the research of Danielle Emma Johnson, Meg Parsons, and Karen Fisher. Their consideration was considered to help reframe and decolonise climate adaptation in line with local communities' experiences. The authors promote adaptation that draws on Indigenous capacities and aspirations for self-determination and cultural continuity, trying to mitigate the risk of maladaptation and avoid entrenching inequitable power dynamics (Johnson et al., 2022). Furthermore, reference was also made to the work of Ugo Rossi about

what is defined as 'Western urbanology' and a possible revision of the role of contemporary urbanism in economic development processes (Rossi, 2020).
Regarding the role of local communities in climate change adaptation processes, it is essential to mention the work of some authors, such as Fiona Miller and Linda Shi, who promote equitable adaptation and explored how communities and governments might anticipate and resolve some of the humanitarian, livelihood, and ecological challenges associated with resettlement in an increasingly risky climate future (Miller, 2020; Shi, 2021).

Secondly, it was essential to consider the research of some authors on Disaster Risk Reduction (DRR) and Climate Change Adaptation (CCA), assuming that the current urban model will necessarily be outdated due to climate change, favouring a long-term vision (Bertin et al., 2019). It also suggested integrating the DRR and CCA cultures to promote economic security and social inclusion for physical and social resilience. This approach can lead to a more radical consideration of climate change issues in local government, fostering new awareness and practices of care of the regional territory (Bertin et al., 2020). Following the authors, it is crucial to understand the value of uncertainty in local recovery planning to design the plan's capability to deal with a future disaster scenario in which it is also necessary to repair the social fabric (Bertin et al., 2024).

The city evolves linearly according to various statistical surveys. However, the evolutionary processes that produce the city are neither linear nor continuous (Aquilué Junyent and Ruiz Sánchez, 2021). This aspect is progressively increasing due to climate change, and uncertainty is drastically rising in environmental and urban dynamics. This makes it necessary to come to terms with a further theme: complexity. Territorial and urban systems, however anthropised, are complex systems (Ruiz Sánchez and Musco, 2021). In mathematical terms, complexity is nothing but the capacity of the system to reach a wide range of unpredictable possible futures. Consequently, the complexity of the urban form appears to stem from accepting a high level of uncertainty and contemplating adaptation at an urban scale, which is the need to recognise uncertainty as a fundamental aspect. To navigate this challenge, one approach is to encourage cities and territories to embrace increased complexity, which does not refer exclusively to diversity but to the ability to access diverse future states (Ruiz et al., n.d.). In building new cities, it's also crucial to recognise our limitations, understand what we don't know and avoid nostalgia for unattainable security (Ruiz Sánchez and Aquilué Junyent, 2023).

These considerations finally bring us to the territory that is the subject of the research proposed in this article. Deconolisation, climate change adaptation, and urban complexity are joined by thoughts and considerations about the Tigris Valley and the environmental, social and economic impacts transforming its territory. In fact, climate change is affecting the Tigris and Euphrates River basins similarly to all other parts of the Middle East and the East Mediterranean region. This is manifested in increased temperatures, reduced precipitation, erratic weather patterns, and decreased annual stream flow of the two rivers (Adamo et al., n.d.). Studies led by Nasrat Adamo and his group revealed that severe shortages occur over the five basins, water resource elements will occur, and the Tigris River stream flow will significantly decline. This situation demands that water and soil management practices be improved to reduce the expected damage (Adamo et al., n.d., n.d.). Droughts are a regular regional feature and have significant social, environmental, and economic impacts. Therefore, there is an urgent need to build riparian areas' resilience and adaptive capacity, focusing on innovative regional-based drought and agricultural investment strategies in the Euphrates and Tigris basins (Özgüler and Yıldız, 2020). As a result of these considerations, it is fundamental to consider the river as the heart of the

proposed plan. The following section describes the approach outlined by the research and the role of the Tigris River in the urban settlements considered.

Methodology

The strategy proposed in the article adopts an adaptive and progressive approach that aims to support the development of city transformation masterplans through an evolutionary model tailored to each town's unique contexts, challenges, and opportunities. By embracing complexity and uncertainty as inherent features of urban form, the strategy ensures that the masterplan remains responsive to dynamic urban landscapes, capable of flexibly accommodating diverse needs and evolving characteristics over time. Central to this approach is the recognition that one-size-fits-all solutions may be unsuitable for addressing the multifaceted complexities of urban environments. Instead, the strategy advocates for a deep understanding of each town's needs and characteristics, allowing for tailored interventions that maximise impact and relevance. Also, a flexible model enables continuous refinement to iterate and adapt strategies in response to emerging challenges and opportunities.
The proposed approach also prioritises adaptability to diverse local design cultures and boasts replicability, allowing local administrations to implement the plan independently. This replication aspect is crucial, as it empowers communities to take ownership of the strategy's implementation process, fostering sustainable and long-term results. By providing a framework that can be readily replicated across various contexts, the research endeavours to catalyse meaningful change at the base level, amplifying the impact of its outcomes. At the same time, while a rigid and colonial approach may be rooted in historical precedents, a flexible methodology seeks to overcome this tendency. It aims to establish an open and adaptable system that empowers planners and administrations to embrace the diverse project cultures inherent in local contexts. By fostering interpretability, a flexible approach strives to cultivate a more inclusive and collaborative environment where local traditions are valued and integrated into the planning process. Through this approach, the research endeavours to navigate from colonialist paradigms towards a more responsive framework for development and decision-making. This approach will apply three main tools, each with a particular role within the overall strategy: the linear attractor, the settlement block, and the matrix.

Using linear attractors as a main design tool is related to their prominent presence within the morphological fabric of urban landscapes. The selection of these elements as focal points stems from the geographical features characterising the chosen cities. For instance, the positioning of these cities along the banks of the Tigris River and adjacent to one of the country's major highways and railways, connecting Baghdad to the northern regions, emerges as crucial factors shaping their urban form.
The river and the transportation routes serve as movement channels and embody multifaceted significance. The Tigris River’s historical, cultural, social, and environmental importance is profound, acting as a conduit for trade, culture, and community life throughout the region's history. Moreover, its presence often defines the cities' spatial organisation and cultural identity along its banks. Similarly, the strategic placement of these cities along key highways and railways underscores their importance as hubs of commerce, transportation, and connectivity. These linear infrastructural elements facilitate the movement of goods and people and serve as nodes for economic activity and urban development. Their strategic significance extends beyond mere transportation routes, influencing the spatial distribution of settlements, industries, and commercial centres along their trajectories. The research recognises and harnesses the inherent value of these linear attractors, endeavouring to leverage their spatial potential in the

design process. These elements can catalyse urban development rooted in their cultural and geographical context through thoughtful integration and reinterpretation.

The settlement block as a tool is related to a widespread feature characterising most Iraqi urban areas: a settlement scheme formed by recognisable blocks. For this reason, the scale of the urban block should be taken as a starting point for developing the transformation strategy. The main goals of an approach based on a settlement block concern the relationship between public and private spaces, between open and built spaces and their possible evolution. A recurring size of blocks allows us to think of a limited number of repeatable solutions that can be combined to meet, whenever, different needs. The scale of these urban blocks plays a crucial role in determining a neighbourhood's overall character and functionality (Figure 4). Larger blocks may accommodate higher-density development, while smaller blocks may prioritise pedestrian-friendly design and green spaces. By carefully calibrating the size and configuration of blocks, it is possible to strike a balance between density and liveability, ensuring that each neighbourhood meets the diverse needs of its residents.

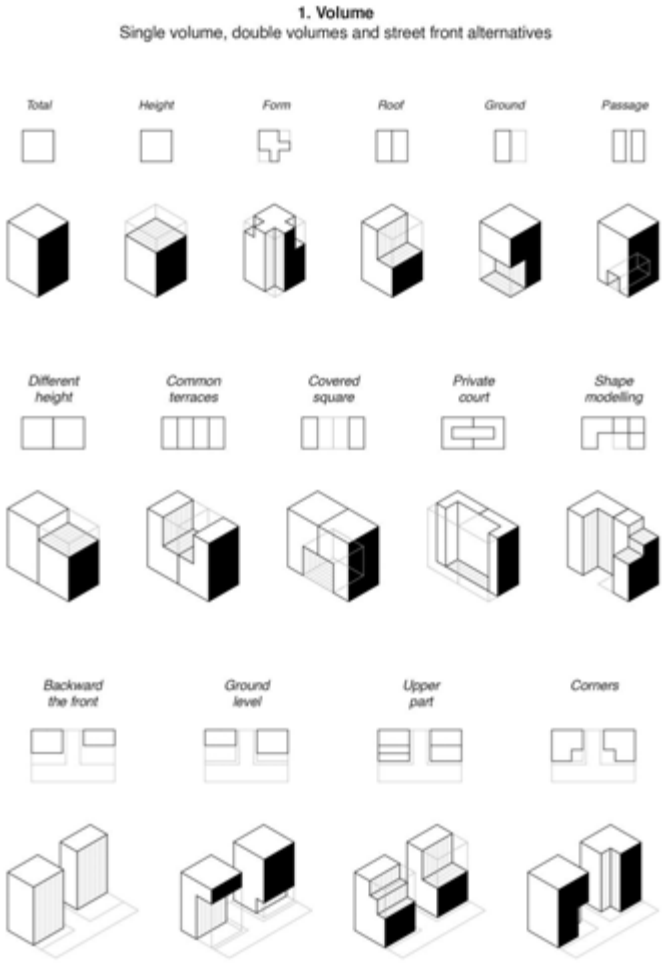

Figure 4. Abacus of volumes

In addition to physical design considerations, the settlement block approach encompasses social and cultural factors, promoting diversity and inclusivity within neighbourhoods. This may involve incorporating affordable housing units and community facilities within the fabric, fostering a sense of belonging and social cohesion. Furthermore, the settlement block approach recognises the importance of adaptive management in urban planning. Cities are dynamic, evolving entities shaped by social, economic, and environmental issues. The strategies involved must be flexible and responsive to changing conditions, allowing for iterative adjustments. Adopting an adaptive management framework makes the proposed tools continuously relevant and practical amid uncertainty and complexity.

This is strongly related to the third tool: the matrix. The matrix proposed combines the most common urban types with the main linear elements of metropolitan areas: the Tigris River and

the main road axes. Integrating a matrix that combines various urban typologies with key linear elements offers a comprehensive framework for organising and synthesising various urban typologies and spatial elements, recognising that cities are composed of diverse land uses, from residential and commercial areas to parks and transportation corridors (Figure 5). By categorising these elements according to their functional and spatial characteristics, it is possible to identify synergies and trade-offs between different components of the urban landscape. One of the key advantages of the matrix approach is its ability to facilitate integrated decision-making, developing more integrated and sustainable solutions to complex urban problems by considering the interdependencies between land uses and infrastructure systems. Moreover, the matrix approach enables planners and local authorities to explore alternative scenarios and evaluate the potential impacts of different planning decisions. By manipulating the variables within the matrix, such as land use mix and density levels, the effects of various development patterns on key performance indicators, such as traffic congestion, air quality, and social equity, may be simulated.

	Industrial	Old town	Residential Low density	Residential High density
Base	A1	A2	A3	A4
Main commercial street	B1	B2	B3	B4
Main street	C1	C2	C3	C4
River	D1	D2	D3	D4

Figure 5. The matrix proposed

Finally, indicators will be used to monitor and evaluate the performance of urban interventions. Indicators provide quantitative measures of progress towards predefined goals and objectives, allowing planners and administrations to track the effectiveness of their strategies over time. Indicators play a crucial role within this approach by providing tangible evidence of the impact of interventions on various aspects of urban life. Planners can make informed decisions and adjust their strategies by establishing clear metrics for assessing environmental, social,

economic, and policy outcomes. In addition to providing valuable insights for decision-making, indicators also serve as a communication tool for engaging stakeholders and the public. By presenting data in a clear and accessible manner, it is possible to foster dialogue and collaboration around urban issues and build support for their initiatives.

Results

The results of the methodology described above unveil a comprehensive understanding of development strategies. A first application hypothesis of the proposed approach has emerged, capitalising on the chosen cities' similar geographical and settlement characteristics. This similarity facilitated the identification of a singular initial proposal, applicable uniformly across all four cities but firstly tested in Al-Dour (Figure 6), Al-Sharquat (Figure 7) and Bajii (Figure 8). Central to this were the linear attractors identified, notably the Tigris River and the principal road and railway networks. The arterial highway linking Baghdad to Mosul, alongside significant trade routes within each city, emerged as the primary consideration. These routes, influenced by traditional Arab commerce and possessing intrinsic cultural and historical significance, also held strategic importance within each city.

Figure 6. Linear attractors for Al-Dour

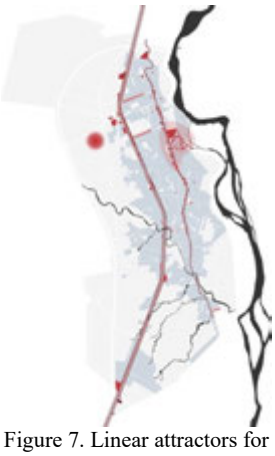

Figure 7. Linear attractors for Al-Sharquat

Figure 8. Linear attractors for Bajii

Further analysis revealed the predominant urban typologies suitable for this approach. These included the residential fabric, characterised by varying densities, the expanding industrial zones crucial for economic growth, and the cherished historical centres steeped in cultural heritage.
Consequently, a matrix emerged, integrating these elements into a clear urban development framework. The Tigris River and primary thoroughfares formed the basis of linear attractors, while residential, industrial, and historic fabrics delineated the identified urban typologies (Figures 9, 10, 11). Each intersection within this matrix was assigned an identification code as a reference point for subsequent planning endeavours.
The formulation of formal rules and parameters, alongside the establishment of abacuses of potential solutions, provided a structured approach to city transformation and development. These regulations encompassed various aspects, including building form and volume,

interventions such as green roofing, street design, and integrating green and public spaces. Additionally, considerations were made for ground floor usage and delineating buffer zones near watercourses, ensuring sustainable and resilient urban environments.

Figure 9. Different urban types for Al-Dour

Figure 10. Different urban types for Al-Sharquat

Figure 11. Different urban types for Bajii

Several considerations emerged in every city, laying the base for a comprehensive urban transformation development. Firstly, in all cities, the Tigris emerged as a complex system composed mainly of public green areas, orchards, cultivated fields, wetlands and protected areas of high landscape value (Figures 12, 13, 14). Associated with this system of green areas is the system of archaeological sites that are often located along the river. Historical city centres also stand along the banks. The city's landscape, particularly the meandering river, coupled with its strategic positioning adjacent to a major thoroughfare, signifies the potential growth across tourist and commercial sectors. Prioritising waterfront revitalisation, the urban plans emphasise the development of the different riverfronts, envisaging the creation of new tourist attractions, recreational facilities, and green spaces along the banks of the Tigris River.

Figure 12. River and green system of Al-Dour

Figure 13. River and green system of Al-Sharquat

Figure 14. River and green system of Bajii

Secondly, a strategic approach to city planning envisions the development along the central spine, primarily the main road, a common and robust urban element for all the cities considered. This structured expansion aims to optimise spatial utilisation and accessibility. Recognising the pivotal role of main roads, master plans allocate commercial zones along these arteries, capitalising on their inherent connectivity and visibility. To alleviate traffic congestion and enhance circulation efficiency, the proposal includes the implementation of a bypass strategically positioned in zones, diverting traffic away from the city centre to permit the transformation of many car-based streets into cyclo-pedestrian paths.

Lastly, formulating rules, parameters, and proposed abacuses represents a pivotal step towards envisioning a transformative system for built space. This system enhances diversity and complexity within various urban areas and serves as a cornerstone in the broader context of climate change adaptation and urban redevelopment. In the face of escalating climate challenges, prioritising complexity in urban design and planning becomes increasingly apparent. Furthermore, recognising complexity as a fundamental tool in urban transformation underscores the importance of adopting an interdisciplinary approach to city planning. The emphasis on complexity in urban transformation represents a paradigm shift towards more inclusive, adaptive, and sustainable urban futures by embracing the intricate web of interactions and interdependencies inherent in urban space. (Figures 15, 16, 17)

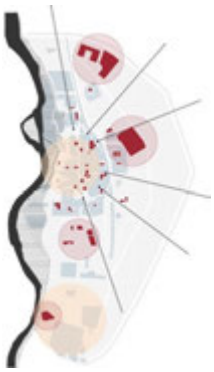

Figure 15. Strategic masterplan of Al-Dour

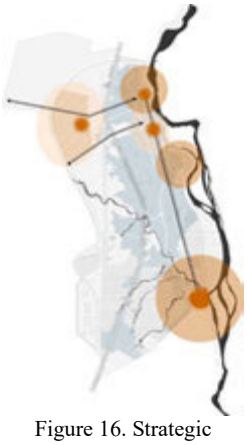

Figure 16. Strategic masterplan of Al-Sharquat

Figure 17. Strategic masterplan of Bajii

Conclusions

In conclusion, the article describes the steps of the research conducted, where the work carried out within the three minor cities emerged as a pivotal pilot experience that will feed into Mosul's transformation and reconstruction plan. Focusing on tailored strategies for each urban centre, the research underscores the potential to unlock these cities' changes while preserving their rich cultural heritage, aspiring to unearth a blueprint that can be customised and implemented in varied urban landscapes. Recognising the urgency for transformation, the study advocates for a comprehensive approach to rebuilding Iraq's cities. Additionally, departing from a colonialist approach, the research outcomes were geared towards a flexible approach tailored to embrace

local planning cultures. Simultaneously, this adaptability fosters envisioning a system amenable to accommodate varying, facilitating the encounter of mitigation, adaptation, and resilience-building measures to address today's challenges.

Acknowledgements

The research involved collaboration at all phases as a private cooperator and funder of Studio Galli SGI of Padua, without which this entire project would not have been possible. We would also like to thank Jacopo Galli and Elisa Vendemini of the Iuav University of Venice for their scientific advice on the areas in question in urban design.

Abstract

Urban regeneration entails navigating complex opportunities and challenges for local governments. It involves collaborative efforts among public, private, non-profit organizations (NGOs), and civil society stakeholders to address community needs through regeneration policies and practices. Incentives play a pivotal role in fostering cooperation and acceptance of regeneration initiatives. This paper examines the effectiveness of urban regeneration incentives in promoting collaborative planning in Zeytinburnu, Istanbul. Zeytinburnu, a significant player in Istanbul's regeneration scene, has extensive experience with incentives. The study examined collaboration and governance strategies in the incentive process through a set of in-depth interviews with key stakeholders, and the hypothesis coding method for analysis. Findings reveal shortcomings in stakeholder involvement, transparency, and expectation fulfillment. Feedback mechanisms highlight conflicts and the need for continuous improvement. Transparency, participatory frameworks, comprehensive stakeholder involvement, justice, and conflict resolution emerge as crucial for successful regeneration initiatives. These insights contribute to urban regeneration management and societal endorsement of constructive incentives regeneration schemes might offer.

Keywords: Urban regeneration incentives; local stakeholders; collaborative planning; governance; Istanbul

1 Urban Regeneration Incentives as a Collaboration Tool

Urban regeneration represents a complex domain wherein local governance entities navigate a myriad of multifaceted opportunities and challenges. Local governments must consider various aspects to ensure cities develop physically, socially, and economically while also prioritizing livability. As a result of its multidimensional nature, urban regeneration necessitates collaboration and coordination among various stakeholders. However, the term urban regeneration did not emerge immediately within the historical process. With the emergence of urban redevelopment concepts in the 1980s, there has been a concurrent shift towards a multi-actor framework. Particularly after the 1990s, the notion of urban regeneration has underscored collaborative processes among stakeholders. These processes aim to foster regeneration policies, practices, and strategies tailored to address the diverse needs of local communities (Roberts, Sykes and Granger, 2017; Wang et al., 2021).

Urban regeneration incentives are crucial for promoting collaboration among stakeholders and securing their support for regeneration efforts (Hanson and Rohlin, 2021). Urban regeneration incentives serve as catalysts for collaborative efforts, promoting synergistic engagement among stakeholders and driving the success of urban regeneration initiatives. However, the issue of how incentives are carried out and how they affect cooperation is an area that has generally not been researched in Türkiye. Therefore, this study provides an important opportunity to understand how Türkiye's urban regeneration incentives contribute to cooperation. The implications for the successful realization of urban regeneration initiatives that emerge from the case study revolve around the imperative of prioritizing transparency, nurturing participatory frameworks, ensuring comprehensive stakeholder involvement, steadfastly upholding principles of justice, and proactively addressing any conflicts. These insights, while contributing to existing scholarly perspectives, can serve as prescriptive benchmarks for the proficient management of urban regeneration and the cultivation of a broad-based societal endorsement. By untangling roles, deciphering initiatives, and examining conflict dynamics, the study may contribute to furthering collaboration and governance dynamics in urban regeneration schemes across and beyond Istanbul. For this reason, with collaboration being crucial for ensuring the applicability and sustainability of incentives provided by central and local governments, this study examines the effectiveness of formal urban regeneration incentives offered by local governments in promoting collaboration in the case of Zeytinburnu, Istanbul.

1.1 Spatially and Economically Targeted Incentives

The influence of globalization and neoliberal policies has prompted significant shifts in urban regeneration practices, with a notable transition from public to private sector involvement in regeneration initiatives (Türkün, Aslan and Kaya Erdoğan, 2014). During this process, regeneration projects have shifted from the public sector to the private sector; factors such as changes in housing values and commodification have played a central role in attracting national and international capital, particularly since the 2000s (Akman, Can and Yalçın, 2018). Urban regeneration incentives, which vary in names and objectives, are diversifying and being implemented across a wide spectrum. The present study undertakes an analysis of the multifaceted landscape of urban regeneration incentives, characterized by a plethora of terminologies and objectives. These incentives are methodically classified into two primary categories: those oriented at spatial targeted and those aimed at economic targeted (Figure 1). This broad variety of incentives aims to provide a comprehensive perspective on stakeholder structures and impact mechanisms.

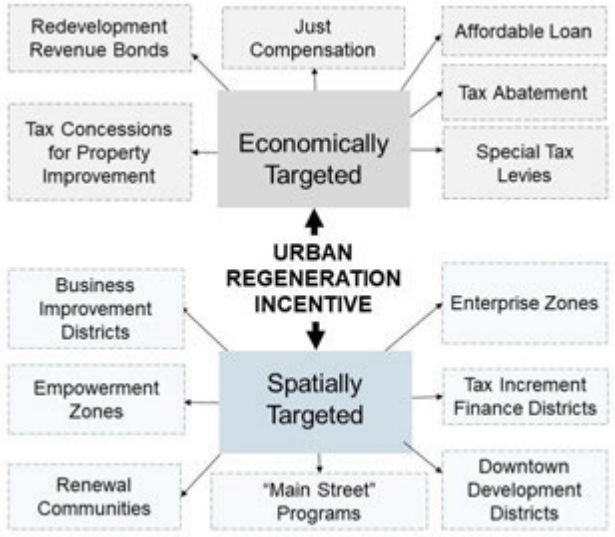

Figure 1. Implementations of urban regeneration incentives around the world (Adapted from Bartosiewicz and Pielesiak, 2019; Chignier-Riboulon and Hall, 2013; Hanson and Rohlin, 2021; Lum, Sim and Malone-Lee, 2004; Slayton, 1960; Tang and Tang, 1999; Williams, 2006)

Spatially targeted incentives encompass measures aimed at promoting the regeneration of a specific region or area, revitalizing economic activities, attracting investments, or enhancing the quality of life in the area. These incentives typically focus on a targeted geographical region or a specific group of people residing within the designated area (Hanson and Rohlin, 2021). Various incentive methods such as (1) *Enterprise Zones*, (2) *Tax Increment Financing Districts (TIF)*, (3) *Business Improvement Districts*, (4) *Empowerment Zones*, and (5) *Main Street Programs* are implemented to provide support for urban regeneration projects across different geographic regions and countries. For instance, *enterprise zones* represent a policy approach employed both in the US and the UK. Initially introduced by individual states in the US and subsequently involving federal government participation, these zones aim to stimulate area-based economic urban regeneration through diverse incentives, including tax exemptions and investment credits. Particularly notable is the collaboration between local and federal authorities, as seen in Illinois, where *enterprise zones* benefit from incentives such as tax relief and expedited bureaucratic procedures (Illinois Department of Commerce, 2014). In the UK, *enterprise zones* offer businesses financial incentives alongside streamlined urban planning processes, thus not only bolstering urban regeneration efforts but also enhancing the efficacy of planning procedures (Ward, 2023). Another incentive, *TIFs* are seen to directly support urban regeneration projects in Chicago (Figure 2). In this context, TIFs provide a significant source for local development efforts and contribute to the realization of urban transformation. In summary, all spatially targeted urban regeneration incentives are closely associated with supporting urban regeneration

by aligning with local needs, embracing strategies tailored to local requirements, fostering effective local participation, and focusing on sustainable development goals. The adaptability of these incentives to the regeneration needs in urban areas in a flexible and suitable manner is crucial for enhancing the success of urban regeneration efforts.

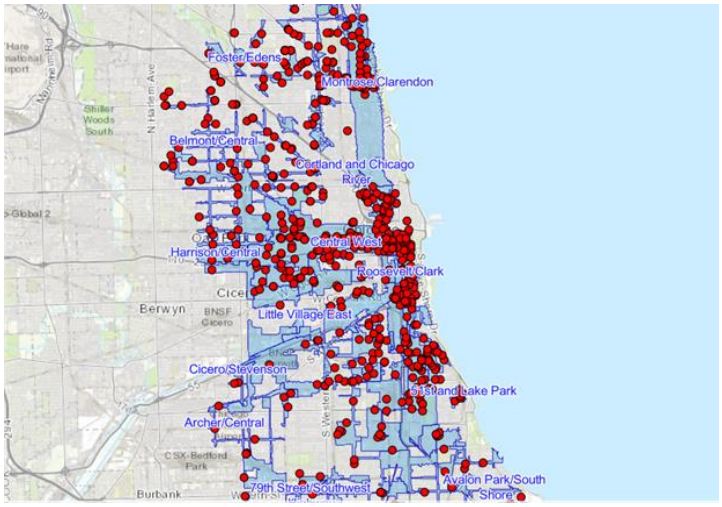

Figure 2. Geographic locations of tax increment financing districts and urban regeneration projects in Chicago (Adapted from Chicago TIF, 2023)

Economically targeted incentives in urban regeneration emphasize two key economic approaches globally: *just compensation* and *affordable loan*. In this context, these economic incentives can serve as effective strategic tools not only to facilitate physical regeneration in cities but also to address income inequalities and promote social justice by focusing on the goal of providing economic incentives. *Just compensation* generally refers to the situation of displacement arising from compulsory processes such as urban regeneration and expropriation by public authorities for public benefit purposes, which is typically described in the literature as the concept of "compensation" (Kelly, 2006). *Affordable loans*, also known as low-cost loans, are utilized by central banks to stimulate economic activity and facilitate the revitalization of vacant or dilapidated areas (Alexandre, 2008). For instance, in Italy, the European Investment Bank has provided over €12 billion in financing between 1995 and 2002, primarily to support urban transformation, construction and rehabilitation of public spaces, social housing projects, and urban infrastructure improvements (European Investment Bank, 2002).

Consequently, spatially targeted incentives target specific regions, while economically targeted incentives are provided by both central and local governments regardless of location. Slayton (1960) emphasizes the pivotal role of local governments in promoting urban regeneration,

particularly through economic incentives. He suggests that local governments can incentivize urban regeneration through aesthetic, zoning, and management strategies. Despite potential barriers posed by zoning regulations, flexible planning tools can mitigate limitations. Effective leadership and coordination by local governments are crucial for enhancing urban regeneration incentives.

1.2 Local Context: Türkiye and Zeytinburnu

With the rapid urbanization process in Türkiye, there has been a need for urban regeneration to cope with issues such as migration, illegal and unhealthy construction, urban decay in city centers, and earthquakes (Özden, 2016). In contrast to the international context, Türkiye's initial experience with urban regeneration took place in *gecekondu*[1] areas. (Uzun, 2006). Following efforts to upgrade *gecekondu* areas in major cities, there has been a frequent occurrence of initiatives aimed at identifying risky areas and reconstructing them through state and public-private partnerships. Since the implementation of the Gecekondu Law (No. 775) in 1966, efforts have been made to establish a legal framework for urban regeneration and incentive policies. Today the legal framework for urban regeneration and incentive policies is primarily established by Law No. 6306, enacted in 2012, titled "Law on Regeneration of Areas under Disaster Risk". This law, aimed at areas prone to earthquakes and disasters, grants authority to the Housing Development Administration of the Republic of Türkiye (TOKİ) and Republic of Türkiye Ministry of Environment, Urbanization, and Climate Change (TMUCC) for its implementation. It also defines the institutions responsible for identifying risky structures, evaluating objections, and conducting demolition processes. The qualifications of engineers appointed to assess risky structures and the oversight processes are elaborately outlined. Procedures and conditions for identifying reserved housing areas and risky zones are also specified. The required information and documents for identifying reserved housing areas, as well as the documents and processes for identifying risky zones, are detailed within this law. Incentives are provided to support urban regeneration projects and to persuade stakeholders to participate and collaborate in urban regeneration. While local governments primarily focus on services that affect and improve the daily lives of local residents, central governments provide services on a national scale targeting the entire population. The situation regarding urban regeneration incentives in Türkiye is similar.

At the national level, various incentives are provided and continuously improved within the framework of Law No. 6306 and its implementation regulations. Among the economic-targeted incentives primarily include rental assistance and interest support. Additionally, the "Half is Offered by Us" incentive, established in 2023, is gradually finding implementation opportunities. Temporary housing or workplace allocation and rental assistance are provided to the owners of structures vacated through agreement or to occupants residing in these structures, whether they are owners, tenants, or holders of limited real rights. For rental assistance, a one-time payment of a specified amount is made to owners monthly, and to tenants and holders of limited real rights once (Akman, Can and Yalçın, 2018). Rental assistance fees are updated every year (Table 1).

[1] The term "*gecekondu*" refers to illegally constructed housing units, typically built without permission and in a haphazard manner, often found in rural areas of Turkey.

Table 1. Rental assistance amounts by province in Turkey, 2023 (TMEUCC, 2023b)

City Name	Owner (Monthly)	Tenant (One-time)	Holder of Limited Real Rights (One-time)
1. İstanbul	3.500 ₺	7.000 ₺	17.500 ₺
2. Ankara, Antalya, Bursa, İzmir	3.000 ₺	6.000 ₺	15.000 ₺
3. Adana, Aydın, Balıkesir, Denizli, Diyarbakır, Erzurum, Eskişehir, Gaziantep, Hatay, Kahramanmaraş, Kayseri, Kocaeli, Konya, Malatya, Manisa, Mardin, Mersin, Muğla, Ordu, Sakarya, Samsun, Şanlıurfa, Tekirdağ, Trabzon, Van	2.500 ₺	5.000 ₺	12.500 ₺
4. Other cities	2.000 ₺	4.000 ₺	10.000 ₺

Interest support is provided for loans obtained by owners from banks for regeneration projects, to be covered from the special account for regeneration projects. Citizens have the right to benefit from only one of rental assistance and interest support programs. Following the earthquakes in Kahramanmaraş on February 4, 2023, there have been updates in the support amounts to accelerate urban regeneration efforts. In 2022, the credit limit was increased from 600,000 ₺ to 1,250,000 ₺. Additionally, it has been announced that interest support will be provided for a total of 48 months, including a 12-month grace period for repayment (TMEUCC, 2023a). And also, the protocol will be signed for the buildings deemed suitable by the ministry upon application from property owners for the support of "Half is Offered by Us" initiative, and the project phase and permit acquisition processes will commence. During these stages, property owners will be provided with a relocation assistance of 10,500 ₺ and a monthly rental support of 5,250 ₺, as stated. It is also indicated that the housing to be built within the scope of this project is expected to be completed within two years, among other conditions (TMEUCC, 2023a).

Spatially targeted urban regeneration incentives are provided through the designation of two areas defined by the law: risky areas and reserved areas. The declaration of these areas is authorized by TOKİ, TMEUCC, and other relevant administrations (both central and local governments). Risk areas and reserve building areas, greater financial incentive is provided compared to other areas. For instance, while rental support extends for 18 months for risky structures, it spans 48 months for property owners in both risky and reserve building zones. Additionally, there are various advantages such as the preparation of area-specific urban regeneration projects, acceleration of bureaucratic processes, and utilization of tax incentives.

At the local level, urban regeneration processes are regulated and delegated authority to local governments through laws such as Law No. 5393 on Municipalities and Law No. 5216 on Metropolitan Municipalities. These legal frameworks govern urban regeneration processes, granting powers to local administrations. These legislative enactments confer upon municipalities and metropolitan municipalities the authority to strategize, execute, and oversee urban regeneration initiatives. Concurrently, they impose upon local administrations responsibilities such as promoting citizen engagement, facilitating the rehabilitation of high-risk areas, and ensuring environmental sustainability. Incentives extended by local authorities are disseminated through zoning ordinances and regulatory frameworks established by district municipalities. However, the nature and scope of these incentives are contingent upon the unique requirements and dynamics of each province, district, and locality.

The selection of Istanbul's Zeytinburnu district as the focal point of this study is underscored by the intricate interplay between the distinctive needs and dynamics inherent to various provinces, districts, and localities. Since the enactment of Law No. 6306, which marked a pivotal juncture in urban regeneration legislation, Istanbul has emerged as a focal point for such endeavors in Türkiye, given its substantial identification of 70 high-risk areas, 152 reserved building areas, and around 84.000 structurally compromised buildings (Istanbul Planning Agency, 2023). Consequently, Istanbul assumes a central role in driving urban regeneration practices nationwide. Within this context, Zeytinburnu stands out as a significant player within the Istanbul metropolitan area and across Türkiye. Its designation as the pilot area for the EU-supported Matra REGIMA project, aimed at enhancing institutional and community capacity for urban regeneration, underscores its extensive two-decade-long experience with regeneration initiatives and associated incentives (Ozcevik, Beygo, and Akcakaya, 2010). Moreover, ongoing efforts by the Zeytinburnu Municipality focused on incentivizing urban regeneration highlight its proactive stance in addressing these critical issues.

Urban regeneration incentives in Türkiye are not fully aligned with principles of collaborative planning. The relevant legislation lacks provisions for public and stakeholder participation, particularly Law No. 6306, which allows the progress of the process based on the approval of a majority of property owners rather than unanimous consent. This may pave the way for the displacement of unwilling property owners. Additionally, the implementation regulation of incentives lacks a system through which property owners can monitor and evaluate the process, including identifying the responsible authority and determining the amount of compensation. For instance, the notification period for property owners to vacate their structures after a decision on risky buildings is issued does not commence until all property owners receive the notification. Property owners must personally inquire at the relevant authority or institution to learn about this period. Transparent monitoring platforms are absent. Consequently, ineffective participation of stakeholders, inadequate monitoring and evaluation mechanisms are observed. Prioritizing effective stakeholder collaboration, transparent communication, sustainability, and consideration of long-term impacts are crucial steps to ensure the future success of urban regeneration incentives.

2 Case Study Design and Methodology

The Zeytinburnu district serves as a pivotal case study, exemplifying significant urban regeneration incentives provided by both central and local authorities over an extended period, alongside witnessing ongoing developments. This case study aims to assess the urban regeneration incentives within the context of cooperation, actor relations, and conflict dynamics prevalent in Zeytinburnu. The case study comprised two stages. The first stage involved the design of the in-depth interview method, which included determining the sample, preparing specific interview guides for stakeholder groups, inquiring about interviewer preferences, conducting interviews, and transcribing them. The second stage focused on the analysis of the interviews, encompassing coding of the discussions and conducting content analysis of the coded data.

Constructing the in-depth interview method: The selection of interviewees was based on purposive or judgment sampling and snowball sampling methods to ensure the comprehensive coverage of the research and the inclusion of diverse perspectives. These methods were combined to maximize the breadth of viewpoints and enhance inclusivity. Participants for in-depth interviews were chosen according to their sectoral affiliations and specific objectives. Local government officials involved in the production, implementation, and approval processes were interviewed. Private sector representatives were selected from architectural, engineering, and contracting firms actively engaged in urban regeneration projects in 2023. NGO stakeholders included representatives from relevant professional associations, local grassroots organizations, and foundation representatives actively involved in urban regeneration efforts at the provincial level. Local community representatives comprised individuals seeking information from urban regeneration offices, operating under association umbrellas, actively participating in urban regeneration activities, and those willing to share opinions despite not directly benefiting from incentives. The interviews aimed to uncover relational dynamics beyond desk-based research, diversify participant profiles, and enrich the study's depth. It employs qualitative research over 37 interviews with key stakeholders, including representatives from the local and central governments, civil society organizations, private sector entities, and the local community (Figure 3).

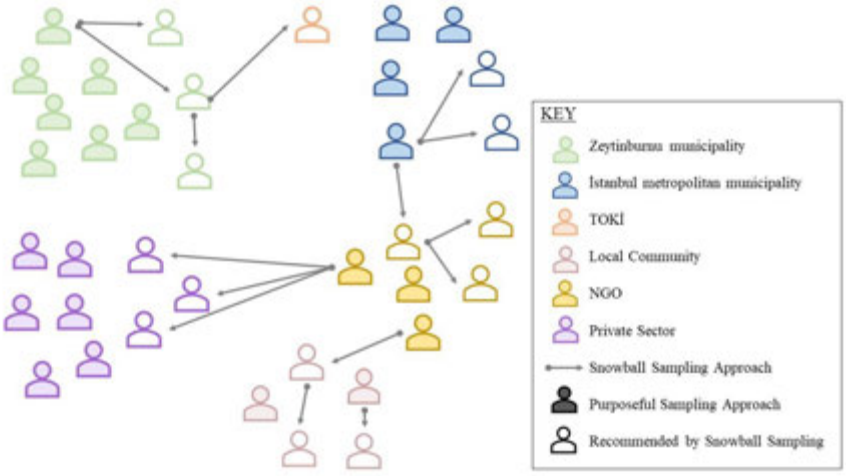

Figure 3. Stakeholders interviewed and sampling methodologies

In terms of interview preparation, informed consent forms and relevant questionnaires were emailed to participants upon accepting the interview invitation to ensure their comprehensive understanding of the research. Interviews were conducted through face-to-face meetings (65%), teleconferences (5%), and video calls (30%) according to participant preferences. Audio and video recordings were obtained with consent, while notes were taken for those declining recording during the interview, totaling 13 participants. Transcribing recorded audio files by the researcher aimed to enhance data familiarity. Transcription facilitated the conversion of interview content into text format for easier comprehension and analysis.

Analyzing the in-depth interviews: The interview data has been systematically coded under specific themes to facilitate structured analysis and determine the frequency of relevant criteria quantitatively. Hypothesis coding method has been preferred for coding. This method enables the analysis of the developed code list by the researcher within a hypothesis framework (Saldana, 2016). Additionally, sub-codes identified during the coding process have been added to the codebook. For the coding process, Google Sheets and MAXQDA software were utilized. The interviews were meticulously examined through content analysis method. As Neuendorf (2017) suggests, this analysis involved a detailed examination and interpretation of the data obtained from the interviews. The aim of this analysis was to identify elements such as conflict and interrelations among actors in the urban regeneration incentive process in the Zeytinburnu district, aiming to better understand the shortcomings in this process.

3 Results and Discussion

3.1 Actors and their Involvement in the Process

The Zeytinburnu district is an important example where various stakeholders are involved in the implementation process of urban regeneration incentives. According to representatives of both central and local governments, the participation of local stakeholders varies in this process. For instance, a representative from TOKİ, who played an active role in the risky area project in the Beştelsiz Neighborhood, stated that they are only one actor in the urban regeneration process, while it has been observed that the Istanbul Metropolitan Municipality (IMM) develops university and international collaborations and involves NGOs in the process. However, it is noted that the Zeytinburnu Municipality does not have established relationships with these actors and that its own units are more involved in the process. This indicates differences in participation processes among local governments and different implementations of collaborative planning criteria. The participation of the local community in the urban regeneration process in the district is also crucial. However, what has been emphasized in the interviews is that the local community only has the opportunity to provide feedback and is not adequately involved in the production process. On the other hand, the Zeytinburnu Municipality officials have made efforts to ensure the active participation of the local community in some important decision-making processes. For example, with some decisions taken by the Zeytinburnu Municipal Council, efforts have been made to protect the property rights of neighborhood residents and alleviate potential conflicts concerning. Another important actor is civil society organizations. However, it is observed that, apart from the local association operating in Zeytinburnu, NGOs are not adequately involved in the process. This indicates the ineffectiveness of civil society organizations in the urban regeneration process. Finally, the participation of the private sector in the process should also be evaluated. The private sector is generally involved in the implementation phase of the urban regeneration process. However, it has been emphasized in the interviews that the private sector should take a more active role as part of the feedback and implementation stages of the process. This indicates the need to develop more effective communication and collaboration mechanisms to encourage greater participation of the private sector in the process.

In order to determine the level of participation in urban regeneration incentives according to the perspectives of stakeholder groups, participation steps were determined based on the IAP2 spectrum (Figure 4)[2]. While the IMM plays a role at the level of involvement and collaboration, the Zeytinburnu Municipality is positioned more between involvement and consultation stages. According to NGOs, the private sector, and the local community, the urban regeneration incentive process does not go beyond informing and consulting.

[2] IAP2 is an organization that provides guidance on the Public Participation Spectrum, which defines the role of the public in community engagement programs and suggests different levels of participation based on goals, time frames, resources, and levels of concern in decision-making processes (International Association for Public Participation Australasia, 2016).

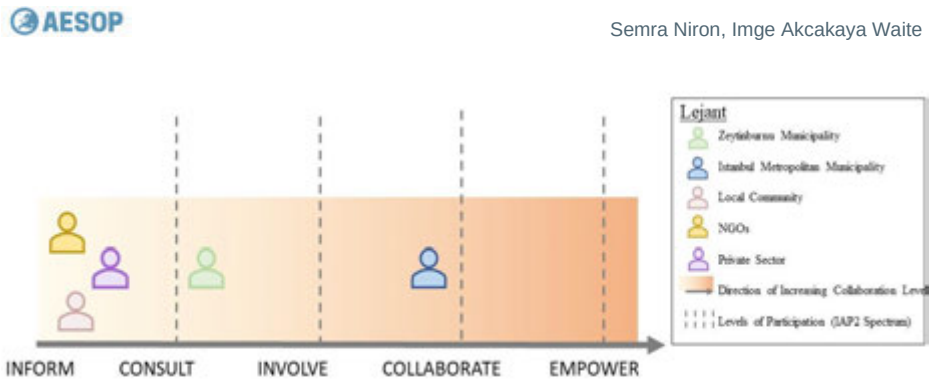

Figure 4. According to the perspective of stakeholder groups, the position of stakeholders in the participation steps based on the IAP2 spectrum in urban regeneration incentives

According to an urban planner from the İstanbul Yenileniyor Platform[3] the process involves informing the citizens, consulting, and decision-making stages at the beginning, but during the collaboration phase, apartment owners expressing negative views are not offered the option of being bought out by other property owners. This situation does not fully align with the IAP2 collaboration understanding, indicating the difficulty of achieving 100% consensus and highlighting the discrepancy between academic ideals and practical implementation. A similar situation exists for the Zeytinburnu Municipality. Local governments evaluate the collaboration and consultation stages with the public as an agreement stage in urban regeneration projects, considering it as an agreement on what they will receive in exchange for their apartments. However, it has been observed that there is a consensus system without active mutual communication and collaboration in this process.

Participation methods that support the collaboration process and encourage creative thinking are generally implemented through meeting methods at both central and local government levels. The IMM employs various implementation methods, including surveys, focus group studies, and workshops, to encourage participation. In this process, local urban regeneration offices and relevant local municipal directorates also play an active role as actors. In particular, subsidiary companies play an important role in obtaining field opinions and conducting transparent discussions. However, it is emphasized that the approach of senior-level officials and political authorities in the management is important. It is stated that the perspective of the management is critical in the formation and design of participation methods. Although in-depth discussions with central government representatives have not been conducted in large numbers, the methods used by the central government and their involvement are described as certain meetings and workshops. In conclusion, the participation methods described by the participants play an effective role in the implementation phase of urban regeneration and incentives. These methods include the opinions and contributions of stakeholders during the implementation of incentive policies, thus ensuring effective implementation of the feedback mechanism.

[3] İstanbul Yenileniyor Platform is a coordinated initiative led by subsidiary companies (i.e. İmar A.Ş., KİPTAŞ, and İŞAT) under the umbrella of the IMM.

3.2 Mediation and conflict resolution measures

The measures for mediation and dispute resolution in the district play a significant role in preventing potential conflicts of interest among various stakeholder groups. However, according to the discussions, there are different perceptions regarding the effectiveness and utilization of these mechanisms. The local residents perceive mediation and intervention during the process as inadequate. On the other hand, other stakeholders refer to various actors, stating that specific technical practices play a preventive role in conflict resolution. In this context, the transfer of knowledge and experience throughout the process is seen as a critical step for subsequent projects. While the local residents and the private sector express that such a process is not being conducted, it is indicated that consultations are held among central government institutions to share information. Additionally, civil society organizations actively participate in the process through their own educational programs and meetings.

According to representatives of the IMM, efforts are made to balance the level of information through education and capacity-building initiatives, as well as through sub-institutions such as the Istanbul Planning Agency (IPA) and the Urban Regeneration Office. Measures such as mobile applications on earthquake awareness and disaster preparedness training are also taken. During reconciliation processes, the importance of empathizing with citizens and conveying accurate information is emphasized. Members of the Zeytinburnu Municipality conduct various internal activities to balance the level of information, including technical staff training, education and information sessions for stakeholders, and informative work such as the Urban Planning Commission. In this way, they contribute to strengthening communication among stakeholders and resolving conflicts.

4 Conclusions

The findings from the discussions reveal significant challenges in ensuring effective stakeholder participation and meeting stakeholders' expectations at various stages of the urban regeneration process. The IMM's approach of involving stakeholders to a greater extent and fostering collaboration allows for the representation of various stakeholder groups and consideration of their views, demonstrating a participatory approach. However, the positioning of the Zeytinburnu Municipality more in the consultation phase indicates limited active participation of local stakeholders, with the process generally not surpassing the stages of informing and consulting. These findings underscore the need to strengthen stakeholder participation in the urban regeneration process and to manage it in a more equitable and inclusive manner. Particularly, the use of more diversified communication tools to ensure effective participation of local residents and adopting more inclusive methods to increase the participation of vulnerable groups are crucial. Additionally, more effective mechanisms should be developed to involve stakeholders more actively at different stages of the process and to consider their feedback. In this way, the urban regeneration process can be managed in a more sustainable and socially acceptable manner.

The involvement of various stakeholders in the urban regeneration process, particularly in the Zeytinburnu district, highlights the complexity and importance of collaborative efforts in urban development initiatives. The varying levels of participation observed among different stakeholder groups underscore the need for tailored approaches and strategies to ensure inclusive decision making and effective implementation. Despite efforts by both central and local governments to engage stakeholders, there are evident disparities in the extent of participation and the effectiveness of mediation and conflict resolution measures. While some stakeholders perceive these measures as inadequate, others recognize the role of technical practices and collaborative efforts in mitigating conflicts of interest. To enhance the effectiveness of participation and conflict resolution mechanisms, there is a clear need for improved communication, capacity building initiatives, and stronger partnerships between stakeholders. Additionally, ensuring transparency, empathy, and active engagement with local communities are essential for fostering trust and promoting meaningful dialogue throughout the urban regeneration process.

Overall, addressing the challenges and complexities associated with urban regeneration requires a holistic and inclusive approach that prioritizes the voices and concerns of all stakeholders. By fostering collaboration, enhancing communication channels, and implementing effective conflict resolution measures, urban development initiatives can achieve greater success and create more sustainable and inclusive communities. Various concrete steps can be taken to enhance stakeholder engagement. Firstly, organizing neighborhood meetings and online surveys can facilitate direct input from the local community. These gatherings and surveys can enable a better understanding of the residents' needs and concerns, fostering more effective participation in the decision-making process. Additionally, practical approaches to mediation and conflict resolution should be adopted. For instance, establishing neighborhood mediation services can ensure fair and effective resolution of disputes among neighbors, promoting a culture of mutual understanding and collaboration. Furthermore, the feasibility and cost-effectiveness of proposed solutions should be taken into account. The time and resources required for initiatives such as establishing new communication channels or providing neighborhood mediation services need to be clearly determined. Most importantly, local authorities should construct a collaborative framework as the dominant authority to support this process effectively.

Urban compounding: Housing what is and what could be

Abstract
This study examines the organic transformation of the South African version of the Victorian/ Edwardian bungalow from a free-standing house into a courtyard form of building – seen as a bungalow 'compound' - as part of wider city-making processes, in a context of rapid urbanisation and continental migration. Based on architectural practice-led research, the study claims that the knowledges embedded in the adapted bungalow properties can significantly contribute to context appropriate planning of lower cost accommodation and emerging mix use. As a result, while associated with connotations of illegality and 'slum life', the study coins the bungalow compound as an 'aspirational house' in the transforming African city, an undercover game changer developing plot-by-plot on an emerging spectrum of housing *what is* and *what could be*.

Keywords: courtyard morphology, compounding aspiration, plot by plot, African urbanity

Introduction
Johannesburg 2024. Hidden behind walls of buildings made in another time and for different people, hundreds and thousands of beds accommodate Johannesburg's post-1990, transitional, multinational population, many of them in rooms on private properties with formerly freestanding bungalows from the Victorian/ Edwardian period, in the inner city belt. The rule of law treats the mainly non-formal[1] appropriation of the buildings, and more importantly, their yards (that is, the open space on the plot), as a spatial illegality. In their official accounts, the City continues to record the current multi-unit room arrangements as the former single-family houses. As a result, it identifies them as inefficient in terms of numbers of occupants – and consequently requiring replacement vis-à-vis desired densification (City of Joburg, 2016).

At the same time, the properties – if recorded 'as built[2] and as inhabited' (as in this study) – suggest a form of occupation (in terms of quantity, costs, diversity of functions and residents) that the city is actually attempting to achieve in the well-located areas with very limited amount of affordable accommodation offered by the state (Dormann, Mkhabela, 2019). They are also lucrative investments and incorporate multiple providers of other services. Mostly, but not entirely operating 'off the record', the multi scalar networks that run through these spaces have created their own 'infra-economy' of material life in the shadows (Braudel, 1981:24) as a form of the everyday that might seem challenging to administer but will nonetheless, most probably, continue to exist.

Contextually, the study focuses on changes of bungalow properties in two central neighbourhoods bordering the inner city, Yeoville and Rosettenville, established at the beginning of the 20th century, for nuclear families of a white, privileged minority. After the official abolition of Apartheid in the early 1990s, these areas have been almost completely re-populated with immense socio-cultural changes – and intensely densified. Much is assumed about the changes, and few of these are considered 'good' by the planning authorities but in

[1] Non-formal implies some form of limitation of applying " regulation" – but does not automatically see this as negative – instead, the capacity to regulate is limited. (Jenkins 2013). Nagati describes this condition as non-binary, on a "spectrum of negotiation and contestation," between not requiring but not negating formal structure (Nagati, 2016:33).
[2] As built: A key architectural instrument to document existing buildings. As-built drawings commonly show changes on-site to original construction plans using redline drawings. Measured drawings are prepared to represent the situation *as is.* Final record drawings "as-built" are typically prepared for submission to the council, incorporating the changes of the red line drawings.

fact, too little is known or understood about how these residencies are being transformed inside out (Charlton, 2019). The metanarrative of crisis and slums that Nuttall and Mbembe (2008) critiqued as dangerously one-sided still prevails here. The study's accounting suggests a grey area between official recordings and lived realities as driver to identify what appear to be misconceptions as actual potential for change.

Methodolgically, the focus turns on the properties themselves, as emerging epitomes of house lives/home spaces (Heer, 2019; Jenkins, 2013), as knowledge sources and as developing citational grounds in a field around the planning of urban accommodation in precarious contexts that is understudied. The approach considers the bungalow compound as an epistemic object (Cetina, 2001; Rheinberger, 2005; Lurry, 2021) that can manifest as a problem space across multiple themes, scales, and contexts. In doing so, the study addresses the misconception of architecture as a finished product and appropriates essential incompleteness as a device to locate relevant knowledge(s). It considers the inevitable lack of complete evidence as an opportunity to understand the documentation of these emerging dynamic 'house worlds' as readings of *what is* and *what could be*, a concept Simone and Pieterse (2017) refer to as the process of *re-description*. The study examines the bungalow compounds via a case study approach, as particularly complex category of 'as built' documentation with the aim to render the, at times, contested spaces, into valid forms of city building. Within theme and context of the conference, this working paper focuses on the transforming residential typology and its morphological connotations as forms of *urban compounding* – a process that operates on a complex spectrum of, at times self-regulated, urban change, and places itself at the intersection of architecture, urban design and planning.

The text is organised into seven sections. The next section introduces the house as a knowledge object as central premise of an approach. Then conceptual model of the "shaering layers of change" (Brand, 1994) are explored as visual, analytical frame to argue for a multi scalar reading of typological change from the ground up. This is followed by methods and results, and then discussed under the premise of new orders. The conclusion reflects on *urban compounding* as a process and product, of housing what is and what could be, in uncertain times.

The house as epistemic object, exclusive knowledges

The work starts from the premise that the house knows, and we as professionals don't, in many occasions. A house is a basic architectural element that is a part of people's everyday lives and also a basic unit of urban morphologies. As private property, it plays a significant role in the planning paradigm of South Africa's historical urban development. It has been argued, that domesticity is as much personal as it is politically, socio-culturally, and economically rooted and legally laid out (Chakravartty & Silva, 2013). The idea of the 'house' is a contested space in South Africa[3], as much as the land it stands on (Braun, 2015) – and indeed, therefore, in terms of its architecture. Architectural practice here (as elsewhere) has long been complicit in the production and reinforcement of social bias and discriminating spatial arrangements (Bhandar, 2018: Aureli, 2012; Weizman & Carlo, 2010). Within this system of unequal distribution of resources, the planning and design professions have inevitably assisted to "craft and spatially define asymmetry" (Aureli & Tattara, 2013).

[3] The study refers to the 'house' as a form of domesticity that was envisioned and designed as a social construction in line with a clear cultural binary. Archival and legal documents (e.g. the Report of the Johannesburg Housing Commission (Chas. Lane Sansom, Chairman, 1903), Black Housing, The Key to a Stable Black Society (The National Development and Management Foundation, South Africa, 1978) Native Housing in South Africa (Calderwood, 1952) and the Minimum Standards of Housing Accommodation for Non-Europeans) display clearly separated strategies and predictions for housing requirements of black, white or coloured people.

Institutionalized and systematically organized, the domestic geometries thus created often appear as the translation of legislation laid out in the past yet retaining some shadow validity as a blueprint in the ground. Within all of this, the City continues to ask for the application of, at times, outdated building codes and regulations, drawing on architectural tropes. Additionally, it does not seem to be able to engage with the physical structures as they are – as built – and hence to accommodate the real-life changes which these cater.

Despite this basis in a form of architectural and morphological 'blindness,' some buildings/properties have managed to help themselves in certain ways – they have learned after they have been built (Brand, 1994)[4] and make most of the opportunities for change. They have, one could say, "the capacity to aspire" (Appadurai, 2004:59; Appadurai, 2003), and their representations are, in many ways, aspirational maps. Here, the architectural structure, as built, turns into a blueprint of people's visions of how they would like to live within the choices they are privileged to make, overwriting previously set times and boundaries.

The history of their transformation can be seen to be embedded in their physical form as traces of an ongoing negotiation between economical, juridical and socio-cultural dynamics (Chakravartty & Silva, 2013). The house thus turns into a knowledge object and a source when zooming out of the wider urban morphology and a socio-economic construct of material civilization across time[5] (Braudel, 1981) – even when zooming into the anatomy of its own materiality (Brand, 1994; Duffy, 1990). Both ends of the spectrum deal with change over time as a response to context on different scales, sometimes to the extent that it becomes a new form of context – as boundaries between house and context merge, and those relations also become a rich knowledge base.

Accessing such 'inner' spatial knowledge is not easy in the areas under investigation due to a high degree of non-formal activities, with a number of them potentially deemed illegal, and a general rise in lack of safety and security. Here we encounter Braudel's' material life (1981) at eye level, " a shadowy zone often hard to see for lack of adequate […] documents," something he calls the "infra economy, the informal other half of economic activity, the world of self-sufficiency and barter of goods and services within a very small radius" (Braudel, 1981:24) People in the 'shadowy zone' are understandably cautious with whom they share what, and access to these intimate forms of knowledge is inevitably limited to some degree. This is more so when, legally, the private properties have the right to exclude. The governing structures do not seem to have resources or a feasible strategy of how to enter or, to look for, in these admittedly complex, dynamically changing territories This increases the exclusivity, and (according to market rules) the value of the embedded knowledge – and, in fact, of the properties, likewise.

Shearing layers of change and red line drawings

[4] Brand discusses the knowledge of buildings from a material perspective and deconstructs the house made of components across six shearing 'lifetime layers' of change further explored in Chapter 4.

[5] Braudel' s (1981) material civilisation is the second layer of a triple division of economic realities. He introduces A) the market economy as "transparent, visible realities […] and easily observed" in the centre, underneath which B) a "shadowy zone often hard to see for lack of adequate […] documents" plays out "elementary basic activity that went on everywhere […] a rich zone, like a layer covering the earth […] called material life or material civilization" In lack for an appropriate word he calls it the "infra economy, the informal other half of economic activity, the world of self-sufficiency and barter of goods and services within a very small radius." The third zone C) is placed above, and even more invisible than the below, and directed by "certain groups of privileged actors' who "could manipulate exchange to their advantage and disturb the established order. In their desire to do so […] they created anomalies, 'zones of turbulence' and conducted their affairs in a very individual way, [operating] from a distance." (Braudel, 1981:23-25). At the time (15th – 18th century) it included the dealings of foreign exchange, linked to distant trade movement and complicated credit arrangements, was transnational and operated upon principles of monopoly (Braudel, 1981). In the bungalow compounds under investigation material life relates to the composite of formal and non-formal activities (and structures) that govern their everyday.

To access these exclusive knowledges, and to understand the role of the house – and what it is housing in a complex and opaque urban context - as architectural element and equally as planning paradigm, the work has developed a particular approach and proposed an analytical format of undertaking and presenting the empirical research work. It so follows Simone and Pieterse's (2017) call for re-description methodologically, by employing the professional format of red line drawings, in combination with analytical layering. The intention is to 'un-see' the house, to make way for new patterns to visually emerge. 'Un-seeing' the house is to view it as if it did not exist as a pre-classified entity through deconstructing the plot and the compound into its elements – identifying the 'small spaces' (Chattopadhyay, 2022) that make everything work in order to reach a better understanding of its workings as an emerging morphology working through **layers of change**.

The study borrows the principles of Brand and Duffy (1990, 1994) to read transformations in buildings through *shearing layers* to analyse the morphological changes – and illustrate new, evolving patterns in compound lives. The research customizes these author's terms of use, making these particular to the place of investigation. Brand's *shearing layers of change* (Brand, 1994) start from Duffy's premise that 'there is no such thing as a building' (Brand, 1994: 12). His concept looks at structures in terms of building components and their ability to adapt or change across different time spans. The term was originally coined by Duffy (1990) as a form of facility management related to costs and life span, which he separated into shell, services, scenery, and set. Brand extended Duffy's concept into six layers that have different times of change and possibilities of adaptation: site, structure, skin, services, space plan, and stuff (Fig 1).

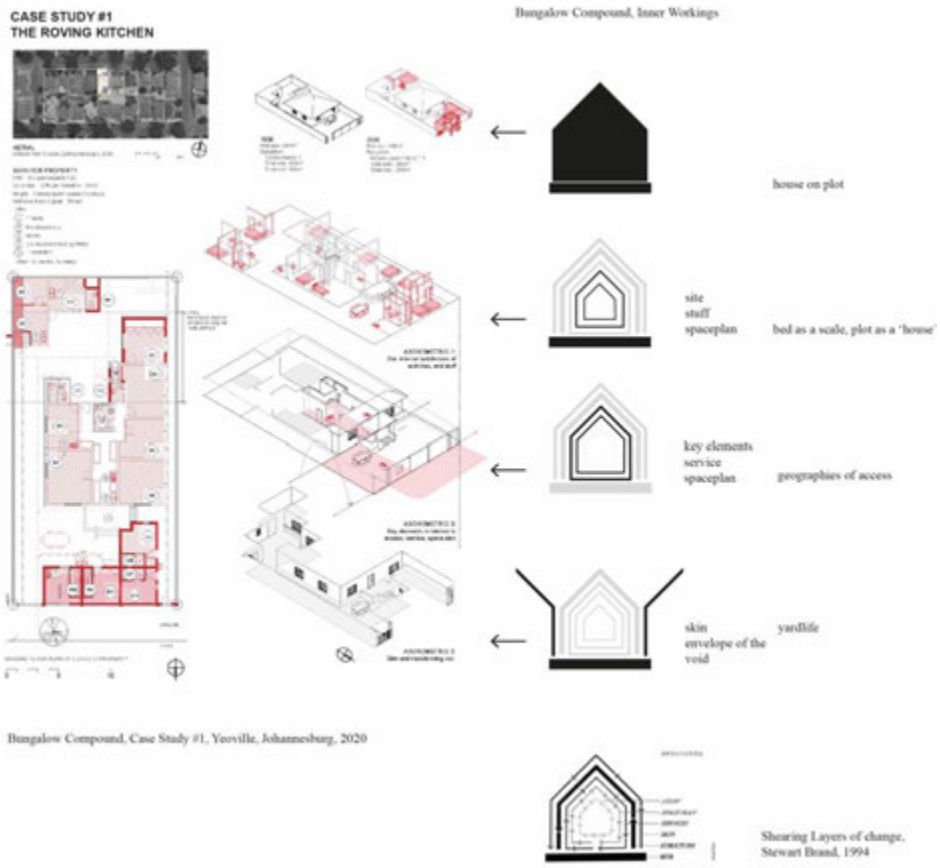

Fig 1: Bungalow compound, analytical layers, appropriated from Brand (1994) (author's own, with S de Villiers 2023)

This study is particularly interested in the role of *site* and *stuff* in the context of the bungalow compound. These two layers seem to have a particular deterministic role in Brand's set-up at each end of the timeline, one being eternal and the other one in constant change or motion. However, due to radical changes in forms of agency that are embedded in both *site* and *stuff* in the Johannesburg samples, they seem to be of high significance for what Duffy calls *use potential* (Duffy, 2009) when applied to the transforming bungalow properties.

The bungalow plot is the unit of analysis taken as the base across an amended version of Brand's shearing layers (Brand, 1994). The "layers" analysis permits the addressing of the gap that "will inevitably occur between developing requirements and the residual long-lasting building shell" (Duffy & Hutton, 2005:40, 1998) – and the "[interesting] absence of fit, that is 'slack'" (Duffy & Hutton, 2005:39, 1998) – as multiple versions of potential and aspiration have been materialised across time.

The empirical part of the study interrogates the material footprint of selected properties across three registers.

- As a **series of spatial patterns** translating social, economic and legal (political) values and related regulations over time.
- As **a transforming building type** with architectural elements transforming in the context and circumstances, reversing an understanding of solid and void/individual and shared spaces.
- As a composite of the above through different **figurings and forms of occupation**, measured in programme, density and infrastructure.

The bungalow compound's changing layout and organisational structure describe the basic shift from the house on the plot to the plot as a compound house and **merge interiority with exteriority,** and the architectural type with urban morphology, by shifting from prescribed functionality to sequences of previously defined elements such as walls, rooms and corridors. The bungalow compound anatomy is then represented in three layers:

- **stuff** on **site**, looking at the **emerging space** plan through domestic practice,
- **services, space plan and key built elements** to interrogate the role of 'small spaces,' and the repurposing of the initial double life of *served* and *serving,*
- **skin** and **boundary wall** as the envelope of **the void,** to explore the form and significance of the emerging void, the courtyard.

The foundation method of the empirical work was initially randomly sampled, that turned purposive on a 'plot by plot' basis[6], unpacking and mirroring the transformation practices of the bungalow properties themselves. This method mimics a practice of city-making termed "plotting urbanism" (Karaman *et al*., 2020), which describes a process of urban development that works incrementally, from property to property, in rapidly urbanising cities in the Global South and beyond. The concept permits us to deal with overlapping forms of formal and non-formal urban growth through repeated and similar incremental building activities on private properties in low-income, highly dynamic neighbourhoods, such as in this study. The above authors use this term to describe how forms of ownership vary, how preferred typologies are linked to the commodification of existing houses, how change is a response to the speculative land market (supply on demand) plus landlords, and how tenants often have social relationships that are governed by physical proximity (Karaman *et al*., 2020).

The Making of the Catalogue, Comparing Unfinished Objects

In order to be able to illustrate the selected bungalow compounds as exploratory 'samples' in a systematic way, on the plot, as part of a block, and along a street in one of the neighbourhoods under investigation, the initial medium that allowed the bungalow's enourmous reach and multiplication – the pattern book – is revisited as a trope to develop an alternative (research) catalogue of properties. A layout template was developed, to capture relevant and available information – as much as the lack thereof (reminding the reader that "lack of" is important as discussed previously). Within its comparative set up, the catalogue of the case study properties is as organic as the changing layout of each plot, and the information collected is as temporary as it differs from sample to sample. While the analysis shows that there are clear patterns in the original layouts, appearances, and materialities – as much as there are in the amendments made over time – it also shows inconsistent, incomplete, and (at the time of thesis submission), already partly outdated data, at least in parts. The study takes

[6] The bungalow compounds were investigated on site from 2018 to 2020.

advantage of this condition and interprets the incongruence of forms and figures as layouts of *aspiration*. The research refers to those as *plot holes.* In fiction, a plot **hole** or plot error is a gap or inconsistency in a storyline that goes against the flow of logic established by the **story's** plot. Such inconsistencies include things as illogical, unlikely or impossible events and statements or events that contradict earlier events in the storyline (Dormann *et al*., 2020). In real life, such narratives challenge our assumptions. This is because in any situation, although we might not understand what happened – yet it did happen – this probably made sense to someone for some reason.

The *plot holes,* figuratively speaking, consequently place the outcome of research on the spectrum between the **forensic** and the **imaginary**. The work thus proposes consideration of potential intersections of the forensic and the imaginary as readings of, at times, diverging and shifting **aspirations** (Appadurai, 1986; Appadurai, 2003; Appadurai,2004). Aspiration looks at the properties as commodities with social lives whose multiple value is determined "by a judgement made about them by subjects" (Appadurai, 1986:3). This means personal interests in the compounds determine their transformation – and their divergent futures. Aspiration is also considered an ability to do something or take action regarding something and relates to the context required to enable these actions. Common aspirations, or re-occurring plot holes, may indicate a trend that is relevant for future urban development, and currently overlooked in the larger narrative.

While the bungalow compounds have been investigated on a case-by-case basis, the research is further interested in what the properties do as a collection. The study considers the sum of what happened in any individual bungalow compound as a basis for the configuration of emerging typicalities as a developing urban register. 'Typicality' (as opposed to typology) encompasses experiences and local practices that are linked to a particular – typical – spatial configuration that hold morphological connotations (Dovey & King, 2011). Following the most common distinctions in typological classifications that have been based on use (programme) and/ or morphology (layout) of the architectural object (Forty, 2000), the *compound typicalities* are based on what happens on **and** with the properties, e.g. as mixed use places of accommodation and business, as neighbourhood networks, as investments on the property market, as infrastructural objects.

They are thus approached as performative and relational forms of temporary categorisation, in a spatial and regulative context. The following section is a transition between methods and findings, or maybe in itself a comment on the finding of methods in contexts under development, in order to outline the emerging typicalities and their various scales, It begins with an assessment of multiple interests, that have resulted in infinite variations of transformation, to conclude with the need to reconfigure existing categories when dealing with cultures of conversion.

Emerging Typicalities: Compound Interests: Multiplying value

Compound interest is commonly understood as a form of long-term (slow) yet exponentially growing financial investment, where interest gathers interest in addition to the principal capital. It describes a multiplication of the principal investment through the accumulation of interest as a most effective principle of exponentially added value to capital.

Architecture, as a practice that designs space to accommodate people and their everyday activities, can frame forms of life and determine values of space, people and their interests as manifested in daily practices – through layout, materialities, sizing, and access to views, and light, services among other things. Like property or real estate, it is also an investment that can gain or lose value over time (see Fig.18 for the transactional history of the case studies). As real estate, property is generally considered an investment with slow but steady returns and low volatility, according to a popular online platform (The Investopedia Team *et al*., 2022), at least in areas of relative political stability.

This study draws an (admittedly blunt) parallel here to the compounding of architectural interests and attempts to translate the principles of financial investment (monetary compound interest) in the context of small-scale owners/landlords of bungalow compounds in the selected focus areas in Johannesburg. While compound interest is a calculable relationship between time and money, the study of existing bungalow plots as DIY development adds 'space' as the third critical factor in the perpetual negotiation of property value – with intended profit figures being often pushed upwards through the highest feasible density at the lowest cost in the shortest turnaround.

To achieve this, the post-1994 bungalow landlords of Yeoville and Rosettenville are compounding the capital output of their properties through **subdivision** (of space) and **multiplication** (of people and use): broadly speaking, the transformation of the one-family house into multiple households organized in rooms, additions of rooms along the boundary walls, the absorption of supplementary programmes, and the **activation of the yard** as productive void, in between space and **outdoor rooms.**
Compounding here is thus also used to mean 'adding to' increasing of' as well as the process of combining more than two different elements. The added value thus could commonly be understood as the accommodation of additional uses and increased densities resulting in more rental income and more relatively affordable places to stay in prime urban locations. Compounded interest, however, also included the need to absorb vehicles, keep up maintenance of the street and its sidewalk, and expand infrastructure and services such as water, electricity and waste removal at the most basic. The growth and value of the single property can be influenced by – as much as it is a contribution to – the neighbourhood's overall condition, its accessibility, cleanliness, safety and security. The plot compounding process is such an urban-level project.

The analogies of compound interests suggested here in the bungalow context are plural and complex, as they are operating with different measures, and this study follows the intersection of the juridical, economic, and ethical as extracted knowledge layers of the physical blueprint. If the traditional economic understanding of compound interest lies in the multiplication of financial value, the bungalow compounds are dealing with division as another form of multiplication, through a number of measures: use, households, income, space per person, forms of business, as well as practices of sharing – resources, relations, space. Plans for contemporary forms of life appear inconsistent in different degrees and configurations. Yet it convinces (some) through its persistent and resistant performance via the organic transformation from the free-standing, single-family house to a rooming courtyard arrangement: that is, urban compounding.

The sum of the single property descriptions presented through the fieldwork is a provisional catalogue of realities, as much as a collection of temporary possibilities. The implicit uncertainty of this phrasing is considered appropriate here as a retainable (urban) quality,

referring back to Lury's notion of incompleteness (2021) and the process of re-description (Simone, Pieterse, 2017). The 'as built' representations are analyses of the spatial configurations of people's everyday lives in an African metropolis, layering visuals that are the product of complex economic transactions, cultural practices, legalities, political 'plotting' and imaginaries. They **reveal** the multiple pieces of knowledge (or parts thereof) that are embedded in the ongoing transformation of bungalow properties. Their visual reconstruction is based on the finding of material 'things' in particular arrangements on each plot. In the attempt to account for their meaning and purpose in context, these relations are illustrated through compound anatomies across three sets of appropriated *shearing layers*. The fieldwork sample illustrations are complemented by single plot descriptions that portray their 'behaviour' in detail through the lens of legalities, forms of aspiration and values, and evolving geometries.

These self-centred objects have extended themselves to the property's boundary line as a network of layers and, ultimately, a system of spaces, integrating (or confronting) lived experience and local practice with institutional/regulatory frameworks. While the 'Victorian' life of other days is still shining through cracks in remaining pressed ceilings and air bricks, the current versions of the bungalow properties share more qualities with the complex compound composites of Ghana and Nigeria than with their original lookalikes in Carshalton, Surrey (Philips, 1926:60). In general, Johannesburg's 'verandah house' (Hindson, 1987) has blended with its yard and its extensions into an ever more "unsettling hybrid structure" (Chakravartty & Ferreira, 2012) – or rather, many variations of these, including doubtless imports for the wider African region.The subsequent section looks at **different aspects of compounding** of the series of case studies and goes on to conclude with a summary of tendencies as overall findings. One case study #1 is subsequently presented as an illustration of the detailed catalogue.

Before and After Physic
'Before and after' illustrations have been used to merge information from council plans and current satellite imagery, both sourced from the CoJ as hard copies and online, on site recordings, as well as information from other publicly available information visible in computer programmes such as Google Earth, Google Maps and Apple Maps. Overall, these drawings show a significant increase in coverage of built form with a 'before' ratio of circa 1:2 (built : unbuilt) as a common proportion on a 495 plot, but the 'after' ratio averages approximately as 1:1 (built : unbuilt) and is, in some cases, more often a relation of 3:2 (built : unbuilt).

Compounding Density, Rooms and People
The density calculations of the bungalow compounds propose to use the single room as a dwelling unit, whether inside or outside the original house. This proposition is based on the recordings of everyday practices across the case studies and the areas under investigation at large. The average number of dwelling unit rooms on the properties lies around 11 to 12, with slightly more of these within the house – a constant of six. The calculation of the amount of people per property is based on a usual standard of two, sometimes three people, per room across the sample. It is also the usual occupancy per room that was found on adverts, repeated in verbal rental, or booking agreements, and supported by real life documentation on site.
As a relative measure, space (floor area) is often set in relation to occupation (demographic / number of people), with varying cultural and geographic understandings of what constitutes a dense urban area (Jenkins & Mottelson, 2020).

A key measure, internationally, is also the house or dwelling unit and its occupants – sometimes defined as households. The bungalow compound negotiates density measurements around a spectrum of variables with one constant: the built structure in the centre of the property, numerous rooms inside and additional rooms outside. In the current bungalow compound context, little is established about how to measure or even define what is a 'household'. Numerous non-typical household compositions have been recorded across the single case study series in Yeoville and Rosettenville, as is often the case in African urban areas (Jenkins, 2013). In average this is an increase of population per plot of 400 to 500% in relation to the original planning. While this sounds like a drastic change - which it indeed is – one must not forget that the inner city suburbs under investigation were kept at an extremely low density as white middle class residential areas, compared to international urban standards.

Compounding Programme

The activities on the case study properties are multiple and mostly mixed. All but two properties have a dominant residential component, that is either short– or long-term rental, or the owner and/or their household resides on the property (or a mixture thereof). The other two non-residential properties offer parallel services only, both educational, to children and women. One property is also a place of (commercially oriented) worship. Overall, only 8% of the properties are solely used as they started off – as a private residence for one family. More importantly, approximately 90% of the properties are income generating, in one way or another, and most rent out rooms on the property for that purpose, and these cover from 10-100% of the available usable built space. However, approximately 50% of the case studies offer additional programmes in addition to any form of dwelling and accommodation.
This change and variety in programme alerts to the biggest change in the properties being an economic one: the **switch** from what can more easily be described as **owner use value to owner exchange value**. In the large majority (92%) of the case studies the purchase serves **income (rental) generation in the everyday use,** as opposed to its original purpose as a **family home**. All the while, nearly all (94%) of the 'exchange value' properties still offer the use value of a home to residents (albeit more and usually unrelated tenants). In one-third of the cases, the owners share the property with tenants who run businesses or live on the premises. However, two-thirds of these properties are purely income generating by offering residential accommodation of different sorts – and other options to conduct business.
Financial profit as a driver for ownership of these transformed bungalow/urban compounds moves one part of the compounded aspirations into the field of **transactions**. It feeds into the basic unit of 'rooms as (urban) currency,'[7] from a commercial, or monetary, and a socio-cultural[8] perspective.

Compounding Scales

Stuff and Internal Subdivisions : The most common objects that move in and out of the bungalow plots are **beds**, double and queen size, to accommodate more than one person if needed. They dominate the internal layout of the properties and are a vital possession of the tenants. They are also the main income generation measure of the landlords, when number of beds equals number of rentable rooms. While bed spaces change at times rather fast, with moving tenants, they are then replaced with copies of the same, hence, somehow constant.

Key elements: The key elements of the bungalow compound form part of a "**geography of small spaces**" (Chattopadhyay, 2022) that participated in the production of the "colour line"

[7] Currency being understood as a standardized medium of exchange that indicates (monetary) value.
[8] David Graeber speaks of forms of 'social currency' and 'human economy' at the intersection of exchanging material goods, services and transforming social relationships (Graeber, 2012).

(Chattopadhyay, 2022) with **political and cultural connotations** beyond served and serving spaces concerning people, across all the scales of plot, block, and city. This role of material parts (the verandah, the stoep, the corridor, the boundary wall) and infrastructural components (the stove and the water tap) has been included in the fieldwork and analysis from a contextual methodological and typological perspective. The drawn analysis has looked at such elements in relation to access, services, and space plan. The resulting figures are complex and, nearly in every case, highly individual, overlaid by information of socio-cultural and economic practices on the plot.

- The **verandah** as part of the entrance sequence has been **closed,** in full or partially, in one-third of the case studies. This happened mostly before 1990 and was often linked to the extension of the room bordering it or making space for a garage, for example.
- The **corridor** has remained unchanged on most properties and is the element that permits the **subdivision** of the house into rooms as single units. It is the **lifeline for internal adaptations**, and at the same time, provides **room for flexibility**, that is, the set-up of different physical arrangements (Rabeneck, et al., 1974; Schneider & Till, 2005). The circulation space is centrally positioned (Fig. 29) and slightly larger in size to allow for a smooth transition to an **internal service spine** or a series of bathrooms and kitchens. This setup also enables the rooms of the freestanding single-family house to become independent entities as units that can be accessed from the outside.
- The **boundary wall** has been undergoing the biggest transformation over time, as visualised in the 'before and after' drawings, and places itelsef at the intersection of planniong, urban design and architecture. From a simple demarcation of land as 'one's own,' as requested per original deeds, and providing some privacy, it has extended in height and depth. It is now a three-dimensional structure with different thicknesses that are in parts inhabited or activated with other programmed activities. The extruded boundary wall turns into the compound version of double (sided) skin has two outsides, and deals through a public service programme (like an eatery) with the sidewalk and also the internal courtyard.

Forms of Flexibility and Adaptability: New Typicalities, Complex Structures

The study suggests that the empirical findings, as a catalogue of possibilities, hold relevant concepts of development in the making. As 'life after on (or in) what was before' they deal with appropriation and adaptation as knowledge from the ground, imaginaries tested in the everyday – that in turn might be worthy of being appropriated in the architecture of future planning and urban accommodation, in these areas or similar applicable contexts.

What has been introduced in this study as forms of flexibility and adaptability that exceed the house as an 'object' and transcend the old social-spatial hierarchies on the plot to create alternative ways of arranging and sharing spaces. This profiles the bungalow compounds as architectures that "compounded" challenge the city in terms of its restructuring. The properties' operations are addressing new forms of production and institutional orders through modes of cultural and physical appropriation and often share wider economic interests. The question of type enters the realm of urban morphology, as a developmental strategy on private properties that is only very partially orchestrated by the public sector.

The analytical drawings recorded transformation from inside out beginning with *"stuff on site makes space plan."* The findings suggest that the *site* can behave as ephemeral as buildings, when the outline of the plot turns into the circumference of the 'house.' At the same time, the

same property line remains inviolate as a legal entity. The convulsion of slow = persistence of site, and fast = change of space plan and arrangement of stuff, collides at the boundary and so changes its nature as a building element, from primarily excluding to potentially accommodating. *Stuff***, on the other hand,** can retain a status of permanence and serve as an evaluating device. While keeping its ability to move, it is simultaneously turned into a constant of the transforming bungalow properties. The bed, as the smallest common denominator, operates as the basic compound scale for measuring room sizes 130, densities, and financial profitability. It is also the valuable possession of every single proprietor and the centrepiece in each room called home.

Dissolving Existing Incongruences: Guiding New Orders

The study started from empirical engagement with the properties studied in context, on a plot-by-plot basis, on a random selection with two defined areas of urban interest. The initially inductive aspect of the research made use of the knowledge embedded in the buildings, the spaces between them, and their transformation. The aim was to understand more about the social, economic and juridical entanglements of 'the house' over time, as accommodation of private lives, and as part of the city. While it has been hard not to notice, the change of the freestanding family home to a multi-unit compound / courtyard arrangement has remained somehow elusive, and unregistered. It seemed important to provide 'proof of life' of their existence 'as built'. As a prerequisite to argue for the legitimacy of the undocumented, and to underline their worthiness, the study developed drawings of the properties with nearly forensic detail, and analytical layers to represent the emerging typological change. As the subsequent more deductive case studies and their history have shown, these recordings deal, on multiple scales, with complex dynamics of recognition (Povinelli, 2011). The findings have shown that the bungalow compounds now are in a deficit of authorative approval – but potentially raw material as samples of popular production, and 1:1 visualizations of aspirations for an updated version of emerging patterns of urban life. This means, from the perspective of design research, there is empirical evidence of the knowledge embedded in the bungalow transformations as a valid contribution to the discourse around the design of urban accommodation provision and a conceptual understanding of the value of the urban compound as a transforming type – but normative references that could apply in a potential process of implementation are missing. The implications here may be to turn to what Carl calls the "topography of praxis" (Carl, 2011). He describes it as "the structure of involvement with people and things that comprise urban praxis" (Carl, 2011), or typicalities, as embedded within constituencies – the particular culture of a place as the basis for bottom-up guidance as opposed to standard generalizations implemented from 'above.' In the case of the bungalow compounds in Yeoville and Rosettenville (and similar places like these two areas), this could result in taking advantage of the density of ownership and start working plot by plot on guiding the diversity as embedded quality, and the transformation processes as forms of low-cost built environment efficiency- as the basis for maintaining and improving.

Such a "guidance" process would imply some form of technical/legal involvement to manage overall and assist in improving the product, directing the discussion towards a professional vacuum (gap) that has been detected in the study. The involvement of the professionals that usually prepare the making of built structures and sign off on them, responsible for their safe and adequate performance – such as architects and engineers – seem notably absent in the world of transforming bungalows. As are the city regulators and their service providers. The profession as a technical provider and city council as a regulating entity appear to lack the capacity to deal with either the administration of 'life on the ground' in the way both

institutions have been doing it, 'traditionally' – or change the format of engagement from prescriptive to proscriptive (Tipple, 2000).

Unexpected Collaborations

The study of the transformed bungalow in the context of urban densification comes at a time when its existence faces major challenges but also explicit opportunities. In the light of manifestations of both urban management and housing crisis in the inner city (Zack et al., 2010), there is a high demand for affordable accommodation, yet little knowledge about space-sharing practices on private properties (Charlton, 2019). The mere recognition of the 'bungalow compound' as a unit in official documentation could support the understanding of their potential within the urban context. But is this enough? Or how would we get there? What does a process of recognition entail that actually works in practice and not only on paper? We should recall that we are dealing with an "unsettling hybrid structure […] a juridical-economic-moral entity that, as *property*, has material (as asset), political (as dominium), and symbolic (as shelter) value" (Chakravartty & Silva, 2013:2). In the case of the bungalow compound, this is a 'house' that currently works in the shadows – and not too badly for the many involved in its manoeuvres.

In coming close to an ending, the question that hovers over this work – as in the life of 'the house' – is: what needs to be done? The research has identified what has been termed compound *doings* as the main drivers for compound operations. As some sort of hypothetical question turning recommendation, what about considering the compound *doings* not solely as drivers for **wha**t happens within the transformation of the properties but equally as ways to deal with these in a more appropriate, supportive way – from a professional, from an institutional, and from a knowledge perspective. This thesis potentially leads to some form of "knowledge transfer" – from the bungalow/compounds and their actors – to the professionals, regulators, financiers, and urban modellers. This could then, in turn, modify the action of these so-called "higher order" entities engaging with the emerging and positive values identified, while mitigating the negative – making all of this more visible.
The curation of knowledges that are embedded in the transforming bungalow compounds addresses the need for the *merging* of disciplines and working in inter-disciplinary or trans-disciplinary ways. Architecture, planning, and urban design are all shifting practices that have not found their role in areas under investigation or similar neighbourhoods. Their active involvement is an exception rather than the norm.

3 Tongji Architectural Design (Group) Co., Ltd, China, zhenyuli@tongji.edu.cn

Biographical note

Ms. Mengying Tang. Doctoral student at Tongji University, majored in Architecture Design and its Theory. Her main research is "Linear Space Design from a Sharing Perspective" leading by her supervisor Prof. Zhenyu Li. She holds a Master of Science degree at Columbia University (2018), majored in Advanced Architectrual Design. She also has a Bachelor's degree in Architecture at Xi'an University of Architecture and Technology (2017). She has been working as an Architect at Sasaki from 2018 to 2022.

Prof. Dr. Zhenyu Li. Deputy Director of Academic Committee, College of Architecture and Urban Planning, Tongji University, Tenured Professor, Doctoral Supervisor. Founder of Atelier sharing Architecture (ASA), Tongji Architectural Design (Group) Co., Ltd, National 1st Class Registered Architect. He is also Member of the Disciplinary Review Team of Architecture, National Committee of Academic Degrees, Member of the Professional Committee of Architectural Design of MOHURD-STC, PRC, and Visiting Professor at TU Berlin. He is Secretary General of the Foreign Exchange Committee of ASC and Charted Member of the RIBA. His research interests are Residential design, Urban design, and Comparison of Chinese and Foreign architecture. He advocates " Architecture for Daily Life & Typological Contribution" and is the first to propose the theoretical framework of "sharing Architecture". He has published more than 10 monographs, including "Introduction to Sharing Architecture", "Flyover, Scanning Cities From the Air " and "Berlin Residence".

Prof.Dr. Zhenyu Li is the Corresponding Author.

Abstract

As urbanization accelerates, addressing the basic walking experience needs of citizens in urban spaces becomes increasingly crucial in urban planning and design. This study focuses on the walking experience during the design of urban spaces, with special attention to the sharing design in linear spaces. The paper focuses on the urban mobility space in Shanghai, China, and employs field research, morphological typology, and ethnographic research to study spatial typologies, and categorises it into five spatial forms and three functional types. The study then proposes five elements and corresponding design strategies for the sharing design of urban linear spaces from the perspective of walking experience, including path networks, spatial interfaces, landscape nodes, sharing spaces and social feedback management. The study hopes to optimise the design of urban linear spaces to make walkable urban spaces, enhancing the walking experience shared by all and promoting the sustainable development of the urban environment.

Keywords: Urban Mobility Space, Linear Space, Walking Experience, Sharing Design, Walkablity

1. Introduction

1.1 Background And Motivation For The Study

1.1.1 Informatisation Development Drives New Demands For Urban Walking Experience

In the context of the information age, urban life and the way of using space are undergoing profound changes. The global connectivity of the Internet, the instantaneous communication of electronic media, the in-depth insights of big data and the accurate predictions of artificial intelligence are technological innovations that have not only changed people's lifestyles, but also redefined the way urban space is used and its social functions. In this process of transformation, people's concept of space use is gradually shifting from the traditional mode of private and exclusive use to a new form of mutual use and sharing.

This shift has further increased the demand for people to experience urban space, driving the sharing development of urban walking. Walking is both a mode of transport and a vehicle for physical activity and social interaction, a fundamental form of behaviour (Garau, Annunziata and Yamu, 2024) . The development of information technology has brought new opportunities for people's walking experience in cities. By using modern information technology such as big data and the Internet of Things, real-time monitoring and data analysis of the walking environment in urban space can be achieved, providing walkers with a more convenient and comfortable walking experience. Functions such as route planning by intelligent navigation systems and information updating by real-time environmental monitoring systems, for example, have optimised people's walking experience in urban spaces and promoted the development of urban linear spaces.

Driven by the wave of information technology, the walking experience in urban spaces is no longer limited to the simple process of walking, but needs to incorporate more sharing elements to meet the growing and diversified needs of people. Cities need to provide sharing public spaces and facilities to

facilitate communication and interaction between different groups, as well as policy support for co-management to maintain the sustainability of sharing spaces. With the dissemination of information and the sharing of resources, not only can people's walking experience in cities become more free and inclusive, but they can also improve the effectiveness and utilisation of space and enrich the urban environment.

1.1.2 The Existence And Development Of Urban Linear Space From Ancient Times To The Present Day

Linear space has its roots in the development of cities since ancient times. The existence of linear space in ancient cities is mainly reflected in buildings and structures such as palaces and city walls. For example, the Palace of Versailles in France and the Forbidden City in China both adopt a rigorous sequential linear layout, presenting a strict order and hierarchy, reflecting the authority of the ruler and the stability of the society, and forming a clear spatial order and visual orientation. This linear spatial layout is based more on the ruler's power and the need for social hierarchy than on the individual's need to move.

However, with the rise of the modernist movement, the concept of the layout of architectural space produced a radical transformation. After modernism, more attention was paid to individual mobility and spatial variability, emphasising the openness and inclusiveness of space. For example, in Corbusier's plan for the city of Algiers, buildings in the city unfolded along with major traffic routes, and the centre of the capital relied on ground transportation such as the automobile to keep expanding, creating the idea of the new modernist city.

And in today's information age, the concept of the sharing economy has reshaped people's understanding and use of space, and people's demand for the walking experience has given new life to linear space in cities. Cities should respect people and urban spaces should serve people (Li, 2020), which is no longer just a symbol of power or a bearer of planning concepts, but is transformed into a dynamic vein connecting people to people, activities to activities, and a new spatial strategy to support diversified uses and social interactions. In this way, linear sharing space has become an indispensable and important element of modern urban space, and its potential to improve the efficiency of space use and promote social interaction is gradually being developed and recognised.

1.1.3 Urbanisation Drives New Uses Of Linear Space

Urbanisation is an important symbol of the development of modern society, which brings about population concentration, industrial concentration and infrastructure improvement. However, as the scale of cities continues to expand, problems such as traffic congestion and environmental pollution are becoming more and more prominent. In this context, how to effectively utilise the limited space in the city, improve the efficiency of its use, improve the quality of life of the people and promote social interaction has become an issue to be considered. At the same time, human scale has not been given the appropriate attention in modernist design, especially in public spaces such as gatherings and pedestrian events (Gehl, 2011) . These issues have fuelled a rethinking of the question of how to make better use of urban public space.

Linear space is the very backbone of urban public space, and public transport and pedestrians are important components of linear urban space. In urban planning, the two important concepts of mobility and walkability of urban space revolve around the notion of providing healthy communities, reducing car dependency and raising awareness of people's health (Ar Romel, 2019) . Urban mobility and walkability are important for the overall image of the city and the quality of life of its citizens. Excellent urban space is not only able to provide citizens with a comfortable and convenient walking environment, but also able to show visitors the characteristics and charms of the city, which is of great research significance.

As the demand for urban renewal increases, linear sharing space can not only regenerate old neighbourhoods and revitalise abandoned sites, but also maintain the continuity of urban culture and local characteristics. At the same time, as an important channel connecting different areas of the city, the organisation of traffic and pedestrian flow in linear space has a significant impact on the operational efficiency and development status of the city. Research on urban linear space not only needs to explore how to optimise the traffic and flow organisation of the space and increase the diversity of functions within the limited space, but also discuss how to promote green travel and ecological diversity to enhance the quality of urban life and ecology. Linear space in the city is no longer a carrier of a single function, but has become a new spatial pattern that is multidimensional, dynamic and able to adapt to the needs of future urbanisation.

1.2 Purpose And Significance Of The Study

Walkability has increasingly been recognised as an important factor for sustainable urban development (Zhang et al., 2019) . This study hopes to analyse the key factors affecting the walking experience by investigating the current situation and problems of walking experience in urban linear space. Through investigating the current situation and problems of walking experience in urban linear space, this study hopes to analyse the key factors affecting walking experience, further explore the spatial elements of urban linear space, and propose design methods that can promote the optimisation and enhancement of urban space, as well as possible future urban travel modes. It will provide theoretical support and practical guidance for urban planning and design, and provide scientific basis and technical support for improving the walking experience in urban linear space.

2 Methodology

2.1 Choose Urban Linear Space In Shanghai As The Research Object

2.1.1 Urbanisation And Spatial Development Characteristics Of Shanghai Municipality

Shanghai is one of the most representative metropolises in China, and its urbanisation process and spatial development have typical characteristics. Since the reform and opening up, Shanghai has experienced a rapid urbanisation process, with an expanding city scale, growing population and increasingly perfect urban functions, which is of great research value and significance in the context of contemporary urbanisation development.

[1] As one of China's national centre cities, Shanghai connects internationally and serves the whole country (Wu et al., 2013) , and is one of the largest metropolitan areas in the world. Since becoming an open commercial port in 1843, Shanghai has grown rapidly to become the largest city in the Far East. The spatial structure of Shanghai includes various types of historical and cultural districts, modern business districts, industrial parks, and dense residential areas, etc. The evolution and interaction of these spaces show the diversity and complexity of the city. At the same time, the urban spatial development of Shanghai is deeply influenced by the two main river axes, the Huangpu River and the Suzhou River, which form a unique ribbon urban form and have a profound impact on urban mobility.

Urbanisation in Shanghai has shifted from monocentric agglomerative development to polycentric and multicore. However, the population distribution and economic activities still maintain a clear monocentric pattern (Zhou and Chen, 2015). The significant agglomeration effect of the central city has led to high density pedestrian activities in the central city. Shanghai has implemented a series of advanced explorations in urban planning and design of the central city, such as "Low Traffic Neighborhoods" and "15-minute Community Living Circles", which provide important practices for sustainable urban development. The city's sustainable development has been recognised as an important practice.

Therefore, this study chooses Shanghai as a typical research object, through in-depth study of its urbanisation process and spatial development characteristics, it can deepen the understanding of China's urbanisation process, explore the impact of urban spatial structure on walking activities, and draw on its practical experience to provide reference for optimising urban spatial layout.

2.1.2 Shanghai Urban Space Design Practices

With the concept of "people's city for the people[1] " deeply rooted in people's minds, Shanghai, an international metropolis, is actively responding to the new urbanisation strategy of the new era, and has put the idea of "people-oriented" into all aspects of urban planning and construction. Especially in the design of urban space, not only focusing on the physical form of the space, but also attaching more importance to the actual impact of space on the lives of citizens, it puts forward the development vision of "buildings can be read, neighbourhoods are suitable for strolling, and the city always has a temperature[2] ", aiming to create a modern city that is suitable for living, working and travelling. On this basis, Shanghai has developed a series of advanced practices in urban space design.

·Creating pedestrian-friendly cities: By adopting a development strategy that prioritises public transport and is friendly to slow-moving traffic, actively building infrastructure such as walking paths and cycling lanes, and optimising the walking environment, such as installing additional resting seats and lighting, the accessibility and comfort of walking in the city has been greatly improved.

[1] During a visit to Shanghai in November 2019, Chinese President Xi Jinping said, "Cities are the people's cities, and the people's cities are for the people."
[2] In May 2017, the report of the 11th Party Congress of Shanghai put forward the need to focus on creating a city of innovation, humanism and ecology, in which it was specifically proposed that "buildings can be read, neighbourhoods are pleasant to walk, and the city always has a temperature".

·Continuity design of urban space: By organically connecting various areas of the city and forming a continuity of urban space, it breaks down the compartmentalisation and restrictions of traditional urban space. On both sides of the Huangpu River and along the Suzhou Creek, Shanghai has built a large number of green spaces, parks and other open spaces, integrating the urban landscape and public space, and providing citizens with more places for leisure, entertainment and interaction.

·Coordinated development of urban transport: Through the establishment of a diversified transport network, basically full coverage of rail stations has been achieved (Shanghai Municipal Bureau of Planning and Natural Resources, 2018), providing citizens with convenient ways of travelling. At the same time, measures to reduce the use of private cars and encourage low-carbon travel through traffic and number restrictions have effectively improved the urban traffic situation and promoted the flow and vitality of urban space.

Through in-depth study of walking experience and urban linear space in Shanghai, it can provide useful reference for the design of walking space and urban planning in other cities.

2.2 Research Methodology

This research proposes to study urban linear sharing spaces and walking experiences using four methods: documentary research, fieldwork, morphological typology, and ethnographic research. These interdisciplinary research methods complement each other and can provide multi-dimensional perspectives and in-depth analyses for the study.

2.2.1 Fieldwork And Literature Research Of Related Cases

As the skeleton of urban public space, urban linear space has always been in the position of being valued in urban construction, and there have been more successful practice cases, which can be used as the case base for related research. This study will collate the relevant literature of Shanghai's excellent urban linear space cases to clarify the development of urban linear space. At the same time, based on the information obtained from the field survey and cross-referenced with the literature, we can analyse the design techniques and strategies in more detail.

2.2.2 Analysing Linear Spatial Types By Morpho-Typological Methods

Morphological typology derives from the concept of biological taxonomy (Zhu, 1992), which refers to the formation of categories according to the common nature and characteristics of things. Architectural typology is an important branch of morphological typology, represented by scholars such as Rossi, which emphasises the concern for urban space and attempts to solve the urban problems brought about by modernism through the study of types.

Architectural typology can be distinguished into two concepts: functional types, which are categorised on the basis of different functions, and formal types, which are categorised on the basis of formal characteristics and involve the study of composition, transformation and grouping forms. Through the

study of building typology, it is possible to gain a deeper understanding of the structure and evolution of urban space, as well as the impact of different types of space on the pedestrian experience.

2.2.3 Ethnographic Research To Study The Experience Of Walking In Linear Spaces

Ethnographic research originated from cultural anthropology, through in-depth field research, observation and interviews with specific groups in order to understand their behavioural patterns, perceptions and experiences. In the Internet era, "cyber ethnographic research" has become an online mode of ethnographic research, which can also be used as an important method to know and understand social and cultural phenomena (Lai, 2020).

When studying urban space, ethnographic research methods interact with pedestrians through field observations, in-depth interviews, questionnaire surveys, etc., to dig deeper into the behavioural motives of walkers, their behavioural patterns, and their perceptions and experiences in urban space, helping to understand how walkers interact with urban space, and how environmental features affect walkers' behaviour and perceptions.

3 Discussion And Results

3.1 Typologies Of Urban Mobility Spaces In Shanghai

Generally speaking, urban space can be analysed by type in terms of both spatial form and internal function. According to the morphological characteristics of the space, the flow space in the city can be classified into four types, horizontally into point, linear and network types, and vertically into a type of flow space. This study focuses on the morphological features and functional characteristics of linear spaces, as well as the role that sharing spaces play for the experience and feelings of people walking in them.

3.1.1 Classification Of Space Types

·Pointed mobility spaces: Transport hubs or transport nodes in cities, such as airports, railway stations, metro stations, bus stops, etc., are point mobility spaces. These spaces have a concentrated traffic flow and a high degree of crowd congregation, so they need to be designed and planned with efficient, safe and comfortable transport facilities and services. There are two types of points: single-point, which is a relatively single and concentrated transport hub, and scattered-point, which is distributed in different parts of the city or in localised areas.

·Linear mobility space: roads, streets, motorways and other traffic corridors in the city undertake the transport functions of vehicles, pedestrians and bicycles, etc. This urban space form is linear and needs to consider problems such as congestion and safety, as well as the living needs of the surrounding residents. According to the distribution of traffic space on both sides of the linear space, the linear flow space can be divided into three types: single-line type, fishbone type and semi-fishbone type.

The single-line type is a main passage space that cannot be penetrated through both sides. Commonly found in the interior of linear buildings, such as the Swatch headquarters building, there is only a single entrance and exit, and there is no other way to pass through both sides of the building. Fishbone refers to a traffic axis consisting of a main arterial road and side roads perpendicular to it on both sides, similar to the structure of a fishbone. This spatial type is common in cities and consists of the main urban arterial road and the roads on both sides. Semi-fishbone is a variant of fishbone, where one side of the main traffic space is impassable and the other side is distributed with branch roads. Commonly found in riverfront and riverside public spaces, the side that backs up to the waterfront extends towards the interior of the city, creating a space guided perpendicular to the waterfront.

·Networked mobility space: The transport network in the city is a networked mobility space, which connects point and line mobility spaces and provides diversified travelling paths and choices for people. Its design and planning need to consider the distribution of traffic flow, intersection design, pedestrian safety and other factors to ensure the smooth operation of the transport system and the interconnection of urban space. Among them, there is the trunk type which takes the main road as the centre and radially extends the branch roads to form a network-like layout form. When there is no clear main road in a certain area, but a traffic network composed of many interconnected roads, it is a network flow space without trunk.

·Vertical mobility space: This mainly refers to three-dimensional transport systems in cities, such as underground subways, viaducts and pedestrian footbridges, which are often used as supplements to the urban transport system and can make effective use of air and underground space, alleviate the pressure of ground-level traffic, and improve the efficiency of traffic and the utilisation of urban space. Such design and planning need to take into account factors such as land use, environmental protection and traffic safety to ensure their coordinated and integrated development with the surrounding environment.

3.1.2 Classification Of Functional Types

Urban mobility space is an area in the city for people's mobility, transport and activities, and the classification of its functions is crucial to urban planning, design and management. According to the main functions of urban mobility spaces, they are classified into the following three categories: streets and pavements, waterfront corridors, and greenways and parks.

·Streets and pavements: Streets, the most basic public goods in the city, are the most closely related public activity places for urban residents (Shanghai Urban Planning and Land Resources Administration, Shanghai Municipal Transportation Commission, Shanghai Urban Planning Design Research Institute, 2016). Streets, as the main traffic corridors in the city, carry the dual functions of pedestrian and vehicular traffic. Some streets will adopt a time-sharing approach, closing the entrances and exits to vehicular traffic on weekends or holidays, so as to allow the public to hold pedestrian activities such as street fairs. Pavements, as an integral part of the street, primarily serve pedestrians by providing a safe and comfortable walking environment. Sidewalks often share areas with storefronts on both sides of the street, providing both usable space for pedestrians and foot traffic for shops. Commercial neighbourhoods and bazaars in cities are also a type of space where people walk to experience urban public space.

· Waterfront corridors: Linear open spaces built along rivers, lakes, oceans and other waters in cities are waterfront corridors. They are close to the water and have unique natural landscape and ecological environment. Not only do they provide an excellent view of the water, but they are also a good place for public leisure, recreation and exercise. Waterfront corridors often host cultural exchange activities to promote the sharing of the waterfront by all people. The design of waterfront corridors usually focuses on coordination with the surrounding environment, emphasising ecology and sustainability; at the same time, water-friendly nodes will be considered in localised areas to provide pedestrians with an interactive experience with the water.

·Blueways and parks: Blueways are linear pathways connecting urban green spaces, parks and other open spaces, and are mainly composed of walking paths, cycling paths and so on. The park space in the city is also an important place for citizens to relax, have fun and socialise, equipped with a variety of facilities to provide walkers with a comfortable and safe walking experience. Together, blueways and parks form the city's green network and carry the city's historical and cultural memories, providing citizens with opportunities to get close to nature and enjoy outdoor life.

3.2 Current Situation And Analysis Of Walking Experience In Urban Linear Spaces In Shanghai

Through the ethnographic research method mentioned in section 2.2 and the research method of landscape anthropology, the authors visited a number of linear flow spaces in the centre of Shanghai and investigated pedestrians' experience of walking in linear flow spaces in Shanghai by means of a questionnaire. The questionnaires were used to understand people's ratings of how they felt about walking in Shanghai, as well as the strengths and weaknesses of the urban spaces they experienced while walking, and their suggestions.

Comprehensive survey results show that the majority of respondents have a high opinion of the walking experience in Shanghai, especially with regard to the spaciousness of the walking paths and the greenery. The survey results show that the majority of respondents walk for 1-5 hours per week, and that the urban linear spaces where they often walk are mainly the streets around the neighbourhoods where they live, as well as the neighbourhood parks and small-scale green spaces. Respondents rated the safety, convenience and ambience of walking in Shanghai highly, with an average score of 7.9/10. Key strengths of walkable urban spaces in Shanghai include spacious and level walking paths, abundant green vegetation, and safe neighbourhoods; however, there are also weaknesses, including crowded walking paths in some areas, and a lack of shade and shelter at times. The survey found that 76 per cent of people thought that urban walking facilities were adequate, while a small number of people suggested that urban planning and design departments should strengthen the maintenance and management of walking paths, increase the area covered by greenery, and arrange more safety measures to enhance the quality of the walking experience. These findings provide useful references for urban planning and design.

3.3 Design Elements And Methods For Urban Sharing Linear Spaces

As an important part of urban planning and design, urban linear space not only carries the operation and expansion of urban functions, but also is an indispensable part of people's daily life. The acceleration of urbanisation and the change of people's lifestyles in the context of information technology have put forward higher requirements for the design of urban linear space. Referring to Kevin Lynch's five images of urban space classification (Lynch, 2002), the elements of urban linear space sharing design are divided into four elements: path network, spatial interface, landscape node, and sharing space, and also focus on social feedback and management mechanism, and design urban linear space from both physical space and spiritual space.

3.3.1 Establishment Of Path Network Connectivity

In the design of urban linear space, the connectivity of the path network is the most basic and core, which directly affects the accessibility and experience of the walkers. In the design, it is necessary to focus on the continuity and convenience of the paths, and at the same time consider the safety and comfort of the walkers.

Paths in linear space first need to ensure their accessibility, rationally plan the path network, reduce unnecessary detours and congestion, and ensure that walkers can reach their destinations efficiently and quickly. Traffic nodes, such as intersections, roundabouts, and stagecoaches, should also be reasonably set up to ensure smooth connections between paths.

When establishing a path network, multi-level path planning and node settings are required to meet the needs of different groups. For example, the Nanjing Road Pedestrian Street in Shanghai has multiple paths along both sides of the main pedestrian road, which enhances the circulation of the whole area; at the same time, the Golden Line[3] is taken as the core of the design, and multiple traffic nodes are set up to limit the dynamic and static activity areas (Zheng, Qi and Wang, 2000), which are closely connected with the surrounding commercial and cultural facilities, realising the integration of historical features and modern functions. It is also closely connected with the surrounding commercial and cultural facilities, realising the integration of historical features and modern functions.

3.3.2 Ambiguity And Transparency Of Spatial Interfaces

The spatial interface of urban linear space should be ambiguous and transparent, taking into account the openness and interactivity of the space by softening the boundaries and integrating the functions, so as to enhance the visual perception and emotional experience of the walkers, and effectively improve the quality and attractiveness of the space.

The technique of interface blurring increases the inclusiveness and openness of the space by creating a private but not closed space that interpenetrates the internal and external space. For example, Changli Garden reconstructs the community wall so that it is replaced by a fuzzy space with garden interest, expands the street space, loads the walking path, and creates a place-based linear garden (Tong and Ren, 2020).

The street interface on both sides of the pedestrian area should appropriately adopt transparent interface design to increase the sense of openness and attractiveness of the space. For example, the design of shops on the pedestrian street of Huaihai Zhong Road mostly adopts open facades and glass curtain walls, so that pedestrians can clearly see the interior of the shops and at the same time feel the vitality and prosperity of the street outside.

3.3.3 Increase Continuous Landscape Nodes for Guidance

Landscape nodes play an important guiding role in urban linear space, attracting pedestrians' attention and enriching the walking experience. Reasonable installation of landscape nodes, such as sculptures, fountains, gardens, etc., so as to form a coherent whole, can increase the walking pleasure. For example, the Sculpture Park in Jing'an District, Shanghai, has become one of the favourite parks for young people in Shanghai by taking sculpture display as its theme and interpenetrating greenery with sculpture vignettes[4] .

Through landscape design techniques, such as plant configuration, terrain changes, and repetitive elements, it is possible to link landscape nodes so that pedestrians are feeling the flow and change of space. The Xuhui Runway Park in Shanghai continues the cultural elements of the original site,

Longhua Airport, and guides pedestrians to fully experience the 1,830-metre-long linear park through subtle design details such as the undulation of the ground and the continuous water system[5] .

3.3.4 Creation And Design Of Sharing Spaces

The 2016 UN Habitat III Conference proposed a vision of cities for all, arguing that future cities should seek to promote inclusiveness and ensure equal access to and enjoyment of the city by all residents[6] . It can be seen that sharing space is an important part of the linear space in contemporary cities, which can promote communication and interaction between cities and citizens, and achieve a balanced use of social resources.

At the intersection of urban public street space and private space such as merchants and residential areas, part of the private space can be opened up to the outside, gaining vitality and richness while yielding space. For example, Xintiandi merchants mostly use open-air café seating, or borrow plazas, or set back their storefronts, attracting a large number of citizens and tourists to experience the neighbourhood, which is full of life.

Various activities at different times, such as cultural exhibitions, performances, bazaars, etc., can be set up in the urban linear space to attract the participation of different groups and enrich the vitality of the space at all times. For example, the Daxue Road in Shanghai organises various cultural activities and bazaars from time to time during weekends and festivals, attracting a large number of people to participate in the experience and share the street at different times.

3.3.5 Social Feedback Mechanisms And Management Policies

As urban linear spaces need to be fully engaged and experienced, it is crucial to establish effective social interaction and feedback mechanisms. By collecting and analysing feedback from walkers, we can continuously optimise design solutions, manage the way space is used and improve the quality of the walking experience.

In areas where crowd activities are more concentrated and the number of residents in the surrounding community is large, the whole process of designing a linear space requires timely information feedback. Facilities such as bulletin boards and information boards can be set up, or a platform for communication and feedback can be provided through community meetings and questionnaire surveys, etc. At the same time, a sound management mechanism needs to be set up, including personnel management and maintenance of facilities in order to safeguard the normal operation and order of the urban space. In the design of Parkview Park, the surrounding residents will participate in the process of design and implementation, guided by professional designers who will design, update and maintain the settlement space. This will not only gain residents' recognition, but also motivate them to take the initiative to maintain and self-manage the public space (Liu and Liang, 2022).

3.4 Challenges And Prospects For The Design Of Urban Linear Sharing Spaces

3.4.1 Facing Challenges

Although Shanghai has achieved a number of success stories in the design of urban linear spaces, there are still some problems and challenges. These include the disconnection of some spaces with poor accessibility; the lack of integration of the surrounding environment; and the lack of safety facilities.

The problem of spatial disconnection sometimes arises due to historical reasons or poor planning. For example, the Suhe Half Horse Park in Putuo District has a riverfront walkway truncated by the Zhenguang Road cut-through, resulting in walkers needing to take a diversion around the footbridge to reach the other side of the road. This situation reduces spatial accessibility and requires the planning of new walkways or footbridges to improve the situation. Certain areas also suffer from environmental incongruity. For example, Shaanxi North Road, as a historical and cultural neighbourhood, the architectural style and commercial environment of some of the shops do not match the overall ambience of the street, which can cause some nuisance and discomfort to walkers. Effective urban design is needed to improve environmental integrity and enhance the walking experience. The lack of safety facilities should not be ignored. In the Suzhou River section of the East China University of

Political Science and Law, part of the section is still under construction, with insufficient lighting at night and broken roads, which increases the safety risk for walkers. The construction and management of safety facilities need to be strengthened to enhance the safety of the walking area.

Taken together, solving these problems requires the joint efforts of the government, planning designers and citizens to continuously improve the quality and experience of urban linear space in Shanghai through rational planning and scientific design.

3.4.2 Future Prospects

With the development of information technology, the construction of urban mobility space will gradually shift: from a focus on motor vehicle traffic to a comprehensive focus on human communication and lifestyles; from the control of road red lines to the control of street space; and from an emphasis on transport functions to the promotion of urban neighbourhood development. Based on this shift, the construction and renovation of streets will be mainly in the areas of integration and assistance.

Integration mainly lies in the integration of transport modes and road facilities. It is possible to articulate different modes of transport through the integration of travel modes, enhance sharing travel services, and increase cooperation with public transport agencies in order to complement the existing transport infrastructure, improve the overall travel choices of the public, and leave safer passageways for walking spaces. In terms of integration of facilities, intensive transformation of street space, intelligent transformation of existing facilities, unified transformation of service facilities such as bus stops, newspaper kiosks and telephone booths, and consolidation of fragmented street facilities such as nymphomaniacs, chairs, street signs and rubbish bins, to create an efficient and smooth traffic space.

Secondly, the goal of sharing mobility in the future also lies in travel assistance. Traffic signals, street lights, traffic monitoring systems and other regulatory systems using intelligent management transformation, such as improving the level of intelligent traffic signals, to provide time-sensitive public transport information release, by the sharing bicycle rental points to provide information on the surrounding rental points and reservation services. It should also enhance the information interaction of public service level, add intelligent monitoring that focuses on maintaining urban safety and focusing on the needs of the disadvantaged, strengthen the environmental management that detects the street environment and reduces energy consumption, and establish a safe and smooth mobility space (Shanghai Urban Planning and Land Resources Administration, Shanghai Municipal Transportation Commission, Shanghai Urban Planning Design Research Institute, 2016) .

Overall, the future of sharing mobility is expected to be characterised by innovation, collaboration and sustainability in an effort to address the current challenges facing urban mobility spaces and to create a more ACCESSIBLE, WALKABLE and SUSTAINABLE transport system for citizens.

4. Summary

Walking is a major type of transport for people to experience urban space and one of the basic human activities. Walking experience in urban linear space requires both physical space and spiritual feeling levels. This study reveals the centrality of walking experience in the design of urban spaces, with particular attention to the sharing experience in linear spaces, and explores the design elements of linear sharing spaces and their impact on walking experience. The study analyses the effectiveness and shortcomings of urban linear space design in Shanghai, and proposes corresponding strategies and suggestions, with a view to providing insights into urban planning and design.

The study firstly elaborates that, driven by the development of information technology, people's demand for walking experience in urban space has increased both qualitatively and quantitatively. Linear space has been the most important component of urban space since ancient times, and as the main spatial form for people to experience walking in the city, it is an important spatial carrier for the study of walking experience. The process of urbanisation has promoted the development of urban linear space, and at the same time generated new possibilities to create a mobile spatial experience for citizens and the city simultaneously.

The study selects the urban linear space in Shanghai, China, as the research object, and on the basis of the field survey and literature research on international excellent urban linear space cases, analyses the types of linear space with morphological typology methods, and investigates people's walking experience and usage feelings in linear space with ethnographic research and landscape anthropology methods, so as to better understand the current situation of the walking experience in urban linear space and problems.

The study classifies the spatial types of urban linear space into four types: point, line, network and vertical, among which linear space is subdivided into three categories; meanwhile, according to the type of internal function of the space, urban linear space can be classified into three categories: street, greenway and waterfront public space. Analysing the characteristics of different space types helps to systematically organise and classify urban linear spaces, and then design and use them in a targeted way. Combined with the perception and experience of pedestrians of Shanghai's linear space in the research report, the study proposes five elements and corresponding design strategies for the sharing design of urban linear space, i.e., establishing path network connectivity, focusing on the transparency and richness of spatial interfaces, increasing the continuity of the landscape nodes to guide the process, paying attention to the establishment of and interaction with the sharing space, as well as strengthening the social feedback mechanism and management, in order to solve the problems and challenges in the design of urban linear space. The problems and challenges in the design of urban linear space are solved.

It can be seen from the study that Shanghai has achieved remarkable results in terms of walking experience in urban linear sharing spaces. However, the city still faces problems such as spatial disconnection and lack of accessibility, lack of environmental integration, and lack of safety facilities. To address these problems, this thesis proposes strategies and recommendations to further optimise the design of urban linear spaces and enhance the walking experience for all. These strategies and recommendations not only guide the urban planning and design of Shanghai, but also provide important insights into the spatial design and enhancement of the walking experience in other cities.

The conception of "axes" in São Paulo, Brasil: a mixture of travelling of managers and ideas, new urban plan methods, in an incomplete incorporation of Transit Oriented Developments (TOD) agenda

Author's Name: Deiny Façanha Costa and Paula Freire Santoro
Affiliation: FAU USP
Email: deinyfcosta@usp.br and paulasantoro@usp.br

Abstract (up to 125 words)
This article focuses on the relationship between urban planning and mobility present in the "axes" of the 2014 São Paulo Strategic Master Plan, which became zones in 2016, understanding the conceptual and theoretical origin of the idea that proposed densifying where there is public transport infrastructure. The initial hypothesis was that the inspiration for the axes came from the concept of Transport Oriented Development (TOD), but a bibliometric analysis of scientific articles and manuals, and interviews with the urban planners responsible for regulation, denied this. Urban regulation in previous decades oscillated between zones and urban design, and the axes ended up incorporating an incomplete TOD agenda without improving active mobility or the climate change agenda.
Keywords: transit oriented development; urban planning; urban design; zoning

Introduction

In the year of 2013, the city of São Paulo in Brazil was experiencing the June's Journeys, a movement triggered by the increase in transport fares that stopped the city pushing for better travel conditions and public transport services. The relationship between urban planning and mobility gained the political scene and was materialised with the strategy of concentrating densification (constructive and, in theory, of population) along high-capacity public transport infrastructures – subways, trains and bus lanes –, creating the Axes for Structuring of Urban Transformation (*Eixos de Estruturação da Transformação Urbana* – EETUs) in the 2014 São Paulo Strategic Master Plan (2014 *Plano Diretor Estratégico* - PDE), which became zones in 2016 Land Subdivision, Use and Occupation Law (2016 *Lei de Parcelamento, Uso e Ocupação do Solo* - LPUOS), as it is known and here will be called "axes".

But what was the conceptual and theoretical origin of the axes idea? The proposal for densification where there is transport is not new and can be seen in previous urban regulations, but how were the concepts and ideals appropriated in the axes proposal? To answer these questions, this article analyses how the TOD concept was disseminated in Latin America through the analysis of international manuals prepared by non-governmental organisations and financial institutions, and a bibliometric analysis of scientific articles. Semi-structured interviews were also carried out with urban managers leading the preparation of the PDE 2014

and LPUOS 2016 to understand the choices and design of regulation[1]. Finally, one table at the end of the paper summarises our main findings about the set of regulations.

The hypothesis was that axes inspiration came from the concept of Transport Oriented Development (TOD) disseminated through manuals from international organisations in Latin America, but the research denied the initial hypothesis. The conception of the axes seems to result from a mixture of: (i) experiences of managers, who participated in previous public administrations that tested some models – such as the “Curitiba model” or other bus rapid transit (BRTs) initiatives; (ii) institutional changes, which united urban and mobility planning in the same institution; and (iii) of new methods for urban proposals, such as economic-legal-financial modelling.
The urban regulation in previous decades oscillated between zones and local planes, and axes are zoning, which ended up with incomplete urban design guidelines, and not incorporating or improving active mobility, nor the climate change agenda and the reduction in transport pollution, in an incomplete incorporation of TOD agenda.

TOD in Latin America

The TOD concept has its origin in the United States in the 1990s as a way to overcome a car-centric, low housing density suburban growth. It is expected to change the model based on road transportation, as it is highly polluting and environmentally predatory, considered “distant, dispersed, and disconnected” (Evers et al., 2018) and unsustainable. The strategy is to strengthen the structure of public transport systems and, in the areas surrounding lines and stations, promote the increase of building and population density, the diversity of uses of the space, and social and housing typology diversity. These measures would generate more demand for public transportation, value active mobility (walking or cycling), and promote the building of quality public spaces (Cervero, 1993).

Through urban development that linked the built environment to the provision of transport (Carlton, 2009), the aim was to change the pattern of urban mobility, promoting compact urban environments with mixed use, which would encourage people to live close to public transport and, thus, reduce dependence on the car. In this context, some movements emerged in urban planning seeking to reverse urban sprawl based on automobiles, such as neotraditional neighbourhoods, walkable communities, pedestrian pocket and transit-oriented development (Cervero, 1993; Ibraeva et al., 2020). The dissemination of the TOD concept can be separated into 3 moments without a well-defined transition and which permeate each other: (i) the elaboration and dissemination in the Global North (1993 - 2010), the association with the climate change agenda (2007 - currently), and insertion in Latin America (2013 - current).

The first publications of the concept were ate the early 1990s by Peter Calthorpe (1993) with the book “The Next American Metropolis" and the report prepared by Robert Cervero and the Federal Transit Administration (1993) “Transit-Oriented Development in the United States:

[1] The list of manuals and academic articles researched are at the appendices. The authors' investigations used as the basis for this article are approved by Plataforma Brasil (CAAE: 73827423.9.0000.5390). The following people have been interviewed until the production of this article: the architect Fernando de Mello Franco, then head of the Department of Urban Development (2013-2016); the urban planner Kazuo Nakano, Director of the Urbanism Office of the São Paulo City Department of Urban Development (2013-2014); Nabil Bonduki, then member of the São Paulo City Council and rapporteur of the 2014 PDE (2013-2016); the architect Marcelo Ignatios, Superintendent of Project Structuring (2013-2016); the architect and engineer Alexandre Seixas, Senior Technical Advisor (2013); and the architect Tácito Pio, Senior Management Analyst (2001-current).

Experiences and Prospects” focusing on disseminating the idea and assisting in the implementation of the first experiences. Probably to facilitate the understanding for a large group, a list of six key components (Calthorpe, 1993) became three dimensions, known as the 3 Ds (Cervero and Kockelman, 1997): density, diversity and design. The first refers to housing and employment density; the second to population diversity, uses, services and facilities, and the third is related to the quality of urban design, especially for pedestrians. The idea is that working synergistically, they would bring better results. Some authors later would include “distance to transit” and “destination accessibility” considering parking supply and demographics conditions forming the 5 Ds (Ewing and Cervero, 2010).

The complexity of the variables, synergy and hierarchy between them and the particular characteristics of each territory make the concept difficult to be applied. Some authors claim that the hierarchy of most important factors for the concept to succeed are reduced travel time for public transport, followed by the presence of a job offer and then the quality of urban design (Arrington and Cervero, 2008). Others warn that the difficulty of applying the concept as a policy took to unfinished proposals (Carlton, 2009) and others alert that the implementation of the concept increases the price of land and could cause gentrification (Ibraeva et al, 2020).

In the middle of 2000s, after the Rio 92 and in face of natural disasters and the warning of climate change, the concept is linked to the climate crisis as a way to reduce the emission of CO2 from urban transport by reducing the use of motorised vehicles, the travel distance and increasing the use of active modes. The first relevant appearance is in the IPCC (Intergovernmental Panel on Climate Change) report in 2007, bringing in the chapter “Transport and its infrastructure” the need to reduce motorization through the association between transport planning and urban planning. It was not directly related to TOD, but brings references from Robert Cervero indicating an approach that effectively happens in the 2014 report appointing the concept as a solution for reducing travel distances in urban areas, approaching green urbanism or green TOD (IPCC, 2014).

In the latest IPCC report (2022), with the aggravation of the climate crisis, the concept enters a global agenda for mitigating the climate crisis, being present in the United Nations SDGs (Sustainable Development Goals) – closely related to SDG 11 of sustainable cities and communities. It is also included in the agendas of international organisations that assist cities, such as C40, which is a global network of city halls that supports cities in actions to combat the climate crisis. C40 has produced a guide to good practices and has actions related to transport planning in São Paulo, such as “Cities100: São Paulo - incentivizing Density Near Public Transit” implemented in 2015 after the 2014 Strategic Master Plan which promoted densification near the public transport, that will be explained in the next section.

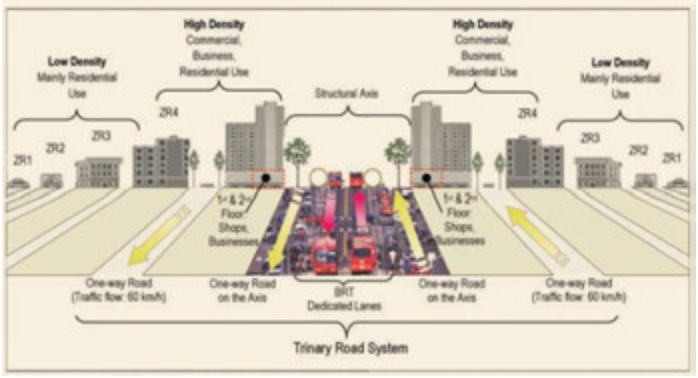
In Latin America, the concept already came with a counterpoint appeal for climate change. Its dissemination began in 2010 with a sustainable transport-oriented development manual (CTS, 2010) in Mexico, but more strongly in 2013 when manuals were published by the WBG (World Bank Group) and ITDP (Institute for Transportation and Development Policy) bringing the concept with an appeal to the sustainability agenda in urban transformations, present in the terms “Sustainable Transit-Oriented Cities”, “Toward Sustainable Urban Cities”, an example of experiences in cities in the Global South, such as Ahmedabad in India, Bogotá in Colombia and Ho Chi Minh in China (WBG, 2013) and a metric model to assess the application of the concept through urban design (ITDP, 2013).

This insertion in Latin America and the Global South was associated with experiences of implementing BRTs (bus rapid transit), justified by the speed and ease of implementing buses as public transport infrastructure compared to rail (WBG, 2013). Also associated with capturing appreciation with the objective of financing implementation, relating to the experience of RICs (Rail Integrated Communities) in Japan (WBG, 2015). The presence of JICA (Japan International Cooperation Agency) as an inducer/seeder of the Japanese concept and experience in Latin America, operating in cities such as Belém (Brazil), Bogotá (Colômbia).

When the concept was introduced in Latin America, there was a difference related to the 3 Ds because its inclusion was related to the analysis criteria as the 3 Ds to be avoided: distant, dispersed and disconnected (WRI, 2018). As a way to change urban development to a more compact, connected and coordinated one.

The Curitiba experience or “Curitiba model” appears in manuals as an example of implementation to be followed, while in academic production there are criticisms. This model is a transformation through a master plan and zoning materialised in the Structural Sectors of the 1966 Master Plan, providing for fast structural roads with an exclusive bus corridor on the central axes of the road, that is, use of the BRT, and one-way roads on the adjacency. The Structural Sectors are areas along the structural roads with greater construction potential, providing for the scaling of the maximum permitted height of buildings through taller, denser buildings close to the road axes and lower, less dense buildings in the middle of the block. Jorge Wilheim was the urban planner that idealised the 1966 Master Plan and in 2002 he was ahead of the São Paulo Master Plan. The mayor of Curitiba that implemented the bus system was Jaime Lerner (1971-1974) during his first term.

Figure 1. Curitiba’s trinary road system (WBG, 2013)



The proposal for densification in Curitiba's axes was widely disseminated as a quick solution, known as the “Curitiba model” that would articulate the expansion of segregated bus lanes, a Latin American example of the implementation of the BRTs agenda, accompanied by a zoning proposal which would allow staggered verticalization. Despite being widespread, there has been criticism since the 2000s about uneven development and deepening socio-spatial inequality

(Pilotto, 2010) with social homogenization of higher-income strata in the most vertical areas along these axes (Stroher, 2014; 2017).

The São Paulo Regulation

The city of São Paulo has historically associated urban planning and its road system, from the beginning with the first communities formed from the paths of the original peoples, which turned into streets (Nigriello, 2024) and with the implementation of road transport, the The city expanded and new communities were formed.

From the 1940s to the present, the automobile has become a protagonist of the urban environment with urban and transport planning focused on it. Some regulations relating verticalization to road infrastructure occurred during the administration of Mayor Prestes Maia (1938-1945), who argued that avenues should be the pillars of urban transformation and proposed a model combining large avenues to improve car accessibility with new occupation patterns expressing an urban design of how transformation should happen.

From the 1970s onwards, São Paulo's regulation was limited to a combination of direct plan and zoning with the first set consisting of the 1971 Integrated Development Master Plan[2] and 1972 Zoning[3]. This set of regulations proposed verticalization along existing or planned road axes to promote commercial or industrial activities close to developed poles. At the time, the city was planning the firsts public transportation with the metro's Lines 1-Blue opened in 1974 and the 3-Red in 1979, also the bus corridors Santo Amaro Avenue and Nove de Julho Avenue implemented in the late 1980s.

The Dictatorship took place from 1964 to 1985 and when the democratic period was starting the 1988 Federal Constitution and the 2001 City Statute[4] brought instruments discussed in the 1960s, such as concepts of Created Land (*Solo Criado*) and the Onerous Granting of the Right to Build (*Ortoga Onerosa do Direito de Construir* – OODC) – promoting the discussion about having one floor area ratio of one time the area of the plot for the entire city associated with the concept of Created Land.

The PDE 2002[5] and LPUOS 2004[6] are the first set of regulations formulated after the Dictatorship and the 2001 City Statute which incorporated the OODC and a more democratic process in the zoning elaboration, where each Subprefecture could discuss the densification rate in a down-top process. The densifiable areas were located near the public transport and scattered within neighbours.

The period was marked by significant advances in São Paulo's urban mobility, including the implementation of *Bilhete Único* (Unified Ticket)[7]; and the expansion of the public transportation network structure greater for bus corridors than for the subway network. Bus

corridors were implemented on Rebouças Avenue, Francisco Matarazzo Avenue, and the *Fura Fila* guided bus project (2007), while 8 lines of the rail system were operating.

And finally the current set in force PDE 2014[8] and LPUOS 2016[9] proposed the end of scattered verticalization by concentrating densification along the medium- and high-capacity public transportation structure network through zoning rules, called “axes,” which correspond to the Axes for Structuring of Urban Transformation (*Eixos de Estruturação da Transformação Urbana* – EETUs) in the 2014 master plan, which later became the Axes Zone for Structuring of Urban Transformation (*Zona Eixo de Estruturação da Transformação Urbana* – ZEU) in the 2016 LPUOS.

These three regulatory sets are related within the evolution of the idea of densification via zoning initially in the centralities of neighbourhoods and road axes - within a context with reduced public transport infrastructure – for densification exclusively on medium and high capacity public transport routes (Costa and Santoro, 2024).

[9] Law No. 16,402, of March 22, 2016.

Source: Costa and Santoro, 2024.

The context leading up to the 2014 PDE is related to the protests staged in June 2013, the first year of the Fernando Haddad administration (2013-2016), as a moment when the mobility agenda, the struggle for better transportation conditions, and the public transportation and active mobility systems strongly emerged. The protests of June 2013 started with the increase of public transport fare in São Paulo city and spread over Brazil for better conditions of mobility and living conditions.

In addition to having successfully overturned the fare hike, these protests "put the transportation and overall urban mobility agenda at the centre of the conversation" (Lemos, 2021, pp. 228-229). Cycling activism had a role in this period with the cycling agenda growing and gaining relevance in previous decades, penetrating institutional structures with activist public managers, through institutional activism (Abers, Sefafim, and Tatagiba, 2014) reflected on the presence of civil society in councils, that shifts the place of active mobility to a "subaltern regime" in relation to the car-centric "ruling regime"[10] (Lemos, 2021).

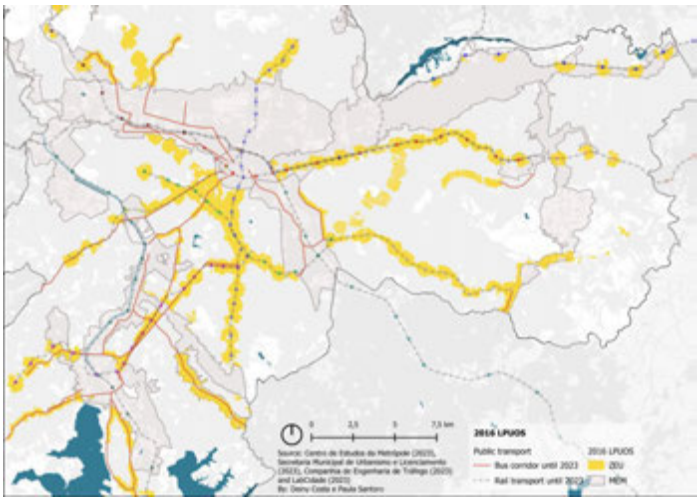
This mobility agenda was so strong that the term "axes" itself had been included in Haddad's political campaign program the year before, as he ran for mayor, in which the connection between development and mobility was being discussed[11]. This axes were designed as the ZEU in the 2016 LPUOS and with the forecast of other areas to be densified after the approval of the expansion projects for the public transport system, the Planned Urban Transformation Structuring Axis Zone (ZEUP – *Zona Eixo de Estruturação da Transformação Urbana Prevista*). The new axes implemented after 2016 are related to the construction of the Line 6-Orange, extension of the Line 2-Green and BRT Aricanduva. Alongside densification in mobility axes, the reduction of densification in the middle of the neighbourhoods, where the construction potential is at most twice the land area, worked in containing the scattered verticalization (Santoro et al., 2023).

Figure 4 – The 2016 LPUOS[12]

[10] On the dominant and subaltern regime, see Geels and Kemp (2012). According to the authors, from a niche segment in the car-centric dominant regime, pressured by protests or disruptive and counter-hegemonic actions, it eventually takes on a place in the regime, albeit subaltern.

[11] Information collected during the interviews.

[12] Map observations: ZEU means zone of urban transformation structuring with minimum FAR of 1 and maximum FAR of 4; MEM means Macro-Area for Urban Structuring with a FAR defined in later regulation. The stations have the colours of the lines to facilitate identification.



Source: CEM (bus corridors), São Paulo city government (2014 LPUOS, and main roads). By the authors, 2023.

In addition to the axes, the possible densification and verticalization in this regulatory set are in areas of Special Zones of Social Interest (*Zonas Especiais de Interesse Social* – ZEIS) and in the Macro Area of Metropolitan Structuring (*Macroárea de Estruturação da Transformação Urbana* – MEM).

Not all ZEIS have construction potential equal to that of the axes, only ZEIS 2 – unbuilt or underused lots suitable for urbanisation –, ZEIS 3 – idle or underused properties, located in regions with good infrastructure and job offer – and ZEIS 5 – these are empty or underused lots in areas equipped with urban services, equipment and infrastructure, where there is a private interest in producing popular market housing developments.

MEM is an area along the Pinheiros and Tietê Marginals and metropolitan connection roads, where land use is predominantly idle and urban transformation is desirable. In this area, densification is possible via specific regulation where urban parameters are defined and an urban design is planned, and this transformation occurs through Urban Intervention Project (*Projeto de Intervenção Urbana* – PIU) or Consortium Urban Operation (*Operação Urbana Consorciada* – OUC).

The urban design experiences in the regulation of São Paulo return to the management of Prestes Maia (1938-1945) in a combination of design for road axes with the definition of the lot's occupation pattern. In the 1970s and 1980s, the CURA Program (Urban Communities for Accelerated Recovery) enabled the transformation of territories with improvements to roads, public facilities and housing (Lucchese, 2004). An example of implementation was the

Jabaquara/Conceição Project, which combined municipal cooperation for improving roads and public equipment, with state cooperation in planning housing complexes. The program was discontinued with the end of the National Housing Bank (*Banco Nacional da Habitação* – BNH) in 1985, its main federal financier, and after unsuccessful cases, such as the Brás-Bresser Project marked by the high cost of expropriations for the construction of the avenue, canalization of streams and other equipment, and the construction of the housing complexes took place a few years later with most of the land being private areas (Anelli, 2011).

The firsts experiences with OUC was in 1997 with the OUC Faria Lima and later with the OUC Água Espraiada 2001. The OUC model was showing signs of depletion as criticism about the instrument does not involve (or has a limited character to) democratic participation and management; criticism about the interventions produced, for being elitist and exclusionary and being essentially road- and infrastructure-oriented; the cost of Certificates of Additional Construction Potential (*Certificados de Potencial Adicional de Construção* – CEPACs) compared to other areas of the city where compensation for building rights is cheaper, easier to get, and less controlled by investors (Santoro, 2021).

In the 2000s, the Urban Intervention Areas (*Área de Intervenção Urbana* – AIU) proposed by the PDE 2004 were polar areas of neighbourhood centralities or mobility hubs and linear areas of road axes capable of densification via future regulation. The idea would be urban transformation through urban design, but it was never implemented. The need for a subsequent specific law to implement land use change became an impediment to urban transformation.

Until 2023, no PIU or new OUC was implemented[13] after the promulgation of the last regulatory set, with densification and verticalization concentrated on the axes, so that zoning was the inducer as in previous regulatory sets. The choice for zoning is based on previous experiences of the urban project not being viable and also on management's choice for rapid implementation, as the possibility of self-application of zoning was an ally for management in the face of the mobility challenges that management was experiencing – in view of the political pressure around June 2013 (Costa and Santoro, 2024).

Although the transformation occurred through zoning, there was an intention to design the urban area, mainly the ground floor of the projects and the interface between public and private[14]. In this sense, the "basket of incentives" is designed to enable an urban design favourable to active modes – pedestrians and cyclists –, restriction to individual motorised modes and a design of the building's volume in exchange for greater construction potential. The items in the basket include mixed use on the ground floor, public enjoyment, sidewalk widening, in addition to restrictions imposed such as the minimum size of the active facade – restricting walls or blind walls – and restrictions on vehicle parking spaces on the facade.

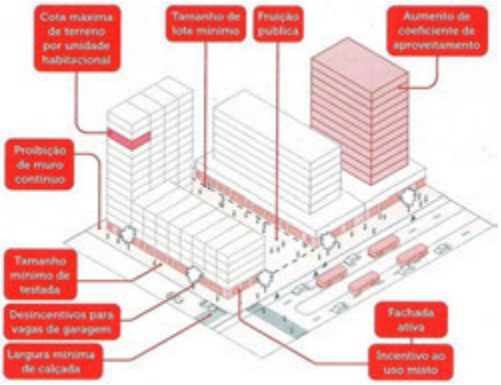
Despite the transformation not being through urban design, there was an intention to design the ground floor – and the interface between public and private – and the building volume. Through a combination of urban incentives, called by one of our interviewees as the "basket of incentives", the regulation of the axes oriented to a built-up volumetric design through non-computable built-up areas.

[13] With the exception of OUC Faria Lima, in force since 1997, and OUC Água Espraiada, since 2001.
[14] Information collected during the interviews.

This basket proposes a design for the interface between public and private areas, allowing the ground floor not to be counted as a built area if amenities were implemented for human scale, such as active façades, lot fencing restrictions, and sidewalk widening. Alongside with this "basket of incentives" the car amenities were restricted such as reduction of parking area for cars on the building facade and limited to the parking area in the garage as a non-computable area – in the previous regulations there was a limit of the minimum number of spaces per square footage or housing unit regulated.

The "basket of incentives" when combined with other instruments also determined the building volume as some areas were considered non-computable areas, such as horizontal circulation and balcony. This possibility and the lack of height limit allowed tall buildings with balconies; and when associated with the solidarity quota – which is an incentive for the real state to produce units for low income population and incentive social diversity – more construction potential is permitted.

Figure 5 - Axes incentive diagram



Source: illustrated PDE 2014.

The incentives that translate into non-computable built-up areas for the purpose of calculating the Onerous Granting of the Right to Build are not new in São Paulo urban planning – they have emerged since the 1950s plans, although restricted to some areas. The 1970s set of regulations – 1971 PDDI and 1972 Zoning Ordinance – already defined areas that would not be included in the calculations of the total built-up area of development projects[15]. The "basket of incentives" works together with the restriction of non-computable built area defined with a limit of 59% of the total built area. This restriction is new in regulation and guides businesses

[15] Defined by the dimensions of the common area of up to 4 sq.m per housing unit and a caretaker's housing unit of up to 60 sq. m. (Art. 15, Par. 4).

in choosing the combination of incentives for the design of the building's volume, such as a menu where parking areas, internal circulation areas, balconies and technical areas are considered.

This urban form was not only guided by urban parameters that had historically guided the relationship with roads – such as building heights in relation to the width of the road, setbacks, etc. –, but by using the basket of urban incentives that adopts the right to build as a “language,” as a “bargaining chip” for certain urban results (Santoro, 2021, p. 81; Stroher et al., 2023). By choosing to create zoning regulations, public managers tried to incorporate the urban design through this “bargaining chip” giving more square length in exchange for a ground floor design with widening of sidewalks, public fruition and active façade.

Advances in this regulation also include mobility by reducing the use of individual vehicles and increasing the use of active modes and public transport. At the beginning of the 2000s, urban regulation allowed up to 50% of the non-computable built area to be covered by parking spaces and garages for cars, being changed in the PDE 2014 and LPUOS 2016 by limiting 1 space per housing unit as a non-computable area. Also this regulation established for the first time a minimum rate for bicycle parking and amenities for cyclists in the garage, such as changing and repair rooms. The incentive for garage buildings close to some peripheral stations were marked in a map in a way to promote the intermodality and reduce the car use in the expanded centre of the city.

In relation to advances in the public transport system, although medium and high capacity transport has expanded, it is still below the needs of the city and the metropolis. The expansion of the bus lane system, managed by the municipality, was an agenda during the administration of Mayor Fernando Haddad (2013 - 2016) as a response to the protests of June 2013 and due to its ease of implementation, since the asphalt network infrastructure was already existing. The railway system – under state responsibility – requires more time to design and implement, and has made less progress than planned since the first lines in the 1970s. Urban regulations already provide for new axes in accordance with the planning of bus corridors and subway or train lines. Some axes already in place are related to the construction of Line 6-Orange, extension of Line 2-Green and BRT Aricanduva.

The process of preparing the PDE 2014 and LPUOS 2016 followed a top-down decision-making model, with the first bill[16] being prepared in less than a year – started in January 2014 and delivered to the São Paulo City Council in September of the same year –, and as soon as the bill was delivered, the drafting of the zoning began. The city government was very active during the discussions around the 2014 PDE law at the City Council, therefore technicians played a central role in the design of the set of regulations, and decisions were more centralised, having a different kind of public participation than the one involved in the previous set (2002 PDE and 2004 LPUOS).

The design of the bill centralised in the administrative and management body is mainly due to the possibility of implementation in a short period of time. The experience of the previous regulatory set, which took place in a decentralised way with the participation of the population through workshops in Subprefectures where urban parameters were discussed, was a long process and reflected areas with different construction potentials. Another issue for short-term

[16] Bill No. 688/2013.

implementation was the urgency in meeting the urban mobility demands of the period represented by the June 2013 protests.

The 2016 LPUOS did not start from decentralised regional plans, unlike the previous one, but rather discussed the city as a whole, in a centralised manner involving economic-financial and legal modelling made by the administrative body. The diversity in institutional structure made it possible to articulate urban and transport planning. This administration counted with a multiplicity of professionals from different specialties, such as urban planners focused in urban design or with experience in others urban planings, transport planners, economists and professionals in the legal field.

This intra-governmental integration was a cohesive and aligned group of elected and technical officials who allowed the axes to be designed in a partnership between the Secretariat of Urban Development and Transport[17] – which also prepared PlanMob 2015 (São Paulo Urban Mobility Plan)[18] – and a team from SP Urbanismo[19]. According to some of our interviewees, a group was formed to conceive urban typologies and urban design for the many different urban scales (including micro) of the axes, to be implemented especially with bus corridors – for which the municipality is responsible. This group also included "transporters", managers coming from the mobility agenda, to be involved in urban planning.

The design of the axes initially came from the desire to improve the implementation of bus corridors, mainly from the experience with the Santo Amaro Corridor with cases of being run over after implementation[20]. The impetus was for the implementation of bus lanes to create a more pedestrian-friendly urban environment, including widening sidewalks and a diversity of uses on the ground floor of the lot – avoiding the blind gables resulting from the latest regulations. This design included economic-financial and legal modelling that enabled the desired urban transformation both on an intra-urban and lot scale, involving the real estate market not only in the volumetric designs and interface between public and private, but also in the production of housing of interest. social (*habitação de interesse social* – HIS).

This production of HIS by the market takes place through the Solidarity Quota, defined by the increase in the construction potential of the project if HIS units are built on the lot itself or another lot in the city or the possibility of payment to Urban Development Fund (*Fundo de Desenvolvimento Urbano* – FUNDURB). The initial idea of the Quota was to promote socioeconomic diversity within the lot itself, but adaptations were made to the design of the regulation, distorting the instrument towards compensation possibilities beyond the lot.

[17] The drafting of the 2015 PlanMob stands out in the period. The plan provides guidance regarding actions to ensure better urban mobility conditions over a 15-year horizon and is the result of the National Urban Mobility Policy (*Política Nacional de Mobilidade Urbana* – 2012 PNMU) – Law No. 12,587 of January 3, 2012.

[18] Decree No. 56,834, February 24, 2015. The plan guides actions to guarantee better conditions for urban mobility within a 15-year horizon and is the result of the National Urban Mobility Policy (*Política Nacional de Mobilidade Urbana* – PNMU 2012) – Law N. 12,587, of January 3 2012.

[19] At the time, it was coordinated by the architect Gustavo Partezani Rodrigues (who has a background in urban and mobility design); the architects Marcelo Fonseca Ignatios (who also worked with real estate assessment) and Alexandre Seixas Rodrigues (who holds a doctoral degree in urban mobility planning); the economists Bruno Borges and André Kwak; and counsel José Apparecido, who has a background in urban design and planning.

[20] Information collected during the interviews.

The mobility crisis was not the only discussion happening at the time, the public discussion around the effects of the verticalization model sparked a massive conversation with different narratives in the media. Groups were divided by: the resistance movements formed by associations of residents of areas impacted by this verticalization accessed and would like to preserve the neighbour as it is; or groups who resisted the destruction of cultural and environmental value which are non-designated heritage assets; or movements in favour of verticalization known as YIMBY (“yes in my backyard”). More recently, another group has emerged aiming to show that, more than being on opposite sides, the ongoing discussion regarding verticalization is a fallacy, because it conceals the interests of the real estate market and finance in producing these changes (Rolnik et al., 2021).

The modelling of the axes reflected the transformation on a municipal and lot scale. This simple and unified densification rule for all public transportation axes did not take into consideration the territorial differences affected by zoning regulations[21], reflecting differences in the urban transformation along these different axes. Although there was an intention, from the beginning, to establish differences between them, as reported by some interviewees, that did not happen as there was limited time to conduct studies to draft the proposal, and it was even more difficult to do so when drafting the 2016 LPUOS, as it could mean reducing floor area ratios, a setback that would make it harder to pass the zoning ordinance law. This single rule applied to all axes reflected a different form of appropriation or abandonment of the different axes by the real estate market.

The combination of rules and incentives in the axes, such as the possibility of greater construction potential, such as the “incentive basket”, and the absence of size limits made the production of large and tall buildings viable, with some projects having 500 housing units. The concentration in one territory and size of these projects led to issues of urban infrastructure overload, production of units without thermal comfort (Viana, 2024), large buildings with a similar design (do Val, 2023) and production of units for social housing distorted from the function (Stroher et al, 2023).

Commenté [1]: seminário dos eixos

It appears that the conceptual theoretical basis of the axes is the concept of TOD through the relationship between urban and transport planning and urban mobility directed towards a modal transition from individual motorised transport to collective and active public modes – on foot and bicycle – through incentives for densification close to public transport axes and modelling of the ground floor and public/private interface. Also due to the temporal convergence of the elaboration and implementation of the PDE 2014 and dissemination of the concept in Latin America and Brazil, both in the mid-2010s. However, this hypothesis was not confirmed in the interviews, with a consensus among those interviewed that the concept was not the basis theoretical.

One of the interviewees mentions that during the discussions about the implementation and improvement of bus lanes, he remembered the concept and looked for references that could help with planning, but that it was not a topic that entered the meetings and guided the axes or the PDE 2014. There is a convergence among some interviewees that the agenda of improving

[21] A broader research hypothesis believes that a reading of location, base, and land structure, the available urban mobility structure, and real estate production, identifying different producers (real estate agents) and the different products produced by them, can be helpful to understand the differences between the proposals and what has been implemented along the axes so far.

bus corridors and the experiences of OUC Água Branca and Bairros do Tamanduateí were what drove the proposal for the axes. Other interviewees and the analysis of densification along the last three sets of regulation (Costa and Santoro, 2024) show that the idea had already been present since the 1972 Zoning, or in the PDE 2002 AIUs, or the 2004 LPUOS. The inspiration from the “Curitiba model” and 1966 PD also appeared in the interviews with a flow of actors and urban planners ahead of the drafting of regulation.

In this way, it is possible to understand that the result is exactly a combination of previous experiences in the urban regulation of the municipality itself and the flow of managers and actors in public administrations testing models and proposing discussions on forms of urban intervention.

Final Remarks

This article shows that despite the TOD concept being related to the discussion around the relationship between urban and transport planning and being disseminated in Latin America in early 2010s, it’s not the conceptual basis of the last urban regulation in São Paulo city – 2014 PDE and 2016 LPUOS.

Despite the TOD concept being disseminated in Latin America at the same period of the axes of São Paulo’s in the 2014 PDE and 2016 LPUOS, it was not a concept that influenced the design of the regulation. The interviews and analyses of institutional historical contexts, models utilised, and proposals for urban regulation lead us to our first hypothesis for this work, according to which the conception of the model that inspires the theoretical-conceptual basis of the axes may be precisely the result of a combination of circulation of actors and planners involved in the structuring of public planning agencies. The different backgrounds of the managers involved in the urban discussion and the flow of these actors into the public administrations that tested some models, such as Candido Malta, Nabil Bonduki and Jorge Wilheim. Also the migration of ideas and the “Curitiba model” brought by Wilheim after his experience in Curitiba.

A densification near medium and high capacity public transport and restriction in the middle of neighbourhoods happened, however there are some differences between the axes and the TOD concept that resulted in an incomplete agenda. The choice of transformation by zoning not by urban design, due to the political moment and the need for short-term implementation. There was a desire to promote social diversification, but the release of the obligation to carry out construction on the same lot and the distortion of the production of social housing made it unworkable. The restrictions on the car use non-computable built areas were those possible within the dynamics that already occurred and were determined in the city's previous regulations.

[1] MSc. Hazal Ertem is graduated with a bachelor's degree in City and Regional Planning. She is research assistant at İzmir Institute of Technology and pursuing a Ph.D. in City and Regional Planning at the same institution. Her research is focused on the intersection of critical infrastructure, green infrastructure, and urban governance.

[2] Asst. Prof. Dr. Zeynep Elburz is a faculty member at the Department of City and Regional Planning at Izmir Institute of Technology. She has studies in the areas of regional economy, industrial geography and regional inequalities.

[3] Prof. Dr. Koray Velibeyoğlu is a faculty member at the Department of City and Regional Planning at Izmir Institute of Technology. He has studies in the areas of urban design theory and practice, asset-oriented local development, smart cities and communities, and nature-based solutions.

Abstract

Urbanization has a direct and negative effect on global problems like climate change and pandemics, which makes disasters in cities more serious. To respond these problems, the concept of 15-minute cities and critical urban infrastructures have gained prominence. The main objective of this research is to assess the accessibility of critical infrastructure in İzmir and determine the equity in the distribution of critical services throughout the city and perception of people to the concept. Reaching critical services is vital during a crisis or ensuring citizens' quality of life. The study examines the conceptualization and operation of critical urban infrastructure in the context of x-minute cities, and whether critical infrastructures were accessible in 5,10,15-minutes by walk in Karşıyaka, İzmir. The findings can contribute to urban development in terms of resilient, accessible, sustainable cities and community well-being.
Keywords: Chrono-urbanism; critical infrastructure; spatial analysis

1. Introduction

The word Anthropocene defines an era characterized by the dominance of human activity, caused by the increase in population density in urban areas. This has consequences and makes urban environments more vulnerable to chronic stresses and sudden shocks. One stress is climate change, and it causes various shocks in cities. In other words, the rapid urbanization in cities causes climate change, and climate change creates crises in cities. National governments, their coalitions, and major international organizations like the European Commission and the United Nations has become more conscious of the critical role that cities play in advancing global and regional sustainability, especially in the context of climate change (Pozoukidou and Angelidou, 2022). Therefore, numerous international policy papers prioritize the issue of climate crisis. They include the Sendai Framework for Disaster Risk Reduction 2015-2030 (United Nations, 2015), New Urban Agenda (United Nations, 2017), and the European Green Deal (European Comission, 2019). Furthermore, the Global Risk Report 2023 (World Economic Forum, 2023) indicates that climate-related risks are in the top ten long-term global risks. “Failure to mitigate climate change”, “failure of climate-change adaptation”, and “natural disasters and extreme weather events” are the first three risks in the report. One more worldwide problem which happened following 2020 is the Covid-19 pandemic. The process of urbanization worsens accessibility challenges, making individuals more vulnerable to pandemic-related crisis.

Multiple strategies and research have been discussed in order to address these concerns and mitigate their impact. The concepts of critical infrastructures and 15-minute cities are two of them. The core concept of 15-minute cities is that they are "compact, complete, and connected". Active modes of transportation like walking and cycling must gradually replace vehicular traffic as the primary source of emissions (Logan *et al.*, 2022). Furthermore, improving the level of connection and accessibility to critical products and services is of utmost importance, particularly in instances with restricted access like pandemics. The 15-minute city relies on chrono-urbanism, arguing that the quality of urban life is inversely proportional to the amount of time spent on transportation, primarily automobiles (Logan et al., 2022). Furthermore, critical infrastructure has played a vital role in the literature. Various nations and organizations own distinct policies related to critical infrastructure. Systems, facilities, and networks are all examples of critical infrastructures because of their significance

to the functioning and well-being of the people. Interdependency (Rinaldi, Peerenboom and Kelly, 2001), and scale (Theoharidou, Kotzanikolaou and Gritza-Lis, 2009; Steele and Legacy, 2017) are two approaches for critical infrastructure. Scale is an essential issue because it is crucial to study critical infrastructures at local and urban scales, which are generally seen to be handled on a national scale. However, scale is mentioned in a limited way in policy documents, and research based on local scales is rare. Therefore, this is a lack in the literature. Cantelmi and others (2021) explain the importance of scale by saying that breakdown in infrastructure can be even more critical if it causes a cascade of breakdowns that have regional, national, or international scale. Besides, Steele and others (2017) ask that “critical at what scale and for whom?”. Therefore, it is imperative to carry out critical infrastructure study within the scope of the 15-minute city concept.

Considering these discussions, this study investigated whether critical infrastructures were accessible in 5, 10, 15-minutes. The main objective of this study is to examine the accessibility of critical infrastructures in Karşıyaka, and to figure out fairness in the distribution of specific critical services in the district. For the study, network analysis is conducted for transportation, and green infrastructures, and it is presented via GIS software. The paper consists of four parts. First, the theoretical framework explains critical infrastructure and the 15-minute city concept. In the methodology part, the study area, methodology, and results and discussion take part. In conclusion, results and limitations are discussed.

2. Theoretical Framework

2.1. X-Minute City Concepts

Chrono-urbanism posits that the quality of urban life is negatively correlated with the amount of time spent on transportation, particularly when relying on automobiles (Moreno *et al.*, 2021). In other words, the concept refers to “the temporal dimension of urban planning” (Moreno *et al.*, 2023). Carlos Moreno, a professor at Sorbonne University, developed this idea in 2015 (Ferrer-ortiz *et al.*, 2022). Urban and territorial proximities are facilitated by the development of polycentric cities or territories that consist of multiple "complete neighbourhoods." This approach aims to minimize daily commutes and facilitate individuals to work in close proximity to their homes (Guzman, Oviedo and Cantillo-Garcia, 2024). According to Moreno and others (2023), the concept seeks to integrate time variable along with the space in the analysis and planning of urban areas. It is important to understand “broadly how time affects urban form, infrastructure, and social interactions” (Moreno *et al.*, 2023).

The idea of x-minute cities is based on the principles of chrono-urbanism (Guzman, Oviedo and Cantillo-Garcia, 2024). In addition, it is noted that the notion of the x-minute city offers a sense of place identification through chrono-urbanism and alternative lifestyles, which reduces dependence on cars by promoting walking distances in cities (Moreno *et al.*, 2021). The x-minute city concept has received significant attention in recent years, primarily due to the urgency to address global warming and the pandemic. Those global crises require the use of different approaches to spatial organization of neighbourhoods. Accordingly, the concept of a x-minute city has a potential to provide solutions by promoting pedestrian and cycling activities to access essential goods and services. Besides, the concept has the capacity to address multiple Sustainable Development Goals (SDGs) and can be adapted to meet the

criteria specified in the United Nations-approved New Urban Agenda (Ferrer-ortiz *et al.*, 2022).

According to Allam and others (2022), 15-minute city may be valuable because of reducing car demand in cities. They indicate that most of emission in urban areas occur due to vehicular transportation. The concept may propose a solution to transportation-related problems that may contribute to climate change. In addition to reducing emissions, the concept of the x-minute city or neighbourhood concept of urban design offers a multitude of extra advantages (Logan *et al.*, 2022). Another crisis that draws attention to the 15 minutes city concept is the covid 19 pandemic. Ferrer-ortiz and others (2022) state that the COVID-19 health crisis has greatly increased interest in the 15-minute city concept. The primary cause of this phenomenon is the concentration of the people in densely populated areas, which gives rise to new challenges in urban settings. Pozoukidou and Angelidou (2022) assert that despite it was first developed in 2015, the popularity of the 15-minute city model increased significantly during the COVID-19 issue. In addition, persons in pedestrian-friendly areas tend to demonstrate a greater degree of confidence in their neighbours, thereby fostering social capital. Research has shown that neighbourhoods designed to be pedestrian-friendly have a positive impact on the well-being of both young and elderly residents (Logan *et al.*, 2022). In addition, the discussions on the concept of the 15-minute city include a fair distribution of essential services to the residents of the city. Pozoukidou and Chatziyiannaki (2021) the importance of developing a sustainable community is emphasized, which can be achieved through “equal access to facilities and opportunities, local social interaction, participation in local community activities, community stability, pride of place, sense of belonging and feeling safe and secure”. Inclusiveness encompasses basic urban services and amenities, such as access to high-quality and affordable housing, mobility infrastructure that serves to people of all ages and abilities, affordable transportation choices, equal chances for employment and education, and a right to a healthy lifestyle (Pozoukidou and Chatziyiannaki, 2021). Increasing access to urban amenities may contribute to optimal consumption achieved without limiting available resources, going beyond common quotas for population and service density. This is also related with mixed used built environment, which include residential, commercial and entertainment places (Allam et al., 2022). Moreno and others (2021) also mention mixed-used development and they indicate that engagement of inhabitants to living, working, commerce, healthcare, education, and entertainment are necessary to maintain remarkable urban life and better quality of life. Briefly, the 15-minute city concept highlights the neighbourhood as the basic component of spatial and functional organization and argues that cities should be organized into neighbourhoods where every need can be met within 15 minutes by foot or bicycle (Pozoukidou and Angelidou, 2022).

The 15-minute city concept emphasizes the accessibility of basic services within a particular time and distance by means of walking or cycling. As mentioned in Allam and others (2022a), this concept enables the strategic positioning of essential urban amenities, infrastructures, and opportunities to promote accessibility. These services are described in the plans and strategies of different cities. It found its way into universal planning practice, with Paris, Portland, Oregon, and Melbourne as the forerunners (Pozoukidou and Angelidou, 2022). One example is Melbourne 2017–2050 plan. Destinations from starting point to the destination are comprised of 800 meters of walking distance (Victoria State Government, n.d.). Education, commercial,

green, open spaces, and transportation are some services accessible within 20 minutes of walking distance (Figure 1). In addition, Ferrer-ortiz and others (2022) indicate that Plan Melbourne is based on walking, cycling, or public transport, with its 20-minute neighbourhood as a chrono-urbanism practice, and Singapore and Beijing's approach combines a more extended threshold for commuting trips (45 to 60 minutes) and a reduced threshold for local daily trips (15–20 minutes).

Figure 1. Features of Melbourne 20-Minute Neighborhood (Victoria State Government, n.d.)

Another example is the Portland Plan, which was created in 2012. A "complete neighbourhood" is defined by the plan as a place where residents may conveniently and safely access essential goods and services for their everyday lives. It involves a variety of housing options, grocery stores and other commercial services, quality public schools, open public spaces, recreational facilities, affordable active transportation options, and civic amenities (Pozoukidou and Angelidou, 2022).

Density, diversity, digitalization, and proximity are four dimensions proposed by Moreno for the 15-minute city concept (Moreno *et al.*, 2021) (Figure 2). The concept aims to shift towards a city that is more polycentric and diverse in its usage. This will be achieved by emphasizing those four key dimensions. The aim is to provide a good quality of living within short distances and reduce dependence on automobiles (Gower and Grodach, 2022). Regarding density, 15-minute city concept advocates for a compact city where people are able to sustain themselves comfortably due to the availability of resources. This approach differs from conventional urban planning concept, which only considers density based on built environment quotas (Allam, Bibri, *et al.*, 2022a). Diversity refers to the mixed-use of the built environment and multiculturality, a social mix. A mixed-built environment consists of “healthy mix of residential, entertainment, and commercial elements” and aims to maximize available spaces and promote the proximity of services (Allam, Bibri, *et al.*, 2022b). The dimension of digitization is intimately linked to the components of smart cities and is crucial in realizing three other dimensions (Moreno *et al.*, 2021). Proximity is another

dimension that aims to reach basic services in 15 minutes (Moreno *et al.*, 2021). This dimension encourages the reduction of travel time and the car usage. Vehicular transportation is a major contributor, accounting for 78% of urban emissions in urban areas. Proximity provides direct ways to reduce emissions through decreased travel requirements and short distances (Allam, Bibri, *et al.*, 2022b). Furthermore, it encourages social engagement (Moreno *et al.*, 2021). This research examines the proximity dimension as a primary dimension of the concept for analysing Izmir.

Figure 2. The 15-Minute City Framework (Moreno *et al.*, 2021)

2.2. Urban Critical Infrastructure

The term "critical infrastructure" emerged in the 1990s and has subsequently been included in policy papers and legislation. A comprehensive understanding of the concept of critical infrastructure is necessary (Henten and Windekilde, 2020). Furthermore, Setola and others (2017) state that critical infrastructures do not have a standard definition, but the main idea is that they harm society when disrupted. Critical infrastructures, in a general sense, refer to assets or systems that are essential for upholding the societal and economic operations of a community (UNISDR, 2017). Serre and Heinzlef (2018) argue that the term "critical" implies a situation where the defence and economic organization could be challenged in the event of a disruption in essential infrastructure. The Organization for Economic Co-operation and Development (OECD, 2019) provides a definition of critical infrastructures as “systems, assets, facilities, and networks that provide essential services for the economy's functioning and the population's safety and well-being”. Critical infrastructures, as defined by many systems, cultures, and professional viewpoints, are responsible for providing vital goods and services that are necessary for the ongoing functioning of society and the economy (Shen, Feng and Peng, 2016).

The perception of critical infrastructure has evolved. Initially, they were viewed as concrete and stable, like physical and information and communication technologies. Nevertheless, there has been a shift in this trend towards a more all-encompassing approach. As stated by Pursiainen (2009), critical infrastructures contain all necessary societal functions. In contrast to earlier views, Mottahedi and others (2021) argue that the human factor is important and emphasize that critical infrastructure systems include the integration of individuals, engineering systems, and ecological surroundings. Furthermore, according to Steele and Legacy (2017), it can be described

as a "multidimensional and lived phenomenon" that relates to place, space, ecology, culture, pipes, wire, and concrete, among other things.

The actual events, shocks, and stresses in cities have an important role in the evolution of debates in critical infrastructure. Even while terrorist threats are discussed in relation to critical infrastructure, this one-hazard approach was insufficient to guarantee the uninterrupted operation of the system. Consequently, the European Union embraced the concept of the "all-hazards" strategy (Pursiainen, 2018). However, climate change has become an increasingly important issue when it comes to maintaining the resilience and protection of critical infrastructure (Hawchar *et al.*, 2020; Salimi and Al-Ghamdi, 2020; Kumar *et al.*, 2021; Silvast *et al.*, 2021). Besides, COVID-19 pandemic is also taking place in discussions (Clark-Ginsberg *et al.*, 2020; Derks, Giessen and Winkel, 2020; Mcphearson, 2020).

Infrastructures have played an important effect on the formation of metropolitan regions throughout the history. Furthermore, while critical infrastructures are typically discussed on a national scale, they are a part of urban development because they both affect and are affected by urban development. Given the existence of spatial difference and sociotechnical rupture, critical infrastructures have a significant impact on “governing and contesting” of urban change (Mcfarlane and Rutherford, 2008). Technological advancements, political strategies, and economic approaches have a significant impact on the development of infrastructure, which in turn affects urban growth. Today's existing political and economic circumstances necessitate new investments in urban infrastructure. Recent political and technical arrangements in cities facilitate the development of mega infrastructure projects. There, new globalized "infrastructure practices" emerge (Addie, Glass and Nelles, 2020).

2.3. Urban Critical Infrastructures in Chrono-Urbanism Perspective

Like definition of the concept, sectors of critical infrastructure also may differ from country to country. OECD (2019), according to surveys, defines 16 critical infrastructure sectors (Table 1). According to Lomba-Fernández and others (2020), cities depend on these sectors for daily life. Some countries have different categories. The "National Strategy for Critical Infrastructure Protection, Germany" report categorizes critical infrastructures into two main groups: basic technical infrastructure (such as power, ICTs, transportation, and water) and socio-economic services infrastructure (including food, public health, emergency services, disaster management, public administration, finance, media, and cultural heritage) (CIP Strategy, 2009). As mentioned, critical infrastructures studies mainly focus on technical infrastructures. The concept of "soft capital" such as human capital and knowledge, is discussed in the literature at gradually. However, it is important to examine the "dynamics of critical social infrastructure" in order to understand their impact on community capacity (O’Sullivan *et al.*, 2013). Furthermore, the discussion surrounding ecological critical infrastructure has achieved significance in recent years. The ecological perception is particularly essential, especially regarding climate change and the pandemic. In addition to OECD, recent studies focus on green infrastructure as critical infrastructure (Derks, Giessen and Winkel, 2020; Amorim, Menezes and Fernandes, 2022). Steele and others (2017) argue that in the context of urbanization, the essential interconnections between critical infrastructure and the equity of human and natural systems highlight the critical role of infrastructure. Therefore, “soft/

green/digital infrastructure (at different scales and for different reasons) qualifies as critical" (Steele et al., 2017 p.85). Because of these reasons, green infrastructure is also considered critical infrastructure in this study.

Table 1. Critical Infrastructure Sectors (OECD, 2019; Derks, Giessen and Winkel, 2020; Amorim, Menezes and Fernandes, 2022)

Critical Infrastructure Sectors
Energy
Nuclear sector
ICT
Transportation
Water
Dams & flood defense
Food supply & distribution
Health
Finance & banking
Government
Public safety
Law enforcement
Chemical industry
Space sector
Defence industry
Critical manufacturing
Green Infrastructure

As mentioned, critical infrastructure sectors consist of technical infrastructures and socio-economic sectors. Within the scope of the x minute city concept, access to various urban services is discussed on a temporal dimension. In this context, some of the services included in x-minute city applications are critical urban services or critical socio-economic services (Table 2). An inclusive and fair distribution to critical services is essential in two ways: quality of life and accessing to services in emergency situations.

Table 2. Critical Infrastructure Sectors within Concept of X-Minute City

Critical infrastructure sectors in x-minute city concept	ICT
	Transportation
	Food supply & distribution
	Finance and banking
	Health
	Green Infrastructure

The two main concepts—urban vital infrastructure and the 15-minute city concept—are examined in the context of this study. These two concepts are often examined independently in several studies, and there is a need for a broader overview of the study on both topics in the literature. Studying these two concepts together consists of an alternative evaluation of cities in the context of resilience, sustainability, and fairness in cities. Therefore, in İzmir, the critical infrastructure sectors within the 15-minute

perimeters are examined. In the study, green infrastructure and public transportation are selected to analyse.

3. Methodology

3.1. Study Area

İzmir located in the western part of Türkiye and around the İzmir bay. It is the third biggest city in Türkiye. The city has been faced with speed urbanization for since 1960s. Also, Izmir is the 3rd city with the highest population density according to 2023 population data (TSI, 2023). The has experienced significant population increase and expansion of built-up regions, resulting in increased pressure on natural resources (Tonyaloğlu, 2020). The city has many policies and projects about both critical service sectors and micro-mobility and pedestrianization. İzmir has 30 districts, and Çiğli, Karşıyaka, Bayraklı, Bornova, Buca, Konak, Balçova, Gaziemir, Karabağlar, Narılıdere and Güzelbahçe are urban areas of the city (Figure 3).

Figure 3. Districts of İzmir

İzmir is a unique city with various strategies and policies focused on sustainable development strategies, resilience, and ecological approaches. The Izmir Metropolitan Municipality has implemented a new urban development strategy in response to the rapid urban growth and its associated ecological, social, and environmental changes. This strategy focuses on a series of projects aimed at addressing climate change (Tonyaloğlu, 2020). In addition, there are various thematic plans focusing on climate change adaptation and nature-based solutions: İzmir Green City Action Plan (İzmir Metropolitan Municipality, 2020a), A Framework for Resilient Cities To Climate Change: Green Revision Guidebook (Berberoğlu, Çilek and Ünlükaplan, 2019), İzmir's Strategy for Living in Harmony With Nature 2021-2030 (İzmir Metropolitan Municipality, 2022) and Izmir Sustainable Energy and Climate Action Plan, 2020 (İzmir Metropolitan Municipality, 2020b).

Additionally, İzmir Metropolitan Municipality has strategies and projects for various critical infrastructure sectors. For instance, the "Cittaslow Neighbourhoods" initiative aims to create neighbourhoods that are both pedestrian-friendly and supportive to a high quality of life. The Cittaslow Metropolis Project is a model developed in cooperation with the Cittaslow International Union and Izmir Metropolitan Municipality to promote the Cittaslow philosophy in metropolitan areas.[4] Sustainable Urban Mobility plan is another project in İzmir. SUMP Izmir takes a holistic approach to all modes of transportation, including pedestrian, cycling, public transport, vehicular traffic, rail and other mobility-related issues such as traffic safety, urban development, climate measures, air pollution, environmentally friendly drivers, new forms of mobility and digitalization[5]. Although the city has no official 15-minute city implementation, it has projects focus on sustainable mobility modes.

In figure 4, a 15-minute accessibility service area map for critical services is demonstrated. These services are public transportation stations, food markets, green areas and Wi-Fi points. As seen in the figure, Konak and Karşıyaka have the highest accessibility level to all critical services. Especially, public transportation stations which are metro and tramway stations are highly accessible in those areas. In this study, Karşıyaka is selected as case area because of its potential to 15-minute city concept and its dense population.

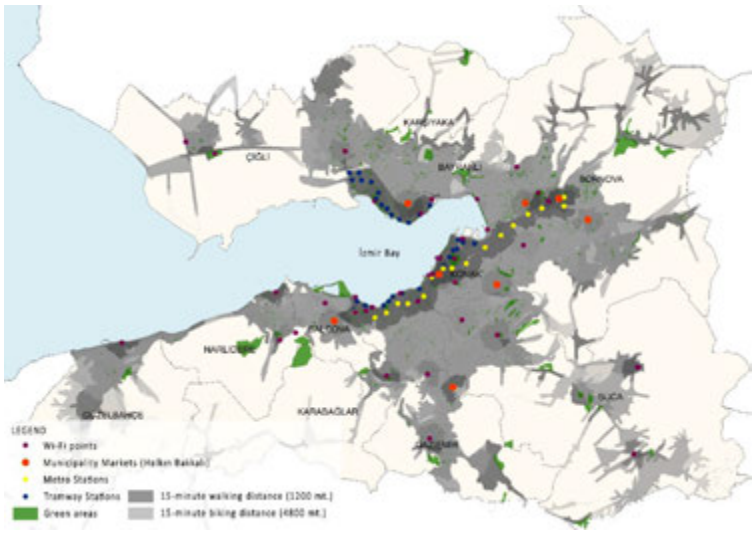

Figure 4. Green areas, metro, Wi-Fi points and tramway stations in 15-minute walking distance and biking distance (produced by authors)

Karşıyaka is located on the northern shore of Izmir Bay. The district has 341857 population, and it is the fourth district with highest population in İzmir. In Karşıyaka, the coastal road, suburban train line (Izban), Anadolu Street and İzmir Ring Road constitute the main transportation axes (Özgen and Türkseven Doğrusoy, 2020). It is

[4] https://cittaslowturkiye.org/tr/dunyanin-ilk-cittaslow-metropol-kenti-izmir/
[5] https://sumpizmir.org/#genel

observed that there are mostly residential areas in the urban structure developing between these axes (Özgen and Türkseven Doğrusoy, 2020). In Türkiye, there were a huge migration from rural to urban areas in 1950s. İzmir was also affected from this movement and urbanization rate increased in those years. As a result of this, the urban fabric in Karşıyaka also transformed, high-rise residential and commercial buildings were built instead of summer houses, the coastline was filled in and widened, the use of the sea was restricted due to sea pollution, and thus daily life changed and social life spread from the coastal area to the inland areas (Özgen and Türkseven Doğrusoy, 2020). Also, the settlement started to expand towards the north with increasing demands over time. Neighborhoods with poor quality and infrastructure problems have also become the main components of the region (Zengin Çelik and Çilingir, 2017). The district has become one of urban centres in İzmir. Easy and multi-modal transportation can be seen as one of the most important reasons for the district to create a dynamic and intense urban experience in daily life by increasing human circulation (Özgen and Türkseven Doğrusoy, 2020).

Considering these, transportation and green infrastructure are selected as critical sectors to figure out their accessibility within 15 minutes. These sectors involve publicly use services.

4. Method

The study has two parts. First, a comprehensive literature review is conducted to determine commonalities in critical urban infrastructure and the 15-minute city concept. Within the scope of this study, public transportation and green infrastructure are selected as critical sectors. Bus, tramway and İZBAN (suburban line) are analysed as public transportation stations, and parks and sport areas are analysed as green infrastructure.

This study examines the proximity component within the concept of the 15-minute city. This dimension involves to the length of travel and the accessibility to critical services. Given the objective of evaluating the accessibility of critical services within a 15-minute, the suitable dimension is proximity. Other three dimensions, density, diversity and digitalization, are not evaluated, but the case area involves them. Karşıyaka is one of high dense areas in terms of population and building. Also, it has become an attraction point in İzmir because it has various land uses such as commercial, education, health, green areas. Besides, there are some attempts for digitalization in İzmir in public transportation. These three dimensions support the research objective of the study, which is proximity. From this point of view, in the scope of the second part of this paper, the accessibility of critical infrastructure services in specific perimeters are investigated. The perimeters are based on various walking distances as 5, 10 and 15 minutes.

Various methodologies are applied throughout the accessibility analysis process. The ratio method, minimum distance model, Geographic Information System (GIS)-based spatial analysis, gravity model, and two-step floating catchment area method are common spatial accessibility methods (Song *et al.*, 2022). Network analysis in GIS refers to the examination of spatial networks, including transportation networks, utility networks, and social networks, using geographic information system (GIS) technology. Further techniques for network analysis comprise buffering and point-to-point straight-

line distance calculation. Nevertheless, these analyses oversimplify the evaluation of access by disregarding the consideration of actual access routes such as paths and roads, as well as obstacles like rivers and trains (Comber, Brunsdon and Green, 2008). In this study, GIS mapping tools and network analysis are used to generate the perimeters. Network studies have the capacity to provide answers to a diverse range of concerns regarding linear networks, including roads, railways, rivers, facilities and utilities. This method of geographical analysis involves calculating the distances between locations or nodes on a network by using network data, which often consists of linear features like roads and footpaths (Comber, Brunsdon and Green, 2008). Walking speed varies according to physical characteristics of people (i.e. age) and geographical characteristics of the area (i.e. slope and climate). Nevertheless, these characteristics are not included in this study. In the study, walking distance is assumed to be ¾ mile or 1200 meters in 15 minutes and cycling distance is assumed to be 3 miles or 4800 meters in 15 minutes (Duany and Steuteville, 2021). 5- and 10-minutes walking distances are 400 meters and 800 meters. Public transportation and green areas are important in well-being of people in their daily life or during emergency situations. Therefore, it is valuable to investigate different accessibility times to make contribution to spatial plans and decisions.

As mentioned in Fazio and others' (2023) study the use of open data can have a determinant impact in situations when resources are limited. Hence, main data source of this study is Open Street Map and İzmir Metropolitan Municipality. Data consists of the location of active green spaces metro, tramway, bus station points, and roads. İzmir Metropolitan Municipality (IMM) provides green spaces data. Public transportation stations are provided by open source of IMM. Public transportation stations are obtained from the application where the IMM shares some spatial data as open source. Roads, forests, building data are from Open Street Map. The network analysis of 5,10,15-minute periphery is based on transportation stations and green spaces as starting points.

5. Results and Discussion

In this study, the accessibility of critical infrastructure of İzmir is measured. Bus stations, metro stations, tramway stations and active green areas have been investigated by service area analysis in network analysis. Figure 5 demonstrates location of green areas (parks and sport, recreation areas, forests) and public transportation stations. Forests and recreations areas are mainly located in north side of the area, which is less dense than south part. Analyses are conducted in highly dense urban area, which is southern part of the area.

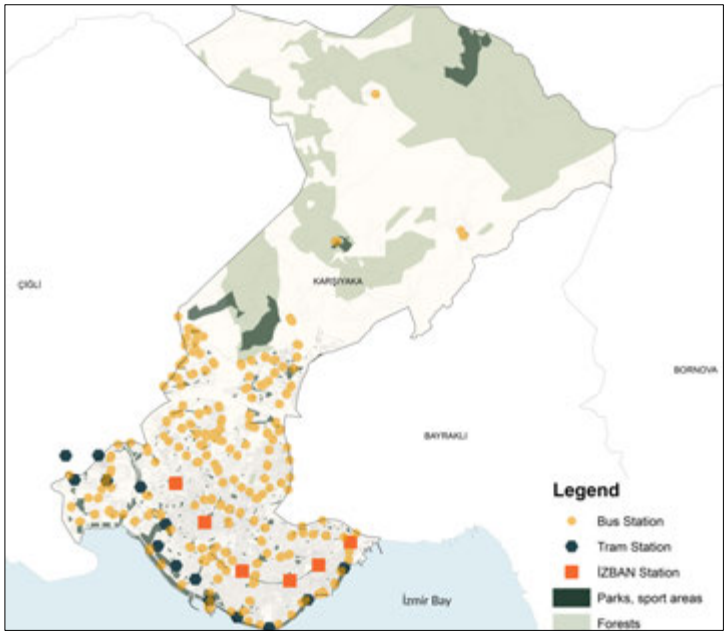

Figure 5. Locations of Green Areas and Public Transportation Stations

The first network analysis is conducted to measure green areas accessibility. In the study actively used green areas are analysed, which are parks and sport areas in 5,10, 15-minute periphery (Figure 6). As seen in the map, parks and sport areas are highly accessible in the area by walking. Most of parks and sport area are accessible in 5-minute walking distance. However, when comparing north and south parts of the area, neighbourhoods in the north have less parks and sport areas and accessibility to them. As seen in the map, shoreline has a huge potential of green areas. There is a green axis along the coast, and it serves as both parks or recreation areas and pedestrian axis. Because of uninterrupted green axis throughout the shoreline, capacity of accessibility of green areas is very high there.

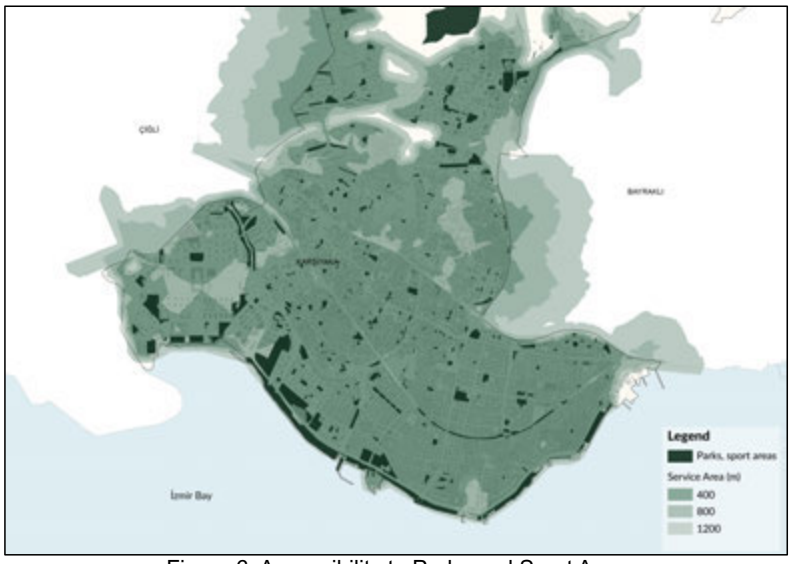

Figure 6. Accessibility to Parks and Sport Area

Compared to tram and İZBAN stations, number of bus stations is higher in the area. However as seen figure 7, they are accessible in 15 minutes, but 5-minute service is not sufficient. Some parts of the area are not served by bus station in 5-minute walking perimeter. Accessibility to bus stations is crucial in the area because public transportation is highly dependent on buses especially in inner sides.

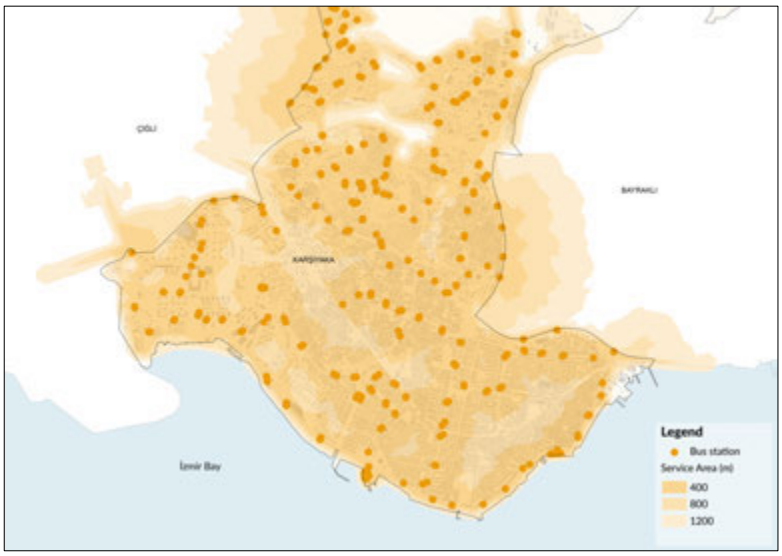

Figure 7. Accessibility to bus stations

Figure 9 demonstrates accessibility to İZBAN stations. İZBAN is a suburban line which connects the area with other parts of İzmir, therefore, accessibility to it is very important. The line connects the rural districts with urban (Figure 8). However, it serves a very limited area within walking distance. The coastal area of İzmir Bay has the most accessibility to both İZBAN and tramway stations. Those stations are accessible in 15-minute walking distance generally. Tramway stop serves along the coast north of the bay, so accessibility of them generally concentrated in these areas. (Figure 10).

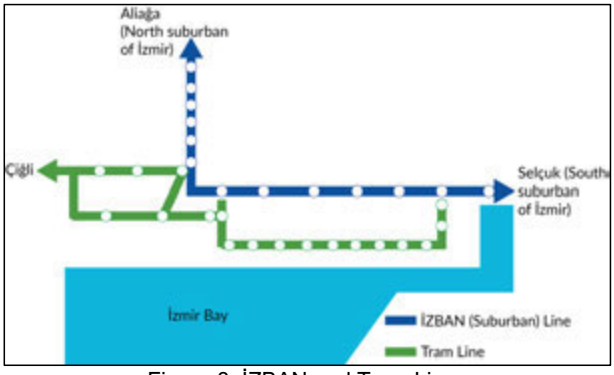

Figure 8. İZBAN and Tram Lines

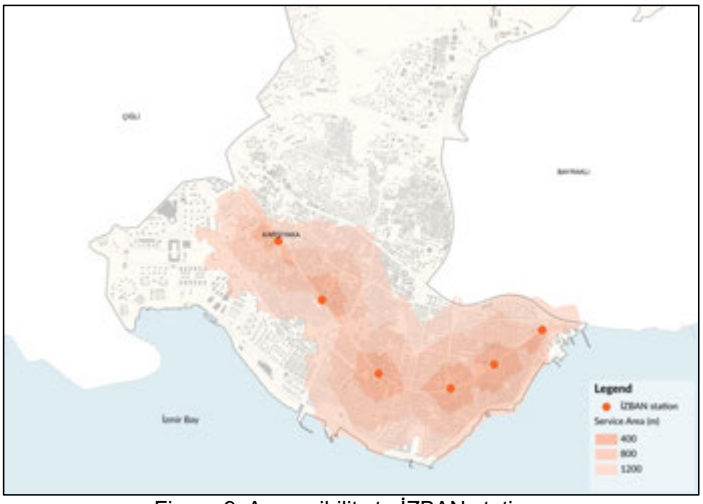

Figure 9. Accessibility to İZBAN stations

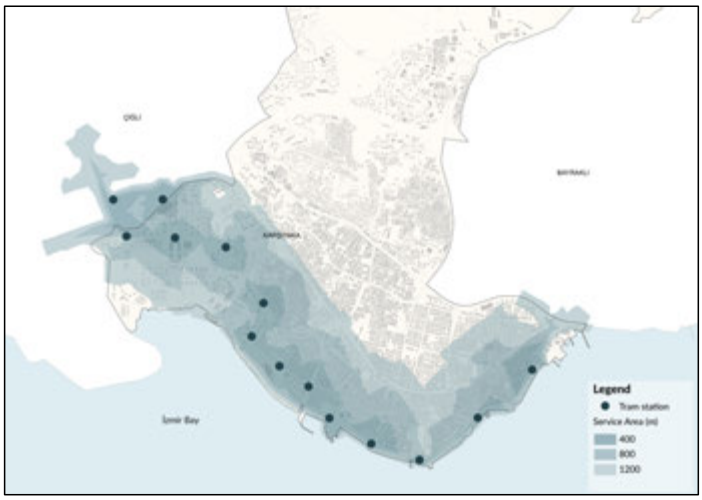

Figure 10. Accessibility and tramway stations

Figure 11 demonstrates all public transportation modes' accessibility in 5, 10, 15-minute walking distance. Coastal areas have the most accessibility for all modes of public transportation. The main reason for this is to be commercial centre of the city, and many commercial and business locates there.

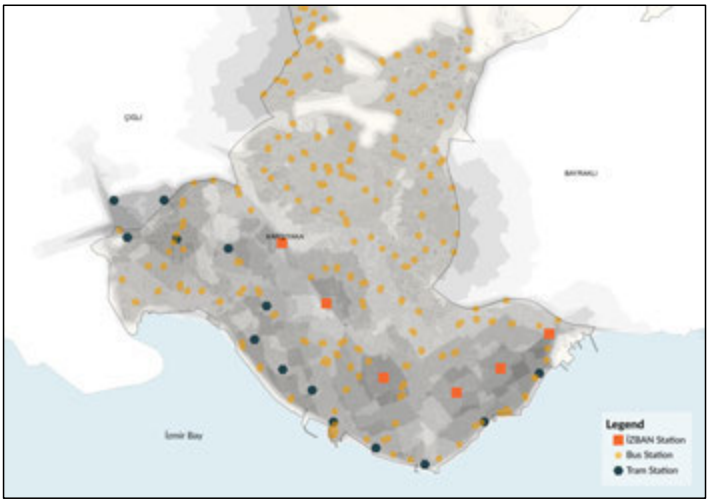

Figure 11. Accessibility to public transportation stations

Green areas and public transportation are evaluated as critical services in İzmir within the context of this study. Therefore, they need to be accessible to all. Steele and others (2017) identify criticality regarding the links between people and environments and their equality. Therefore, the study investigates the fair distribution of critical infrastructure in İzmir.

As seen in results, most of public transportation modes are in southern and coastal parts of Karşıyaka. Although, distribution of bus stations serves most of Karşıyaka district, people live in southern part have more alternatives of public transportation. Therefore, it can be said that distribution of public transportation stations is not balanced in Karşıyaka district.

6. Conclusion

Critical urban infrastructures have services sectors to ensure well-being and resilience of communities, and 15-minute cities consist of essential services accessible in 15 minutes. Critical services such as transportation, food, health, etc. should be considered in terms of accessibility. They are needed to be accessible for all within walking distance to provide resilient and fair cities. According to review on 15-minute city and critical infrastructure literature and İzmir, green areas and public transportation stations are evaluated within scope of this study.

Different approaches to critical infrastructures are necessary for more resilient and sustainable cities. While critical infrastructure studies primarily focus on technical infrastructures, it is equally necessary to include social and ecological critical sectors in cities. Reaching critical services such as education, health green spaces is necessary for quality of life of citizens. Besides, it is vital to access those services during crisis. 15-minute city concept mainly focuses on accessible to services to minimize vehicular transportation demand. However, it is also valuable considering crisis situations such as restriction in pandemics, or emergent safe places after earthquakes. Thus, critical infrastructure and 15-minute city concepts may complement each other. Also, the study of critical infrastructure on a neighbourhood scale is an important contribution to the literature because it is handled in national documents generally.

The city of İzmir does not implement the 15-minute city concept. However, this study aims to evaluate the potential to apply this concept in terms of critical services Karşıyaka. Besides, it aims to assess critical urban services in the 5, 10, 15-minute periphery by walking. Distribution of public transportation stations and parks and sport areas are evaluated. In results, especially the centre parts of Karşıyaka have accessibility in 5 and 10-minutes accessibility by walking or biking. In Karşıyaka, there is a potential to implement critical urban infrastructures in a 15-minute city concept, according to the results. However, the distribution of critical services should be more equitable through walking and biking especially in the outer ring.

The study has limitations. Firstly, geographical information such as slope is not considered, but it affects the ability and travel time of walking and biking. Also, walking infrastructure should be taken considered because there may be obstacles due to insufficient walking infrastructures. In addition, inclusive urban settings necessitate the consideration of a diverse priorities, including healthcare, education, job, and cultural and recreational amenities, during the urban planning process (Guzman, Oviedo and Cantillo-Garcia, 2024). Personal preferences are lack in the study. However, it is important to survey people their thought about accessibility to services by walking or biking.

Research on Carbon Accounting Methods for Urban Areas Based on Spatial Data Utilization

Abstract: As climate change becomes a significant global threat, the pursuit of carbon peak and carbon neutrality is now essential for urban development in China. Carbon accounting is a crucial technical tool for monitoring urban carbon emissions and guiding low-carbon urban construction. This study, which focuses on urban built-up areas, integrates carbon accounting methods with urban spatial elements, significantly aiding the achievement of 'dual carbon' development goals in cities. Using Harbin City, Heilongjiang Province as a case study, this paper summarizes and analyzes fifteen years of data on energy and spatial usage to develop a carbon accounting system for urban built-up areas. Additionally, it formulates a carbon accounting method for urban built-up areas based on spatial usage, and validates its accuracy by comparing the results with those from energy usage carbon accounting. Based on these findings, the study proposes pathways for predicting urban carbon neutrality and specialized assessments for low-carbon construction, thus supporting the 'carbon neutrality' goals in national spatial planning.

Keywords: Carbon Neutrality Goals; Built-Up Area; Spatial Usage Activity Data; Carbon Accounting; Application Pathways

1. Introduction

To address global climate change risks, China announced at the 75th United Nations General Assembly its commitment to reach carbon peak by 2030 and achieve carbon neutrality by 2060. Cities, as hubs of human activity, are major contributors to high energy consumption and carbon emissions, accounting for over 80% of global greenhouse gas emissions (Lynn and Peeva, 2021a, Dhakal, 2009a). Research indicates that strategically arranging and coordinating urban spaces effectively reduces regional carbon emissions (Li *et al.*, 2022a, Newman and Kenworthy, 1998). Therefore, developing a low-carbon, sustainable urban strategy is crucial for achieving carbon neutrality goals.

With the complete implementation of national land and spatial planning, supporting carbon neutrality goals and fostering urban low-carbon development have become key objectives in urban construction (Xiong *et al.*, 2021b, Zheng *et al.*, 2022b). Currently, urban carbon accounting methods are crucial technical tools in low-carbon urban planning research (Ye, 2009b, Zheng *et al.*, 2021c, Chen *et al.*, 2022c). However, current carbon accounting methods face challenges such as poor integration with spatial elements, and their scope often misaligns with the national land and spatial master plans at the central city level. To enhance the role of urban carbon accounting in supporting land and spatial planning, this study develops a built-up area carbon accounting system based on space use activities, following the "accounting system - benchmark formulation - method construction - result verification" framework. Harbin City is used as a case study to validate the method's accuracy. Building on this, the study proposes an application pathway for this carbon accounting method in territorial spatial planning.

Currently, urban carbon accounting is categorized into production-based methods (PBA), which utilize energy use data, and consumption-based methods (CBA), which rely on economic input and output data (Peters, 2008, Guan *et al.*, Wiedmann, 2009c). The "IPCC National Greenhouse Gas Inventory" is a production-based carbon accounting model developed by the Intergovernmental Panel on Climate Change, established by the World Meteorological Organization and the United Nations Environment Program. It is an important tool for countries and cities around

the world to establish greenhouse gas emissions. The more authoritative approach to the inventory process (Chen, 2011). This method categorizes regional carbon emissions into four sectors: energy activities, industrial processes, agriculture and forestry, and waste disposal. Energy activity data is used to calculate the carbon emissions of each sector and summarize them step by step, and finally calculates regional greenhouses. Gas emissions. Its global use in climate monitoring has led many cities and regions to adopt this model for calculating urban carbon emissions and compiling greenhouse gas inventories. Urban policymakers and researchers can use these accounting results to assess the impacts of energy use changes on carbon emissions and monitor shifts in the city's emission structure. Therefore, this method has become the most commonly used urban carbon accounting technology in the field of urban planning (Steininger *et al.*, 2014a, Lin and Sun, 2010, Chen *et al.*). Despite its advantages, the integration of energy-based carbon accounting with urban spatial elements is poor, negatively affecting urban planning due to low correlation between results and spatial factors. Insufficient feedback, interaction and support (Zheng *et al.*, 2021c, Xu *et al.*, 2022d, Chen *et al.*, 2022c).

Enhancing the correlation between carbon accounting results and urban spatial elements has emerged as a crucial research direction (Su *et al.*, 2014b). Scholars have utilized nighttime light data to analyze the temporal evolution and spatial distribution of urban carbon emissions, initially establishing a coupling relationship with urban spatial elements (Meng *et al.*, 2017, Shi *et al.*, 2016, Lv *et al.*, 2020, Ao *et al.*, 2022e). In-depth research into the emission reduction mechanisms of urban and rural spatial development has led to the establishment of a "land use-carbon emission" correlation framework, based on classifications, inventory divisions, and emission reduction paths. This approach has been applied in cities like Beijing and Shanghai, with urban elements as core components of the carbon accounting method (Jiang *et al.*, 2013a, Ju, 2013b, Li and Ren, 2019). Currently, the urban spatial elements used in research are relatively simple, primarily involving data on land use scales and average activity levels, with some key activity data being difficult to obtain. Scholars have proposed a universal carbon accounting method for urban spaces that uses the national greenhouse gas inventory framework to integrate energy consumption data with urban land use, establishing a research framework focused on industry, construction, transportation, and carbon sinks (Wang and He, 2015, Xu *et al.*, 2022d). Building on this, scholars have developed a carbon assessment framework for municipal master plans that incorporates all natural resource elements, using Wuhan as a case study for validation (Luo *et al.*, 2023). Currently, there has been progress in developing carbon accounting methods for urban spaces, although these methods typically focus on entire cities and account for all urban space elements' carbon emissions. This approach is particularly effective in urban areas characterized by extensive construction and high development intensity. However, this method often yields inaccurate results for cities dependent on agriculture and mineral resources, failing to accurately reflect their development and construction levels. Additionally, this method provides limited guidance for comprehensive land and spatial planning at the central urban level.

In summary, the prevalent method of urban carbon accounting based on energy data is widely utilized. However, its integration with spatial elements is inadequate, and its results provide limited support for spatial planning. In urban planning, considerable research has focused on refining carbon accounting systems for urban spatial elements. Yet, the scope of most studies does not align with central city planning, leading to significant discrepancies in the accounting results for resource-dependent cities and limited feedback on spatial changes in urban areas. Consequently, it is crucial to develop an urban carbon accounting method that aligns with municipal planning scopes and focuses on urban spatial activity elements.

2. Methodology

2.1 Establishing a carbon accounting system for urban built-up areas

To improve compatibility and support between urban carbon accounting results and central urban master planning, a universal carbon accounting method for urban built-up areas needs to be established. During this process, a carbon accounting system tailored for urban built-up areas should be established, utilizing energy activity data to calculate their carbon emissions. This establishes benchmark data and lays the groundwork for the methods detailed in subsequent sections. This system will also set standards to validate the results.

The "IPCC National Greenhouse Gas Inventory" is the principal method for preparing greenhouse gas emission inventories globally, recognized for its high authority and scientific rigor. As a method for carbon emission accounting across municipalities and larger regions, this approach provides a comprehensive and generalized division of accounting categories. However, within the smaller scope of urban built-up areas, this method includes carbon emissions from non-built-up sectors like agriculture and forestry in the energy and waste treatment calculations, complicating data acquisition. This study adapts the carbon accounting framework from the "IPCC National Greenhouse Gas Inventory". It reclassifies carbon emission categories to suit the specific characteristics and research requirements of urban built-up areas, as shown in Figure 1. The changes in accounting scope mean that the carbon accounting system for urban built-up areas differs from the IPCC guidelines. Specifically, carbon emissions from electricity in urban built-up areas are allocated to the electricity use processes across different sectors. To prevent double counting, it excludes carbon emissions from electricity production in industrial and mining sectors. Additionally, as urban built-up areas exclude agricultural land, agricultural carbon emissions are omitted from the accounting. This adaptation links the urban built-up area carbon accounting system with the "IPCC National Greenhouse Gas Inventory", setting the stage for further development of carbon accounting methods.

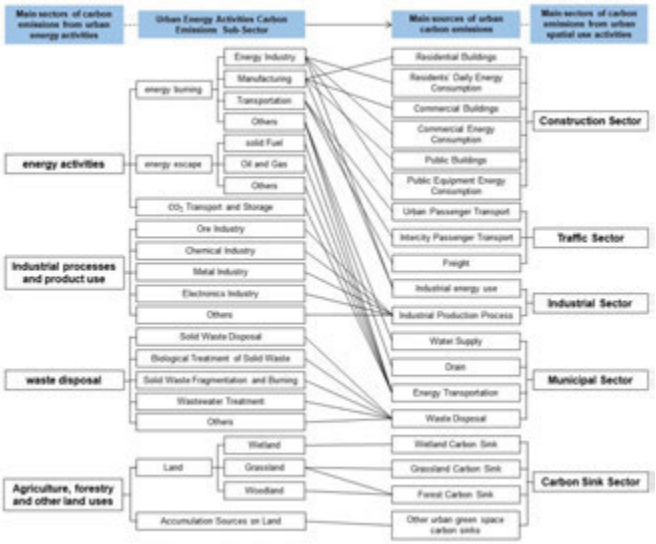

Figure 1 Carbon accounting system for urban built-up areas

2.2 Developing benchmark data for carbon accounting in urban built-up areas based on energy activity data

To establish accurate benchmark data for verifying carbon emissions in urban built-up areas, detailed calculations for each emission category should be performed using the most commonly used energy activity data. Changes in accounting entities necessitate adjustments to the specific accounting processes. Consequently, this study employs the IPCC model within the urban built-up area accounting system to calculate carbon emissions across various sectors, thereby developing an energy data-oriented carbon accounting method for urban built-up areas, as detailed in Table 1. Using this method, energy activity data for urban built-up areas is sourced from resources like the Urban Statistical Yearbook and the Urban Energy Statistical Yearbook. Furthermore, using energy conversion tables, challenging-to-calculate energy data (like raw coal, coke, gasoline, diesel) are converted into standard coal equivalents. Building on this, carbon emission coefficients for electricity, standard coal, and other energies are derived from provincial and national greenhouse gas inventory guidelines, leading to the development of a carbon accounting method tailored for urban built-up areas.

Table 1 Carbon accounting method for urban built-up areas based on energy activity data

Sectors	City Energy Activity Data	Data Related to Carbon Emission Calculations	Data Sources	Calculation Method
Construction Sector	residential electricity consumption of urban residents, electricity consumption in commercial and service industries, gas consumption in residential and service industries, energy consumption in the construction process of new buildings, and energy consumption in maintenance of old buildings	electricity carbon emission coefficient, natural gas carbon emission coefficient, liquefied petroleum gas carbon emission coefficient, unit standard coal energy consumption carbon emission coefficient	City Statistical Yearbook, City Energy Statistical Yearbook, Provincial Greenhouse Gas Inventory Preparation Guide, National Greenhouse Gas Inventory Guide	$C_b^c = \sum E_{electricity}^i \times f_{electricity} + \sum E_{gas}^i \times k_{gas}^{tce} \times f_{tce} + \sum E_{LPG}^i \times k_{LPG}^{tce} \times f_{tce} + \left(E_{tce}^{construction} + E_{tce}^{maintenance}\right) \times f_{tce}$
Industrial and Mining Sector	in addition to electricity production, energy used in industrial production (including raw coal, coke, natural gas, gasoline, crude oil, kerosene, diesel, and electricity)	standard coal conversion coefficient for various types of energy and carbon emission coefficient of energy consumption per unit of standard coal	City Energy Statistical Yearbook, Standard Coal Conversion Reference Coefficient Table for Various Energy Resources, National Greenhouse Gas Inventory Guide	$C_i^c = \sum E_i^{industry} \times k_i^{tce} \times f_{tce}$

Municipal Sector	public utility electricity consumption, domestic waste treatment capacity, domestic sewage treatment capacity, heating steam heat, heating hot water heat	electricity carbon emission coefficient, unit waste treatment electricity consumption, unit sewage treatment electricity consumption, thermal energy conversion coefficient to standard coal, unit standard coal energy consumption carbon emission coefficient	City Statistical Yearbook, City Energy Statistical Yearbook, Various Energy Standard Coal Conversion Reference Coefficients Table, Provincial Greenhouse Gas Inventory Preparation Guide, National Greenhouse Gas Inventory Guide	$C_m^c = E_{electricity}^{public\ utilities} \times f_{electricity} + \left(V_{waste} \times k_{waste}^{electricity} + V_{sewage} \times k_{sewage}^{electricity}\right) \times f_{electricity} + \left(V_{steam}^{central\ heating} + V_{hot\ water}^{central\ heating}\right) \times k_{heat}^{tce} \times f_{tce}$
Traffic Sector	transportation electricity consumption, transportation gasoline amount, transportation diesel amount, transportation kerosene amount, transportation natural gas amount	standard coal conversion coefficient for various types of energy and carbon emission coefficient of energy consumption per unit of standard coal	City Statistical Yearbook, City Energy Statistical Yearbook, Various Energy Standard Coal Conversion Reference Coefficients Table, Provincial Greenhouse Gas Inventory Preparation Guide, National Greenhouse Gas Inventory Guide	$C_t^c = \sum E_i^{traffic} \times k_i^{tce} \times f_{tce}$
Carbon Sink Sector	woodland, grassland, wetland, urban green space area, water area	carbon sequestration coefficients of woodlands, grasslands, wetlands, urban green spaces, and water bodies	City Statistical Yearbook, Provincial Greenhouse Gas Inventory Compilation Guide	$C_s^c = \sum A_i \times c_i$

C_b^c is the building sector's carbon emissions; $E_{electricity}^i$ is electricity consumption of class i buildings, i is various urban land building types, including residential buildings, commercial buildings, and public service buildings; $f_{electricity}$ is the carbon emission coefficient per unit of electricity use; E_{gas}^i is the amount of natural gas used in class i buildings; k_{gas}^{tce} is the unit natural gas conversion standard coal coefficient; f_{tce} is the carbon emission coefficient per unit of standard coal; E_{LPG}^i is the amount of liquefied petroleum gas used in type i buildings; k_{LPG}^{tce} is the liquefied petroleum gas conversion coefficient to standard coal; $E_{tce}^{construction}$ is the standard coal usage converted from energy in the construction process of new buildings; $E_{tce}^{maintenance}$ is the energy−converted standard coal usage in the maintenance process of old buildings; C_i^c is the carbon emissions of the industrial and

mining sector; $E_i^{industry}$ is the energy usage of category i in industrial production processes above regulations except for electricity production. i represents various energy types, including raw coal, coke, natural gas, gasoline, crude oil, kerosene, diesel, electricity, etc.; k_i^{tce} is the standard coal conversion coefficient of type i energy; C_m^c is the carbon emissions of the municipal sector; $E_{electricity}^{public\ utilities}$ is the electricity consumption of public utilities; V_{waste} is the amount of solid waste discharge; $k_{waste}^{electricity}$ is the electricity consumption per unit of solid waste treatment; V_{sewage} is the amount of sewage discharge; $k_{sewage}^{electricity}$ is the electricity consumption per unit of sewage treatment; $V_{steam}^{central\ heating}$ is the central heating steam usage; $V_{hot\ water}^{central\ heating}$ is the usage of central heating hot water; k_{heat}^{tce} is the coefficient of conversion of unit thermal value to standard coal; C_t^c is the carbon emissions of the transportation sector; $E_i^{traffic}$ is the energy usage of category i in the transportation sector, where i represents each energy type, including raw natural gas, gasoline, kerosene, diesel, electricity, etc.; C_s^c is the carbon absorption amount of the carbon sink department; A_i is the area of type i land, and i represents various types of land that can provide carbon sinks, including woodland, grassland, wetland, urban green space, and water area; c_i is the carbon sink coefficient of various land uses;

2.3 Establishing an urban built-up area accounting method oriented to space use activity data

To strengthen the integration of carbon accounting methods with urban spatial elements, we investigated how to extract human activity and space use data within urban built-up areas. Using the urban built-up area carbon accounting framework that relies on energy data, we replaced energy use data in each department with space use activity data, establishing a new carbon accounting method centered on urban spatial elements.

Using the urban built-up area carbon accounting system, this study calculates carbon emissions for each sub-sector using urban space use activity data, and develops a spatial activity data-oriented accounting method, as detailed in Table 2. In this method, basic urban space and space use activity data are sourced from planning documents, texts, and statistical yearbooks, while data on the average annual travel distance of private cars is derived from urban traffic surveys or questionnaires. This provides a method to obtain necessary data. Compared to energy data-based methods, this approach reduces reliance on energy data for carbon accounting in urban built-up areas, utilizing spatial activity data to produce more timely results. Additionally, the results clearly illustrate the impact of changes in urban spatial development and activities on carbon emissions, supporting low-carbon urban spatial planning.

Table 2 Carbon accounting method for urban built-up areas based on space utilization activity data

Sectors	Urban spatial basic data	Space utilization activity data	Data related to carbon emission calculations	Data sources	Calculation method
Construction Sector	residential building area, commercial service facility land area, public management and public service land area, new building area	residential vacancy rate	residential energy consumption coefficient per unit building area, energy consumption coefficient for commercial and service facilities per unit land area, energy consumption coefficient during	provincial energy statistical yearbook, city statistical yearbook, standard coal conversion reference coefficient table for various energy sources,	$C_b^c = \left(S_{residence} \times r_{vacancy\ rate} \times k_{residence}^{tce} + \sum A_i \times k_i^{tce} + S_{new} \times k_{new}^{tce}\right) \times f_{tce}$

			construction process per unit building area, and carbon emission coefficient for energy consumption per unit standard coal	national greenhouse gas inventory guide	
Industrial and Mining Sector	industrial and mining storage land area	average industrial output value	energy consumption per unit of industrial GDP, carbon emission coefficient of energy consumption per unit of standard coal	Provincial Energy Statistical Yearbook, City Statistical Yearbook, National Greenhouse Gas Inventory Guide	$C_i^c = A_m \times p_m \times k_m^{tce} \times f_{tce}$
Municipal Sector	heating building area, water supply pipeline length	population, per capita garbage collection volume, harmless garbage treatment rate, per capita sewage discharge	energy consumption per unit of garbage removal, energy consumption per unit sewage treatment, electricity consumption per unit length of pipeline water transportation, energy consumption per unit heating area, carbon emission coefficient of unit standard coal energy consumption, electricity carbon emission coefficient	Provincial Energy Statistical Yearbook, City Statistical Yearbook, City Energy Statistical Yearbook, Provincial Greenhouse Gas Inventory Preparation Guide, National Greenhouse Gas Inventory Guide	$C_m^c = L_{water} \times j_{water}^{electricity} \times f_{electricity} + (P \times \mu_{waste} \times r_{harmless} \times k_{waste}^{tce} + P \times \mu_{sewage} \times k_{sewage}^{tce} + S_{heating} \times j_{heating}^{tce}) \times f_{tce}$

Traffic Sector	average annual travel distance of private cars, total freight distance, and total passenger distance	number of private cars, electrification rate of residents' travel, total freight volume, total passenger trips	energy consumption per unit turnover, electricity consumption per unit travel distance, electricity consumption per unit travel distance of new energy vehicles, energy consumption of fuel vehicles per unit travel distance	Urban Traffic Survey Report, Urban Statistical Yearbook, Urban Energy Statistical Yearbook, Provincial Greenhouse Gas Inventory Preparation Guide, National Greenhouse Gas Inventory Guide	$C_t^c = L_{private\ car} \times C_{private\ car} \times r_{electrical} \times j_{new\ energy}^{electricity} \times f_{electricity} + L_{private\ car} \times C_{private\ car} \times (1 - r_{electrical}) \times j_{fuel}^{tce} \times f_{tce} + \sum L_i \times T_i \times k_{turnover}^{tce} \times f_{tce}$
Carbon Sink Sector	woodland, grassland, wetland, urban green space area, water area	—	carbon sequestration coefficients of woodlands, grasslands, wetlands, urban green spaces, and water bodies	City Statistical Yearbook, Provincial Greenhouse Gas Inventory Compilation Guide	$C_s^c = \sum A_i \times c_i$

C_b^c is the carbon emissions of the construction sector; $S_{residence}$ is the residential building area; $r_{vacancy\ rate}$ is the residential vacancy rate; $k_{residence}^{tce}$ is the energy consumption per unit residential building area (converted in standard coal); A_i is the area of type i urban land, including land for commercial service industry facilities, public management and public services; k_i^{tce} is the energy consumption per unit area of type i land (converted in standard coal); S_{new} is the new building area; k_{new}^{tce} is the energy consumption per unit of new building area (converted in standard coal); f_{tce} is the carbon emission coefficient per unit of standard coal; C_i^c is the carbon emissions of the industrial and mining sector; A_m is the area of industrial and mining land; p_m is the average industrial output value; k_m^{tce} is the energy consumption per unit of industrial GDP; C_m^c is the carbon emissions of the municipal department; L_{water} is the length of the water supply pipeline; $j_{water}^{electricity}$ is the electricity consumption per unit water supply distance; $f_{electricity}$ is the carbon emission coefficient per unit electricity consumption; P is the population; μ_{waste} is the average garbage removal volume; $r_{harmless}$ is the harmless garbage chemical treatment rate; $k_{waste}^{electricity}$ is the energy consumption for harmless treatment of garbage; μ_{sewage} is the per capita sewage discharge; k_{sewage}^{tce} is the unit sewage treatment energy consumption; $S_{heating}$ is the central heating building area; $j_{heating}^{tce}$ is the energy consumption per unit heating area; C_t^c is the carbon emissions of the transportation sector; $L_{private\ car}$ is the average annual driving distance of private cars; $C_{private\ car}$ is the number of private cars; $r_{electrical}$ is the electrification rate of private cars; $j_{new\ energy}^{electricity}$ is the electricity consumption of new energy vehicles per unit travel distance; $f_{electricity}$ is the unit electricity consumption carbon emission coefficient; j_{fuel}^{tce} is the energy consumption of fuel vehicles per unit travel distance (converted to standard coal); L_i is the transportation distance of type i, i represents the type of transportation, including passenger transportation and freight; T_i is the transportation volume of type i, among them, freight is the freight volume, and passenger transportation is the converted passenger volume; $k_{turnover}^{tce}$ is the unit turnover energy consumption; C_s^c is the carbon absorption amount of the carbon sink department; A_i is the I type land area, and i represents the various types of land that can be provided the types of land used for carbon sinks include woodland, grassland, wetland, urban green space, and

water bodies; c_i is the carbon sink coefficient of various land uses;

3. Case study

Based on the carbon accounting method described earlier, this study calculates carbon emissions for various sectors in Harbin's built-up areas from 2007 to 2021 using energy activity data, establishing this as benchmark data (see Figure 2). The accounting results indicate that total carbon emissions in Harbin's built-up areas have generally increased. Specifically, the industrial and mining sector, which contributes over 50% of the emissions, displays a fluctuating but overall upward trend. However, as urban development and industrial transformation progress, its share of total emissions has gradually declined. In contrast, the transportation sector is the only one showing a downward trend in emissions. This decline is attributed to the growing electrification of transportation, leading to a decrease in gasoline and diesel use and an increase in electricity consumption each year. Due to the lower carbon emission coefficient of electricity compared to other fossil fuels, emissions from this source are decreasing. The carbon accounting results from energy data clearly illustrate changes in emissions within the urban built-up area and accurately analyze the impact of energy use changes on these emissions. These results have gained broad recognition in the academic community. Using these calculation results as benchmark data provides solid support for verifying accuracy in subsequent analyses.

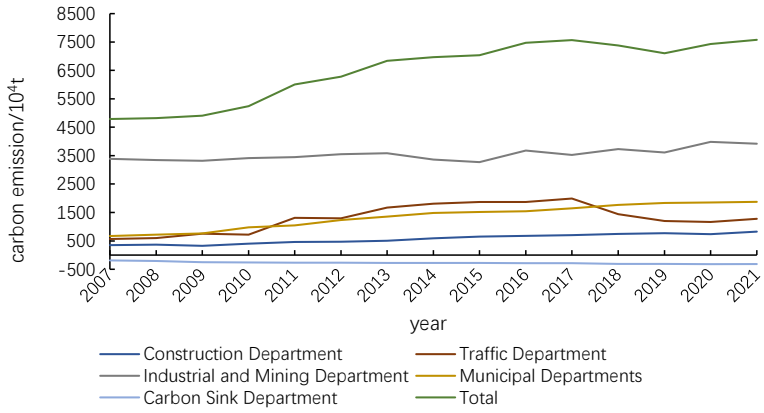

Figure 2 Harbin built-up area carbon accounting benchmark data for energy activity data

Utilizing the space use activity carbon accounting method, we analyzed statistical yearbooks and traffic survey reports to gather basic spatial and activity data for Harbin. We then calculated total and departmental carbon emissions in built-up areas. These results were compared with those from energy use activities, as detailed in Figure 3. The overall accounting results closely align with those derived from energy data. Specifically, the construction sector shows similar trends in both sets of data, though there are some differences in the values. The transportation department's accounting results from 2012 to 2017 show significant differences, primarily due to estimations based on per capita travel expenditure and survey data, leading to substantial discrepancies. For other years, data from urban traffic surveys provide more accurate results, resulting in minimal discrepancies in the accounting.

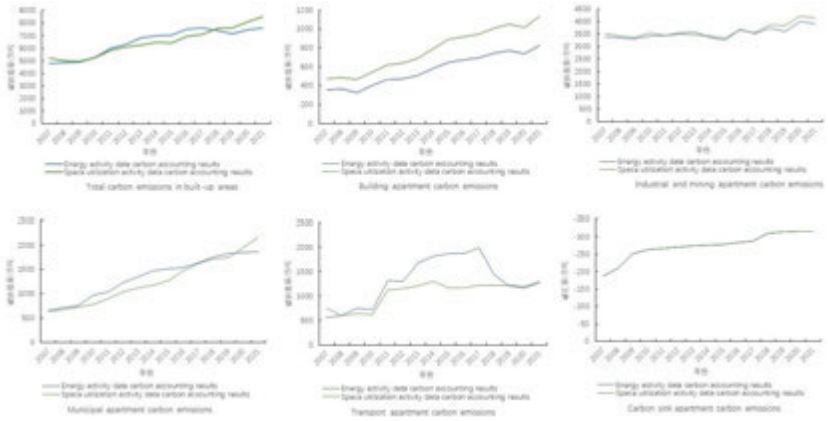

Figure 3 Comparison chart of dual method calculation results

To scientifically validate the accuracy of the carbon accounting method for space activities, we employed regression analysis to compare the results of space use activities with those from energy activities. The findings are presented in Figure 4 and Table 3. The verification indicates a high correlation of 99.2% between the two methods, with a standard error of 256.7, suggesting significant model reliability. These results confirm the high accuracy of the carbon accounting for space use activities, with minimal discrepancies compared to energy use results, demonstrating practical application value.

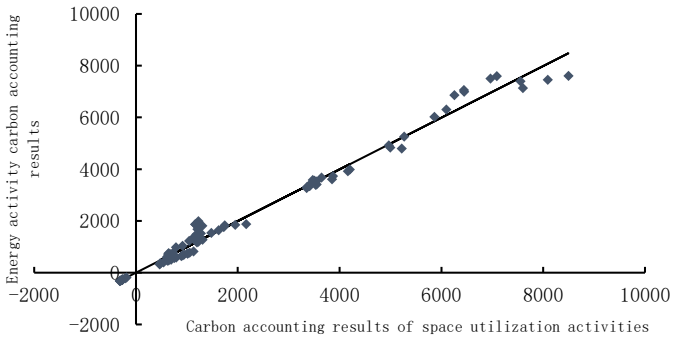

Figure 4 Dual method accuracy verification results

Table 3 Regression model statistics table

R	R^2	Adjusted R^2	Standard Deviation	Significance
.996	.992	.992	256.697	0.000

Unlike the energy-based method, the carbon accounting method for space use activities calculates emissions within built-up areas based on the city's spatial characteristics. In particular, the construction sector's results are heavily influenced by the accuracy of data on building vacancy rates and energy consumption per unit area. Accurate statistics ensure that carbon accounting for space use activities aligns closely with energy-based results. In the transportation sector, the accuracy of private car travel data significantly influences accounting results. However, statistical

yearbooks rarely contain official data on this. This data must be compiled from urban traffic surveys or questionnaires, potentially introducing errors. For other sectors, data from statistical yearbooks and greenhouse gas inventories ensure highly accurate accounting results. Overall, the results from the space use activity method are numerically close to those from energy methods, with simpler data acquisition and broad applicability. Additionally, this method's close link to urban spatial elements allows for real-time adjustments to the accounting results based on spatial changes, enhancing its flexibility and scalability. In summary, developing a carbon accounting method based on space usage activity data is crucial for achieving dual carbon goals and supporting the creation of low-carbon cities through land spatial planning.

4. application path

As the carbon accounting method for urban built-up areas, based on space use activity data, is refined, it can be integrated into the preparation, monitoring, and evaluation phases of the central city's national land and space master plan. During the planning phase, this method can predict the carbon reduction potential of development plans and support decision-making in building low-carbon cities. In the monitoring and evaluation phase, this method enables the establishment of low-carbon city evaluation indicators, facilitating the use of scientific and technological approaches to assess low-carbon city development.

Urban carbon emission prediction is a crucial technical tool for guiding low-carbon city construction and forecasting urban development trajectories. Current methods generally use data on urban population, energy consumption, and economic growth to simulate and forecast city-wide carbon emission changes. However, these data can be difficult to acquire, often show weak correlation with urban spatial elements, and do not allow for periodic adjustments based on urban development. As carbon accounting for urban built-up areas expands to include spatial usage data, a time series prediction model using neural networks can be developed to estimate emissions more precisely. This model integrates closely with spatial usage activities in urban built-up areas, enhancing its relevance and accuracy. It enables real-time predictions of carbon emissions based on changes in land use and urban spatial planning, clearly demonstrating the impact of these strategies on carbon reduction. Additionally, the model incorporates multi-scenario simulation and prediction to evaluate different urban development scenarios—baseline, low-carbon, and high-carbon—and to establish respective carbon emission forecasts for various urban spatial strategies.

To ensure steady progress in low-carbon city development and the achievement of dual-carbon goals, my country has initiated several low-carbon city pilot projects and continuously evaluates their progress. A key tool in this effort is the special assessment of low-carbon city construction, which supports planning decisions and ensures the implementation of carbon reduction strategies. Within the carbon accounting framework for urban built-up areas based on space use data, the LMDI decomposition method measures the contribution and sensitivity of each element by analyzing changes in their carbon emission impacts. The contribution reflects the influence of various factors on the rates and amounts of carbon emissions and absorption, while sensitivity indicates the efficiency and effectiveness of these factors in reducing emissions and enhancing carbon sinks (Luo *et al.,* 2023). By identifying key factors, we can pinpoint the most impactful elements of space use activities on urban carbon emissions and develop a specialized evaluation index system for low-carbon cities based on carbon accounting. The introduction of this indicator system offers quantitative standards for monitoring and evaluating urban planning, and provides technical support for optimizing low-carbon urban spatial resources.

5. Conclusion

Currently, China's strategies for achieving carbon peak and carbon neutrality have introduced

new requirements and visions for urban planning. Developing carbon accounting technology that integrates urban spatial elements and aligns with central urban areas' master plans is crucial for advancing low-carbon city construction and achieving the carbon neutrality goals. Accordingly, this study uses Harbin as a case study, following the “accounting system-benchmark formulation-method construction-result verification” approach to develop a carbon accounting method for urban built-up areas based on space usage activity data. This method transforms the carbon accounting process in urban built-up areas from relying on energy data to focusing on urban spatial elements. The results more accurately demonstrate how urban planning and changes in urban space affect carbon emissions. Building on this, the study proposes using carbon accounting methods to predict urban carbon neutrality and conduct specialized assessments of low-carbon city construction. This supports comprehensive urban planning in central areas aimed at achieving carbon neutrality.

Investigating the carbon elements based on remote sensing, UAV oblique photography, and AI technologies: A case study of Nanhui New Town, Shanghai

Wei Wei [1], Junqiao Li[2]
[1]College of Architecture and Urban Planning, Tongji University, Shanghai, Ghibli.Wei@foxmail.com
[2]The Bartlett School of Architecture, University College London, London

Abstract: This study investigates carbon dynamics within Shanghai's Nanhui New Town, exploring the intricate relationships among land cover, climate factors, and carbon sequestration processes. Utilizing advanced methodologies such as remote sensing, UAV, and AI technologies, we conduct a thorough assessment of carbon sinks and emissions, with particular emphasis on the contributions of vegetation and water bodies. Our analysis highlights the importance of integrated land management strategies in optimizing carbon sequestration potential and mitigating emissions. Furthermore, we discuss Shanghai's proactive initiatives towards peak carbon emissions and carbon neutrality. Overall, this research offers valuable insights into carbon management strategies for sustainable urban development, contributing to efforts aimed at building resilient and low-carbon cities in the face of climate change.

Key words: carbon assessment, carbon neutrality, sustainable development, AI

1. Introduction

The pursuit of sustainable urban development has become increasingly urgent in the face of climate change and environmental degradation. Cities, as centers of economic activity and human habitation, play a critical role in shaping a sustainable future (Wang et al., 2023). One key aspect of this endeavor is the transition towards low-carbon cities, which prioritize reducing carbon emissions and promoting environmental sustainability. This transition aligns with broader global efforts towards carbon peaking and carbon neutrality, integral components of the Paris Agreement's goals to limit global warming (Colona, 2023).

Shanghai, China's economic powerhouse and a sprawling metropolis, exemplifies the challenges and opportunities inherent in this transition. With its dense population and rapid urbanization, Shanghai faces pressing environmental issues, including air pollution and carbon emissions. However, the city has also demonstrated a strong commitment to addressing these challenges through ambitious targets for carbon peaking and carbon neutrality.

2. Sustainable development, low-carbon city and carbon neutrality

The concept of sustainable development, first defined in the Brundtland Report of 1987, emphasizes the importance of meeting current needs without compromising the ability of future generations to meet their own (Li et al., 2023). This principle was globally embraced at the 1992 Earth Summit in Rio de Janeiro, where the Agenda 21 program was launched to foster sustainable development through global cooperation, marking a significant milestone in the integration of environmental and developmental concerns (Zou et al., 2023).

Building on the foundation of sustainable development, the movement towards low-carbon cities gained momentum as an essential strategy for mitigating climate change (Andrews et al., 2023). These cities aim to reduce their carbon footprints by integrating sustainable practices such as enhancing energy efficiency, broadening renewable energy use, promoting green urban planning, and improving public transportation systems. The success stories of cities like Copenhagen and Stockholm have illustrated the potential of urban areas to lead in reducing

greenhouse gas emissions while enhancing the quality of urban life. These cities serve as living laboratories, showcasing effective strategies for sustainability that can be replicated and adapted elsewhere.

The concepts of carbon peaking and carbon neutrality further define the trajectory towards sustainable urban development. Carbon peaking occurs when a city or country's carbon dioxide emissions reach their highest point before subsequently declining (Lijun et al., 2023). This is a crucial target for countries committed to reversing the trend of rising greenhouse gas emissions, such as China, which aims to reach carbon peak by 2030. Following this, the goal of carbon neutrality involves balancing emitted carbon with the amount removed from the atmosphere, achieving a net-zero carbon footprint. This ambitious objective is central to the Paris Agreement, encouraging nations to set and pursue strategies to neutralize their carbon emissions by mid-century.

The interplay between sustainable development, low-carbon cities, carbon peak, and carbon neutrality is integral to modern environmental strategy. These interconnected concepts create a comprehensive approach to tackling climate change, promoting economic stability, and ensuring social equity (Ran et al., 2023). The transition to low-carbon cities embodies the practical application of sustainable development principles, directly contributing to the broader goals of carbon peaking and neutrality. Each city’s efforts to reduce emissions and implement sustainable practices contribute cumulatively to national and global targets.

Moreover, the shift towards these sustainable models stimulates innovation in technology and infrastructure, fostering economic opportunities and job creation in new sectors such as renewable energy and energy efficiency (Shi et al., 2023). This holistic approach not only addresses the pressing issue of climate change but also promotes a sustainable economic model that integrates environmental, social, and economic goals.

Thus, the global commitment to sustainable development through the implementation of low-carbon cities and the pursuit of carbon peaking and neutrality represents a forward-thinking approach to ensuring a balanced coexistence with our planet, aiming to secure a viable and prosperous future for all generations.

3. Decarbonization and carbon neutrality of Shanghai

Shanghai, as China's economic hub and a densely populated metropolis, has been actively addressing the challenges of climate change and environmental protection (Terhaar et al., 2023). To combat global climate change, the Shanghai government has set a series of targets for peak carbon emissions and carbon neutrality, while also initiating the construction of a carbon financial market to promote the development of a low-carbon economy. Firstly, Shanghai's peak carbon emissions target aims to reach the peak of carbon dioxide emissions by 2030, followed by a gradual reduction. This commitment is a significant part of Shanghai's efforts to combat climate change and is aligned with China's broader efforts to reduce emissions globally. To achieve this goal, Shanghai has implemented a series of measures, including improving energy efficiency, increasing the use of clean energy, and promoting the optimization of industrial structures. Additionally, Shanghai has set an ambitious target to achieve carbon neutrality by 2060. Carbon neutrality refers to reducing carbon emissions to zero or balancing emissions with carbon absorption, thereby achieving climate neutrality. Shanghai's carbon neutrality target means that by 2060, all economic activities in the city will no longer produce carbon emissions, or emissions will be offset through carbon compensation and carbon absorption. To achieve this goal, Shanghai will continue to intensify emission reduction efforts,

promote green technological innovation, and strengthen carbon trading and carbon market construction.

Fig.1 Shanghai's carbon peak and carbon neutrality goals and plans

In addition to setting peak carbon emissions and carbon neutrality targets, Shanghai has also begun constructing a carbon financial market to promote the development of a low-carbon economy. A carbon financial market refers to a financial market centered on carbon emissions rights, promoting carbon trading, carbon quota allocation, and carbon financial products to facilitate carbon emission reduction and carbon marketization. The construction of Shanghai's carbon financial market mainly includes the following aspects: Firstly, establishing a carbon trading platform. Shanghai will establish a dedicated carbon trading market or platform to provide carbon emissions rights trading, carbon quota allocation, and carbon trading services. This will provide enterprises and institutions with a convenient channel to participate in carbon market transactions. Secondly, promoting the innovation of carbon financial products. Shanghai will encourage financial institutions to innovate carbon financial products, including carbon emissions rights futures, carbon trust funds, and carbon asset securitization, to meet the needs of different market entities. Thirdly, strengthening carbon market supervision. Shanghai will establish a sound carbon market supervision system, strengthen supervision and management of carbon trading, carbon reporting, and carbon auditing, to ensure the fairness, transparency, and effective operation of the market. Lastly, promoting international cooperation in the carbon market. Shanghai will actively participate in international cooperation in the carbon market, strengthen cooperation with international carbon trading platforms and institutions, and promote the interconnection and cooperative development of global carbon markets.

Overall, Shanghai's targets for peak carbon emissions and carbon neutrality, as well as the construction of a carbon financial market, demonstrate the city's proactive exploration and efforts in addressing climate change and promoting the development of a low-carbon economy. With the continuous improvement and implementation of relevant policies and measures, Shanghai is expected to become a leader in low-carbon transformation, making greater contributions to global sustainable development.

4. Carbon elements assessment based on big data

In the five new towns of Shanghai, we have conducted carbon assessment work, primarily focusing on evaluating carbon emissions and carbon sinks. To achieve carbon neutrality at the scale of the new towns, which entails no net carbon emissions from the new towns externally, it is essential for the quantity of carbon emissions to be equivalent to that of carbon sinks within the new towns. Carbon emissions refer to the carbon produced by various elements and human activities within the urban space. This includes carbon dioxide emissions from energy consumption, transportation, industrial production, as well as emissions of other greenhouse gases. On the other hand, carbon sinks are natural or artificial systems within the urban space capable of absorbing and storing carbon, such as forests, wetlands, vegetation, and soil. By assessing the carbon emissions and sinks of the new towns, we can gain a better understanding

of their carbon footprint, providing a scientific basis for implementing emission reduction measures and enhancing carbon sinks.

Taking Nanhui new town as an example, we conducted a series of assessment. Nanhui New Town, situated at the juncture of the Yangtze River estuary and Hangzhou Bay, exhibits diverse land cover types, with arable land comprising the majority at 54.93% of the total area. Forest land, grassland, wetland, water bodies, and built-up land are also notable components of the landscape. According to the land use data from 2020, the town features 5.11% forest land, 0.43% grassland, 0.08% wetland, and 5.53% water bodies, with built-up land accounting for 33.70% of the area. Analysis of river network density reveals a value of 1.62 km/km^2 for Nanhui New Town, with the southern region exhibiting a slightly lower density of 1.34 km/km^2. Additionally, meteorological data indicates an average annual sunshine duration of 2114.8 hours and an average solar radiation total of 4793 MJ/m^2, contributing to favorable conditions for carbon sequestration.

The carbon assessment employed a comprehensive methodology integrating remote sensing analysis, meteorological data evaluation, and carbon modeling techniques. Remote sensing data facilitated land cover classification and mapping, allowing for the identification of carbon-rich ecosystems such as forests and wetlands. Meteorological data, including precipitation and solar radiation, provided insights into climatic conditions conducive to carbon uptake and storage. Carbon modeling techniques were then employed to quantify carbon stocks and fluxes, including emissions from anthropogenic activities and sequestration by natural ecosystems.

Quantitative analysis revealed significant carbon stocks and fluxes within Nanhui New Town. The predominant arable land presents a substantial carbon sink potential, with estimates suggesting carbon sequestration rates of up to 62.7 metric tons of CO_2 per hectare annually through improved agricultural practices and afforestation initiatives. However, the uneven distribution of forest and grassland areas poses challenges to optimizing carbon sequestration across the landscape. The presence of water bodies contributes to carbon storage through aquatic ecosystems, with estimates indicating carbon sequestration rates of 34.2 metric tons of CO_2 per year. Furthermore, river network density influences carbon cycling dynamics, with higher densities facilitating the transport of organic carbon and promoting carbon storage in aquatic environments.

In conclusion, the carbon assessment highlights the complex interplay between land cover, climate, and carbon dynamics in Nanhui New Town. The findings underscore the importance of implementing integrated land management strategies to enhance carbon sequestration potential and mitigate carbon emissions. Targeted interventions, including reforestation, wetland restoration, and sustainable agricultural practices, are essential for maximizing carbon sinks and achieving carbon neutrality in the region. By leveraging quantitative analysis and advanced modeling techniques, this study provides valuable insights for informed decision-making and the development of effective carbon management strategies in Nanhui New Town.

Fig.2 Land Spatial Distribution of Shanghai's Nanhui New Town

Quantitative analysis revealed significant carbon stocks and fluxes within Nanhui New Town. The predominant arable land presents a substantial carbon sink potential, with estimates suggesting carbon sequestration rates of up to 62.7 metric tons of CO_2 per hectare annually through improved agricultural practices and afforestation initiatives. However, the uneven distribution of forest and grassland areas poses challenges to optimizing carbon sequestration across the landscape. The presence of water bodies contributes to carbon storage through aquatic ecosystems, with estimates indicating carbon sequestration rates of 34.2 metric tons of CO_2 per year. Furthermore, river network density influences carbon cycling dynamics, with higher densities facilitating the transport of organic carbon and promoting carbon storage in aquatic environments.

In conclusion, the carbon assessment highlights the complex interplay between land cover, climate, and carbon dynamics in Nanhui New Town. The findings underscore the importance of implementing integrated land management strategies to enhance carbon sequestration potential and mitigate carbon emissions. Targeted interventions, including reforestation, wetland restoration, and sustainable agricultural practices, are essential for maximizing carbon sinks and achieving carbon neutrality in the region. By leveraging quantitative analysis and advanced modeling techniques, this study provides valuable insights for informed decision-making and the development of effective carbon management strategies in Nanhui New Town.

Using data from Gaode Maps Points of Interest (POI), we conducted a comprehensive analysis of carbon emissions associated with power sources in Nanhui New Town. The integration of Gaode Maps POI data allowed us to capture a detailed understanding of the spatial distribution of carbon emissions within the area. The resulting heat map provides a visual representation of the concentration of carbon emissions, particularly highlighting the significant clustering observed in the southern region of Nanhui New Town (Figure 3). Upon juxtaposing this data with land use maps, a striking correlation emerged, indicating that areas designated for construction purposes coincide closely with high levels of spatial carbon emissions. This correlation underscores the impact of human activities, particularly those related to urban development, on carbon emissions within the region. Further analysis revealed that the primary contributors to point-source carbon emissions are buildings, factories, and clusters of human production activities. The utilization of Gaode Maps POI data not only facilitated the

identification of these emission sources but also provided valuable insights into the specific industries and infrastructural elements driving carbon emissions in the area. In addition to traditional data analysis techniques, we leveraged advanced methodologies such as Geographic Information System (GIS) technology and spatial data mining algorithms. These sophisticated approaches enabled us to extract actionable insights from the vast amount of spatial data available, ultimately informing future urban planning initiatives and the development of targeted carbon reduction strategies for Nanhui New Town.

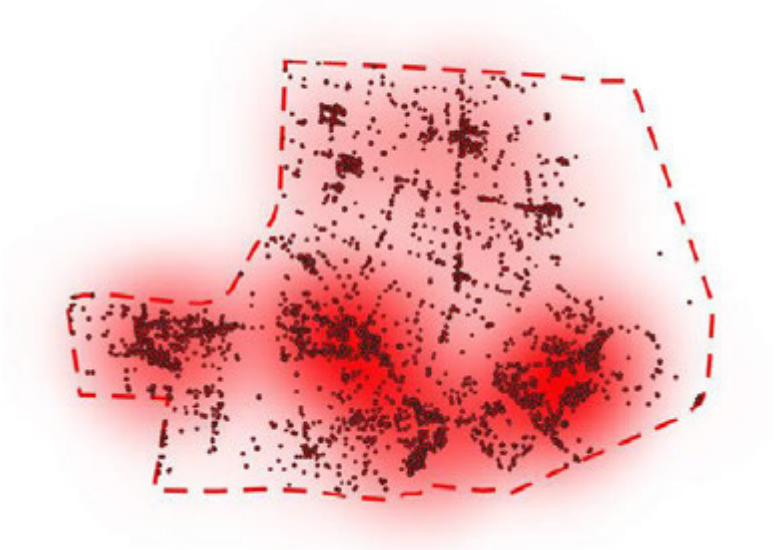

Fig.3 Point-source carbon emissions heat map of Nanhui New Town

5. Carbon sink evaluation based on Remote sensing

In order to comprehensively understand the distribution of vegetation and its role in carbon sequestration within the five new cities of Shanghai, our research utilized satellite remote sensing data and synthesized Net Primary Productivity (NPP) data for analysis and estimation. NPP, which represents the amount of energy or organic matter fixed by plants per unit area over a specific period, serves as a primary indicator of vegetation growth and is a crucial parameter in terrestrial ecosystems. Widely acknowledged in Earth sciences, NPP plays a significant role in delineating ecosystem functionality and productivity.

By examining satellite remote sensing NPP data covering the primary urban areas of Shanghai, our objective is to delve deeper into the dynamics of vegetation growth and the spatial distribution of carbon sinks. The acquisition of NPP data relies on the utilization of light energy and its conversion efficiency by vegetation through photosynthesis. This process is integral to the global carbon cycle, wherein plants assimilate carbon dioxide (CO_2) from the atmosphere during photosynthesis, convert it into organic matter, and store it within plant biomass or soil organic matter.

The relationship between NPP and carbon sequestration is inherently linked to vegetation's ability to absorb atmospheric CO_2 through photosynthesis and retain carbon within biomass and soils. As NPP reflects the net carbon uptake by plants, it serves as a key determinant of ecosystem carbon storage capacity. High NPP values indicate robust vegetation growth and

increased carbon fixation, thereby enhancing the carbon sequestration potential of ecosystems. Conversely, regions with low NPP may indicate limited vegetation productivity and reduced carbon uptake, potentially leading to decreased carbon storage capacity and elevated atmospheric CO_2 concentrations.

Furthermore, understanding the spatial distribution of NPP offers valuable insights into regional carbon dynamics and ecosystem services. Areas with dense vegetation cover and high NPP values often exhibit greater carbon sequestration potential, contributing to climate change mitigation efforts as carbon sinks. Conversely, regions characterized by sparse vegetation and low NPP may act as carbon sources, releasing stored carbon back into the atmosphere through processes such as deforestation or land degradation.

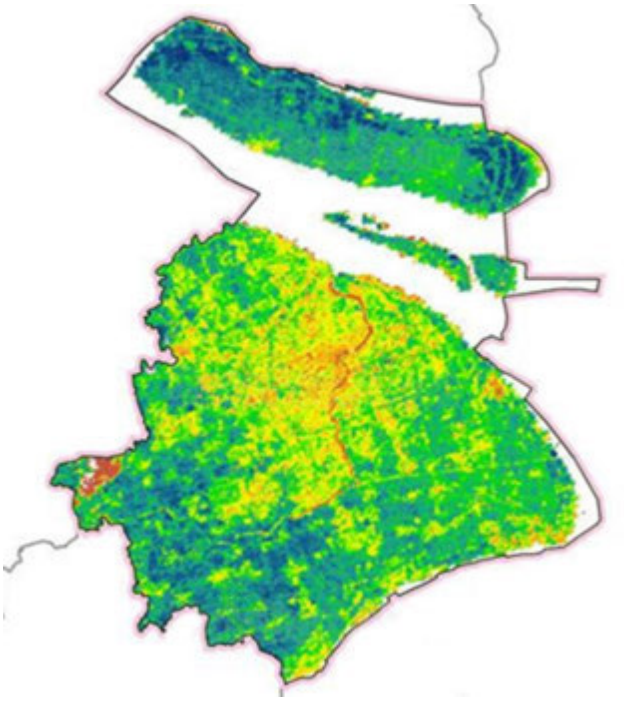

Fig.4 NPP map of Shanghai

In summary, the analysis of NPP data provides a comprehensive perspective on vegetation dynamics, carbon sequestration potential, and ecosystem health. By elucidating the intricate relationship between NPP and carbon sequestration, our research aims to contribute to the sustainable management of ecosystems and the mitigation of climate change impacts at a regional scale. Expanding upon this, our study delves into the nuances of NPP dynamics across different vegetation types and land-use patterns within the urban context of Shanghai's five new cities, offering insights into the efficacy of carbon sequestration strategies and informing decision-making processes for sustainable urban development.

6. Carbon sink evaluation based on UAV and AI

At the microscale, we have developed a method for calculating urban carbon sinks based on UAVs and AI. To investigate vegetation carbon sinks at the microscale, we have advanced a workflow primarily comprising "UAV scanning and model cleaning - extraction of vegetation

physical characteristics - deduction of carbon sink logic". We employ quadcopter UAVs equipped with image sensors to scan on-site scenes and utilize the structure from motion (SfM) algorithm to construct three-dimensional scene scan models. Following manual and intelligent algorithmic repairs to these models, we utilize artificial intelligence image recognition algorithms to extract urban green vegetation from the models and identify vegetation types. Based on the physical characteristics of various types of vegetation, such as vegetation height and crown diameter, and biological properties such as chlorophyll content per unit volume, we compute the carbon sink value of urban green vegetation. Through this methodology, we achieve a detailed understanding of carbon sequestration dynamics at the microscale, providing valuable insights for urban planning and environmental management strategies.

Fig.5 UAV 3D modelling and carbon sink assessment

As shown in the figure, we have established a 3D model of a park area in the new city through UAV scanning and modeling. Using AI, we automatically extract vegetation and calculate the vegetation carbon sink. The calculated carbon sink generated by this park is 30,041 tons per year. Our approach is highly suitable for precise carbon sink measurement at the microscale, complementing the assessments discussed earlier at larger scales. This method provides detailed insights into carbon sequestration dynamics at a localized level, offering valuable supplementary information for comprehensive carbon accounting and environmental management strategies.

7. Conclusion

In conclusion, our study offers a comprehensive analysis of carbon dynamics in Shanghai's Nanhui New Town, emphasizing the pivotal role of vegetation and water bodies in carbon sequestration. By employing advanced methodologies such as remote sensing, UAV, and AI technologies, we have identified significant carbon stocks and fluxes, providing valuable insights for informed decision-making towards achieving carbon neutrality and promoting sustainable urban development. Shanghai's proactive measures towards peak carbon emissions and carbon neutrality, alongside the establishment of a carbon financial market, underscore the city's commitment to addressing climate change and fostering a low-carbon economy. Overall, our research contributes to advancing our understanding of carbon dynamics in urban environments and provides a foundation for implementing effective carbon management strategies to build greener, healthier, and more resilient cities.

REFLECTION ON THE TRANSFORMATION OF TIRANA'S ARCHITECTURAL SPACES

PhD. Jonida Meniku
Polytechnic University of Tirana, Faculty of Architecture and Urbanism, Department of Restoration and Technology of Architecture, Albania; e-mail: jonidameniku@yahoo.com

ABSTRACT

The architectural spaces that form the function of the main squares and bazaars are often considered the best place to understand the history of the city due to their many layers of construction. These areas, as the first urban core of the city, represented a meeting place for people, a place of recreation, and a place where people could discuss politics. This research presents the transformation of two of Tirana's public spaces that have had interventions, as illustrated by the cases of Skenderbeg Square and Tirana-Old Bazaar, which is significant and almost prophetic for the understanding of a country such as Albania. The goal of this study is "participatory architecture," which regenerates infrastructure and public space. These interactions have recently been facilitated by the use of physical and digital planning production through analysis. This method stimulates innovative design, economic growth, cultural heritage activity, and greater tourist coherence.

Keywords: architectural square, bazaar, participatory architecture, digital-realistic models, community voice.

Historical city background

Every political regime tried to leave their mark on each city, often by constructing a building and often by destroying one from a previous regime in the process. Tirana started as an organic settlement at the beginning of the seventeenth century (Frashëri 2004, p. 17), at which time this part of the Balkan territory was dominated by the Ottoman Empire. The beginning of the construction of modern Tirana started in the 1920s, when it became the capital of Albania. It remained a small and insignificant centre until 1920. Historians and other scholars agree that the first urban nucleus in the Tirana valley emerged close to the Lana River, at the intersection of the commercial routes emanating from the more important regional centres of the time (Fig. 1).

During the seventeenth century and until 1912, the urban structure of Tirana was underpinned by Muslim propaganda. Tirana's predominant ideology and culture were dictated by the Ottoman Empire, which sought to expand its territory on the Balkan Peninsula and beyond. Over time, the sociological units, or community clusters, merged into a dense urban core centred on the most important public buildings of the time: the Old Mosque and the Old Bazaar.

Fig.1 The city of Tirana, at the beginning of the 1920s. Source: National Technical Archive

Fig.2 Street of Durres and Kavaja, New boulevard of Zogu i Pare. Tirana, 1920.
Source: National Technical Archive

King Zog prepared the first projects of European-style urban design and architecture for the city centre, including a big new boulevard. The new square was symbolic and functioned as a conciliation space between the inherited organic city and the new modern Tirana. (Fig.2). The most significant project was the ceremonial complex of the ministry square and the central axis of the new boulevard, first designed by the Italian architect Armando Brasini in 1925. This project was highlighted as the most important element and the symmetric axis of Tirana in both the regulatory plan of 1929 formulated under King Zog and the regulatory plan of 1939–1943 formulated during the Italian Fascist occupation. After the Second World War, Tirana underwent the simultaneous clash and intertwining of drastically different cultures, as reflected in many aspects of daily life, where the anthropology of space represented at once or separately the Ottoman and Western civilizations. However, between 1944, when the Communist dictatorship was installed in Albania, and 1991, other important changes occurred in the structure of the city. Architecture and urban planning became ideological instruments for the so-called progressive transformation of the country and the creation of a new physical and social reality. Despite the isolation that dominated this period, Albania followed a similar track to other Eastern Bloc

countries in terms of architecture and urbanism, albeit within the framework of a struggling economy, a lack of technology and know-how, and aggressive ideological pressure and dogmatic irrationalities.
The architectural heritage of Albanian cities today is mostly composed of a long tradition of Ottoman buildings, a short but impressive period of Italian and fascist constructions, four decades of socialist planning, and newly incorporated post-socialist and post-modernist structures. If somebody visits Albania today, they can inspect some elements very similar to those of the former Soviet countries; others can be very similar to Turkish traditions; and the overall impression is an organised urban chaos of the post-Soviet cities, which is also reflected in their daily lives.

Understanding the transformation of two public spaces in Tirana city

This research presents the transformation of two of Tirana's public spaces that have had interventions and promoted new forms and functions of cultural and environmental tourism, as illustrated by the cases of Skenderbeg Square and Tirana-Old Bazaar, which is significant and almost prophetic for the understanding of a country such as Albania, whose destiny is suspended between East and West: "two circles, one with Tirana at its centre and a radius equal to the distance between Rome and Tirana, and another with the same radius yet with Istanbul at the centre, which meet at the eastern border of Albania."
The city squares were the first to be subjected to democratic changes, although they were constructed for different purposes. Their initial construction was for public manifestations supporting the regimes. Regularly organised demonstrations backing the system, meetings, gatherings, and marches created demand for spacious streets and squares, which were very important modes or axes of spatial organisation in socialist cities and were distinguishable and particularly visible in large and small cities. (Fig. 3)

The transformation of Tirana's central square (Skenderbeg Square) in nearly a century demonstrates the main ideological purposes of two different totalitarian regimes, fascism and communism, as well as the post-Soviet urban developments. After communists came into power, the idea of city and public space didn't change so much. Totalitarian regimes all meet in relation to questions that have to do with monumentality and huge urban scale. Both fascists and communists agreed on the form, size, and use of public space. In Albania, officially, the main idea was to use them for manifestations and grand marches of workers and military officials

During the years of socialism from the 1960s to the 1970s, further interventions were implemented to permanently define the shape and size of the main square. These interventions consisted of the demolishment of the Old Bazaar in order to build a huge Palace of Culture that was inaugurated in 1966. During the years of socialism from the 1960s to the 1970s, further interventions were implemented to permanently define the shape and size of the main square. These interventions consisted of the demolishment of the Old Bazaar in order to build a huge Palace of Culture that was inaugurated in 1966. (Fig. 4)

Fig.4 The city of Tirana,

Skanderbeg Square during 30s
Source: National Technical Archiv

.

The formation of Skanderbeg Square is in itself a product of an imposed ideological process, mostly created by authoritarian regimes, although that method is rarely a linear one. We seem intermittently aware of the layering of history that the city represents, with its manifestation of political conflicts and changes. This happened until the great protests of the 1990s against the communist regime, when plazas and Grand Boulevard became fighting areas.

Fortunately, there are still some places in Tirana that show a degree of identity continuity, and these are not the squares any more. The main heritages of Tirana from the Ottoman Empire period were the Old Mosque, the Mosque of Ethem Bey, the Tirana clock tower, the old bazaar, et cetera. The first and last of this list were destroyed by the communist regime soon after it was raised into power, while the Mosque of Ethem Bey and the clock tower still remain today the most iconic buildings of the city.(Fig. 5)

After the fall of communism, the square became the arena of people's free will and expression, the symbol of change, and the space where the voice of everyone could be heard. At no other time, like in the 1990s, has the Scanderbeg Square served its purpose as a "positive space.".

Before 2003, Tirana's central square was a relatively simple transit open space and had never been a place for people to meet; it was rather a place for traffic regulation and

Fig.5 Old Bazaar The city of Tirana,
1930 Source: National Technical Archive

authorised political meetings and/or protests. (Aliaj et al., 2003) A city's main square can be understood as a type of urban landscape, and this can be understood not only as the built morphology of the city—its urban tissue, outlook, and layout—but also as a complex set of meanings, representations, and values. Places, such as urban squares and bazaars, have no inherent identity. Identity is a mental quality; it is constructed by human behaviour in reaction to places. It is a reciprocal relationship—people produce places, and they derive identities from them. Identity may be given to a place by a government, but whether this identity is embraced by the people is a different matter. Places are both material and social in the sense that they provide space people use for all kinds of activities. Celebrating the victory of a team, organising an urban protest, a president speaking to a crowd, etc., all signify the identity activities of groups, between groups, and institutions like government.

Theoretical background: Understanding Participatory Architecture Approach

During the 1970s and 1980s, political agendas in Europe also promoted participatory planning and community-led architecture [Luck, 2018, p.144]. Yet in the 1990s this support disappeared alongside funding and PA turned into a minority practice. However, from the mid-2000s onwards, a revival of PA emerged from practices such as Aravena's Elemental on affordable homes in 1994-; atelier d'architecture autogérée (2001); "The sooner the community becomes involved in the planning process the better–ideally before any planning has been done," as Kathy Madden and Fred Kent emphasis in the book How to Turn A Place Around. "And people should be encouraged to stay involved throughout the improvement effort so that they become owners or stewards of the place as it evolves."

The voice of the community should be taken more seriously since any decision could affect their lives. The public has the right to know on what is happening in the surrounding environment and the right to get involve in decision-making process which particularly affect them in places where they live and work.

Participatory architecture. Methodology and projects review.

The research is focused on questions related to the context, methodology, engagement method, processes of participation, and the successes within their projects. All two projects operate at diverse scales of intervention, which represents the new wave of PA practices in Tirana after 2000s. This analysis was guided by the notions of strategies and tactics, and observations from field visits in some of the locations where the projects were taking place.

Fig.6 Tirana Old Bazaar 1920

Fig 7 Tirana New Bazaar 2017

Source: Municipality of Tirana

Case study Tirana New Bazaar

The New Bazaar was built, in 1931 at the same place where the historic Old Bazaar were built, the latter extending up to present day Skanderbeg Square. It is located east of the central boulevard. It forms part of the Old Town of Tirana and is one of the oldest areas of the city. However in 2017, the bazaar were renovated and reconstructed. (Fig. 5,6)

The project was effective in giving architects an opportunity to appreciate the importance of considering traditional architectural solutions in their future designs. The real model introduces the application of approaches representing various dimensions of revitalizing architectural design studios and learning with the aid of information and communication technologies. This scheme has been facilitated by the use of engineering techniques, as scanning and surveying technologies, simulation purposes in symmetry, building facades, colours, space, and meditation in the interior in the urban landscape of New Bazaar in Tirana. Knowledge is retrieved both from the model as well as from its examination and analysis. An example of undirected production is the modelling process that supported the design of the New Bazaar in Tirana.

The project is designed to get continuous feedback from stakeholders throughout this process. Across the administrative areas, which have been part of the journey from the very beginning, have developed a series of public hearings from citizens, architects, engineers and MT's [Tirana Municipality] planners. It is to be appreciated that some of the proposals and suggestions of

stakeholders have enriched the project and contributed to refining and implementing the idea on the detailed design. The project was effective in giving architects an opportunity to appreciate the importance of traditional architecture. Preserving shapes of vernacular house. Considering the traditional solution. Integration of historical Tirana to a Modern City. Testify spiritual and Traditional effect. Transforming a Memory place to a Livable Space.

The PA tactics consisted of (a) visiting residents separately; (b) developing a personalized inventory to understand the residents' lifestyles and needs, and to consider the work and renewals that had already been carried out; (c) setting up a community hub. The objective was to reconnect the residents with new area, markets, buildings, and then invite them to go outside and take care of immediate surroundings.

They prepared a participatory community process, through developing series of public hearings with citizens, informal meetings between different groups; architects, engineers and MT's urban planners; several round table discussions, by spreading information in the media, by advisory committees and coordination bodies.

Case study: Tirana's Skanderbeg Square

In 2003, an international design competition organised by the Municipality of Tirana resulted in a winning design by 51N4E architecture studio, Belgium, but it was only in 2017 before it was implemented.
This phase of intervention proposals has a more ideological approach. It consists of a constant search for the dematerialization of the true nature of the original square and somehow its decomposition. Now the dominant transformation factor is not an economic one but a social one. The citizen is placed in the centre of the idea of the square. So much is evaluated about the role of a single citizen, and only one can perceive the square at a time, as the pyramidal square arises from the ground. Even with this proposal, the space is "controlled," but in this case, the centre of the control system is not the totalitarian ideology nor the market economy, but the citizen. Symbolically and as a modern open society approach, the proposition has many positive aspects in relation to finding a way to represent the new Albanian society as free and in control of itself, but at the same time fails in relation to staying true to the context. (Fig. 7,8)

A new main square, in fact an empty space, has been given integrative symbolism. It has a focus on the future. The national symbol, the statue of the national hero Skanderbeg (a warrior on a horse as a defender of Christianity and Europe), is no longer the focal point of the square; it has become peripheral. The emptiness of the square and the topography of a low pyramidal shape oppose the monumentality of existing classic and modernist architecture.

The proposed change was radical, and mass opinion and civil society never fully supported the winning propositions of both phases. It showed that the projects did not achieve reconciliation with the social approach and the memory that society had for the square. Protestors point at legal and procedural mistakes, lack of involvement, participatory architecture, and the destruction of urban heritage, all for the sake of modernization, which is at the cost of democracy and respect for the rule of law. The new square is a multisensory experience; next to the visual experience and pyramidal topography (a three-sense symbol for Albanians because of the 'Pyramid', a mausoleum structure in honour of the past dictator), there are fountains with light arrangements, bikers playing, visitors making selfies, or just transit walkers passing. While the appearance is new, the critical question is about its value: will the citizens of Tirana, Albania, attach importance to this new space? Will they develop a form of place attachment? The administration of the local government made possible the implementation of the project in a short time and even added to the original project design a large underground public parking space. The Skanderbeg square is identified as the most important public space in Tirana and is still perceived as the most representative plaza in Albania.

Fig.7 The historical center of Tirana was almost entirely erased. New Skanderberg Square ≈1980 [39] Palace of Culture Source: National Technical Archive

The totalitarian squares in Albania present aspects of a lack of adaptability and flexibility overtime. In the absence of a dominant political power, these squares, in their bigness, are often mute and full of solitude, testifying to the heavy historical failures that influenced urban radicalism and city-making. On the other side, central space, with its rich history, gives us as architects and planners the eternal lesson that these spaces first need to be understood if we tend to intervene on them. This process can only be achieved through deep knowledge of the history that made them and which they help to make.Tirana's main square project intends to enact a new image and a new identity for the city and the country. The new square was not a popular demand but rather the perception of the political.

Photo 8:

Skanderbeg Square (Facebook Edi Rama, public realm)

The participatory process was structured based on the spatial practice's strategies:

(a) not seeking consensus but rather opening a citizen debate via community engagement (b) a non-prescriptive, open-ended, and responsive process of participatory events—each event informed the subsequent ones based on the connections, interactions, and assemblage of actors; (c) open-ended and emergent outputs; a decision-making process rather than a voting process; (d) generating initial design ideas by responding to community feedback; (e) consulting on these design ideas with local community stakeholders (including the landowners and its residents); (f) providing the vision for the community; (g) negotiating with the citizens, including community members, musicians, teachers, and local authority representatives, who were ceremonially given the keys to the school building.

Discussions

Regarding the analysis of the context of two case studies of the PA projects, we can appreciate different urban situations that vary in types and levels of participation. Both projects illustrate strong connections with PA historical practices and evolutions of participatory tactics and strategies. The cases are aligned with the types of participatory planning defined by [Guedes, 2019]: formal participation (initiated by public authorities), and community-led participation (driven by communities).

The New Bazaar project, is the only project instigated by the local communities and Tirana Municipality and greatly diverse community groups, who approached the PA.

New Bazaar project where architects had a more intimate engagement approach with the community and the proposed engagement process was centered on the citizens' needs using a personal, empathetic, and ethnographic participative approach, which ensured the participation of low-income communities and residents during the process, and Skenderbeg square, where participants adopted passive or consultative roles, describing more controlled strategies and tactics, with architects mediating and filtering the design outputs. Similarly to co-design, PA is

not possible without building trust and relationships among architects, residents, and stakeholders [McKercher, 2020].

In practice, the combination of PA strategies and tactics allows architects to develop workable participatory methodologies to build a bridge between citizens and the public sector. This combination helps to flatten pre-existing power structures and hierarchies, facilitating collaboration between diverse groups, enabling them to become active agents in architectural processes. Although strategies and tactics are usually identified as separate concepts, in both projects reviewed, it is clear they actually work in unison, and often the lines between strategy and tactic are blurred. New Bazaar project set up tactics for engagement of the physical lab – engaging local community in urban actions to prototype the ideas generated using from digital lab and Skenderbeg square, school set up tactics for the digital lab – engaging young architects and practitioners to promote a global debate, but also generating a vessel for international concepts, which was simultaneously a tactic and a strategy;

Looking across the PA projects, the following common strategies and tactics must be identified:

Build trust and meaningful relationships; encourage citizen participation and tactic as: each resident's situation needs to be considered differently and give them the freedom during the process while trying to develop a sense of the collective good rather than just an individualistic viewpoint.

Conclusons:

In conclusion, this visionary model may help in the encouragement of PA and serve as a model for further collaborative processes between different stakeholders. This paper introduces PA as a strong alternative to overcome the issues associated with conventional approaches to architecture that exclude people from the design process. None of these two projects have directly led to immediate wider societal changes, which indicates that there is a need to evaluate PA approaches and track the impact of PA over time. Today we live in a period that needs deep and rapid transformations, where research on PA is highly required to adapt our environments to sustainable ways of living and to address the upcoming climate changes. Good communication between the local authorities and the community is necessary, not only in terms of use but also in the terms of design, and this will be the real regeneration of educational and social infrastructure and the key to a healthy and participatory democratic political culture.

Assessing Public Sentiments in Post-Urban Regeneration: A Location-based Analysis of the Karaköy Salıpazarı, İstanbul

Selin Aslan, Fatih Terzi
Istanbul Technical University
aslansel19@itu.edu.tr, terzifati@itu.edu.tr

Abstract

The historical Karaköy, Salıpazarı District in İstanbul, with its rich urban heritage, has undergone significant transformation catalyzed by the implementation of the Galataport urban regeneration project. This urban endeavor, while aiming to revitalize the waterfront area and enhance the connectivity, has prompted concerns about its impact on the social, physical, daily life practices and the overall identity of locale. Focusing on the social context of urban regeneration, the study aims to discover public attachment patterns in Karaköy Salıpazarı district post urban regeneration

Utilizing Location-Based Social Media data, the study conducted sentiment analysis based on Google Maps reviews published in the last year. The data underwent Neuro Linguistic Programing (NLP) process within Microsoft Excel Azure Add-in, and subsequently mapped by employing spatial interpolation methods in ArcGIS. In conjunction with the hot spot analysis of overall ratings and review density heat map, the study claimed that the regeneration efforts in area do not fully align with the needs of city dwellers.

KeyWords: Urban Regeneration, Sentiment Analysis, GIS, Istanbul

1. Introduction

Urban regeneration initiatives worldwide have become prominent in academic discourse, not only due to their impact on physical structure of cities but also with their social contributions to daily life experiences of urban habitants. To achieve successful urban regeneration endeavors, scholars emphasize the imperative of considering social aspect, and suggest that such projects should aim to integrate the city and its dwellers by taking daily life dynamics of local residents into account (Karslı,2015). In the cases where the social dimension is not adequately addressed, urban areas and their component parts experience the emergence of new social memory and identity pressures within the region. This circumstance is highly observable with the tendency of contemporary urban regeneration practices to impose popular culture on urban life, particularly in areas of historical significance (Creve and Beaverstock, 1998).

Although the social integration was highlighted as one of the primary aspects in urban regeneration (dos Santos Figueiredo et. al., 2022; Heat et. al., 2017; De Rosa and Di Palma, 2013), it might be challenging to make definitive assumptions regarding social effects of regeneration projects. Herein, revealing the existing community sentiment patterns can serve as a valuable social-spatial source to observe symbiotic relationship between human and their environment (Yang et. al., 2022).

The challenge of understanding social patterns of community necessitates use of advanced methodologies. In this regard, Geographic Information Systems (GIS) emerge as a quite beneficial tool for socio-spatial analyses of specific districts. Particularly, utilizing public sentiment analysis based on location-based social media data in ArcGIS environment enables to comprehend social spatial dynamics of specific district.

Within this theoretical framework, the study approaches the social dimension of urban regeneration through the case of Karaköy Salıpazarı district. The intricate urban regeneration process of the area and implementation of the Galataport Complex within the historical

landscape of the Karaköy area has recently raised criticism and became one of the central subjects in urban research. While several researchers and urban practitioners criticize the project for its perceived deficiency in social integrity and responsiveness to the historical characteristics of the site (Korkut and Nalbantoğlu, 2023; Karslı, 2015; Köksal, 2012; Durmuş, 2009), the current literature fall behind to provide a perceptible claim about the socio-spatial transformation experienced by the site. The stated gap in the literature makes it crucial to investigate transformative power of Galataport urban regeneration project on the socio-cultural fabric of the locale as well as its associated reflection on public sentiments.

Following this objective, the study investigates public sentiments arising from post-urban regeneration in the Karaköy Salıpazarı area. By implementing sentiment analysis techniques applied to Google Maps data via Geographic Information Systems, the study not only achieves to discern the accuracy of criticized aspects of Galataport Complex, but also reveals social engagement patterns of the public in the context of post-urban regeneration. In the conclusion part, the reader is invited to the discussion about the integration of urban planning tools into the urban regeneration process that could provide successful impacts on public sentiments and enhance the level of social integration.

2. Urban Regeneration Dynamics and Public Sentiments

2.1. Urban Regeneration of Historical Landscape

Urban regeneration is a multifaceted endeavor requiring theoretical insight and solid strategies encompassing economic, physical, environmental and social issues regarding urban environment (Chen et. al., 2012, cited in Lak et. al., 2020;). For many scholars, successful urban regeneration projects distinguish themselves by transcending mere physical transformation and advocating for a holistic approach including diverse dimensions (Güzey, 2009; Turok, 2004; Atkinson, 2004; Roberts and Sykes, 2004). In particular, the importance of social dimension is underscored

as such projects serve to public, who has no chance to live without them. Considering the social aspect emerges as an integral part of urban regeneration, only could be achieved by improving the quality of life and social relations, improving the access to public services, decreasing the crime rates, overcoming social exclusion and so on (Güzey, 2009).

Contemporary urban regeneration initiatives, as criticized by several researchers, associate success only with an added income, and exhibit noticeable deficiency in addressing these social concerns (dos Santos Figueiredo et. al., 2022; Boussa, 2017; De Rosa and Di Palma, 2013). This critique becomes particularly notable in the context of historical landscapes, where urban regeneration initiatives display a complex dilemma. Justifying public interest by recovering architectural heritage (Couch et. al., 2002) and representing new economy and consumption demands of the middle-high classes (Zukin, 1998), contemporary implications often cause consequential challenges in strategic urban areas such as displacement of existing populations (Heat et. al., 2017), erasure of city identity (Boussa, 2017), heightened spatial segregation (Marcuse, 1998).

To eliminate this consequences, it is deemed important to elucidate the social psychological processes involved in the establishment of social cohesion, and impact of these processes on public engagement patterns (Heat, 2017). While solid definition of ‘social’ element in the urban planning and regeneration processes remains challenging (Chatfield and Reddick, 2016), improvements in technology and the prominence of social media offer promising paths for the observation of evolving social patterns.

2.2. User-Generated Data in Understanding Urban Dynamics

In the contemporary era of Information and Communication Technologies (IoT), widespread technology, and the rise of social media usage facilitate cities to be contributed both by human and machine intelligence. This assembly not only enables public to actively contribute and receive information from the urban space but also encourages a socially informed urban environment (Crooks et. al., 2016). In this regard, the integration of Location-Based Social Networking (LBSN) data in urban studies plays a crucial role in understanding social dynamics of urban landscapes. The imperative of this integration lies in its potential to reveal the values of the public in relation with their location (Ilieya and McPhearson, 2018). According to Crooks et. al. (2016), urban research is bound to explore the relationship between physical spaces, perceptible spaces and the linked spaces through the interconnected nature of social media. Several researchers contributed urban research utilizing from this type of data in diverse topics covering urban mobility (Mohammadbagherzadeh and Terzi, 2022; Oven, 2017), public health, economic development (Hong, 2015), urban green spaces (Chen et. al., 2022; Ghahramani et. al., 2021; Kovacs-Györi et. al., 2018), urban activity patterns (Üsküplü et. al., 2019; Agryzkov et. al., 2016) and human environment relationships (Huang et. al., 2021; Hasnat and Hasan, 2018; Marine-Roig and Clave, 2015).

LBSN data, a product of millions of users worldwide (Hu et. al., 2015) constitutes a valuable resource in contemporary academic research, representing user's voluntarily published perceptions, interests, needs, and behaviors specific to urban locations (Estrada & Nolasco-Cirugeda, 2019). Collection of this type of data is facilitated through three types of social media platforms: Microblogs (i. e., Twitter, Facebook), Photo/video sharing (i.e., Flickr, Instagram, Youtube), and Point of Interest (POI) platforms (i. e., Open Street Map, Foursquare, Google Places) (McKitick et al., 2023). Variety of Location-Based Social Networking platforms provide researchers with a comprehensive understanding of urban dynamics, behaviors and social interactions.

2.3. Public Sentiment Analysis

For a comprehensive exploration into the interconnected psychological relationship between individuals and their environment, Location-Based Social Network data presents valuable opportunities. In particular, the investigation of community attachment patterns to specific urban areas can be accomplished through the utilization of sentiment analysis, which asses the individuals' emotional states according to their written statements in social platforms (Lopez-Mosquera and Sanchez, 2011). The analytical process requires the application of Neuro Linguistic Programming (NLP) methods, categorizing individuals' statements as indicatives of positive, neutral or negative emotions.

In the context of urban research, sentiment analysis proves a valuable social-spatial reference dataset in monitoring and investigating human-environment relationship in various aspects. Firstly, providing a broad social layer to smart city governance, it contributes a shift from a single government-centric paradigm to a data driven, multi-stakeholder mode (Meijer & Bolivar, 2016). Moreover, sentiment analysis is seen beneficial for disclosing the local daily life and embedded social and cultural context that were usually overlooked by authorized official data. (Yang et. al., 2022). In these ways, the analysis is considered as an active instrument in terms of urban governance, by monitoring public response, evaluating urban facilities and well-being, and promoting smart city approach (Yang et.al., 2022).

Several researchers have contributed urban research analyzing public sentiment patterns of distinctive case areas. By utilizing the sentiment analysis, these scholars provided valuable

information to the literature about broad range of topics covering urban identity (Hang, 2015), activity patterns (Yang & Dvale, 2021; Üsküplü et. al., 2021), social spatial interactions (Yang et. al., 2022; Chen et. al., 2022; Gyori et. al., 2018; Stojanarski et. al., 2016), urban street networks (Agyzkoo et. al., 2016, 2017), and green spaces (Kovacs-Gyori, 2018). The source of the LBSN data is mainly observed as Twitter platform within the studies investigating social spatial interactions while Foursquare platform is used in research focusing on urban identity, urban street network and urban activity patterns (Table 1). However, new data sharing policies of these platforms highly restricted the LBSN data based research in current situation.

Table 1. Contribution to Public Sentiment Research in Urban Environment

Author	Year	Data Source	Research Context	Methodology /Visualization
Hang	2015	Foursquare	Urban Identity	Sentiment HeatMap
Stojanarski et. al.	2016	Twitter	Socio-Spatial Interactions	Sentiment HeatMap
Agryzkoo et. al.	2016	Foursquare/ Twitter	Urban Street Network	Network Analysis
	2017	Foursquare	Urban Street Network	Network Analysis
Kovacs-Gyori et. al.	2018	Twitter/ OpenStreetMap	Urban Green Space	Spatial Distribution/ Natural Breaks
Gyori et. al.	2018	Twitter	Socio-Spatial Interactions	Hot Spot Analysis
Üsküplü et. al.,	2020	Foursquare	Urban Activity Pattern	Hotspot Analysis/ Spatial IDW
Yang & Dvale	2021	Foursquare	Urban Activity Pattern	Network Analysis
Chen et. al.	2022	Twitter	Socio-Spatial Interactions	Spatial Distribution/ Natural Breaks
Yang et. al.	2022	Twitter	Socio-Spatial Interactions	Spatial Distribution/ Average Density

Specific to the context of research, these studies conducted various methodologies such as Hot Spot Analysis, Network Analysis, Spatial Distribution, Spatial Interpolation and Sentiment Heat Map techniques utilized in ArcGIS environment. To identify the clustering of positive and negative sentiments, Hot Spot Analysis and Spatial Interpolation methodologies are highlighted in public sentiment studies.

2.4. The Study Area

The study area is located in the southern part of Beyoğlu, one of the crowded commercial districts of Istanbul (Figure 1). This area particularly is considered as a significant part of the city, characterized by a mixed used of opportunities within its historical fabric. Karaköy Salıpazarı district, the focus area of the study, represents the modern and bohemian characteristics inherent to the city of Istanbul.

Figure 1. Location of the Study Area

2.4.1. Historical Development

Due to its strategic location, the Karaköy area has functioned as a port center with commercial characteristics since early ages. Following the 19th century, numerous banking headquarters and large companies started to be located in the district. Over time, Karaköy gained the characteristics of a city center, accommodating financial, commercial, and transport facilities (Karslı, 2019).

Physical and social changes in the area has started in 1950s, prompted by new zoning plans suggesting the construction of higher buildings and larger roads. Consequently, the historical landscape of the area underwent inevitable disruptions due to new road arrangements and construction activities (Ocakçı & Tepeli, 2017). Following the 1980s, the relocation of banking headquarters and large scale companies to the new Cetral Business District (CBD) of Istanbul, Zincirlikuyu-Maslak area. In this way, the area became a secondary center, losing its commercial significance. Also, the introduction of inappropriate functions and workshops catalyzed extensive changes in both social and physical landscape of the area (Korkut & Nalbantoğlu, 2023; Karslı, 2015).

2.4.2. Implementation of Galataport Complex

The strategic location of the Karaköy Salıpazarı area and its historical texture have given not only a commercial characteristic to it, but also substantial potential as a touristic attraction. Inevitably, tourist attraction to the area hasincreased and overlapped with daily lives of habitants (Korkut & Nalbantoğlu, 2023). Catalyzed by the tourist attraction as well as existence of abandoned historical buildings, Galataport urban regeneration project has been suggested in the area. Covering the massive land within the historical fabric of Karaköy, the project is considered as a cruise port initiative aimed at boosting public space through mixed used development.

Started in 2015, construction of the Galataport urban regeneration project has been driven by multifaceted set of objectives. These include the transformation of the area into a cruise port meeting with global standards, the opening access to the long-closed coastal strip, the enhancement of visitor experience, and the preservation of the historical port's significance (Galataport Istanbul, n.d.). However, during and after the construction, the project has been subject of many criticisms, mainly focusing on the social spatial segregation that the project causes in the area. According to Korkut and Nalbantoğlu (2023), the luxurious commercial businesses and profit-oriented functions suggested in the project only serve to attract tourists' fancy, rather than integrating with the needs of city dwellers. Consequently, the attraction of a

new socio-economical profile has let the disruption of social integrity with the other areas nearby, particularly social flow with Kabataş area is stressed. Furthermore, several scholars criticize the massive scale of the project as it destroys the historical characteristics of the city, creating a barrier between sea and the urban area (Karslı, 2015; Köksal, 2012; Durmuş, 2009).

3. Methodology

Using the location-based Google Maps data, a case study approach is adopted to inquire subtle dynamics of urban regeneration within the Karaköy Salıpazarı district, and provide a comprehensive understanding about public sentiment patterns (Figure 2).

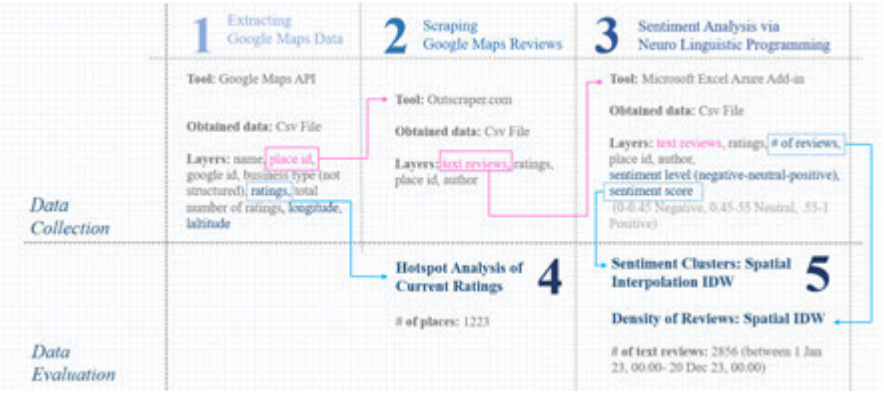

Figure 2. Research Flowchart

3.1. Data Collection

The main evaluation of the study relies on location-based data derived from Google Maps. Google Maps data is considered as a highly convenient source for the research since it enables users to rate places and share associative reviews. The places in obtained data covers wide range of functions (i.e., administrative, commercial, cultural, financial, service activities, food sector, health and sport facilities, religious buildings and so on) as well as point of interests (open spaces, parks, viewpoints, nodes and so on).

Data is obtained through Google Maps' Application Programming Interface (API). However, in this step, the research faced with a limitation imposed by data sharing policy of Google maps, which restricted retrieving data to maximum of 60 venues per one search. Therefore, the study area which occupies land area of approximately 31 hectares, was subdivided into 32 circles with varying radius ranging from 30 to 100 units (Figure 3). For an inclusive outcome, places that are not covered in specified circles are detected manually and added to the dataset. The result is acquired as a csv file, which includes attributes of place ID, google ID, business type (with 5 keywords), ratings, total number of ratings, longitude and latitude of total 1223 venue points.

In the second step, Google Maps reviews of each venue between the time interval from January 1, 2023, 00.01, to December 23, 2023, 00.01, is acquired by utilizing a data scraping platform, specifically outscraper.com. Obtained csv file consists of 2856 text reviews, and their corresponding ratings, place ID attributes.

Figure 3. Exact Locations of Circles for API Search (created by author using mapdevelopers.com platform)

Lastly, sentiment analysis is performed on the text reviews associated with places through Microsoft Excel Azure Machine Learning add-in due to its recognized effectiveness in Neuro Linguistic Programming (NLP) tasks (Peslak, 2018). As a result, processed data along with sentiment level (negative, neutral, positive) and sentiment score (0-0.45: negative, 0.45-0.55: neutral, 0.55-1: positive) attributes is exported as csv file.

3.2. Data Evaluation

Collected data has undergone through two primary analyses and was mapped using ArcGIS Pro. Firstly, Hotspot Analysis was applied to aggregated ratings of venue points, to identify clusters with both high and low popularity. Secondly, in order to identify sentiment clusters, Spatial Interpolation with Inverse Distance Weighting (IDW) was implemented on the sentiment scores corresponding to respective venues. For a comparative analysis, the count of reviews was visually represented using a heat map technique within ArcGIS Pro environment.

4. Results and Discussion

4.1. Spatial Distribution of Venues

The LBSN data obtained from Google Maps comprises 1223 venues within the borders of the Karaköy Salıpazarı district. The predominant concentration of venues is observed in the southwestern region, near the port side, while the northeastern part, where the Galataport Complex is located, displays a sparse distribution of venues (Figure 4).

The study area encompasses a diverse range of urban functions. Since Location-based Google Maps data classifies function of each venue with five keywords, the determination of utilities are determined based on the first keyword representing the dominant use of respective venue. The functional composition of the area comprises administrative, commercial, cultural, educational, financial, food-related, health, religious, and sports facilities as well as interaction/attraction points (Figure 5).

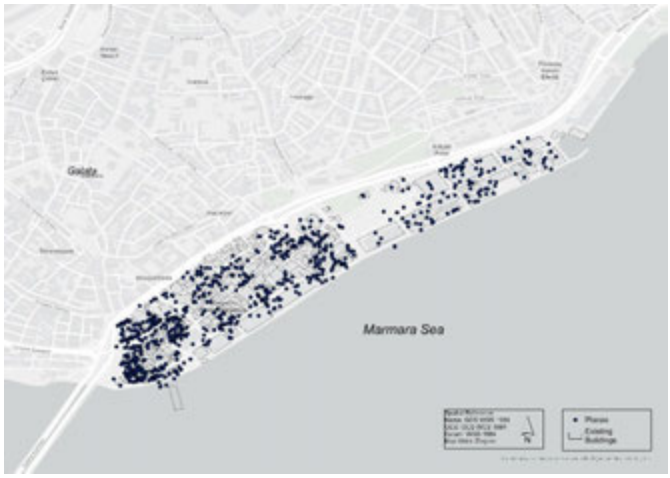

Figure 4. Distribution of Venues (created by author using ArcGIS Pro)

Figure 5. Building Functions (created by author using ArcGIS Pro)

4.2. Public Attachment Patterns

Cluster and hotspot characteristics of footprints and trends were analyzed as an initial step in the investigation of community attachment in the area. To achieve this, Getis-Ord Gİ* analyses were performed based on the attribute value of overall ratings of the venues. The results of the hot spots analyses revealed two notable clusters within the case area. A significant cold spot emerged near the portside, around Rıhtım Avenue, where food-based, financial and administrative functions are evidently concentrated. Adjacent to this cold spot, around Necatibey Avenue on the northern side, a distinct hot spot cluster was observed. This hot spot district is predominantly characterized by commercial and food-based venues, as well as nodes and interaction/attraction points such as viewpoints. In addition to these two clusters, the western part of the area displays several small hot spot clusters distributed across diverse districts (Figure 6).

Hot spot analyses provided a significant outcome, revealing the small cold spot clusters within the eastern part of the area, coinciding with the focus on the inquiry, Galataport Complex. This finding leads to the inference that Galataport area reflects a clustered pattern characterized by lower overall ratings, indicating a concentration of venues with lower satisfaction levels.

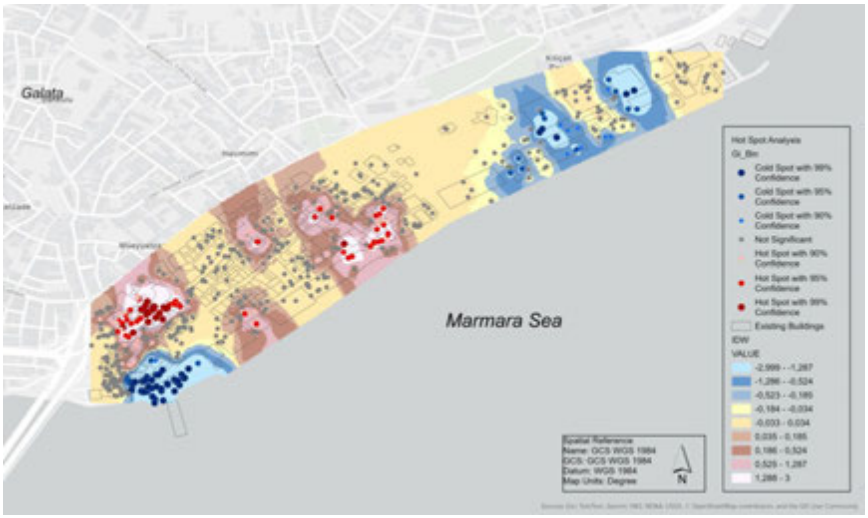

Figure 6. HotSpot Analysis and Spatial Interpolation of Venue Ratings (created by author using ArcGIS Pro)

Secondly, sentiment scores of venues were calculated in Microsoft Excel Azure Add-in, based on Google Maps reviews published in time interval of 1st January 1 am and 20th December 1 am., 2023. To see the distribution of positive and negative sentiments, Spatial Interpolation with Inverse Distance Weighting (IDW) was implemented on the sentiment scores corresponding to respective venues.

The analysis showed an interesting result, indicating a presence of positive sentiment cluster near the portside. This location intersects with the significant cold spot cluster regarding venue ratings, observed in the previous analyses. Although it is not possible to make a definitive inference, this result suggests a potential shift in public attachment patterns to this area in recent years (Figure 7).

Concerning the area where Galataport Complex is located, public sentiments showed a negative-neutral tendency, in parallel with the formations of small cold spot clusters in the area. For further investigation, the study is elaborated to comprehensive comparison of public sentiment distribution and density of the reviews, utilizing spatial interpolation techniques based on number of reviews in respective venues (Figure 8).

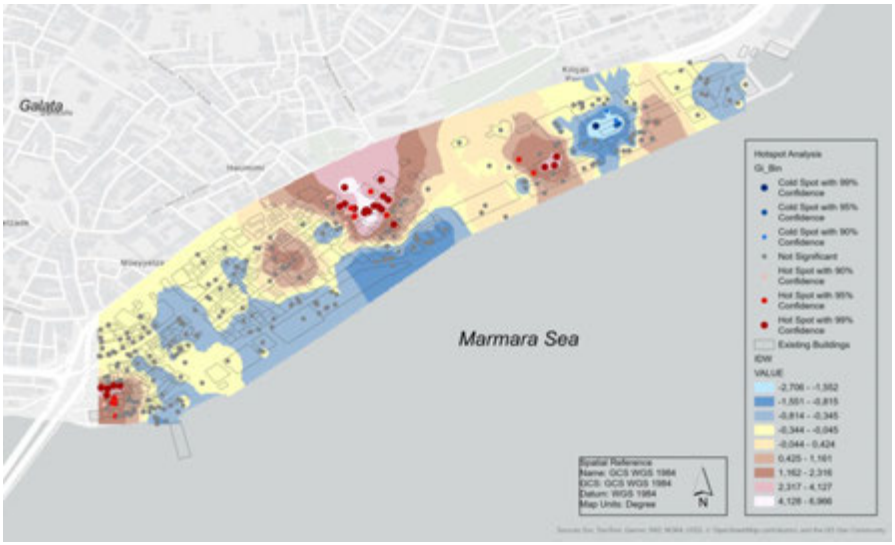

Figure 7. Hotspot Analysis and Spatial Interpolation of Public Sentiments with (created by author using ArcGIS Pro)

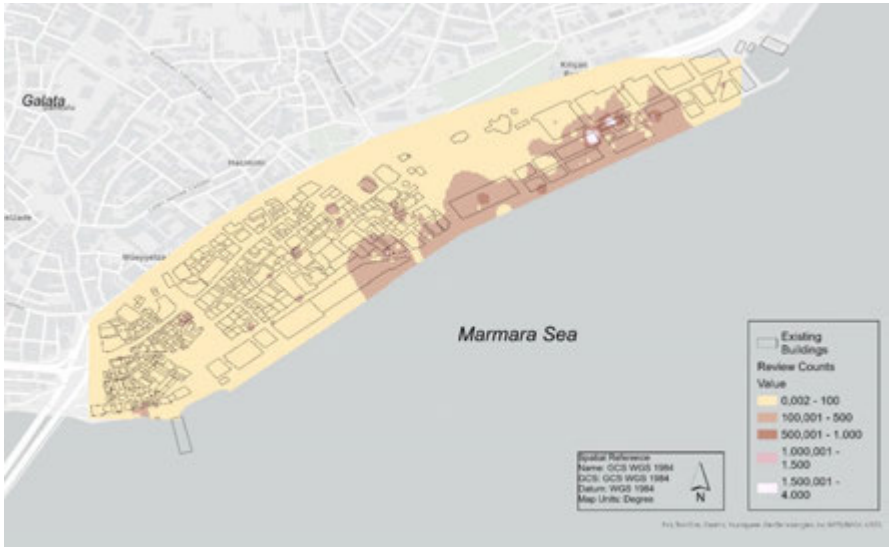

Figure 8**.** Review Density Spatial Interpolation Map (created by author using ArcGIS Pro)

The results highlighted that, in Galataport Area, where negative sentiment clustering is evident, density of reviews published in recent year tends to be in the highest degree. Therefore, the study revealed that the Galataport area not only reflects the negative public attachment patterns, but also indicates a strong prevalence of negative sentiments within the community, suggesting a sense of detachment from this area.

5. Conclusion

The study utilized spatial sentiment analysis to observe the public attachment patterns related to the Karaköy Salıpzarı area, which has undergone the Galataport urban regeneration initiative in recent years. The primary focus of the study revolves around substantial criticism directed at the project within the context of social integrity. The source of the analyses was Location-based Social Media (LBSN) data derived from Google Maps platform, as it enables users to rate places and share associative reviews.

During the data collection phase, the study faced with several limitations. While retrieving Google Maps data, the study was restricted by new data sharing policy of Google Maps, allowing to scrape only limited number of reviews linked to the venues. Consequently, the study utilized data scraping platforms, namely outscraper.com. Additionally, during sentiment analysis of obtained reviews, another limitation arose by Natural Language Processing (NLP) tool within Microsoft Excel's Azure Add-in. This tool only computes sentiments for text reviews written in Latin alphabet, resulting in the exclusion of numerous reviews in languages using different alphabets.

The study has contributed urban literature by evaluating sentiments of post urban regeneration in Karaköy Salıpazarı area. The primary claim of the research indicates that, even Galataport Complex has a popularity with a substantial number of reviews over the past year, public sentiments tend to be in low-moderate level. This result aligns with the criticism about the project, suggesting that the regeneration efforts in area do not fully integrate with the needs of city dwellers (Korkut&Nalbantoğlu, 2023; Karslı, 2015; Köksal, 2012; Durmuş, 2009). Highlighted with this outcome, the study underscores the significance of the social dimension in the urban regeneration process, revealing the negative reflections on public settlements patterns in instances where its realization proves elusive. In navigating complex landscape of urban regeneration, and for fostering inclusive and resilient urban environments, the study recommends the adoption of a comprehensive approach in future planning endeavors.

For further investigations, it is highly suggested to inquire about the reasons of negative sentiments and cold spot clustering within the Galataport Complex. This investigation might require detailed content analysis of text reviews retrieved from Location-based Social Media (LBSN) platforms.

TIRANA'S HOUSING UNITS AND PARKING IN 2024

Parashqevi Tashi[1], Ani Tola[1], Ani Tashi[2]

Abstract
Open parking spaces in residential areas of Tirana today are more concerned with finding suitable locations than merely accommodating a specific number of vehicles. This study aims to analyse the challenges associated with open parking within residential units and internal streets of the city. The construction of new residential complexes over the past 35 years has introduced changes in their design elements compared to the housing stock from the single-party system, prior to the 1990s.The objective is to identify and evaluate the issues arising from the unplanned allocation of parking spaces within the residual areas of residential units designed 40-50 years ago. Finally, it underscores the impact of these improvised parking solutions on urban living conditions and residential environments. Challenges posed by the lack of planned parking spaces, and their distribution within streets and squares of residential units are identifies by employing exploratory, comparative, quantitative, and qualitative methods of analysis. Questionnaires were conducted in the premises of the case study area, in order to get the insight of residents and users.

Keywords: Residential housing units, underground parking, open parking, street parking.

Introduction
Every vehicle user in Tirana experiences in a typical workday significant traffic congestion at nearly every hour, particularly in the city centre or other populated spots throughout the city. Throughout continuous economic and political changes, mobility has undergone substantial changes. This shift is more accurately described as a transformation rather than a simple change. Thirty-four years ago, residents of Tirana predominantly relied on public transportation such as local buses, bicycles, and walking, with taxis used only in exceptional circumstances. The number of taxis in Tirana at that time was almost symbolic.
Following the transition to a different political system, owning a private vehicle become more and more common. Today, Tirana's streets are predominantly occupied by personal vehicles, taxis, public transportation, school vans, and, to a lesser extent, bicycles and motorcycles. The convenience of private cars, together with the lack of more possibilities of transport, has driven their increased usage. However, a more pressing issue than traffic itself is the parking of vehicles: open parking spaces, both free or paid, as well as parking within inner streets. In some parts of the city, particularly in newly developed units, the parking issue has been effectively addressed and no longer causes significant stress for its residents. The adequate conditions and location of parking spaces is as crucial to residents as their living space. Thus, for vehicle owners residing in units constructed before the 2000s, parking is often problematic.
Previously, the major part of residents did not possess personal vehicles, and mobility was primarily facilitated through public transportation. In contemporary Tirana, spaces that were once designated for recreation, greenery, and other communal purposes have been repurposed. During the initial years of the political transition period, in the 2000s, a considerable number of residential buildings were constructed, in addition to several formal and informal extensions to existing constructions, without following appropriate urban planning standards. Additionally, the majority of these residences did not include any internal parking facilities, neither closed or open leading to significant changes in the quality of life for residents and service users.
Since the 2000s, the number of owners of personal vehicles has increased significantly. A considerable portion of green spaces has been replaced by commercial and service areas on ground floors. Consequently, parking spaces are used mostly by their users, in addition to

residents. Considering parking as a crucial factor affecting the daily lives of residents, the following research conducts a morphological analysis of areas designated for parking from 1990 to the present.

The population of Tirana, which was approximately 250,000 thirty-four years ago, is now estimated to be around 1,000,000, accounting for more than one-third of the national population. This dramatic increase has significantly escalated the demand for parking, transforming it into a general source of stress, particularly problematic for residential units constructed before 1990.

Over these thirty-four years, numerous elements have been transformed, including the concept of mobility. Previously, public transport, bicycles, and walking were the primary modes of movement. Today, although these modes still exist, there is a marked preference for personal vehicles, taxis, and lately also scooters. Moreover, the ground floors of buildings, which were predominantly used for residential purposes in the past, have been repurposed for business activities. These businesses not only require parking spaces for their vehicles, clients, and services but also include establishments such as bars, restaurants, and other venues that occupy surrounding spaces with parking. The areas once designated for greenery and residential use, are now public spaces congested with vehicle parking. Consequently, green spaces have been significantly reduced.

Residential units constructed over the past two decades, however, present a better situation. Building blocks have been designed with underground parking facilities, contrasting with the older housing stock. Consequently, contemporary residential units, with their internal streets and available open spaces, face significant challenges due to the proximity and considerable number of vehicle parking, including noise, pollution, safety concerns, and a shortage of parking spaces. Historically, the internal streets of residential complexes built before 1990 were primarily traversed by service vehicles. Occasional use was made by fire trucks, ambulances, fuel supply vehicles in winter, taxis during weddings or similar events, and bicycles, as private car ownership was not allowed for the large population.

In contrast, contemporary times face private cars reaching almost the very entrances of collective residences, with very few families lacking private vehicles. Most families own at least one vehicle, and many possess multiple ones, depending on economic conditions and workplace proximity. While public transport disseminates passengers at designated stations along its route and continues onward, and taxis operate similarly, the use of private vehicles—despite their convenience in providing direct travel to destinations—necessitates the allocation of parking spaces. This convenience incurs additional costs and demands space for vehicles to remain stationary. Typically, the tendency is to park on the sides of roads, secondary streets, or within the internal spaces of residential units.

This practice exacerbates issues such as stress, pollution, dust, and noise, and it diminishes the availability of green spaces. These green spaces are essential not only as recreational areas but also as protective "green walls" for collective residences. For the first time in 2015, the Municipality of Tirana undertook initial interventions to create collective parking spaces, a part of which were offered to residents for free and the rest with payment.

Despite these measures, residential complexes in Tirana and their inhabitants face a chaotic situation regarding vehicle parking and the associated challenges.

Materials and methods

The research presents issues related to parking in residential units constructed prior to the shift to a democratic system, using data from collected questionnaires. The questionnaires have been conducted between February and April 2024, involving 245 randomly selected residents and passers-by in an approximately 2-hectare residential complex. This area is located near the center of Tirana and is bordered by two major roads, Gjergj Fishta Boulevard and Myslym Shyri Street.

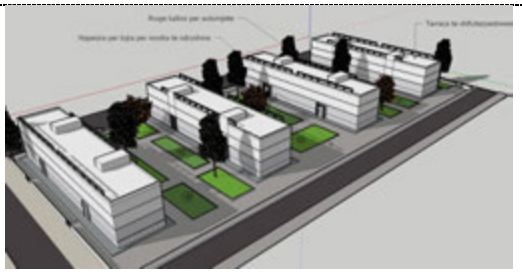
The questionnaire consists of 22 topics, with the first five addressing basic information and the remaining 17 focused on the elements that should be present in the spaces between residential buildings. The data from the questionnaires were processed using IBM SPSS Statistics Version 22 and Microsoft Excel.
By analyzing the transformation of the residential unit through different phases, the main parking issues and elements have been identified through graphical representations. Following data processing, comparative, quantitative, and qualitative methods were implemented. Additionally, a typical residential unit was analyzed as a case study and illustrated with graphical drawings, highlighting the main parking issues and elements.

Research
In the first part of the research, the residential unit is presented graphically in 3D, based on plans obtained from AQTN. The phases that the residential unit has undergone are depicted: its initial project design, its implementation, its condition after 1990 and its current state. As a case study, the multifamily residential unit known as "Godinat e Nëpunësve" (Employees' Buildings), designed in 1942 in Tirana, has been selected. The presented volumes are based on projects preserved in the AQTN archives.

Residential unit project
The residential complex includes 4 buildings, each 4-storey high and 1 underground floor. It was designed from Piero Bartolini in June 12, 1940. It belongs to the monarchical system in Albania, during the fascist Italian occupation. The urban planning scheme (October 10, 1941) did not envisage underground parking but rather open parking spaces for vehicles.

Figure 1. 3D view of the residential unit as designed in the original project. Source: author drawings based on plans from AQTN, Tirana.

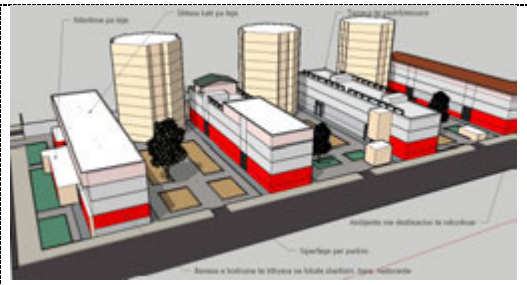
The space between the buildings was accessible by vehicle directly from the main road, with vehicles being parked in the external area. The basements of the buildings functioned as storage service areas.



Residential unit construction
In the period from 1945 to 1990, the complex was inherited within the one-party political system without any alterations to its original architectural and urban plan. The space incorporates elements such as greenery and open areas for recreational activities for residents of different age groups. The project was implemented without provision for parking spaces for residents.

Figure 2. 3D view of the residential unit after construction. Source: author drawings based on plans from AQTN, Tirana.

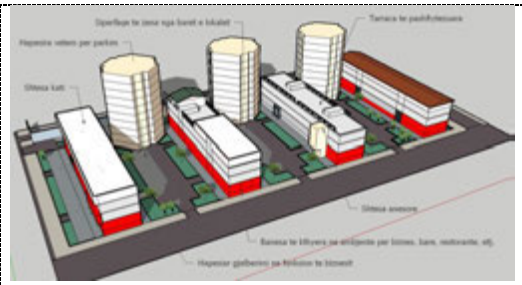
After World War II, these residences were finally utilized. At this time, after the 1960s, citizens were not permitted to own private vehicles. The internal spaces featured greenery and recreational areas, including sports corners for various age groups.



Residential unit after 1990
With the transition to the democratic political system, during the period from 1990 to 2005, there were significant urban transformations in this residential unit. New constructions, both formal and informal, as well as extensions to existing constructions altered the residences themselves and spaces between them. Green areas were demolished, and the space was occupied by unauthorized private parking.

Figure 3. 3D view of the residential unit after 1990. Source: author drawings based on plans from AQTN, Tirana.

With the political system transition in 1990, previous open space between buildings was used for the construction of first multi-story buildings by private entities with building permits. These buildings included one underground parking level, but only for a small number of their residents. The remaining residents parked in the external area. Simultaneously, existing buildings experienced unauthorized extensions, as notable in the 3D view. Consequently, the density increased, the available space diminished, and the number of vehicles in the area grew.



Residential unit today
Today, this space presents a less chaotic appearance. The linear gardens within the square have been redeveloped. However, the major part of the surrounding space is utilized by cafes, bars, and restaurants, as well as for parking individual and service vehicles. The surface area allocated for resident parking is considerably smaller than the demand.

Figure 4. 3D image of the residential unit in the existing situation. Source: author drawings based on plans from AQTN, Tirana.

The 3D views clearly illustrate the transformation undergone by this residential unit. This situation is similar throughout the entire city of Tirana in the residential units inherited from the previous system. Drastic changes were also observed in green areas, external parking spaces, internal roads, sidewalks, lighting, and safety measures. Furthermore, the ground floors of residences have altered their purpose, with nearly 90% of the residential stock in ground floors inherited from before the 1990s being repurposed.
The second part of the research presents the results of the questionnaires conducted in the field.

Name, Surname			
		Frequency	Percent
Valid	passer-by	34	13.9

	resident	211	86.1
	Total	245	100

Figure 5. Table of number of respondents to questionnaires

A total of 245 individuals were surveyed, of which 14% were passers-by who frequented the area for various reasons, such as meeting friends in the recreational spaces of this complex or visiting relatives. Others used the area for shopping or as a daily transit route to work or school. The remaining 86% of respondents were residents of different ages (Figure 5).
To the question, "Do you own a vehicle?" 100% of respondents provided answers (Figure 6). The question referred to whether they had a private car in their household, not necessarily an individual one. Of the respondents, 62.4% owned private vehicles, primarily employed or self-employed individuals, some of whom both work and live in this area. The remaining 37.6% did not own private cars, predominantly students and the unemployed.

Do you own a vehicle?			
		Frequency	Percent
Valid	Yes	153	62.4
	No	92	37.6
	Total	245	100

Figure 6. Results from Question nr. 6: Do you own a vehicle?

In response to Question 7, "Where do you park the vehicle?" 155 out of 245 respondents provided answers (Figure 7). Among those who answered, 26.5% park their cars in private parking spaces. Collective parking areas are used by 30.3% of respondents, indicating that they utilize above-ground and underground parking in new constructions, which are mostly paid parking spaces. The majority, 43.2%, park in public spaces such as streets and squares.
The spaces between residential buildings are filled with parked cars, making them unusable for children or the elderly, and leading to noise, pollution, chaos, and safety issues. Additionally, there is the problem of driver stress due to the time spent searching for parking, as well as the potential for fines from improper parking.

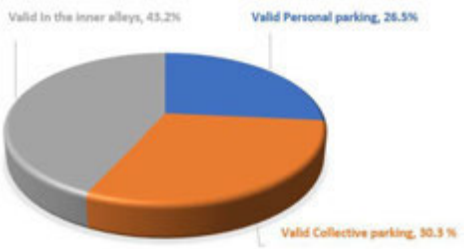


Figure 7. Results from Question nr. 7: Where do you park the vehicle?

Similar questionnaires have been conducted five years ago in in other residential areas of Tirana. When comparing the most recent results with the previous ones, it becomes evident that the percentage of parking in streets and interior spaces of residential units has increased. This indicates that the problem is worsening. Meanwhile, the number of vehicles circulating in Tirana continues to rise, as does the number of new constructions. This leads to a reduction in existing spaces, exacerbating the issue of parking in streets, squares, and public areas.
For most questions, respondents were allowed to provide 1-3 alternatives. The results present the first alternative.

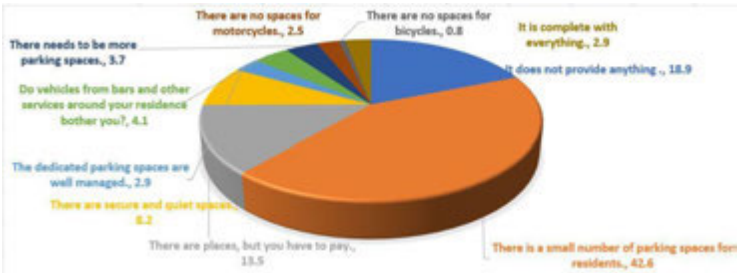

Figure 8. Results from Question nr. 11: Where do you park the vehicle?

For Question No. 11, "Does the space around the building, outside or underground, provide parking for you as a resident?" 244 out of 245 respondents answered. This question includes 10 response options, as following:

0. It does not provide anything.
1. There is a small number of parking spaces for residents.
2. There are places, but you have to pay.
3. There are secure and quiet spaces.
4. The dedicated parking spaces are well managed.
5. Do vehicles from bars and other services around your residence bother you?
6. There needs to be more parking spaces.
7. There are no spaces for motorcycles.
8. There are no spaces for bicycles.
9. There are no spaces for people with disabilities.
10. It is complete with everything.

The processing of the responses to Question No. 11 reveals that 18.9% of the respondents indicated that the space around the building does not provide any parking facilities for them. This implies that the area lacks essential elements necessary for accommodating parking needs. A significant 42.6% of the respondents selected the first option, indicating that residents with private vehicles encounter difficulties in finding parking spaces. This issue impacts their daily lives, reduces their quality of life, increases stress, consumes their time, and affects their psychological well-being. It suggests that local authorities need to take measures to ensure a greater number of parking spaces for residents. Resident parking typically falls under the category of free parking.

In contrast, 13.5% of the respondents chose the second option related to paid parking. Paid parking in Tirana is managed by the institution Tirana Parking and is known as "Parkim me SMS" (Parking by SMS). The city of Tirana is divided into four parking administration zones. Residents are guaranteed free parking spaces within their residential zone, except in designated main road areas subject to a fee system. These paid parking areas are marked by white lines and signs. Short-term parking spaces intended for business purposes are classified as Reserved Parking, which businesses obtain through annual payments. The number of these spaces is usually limited compared to demand, causing residents' parking spots to be occupied by business clients.

With the political system change after 1990, existing collective housing underwent functional transformations. Many of the ground-floor and first-floor apartments were converted into various types of businesses. Even today, they continuously change their purpose. Former service areas, equipped with permits from local authorities, are being turned into cafes or bars. This consequently affects the residents' lives. Apart from the noise generated by these establishments, concerns also arise from the vehicles and service cars. Regarding the fifth question, 4.1% of the respondents express their concern regarding the parking of vehicles from

the businesses on the ground floors. In addition to the problems of noise pollution, this also leads to a lack of security for the residents of units. Although the questionnaire was conducted in a specific complex, the same symptoms can be viewed in the entire city of Tirana.
Another important issue is the lack of designated parking spaces for bicycles or motorcycles. Additionally, inadequate conditions for the mobility of persons with disabilities has been mentioned through the questionnaires. 15% of the respondents have chosen as their second and third alternatives of issues to the question that elements for persons with disabilities are lacking in the spaces around their homes. This is especially true for housing units built before the 1990s, which do not provide any mobility conditions. There are sporadic interventions on the sidewalks along the main roads, while within the same housing units, there are no elevators or ramps. Question 12, "Which common space do you use the most?" was answered by 243 out of 245 respondents (Figure 9).

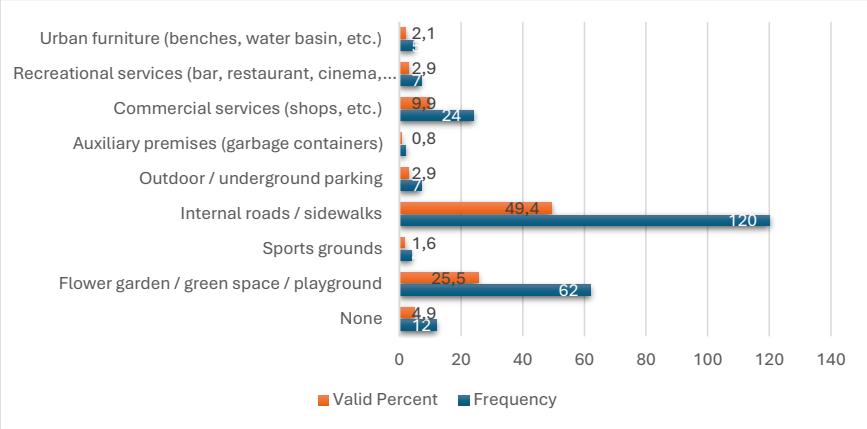

Figure 9. Results from Question nr. 12: Which common space(s) do you use the most?

Respondents could choose up to three alternatives for the question. The table (Figure 9) shows the results of their first choice. The options of question 12 were as following:
0. None
1. Flower gardens / Green space / Playground
2. Sports grounds
3. Internal roads / sidewalks
4. Outdoor / Underground parking
5. Auxiliary premises (f.e. garbage containers)
6. Commercial services (f.e. shops)
7. Recreational services (f.e. bars, restaurants, cinema etc.)
8. Urban Furniture (f.e. benches, water basins etc.)
9. Other
The analysis of the questionnaire outcomes distinctly reveals that spaces between buildings, in the majority of instances, lack essential elements, including green areas, urban furnishings, secure pathways, sidewalks, adequate open parking facilities for residents, service amenities, recreational zones catering to various age groups, lighting, security measures, among others.
Among the surveyed individuals, approximately 49.4% noted that the space surrounding their residences merely consists of access roads facilitating entry and exit. Notably, the designated parking spaces are limited, with a mere 3% utilizing the parking provisions allocated for them. Specifically for the case study illustrated graphically in Figure 4, the space between the

residential buildings predominantly consists of decorative greenery and parking spaces. Nonetheless, these spaces are predominantly used by local businesses. It's noteworthy that the design and allocation of these spaces before 1990 were primarily intended to cater to the needs of the residents. Presently, however, the parking provisions available to them fall short in adequacy. This insufficiency is further compounded by the observation that a significant number of families, particularly those with an average age surpassing 60 years, do not possess private vehicles. Consequently, the quality of life within these residences has been compromised, attributed to their proximity to the urban core and primary thoroughfares. While these circumstances may contribute to a heightened sense of safety, they do not necessarily ensure comfort. Significant concerns mentioned by residents include noise pollution, dust, vehicular emissions, and any potential encroachment by new developments within the immediate courtyard surroundings.

Question 15. " How much do the noises of cars, unpleasant smells, dust from the premises, from the gases of vehicles or new constructions (if any) in the surrounding yard bother you in your apartment?" elicited responses from 245 respondents. (Figure 10)

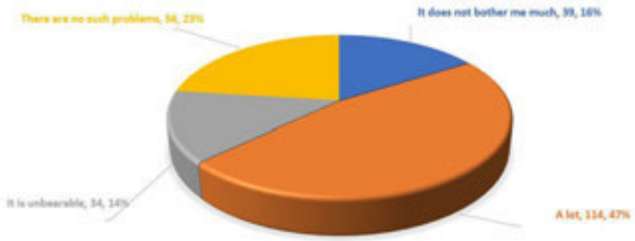

Figure 10. Results from Question nr. 15: How much do the noises of cars, unpleasant smells, dust from the premises, from the gases of vehicles or new constructions (if any) in the surrounding yard bother you in your apartment?

The graphic depicts from the collected data, and indicates that out of the total 245 respondents, 114 individuals (constituting 47% of the total) have chosen the option "A lot." When combined with the 14% who have expressed "It's unbearable", this collective represents more than half of the surveyed population. Notably, those respondents who reported being undisturbed or lacking concerns predominantly reside in upper-floor apartments or newly constructed dwellings. The utilization of new and high-quality materials for window frames and façade walls suggests a meticulous consideration of architectural elements. However, this analysis underscores potential inadequacies in the organization of housing unit forms. Internal streets are observed to be in close proximity to residential structures, and the presence of tall greenery, which could serve as a barrier against noise and dust pollution, is notably lacking. Furthermore, the placement of vehicle parking facilities appears to be inadequate. In addition to these factors, the material composition of window frames, walls, and other selected interior elements plays a crucial role in shaping residents' experiences and perceptions.

Conclusions

One of the most insightful questions of the questionnaire is the following: "What fundamental issues (in your opinion) exist in the spaces between residential buildings (courtyards)?" For this question, respondents freely expressed their views on the problems associated with the spaces surrounding their residences. The most frequently cited issues were:

"Proximity to the road and vehicular traffic"

"Air pollution from vehicles passing very close"

"Close distance between buildings and lack of adequate infrastructure for insulation"

"Lack of lighting and security"
"High-speed vehicle movement"
"Narrow streets, heavy traffic"
"Noise from frequently visited bars"
"Previously free spaces are now overcrowded"
"Common spaces have been encroached upon and transformed into gardens in front of ground-floor apartments"
"It has been transformed; spaces once filled with children playing have been converted into parking areas"
"Residences have been constructed, roads expanded, and commercial units established"
"Many free spaces have been turned into parking or construction sites"
"Our former spaces have been taken over; if organized well, the parking problem can be resolved"

Through the highlight of issues resulting from the collation of questionnaire data and the conducted qualitative analysis, it becomes evident that security within pre-1990s existing residential units has undergone a noticeable decline. Concurrently, an escalation in noise levels and pollution has been increased. Interventions in existing spaces between buildings, with the ongoing intensive construction of new tower-type residential buildings, has significantly augmented the number of vehicles circulating in the area. The predicted necessary area and number for parking spaces has been calculated in accordance to the number of residents only, not including all users of other services. Moreover, there is a conspicuous absence of varied greenery, particularly the presence of tall trees through sidewalks.

Shifting vehicular traffic at a safe distance from entrances of residential buildings is critical. Residents often perceive the large number of commercial activities, like bars and cafes, taking the place of green spaces and even small gardens, as pressing issues necessitating resolution. Local authorities grant permits for such activities.

According to respondents, in order to spend leisure time in the proximity of their residence, individuals frequent commercial venues and service areas due to a perceived lack of alternatives, as these spaces notably affect the residential environment. Residents note that elements like greenery, urban furniture, service amenities, and designated play areas positively impact psychological well-being.

Adherence to planning and design standards is crucial for ensuring adequate natural light and maintaining apartment privacy, which are currently compromised. The common spaces between buildings serve primarily as transition zones rather than recreational areas, hindering efforts to foster community engagement and enhance daily living experiences.

The construction of new multi-story residential buildings within or adjacent to existing buildings built before the 1990s has exacerbated issues of parking such as shortages, noise pollution, and environmental concerns. The increasing number of vehicles will continue to aggravate these issues, underscoring thus the urgent need for calculated parking provisions, not only to the selected case study but also similar contexts.

Throughout Tirana, the conversion of ground-floor residential spaces into commercial and service establishments has become a common trend in residential buildings dating from before the 1990s. Consequently, residents find themselves using only communal areas within the building, such as halls, stairs or others, while the surrounding spaces are managed by local authorities as public spaces.

Residents bring the issue of the absence of dedicated services surrounding their residences beyond basic infrastructure like roads and sidewalks. Consequently, they feel increasingly disconnected from the spaces surrounding their homes.

These findings underscore the urgent need for revaluation and potential requalification of the surrounding spaces, particularly to address deficiencies in greenery and recreational amenities.
